One of the first attempts to use the network as a resource in the UNIX community resulted in the design and implementation of the remote shell protocol, which included the remote shell (rsh) and remote copy (rcp) functions. Rsh and rcp give users the ability to execute commands remotely and copy files to and from a file system residing on a remote host or server on the network. The Cisco implementation of rsh and rcp interoperates with standard implementations.

The rcp **copy** commands rely on the rsh server (or daemon) on the remote system. To copy files using rcp, you need not create a server for file distribution, as you do with TFTP. You need only to have access to a server that supports the remote shell (rsh). (Most UNIX systems support rsh.) Because you are copying a file from one place to another, you must have read permission on the source file and write permission on the destination file. If the destination file does not exist, rcp creates it for you.

Although the Cisco rcp implementation emulates the functions of the UNIX rcp implementation—copying files among systems on the network—the Cisco command syntax differs from the UNIX rcp command syntax. The Cisco rcp support offers a set of **copy** commands that use rcp as the transport mechanism. These rcp **copy** commands are similar in style to the Cisco TFTP **copy** commands, but they offer an alternative that provides faster performance and reliable delivery of data. These improvements are possible because the rcp transport mechanism is built on and uses the TCP/IP stack, which is connection-oriented. You can use rcp commands to copy system images and configuration files from the device to a network server and vice versa.

You also can enable rcp support to allow users on remote systems to copy files to and from the device.

To configure the Cisco IOS software to allow remote users to copy files to and from the device, use the **ip rcmd rcp-enable** global configuration command.

Restrictions

The RCP protocol requires a client to send a remote username on each RCP request to a server. When you copy a configuration file from the device to a server using RCP, the Cisco IOS software sends the first valid username it encounters in the following sequence:

1. The username specified in the **copy** EXEC command, if a username is specified.
2. The username set by the **ip rcmd remote-username** global configuration command, if the command is configured.
3. The remote username associated with the current tty (terminal) process. For example, if the user is connected to the device through Telnet and was authenticated through the **username** command, the device software sends the Telnet username as the remote username.
4. The device host name.

For the RCP copy request to execute successfully, an account must be defined on the network server for the remote username. If the server has a directory structure, the configuration file or image is written to or copied from the directory associated with the remote username on the server. For example, if the system image resides in the home directory of a user on the server, you can specify that user name as the remote username.

Use the **ip rcmd remote-username** command to specify a username for all copies. (Rcmd is a UNIX routine used at the super-user level to execute commands on a remote machine using an authentication scheme based on reserved port numbers. Rcmd stands for “remote command”). Include the username in the **copy** command if you want to specify a username for that copy operation only.

If you are writing to the server, the RCP server must be properly configured to accept the RCP write request from the user on the device. For UNIX systems, you must add an entry to the .rhosts file for the remote user on the RCP server. For example, suppose the device contains the following configuration lines:

```
hostname Device1
ip rcmd remote-username User0
```

If the device IP address translates to device1.example.com, then the .rhosts file for User0 on the RCP server should contain the following line:

```
Device1.example.com Device1
```

Requirements for the RCP Username

The RCP protocol requires a client to send a remote username on each RCP request to a server. When you copy a configuration file from the device to a server using RCP, the Cisco IOS software sends the first valid username it encounters in the following sequence:

1. The username specified in the **copy** EXEC command, if a username is specified.
2. The username set by the **ip rcmd remote-username** global configuration command, if the command is configured.
3. The remote username associated with the current tty (terminal) process. For example, if the user is connected to the device through Telnet and is authenticated through the **username** command, the device software sends the Telnet username as the remote username.
4. The device host name.

For the RCP copy request to execute, an account must be defined on the network server for the remote username. If the server has a directory structure, the configuration file or image is written to or copied from the directory associated with the remote username on the server. For example, if the system image resides in the home directory of a user on the server, specify that user name as the remote username.

Refer to the documentation for your RCP server for more information.

Copying a Configuration File from the Device to an FTP Server

You can copy a configuration file from the device to an FTP server.

Understanding the FTP Username and Password

Note The password must not contain the special character '@'. If the character '@' is used, the copy fails to parse the IP address of the server.

The FTP protocol requires a client to send a remote username and password on each FTP request to a server. When you copy a configuration file from the device to a server using FTP, the Cisco IOS software sends the first valid username it encounters in the following sequence:

1. The username specified in the **copy** EXEC command, if a username is specified.
2. The username set by the **ip ftp username** global configuration command, if the command is configured.

3. Anonymous.

The device sends the first valid password it encounters in the following sequence:

1. The password specified in the **copy** command, if a password is specified.
2. The password set by the **ip ftp password** command, if the command is configured.
3. The device forms a password *username @devicename.domain* . The variable *username* is the username associated with the current session, *devicename* is the configured host name, and *domain* is the domain of the device.

The username and password must be associated with an account on the FTP server. If you are writing to the server, the FTP server must be properly configured to accept the FTP write request from the user on the device.

If the server has a directory structure, the configuration file or image is written to or copied from the directory associated with the username on the server. For example, if the system image resides in the home directory of a user on the server, specify that user name as the remote username.

Refer to the documentation for your FTP server for more information.

Use the **ip ftp username** and **ip ftp password** global configuration commands to specify a username and password for all copies. Include the username in the **copy** EXEC command if you want to specify a username for that copy operation only.

Copying files through a VRF

You can copy files through a VRF interface specified in the **copy** command. Specifying the VRF in the **copy** command is easier and more efficient as you can directly change the source interface without using a change request for the configuration.

Example

The following example shows how to copy files through a VRF, using the **copy** command:

```
Device#
Address or name of remote host [10.1.2.3]?
Source username [ScpUser]?
Source filename [/auto/tftp-server/ScpUser/vrf_test.txt]?
Destination filename [vrf_test.txt]?
Getting the vrf name as test-vrf
Password:
Sending file modes: C0644 10 vrf_test.txt
!
223 bytes copied in 22.740 secs (10 bytes/sec)
```

Copy Configuration Files from a Switch to Another Switch

You can copy the configurations from one switch to another. This is a 2-step process - Copy the configurations from the switch to the TFTP server, and then from TFTP to another switch.

To copy your current configurations from the switch, run the command **copy startup-config tftp:** and follow the instructions. The configurations are copied onto the TFTP server.

Then, login to another switch and run the command **copy tftp: startup-config** and follow the instructions. The configurations are now copied onto the other switch.

After the configurations are copied, to save your configurations, use **write memory** command and then either reload the switch or run the **copy startup-config running-config** command

Configuration Files Larger than NVRAM

To maintain a configuration file that exceeds the size of NVRAM, you should be aware of the information in the following sections.

Compressing the Configuration File

The **service compress-config** global configuration command specifies that the configuration file be stored compressed in NVRAM. Once the configuration file has been compressed, the device functions normally. When the system is booted, it recognizes that the configuration file is compressed, expands it, and proceeds normally. The **more nvram:startup-config** EXEC command expands the configuration before displaying it.

Before you compress configuration files, refer to the appropriate hardware installation and maintenance publication. Verify that your system's ROMs support file compression. If not, you can install new ROMs that support file compression.

The size of the configuration must not exceed three times the NVRAM size. For a 128-KB size NVRAM, the largest expanded configuration file size is 384 KB.

Storing the Configuration in Flash Memory on Class A Flash File Systems

On class A Flash file system devices, you can store the startup configuration in flash memory by setting the **CONFIG_FILE** environment variable to a file in internal flash memory or flash memory in a PCMCIA slot.

See the Specifying the CONFIG_FILE Environment Variable on Class A Flash File Systems , on page 2177 section for more information.

Care must be taken when editing or changing a large configuration. Flash memory space is used every time a **copy system:running-config nvram:startup-config** EXEC command is issued. Because file management for flash memory (such as optimizing free space) is not done automatically, you must pay close attention to available flash memory. Use the **squeeze** command to reclaim used space. We recommend that you use a large-capacity Flash card of at least 20 MB.

Loading the Configuration Commands from the Network

You can also store large configurations on FTP, RCP, or TFTP servers and download them at system startup. To use a network server to store large configurations, see the Copying a Configuration File from the Device to a TFTP Server , on page 2158 and Configuring the Device to Download Configuration Files, on page 2155 sections for more information on these commands.

Configuring the Device to Download Configuration Files

You can configure the device to load one or two configuration files at system startup. The configuration files are loaded into memory and read in as if you were typing the commands at the command line. Thus, the configuration for the device is a mixture of the original startup configuration and the one or two downloaded configuration files.

Network Versus Host Configuration Files

For historical reasons, the first file the device downloads is called the network configuration file. The second file the device downloads is called the host configuration file. Two configuration files can be used when all of the devices on a network use many of the same commands. The network configuration file contains the

standard commands used to configure all of the devices. The host configuration files contain the commands specific to one particular host. If you are loading two configuration files, the host configuration file should be the configuration file you want to have precedence over the other file. Both the network and host configuration files must reside on a network server reachable via TFTP, RCP, or FTP, and must be readable.

How to Manage Configuration File Information

Displaying Configuration File Information

To display information about configuration files, complete the tasks in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show boot** **Example:** `Device# show boot`	Lists the contents of the BOOT environment variable (if set), the name of the configuration file pointed to by the CONFIG_FILE environment variable, and the contents of the BOOTLDR environment variable.
Step 3	**more** *file-url* **Example:** `Device# more 10.1.1.1`	Displays the contents of a specified file.
Step 4	**show running-config** **Example:** `Device# show running-config`	Displays the contents of the running configuration file. (Command alias for the **more system:running-config** command.)
Step 5	**show startup-config** **Example:** `Device# show startup-config`	Displays the contents of the startup configuration file. (Command alias for the **more nvram:startup-config** command.) On all platforms except the Class A Flash file system platforms, the default startup-config file usually is stored in NVRAM. On the Class A Flash file system platforms, the CONFIG_FILE environment variable points to the default startup-config file. The CONFIG_FILE variable defaults to NVRAM.

Modifying the Configuration File

The Cisco IOS software accepts one configuration command per line. You can enter as many configuration commands as you want. You can add comments to a configuration file describing the commands you have entered. Precede a comment with an exclamation point (!). Because comments are *not* stored in NVRAM or in the active copy of the configuration file, comments do not appear when you list the active configuration with the **show running-config** or **more system:running-config** EXEC commands. Comments do not display when you list the startup configuration with the **show startup-config** or **more nvram:startup-config** EXEC mode commands. Comments are stripped out of the configuration file when it is loaded onto the device. However, you can list the comments in configuration files stored on a File Transfer Protocol (FTP), Remote Copy Protocol (RCP), or Trivial File Transfer Protocol (TFTP) server. When you configure the software using the CLI, the software executes the commands as you enter them. To configure the software using the CLI, use the following commands in privileged EXEC mode:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	*configuration-command* **Example:** `Device(config)# <configuration command>`	Enter any configuration command. The Cisco IOS documentation set describes configuration commands organized by technology.
Step 4	**end** **Example:** `Device(config)# end`	Ends the configuration session and exits to EXEC mode.
Step 5	**copy system:running-config nvram:startup-config** **Example:** `Device# copy system:running-config nvram:startup-config`	Saves the running configuration file as the startup configuration file. You may also use the **copy running-config startup-config** command alias, but you should be aware that this command is less precise. On most platforms, this command saves the configuration to NVRAM. On the Class A Flash file system platforms, this step saves the configuration to the location specified by the CONFIG_FILE environment variable (the

	Command or Action	Purpose
		default CONFIG_FILE variable specifies that the file should be saved to NVRAM).

Examples

In the following example, the device prompt name of the device is configured. The comment line, indicated by the exclamation mark (!), does not execute any command. The **hostname** command is used to change the device name from device to new_name. By pressing Ctrl-Z (^Z) or entering the **end** command, the user quits configuration mode. The **copy system:running-config nvram:startup-config** command saves the current configuration to the startup configuration.

```
Device# configure terminal
Device(config)# !The following command provides the switch host name.
Device(config)# hostname new_name
new_name(config)# end
new_name# copy system:running-config nvram:startup-config
```

When the startup configuration is NVRAM, it stores the current configuration information in text format as configuration commands, recording only non-default settings. The memory is checksummed to guard against corrupted data.

Note Some specific commands might not get saved to NVRAM. You need to enter these commands again if you reboot the machine. These commands are noted in the documentation. We recommend that you keep a list of these settings so that you can quickly reconfigure your device after rebooting.

Copying a Configuration File from the Device to a TFTP Server

To copy configuration information on a TFTP network server, complete the tasks in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**copy system:running-config tftp:** [[[*//location*]*/directory*]*/filename*] **Example:** `Device# copy system:running-config tftp: //server1/topdir/file10`	Copies the running configuration file to a TFTP server.

	Command or Action	Purpose
Step 3	**copy nvram:startup-config tftp:** [[[*//location]/directory]/filename*] **Example:** `Device# copy nvram:startup-config tftp: //server1/1stdir/file10`	Copies the startup configuration file to a TFTP server.

Examples

The following example copies a configuration file from a device to a TFTP server:

```
Device# copy system:running-config tftp://172.16.2.155/tokyo-confg
Write file tokyo-confg on host 172.16.2.155? [confirm] Y
Writing tokyo-confg!!! [OK]
```

What to Do Next

After you have issued the **copy** command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the **copy** command and the current setting of the **file prompt** global configuration command.

Copying a Configuration File from the Device to an RCP Server

To copy a startup configuration file or a running configuration file from the device to an RCP server, use the following commands beginning in privileged EXEC mode:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**ip rcmd remote-username** *username* **Example:** `Device(config)# ip rcmd remote-username NetAdmin1`	(Optional) Changes the default remote username.

	Command or Action	Purpose
Step 4	**end** **Example:** `Device(config)# end`	(Optional) Exits global configuration mode.
Step 5	Do one of the following: • **copy system:running-config rcp:** [[[//[*username@*]*location*]/*directory*]/*filename*] • **copy nvram:startup-config rcp:** [[[//[*username@*]*location*]/*directory*]/*filename*] **Example:** `Device# copy system:running-config rcp: //NetAdmin1@example.com/dir-files/file1`	• Specifies that the device running configuration file is to be stored on an RCP server or • Specifies that the device startup configuration file is to be stored on an RCP server

Examples

Storing a Running Configuration File on an RCP Server

The following example copies the running configuration file named runfile2-confg to the netadmin1 directory on the remote host with an IP address of 172.16.101.101:

```
Device# copy system:running-config rcp://netadmin1@172.16.101.101/runfile2-confg
Write file runfile2-confg on host 172.16.101.101?[confirm]
Building configuration...[OK]
Connected to 172.16.101.101
Device#
```

Storing a Startup Configuration File on an RCP Server

The following example shows how to store a startup configuration file on a server by using RCP to copy the file:

```
Device# configure terminal

Device(config)# ip rcmd remote-username netadmin2

Device(config)# end

Device# copy nvram:startup-config rcp:

Remote host[]? 172.16.101.101

Name of configuration file to write [start-confg]?
Write file start-confg on host 172.16.101.101?[confirm]
![OK]
```

What to Do Next

After you have issued the **copy** EXEC command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the **copy** command and the current setting of the **file prompt** global configuration command.

Copying a Configuration File from the Device to the FTP Server

To copy a startup configuration file or a running configuration file from the device to an FTP server, complete the following tasks:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode on the device.
Step 3	**ip ftp username** *username* **Example:** `Device(config)# ip ftp username NetAdmin1`	(Optional) Specifies the default remote username.
Step 4	**ip ftp password** *password* **Example:** `Device(config)# ip ftp password adminpassword`	(Optional) Specifies the default password.
Step 5	**end** **Example:** `Device(config)# end`	(Optional) Exits global configuration mode. This step is required only if you override the default remote username or password (see Steps 2 and 3).
Step 6	Do one of the following: • **copy system:running-config ftp:** [[[//[*username* [**:***password*]**@**]*location*]/*directory*]/*filename*] or • **copy nvram:startup-config ftp:** [[[//[*username* [**:***password*]**@**]*location*]/*directory*]/*filename*] **Example:**	Copies the running configuration or startup configuration file to the specified location on the FTP server.

	Command or Action	Purpose
	`Device# copy system:running-config ftp:`	

Examples

Storing a Running Configuration File on an FTP Server

The following example copies the running configuration file named runfile-confg to the netadmin1 directory on the remote host with an IP address of 172.16.101.101:

```
Device# copy system:running-config ftp://netadmin1:mypass@172.16.101.101/runfile-confg
Write file runfile-confg on host 172.16.101.101?[confirm]
Building configuration...[OK]
Connected to 172.16.101.101
Device#
```

Storing a Startup Configuration File on an FTP Server

The following example shows how to store a startup configuration file on a server by using FTP to copy the file:

```
Device# configure terminal

Device(config)# ip ftp username netadmin2

Device(config)# ip ftp password mypass

Device(config)# end

Device# copy nvram:startup-config ftp:

Remote host[]? 172.16.101.101

Name of configuration file to write [start-confg]?
Write file start-confg on host 172.16.101.101?[confirm]
![OK]
```

What to Do Next

After you have issued the **copy** EXEC command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the **copy** command and the current setting of the **file prompt** global configuration command.

Copying a Configuration File from a TFTP Server to the Device

To copy a configuration file from a TFTP server to the device, complete the tasks in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable**	Enables privileged EXEC mode.

	Command or Action	Purpose
	Example: `Device> enable`	• Enter your password if prompted.
Step 2	**copy tftp:** [[[*//location*]/*directory*]/*filename*] **system:running-config** **Example:** `Device# copy tftp://server1/dir10/datasource system:running-config`	Copies a configuration file from a TFTP server to the running configuration.
Step 3	**copy tftp:** [[[*//location*]/*directory*]/*filename*] **nvram:startup-config** **Example:** `Device# copy tftp://server1/dir10/datasource nvram:startup-config`	Copies a configuration file from a TFTP server to the startup configuration.
Step 4	**copy tftp:** [[[*//location*]/*directory*]/*filename*] **flash-[n]:/directory/startup-config** **Example:** `Device# copy tftp://server1/dir10/datasource flash:startup-config`	Copies a configuration file from a TFTP server to the startup configuration.

Examples

In the following example, the software is configured from the file named **tokyo-confg** at IP address 172.16.2.155:

```
Device# copy tftp://172.16.2.155/tokyo-confg system:running-config

Configure using tokyo-confg from 172.16.2.155? [confirm] Y

Booting tokyo-confg from 172.16.2.155:!!! [OK - 874/16000 bytes]
```

What to Do Next

After you have issued the **copy** EXEC command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the **copy** command and the current setting of the **file prompt** global configuration command.

Copying a Configuration File from the rcp Server to the Device

To copy a configuration file from an rcp server to the running configuration or startup configuration, complete the following tasks:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	(Optional) Enters configuration mode from the terminal. This step is required only if you override the default remote username (see Step 3).
Step 3	**ip rcmd remote-username** *username* **Example:** `Device(config)# ip rcmd remote-username NetAdmin1`	(Optional) Specifies the remote username.
Step 4	**end** **Example:** `Device(config)# end`	(Optional) Exits global configuration mode. This step is required only if you override the default remote username (see Step 2).
Step 5	Do one of the following: • **copy rcp://**[[*username*@]*location*]/*directory*/*filename* **system:running-config** • **copy rcp://**[[*username*@]*location*]/*directory*/*filename* **nvram:startup-config** **Example:** `Device# copy rcp://[user1@example.com/dir10/fileone] nvram:startup-config`	Copies the configuration file from an rcp server to the running configuration or startup configuration.

Examples

Copy RCP Running-Config

The following example copies a configuration file named host1-confg from the netadmin1 directory on the remote server with an IP address of 172.16.101.101, and loads and runs the commands on the device:

```
device# copy rcp://netadmin1@172.16.101.101/host1-confg system:running-config
Configure using host1-confg from 172.16.101.101? [confirm]
Connected to 172.16.101.101
Loading 1112 byte file host1-confg:![OK]
device#
%SYS-5-CONFIG: Configured from host1-config by rcp from 172.16.101.101
```

Copy RCP Startup-Config

The following example specifies a remote username of netadmin1. Then it copies the configuration file named host2-confg from the netadmin1 directory on the remote server with an IP address of 172.16.101.101 to the startup configuration.

```
device# configure terminal
device(config)# ip rcmd remote-username netadmin1
device(config)# end
device# copy rcp: nvram:startup-config
Address of remote host [255.255.255.255]? 172.16.101.101
Name of configuration file[rtr2-confg]? host2-confg
Configure using host2-confg from 172.16.101.101?[confirm]
Connected to 172.16.101.101
Loading 1112 byte file host2-confg:![OK]
[OK]
device#
%SYS-5-CONFIG_NV:Non-volatile store configured from host2-config by rcp from 172.16.101.101
```

What to Do Next

After you have issued the **copy** EXEC command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the **copy** command and the current setting of the **file prompt** global configuration command.

Copying a Configuration File from an FTP Server to the Device

To copy a configuration file from an FTP server to the running configuration or startup configuration, complete the tasks in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	(Optional) Allows you to enter global configuration mode. This step is required only if you want to override the default remote username or password (see Steps 3 and 4).
Step 3	**ip ftp username** *username* **Example:** `Device(config)# ip ftp username NetAdmin1`	(Optional) Specifies the default remote username.
Step 4	**ip ftp password** *password* **Example:**	(Optional) Specifies the default password.

	Command or Action	Purpose
	`Device(config)# ip ftp password adminpassword`	
Step 5	**end** **Example:** `Device(config)# end`	(Optional) Exits global configuration mode. This step is required only if you override the default remote username or password (see Steps 3 and 4).
Step 6	Do one of the following: • **copy ftp:** [[[//[*username*[**:***password*]**@**]*location*] **/***directory*]/*filename*]**system:running-config** • **copy ftp** [[[*/[username[:password]@]location]/directory/filename]**nvram:startup-config** **Example:** `Device# copy ftp:nvram:startup-config`	Using FTP copies the configuration file from a network server to running memory or the startup configuration.

Examples

Copy FTP Running-Config

The following example copies a host configuration file named host1-confg from the netadmin1 directory on the remote server with an IP address of 172.16.101.101, and loads and runs the commands on the device:

```
device# copy ftp://netadmin1:mypass@172.16.101.101/host1-confg system:running-config
Configure using host1-confg from 172.16.101.101? [confirm]
Connected to 172.16.101.101
Loading 1112 byte file host1-confg:![OK]
device#
%SYS-5-CONFIG: Configured from host1-config by ftp from 172.16.101.101
```

Copy FTP Startup-Config

The following example specifies a remote username of netadmin1. Then it copies the configuration file named host2-confg from the netadmin1 directory on the remote server with an IP address of 172.16.101.101 to the startup configuration:

```
device# configure terminal
device(config)# ip ftp username netadmin1
device(config)# ip ftp password mypass
device(config)# end
device# copy ftp: nvram:startup-config
Address of remote host [255.255.255.255]? 172.16.101.101
Name of configuration file[host1-confg]? host2-confg
Configure using host2-confg from 172.16.101.101?[confirm]
Connected to 172.16.101.101
Loading 1112 byte file host2-confg:![OK]
[OK]
device#
```

```
%SYS-5-CONFIG_NV:Non-volatile store configured from host2-config by ftp from 172.16.101.101
```

What to Do Next

After you have issued the **copy** EXEC command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the **copy** command and the current setting of the **file prompt** global configuration command.

Maintaining Configuration Files Larger than NVRAM

To maintain a configuration file that exceeds the size of NVRAM, perform the tasks described in the following sections:

Compressing the Configuration File

To compress configuration files, complete the tasks in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**service compress-config** **Example:** `Device(config)# service compress-config`	Specifies that the configuration file be compressed.
Step 4	**end** **Example:** `Device(config)# end`	Exits global configuration mode.
Step 5	Do one of the following: • Use FTP, RCP, or TFTP to copy the new configuration. • **configure terminal** **Example:** `Device# configure terminal`	Enters the new configuration: • If you try to load a configuration that is more than three times larger than the NVRAM size, the following error message is displayed: "[buffer overflow - *file-size* /*buffer-size* bytes]."

	Command or Action	Purpose
Step 6	**copy system:running-config nvram:startup-config** **Example:** `Device(config)# copy system:running-config nvram:startup-config`	When you have finished changing the running-configuration, save the new configuration.

Examples

The following example compresses a 129-KB configuration file to 11 KB:

```
Device# configure terminal

Device(config)# service compress-config

Device(config)# end

Device# copy tftp://172.16.2.15/tokyo-confg system:running-config

Configure using tokyo-confg from 172.16.2.155? [confirm] y

Booting tokyo-confg from 172.16.2.155:!!! [OK - 874/16000 bytes]
Device# copy system:running-config nvram:startup-config

Building configuration...
Compressing configuration from 129648 bytes to 11077 bytes
[OK]
```

Storing the Configuration in Flash Memory on Class A Flash File Systems

To store the startup configuration in flash memory, complete the tasks in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**copy nvram:startup-config** *flash-filesystem:filename* **Example:** `Device# copy nvram:startup-config usbflash0:switch-config`	Copies the current startup configuration to the new location to create the configuration file.

	Command or Action	Purpose
Step 3	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 4	**boot config flash-filesystem:** *filename* **Example:** `Device(config)# boot config usbflash0:switch-config`	Specifies that the startup configuration file be stored in flash memory by setting the CONFIG_FILE variable.
Step 5	**end** **Example:** `Device(config)# end`	Exits global configuration mode.
Step 6	Do one of the following: • Use FTP, RCP, or TFTP to copy the new configuration. If you try to load a configuration that is more than three times larger than the NVRAM size, the following error message is displayed: "[buffer overflow - *file-size* /*buffer-size* bytes]. " • **configure terminal** **Example:** `Device# configure terminal`	Enters the new configuration.
Step 7	**copy system:running-config nvram:startup-config** **Example:** `Device(config)# copy system:running-config nvram:startup-config`	When you have finished changing the running-configuration, save the new configuration.

Examples

The following example stores the configuration file in usbflash0:

```
Device# copy nvram:startup-config usbflash0:switch-config

Device# configure terminal

Device(config)# boot config usbflash0:switch-config

Device(config)# end
```

```
Device# copy system:running-config nvram:startup-config
```

Loading the Configuration Commands from the Network

To use a network server to store large configurations, complete the tasks in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**copy system:running-config** {**ftp:** | **rcp:** | **tftp:**} **Example:** `Device# copy system:running-config ftp:`	Saves the running configuration to an FTP, RCP, or TFTP server.
Step 3	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 4	**boot network** {**ftp:**[[[//[*username* [**:***password*]**@**]*location*]/*directory*]/*filename*] | **rcp:**[[[//[*username***@**]*location*]/*directory*]/*filename*] | **tftp:**[[[//*location*]/*directory*]/*filename*]} **Example:** `Device(config)# boot network ftp://user1:guessme@example.com/dir10/file1`	Specifies that the startup configuration file be loaded from the network server at startup.
Step 5	**service config** **Example:** `Device(config)# service config`	Enables the switch to download configuration files at system startup.
Step 6	**end** **Example:** `Device(config)# end`	Exits global configuration mode.
Step 7	**copy system:running-config nvram:startup-config**	Saves the configuration.

	Command or Action	Purpose
	Example: `Device# copy system:running-config nvram:startup-config`	

Copying Configuration Files from Flash Memory to the Startup or Running Configuration

To copy a configuration file from flash memory directly to your startup configuration in NVRAM or your running configuration, enter one of the commands in Step 2:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	Do one of the following: • **copy** *filesystem*: [*partition-number***:**][*filename*] **nvram:startup-config** • **copy** *filesystem*: [*partition-number***:**][*filename*] **system:running-config** **Example:** `Device# copy usbflash0:4:ios-upgrade-1 nvram:startup-config`	• Loads a configuration file directly into NVRAM or • Copies a configuration file to your running configuration

Examples

The following example copies the file named ios-upgrade-1 from partition 4 of the flash memory PC Card in usbflash0 to the device startup configurations:

```
Device# copy usbflash0:4:ios-upgrade-1 nvram:startup-config

Copy 'ios-upgrade-1' from flash device as 'startup-config' ? [yes/no] yes

[OK]
```

Copying Configuration Files Between Flash Memory File Systems

On platforms with multiple flash memory file systems, you can copy files from one flash memory file system, such as internal flash memory to another flash memory file system. Copying files to different flash memory file systems lets you create backup copies of working configurations and duplicate configurations for other devices. To copy a configuration file between flash memory file systems, use the following commands in EXEC mode:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**show** *source-filesystem*: **Example:** `Device# show flash:`	Displays the layout and contents of flash memory to verify the filename.
Step 3	**copy** *source-filesystem*:[*partition-number***:**][*filename*] *dest-filesystem***:**[*partition-number***:**][*filename*] **Example:** `Device# copy flash: usbflash0:`	Copies a configuration file between flash memory devices. • The source device and the destination device cannot be the same. For example, the **copy usbflash0: usbflash0:** command is invalid.

Example

The following example copies the file named running-config from partition 1 on internal flash memory to partition 1 of usbflash0 on a device. In this example, the source partition is not specified, so the device prompts for the partition number:

```
Device# copy flash: usbflash0:

System flash
Partition   Size    Used      Free      Bank-Size  State          Copy Mode
  1         4096K   3070K     1025K     4096K      Read/Write     Direct
  2        16384K   1671K    14712K     8192K      Read/Write     Direct
[Type ?<no> for partition directory; ? for full directory; q to abort]
Which partition? [default = 1]
System flash directory, partition 1:
File  Length   Name/status
  1   3142748  dirt/network/mars-test/c3600-j-mz.latest
  2   850      running-config
[3143728 bytes used, 1050576 available, 4194304 total]
usbflash0 flash directory:
File  Length   Name/status
  1   1711088  dirt/gate/c3600-i-mz
```

```
  2   850      running-config
[1712068 bytes used, 2482236 available, 4194304 total]
Source file name? running-config

Destination file name [running-config]?
Verifying checksum for 'running-config' (file # 2)...  OK
Erase flash device before writing? [confirm]
Flash contains files. Are you sure you want to erase? [confirm]
Copy 'running-config' from flash: device
  as 'running-config' into usbflash0: device WITH erase? [yes/no] yes

Erasing device... eeee
```

	Command or Action	Purpose
Step 6	**copy ftp:** [[*//location*]*/directory*]*/bundle_name* **flash:** **Example:** `Device>copy ftp:/ie35xx-17.17.1.spa.bin flash:`	Copies the configuration file from a network server to the flash memory device using FTP.

What to Do Next

After you have issued the **copy** EXEC command, you may be prompted for additional information or for confirmation of the action. The prompt displayed depends on how much information you provide in the **copy** command and the current setting of the **file prompt** global configuration command.

Copying a Configuration File from an RCP Server to Flash Memory Devices

To copy a configuration file from an RCP server to a flash memory device, complete the tasks in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	(Optional) Enters global configuration mode. This step is required only if you override the default remote username or password (see Step 3).
Step 3	**ip rcmd remote-username** *username* **Example:** `Device(config)# ip rcmd remote-username Admin01`	(Optional) Specifies the remote username.
Step 4	**end** **Example:** `Device(config)# end`	(Optional) Exits configuration mode. This step is required only if you override the default remote username or password (see Step 3).
Step 5	**copy rcp:** [[[*//*[*username@*]*location*]*/directory*] */bundle_name*] **flash:** **Example:** `Device# copy`	Copies the configuration file from a network server to the flash memory device using RCP. Respond to any device prompts for additional information or confirmation. Prompting depends on how much information you provide in the

	Command or Action	Purpose
	`rcp://netadmin@172.16.101.101/bundle1 flash:`	**copy** command and the current setting of the **file prompt** command.

Copying a Configuration File from a TFTP Server to Flash Memory Devices

To copy a configuration file from a TFTP server to a flash memory device, complete the tasks in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**copy tftp:** [[[*//location*]*/directory*]/bundle_name **flash:** **Example:** `Device# copy tftp://ie35xx_aa-universalk9.SSA.03.12.02.EZP.150-12.02.EZP.150-12.02.EZP.bin flash:`	Copies the file from a TFTP server to the flash memory device. Reply to any device prompts for additional information or confirmation. Prompting depends on how much information you provide in the **copy** command and the current setting of the **file prompt** command.

Examples

The following example shows the copying of the configuration file named switch-config from a TFTP server to the flash memory card inserted in usbflash0. The copied file is renamed new-config.

```
Device#
copy tftp:switch-config usbflash0:new-config
```

Re-executing the Configuration Commands in the Startup Configuration File

To re-execute the commands located in the startup configuration file, complete the task in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure memory** **Example:** `Device# configure memory`	Re-executes the configuration commands located in the startup configuration file.

Clearing the Startup Configuration

You can clear the configuration information from the startup configuration. If you reboot the device with no startup configuration, the device enters the Setup command facility so that you can configure the device from scratch. To clear the contents of your startup configuration, complete the task in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**erase nvram** **Example:** `Device# erase nvram`	Clears the contents of your startup configuration. **Note** For all platforms except the Class A Flash file system platforms, this command erases NVRAM. The startup configuration file cannot be restored once it has been deleted. On Class A Flash file system platforms, when you use the **erase startup-config** EXEC command, the device erases or deletes the configuration pointed to by the CONFIG_FILE environment variable. If this variable points to NVRAM, the device erases NVRAM. If the CONFIG_FILE environment variable specifies a flash memory device and configuration filename, the device deletes the configuration file. That is, the device marks the file as "deleted," rather than erasing it. This feature allows you to recover a deleted file.

Deleting a Specified Configuration File

To delete a specified configuration on a specific flash device, complete the task in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**delete** *flash-filesystem***:***filename* **Example:** `Device# delete usbflash0:myconfig`	Deletes the specified configuration file on the specified flash device. **Note** On Class A and B Flash file systems, when you delete a specific file in flash memory, the system marks the file as deleted, allowing you to later recover a deleted file using the **undelete** EXEC command. Erased files cannot be recovered. To permanently erase the configuration file, use the **squeeze** EXEC command. On Class C Flash file systems, you cannot recover a file that has been deleted. If you attempt to erase or delete the configuration file specified by the CONFIG_FILE environment variable, the system prompts you to confirm the deletion.

Specifying the CONFIG_FILE Environment Variable on Class A Flash File Systems

On Class A flash file systems, you can configure the Cisco IOS software to load the startup configuration file specified by the CONFIG_FILE environment variable. The CONFIG_FILE variable defaults to NVRAM. To change the CONFIG_FILE environment variable, complete the tasks in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**copy** [*flash-url* | *ftp-url* | *rcp-url* | *tftp-url* | **system:running-config** | **nvram:startup-config**] *dest-flash-url* **Example:**	Copies the configuration file to the flash file system from which the device loads the file on restart.

	Command or Action	Purpose
	`Device# copy system:running-config nvram:startup-config`	
Step 3	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 4	**boot config** *dest-flash-url* **Example:** `Device(config)# boot config 172.16.1.1`	Sets the CONFIG_FILE environment variable. This step modifies the runtime CONFIG_FILE environment variable.
Step 5	**end** **Example:** `Device(config)# end`	Exits global configuration mode.
Step 6	**copy system:running-config nvram:startup-config** **Example:** `Device# copy system:running-config nvram:startup-config`	Saves the configuration performed in Step 3 to the startup configuration.
Step 7	**show boot** **Example:** `Device# show boot`	(Optional) Allows you to verify the contents of the CONFIG_FILE environment variable.

Examples

The following example copies the running configuration file to the device. This configuration is then used as the startup configuration when the system is restarted:

```
Device# copy system:running-config usbflash0:config2
Device# configure terminal
Device(config)# boot config usbflash0:config2
Device(config)# end
Device# copy system:running-config nvram:startup-config
[ok]
Device# show boot
BOOT variable = usbflash0:rsp-boot-m
CONFIG_FILE variable = nvram:
Current CONFIG_FILE variable = usbflash0:config2
Configuration register is 0x010F
```

What to Do Next

After you specify a location for the startup configuration file, the **nvram:startup-config** command is aliased to the new location of the startup configuration file. The **more nvram:startup-config** EXEC command displays the startup configuration, regardless of its location. The **erase nvram:startup-config** EXEC command erases the contents of NVRAM and deletes the file pointed to by the CONFIG_FILE environment variable.

When you save the configuration using the **copy system:running-config nvram:startup-config** command, the device saves a complete version of the configuration file to the location specified by the CONFIG_FILE environment variable and a distilled version to NVRAM. A distilled version is one that does not contain access list information. If NVRAM contains a complete configuration file, the device prompts you to confirm your overwrite of the complete version with the distilled version. If NVRAM contains a distilled configuration, the device does not prompt you for confirmation and proceeds with overwriting the existing distilled configuration file in NVRAM.

Note If you specify a file in a flash device as the CONFIG_FILE environment variable, every time you save your configuration file with the **copy system:running-config nvram:startup-config** command, the old configuration file is marked as "deleted," and the new configuration file is saved to that device. Eventually, Flash memory fills up as the old configuration files still take up memory. Use the **squeeze** EXEC command to permanently delete the old configuration files and reclaim the space.

Configuring the Device to Download Configuration Files

You can specify an ordered list of network configuration and host configuration filenames. The Cisco IOS XE software scans this list until it loads the appropriate network or host configuration file.

To configure the device to download configuration files at system startup, perform at least one of the tasks described in the following sections:

- "Configuring the Switch to Download the Network Configuration File"
- "Configuring the Switch to Download the Network Configuration File"

If the device fails to load a configuration file during startup, it tries again every 10 minutes (the default setting) until a host provides the requested files. With each failed attempt, the device displays the following message on the console terminal:

```
Booting host-confg... [timed out]
```

If there are any problems with the startup configuration file, or if the configuration register is set to ignore NVRAM, the device enters the Setup command facility.

Configuring the Device to Download the Network Configuration File

To configure the Cisco IOS software to download a network configuration file from a server at startup, complete the tasks in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**boot network** {**ftp:**[[[//[*username* [**:***password*]**@**]*location*]/*directory*]/*filename*] | **rcp:**[[[//[*username***@**]*location*]/*directory*]/*filename*] | **tftp:**[[[//*location*]/*directory*]/*filename*]} **Example:** `Device(config)# boot network tftp:hostfile1`	Specifies the network configuration file to download at startup, and the protocol to be used (TFTP, RCP, or FTP). • If you do not specify a network configuration filename, the Cisco IOS software uses the default filename network-confg. If you omit the address, the device uses the broadcast address. • You can specify more than one network configuration file. The software tries them in order entered until it loads one. This procedure can be useful for keeping files with different configuration information loaded on a network server.
Step 4	**service config** **Example:** `Device(config)# service config`	Enables the system to automatically load the network file on restart.
Step 5	**end** **Example:** `Device(config)# end`	Exits global configuration mode.
Step 6	**copy system:running-config nvram:startup-config** **Example:** `Device# copy system:running-config nvram:startup-config`	Saves the running configuration to the startup configuration file.

Configuring the Device to Download the Host Configuration File

To configure the Cisco IOS software to download a host configuration file from a server at startup, complete the tasks in this section:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**boot host** {**ftp:**[[[//[*username* [**:***password*]**@**]*location*]/*directory*]/*filename*] | **rcp:**[[[//[*username***@**]*location*]/*directory*]/*filename*] | **tftp:**[[[//*location*]/*directory*]/*filename*] } **Example:** `Device(config)# boot host tftp:hostfile1`	Specifies the host configuration file to download at startup, and the protocol to be used (FTP, RCP, or TFTP): • If you do not specify a host configuration filename, the device uses its own name to form a host configuration filename by converting the name to all lowercase letters, removing all domain information, and appending "-confg." If no host name information is available, the software uses the default host configuration filename device-confg. If you omit the address, the device uses the broadcast address. • You can specify more than one host configuration file. The Cisco IOS software tries them in order entered until it loads one. This procedure can be useful for keeping files with different configuration information loaded on a network server.
Step 4	**service config** **Example:** `Device(config)# service config`	Enables the system to automatically load the host file upon restart.
Step 5	**end** **Example:** `Device(config)# end`	Exits global configuration mode.

	Command or Action	Purpose
Step 6	**copy system:running-config nvram:startup-config** **Example:** `Device# copy system:running-config nvram:startup-config`	Saves the running configuration to the startup configuration file.

Example

In the following example, a device is configured to download the host configuration file named hostfile1 and the network configuration file named networkfile1. The device uses TFTP and the broadcast address to obtain the file:

```
Device# configure terminal
Device(config)# boot host tftp:hostfile1
Device(config)# boot network tftp:networkfile1
Device(config)# service config
Device(config)# end
Device# copy system:running-config nvram:startup-config
```

CHAPTER 145

Secure Copy

This document provides the procedure to configure a Cisco device for Secure Copy (SCP) server-side functionality.

- Prerequisites for Secure Copy, on page 2183
- Information About Secure Copy, on page 2183
- How to Configure Secure Copy, on page 2184
- Configuration Examples for Secure Copy, on page 2187

Prerequisites for Secure Copy

- Configure Secure Shell (SSH), authentication, and authorization on the device.
- Because the Secure Copy Protocol (SCP) relies on SSH for its secure transport, the device must have a Rivest, Shamir, and Adelman (RSA) key pair.

Information About Secure Copy

The Secure Copy feature provides a secure and authenticated method for copying switch configurations or switch image files. The Secure Copy Protocol (SCP) relies on Secure Shell (SSH), an application and a protocol that provides a secure replacement for the Berkeley r-tools.

The behavior of SCP is similar to that of Remote Copy Protocol (RCP), which comes from the Berkeley r-tools suite (Berkeley university's own set of networking applications), except that SCP relies on SSH for security. In addition, SCP requires authentication, authorization, and accounting (AAA) to be configured to ensure that the device can determine whether a user has the correct privilege level.

SCP allows only users with a privilege level of 15 to copy a file in the Cisco IOS File System (Cisco IFS) to and from a device by using the **copy** command. An authorized administrator can also perform this action from a workstation.

Note

- Enable the SCP option while using the `pscp.exe` file.
- An RSA public-private key pair must be configured on the device for SSH to work.

Similar to SCP, SSH File Transfer Protocol (SFTP) can be used to copy switch configuration or image files. For more information, refer the *Configuring SSH File Transfer Protocol* chapter of the *Security Configuration Guide*.

Secure Copy Performance Improvements

SSH bulk data transfer mode can be used to enhance the throughput performance of SCP that is operating in the capacity of a client or a server. SSH bulk data transfer mode is enabled by default with default window size of 128KB. TCP selective acknowledgement (SACK) is enabled by default if the bulk mode window size is configured.

The default bulk mode window size of 128 KB is optimal to copy large files in most network settings. However, in long big networks where the round-trip time (RTT) is high, 128 KB is not enough. You can enable the most optimal SCP throughput performance by configuring the bulk mode window size using the **ip ssh bulk-mode** *window-size* command. For example, in an ideal lab testing environment, a window size of 2 MB in a 200-milliseconds round-trip time setting can give around 500 percent improved throughput performance when compared to the default 128-KB window size.

The bulk mode window size must be configured as per the network bandwidth-delay product, that is, a multiple of total available bandwidth in bits per second and the round-trip time in seconds. Because the CPU usage may increase with the increased window size, make sure to balance this by choosing the right window size.

How to Configure Secure Copy

The following sections provide information about the Secure Copy configuration tasks.

Configuring Secure Copy

To configure a Cisco device for SCP server-side functionality, perform the following steps.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**aaa new-model** **Example:** `Device(config)# aaa new-model`	Sets AAA authentication at login.

	Command or Action	Purpose
Step 4	**aaa authentication login** {**default** | *list-name*} *method1* [*method2...*] **Example:** `Device(config)# aaa authentication login default group tacacs+`	Enables the AAA access control system.
Step 5	**username** *name* [**privilege** *level*] **password** *encryption-type encrypted-password* **Example:** `Device(config)# username superuser privilege 2 password 0 superpassword`	Establishes a username-based authentication system. **Note** You can omit this step if a network-based authentication mechanism, such as TACACS+ or RADIUS, has been configured.
Step 6	**ip scp server enable** **Example:** `Device(config)# ip scp server enable`	Enables SCP server-side functionality.
Step 7	**exit** **Example:** `Device(config)# exit`	Exits global configuration mode and returns to privileged EXEC mode.
Step 8	**debug ip scp** **Example:** `Device# debug ip scp`	(Optional) Troubleshoots SCP authentication problems.

Configuring SCP Username Password

To configure a username and password for SCP, perform the following steps:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.

	Command or Action	Purpose
Step 3	**ip scp username***username* **Example:** `Device# ip scp username cisco`	Defines the username.
Step 4	**ip scp password***password* **Example:** `Device# ip scp password 0 cisco`	Defines the password. Specify the encryption level. • 0 – Unencrypted password. • 0 – Encrypted password. • Line – Clear text password.
Step 5	**exit** **Example:** `Device(config)# exit`	Exits global configuration mode and returns to privileged EXEC mode.

Enabling Secure Copy on the SSH Server

The following task shows how to configure the server-side functionality for SCP. This task shows a typical configuration that allows a device to securely copy files from a remote workstation.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**aaa new-model** **Example:** `Device(config)# aaa new-model`	Enables the Authentication, Authorization, and Accounting (AAA) access control model.
Step 4	**aaa authentication login default local** **Example:** `Device(config)# aaa authentication login default local`	Sets AAA authentication to use the local username database for authentication at login.
Step 5	**aaa authorization exec default local** **Example:**	Sets the parameters that restrict user access to a network, runs the authorization to determine if the user ID is allowed to run an privileged

	Command or Action	Purpose
	`Device(config)# aaa authorization exec default local`	EXEC shell, and specifies that the system must use the local database for authorization.
Step 6	**username** *name* **privilege** *privilege-level* **password** *password* **Example:** `Device(config)# username samplename privilege 15 password password1`	Establishes a username-based authentication system, and specifies the username, privilege level, and an unencrypted password. **Note** The minimum required value for the *privilege-level* argument is 15. A privilege level of less than 15 results in the connection closing.
Step 7	**ip ssh time-out** *seconds* **Example:** `Device(config)# ip ssh time-out 120`	Sets the time interval (in seconds) that the device waits for the SSH client to respond.
Step 8	**ip ssh authentication-retries** *integer* **Example:** `Device(config)# ip ssh authentication-retries 3`	Sets the number of authentication attempts after which the interface is reset.
Step 9	**ip scp server enable** **Example:** `Device(config)# ip scp server enable`	Enables the device to securely copy files from a remote workstation.
Step 10	**ip ssh bulk-mode** *window-size* **Example:** `Device(config)# ip ssh bulk-mode 33107232`	(Optional) Sets the bulk mode window size to enhance the throughput performance of SCP. **Note** SSH bulk data transfer mode is enabled by default with default window size of 128KB.
Step 11	**exit** **Example:** `Device(config)# exit`	Exits global configuration mode and returns to privileged EXEC mode.
Step 12	**debug ip scp** **Example:** `Device# debug ip scp`	(Optional) Provides diagnostic information about SCP authentication problems.

Configuration Examples for Secure Copy

The following are examples of the Secure Copy configuration.

Example: Secure Copy Configuration Using Local Authentication

The following example shows how to configure the server-side functionality of Secure Copy. This example uses a locally defined username and password.

```
! AAA authentication and authorization must be configured properly in order for SCP to work.
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authentication login default local
Device(config)# aaa authorization exec default local
Device(config)# username user1 privilege 15 password 0 lab
! SSH must be configured and functioning properly.
Device(config)# ip scp server enable
Device(config)# end
```

Example: Secure Copy Server-Side Configuration Using Network-Based Authentication

The following example shows how to configure the server-side functionality of Secure Copy using a network-based authentication mechanism:

```
! AAA authentication and authorization must be configured properly for SCP to work.
Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authentication login default group tacacs+
Device(config)# aaa authorization exec default group tacacs+
! SSH must be configured and functioning properly.
Device(config)# ip ssh time-out 120
Device(config)# ip ssh authentication-retries 3
Device(config)# ip scp server enable
Device(config)# end
```

CHAPTER 146

Configuration Replace and Configuration Rollback

- Prerequisites for Configuration Replace and Configuration Rollback, on page 2189
- Restrictions for Configuration Replace and Configuration Rollback, on page 2190
- Information About Configuration Replace and Configuration Rollback, on page 2190
- How to Use Configuration Replace and Configuration Rollback, on page 2193
- Configuration Examples for Configuration Replace and Configuration Rollback, on page 2199

Prerequisites for Configuration Replace and Configuration Rollback

The format of the configuration files used as input by the Configuration Replace and Configuration Rollback feature must comply with standard Cisco software configuration file indentation rules as follows:

- Start all commands on a new line with no indentation, unless the command is within a configuration submode.
- Indent commands within a first-level configuration submode one space.
- Indent commands within a second-level configuration submode two spaces.
- Indent commands within subsequent submodes accordingly.

These indentation rules describe how the software creates configuration files for such commands as **show running-config** or **copy running-config** *destination-url*. Any configuration file generated on a Cisco device complies with these rules.

Free memory larger than the combined size of the two configuration files (the current running configuration and the saved replacement configuration) is required.

Restrictions for Configuration Replace and Configuration Rollback

If the device does not have free memory larger than the combined size of the two configuration files (the current running configuration and the saved replacement configuration), the configuration replace operation is not performed.

Certain Cisco configuration commands such as those pertaining to physical components of a networking device (for example, physical interfaces) cannot be added or removed from the running configuration. For example, a configuration replace operation cannot remove the **interface gigabitethernet 1/1** command line from the current running configuration if that interface is physically present on the device. Similarly, the **interface gigabitethernet 1/3** command line cannot be added to the running configuration if no such interface is physically present on the device. A configuration replace operation that attempts to perform these types of changes results in error messages indicating that these specific command lines failed.

In very rare cases, certain Cisco configuration commands cannot be removed from the running configuration without reloading the device. A configuration replace operation that attempts to remove this type of command results in error messages indicating that these specific command lines failed.

Information About Configuration Replace and Configuration Rollback

Configuration Archive

The Cisco IOS configuration archive is intended to provide a mechanism to store, organize, and manage an archive of Cisco IOS configuration files to enhance the configuration rollback capability provided by the **configure replace** command. Before this feature was introduced, you could save copies of the running configuration using the **copy running-config** *destination-url* command, storing the replacement file either locally or remotely. However, this method lacked any automated file management. On the other hand, the Configuration Replace and Configuration Rollback feature provides the capability to automatically save copies of the running configuration to the Cisco IOS configuration archive. These archived files serve as checkpoint configuration references and can be used by the **configure replace** command to revert to previous configuration states.

The **archive config** command allows you to save Cisco IOS configurations in the configuration archive using a standard location and filename prefix that is automatically appended with an incremental version number (and optional timestamp) as each consecutive file is saved. This functionality provides a means for consistent identification of saved Cisco IOS configuration files. You can specify how many versions of the running configuration are kept in the archive. After the maximum number of files are saved in the archive, the oldest file is automatically deleted when the next, most recent file is saved. The **show archive** command displays information for all configuration files saved in the Cisco IOS configuration archive.

The Cisco IOS configuration archive, in which the configuration files are stored and available for use with the **configure replace** command, can be located on the following file systems: FTP, HTTP, RCP, TFTP.

Configuration Replace

The **configure replace** privileged EXEC command provides the capability to replace the current running configuration with any saved Cisco IOS configuration file. This functionality can be used to revert to a previous configuration state, effectively rolling back any configuration changes that were made since the previous configuration state was saved.

When using the **configure replace** command, you must specify a saved Cisco IOS configuration as the replacement configuration file for the current running configuration. The replacement file must be a complete configuration generated by a Cisco IOS device (for example, a configuration generated by the **copy running-config** *destination-url* command), or, if generated externally, the replacement file must comply with the format of files generated by Cisco IOS devices. When the **configure replace** command is entered, the current running configuration is compared with the specified replacement configuration and a set of diffs is generated. The algorithm used to compare the two files is the same as that employed by the **show archive config differences** command. The resulting diffs are then applied by the Cisco IOS parser to achieve the replacement configuration state. Only the diffs are applied, avoiding potential service disruption from reapplying configuration commands that already exist in the current running configuration. This algorithm effectively handles configuration changes to order-dependent commands (such as access lists) through a multiple pass process. Under normal circumstances, no more than three passes are needed to complete a configuration replace operation, and a limit of five passes is performed to preclude any looping behavior.

The Cisco IOS **copy** *source-url* **running-config** privileged EXEC command is often used to copy a stored Cisco IOS configuration file to the running configuration. When using the **copy** *source-url* **running-config** command as an alternative to the **configure replace** *target-url* privileged EXEC command, the following major differences should be noted:

- The **copy** *source-url* **running-config** command is a merge operation and preserves all of the commands from both the source file and the current running configuration. This command does not remove commands from the current running configuration that are not present in the source file. In contrast, the **configure replace** *target-url* command removes commands from the current running configuration that are not present in the replacement file and adds commands to the current running configuration that need to be added.
- The **copy** *source-url* **running-config** command applies every command in the source file, whether or not the command is already present in the current running configuration. This algorithm is inefficient and, in some cases, can result in service outages. In contrast, the **configure replace** *target-url* command only applies the commands that need to be applied—no existing commands in the current running configuration are reapplied.
- A partial configuration file may be used as the source file for the **copy** *source-url* **running-config** command, whereas a complete Cisco IOS configuration file must be used as the replacement file for the **configure replace** *target-url* command.

A locking feature for the configuration replace operation was introduced. When the **configure replace** command is used, the running configuration file is locked by default for the duration of the configuration replace operation. This locking mechanism prevents other users from changing the running configuration while the replacement operation is taking place, which might otherwise cause the replacement operation to terminate unsuccessfully. You can disable the locking of the running configuration by using the **no lock** keyword when issuing the **configure replace** command.

The running configuration lock is automatically cleared at the end of the configuration replace operation. You can display any locks that may be currently applied to the running configuration using the **show configuration lock** command.

Configuration Rollback

The concept of rollback comes from the transactional processing model common to database operations. In a database transaction, you might make a set of changes to a given database table. You then must choose whether to commit the changes (apply the changes permanently) or to roll back the changes (discard the changes and revert to the previous state of the table). In this context, rollback means that a journal file containing a log of the changes is discarded, and no changes are applied. The result of the rollback operation is to revert to the previous state, before any changes were applied.

The **configure replace** command allows you to revert to a previous configuration state, effectively rolling back changes that were made since the previous configuration state was saved. Instead of basing the rollback operation on a specific set of changes that were applied, the Cisco IOS configuration rollback capability uses the concept of reverting to a specific configuration state based on a saved Cisco IOS configuration file. This concept is similar to the database idea of saving a checkpoint (a saved version of the database) to preserve a specific state.

If the configuration rollback capability is desired, you must save the Cisco IOS running configuration before making any configuration changes. Then, after entering configuration changes, you can use that saved configuration file to roll back the changes (using the **configure replace** *target-url* command). Furthermore, because you can specify any saved Cisco IOS configuration file as the replacement configuration, you are not limited to a fixed number of rollbacks, as is the case in some rollback models.

Configuration Rollback Confirmed Change

The Configuration Rollback Confirmed Change feature allows configuration changes to be performed with an optional requirement that they be confirmed. If this confirmation is not received, the configuration is returned to the state prior to the changes being applied. The mechanism provides a safeguard against inadvertent loss of connectivity between a network device and the user or management application due to configuration changes.

Benefits of Configuration Replace and Configuration Rollback

- Allows you to revert to a previous configuration state, effectively rolling back configuration changes.
- Allows you to replace the current running configuration file with the startup configuration file without having to reload the device or manually undo CLI changes to the running configuration file, therefore reducing system downtime.
- Allows you to revert to any saved Cisco IOS configuration state.
- Simplifies configuration changes by allowing you to apply a complete configuration file to the device, where only the commands that need to be added or removed are affected.
- When using the **configure replace** command as an alternative to the **copy** *source-url* **running-config** command, increases efficiency and prevents risk of service outages by not reapplying existing commands in the current running configuration.

How to Use Configuration Replace and Configuration Rollback

Creating a Configuration Archive

No prerequisite configuration is needed to use the **configure replace** command. Using the **configure replace** command in conjunction with the Cisco IOS configuration archive and the **archive config** command is optional but offers significant benefit for configuration rollback scenarios. Before using the **archive config** command, the configuration archive must be configured. Perform this task to configure the characteristics of the configuration archive.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**archive** **Example:** `Device(config)# archive`	Enters archive configuration mode.
Step 4	**path** *url* **Example:** `Device(config-archive)# path flash:myconfiguration`	Specifies the location and filename prefix for the files in the Cisco IOS configuration archive. **Note** If a directory is specified in the path instead of file, the directory name must be followed by a forward slash as follows: path flash:/directory/. The forward slash is not necessary after a filename; it is only necessary when specifying a directory.
Step 5	**maximum** *number* **Example:** `Device(config-archive)# maximum 14`	(Optional) Sets the maximum number of archive files of the running configuration to be saved in the Cisco IOS configuration archive. • The *number* argument is the maximum number of archive files of the running configuration to be saved in the Cisco IOS

	Command or Action	Purpose
		configuration archive. Valid values are from 1 to 14. The default is 10. **Note** Before using this command, you must configure the **path** command to specify the location and filename prefix for the files in the Cisco IOS configuration archive.
Step 6	**time-period** *minutes* **Example:** `Device(config-archive)# time-period 1440`	(Optional) Sets the time increment for automatically saving an archive file of the current running configuration in the Cisco IOS configuration archive. • The *minutes* argument specifies how often, in minutes, to automatically save an archive file of the current running configuration in the Cisco IOS configuration archive. **Note** Before using this command, you must configure the **path** command to specify the location and filename prefix for the files in the Cisco IOS configuration archive.
Step 7	**end** **Example:** `Device(config-archive)# end`	Exits to privileged EXEC mode.
Step 8	**archive config** **Example:** `Device# archive config`	Saves the current running configuration file to the configuration archive. **Note** The **path** command must be configured before using this command.

Performing a Configuration Replace or Configuration Rollback Operation

Perform this task to replace the current running configuration file with a saved Cisco IOS configuration file.

Note You must create a configuration archive before performing this procedure. See Creating a Configuration Archive for detailed steps. The following procedure details how to return to that archived configuration in the event of a problem with the current running configuration.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure replace** *target-url* [**nolock**] [**list**] [**force**] [**ignore case**] [**revert trigger** [**error**] [**timer** *minutes*] | **time** *minutes*]] **Example:** `Device# configure replace flash: startup-config time 120`	Replaces the current running configuration file with a saved Cisco IOS configuration file. • The *target - url* argument is a URL (accessible by the Cisco IOS file system) of the saved Cisco IOS configuration file that is to replace the current running configuration, such as the configuration file created using the **archive config** command. • The **list** keyword displays a list of the command lines applied by the Cisco IOS software parser during each pass of the configuration replace operation. The total number of passes performed is also displayed. • The **force** keyword replaces the current running configuration file with the specified saved Cisco IOS configuration file without prompting you for confirmation. • The **time** *minutes* keyword and argument specify the time (in minutes) within which you must enter the **configure confirm** command to confirm replacement of the current running configuration file. If the **configure confirm** command is not entered within the specified time limit, the configuration replace operation is automatically reversed (in other words, the current running configuration file is restored to the configuration state that existed prior to entering the **configure replace** command). • The **nolock** keyword disables the locking of the running configuration file that prevents other users from changing the running configuration during a configuration replace operation.

	Command or Action	Purpose
		• The **revert trigger** keywords set the following triggers for reverting to the original configuration: • **error**: Reverts to the original configuration upon error. • **timer** *minutes*: Reverts to the original configuration if specified time elapses. **Note** In some cases, while performing the **revert trigger** operation for multiple pass operations, a partial configuration may be missed out causing the revert operation to the original configuration state to fail. • The **ignore case** keyword allows the configuration to ignore the case of the confirmation command.
Step 3	**configure revert** { **now** | **timer** {*minutes* | **idle** *minutes*} } **Example:** `Device# configure revert now`	(Optional) To cancel the timed rollback and trigger the rollback immediately, or to reset parameters for the timed rollback, use the **configure revert**command in privileged EXEC mode. • **now**: Triggers the rollback immediately. • **timer**: Resets the configuration revert timer. • Use the *minutes* argument with the **timer** keyword to specify a new revert time in minutes. • Use the **idle** keyword along with a time in minutes to set the maximum allowable time period of no activity before reverting to the saved configuration.
Step 4	**configure confirm** **Example:** `Device# configure confirm`	(Optional) Confirms replacement of the current running configuration file with a saved Cisco IOS configuration file. **Note** Use this command only if the **time** *seconds* keyword and argument of the **configure replace** command are specified.

	Command or Action	Purpose
Step 5	**exit** **Example:** `Device# exit`	Exits to user EXEC mode.

Monitoring and Troubleshooting the Feature

Perform this task to monitor and troubleshoot the Configuration Replace and Configuration Rollback feature.

Procedure

Step 1 **enable**

Use this command to enable privileged EXEC mode. Enter your password if prompted.

Example:

```
Device> enable
Device#
```

Step 2 **show archive**

Use this command to display information about the files saved in the Cisco IOS configuration archive.

Example:

```
Device# show archive
There are currently 1 archive configurations saved.
The next archive file will be named flash:myconfiguration-2
 Archive #  Name
   0
   1       flash:myconfiguration-1 <- Most Recent
   2
   3
   4
   5
   6
   7
   8
   9
   10
   11
   12
   13
   14
```

The following is sample output from the **show archive** command after several archive files of the running configuration have been saved. In this example, the maximum number of archive files to be saved is set to three.

Example:

```
Device# show archive
```

```
There are currently 3 archive configurations saved.
The next archive file will be named flash:myconfiguration-8
 Archive #  Name
   0
   1       :Deleted
   2       :Deleted
   3       :Deleted
   4       :Deleted
   5       flash:myconfiguration-5
   6       flash:myconfiguration-6
   7       flash:myconfiguration-7 <- Most Recent
   8
   9
   10
   11
   12
   13
   14
```

Step 3 debug archive versioning

Use this command to enable debugging of the Cisco IOS configuration archive activities to help monitor and troubleshoot configuration replace and rollback.

Example:

```
Device# debug archive versioning
Jan  9 06:46:28.419:backup_running_config
Jan  9 06:46:28.419:Current = 7
Jan  9 06:46:28.443:Writing backup file flash:myconfiguration-7
Jan  9 06:46:29.547: backup worked
```

Step 4 debug archive config timestamp

Use this command to enable debugging of the processing time for each integral step of a configuration replace operation and the size of the configuration files being handled.

Example:

```
Device# debug archive config timestamp
Device# configure replace flash:myconfiguration force
Timing Debug Statistics for IOS Config Replace operation:
       Time to read file usbflash0:sample_2.cfg = 0 msec (0 sec)
       Number of lines read:55
       Size of file        :1054
Starting Pass 1
       Time to read file system:running-config = 0 msec (0 sec)
       Number of lines read:93
       Size of file        :2539
       Time taken for positive rollback pass = 320 msec (0 sec)
       Time taken for negative rollback pass = 0 msec (0 sec)
       Time taken for negative incremental diffs pass = 59 msec (0 sec)
       Time taken by PI to apply changes = 0 msec (0 sec)
       Time taken for Pass 1 = 380 msec (0 sec)
Starting Pass 2
       Time to read file system:running-config = 0 msec (0 sec)
       Number of lines read:55
       Size of file        :1054
       Time taken for positive rollback pass = 0 msec (0 sec)
       Time taken for negative rollback pass = 0 msec (0 sec)
       Time taken for Pass 2 = 0 msec (0 sec)
Total number of passes:1
Rollback Done
```

Step 5 **exit**

Use this command to exit to user EXEC mode.

Example:

```
Device# exit
Device>
```

Configuration Examples for Configuration Replace and Configuration Rollback

Creating a Configuration Archive

The following example shows how to perform the initial configuration of the Cisco IOS configuration archive. In this example, flash:myconfiguration is specified as the location and filename prefix for the files in the configuration archive and a value of 10 is set as the maximum number of archive files to be saved.

```
configure terminal
!
archive
 path flash:myconfiguration
 maximum 10
end
```

Replacing the Current Running Configuration with a Saved Cisco IOS Configuration File

The following example shows how to replace the current running configuration with a saved Cisco IOS configuration file named flash:myconfiguration. The **configure replace** command interactively prompts you to confirm the operation.

```
Device# configure replace flash:myconfiguration
This will apply all necessary additions and deletions
to replace the current running configuration with the
contents of the specified configuration file, which is
assumed to be a complete configuration, not a partial
configuration. Enter Y if you are sure you want to proceed. ? [no]: Y
Total number of passes: 1
Rollback Done
```

In the following example, the **list** keyword is specified in order to display the command lines that were applied during the configuration replace operation:

```
Device# configure replace flash:myconfiguration list
This will apply all necessary additions and deletions
to replace the current running configuration with the
contents of the specified configuration file, which is
```

```
assumed to be a complete configuration, not a partial
configuration. Enter Y if you are sure you want to proceed. ? [no]: Y
!Pass 1
!List of Commands:
no snmp-server community public ro
snmp-server community mystring ro

end
Total number of passes: 1
Rollback Done
```

Reverting to the Startup Configuration File

The following example shows how to revert to the Cisco IOS startup configuration file using the **configure replace** command. This example also shows the use of the optional **force** keyword to override the interactive user prompt:

```
Device# configure replace flash:startup-config force
Total number of passes: 1
Rollback Done
```

Performing a Configuration Replace Operation with the configure confirm Command

The following example shows the use of the **configure replace** command with the **time** *minutes* keyword and argument. You must enter the **configure confirm** command within the specified time limit to confirm replacement of the current running configuration file. If the **configure confirm** command is not entered within the specified time limit, the configuration replace operation is automatically reversed (in other words, the current running configuration file is restored to the configuration state that existed prior to entering the **configure replace** command).

```
Device# configure replace flash:startup-config time 120
This will apply all necessary additions and deletions
to replace the current running configuration with the
contents of the specified configuration file, which is
assumed to be a complete configuration, not a partial
configuration. Enter Y if you are sure you want to proceed. ? [no]: Y
Total number of passes: 1
Rollback Done
Device# configure confirm
```

The following example shows the use of the **configure revert** command with the **timer** keyword. You must enter the **configure revert** command to cancel the timed rollback and trigger the rollback immediately, or to reset parameters for the timed rollback.

```
Device# configure revert timer 100
```

Performing a Configuration Rollback Operation

The following example shows how to make changes to the current running configuration and then roll back the changes. As part of the configuration rollback operation, you must save the current running configuration before making changes to the file. In this example, the **archive config** command is used to save the current

running configuration. The generated output of the **configure replace** command indicates that only one pass was performed to complete the rollback operation.

Note Before using the **archive config** command, you must configure the **path** command to specify the location and filename prefix for the files in the Cisco IOS configuration archive.

You first save the current running configuration in the configuration archive as follows:

```
archive config
```

You then enter configuration changes as shown in the following example:

```
configure terminal
!
user netops2 password rain
user netops3 password snow
exit
```

After having made changes to the running configuration file, assume you now want to roll back these changes and revert to the configuration that existed before the changes were made. The **show archive** command is used to verify the version of the configuration to be used as a replacement file. The **configure replace** command is then used to revert to the replacement configuration file as shown in the following example:

```
Device# show archive
There are currently 1 archive configurations saved.
The next archive file will be named flash:myconfiguration-2
 Archive #  Name
   0
   1       flash:myconfiguration-1 <- Most Recent
   2
   3
   4
   5
   6
   7
   8
   9
   10
Device# configure replace flash:myconfiguration-1
Total number of passes: 1
Rollback Done
```

CHAPTER 147

Software Maintenance Upgrade

Software Maintenance Upgrade (a SMU), is a package that can be installed on a system to provide a fix or a security resolution to a released image.

- Restrictions for Software Maintenance Upgrade, on page 2203
- Information About Software Maintenance Upgrade, on page 2203
- How to Manage Software Maintenance Updates, on page 2204
- Configuration Examples for Software Maintenance Upgrade, on page 2207

Restrictions for Software Maintenance Upgrade

- Hot patching is not supported.
- SMU supports cold patching using install mode only.
- SMU installation will be supported in install mode only.

Information About Software Maintenance Upgrade

SMU Overview

An SMU is a package that can be installed on a system, to provide a fix or a security resolution to a released image. An SMU package is provided on a per release and per component basis.

An SMU provides a significant benefit over classic Cisco IOS software because it allows you to address network issues quickly while reducing the time and scope of the testing required. The Cisco IOS XE platform internally validates SMU compatibility and does not allow you to install incompatible SMUs.

All SMUs are integrated into the subsequent Cisco IOS XE software maintenance releases. An SMU is an independent and self-sufficient package and it does not have any prerequisites or dependencies. You can choose which SMUs to install or uninstall in any order.

SMUs are supported only on Extended Maintenance releases and for the full lifecycle of the underlying software release.

Perform these basic steps to install an SMU:

1. Add the SMU to the filesystem.

2. Activate the SMU on the system.
3. Commit the SMU changes so that it is persistent across reloads.

SMU Workflow

The SMU process is initiated with a request to the Cisco Customer Support. Contact your customer support to raise an SMU request.

At release time, the SMU package is posted to the Cisco Software Download page and can be downloaded and installed.

SMU Package

The SMU package contains a small set of files for patching the release along with metadata that describes the contents of the package, and fix for the reported issue that the SMU is requested for. The SMU package also supports patching of the public key infrastructure (PKI) component.

SMU Reload

All SMUs require a cold reload of the system during activation. A cold reload is the complete reload of the operating system. This action affects the traffic flow for the duration of the reload. This reload ensures that all processes are started with the correct libraries and files that are installed as part of the SMU.

Note If the user deletes the SMU file from the directory and performs a bootup, the device displays the error message **`%BOOT-3-BOOTTIME_SMU_MISSING_DETECTED: R0/0: install_engine: SMU file /bootflash/ie35xx-lni.17.17.1.SSA.bin missing and system impact will be unknown`**. However, this will not lead to any functional error.

How to Manage Software Maintenance Updates

The following sections provide information about managing SMUs.

You can install, activate, and commit an SMU package using a single command (1-step process) or using separate commands (3-step process).

Tip Use the 1-step process when you have to install just one SMU package file and use the 3-step process when you have to install multiple SMUs. The 3-step process minimises the number of reloads required when you have more than one SMU package file to install.

Installing an SMU Package: 1-Step Process

This task shows how to use the single **install add file activate commit** command for installing an SMU package.

Before you begin

Check that the SMU you are about to install corresponds to the software image installed on your device. For example, SMU `/auto/tftp-blr-users2/much/SMU_BUILDS/ie35xx-universalk9.2024-12 03_06.55_much.0.CSCwm26661.SSA.smu.bin` is compatible with software image `ie35xx-17.17.1.SPA.bin`.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	**install add file flash:** *filename* [**activate commit**] **Example:** `Device# install add file flash:ie35xx-universalk9.2024-12 03_06.55_much.0.CSCwm26661.SSA.smu.bin activate commit`	Copies the maintenance update package from flash to the device, performs a compatibility check for the platform and image versions, activates the SMU package, and makes the package persistent across reloads. This command extracts the individual components of the .bin file into the subpackages and packages.conf files. You can also copy the SMU package from from a remote location (through FTP, HTTP, HTTPS, or TFTP). **Note** If the SMU file is copied using TFTP, use bootflash to activate the SMU.
Step 3	**exit** **Example:** `Device# exit`	Exits privileged EXEC mode and returns to user EXEC mode.

Installing an SMU Package: 3-Step Process

This task shows you the 3-step process for installing an SMU package. Use this method to install multiple SMUs and avoid multiple reloads.

Before you begin

Check that the SMU you are about to install corresponds to the software image installed on your device. For example, SMU `/auto/tftp-blr-users2/much/SMU_BUILDS/ie35xx-universalk9.2024-12 03_06.55_much.0.CSCwm26661.SSA.smu.bin` is compatible with software image `ie35xx-17.17.1.SPA.bin`.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**install add file** *location filename* **Example:** `Device# install add file flash:ie35xx-universalk9.2024-12 03_06.55_much.0.CSCwm26661.SSA.smu.bin` `Device# install add file flash:ie35xx-universalk9.2024-12 03_06.55_much.0.CSCwm26661.SSA.smu.bin`	Copies the maintenance update package from flash to the device, and then performs a compatibility check for the platform and image versions, and adds the SMU package on all member nodes or FRUs, as applicable. This command also runs base compatibility checks on a file to ensure that the SMU package is supported on the platform. It also adds an entry in the package/SMU.sta file, so that its status can be monitored and maintained. You can also copy the SMU package from a remote location (through FTP, HTTP, HTTPS, or TFTP).
Step 3	**install activate file** *location filename* **Example:** `Device# install activate file flash:ie35xx-universalk9.2024-12 03_06.55_much.0.CSCwm26661.SSA.smu.bin, ie35xx-universalk9.2024-12 03_06.55_much.0.CSCwm26661.SSA.smu.bin`	Activates the SMU package file that was added and updates the package status details. You will be promped to reload the system in order to complete the activation process. When entering multiple SMUs, use a comma (without a space before or after), to separate file names. Also ensure that total number of characters does not exceed 128. This step involves a reload.
Step 4	**install commit** **Example:** `Device# install commit`	Commits the activation changes to be persistent across reloads. The commit can be done after activation while the system is up, or after the first reload. If a package is activated but not committed, it remains active after the first reload, but not after the second reload.

Managing an SMU

This task shows how to rollback the installation state, deactivate, and remove a previously installed SMU package from the device. This can be used for a SMU that has been installed with the 1-step and 3-step process.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**install rollback to** {**base** | **committed** | **id** *commit-ID*} **Example:** `Device# install rollback to committed`	Returns the device to the previous installation state. After the rollback, a reload is required.
Step 3	**install deactivate file** *location filename* **Example:** `Device# install deactivate file flash:ie35xx-17.17.1.SPA.smu.bin`	Deactivates an active package, updates the package status, and triggers a process to restart or reload.
Step 4	**install remove** {**file** *location filename* | **inactive**} **Example:** `Device# install remove file flash:ie35xx-17.17.1.SPA.smu.bin`	Checks if the specified SMU is inactive and if it is, deletes it from the file system. The **inactive** option deletes all the inactive packages from the file system.
Step 5	**show version** **Example:** `Device# show version`	Displays the image version on the device.
Step 6	**show install summary** **Example:** `Device# show install summary`	Displays information about the active package. The output of this command varies according to the **install** commands that are configured.

Configuration Examples for Software Maintenance Upgrade

The following is a list of SMU configuration examples.

- Installing an SMU (3-Step Process, Using flash:), on page 2207
- Example: Installing an SMU (3-Step Process, Using TFTP), on page 2210

Installing an SMU (3-Step Process, Using flash:)

The following example shows how to install a SMU package by using the 3-step process. Here the SMU package file is saved in the device's flash.

1. Copying the SMU package file from flash and installing it.

```
Device# install add file flash:ie35xx_lite_iosxe.xx.xx.xx.CSCvk70181.SPA.smu.bin
install_add: START Wed Mar 10 14:17:45 IST 2025
install_add: Adding SMU

--- Starting initial file syncing ---
Info: Finished copying flash:ie35xx_lite_iosxe.xx.xx.xx.CSCvk70181.SPA.smu.bin to the
selected switch(es)
Finished initial file syncing

*Mar 10 14:17:48.128 IST: %INSTALL-5-INSTALL_START_INFO: Switch 1 R0/0: install_engine:

- Setting the Default File System, on page 2215
- Displaying Information About Files on a File System, on page 2215
- Changing Directories and Displaying the Working Directory , on page 2216
- Creating Directories , on page 2217
- Copying Files, on page 2218
- Creating, Displaying and Extracting Files , on page 2219

Information About the Flash File System

The flash file system is a single flash device on which you can store files. It also provides several commands to help you manage software bundles and configuration files. The default flash file system on the device is named flash:.

As viewed from the active device, flash: refers to the local flash device, which is the device attached to the same device on which the file system is being viewed.

Only one user at a time can manage the software bundles and configuration files.

Displaying Available File Systems

To display the available file systems on your device, use the **show file systems** privileged EXEC command as shown in this example for a standalone device:

```
Device# show file systems
File Systems:
Size(b) Free(b) Type Flags Prefixes
- - opaque rw system:
- - opaque rw tmpsys:
1651314688 1467920384 disk rw crashinfo:
* 11353194496 6942072832 disk rw flash:
7723847680 7646384128 disk ro webui:
- - opaque rw null:
- - opaque ro tar:
- - network rw tftp:
```

```
2097152 2089932 nvram rw nvram:
- - network rw rcp:
- - network rw http:
- - network rw ftp:
- - network rw scp:
- - network rw https:
- - opaque ro cns:
118014062592 111933124608 disk rw usbflash1:
```

This example displays the usbflash1 filesystem format.

```
Device#show usbflash1: filesys
Filesystem: usbflash1
Filesystem Path: /vol/usb1
Filesystem Type: ext4
Mounted: Read/Write
```

Table 158: show file systems Field Descriptions

Field	Value
Size(b)	Amount of memory in the file system in bytes.
Free(b)	Amount of free memory in the file system in bytes.
Type	Type of file system. **disk**—The file system is for a flash memory device, USB flash, and crashinfo file. **network**—The file system for network devices; for example, an FTP server or and HTTP server. **nvram**—The file system is for a NVRAM device. **opaque**—The file system is a locally generated pseudo file system (for example, the system) or a download interface, such as brimux. **unknown**—The file system is an unknown type.
Flags	Permission for file system. **ro**—read-only. **rw**—read/write. **wo**—write-only.

Field	Value
Prefixes	Alias for file system. **crashinfo:**—Crashinfo file. **flash:**—Flash file system. **ftp:**—FTP server. **http:**—HTTP server. **https:**—Secure HTTP server. **nvram:**—NVRAM. **null:**—Null destination for copies. You can copy a remote file to null to find its size. **rcp:**—Remote Copy Protocol (RCP) server. **scp:**—Session Control Protocol (SCP) server. **system:**—Contains the system memory, including the running configuration. **tftp:**—TFTP network server. **usbflash0:**—USB flash memory. **usbflash1:**—External USB flash memory. **ymodem:**—Obtain the file from a network machine by using the Ymodem protocol.

Setting the Default File System

You can specify the file system or directory that the system uses as the default file system by using the **cd** *filesystem:* privileged EXEC command. You can set the default file system to omit the *filesystem:* argument from related commands. For example, for all privileged EXEC commands that have the optional *filesystem:* argument, the system uses the file system specified by the **cd** command.

By default, the default file system is *flash:*.

You can display the current default file system as specified by the **cd** command by using the **pwd** privileged EXEC command.

Displaying Information About Files on a File System

You can view a list of the contents of a file system before manipulating its contents. For example, before copying a new configuration file to flash memory, you might want to verify that the file system does not already contain a configuration file with the same name. Similarly, before copying a flash configuration file to another location, you might want to verify its filename for use in another command. To display information about files on a file system, use one of the privileged EXEC commands listed in the following table.

Table 159: Commands for Displaying Information About Files

Command	Description
dir [/all] **[***filesystem:filename***]**	Displays a list of files on a file system.
show file systems	Displays more information about each of the files on a file system.
show file information *file-url*	Displays information about a specific file.
show file descriptors	Displays a list of open file descriptors. File descriptors are the internal representations of open files. You can use this command to see if another user has a file open.

For example, to display a list of all files in a file system, use the **dir** privileged EXEC command:

```
Device# dir flash:
DDirectory of bootflash:/

616513  drwx             4096  Jul 15 2015 07:11:35 +00:00  .installer

11250098176 bytes total (9128050688 bytes free)
Device#
```

Changing Directories and Displaying the Working Directory

Follow these steps to change directories and to display the working directory:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**dir** *filesystem:* **Example:** `Device# dir flash:`	Displays the directories on the specified file system. For *filesystem:*, use flash: for the system board flash device.
Step 3	**cd** *directory_name* **Example:** `Device# cd new_configs`	Navigates to the specified directory. The command example shows how to navigate to the directory named *new_configs*.
Step 4	**pwd** **Example:** `Device# pwd`	Displays the working directory.
Step 5	**cd** **Example:** `Device# cd`	Navigates to the default directory.

Creating Directories

Beginning in privileged EXEC mode, follow these steps to create a directory:

Procedure

	Command or Action	Purpose
Step 1	**dir** *filesystem:* **Example:** `Device# dir flash:`	Displays the directories on the specified file system. For *filesystem:*, use flash: for the system board flash device.
Step 2	**mkdir** *directory_name* **Example:**	Creates a new directory. Directory names are case sensitive and are limited to 45 characters between the slashes (/); the name cannot contain

	Command or Action	Purpose
	`Device# mkdir new_configs`	control characters, spaces, slashes, quotes, semicolons, or colons.
Step 3	**dir** *filesystem:* **Example:** `Device# dir flash:`	Verifies your entry.

Removing Directories

To remove a directory with all its files and subdirectories, use the **delete /force /recursive** *filesystem:/file-url* privileged EXEC command.

Use the **/recursive** keyword to delete the named directory and all subdirectories and the files contained in it. Use the **/force** keyword to suppress the prompting that confirms a deletion of each file in the directory. You are prompted only once at the beginning of this deletion process.

For *filesystem*, use **flash:** for the system board flash device. For *file-url*, enter the name of the directory to be deleted. All of the files in the directory and the directory are removed.

Caution When directories are deleted, their contents cannot be recovered.

Copying Files

To copy a file from a source to a destination, use the **copy** *source-url destination-url* privileged EXEC command. For the source and destination URLs, you can use **running-config** and **startup-config** keyword shortcuts. For example, the **copy running-config startup-config** command saves the currently running configuration file to the NVRAM section of flash memory to be used as the configuration during system initialization.

You can also copy from special file systems (**xmodem:**, **ymodem:**) as the source for the file from a network machine that uses the Xmodem or Ymodem protocol. SSH File Transfer Protocol (SFTP) is also another option to copy switch configuration or image files. For more information, refer the *Configuring SSH File Transfer Protocol* chapter of the *Security Configuration Guide*.

Network file system URLs include ftp:, rcp:, tftp:, scp:, http:, and https: and have these syntaxes:

- FTP—ftp:[[//username [:password]@location]/directory]/filename
- RCP—rcp:[[//username@location]/directory]/filename
- TFTP—tftp:[[//location]/directory]/filename
- SCP—scp:[[//username [:password]@location]/directory]/filename
- HTTP—http:[[//username [:password]@location]/directory]/filename
- HTTPS—https:[[//username [:password]@location]/directory]/filename

Note The password must not contain the special character '@'. If the character '@' is used, the copy fails to parse the IP address of the server.

Local writable file systems include flash:.

Some invalid combinations of source and destination exist. Specifically, you cannot copy these combinations:

- From a running configuration to a running configuration
- From a startup configuration to a startup configuration

Deleting Files

When you no longer need a file on a flash memory device, you can permanently delete it. To delete a file or directory from a specified flash device, use the **delete** [**/force**] [**/recursive**] [*filesystem:*]*/file-url* privileged EXEC command.

Use the **/recursive** keyword for deleting a directory and all subdirectories and the files contained in it. Use the **/force** keyword to suppress the prompting that confirms a deletion of each file in the directory. You are prompted only once at the beginning of this deletion process. Use the **/force** and **/recursive** keywords for deleting old software images that were installed by using the **archive download-sw** command but are no longer needed.

If you omit the *filesystem:* option, the device uses the default device specified by the **cd** command. For *file-url*, you specify the path (directory) and the name of the file to be deleted.

When you attempt to delete any files, the system prompts you to confirm the deletion.

Caution When files are deleted, their contents cannot be recovered.

This example shows how to delete the file *myconfig* from the default flash memory device:

```
Device# delete myconfig
```

Creating, Displaying and Extracting Files

You can create a file and write files into it, list the files in a file, and extract the files from a file as described in the next sections.

Beginning in privileged EXEC mode, follow these steps to create a file, display the contents, and extract it:

Procedure

	Command or Action	Purpose
Step 1	**archive tar /create** *destination-url* **flash:** */file-url*	Creates a file and adds files to it.

	Command or Action	Purpose
	Example: `Device# archive tar /create tftp:172.20.10.30/saved. flash:/new-configs`	For destination-url, specify the destination URL alias for the local or network file system and the name of the file to create: • Local flash file system syntax: **flash:** • FTP syntax: **ftp**:[[//*username*[:*password*]@*location*]/*directory*]/*-filename*. • RCP syntax: **rcp**:[[//*username@location*]/*directory*]/*-filename*. • TFTP syntax: **tftp**:[[//*location*]/*directory*]/*-filename*. For **flash:***/file-url*, specify the location on the local flash file system in which the new file is created. You can also specify an optional list of files or directories within the source directory to add to the new file. If none are specified, all files and directories at this level are written to the newly created file.
Step 2	**archive tar /table** *source-url* **Example:** `Device# archive tar /table flash: /new_configs`	Displays the contents of a file. For *source-url*, specify the source URL alias for the local or network file system. The *-filename.* is the file to display. These options are supported: • Local flash file system syntax: **flash:** • FTP syntax: **ftp**:[[//*username*[:*password*]@*location*]/*directory*]/*-filename*. • RCP syntax: **rcp**:[[//*username@location*]/*directory*]/*-filename*. • TFTP syntax: **tftp**:[[//*location*]/*directory*]/*-filename*. You can also limit the file displays by specifying a list of files or directories after the file. Only those files appear. If none are specified, all files and directories appear.
Step 3	**archive tar /xtract** *source-url* **flash:***/file-url* [*dir/file...*] **Example:** `Device# archive tar /xtract`	Extracts a file into a directory on the flash file system. For *source-url*, specify the source URL alias for the local file system. The *-filename.* is the

	Command or Action	Purpose
	`tftp:/172.20.10.30/saved.` `flash:/new-configs`	file from which to extract files. These options are supported: • Local flash file system syntax: **flash:** • FTP syntax: **ftp**:[[//*username*[:*password*]@*location*]/*directory*]/*-filename*. • RCP syntax: **rcp**:[[//*username*@*location*]/*directory*]/*-filename*. • TFTP syntax: **tftp**:[[//*location*]/*directory*]/*-filename*. For **flash:**/*file-url* [*dir/file...*], specify the location on the local flash file system from which the file is extracted. Use the *dir/file...* option to specify a list of files or directories within the file to be extracted. If none are specified, all files and directories are extracted.

Step 4	**more** [/**ascii** | /**binary** | /**ebcdic**] /*file-url*
	Example:
	`Device# more`
	`flash:/new-configs`
		Displays the contents of any readable file, including a file on a remote file system.

CHAPTER 149

Performing Factory Reset

- Prerequisites for Performing a Factory Reset, on page 2223
- Restrictions for Performing a Factory Reset, on page 2223
- Information About Performing a Factory Reset, on page 2223
- How to Perform a Factory Reset, on page 2224
- Configuration Examples for Performing a Factory Reset, on page 2226

Prerequisites for Performing a Factory Reset

- Ensure that all the software images, including the current image, configurations, and personal data are backed up before you begin the factory reset process.
- Ensure that there is uninterrupted power supply when the factory reset process is in progress.
- Ensure that In-Service Software Upgrade (ISSU) or In-Service Software Downgrade (ISSD) are not in progress before you begin the factory reset process.

Restrictions for Performing a Factory Reset

- Software patches, if installed on the device, will not be restored after the factory reset process.
- If the **factory-reset** command is issued through a VTY session, the session is not restored after completion of the factory reset process.

Information About Performing a Factory Reset

Factory reset erases all the customer-specific data stored in a device and restores the device to its original configuration at the time of shipping. Data that is erased includes configurations, log files, boot variables, core files, and credentials such as Federal Information Processing Standard-related (FIPS-related) keys. The erasure is consistent with the clear method, as described in NIST SP 800-88 Rev. 1.

The factory reset process is used in the following scenarios:

- Return Material Authorization (RMA) for a device: If you have to return a device to Cisco for RMA, remove all the customer-specific data before obtaining an RMA certificate for the device.

- Recovering a compromised device: If the key material or credentials that are stored on a device are compromised, reset the device to the factory configuration, and then reconfigure the device.

During a factory reset, the device reloads and enters ROMMON mode. After the factory reset, the device removes all its environment variables, including the **MAC_ADDRESS** and the **SERIAL_NUMBER** variables, which are required to locate and load the software. Perform a reset in ROMmon mode to automatically set the environment variables. The BAUD rate environment variable returns to its default value after a factory reset. Make sure that the BAUD rate and the console speed are the same at all times. Otherwise, the console becomes unresponsive.

After the system reset in ROMmon mode is complete, add the Cisco IOS image either through an USB or TFTP.

The following table provides details about the data that is erased and retained during the factory reset process:

Table 160: Data Erased and Retained During Factory Reset

Data Erased	Data Retained
All Cisco IOS images, including the current boot image	Data from remote field-replaceable units (FRUs)
Crash information and logs	Value of the configuration register.
User data, startup and running configuration, and contents of removable storage devices, such as Serial Advanced Technology Attachment (SATA), Solid State Drive (SSD), or USB	—
Credentials such as FIPS-related keys	Credentials such as Secure Unique Device Identifier (SUDI) certificates, and public key infrastructure (PKI) keys.
Onboard Failure Logging (OBFL) logs	
ROMmon variables added by a user.	—

Secure Data Wipe

The device storage is used to maintain software images, device configuration, software logs and operational history. Customer-specific data can be contained in any of these areas. The information can include network architecture and design used by customers.

The **all secure** option in the **factory-reset** command performs data sanitization and securely resets the device. After data sanitization, the device reloads and boots with the software image present in flash.

Secure data wipe feature implements guidelines for media sanitization as described in NIST SP 800-88 Rev. 1.

How to Perform a Factory Reset

To perform a factory reset, complete this procedure:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	• For a standalone device: **factory-reset** {**all** [**secure**] [**3-pass**] | **config** | **boot-vars**} **Example:** `Device# factory-reset all`	Resets the device to its configuration at the time of its shipping. No system configuration is required to use the **factory reset** command. The following options are available: • **all**: Erases all the content from the NVRAM, all the Cisco IOS images, including the current boot image, boot variables, startup and running configuration data, and user data. We recommend that you use this option. • **all secure**: Performs data sanitization and securely resets the device. **Note** • You can use the **all secure** option only on standalone devices. • This option implements guidelines for media sanitization as described in NIST SP 800-88 Rev. 1. • The **factory-reset all secure** command initiates data sanitization. The booted image of the device is retained. • When data sanitization is completed, the device reloads, and the device image is retained in flash if it was booted with an image from the flash. • **secure 3-pass**: Erases all the content from the device with 3-pass overwrite. • Pass 1: Overwrites all addressable locations with binary zeroes. • Pass 2: Overwrites all addressable locations with binary ones.

	Command or Action	Purpose
		• Pass 3: Overwrites all addressable locations with a random bit pattern. **Note** This option takes approximately thrice the time taken to perform any other option. • **config**: Resets the startup configurations. • **boot-vars**: Resets the user-added boot variables. After the factory reset process is successfully completed, the device reboots and enters ROMmon mode.

Configuration Examples for Performing a Factory Reset

The following example shows how to perform a factory reset on a standalone switch:

```
Device> enable
Device# factory-reset all

The factory reset operation is irreversible for all operations. Are you sure? [confirm]
The following will be deleted as a part of factory reset:
1: Crash info and logs
2: User data, startup and running configuration
3: All IOS images, including the current boot image
4: OBFL logs
5: User added rommon variables
6: Data on Field Replaceable Units(USB/SSD/SATA)
The system will reload to perform factory reset.
It will take some time to complete and bring it to rommon.
You will need to load IOS image using USB/TFTP from rommon after
this operation is completed.
DO NOT UNPLUG THE POWER OR INTERRUPT THE OPERATION
Are you sure you want to continue? [confirm]
```

The following sample output from the **show platform software factory-reset secure log** command displays the data sanitization report:

```
Device# show platform software factory-reset secure log
Factory reset log:
#CISCO IE35xx DATA SANITIZATION REPORT#
START : 18-09-2022, 06:18:44
  END : 18-09-2022, 06:23:36
-MTD-
PNM : nor

CHAPTER 150

Configuring Secure Storage

- Information About Secure Storage, on page 2229
- Enabling Secure Storage , on page 2229
- Disabling Secure Storage , on page 2230
- Verifying the Status of Encryption, on page 2230

Information About Secure Storage

Secure Storage feature allows you to secure critical configuration information by encrypting it. It encrypts asymmetric key-pairs, pre-shared secrets, the type 6 password encryption key and certain credentials. An instance-unique encryption key is stored in the hardware trust anchor to prevent it from being compromised.

Enabling Secure Storage

Before you begin

By default, this feature is disabled.

Procedure

	Command or Action	Purpose
Step 1	**configure terminal** **Example:** `Device# configure terminal`	Enters the global configuration mode.
Step 2	**service private-config-encryption** **Example:** `DEvice(config)# service private-config-encryption`	Enables the Secure Storage feature on your device.
Step 3	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.

	Command or Action	Purpose
Step 4	**write memory** **Example:** `Device# write memory`	Encrypts the private-config file and saves the file in an encrypted format.

Disabling Secure Storage

Before you begin

To disable Secure Storage feature on a device, perform this task:

Procedure

	Command or Action	Purpose
Step 1	**configure terminal** **Example:** `Device# configure terminal`	Enters the global configuration mode.
Step 2	**no service private-config-encryption** **Example:** `Device(config)# no service private-config-encryption`	Disables the Secure Storage feature on your device. When secure storage is disabled, all the user data is stored in plain text in the NVRAM.
Step 3	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 4	**write memory** **Example:** `Device# write memory`	Decrypts the private-config file and saves the file in plane format.

Verifying the Status of Encryption

Use the **show parser encrypt file status** command to verify the status of encryption. The following command output indicates that the feature is available but the file is not encrypted. The file is in 'plain text' format.

This is an example of unencrypted file and shows the status here as plain text.

```
Device#show parser encrypt file status
Feature: Enabled
File Format: Plain Text
Encryption Version: Ver1
```

CHAPTER 151

Trace Management

- Information About Trace Management, on page 2231
- How to Configure Conditional Debugging, on page 2234
- Configuration Examples for Trace Management, on page 2237

Information About Trace Management

The tracing functionality logs internal events. Trace files are automatically created and saved on the persistent storage device of specific platforms.

If the device has issues, the contents of the trace files are useful to troubleshoot the issue. The trace file outputs provide logs that are used to locate and solve the issue, and helps to get a detailed view of system actions and operations.

To view the recent trace information for a specific process, use the **show logging [process | Profile | process-helper]** command. The **process** keyword uses the first few letters of the name of a process and provides trace logs of the process that starts or matches with the entered string, the **profile** keyword lists the predefined set of process names, and the **profile-helper** keyword displays the available names.

To change the verbosity in a trace message output, you can adjust the trace level of processes using the **set platform software trace level** command. You can choose the **all** keyword to adjust the trace level for all the processes listed or you can select a specific process. When you select a specific process, there's also the option to adjust the trace level for a specific module, or you can use the **all-modules** keyword to adjust all the modules of processes.

Introduction to Binary Tracing

Binary tracing is helpful in gathering trace information with a minimal impact on performance. In binary tracing, the tracing is always on for the system components and a basic level of trace is collected on all the time; thus, the data necessary for troubleshooting a problem has been captured the first time it occurs.

Introduction to Conditional Debugging and Radioactive Tracing

The Conditional Debugging feature allows you to enable debugging and logging for specific features based on the set of conditions you define. This feature is useful in systems where many features are supported.

The Conditional debug allows granular debugging in a network that is operating at a large scale with a large number of features. It allows you to observe detailed debugs for granular instances within the system. This

type of debugging is useful when we need to debug only a particular session among thousands of sessions. It's also possible to specify multiple conditions.

A condition refers to a feature or identity, where an identity could be an interface, IP Address, or a MAC address and so on.

Conditional debugging is in contrast to the general debug command, that produces its output without discriminating on the feature objects that are being processed. General debug command consumes numerous system resources and impacts the system performance.

Radioactive tracing provides the ability to form a chain of execution for operations of interest across the system, at an increased verbosity level. This provides a way to print conditionally debug information (up to DEBUG Level or a specified level) across threads, processes, and function calls.

Radioactive Tracing when coupled with Conditional Debugging, provides a single debug command to debug all execution contexts related to the condition. You can execute this command without being aware of the various control flow processes of the feature within the box and without having to issue debugs at these processes individually.

Tracing Levels

Trace level determines the types of traces outputted. Each trace message is assigned a trace level. If the trace level of a process or its module it set as greater than or equal to the level as the trace message, the trace message is displayed otherwise, it's skipped. For example, the default trace level is **Notice** level, so all traces with the **Notice** level and below the notice level are included while the traces above the **Notice** level are excluded.

The following table shows the available tracing levels, and provides descriptions of the message that are displayed with each tracing level. The tracing levels listed in the table are from the lowest to the highest order. The default trace level is **Notice**.

Table 161: Tracing Levels and Descriptions

Tracing Level	Description
Fatal	The message stating the process is aborted.
Emergency	The message is regarding an issue that makes the system unusable.
Alert	The message indicating that an action must be taken immediately.
Critical	The message is regarding a critical event causing loss of important functions.
Error	The message is regarding a system error.
Warning	The message is regarding a system warning.
Notice	The message is regarding a significant event.
Informational	The message is useful for informational purposes only.
Debug	The message provides debug-level output.

Tracing Level	Description
Verbose	All possible trace messages are sent.
Noise	All possible trace messages for the module are logged. The noise level is always equal to the highest possible tracing level. Even if a future enhancement to tracing introduces a higher tracing level, the noise level will become equal to the level of that new enhancement.

Payload Filter

This feature is used to filter trace messages. Trace messages contain actual debug information such as text strings, special characters, and variable arguments (strings), integers, long, IPv4/IPv6/MAC addresses, and so on. Using the payload feature, the trace messages can be filtered based on the selected criteria and without string operations.

You can use the following set and show commands to configure a payload filter and to view the applied filters.

Table 162: Set Commands for Payload Filter

set platform software btrace-manager ... utm-pf enable	Enables and disables the payload filtering feature.
set platform software btrace-manager ... utm-pf disable	
set platform software btrace-manager ... consumer-name <input> create	Creates and deletes consumer/stream.
set platform software btrace-manager ... consumer-name <input> delete	
set platform software btrace-manager ... consumer-name <input> filter <input> add	Applies and removes filter on stream/consumer
set platform software btrace-manager ... consumer-name <input> filter <input> remove	

Table 163: Show Commands for Payload Filter

#show platform software btrace-manager ... utm-pf	Shows the current status of the payload feature and other additional details
show platform software btrace-manager ... utm-pf consumer-name <input> all-filters	Shows all filters currently applied on consumer/stream.
show platform software btrace-manager ... utm-pf consumer-name <input> all-luids	Shows all or selected LUID of consumer for the applied filter.
show platform software btrace-manager ... utm-pf consumer-name <input> filter <input>	

show platform software btrace-manager ... utm-pf message	Shows consumer/stream messages.

How to Configure Conditional Debugging

Conditional Debugging and Radioactive Tracing

Radioactive Tracing when coupled with Conditional Debugging, prpvides a single debug command to debug all execution contexts related to the condition. You can execute this command without being aware of the various control flow processes of the feature within the box and without having to issue debugs at these processes individually.

Configuring Conditional Debugging

Follow the steps to configure conditional debugging:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**debug platform condition mac** {*mac-address*} **Example:** `Device# debug platform condition mac bc16.6509.3314`	Configures conditional debugging for the MAC Address specified.
Step 3	**debug platform condition start** **Example:** `Device# debug platform condition start`	Starts conditional debugging (this step starts radioactive tracing if there's a match on one of the preceding conditions).

Step 4	**show platform condition** OR **show debug**
	Example:
	`Device# show platform condition`
	`Device# show debug`
		Displays the current conditions set.

Step 5	**debug platform condition stop** **Example:** `Device# debug platform condition stop`	Stops conditional debugging (this step stops radioactive tracing).

	Command or Action	Purpose
Step 6	**request platform software trace archive** [**last** {*number*} **days**] [**target** {*crashinfo:* | *flashinfo:*}] **Example:** `# request platform software trace archive last 2 days`	(Optional) Displays historical logs of merged tracefiles on the system. Filter on any combination of number of days or location.
Step 7	**show platform software trace** [**filter-binary** | **level** | **message**] **Example:** `Device# show platform software trace message`	(Optional) Displays logs merged from the latest trace file. Filter on any combination of application condition, trace module name, and trace level. • **filter-binary** - Filter the modules to be collated • **level** - Show trace levels • **message** - Show trace message ring contents **Note** On the device: • Available from IOS console in addition to linux shell. • Generates a file with merged logs • Displays merged logs only from staging area.
Step 8	**clear platform condition all** **Example:** `Device# clear platform condition all`	Clears all conditions.

What to do next

Note The commands **request platform software trace filter-binary** and **show platform software trace filter-binary** work in a similar way. The only difference is:

- **request platform software trace filter-binary** - Sources the data from historical logs.
- **show platform software trace filter-binary** – Sources the data from the flash Temp directory.

The *mac_log* <*..date..*> is the important file, as it provides messages for the MAC that is being debugged. The command **show platform software trace filter-binary** also generates the same flash files, and also prints the mac_log on the screen.

Collecting Trace Files

To collect trace files from a device, follow these steps:

1. To request the tracelogs for a specific time period (For example: Five days), use the command:

   Device# **request platform software trace archive last 5 day**

2. The system generates a tar ball (.gz file) of the tracelogs in the location **/flash**:

Copying Archived Trace Files

The following is an example of the trace file for a switching device:

```
Device# dir crashinfo:/tracelogs
Directory of crashinfo:/tracelogs/

50664 -rwx 760 Sep 22 2015 11:12:21 +00:00 plogd_F0-0.bin_0.gz
50603 -rwx 991 Sep 22 2015 11:12:08 +00:00 fed_pmanlog_F0-0.bin_0.9558.20150922111208.gz
50610 -rw- 11 Nov 2 2015 00:15:59 +00:00 timestamp
50611 -rwx 1443 Sep 22 2015 11:11:31 +00:00
auto_upgrade_client_sh_pmanlog_R0-.bin_0.3817.20150922111130.gz
50669 -rwx 589 Sep 30 2015 03:59:04 +00:00 cfgwr-8021_R0-0.bin_0.gz
50612 -rwx 1136 Sep 22 2015 11:11:46 +00:00 reflector_803_R0-0.bin_0.1312.20150922111116.gz
50794 -rwx 4239 Nov 2 2015 00:04:32 +00:00 IOSRP_R0-0.bin_0.14239.20151101234827.gz
50615 -rwx 131072 Nov 2 2015 00:19:59 +00:00 linux_iosd_image_pmanlog_R0-0.bin_0
--More—
```

You can copy the trace files using one of the following options:

```
Device# copy crashinfo:/tracelogs ?
  crashinfo: Copy to crashinfo: file system
  flash: Copy to flash: file system
  ftp: Copy to ftp: file system
  http: Copy to http: file system
  https: Copy to https: file system
  null: Copy to null: file system
  nvram: Copy to nvram: file system
  rcp: Copy to rcp: file system
  running-config Update (merge with) current system configuration
  scp: Copy to scp: file system
  startup-config Copy to startup configuration
  syslog: Copy to syslog: file system
  system: Copy to system: file system
  tftp: Copy to tftp: file system
  tmpsys: Copy to tmpsys: file system
```

The general syntax for copying onto a TFTP server is as follows:

```
Device# copy source: tftp:
Device# copy crashinfo:/tracelogs/IOSRP_R0-0.bin_0.14239.20151101234827.gz tftp:
Address or name of remote host []? 2.2.2.2
Destination filename [IOSRP_R0-0.bin_0.14239.20151101234827.gz]?
```

Note It's important to clear the generated report or archive files off the device so that there's flash space available for tracelog and other purposes.

Configuring Payload Filter

To configure a payload filter, you must create a consumer and add the relevant payload filter data.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

Step 2	**set platform software btrace-manager utm-pf enable**
	Example:
	`Device# set platform software btrace-manager chassis active r0 utm-pf enable`
	`Device# set platform software btrace-manager chassis active r0 utm-pf disable`
		Enables or disables the payload filter.

Step 3	**set platform software btrace-manager** {*consumer-name*} **create** **Example:** `Device# set platform software btrace-manager chassis active r0 consumer-name utm_pf_test create`	Creates a consumer name.
Step 4	**set platform software btrace-manager consumer** {*consumer-name*} **filter** {*input*} **add** **Example:** `Device# set platform software btrace-manager chassis active r0 consumer-name utm_pf_test filter "Failed to retrieve an interface" add`	Add a filter data.

Configuration Examples for Trace Management

The following is an output example of the *show platform condition* command.

The following is a sample of the *debug platform condition stop* command.

```
Device# debug platform condition stop
Conditional Debug Global State: Stop
```

The following is an example of the **show logging** command for the **ios** process.

```
Device# show logging process ios

CHAPTER 152

Consent Token

- Restrictions for Consent Token, on page 2241
- Information About Consent Token, on page 2241
- Consent Token Authorization Process for System Shell Access, on page 2242

Restrictions for Consent Token

- Consent Token is enabled by default and cannot be disabled.
- After the challenge has been sent from the device, the response needs to be entered within 30 minutes. If it is not entered, the challenge expires and a new challenge must be requested.
- A single response is valid only for one time for a corresponding challenge.
- The maximum authorization timeout for root-shell access is seven days.
- After a switchover event, all the existing Consent Token based authorizations would be treated as expired. You must then restart a fresh authentication sequence for service access.
- Only Cisco authorized personnel have access to Consent Token response generation on Cisco's challenge signing server.
- In System Shell access scenario, exiting the shell does not terminate authorization until the authorization timeout occurs or the shell authorization is explicitly terminated by the consent token terminate authorization command.

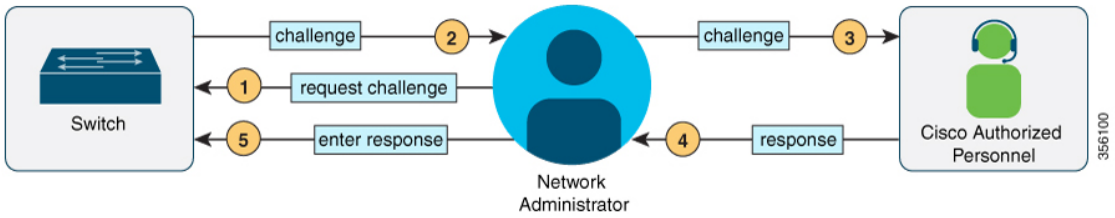
  We recommend that you force terminate System Shell authorization by explicitly issuing the Consent Token terminate command once the purpose of System Shell access is complete.

Information About Consent Token

Consent Token is a security feature that is used to authenticate the network administrator of an organization to access system shell with mutual consent from the network administrator and Cisco Technical Assistance Centre (Cisco TAC).

In some debugging scenarios, the Cisco TAC engineer may have to collect certain debug information or perform live debug on a production system. In such cases, the Cisco TAC engineer will ask you (the network

administrator) to access system shell on your device. Consent Token is a lock, unlock and re-lock mechanism that provides you with privileged, restricted, and secure access to the system shell.



When you request access to system shell, you need to be authorized. You must first run the command to generate a challenge using the Consent Token feature on your device. The device generates a unique challenge as output. You must then copy this challenge string and send it to a Cisco Authorized Personnel through e-mail or Instant Message.

The Cisco Authorized Personnel processes the unique challenge string and generates a response that is unique. The Cisco Authorized Personnel copies this response string and sends it to you through e-mail or Instant Message.

You must then input this response string into your device. If the challenge-response pair match, you are authorized to access system shell. If not, an error is displayed and you are required to repeat the authentication process.

Once you gain access to system shell, collect the debug information required by the Cisco TAC engineer. After you are done accessing system shell, terminate the session and continue the debugging process.

Figure 143: Consent Token

Consent Token Authorization Process for System Shell Access

This section describes the process of Consent Token authorization to access system shell:

Procedure

Step 1 Generate a challenge requesting for access to system shell for the specified time period.

Example:

```
Device# request consent-token generate-challenge shell-access auth-timeout 900
zSSdrAAAAQEBAAQAAAABAgAEAAAAAAMACH86csUhmDl0BAAQ0Fvd7CxqRYUeoD7B4AwW7QUABAAAAG8GAAhDVEFf
REVNTwcAGENUQV9ERU1PX0NUQV9TSUdOSU5HX0tFWQgAC0M5ODAwLUNMLUs5CQALOVpQUEVESE5KRkI=
Device#
*Jan 18 02:47:06.733: %CTOKEN-6-AUTH_UPDATE: Consent Token Update (challenge generation
attempt: Shell access 0).
```

Send a request for a challenge using the **request consent-token generate-challenge shell-access** *time-validity-slot* command. The duration in minutes for which you are requesting access to system shell is the time-slot-period.

In this example, the time period is 900 minutes after which the session expires.

The device generates a unique challenge as output. This challenge is a base-64 format string.

Step 2 Send the challenge string to a Cisco Authorized Personnel.

Send the challenge string generated by the device to a Cisco Authorized Personnel through e-mail or Instant Message.

The Cisco Authorized Personnel processes the unique challenge string and generates a response. The response is also a base-64 string that is unique. The Cisco Authorized Personnel copies this response string and sends it to you through e-mail or Instant Message.

Step 3 Input the response string onto your device.

Example:

```
Device# request consent-token accept-response shell-access
lR1y2AAUKFcAAAABAAABYlVDZ2d6MnkxL3JxTTJSSC9FZE5aW
nRSa1FteS9POWZqRUNlTk1LL3VoUWkIc0FsOHl5OW5vckQ4YWVOelpZZGYNCkNpWHY0b1B4Q000UGs1M2ZEMUpoazBCUkYyM3FML1A2ckVjM3paR05wd
Hcvck95UVduYUVufnA5bnhIZ09CNE0NCjBmVjh4b3I4TzE3aHNMaU1JeDQ3YWtkdE9Xb0JhImlzMVRweFBVZE93QUxvZDVEbmo4UEtiR01VVUM5b3lZ
WXQNCjFIRnJPbXczcmpsZTJHUnIxOWJUNkZLIWlpZ0ZmbENVRWo4K2xoaXgxS0ZtdDVPcDBYczVPSU43L0dSK1pGInoNCmYxIUtjaWlOWDhWTlNLQ0Z
WNURHU3pIenF1UFBxZVNDU0xLNkhXUTFROTlFMXJVakdlZ1NqIWxnNF1ySkJYL0wNCnpaTDVVRnVFdWpRWDdDUThIdkVPM1E9PQ==
% Consent token authorization success
*Jan 18 02:51:37.807: %CTOKEN-6-AUTH_UPDATE: Consent Token Update (authentication success:
 Shell access 0).

Device# request platform software system shell
Activity within this shell can jeopardize the functioning of the system.
Are you sure you want to continue? [y/n] y
Device#
*Jan 18 02:56:59.714: %CTOKEN-6-AUTH_UPDATE: Consent Token Update (authorization for Shell
 access 0 will expire in 10 min).
```

Input the response string sent to you by the Cisco Authorized Personnel using the **request consent-token accept-response shell-access** *response-string* command.

If the challenge-response pair match, you are authorized to access system shell. If the challenge-response pair do not match, an error is displayed and you are required to repeat steps 1 to 3.

After you are authorized, you can access system shell for the requested time-slot.

The device sends a message when there is ten minutes remaining of the authorization session.

Step 4 Terminate the session.

Example:

```
Device# request consent-token terminate-auth
% Consent token authorization termination success

Device#
*Jan 18 23:33:02.937: %CTOKEN-6-AUTH_UPDATE: Consent Token Update (terminate authentication:
 Shell access 0).
Device#
```

When you finish accessing system shell, you can end the session using the **request consent-token terminate-auth** command. You can also force terminate the session prior to the authorization timeout using this command. The session also gets terminated automatically when the requested time slot expires.

CHAPTER 153

Troubleshooting the Software Configuration

This chapter describes how to identify and resolve software problems related to the Cisco IOS software on the switch. Depending on the nature of the problem, you can use the command-line interface (CLI), Device Manager, or Network Assistant to identify and solve problems.

Additional troubleshooting information, such as LED descriptions, is provided in the hardware installation guide.

- Information About Troubleshooting the Software Configuration, on page 2245
- How to Troubleshoot the Software Configuration, on page 2251
- Verifying Troubleshooting of the Software Configuration, on page 2259
- Scenarios for Troubleshooting the Software Configuration, on page 2260
- Configuration Examples for Troubleshooting Software, on page 2262

Information About Troubleshooting the Software Configuration

Software Failure on a Switch

Switch software can be corrupted during an upgrade by downloading the incorrect file to the switch, and by deleting the image file. In all of these cases, there is no connectivity.

Lost or Forgotten Password on a Device

The default configuration for the device allows an end user with physical access to the device to recover from a lost password by interrupting the boot process during power-on and by entering a new password. These recovery procedures require that you have physical access to the device.

Note On these devices, a system administrator can disable some of the functionality of this feature by allowing an end user to reset a password only by agreeing to return to the default configuration. If you are an end user trying to reset a password when password recovery has been disabled, a status message reminds you to return to the default configuration during the recovery process.

Note You cannot recover encryption password key, when Cisco WLC configuration is copied from one Cisco WLC to another (in case of an RMA).

Follow the steps described in the section Recovering from a Lost or Forgotten Password, on page 2252 to recover from a lost or forgotten password.

Ping

The device supports IP ping, which you can use to test connectivity to remote hosts. Ping sends an echo request packet to an address and waits for a reply. Ping returns one of these responses:

- Normal response—The normal response (*hostname* is alive) occurs in 1 to 10 seconds, depending on network traffic.
- Destination does not respond—If the host does not respond, a *no-answer* message is returned.
- Unknown host—If the host does not exist, an *unknown host* message is returned.
- Destination unreachable—If the default gateway cannot reach the specified network, a *destination-unreachable* message is returned.
- Network or host unreachable—If there is no entry in the route table for the host or network, a *network or host unreachable* message is returned.

Refere the section Executing Ping, on page 2257 to understand how **ping** works.

Layer 2 Traceroute

The Layer 2 traceroute feature allows the switch to identify the physical path that a packet takes from a source device to a destination device. Layer 2 traceroute supports only unicast source and destination MAC addresses. Traceroute finds the path by using the MAC address tables of the devices in the path. When the Device detects a device in the path that does not support Layer 2 traceroute, the Device continues to send Layer 2 trace queries and lets them time out.

The Device can only identify the path from the source device to the destination device. It cannot identify the path that a packet takes from source host to the source device or from the destination device to the destination host.

Layer 2 Traceroute Guidelines

- Cisco Discovery Protocol (CDP) must be enabled on all the devices in the network. For Layer 2 traceroute to function properly, do not disable CDP.

  If any devices in the physical path are transparent to CDP, the switch cannot identify the path through these devices.

- A device is reachable from another device when you can test connectivity by using the **ping** privileged EXEC command. All devices in the physical path must be reachable from each other.
- The maximum number of hops identified in the path is ten.

- You can enter the **traceroute mac** or the **traceroute mac ip** privileged EXEC command on a device that is not in the physical path from the source device to the destination device. All devices in the path must be reachable from this switch.
- The **traceroute mac** command output shows the Layer 2 path only when the specified source and destination MAC addresses belong to the same VLAN. If you specify source and destination MAC addresses that belong to different VLANs, the Layer 2 path is not identified, and an error message appears.
- If you specify a multicast source or destination MAC address, the path is not identified, and an error message appears.
- If the source or destination MAC address belongs to multiple VLANs, you must specify the VLAN to which both the source and destination MAC addresses belong. If the VLAN is not specified, the path is not identified, and an error message appears.
- The **traceroute mac ip** command output shows the Layer 2 path when the specified source and destination IP addresses belong to the same subnet. When you specify the IP addresses, the device uses the Address Resolution Protocol (ARP) to associate the IP addresses with the corresponding MAC addresses and the VLAN IDs.
  - If an ARP entry exists for the specified IP address, the device uses the associated MAC address and identifies the physical path.
  - If an ARP entry does not exist, the device sends an ARP query and tries to resolve the IP address. If the IP address is not resolved, the path is not identified, and an error message appears.
- When multiple devices are attached to one port through hubs (for example, multiple CDP neighbors are detected on a port), the Layer 2 traceroute feature is not supported. When more than one CDP neighbor is detected on a port, the Layer 2 path is not identified, and an error message appears.
- This feature is not supported in Token Ring VLANs.
- Layer 2 traceroute opens a listening socket on the User Datagram Protocol (UDP) port 2228 that can be accessed remotely with any IPv4 address, and does not require any authentication. This UDP socket allows to read VLAN information, links, presence of particular MAC addresses, and CDP neighbor information, from the device. This information can be used to eventually build a complete picture of the Layer 2 network topology.
- Layer 2 traceroute is enabled by default and can be disabled by running the **no l2 traceroute** command in global configuration mode. To re-enable Layer 2 traceroute, use the **l2 traceroute** command in global configuration mode.

IP Traceroute

You can use IP traceroute to identify the path that packets take through the network on a hop-by-hop basis. The command output displays all network layer (Layer 3) devices, such as routers, that the traffic passes through on the way to the destination.

Your Device can participate as the source or destination of the **traceroute** privileged EXEC command and might or might not appear as a hop in the **traceroute** command output. If the Device is the destination of the traceroute, it is displayed as the final destination in the traceroute output. Intermediate devices do not show up in the traceroute output if they are only bridging the packet from one port to another within the same VLAN. However, if the intermediate Device is a multilayer Device that is routing a particular packet, this device shows up as a hop in the traceroute output.

The **traceroute** privileged EXEC command uses the Time To Live (TTL) field in the IP header to cause routers and servers to generate specific return messages. Traceroute starts by sending a User Datagram Protocol (UDP) datagram to the destination host with the TTL field set to 1. If a router finds a TTL value of 1 or 0, it drops the datagram and sends an Internet Control Message Protocol (ICMP) time-to-live-exceeded message to the sender. Traceroute finds the address of the first hop by examining the source address field of the ICMP time-to-live-exceeded message.

To identify the next hop, traceroute sends a UDP packet with a TTL value of 2. The first router decrements the TTL field by 1 and sends the datagram to the next router. The second router sees a TTL value of 1, discards the datagram, and returns the time-to-live-exceeded message to the source. This process continues until the TTL is incremented to a value large enough for the datagram to reach the destination host (or until the maximum TTL is reached).

To learn when a datagram reaches its destination, traceroute sets the UDP destination port number in the datagram to a very large value that the destination host is unlikely to be using. When a host receives a datagram destined to itself containing a destination port number that is unused locally, it sends an ICMP *port-unreachable* error to the source. Because all errors except port-unreachable errors come from intermediate hops, the receipt of a port-unreachable error means that this message was sent by the destination port.

Go to Example: Performing a Traceroute to an IP Host, on page 2263 to see an example of IP traceroute process.

Debug Commands

Caution Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. It is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

All **debug** commands are entered in privileged EXEC mode, and most **debug** commands take no arguments.

System Report

System reports or crashinfo files save information that helps Cisco technical support representatives to debug problems that caused the Cisco IOS image to fail (crash). It is necessary to quickly and reliably collect critical crash information with high fidelity and integrity. Further, it is necessary to collect this information and bundle it in a way that it can be associated or identified with a specific crash occurrence.

System reports are generated in case of a switchover: System reports are generated only on high availability (HA) member switches. Reports are not generated for non-HA members.

The system does not generate reports in case of a reload.

During a process crash, the following is collected locally from the switch:

1. Full process core
2. Tracelogs
3. IOS syslogs (not guaranteed in case of non-active crashes)
4. System process information

5. Bootup logs
6. Reload logs
7. Certain types of /proc information

This information is stored in separate files which are then archived and compressed into one bundle. This makes it convenient to get a crash snapshot in one place, and can be then moved off the box for analysis. This report is generated before the switch goes down to rommon/bootloader.

Except for the full core and tracelogs, everything else is a text file.

Use the **request platform software process core fed switch active** command to generate the core dump.

```
Device# request platform software process core fed switch active
SUCCESS: Core file generated.

Device# dir bootflash:/core
Directory of bootflash:/core/
16430   -rw-         10941657   Apr 6 2022 00:15:20 +00:00
Switch_1_RP_0_fed_18469_20220406-001511-UTC.core.gz
16812   -rw-               1   Apr 6 2022 00:01:48 +00:00  .callhome
16810   drwx            4096  Jan 18 2022 21:10:35 +00:00  modules
```

Crashinfo Files

By default the system report file will be generated and saved into the /crashinfo directory. Ifit cannot be saved to the crashinfo partition for lack of space, then it will be saved to the /flash directory.

To display the files, enter the **dir crashinfo:** command. The following is sample output of a crashinfo directory:

System reports are located in the crashinfo directory in the following format:

```
system-report_[switch number]_[date]-[timestamp]-UTC.gz
```

After a switch crashes, check for a system report file. The name of the most recently generated system report file is stored in the last_systemreport file under the crashinfo directory. The system report and crashinfo files assist TAC while troubleshooting the issue.

The system report generated can be further copied using TFTP, HTTP and few other options.

```
Device# copy crashinfo: ?
crashinfo:     Copy to crashinfo: file system
flash:         Copy to flash: file system
ftp:           Copy to ftp: file system
http:          Copy to http: file system
https:         Copy to https: file system
null:          Copy to null: file system
nvram:         Copy to nvram: file system
rcp:           Copy to rcp: file system
running-config Update (merge with) current system configuration
scp:           Copy to scp: file system
startup-config Copy to startup configuration
syslog:        Copy to syslog: file system
system:        Copy to system: file system
tftp:          Copy to tftp: file system
tmpsys:        Copy to tmpsys: file system
```

The general syntax for copying onto TFTP server is as follows:

```
Device# copy crashinfo: tftp:
Source filename [system-report_1_20150909-092728-UTC.gz]?
Address or name of remote host []? 1.1.1.1
Destination filename [system-report_1_20150909-092728-UTC.gz]?
```

The tracelogs can be collected by issuing a trace archive command. This command provides time period options. The command syntax is as follows:

```
Device# request platform software trace archive ?
last     Archive trace files of last x days
target   Location and name for the archive file
```

The tracelogs stored in crashinfo: or flash: directory from within the last 3650 days can be collected.

```
Device# request platform software trace archive last ?
<1-3650> Number of days (1-3650)
Device# request platform software trace archive last 3650 days target ?
crashinfo: Archive file name and location
flash:     Archive file name and location
```

Note It is important to clear the system reports or trace archives from flash or crashinfo directory once they are copied out, in order to have space available for tracelogs and other purposes.

In a complex network it is difficult to track the origin of a system-report file. This task is made easier if the system-report files are uniquely identifiable. The hostname will be prepended to the system-report file name making the reports uniquely identifiable.

The following example displays system-report files with the hostname prepended:

```
HOSTNAME# dir flash:/core | grep HOSTNAME
40486  -rw-        108268293  Oct 21 2019 16:07:50 -04:00
HOSTNAME-system-report_20191021-200748-UTC.tar.gz
40487  -rw-            17523  Oct 21 2019 16:07:56 -04:00
HOSTNAME-system-report_20191021-200748-UTC-info.txt
40484  -rw-         48360998  Oct 21 2019 16:55:24 -04:00
HOSTNAME-system-report_20191021-205523-UTC.tar.gz
40488  -rw-            14073  Oct 21 2019 16:55:26 -04:00
HOSTNAME-system-report_20191021-205523-UTC-info.txt
```

Onboard Failure Logging on the Switch

You can use the onboard failure logging (OBFL) feature to collect information about the device. The information includes uptime, temperature, and voltage information and helps Cisco technical support representatives to troubleshoot device problems. We recommend that you keep OBFL enabled and do not erase the data stored in the flash memory.

By default, OBFL is enabled. It collects information about the device and small form-factor pluggable (SFP) modules. The device stores this information in the flash memory:

- CLI commands—Record of the OBFL CLI commands that are entered on a standalone device.
- Message—Record of the hardware-related system messages generated by a standalone device .
- Temperature—Temperature of a standalone device.
- Uptime data—Time when a standalone device starts, the reason the device restarts, and the length of time the device has been running since it last restarted.
- Voltage—System voltages of a standalone device.

You should manually set the system clock or configure it by using Network Time Protocol (NTP).

When the device is running, you can retrieve the OBFL data by using the **show logging onboard** privileged EXEC commands. If the device fails, contact your Cisco technical support representative to find out how to retrieve the data.

When an OBFL-enabled device is restarted, there is a 10-minute delay before logging of new data begins.

Possible Symptoms of High CPU Utilization

Excessive CPU utilization might result in these symptoms, but the symptoms might also result from other causes, some of which are the following:

- Spanning tree topology changes
- EtherChannel links brought down due to loss of communication
- Failure to respond to management requests (ICMP ping, SNMP timeouts, slow Telnet or SSH sessions)
- UDLD flapping
- IP SLAs failures because of SLAs responses beyond an acceptable threshold
- DHCP or IEEE 802.1x failures if the switch does not forward or respond to requests

How to Troubleshoot the Software Configuration

Booting from the Recovery Partition

The switch support booting from the recovery partition. This is beneficial to end users if they face an issue while trying to boot the switch from Flash or an external device, such as USB or SDflash. The recovery image is the same as the recommended Cisco IOS image for the switch, and is stored in a partition named **drec0**.

Note You can not access recovery partition when the switch is in Cisco IOS prompt. Note that the factory-reset process does not erase this image.

To check the partition image name, enter **dir drec0:**

```
switch: dir drec0:

Attributes        Size         Name

- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -

-rw-r--r--   490586943   ie35xx-17.17.1.SPA.bin

- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -

switch:
```

To boot from the recovery partition, enter **boot drec0:<image name>**:

```
switch: boot drec0:ie35xx_lite_iosxe.17.17.01.SPA.bin

boot: attempting to boot from [drec0:ie35xx-17.17.1.SPA.bin]
```

```
boot: reading file ie35xx-17.17.1.SPA.bin
##############################
```

Recovering from a Lost or Forgotten Password

The default configuration for the switch allows an end user with physical access to the switch to recover from a lost password by interrupting the boot process during power-on and by entering a new password. These recovery procedures require that you have physical access to the switch.

Note On these switches, a system administrator can disable some of the functionality of this feature by allowing an end user to reset a password only by agreeing to return to the default configuration. If you are an end user trying to reset a password when password recovery has been disabled, a status message shows this during the recovery process.

Procedure

Step 1 Connect a terminal or PC to the switch.

- Connect a terminal or a PC with terminal-emulation software to the switch console port.
- Connect a PC to the Ethernet management port.

Step 2 Set the line speed on the emulation software to 9600 baud.

Step 3 Power off the standalone switch.

Step 4 Reconnect the power cord to the switch or the active switch. As soon as the System LED blinks, press and release the Mode button 2-3 times. The switch enters the ROMMON mode.

The following console messages are displayed during the reload:

```
Initializing Hardware...

System Bootstrap, Version xx.x.1r [FC1], RELEASE SOFTWARE (P)
Compiled Tue 10/29/2024 18:05:06 by rel

Current ROMMON image : Primary
IE35xx-24P platform with 4194304 Kbytes of main memory

Preparing to autoboot. [Press Ctrl-C to interrupt]  4    (interrupted) <-------- break
sequence to be pressed
```

Proceed to the *Procedure with Password Recovery Enabled* section, and follow the steps.

Step 5 After recovering the password, reload the switch or the active switch.

On a switch:

```
Switch> reload
Proceed with reload? [confirm] y
```

Procedure with Password Recovery Enabled

Procedure

Step 1 Enable manual boot mode.

```
Device: MANUAL_BOOT=yes
```

Step 2 Ignore the startup configuration with the following command:

```
Device: SWITCH_IGNORE_STARTUP_CFG=1
```

Step 3 Boot the switch with the *packages.conf* file from flash.

```
Device: boot flash:packages.conf
```

Step 4 Terminate the initial configuration dialog by answering **No**.

```
Would you like to enter the initial configuration dialog? [yes/no]: No
```

Step 5 At the switch prompt, enter privileged EXEC mode.

```
Device> enable
Device#
```

Step 6 Copy the startup configuration to running configuration.

```
Device# copy startup-config running-config Destination filename [running-config]?
```

Press Return in response to the confirmation prompts. The configuration file is now reloaded, and you can change the password.

Step 7 Enter global configuration mode and change the **enable** password.

```
Device# configure terminal
Device(config)# enable secret password
```

Step 8 Set the SWITCH_IGNORE_STARTUP_CFG parameter to 0.

```
Device(config)# no system ignore startupconfig switch all
Device(config)# end
```

Step 9 Write the running configuration to the startup configuration file and save the configuration.

```
Device# copy running-config startup-config
```

```
Device# write memory
```

Step 10 Confirm that manual boot mode is enabled.

```
Device# show boot

 BOOT variable = flash:packages.conf;
 Manual Boot = yes
 Enable Break = yes
```

Step 11 Reload the device.

```
Device# reload
```

Step 12 Boot the device with the *packages.conf* file from flash.

```
Device: boot flash:packages.conf
```

Step 13 After the device boots up, disable manual boot on the device.

```
Device(config)# no boot manual
```

Procedure with Password Recovery Disabled

If the password-recovery mechanism is disabled, this message appears:

```
The password-recovery mechanism has been triggered, but
is currently disabled.  Access to the boot loader prompt
through the password-recovery mechanism is disallowed at
this point.  However, if you agree to let the system be
reset back to the default system configuration, access
to the boot loader prompt can still be allowed.

Would you like to reset the system back to the default configuration (y/n)?
```

Caution Returning the device to the default configuration results in the loss of all existing configurations. We recommend that you contact your system administrator to verify if there are backup device and VLAN configuration files.

- If you enter **n** (no), the normal boot process continues as if the **Mode** button had not been pressed; you cannot access the boot loader prompt, and you cannot enter a new password. You see the message:

```
Press Enter to continue........
```

- If you enter **y** (yes), the configuration file in flash memory and the VLAN database file are deleted. When the default configuration loads, you can reset the password.

Procedure

Step 1 Choose to continue with password recovery and delete the existing configuration:

```
Would you like to reset the system back to the default configuration (y/n)? Y
```

Step 2 Display the contents of flash memory:

```
Device: dir flash:
```

The device file system appears.

Step 3 Boot up the system:

```
Device: boot
```

You are prompted to start the setup program. To continue with password recovery, enter **N** at the prompt:

```
Continue with the configuration dialog? [yes/no]: N
```

Step 4 At the device prompt, enter privileged EXEC mode:

```
Device> enable
```

Step 5 Enter global configuration mode:

```
Device# configure terminal
```

Step 6 Change the password:

```
Device(config)# enable secret password
```

The secret password can be from 1 to 25 alphanumeric characters, can start with a number, is case sensitive, and allows spaces but ignores leading spaces.

Step 7 Return to privileged EXEC mode:

```
Device(config)# exit
Device#
```

Step 8 Write the running configuration to the startup configuration file:

```
Device# copy running-config startup-config
```

The new password is now in the startup configuration.

Step 9 You must now reconfigure the device. If the system administrator has the backup device and VLAN configuration files available, you should use those.

Preventing Autonegotiation Mismatches

The IEEE 802.3ab autonegotiation protocol manages the device settings for speed (10 Mb/s, 100 Mb/s, and 1000 Mb/s, excluding SFP module ports) and duplex (half or full). There are situations when this protocol can incorrectly align these settings, reducing performance. A mismatch occurs under these circumstances:

- A manually set speed or duplex parameter is different from the manually set speed or duplex parameter on the connected port.
- A port is set to autonegotiate, and the connected port is set to full duplex with no autonegotiation.

To maximize the device performance and ensure a link, follow one of these guidelines when changing the settings for duplex and speed:

- Let both ports autonegotiate both speed and duplex.
- Manually set the speed and duplex parameters for the ports on both ends of the connection.

Note If a remote device does not autonegotiate, configure the duplex settings on the two ports to match. The speed parameter can adjust itself even if the connected port does not autonegotiate.

Troubleshooting SFP Module Security and Identification

Cisco small form-factor pluggable (SFP) modules have a serial EEPROM that contains the module serial number, the vendor name and ID, a unique security code, and cyclic redundancy check (CRC). When an SFP module is inserted in the device, the device software reads the EEPROM to verify the serial number, vendor name and vendor ID, and recompute the security code and CRC. If the serial number, the vendor name or vendor ID, the security code, or CRC is invalid, the software generates a security error message and places the interface in an error-disabled state.

Note The security error message references the GBIC_SECURITY facility. The device supports SFP modules and does not support GBIC modules. Although the error message text refers to GBIC interfaces and modules, the security messages actually refer to the SFP modules and module interfaces.

If you are using a non-Cisco SFP module, remove the SFP module from the device, and replace it with a Cisco module. After inserting a Cisco SFP module, use the **errdisable recovery cause gbic-invalid** global configuration command to verify the port status, and enter a time interval for recovering from the error-disabled state. After the elapsed interval, the device brings the interface out of the error-disabled state and retries the operation. For more information about the **errdisable recovery** command, see the command reference for this release.

If the module is identified as a Cisco SFP module, but the system is unable to read vendor-data information to verify its accuracy, an SFP module error message is generated. In this case, you should remove and reinsert the SFP module. If it continues to fail, the SFP module might be defective.

Executing Ping

If you attempt to ping a host in a different IP subnetwork, you must define a static route to the network or have IP routing configured to route between those subnets.

IP routing is disabled by default on all devices.

Note Though other protocol keywords are available with the **ping** command, they are not supported in this release.

Use this command to ping another device on the network from the device:

Command	Purpose
ping ip *host* | *address* `Device# ping 172.20.52.3`	Pings a remote host through IP or by supplying the hostname or network address.

Monitoring the Physical Path

You can monitor the physical path that a packet takes from a source device to a destination device by using one of these privileged EXEC commands:

Table 164: Monitoring the Physical Path

Command	Purpose
tracetroute mac [**interface** *interface-id*] {*source-mac-address*} [**interface** *interface-id*] {*destination-mac-address*} [**vlan** *vlan-id*] [**detail**]	Displays the Layer 2 path taken by the packets from the specified source MAC address to the specified destination MAC address.
tracetroute mac ip {*source-ip-address* | *source-hostname*} {*destination-ip-address* | *destination-hostname*} [**detail**]	Displays the Layer 2 path taken by the packets from the specified source IP address or hostname to the specified destination IP address or hostname.

Executing IP Traceroute

Note Though other protocol keywords are available with the **traceroute** privileged EXEC command, they are not supported in this release.

Command	Purpose
traceroute ip *host* `Device# traceroute ip 192.51.100.1`	Traces the path that packets take through the network.

Redirecting Debug and Error Message Output

By default, the network server sends the output from **debug** commands and system error messages to the console. If you use this default, you can use a virtual terminal connection to monitor debug output instead of connecting to the console port .

Possible destinations include the console, virtual terminals, internal buffer, and UNIX hosts running a syslog server. The syslog format is compatible with 4.3 Berkeley Standard Distribution (BSD) UNIX and its derivatives.

Note Be aware that the debugging destination you use affects system overhead. When you log messages to the console, very high overhead occurs. When you log messages to a virtual terminal, less overhead occurs. Logging messages to a syslog server produces even less, and logging to an internal buffer produces the least overhead of any method.

For more information about system message logging, see *Configuring System Message Logging*.

Using the show platform Command

The output from the **show platform** privileged EXEC command provides some useful information about the forwarding results if a packet entering an interface is sent through the system. Depending upon the parameters entered about the packet, the output provides lookup table results and port maps used to calculate forwarding destinations, bitmaps, and egress information.

Most of the information in the output from the command is useful mainly for technical support personnel, who have access to detailed information about the device application-specific integrated circuits (ASICs). However, packet forwarding information can also be helpful in troubleshooting.

Using the show debug command

The **show debug** command is entered in privileged EXEC mode. This command displays all debug options available on the switch.

To view all conditional debug options run the command **show debug condition** The commands can be listed by selecting either a condition identifier *<1-1000>* or *all* conditions.

To disable debugging, use the **no debug all** command.

Caution Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with Cisco technical support staff. Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

Verifying Troubleshooting of the Software Configuration

Displaying OBFL Information

Example: Verifying the Problem and Cause for High CPU Utilization

To determine if high CPU utilization is a problem, enter the **show processes cpu sorted** privileged EXEC command. Note the underlined information in the first line of the output example.

```
Device# show processes cpu sorted
CPU utilization for five seconds: 8%/0%; one minute: 7%; five minutes: 8%
PID Runtime(ms) Invoked uSecs 5Sec 1Min 5Min TTY Process
309 42289103 752750 56180 1.75% 1.20% 1.22% 0 RIP Timers
140 8820183 4942081 1784 0.63% 0.37% 0.30% 0 HRPC qos request
100 3427318 16150534 212 0.47% 0.14% 0.11% 0 HRPC pm-counters
192 3093252 14081112 219 0.31% 0.14% 0.11% 0 Spanning Tree
143 8 37 216 0.15% 0.01% 0.00% 0 Exec
...
<output truncated>
```

This example shows normal CPU utilization. The output shows that utilization for the last 5 seconds is 8%/0%, which has this meaning:

- The total CPU utilization is 8 percent, including both time running Cisco IOS processes and time spent handling interrupts.
- The time spent handling interrupts is zero percent.

Table 165: Troubleshooting CPU Utilization Problems

Type of Problem	Cause	Corrective Action
Interrupt percentage value is almost as high as total CPU utilization value.	The CPU is receiving too many packets from the network.	Determine the source of the network packet. Stop the flow, or change the switch configuration. See the section on "Analyzing Network Traffic."
Total CPU utilization is greater than 50% with minimal time spent on interrupts.	One or more Cisco IOS process is consuming too much CPU time. This is usually triggered by an event that activated the process.	Identify the unusual event, and troubleshoot the root cause. See the section on "Debugging Active Processes."

Scenarios for Troubleshooting the Software Configuration

Scenarios to Troubleshoot Power over Ethernet (PoE)

Table 166: Power over Ethernet Troubleshooting Scenarios

Symptom or Problem	Possible Cause and Solution
Only one port does not have PoE. Trouble is on only one switch port. PoE and non-PoE devices do not work on this port, but do on other ports.	Verify that the powered device works on another PoE port. Use the **show run**, or **show interface status** user EXEC commands to verify that the port is not shut down or error-disabled. **Note** Most switches turn off port power when the port is shut down, even though the IEEE specifications make this optional. Verify that **power inline never** is not configured on that interface or port. Verify that the Ethernet cable from the powered device to the switch port is good: Connect a known good non-PoE Ethernet device to the Ethernet cable, and make sure that the powered device establishes a link and exchanges traffic with another host. **Note** Cisco powered device works only with straight cable and not with crossover one. Verify that the total cable length from the switch front panel to the powered device is not more than 100 meters. Disconnect the Ethernet cable from the switch port. Use a short Ethernet cable to connect a known good Ethernet device directly to this port on the switch front panel (not on a patch panel). Verify that it can establish an Ethernet link and exchange traffic with another host, or ping the port VLAN SVI. Next, connect a powered device to this port, and verify that it powers on. If a powered device does not power on when connected with a patch cord to the switch port, compare the total number of connected powered devices to the switch power budget (available PoE). Use the **show power inline** command to verify the amount of available power.

Symptom or Problem	Possible Cause and Solution
No PoE on all ports or a group of ports. Trouble is on all switch ports. Nonpowered Ethernet devices cannot establish an Ethernet link on any port, and PoE devices do not power on.	If there is a continuous, intermittent, or reoccurring alarm related to power, replace the power supply if possible it is a field-replaceable unit. Otherwise, replace the switch. If the problem is on a consecutive group of ports but not all ports, the power supply is probably not defective, and the problem could be related to PoE regulators in the switch. Use the **show log** privileged EXEC command to review alarms or system messages that previously reported PoE conditions or status changes. If there are no alarms, use the **show interface status** command to verify that the ports are not shut down or error-disabled. If ports are error-disabled, use the **shut** and **no shut** interface configuration commands to reenable the ports. Use the **show env power** and **show power inline** privileged EXEC commands to review the PoE status and power budget (available PoE). Review the running configuration to verify that **power inline never** is not configured on the ports. Connect a nonpowered Ethernet device directly to a switch port. Use only a short patch cord. Do not use the existing distribution cables. Enter the **shut** and **no shut** interface configuration commands, and verify that an Ethernet link is established. If this connection is good, use a short patch cord to connect a powered device to this port and verify that it powers on. If the device powers on, verify that all intermediate patch panels are correctly connected. Disconnect all but one of the Ethernet cables from switch ports. Using a short patch cord, connect a powered device to only one PoE port. Verify the powered device does not require more power than can be delivered by the switch port. Use the **show power inline** privileged EXEC command to verify that the powered device can receive power when the port is not shut down. Alternatively, watch the powered device to verify that it powers on. If a powered device can power on when only one powered device is connected to the switch, enter the **shut** and **no shut** interface configuration commands on the remaining ports, and then reconnect the Ethernet cables one at a time to the switch PoE ports. Use the **show interface status** and **show power inline** privileged EXEC commands to monitor inline power statistics and port status. If there is still no PoE at any port, a fuse might be open in the PoE section of the power supply. This normally produces an alarm. Check the log again for alarms reported earlier by system messages.

Symptom or Problem	Possible Cause and Solution
IEEE 802.3af-compliant or IEEE 802.3at-compliant powered devices do not work on Cisco PoE switch. A non-Cisco powered device is connected to a Cisco PoE switch, but never powers on or powers on and then quickly powers off. Non-PoE devices work normally.	Use the **show power inline** command to verify that the switch power budget (available PoE) is not depleted before or after the powered device is connected. Verify that sufficient power is available for the powered device type before you connect it. Use the **show interface status** command to verify that the switch detects the connected powered device. Use the **show log** command to review system messages that reported an overcurrent condition on the port. Identify the symptom precisely: Does the powered device initially power on, but then disconnect? If so, the problem might be an initial surge-in (or *inrush*) current that exceeds a current-limit threshold for the port.

Configuration Examples for Troubleshooting Software

Example: Pinging an IP Host

This example shows how to ping an IP host:

```
Device# ping 172.20.52.3

Type escape sequence to abort.
Sending 5, 100-byte ICMP Echoes to 172.20.52.3, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/4 ms
Device#
```

Table 167: Ping Output Display Characters

Character	Description
!	Each exclamation point means receipt of a reply.
.	Each period means the network server timed out while waiting for a reply.
U	A destination unreachable error PDU was received.
C	A congestion experienced packet was received.
I	User interrupted test.
?	Unknown packet type.
&	Packet lifetime exceeded.

To end a ping session, enter the escape sequence (**Ctrl-^ X** by default). Simultaneously press and release the **Ctrl**, **Shift**, and **6** keys and then press the **X** key.

Example: Performing a Traceroute to an IP Host

This example shows how to perform a **traceroute** to an IP host:

```
Device# traceroute ip 192.0.2.10

Type escape sequence to abort.
Tracing the route to 192.0.2.10

  1 192.0.2.1 0 msec 0 msec 4 msec
  2 192.0.2.203 12 msec 8 msec 0 msec
  3 192.0.2.100 4 msec 0 msec 0 msec
  4 192.0.2.10 0 msec 4 msec 0 msec
```

The display shows the hop count, the IP address of the router, and the round-trip time in milliseconds for each of the three probes that are sent.

Table 168: Traceroute Output Display Characters

Character	Description
*	The probe timed out.
?	Unknown packet type.
A	Administratively unreachable. Usually, this output means that an access list is blocking traffic.
H	Host unreachable.
N	Network unreachable.
P	Protocol unreachable.
Q	Source quench.
U	Port unreachable.

To end a trace in progress, enter the escape sequence (**Ctrl-^ X** by default). Simultaneously press and release the **Ctrl**, **Shift**, and **6** keys and then press the **X** key.

CHAPTER 154

Line Auto Consolidation

- Line Auto Consolidation, on page 2265

Line Auto Consolidation

Cisco IOS XE software runs a nonvolatile generation (NVGEN) process to retrieve the configuration state of the device. During the NVGEN process, the system auto consolidates the LINE commands based on common parameters.

When the device connects to Cisco Catalyst Center Center, the center sends a line configuration through the Yet Another Next Generation (YANG) interface the resulting configuration is auto consolidated. This can cause a mismatch between the device and the Cisco Catalyst Center. The mismatch in configurations can lead to reverse sync from the device to the Cisco Catalyst Center. The device will be locked from any other configuration changes during this reverse sync. This can affect the performance of the device.

You can use the **no line auto-consolidation** command, in the global configuration mode, to disable the auto consolidation of LINE commands. Auto consolidation is enabled by default. To disable it use the no form of the command.

You can use the **show running-configuration all** command to display the configuration on the device. In the following example line auto-consolidation is enabled.

```
Device#sh running-config all | i auto-consolidation
line auto-consolidation
```

After auto consolidation is disabled the **show run** command output will be lengthy. This will impact the sizes of the running configuration and start-up configuration files. If you disable auto consolidation you will observe the following behaviors:

- Contiguous groups of lines that belong to the same configuration in a sub-mode will not be combined into a single range.

```
Device#show run | sec line
line con 0
stopbits 1
line vty 0 4
transport input ssh
line vty 5 9
transport input all
Device#configure terminal
Device(config)#no line auto-consolidation
Device(config)#line vty 10 15
Device(config-line)#transport input all
```

```
Device(config-line)#end
Device#show run | sec line
no line auto-consolidation
line con 0
stopbits 1
line vty 0 4
transport input ssh
line vty 5 9
transport input all
line vty 10 15
transport input all
```

- If you disable auto consolidation after configuring some lines with auto consolidation enabled, only the lines which were configured after auto consolidation was disabled will not be consolidated.

```
Device#show run | sec line
line con 0
stopbits 1
line vty 0 4
transport input ssh
line vty 5 9
transport input all
Device#configure terminal
Device(config)#line vty 10 15
Device(config-line)#transport input all
Device(config-line)#end
Device#show run | sec line
line con 0
stopbits 1
consolidated line vty 0 4
transport input ssh
line vty 5 15
transport input all
Device#configure terminal
Device(config)#no line auto-consolidation
Device(config)#line vty 16 20
Device(config-line)#transport input all
Device(config-line)#end
Device#show run | sec line
no line auto-consolidation
line con 0
stopbits 1
consolidated line vty 0 4
transport input ssh
line vty 5 15
transport input all
line vty 16 20
transport input all
```

- If you enable auto consolidation after it has been disabled, lines that were not consolidated will be auto consolidated.

```
Device#sh running-config | sec line
no line auto-consolidation
line con 0
exec-timeout 0 0
logging synchronous
stopbits 1
line vty 0 4
transport input ssh
line vty 5 15
transport input ssh
line vty 16 19
transport input ssh
```

```
Device#configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)#line vty 20 25
Device(config-line)#transport input ssh
Device(config-line)#end
Device#sh running-config | sec line
no line auto-consolidation
line con 0
exec-timeout 0 0
logging synchronous
stopbits 1
line vty 0 4
transport input ssh
line vty 5 15
transport input ssh
line vty 16 19

```

- You can modify subranges in autonomous mode. This will cause the lines to split which will cause a reverse sync of the configuration. You can’t modify subranges in the controller mode. This is a behavioural change between the controller and autonomous modes. In the controller mode, any modification of subranges is rejected to avoid discrepancy with the configuration pushed from a controller.

  The following examples shows how you can modify subranges in autonomous mode.

```
Device#show run | sec line
no line auto-consolidation
line con 0
stopbits 1
line vty 0 4
transport input ssh

CHAPTER 155

Troubleshooting System Management

- Overview, on page 2273
- Feedback Request, on page 2273
- Disclaimer and Caution, on page 2273

Overview

This chapter provides links to documents authored by Cisco subject matter experts (SMEs). They aim to help you resolve technical issues without requiring a support ticket. If these documents are unable to resolve your issue, we recommend visiting the applicable Cisco Community. There is a wealth of information and advice available from fellow Cisco customers who may have experienced this issue already and provided a solution. If you are not able to find a resolution on the Community, it may be best that you raise a support ticket at Cisco Support. In cases where a support ticket has to be raised, these documents provide guidance about the data that should be collected and added to the support ticket. Specify the support document you referred, and TAC can create an improvement request with the document owner.

For information about the licensing packages for features available on the Switches, see the Licensing document.

Feedback Request

Your input helps. A key aspect to improving these support documents is customer feedback. Note that these documents are owned and maintained by multiple teams within Cisco. If you find an issue specific to the document (unclear, confusing, information missing, etc):

- Provide feedback using the **Feedback** button located at the right panel of the corresponding article. The document owner will be notified, and will either update the article, or flag it for removal.
- Include information regarding the section, area, or issue you had with the document and what could be improved. Provide as much detail as possible.

Disclaimer and Caution

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, ensure that you understand the potential impact of any command.

CHAPTER 156

Dying Gasp

- Dying Gasp, on page 2275
- Configuring Dying Gasp, on page 2275

Dying Gasp

The dying gasp feature provides a warning when the power to a network device fails, enabling a temporary power supply. When the host network detects a complete power failure or the removal of a power supply cable, it sends a messsage or signal to the network management system (NMS) through an SNMP trap.

Network devices rely on a temporary backup power supply on a capacitor, which allows for a graceful shutdown and the generation of the dying-gasp message. This temporary power supply is designed to last from 5 to 10 milliseconds to perform these tasks.

Dying gasp packets can be sent to a maximum number of five servers for each notification type.

You configure dying gasp using the following CLI commands:

- **dying-gasp**: Configures the host to create and send dying-gasp packets.
- **show dying-gasp packets**: Displays detailed information about the created packets.
- **snmp-server host**: Specifies the SNMP server for the dying-gasp message.
- **logging host hostname-or-ipaddress transport udp**: Specifies the syslog server sending the syslog dying gasp message.

For further information about dying gasp configuration commands, see the remaining sections of this chapter.

Configuring Dying Gasp

dying-gasp

To enable dying-gasp notification through syslog, SNMP trap, or Ethernet OAM, use the dying-gasp command:

Command Syntax	Description
dying-gasp primary {syslog | snmp-trap | ethernet-oam} secondary {syslog | snmp-trap | ethernet-oam}	• **dying-gasp**: Dying-gasp configuration command • **primary**: Dying-gasp primary notification • **secondary**: Dying-gasp secondary notification • **ethernet-oam**: Enable Ethernet-OAM notification command • **snmp-trap**: Send trap notification to SNMP server command • **syslog**: Enable system logger

The following example shows how to configure SNMP traps as primary notification and syslog as secondary notification:

```
switch(config)# dying-gasp primary snmp-trap secondary syslog
```

show dying-gasp

This section provides descriptions of the **show dying-gasp** command keywords:

Command Syntax	Description
show dying-gasp {status | packets [snmp-trap | syslog | ethernet-oam]}	• **dying-gasp**: Dying-Gasp information • **status**: Dying-Gasp configuration status • **packets**: Detailed information about the created packets • **snmp-trap**: Dying-gasp SNMP trap information • **syslog**: Dying-gasp syslog message information • **ethernet-oam**: Dying-gasp Ethernet OAM message information

show dying-gasp Output Examples

The following text is an example of the **dying gasp packets** command and its output:

```
Switch# show dying-gasp packets
SNMP Trap packet for server 192.168.0.2, link type IP
  interface, via GigabitEthernet1/1, local IP address 12.1.1.40
  encap type is ARPA, local hardware address 6c03.09e7.23c0
  next hop IP address 12.1.1.200, next hop hardware address 6c03.09e7.23c0
Syslog errmsg packet for server 192.168.0.2, link type IP
  interface, via GigabitEthernet1/1, local IP address 12.1.1.40
  encap type is ARPA, local hardware address 6c03.09e7.23c0
  next hop IP address 12.1.1.200, next hop hardware address 6c03.09e7.23c0
```

The following is sample output for the **show dying-gasp status** command:

```
Switch# show dying-gasp status
Dying Gasp Configuration
        SNMP Trap             Enabled (secondary)
        Syslog                Enabled (primary)
```

The following is sample output for the **show dying-gasp packets snmp-trap** command:

```
Switch# show dying-gasp packets snmp-trap
SNMP Trap packet for server 192.168.0.2, link type IP
  interface, via GigabitEthernet1/1, local IP address 12.1.1.40
  encap type is ARPA, local hardware address 6c03.09e7.23c0
  next hop IP address 12.1.1.200, next hop hardware address 6c03.09e7.23c0
```

The following is sample output for the **show dying-gasp packets syslog** command:

```
Switch# show dying-gasp packets syslog
Syslog errmsg packet for server 192.168.0.2, link type IP
  interface, via GigabitEthernet1/1, local IP address 12.1.1.40
  encap type is ARPA, local hardware address 6c03.09e7.23c0
  next hop IP address 12.1.1.200, next hop hardware address 6c03.09e7.23c0
```

CHAPTER 157

Cisco Catalyst Center

• Cisco Catalyst Center, on page 2279

Cisco Catalyst Center

The IE3500 devices can be managed and monitored by Catalyst Center, just like other IE switches.

For more details on configuring, managing, and monitoring the IE3500 series devices through Catalyst Center, please refer to the Catalyst Center User Guides available at: https://www.cisco.com/c/en/us/support/cloud-systems-management/dna-center/products-user-guide-list.html.

CHAPTER 158

Migration to Meraki Cloud Management Dashboard

- Meraki cloud management dashboard migration, on page 2281
- Supported switch models for cloud-managed mode, on page 2282
- How to migrate to a Meraki cloud management dashboard, on page 2282
- How the device behaves during migration, on page 2287

Meraki cloud management dashboard migration

The Meraki cloud management dashboard is a centralized, web-based platform used to configure and monitor Cisco devices and services. Starting from release 26.1.1 , you can migrate the Cisco IE3500 rugged series switch to cloud-managed mode. This migration enables you to manage and control your device through the Meraki cloud-based dashboard.

Key aspects of this migration behaviour and access include:

- After migration, the switch operates entirely under the control of the Meraki cloud management dashboard.
- Console access to the switch is unavailable after migration. To troubleshoot or configure the device, use the Meraki cloud management dashboard.

  If you cannot use the DNS name, you can access the local status page by entering the device's IP address in your browser. This approach helps if you set up the device on a network without Dynamic Host Configuration Protocol (DHCP) or before assigning its final IP address.

  You can use the IP address 1.1.1.100 from the client device to access the local status page (LSP). To access this address, configure a device with these IP settings and browse to the address in a web browser.

  - IP address: 1.1.1.99
  - Subnet mask: 255.255.255.0

- During migration, the flash memory, USB drives, and SD card of the switch are formatted and reconfigured for the Meraki cloud management runtime environment. This process erases all previous configurations and the device must be reconfigured through the Meraki cloud management dashboard.

Supported switch models for cloud-managed mode

The following Cisco Industrial Ethernet IE3500 series switch models support management in cloud-managed mode using the Meraki cloud management Dashboard. The minimum Cisco IOS XE software release required for IE3500 platform is specified below.

Platform and release compatibility

The table outlines the minimum Cisco IOS XE software release required for Meraki Dashboard management.

Table 169: Platform and release compatibility

Platform	Minimum Software Release	Dashboard Support Status
IE3500 • IE-3500-8T3S • IE-3500-8P3S • IE-3505-8T3S • IE-3505-8P3S • IE-3500-8T3X • IE-3500-8U3X	26.1.1	Supported

How to migrate to a Meraki cloud management dashboard

Follow these steps to migrate your device to Meraki cloud management dashboard.

Before you begin

- Ensure that you have access to the Meraki cloud management dashboard.
- Ensure the device runs IOS-XE version 26.1.1 or later in install mode.
- Ensure that the uplink interface connecting to the Meraki cloud management dashboard is configured in trunk mode. Also, ensure that the port on the peer device is configured in trunk mode.
- Ensure that the device can resolve DNS names and that it has a routable IP address on the appropriate VLAN via DHCP. For more details, see DHCP IP and DNS configuration, on page 2284 .
- Ensure that the clock settings (date and time) are configured correctly before onboarding the device. Incorrect settings can cause onboarding or connectivity issues. For more information, see Configure the device clock, on page 2283.

Note Before initiating the device onboarding process, ensure that the system date and time are configured correctly. Accurate time synchronization is required for certificate validation, secure communication, and event logging. If the system time is not synchronized, authentication errors or onboarding failures may occur.

- Obtain the Cloud ID before adding the device to the network. To register your device and retrieve the Cloud ID, see the Register and migrate to Meraki cloud management dashboard, on page 2286 section.

Procedure

Step 1 Validate device compatibility. See Validate device compatibility, on page 2285 for more information.

Step 2 Register and migrate the device. See Register and migrate to Meraki cloud management dashboard, on page 2286 for more information.

Configure the device clock

Configure the device clock to maintain accurate system time. Accurate system time is required for certificate validation, secure communication, device onboarding, and event logging.

Use Network Time Protocol (NTP) to synchronize the device clock with an external time source. If an NTP server is not available, set the clock manually.

Before you begin

Ensure that the device has network reachability to the NTP server, if you are configuring NTP.

Follow these steps to configure the device clock:

Procedure

Step 1 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Switch# configure terminal
```

Step 2 Use the **ntp server** *ntp-server-ip-or-hostname* command to configure the NTP server for time synchronization.

Example:

```
Switch# (config)# ntp server 111.0.1.11
```

Step 3 Use the **exit** command to return to privileged EXEC mode.

Example:

```
Switch# (config)# exit
```

Step 4 (Optional) Use the **clock set** <*hh:mm:ss*> <*day*> <*month-name*> <*year*> command to set the system clock manually when an NTP server is not available. Use this command in privileged EXEC mode.

Example:

```
Switch# clock set 14:30:00 9 July 2026
```

Step 5 Use the **show clock** command to verify the system date and time.

Example:

```
Switch# show clock
```

DHCP IP and DNS configuration

Perform this task to verify that the device can resolve DNS names and that it has a routable IP address on the appropriate VLAN via DHCP. You can also verify that the device routes traffic to external networks through the default gateway. To optimize performance and system reliability, use Cisco-validated SFP modules with Meraki cloud management dashboard hardware. Configure the Cisco Catalyst IE9300 Rugged Series uplink port as a Trunk port to enable VLAN traffic and support network integration.

Before you begin

If your management VLAN exceeds 512, follow the LSP process to change the upstream VLAN to the management VLAN. For more details on LSP, refer Cisco Meraki Local Status Page.

Procedure

Step 1 Use the **ip name-server** *dns-server* command to configure the device to use a DNS name server.

Example:

```
Device(config)# ip name-server 192.0.2.10
```

You can specify up to six DNS servers if needed.

Step 2 Configure a switch virtual interface (SVI) or routed interface with a routable IP address.

a) Use the **vlan** *vlan-id* command to create the VLAN for cloud connectivity.

Example:

```
Device(config)# vlan 10        ! VLAN used for cloud connectivity
```

b) Use the **exit** command to exit VLAN configuration mode.

Example:

```
Device(config-vlan)# exit
```

c) Use the **interface vlan** *vlan-id* command to enter interface configuration mode for the VLAN.

Example:

```
Device(config)# interface vlan 10
```

Use the same VLAN ID where the DHCP is present.

d) Use the **ip address dhcp** command to assign an IP address through DHCP.

Example:

```
Device(config-if)# ip address dhcp
```

The DHCP provides gateway and DNS information.

e) Use the **no shutdown** command to enable the VLAN interface.

Example:

```
Device(config-if)# no shutdown
```

f) Use the **exit** command to exit the interface configuration mode.

Example:

```
Device(config-if)# exit
```

g) Use the **ping meraki.com** command to verify that the ping is successful to the Meraki cloud management dashboard.

Example:

```
Device# ping meraki.com

Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 52.84.205.125, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 4/4/4 ms
Device#
```

Validate device compatibility

Follow this procedure to validate if your device is compatible for migration.

Procedure

Use the **show cloud-mgmt compatibility** command to verify if your device is compatible for migration.

Example:

```
Device# show cloud-mgmt compatibility
=============================================================================================

Compatibility Check Status
---------------------------------------------------------------------------------------------

Boot Mode INSTALL  - Compatible
---------------------------------------------------------------------------------------------

Switch#  SKU                                 Bootloader Version              Network Modules
---------------------------------------------------------------------------------------------
1        IE-3500-8T3S (M)    - Compatible    17_18_1r        - Compatible    N/A

Compatible NMs :

---------------------------------------------------------------------------------------------
```

Note
If you attempt to migrate an incompatible device or a compatible device with an incompatible network module, the process fails and displays an error message.

Register and migrate to Meraki cloud management dashboard

Perform this procedure to register your device and migrate to cloud management mode.

Before you begin

Complete these steps before you initiate the migration process. You can also refer How to migrate to a Meraki cloud management dashboard, on page 2282.

- Back up your device configuration and any relevant local files, including any USB flash drives, and SD cards connected to the device. This is important because all file systems will be formatted once you initiate the migration process.
- Upgrade to Cisco IOS XE 26.1.1 or later in install mode. For details about install mode upgrades, see the Release Notes for Cisco IE3500 Series Switches.

Procedure

Step 1 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Device# configure terminal
```

Step 2 Use the **service cloud-mgmt connect** command to register and initiate migration of your device to cloud-mgmt mode.

Running this command generates a *cloud-ID*, which is required to claim the switch in the Meraki cloud management dashboard.

The device contacts resources on the Meraki cloud management dashboard to register. Use the Cloud ID to add each device to the dashboard. After adding the device to a dashboard network with an active uplink and cloud access, it begins converting to Meraki cloud management cloud mode. When this occurs, the device performs a factory reset, which then restricts console access.

Example:

```
Switch(config)# service cloud-mgmt connect
        Starting to connect switch 1
        Successfully connect to Meraki Dashboard
        Switch 1 has been successfully registered
        Received MAC: AABBCCDDEEFF
        Cloud ID: ABCD-ABCD

Device Registration Status:
-------------------------------------------------------------------------------------------------
Switch                                                                                 Migration
Num      PID             Serial Number     Cloud ID       Mac Address          Status
  Mode
-------------------------------------------------------------------------------------------------
```

```
1    IE-9320-16P8U4X     ABCD-ABCD        ABCD-ABCD       aaa.bbb.cccc   Registered IE9K-C
 [Monitoring]

Please note down the Cloud ID as that is required for claiming it in Cloud-Mgmt Dashboard
```

Example:

```
Switch# show cloud-mgmt
Switch                Serial                                          Migration
Num    PID            Number           Cloud ID      Mac Address       Status       Mode
-------------------------------------------------------------------------------------------
1   IE-9320-26S2C    FDO2546J16L      ABCD-ABCD      aaa.bbb.cccc     Registered     IE9K-C
 [Monitoring]
```

Step 3 Use the **exit** command to exit global configuration mode.

Example:

```
Device(config)# exit
```

Revert the switch to IOS-XE mode

Contact Meraki cloud management support to migrate your device back to IOS-XE mode.

Consider these key aspects when migrating the device:

- Ensure that the device is online and connected to the Meraki cloud management dashboard before beginning the process.
- The migration process resets the device to its default factory settings and configurations.
- Ensure the migration to IOS-XE mode is complete before deploying the device in production networks.

How the device behaves during migration

Summary

This section lists the events that occur on the device during migration.

- The device boots up with the default configuration and obtains its operational configuration from the Meraki cloud management dashboard. This migration process usually takes 5 to 10 minutes.
- During the migration process to Meraki cloud management mode, external removable storage such as SD cards and USB drives will be formatted and disabled. These storage devices will not be operational.
- When the migration is complete, you can control your device from the Meraki cloud management dashboard.

Refer to the Configure your Dashboard Network documentation for more information and configuration best practices.

CHAPTER 159

Configure FPGA Profile

- FPGA Profile, on page 2289

FPGA Profile

The FPGA Profile feature turns certain software features assisted by field-programmable gate array (FPGA) on or off. Some switch features such as Parallel Redundancy Protocol (PRP), High-Availability Seamless Redundancy (HSR), and Device Level Ring (DLR) rely heavily on FPGA implementation. FPGA Profiles allow for efficient allocation of platform resources for the operation of multiple time sensitive, resilient industrial protocols without changes to hardware.

Note Starting with Cisco IOS XE Release 17.17.1, FPGA profiles are supported on Cisco IE3505 and IE3505H Series Switches. FPGA Profiles are applied globally to the base switch. If an expansion module is present, it uses the same FPGA Profile as configured for the base switch.

The switch supports four FPGA profiles with different combinations of features supported in each profile, as shown in the following table.

FPGA Profile Name	17.18.x	26.1.1
Default	Supports one instance of PRP or HSR and three instances of DLR.	Supports one instance of PRP or HSR and two instances of DLR. **Note** The number of HSR rings supported on the system remains one and cannot be increased by the use of expansion module. The **hsr-quadbox** profile is an exception to this limitation. For more information, see HSR-HSR QuadBox.

FPGA Profile Name	17.18.x	26.1.1
Redundancy	Supports two instances of DLR and two instances of PRP or one instance of HSR.	Supports two instances of PRP or one instance HSR.
HSR-Quadbox	Not applicable	Supports HSR-HSR quadbox.
DLR	Not applicable	Supports three instances of DLR and one instance of PRP or HSR.

Note HSR-PRP RedBox mode is supported with both the **default**, **redundancy**, and **dlr** FPGA profiles.

Prerequisites

- Before changing the FPGA Profile, we suggest that you remove the configurations related to the current active FPGA Profile, because those configurations are not valid for the new profile.

Guidelines and Limitations

- You must reload the switch after changing the configured FPGA Profile to activate the profile.
- FPGA Profile is supported on Cisco IE3505 and Cisco IE3505H switches in the Cisco Catalyst IE3500 Rugged Series Switches.

  To keep the existing profile and feature configurations after an upgrade:

  1. After booting the switch, select the required FPGA Profile as described in Configure the FPGA Profile, on page 2290.

     The selected FPGA profile takes effect only after you reload the switch. To prevent unsupported feature configurations from being saved or discarded before the new profile becomes active, do not copy the running configuration to the startup configuration or run the **write memory** command before reloading the switch.

  2. Reload the switch.

     The required feature configurations will not be discarded because they are supported by the selected profile.

Default Settings

The default FPGA Profile name is "default".

Configure the FPGA Profile

Follow these steps to configure the FPGA Profile.

Procedure

Step 1 Use the **fpga-profile activate { default | dlr | hsr-quadbox | redundancy }** command in EXEC mode to activate the required FPGA profile.

Example:

```
Switch# fpga-profile activate dlr
```

If you use the switch as a PRP or HSR RedBox and require one PRP channel or one HSR ring, you can use either the, **default** profile or the **dlr** profile. Use the **dlr** profile when the deployment also requires three DLR rings.

- **default**: Two DLR rings and one PRP-channel or one HSR-ring
- **dlr**: Three DLR rings and one PRP-channel or one HSR-ring
- **hsr-quadbox**: HSR-HSR quadbox
- **redundancy**: Two PRP-channels or one HSR-ring

Step 2 (Optional) Use the **fpga-profile deactivate** command in EXEC mode to change to the default FPGA profile.

Example:

```
Switch# fpga-profile deactivate
```

Step 3 (Optional) Use the **show platform fpga-profile active** command to display the FPGA profile that is currently active on the switch:

Example:

```
Switch# show platform fpga-profile active
Active FPGA profile       : dlr
Active feature set        : 3 DLR rings and 1 PRP-channel/1 HSR-ring

FPGA profile upon reload  : dlr
Feature set upon reload   : 3 DLR rings and 1 PRP-channel/1 HSR-ring
```

Displays the active FPGA profile and FPGA profile after reload.

- **active**: Displays the current active application profile information.
- **all**: Displays all supported application profile information.
- **default**: Displays the default application profile.

Step 4 Use the **reload** command to reload the switch.

Example:

```
Switch#reload
```

CHAPTER 160

Configuring Autoconf

The following sections provide information about Autoconf and how to configure Autoconf:

- Prerequisites for Autoconf, on page 2295
- Restrictions for Autoconf, on page 2295
- Information about Autoconf , on page 2296
- How to Configure Autoconf, on page 2301
- Configuration Examples for Autoconf, on page 2310

Prerequisites for Autoconf

- Before enabling Autoconf, disable the Auto SmartPort (ASP) macro, device classifier, and then access the session monitor.

Restrictions for Autoconf

- ASP macro and Autoconf are not supported on the same interface at the same time. Either Autoconf or ASP must be disabled on a per-interface level.
- Interface templates are not applicable for wireless sessions.
- When the Autoconf feature is enabled using the **autoconf enable** command, the default Autoconf service policy is applied to all the interfaces. No other service policy can be applied globally using the **service-policy** command. To apply a different service policy, you must disable Autoconf on that interface. When a service policy is applied globally, you must disable it before enabling the Autoconf feature.
- When both local (interface level) and global service policies exist, the local policy takes precedence. The global service policy comes into effect only when the local policy is removed.
- Service templates cannot be applied to interfaces, and interface templates cannot be applied to service instances.
- Only one service template can be nested inside an interface template.
- Autoconf does not support the switchover feature.

Information about Autoconf

The following sections provide information about Autoconf.

Benefits of Autoconf

The Autoconf feature permits hardbinding between an end device and an interface. Autoconf falls under the umbrella of the Cisco Smart Operations solution. Smart Operations is a comprehensive set of capabilities that can simplify and improve LAN switch deployment, and help organizations deliver operational excellence and scale services on the network.

The Autoconf feature automatically applies the necessary configurations on the device ports to enable the efficient performance of each directly connected end device using a set of interface configurations that are configured inside an interface template:

- Autoconf efficiently applies commands to an interface because the parser does not need to parse each command each time.
- Configurations that are applied through the Autoconf feature can be reliably removed from a port without impacting previous or subsequent configurations on the port.
- The Autoconf feature provides built-in and user-defined configurations using interface and service templates. Configurations applied through templates can be centrally updated with a single operation.
- Using the Autoconf feature, a configuration can be applied to ports and access sessions.
- The Autoconf feature reduces ongoing maintenance for devices and attached end devices by making them intuitive and autoconfigurable. This reduces operation expenses (OPEX) and lowers the total cost of ownership (TCO).

Identity Session Management and Templates

A key advantage of the Autoconf feature is that the core session management capability is decoupled from the application-specific logic, allowing the same framework to be used regardless of the criteria for policy determination or the nature of the policies applied.

The identity session management infrastructure allows configurations or policies or both to be applied as templates.

Both service and interface templates are named as containers of configuration and policy. Service templates can be applied only to access sessions, while interface templates can be applied only to ports. When a service template is applied to an access session, the contained configuration and policy are applied only to the target session, and has no impact on other sessions that may be hosted on the same access port. Similarly, when an interface template is applied to an access port, it impacts all the traffic exchanged on the port.

The Autoconf feature uses a set of built-in maps and built-in templates. The built-in templates are designed based on best practices for interface configurations. Built-in templates can be modified by users to include customized configurations, limiting the need to create a new template.

The templates created by users are referred to as user-defined templates. These templates can be defined on a device and can be mapped to any built-in or user-defined trigger.

Use the **show derived-config** command, to view the overall applied configurations applied by Autoconf template and manual configuration. The interface commands shown in the output of the **show running-config interface** *type number* command are not necessarily the operational configuration. The Autoconf feature dynamically applies a template to the interface, and overrides any conflicting static configuration that is already applied.

Autoconf Operation

Autoconf uses the Device Classifier to identify the end devices that are connected to a port.

The Autoconf feature uses the device classification information gleaned from Cisco Discovery Protocol, LLDP, DHCP, MAC addresses, and the Organizationally Unique Identifier (OUI) that is identified by the Device Classifier.

The Device Classifier provides improved device classification capabilities and accuracy, and increased device visibility for enhanced configuration management.

Device classification is enabled when you enable the Autoconf feature using the **autoconf enable** command in global configuration mode.

The device detection acts as an event trigger, which in turn applies the appropriate automatic template to the interface.

The Autoconf feature is based on a three-tier hierarchy.

- A policy map identifies the trigger type for applying the Autoconf feature.
- A parameter map identifies the appropriate template that must be applied, based on the end device.
- The templates contain the configurations to be applied.

The Autoconf built-in templates and triggers perform the above tasks automatically.

The Autoconf feature provides the following built-in templates:

- AP_INTERFACE_TEMPLATE
- DMP_INTERFACE_TEMPLATE
- IP_CAMERA_INTERFACE_TEMPLATE
- IP_PHONE_INTERFACE_TEMPLATE
- LAP_INTERFACE_TEMPLATE
- MSP_CAMERA_INTERFACE_TEMPLATE
- MSP_VC_INTERFACE_TEMPLATE
- PRINTER_INTERFACE_TEMPLATE
- ROUTER_INTERFACE_TEMPLATE
- SWITCH_INTERFACE_TEMPLATE
- TP_INTERFACE_TEMPLATE

Note By default, built-in templates are not displayed under running configuration. The built-in templates are displayed in the running configuration only if you edit them.

The template that is selected is based on parameter map information applied to an interface. This information can be based on the following criteria:

- End Device type
- MAC address
- OUI
- Platform type
- User role
- Username

The Autoconf feature provides one built-in parameter map (BUILTIN_DEVICE_TO_TEMPLATE) with the following configuration:

```
Parameter-map name: BUILTIN_DEVICE_TO_TEMPLATE
 Map: 10 map device-type regex "Cisco-IP-Phone"
  Action(s):
   20 interface-template IP_PHONE_INTERFACE_TEMPLATE
 Map: 20 map device-type regex "Cisco-IP-Camera"
  Action(s):
   20 interface-template IP_CAMERA_INTERFACE_TEMPLATE
 Map: 30 map device-type regex "Cisco-DMP"
  Action(s):
   20 interface-template DMP_INTERFACE_TEMPLATE
 Map: 40 map oui eq "00.0f.44"
  Action(s):
   20 interface-template DMP_INTERFACE_TEMPLATE
 Map: 50 map oui eq "00.23.ac"
  Action(s):
   20 interface-template DMP_INTERFACE_TEMPLATE
 Map: 60 map device-type regex "Cisco-AIR-AP"
  Action(s):
   20 interface-template AP_INTERFACE_TEMPLATE
 Map: 70 map device-type regex "Cisco-AIR-LAP"
  Action(s):
   20 interface-template LAP_INTERFACE_TEMPLATE
 Map: 80 map device-type regex "Cisco-TelePresence"
  Action(s):
   20 interface-template TP_INTERFACE_TEMPLATE
 Map: 90 map device-type regex "Surveillance-Camera"
  Action(s):
   10 interface-template MSP_CAMERA_INTERFACE_TEMPLATE
 Map: 100 map device-type regex "Video-Conference"
  Action(s):
   10 interface-template MSP_VC_INTERFACE_TEMPLATE
```

Note Use the **show parameter-map type subscriber attribute-to-service All** command to view the configuration for the built-in parameter map.

The Autoconf feature provides one built-in policy map (BUILTIN_AUTOCONF_POLICY) with the following configuration:

```
BUILTIN_AUTOCONF_POLICY
  event identity-update match-all
    10 class always do-until-failure
      10 map attribute-to-service table BUILTIN_DEVICE_TO_TEMPLATE
```

Note Use the **show policy-map type control subscriber BUILTIN_AUTOCONF_POLICY** command to view the configuration for the built-in policy map.

You can also manually create policy maps, parameter maps, and templates.

When a trigger is created that is based on specific user information, a local 802.1X Cisco Identity Services Engine (ISE) server authenticates it, ensuring the security of the operation.

An interface template can be dynamically activated (on an interface) using any of the following methods:

- RADIUS CoA: While Change of Authorization (CoA) commands are targeted at one or more access sessions, any referenced template must be applied to the interface that is hosting the referenced session.
- RADIUS Access-Accept for client authentication or authorization: Any referenced interface template returned in an Access-Accept must be applied to the port that is hosting the authorized access session.
- Service template: If an interface template is referenced in a service template that is either locally defined or sourced from the AAA server, the interface template must be applied to the interface hosting an access-session on which the service template is applied. (Add a new command for interface template reference from within a locally defined service template.)
- Subscriber control-policy action: A mapping action under the subscriber control policy activates service or interface template (as referenced in a parameter map) or both based on the type of filter, and removes templates, if any, associated with a previous policy.
- Device-to-template parameter map: A subscriber parameter map that allows the filter type-to-service or interface template mappings or both to be specified in an efficient and readable manner.

Advantages of Using Templates

Using templates for auto configuration has the following benefits:

- Templates are parsed once when they are being defined. This makes the dynamic application of the templates very efficient.
- Templates can be applied to an Ethernet interface that is connected to an end device, based on the type of end device.
- Service templates allow the activation of session-oriented features, whereas interface templates apply configurations to the interface that is hosting a session.
- Service templates are applied to access sessions and hence only impact the traffic exchanged with a single endpoint on a port.
- Startup and running configurations of a device are not modified by the dynamic application of a template.
- Policy application is synchronized with the access-session life cycle. This is tracked by the framework by using all the available techniques, including link-up or link-down.

- Templates can be updated with a single operation. All the applied instances of templates are also updated during this operation.
- Constituent commands of templates do not appear in the running configuration.
- Templates can be removed with no impact on previous or subsequent configurations.
- Template application is acknowledged, allowing for synchronization and performance of remedial actions when failures occur.
- Data VLAN, quality of service (QoS) parameters, storm control, and MAC-based port security are configured automatically based on the end device that is connected to the switch.
- The switch port is cleaned up completely by removing configurations when the device is disconnected from a port.
- Human error is reduced in the installation and configuration process.

Autoconf Functionality

The Autoconf feature is disabled by default in global configuration mode. When you enable the Autoconf feature in global configuration mode, it is enabled by default at the interface level. The built-in template configurations are applied based on the end devices detected on all the interfaces.

Use the **access-session inherit disable autoconf** command to manually disable Autoconf at the interface level, even when Autoconf is enabled at the global level.

If you disable Autoconf at the global level, all the interface-level configurations are disabled.

Table 170: Autoconf Functionality

Global	Interface Level	AutoConf Status
Disable	Disable	No automatic configurations are applied when an end device is connected.
Enable	Enable	If Autoconf is enabled at the global level, it is also enabled at the interface level by default. Built-in template configurations are applied based on the end devices that are detected on all the interfaces.
Enable	Disable	Enabled at global level. Disabled at interface level. No automatic configurations are applied when an end device is connected to the interface on which Autoconf is disabled.

Autoconf allows you to retain the template even when the link to the end device is down or the end device is disconnected, by configuring the autoconf sticky feature **access-session interface-template sticky** command in global configuration mode. The Autoconf sticky feature avoids the need for detecting the end device and applying the template every time the link flaps or the device is removed and connected back.

The **access-session interface-template sticky** command is mandatory to apply an inbuilt template that contains **access-session** commands on an interface. Configure the **access-session interface-template sticky** command to apply interface template on a port using a service policy.

To disable the Autoconf feature on a specific interface, use the **access-session inherit disable interface-template-sticky** command in interface configuration mode.

How to Configure Autoconf

The following sections provide information about how to configure Autoconf.

Applying a Built-In Template to an End Device

The following task shows how to apply a built-in template on an interface that is connected to an end device, for example, a Cisco IP phone.

Before you begin

Make sure that the end device, for example, a Cisco IP phone, is connected to a switch port.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device(config)# configure terminal`	Enters global configuration mode.
Step 3	**autoconf enable** **Example:** `Device(config)# autoconf enable`	Enables the Autoconf feature.
Step 4	**end** **Example:** `Device(config)# end`	Exits global configuration mode and enters privileged EXEC mode.
Step 5	**show device classifier attached interface** *interface-type interface-number* **Example:** `Device# show device classifier attached interface Gi3/0/26`	(Optional) Displays whether the end device is classified by the device classifier with correct attributes.
Step 6	**show template binding target** *interface-type interface-number* **Example:** `Device# show template binding target gi3/0/26`	Displays the configuration applied through the template on the interface.

Example

The following example shows that an IP phone is classified by the device classifier with correct attributes:

```
Device# show device classifier attached interface GigabitEthernet 1/1

Summary:

MAC_Address       Port_Id       Profile Name                        Device Name
==============    ==========    ==================                  ==================
0026.0bd9.7bbb    Gi3/0/26      Cisco-IP-Phone-7962                 Cisco IP Phone 7962
```

The following example shows that a built-in interface template is applied on an interface:

```
Device# show template binding target GigabitEthernet 1/1

Interface Templates
===================
Interface: Gi4/0/11
Method              Source            Template-Name
------              ------            -------------
dynamic             Built-in          IP_PHONE_INTERFACE_TEMPLATE
```

The following example shows how to verify the interface configuration after the interface template is applied to an IP phone connected to the GigabitEthernet interface 1/1:

```
Device# show running-config interface GigabitEthernet 1/1
Building configuration...

Current configuration : 624 bytes
!
interface GigabitEthernet1/1
!
End

Device# show derived-config interface GigabitEthernet1/1

Building configuration...

Derived configuration : 649 bytes
!
interface GigabitEthernet1/1
 switchport mode access
 switchport block unicast
 switchport port-security maximum 3
 switchport port-security maximum 2 vlan access
 switchport port-security violation restrict
 switchport port-security aging time 2
 switchport port-security aging type inactivity
 switchport port-security
 load-interval 30
 storm-control broadcast level pps 1k
 storm-control multicast level pps 2k
 storm-control action trap
 spanning-tree portfast
 spanning-tree bpduguard enable
 service-policy input AutoConf-4.0-CiscoPhone-Input-Policy
 service-policy output AutoConf-4.0-Output-Policy
 ip dhcp snooping limit rate 15
```

```
end
```

The following example shows how to verify the global configuration after configuring Autoconf:

```
Device# show running config

Applying a Modified Built-In Template to an End Device

The following task shows how to modify a built-in template when multiple wireless access points and IP cameras are connected to a switch:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device(config)# configure terminal`	Enters global configuration mode.
Step 3	**template** *template-name* **Example:** `Device(config)# template AP_INTERFACE_TEMPLATE`	Enters template configuration mode for the built-in template.
Step 4	**switchport access vlan** *vlan-id* **Example:** `Device(config-template)# switchport access vlan 20`	Sets the VLAN when the interface is in access mode.
Step 5	**description** *description* **Example:** `Device(config-template)# description modifiedAP`	Modifies the description of the built-in template.
Step 6	**exit** **Example:**	Exits template configuration mode and enters global configuration mode.

	Command or Action	Purpose
	`Device(config-template)# exit`	
Step 7	**autoconf enable** **Example:** `Device(config)# autoconf enable`	Enables the Autoconf feature.
Step 8	**end** **Example:** `Device(config)# end`	Exits global configuration mode and enters privileged EXEC mode.
Step 9	**show template interface binding all** **Example:** `Device# show template interface binding all`	Displays whether the template is applied on the interface.

Example

The following example shows that an IP camera and access points are classified by the device classifier with correct attributes:

```
Device# show device classifier attached detail

DC default profile file version supported = 1

Detail:
MAC_Address     Port_Id    Cert Parent Proto    ProfileType     Profile Name
Device_Name
=============================================================================================================
001d.a1ef.23a8  Gi1/1     30    3    C     M    Default      Cisco-AIR-AP-1130      cisco
AIR-AP1131AG-A-K9
001e.7a26.eb05  Gi1/1     70    2    C     M    Default      Cisco-IP-Camera        Cisco
IP Camera
```

The following example shows that the built-in interface template is applied on an interface:

```
Device# show template interface binding all

Template-Name                   Source            Method          Interface
-------------                   ------            ------          ---------
IP_CAMERA_INTERFACE_TEMPLATE     Built-in          dynamic         Gi1/1
AP_INTERFACE_TEMPLATE          Modified-Built-in   dynamic         Gi1/1
```

Migrating from ASP to Autoconf

Before you begin

Verify that the AutoSmart Port (ASP) macro is running by using the **show running-config | include macro auto global** command.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**no macro auto global processing** **Example:** `Device(config)# no macro auto global processing`	Disables ASP on a global level.
Step 4	**exit** **Example:** `Device(config)# exit`	Exits global configuration mode and returns to privileged EXEC mode.
Step 5	**clear macro auto configuration all** **Example:** `Device# clear macro auto configuration all`	Clears macro configurations for all interfaces.
Step 6	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 7	**autoconf enable** **Example:** `Device(config)# autoconf enable`	Enables the Autoconf feature.
Step 8	**end** **Example:** `Device(config)# end`	Exits global configuration mode and returns to privileged EXEC mode.

Configuring a Platform Type Filter

The following tasks shows how to configure a platform type filter for class maps and parameter maps.

Configuring a Platform Type Filter for a Class Map

A control class defines the conditions under which the actions of a control policy are executed. You should define whether all, any, or none of the conditions must be evaluated to execute the actions of the control policy. Platform types are evaluated based on the specified platform name in the control policy.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**class-map type control subscriber** {**match-all** | **match-any** | **match-none**} *control-class-name* **Example:** `Device(config)# class-map type control subscriber match-all DOT1X_NO_AGENT`	Creates a control class and enters control class-map filter mode. • **match-all**: Must match all the conditions in the control class. • **match-any**: Must match at least one condition in the control class. • **match-none**: Must not match any of the conditions in the control class.
Step 4	**match platform-type** *platform-name* **Example:** `Device(config-filter-control-classmap)# match platform-type C3850`	Creates a condition to evaluate control classes based on the specified platform type.
Step 5	**end** **Example:** `Device(config-filter-control-classmap)# end`	Exits control class-map filter mode and returns to privileged EXEC mode.
Step 6	**show class-map type control subscriber** {**all** | **name** *control-class-name*} **Example:** `Device# show class-map type control subscriber all`	(Optional) Displays information about control policies for all the class maps or a specific class map.

Configuring a Platform Type Filter for a Parameter Map

We recommend that you use the parameter map.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**parameter-map type subscriber attribute-to-service** *parameter-map-name* **Example:** `Device(config)# parameter-map type subscriber attribute-to-service Aironet-Policy-para`	Specifies the parameter map type and name, and enters parameter-map filter mode.
Step 4	*map-index* **map platform-type** {{**eq** | **not-eq** | **regex**} *filter-name*} **Example:** `Device(config-parameter-map-filter)# 10 map platform-type eq C9xxx`	Specifies the parameter map attribute filter criteria to the platform type.
Step 5	**end** **Example:** `Device(config-parameter-map-filter-submode)# end`	Exits parameter-map filter mode and returns to privileged EXEC mode.
Step 6	**show parameter-map type subscriber attribute-to-service**{**all | name** *parameter-map-name*} **Example:** `Device# show parameter-map type subscriber attribute-to-service`	(Optional) Displays the parameter map attributes.

Configuring a Device Type Filter for a Class Map

A control class defines the conditions under which the actions of a control policy are executed. You should define whether all, any, or none of the conditions must be evaluated to execute the actions of the control policy. Device types are evaluated based on the specified device name in the control policy.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**class-map type control subscriber** {**match-all** | **match-any** | **match-none**} *control-class-name* **Example:** `Device(config)# class-map type control subscriber match-all Device-Type-Match`	Creates a control class and enters control class-map filter mode. • **match-all**: Must match all the conditions in the control class. • **match-any**: Must match at least one condition in the control class. • **match-none**: Must not match any of the conditions in the control class.

Step 4	**match device-type** {*device-name*|**regex** *regular-expression*}
	Example:
	`Device(config-filter-control-classmap)# match device-type laptop`
	`Device(config-filter-control-classmap)# match device-type regex cis*`
		Creates a condition to evaluate control classes based on the specified device type.
		• *device-name*: Enter a device name for the class map attribute filter criteria.
		• **regex** *regular-expression*: Enter a regular expression to specify the filter type.

Step 5	**end** **Example:** `Device(config-filter-control-classmap)# end`	Exits control class-map filter mode and returns to privileged EXEC mode.
Step 6	**show class-map type control subscriber** {**all** | **name** *control-class-name*} **Example:** `Device# show class-map type control subscriber all`	(Optional) Displays information about control policies for all the class maps or a specific class map.

Configuration Examples for Autoconf

The following sections provide configuration examples for the Autoconf feature.

Example: Applying a Built-In Template to an End Device

The following example shows how to apply a built-in template to an end device connected to an interface:

```
Device> enable
Device(config)# configure terminal
Device(config)# autoconf enable
Device(config)# end
Device# show device classifier attached interface Gi3/0/26
Device# show template binding target GigabitEthernet 1/1
```

Example: Applying a Modified Built-In Template to an End Device

The following example shows how to apply a modified built-in template to an end device and verify the configuration:

```
Device> enable
Device(config)# configure terminal
Device(config)# template AP_INTERFACE_TEMPLATE
Device(config-template)# switchport access vlan 20
Device(config-template)# description modifiedAP
Device(config-template)# exit
Device(config)# autoconf enable
Device(config)# end
Device# show template interface binding all
```

Example: Migrating from ASP Macros to Autoconf

The following example shows how to migrate from ASP to Autoconf:

```
Device> enable
Device# configure terminal
Device(config)# no macro auto global processing
Device(config)# exit
Device# clear macro auto configuration all
Device# configure terminal
Device(config)# autoconf enable
Device(config)# end
```

Example: Configuring a Platform Type Filter

The following example shows how to configure a platform type filter for a class map:

```
Device> enable
Device# configure terminal
Device(config)# class-map type control subscriber match-all DOT1X_NO_AGENT
Device(config-filter-control-classmap)# match platform-type C9xxx
Device(config-filter-control-classmap)# end
Device#
```

The following example shows how to configure a platform type filter for a parameter map:

```
Device> enable
Device# configure terminal
```

```
Device(config)# parameter-map type subscriber attribute-to-service Aironet-Policy-para
Device(config-parameter-map-filter)# 10 map platform-type eq C9xxx
Device(config-parameter-map-filter-submode)# end
Device#
```

CHAPTER 161

Configuring Interface Templates

The following sections provide information about Interface Templates and how to configure and bind Interface Templates to a target:

- Restrictions for Interface Templates, on page 2313
- Information About Interface Templates, on page 2313
- How to Configure Interface Templates, on page 2316
- Configuration Examples for Interface Templates, on page 2324

Restrictions for Interface Templates

- Remote storing and downloading of templates is not supported.
- To dynamically bind an interface template, the interface template with the same name as referred by AAA Authorization has to be configured on the device.

Information About Interface Templates

This section describes an interface template, its types and usage.

Interface Template Overview

An interface template is a container of configurations or policies that can be applied to specific ports. When an interface template is applied to an access port, it impacts all traffic that is exchanged on the port.

There are two types of interface templates; user and builtin templates. Builtin templates are created by the system.

You can modify builtin templates. If you delete a modified builtin template, the system restores the original definition of the template.

The following are the available builtin templates:

- AP_INTERFACE_TEMPLATE (Access Point)
- DMP_INTERFACE_TEMPLATE (Digital Media Player)
- IP_CAMERA_INTERFACE_TEMPLATE

- IP_PHONE_INTERFACE_TEMPLATE
- LAP_INTERFACE_TEMPLATE (Lightweight Access Point)
- MSP_CAMERA_INTERFACE_TEMPLATE
- MSP_VC_INTERFACE_TEMPLATE (Video Conferencing)
- PRINTER_INTERFACE_TEMPLATE
- ROUTER_INTERFACE_TEMPLATE
- SWITCH_INTERFACE_TEMPLATE
- TP_INTERFACE_TEMPLATE (TelePresence)

Following is an example of a builtin interface template:

```
Template Name       : IP_CAMERA_INTERFACE_TEMPLATE
Modified            : No
Template Definition :
 spanning-tree portfast
 spanning-tree bpduguard enable
 switchport mode access
 switchport block unicast
 switchport port-security
 srr-queue bandwidth share 1 30 35 5
 priority-queue out
!
```

You can also create specific user templates with the commands that you want to include.

Note The template name must not contain spaces.

You can create an interface template using the **template** command in global configuration mode. In template configuration mode, enter the required commands. The following commands can be entered in template configuration mode:

Command	Description
access-session	Configures access session-specific interface commands. This is applicable to Identity-Based Networking Services (IBNS) 2.0
authentication	Configures authentication manager Interface Configuration commands. This is applicable to IBNS1.0
carrier-delay	Configures delay for interface transitions.
cts manual	Supplies local configuration for Cisco TrustSec (CTS) parameters and puts the device in CTS manual interface configuration mode.
default	Sets a command to its defaults.

Command	Description
description	Configures interface-specific description.
dot1x	Configures interface configuration commands for IEEE 802.1X.
ip	Configures IP template.
keepalive	Enables keepalive.
load-interval	Specifies interval for load calculation for an interface.
mab	Configures MAC authentication bypass Interface.
peer	Configures peer parameters for point to point interfaces.
service-policy	Configures CPL service policy.
source	Gets configurations from another source.
spanning-tree	Configures spanning tree subsystem
storm-control	Configures storm control.
subscriber	Configures subscriber inactivity timeout value.
switchport	Sets switching mode configurations

Note System builtin templates aren't displayed in the running configuration. These templates show up in the running configuration only if you edit them.

Binding an Interface Template to a Target

Each template can be bound to a target, like an interface or a sub-interface. A template can be attached to a target either statically or dynamically. Static binding of a template involves binding the template to a target, like an interface. Only one template can be bound at a time using static binding. Static binding of another template to the same target will unbind the previously bound template. To configure static binding, use the **source template** command in interface configuration mode.

Any number of templates can be bound dynamically to a target. To configure dynamic binding using builtin policy maps and parameter maps, enable the Autoconf feature using the **autoconf enable** command.

Note You can have statically and dynamically bound templates on the same interface at a time.

Priority for Configurations Using Interface Templates

Configuration applied through dynamically-bound templates has the highest priority, followed by configuration applied directly on the interface, and then configuration applied through statically-bound templates. When similar commands are present at different priority levels, the one at the highest priority is applied. If a configuration at a higher priority level is not applied, then the configuration with the next highest priority is applied to the target.

Multiple templates can be dynamically bound to a target. When multiple templates are dynamically bound, the template that is applied last has the highest priority.

To delete a template, you must remove the binding to all targets. If you bind a template that does not exist, a new template is created with no configurations.

How to Configure Interface Templates

Perform the following tasks to configure a user interface template and bind it to a target.

Configuring Interface Templates

Perform the following task to create user interface templates:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**template** *name* **Example:** `Device(config)# template user-template1`	Creates a user template and enters template configuration mode. **Note** Builtin templates are system-generated.
Step 4	**load-interval** *interval* **Example:** `Device(config-template)# load-interval 60`	Configures the sampling interval for statistics collections on the template. **Note** Builtin templates are system-generated.
Step 5	**description** *description* **Example:**	Configures the description for the template.

	Command or Action	Purpose
	`Device(config-template)# description This is a user template`	
Step 6	**keepalive** *number* **Example:** `Device(config-template)# Keepalive 60`	Configures the keepalive timer.
Step 7	**end** **Example:** `Device(config)# end`	Exits global configuration mode and returns to privileged EXEC mode.

Configuring Static Binding for Interface Templates

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type number* **Example:** `Device(config)# interface GigabitEthernet 1/1`	Specifies the interface type and number and enters interface configuration mode.
Step 4	**source template** *name* **Example:** `Device(config-if)# source template user-template1`	Statically applies an interface template to a target.
Step 5	**end** **Example:** `Device(config-if)# end`	Exits interface configuration mode and returns to privileged EXEC mode.

Example

To verify static binding use the **show running-config interface** *int-name* and the **show derived-config interface** *int-name* commands.

```
Device# show running-config interface GigabitEthernet 1/1

Building configuration...

Current configuration : 71 bytes
!
interface GigabitEthernet1/1
source template user-template1
end
```

```
Device# show derived-config interface GigabitEthernet 1/1
Building configuration...

Derived configuration : 108 bytes
!
interface GigabitEthernet1/1
description This is a user template
load-interval 60
keepalive 60
end
```

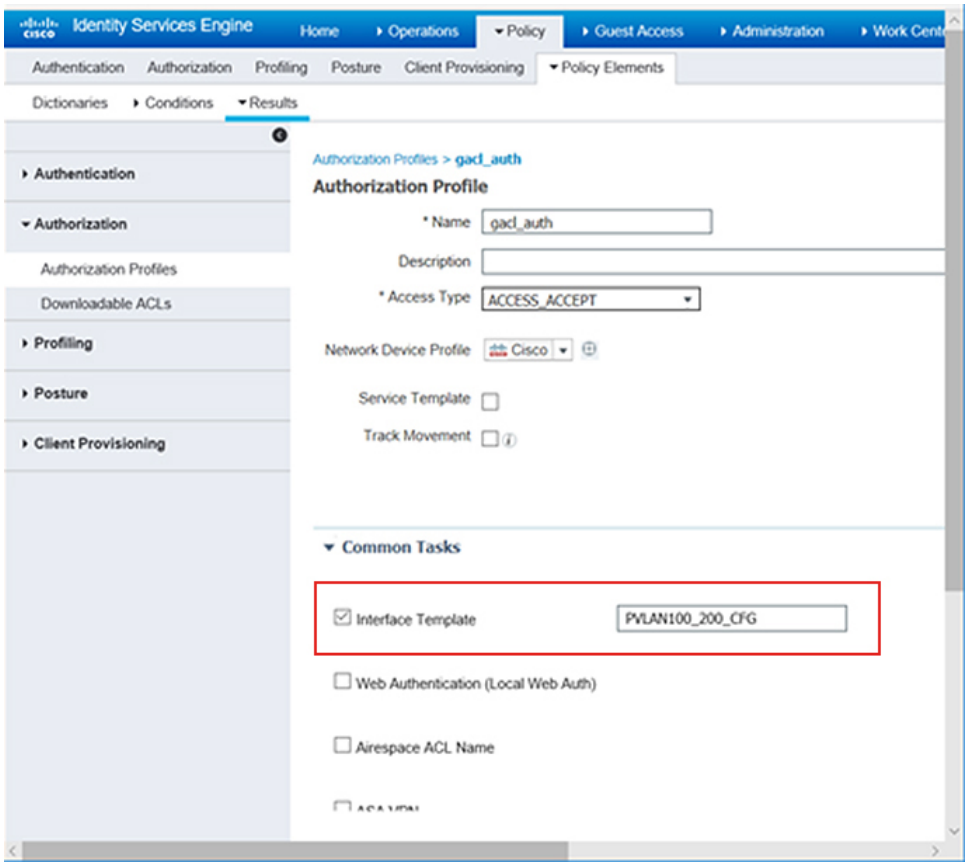
Configuring Dynamic Binding of Interface Templates

To configure dynamic binding of interface templates, perform the following tasks:

Before you begin

Ensure that 802.1x port-based authentication is configured on the device. When you are using the ISE server to download and assign a template that includes **switchport mode** and vlan change commands, the **access-session interface-template sticky** command is used, which is available only in IBNS 2.0. Hence, VLAN changes using a template require IBNS 2.0.

Procedure



Step 1 Create a template on the device, as specified in the Configuring Interface Templates, on page 2316 procedure.

Step 2 Configure the Identity Services Engine (ISE) or any other RADIUS server to download the template name to the device interface. The template is assigned after the device is authenticated successfully.

If you're using ISE, go to the **Policy** > **Policy Elements** > **Authorization** > **Authorization Profile** page.

Check the **Interface Template** check box and enter the name of the template to be assigned to the client interface.

Figure 144: Configure ISE to Assign Interface Template

If you're using a different RADIUS server, configure the attribute **Cisco-AVpair="interface:template=*name*"** with the name of the template. This configuration pushes the template to the device after the initial client authentication is completed.

Step 3 To verify that the template name is downloaded to the interface, use the **show access-session interface** *interface-id* **details** or **show access-session interface** *interface-id* **details** command. To verify that the interface template commands are applied to the interface, use the **show derived-config interface** *interface-id* command.

Example

The following example shows how to verify that a template named del_template is downloaded and applied to the gigabitethernet 1/1 interface on the device:

```
Device# show running-config | section del_template
template del_template
access-session port-control auto
no access-session monitor
authentication periodic

Device# show access-session interface gigabitethernet 1/1 details
Interface: gigabitethernet 1/1
IIF-ID: 0x1F9EBBA9
MAC Address: 002f.0100.0001
```

```
IPv6 Address: Unknown
IPv4 Address: Unknown
User-Name: NOAS
Device-type: Un-Classified Device
Device-name: Unknown Device
Status: Authorized
Domain: DATA
Oper host mode: multi-auth
Oper control dir: both
Session timeout: N/A
Common Session ID: 0404140B00004E1C6E569E0B
Acct Session ID: Unknown
Handle: 0xdb000e24
Current Policy: DOT1x

Server Policies:
Interface Template: del_template

Method status list:
Method State
dot1x Authc Success

Device# show derived-config interface gigabitethernet 1/1
Building configuration...

Derived configuration : 321 bytes
!
interface gigabitethernet 1/1
switchport access vlan 44
switchport mode access
switchport port-security violation restrict
switchport port-security
authentication periodic
access-session port-control auto
no access-session monitor
mab
dot1x pae authenticator
service-policy type control subscriber DOT1x
end
```

Verifying Interface Templates

Use one or more of the commands listed below to verify the interface template configuration.

Table 171: Show commands to verify Interface Template Configuration

Command	Purpose
show template interface all {**all** | **binding** {*temp-name* | **all** | **target** *int-name*} | **brief** }	Shows all interface template configurations.
show template interface source {**built-in** [**original**] | **user**}{*temp-name* | **all**}}	Shows interface template source configurations.
show template service{**all** | **binding target** *int-name* | **brief** | **source** {**aaa** | **built-in** | **user** {**temp-name** | **all**}}	Shows all interface template service configurations.

Example: Verifying Interface User Template

```
Device# show template interface source user all
    Template Name : TEST-1
    Template Definition:
    load-interval 60
    description TEST_1_TEMPLATE
    keepalive 200
    !
    Template Name : TEST-2
    Template Definition:
    load-interval 60
    description TEST-1_TEMPLATE
    keepalive 200
```

Example: Verifying all Builtin Templates

```
Device#  show template interface source built-in all

Building configuration...

   SVC2                 built-in       ab-ab-ab-ab-ab-ab
   SVC3                 aaa            ac-ac-ac-ac-ac-ac
```

Configuration Examples for Interface Templates

Example: Configuring User Interface Templates

Example: Configuring User Templates

```
Device# enable
Device (config)# configure terminal
Device(config)# template user-template1
Device(config-template)# load-interval 60
Device(config-template)# description This is a user template
Device(config-template)# Keepalive 60
Device(config)# end
```

Example: Sourcing Interface Templates

```
Device> enable
Device# configure terminal
Device(config-if)# source template user-template1
Device(config-if)# end
```

Example: Dynamically Binding Interface Templates

Configure a template on the device:

```
Device# configure terminal
Device(config)# tempalte user_template
Device(config-template)# access-session port-control auto
Device(config-template)# no access-session monitor
Device(config-template)# authentication periodic
```

Configure RADIUS Server attribute with the template name:

```
Cisco-AVpair="interface:template=user_template"
```

CHAPTER 163

Configuring Cisco Discovery Protocol

Cisco Discovery Protocol is a Layer 2, media-independent, and network-independent protocol that runs on Cisco devices and enables networking applications to learn about directly connected devices nearby. This protocol facilitates the management of Cisco devices by discovering these devices, determining how they are configured, and allowing systems using different network-layer protocols to learn about each other.

This module describes Cisco Discovery Protocol Version 2 and how it functions with SNMP.

- Information about Cisco Discovery Protocol, on page 2329
- How to Configure Cisco Discovery Protocol, on page 2330
- Monitoring and Maintaining Cisco Discovery Protocol, on page 2336

Information about Cisco Discovery Protocol

The following sections provide information about Cisco Discovery Protocol

Default Cisco Discovery Protocol Configuration

This table shows the default Cisco Discovery Protocol configuration.

Feature	Default Setting
Cisco Discovery Protocol global state	Enabled
Cisco Discovery Protocol interface state	Enabled
Cisco Discovery Protocol timer (packet update frequency)	60 seconds
Cisco Discovery Protocol holdtime (before discarding)	180 seconds
Cisco Discovery Protocol Version-2 advertisements	Enabled

Cisco Discovery Protocol Overview

Cisco Discovery Protocol is a device discovery protocol that runs over Layer 2 (the data-link layer) on all Cisco-manufactured devices (routers, bridges, access servers, controllers, and switches) and allows network management applications to discover Cisco devices that are neighbors of already known devices. With Cisco Discovery Protocol, network management applications can learn the device type and the SNMP agent address

of neighboring devices running lower-layer, transparent protocols. This feature enables applications to send SNMP queries to neighboring devices.

Cisco Discovery Protocol runs on all media that support Subnetwork Access Protocol (SNAP). Because Cisco Discovery Protocol runs over the data-link layer only, two systems that support different network-layer protocols can learn about each other.

Each Cisco Discovery Protocol-configured device sends periodic messages to a multicast address, advertising at least one address at which it can receive SNMP messages. The advertisements also contain time-to-live, or holdtime information, which is the length of time a receiving device holds Cisco Discovery Protocol information before discarding it. Each device also listens to the messages sent by other devices to learn about neighboring devices.

On the device, Cisco Discovery Protocol enables Network Assistant to display a graphical view of the network. The device uses Cisco Discovery Protocol to find cluster candidates and maintain information about cluster members and other devices up to three cluster-enabled devices away from the command device by default.

The following applies to a device and connected endpoint devices:

- Cisco Discovery Protocol identifies connected endpoints that communicate directly with the device.
- To prevent duplicate reports of neighboring devices, only one wired device reports the location information.
- The wired device and the endpoints both send and receive location information.

How to Configure Cisco Discovery Protocol

The following sections provide information about how to configure Cisco Discovery Protocol.

Configuring Cisco Discovery Protocol Characteristics

You can configure these Cisco Discovery Protocol characteristics:

- Frequency of Cisco Discovery Protocol updates
- Amount of time to hold the information before discarding it
- Whether or not to send Version 2 advertisements

Note Steps 3 through 5 are all optional and can be performed in any order.

Follow these steps to configure the Cisco Discovery Protocol characteristics.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device>enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Device# configure terminal`	
Step 3	**cdp timer** *seconds* **Example:** `Device(config)# cdp timer 20`	(Optional) Sets the transmission frequency of Cisco Discovery Protocol updates in seconds. The range is 5 to 254; the default is 60 seconds.
Step 4	**cdp holdtime** *seconds* **Example:** `Device(config)# cdp holdtime 60`	(Optional) Specifies the amount of time a receiving device should hold the information sent by your device before discarding it. The range is 10 to 255 seconds; the default is 180 seconds.
Step 5	**cdp advertise-v2** **Example:** `Device(config)# cdp advertise-v2`	(Optional) Configures Cisco Discovery Protocol to send Version 2 advertisements. This is the default state.
Step 6	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 7	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 8	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

What to do next

Use the **no** form of the Cisco Discovery Protocol commands to return to the default settings.

Disabling Cisco Discovery Protocol

Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange Cisco Discovery Protocol messages. Disabling Cisco Discovery Protocol can interrupt cluster discovery and device connectivity.

Note Cisco Discovery Protocol is enabled by default.

Follow these steps to disable the Cisco Discovery Protocol device discovery capability.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device>enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**no cdp run** **Example:** `Device(config)# no cdp run`	Disables Cisco Discovery Protocol.
Step 4	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 5	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 6	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

What to do next

You must reenable Cisco Discovery Protocol to use it.

Enabling Cisco Discovery Protocol

Cisco Discovery Protocol is enabled by default.

Note Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange Cisco Discovery Protocol messages. Disabling Cisco Discovery Protocol can interrupt cluster discovery and device connectivity.

Follow these steps to enable Cisco Discovery Protocol when it has been disabled.

Before you begin

Cisco Discovery Protocol must be disabled, or it cannot be enabled.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device>enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**cdp run** **Example:** `Device(config)# cdp run`	Enables Cisco Discovery Protocol if it has been disabled.
Step 4	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 5	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.

	Command or Action	Purpose
Step 6	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

What to do next

Use the **show run all** command to check if Cisco Discovery Protocol has been enabled. If you run the **show run** command, the enabling of Cisco Discovery Protocol may not be displayed.

Disabling Cisco Discovery Protocol on an Interface

Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange Cisco Discovery Protocol messages. Disabling Cisco Discovery Protocol can interrupt cluster discovery and device connectivity.

Note

- Cisco Discovery Protocol is enabled by default on all supported interfaces to send and to receive Cisco Discovery Protocol information.
- Cisco Discovery Protocol bypass is not supported and may cause a port go into err-disabled state.

Follow these steps to disable Cisco Discovery Protocol on a port.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device>enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *interface-id* **Example:** `Device(config)# interface gigabitethernet 1/1`	Specifies the interface on which you are disabling Cisco Discovery Protocol, and enters interface configuration mode.
Step 4	**no cdp enable** **Example:**	Disables Cisco Discovery Protocol on the interface specified in Step 3.

	Command or Action	Purpose
	`Device(config-if)# no cdp enable`	
Step 5	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 6	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 7	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Enabling Cisco Discovery Protocol on an Interface

Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange Cisco Discovery Protocol messages. Disabling Cisco Discovery Protocol can interrupt cluster discovery and device connectivity.

Note

- Cisco Discovery Protocol is enabled by default on all supported interfaces to send and to receive Cisco Discovery Protocol information.
- Cisco Discovery Protocol bypass is not supported and may cause a port go into err-disabled state.

Follow these steps to enable Cisco Discovery Protocol on a port on which it has been disabled.

Before you begin

Cisco Discovery Protocol must be disabled on the port that you are trying to Cisco Discovery Protocol enable on, or it cannot be enabled.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device>enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface** *interface-id* **Example:** `Device(config)# interface gigabitethernet 1/1`	Specifies the interface on which you are enabling Cisco Discovery Protocol, and enters interface configuration mode.
Step 4	**cdp enable** **Example:** `Device(config-if)# cdp enable`	Enables Cisco Discovery Protocol on a disabled interface.
Step 5	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 6	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 7	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Monitoring and Maintaining Cisco Discovery Protocol

Table 172: Commands for Displaying Cisco Discovery Protocol Information

Command	Description
clear cdp counters	Resets the traffic counters to zero.
clear cdp table	Deletes the Cisco Discovery Protocol table of information about neighbors.
show cdp	Displays global information, such as frequency of transmissions and the holdtime for packets being sent.

Command	Description
show cdp entry *entry-name* [**version**] [**protocol**]	Displays information about a specific neighbor. You can enter an asterisk (*) to display all Cisco Discovery Protocol neighbors, or you can enter the name of the neighbor about which you want information. You can also limit the display to information about the protocols enabled on the specified neighbor or information about the version of software running on the device.
show cdp interface [*interface-id*]	Displays information about interfaces where Cisco Discovery Protocol is enabled. You can limit the display to the interface about which you want information.
show cdp neighbors [*interface-id*] [*detail*]	Displays information about neighbors, including device type, interface type and number, holdtime settings, capabilities, platform, and port ID. You can limit the display to neighbors of a specific interface or expand the display to provide more detailed information.
show cdp traffic	Displays Cisco Discovery Protocol counters, including the number of packets sent and received and checksum errors.
show ap cdp neighbors	Displays information regarding the access point's Cisco Discovery Protocol neighbors.
show ap cdp neighbors detail	Displays detailed information regarding the access point's Cisco Discovery Protocol neighbors.
show ap name *ap-name* **cdp neighbors**	Displays the Cisco Discovery Protocol information for an access point.
show ap name *ap-name* **cdp neighbors detail**	Displays details about a specific access point neighbor that is using Cisco Discovery Protocol.

CHAPTER 164

Configuring Cisco Discovery Protocol Bypass

In Cisco Discovery Protocol Bypass mode Cisco Discovery Protocol packets are received and transmitted unchanged. Received packets are not processed. No packets are generated. In this mode, 'bump-in-the-wire' behavior is applied to Cisco Discovery Protocol packets. This is a backward compatible mode, equivalent to not having Cisco Discovery Protocol support.

- Restrictions for Cisco Discovery Protocol Bypass, on page 2339
- Information about Cisco Discovery Protocol Bypass, on page 2339
- How to configure Cisco Discovery Protocol Bypass, on page 2340
- Configuration Examples for Cisco Discovery Protocol Bypass, on page 2341

Restrictions for Cisco Discovery Protocol Bypass

Cisco Discovery Protocol Bypass does not support standard ACLs on the switch port.

Information about Cisco Discovery Protocol Bypass

When a Cisco IP Phone is plugged into a port that is configured with a Voice VLAN and single-host mode, the phone will be silently allowed onto the network by way of a feature known as Cisco Discovery Protocol Bypass. The phone (or any device) that sends the appropriate Type Length Value (TLV) in a Cisco Discovery Protocol message will be allowed access to the voice VLAN.

In Cisco Discovery Protocol Bypass mode, Cisco Disocvery Protocol packets are received and transmitted unchanged. Received packets are not processed. No packets are generated. In this mode, 'bump-in-the-wire' behaviour is applied to Cisco Discovery Protocol packets. This is a backward compatible mode, equivalent to not having Cisco Discovery Protocol support.

In Cisco Discovery Protocol Bypass mode authentication sessions are established in single and multi-host modes for IP Phones. However, if voice VLAN and 802.1x on an interface port is enabled, then Cisco Discovery Protocol Bypass is enabled when the host mode is set to single or multi-host mode.

It is possible to use the Multi-Domain Authentication (MDA) feature instead of Cisco Discovery Protocol Bypass feature as it provides better Access Control, Visibility and Authorization.

Note By default the host mode is set to single mode in legacy mode and multi-authentication in the edge mode.

Cisco Discovery Protocol Enhancement for Second Port Disconnect—Allows a Cisco IP phone to send a Cisco Discovery Protocol message to the switch when a host unplugs from behind the phone. The switch is then able to clear any authenticated session for the indirectly connected host, the same as if the host had been directly connected and the switch had detected a link down event. This is supported in latest IP telephones.

Cisco Discovery Protocol Bypass provides no support for third-party phones—Cisco Discovery Protocol Bypass works only with Cisco phones.

How to configure Cisco Discovery Protocol Bypass

Follow these steps to enable Cisco Discovery Protocol Bypass:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `# configure terminal`	Enters the global configuration mode.
Step 3	**interface** *interface-id* **Example:** `(config)# interface gigabitethernet 1/1`	Specifies a physical port, and enters interface configuration mode. • Valid interfaces are physical ports.
Step 4	**switchport mode access** **Example:** `(config-if)# switchport mode access`	Specifies that the interface is in access mode.
Step 5	**switchport access vlan** *vlan id* **Example:** `(config-if)# switchport access vlan 10`	Assigns all ports as static-access ports in the same VLAN • If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094.
Step 6	**switchport voice vlan** *vlan-id* **Example:** `(config-if)# switchport voice vlan 3`	Instruct the Cisco IP phone to forward all voice traffic through the specified VLAN. By default, the Cisco IP phone forwards the voice traffic with an 802.1Q priority of 5. Valid VLAN IDs are from 1 to 4094 when the enhanced software image (EI) is installed and 1 to 1001 when the standard software image is installed. Do not enter leading zeros.

	Command or Action	Purpose
Step 7	**authentication port-control auto** **Example:** `(config-if)# authentication port-control auto`	Enables 802.1x authentication on the port.
Step 8	**authentication host-mode** {**single-host** | **multi-host**} **Example:** `(config-if)# authentication host-mode single | multi-host`	The keywords allow the following: • single-host-Single host (client) on an IEEE 802.1X-authorized port. • multi-host-Multiple hosts on an 802.1X-authorized port after a authenticating a single host.
Step 9	**dot1x pae authenticator** **Example:** `(config-if)# dot1x pae authenticator`	Enables 802.1X authentication on the port with default parameters

Configuration Examples for Cisco Discovery Protocol Bypass

Example: Enabling Cisco Discovery Protocol Bypass

Cisco Discovery Protocol Bypass is enabled by default once 'Authetication port-control auto' is configured with dotx1 or MAB or if voice vlan is configured on interface along with single/multiple host mode.

This following configuration example configures Cisco Disovery Protocol Bypass when authenticating using MAB.

```
 (config)# interface gigabitethernet 1/1
(config-if)# switchport mode access
(config-if)# switchport access vlan 10
(config-if)# switchport voice vlan 3
(config-if)# authentication port-control auto
(config-if)# mab
```

Displaying Cisco Discovery Protocol neighbours

The following configuration example displays Cisco Discovery Protocol neighbours.

```
# show cdp neighbors gigabitethernet 1/1 detail
Device ID: SEP24B657B038DF
Entry address(es):
Platform: Cisco IP Phone 9971,  Capabilities: Host Phone Two-port Mac Relay
Interface: gigabitethernet 1/1,  Port ID (outgoing port): Port 1
Holdtime : 157 sec
Second Port Status: Down <<<<<<<<<<
Version :
```

```
sip9971.9-1-1SR1
advertisement version: 2
Duplex: full
Power drawn: 12.804 Watts
Power request id: 57146, Power management id: 4
Power request levels are:12804 0 0 0 0
Total cdp entries displayed : 1
```

Example:Disabling Cisco Discovery Protocol Bypass

To disable Cisco Discovery Protocol Bypass,‘Authetication port-control auto’ needs to be removed from the interface.

CHAPTER 165

Configuring Simple Network Management Protocol

- SNMP versions and security models, on page 2343
- Guidelines and limitations, on page 2344
- SNMP overview, on page 2344
- Configure SNMP, on page 2352
- SNMP examples, on page 2360
- Monitor SNMP status, on page 2362

SNMP versions and security models

This software release supports SNMPv1, SNMPv2C, and SNMPv3. Each version offers distinct features and security models to manage network devices effectively.

Supported SNMP versions

- **SNMPv1:** The Simple Network Management Protocol, a Full Internet Standard, defined in RFC 1157.
- **SNMPv2C:** The community-string-based administrative framework for SNMPv2, an experimental internet protocol defined in RFC 1901. It retains the bulk retrieval and improved error handling of SNMPv2Classic.
- **SNMPv3:** An interoperable standards-based protocol defined in RFCs 2273 to 2275. It provides secure access to devices through these features.
  - Message integrity ensures that a packet was not tampered with in transit.
  - Authentication determines that the message is from a valid source.
  - Encryption prevents unauthorized sources from reading packet contents.

Note Both SNMPv1 and SNMPv2C use a community-based form of security. The management station access is defined by an IP address access control list and a password.

SNMPv3 security models and levels

SNMPv3 provides security models and levels. A security model is an authentication strategy set up for a user and their group. A security level defines the type of security permitted in a security model. Available security models include SNMPv1, SNMPv2C, and SNMPv3.

Note To select encryption, enter the **priv** keyword.

The table identifies characteristics and compares combinations of security models and levels:

Table 173: SNMP security models and levels

Model	Level	Authentication	Encryption	Result
SNMPv1	noAuthNoPriv	Community string	No	Uses a community string match for authentication.
SNMPv2C	noAuthNoPriv	Community string	No	Uses a community string match for authentication.
SNMPv3	noAuthNoPriv	Username	No	Uses a username match for authentication.
SNMPv3	authNoPriv	MD5 or SHA	No	Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms.
SNMPv3	authPriv	MD5 or SHA	Data Encryption Standard (DES) or Advanced Encryption Standard (AES)	Provides authentication based on HMAC-MD5 or HMAC-SHA algorithms and allows this encryption: • DES 56-bit encryption. • 3DES 168-bit encryption. • AES 128-bit, 192-bit, or 256-bit encryption.

Guidelines and limitations

- SNMPv1 does not support informs.
- To prevent SNMPv3 authentication failures, manually configure the SNMP engineID before adding SNMPv3 users. This process ensures that the user is associated with the correct engineID, enabling consistent device management.

SNMP overview

SNMP is a network management protocol used to monitor and manage network devices.

SNMP system components

SNMP system consists of these components:

- **SNMP manager:** A system, often part of a network management system (NMS), that requests or changes values in the MIB.
- **SNMP agent:** A software component residing on the device that gathers data from the MIB and responds to manager requests.
- **Management information base (MIB):** A repository that stores information about device parameters and network data.The agent and MIB reside on the device.

SNMP communication

SNMP enables managers to request or change MIB variable values on agents, and agents to respond or send traps to managers.

- The SNMP agent contains MIB variables whose values the SNMP manager can request or change.
- The agent gathers data from the MIB, which stores information about device parameters and network data.
- An agent can send unsolicited traps to the manager, alerting the SNMP manager to network conditions.

Traps can indicate events such as improper user authentication, device restarts, link status changes, MAC address tracking, TCP connection closure, or loss of connection to a neighbor.

SNMP manager functions

- The SNMP manager uses information in the MIB to perform various operations for network management.
- Key SNMP operations include retrieving, storing, and responding to variable values, as well as handling unsolicited messages from agents.

SNMP manager operations

The table describes the main SNMP operations performed by the SNMP manager using the MIB.

Table 174: SNMP Operations

Operation	Description
get-request	Retrieves a value from a specific variable.
get-next-request	Retrieves a value from a variable within a table. With this operation, an SNMP manager does not need to know the exact variable name. A sequential search is performed to find the needed variable from within a table.
get-bulk-request	Retrieves large blocks of data, such as multiple rows in a table, to minimize transmissions. This operation requires SNMPv2 or later.

Operation	Description
get-response	Replies to a get-request, get-next-request, or set-request sent by an NMS.
set-request	Stores a value in a specific variable.
trap	Sends an unsolicited message from an SNMP agent to an SNMP manager when an event occurs.

Note Exclude the **ciscoFlashFileDate** MIB object from SNMP manager queries to prevent performance issues. Although this object is published in the MIB, it is not supported on the product.

SNMP agent functions

The SNMP agent is a software component that receives and responds to requests from one or more SNMP managers. The agent tracks the NMS IP address, the number of polls, and the polling timestamp for both IPv4 and IPv6 servers.

SNMP agent request handling

The SNMP agent performs these functions in response to NMS requests:

- **Get a MIB variable:** The agent retrieves the value of the requested MIB variable and sends the value to the NMS.
- **Set a MIB variable:** The agent retrieves the value of the requested MIB variable and sends the value to the NMS.

SNMP statistics commands

Use these commands to manage SNMP statistics:

- The **show snmp stats hosts** command to display the list of SNMP manager requests in the queue.
- The **clear snmp stats hosts** command to clear the queue.

SNMP trap notifications

The SNMP agent sends unsolicited trap messages to notify an NMS that a significant event has occurred. Trap conditions include:

- Port or module status changes (up or down)
- Spanning-tree topology changes
- Authentication failures

SNMP community strings

SNMP community strings authenticate access to MIB objects and serve as embedded passwords. For an NMS to access a device, the community string configured on the NMS must match one of the community strings defined on the device.

SNMP community string attributes

SNMP community strings have these attributes. Their configuration affects how management stations interact with devices.

- **Read-only (RO):** Grants authorized management stations read access to all MIB objects but denies write access.
- **Read-write (RW):** Grants authorized management stations read and write access to all MIB objects but denies access to the community strings.

When you create a cluster, the command device manages message exchange between member devices and the SNMP application. Network Assistant appends the member device number (@esN, where N is the device number) to the first configured RW and RO community strings on the command device. It then copies these strings to the member device.

SNMP MIB variable access

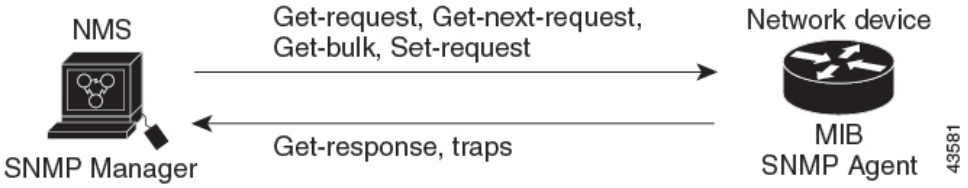
SNMP MIB Variables Access refers to the process by which NMS software interacts with device MIB variables to monitor and manage network devices.

- NMS software uses MIB variables to set device parameters and poll devices for information.
- SNMP agents gather data from the MIB and send traps (notifications) to the SNMP manager about network events.
- SNMP agents respond to MIB-related queries from the SNMP manager in **get-request** , **get-next-request** , and **set-request** formats.

Accessing SNMP MIB variables

SNMP MIB variable access involves communication between NMS software, SNMP agents, and SNMP managers to monitor and manage network devices.

- NMS software polls devices for specific information using MIB variables.
- Results from polls can be displayed as graphs and analyzed for troubleshooting, performance monitoring, and configuration verification.
- SNMP agents send traps to notify the SNMP manager of network events such as authentication failures, restarts, link status changes, and MAC address tracking.



SNMP queries

SNMP agents respond to queries from the SNMP manager using specific request formats.

1. **get-request**

2. **get-next-request**
3. **set-request**

Figure 145: SNMP Network

SNMP Flash MIB

The Flash MIB queries flash file data from Cisco devices. The Flash MIB fetches all files from the flash file system, removing the previous 100-file limitation per partition.

Use the **snmp mib flash cache** command to prefetch all files into the local Flash MIB cache before performing a Flash MIB walk. Retrieving all files from the file system increases the time required to complete a Flash MIB walk.

Flash MIB usage and recommendations

Follow these guidelines to maintain system performance and prevent SNMP walk timeouts:

- Use the **snmp mib flash cache** command with caution, as it may impact CPU performance.
- Set the SNMP walk timeout period to at least 10 seconds and the default retry interval to 5 seconds. These values help prevent SNMP walks from timing out.

SNMP notifications

SNMP notifications are messages that a device sends to SNMP managers when specific events occur. Devices can send these messages as traps or inform requests.

- Traps are notifications sent without acknowledgment. They may not reach their destination.
- Inform requests require acknowledgment and can be resent if not received, making them more reliable.
- Choosing between traps and informs involves a trade-off between reliability and resource consumption.

Notification reliability and resource trade-offs

Traps and informs require a trade-off between reliability and resource consumption.

- **Traps:** Unreliable because the receiver does not acknowledge receipt. The sender discards the trap immediately after sending it.
- **Informs:** Reliable because the SNMP manager acknowledges receipt with an SNMP response protocol data unit (PDU). The sender holds the inform request in memory until it receives a response or the request times out. If the sender does not receive a response, it resends the inform request.

Note SNMPv1 does not support informs.

Characteristic	Traps	Informs
Reliability	Low	High
Acknowledgment	No	Yes
Resource consumption	Low	High
Network traffic	Low	High (due to retries)

Configuration principle

Follow these guidelines to choose the appropriate notification type:

- Use inform requests if it is critical that the SNMP manager receives every notification.
- Use traps if network traffic or device memory is a concern and guaranteed delivery is not required.

SNMP ifIndex MIB object values

The SNMP ifIndex MIB object value is a unique identifier assigned by the IF-MIB module to each physical interface as drivers are initialized after a device reboot.

- The IF-MIB module assigns ifIndex numbers on a first-come-first-served basis as interface drivers register.
- Driver initialization order can vary between reboots, causing the same physical interface to receive a different ifIndex number.
- IfIndex persistency must be enabled to maintain consistent ifIndex assignments across reboots.

SNMP ENTITY-MIB identifiers

ENTITY-MIB contains information for managing physical entities such as field-replaceable units (FRUs) on a device. Each entity is identified by a unique index number, *entPhysicalIndex*, which is used to access information about the entity in current and other MIBs.

- An online insertion and removal (OIR) operation results in the entity being assigned the next available *entPhysicalIndex* number.
- The *entPhysicalIndex* changes after OIR, even if the same entity is reinserted.

SNMP and Syslog over IPv6

SNMP and syslog over IPv6 are network management and logging features that support both IPv4 and IPv6 transports. These features:

SNMP and syslog over IPv6 provide these features:

- Support for both IPv4 and IPv6
- IPv6 transport for SNMP and modification of the SNMP agent to support traps for an IPv6 host
- SNMP- and syslog-related MIBs to support IPv6 addressing
- Configuration of IPv6 hosts as trap receivers

Features and operations

SNMP actions that support IPv6 transport management include:

1. Opens User Datagram Protocol (UDP) SNMP socket with default settings
2. Provides a new transport mechanism called *SR_IPV6_TRANSPORT*
3. Sends SNMP notifications over IPv6 transport
4. Supports SNMP-named access lists for IPv6 transport
5. Supports SNMP proxy forwarding using IPv6 transport
6. Verifies SNMP Manager feature works with IPv6 transport

Note For information on SNMP over IPv6, including configuration procedures, see the "Managing Cisco IOS Applications over IPv6" chapter in the *Cisco IOS IPv6 Configuration Library* on the Cisco website. For information about syslog over IPv6, including configuration procedures, see the "Implementing IPv6 Addressing and Basic Connectivity" chapter in the *Cisco IOS IPv6 Configuration Library* on the Cisco website.

Default SNMP configuration

If the device starts and no snmp-server global configuration commands are present in the startup configuration, the device operates using the default SNMP settings.

Table 175: Default SNMP Configuration Table

Feature	Default Setting
SNMP agent	Disabled. This is the default when the device starts and the startup configuration does not have any **snmp-server** global configuration commands.
SNMP trap receiver	None configured.
SNMP traps	None enabled except the trap for TCP connections (tty).
SNMP version	If no version keyword is present, the default is Version 1.

Feature	Default Setting
SNMPv3 authentication	If no keyword is entered, the default is the **noauth** (noAuthNoPriv) security level.
SNMP notification type	If no type is specified, all notifications are sent.

SNMP configuration guidelines

These SNMP configuration guidelines define the requirements and best practices for enabling and managing SNMP agents on a device.

- At least one global SNMP command (**snmp-server host** , **snmp-server user** , **snmp-server community** , or **snmp-server manager**) must be configured to open SNMP UDP ports 161 and 162.
- An SNMP *group* maps users to views. A *user* is a group member, a *host* receives traps, and an *engine ID* identifies the SNMP engine.
- Proper configuration of SNMP groups, users, engine IDs, and UDP ports is essential for secure and functional SNMP operation.

When configuring SNMP, follow these guidelines to ensure correct and secure operation:

- When configuring an SNMP group, do not specify a notify view. The **snmp-server host** command auto-generates a notify view for the user and adds it to the group. Modifying the group's notify view affects all users in that group.
- To configure a remote user, specify the IP address or port number for the remote SNMP agent where the user resides.
- Before configuring remote users for an agent, configure the SNMP engine ID using the **snmp-server engineID** command with the **remote** option. The remote agent's SNMP engine ID and user password are used to compute authentication and privacy digests. If the remote engine ID is not configured first, the command fails.
- When configuring SNMP informs, configure the SNMP engine ID for the remote agent in the SNMP database before sending proxy requests or informs to it.
- If a local user is not associated with a remote host, the device does not send informs for the **auth** (authNoPriv) and **priv** (authPriv) authentication levels.
- Changing the SNMP engine ID value has significant effects. A user's password is converted to an MD5 or SHA digest based on the password and local engine ID, and the command-line password is destroyed as required by RFC 2274. If the engine ID changes, SNMPv3 user digests become invalid and users must be reconfigured using the **snmp-server user** *username* command. Community strings must also be reconfigured when the engine ID changes.
- When you configure the SNMP server host with the default UDP port 162, the output of the **show running-config** command does not display the UDP port value. If you specify a UDP port other than the default using the **snmp-server host** { *host-addr* } *community-string* **udp-port** *value* command, the UDP port number will be displayed in the **show running-config** output. You can configure the **snmp-server host** command with or without the default UDP port 162, but not both simultaneously.

Correct configuration examples:

- Device(config)# **snmp-server host 10.10.10.10 community udp-port 163**
- Device(config)# **snmp-server host 10.10.10.10 community**
- Device(config)# **snmp-server host 10.10.10.10 community udp-port 163**
- Device(config)# **snmp-server host 10.10.10.10 community udp-port 162**

Incorrect configuration examples:

- Device(config)# **snmp-server host 10.10.10.10 community udp-port 163**
- Device(config)# **snmp-server host 10.10.10.10 community**
- Device(config)# **snmp-server host 10.10.10.10 community udp-port 162**
- Device(config)# **snmp-server host 10.10.10.10 community udp-port 163**
- Device(config)# **snmp-server host 10.10.10.10 community udp-port 162**
- Device(config)# **snmp-server host 10.10.10.10 community**

Configure SNMP

Configure SNMP to enable standardized network device monitoring and management by setting community strings, user groups, UDP ports, notifications, and system identification details.

SNMP community strings

SNMP community strings authenticate access to MIB objects and serve as embedded passwords. For an NMS to access a device, the community string configured on the NMS must match one of the community strings defined on the device.

SNMP community string attributes

SNMP community strings have these attributes. Their configuration affects how management stations interact with devices.

- **Read-only (RO):** Grants authorized management stations read access to all MIB objects but denies write access.
- **Read-write (RW):** Grants authorized management stations read and write access to all MIB objects but denies access to the community strings.

When you create a cluster, the command device manages message exchange between member devices and the SNMP application. Network Assistant appends the member device number (@esN, where N is the device number) to the first configured RW and RO community strings on the command device. It then copies these strings to the member device.

Configure SNMP groups and users

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the device. You can configure an SNMP server group to map SNMP users to SNMP views. You can also add new users to the SNMP group.

Complete these steps to configure SNMP groups and users on the device.

Procedure

Step 1 Use the **enable** command to enter privileged EXEC mode.

Example:

```
Device# enable
```

Enter your password if prompted.

Step 2 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Device# configure terminal
```

Enters global configuration mode.

Step 3 Use **snmp-server engineID** { **local** *engineid-string* | **remote** *ip-address* [**udp-port** *port-number*] *engineid-string* } command to configure a name for the local SNMP engine.

Example:

- `Device(config)# snmp-server engineID local 1234`

  The device configures the engine ID as "123400000000000000000000" (trailing zeros can be omitted). You do not need to specify the entire 24-character engine ID value if it has trailing zeros. You only need to specify the part of the engine ID before the trailing zeros.

- `Device(config)# snmp-server group public v2c access lmnop`

  Configures the engine ID for a remote SNMP server at IP 10.1.1.1 on UDP port 162. If you select **remote**, specify the *ip-address* of the device that contains the remote copy of SNMP and the optional UDP port on the remote device. The default value is 162.

Step 4 Use the **snmp-server group** *group-name* { **v1** | **v2c** | **v3** { **auth** | **noauth** | **priv** } } [**read** *readview*] [**write** *writeview*] [**notify** *notifyview*] [**access** *access-list*]

Example:

```
Device(config)# snmp-server group public v2c access lmnop
```

Note

Creates an SNMP group named *public* using SNMP version 2c with access list *lmnop*. Security models include:

- **v1**: least secure
- **v2c**: supports informs and wider integers
- **v3**: most secure, requires auth level

- **auth** —Enables the Message Digest 5 (MD5) and the Secure Hash Algorithm (SHA) packet authentication.
- **noauth** —Enables the noAuthNoPriv security level. This is the default if no keyword is specified.
- **priv** —Enables Data Encryption Standard (DES) packet encryption (also called privacy).

Optional parameters (not to exceed 64 characters):

- **read** *readview* : view for read-only access
- **write** *writeview* : view for write access
- **notify** *notifyview* : view for notifications
- **access** *access-list* : access control list name

Step 5 Use the **snmp-server user** *username group-name* { **remote** *host* [**udp-port** *port*] } { **v1** [**access** *access-list*] | **v2c** [**access** *access-list*] | **v3** [**encrypted**] [**access** *access-list*] [**auth** { **md5** | **sha** } *auth-password*] } [*priv* { **des** | **3des** | **aes** { **128** | **192** | **256** } } *priv-password*] command to add a new user to an SNMP group with version and authentication options.

Example:

```
Device(config)# snmp-server user Pat public v2c
```

Adds user *Pat* to group *public* using SNMP version 2c. For SNMPv3, additional options include:

- **encrypted**: password is encrypted
- **auth** {**md5** | **sha** } *auth-password*: authentication protocol and password
- *priv*{**des** | **3des** | **aes** { **128** | **192** | **256** } } *priv-password*: privacy encryption and password
- **remote** *host* [**udp-port** *port*]: specify remote SNMP entity and optional UDP port
- **access** *access-list*: specify access list

Note
Algorithms md5, des, and 3des require compliance shield enabled using `crypto engine compliance shield enable` command and device reboot.

Step 6 Use **end** command to exit global configuration mode.

Example:

```
Device(config)# end
```

Returns to privileged EXEC mode.

Step 7 Use the **show running-config** command to verify your SNMP configuration.

Example:

```
Device# show running-config
```

Step 8 (Optional) Use **copy running-config startup-config** command to save the configuration.

Example:

```
Device# copy running-config startup-config
```

Saves the running configuration to startup configuration.

Open or close SNMP UDP ports

The SNMP process uses UDP ports 161 and 162, where port 161 is designated for polling the device, and port 162 is used for sending notifications from the agent to the server. These SNMP UDP ports remain closed by default and open only when one of the required SNMP configuration commands is applied. This approach enhances security by ensuring the device listens on these ports only when necessary, reducing exposure to unnecessary network traffic.

To open SNMP UDP ports, start in user EXEC mode and execute these steps:

Procedure

Step 1 Use the **enable** command to enter privileged EXEC mode.

Example:

```
Device# enable
```

Enter your password if prompted.

Step 2 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Device# configure terminal
```

Step 3 Use the **snmp-server** { **host** | **user** | **community** | **manager** } commands to open ports 161 and 162.

Example:

```
Device(config)# snmp-server host 10.10.10.10
```

Configuring any one of these options opens both UDP ports. To close the ports, enter the no form of all configured options. The ports remain open if at least one of these commands is active. Using the **no snmp-server** command without options shuts down the entire SNMP process.

Step 4 Use the **end** command to return to privileged EXEC mode.

Example:

```
Device(config)# end
```

Step 5 Use the **show udp** command to verify that ports 161 and 162 are listening.

Example:

```
Device# show udp
```

If the requisite commands are configured, ports 161 and 162 will show a **listen** status under the remote field.

Step 6 (Optional) Use the **copy running-config startup-config** command to save the configuration.

Example:

```
Device# copy running-config startup-config
```

This procedure opens SNMP UDP ports securely and only when required. It aligns with best practices for device security and management.

SNMP notifications

SNMP notifications are messages that a device sends to SNMP managers when specific events occur. Devices can send these messages as traps or inform requests.

- Traps are notifications sent without acknowledgment. They may not reach their destination.
- Inform requests require acknowledgment and can be resent if not received, making them more reliable.
- Choosing between traps and informs involves a trade-off between reliability and resource consumption.

Notification reliability and resource trade-offs

Traps and informs require a trade-off between reliability and resource consumption.

- **Traps:** Unreliable because the receiver does not acknowledge receipt. The sender discards the trap immediately after sending it.
- **Informs:** Reliable because the SNMP manager acknowledges receipt with an SNMP response protocol data unit (PDU). The sender holds the inform request in memory until it receives a response or the request times out. If the sender does not receive a response, it resends the inform request.

Note SNMPv1 does not support informs.

Characteristic	Traps	Informs
Reliability	Low	High
Acknowledgment	No	Yes
Resource consumption	Low	High
Network traffic	Low	High (due to retries)

Configuration principle

Follow these guidelines to choose the appropriate notification type:

- Use inform requests if it is critical that the SNMP manager receives every notification.
- Use traps if network traffic or device memory is a concern and guaranteed delivery is not required.

Set the SNMP agent contact and location information

Set the system contact and location information for the SNMP agent to ensure these descriptions are accessible through the configuration file.

Procedure

Step 1 Use the **enable** command to enter privileged EXEC mode.

Example:

```
Device# enable
```

Enter your password if prompted.

Step 2 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Device# configure terminal
```

Step 3 Use the **snmp-server contact** *text* command to set the system contact string.

Example:

```
Device(config)# snmp-server contact Dial System Operator at beeper 21555
```

Step 4 Use the **snmp-server location** *text* command to set the system location string.

Example:

```
Device(config)# snmp-server location Building 3/Room 222
```

Sets the system location string.

Step 5 Use the **end** command to return to privileged EXEC mode.

Example:

```
Device(config)# end
```

Step 6 Use the **show running-config** command to verify your entries.

Example:

```
Device# show running-config
```

Step 7 (Optional) Use the **copy running-config startup-config** command to save your entries in the configuration file.

Example:

```
Device# copy running-config startup-config
```

Limit TFTP servers for SNMP configuration transfers

Follow these steps to limit the TFTP servers used for saving and loading configuration files through SNMP to the servers specified in an access list.

Procedure

Step 1 Use the **enable** command to enter privileged EXEC mode.

Example:

```
Device# enable
```

Enter your password if prompted.

Step 2 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Device# configure terminal
```

Enters global configuration mode.

Step 3 Use the **snmp-server tftp-server-list** *access-list-number* command to limit the TFTP servers used for saving and loading configuration files through SNMP to those specified in the access list.

Example:

```
Device(config)# snmp-server tftp-server-list 44
```

For *access-list-number*, specify an IP standard access list numbered from 1 to 99 or 1300 to 1999.

Step 4 Use the **access-list** *access-list-number* { **deny** | **permit** } *source* [*source-wildcard*] command to create a standard access list that defines which TFTP servers are permitted or denied access. Repeat this command as needed for multiple entries.

Example:

```
Device(config)# access-list 44 permit 10.1.1.2
```

- *access-list-number* must match the value used in step 3.
- **deny** denies access if conditions match; **permit** keyword allows access.
- *source* is the IP address of the TFTP server allowed or denied.
- *source* is optional and specifies wildcard bits in dotted decimal notation to ignore bits in the source IP address.

Note
The access list always ends with an implicit deny for all other addresses.

Step 5 Use **end** command to exit global configuration mode.

Example:

```
Device(config)# end
```

Returns to privileged EXEC mode.

Step 6 Use the **show running-config** command to verify your SNMP configuration.

Example:

```
Device# show running-config
```

Step 7 (Optional) Use **copy running-config startup-config** command to save the configuration.

Example:

```
Device# copy running-config startup-config
```

Saves the running configuration to startup configuration.

Disable the SNMP agent

Use this procedure to disable the SNMP agent on your device.

This procedure applies to all SNMP versions (Version 1, Version 2c, and Version 3) and ensures that the SNMP process on the device is completely shut down.

You can re-enable all versions of the SNMP agent by using any one of these commands in global configuration mode.

- **snmp-server host**
- **snmp-server user**
- **snmp-server community**
- **snmp-server manager**

Note There is no Cisco IOS command specifically designated for enabling SNMP.

Before you begin

The SNMP agent must be enabled before it can be disabled. The SNMP agent is enabled by the first **snmp-server** global configuration command entered on the device.

Procedure

Step 1 Use the **enable** command to enter privileged EXEC mode.

Example:

```
Device# enable
```

Enter your password if prompted.

Step 2 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Device# configure terminal
```

Enters global configuration mode.

Step 3 Use the **no snmp-server** command to disable the SNMP agent operation.

Example:

```
Device(config)# no snmp-server
```

Disables the SNMP agent operation.

Step 4 Use **end** command to exit global configuration mode.

Example:

```
Device(config)# end
```

Returns to privileged EXEC mode.

Step 5 Use the **show running-config** command to verify your SNMP configuration.

Example:

```
Device# show running-config
```

Step 6 (Optional) Use **copy running-config startup-config** command to save the configuration.

Example:

```
Device# copy running-config startup-config
```

Saves the running configuration to startup configuration.

The SNMP agent is disabled and the SNMP process is shut down. All SNMP agent versions are no longer operational on the device.

SNMP examples

SNMP configuration involves enabling SNMP, setting community strings, sending traps to hosts, and managing user access and authentication.

Here are a few examples that demonstrate how to configure SNMP on Cisco devices for various use cases:

- **Enable all SNMP versions with read-only access**

  Any SNMP manager can access all objects with read-only permissions using the community string **public**. This configuration does not send any traps from the device.

  ```
  Device(config)# snmp-server community public
  ```

- **Enable SNMP with VTP traps to specific hosts**

  Any SNMP manager can access all objects with read-only permission using the community string **public**. The device sends VTP traps to hosts `192.180.1.111` and `192.180.1.33` using SNMPv1, and to host `192.180.1.27` using SNMPv2C. The community string **public** is sent with the traps.

  ```
  Device(config)# snmp-server community public
  Device(config)# snmp-server enable traps vtp
  Device(config)# snmp-server host 192.180.1.27 version 2c public
  Device(config)# snmp-server host 192.180.1.111 version 1 public
  Device(config)# snmp-server host 192.180.1.33 public
  ```

- **Restrict SNMP access using an access list**

  Members of access list 4 who use the community string **comaccess** have read-only access to all objects. No other SNMP managers have access. SNMP Authentication Failure traps are sent by SNMPv2C to host `cisco.com` using community string **public**.

```
Device(config)# snmp-server community comaccess ro 4
Device(config)# snmp-server enable traps snmp authentication
Device(config)# snmp-server host cisco.com version 2c public
```

- **Send Entity MIB traps to a restricted host**

  Enables the device to send Entity MIB traps to host `cisco.com`. The device restricts the use of the community string. The second command overwrites any previous **snmp-server host** commands for that host.

```
Device(config)# snmp-server enable traps entity
Device(config)# snmp-server host cisco.com restricted entity
```

- **Send all traps to a host**

  Enables the device to send all traps to host `myhost.cisco.com` using community string `public`.

```
Device(config)# snmp-server enable traps
Device(config)# snmp-server host myhost.cisco.com public
```

- **Configure SNMPv3 user with authentication and informs**

  Associates a user with a remote host and sends auth-level (authNoPriv) informs when the user enters global configuration mode.

```
Device(config)# snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b
Device(config)# snmp-server group authgroup v3 auth
Device(config)# snmp-server user authuser authgroup remote 192.180.1.27 v3 auth md5
mypassword
Device(config)# snmp-server user authuser authgroup v3 auth md5 mypassword
Device(config)# snmp-server host 192.180.1.27 informs version 3 auth authuser config
Device(config)# snmp-server enable traps
Device(config)# snmp-server inform retries 0
```

- **Display SNMP manager polling statistics**

  Show entries of SNMP managers polled to an SNMP agent.

```
Device# show snmp stats host
Request Count                  Last Timestamp              Address
2                               00:00:01 ago               3.3.3.3
1                               1w2d ago                   2.2.2.2
```

- **SNMPv3 algorithm deprecation warnings**

  If you configure SNMPv3 users with the `md5`, `des`, or `3des` algorithms while compliance shield is disabled, the device displays warning messages indicating that these protocols will be deprecated.

```
Device(config)# snmp-server user md5user grp v3 auth md5 cisco1234 priv des
Sep  1 00:14:51.582 IST: %SNMP-6-AUTHPROTOCOLMD5: Authentication protocol md5 support
will be deprecated in future
Sep  1 00:14:51.582 IST: %SNMP-6-PRIVPROTOCOLDES: Privacy protocol des support will be
 deprecated in future
Sep  1 00:14:51.645 IST: %SNMP-5-WARMSTART: SNMP agent on host Switch is undergoing a
warm start
```

- **Compliance shield enabled warning for weaker algorithms**

  When compliance shield is enabled, the use of weaker algorithms `MD5`, `DES`, and `3DES` is not allowed for SNMP users, with a warning message.

```
Device(config)# snmp-server user md5user grp v3 auth md5 cisco1234
weaker algorithm MD5, DES and 3DES is not allowed for snmp user
```

Monitor SNMP status

To display SNMP input and output statistics, including the number of illegal community string entries, errors, and requested variables, use the **show snmp** privileged EXEC command.

You can use these privileged EXEC commands to display SNMP information.

Table 176: Commands to display SNMP status

Command	Purpose
show snmp	Displays SNMP statistics.
	Displays information on the local SNMP engine and all remote engines that have been configured on the device.
show snmp group	Displays information on each SNMP group on the network.
show snmp pending	Displays information on pending SNMP requests.
show snmp sessions	Displays information on the current SNMP sessions.
show snmp user	Displays information on each SNMP user name in the SNMP users table. **Note** You must use this command to display SNMPv3 configuration information for **auth** | **noauth** | **priv** mode. This information is not displayed in the **show running-config** output.

Note By default, most IE switches have the PROFINET feature enabled. According to PROFINET specifications, if an interface requires an SFP module and the SFP module is not present, the SNMP `OID IF-MIB::ifOperStatus` reports the operational status as `notPresent(6)`. This status is returned when the SFP module is not plugged in, not detected, or is corrupted.

CHAPTER 166

Configuring Cisco IOS IP Service Level Agreements

This chapter describes how to use Cisco IOS IP Service Level Agreements (SLAs) on the switch.

Unless otherwise noted, the term *switch* refers to a standalone switch.

- Restrictions on Service Level Agreements, on page 2363
- Information About Service Level Agreements, on page 2363
- How to Configure IP SLAs Operations, on page 2369
- Monitoring IP SLA Operations, on page 2382
- Monitoring IP SLA Operation Examples, on page 2382

Restrictions on Service Level Agreements

The following are restrictions on IP SLAs network performance measurement:

- The device does not support VoIP service levels using the gatekeeper registration delay operations measurements.
- Only a Cisco IOS device can be a source for a destination IP SLAs responder.
- You cannot configure the IP SLAs responder on non-Cisco devices and Cisco IOS IP SLAs can send operational packets only to services native to those devices.

Information About Service Level Agreements

The following sections provide information about Service Level Agreements.

Cisco IOS IP Service Level Agreements (SLAs)

Cisco IOS IP SLAs send data across the network to measure performance between multiple network locations or across multiple network paths. They simulate network data and IP services and collect network performance information in real time. Cisco IOS IP SLAs generate and analyze traffic either between Cisco IOS devices or from a Cisco IOS device to a remote IP device such as a network application server. Measurements provided

by the various Cisco IOS IP SLA operations can be used for troubleshooting, for problem analysis, and for designing network topologies.

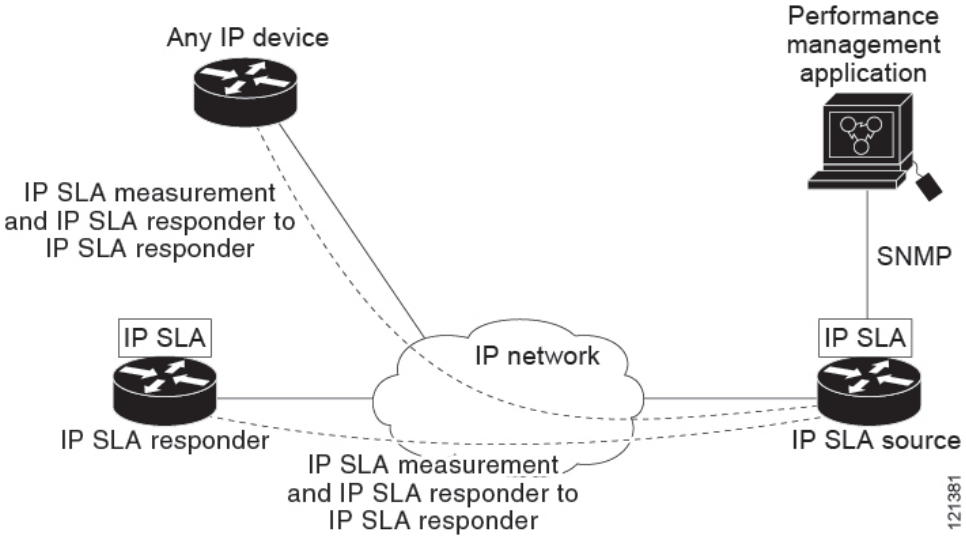
Depending on the specific Cisco IOS IP SLA operations, various network performance statistics are monitored within the Cisco device and stored in both command-line interface (CLI) and Simple Network Management Protocol (SNMP) MIBs. IP SLA packets have configurable IP and application layer options such as source and destination IP address, User Datagram Protocol (UDP)/TCP port numbers, a type of service (ToS) byte (including Differentiated Services Code Point [DSCP] and IP Prefix bits), Virtual Private Network (VPN) routing/forwarding instance (VRF), and URL web address.

Because Cisco IP SLAs are Layer 2 transport independent, you can configure end-to-end operations over disparate networks to best reflect the metrics that an end user is likely to experience. IP SLAs collect and analyze the following performance metrics:

- Delay (both round-trip and one-way)
- Jitter (directional)
- Packet loss (directional)
- Packet sequencing (packet ordering)
- Path (per hop)
- Connectivity (directional)
- Server or website download time

Because Cisco IOS IP SLA is SNMP-accessible, it can also be used by performance-monitoring applications like Cisco Prime Internetwork Performance Monitor (IPM) and other third-party Cisco partner performance management products.

Using IP SLAs can provide the following benefits:



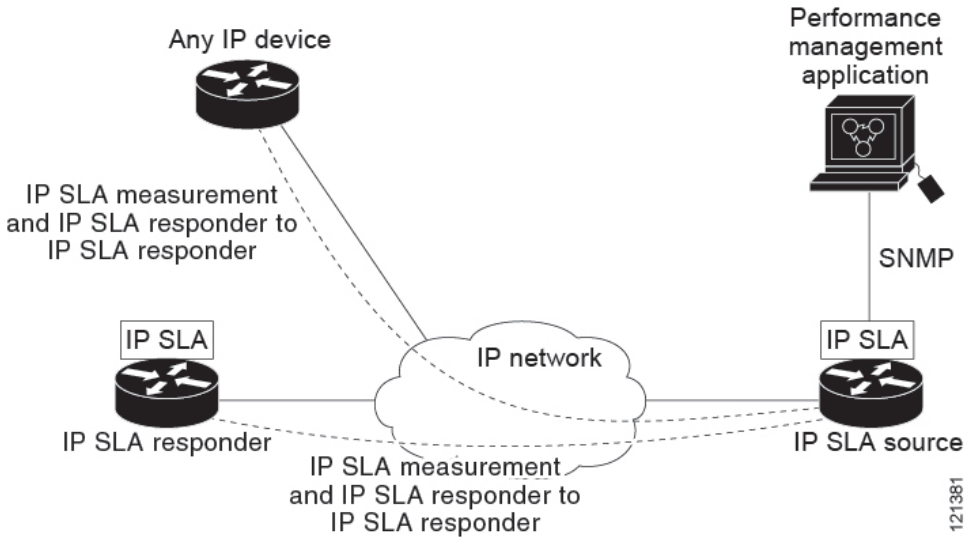
- Service-level agreement monitoring, measurement, and verification.
- Network performance monitoring:
  - Measurement of jitter, latency, or packet loss in the network.
  - Continuous, reliable, and predictable measurements.
- IP service network health assessment to verify that the existing QoS is sufficient for new IP services.
- Edge-to-edge network availability monitoring for proactive verification and connectivity testing of network resources (for example, shows the network availability of an NFS server used to store business critical data from a remote site).
- Network operation troubleshooting by providing consistent, reliable measurement that immediately identifies problems and saves troubleshooting time.
- Multiprotocol Label Switching (MPLS) performance monitoring and network verification (if the device supports MPLS).

Network Performance Measurement with Cisco IOS IP SLAs

You can use IP SLAs to monitor the performance between any area in the network—core, distribution, and edge—without deploying a physical probe. It uses generated traffic to measure network performance between two networking devices.

Figure 146: Cisco IOS IP SLAs Operation

The following figure shows how IP SLAs begin when the source device sends a generated packet to the destination device. After the destination device receives the packet, depending on the type of IP SLAs operation, it responds with time-stamp information for the source to make the calculation on performance metrics. An IP SLAs operation performs a network measurement from the source device to a destination in the network using a specific protocol such as UDP.



IP SLA Responder and IP SLA Control Protocol

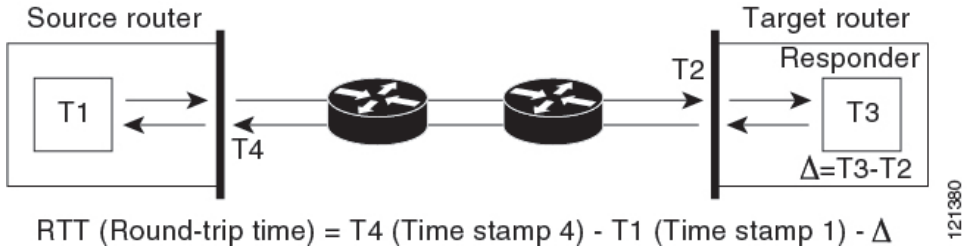
The IP SLA responder is a component embedded in the destination Cisco device that allows the system to anticipate and respond to IP SLA request packets. The responder provides accurate measurements without the need for dedicated probes. The responder uses the Cisco IOS IP SLA Control Protocol to provide a mechanism through which it can be notified on which port it should listen and respond.

Note The IP SLA responder can be a Cisco IOS Layer 2, responder-configurable device. The responder does not need to support full IP SLA functionality.

The following figure shows where the Cisco IOS IP SLA responder fits in the IP network. The responder listens on a specific port for control protocol messages sent by an IP SLA operation. Upon receipt of the control message, it enables the specified UDP or TCP port for the specified duration. During this time, the responder accepts the requests and responds to them. It disables the port after it responds to the IP SLA packet, or when the specified time expires. MD5 authentication for control messages is available for added security.

Figure 147: Cisco IOS IP SLAs Operation

You do not need to enable the responder on the destination device for all IP SLA operations. For example, a responder is not required for services that are already provided by the destination router (such as Telnet or HTTP).



Response Time Computation for IP SLAs

Switches, controllers, and routers can take tens of milliseconds to process incoming packets due to other high priority processes. This delay affects the response times because the test-packet reply might be in a queue while waiting to be processed. In this situation, the response times would not accurately represent true network delays. IP SLAs minimize these processing delays on the source device as well as on the target device (if the responder is being used) to determine true round-trip times. IP SLA test packets use time stamping to minimize the processing delays.

When the IP SLA responder is enabled, it allows the target device to take time stamps when the packet arrives on the interface at interrupt level and again just as it is leaving, eliminating the processing time. This time stamping is made with a granularity of sub-milliseconds (ms).

Figure 148: Cisco IOS IP SLA Responder Time Stamping

The following figure demonstrates how the responder works. Four time stamps are taken to make the calculation for round-trip time. At the target router, with the responder functionality enabled, time stamp 2 (TS2) is subtracted from time stamp 3 (TS3) to produce the time spent processing the test packet as represented by delta. This delta value is then subtracted from the overall round-trip time. Notice that the same principle is applied by IP SLAs on the source router where the incoming time stamp 4 (TS4) is also taken at the interrupt level to allow for greater accuracy.

An additional benefit of the two time stamps at the target device is the ability to track one-way delay, jitter, and directional packet loss. Because much network behavior is asynchronous, it is critical to have these statistics. However, to capture one-way delay measurements, you must configure both the source router and target router with Network Time Protocol (NTP) so that the source and target are synchronized to the same clock source. One-way jitter measurements do not require clock synchronization.

IP SLAs Operation Scheduling

When you configure an IP SLAs operation, you must schedule the operation to begin capturing statistics and collecting error information. You can schedule an operation to start immediately or to start at a certain month, day, and hour. You can use the *pending* option to set the operation to start at a later time. The pending option is an internal state of the operation that is visible through SNMP. The pending state is also used when an operation is a reaction (threshold) operation waiting to be triggered. You can schedule a single IP SLAs operation or a group of operations at one time.

You can schedule several IP SLAs operations by using a single command through the Cisco IOS CLI or the CISCO RTTMON-MIB. Scheduling the operations to run at evenly distributed times allows you to control the amount of IP SLAs monitoring traffic. This distribution of IP SLA operations helps minimize the CPU utilization and thus improves network scalability.

For more details about the IP SLA multi-operations scheduling functionality, see the “IP SLAs—Multiple Operation Scheduling” chapter of the *Cisco IOS IP SLAs Configuration Guide*.

When you try to reconfigure a scheduled IP SLA operation, the active status of the IP SLA operation is checked. If the operation is active, the following message is displayed.

```
Entry already running and cannot be modified.

(only can delete (no) and start over)

(check to see if the probe has finished exiting)
```

You can reconfigure the parameters of a scheduled IP SLA operation. You can use the **configure replace** command to replace the current running configuration with a new configuration. The **configure replace** command is a general command and is not specific to IP SLAs. The command will replace the entire current configuration with the new configuration provided. The IP SLA operation will be stopped, and restarted with the new parameters. You cannot change the IP SLA probe type or IP SLA socket related parameters such as the destination IP address, source IP address, destination port and source port using the **configure replace** command.

IP SLA Operation Threshold Monitoring

To support successful service level agreement monitoring, you must have mechanisms that notify you immediately of any possible violation. IP SLAs can send SNMP traps that are triggered by events such as the following:

- Connection loss
- Timeout
- Round-trip time threshold
- Average jitter threshold
- One-way packet loss

- One-way jitter
- One-way mean opinion score (MOS)
- One-way latency

An IP SLA threshold violation can also trigger another IP SLA operation for further analysis. For example, the frequency could be increased or an Internet Control Message Protocol (ICMP) path echo or ICMP path jitter operation could be initiated for troubleshooting.

ICMP Echo

The ICMP echo operation measures the end-to-end response time between a Cisco device and any other device that uses IP. The response time is computed by measuring the time it takes to send an ICMP echo request message to a destination and receive an ICMP echo reply. Many customers use IP SLA ICMP-based operations, in-house ping testing, or ping-based dedicated probes to measure this response time. The IP SLA ICMP echo operation conforms to the same specifications as ICMP ping testing, and both methods result in the same response times.

UDP Jitter

Jitter is a simple term that describes interpacket delay variance. When multiple packets are sent consecutively at an interval of 10 ms from source to destination, the destination should receive them 10 ms apart (if the network is behaving correctly). However, if there are delays in the network (such as queuing, arriving through alternate routes, and so on), the time interval between packet arrivals might be more or less than 10 ms. A positive jitter value indicates that the packets arrived more than 10 ms apart. A negative jitter value indicates that the packets arrived less than 10 ms apart. If the packets arrive 12 ms apart, the positive jitter is 2 ms; if the packets arrive 8 ms apart, the negative jitter is 2 ms. For delay-sensitive networks, positive jitter values are undesirable, and a jitter value of 0 is ideal.

In addition to monitoring jitter, the IP SLA UDP jitter operation can be used as a multipurpose data gathering operation. The packets generated by IP SLAs carry sequence information and time stamps from the source and operational target that include packet sending and receiving data. Based on this data, UDP jitter operations measure the following:

- Per-direction jitter (source to destination and destination to source)
- Per-direction packet-loss
- Per-direction delay (one-way delay)
- Round-trip delay (average round-trip time)

Because the paths for the sending and receiving of data can be different (asymmetric), you can use the per-direction data to more readily identify where congestion or other problems are occurring in the network.

The UDP jitter operation generates synthetic (simulated) UDP traffic and sends a number of UDP packets, each of a specified size, sent a specified number of milliseconds apart, from a source router to a target router, at a given frequency. By default, ten packet-frames, each with a payload size of 10 bytes are generated every 10 ms, and the operation is repeated every 60 seconds. You can configure each of these parameters to best simulate the IP service you want to provide.

To provide accurate one-way delay (latency) measurements, time synchronization (as provided by NTP) is required between the source and the target device. Time synchronization is not required for the one-way jitter and packet loss measurements. If the time is not synchronized between the source and target devices, one-way

jitter and packet loss data is returned, but values of 0 are returned for the one-way delay measurements provided by the UDP jitter operation.

How to Configure IP SLAs Operations

This section does not include configuration information for all available operations as the configuration information details are included in the *Cisco IOS IP SLAs Configuration Guide*. It does include several operations as examples, including configuring the responder, configuring a UDP jitter operation, which requires a responder, and configuring an ICMP echo operation, which does not require a responder. For details about configuring other operations, see the *Cisco IOS IP SLAs Configuration Guide*.

Default Configuration

No IP SLAs operations are configured.

Configuration Guidelines

For information on the IP SLA commands, see the *Cisco IOS IP SLAs Command Reference, Release 12.4T* .

For detailed descriptions and configuration procedures, see the *Cisco IOS IP SLAs Configuration Guide, Release 12.4TL*.

Not all of the IP SLA commands or operations described in the referenced guide are supported on the device. The device supports IP service level analysis by using UDP jitter, UDP echo, HTTP, TCP connect, ICMP echo, ICMP path echo, ICMP path jitter, FTP, DNS, and DHCP, as well as multiple operation scheduling and proactive threshold monitoring. It does not support VoIP service levels using the gatekeeper registration delay operations measurements.

Before configuring any IP SLAs application, you can use the **show ip sla application** privileged EXEC command to verify that the operation type is supported on your software image. This is an example of the output from the command:

```
Device# show ip sla application

        IP Service Level Agreements
Version: Round Trip Time MIB 2.2.0, Infrastructure Engine-III

Supported Operation Types:
        icmpEcho, path-echo, path-jitter, udpEcho, tcpConnect, http
        dns, udpJitter, dhcp, ftp, udpApp, wspApp

Supported Features:
        IPSLAs Event Publisher

IP SLAs low memory water mark: 33299323
Estimated system max number of entries: 24389

Estimated number of configurable operations: 24389
Number of Entries configured  : 0
Number of active Entries      : 0
Number of pending Entries     : 0
Number of inactive Entries    : 0
Time of last change in whole IP SLAs: *13:04:37.668 UTC Wed Dec 19 2012
```

Configuring the IP SLA Responder

The IP SLA responder is available only on Cisco IOS software-based devices, including some Layer 2 devices that do not support full IP SLA functionality.

Follow these steps to configure the IP SLA responder on the target device (the operational target):

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# config t`	Enters the global configuration mode.
Step 3	**ip sla responder** {**tcp-connect** | **udp-echo**} **ipaddress** *ip-address* **port** *port-number* **Example:** `Device(config)# ip sla responder udp-echo 172.29.139.134 5000`	Configures the device as an IP SLA responder. The keywords have these meanings: • **tcp-connect**—Enables the responder for TCP connect operations. • **udp-echo**—Enables the responder for User Datagram Protocol (UDP) echo or jitter operations. • **ipaddress** *ip-address*—Enter the destination IP address. • **port** *port-number*—Enter the destination port number. **Note** The IP address and port number must match those configured on the source device for the IP SLA operation.
Step 4	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 5	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.

	Command or Action	Purpose
Step 6	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 7	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Implementing IP SLA Network Performance Measurement

Follow these steps to implement IP SLA network performance measurement on your device:

Before you begin

Use the **show ip sla application** privileged EXEC command to verify that the desired operation type is supported on your software image.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# config t`	Enters the global configuration mode.
Step 3	**ip sla** *operation-number* **Example:** `Device(config)# ip sla 10`	Creates an IP SLA operation, and enters IP SLA configuration mode.
Step 4	**udp-jitter** {*destination-ip-address* | *destination-hostname*} *destination-port* [**source-ip** {*ip-address* | *hostname*}] [**source-port** *port-number*] [**control** {**enable** | **disable**}] [**num-packets** *number-of-packets*] [**interval** *interpacket-interval*]	Configures the IP SLA operation as the operation type of your choice (a UDP jitter operation is used in the example), and enters its configuration mode (UDP jitter configuration mode is used in the example).

	Command or Action	Purpose
	Example: `Device(config-ip-sla)# udp-jitter 172.29.139.134 5000 source-ip 172.29.139.140 source-port 4000`	• *destination-ip-address* | *destination-hostname*: Specifies the destination IP address or hostname. • *destination-port*: Specifies the destination port number in the range from 1 to 65535. • (Optional) **source-ip** {*ip-address* | *hostname*}: Specifies the source IP address or hostname. When a source IP address or hostname is not specified, IP SLA chooses the IP address nearest to the destination • (Optional) **source-port** *port-number*: Specifies the source port number in the range from 1 to 65535. When a port number is not specified, IP SLA chooses an available port. **Note** If the **udp-jitter** command does not have the source port configured, UDP chooses any random port for control packets. In case UDP chooses the reserved port 1967, it may result in high CPU utilisation by the IP SLA responder. • (Optional) **control**: Enables or disables sending of IP SLA control messages to the IP SLA responder. By default, IP SLA control messages are sent to the destination device to establish a connection with the IP SLA responder • (Optional) **num-packets** *number-of-packets*: Enters the number of packets to be generated. The range is 1 to 6000; the default is 10. • (Optional) **interval** *inter-packet-interval*: Enters the interval between sending packets in milliseconds. The range is 1 to 6000; the default value is 20 ms.
Step 5	**frequency** *seconds* **Example:** `Device(config-ip-sla-jitter)# frequency 45`	(Optional) Configures options for the SLA operation. This example sets the rate at which a specified IP SLA operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.

	Command or Action	Purpose
Step 6	**threshold** *milliseconds* **Example:** `Device(config-ip-sla-jitter)# threshold 200`	(Optional) Configures threshold conditions. This example sets the threshold of the specified IP SLA operation to 200. The range is from 0 to 60000 milliseconds.
Step 7	**exit** **Example:** `Device(config-ip-sla-jitter)# exit`	Exits the SLA operation configuration mode (UDP jitter configuration mode in this example), and returns to global configuration mode.
Step 8	**ip sla schedule** *operation-number* [**life** {**forever** | *seconds*}] [**start-time** {*hh:mm* [:*ss*] [*month day* | *day month*] | **pending** | **now** | **after** *hh:mm:ss*] [**ageout** *seconds*] [**recurring**] **Example:** `Device(config)# ip sla schedule 10 start-time now life forever`	Configures the scheduling parameters for an individual IP SLA operation. • *operation-number*: Enter the RTR entry number. • (Optional) **life**: Sets the operation to run indefinitely (**forever**) or for a specific number of *seconds*. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour). • (Optional) **start-time**: Enters the time for the operation to begin collecting information: To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. If no month is entered, the default is the current month. Enter **pending** to select no information collection until a start time is selected. Enter **now** to start the operation immediately. Enter **after** *hh:mm:ss* to show that the operation should start after the entered time has elapsed. • (Optional) **ageout** *seconds*: Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds, the default is 0 seconds (never ages out). • (Optional) **recurring**: Set the operation to automatically run every day.

	Command or Action	Purpose
Step 9	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 10	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 11	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

UDP Jitter Configuration

This example shows how to configure a UDP jitter IP SLA operation:

```
Device(config)# ip sla 10
Device(config-ip-sla)# udp-jitter 172.29.139.134 5000 source-ip 172.29.139.140 source-port
 4000
Device(config-ip-sla-jitter)# frequency 30
Device(config-ip-sla-jitter)# exit
Device(config)# ip sla schedule 10 start-time now life forever
Device(config)# end
Device# show ip sla configuration 10
IP SLAs, Infrastructure Engine-II.

Analyzing IP Service Levels by Using the UDP Jitter Operation

Follow these steps to configure a UDP jitter operation on the source device:

Before you begin

You must enable the IP SLA responder on the target device (the operational target) to configure a UDP jitter operation on the source device.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# config t`	Enters the global configuration mode.
Step 3	**ip sla** *operation-number* **Example:** `Device(config)# ip sla 10`	Creates an IP SLA operation, and enters IP SLA configuration mode.
Step 4	**udp-jitter** {*destination-ip-address* | *destination-hostname*} *destination-port* [**source-ip** {*ip-address* | *hostname*}] [**source-port** *port-number*] [**control** {**enable** | **disable**}] [**num-packets** *number-of-packets*] [**interval** *interpacket-interval*] **Example:** `Device(config-ip-sla)# udp-jitter 172.29.139.134 5000 source-ip 172.29.139.140 source-port 4000`	Configures the IP SLA operation as a UDP jitter operation, and enters UDP jitter configuration mode. • *destination-ip-address* | *destination-hostname*: Specifies the destination IP address or hostname. • *destination-port*: Specifies the destination port number in the range from 1 to 65535. • (Optional) **source-ip** {*ip-address* | *hostname*}: Specifies the source IP address or hostname. When a source IP address or hostname is not specified, IP

	Command or Action	Purpose
		SLA chooses the IP address nearest to the destination. • (Optional) **source-port** *port-number*: Specifies the source port number in the range from 1 to 65535. When a port number is not specified, IP SLA chooses an available port. **Note** If the **udp-jitter** command does not have the source port configured, UDP chooses any random port for control packets. In case UDP chooses the reserved port 1967, it may result in high CPU utilisation by the IP SLA responder. • (Optional) **control**: Enables or disables sending of IP SLA control messages to the IP SLA responder. By default, IP SLA control messages are sent to the destination device to establish a connection with the IP SLA responder. • (Optional) **num-packets** *number-of-packets*: Enters the number of packets to be generated. The range is 1 to 6000; the default is 10. • (Optional) **interval** *inter-packet-interval*: Enters the interval between sending packets in milliseconds. The range is 1 to 6000; the default value is 20 ms.
Step 5	**frequency** *seconds* **Example:** `Device(config-ip-sla-jitter)# frequency 45`	(Optional) Sets the rate at which a specified IP SLA operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.
Step 6	**exit** **Example:** `Device(config-ip-sla-jitter)# exit`	Exits UDP jitter configuration mode, and returns to global configuration mode.
Step 7	**ip sla schedule** *operation-number* [**life** {**forever** | *seconds*}] [**start-time** {*hh:mm* [*:ss*] [*month day* | *day month*] | **pending** | **now** | **after** *hh:mm:ss*] [**ageout** *seconds*] [**recurring**]	Configures the scheduling parameters for an individual IP SLA operation.

	Command or Action	Purpose
	Example: `Device(config)# ip sla schedule 10 start-time now life forever`	• *operation-number*: Enter the RTR entry number. • (Optional) **life**: Sets the operation to run indefinitely (**forever**) or for a specific number of *seconds*. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour). • (Optional) **start-time**: Enters the time for the operation to begin collecting information: To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. If no month is entered, the default is the current month. Enter **pending** to select no information collection until a start time is selected. Enter **now** to start the operation immediately. Enter **after** *hh:mm:ss* to show that the operation should start after the entered time has elapsed. • (Optional) **ageout** *seconds*: Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds, the default is 0 seconds (never ages out). • (Optional) **recurring**: Set the operation to automatically run every day.
Step 8	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 9	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 10	**copy running-config startup-config** **Example:**	(Optional) Saves your entries in the configuration file.

	Command or Action	Purpose
	`Device# copy running-config startup-config`	

Configuring a UDP Jitter IP SLA Operation

This example shows how to configure a UDP jitter IP SLA operation:

```
Device(config)# ip sla 10
Device(config-ip-sla)# udp-jitter 172.29.139.134 5000 source-ip 172.29.139.140 source-port
 4000
Device(config-ip-sla-jitter)# frequency 30
Device(config-ip-sla-jitter)# exit
Device(config)# ip sla schedule 10 start-time now life forever
Device(config)# end
Device# show ip sla configuration 10
IP SLAs, Infrastructure Engine-II.

Entry number: 10

Analyzing IP Service Levels by Using the ICMP Echo Operation

Follow these steps to configure an ICMP echo operation on the source device:

Before you begin

This operation does not require the IP SLA responder to be enabled.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# config terminal`	Enters the global configuration mode.
Step 3	**ip sla** *operation-number* **Example:** `Device(config)# ip sla 10`	Creates an IP SLA operation and enters IP SLA configuration mode.
Step 4	**icmp-echo** {*destination-ip-address* | *destination-hostname*} [**source-ip** {*ip-address* | *hostname*} | **source-interface** *interface-id*] **Example:** `Device(config-ip-sla)# icmp-echo 172.29.139.134`	Configures the IP SLA operation as an ICMP Echo operation and enters ICMP echo configuration mode. • *destination-ip-address* | *destination-hostname*—Specifies the destination IP address or hostname. • (Optional) **source-ip** {*ip-address* | *hostname*}—Specifies the source IP address or hostname. When a source IP address or hostname is not specified, IP SLA chooses the IP address nearest to the destination. • (Optional) **source-interface** *interface-id*—Specifies the source interface for the operation.
Step 5	**frequency** *seconds* **Example:** `Device(config-ip-sla-echo)# frequency 30`	(Optional) Sets the rate at which a specified IP SLA operation repeats. The range is from 1 to 604800 seconds; the default is 60 seconds.
Step 6	**exit** **Example:** `Device(config-ip-sla-echo)# exit`	Exits UDP echo configuration mode, and returns to global configuration mode.

	Command or Action	Purpose
Step 7	**ip sla schedule** *operation-number* [**life** {**forever** | *seconds*}] [**start-time** {*hh:mm* [*:ss*] [*month day* | *day month*] | **pending** | **now** | **after** *hh:mm:ss*] [**ageout** *seconds*] [**recurring**] **Example:** `Device(config)# ip sla schedule 10 start-time now life forever`	Configures the scheduling parameters for an individual IP SLA operation. • *operation-number*—Enter the RTR entry number. • (Optional) **life**—Sets the operation to run indefinitely (**forever**) or for a specific number of *seconds*. The range is from 0 to 2147483647. The default is 3600 seconds (1 hour) • (Optional) **start-time**—Enter the time for the operation to begin collecting information: To start at a specific time, enter the hour, minute, second (in 24-hour notation), and day of the month. If no month is entered, the default is the current month. Enter **pending** to select no information collection until a start time is selected. Enter **now** to start the operation immediately. Enter **after** *hh:mm:ss* to indicate that the operation should start after the entered time has elapsed. • (Optional) **ageout** *seconds*—Enter the number of seconds to keep the operation in memory when it is not actively collecting information. The range is 0 to 2073600 seconds; the default is 0 seconds (never ages out). • (Optional) **recurring**—Sets the operation to automatically run every day.
Step 8	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 9	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.

	Command or Action	Purpose
Step 10	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Configuring an ICMP Echo IP SLA Operation

This example shows how to configure an ICMP echo IP SLA operation:

```
Device(config)# ip sla 10
Device(config-ip-sla)# icmp-echo 172.29.139.134
Device(config-ip-sla-echo)# frequency 30
Device(config-ip-sla-echo)# exit
Device(config)# ip sla schedule 10 start-time now life forever
Device(config)# end
Device# show ip sla configuration 22
IP SLAs, Infrastructure Engine-II.

Monitoring IP SLA Operations

The following table describes the commands used to display IP SLA operation configurations and results:

Table 177: Monitoring IP SLA Operations

Command	Description
show ip sla application	Displays global information about Cisco IOS IP SLAs.
show ip sla authentication	Displays IP SLA authentication information.
show ip sla configuration [*entry-number*]	Displays configuration values including all defaults for all IP SLA operations or a specific operation.
show ip sla enhanced-history {**collection-statistics** | **distribution statistics**} [*entry-number*]	Displays enhanced history statistics for collected history buckets or distribution statistics for all IP SLA operations or a specific operation.
show ip sla ethernet-monitor configuration [*entry-number*]	Displays IP SLA automatic Ethernet configuration.
show ip sla group schedule [*schedule-entry-number*]	Displays IP SLA group scheduling configuration and details.
show ip sla history [*entry-number* | **full** | **tabular**]	Displays history collected for all IP SLA operations.
show ip sla mpls-lsp-monitor {**collection-statistics** | **configuration** | **ldp operational-state** | **scan-queue** | **summary** [*entry-number*] | **neighbors**}	Displays MPLS label switched path (LSP) Health Monitor operations.
show ip sla reaction-configuration [*entry-number*]	Displays the configured proactive threshold monitoring settings for all IP SLA operations or a specific operation.
show ip sla reaction-trigger [*entry-number*]	Displays the reaction trigger information for all IP SLA operations or a specific operation.
show ip sla responder	Displays information about the IP SLA responder.
show ip sla statistics [*entry-number* | **aggregated** | **details**]	Displays current or aggregated operational status and statistics.

Monitoring IP SLA Operation Examples

The following example shows all IP SLAs by application:

```
Device# show ip sla application

CHAPTER 167

Configuring SPAN and RSPAN

- Prerequisites for SPAN and RSPAN, on page 2385
- Restrictions for SPAN and RSPAN, on page 2385
- Information About SPAN and RSPAN, on page 2387
- Configuring SPAN and RSPAN, on page 2396
- How to Configure SPAN and RSPAN, on page 2397
- Monitoring SPAN and RSPAN Operations, on page 2418
- Configuration Examples for SPAN and RSPAN, on page 2418

Prerequisites for SPAN and RSPAN

SPAN

You can limit SPAN traffic to specific VLANs by using the **filter vlan** keyword. If a trunk port is being monitored, only traffic on the VLANs specified with this keyword is monitored.

Note By default, all VLANs are monitored on a trunk port.

RSPAN

You can configure an RSPAN source or a destination session.

Note We recommend that you configure an RSPAN VLAN before you configure an RSPAN source or a destination session.

Restrictions for SPAN and RSPAN

SPAN

The restrictions for SPAN are as follows:

- On each device, you can use 1 to 66 span session number for configuration of SPAN or RSPAN. A maximum of 8 monitor sessions can be configured in a mix of SPAN and RSPAN.
- For SPAN sources, you can monitor traffic for a single port or VLAN or a series or range of ports or VLANs for each session. You cannot mix source ports and source VLANs within a single SPAN session.
- The destination port cannot be a source port; a source port cannot be a destination port.
- You cannot have two SPAN sessions using the same destination port.
- When you configure a device port as a SPAN destination port, it is no longer a normal device port; only monitored traffic passes through the SPAN destination port.
- Entering SPAN configuration commands does not remove previously configured SPAN parameters. You must enter the **no monitor session** {*session_number* | **all** | **local** | **remote**} global configuration command to delete configured SPAN parameters.
- For local SPAN, outgoing packets through the SPAN destination port carry the original encapsulation headers—untagged, ISL, or IEEE 802.1Q—if the **encapsulation replicate** keywords are specified. If the keywords are not specified, the packets are sent in native form.
- You can configure a disabled port to be a source or destination port, but the SPAN function does not start until the destination port and at least one source port or source VLAN are enabled.
- You cannot mix source VLANs and filter VLANs within a single SPAN session.

Traffic monitoring in a SPAN session has the following restrictions:

- Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.
- Wireshark does not capture egress packets when egress span is active.
- You can run both a local SPAN and an RSPAN source session in the same device. The device supports a total of 66 source and RSPAN destination sessions.
- You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.
- You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per device. .
- SPAN sessions do not interfere with the normal operation of the device. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.
- When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.
- You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.
- The device does not support a combination of local SPAN and RSPAN in a single session.
  - An RSPAN source session cannot have a local destination port.
  - An RSPAN destination session cannot have a local source port.

- An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same device.

RSPAN

The restrictions for RSPAN are as follows:

- RSPAN does not support BPDU packet monitoring or other Layer 2 device protocols.
- The RSPAN VLAN is configured only on trunk ports and not on access ports. To avoid unwanted traffic in RSPAN VLANs, make sure that the VLAN remote-span feature is supported in all the participating devices.
- RSPAN VLANs are included as sources for port-based RSPAN sessions when source trunk ports have active RSPAN VLANs. RSPAN VLANs can also be sources in SPAN sessions. However, since the device does not monitor spanned traffic, it does not support egress spanning of packets on any RSPAN VLAN identified as the destination of an RSPAN source session on the device.
- If you enable VTP and VTP pruning, RSPAN traffic is pruned in the trunks to prevent the unwanted flooding of RSPAN traffic across the network for VLAN IDs that are lower than 1005.
- It is recommended not to configure RSPAN VLAN as Native VLAN.
- RSPAN sessions do not capture DHCP-inject packets. DHCP-inject packets refer to DHCP packets (DISCOVER, OFFER, REQUEST, and ACK packets) which are modified by the CPU and inserted back into the network.

Information About SPAN and RSPAN

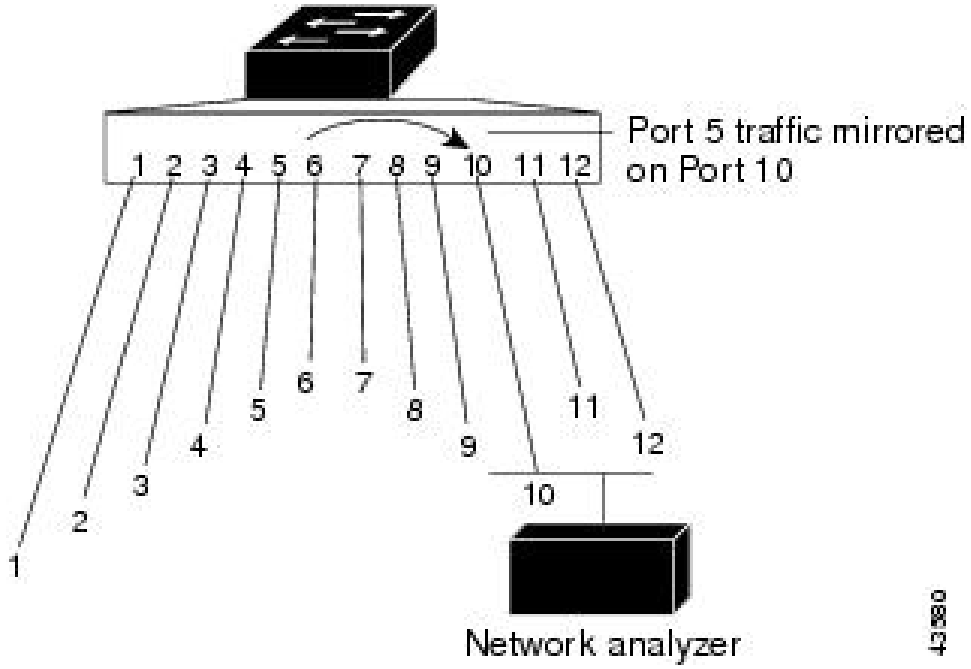
The following sections provide information about SPAN and RSPAN.

SPAN and RSPAN

You can analyze network traffic passing through ports or VLANs by using SPAN or RSPAN to send a copy of the traffic to another port on the device or on another device that has been connected to a network analyzer or other monitoring or security device. SPAN copies (or mirrors) traffic received or sent (or both) on source ports or source VLANs to a destination port for analysis. SPAN does not affect the switching of network traffic on the source ports or VLANs. You must dedicate the destination port for SPAN use. Except for traffic that is required for the SPAN or RSPAN session, destination ports do not receive or forward traffic.

Only traffic that enters or leaves source ports or traffic that enters or leaves source VLANs can be monitored by using SPAN; traffic routed to a source VLAN cannot be monitored. For example, if incoming traffic is being monitored, traffic that gets routed from another VLAN to the source VLAN cannot be monitored; however, traffic that is received on the source VLAN and routed to another VLAN can be monitored.

You can use the SPAN or RSPAN destination port to inject traffic from a network security device. For example, if you connect a Cisco Intrusion Detection System (IDS) sensor appliance to a destination port, the IDS device can send TCP reset packets to close down the TCP session of a suspected attacker.



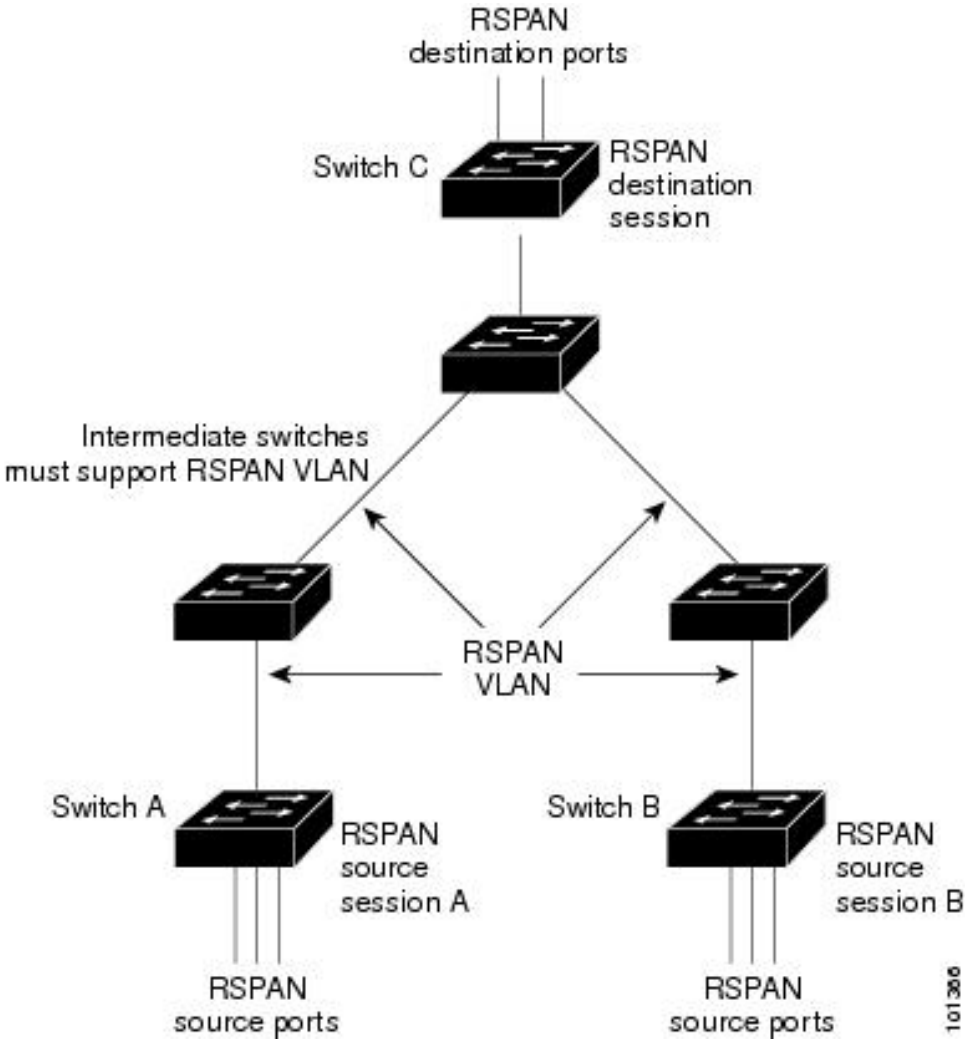
Local SPAN

Local SPAN supports a SPAN session entirely within one device; all source ports or source VLANs and destination ports are in the same device. Local SPAN copies traffic from one or more source ports in any VLAN or from one or more VLANs to a destination port for analysis.

Local SPAN supports a SPAN session entirely within one switch; all source ports and destination ports are in the same switch. Local SPAN copies traffic from one or more source ports to a destination port for analysis.

Figure 149: Example of Local SPAN Configuration on a Single Device

All traffic on port 5 (the source port) is mirrored to port 10 (the destination port). A network analyzer on port 10 receives all network traffic from port 5 without being physically attached to port 5.



Remote SPAN

RSPAN supports source ports, source VLANs, and destination ports on different devices, enabling remote monitoring of multiple devices across your network.

Figure 150: Example of RSPAN Configuration

The figure below shows source ports on Device A and Device B. The traffic for each RSPAN session is carried over a user-specified RSPAN VLAN that is dedicated for that RSPAN session in all participating devices. The RSPAN traffic from the source ports or VLANs is copied into the RSPAN VLAN and forwarded over trunk ports carrying the RSPAN VLAN to a destination session monitoring the RSPAN VLAN. Each RSPAN source device must have either ports or VLANs as RSPAN sources. The destination is always a physical port,

as shown on Device C in the figure.

SPAN and RSPAN Concepts and Terminology

SPAN Sessions

SPAN sessions (local or remote) allow you to monitor traffic on one or more ports, or one or more VLANs, and send the monitored traffic to one or more destination ports.

A local SPAN session is an association of a destination port with source ports or source VLANs, all on a single network device. Local SPAN does not have separate source and destination sessions. Local SPAN sessions gather a set of ingress and egress packets specified by the user and form them into a stream of SPAN data, which is directed to the destination port.

RSPAN consists of at least one RSPAN source session, an RSPAN VLAN, and at least one RSPAN destination session. You separately configure RSPAN source sessions and RSPAN destination sessions on different network devices. To configure an RSPAN source session on a device, you associate a set of source ports or source VLANs with an RSPAN VLAN. The output of this session is the stream of SPAN packets that are sent to the RSPAN VLAN. To configure an RSPAN destination session on another device, you associate the

destination port with the RSPAN VLAN. The destination session collects all RSPAN VLAN traffic and sends it out the RSPAN destination port.

An RSPAN source session is very similar to a local SPAN session, except for where the packet stream is directed. In an RSPAN source session, SPAN packets are relabeled with the RSPAN VLAN ID and directed over normal trunk ports to the destination device.

An RSPAN destination session takes all packets received on the RSPAN VLAN, strips off the VLAN tagging, and presents them on the destination port. The session presents a copy of all RSPAN VLAN packets (except Layer 2 control packets) to the user for analysis.

Traffic monitoring in a SPAN session has these restrictions:

- Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.
- You can run both a local SPAN and an RSPAN source session in the same device. The device supports a total of 66 source and RSPAN destination sessions.
- You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.
- SPAN sessions do not interfere with the normal operation of the device. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.
- When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Therefore monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.
- You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.
- The device does not support a combination of local SPAN and RSPAN in a single session.
  - An RSPAN source session cannot have a local destination port.
  - An RSPAN destination session cannot have a local source port.
  - An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same device.

Monitored Traffic

SPAN sessions can monitor these traffic types:

- Receive (Rx) SPAN—Receive (or ingress) SPAN monitors as much as possible all of the packets received by the source interface or VLAN before any modification or processing is performed by the device. A copy of each packet received by the source is sent to the destination port for that SPAN session.

  Packets that are modified because of routing or Quality of Service (QoS)—for example, modified Differentiated Services Code Point (DSCP)—are copied before modification.

  Features that can cause a packet to be dropped during receive processing have no effect on ingress SPAN; the destination port receives a copy of the packet even if the actual incoming packet is dropped. These features include IP standard and extended input Access Control Lists (ACLs), ingress QoS policing, VLAN ACLs, and egress QoS policing.

- Transmit (Tx) SPAN—Transmit (or egress) SPAN monitors as much as possible all of the packets sent by the source interface after all modification and processing is performed by the device. A copy of each packet sent by the source is sent to the destination port for that SPAN session. The copy is provided after the packet is modified.

  Packets that are modified because of routing (for example, with modified time-to-live (TTL), MAC address, or QoS values) are duplicated (with the modifications) at the destination port.

  Features that can cause a packet to be dropped during transmit processing also affect the duplicated copy for SPAN. These features include IP standard and extended output ACLs and egress QoS policing.

- Both—In a SPAN session, you can also monitor a port or VLAN for both received and sent packets. This is the default.

Therefore, a local SPAN session with encapsulation replicate enabled can have a mixture of untagged and IEEE 802.1Q tagged packets appear on the destination port.

Device congestion can cause packets to be dropped at ingress source ports, egress source ports, or SPAN destination ports. In general, these characteristics are independent of one another. For example:

- A packet might be forwarded normally but dropped from monitoring due to an oversubscribed SPAN destination port.
- An ingress packet might be dropped from normal forwarding, but still appear on the SPAN destination port.
- An egress packet dropped because of device congestion is also dropped from egress SPAN.

In some SPAN configurations, multiple copies of the same source packet are sent to the SPAN destination port. For example, a bidirectional (both Rx and Tx) SPAN session is configured for the Rx monitor on port A and Tx monitor on port B. If a packet enters the device through port A and is switched to port B, both incoming and outgoing packets are sent to the destination port. Both packets are the same unless a Layer 3 rewrite occurs, in which case the packets are different because of the packet modification.

Source Ports

A source port (also called a monitored port) is a switched or routed port that you monitor for network traffic analysis.

In a local SPAN session or RSPAN source session, you can monitor source ports or VLANs for traffic in one or both directions.

The device supports any number of source ports (up to the maximum number of available ports on the device) and any number of source VLANs (up to the maximum number of VLANs supported).

You cannot mix ports and VLANs in a single session.

A source port has these characteristics:

- It can be monitored in multiple SPAN sessions.
- Each source port can be configured with a direction (ingress, egress, or both) to monitor.
- It can be any port type (for example, EtherChannel, Gigabit Ethernet, and so forth).
- For EtherChannel sources, you can monitor traffic for the entire EtherChannel or individually on a physical port as it participates in the port channel.
- It can be an access port, trunk port, routed port, or voice VLAN port.

- It cannot be a destination port.
- Source ports can be in the same or different VLANs.
- You can monitor multiple source ports in a single session.

Source VLANs

VLAN-based SPAN (VSPAN) is the monitoring of the network traffic in one or more VLANs. The SPAN or RSPAN source interface in VSPAN is a VLAN ID, and traffic is monitored on all the ports for that VLAN.

VSPAN has these characteristics:

- All active ports in the source VLAN are included as source ports and can be monitored in either or both directions.
- On a given port, only traffic on the monitored VLAN is sent to the destination port.
- If a destination port belongs to a source VLAN, it is excluded from the source list and is not monitored.
- If ports are added to or removed from the source VLANs, the traffic on the source VLAN received by those ports is added to or removed from the sources being monitored.
- You cannot use filter VLANs in the same session with VLAN sources.
- You can monitor only Ethernet VLANs.

VLAN Filtering

When you monitor a trunk port as a source port, by default, all VLANs active on the trunk are monitored. You can limit SPAN traffic monitoring on trunk source ports to specific VLANs by using VLAN filtering.

- VLAN filtering applies only to trunk ports or to voice VLAN ports.
- VLAN filtering applies only to port-based sessions and is not allowed in sessions with VLAN sources.
- When a VLAN filter list is specified, only those VLANs in the list are monitored on trunk ports or on voice VLAN access ports.
- SPAN traffic coming from other port types is not affected by VLAN filtering; that is, all VLANs are allowed on other ports.
- VLAN filtering affects only traffic forwarded to the destination SPAN port and does not affect the switching of normal traffic.

Destination Port

Each local SPAN session or RSPAN destination session must have a destination port (also called a monitoring port) that receives a copy of traffic from the source ports or VLANs and sends the SPAN packets to the user, usually a network analyzer.

A destination port has these characteristics:

- For a local SPAN session, the destination port must reside on the same device as the source port. For an RSPAN session, it is located on the device containing the RSPAN destination session. There is no destination port on a device running only an RSPAN source session.

- When a port is configured as a SPAN destination port, the configuration overwrites the original port configuration. When the SPAN destination configuration is removed, the port reverts to its previous configuration. If a configuration change is made to the port while it is acting as a SPAN destination port, the change does not take effect until the SPAN destination configuration had been removed.
- If the port was in an EtherChannel group, it is removed from the group while it is a destination port. If it was a routed port, it is no longer a routed port.
- It can be any Ethernet physical port.
- It cannot be a secure port.
- It cannot be a source port.
- It can be an EtherChannel group (**ON** mode only).
- It can participate in only one SPAN session at a time (a destination port in one SPAN session cannot be a destination port for a second SPAN session).
- When it is active, incoming traffic is disabled. The port does not transmit any traffic except that required for the SPAN session. Incoming traffic is never learned or forwarded on a destination port.
- If ingress traffic forwarding is enabled for a network security device, the destination port forwards traffic at Layer 2.
- It does not participate in any of the Layer 2 protocols (STP, VTP, CDP, DTP, PagP).
- A destination port that belongs to a source VLAN of any SPAN session is excluded from the source list and is not monitored.
- The maximum number of destination ports in a device is 64.

Local SPAN and RSPAN destination ports function differently with VLAN tagging and encapsulation:

- For local SPAN, if the **encapsulation replicate** keywords are specified for the destination port, these packets appear with the original encapsulation (untagged, ISL, or IEEE 802.1Q). If these keywords are not specified, packets appear in the untagged format. Therefore, the output of a local SPAN session with **encapsulation replicate** enabled can contain a mixture of untagged, ISL, or IEEE 802.1Q-tagged packets.
- For RSPAN, the original VLAN ID is lost because it is overwritten by the RSPAN VLAN identification. Therefore, all packets appear on the destination port as untagged.

RSPAN VLAN

The RSPAN VLAN carries SPAN traffic between RSPAN source and destination sessions. RSPAN VLAN has these special characteristics:

- All traffic in the RSPAN VLAN is always flooded.
- No MAC address learning occurs on the RSPAN VLAN.
- RSPAN VLAN traffic only flows on trunk ports.
- RSPAN VLANs must be configured in VLAN configuration mode by using the **remote-span** VLAN configuration mode command.
- STP can run on RSPAN VLAN trunks but not on SPAN destination ports.
- An RSPAN VLAN cannot be a private-VLAN primary or secondary VLAN.

For VLANs 1 to 1005 that are visible to VLAN Trunking Protocol (VTP), the VLAN ID and its associated RSPAN characteristic are propagated by VTP. If you assign an RSPAN VLAN ID in the extended VLAN range (1006 to 4094), you must manually configure all intermediate devices.

It is normal to have multiple RSPAN VLANs in a network at the same time with each RSPAN VLAN defining a network-wide RSPAN session. That is, multiple RSPAN source sessions anywhere in the network can contribute packets to the RSPAN session. It is also possible to have multiple RSPAN destination sessions throughout the network, monitoring the same RSPAN VLAN and presenting traffic to the user. The RSPAN VLAN ID separates the sessions.

SPAN and RSPAN Interaction with Other Features

SPAN interacts with these features:

- Routing—SPAN does not monitor routed traffic. VSPAN only monitors traffic that enters or exits the device, not traffic that is routed between VLANs. For example, if a VLAN is being Rx-monitored and the device routes traffic from another VLAN to the monitored VLAN, that traffic is not monitored and not received on the SPAN destination port.
- STP—A destination port does not participate in STP while its SPAN or RSPAN session is active. The destination port can participate in STP after the SPAN or RSPAN session is disabled. On a source port, SPAN does not affect the STP status. STP can be active on trunk ports carrying an RSPAN VLAN.
- CDP—A SPAN destination port does not participate in CDP while the SPAN session is active. After the SPAN session is disabled, the port again participates in CDP.
- VTP—You can use VTP to prune an RSPAN VLAN between devices.
- VLAN and trunking—You can modify VLAN membership or trunk settings for source or destination ports at any time. However, changes in VLAN membership or trunk settings for a destination port do not take effect until you remove the SPAN destination configuration. Changes in VLAN membership or trunk settings for a source port immediately take effect, and the respective SPAN sessions automatically adjust accordingly.
- EtherChannel—You can configure an EtherChannel group as a source port. When a group is configured as a SPAN source, the entire group is monitored.

  If a physical port is added to a monitored EtherChannel group, the new port is added to the SPAN source port list. If a port is removed from a monitored EtherChannel group, it is automatically removed from the source port list.

  A physical port that belongs to an EtherChannel group can be configured as a SPAN source port and still be a part of the EtherChannel. In this case, data from the physical port is monitored as it participates in the EtherChannel. However, if a physical port that belongs to an EtherChannel group is configured as a SPAN destination, it is removed from the group. After the port is removed from the SPAN session, it rejoins the EtherChannel group. Ports removed from an EtherChannel group remain members of the group, but they are in the inactive or suspended state.

  If a physical port that belongs to an EtherChannel group is a destination port and the EtherChannel group is a source, the port is removed from the EtherChannel group and from the list of monitored ports.
- Multicast traffic can be monitored. For egress and ingress port monitoring, only a single unedited packet is sent to the SPAN destination port. It does not reflect the number of times the multicast packet is sent.
- A private-VLAN port cannot be a SPAN destination port.
- A secure port cannot be a SPAN destination port.

For SPAN sessions, do not enable port security on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable port security on any ports with monitored egress.

- An IEEE 802.1x port can be a SPAN source port. You can enable IEEE 802.1x on a port that is a SPAN destination port; however, IEEE 802.1x is disabled until the port is removed as a SPAN destination.

  For SPAN sessions, do not enable IEEE 802.1x on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable IEEE 802.1x on any ports that are egress monitored.

- DHCP Snooping and Local SPAN can be configured on the same VLAN for non-SDA deployments.

Flow-Based SPAN

You can control the type of network traffic to be monitored in SPAN or RSPAN sessions by using flow-based SPAN (FSPAN) or flow-based RSPAN (FRSPAN), which apply access control lists (ACLs) to the monitored traffic on the source ports. The FSPAN ACLs can be configured to filter IPv4, IPv6, and non-IP monitored traffic.

You apply an ACL to a SPAN session through the interface. It is applied to all the traffic that is monitored on all interfaces in the SPAN session.The packets that are permitted by this ACL are copied to the SPAN destination port. No other packets are copied to the SPAN destination port.

The original traffic continues to be forwarded, and any port, VLAN, and router ACLs attached are applied. The FSPAN ACL does not have any effect on the forwarding decisions. Similarly, the port, VLAN, and router ACLs do not have any effect on the traffic monitoring. If a security input ACL denies a packet and it is not forwarded, the packet is still copied to the SPAN destination ports if the FSPAN ACL permits it. But if the security output ACL denies a packet and it is not sent, it is not copied to the SPAN destination ports. However, if the security output ACL permits the packet to go out, it is only copied to the SPAN destination ports if the FSPAN ACL permits it. This is also true for an RSPAN session.

You can attach three types of FSPAN ACLs to the SPAN session:

- IPv4 FSPAN ACL— Filters only IPv4 packets.
- IPv6 FSPAN ACL— Filters only IPv6 packets.
- MAC FSPAN ACL— Filters only non-IP packets.

The FSPAN ACL continues to be correctly applied, and traffic is copied to the SPAN destination ports on the devices where the FSPAN ACL fits in the hardware memory.

When an empty FSPAN ACL is attached, some hardware functions copy all traffic to the SPAN destination ports for that ACL. If sufficient hardware resources are not available, even an empty FSPAN ACL can be unloaded.

Default SPAN and RSPAN Configuration

Table 178: Default SPAN and RSPAN Configuration

Feature	Default Setting
SPAN state (SPAN and RSPAN)	Disabled.
Source port traffic to monitor	Both received and sent traffic (**both**).

Feature	Default Setting
Encapsulation type (destination port)	Native form (untagged packets).
Ingress forwarding (destination port)	Disabled.
VLAN filtering	On a trunk interface used as a source port, all VLANs are monitored.
RSPAN VLANs	None configured.

Configuring SPAN and RSPAN

SPAN Configuration Guidelines

- To remove a source or destination port or VLAN from the SPAN session, use the **no monitor session** *session_number* **source interface** *interface-id* {**interface** *interface-id* | **vlan** *vlan-id*} global configuration command or the **no monitor session** *session_number* **destination interface** *interface-id* global configuration command. For destination interfaces, the **encapsulation** options are ignored with the **no** form of the command.
- To monitor all VLANs on the trunk port, use the **no monitor session** *session_number* **filter** global configuration command.

RSPAN Configuration Guidelines

- All the SPAN configuration guidelines apply to RSPAN.
- As RSPAN VLANs have special properties, you should reserve a few VLANs across your network for use as RSPAN VLANs; do not assign access ports to these VLANs.
- You can apply an output ACL to RSPAN traffic to selectively filter or monitor specific packets. Specify these ACLs on the RSPAN VLAN in the RSPAN source device.
- For RSPAN configuration, you can distribute the source ports and the destination ports across multiple devices in your network.
- Access ports (including voice VLAN ports) on the RSPAN VLAN are put in the inactive state.
- You can configure any VLAN as an RSPAN VLAN as long as these conditions are met:
  - The same RSPAN VLAN is used for an RSPAN session in all the devices.
  - All participating devices support RSPAN.

FSPAN and FRSPAN Configuration Guidelines

- When at least one FSPAN ACL is attached, FSPAN is enabled.

- When you attach at least one FSPAN ACL that is not empty to a SPAN session, and you have not attached one or more of the other FSPAN ACLs (for instance, you have attached an IPv4 ACL that is not empty, and have not attached IPv6 and MAC ACLs), FSPAN blocks the traffic that would have been filtered by the unattached ACLs. Therefore, this traffic is not monitored.

How to Configure SPAN and RSPAN

The following sections provide information on how to configure SPAN and RSPAN.

Creating a Local SPAN Session

Follow these steps to create a SPAN session and specify the source (monitored) ports or VLANs and the destination (monitoring) ports.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**no monitor session** {*session_number* | **all** | **local** | **remote**} **Example:** `Device(config)# no monitor session all`	Removes any existing SPAN configuration for the session. • For *session_number*, the range is 1 to 66. • **all**—Removes all SPAN sessions. • **local**—Removes all local sessions. • **remote**—Removes all remote SPAN sessions.
Step 4	**monitor session** *session_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [**,** | **-**] [**both** | **rx** | **tx**] **Example:** `Device(config)# monitor session 1 source interface gigabitethernet1/1`	Specifies the SPAN session and the source port (monitored port). • For *session_number*, the range is 1 to 66. • For *interface-id*, specify the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (**port-channel**

	Command or Action	Purpose
		port-channel-number). Valid port-channel numbers are 1 to 48. • For *vlan-id*, specify the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN). **Note** A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session. • (Optional) [**,** | **-**] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • (Optional) **both** | **rx** | **tx**—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both sent and received traffic. • **both**—Monitors both received and sent traffic. • **rx**—Monitors received traffic. • **tx**—Monitors sent traffic. **Note** You can use the **monitor session** *session_number* **source** command multiple times to configure multiple source ports.
Step 5	**monitor session** *session_number* **destination** {**interface** *interface-id* [**,** | **-**] [**encapsulation {replicate | dot1q}**]} **Example:** `Device(config)# monitor session 1 destination interface gigabitethernet 1/1 encapsulation replicate`	Specifies the SPAN session and the destination port (monitoring port). The port LED changes to amber when the configuration changes take effect. The LED returns to its original state (green) only after removing the SPAN destination configuration. **Note** For local SPAN, you must use the same session number for the source and destination interfaces. • For *session_number*, specify the session number entered in step 4.

	Command or Action	Purpose
		• For *interface-id*, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN. • (Optional) [**,** | **-**] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. (Optional) **encapsulation replicate** specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged). (Optional) **encapsulation dot1q**specifies that the destination interface accepts the source interface incoming packets with IEEE 802.1Q encapsulation. **Note** You can use **monitor session** *session_number* **destination** command multiple times to configure multiple destination ports.
Step 6	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 7	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 8	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Creating a Local SPAN Session and Configuring Incoming Traffic

Follow these steps to create a SPAN session, to specify the source ports or VLANs and the destination ports, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**no monitor session** {*session_number* | **all** | **local** | **remote**} **Example:** `Device(config)# no monitor session all`	Removes any existing SPAN configuration for the session. • For *session_number*, the range is 1 to 66. • **all**—Removes all SPAN sessions. • **local**—Removes all local sessions. • **remote**—Removes all remote SPAN sessions.
Step 4	**monitor session** *session_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [**,** | **-**] [**both** | **rx** | **tx**] **Example:** `Device(config)# monitor session 2 source gigabitethernet1/1 rx`	Specifies the SPAN session and the source port (monitored port).
Step 5	**monitor session** *session_number* **destination** {**interface** *interface-id* [**,** | **-**] [**encapsulation replicate**] [**ingress** {**dot1q vlan** *vlan-id* | **untagged vlan** *vlan-id* | **vlan** *vlan-id*}]} **Example:** `Device(config)# monitor session 2 destination interface gigabitethernet1/2 encapsulation replicate ingress dot1q vlan 6`	Specifies the SPAN session, the destination port, the packet encapsulation, and the ingress VLAN and encapsulation. • For *session_number*, specify the session number entered in Step 4. • For *interface-id*, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN.

	Command or Action	Purpose
		• (Optional) [**,** | -]—Specifies a series or range of interfaces. Enter a space before and after the comma or hyphen. • (Optional) **encapsulation replicate** specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged). • (Optional) **encapsulation dot1q**specifies that the destination interface accepts the source interface incoming packets with IEEE 802.1Q encapsulation. • **ingress** enables forwarding of incoming traffic on the destination port and to specify the encapsulation type: • **dot1q vlan** *vlan-id*—Accepts incoming packets with IEEE 802.1Q encapsulation with the specified VLAN as the default VLAN. • **untagged vlan** *vlan-id* or **vlan** *vlan-id*—Accepts incoming packets with untagged encapsulation type with the specified VLAN as the default VLAN.
Step 6	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 7	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 8	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Specifying VLANs to Filter

Follow these steps to limit SPAN source traffic to specific VLANs.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**no monitor session** {*session_number* | **all** | **local** | **remote**} **Example:** `Device(config)# no monitor session all`	Removes any existing SPAN configuration for the session. • For *session_number*, the range is 1 to 66. • **all**—Removes all SPAN sessions. • **local**—Removes all local sessions. • **remote**—Removes all remote SPAN sessions.
Step 4	**monitor session** *session_number* **source interface** *interface-id* **Example:** `Device(config)# monitor session 2 source interface gigabitethernet 1/1 rx`	Specifies the characteristics of the source port (monitored port) and SPAN session. • For *session_number*, the range is 1 to 66. • For *interface-id*, specify the source port to monitor. The interface specified must already be configured as a trunk port.
Step 5	**monitor session** *session_number* **filter vlan** *vlan-id* [**,** | **-**] **Example:** `Device(config)# monitor session 2 filter vlan 1 - 5 , 9`	Limits the SPAN source traffic to specific VLANs. • For *session_number*, enter the session number specified in Step 4. • For *vlan-id*, the range is 1 to 4094. • (Optional) Use a comma (**,**) to specify a series of VLANs, or use a hyphen (**-**) to specify a range of VLANs. Enter a space before and after the comma; enter a space before and after the hyphen.

	Command or Action	Purpose
Step 6	**monitor session** *session_number* **destination** {**interface** *interface-id* [**,** | **-**] [**encapsulation replicate**]} **Example:** `Device(config)# monitor session 2 destination interface gigabitethernet 1/1`	Specifies the SPAN session and the destination port (monitoring port). • For *session_number*, specify the session number entered in Step 4. • For *interface-id*, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN. • (Optional) [**,** | **-**] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • (Optional) **encapsulation replicate** specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).
Step 7	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 8	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 9	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Configuring a VLAN as an RSPAN VLAN

Follow these steps to create a new VLAN, then configure it to be the RSPAN VLAN for the RSPAN session.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**vlan** *vlan-id* **Example:** `Device(config)# vlan 100`	Enters a VLAN ID to create a VLAN, or enters the VLAN ID of an existing VLAN, and enters VLAN configuration mode. The range is 2 to 1001 and 1006 to 4094. The RSPAN VLAN cannot be VLAN 1 (the default VLAN) or VLAN IDs 1002 through 1005 (reserved for Token Ring and FDDI VLANs).
Step 4	**remote-span** **Example:** `Device(config-vlan)# remote-span`	Configures the VLAN as an RSPAN VLAN.
Step 5	**end** **Example:** `Device(config-vlan)# end`	Returns to privileged EXEC mode.
Step 6	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 7	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

What to do next

You must create the RSPAN VLAN in all devices that will participate in RSPAN. If the RSPAN VLAN-ID is in the normal range (lower than 1005) and VTP is enabled in the network, you can create the RSPAN VLAN in one device, and VTP propagates it to the other devices in the VTP domain. For extended-range VLANs (greater than 1005), you must configure RSPAN VLAN on both source and destination devices and any intermediate devices.

Use VTP pruning to get an efficient flow of RSPAN traffic, or manually delete the RSPAN VLAN from all trunks that do not need to carry the RSPAN traffic.

To remove the remote SPAN characteristic from a VLAN and convert it back to a normal VLAN, use the **no remote-span** VLAN configuration command.

To remove a source port or VLAN from the SPAN session, use the **no monitor session** *session_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} global configuration command. To remove the RSPAN VLAN from the session, use the **no monitor session** *session_number* **destination remote vlan** *vlan-id*.

Creating an RSPAN Source Session

Follow these steps to create and start an RSPAN source session and to specify the monitored source and the destination RSPAN VLAN.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**no monitor session** {*session_number* | **all** | **local** | **remote**} **Example:** `Device(config)# no monitor session 1`	Removes any existing SPAN configuration for the session. • For *session_number*, the range is 1 to 66. • **all**—Removes all SPAN sessions. • **local**—Removes all local sessions. • **remote**—Removes all remote SPAN sessions.
Step 4	**monitor session** *session_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [**,** | **-**] [**both** | **rx** | **tx**] **Example:**	Specifies the RSPAN session and the source port (monitored port). • For *session_number*, the range is 1 to 66.

	Command or Action	Purpose
	`Device(config)# monitor session 1 source interface gigabitethernet 1/1 tx`	• Enter a source port or source VLAN for the RSPAN session: • For *interface-id*, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (**port-channel** *port-channel-number*). Valid port-channel numbers are 1 to 48. • For *vlan-id*, specifies the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN). A single session can include multiple sources (ports or VLANs), defined in a series of commands, but you cannot combine source ports and source VLANs in one session. • (Optional) [**,** | -]—Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • (Optional) **both** | **rx** | **tx**—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both sent and received traffic. • **both**—Monitors both received and sent traffic. • **rx**—Monitors received traffic. • **tx**—Monitors sent traffic.
Step 5	**monitor session** *session_number* **destination remote vlan** *vlan-id* **Example:** `Device(config)# monitor session 1 destination remote vlan 100`	Specifies the RSPAN session, the destination RSPAN VLAN, and the destination-port group. • For *session_number*, enter the number defined in Step 4. • For *vlan-id*, specify the source RSPAN VLAN to monitor.
Step 6	**end** **Example:**	Returns to privileged EXEC mode.

	Command or Action	Purpose
	`Device(config)# end`	
Step 7	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 8	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Specifying VLANs to Filter

Follow these steps to configure the RSPAN source session to limit RSPAN source traffic to specific VLANs.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**no monitor session** {*session_number* | **all** | **local** | **remote**} **Example:** `Device(config)# no monitor session 2`	Removes any existing SPAN configuration for the session. • For *session_number*, the range is 1 to 66. • **all**—Removes all SPAN sessions. • **local**—Removes all local sessions. • **remote**—Removes all remote SPAN sessions.
Step 4	**monitor session** *session_number* **source interface** *interface-id*	Specifies the characteristics of the source port (monitored port) and SPAN session.

	Command or Action	Purpose
	Example: `Device(config)# monitor session 2 source interface gigabitethernet 1/1 rx`	• For *session_number*, the range is 1 to 66. • For *interface-id*, specify the source port to monitor. The interface specified must already be configured as a trunk port.
Step 5	**monitor session** *session_number* **filter vlan** *vlan-id* [**,** | **-**] **Example:** `Device(config)# monitor session 2 filter vlan 1 - 5 , 9`	Limits the SPAN source traffic to specific VLANs. • For *session_number*, enter the session number specified in step 4. • For *vlan-id*, the range is 1 to 4094. • (Optional) **,** | **-** Use a comma (**,**) to specify a series of VLANs or use a hyphen (**-**) to specify a range of VLANs. Enter a space before and after the comma; enter a space before and after the hyphen.
Step 6	**monitor session** *session_number* **destination remote vlan** *vlan-id* **Example:** `Device(config)# monitor session 2 destination remote vlan 902`	Specifies the RSPAN session and the destination remote VLAN (RSPAN VLAN). • For *session_number*, enter the session number specified in Step 4. • For *vlan-id*, specify the RSPAN VLAN to carry the monitored traffic to the destination port.
Step 7	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 8	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 9	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Creating an RSPAN Destination Session

You configure an RSPAN destination session on a different device; that is, not the device on which the source session was configured.

Follow these steps to define the RSPAN VLAN on that device, to create an RSPAN destination session, and to specify the source RSPAN VLAN and the destination port.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**vlan** *vlan-id* **Example:** `Device(config)# vlan 901`	Specifies the VLAN ID of the RSPAN VLAN created from the source device, and enters VLAN configuration mode. If both devices are participating in VTP and the RSPAN VLAN ID is from 2 to 1005, Steps 3 through 5 are not required because the RSPAN VLAN ID is propagated through the VTP network.
Step 4	**remote-span** **Example:** `Device(config-vlan)# remote-span`	Identifies the VLAN as the RSPAN VLAN.
Step 5	**exit** **Example:** `Device(config-vlan)# exit`	Returns to global configuration mode.
Step 6	**no monitor session** {*session_number* | **all** | **local** | **remote**} **Example:** `Device(config)# no monitor session 1`	Removes any existing SPAN configuration for the session. • For *session_number*, the range is 1 to 66. • **all**—Removes all SPAN sessions. • **local**—Removes all local sessions. • **remote**—Removes all remote SPAN sessions.

	Command or Action	Purpose
Step 7	**monitor session** *session_number* **source remote vlan** *vlan-id* **Example:** `Device(config)# monitor session 1 source remote vlan 901`	Specifies the RSPAN session and the source RSPAN VLAN. • For *session_number*, the range is 1 to 66. • For *vlan-id*, specify the source RSPAN VLAN to monitor.
Step 8	**monitor session** *session_number* **destination interface** *interface-id* **Example:** `Device(config)# monitor session 1 destination interface gigabitethernet2/0/1`	Specifies the RSPAN session and the destination interface. • For *session_number*, enter the number defined in Step 7. In an RSPAN destination session, you must use the same session number for the source RSPAN VLAN and the destination port. • For *interface-id*, specify the destination interface. The destination interface must be a physical interface. • Though visible in the command-line help string, **encapsulation replicate** is not supported for RSPAN. The original VLAN ID is overwritten by the RSPAN VLAN ID, and all packets appear on the destination port as untagged.
Step 9	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 10	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 11	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Creating an RSPAN Destination Session and Configuring Incoming Traffic

Follow these steps to create an RSPAN destination session, to specify the source RSPAN VLAN and the destination port, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**no monitor session** {*session_number* | **all** | **local** | **remote**} **Example:** `Device(config)# no monitor session 2`	Removes any existing SPAN configuration for the session. • For *session_number*, the range is 1 to 66. • **all**—Removes all SPAN sessions. • **local**—Removes all local sessions. • **remote**—Removes all remote SPAN sessions.
Step 4	**monitor session** *session_number* **source remote vlan** *vlan-id* **Example:** `Device(config)# monitor session 2 source remote vlan 901`	Specifies the RSPAN session and the source RSPAN VLAN. • For *session_number*, the range is 1 to 66. • For *vlan-id*, specify the source RSPAN VLAN to monitor.
Step 5	**monitor session** *session_number* **destination** {**interface** *interface-id* [**,** | -] [**ingress** {**dot1q vlan** *vlan-id* | **untagged vlan** *vlan-id* | **vlan** *vlan-id*}]} **Example:** `Device(config)# monitor session 2 destination interface gigabitethernet 1/1 ingress vlan 6`	Specifies the SPAN session, the destination port, the packet encapsulation, and the incoming VLAN and encapsulation. • For *session_number*, enter the number defined in Step 5. In an RSPAN destination session, you must use the same session number for the source RSPAN VLAN and the destination port.

	Command or Action	Purpose
		• For *interface-id*, specify the destination interface. The destination interface must be a physical interface. • Though visible in the command-line help string, **encapsulation replicate** is not supported for RSPAN. The original VLAN ID is overwritten by the RSPAN VLAN ID, and all packets appear on the destination port as untagged. • (Optional) [**,** | -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • Enter **ingress** with additional keywords to enable forwarding of incoming traffic on the destination port and to specify the encapsulation type: • **dot1q vlan** *vlan-id*—Forwards incoming packets with IEEE 802.1Q encapsulation with the specified VLAN as the default VLAN. • **untagged vlan** *vlan-id* or **vlan** *vlan-id*—Forwards incoming packets with untagged encapsulation type with the specified VLAN as the default VLAN.
Step 6	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 7	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 8	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Configuring an FSPAN Session

Follow these steps to create a SPAN session, specify the source (monitored) ports or VLANs and the destination (monitoring) ports, and configure FSPAN for the session.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**no monitor session** {*session_number* | **all** | **local** | **remote**} **Example:** `Device(config)# no monitor session 2`	Removes any existing SPAN configuration for the session. • For *session_number*, the range is 1 to 66. • **all**—Removes all SPAN sessions. • **local**—Removes all local sessions. • **remote**—Removes all remote SPAN sessions.
Step 4	**monitor session** *session_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [**,** | **-**] [**both** | **rx** | **tx**] **Example:** `Device(config)# monitor session 2 source interface gigabitethernet1/1`	Specifies the SPAN session and the source port (monitored port). • For *session_number*, the range is 1 to 66. • For *interface-id*, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (**port-channel** *port-channel-number*). Valid port-channel numbers are 1 to 48. • For *vlan-id*, specify the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN). **Note** A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session.

	Command or Action	Purpose
		• (Optional) [**,** | -]—Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • (Optional) [**both** | **rx** | **tx**]—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the SPAN monitors both sent and received traffic. • **both**—Monitors both sent and received traffic. This is the default. • **rx**—Monitors received traffic. • **tx**—Monitors sent traffic. **Note** You can use the **monitor session** *session_number* **source** command multiple times to configure multiple source ports.
Step 5	**monitor session** *session_number* **destination** {**interface** *interface-id* [**,** | -] [**encapsulation replicate**]} **Example:** `Device(config)# monitor session 2 destination interface gigabitethernet1/2 encapsulation replicate`	Specifies the SPAN session and the destination port (monitoring port). • For *session_number*, specify the session number entered in Step 4. • For **destination**, specify the following parameters: • For *interface-id*, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN. • (Optional) [**,** | -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • (Optional) **encapsulation replicate** specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged). **Note**

	Command or Action	Purpose
		For local SPAN, you must use the same session number for the source and destination interfaces. You can use **monitor session** *session_number* **destination** command multiple times to configure multiple destination ports.
Step 6	**monitor session** *session_number* **filter** {**ip** | **ipv6** | **mac**} **access-group** {*access-list-number* | *name*} **Example:** `Device(config)# monitor session 2 filter ipv6 access-group 4`	Specifies the SPAN session, the types of packets to filter, and the ACLs to use in an FSPAN session. • For *session_number*, specify the session number entered in Step 4. • For *access-list-number*, specify the ACL number that you want to use to filter traffic. • For *name*, specify the ACL name that you want to use to filter traffic.
Step 7	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 8	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 9	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Configuring an FRSPAN Session

Follow these steps to start an RSPAN source session, specify the monitored source and the destination RSPAN VLAN, and configure FRSPAN for the session.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**no monitor session** {*session_number* | **all** | **local** | **remote**} **Example:** `Device(config)# no monitor session 2`	Removes any existing SPAN configuration for the session. • For *session_number*, the range is 1 to 66. • **all**—Removes all SPAN sessions. • **local**—Removes all local sessions. • **remote**—Removes all remote SPAN sessions.
Step 4	**monitor session** *session_number* **source** {**interface** *interface-id* | **vlan** *vlan-id*} [**,** | **-**] [**both** | **rx** | **tx**] **Example:** `Device(config)# monitor session 2 source interface gigabitethernet 1/1`	Specifies the SPAN session and the source port (monitored port). • For *session_number*, the range is 1 to 66. • For *interface-id*, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (**port-channel** *port-channel-number*). Valid port-channel numbers are 1 to 48. • For *vlan-id*, specify the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN). **Note** A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session. • (Optional) [**,** | **-**]—Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen.

	Command or Action	Purpose
		• (Optional) [**both** | **rx** | **tx**]—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the SPAN monitors both sent and received traffic. • **both**—Monitors both sent and received traffic. This is the default. • **rx**—Monitors received traffic. • **tx**—Monitors sent traffic. **Note** You can use the **monitor session** *session_number* **source** command multiple times to configure multiple source ports.
Step 5	**monitor session** *session_number* **destination remote vlan** *vlan-id* **Example:** `Device(config)# monitor session 2 destination remote vlan 5`	Specifies the RSPAN session and the destination RSPAN VLAN. • For *session_number*, enter the number defined in Step 4. • For *vlan-id*, specify the destination RSPAN VLAN to monitor.
Step 6	**vlan** *vlan-id* **Example:** `Device(config)# vlan 10`	Enters the VLAN configuration mode. For *vlan-id*, specify the source RSPAN VLAN to monitor.
Step 7	**remote-span** **Example:** `Device(config-vlan)# remote-span`	Specifies that the VLAN you specified in Step 5 is part of the RSPAN VLAN.
Step 8	**exit** **Example:** `Device(config-vlan)# exit`	Returns to global configuration mode.
Step 9	**monitor session** *session_number* **filter** {**ip** | **ipv6** | **mac**} **access-group** {*access-list-number* | *name*} **Example:** `Device(config)# monitor session 2 filter ip access-group 7`	Specifies the RSPAN session, the types of packets to filter, and the ACLs to use in an FRSPAN session. • For *session_number*, specify the session number entered in Step 4.

	Command or Action	Purpose
		• For *access-list-number*, specify the ACL number that you want to use to filter traffic. • For *name*, specify the ACL name that you want to use to filter traffic.
Step 10	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 11	**show running-config** **Example:** `Device# show running-config`	Verifies your entries.
Step 12	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Monitoring SPAN and RSPAN Operations

The following table describes the command used to display SPAN and RSPAN operations configuration and results to monitor operations:

Table 179: Monitoring SPAN and RSPAN Operations

Command	Purpose
show monitor	Displays the current SPAN, RSPAN, FSPAN, or FRSPAN configuration.

Configuration Examples for SPAN and RSPAN

The following sections provide configuration examples for SPAN and RSPAN

Example: Configuring Local SPAN

This example shows how to set up SPAN session 1 for monitoring source port traffic to a destination port. First, any existing SPAN configuration for session 1 is deleted, and then bidirectional traffic is mirrored from source Gigabit Ethernet port 1 to destination Gigabit Ethernet port 2, retaining the encapsulation method.

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1
Device(config)# monitor session 1 source interface gigabitethernet 1/1
Device(config)# monitor session 1 destination interface gigabitethernet 1/1
encapsulation replicate
Device(config)# end
```

This example shows how to remove port 1 as a SPAN source for SPAN session 1:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1 source interface gigabitethernet 1/1
Device(config)# end
```

This example shows how to disable received traffic monitoring on port 1, which was configured for bidirectional monitoring:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1 source interface gigabitethernet 1/1 rx
```

The monitoring of traffic received on port 1 is disabled, but traffic sent from this port continues to be monitored.

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on all ports belonging to VLANs 1 through 3, and send it to destination Gigabit Ethernet port 2. The configuration is then modified to also monitor all traffic on all ports belonging to VLAN 10.

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source vlan 1 - 3 rx

Device(config)# monitor session 2 destination interface gigabitethernet 1/2
Device(config)# monitor session 2 source vlan 10
Device(config)# end
```

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on Gigabit Ethernet source port 1, and send it to destination Gigabit Ethernet port 2 with the same egress encapsulation type as the source port, and to enable ingress forwarding with VLAN 6 as the default ingress VLAN:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source gigabitethernet0/1 rx
Device(config)# monitor session 2 destination interface gigabitethernet 1/1 encapsulation
replicate ingress vlan 6
Device(config)# end
```

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor traffic received on Gigabit Ethernet trunk port 2, and send traffic for only VLANs 1 through 5 and VLAN 9 to destination Gigabit Ethernet port 1:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source interface gigabitethernet 1/1 rx
Device(config)# monitor session 2 filter vlan 1 - 5 , 9
Device(config)# monitor session 2 destination interface gigabitethernet 1/1
Device(config)# end
```

Examples: Creating an RSPAN VLAN

This example shows how to create the RSPAN VLAN 901:

```
Device> enable
Device# configure terminal
Device(config)# vlan 901
Device(config-vlan)# remote span
Device(config-vlan)# end
```

This example shows how to remove any existing RSPAN configuration for session 1, configure RSPAN session 1 to monitor multiple source interfaces, and configure the destination as RSPAN VLAN 901:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1
Device(config)# monitor session 1 source interface gigabitethernet 1/1 tx
Device(config)# monitor session 1 source interface gigabitethernet 1/1 rx
Device(config)# monitor session 1 source interface port-channel 2
Device(config)# monitor session 1 destination remote vlan 901
Device(config)# end
```

This example shows how to remove any existing configuration on RSPAN session 2, configure RSPAN session 2 to monitor traffic received on trunk port 2, and send traffic for only VLANs 1 through 5 and 9 to destination RSPAN VLAN 902:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source interface gigabitethernet 1/2 rx
Device(config)# monitor session 2 filter vlan 1 - 5 , 9
Device(config)# monitor session 2 destination remote vlan 902
Device(config)# end
```

This example shows how to configure VLAN 901 as the source remote VLAN and port 1 as the destination interface:

```
Device> enable
Device# configure terminal
Device(config)# monitor session 1 source remote vlan 901
Device(config)# monitor session 1 destination interface gigabitethernet 1/1
Device(config)# end
```

This example shows how to configure VLAN 901 as the source remote VLAN in RSPAN session 2, to configure Gigabit Ethernet source port 2 as the destination interface, and to enable forwarding of incoming traffic on the interface with VLAN 6 as the default receiving VLAN:

```
Device> enable
Device# configure terminal
Device(config)# monitor session 2 source remote vlan 901
Device(config)# monitor session 2 destination interface gigabitethernet 1/1 ingress vlan 6
Device(config)# end
```

Here are the list of debug CLIs to debug the monitor:

```
Device(config)# debug monitor
  all             All SPAN debugging messages
  capture         Show Capture tracing
  errors          Show SPAN error detail
  erspan          Show ERSPAN tracing
  idb-update      Show SPAN IDB update traces
  info            Show SPAN Informational tracing
  list            Show SPAN port and VLAN list tracing
  notifications   Show SPAN notifications
  platform        Show SPAN platform tracing
  redundancy      Show SPAN Redundancy tracing
  requests        Show SPAN requests
  scp             Show SPAN SCP tracing
  snmp            Show SPAN SNMP tracing
```

CHAPTER 168

ERSPAN

- ERSPAN, on page 2423
- Information About Configuring ERSPAN, on page 2424
- How to Configure ERSPAN, on page 2425

ERSPAN

The Cisco Encapsulated Remote Switched Port Analyzer (ERSPAN) feature allows you to monitor traffic on ports or VLANs, and send the monitored traffic to destination ports over a Layer 3 (IP) network using Generic Routing Encapsulation (GRE) encapsulation. ERSPAN sends traffic to a network analyzer, such as a Switch Probe device or a Remote Monitoring (RMON) probe. ERSPAN supports source ports, source VLANs, and destination ports on different devices, which help remote monitoring of multiple devices across a network.

ERSPAN supports encapsulated packets of up to 9180 bytes. ERSPAN consists of an ERSPAN source session, routable ERSPAN GRE-encapsulated traffic, and an ERSPAN destination session.

You can configure an ERSPAN source session, an ERSPAN destination session, or both on a device. A device on which only an ERSPAN source session is configured is called an ERSPAN source device. A device on which only an ERSPAN destination session is configured is called an ERSPAN termination device. A device can act as both; an ERSPAN source device and a termination device.

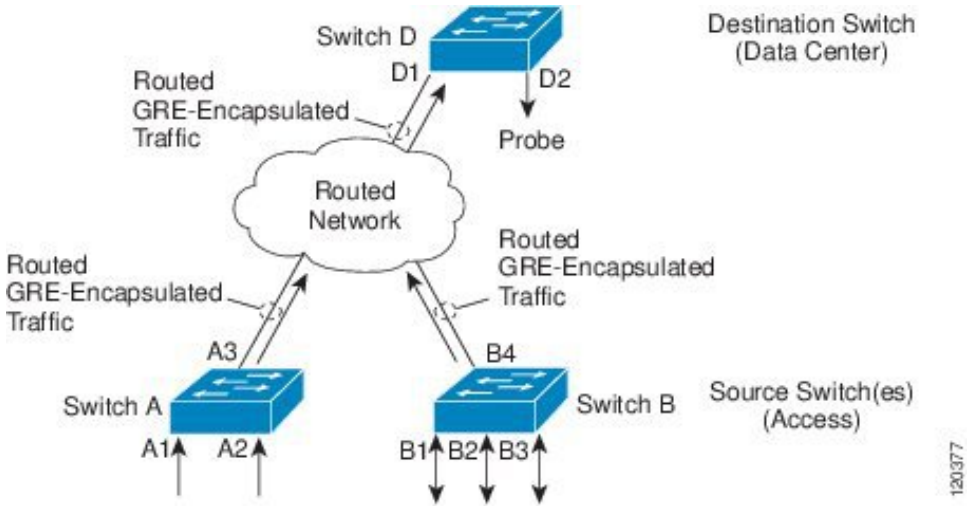
Over-subscription of traffic can lead to a drop in management traffic on the destination device. To avoid over-subscription, ensure that the destination session is configured and is working on the destination device, before configuring a source session on the source device.

For a source port or a source VLAN, the ERSPAN can monitor the ingress, egress, or both ingress and egress traffic. By default, ERSPAN monitors all traffic, including multicast, and Bridge Protocol Data Unit (BPDU) frames.

A device supports up to 66 sessions. A maximum of eight source sessions can be configured and the remaining sessions can be configured as RSPAN destinations sessions. A source session can be a local SPAN source session or an RSPAN source session or an ERSPAN source session.

An ERSPAN source session is defined by the following parameters:

- A session ID.
- ERSPAN flow ID.
- List of source ports or source VLANs that are monitored by the session.



- Optional attributes, such as, IP type of service (ToS) and IP Time to Live (TTL), related to the Generic Routing Encapsulation (GRE) envelope.
- The destination and origin IP addresses. These are used as the destination and source IP addresses of the GRE envelope for the captured traffic, respectively.

Note

- ERSPAN source sessions do not copy ERSPAN GRE-encapsulated traffic from source ports. Each ERSPAN source session can have either ports or VLANs as sources, but not both.
- IPv4 delivery and transport headers are supported; including Type-II and Type-III headers.

  Port channel and switch virtual interface (SVI) are supported.

Figure 151: ERSPAN Configuration

Information About Configuring ERSPAN

The following sections provide information about configuring ERSPAN.

Restrictions for Configuring ERSPAN

The following restrictions apply for this feature:

- Truncation is supported only on IPv4 spanned packets and not on Layer 2 packets without an IP header.
- An ERSPAN destination interface can be part of only one session. The same destination interface cannot be configured for multiple ERSPANs/SPANs.
- You can configure either a list of ports or a list of VLANs as a source, but cannot configure both for a given session.
- Filter IP/MAC/VLAN access-group and filter SGT cannot be configured at the same time.

- When a session is configured through the ERSPAN CLI, the session ID and the session type cannot be changed. To change them, you must use the **no** form of the commands to remove the session and then reconfigure it.
- ERSPAN source sessions do not copy locally-sourced RSPAN VLAN traffic from source trunk ports that carry RSPAN VLANs.
- ERSPAN source sessions do not copy locally-sourced ERSPAN Generic routing encapsulation (GRE)-encapsulated traffic from source ports.
- Disabling the **ip routing** command for IPv4 connections stops ERSPAN traffic flow to the destination port.

ERSPAN Sources

The Cisco ERSPAN feature supports the following sources:

- Source ports: A source port that is monitored for traffic analysis. Source ports in any VLAN can be configured and trunk ports can be configured as source ports along with nontrunk source ports.
- Source VLANs: A VLAN that is monitored for traffic analysis.

ERSPAN Destination Ports

A destination port is a Layer 2 or Layer 3 port to which ERSPAN source sends traffic for analysis.

When you configure a port as a destination port, it can no longer receive any traffic. The port is dedicated for use only by the ERSPAN feature. An ERSPAN destination port does not forward any traffic except that required for the ERSPAN session. You can configure trunk ports as destination ports, which allows destination trunk ports to transmit encapsulated traffic.

SGT-Based ERSPAN

A Security Group Tag (SGT) is a 16-bit value that the Cisco Identity Services Engine (ISE) assigns to the user or endpoint session upon login. The network infrastructure views the SGT as another attribute to assign to the session and inserts the Layer 2 tag to all traffic from that session. A platform can support a maximum of 50 SGT policies per session.

On an existing flow-based SPAN (FSPAN) or VLAN filter session, SGT filtering configurations are not allowed.

Prerequisites for Configuring ERSPAN

Apply the Access control list (ACL) filter before sending the monitored traffic on to the tunnel.

How to Configure ERSPAN

The following sections provide information about how to configure ERSPAN.

Configuring an ERSPAN Source Session

The ERSPAN source session defines the session configuration parameters and the ports or VLANs to be monitored. To define an IPv4 ERSPAN source session, complete the following procedure:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**monitor session** *span-session-number* **type erspan-source** **Example:** `Device(config)# monitor session 1 type erspan-source`	Defines an ERSPAN source session using the session ID and the session type, and enters ERSPAN monitor source session configuration mode. • The *span-session-number* argument range is from 1 to 66. The same session number cannot be used more than once. • The session IDs for source sessions or destination sessions are in the same global ID space, so each session ID is globally unique for both session types. • The session ID (configured by the *span-session-number* argument) and the session type (configured by the **erspan-source** keyword) cannot be changed once entered. Use the **no** form of this command to remove the session and then re-create the session, with a new session ID or a new session type.
Step 4	**description** *string* **Example:** `Device(config-mon-erspan-src)# description source1`	(Optional) Describes the ERSPAN source session. • The *string* argument can be up to 240 characters and cannot contain special characters or spaces.
Step 5	[**no**] **header-type 3** **Example:** `Device(config-mon-erspan-src)# header-type 3`	(Optional) Configures a switch to Type-III ERSPAN header. The default type is Type-II ERSPAN header.

	Command or Action	Purpose
Step 6	**source** {**interface** *interface-type interface-number* | **vlan** *vlan-id*} [**,** | **-** | **both** | **rx** | **tx**] **Example:** `Device(config-mon-erspan-src)# source interface gigabitethernet 1/1 rx`	Configures the source interface or the VLAN, and the traffic direction to be monitored.
Step 7	**filter** {**ip access-group** {*standard-access-list* | *expanded-access-list* | *acl-name* } | **mac access-group** *acl-name* | **sgt** *sgt-ID* [**,** | **-**] | **vlan** *vlan-ID* [**,** | **-**]} **Example:** `Switch(config-mon-erspan-src)# filter vlan 3`	(Optional) Configures source VLAN filtering when the ERSPAN source is a trunk port. **Note** You cannot include source VLANs and filter VLANs in the same session.
Step 8	**destination** **Example:** `Device(config-mon-erspan-src)# destination`	Enters ERSPAN source session destination configuration mode.
Step 9	**erspan-id** *erspan-flow-id* **Example:** `Device(config-mon-erspan-src-dst)# erspan-id 100`	Configures the ID used by source and destination sessions to identify the ERSPAN traffic, which must also be entered in the ERSPAN destination session configuration.
Step 10	**ip address** *ip-address* **Example:** `Device(config-mon-erspan-src-dst)# ip address 10.1.0.2`	Configures the IP address that is used as the destination of the ERSPAN traffic.
Step 11	**ip dscp** *dscp-value* **Example:** `Device(config-mon-erspan-src-dst)# ip dscp 10`	(Optional) Enables the use of IP differentiated services code point (DSCP) for packets that originate from a circuit emulation (CEM) channel.
Step 12	**ip ttl** *ttl-value* **Example:** `Device(config-mon-erspan-src-dst)# ip ttl 32`	(Optional) Configures the IP TTL value of packets in the ERSPAN traffic.
Step 13	**mtu** *mtu-size* **Example:** `Device(config-mon-erspan-src-dst)# mtu 512`	Configures the MTU size for truncation. Any ERSPAN packet that is larger than the configured MTU size is truncated to the configured size. The MTU size range is 176 to 9000 bytes. The default value is 9000 bytes.

	Command or Action	Purpose
Step 14	**origin ip-address** *ip-address* **Example:** `Device(config-mon-erspan-src-dst)# origin ip address 10.10.0.1`	Configures the IP address used as the source of the ERSPAN traffic.
Step 15	**vrf** *vrf-id* **Example:** `Device(config-mon-erspan-src-dst)# vrf 1`	(Optional) Configures the VRF name to use instead of the global routing table.
Step 16	**exit** **Example:** `Device(config-mon-erspan-src-dst)# exit`	Exits ERSPAN source session destination configuration mode, and returns to ERSPAN source session configuration mode.
Step 17	**no shutdown** **Example:** `Device(config-mon-erspan-src)# no shutdown`	Enables the configured sessions on an interface.
Step 18	**end** **Example:** `Device(config-mon-erspan-src)# end`	Exits ERSPAN source session configuration mode, and returns to privileged EXEC mode.

Configuring an ERSPAN Destination Session

The ERSPAN destination session defines the session configuration parameters and the ports that receive the monitored traffic. To define an IPv4 ERSPAN destination session, complete the following procedure:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**monitor session** *session-number* **type erspan-destination** **Example:** `Device(config)# monitor session 1 type erspan-destination`	Defines an ERSPAN destination session using the session ID and the session type, and enters ERSPAN monitor destination session configuration mode.

	Command or Action	Purpose
		• The *session-number* argument range is from 1 – 66. The session number must be unique and cannot be used more than once. • The session IDs for source sessions or destination sessions are in the same global ID space, so each session ID is globally unique for both session types. • The session ID (configured by the *session-number* argument) and the session type (configured by the **erspan-destination**) cannot be changed once entered. Use the **no** form of this command to remove the session, and then recreate the session with a new session ID or a new session type.
Step 4	**description** *string* **Example:** `Device(config-mon-erspan-dst)# description source1`	(Optional) Describes the ERSPAN destination session. • The *string* argument can be up to 240 characters in length and cannot contain special characters or spaces.
Step 5	**destination interface** *interface-type* **Example:** `Device(config-mon-erspan-dst)# destination interface GigabitEthernet1/1`	Associates the ERSPAN destination session number with source ports, and selects the traffic direction to be monitored.
Step 6	**source** **Example:** `Device(config-mon-erspan-dst)# source`	Enters ERSPAN destination session source configuration mode.
Step 7	**erspan-id** *erspan-flow-id* **Example:** `Device(config-mon-erspan-dst-src)# erspan-id 100`	Configures the ID used by source and destination sessions to identify the ERSPAN traffic, which must also be entered in the ERSPAN source session configuration.
Step 8	**ip address** *ip-address* [**force**] **Example:** `Device(config-mon-erspan-dst-src)# ip address 10.1.0.2`	Configures the IP address that is used as the destination of the ERSPAN traffic. • This IP address must be an address on a local interface or loopback interface, and match the address on the destination switch. • The **ip address** *ip-address* **force** command changes the destination IP

	Command or Action	Purpose
		address for all ERSPAN destination sessions.
Step 9	**vrf** *vrf-id* **Example:** `Device(config-mon-erspan-dst-src)# vrf 1`	(Optional) Configures the VRF name to use instead of the global routing table.
Step 10	**no shutdown** **Example:** `Device(config-mon-erspan-dst-src)# no shutdown`	Enables the configured sessions on an interface.
Step 11	**end** **Example:** `Device(config-mon-erspan-dst-src)# end`	Exits ERSPAN destination session source configuration mode, and returns to privileged EXEC mode.

Configuration Examples for ERSPAN

The following sections provide configuration examples for ERSPAN.

Example: Configuring an ERSPAN Source Session

The following example shows how to configure an ERSPAN source session:

```
Device> enable
Device# configure terminal
Device(config)# monitor session 1 type erspan-source
Device(config-mon-erspan-src)# description source1
Device(config-mon-erspan-src)# source interface GigabitEthernet 1/1 rx
Device(config-mon-erspan-src)# source interface GigabitEthernet 1/1 - 8 tx
Device(config-mon-erspan-src)# source interface GigabitEthernet 1/1
Device(config-mon-erspan-src)# destination
Device(config-mon-erspan-src-dst)# erspan-id 100
Device(config-mon-erspan-src-dst)# ip address 10.1.0.2
Device(config-mon-erspan-src-dst)# ip dscp 10
Device(config-mon-erspan-src-dst)# ip ttl 32
Device(config-mon-erspan-src-dst)# mtu 512
Device(config-mon-erspan-src-dst)# origin ip address 10.10.0.1
Device(config-mon-erspan-src-dst)# vrf monitoring
Device(config-mon-erspan-src-dst)# exit
Device(config-mon-erspan-src)# no shutdown
Device(config-mon-erspan-src)# end
```

Example: Configuring an ERSPAN Destination Session

The following example shows how to configure an ERSPAN destination session:

```
Device(config)# monitor session 2 type erspan-destination
Device(config-mon-erspan-dst)# destination interface GigabitEthernet1/1
Device(config-mon-erspan-dst)# destination interface GigabitEthernet1/1
```

```
Device(config-mon-erspan-dst)# source
Device(config-mon-erspan-dst-src)# erspan-id 100
Device(config-mon-erspan-dst-src)# ip address 10.1.0.2
```

The following example shows how to configure a source VRF for an ERSPAN destination session:

```
Device(config)# monitor session 2 type erspan-destination
Device(config-mon-erspan-dst)# destination interface GigabitEthernet1/1
Device(config-mon-erspan-dst)# destination interface GigabitEthernet1/1
Device(config-mon-erspan-dst)# source
Device(config-mon-erspan-dst-src)# erspan-id 100
Device(config-mon-erspan-dst-src)# ip address 10.1.0.2
Device(config-mon-erspan-dst-src)# vrf 1
```

Verifying ERSPAN

To verify the ERSPAN configuration, use the following commands:

The following is sample output from the **show monitor session erspan-source** command:

```
Device# show monitor session erspan-source

Type : ERSPAN Source Session
Status : Admin Enabled
Source Ports :
RX Only : Gi1/1
Destination IP Address : 192.0.2.1
Destination ERSPAN ID : 110
Origin IP Address : 10.10.10.216
 Flow Label : None

Device# show monitor session 53

Session 53
----------
Type                    : ERSPAN Source Session

ERSPAN header-type       : 3
```

The following output from the **show capability feature monitor erspan-source** command displays information about the configured ERSPAN source sessions:

```
Device# show capability feature monitor erspan-source

ERSPAN Source Session:ERSPAN Source Session Supported: TRUE
No of Rx ERSPAN source session: 8
No of Tx ERSPAN source session: 8
ERSPAN Header Type supported: II and III
ACL filter Supported: TRUE
SGT filter Supported: TRUE
Fragmentation Supported: TRUE
Truncation Supported: FALSE
Sequence number Supported: FALSE
QOS Supported: TRUE
```

The following output from the **show capability feature monitor erspan-destination** command displays all the configured global built-in templates:

```
Device# show capability feature monitor erspan-destination

ERSPAN Destination Session:ERSPAN Destination Session Supported: TRUE
Maximum No of ERSPAN destination session: 8
ERSPAN Header Type supported: II and III
```

Configure Industrial Asset Discovery

- Industrial asset discovery , on page 2435
- Industrial asset discovery operation, on page 2436
- Guidelines and Limitations, on page 2438
- Default configuration, on page 2438
- Configure industrial asset discovery, on page 2438
- Export IAD records to syslog server, on page 2439
- Verify IAD status, on page 2441
- Feature history, on page 2443

Industrial asset discovery

The Industrial Asset Discovery (IAD) feature provides enhanced visibility into directly connected end devices within an industrial network. IAD leverages discovery messages that are inherent to standard industrial protocols, such as Common Industrial Protocol (CIP) and Profinet, to identify and collect detailed information about these devices. Cisco Industrial Ethernet (IE) switches utilize the same protocol messages as CIP and Profinet devices to ensure that there is no operational impact on end devices. The devices continue to respond as expected within the network.

How IAD works

IAD sends and processes discovery messages from CIP and Profinet protocols. These messages allow the switch to identify connected industrial devices, such as programmable logic controllers (PLCs) and intelligent electronic devices (IEDs), and to gather detailed information about their network connectivity. Since IAD uses the same protocol messages as the connected devices, it does not disrupt normal device communication.

IAD collects layer 2 network connectivity details, such as the switch, interface, and VLAN assignments, for each discovered device. This information is processed and maintained in a local inventory database on the switch. IAD collects information from IP Device Tracking (IPDT) and device discovery protocols such as Cisco Discovery Protocol (CDP) and Link Layer Discovery Protocol (LLDP), to provide a comprehensive view of all connected assets.

Key benefits

- **Enhanced device visibility:** Provides granular information about connected industrial devices, switch port, and VLAN assignment.

- **Improved network segmentation:** Supports identification of unauthorized devices, which helps network administrators identify misconnection and misconfiguration, and assist with their network segmentation policies.
- **Automated data export:** Enables export of device inventory data using JSON syslog integration for external monitoring or asset management.
- **Non-intrusive operation:** Uses standard protocol messages, ensuring no impact to end device behavior or network performance.

Supported protocols

IAD collects and correlates device information using these protocols:

- CIP
- Profinet
- IPDT
- CDP
- LLDP

Industrial asset discovery operation

After the switch boots and you enable IAD, the system waits for a period before sending discovery messages to the enabled industrial protocols. The system sends subsequent notifications at periodic intervals.

You can:

- Configure the interval to send notifications by using **iad refresh-interval** command.
- Enable and disable discovery for any, or all of the supported protocols in IAD.

Each access switch maintains a local IAD database to store collated device information collected from the supported protocols. The system refreshes the local database dynamically according to the configured timer values.

The system automatically refreshes the database when an interface state changes from *down* to *up*. During a link flap event, IAD sends a discovery message, waits for a predefined interval, and then sends the next discovery message to prevent excessive traffic.

IAD discovery gathers and stores these details about each end device.

- Status of connected physical port in **Up** or **Down** state
- IP address
- MAC address
- Serial number
- Device PID
- Vendor

- Device type

Device code	Device
R	Router
B	Source route bridge
T	Telephone
H	Host
C	DOCSIS cable device
W	WLAN access point
P	Repeater
G	Trans bridge
F	Switch
I	IGMP
E	Phone
S	Station
D	Remote
A	CVTA
M	Two-port Mac relay
O	Other

- Software version
- Protocol
- Timestamp
- Physical port
- Port mode

Code	Port mode
ACC	Access
TR	Trunk
RO	Routed

- VLAN
- Reported time

The device details stored by IAD and displayed in the console can vary based on the network configuration and device characteristics.

Guidelines and Limitations

Consider these guidelines and limitations when configuring IAD:

- For CIP and Profinet protocols, it is assumed that the end devices are connected through access ports, while switch-to-switch peer links use trunk ports. The system does not record end devices detected on trunk interfaces in the local database.
- When an interface goes down, the system updates the Interface Status for all related records to **down**. When the interface comes up, the system sends discovery messages, refreshes the records, and updates the Interface Status to **up**.
- For CIP and Profinet discovery messages, assign an IP address to the Switched Virtual Interface (SVI) for the VLAN. Use the same VLAN for Profinet or CIP devices.
- The IAD database supports a maximum of 100 records (devices). No limit exists for the number of records an interface can receive.
- Enable at least one protocol—Profinet, CIP, LLDP, IPDT, or CDP— for IAD operation. For instructions, see Enable PROFINET, Enable CIP, Enable LLDP, Enable IPDT, and Enable CDP.

Default configuration

IAD is disabled by default. When you enable IAD, the system applies specific default settings for protocol discovery and database updates.

The system uses these default settings:

- Sends discovery messages for CIP and Profinet.
- Receives device records from CDP, LLDP, and IPDT.
- Sets the default refresh interval for protocol discovery notifications as 6 hours (21,600 seconds).

Configure industrial asset discovery

Perform this task to enable IAD and set the discovery packet refresh interval.

Before you begin

Ensure that the protocols you want to enable for IAD are active at the switch level.

Procedure

Step 1 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Device# configure terminal
```

Step 2 Use the **iad enable {cdp | cip | ipdt | lldp | profinet}** command to enable IAD for a specific protocol.

Example:

```
Device(config)# iad enable cip
```

Note
If you do not specify a protocol, the system enables IAD for all supported protocols.

Step 3 Use the **iad refresh-interval** *seconds* command to specify the rate at which CIP or Profinet discovery packets are sent in seconds.

Example:

```
Device(config)# iad refresh-interval 10800
```

Example:

Note
The **refresh-interval** range is 10 to 86400 seconds. The default value is 21600 seconds (6 hours).

Export IAD records to syslog server

IAD can periodically export inventory records as syslog JSON strings to a syslog server. To enable this feature, you must configure IAD export and a syslog session using a logging discriminator and a TCP session for asset discovery events.

Configure IAD export

Perform this task to enable the periodic export of IAD inventory records.

Procedure

Step 1 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Device# configure terminal
```

Step 2 Use the **iad export enable** command to enable IAD export.

Example:

```
Device(config)# iad export enable
```

Step 3 Use the **iad export export-interval** *seconds* command to set the export frequency in seconds.

Example:

```
Device(config)# iad export export-interval 300
```

The **export-interval** range is 1 to 1440 seconds.

Configure syslog session for IAD

Perform this task to configure a syslog session using logging discriminators and TCP transport to filter and export asset discovery messages in JSON format.

Before you begin

Ensure you have:

- Administrative privileges to access the device CLI.
- Network connectivity to the syslog server.
- The IP address and TCP port of the syslog server.

Procedure

Step 1 Use the **logging discriminator** *discriminator-name* [**severity includes** *severity-level*] [**facility includes** *facility-name*] [**mnemonics includes** *mnemonic-string*] [**rate-limit** *rate*] command to define the criteria for filtering syslog messages based on severity, facility, or mnemonics.

Example:

```
Device(config)# logging discriminator my_desc severity includes 5 facility includes %IAD
mnemonics includes ASSET_DISCOVERY rate-limit 10
```

Note

- Adjust discriminator parameters according to your operational and security requirements.
- The **rate-limit** value set to 10, limits the number of messages per second to 10. This value prevents flooding of the syslog server.

Step 2 Use the **logging host** *ip-address* [**transport {tcp | udp}**] [**discriminator** *discriminator-name*] command to configure the remote syslog server IP address, specify the TCP transport port, and link the session to the defined discriminator.

Example:

```
Device(config)# logging host 192.168.1.77 transport tcp port 602 discriminator my_desc
```

Note
Ensure the syslog server is configured to accept TCP connections on the specified port.

The system generates a syslog entry in JSON format when a new asset is discovered.

Example syslog entry:

```
*Jan 16 03:50:52.535: %IAD-6-ASSET_DISCOVERY: New Asset {
"Interface": "Gi2/1",
"Status": "UP",
"IP-Address": "xx.xx.xx.xxx",
"MAC Addr": "D0:xx:xx:xx:xx:xx",
```

```
"Port Mode": "ACC",
"VLAN": 134,
"Serial No": "0x504D415",
"Device PID": "EtherNetIP Master S",

Verify IAD status

Perform this task to verify the IAD inventory and current configuration status.

Procedure

Step 1 Use the **show iad inventory {interface | protocol}** command to display the IAD device inventory.

Example:

```
Device# show iad inventory
```

Supported protocols are cdp, cip, ipdt, lldp, and profinet.

Output:

```
Device# show iad inventory
Capability codes:
(R) Router, (B) Source Route Bridge, (T) Telephone, (H) Host
(C) DOCSIS Cable Device (W) WLAN Access Point (P) Repeater
(G) Trans Bridge, (F) Switch, (I) IGMP, (E) Phone, (S) Station
(D) Remote, (A) CVTA, (M) Two-port Mac Relay, (O) Other

Port Modes:
(ACC) Access , (TR) Trunk, (RO) Routed

Total entries displayed : 11
```

IAD is an aggregator protocol that collects information from supported discovery protocols and presents it in the output of the `show iad inventory` command. This command displays a table of discovered device entries with detailed attributes. For example, consider this entry:

```
Port    Mode  Vlan  Status  IP-Address       Mac Addr           Serial No    Device PID
    Vendor      Device Type    SW ver       Protocol      Reported Time
Gi1/4   ACC     1     UP    192.168.1.248   38:4B:24:6A:A6:48    Unknown     SCALANCE XC-200
    42          IO           Unknown      PN            19700121 20:49:59
```

The table presents device discovery fields and descriptions.

Field	Value	Description
Port	Gi1/4	The interface on which the device was discovered
Mode	ACC	Port mode
Vlan	1	VLAN ID associated with the port
Status	UP	The operational status of the port
IP-Address	xxx.xxx.x.xxx	IP address of the discovered device
Mac Addr	xx:xx:xx:xx:xx:xx	MAC address of the device
Serial No	Unknown	Product CIP Serial Number. Entries discovered through the CIP protocol will have a value included in this field.
Device PID	SCALANCE XC-200	Product ID or device name
Vendor	42	Vendor ID as reported by the discovery protocol
Device Type	IO	Type of the device
SW ver	Unknown	Software version of the device. Unknown value indicates that SW ver details are not provided by this protocol.
Protocol	PN	The discovery protocol used.
Reported Time	19700121 20:49:59	Timestamp when the device information was reported

Step 2 Use the **show iad status** command to display the current IAD configuration status.

Example:

```
Device# show iad status
```

Output:

```
Device# show iad status
IAD Information:
Status : Enabled
Export Status : Disabled
Send/Receive Notification to CDP : Enabled
Send/Receive Notification to CIP : Enabled
Send/Receive Notification to IPDT : Enabled
Send/Receive Notification to LLDP : Enabled
Send/Receive Notification to PROFINET : Enabled
Last discovery sent for CIP/Profinet : 16:39:20 UTC Fri Mar 21 2025
IAD Records Refresh Interval Rate : 21600 secs
IAD Records Export Interval Rate : 300 secs
```

Feature history

Table 180: IAD Feature history

Feature name	Release	Description
Industrial Asset Discovery (IAD) Completion	Cisco IOS XE 26.1.1	Initial release on IE3500 series switches.

CHAPTER 170

Configuring Packet Capture

- Prerequisites for Configuring Packet Capture, on page 2445
- Restrictions for Configuring Embedded Packet Capture, on page 2445
- Information About Packet Capture, on page 2446
- How to Implement Embedded Packet Capture, on page 2447
- Configuration Examples for Embedded Packet Capture, on page 2450

Prerequisites for Configuring Packet Capture

Packet capture is supported.

The following section provides information about the prerequisites for configuring packet capture.

Prerequisites for Configuring Embedded Packet Capture

The Embedded Packet Capture (EPC) software subsystem consumes CPU and memory resources during its operation. You must have adequate system resources for different types of operations. The following table provides some guidelines for using the system resources.

Table 181: System Requirements for the EPC Subsystem

System Resources	Requirements
Hardware	CPU utilization requirements are platform-dependent.
Memory	The DRAM stores the packet buffer. The size of the packet buffer is user specified.
Disk space	Packets can be exported to external devices. No intermediate storage on flash disk is required.

Restrictions for Configuring Embedded Packet Capture

- Layer 2 EtherChannels aren't supported.
- You can't use VRFs, management ports, and private VLANs as attachment points.

- Embedded Packet Capture (EPC) isn't supported on logical ports, which includes port channels and switch virtual interfaces (SVIs). It's supported only on physical ports.
- A VLAN interface that is in shutdown state doesn't support EPC.
- If you change interface from switch port to routed port (Layer 2 to Layer 3) or the opposite way, you must delete the capture point and create a new one, once the interface comes back up. Stop/start the capture point won't work.
- Packets captured in the output direction of an interface might not reflect the changes made by the device rewrite. This includes TTL, VLAN tag, CoS, checksum, MAC addresses, DSCP, precedent, UP, etc.
- Even though the minimum configurable duration for packet capture is 1 second, packet capture works for a minimum of 2 seconds.
- It's not possible to modify a capture point parameter when a capture is already active or has started.
- EPC captures multicast packets only on ingress and doesn't capture the replicated packets on egress.
- The Rewrite information of both ingress and egress packets aren't captured.
- CPU-injected packets are considered control plane packets. Therefore, these types of packets won't be captured on an interface egress capture.
- Control plane packets aren't rate limited and performance impacting. Use filters to limit control plane packet capture.
- DNA Advantage supports decoding of protocols such as Control and Provisioning of Wireless Access Points (CAPWAP).
- You can define up to eight capture points, but only one can be active at a time. Stop one before you can start the other.
- MAC filter won't capture IP packets even if it matches the MAC address. This applies to all interfaces (Layer 2 switch port, Layer 3 routed port).
- MAC ACL is only used for non-IP packets such as ARP. It won't be supported on a Layer 3 port or SVI.
- MAC filter can't capture Layer 2 packets (ARP) on Layer 3 interfaces.
- VACL doesn't support IPv6-based ACLs.
- EPC cannot capture based on the underlying routing protocols in MPLS packets.

Information About Packet Capture

The Packet Capture feature is an onboard packet capture facility that allows network administrators to capture packets flowing to, through, and from the device. You can analyze them locally or save and export them for offline analysis by using Embedded Packet Capture (EPC). This feature simplifies network operations by allowing devices to become active participants in the management and operation of the network. This feature facilitates troubleshooting by gathering information about the packet format. This feature also facilitates application analysis and security.

About Embedded Packet Capture

EPC provides an embedded systems management facility that helps in tracing and troubleshooting packets. This feature allows network administrators to capture data packets flowing through, to, and from a Cisco device. The network administrator may define the capture buffer size and type (circular, or linear) and the maximum number of bytes of each packet to capture. You can throttle the packet capture rate using further administrative controls. For example, You can filter the packets using an Access Control List. You can further define the controls by specifying a maximum packet capture rate or by specifying a sampling interval.

EPC is supported on an interface in shutdown state. This is useful in capturing packets on an interface as it's being brought up.

Benefits of Embedded Packet Capture

- Ability to capture IPv4 and IPv6 packets in the device, and also capture non-IP packets with MAC filter or match any MAC address.
- Extensible infrastructure for enabling packet capture points. A capture point is a traffic transit point where a packet is captured and associated with a buffer.
- Facility to export the packet capture in packet capture file (PCAP) format suitable for analysis using any external tool.
- Methods to decode data packets captured with varying degrees of detail.

Packet Data Capture

Packet data capture is the capture of data packets that are then stored in a buffer. You can define packet data captures by providing unique names and parameters.

You can perform the following actions on the capture:

- Activate captures at any interface.
- Apply access control lists (ACLs) or class maps to capture points.

Note Network Based Application Recognition (NBAR) and MAC-style class map is not supported.

- Destroy captures.
- Specify buffer storage parameters such as size and type. The size ranges from 1 MB to 100 MB. The default option for the buffer is linear and the other option for the buffer is circular.
- Specify match criteria that includes information about the protocol, IP address or port address.

How to Implement Embedded Packet Capture

The following sections provide information on how to implement EPC.

Managing Packet Data Capture

To manage Packet Data Capture in the buffer mode, perform the following steps:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**monitor capture** *capture-name* **access-list** *access-list-name* **Example:** `Device# monitor capture mycap access-list v4acl`	Configures a monitor capture specifying an access list as the core filter for the packet capture.
Step 3	**monitor capture** *capture-name* **limit duration** *seconds* **Example:** `Device# monitor capture mycap limit duration 1000`	Configures monitor capture limits.
Step 4	**monitor capture** *capture-name* **interface** *interface-name* **both** **Example:** `Device# monitor capture mycap interface GigabitEthernet 1/1 both`	Configures monitor capture specifying an attachment point and the packet flow direction.
Step 5	**monitor capture** *capture-name* **buffer circular size** *bytes* **Example:** `Device# monitor capture mycap buffer circular size 10`	Configures a buffer to capture packet data.
Step 6	**monitor capture** *capture-name* **start** **Example:** `Device# monitor capture mycap start`	Starts the capture of packet data at a traffic trace point into a buffer.
Step 7	**monitor capture** *capture-name* **stop** **Example:** `Device# monitor capture mycap stop`	Stops the capture of packet data at a traffic trace point.

	Command or Action	Purpose
Step 8	**monitor capture** *capture-name* **export** *file--location/file-name* **Example:** `Device# monitor capture mycap export tftp://10.1.88.9/mycap.pcap`	Exports captured data for analysis.
Step 9	**end** **Example:** `Device# end`	Returns to privileged EXEC mode.

Monitoring and Maintaining Captured Data

Perform this task to monitor and maintain the packet data captured. Capture buffer details and capture point details are displayed.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**show monitor capture** *capture-buffer-name* **buffer dump** **Example:** `Device# show monitor capture mycap buffer dump`	(Optional) Displays a hexadecimal dump of captured packet and its metadata.
Step 3	**show monitor capture** *capture-buffer-name* **parameter** **Example:** `Device# show monitor capture mycap parameter`	(Optional) Displays a list of commands that were used to specify the capture.
Step 4	**debug epc capture-point** **Example:** `Device# debug epc capture-point`	(Optional) Enables packet capture point debugging.

	Command or Action	Purpose
Step 5	**debug epc provision** **Example:** `Device# debug epc provision`	(Optional) Enables packet capture provisioning debugging.
Step 6	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.

Configuration Examples for Embedded Packet Capture

Example: Managing Packet Data Capture

The following example shows how to manage packet data capture:

```
Device> enable
Device# monitor capture mycap access-list v4acl
Device# monitor capture mycap limit duration 1000
Device# monitor capture mycap interface GigabitEthernet 1/1 both
Device# monitor capture mycap buffer circular size 10
Device# monitor capture mycap start
Device# monitor capture mycap stop
Device# monitor capture mycap export tftp://10.1.88.9/mycap.pcap
Device# end
```

Example: Monitoring and Maintaining Captured Data

The following example shows how to dump packets in ASCII format:

```
Device# show monitor capture mycap buffer dump
Starting the packet display ........ Press Ctrl + Shift + 6 to exit

*Jun 4 14:18:02.504: EPC PROV: Found action for policy-map epc_policy_cap1 class-map
epc_class_cap1
*Jun 4 14:18:02.504: EPC PROV: Deleting EPC action
*Jun 4 14:18:02.504: EPC PROV: Successful. CLASS_REMOVE, policy-map epc_policy_cap1, class
 epc_class_cap1
*Jun 4 14:18:02.504: %BUFCAP-6-DISABLE: Capture Point cap1 disabled.
```

CHAPTER 171

Configuring Flexible NetFlow

- Prerequisites for Flexible NetFlow, on page 2453
- Restrictions for Flexible NetFlow, on page 2454
- Information About Flexible NetFlow, on page 2456
- How to Configure Flexible Netflow, on page 2470
- Monitoring Flexible NetFlow, on page 2481
- Configuration Examples for Flexible NetFlow, on page 2481

Prerequisites for Flexible NetFlow

- You are familiar with the Flexible NetFlow key fields as they are defined in the following commands:
  - **match flow**
  - **match interface**
  - **match** {**ipv4** | **ipv6**}
  - **match routing**
  - **match transport**
- You are familiar with the Flexible NetFlow nonkey fields as they are defined in the following commands:
  - **collect counter**
  - **collect flow**
  - **collect interface**
  - **collect**{**ipv4** | **ipv6**}
  - **collect routing**
  - **collect timestamp sys-uptime**
  - **collect transport**
  - **collect policy**
- The networking device must be running a Cisco release that supports Flexible NetFlow.

IPv4 Traffic

- The networking device must be configured for IPv4 routing.
- One of the following must be enabled on your device and on any interfaces on which you want to enable Flexible NetFlow: Cisco Express Forwarding or distributed Cisco Express Forwarding.

IPv6 Traffic

- The networking device must be configured for IPv6 routing.
- One of the following must be enabled on your device and on any interfaces on which you want to enable Flexible NetFlow: Cisco Express Forwarding IPv6 or distributed Cisco Express Forwarding.

Restrictions for Flexible NetFlow

The following are restrictions for Flexible NetFlow:

- Flexible NetFlow is not supported on the Layer 2 port-channel interface, but is supported on the Layer 2 port-channel member ports.
- Flexible NetFlow is supported on the Layer 3 port-channel interfaces and member ports but not on both at the same time for the same traffic type and direction.
- Multiple Flexible Netflow configurations are supported either on port-channel interface or port-channel member ports but not on both.
- Traditional NetFlow accounting is not supported.
- Flexible NetFlow Version 9 and Version 10 export formats are supported. However, if you have not configured the export protocol, Version 9 export format is applied by default.
- For wired Application Visibility and Control (AVC) traffic, only one flow monitor can be configured on one or more Layer 2 or Layer 3 physical interfaces on the system.
- Flexible NetFlow and NBAR cannot be configured together at the same time on the same interface.
- Layer 2, IPv4, and IPv6 traffic types are supported. Multiple flow monitors of different traffic types can be applied for a given interface and direction. Multiple flow monitors of same traffic type cannot be applied for a given interface and direction.
- Layer 2, VLAN, Layer 3 and SVI interfaces are supported, but the device does not support tunnels.
- Depending on the switch type, a switch will have one or two forwarding ASICs. The capacities listed in the above table are on a per-Core/per-ASIC basis.
- The switch has a single core ASIC and the total flows supported is 16K flows (8K per ingress and egress directions). The TCAM limit is 128 entries per direction.
- The NetFlow tables are on separate compartments and cannot be combined. Depending on which core processed the packet, the flows will be created in the table in the corresponding core.
- NetFlow hardware implementation supports four hardware samplers. You can select a sampler rate from 1 out of 2 to 1 out of 1024. Both — random and deterministic — sampling modes are supported.

- NetFlow hardware uses hash tables internally. Hash collisions can occur in the hardware. Therefore, in spite of the internal overflow Content Addressable Memory (CAM), the actual NetFlow table utilization could be about 80 percent.
- Depending on the fields that are used for the flow, a single flow could take two consecutive entries. IPv6 and datalink flows also take two entries. In these situations, the effective usage of NetFlow entries is half the table size, which is separate from the above hash collision limitation.
- The device supports up to 15 flow monitors.
- The NetFlow software implementation supports distributed NetFlow export, so the flows are exported from the same device in which the flow was created.
- Ingress flows are present in the ASIC that first received the packets for the flow. Egress flows are present in the ASIC from which the packets actually left the device set up.
- The reported value for the bytes count field (called “bytes long”) is Layer-2-packet-size—18 bytes. For classic Ethernet traffic (802.3), this will be accurate. For all other Ethernet types, this field will not be accurate. Use the "bytes layer2” field, which always reports the accurate Layer 2 packet size. For information about supported Flexible NetFlow fields, see 'Supported Flexible NetFlow Fields' topic.
- Configuration of IPFIX exporter on an AVC flow monitor is not supported.
- Flexible NetFlow export is not supported on the Ethernet management port, GigabitEthernet 1/1.
- When a flow record has only Source Group Tag (SGT) and Destination Group Tag (DGT) fields (or only either of the two) and if both the values are not applicable, then a flow will still be created with zero values for SGT and DGT. The flow records are expected to include source and destination IP addresses, along with SGT and DGT fields.
- On non-Cisco TrustSec interfaces, an SGT value of zero implies that there is no command header. On Cisco TrustSec interfaces, an SGT value of zero implies an unknown tag.
- When a quality of service (QoS) marked packet is received on an interface which has NetFlow configured in the ingress direction, the QoS value of the packet is captured by the NetFlow collector. However, when the packet is received on an interface which has NetFlow configured in the egress direction and the QoS value has been rewritten on ingress by the switch, the new QoS value of the packet is not captured by the collector.
- For an IPv6 flow monitor, Source Group Tag (SGT) and Destination Group Tag (DGT) fields cannot co-exist with MAC address fields.
- NetFlow records do not support MultiProtocol Label Switching-enabled (MPLS-enabled) interfaces.
- A flow monitor cannot be shared across Layer 3 physical interfaces and logical interfaces (such as, Layer 3 port-channel interface, Layer 3 port-channel member, and switch virtual interface [SVI]), but a flow monitor can be shared across logical interfaces or Layer 3 physical interfaces.
- When Flexible NetFlow and Network Address Translation (NAT) are configured on an interface,
  - Flexible NetFlow will display and export the actual flow details; but not the translated flow details. Application-level gateway (ALG) flow details are not part of the actual flow details that are exported.
  - If the ALG traffic gets translated through the CPU, Flexible NetFlow will display and export the translated flow details for the ALG traffic.

- When configuring a flow record if you include the **match application name** field, the corresponding flow monitor will not support a flow sampler.

Information About Flexible NetFlow

The following sections provide information about Flexible NetFlow.

Flexible NetFlow Overview

Flexible NetFlow uses flows to provide statistics for accounting, network monitoring, and network planning.

A flow is a unidirectional stream of packets that arrives on a source interface and has the same values for the keys. A key is an identified value for a field within the packet. You create a flow using a flow record to define the unique keys for your flow.

The device supports the Flexible NetFlow feature that enables enhanced network anomalies and security detection. Flexible NetFlow allows you to define an optimal flow record for a particular application by selecting the keys from a large collection of predefined fields.

All key values must match for the packet to count in a given flow. A flow might gather other fields of interest, depending on the export record version that you configure. Flows are stored in the Flexible NetFlow cache.

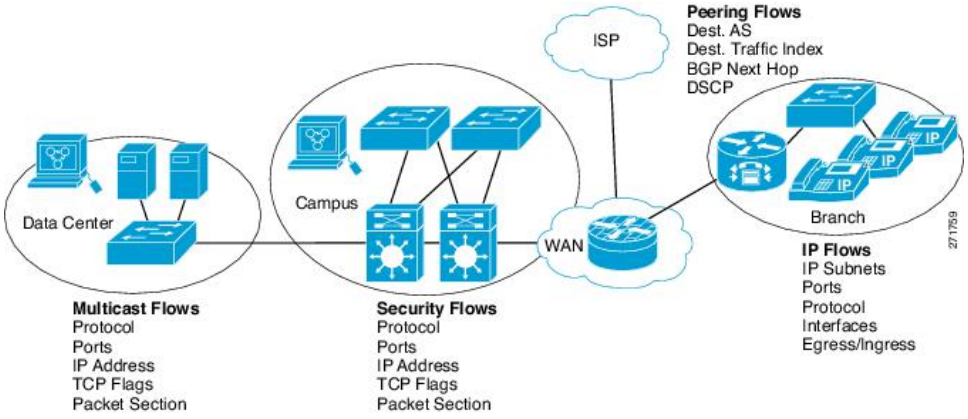
You can export the data that Flexible NetFlow gathers for your flow by using an exporter and export this data to a remote system such as a Flexible NetFlow collector. The Flexible NetFlow collector can use an IPv4 address.

You define the size of the data that you want to collect for a flow using a monitor. The monitor combines the flow record and exporter with the Flexible NetFlow cache information.

The Source Group Tag (SGT) and Destination Group Tag (DGT) fields over Flexible NetFlow are supported for IPv6 traffic.

Original NetFlow and Benefits of Flexible NetFlow

Flexible NetFlow allows the flow to be user defined. The benefits of Flexible NetFlow include:



- High-capacity flow recognition, including scalability and aggregation of flow information.
- Enhanced flow infrastructure for security monitoring and dDoS detection and identification.
- New information from packets to adapt flow information to a particular service or operation in the network. The flow information available will be customizable by Flexible NetFlow users.
- Extensive use of Cisco’s flexible and extensible NetFlow Version 9.
- A comprehensive IP accounting feature that can be used to replace many accounting features, such as IP accounting, Border Gateway Protocol (BGP) Policy Accounting, and persistent caches.

Flexible NetFlow allows you to understand network behavior with more efficiency, with specific flow information tailored for various services used in the network. The following are some example applications for a Flexible NetFlow feature:

- Flexible NetFlow enhances Cisco NetFlow as a security monitoring tool. For instance, new flow keys can be defined for packet length or MAC address, allowing users to search for a specific type of attack in the network.
- Flexible NetFlow allows you to quickly identify how much application traffic is being sent between hosts by specifically tracking TCP or UDP applications by the class of service (CoS) in the packets.
- The accounting of traffic entering a Multiprotocol Label Switching (MPLS) or IP core network and its destination for each next hop per class of service. This capability allows the building of an edge-to-edge traffic matrix.

The figure below is an example of how Flexible NetFlow might be deployed in a network.

Figure 152: Typical Deployment for Flexible NetFlow

Flexible NetFlow Components

Flexible NetFlow consists of components that can be used together in several variations to perform traffic analysis and data export. The user-defined flow records and the component structure of Flexible NetFlow facilitates the creation of various configurations for traffic analysis and data export on a networking device with a minimum number of configuration commands. Each flow monitor can have a unique combination of flow record, flow exporter, and cache type. If you change a parameter such as the destination IP address for a flow exporter, it is automatically changed for all the flow monitors that use the flow exporter. The same flow monitor can be used in conjunction with different flow samplers to sample the same type of network traffic at different rates on different interfaces. The following sections provide more information on Flexible NetFlow components:

Flow Records

In Flexible NetFlow a combination of key and nonkey fields is called a record. Flexible NetFlow records are assigned to Flexible NetFlow flow monitors to define the cache that is used for storing flow data. Flexible NetFlow includes several predefined records that can help you get started using Flexible NetFlow.

A flow record defines the keys that Flexible NetFlow uses to identify packets in the flow, as well as other fields of interest that Flexible NetFlow gathers for the flow. You can define a flow record with any combination of keys and fields of interest. The device supports a rich set of keys. A flow record also defines the types of counters gathered per flow. You can configure 64-bit packet or byte counters. The device enables the following match fields as the defaults when you create a flow record:

- **match datalink**—Layer 2 attributes
- **match flow direction**—Specifies a match to the fields identifying the direction of flow.
- **match interface**—Interface attributes
- **match ipv4**—IPv4 attributes
- **match ipv6**—IPv6 attributes
- **match transport**—Transport layer fields
- **match flow cts**—Cisco TrustSec fields

NetFlow Predefined Records

Flexible NetFlow includes several predefined records that you can use to start monitoring traffic in your network. The predefined records are available to help you quickly deploy Flexible NetFlow and are easier to use than user-defined flow records. You can choose from a list of already defined records that may meet the needs for network monitoring. As Flexible NetFlow evolves, popular user-defined flow records will be made available as predefined records to make them easier to implement.

Note Predefined records are not supported for regular Flexible NetFlow.

User-Defined Records

Flexible NetFlow enables you to define your own records for a Flexible NetFlow flow monitor cache by specifying the key and nonkey fields to customize the data collection to your specific requirements. When you define your own records for a Flexible NetFlow flow monitor cache, they are referred to as *user-defined records*. The values in nonkey fields are added to flows to provide additional information about the traffic in the flows. A change in the value of a nonkey field does not create a new flow. In most cases the values for nonkey fields are taken from only the first packet in the flow. Flexible NetFlow enables you to capture counter values such as the number of bytes and packets in a flow as nonkey fields.

You can create user-defined records for applications such as QoS and bandwidth monitoring, application and end user traffic profiling, and security monitoring for dDoS attacks. Flexible NetFlow user-defined records provide the capability to monitor a contiguous section of a packet of a user-configurable size, and use it in a flow record as a key or a nonkey field along with other fields and attributes of the packet. The section may include any Layer 3 data from the packet. The ability to analyze packet fields, enables more detailed traffic monitoring, facilitates the investigation of dDoS attacks, and enables implementation of other security applications such as URL monitoring.

The *bytes* values are the sizes in bytes of these fields in the flow record. If the corresponding fragment of the packet is smaller than the requested section size, Flexible NetFlow will fill the rest of the section field in the flow record with zeros. If the packet type does not match the requested section type, Flexible NetFlow will fill the entire section field in the flow record with zeros.

Flexible NetFlow adds a new Version 9 export format field type for the header and packet section types. Flexible NetFlow will communicate to the NetFlow collector the configured section sizes in the corresponding Version 9 export template fields. The payload sections will have a corresponding length field that can be used to collect the actual size of the collected section.

Flexible NetFlow Match Parameters

The following table describes Flexible NetFlow match parameters. You must configure at least one of the following match parameters for the flow records.

Table 182: Match Parameters

Command	Purpose
match datalink {**dot1q** | **ethertype** | **mac** | **vlan** }	Specifies a match to datalink or Layer 2 fields. The following command options are available: • **dot1q**—Matches to the dot1q field. • **ethertype**—Matches to the ethertype of the packet. • **mac**—Matches the source or destination MAC fields. • **vlan**—Matches to the VLAN that the packet is located on (input or output).
match flow direction	Specifies a match to the flow identifying fields.
match interface {**input** | **output**}	Specifies a match to the interface fields. The following command options are available: • **input**—Matches to the input interface. • **output**—Matches to the output interface.
match ipv4 {**destination** | **protocol** | **source** | **tos** | **ttl** | **version**}	Specifies a match to the IPv4 fields. The following command options are available: • **destination**—Matches to the IPv4 destination address-based fields. • **protocol**—Matches to the IPv4 protocols. • **source**—Matches to the IPv4 source address based fields. • **tos**—Matches to the IPv4 Type of Service fields. • **ttl**—Matches to the IPv4 Time To Live fields. • **version**—Matches to the IP version from the IPv4 header.

Command	Purpose
match ipv6 {**destination** | **hop-limit** | **protocol** | **source** | **traffic-class** | **version** }	Specifies a match to the IPv6 fields. The following command options are available: • **destination**—Matches to the IPv6 destination address-based fields. • **hop-limit**—Matches to the IPv6 hop limit fields. • **protocol**—Matches to the IPv6 payload protocol fields. • **source**—Matches to the IPv6 source address based fields. • **traffic-class**—Matches to the IPv6 traffic class. • **version**—Matches to the IP version from the IPv6 header.
match transport {**destination-port** | **igmp** | **icmp** | **source-port**}	Specifies a match to the Transport Layer fields. The following command options are available: • **destination-port**—Matches to the transport destination port. • **icmp**—Matches to ICMP fields, including ICMP IPv4 and IPv6 fields. • **igmp**—Matches to IGMP fields. • **source-port**—Matches to the transport source port.

Flexible NetFlow Collect Parameters

The following table describes the Flexible NetFlow collect parameters.

Table 183: Collect Parameters

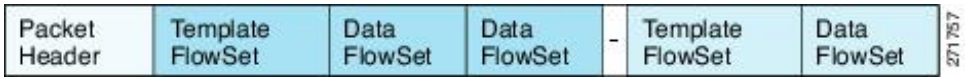
Command	Purpose
collect counter { **bytes** { **layer2** { **long** } | **long** } | **packets** { **long** } }	Collects the counter fields total bytes and total packets.
collect interface {**input** | **output**}	Collects the fields from the input or output interface.
collect timestamp absolute {**first** | **last**}	Collects the fields for the absolute time the first packet was seen or the absolute time the most recent packet was last seen (in milliseconds).

Command	Purpose
collect transport	• **packets**—packet fields • **rcp**—RCP fields • **tcp**—TCP fields
collect transport tcp flags	Collects the following transport TCP flags: • **ack**—TCP acknowledgement flag • **cwr**—TCP congestion window reduced flag • **ece**—TCP ECN echo flag • **fin**—TCP finish flag • **psh**—TCP push flag • **rst**—TCP reset flag • **syn**—TCP synchronize flag • **urg**—TCP urgent flag **Note** On the device, you cannot specify which TCP flag to collect. You can only specify to collect transport TCP flags. All TCP flags will be collected with this command.
collect flow {**sampler** |**username**}	Collects the following flow values: • **sampler**— Configures a flow sampler ID as a non-key field for the record. This field contains the ID of the flow sampler used to monitor the flow. • **username**— Configures the username associated with the flow.
collect ipv4 {**source**|**destination**}	Collects the following IPv4 fields: • **source**— Configures the IPv4 source as a non-key field for a flow record. • **destination**— Configures the IPv4 destination as a non-key field for a flow record.
collect ipv6 {**source**|**destination**}	Collects the following IPv6 information: • **source**— Configures the IPv6 source as a non-key field for a flow record. • **destination**— Configures the IPv6 destination as a non-key field for a flow record.

Command	Purpose
collect routing{ **next-hop address** |**destination**|**source**|**forwarding-status**|**multicast**	Collects the following routing values: • **next-hop address**— Information regarding the next hop from the flows. • **destination**— Destination routing attributes. • **source**— Source routing attributes. • **forwarding status**— Forwarding status of the packet. • **multicast**— Multicast routing attributes.
collect policy firewall event	Configures the collect policy firewall event as a non-key field and enables collecting information on SGACL denied or permitted traffic based on the traffic pattern.

Flow Exporters

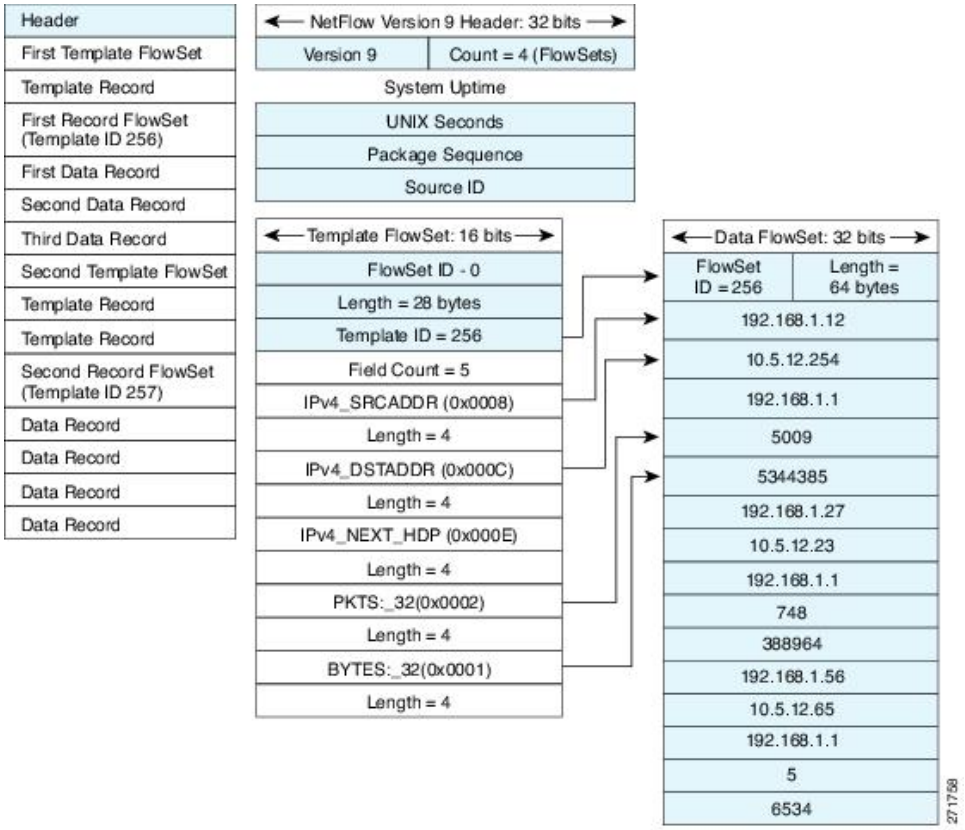
Flow exporters export the data in the flow monitor cache to a remote system, such as a server running NetFlow collector, for analysis and storage. Flow exporters are created as separate entities in the configuration. Flow exporters are assigned to flow monitors to provide data export capability for the flow monitors. You can create several flow exporters and assign them to one or more flow monitors to provide several export destinations. You can create one flow exporter and apply it to several flow monitors.



NetFlow Data Export Format Version 9

The basic output of NetFlow is a flow record. Several different formats for flow records have evolved as NetFlow has matured. The most recent evolution of the NetFlow export format is known as Version 9. The distinguishing feature of the NetFlow Version 9 export format is that it is template-based. Templates provide an extensible design to the record format, a feature that should allow future enhancements to NetFlow services without requiring concurrent changes to the basic flow-record format. Using templates provides several key benefits:

- Third-party business partners who produce applications that provide collector or display services for NetFlow do not have to recompile their applications each time a new NetFlow feature is added. Instead, they should be able to use an external data file that documents the known template formats.
- New features can be added to NetFlow quickly without breaking current implementations.
- NetFlow is “future-proofed” against new or developing protocols because the Version 9 format can be adapted to provide support for them.



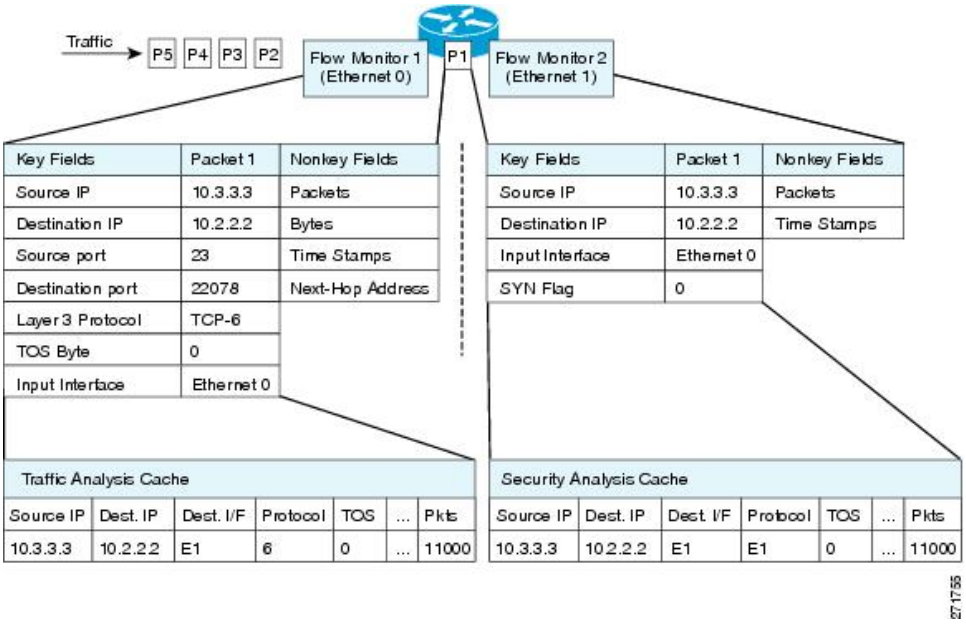
The Version 9 export format consists of a packet header followed by one or more template flow or data flow sets. A template flow set provides a description of the fields that will be present in future data flow sets. These data flow sets may occur later within the same export packet or in subsequent export packets. Template flow and data flow sets can be intermingled within a single export packet, as illustrated in the figure below.

Figure 153: Version 9 Export Packet

NetFlow Version 9 will periodically export the template data so the NetFlow collector will understand what data is to be sent and also export the data flow set for the template. The key advantage to Flexible NetFlow is that the user configures a flow record, which is effectively converted to a Version 9 template and then forwarded to the collector. The figure below is a detailed example of the NetFlow Version 9 export format, including the header, template flow, and data flow sets.

Figure 154: Detailed Example of the NetFlow Version 9 Export Format

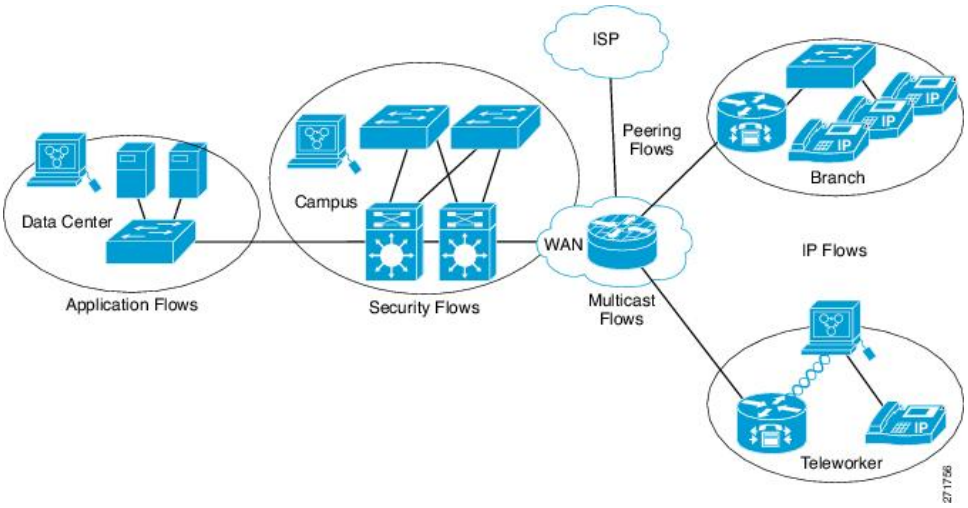
For more information on the Version 9 export format, refer to the white paper titled Cisco IOS NetFlow Version 9 Flow-Record Format, available at this URL: http://www.cisco.com/en/US/tech/tk648/tk362/technologies_white_paper09186a00800a3db9.shtml.



Flow Monitors

Flow monitors are the Flexible NetFlow component that is applied to interfaces to perform network traffic monitoring.

Flow data is collected from the network traffic and added to the flow monitor cache during the monitoring process based on the key and nonkey fields in the flow record.



Flexible NetFlow can be used to perform different types of analysis on the same traffic. In the figure below, packet 1 is analyzed using a record designed for standard traffic analysis on the input interface and a record designed for security analysis on the output interface.

Figure 155: Example of Using Two Flow Monitors to Analyze the Same Traffic

The figure below shows a more complex example of how you can apply different types of flow monitors with custom records.

Figure 156: Complex Example of Using Multiple Types of Flow Monitors with Custom Records

Normal

The default cache type is “normal”. In this mode, the entries in the cache are aged out according to the timeout active and timeout inactive settings. When a cache entry is aged out, it is removed from the cache and exported via any exporters configured.

Flow Samplers

Flow samplers are created as separate components in a router's configuration. Flow samplers are used to reduce the load on the device that is running Flexible NetFlow by limiting the number of packets that are selected for analysis.

Flow sampling exchanges monitoring accuracy for router performance. When you apply a sampler to a flow monitor, the overhead load on the router of running the flow monitor is reduced because the number of packets that the flow monitor must analyze is reduced. The reduction in the number of packets that are analyzed by the flow monitor causes a corresponding reduction in the accuracy of the information stored in the flow monitor's cache.

Samplers are combined with flow monitors when they are applied to an interface with the **ip flow monitor** command.

Supported Flexible NetFlow Fields

The following tables provide a consolidated list of supported fields in Flexible NetFlow (FNF) for various traffic types and traffic direction.

Note If the packet has a VLAN field, then that length is not accounted for.

Field	Layer 2 In	Layer 2 Out	IPv4 In	IP v4 Out	IPv6 In	IPv6 Out	Notes
Key or Collect Fields							
Interface input	Yes	—	Yes	—	Yes	—	If you apply a flow monitor in the input direction: • Use the **match** keyword and use the input interface as a key field. • Use the **collect** keyword and use the output interface as a collect field. This field will be present in the exported records but with a value of 0.

Field	Layer 2 In	Layer 2 Out	IPv4 In	IP v4 Out	IPv6 In	IPv6 Out	Notes
Interface output	—	Yes	—	Yes	—	Yes	If you apply a flow monitor in the output direction: • Use the **match** keyword and use the output interface as a key field. • Use the **collect** keyword and use the input interface as a collect field. This field will be present in the exported records but with a value of 0.

Field	Layer 2 In	Layer 2 Out	IPv4 In	IP v4 Out	IPv6 In	IPv6 Out	Notes
Key Fields							
Flow direction	Yes	Yes	Yes	Yes	Yes	Yes	
Ethertype	Yes	Yes	—	—	—	—	
VLAN input	Yes	—	Yes	—	Yes	—	Supported only for a switch port.
VLAN output	—	Yes	—	Yes	—	Yes	Supported only for a switch port.
dot1q VLAN input	Yes	—	Yes	—	Yes	—	Supported only for a switch port.
dot1q VLAN output	—	Yes	—	Yes	—	Yes	Supported only for a switch port.
dot1q priority	Yes	Yes	Yes	Yes	Yes	Yes	Supported only for a switch port.
MAC source address input	Yes	Yes	Yes	Yes	Yes	Yes	

Field	Layer 2 In	Layer 2 Out	IPv4 In	IP v4 Out	IPv6 In	IPv6 Out	Notes
MAC source address output	—	—	—	—	—	—	
MAC destination address input	Yes	—	Yes	—	Yes	—	
MAC destination address output	—	Yes	—	Yes	—	Yes	
IPv4 version	—	—	Yes	Yes	Yes	Yes	
IPv4 TOS	—	—	Yes	Yes	Yes	Yes	
IPv4 protocol	—	—	Yes	Yes	Yes	Yes	Must use if any of src/dest port, ICMP code/type, IGMP type or TCP flags are used.
IPv4 TTL	—	—	Yes	Yes	Yes	Yes	
IPv4 TTL	—	—	Yes	Yes	Yes	Yes	Same as IPv4 TTL.
IPv4 protocol	—	—	Yes	Yes	Yes	Yes	Same as IPv4 protocol. Must use if any of src/dest port, ICMP code/type, IGMP type or TCP flags are used.
IPv4 source address	—	—	Yes	Yes	—	—	

Field	Layer 2 In	Layer 2 Out	IPv4 In	IP v4 Out	IPv6 In	IPv6 Out	Notes
IPv4 destination address	—	—	Yes	Yes	—	—	
ICMP IPv4 type	—	—	Yes	Yes	—	—	
ICMP IPv4 code	—	—	Yes	Yes	—	—	
IGMP type	—	—	Yes	Yes	—	—	

Field	Layer 2 In	Layer 2 Out	IPv4 In	IP v4 Out	IPv6 In	IPv6 Out	Notes
Key Fields continued							
IPv6 version	—	—	Yes	Yes	Yes	Yes	Same as IP version.
IPv6 protocol	—	—	Yes	Yes	Yes	Yes	Same as IP protocol. Must use if any of src/dest port, ICMP code/type, IGMP type or TCP flags are used.
IPv6 source address	—	—	—	—	Yes	Yes	
IPv6 destination address	—	—	—	—	Yes	Yes	
IPv6 traffic-class	—	—	Yes	Yes	Yes	Yes	Same as IP TOS.
IPv6 hop-limit	—	—	Yes	Yes	Yes	Yes	Same as IP TTL.
ICMP IPv6 type	—	—	—	—	Yes	Yes	
ICMP IPv6 code	—	—	—	—	Yes	Yes	
source-port	—	—	Yes	Yes	Yes	Yes	

Field	Layer 2 In	Layer 2 Out	IPv4 In	IP v4 Out	IPv6 In	IPv6 Out	Notes
dest-port	—	—	Yes	Yes	Yes	Yes	

Field	Layer 2 In	Layer 2 Out	IPv4 In	IP v4 Out	IPv6 In	IPv6 Out	Notes
Collect Fields							
Bytes long	Yes	Yes	Yes	Yes	Yes	Yes	Packet size = (Ethernet frame size including FCS - 18 bytes) **Recommended:** Avoid this field and use Bytes layer2 long.
Packets long	Yes	Yes	Yes	Yes	Yes	Yes	
Timestamp absolute first	Yes	Yes	Yes	Yes	Yes	Yes	
Timestamp absolute last	Yes	Yes	Yes	Yes	Yes	Yes	
TCP flags	Yes	Yes	Yes	Yes	Yes	Yes	Collects all flags.
Bytes layer2 long	Yes	Yes	Yes	Yes	Yes	Yes	

Default Settings

The following table lists the Flexible NetFlow default settings for the device.

Table 184: Default Flexible NetFlow Settings

Setting	Default
Flow active timeout	1800 seconds
Flow timeout inactive	15 seconds

Flexible NetFlow—Ingress VRF Support Overview

The Flexible NetFlow—Ingress VRF Support feature enables collecting the virtual routing and forwarding (VRF) ID from incoming packets on a device by applying an input flow monitor having a flow record that collects the VRF ID as a key field.

Flexible Netflow—Egress VRF Support Overview

The Flexible Netflow—Egress VRF Support feature enables collecting the VRF ID from outgoing packets on a device by applying an output flow monitor having a flow record that collects the VRF ID as a key field.

Autonomous System Number

The Autonomous System number space is a 32 bit field with 4,294,967,296 unique values, which are available for use to support the Internet's public inter-domain routing system.

An Autonomous System Number (AS number) is a special number assigned by IANA, used primarily with Border Gateway Protocol. It uniquely identifies a network under a single technical administration that has a unique routing policy, or is multi-homed to the public internet. This autonomous system number is required to run BGP and peer with your internet service provider, between internet service providers at peering points, and Internet Exchanges (IX). The AS number must be globally unique so that IP address blocks appear to come from a unique location that BGP can find and route to. BGP uses Prefixes and Autonomous System Paths (AS Paths) to determine the shortest path to a destination where a prefix is located.

NetFlow V9 and IPFIX export types support 32 bit AS number. NetFlow V5 export protocol does not support this 32 AS field, as it follows fixed 16 bit source and destination AS format.

You can export the below BGP parameters in Netflow:

- BGP source origin or peer AS number
- BGP destination origin or peer AS number

Configuration

Use the below command to configure AS number system:

[no] collect routing { **`destination | source`** } as **[[4-octet] peer] [4-octet]**

How to Configure Flexible Netflow

To configure Flexible Netflow, follow these general steps:

1. Create a flow record by specifying keys and non-key fields to the flow.
2. Create an optional flow exporter by specifying the protocol and transport destination port, destination, and other parameters.
3. Create a flow monitor based on the flow record and flow exporter.
4. Create an optional sampler.
5. Apply the flow monitor to a Layer 2 port, Layer 3 port, or VLAN.

Creating a Flow Record

Perform this task to configure a customized flow record.

Customized flow records are used to analyze traffic data for a specific purpose. A customized flow record must have at least one **match** criterion for use as the key field and typically has at least one **collect** criterion for use as a nonkey field.

There are hundreds of possible permutations of customized flow records. This task shows the steps that are used to create one of the possible permutations. Modify the steps in this task as appropriate to create a customized flow record for your requirements.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**flow record** *record-name* **Example:** `Device(config)# flow record FLOW-RECORD-1`	Creates a flow record and enters Flexible NetFlow flow record configuration mode. • This command also allows you to modify an existing flow record.
Step 4	**description** *description* **Example:** `Device(config-flow-record)# description Used for basic traffic analysis`	(Optional) Creates a description for the flow record.
Step 5	**match** {**ip** | **ipv6**} {**destination** | **source**} **address** **Example:** `Device(config-flow-record)# match ipv4 destination address`	**Note** This example configures the IPv4 destination address as a key field for the record.
Step 6	Repeat Step 5 as required to configure additional key fields for the record.	—
Step 7	**end** **Example:** `Device(config-flow-record)# end`	Exits Flexible NetFlow flow record configuration mode and returns to privileged EXEC mode.

	Command or Action	Purpose
Step 8	**show flow record** *record-name* **Example:** `Device# show flow record FLOW_RECORD-1`	(Optional) Displays the current status of the specified flow record.
Step 9	**show running-config flow record** *record-name* **Example:** `Device# show running-config flow record FLOW_RECORD-1`	(Optional) Displays the configuration of the specified flow record.

Creating a Flow Exporter

You can create a flow export to define the export parameters for a flow.

Note Each flow exporter supports only one destination. If you want to export the data to multiple destinations, you must configure multiple flow exporters and assign them to the flow monitor.

You can export to a destination using IPv4 address.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device(config)# configure terminal`	Enters global configuration mode.
Step 3	**flow exporter** *name* **Example:** `Device(config)# flow exporter ExportTest`	Creates a flow exporter and enters flow exporter configuration mode.
Step 4	**description** *string* **Example:** `Device(config-flow-exporter)#`	(Optional) Describes this flow record as a maximum 63-character string.

	Command or Action	Purpose
	`description ExportV9`	
Step 5	**destination** {*ipv4-address*} **Example:** `Device(config-flow-exporter)# destination 192.0.2.1 (IPv4 destination)`	Sets the IPv4 destination address or hostname for this exporter.
Step 6	**dscp** *value* **Example:** `Device(config-flow-exporter)# dscp 0`	(Optional) Specifies the differentiated services codepoint value. The range is from 0 to 63. The default is 0.
Step 7	**source** *interface type interface number* **Example:** `Device(config-flow-exporter)# source gigabitEthernet 1/1`	(Optional) Specifies the interface to use to reach the NetFlow collector at the configured destination. **Note** Flow Exporter does not support unnumbered IP interface as source interface. The following interfaces can be configured as source: • **Auto Template**—Auto-Template interface • **Capwap**—CAPWAP tunnel interface • **GigabitEthernet**—Gigabit Ethernet IEEE 802 • **GroupVI**—Group virtual interface • **Internal Interface**—Internal interface • **Loopback**—Loopback interface • **Null**—Null interface • **Port-channel**—Ethernet Channel of interface • **Tunnel**—Tunnel interface • **Vlan**—VLANs
Step 8	**transport udp** *number* **Example:**	(Optional) Specifies the UDP port to use to reach the NetFlow collector.

	Command or Action	Purpose
	`Device(config-flow-exporter)# transport udp 200`	
Step 9	**ttl** *seconds* **Example:** `Device(config-flow-exporter)# ttl 210`	(Optional) Configures the time-to-live (TTL) value for datagrams sent by the exporter. The range is from 1 to 255 seconds. The default is 255.
Step 10	**export-protocol** {**netflow-v9**} **Example:** `Device(config-flow-exporter)# export-protocol netflow-v9`	Specifies the version of the NetFlow export protocol used by the exporter.
Step 11	**end** **Example:** `Device(config-flow-record)# end`	Returns to privileged EXEC mode.
Step 12	**show flow exporter** [**name** *record-name*] **Example:** `Device# show flow exporter ExportTest`	(Optional) Displays information about NetFlow flow exporters.
Step 13	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

What to do next

Define a flow monitor based on the flow record and flow exporter.

Creating a Customized Flow Monitor

Perform this required task to create a customized flow monitor.

Each flow monitor has a separate cache assigned to it. Each flow monitor requires a record to define the contents and layout of its cache entries. These record formats can be one of the predefined formats or a user-defined format. An advanced user can create a customized format using the **flow record** command.

Before you begin

If you want to use a customized record instead of using one of the Flexible NetFlow predefined records, you must create the customized record before you can perform this task. If you want to add a flow exporter to the flow monitor for data export, you must create the exporter before you can complete this task.

Note You must use the **no ip flow monitor** command to remove a flow monitor from all of the interfaces to which you have applied it before you can modify the parameters for the **record** command on the flow monitor.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**flow monitor** *monitor-name* **Example:** `Device(config)# flow monitor FLOW-MONITOR-1`	Creates a flow monitor and enters Flexible NetFlow flow monitor configuration mode. • This command also allows you to modify an existing flow monitor.
Step 4	**description** *description* **Example:** `Device(config-flow-monitor)# description Used for basic ipv4 traffic analysis`	(Optional) Creates a description for the flow monitor.
Step 5	**record** {*record-name* | **netflow-original** | **netflow** {**ipv4** | **ipv6**} *record* [**peer**]} **Example:** `Device(config-flow-monitor)# record FLOW-RECORD-1`	Specifies the record for the flow monitor.
Step 6	**cache** {**timeout** {**active** | **inactive** | **update**} *seconds* | **type normal** } **Example:** `Device(config-flow-monitor)# cache type normal`	(Optional) Modifies the flow monitor cache parameters such as timeout values, and the cache type. Associates a flow cache with the specified flow monitor.

	Command or Action	Purpose
	`Device(config-flow-monitor)# cache timeout active`	
Step 7	Repeat Step 6 as required to finish modifying the cache parameters for this flow monitor.	—
Step 8	**statistics packet protocol** **Example:** `Device(config-flow-monitor)# statistics packet protocol`	(Optional) Enables the collection of protocol distribution statistics for Flexible NetFlow monitors.
Step 9	**statistics packet size** **Example:** `Device(config-flow-monitor)# statistics packet size`	(Optional) Enables the collection of size distribution statistics for Flexible NetFlow monitors.
Step 10	**exporter** *exporter-name* **Example:** `Device(config-flow-monitor)# exporter EXPORTER-1`	(Optional) Specifies the name of an exporter that was created previously.
Step 11	**end** **Example:** `Device(config-flow-monitor)# end`	Exits Flexible NetFlow flow monitor configuration mode and returns to privileged EXEC mode.
Step 12	**show flow monitor** [[**name**] *monitor-name* [**cache** [**format** {**csv** | **record** | **table**}]] [**statistics**]] **Example:** `Device# show flow monitor FLOW-MONITOR-2 cache`	(Optional) Displays the status and statistics for a Flexible NetFlow flow monitor.
Step 13	**show running-config flow monitor** *monitor-name* **Example:** `Device# show running-config flow monitor FLOW_MONITOR-1`	(Optional) Displays the configuration of the specified flow monitor.
Step 14	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Creating a Flow Sampler

Perform this required task to configure and enable a flow sampler.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**sampler** *sampler-name* **Example:** `Device(config)# sampler SAMPLER-1`	Creates a sampler and enters sampler configuration mode. • This command also allows you to modify an existing sampler.
Step 4	**description** *description* **Example:** `Device(config-sampler)# description Sample at 50%`	(Optional) Creates a description for the flow sampler.
Step 5	**mode** {**random**} **1 out-of** *window-size* **Example:** `Device(config-sampler)# mode random 1 out-of 2`	Specifies the sampler mode and the flow sampler window size. • The range for the *window-size* argument is from 0 to 1024.
Step 6	**exit** **Example:** `Device(config-sampler)# exit`	Exits sampler configuration mode and returns to global configuration mode.
Step 7	**interface** *type number* **Example:** `Device(config)# interface GigabitEthernet 1/1`	Specifies an interface and enters interface configuration mode.
Step 8	{**ip** | **ipv6**} **flow monitor** *monitor-name* [[**sampler**] *sampler-name*] {**input** | **output**} **Example:**	Assigns the flow monitor and the flow sampler that you created to the interface to enable sampling.

	Command or Action	Purpose
	`Device(config-if)# ip flow monitor FLOW-MONITOR-1 sampler SAMPLER-1 input`	
Step 9	**end** **Example:** `Device(config-if)# end`	Exits interface configuration mode and returns to privileged EXEC mode.
Step 10	**show sampler sampler-name** **Example:** `Device# show sampler SAMPLER-1`	Displays the status and statistics of the flow sampler that you configured and enabled.

Applying a Flow to an Interface

You can apply a flow monitor and an optional sampler to an interface.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device(config)# configure terminal`	Enters global configuration mode.
Step 3	**interface** *type* **Example:** `Device(config)# interface gigabitethernet 1/1`	Enters interface configuration mode and configures an interface. Flexible NetFlow is not supported on the L2 port-channel interface, but is supported on the L2 port-channel member ports. Flexible NetFlow is supported on the L3 port-channel interfaces and member ports but not on both at the same time.
Step 4	{**ip flow monitor** | **ipv6 flow monitor** | **datalink flow monitor**} *name* [**sampler** *name*] {**input** | **output**} **Example:** `Device(config-if)# ip flow monitor MonitorTest input`	Associates an IPv4, IPv6 and datalink flow monitor, and an optional sampler to the interface for input or output packets. **ip flow monitor** – Enables Flexible NetFlow to monitor IPv4 traffic. **ipv6 flow monitor** – Enables Flexible NetFlow to monitor IPv6 traffic.

	Command or Action	Purpose
		datalink flow monitor – Enables Flexible NetFlow to monitor non-IP traffic.
Step 5	**end** **Example:** `Device(config-flow-monitor)# end`	Returns to privileged EXEC mode.
Step 6	**show flow interface** [*interface-type number*] **Example:** `Device# show flow interface`	(Optional) Displays information about NetFlow on an interface.
Step 7	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Configuring a Bridged NetFlow on a VLAN

You can apply a flow monitor and an optional sampler to a VLAN.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device(config)# configure terminal`	Enters global configuration mode.

Step 3	**vlan** [**configuration**] *vlan-id*
	Example:
	`Device(config)# vlan configuration 30`
	`Device(config-vlan-config)#`
		Enters VLAN or VLAN configuration mode.

Step 4	**ip flow monitor** *monitor name* [**sampler** *sampler name*] {**input** }	Associates a flow monitor and an optional sampler to the VLAN for input packets.

	Command or Action	Purpose
	Example: `Device(config-vlan-config)# ip flow monitor MonitorTest input`	
Step 5	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Configuring Layer 2 NetFlow

You can define Layer 2 keys in Flexible NetFlow records that you can use to capture flows in Layer 2 interfaces.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device(config)# configure terminal`	Enters global configuration mode.

Step 3	**flow record** *name*
	Example:
	`Device(config)# flow record L2_record`
	`Device(config-flow-record)#`
		Enters flow record configuration mode.

Step 4	**match datalink** {**dot1q** |**ethertype** | **mac** | **vlan**} **Example:** `Device(config-flow-record)# match datalink ethertype`	Specifies the Layer 2 attribute as a key.
Step 5	**end** **Example:** `Device(config-flow-record)#  end`	Returns to privileged EXEC mode.

	Command or Action	Purpose
Step 6	**show flow record** [*name*] **Example:** `Device# show flow record`	(Optional) Displays information about NetFlow on an interface.
Step 7	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the configuration file.

Monitoring Flexible NetFlow

The commands in the following table can be used to monitor Flexible NetFlow.

Table 185: Flexible NetFlow Monitoring Commands

Command	Purpose
show flow exporter [**broker** | **export-ids** | **name** | *name* | **statistics** | **templates**]	Displays information about NetFlow flow exporters and statistics.
show flow exporter [**name** *exporter-name*]	Displays information about NetFlow flow exporters and statistics.
show flow interface	Displays information about NetFlow interfaces.
show flow monitor [**name** *exporter-name*]	Displays information about NetFlow flow monitors and statistics.
show flow monitor statistics	Displays the statistics for the flow monitor
show flow monitor cache format {**table** | **record** | **csv**}	Displays the contents of the cache for the flow monitor, in the format specified.
show flow record [**name** *record-name*]	Displays information about NetFlow flow records.
show sampler [**broker** | **name** | *name*]	Displays information about NetFlow samplers.

Configuration Examples for Flexible NetFlow

Example: Configuring a Flow

This example shows how to create a flow and apply it to an interface:

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Device(config)# flow export export1
Device(config-flow-exporter)# destination 10.0.101.254
Device(config-flow-exporter)# transport udp 2055
Device(config-flow-exporter)# exit
Device(config)# flow record record1
Device(config-flow-record)# match ipv4 source address
Device(config-flow-record)# match ipv4 destination address
Device(config-flow-record)# match ipv4 protocol
Device(config-flow-record)# match transport source-port
Device(config-flow-record)# match transport destination-port

Device(config-flow-record)# collect counter byte long
Device(config-flow-record)# collect counter packet long
Device(config-flow-record)# collect timestamp absolute first
Device(config-flow-record)# collect timestamp absolute last
Device(config-flow-record)# exit
Device(config)# flow monitor monitor1
Device(config-flow-monitor)# record record1
Device(config-flow-monitor)# exporter export1
Device(config-flow-monitor)# exit
Device(config)# interface gigabitethernet 1/1
Device(config-if)# ip flow monitor monitor1 input
Device(config-if)# end
```

Example: Monitoring IPv4 ingress traffic

This example shows how to monitor IPv4 ingress traffic .

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# flow record  fr-1
Device(config-flow-record)# match ipv4 source address
Device(config-flow-record)# match ipv4 destination address
Device(config-flow-record)# match interface input
Device(config-flow-record)# collect counter bytes long
Device(config-flow-record)# collect counter packets long
Device(config-flow-record)# collect timestamp absolute first
Device(config-flow-record)# collect timestamp absolute last
Device(config-flow-record)# collect counter bytes layer2 long
Device(config-flow-record)# exit

Device(config)# flow exporter fe-ipfix6
Device(config-flow-exporter)# destination 2001:0:0:24::10
Device(config-flow-exporter)# source Vlan106
Device(config-flow-exporter)# transport udp 4739
Device(config-flow-exporter)# export-protocol ipfix
Device(config-flow-exporter)# template data timeout 240
Device(config-flow-exporter)# exit

Device(config)# flow exporter fe-ipfix
Device(config-flow-exporter)# description IPFIX format collector 100.0.0.80
Device(config-flow-exporter)# destination 100.0.0.80
Device(config-flow-exporter)# dscp 30
```

```
Device(config-flow-exporter)# ttl 210
Device(config-flow-exporter)# transport udp 4739
Device(config-flow-exporter)# export-protocol ipfix
Device(config-flow-exporter)# template data timeout 240
Device(config-flow-exporter)# exit

Device(config)# flow exporter fe-1
Device(config-flow-exporter)# destination 10.5.120.16
Device(config-flow-exporter)# source Vlan105
Device(config-flow-exporter)# dscp 32
Device(config-flow-exporter)# ttl 200
Device(config-flow-exporter)# transport udp 2055

Device(config-flow-exporter)# template data timeout 240
Device(config-flow-exporter)# exit

Device(config)# flow monitor fm-1
Device(config-flow-monitor)# exporter fe-ipfix6
Device(config-flow-monitor)# exporter fe-ipfix
Device(config-flow-monitor)# exporter fe-1
Device(config-flow-monitor)# cache timeout inactive 60
Device(config-flow-monitor)#  cache timeout active 180
Device(config-flow-monitor)# record fr-1
Device(config-flow-monitor)# end

Device# show running-config interface gigabitethernet 1/1
Device# show flow monitor fm-1 cache format table
```

Example: Monitoring IPv4 egress traffic

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# flow record  fr-1 out
Device(config-flow-record)# match ipv4 source address
Device(config-flow-record)# match ipv4 destination address
Device(config-flow-record)# match interface output
Device(config-flow-record)# collect counter bytes long
Device(config-flow-record)# collect counter packets long
Device(config-flow-record)# collect timestamp absolute first
Device(config-flow-record)# collect timestamp absolute last
Device(config-flow-record)# exit

Device(config)# flow exporter fe-1
Device(config-flow-exporter)# destination 10.5.120.16
Device(config-flow-exporter)# source Vlan105
Device(config-flow-exporter)# dscp 32
Device(config-flow-exporter)# ttl 200
Device(config-flow-exporter)# transport udp 2055
Device(config-flow-exporter)# template data timeout 240
Device(config-flow-exporter)# exit

Device(config)# flow exporter fe-ipfix6
Device(config-flow-exporter)# destination 2001:0:0:24::10
Device(config-flow-exporter)# source Vlan106
Device(config-flow-exporter)# transport udp 4739
Device(config-flow-exporter)# export-protocol ipfix
Device(config-flow-exporter)# template data timeout 240
Device(config-flow-exporter)# exit
```

```
Device(config)# flow exporter fe-ipfix
Device(config-flow-exporter)# description IPFIX format collector 100.0.0.80
Device(config-flow-exporter)# destination 100.0.0.80
Device(config-flow-exporter)# dscp 30
Device(config-flow-exporter)# ttl 210
Device(config-flow-exporter)# transport udp 4739
Device(config-flow-exporter)# export-protocol ipfix
Device(config-flow-exporter)# template data timeout 240
Device(config-flow-exporter)# exit

Device(config)# flow monitor fm-1-output
Device(config-flow-monitor)# exporter fe-1
Device(config-flow-monitor)# exporter fe-ipfix6
Device(config-flow-monitor)# exporter fe-ipfix
Device(config-flow-monitor)# cache timeout inactive 50
Device(config-flow-monitor)#  cache timeout active 120
Device(config-flow-monitor)# record fr-1-out
Device(config-flow-monitor)# end

Device# show flow monitor fm-1-output cache format table
```

Example: Configuring Flexible NetFlow for Ingress VRF Support

The following example configures the collection of theVRF ID from incoming packets on a device by applying an input flow monitor having a flow record that collects the VRF ID as a key field.

```
Device> enable
Device# configure terminal
Device(config)# flow record rm_1
Device(config-flow-record)# match routing vrf input
Device(config-flow-record)# match ipv4 source address
Device(config-flow-record)# match ipv4 destination address
Device(config-flow-record)# collect interface input
Device(config-flow-record)# collect interface output
Device(config-flow-record)# collect counter packets
Device(config-flow-record)# exit

Device(config)# flow monitor mm_1
Device(config-flow-record)# record rm_1
Device(config-flow-record)# exit

Device(config)# interface GigabitEthernet 1/1
Device(config-if)# ip vrf forwarding green
Device(config-if)# ip address 172.16.2.2 255.255.255.252
Device(config-if)# ip flow monitor mm_1 input
Device(config-if)# end
```

Example: Configuring Flexible NetFlow for Egress VRF Support

The following example configures the collection of the VRF ID from outgoing packets on a device by applying an output flow monitor having a flow record that collects the VRF ID as a key field.

```
Device> enable
Device# configure terminal
Device(config)# flow record rm_1
Device(config-flow-record)# match routing vrf intput
```

```
Device(config-flow-record)# match ipv4 source address
Device(config-flow-record)# match ipv4 destination address
Device(config-flow-record)# collect interface input
Device(config-flow-record)# collect interface output
Device(config-flow-record)# collect counter packets
Device(config-flow-record)# exit

Device(config)# flow monitor mm_1
Device(config-flow-record)# record rm_1
Device(config-flow-record)# exit

Device(config)# interface GigabitEthernet 1/1
Device(config-if)# ip vrf forwarding green
Device(config-if)# ip address 172.16.2.2 255.255.255.252
Device(config-if)# ip flow monitor mm_1 output
Device(config-if)# end
```

CHAPTER 172

BGP EVPN VXLAN

• BGP EVPN VXLAN, on page 2487

BGP EVPN VXLAN

BGP EVPN VXLAN is a campus network solution for Industrial Ethernet switches running Cisco IOS XE software.

For more details on configuring BGP EVPN VXLAN on the IE3500 series devices, refer to the BGP EVPN VXLAN Configuration Guide available at: https://www.cisco.com/c/en/us/td/docs/switches/lan/cisco_ie9300/software/Configuration_Guide/BGP-EVPN-VXLAN/b-bgp-evpn-vxlan-cg.html.

When referencing configuration examples or deployment guidance from the BGP EVPN VXLAN Configuration Guide, note that interface naming conventions differ from those on the IE3500 platform. The IE3500 platform utilizes the GigabitEthernet x/x format (e.g., GigabitEthernet1/1), whereas the BGP EVPN VXLAN Configuration Guide follows a three-tiered format: GigabitEthernet x/x/x (e.g., GigabitEthernet1/0/1). Ensure that the interface references are appropriately mapped and adjusted when translating configurations between platforms to avoid misconfiguration.

IOx

- Configure the Network for IOx Applications, on page 2491
- IOx Applications Deployment on the Switch, on page 2495

CHAPTER 173

Configure the Network for IOx Applications

- Connections from Switch to IOx Applications , on page 2491
- Workflow to Connect and Manage the VLAN, on page 2492

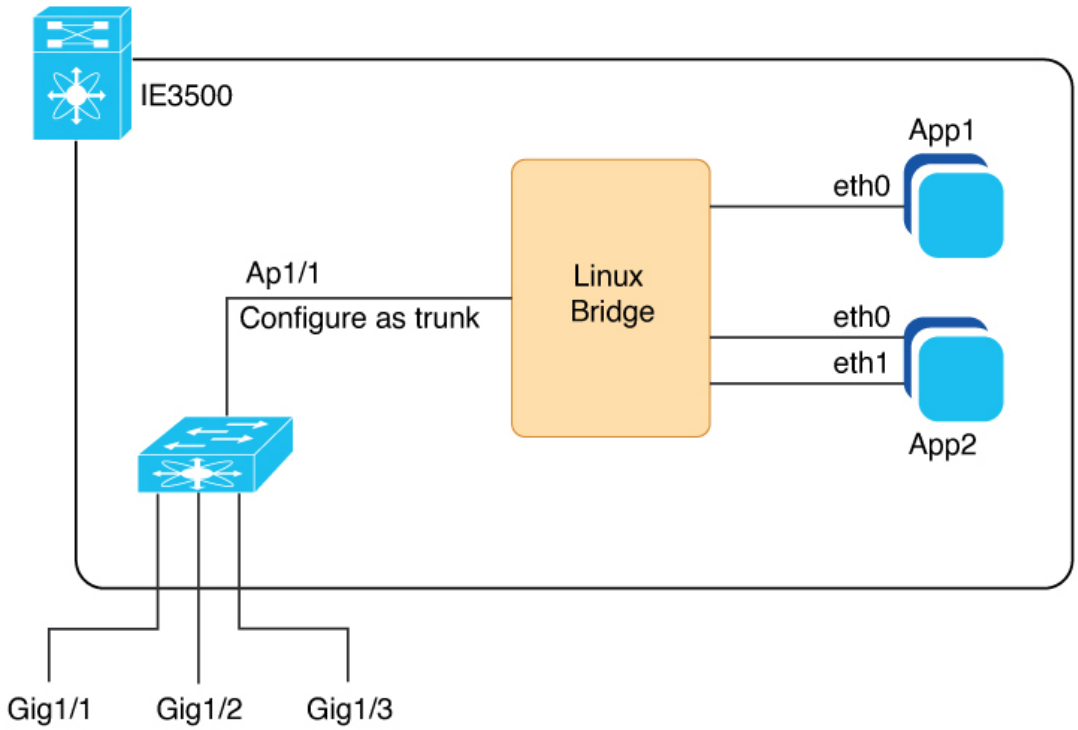
Connections from Switch to IOx Applications

The switch has an additional interface known as AppGigabitEthernet1/1, which can be configured as a standard physical interface in trunk mode for connectivity with IOx applications.

Prerequisites for Establishing a Connection Between Switch and Cisco IOx Applications

- Configure a VLAN ID for the AppGigabitEthernet1/1 interface, regardless of trunk mode.

  Ensure that the configured VLAN is not the default VLAN. By default, VLAN 1 serves as the native VLAN and carries untagged packets.



- Assign an IP address to a VLAN interface that is also a member of the AppGigabitEthernet1/1 trunk interface.

Note The VLANs on the AppGigabitEthernet1/1 trunk interface should match VLANs (including management VLANs) that carry data traffic between applications on IOx. For example, if VLAN 10 carries traffic between application and network, including management IP traffic, use the same VLAN for managing applications.

If you intend to use vlan 1 to communicate with the network, then choose a different native VLAN on AppGigabitEthernet1/1.

After configuring the network, enable IOx in the switch. For more information, see Enable IOx Application in the Switch section.

Figure 157: Connections of IOx Network with Applications

This image depicts the Ethernet and Layer 2 connections within an IOx-enabled network on a Switch. The additional interface, AppGigabitEthernet1/1, is internally connected to a Linux bridge and is configured as a trunk to support multiple IOx applications.

The IOx applications can maintain several Ethernet connections and be assigned to any VLAN as required.

See Deployment of IOx Application Using the IOS-XE CLI for an illustration showing a sample network configuration in this guide.

Workflow to Connect and Manage the VLAN

To connect and manage the VLAN, complete all these procedures in given order:

Configure a VLAN for the IOx Interface

Note VLAN ID must be configured on the AppGigabitEthernet1/1 interface, regardless of its trunk mode configuration. Also, verify that the VLAN is routable throughout the network.

Procedure

Step 1 Enter global configuration mode.

```
Device# configure terminal
```

Step 2 Enter interface configuration mode.

```
Device(config)# interface AppGigabitEthernet1/1
```

Step 3 Configure allowed VLANs on the trunk.

```
Device(config-if)#switchport trunk allowed vlan 10
```

Step 4 Configure the interface to operate in trunk mode.

```
Device(config-if)#switchport mode trunk
```

Step 5 Exit interface configuration mode.

```
Device(config-if)#end
```

Configure an SVI address for the VLAN

Procedure

Step 1 Enter global configuration mode.

```
Device# configure terminal
```

Step 2 Enter VLAN interface configuration mode.

```
Device(config)# interface vlan 10
```

Step 3 Assign an IP Address to the VLAN Interface.

```
Device(config-if)#ip address 192.168.0.1 255.255.255.0
```

Step 4 Exit interface configuration mode.

```
Device(config-if)#end
```

Enable IOx Application in the Switch

Before you begin

- Verify that you have a minimum of 4GB memory SD card. Use the SD card for IOx and format it as SD Flash to EXT4, or partition the SD card with at least 1 GB designated for IOs and the remaining space for IOx.
- Verify that you have configured the VLAN for the IOx interface.

Procedure

Step 1 Format the SD card IOx partition with EXT4 filesystem.

```
Device# partition sdflash: iox
Partitioning IOS:IOX(30%:70%) Default
Partition command reloads the switch, Continue?[confirm]
Please make sure to back-up "sdflash:" contents
Partition operation will destroy all data in "sdflash:". Continue? [confirm]
```

Note
The partition command allocates 70 percent of space on the SD card to IOx and 30 percent to IOS as a backup.

Step 2 Enter global configuration mode.

```
Device# configure terminal
```

Step 3 Enable IOx.

```
Device(config)#iox
Warning: Do not remove SD flash card when IOx is enabled or errors on SD device could occur.
*Feb 21 12:49:18.310: %UICFGEXP-6-SERVER_NOTIFIED_START: R0/0: psd: Server iox has been
notified
to start
*Feb 21 12:49:48.165: %IM-6-IOX_ENABLEMENT: R0/0: ioxman: IOX is ready.
```

Step 4 Save the configuration and returns to privileged EXEC mode.

```
Device(config)# end
```

Verify the IOx Infrastructure

Verify that the IOx infrastructure is ready to use, as shown here.

```
Device#show iox-service
IOx Infrastructure Summary:
---------------------------
IOx service (CAF) : Running
IOx service (HA) : Running
IOx service (IOxman) : Running
IOx service (Sec storage) : Running
Libvirtd 5.5.0 : Running
Dockerd v19.03.13-ce : Running
```

CHAPTER 174

IOx Applications Deployment on the Switch

- Introduction to IOx Application Management on the Switch, on page 2495
- Guidelines for IOx Applications Deployment, on page 2495
- Limitations for IOx Application Deployment, on page 2496
- Methods of IOx Applications Deployment, on page 2496
- Resource Profile Options in Cisco IOx Local Manager, on page 2496
- Deployment of IOx Application Using the IOS-XE CLI, on page 2497
- Deploy an IOx Application using Cisco IOx Local Manager, on page 2504

Introduction to IOx Application Management on the Switch

Switch support both LXC and Docker-based applications that utilize ARM64 architecture, offering a range of deployment options. The switches are designed to accommodate IPv4 and IPv6 configurations, allowing for flexible network integration.

The IOx application framework provides configuration options for Docker runtime settings and supports configuring multiple guest or Layer 2 interfaces (ranging from 0 to 63) for each application. Each Layer 2 interface can be assigned to a distinct VLAN, enhancing network organization and segmentation.

Guidelines for IOx Applications Deployment

- Place the application package or tar file in the flash or SD card storage within the IOS partition.
- Use interface AppGigabitEthernet1/1 on the switch to forward Layer 2 application traffic. Verify that the interface is active and configured as a trunk port.
- Use interface AppGigabitEthernet1/1 on the switch to configure Layer 2 interfaces and assign a VLAN with an IP address within the same VLAN network. Next, configure gateway interfaces with an SVI or an IP address in the same network.
- You can install IOx apps using an SD card that is either fully formatted as ext4 for IOx only, or partitioned to support both IOx (ext4) and IOS (vfat).
- When you install an IOx app from an HTTP or HTTPS location, the system copies the file to the IOS partition of SD card (sdflash:/apps/ directory) before installing it.

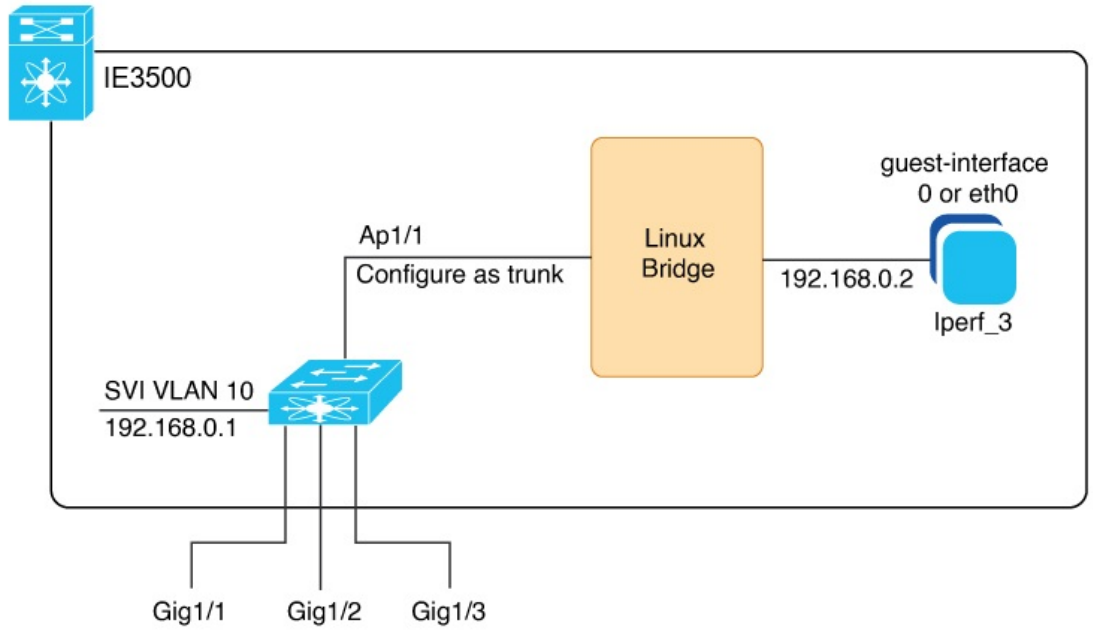
- If you use an SD card fully formatted as ext4, the card supports IOx only and not IOS, so app installation from HTTP or HTTPS fails.
- IOx app installation from HTTP or HTTPS works only if the SD card is partitioned to support both IOx and IOS.

Limitations for IOx Application Deployment

- Installing apps on system flash is not allowed.

Methods of IOx Applications Deployment

The Switch supports these two methods for deploying IOx applications.



- Deploy IOx application using IOS-XE Command-Line Interface (CLI).
- Deploy IOx application using Cisco IOx Local Manager (GUI).

Resource Profile Options in Cisco IOx Local Manager

- The Cisco IOx Local Manager provides several resource profiles, such as:
  - tiny
  - exclusive
  - default, and
  - custom.
- The custom profile allows you to adjust CPU, memory, and disk allocations according to the specific requirements of your IOx application.

Deployment of IOx Application Using the IOS-XE CLI

Figure 158: Example of IOx Deployment with Application

The configuration example here depicts a typical IOx application deployment on a Switch. The interface AppGigabitEthernet1/1 is internally linked to a Linux bridge and set up as a trunk to facilitate multiple IOx applications. The application "Iperf_3" is assigned the IP address 192.168.0.2 on its guest interface. And the default gateway for the network is configured on the Switch Virtual Interface (SVI) VLAN 10, using the IP address 192.168.0.1.

See Connections from Switch to IOx Applications , on page 2491 for an illustration without interface examples in this guide.

Configure IOx Application Using CLI

Before you begin

Verify that you have configured the network for IOx, as described in the Connections from Switch to IOx Applications , on page 2491 section.

Procedure

Step 1 Enter global configuration mode.

```
Device# configure terminal
```

Step 2 Configure an application name and enter application-hosting configuration mode.

```
Device(config)# app-hosting appid iperf_3
```

Step 3 Configure AppGigabitEthernet trunk.

```
Device(config-app-hosting)#app-vnic AppGigabitEthernet trunk
```

Step 4 Configure a VLAN guest interface. This configuration places Eth0 into VLAN 10.

```
Device(config-config-app-hosting-trunk)#vlan 10 guest-interface 0
```

Step 5 Configure a static IP address.

- IPv4

  ```
  Device(config-config-app-hosting-vlan-access-ip)#guest-ipaddress 192.168.0.2 netmask
  255.255.255.0
  ```

- IPv6

  ```
  Device(config-config-app-hosting-vlan-access-ip)#guest-ipv6address 2001::1 prefix 64
  ```

Step 6 Exit sub-interface mode.

```
Device(config-config-app-hosting-vlan-access-ip)#exit
```

Step 7 Exit app hosting trunk sub-interface mode.

```
Device(config-config-app-hosting-trunk)#exit
```

Step 8 Configure the default gateway for the application. Use the VLAN ID interface of the switch as the gateway.

```
Device(config-app-hosting)#app-default-gateway 192.168.0.1 guest-interface 0
```

Note
Support on default gateway for Ipv4 and one for IPv6.

Step 9 Save the configuration and return to privileged EXEC mode

```
Device(config-if)#end
```

Configure Docker Runtime Options for IOx Applications

Before you begin

- **Set Up Runtime Options:** You can configure up to 30 separate lines of Docker runtime options for IOx applications. The system compiles these options into a single string, proceeding from line 1 through line 30. Each string may contain multiple Docker runtime options.
- **Apply Changes to Runtime Options:** To apply changes to the runtime options, first stop the application, then deactivate it, reactivate it, and finally restart it. This process guarantees the correct implementation of the new runtime options.

Procedure

Step 1 Enter global configuration mode.

```
Device# configure terminal
```

Step 2 Configure an application name and enter application-hosting configuration mode.

```
Device(config)# app-hosting appid iperf_3
```

Step 3 Enter application-hosting Docker-configuration mode.

```
Device(config-app-hosting)#app-resource docker
```

Step 4 Specify the Docker run time options.

```
Device(config-app-hosting-docker)#run-opts 1 "--entrypoint '/bin/sleep 10000'"
```

Step 5 Exit application-hosting Docker-configuration mode.

```
Device(config-app-hosting-docker)#exit
```

Step 6 Save the configuration and return to privileged EXEC mode

```
Device(config-if)#end
```

Configure Application Resource Profiles for Application Hosting

Before you begin

- Before making resource changes, ensure the application is either not installed or in the deployed state.
- Check the memory and storage using **show app-hosting resource** command.

Procedure

Step 1 Enter global configuration mode.

```
Device# configure terminal
```

Step 2 Configure an application name to enter application-hosting configuration mode.

```
Device(config)# app-hosting appid iperf_3
```

Step 3 Configure the custom application resource profile.

```
Device(config-app-hosting)#app-resource profile custom
```

Note
The system supports only custom profile name.

Step 4 Configure the CPU resources.

```
Device(config-app-resource-profile-custom)#cpu 500
```

Step 5 Allocate memory for the application in megabytes.

```
Device(config-app-resource-profile-custom)#memory 256
```

Step 6 Assign persistent disk space for the application, in megabytes.

```
Device(config-app-resource-profile-custom)#persist-disk 256
```

Step 7 Save the configuration and return to privileged EXEC mode

```
Device(config-if)#end
```

Install, Activate, and Start the IOx Application on the Switch

Before you begin

Verify that you have configured the network and the IOx application.

Procedure

Step 1 Install the application and move it into the deployed state.

```
Device#app-hosting install appid iperf_3 package flash:iperf_3_eft_dockerimage_aarch.tar
Installing package 'flash:iperf_3_eft_dockerimage_aarch.tar' for 'iperf_3'. Use 'show
app-hosting list' for progress
```

Note
During installation, the application's signature is verified if signature verification is enabled, which is the default behavior, as described in the Cisco IOx Application Signature Verification and Automatic Activation section.

Step 2 (Optional) Enter this show command to check the state of the IOx application.

```
switch #show app-hosting list
App id                                   State
---------------------------------------------------------
iperf_3                                  DEPLOYED
```

Step 3 Allocate resources and activate the application.

```
Device# app-hosting activate appid iperf_3
Current state is: ACTIVATED
```

Step 4 Start the IOx application.

```
Device# app-hosting start appid iperf_3
iperf_3 started successfully
Current state is: RUNNING
```

Cisco IOx Application Signature Verification and Automatic Activation

IOx infrastructure checks the signature verification of a Cisco IOx application during its installation. The application package signature ensures the validity of the package and confirms that the installed application on the device comes from a trusted source.

Conditions for Signature Verification

IOx infrastructure checks for a signature under these circumstances:

- when signature verification is enabled.
- the application utilizes a restricted resource, such as secure storage.

If signature verification is enabled, and the application lacks a signature, the system prevents the application from running.

Conditions to Run Unsigned Non-Cisco Applications

The system does not permit non-Cisco applications to operate without enabling signature verification. However, the system permits unsigned non-Cisco applications to run if:

- signature verification is disabled.
- the application is not using a restricted resource.

Automated Activation and Startup of Applications with the Start Keyword

The system provides a start keyword option under the application-hosting configuration. When this start keyword is used, the IOx infrastructure automatically activates and starts the application after installation. If the start keyword is not used, manual activation and startup are required using the activate and start commands.

Signature Verification Management and Status Check

Procedure

Step 1 To enable signature verification, use this command.

```
Device#app-hosting verification enable
```

Step 2 (Optional)To disable signature verification, use this command.

```
Device#app-hosting verification disable
```

Step 3 (Optional)To check whether signature verification is enabled or disabled, use this command.

```
Device# show app-hosting infra
IOX version: 2.13.0.0
App signature verification: disabled
Internal working directory: /mnt/usb0/iox
Application Interface Mapping
AppGigabitEthernet Port # Interface Name Port Type Bandwidth
1 AppGigabitEthernet1/1 KR Port - Internal 1G
CPU:
```

```
Quota: 33(Percentage)
Available: 26(Percentage)
Quota: 1000(Units)
Available: 800(Units)
```

Note
You can enable or disable sign verification at any time regardless of any installed application states.

Display Maximum Resource Allocation for Application

To display the maximum resources allocated to an application in the switch, use this command:

```
Device# show app-hosting resource
CPU:
  Quota: 33(Percentage)
  Available: 29(Percentage)
VCPU:
  Count: 2
Memory:
  Quota: 4096(MB)
  Available: 3996(MB)
Storage space:
  Total: 14868(MB)
  Available: 12383(MB)
```

Resources Available in the Switch After IOx Application Configuration

To view the resources remaining in the switch after IOx application configuration, use this command:

```
Device# show app-hosting resource
CPU:
  Quota: 33(Percentage)
  Available: 29(Percentage)
VCPU:
  Count: 2
Memory:
  Quota: 4096(MB)
  Available: 3996(MB)
Storage space:
  Total: 14868(MB)
  Available: 12383(MB)
------------------------------------------
Device# show app-hosting infra
IOX version: 2.13.0.2
App signature verification: enabled
CAF Health: Stable
Internal working directory: /mnt/usb0/iox

Application Interface Mapping

```

Stop, Deactivate, and Uninstall IOx Application on the Switch

Procedure

Step 1 To stop the IOx application, use this command.

```
Device# app-hosting stop appid iperf_3
iperf_3 stopped successfully
Current state is: STOPPED
```

Step 2 To deactivate the IOx application, use this command.

```
Device# app-hosting deactivate appid iperf_3
iperf_3 deactivated successfully
Current state is: DEPLOYED
```

Step 3 To uninstall the IOx application, use this command.

```
Device# app-hosting uninstall appid iperf_3
Uninstalling 'iperf_3'. Use 'show app-hosting list' for progress.
```

Display App-Hosting Commands

To display the list of subcommands for the **app-hosting** command, use the command as given here:

```
Device# app-hosting ?
  activate      Application activate  <== to activate app
  clear         Clear console/aux connection     <== to clear console or aux session if
connected
  connect       Application connect              <== to connect the app console or aux or
session once in run state
  data          Application data            <== to upload files to the apps
  deactivate    Application deactivate      <== to deactivate an app
  debug         debug            <== for caf related debug commands
  install       Application install         <== to install app
  move          Move File             <== to move trace or core file
  settings      Application settings        <== to configure app specific setting using
file
  start         Application start           <== to start an app
  stop          Application stop            <== to stop an app
  uninstall     Application uninstall       <== to uninstall an app`
  upgrade       Application upgrade         <== to upgrade app to new version
  verification Application signature verification setting (global)  <== to enable/disable
the sign verification
```

Deploy an IOx Application using Cisco IOx Local Manager

Cisco IOx Local Manager offers a web-based interface for managing, administering, monitoring, and troubleshooting applications on a host system and to perform various related activities.

You can access Cisco IOx Local Manager from the web-based UI and use Cisco IOx Local Manager to deploy applications.

Switch Configuration

1. Enable the web server.

```
Device(config)# ip http secure-server
```

2. Create a user account for access.

```
Device(config)# username admin privilege 15 password 0 secret
```

Access the Cisco IOx Local Manager Application

1. Log in to the web-based UI.
2. Navigate to **Configuration > IOx**. The IOx option is located under the **Services** section.
3. In the Cisco IOx Local Manager, enter your Cisco IOS username and password.
4. Click Log In to proceed.

See Cisco IOx Local Manager Reference Guide. page for more information

Note You can access WebUI when the management interface is in a VRF.

Precision Time Protocol

Precision Time Protocol (PTP) is defined in IEEE 1588 as Precision Clock Synchronization for Networked Measurements and Control Systems, and was developed to synchronize the clocks in packet-based networks that include distributed device clocks of varying precision and stability. PTP is designed specifically for industrial, networked measurement and control systems, and is optimal for use in distributed systems because it requires minimal bandwidth and little processing overhead.

Benefits of PTP

Smart grid power automation applications such as peak-hour billing, virtual power generators, and outage monitoring and management, require precise time accuracy and stability. Timing precision improves network monitoring accuracy and troubleshooting ability.

In addition to providing time accuracy and synchronization, the PTP message-based protocol can be implemented on packet-based networks, such as Ethernet networks. The benefits of using PTP in an Ethernet network include:

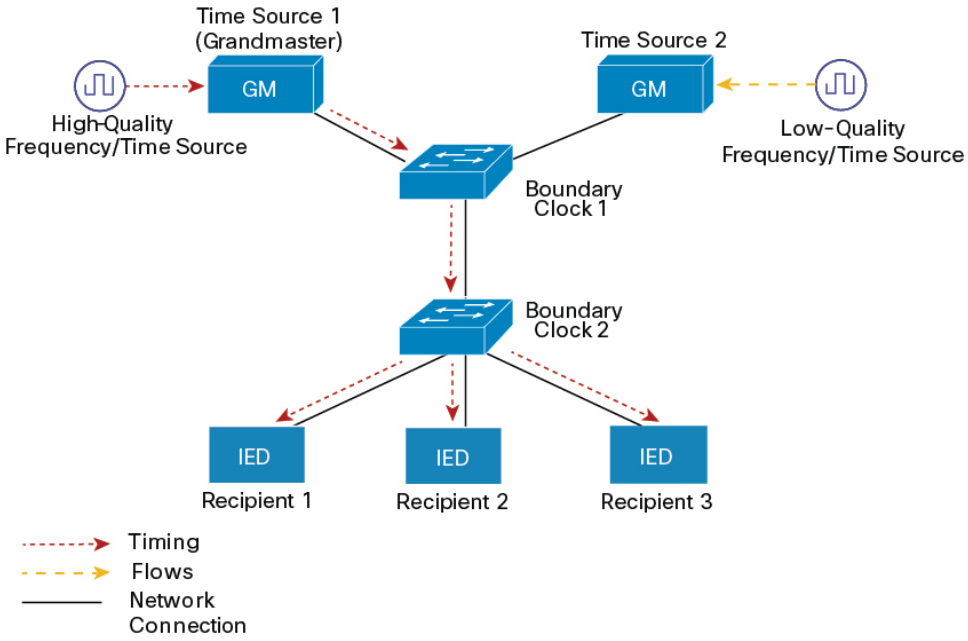
- Low cost and easy setup in existing Ethernet networks

- Limited bandwidth is required for PTP data packets

Message-Based Synchronization

To ensure clock synchronization, PTP requires an accurate measurement of the communication path delay between time source (grandmaster clock) and the time recipient. PTP sends messages between the time source and time recipient to determine the delay measurement. Then, PTP measures the exact message transmit and receive times and uses these times to calculate the communication path delay. PTP then adjusts current time information contained in network data for the calculated delay, resulting in more accurate time information.

This delay measurement principle determines path delay between devices on the network. The local clocks are adjusted for this delay using a series of messages sent between time source and time recipient devices. The one-way delay time is calculated by averaging the path delay of the transmit and receive messages. This calculation assumes a symmetrical communication path; however, switched networks do not necessarily have symmetrical communication paths, due to the buffering process.



PTP provides a method, using transparent clocks, to measure and account for the delay in a time-interval field in network timing packets. Doing so makes the switches temporarily transparent to the time source and time recipient nodes on the network. An end-to-end transparent clock forwards all messages on the network in the same way that a switch does.

Note Cisco PTP supports multicast PTP messages only.

To read a detailed description of synchronization messages, refer to PTP Event Message Sequences, on page 2511. To learn more about how transparent clocks calculate network delays, refer to Transparent Clock, on page 2514.

The following figure shows a typical 1588 PTP network that includes grandmaster clocks, switches in boundary clock mode, and Intelligent Electronic Device (IEDs) such as a digital relays or protection devices. In this diagram, Time Source 1 is the grandmaster clock. If Time Source 1 becomes unavailable, the time recipient boundary clocks switch to Time Source 2 for synchronization.

Figure 159: PTP Network

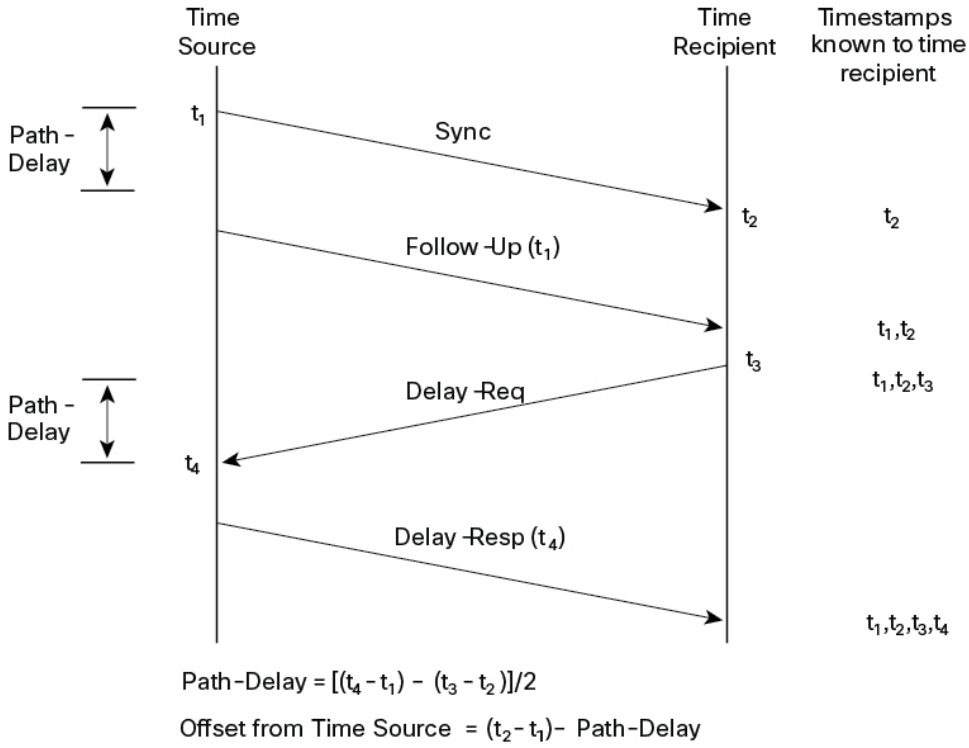
PTP Event Message Sequences

This section describes the PTP event message sequences that occur during synchronization.

Synchronizing with Boundary Clocks

The ordinary and boundary clocks configured for the delay request-response mechanism use the following event messages to generate and communicate timing information:

- Sync
- Delay_Req
- Follow_Up
- Delay_Resp



These messages are sent in the following sequence:

1. The time source sends a Sync message to the time recipient and notes the time (t1) at which it was sent.
2. The time recipient receives the Sync message and notes the time of reception (t2).
3. The time source conveys to the time recipient the timestamp t1 by embedding the timestamp t1 in a Follow_Up message.
4. The time recipient sends a Delay_Req message to the time source and notes the time (t3) at which it was sent.
5. The time source receives the Delay_Req message and notes the time of reception (t4).
6. The time source conveys to the time recipient the timestamp t4 by embedding it in a Delay_Resp message.

After this sequence, the time recipient possesses all four timestamps. These timestamps can be used to compute the offset of the time recipient clock relative to the time source, and the mean propagation time of messages between the two clocks.

The offset calculation is based on the assumption that the time for the message to propagate from time source to time recipient is the same as the time required from time recipient to time source. This assumption is not always valid on an Ethernet network due to asymmetrical packet delay times.

Figure 160: Detailed Steps—Boundary Clock Synchronization

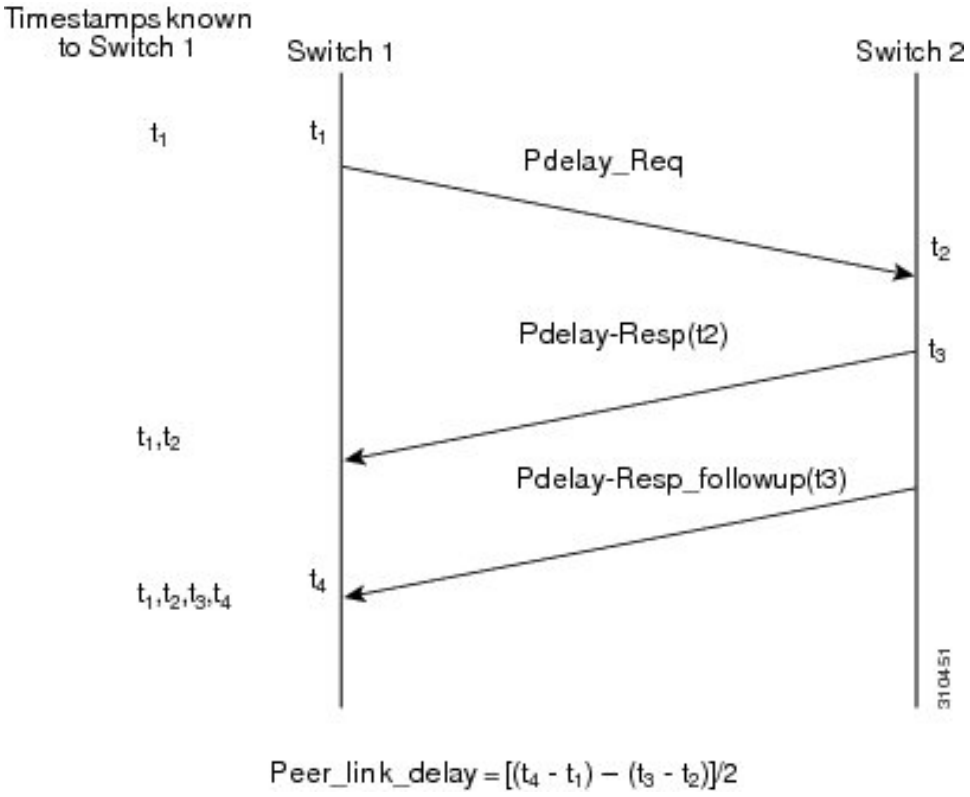
Synchronizing with Peer-to-Peer Transparent Clocks

When the network includes multiple levels of boundary clocks in the hierarchy, with non-PTP enabled devices between them, synchronization accuracy decreases.

The round-trip time is assumed to be equal to mean_path_delay/2, however this is not always valid for Ethernet networks. To improve accuracy, the resident time of each intermediary clock is added to the offset in the end-to-end transparent clock. Resident time, however, does not consider the link delay between peers, which is handled by peer-to-peer transparent clocks.

Peer-to-peer transparent clocks measure the link delay between two clock ports implementing the peer delay mechanism. The link delay is used to correct timing information in Sync and Follow_Up messages.

Peer-to-peer transparent clocks use the following event messages:



- Pdelay_Req
- Pdelay_Resp
- Pdelay_Resp_Follow_Up

These messages are sent in the following sequence:

1. Port 1 generates timestamp t1 for a Pdelay_Req message.
2. Port 2 receives and generates timestamp t2 for this message.
3. Port 2 returns and generates timestamp t3 for a Pdelay_Resp message.

   To minimize errors due to any frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message.
4. Port 2 returns timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages respectively.
5. Port 1 generates timestamp t4 after receiving the Pdelay_Resp message. Port 1 then uses the four timestamps (t1, t2, t3, and t4) to calculate the mean link delay.

Figure 161: Detailed Steps—Peer-to-Peer Transparent Clock Synchronization

Synchronizing the Local Clock

In an ideal PTP network, the time source and time recipient clocks operate at the same frequency. However, *drift* can occur on the network. Drift is the frequency difference between the time source and time recipient clocks. You can compensate for drift by using the time stamp information in the device hardware and follow-up messages (intercepted by the switch) to adjust the frequency of the local clock to match the frequency of the time source clock.

Best Master Clock Algorithm

The Best Master Clock Algorithm (BMCA) is the basis of PTP functionality. The BMCA specifies how each clock on the network determines the best time source clock in its subdomain of all the clocks it can see, including itself. The BMCA runs on the network continuously and quickly adjusts for changes in network configuration.

The BMCA uses the following criteria to determine the best time source clock in the subdomain:

- Clock quality (for example, GPS is considered the highest quality)
- Clock accuracy of the clock's time base.
- Stability of the local oscillator
- Closest clock to the grandmaster

In addition to identifying the best time source clock, the BMCA also ensures that clock conflicts do not occur on the PTP network by ensuring that:

- Clocks do not have to negotiate with one another.
- There is no misconfiguration, such as two time source clocks or no time source clocks, as a result of the time source clock identification process.

PTP Clocks

A PTP network is made up of PTP-enabled devices and devices that are not using PTP. The PTP-enabled devices typically consist of the following clock types.

Grandmaster Clock

The grandmaster clock is a network device physically attached to the server time source. All clocks are synchronized to the grandmaster clock.

Within a PTP domain, the grandmaster clock is the primary source of time for clock synchronization using PTP. The grandmaster clock usually has a precise time source, such as a GPS or atomic clock. When the network does not require any external time reference and only needs to be synchronized internally, the grandmaster clock can free run.

Boundary Clock

A boundary clock in a PTP network operates in place of a standard network switch or router. Boundary clocks have more than one PTP port, and each port provides access to a separate PTP communication path. They intercept and process all PTP messages, and pass all other network traffic. The boundary clock uses the BMCA to select the best clock seen by any port. The selected port is then set to nonmaster mode. The master port synchronizes the clocks connected downstream, while the nonmaster port synchronizes with the upstream master clock.

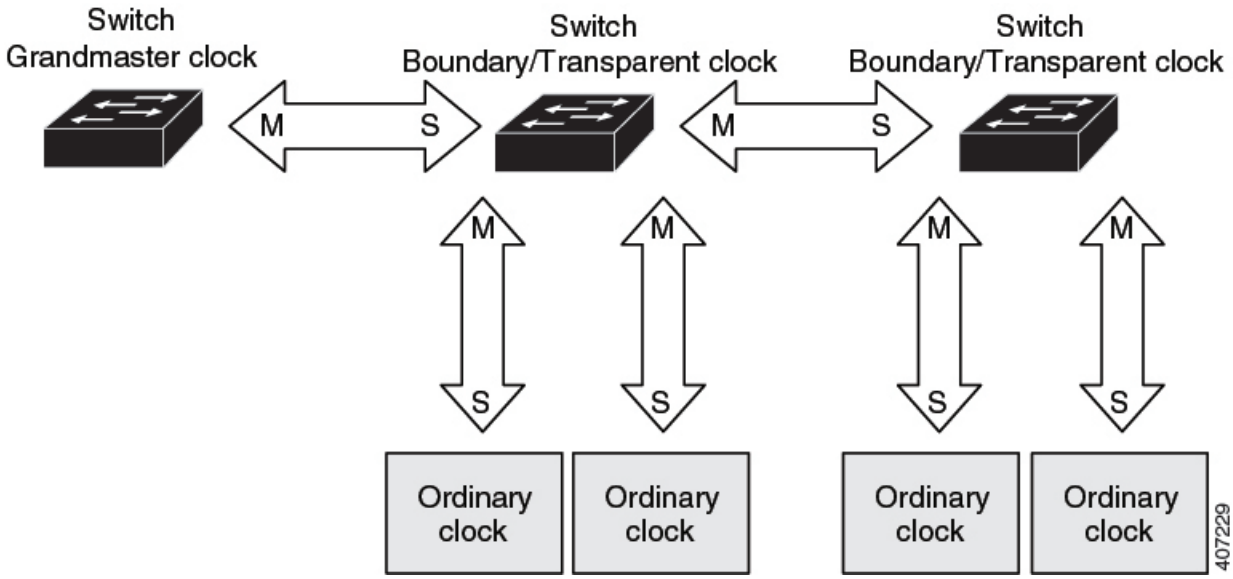
Transparent Clock

The role of transparent clocks in a PTP network is to update the time-interval field that is part of the PTP event message. This update compensates for switch delay and has an accuracy of within one picosecond.

There are two types of transparent clocks:

End-to-end (E2E) transparent clocks measure the PTP event message transit time (also known as *resident time)* for SYNC and DELAY_REQUEST messages. This measured transit time is added to a data field (correction field) in the corresponding messages:

- The measured transit time of a SYNC message is added to the correction field of the corresponding SYNC or the FOLLOW_UP message.
- The measured transit time of a DELAY_REQUEST message is added to the correction field of the corresponding DELAY_RESPONSE message.



The time recipient uses this information when determining the offset between the time recipient's and the time source's time. E2E transparent clocks do not provide correction for the propagation delay of the link itself.

Peer-to-peer (P2P) transparent clocks measure PTP event message transit time in the same way E2E transparent clocks do, as described above. In addition, P2P transparent clocks measure the upstream link delay. The upstream link delay is the estimated packet propagation delay between the upstream neighbor P2P transparent clock and the P2P transparent clock under consideration.

These two times (message transit time and upstream link delay time) are both added to the correction field of the PTP event message, and the correction field of the message received by the time recipient contains the sum of all link delays. In theory, this is the total end-to-end delay (from time source to time recipient) of the SYNC packet.

The following figure illustrates PTP clocks in a time source-time recipient hierarchy within a PTP network.

Figure 162: PTP Clock Hierarchy

Note In the preceding illustration, *M* signifies master port, and *S* signifies nonmaster, or subordinate port.

Clock Configuration

- All PHY PTP clocks are synchronized to the grandmaster clock. The switch system clock is not synchronized as part of PTP configuration and processes.
- When VLAN is enabled on the grandmaster clock, it must be in the same VLAN as the native VLAN of the PTP port on the switch.
- Grandmaster clocks can drop untagged PTP messages when a VLAN is configured on the grandmaster clock. To force the switch to send tagged packets to the grandmaster clock, enter the global **vlan dot1q tag native** command.

PTP Profiles

This section describes the following PTP profiles available on the switch:

- Default Profile
- Power Profile

Power Profile-2011 is supported as defined in PC37.238-2011 - IEEE Draft Standard Profile for Use of IEEE 1588 Precision Time Protocol in Power System Applications. This documentation uses the terms Power Profile mode and Default Profile mode when referring to this IEEE 1588 profile and its associated configuration values.

Two Power Profiles are supported: Power Profile-2011 and Power Profile-2017. Power Profile-2017 is defined in IEEE Standard C37.238™-2017 (Revision of IEEE Std C37.238-2011) for use of IEEE 1588 Precision Time Protocol in Power System Applications.

This documentation uses the terms Power Profile mode and Default Profile mode when referring to this IEEE 1588 profile and its associated configuration values. The IEEE 1588 definition of a PTP profile is *the set of allowed PTP features applicable to a device*. A PTP profile is usually specific to a particular type of application or environment and defines the following values:

- Best master clock algorithm options
- Configuration management options
- Path delay mechanisms (peer delay or delay request-response)
- Range and default values of all PTP configurable attributes and data set members
- Transport mechanisms that are required, permitted, or prohibited
- Node types that are required, permitted, or prohibited
- Options that are required, permitted, or prohibited

Default Profile Mode

The default PTP profile mode on the switch is Default Profile mode. In this mode:

- Supports transparent clock, boundary clock, grandmaster boundary clock, and PTP forward mode (PTP passthrough) on the default profile.
- Ordinary clocks are not supported.

Power Profile Mode

The IEEE Power Profile defines specific or allowed values for PTP networks used in power substations. The defined values include the optimum physical layer, the higher-level protocol for PTP messages, and the preferred best master clock algorithm. The Power Profile values ensure consistent and reliable network time distribution within substations, between substations, and across wide geographic areas.

The following table lists the configuration values defined by the IEEE 1588 Power Profile and the values that the switch uses for each PTP profile mode.

Table 186: Configuration Values for the IEEE PTP Power Profile and Switch Modes

PTP Field	Switch Configuration Value	
	Power Profile Mode	**Default Profile Mode**
Message transmission	**Access ports**: Untagged Layer 2 packets. **Trunk ports**: PTP packets are tagged with the PTP VLAN. If the PTP VLAN is not configured, packets go untagged over the native VLAN.	Layer 3 packets. By default, 802.1q tagging is disabled.
MAC address– Nonpeer delay messages	01-00-5e-00-01-81.	Default profile uses L3 transport multicast address 224.0.1.129 for all PTP messages. Equivalent mac address is 01-00-5e-00-01-81.
MAC address– Peer delay messages	01-80-C2-00-00-0E.	Not applicable to this mode.
Domain number	0.	0.
Path delay calculation	Peer-to-peer transparent clocks using the peer_delay mechanism.	End-to-end transparent clocks using the delay_request mechanism.
BMCA	Enabled.	Enabled.
Clock type	Two-step.	Two-step.
Time scale	Epoch.	Epoch.
Grandmaster ID and local time determination	PTP-specific TLV to indicate Grandmaster ID.	PTP-specific type, length, and value to indicate Grandmaster ID.
Time accuracy over network hops	Over 16 hops, end device synchronization accuracy is within 1 usec (1 microsecond).	Not applicable in this mode.

PTP Profile Comparison

Table 187: Comparison of PTP Profiles on IE Switches

Profile	Default (*)	Power Profile-2011	Power Profile-2017
Standard	IEEE1588 v2 (J.3)	IEEE C37.238-2011	IEEE C37.238-2017

Profile	Default (*)		Power Profile-2011		Power Profile-2017
Mode	Boundary	End-to-End transparent	Boundary	Peer-to-Peer transparent	Peer-to-Peer transparent
Path Delay	Delay req/res	Delay req/res	Peer delay req/res	Peer delay req/res	Peer delay req/res
Non-PTP device allowed in PTP domain	Yes	Yes	No	No	No
Transport	UDP over IP (multicast)		L2 Multicast		L2 Multicast

* Delay Request-Response Default PTP profile (as defined in IEEE1588 J.3).

Tagging Behavior of PTP Packets

The following table describes the switch tagging behavior in Power Profile and Default Profile modes.

Table 188: Tagging Behavior for PTP Packets

Switch Port Mode	Configuration	Power Profile Mode		Default Profile Mode	
		Behavior	Priority	Behavior	Priority
Trunk Port	**vlan dot1q tag native** enabled	Switch tags packets	7	Switch tags packets	7
Trunk Port	**vlan dot1q tag native** disabled	PTP software tags packets	4	Untagged	None
Access Port	N/A	Untagged	None	Untagged	None

Configurable Boundary Clock Synchronization Algorithm

You can configure the BC synchronization algorithm to accommodate various PTP use cases, depending on whether you need to prioritize filtering of input time errors or faster convergence. A PTP algorithm that filters packet delay variation (PDV) converges more slowly than a PTP algorithm that does not.

By default, the BC uses a linear feedback controller (that is, a servo) to set the BC's time output to the next clock. The linear servo provides a small amount of PDV filtering and converges in an average amount of time. For improved convergence time, BCs can use the TC feedforward algorithm to measure the delay added by the network elements forwarding plane (the disturbance) and use that measured delay to control the time output.

While the feedforward BC dramatically speeds up the boundary clock, the feedforward BC does not filter any PDV. The adaptive PDV filter provides high-quality time synchronization in the presence of PDV over wireless access points (APs) and enterprise switches that do not support PTP and that add significant PDV.

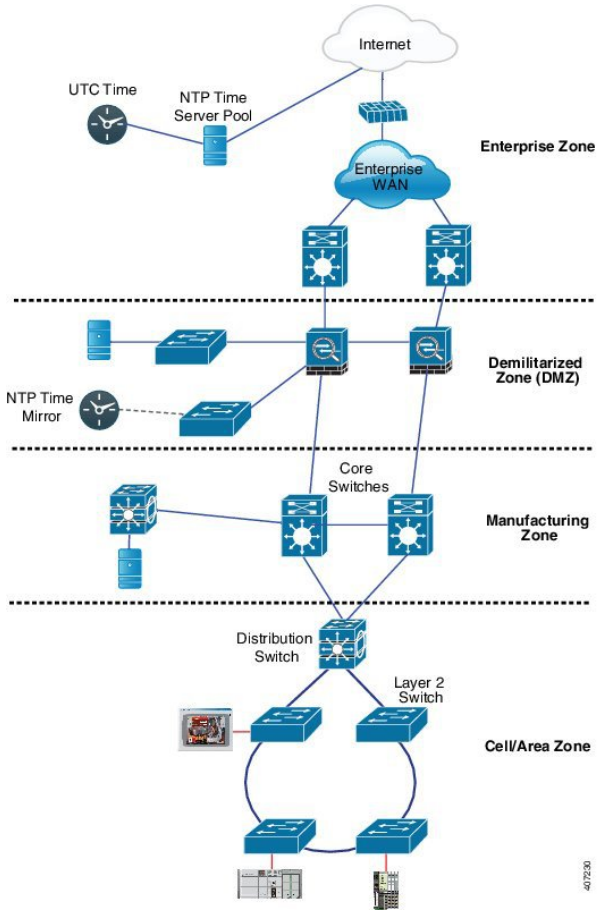
Three options are available for BC synchronization (all are compliant with IEEE 1588-2008):

- Feedforward: For very fast and accurate convergence; no PDV filtering.
- Adaptive: Filters as much PDV as possible, given a set of assumptions about the PDV characteristics, the hardware configuration, and the environmental conditions.

Note With the adaptive filter, the switch does not meet the time performance requirements specified in ITU-T G.8261.

- Linear: Provides simple linear filtering (the default).

Adaptive mode (**ptp transfer filter adaptive**) is not available in Power Profile mode.



NTP to PTP Time Conversion

NTP to PTP Time Conversion allows you to use Network Time Protocol (NTP) as a time source for PTP. Customers who use PTP for precise synchronization within a site can use NTP across sites, where precise synchronization is not required.

NTP is the traditional method of synchronizing clocks across packet-based networks. NTP uses a two-way time transfer mechanism, between a time source and an end device. NTP is capable of synchronizing a device within a few 100 milliseconds across the Internet, and within a few milliseconds in a tightly controlled LAN. The ability to use NTP as a time source for PTP allows customers to correlate data generated in their PTP network with data in their enterprise data centers running NTP.

The following figure shows an example of an industrial network based on the Industrial Automation and Control System Reference Model. The enterprise zone and demilitarized zone run NTP, and the manufacturing zone and cell/area zone run PTP with NTP as the time source. The switch with the NTP to PTP conversion feature can be either the Layer 2 Switch or the Distribution Switch in the Cell/Area Zone.

Figure 163: Industrial Network with NTP and PTP

Note The NTP to PTP feature supports the Default E2E Profile and Power Profile.

Clock Manager

The clock manager is the component in the Cisco NTP to PTP software architecture that tracks the various time services and selects the clock that actively provides time. The clock manager notifies the time services of important changes, such as state changes, leap seconds, or daylight saving time.

The clock manager selects the NTP or manually set clock first, followed by PTP and the real-time clock if NTP is not active. The following table shows the results of the clock selection process.

Table 189: Time Service Selection

NTP (Active) or Manually Set	PTP (Active)	Real-Time Clock	Selected Output
True	Don’t care	Don’t care	NTP or Manually Set

NTP (Active) or Manually Set	PTP (Active)	Real-Time Clock	Selected Output
False	True	Don’t care	PTP
False	False	True	Real-Time Clock

In general, the clock manager ensures that the time displayed in the Cisco IOS commands **show ptp clock** and **show clock** match. The **show clock** command always follows this priority, but there are two corner cases where the **show ptp clock** time may differ:

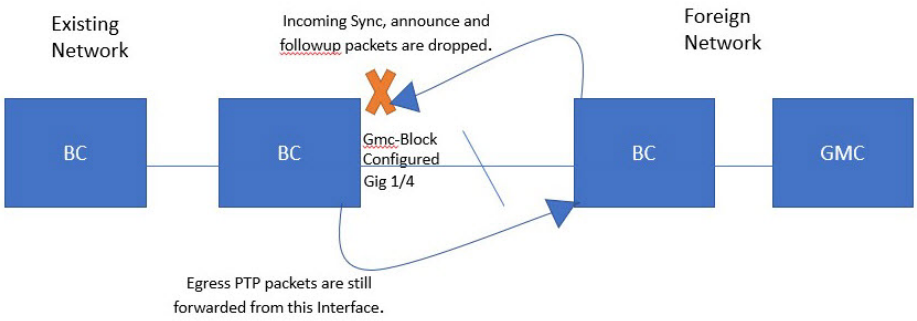
- The switch is either a TC or a BC, and there is no other active reference on the network. To preserve backwards compatibility, the TC and BC never take their time from the clock manager, only from the network PTP GMC. If there is no active PTP GMC, then the time displayed in the **show clock** and the **show ptp clock** command output may differ.
- The switch is a synchronizing TC, a BC with a subordinate port, or a GMC-BC with subordinate port, and the time provided by the PTP GMC does not match the time provided by NTP or the user (that is, manually set). In this case, the PTP clock must forward the time from the PTP GMC. If the PTP clock does not follow the PTP GMC, then the PTP network ends up with two different time bases, which would break any control loops or sequence of event applications using PTP.

The following table shows how the Cisco IOS and PTP clocks behave given the various configurations. Most of the time, the two clocks match. Occasionally, the two clocks are different; those configurations are highlighted in the table.

Table 190: Expected Time Flow

IOS Clock Configuration	PTP Clock Configuration	IOS Clock Source	PTP Clock Source
Calendar	PTP BC, E2E TC, or GMC-BC in BC Mode	PTP	PTP
Manual	PTP BC, E2E TC, or GMC-BC in BC Mode	Manual	PTP
NTP	PTP BC, E2E TC, or GMC-BC in BC Mode	NTP	PTP
Calendar	GMC-BC in GM Mode	Calendar	Calendar
Manual	GMC-BC in GM Mode	Manual	Manual
NTP	GMC-BC in GM Mode	NTP	NTP

GMC Block



GMC Block protects an existing network from any rogue GMC that might try to synchronize with the devices inside the network. This feature is supported for all PTP clock modes except Forward mode. After the feature is enabled on an interface, only the egress Announce, Sync, and Followup PTP packets are allowed and all ingress Announce, Sync, and Followup packets are dropped on this interface. This prevents the port state transition to time recipient.

Information about a rogue GMC is retrieved from the packets before dropping them. However, egress PTP packets are still allowed from this interface, so it can act as a GMC. To identify the rogue device, details such as IP address and clock ID are stored and displayed for the interface. Two Syslog messages are also generated to notify the presence and clearance of rogue devices.

You can configure PTP gmc-block on multiple ports, if you suspect multiple foreign networks are connected to your existing system. Per-port Syslog messages are displayed after an interval of 30 seconds of receiving rogue packets and after 180 -240 seconds when packets stop coming. Relay minor alarms and SNMP traps are also generated to notify of the presence of foreign rogue devices.

Packet Flow with GMC Block

The following figure shows an example of a PTP network topology with the GMC Block feature configured on an interface.

PTP packets originate in the GMC of the foreign network in an attempt to sync with the existing network. When the PTP packets reach the port configured with GMC Block, the packets are dropped after the system retrieves the required information from them.

Because packets from the foreign network are restricted, the system syncs with the local GMC present in the existing system. PTP packets originated on the port configured with GMC Block are still allowed to egress from this interface, which allows devices in the existing network to be GMC.

Guidelines and Limitations

This section lists the guidelines and limitations when using PTP.

General PTP Guidelines

- The Cisco PTP implementation supports only two-step clock operation in BC mode; one-step clock in not supported.
- In transparent clock mode, the switch converts any one-step Sync message received from the grandmaster clock into a two-step message.
- Cisco PTP supports multicast PTP messages only.
- Cisco PTP supports only PTP version2.
- Power Profile-2017 supports only transparent clock mode.

PTP Mode and Profile

- The switch and the grandmaster clock must be in the same PTP domain.

- When Power Profile mode is enabled, the switch drops the PTP announce messages that do not include these two Types, Length, Value (TLV) message extensions: *Organization_extension* and *Alternate_timescale*.

  If the grandmaster clock is not compliant with PTP and sends announce messages without these TLVs, configure the switch to process the announce message by entering the following command:

  ```
  ptp clock boundary domain 1 profile power
  allow-without-tlv
  ```

- When the switch is in Power Profile mode, only the peer_delay mechanism is supported.

  To enable power profile boundary mode and associate interfaces using the clock-port suboption, enter the following command:

  ```
  ptp clock boundary domain 1 profile power
  clock-port 1
  transport ethernet multicast interface gi1/1
  ```

- To disable power profile transparent mode, enter the following command, which returns the switch to forward mode.

  ```
  no ptp clock transparent domain x profile power
  ```

- To enable the E2E transparent clock, use the following command:

  ```
  ptp clock transparent domain x profile default
  ```

- In Default Profile mode, only the delay_request mechanism is supported.

  To enable default profile boundary clock mode and interfaces associated with clock-port suboption, enter the following command:

  ```
  ptp clock boundary domain 1 profile default
  clock-port 1
  transport ipv4 multicast interface gi1/1
  ```

Packet Format

- The packet format for PTP messages can be 802.1q tagged packets or untagged packets.
- The switch does not support 802.1q QinQ tunneling of PTP packets.
- In Power Profile mode:
  - When the PTP interface is configured as an access port, PTP messages are sent as untagged, Layer 2 packets.
  - When the PTP interface is configured as a trunk port, two cases are possible:
    - When native VLAN is enabled on the interface, PTP packets go untagged over the native VLAN.
    - When PTP VLAN is configured under the clock-port, PTP packets are tagged with the PTP VLAN configured.
- Time recipient IEDs must support tagged and untagged packets.
- When PTP packets are sent on the native VLAN in E2E Transparent Clock Mode, they are sent as untagged packets. To configure the switch to send them as tagged packets, enter the global **vlan dot1q tag native** command.

NTP to PTP Conversion

The NTP to PTP feature supports the Default E2E Profile and Power Profile.

PTP Interaction with Other Features

- PTP over Media Redundancy Protocol (MRP) is not supported.
- PTP over Port Channels is not supported.
- PTP over Cisco Resilient Ethernet Protocol (REP) is not supported.
- The following PTP clock modes only operate on a single VLAN:
  - e2etransparent
  - p2ptransparent

Default Settings

- PTP is enabled on the switch by default.
- By default, the switch uses configuration values defined in the Default Profile (Default Profile mode is enabled).
- The switch default PTP clock mode is E2E Transparent Clock Mode.
- The default BC synchronization algorithm is linear filter.

VLAN Configuration

This section contains information about VLAN configuration.

- Sets the PTP VLAN on a trunk port. The range is from 1 to 4094. The default is the native VLAN of the trunk port.
- In boundary mode, only PTP packets in PTP VLAN are processed; PTP packets from other VLANs are dropped.
- Before configuring the PTP VLAN on an interface, the PTP VLAN must be created and allowed on the trunk port.
- Most grandmaster clocks use the default VLAN 0. In Power Profile mode, the switch default VLAN is VLAN 1 and VLAN 0 is reserved. When you change the default grandmaster clock VLAN, it must be changed to a VLAN other than 0.
- When VLAN is disabled on the grandmaster clock, the PTP interface must be configured as an access port.

Configuring GMC Mode

The following sections provide steps for configuring GMC mode for default and power profiles:

- Configuring GMC Mode for a Default Profile, on page 2525
- Configure GMC Mode for a Power Profile, on page 2525

Configuring GMC Mode for a Default Profile

Complete the steps in this section to configure GMC mode for a default profile.

Procedure

	Command or Action	Purpose
Step 1	**ptp clock boundary domain** *domain number* **profile default** **Example:** `switch(config)# ptp clock boundary domain 0 profile default`	Enable the default profile boundary mode.
Step 2	**gmc default** **Example:** `switch(config-ptp-clk)# gmc default`	Enable the GMC boundary clock.
Step 3	**clock-port** *port name* **Example:** `switch(config-ptp-clk)# clock-port port1`	Define a new clock port.
Step 4	**transport ipv4 multicast** *interface type interface number* **Example:** `switch(config-ptp-port)# transport ipv4 multicast interface Gi1/1`	Specify the transport mechanism for clocking traffic.

Configure GMC Mode for a Power Profile

Complete the steps in this section to configure GMC mode for a power profile.

Procedure

	Command or Action	Purpose
Step 1	**ptp clock boundary domain** *domain number* **profile power**	Enable the power profile boundary mode.

	Command or Action	Purpose
	Example: `switch(config)# ptp clock boundary domain 0 profile power`	
Step 2	**gmc default** **Example:** `switch(config-ptp-clk)# gmc default`	Enable the GMC boundary clock.
Step 3	**clock-port** *port name* **Example:** `switchswitch(config-ptp-clk)# clock-port port1`	Defines a new clock port.
Step 4	**transport ethernet multicast** *interface type interface number* **Example:** `switch(config-ptp-port)# transport ethernet multicast interface gi1/1`	Specifies the transport mechanism for clocking traffic.

Configuring PTP Default Profile

This section describes how to configure the switch to operate in Default Profile mode.

Configure a Boundary Clock

If an interface is not added as part of BC clock, it will be in forward mode exchanging PTP packets, which will cause instability in PTP operation. To avoid this, it is recommended to disable PTP on all such interfaces using the **no ptp enable** command.

Follow these steps to configure the switch as a boundary clock:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `switch> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `switch# configure terminal`	Enters configuration mode.
Step 3	**ptp clock boundary domain** *domain-number* **profile default**	This step configures the boundary type PTP clock, which terminates the PTP session from

	Command or Action	Purpose
	Example: `switch(config)# ptp clock boundary domain 0  profile default`	the grandmaster clock and acts as a PTP server or client clock downstream.
Step 4	**clock-port** *port-name* **Example:** `switch(config-ptp-clk)# clock-port dyn1`	Defines a new clock port.
Step 5	**transport ipv4 multicast interface** *interface-type interface-number* **Example:** `switch(config-ptp-port)# transport ipv4 multicast interface Gi1/1`	Specifies the transport mechanism for clocking traffic.
Step 6	(Optional) **vlan** *vlan-id* **Example:** `config-ptp-port)# vlan 100`	Configure VLAN for tagged packets.

Example

Example of Untagged

```
ptp clock boundary domain 0  profile default
 clock-port dyn1
  transport ipv4 multicast interface Gi1/1
 clock-port dyn2
  transport ipv4 multicast interface Gi1/1
```

Example of Tagged

```
ptp clock boundary domain 0  profile default
 clock-port dyn1
  transport ipv4 multicast interface Gi1/1
  vlan 100
 clock-port dyn2
  transport ipv4 multicast interface Gi1/1
  vlan 200
```

Configure a Transparent Clock

All interfaces will be part of TC mode once configured.

Follow these steps to configure the switch as a transparent clock.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:**	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
	`switch> enable`	
Step 2	**configure terminal** **Example:** `switch# configure terminal`	Enters configuration mode.
Step 3	**ptp clock transparent domain** *domain-number* **profile default** **Example:** `switch(config)# ptp clock transparent domain 0  profile default`	This step configures the transparent type PTP clock, which updates the PTP time correction field to account for the delay in forwarding the traffic.
Step 4	(Optional) **vlan** *vlan-id* **Example:** `(config-ptp-clk)# vlan 100`	Configure VLAN for tagged packets.

Example

Example of Untagged

```
ptp clock transparent domain 0  profile default
```

Example of Tagged

```
ptp clock transparent domain 0  profile default
vlan 100
```

Configuring a PTP Power Profile

This section describes how to configure the switch to use the PTP Power Profile.

The Power Profile defines a subset of PTP which is intended to run over layer 2 networks, that is, Ethernet, but no Internet Protocol.

Note Power Profile-2017 is supported only in Transparent Clock mode.

Configure a Boundary Clock

If an interface is not added as part of BC clock, it is in forward mode exchanging PTP packets, which causes instability in PTP operation. To avoid this, disable PTP on all such interfaces using the **no ptp enable** command.

Follow these steps to configure the switch as a boundary clock:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `switch> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `switch# configure terminal`	Enters configuration mode.
Step 3	**ptp clock boundary domain** *domain-number* **profile power** **Example:** `switch(config)# ptp clock boundary domain 0 profile default`	This step configures the boundary type PTP clock, which stops the PTP session from the grandmaster clock and acts as a PTP server or client clock downstream.
Step 4	**clock-port** *port-name* **Example:** `switch(config-ptp-clk)# clock-port dyn1`	Defines a new clock port.
Step 5	**transport ethernet multicast interface** *interface-type interface-number* **Example:** `switch(config-ptp-port)# transport ethernet multicast interface Gi1/1`	Specifies the transport mechanism for clocking traffic.
Step 6	(Optional) **vlan** *vlan-id* **Example:** `(config-ptp-port)# vlan 100`	Configure VLAN for tagged packets.

Example

Example of Untagged

```
ptp clock boundary domain 0  profile power
 clock-port dyn1
  transport ethernet multicast interface Gi1/1
 clock-port dyn2
  transport ethernet multicast interface Gi1/2
```

Example of Tagged

```
ptp clock boundary domain 0  profile power
 clock-port dyn1
  transport ethernet multicast interface Gi1/1
  vlan 100
 clock-port dyn2
  transport ethernet multicast interface Gi1/2
  vlan 100
```

Example of not Including TLV Extensions

```
ptp clock boundary domain 0 profile power
allow-without-tlv
```

Configure a Transparent Clock

Follow these steps to configure the switch as a transparent clock.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `switch> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `switch# configure terminal`	Enters configuration mode.
Step 3	**ptp clock transparent domain** *domain-number* **profile power** **Example:** `switch(config)# ptp clock transparent domain 0  profile power`	This step configures the transparent type PTP clock, which updates the PTP time correction field to account for the delay in forwarding the traffic.
Step 4	(Optional) **vlan** *vlan-id* **Example:** `(config-ptp-clk)# vlan 100`	Configure VLAN for tagged packets.

Example

Example of Untagged

```
ptp clock transparent domain 0 profile power
```

Example of Tagged

```
ptp clock transparent domain 0 profile power
vlan 100
```

Example of not Including TLV Extensions: Power Profile-2011

```
ptp clock transparent domain 0 profile power
allow-without-tlv
```

Example of not Including TLV Extensions: Power Profile-2017

```
ptp clock transparent domain 0 profile power-2017
allow-without-tlv
```

Enable PTP Forward Mode

Complete the steps in this section to enable PTP forward mode.

To enable PTP forward mode, and remove existing PTP clock configurations, you remove the existing PTP clock. When you do so, all interfaces automatically become part of forward mode.

Note Forward mode supports only the default profile.

Procedure

	Command or Action	Purpose
Step 1	**ptp clock boundary domain** *domain-number* **profile default** **Example:** `switch(config)# ptp clock boundary domain 0 profile default`	Configure the boundary type PTP clock. Doing so terminates the PTP session from the grandmaster clock and acts as a PTP server or client clock downstream.
Step 2	**clock-port** *port-name* **Example:** `switch(config)# clock-port 1`	Define a new clock port.
Step 3	**transport ipv4 multicast interface** *interface-type interface-number* **Example:** `switch(config-ptp-port)# transport ipv4 multicast interface Gi1/1`	Specifies the transport mechanism for clocking traffic.
Step 4	**exit**	Enters global configuration mode.
Step 5	**no ptp clock boundary domain** *domain-number* **profile default** **Example:** `switch(config)# no ptp clock boundary domain 0 profile default`	Remove the PTP clock configuration.
Step 6	**end**	Exit global configuration mode and returns to privileged EXEC mode.

Remove PTP Forward Mode

Complete the steps in this section to remove PTP forward mode.

To remove forward PTP forward mode configuration, you enable a PTP clock.

Note Forward mode supports only the default profile.

Procedure

Step 1 **no ptp clock**

Configure a clock to get out of forward mode.

Step 2 **ptp clock boundary domain** *domain-number* **profile default**

Example:

```
switch(config)# ptp clock boundary domain 0 profile default
```

Configure the boundary type PTP clock. Doing so terminates the PTP session from the grandmaster clock and acts as a PTP server or client clock downstream.

Step 3 **end**

Exit global configuration mode and returns to privileged EXEC mode.

Disable PTP

Complete the steps in this section to disable PTP on an interface.

Note The following procedure applies to both default and power modes.

Procedure

	Command or Action	Purpose
Step 1	**interface** *interface-id* **Example:** `switch(config)# interface gi1/1`	Enter interface configuration mode.
Step 2	**no ptp enable**	Disable PTP on the interface.

Enable GMC Block in Boundary Mode

Complete the steps in this section to enable GMC Block in boundary mode.

Procedure

	Command or Action	Purpose
Step 1	**ptp clock boundary domain** *domain number* **profile default** **Example:** `switch(config)# ptp clock boundary domain 0 profile default`	Configure the boundary type PTP clock, which terminates the PTP session from the grandmaster clock and acts as a PTP server or client clock downstream.
Step 2	**clock-port** *port-name* **Example:** `switch(config-ptp-clk)# clock-port 1`	Define a new clock port.
Step 3	**transport ipv4 multicast interface** *interface type interface number* **Example:** `switch(config-ptp-port)# transport ipv4 multicast interface Gi1/1`	
Step 4	**gmc-block** **Example:** `switch(config-ptp-port)# gmc-block`	Enable GMC Block.

Enable GMC Block in Transparent Mode

Complete the steps in this section to enable GMC Block in transparent mode.

Procedure

	Command or Action	Purpose
Step 1	**ptp clock transparent domain** *domain number* **profile power** **Example:** `switch(config)# ptp clock transparent domain 0 profile power`	This step configures the transparent type PTP clock, which updates the PTP time correction field to account for the delay in forwarding the traffic. The transparent clock can update some fields in the PTP packets to ensure that the client has greater time accuracy.
Step 2	**gmc-block** *interface* **Example:** `switch(config-ptp-clk)# gmc-block gi1/1`	Enable GMC Block.

PTP Alarms

PTP alarms can help you manage and monitor PTP on the switch. You can configure the PTP alarms to trigger the external alarm relay output and send system messages to a syslog server. The PTP alarms are raised only once for the first 5-minute interval and subsequently once every 30 minutes. PTP alarms are disabled by default.

The following sequence describes how PTP alarm timing works:

1. PTP alarm monitoring starts 5 minutes after bootup.
2. The PTP alarm is raised only once for the first 5-minute interval and subsequently once for an interval of 30 minutes.
3. The alarms are damped when there is continuous state change, for example, PTP port state flapping or PTP parent flapping.

The following table describes the types of PTP alarms:

Table 191: PTP Alarms

Alarm	Alarm Type	Clock Mode Supported	Description
PTP SLAVE port state change	Minor	Boundary and transparent clock modes	This alarm is raised when the PTP port state changes from "SLAVE" to any of the following PTP port states: Initializing, Faulty, Disabled, Listening, Pre_Master, Master, Passive, or Uncalibrated. A system message is generated when the PTP port state transitions between Slave and Passive Slave. This alarm remains raised until you clear the alarm.

Alarm	Alarm Type	Clock Mode Supported	Description
PTP PASSIVE_SLAVE port state change	Minor	Boundary and transparent clock modes	This alarm is raised when the PTP port state changes from "PASSIVE-SLAVE" to any of the following PTP port states: Initializing, Faulty, Disabled, Listening, Pre_Master, Master, Passive, or Uncalibrated. A system message is generated when the PTP port state transitions between Slave and Passive Slave.
PTP Parent change	Minor	Boundary clock mode	This alarm raised when there is a change in PTP parent. This alarm remains raised until you clear the alarm.
PTP Time Property Clock Synchronized	Minor	Transparent clock mode	This alarm is raised when the PTP Clock Time Property "Clock Syntonized" field changes from TRUE to FALSE. This alarm is cleared when the "Clock Syntonized" field changes from FALSE to TRUE.

Configuring PTP Alarms

To enable and configure the global PTP alarms:

Procedure

Step 1 Enter global configuration mode:

configure terminal

Step 2 Enable PTP alarms:

alarm facility ptp enable

Step 3 Enable notifications to be sent to an SNMP server:

alarm facility ptp notifies

Step 4 Associate the PTP alarms to a relay.

alarm facility ptp relay major

Step 5 Send PTP alarm traps to a syslog server.

alarm facility ptp syslog

Example

```
Switch#configure terminal
Switch(config)#alarm facility ptp enable
Switch(config)#alarm facility ptp syslog
Switch(config)#end
Switch#show alarm settings
…..
…..
…..
PTP
     Alarm     Enabled
     Relay     MIN
     Notifies  Enabled
     Syslog    Enabled
Switch#show facility-alarm status
Source                  Severity Description                          Relay    Time
Switch                  MINOR    32 PTP Clock Parent change           NONE     Mar 09 2022
 01:23:45
GigabitEthernet1/1    MINOR    5 PTP SLAVE port state changed      NONE     Mar 09 2022
01:23:45
```

PTP over MACsec

Precision Time Protocol (PTP) over MACsec is a network timing feature that

- allows PTP messages to be transmitted and received over encrypted MACsec links,
- ensures accurate time synchronization even when traffic is secured by MACsec encryption, and
- provides robust, standards-based timing for industrial and enterprise networks with high-security requirements.

This capability allows devices to maintain precise timing across secure Ethernet connections, supporting applications where both security and clock synchronization are critical.

MACsec encrypts the network traffic. When the network receives PTP packets, timestamp cannot be identified until after they are decrypted. This decryption process introduces variable delays that change timing precision. To solve this, packet timestamps are handled directly in the hardware before MACsec encrypts for both ingress and egress traffic. MACsec encrypts the entire packet while essential timing metadata is preserved.

Ingress timestamp

When the network receives a PTP packet, a precise hardware timestamp is captured at the physical port, before any other processing. The device securely carries this timestamp with the PTP packet and attaches it after decryption to ensure that encryption does not affect timing accuracy.

Egress timestamp

Outgoing PTP packets are flagged with a special signature that instructs the hardware to add a timestamp. The hardware then applies a precise departure timestamp as the packet leaves the port. This guarantees timing accuracy.

Limitations of PTP over MACsec

PTP over MACsec supports:

- IEEE 1588v2 default, C37.238-2011, and C37.238-2017 power profiles.
- Default PTP profile for boundary clock (BC) mode, End-to-End (E2E), GMC-BC mode, and Transparent Clock (TC)
- Power profile for boundary clock (BC) mode, peer-to-peer (P2P) mode, GMC-BC mode with forward mode, and transparent clock (TC) with less than 50 ns time inaccuracy in transparent clock mode.
- All types of MACsec (pre-shared key or certificate-based).
- 100 Mbps, 1 Gbps, and 10 Gbps interface speeds, but not 2.5 Gbps (mGig) interface speed.
- Simple Network Management Protocol (SNMP).

PTP over MACsec configuration on interfaces does not support Parallel Redundancy Protocol (PRP), High-availability Seamless Redundancy (HSR), Resilient Ethernet Protocol (REP), Device Level Ring (DLR), Media Redundancy Protocol (MRP), or port-channels.

Ensure that both PTP and MACsec are enabled and operational on the same interface.

Configure PTP over MACsec

Enable and verify PTP operation over encrypted MACsec links to maintain accurate time synchronization with secure traffic.

Use this task when you require both PTP timing and MACsec encryption on the same interface, for example, in secure industrial or utility networks.

Before you begin

- Ensure your MACsec and PTP licenses (if required) are active. For information on licenses, see Data Sheet

Perform these steps to configure PTP over MACsec.

Procedure

Step 1 Enable MACsec. To enable MACsec on the desired interfaces refer to How to Configure MACsec Encryption section of chapter Configuring MACsec Encryption.

Step 2 Configure PTP. To configure PTP globally and on the same interface(s), see the *Precision Time Protocol* chapter from the *Cisco IE3500 Series Switch Software Configuration Guide*.

Step 3 Verify PTP configuration. see the *Verifying the Configuration* chapter from the*Cisco IE3500 Series Switch Software Configuration Guide*.

Step 4 (Optional) Use the **show macsec interface GigabitEthernet***1/1* command to verify that encryption is active.

Example:

```
Switch# show macsec interface GigabitEthernet 1/1

MACsec is enabled

SNMP Support for PTP MIBs

SNMP management information bases (MIBs) for Precision Time Protocol (PTP) is supported. These include CISCO-PTP-MIB. The feature enables you to get PTP-related information from a switch remotely.

The MIB is supported with boundary clock and transparent clock modes. It is supported in both the default and power profiles.

SNMP is an application-layer protocol that provides a message format for communication between SNMP managers and agents. SNMP provides a standardized framework and a common language used for monitoring and managing devices in a network. An SNMP networks includes the following components:

- **SNMP Manager:** A system that controls and monitors the activities of network hosts using SNMP. The most common managing system is a network management system (NMS). The term An can be a dedicated device used for network management or the applications used on such a device.
- **SNMP Agent:** The software component within a managed device that maintains the data for the device and reports this data, as needed, to managing systems. The agent resides on the switch. To enable an SNMP agent on a Cisco switch, you must define the relationship between the manager and the agent.
- **SNMP MIB**: An SNMP agent contains MIB variables. The SNMP manager can request information from an agent to store information in the agent. The agent gathers data from the SNMP MIB, the repository for information about device parameters and network data. The agent can also respond to manager requests to get or set data.

Note

- PTP over REP is not supported.

SNMP MIBs Supported with PTP Modes

This section lists the SNMP MIBs supported in different PTP modes.

The following MIBs are supported when the switch is configured with PTP boundary clock mode:

MIB	OID
cPtpClockNodeTable	1.3.6.1.4.1.9.9.760.1.1.3
cPtpClockCurrentDSTable	1.3.6.1.4.1.9.9.760.1.2.1
cPtpClockParentDSTable	1.3.6.1.4.1.9.9.760.1.2.2
cPtpClockDefaultDSTable	1.3.6.1.4.1.9.9.760.1.2.3
cPtpClockTimePropertiesDSTable	1.3.6.1.4.1.9.9.760.1.2.5
cPtpClockPortTable	1.3.6.1.4.1.9.9.760.1.2.7
cPtpClockPortRunningTable	1.3.6.1.4.1.9.9.760.1.2.9

The following MIBs are supported when the switch is configured with PTP transparent clock mode:

MIB	OID
cPtpClockNodeTable	1.3.6.1.4.1.9.9.760.1.1.3
cPtpClockParentDSTable	1.3.6.1.4.1.9.9.760.1.2.2

MIB	OID
cPtpClockDefaultDSTable	1.3.6.1.4.1.9.9.760.1.2.3
cPtpClockPortTable	1.3.6.1.4.1.9.9.760.1.2.7
cPtpClockPortRunningTable	1.3.6.1.4.1.9.9.760.1.2.9
cPtpClockSystemTimePropertiesTable	1.3.6.1.4.1.9.9.760.1.2.12

Prerequisites for Configuring SNMP PTP MIBs

Before you configure SNMP PTP MIBs, you should be familiar with the PTP protocol and configurations.

You should also be familiar with the Cisco SNMP Object Navigator, which translates an object identifier (OID) into object name or an object name into OID, enabling you to receive PTP object details. OIDs identify manged objects in an MIB.

Verifying the Configuration

PTP Configuration

You can use the following commands to verify the PTP configuration:

- show ptp clock dataset parent
- show ptp clock dataset current
- show ptp clock dataset time-properties
- show ptp clock dataset default
- show ptp clock running
- show ptp port dataset port
- show ptp lan clock
- show ptp lan port counters messages
- show ptp lan port counters errors
- show ptp lan foreign-master-record
- show ptp lan rogue-master-record
- show ptp lan histogram ?

  delay—Show PTP histogram of mean path delay

  offset—Show PTP histogram of offset

  time-error—Show PTP history of time error (last 15 days)

- show ptp lan history ?

  delay—Show PTP history of mean path delay (last 15 days)

offset—Show PTP history of offset (last 15 days)

time-error—Show PTP history of time error (last 15 days)

Default Profile Configuration

The following example shows the Default profile configuration:

```
Default profile MASTER

```

Troubleshooting PTP

This section contains instructions for troubleshooting PTP by checking if the Transparent Clock is receiving messages from the Grandmaster Clock, verifying packet message and error counters, and running debug commands.

Verify that the Transparent Clock is Syntonized

You might want to verify that the Transparent Clock is syntonized to the Grand Master Clock—that is, that the Transparent Clock is logged to the Grand Master Clock. You might want to verify syntonization because the `show ptp clock running` command does not appy to the Transparent Clock. Subordinate clocks in the PTP network do not synchronize with the Grand Master Clock if the Transparent Clock is not syntonized.

Procedure

Verify that the Transparent Clock is syntonized.

Example:

```
switch(config-ptp-port)# sh ptp clock dataset time-properties
Clock Syntonized: TRUE
```

The command output is `TRUE` if the Transparent Clock is syntonized and `FALSE` if it is not. You also can check counters to see if PTP messages are being received.

Verify PTP Messages

You can verify whether messages are being received from the Grandmaster Clock.

Procedure

Verify PTP LAN port packet message.

Example:

```
switch# show ptp lan port counters messages

GigabitEthernet1/1

    Transmit                          Receive
    250    Announce                   0    Announce
    248    Sync                       0    Sync
    248    Follow_Up                  0    Follow_Up
     0     Delay_Req                  0    Delay_Req
     0     Delay_Resp                 0    Delay_Resp
    251    Pdelay_Req                251   Pdelay_Req
    251    Pdelay_Resp               251   Pdelay_Resp
    251    Pdelay_Resp_Follow_Up     251   Pdelay_Resp_Follow_Up
     0     Signaling                  0    Signaling
     0     Management                 0    Management
```

The preceding example shows that all the packets are being received.

The output of the command would vary, depending on which packets are not received. The following example shows output if follow-ups are not received.

```
GigabitEthernet1/1

Transmit Receive
0 Announce 1359 Announce
0 Sync 1359 Sync
0 Follow_Up 0 Follow_Up <<<
0 Delay_Req 0 Delay_Req
0 Delay_Resp 0 Delay_Resp
1362 Pdelay_Req 1359 Pdelay_Req
1359 Pdelay_Resp 1360 Pdelay_Resp
1359 Pdelay_Resp_Follow_Up 1360 Pdelay_Resp_Follow_Up
0 Signaling 0 Signaling
0 Management 0 Management
```

Note
You can use the following command to reset the counters: **`clear ptp all all-clocks`**

Verify PTP Error Counters

You can verify whether the error counters are continously incrementing, indicating that messages from the Grandmaster Clock aren't being received.

Procedure

Verify PTP LAN port

Example:

```
switch# show ptp lan port counters errors

GigabitEthernet1/1

     0   Sanity check failed      0   Blocked port
     0   Timestamp get failed     0   ParentId invalid
     0   Vlan mismatch            0   Gmcld invalid
     0   Domain mismatch          0   SequenceId invalid
     0   Sync fault               0   Unmatched Follow_Up
     0   Duplicate Sync           0   Unmatched Delay_Resp
     0   Duplicate Announce       0   Unmatched Pdelay_Resp
     0   Send error               0   Unmatched Pdelay_Resp_Follow_Up
     0   Misc error               0   Rogue master Sync
     0   Rogue master Follow-Up   0   Rogue master Announce
```

The preceding example shows that no error counters are being incremented.

The following example shows how errors increment when the VLAN in the ingress PTP message is different from the PTP VLAN used on the port.

```
switch# sh ptp lan port counters errors | beg 1/1
GigabitEthernet1/1

0 Sanity check failed 0 Blocked port
0 Timestamp get failed 0 ParentId invalid
1482 Vlan mismatch 0 GmcId invalid
0 Domain mismatch 0 SequenceId invalid
0 Sync fault 0 Unmatched Follow_Up
0 Duplicate Sync 0 Unmatched Delay_Resp
0 Duplicate Announce 0 Unmatched Pdelay_Resp
0 Send error 0 Unmatched Pdelay_Resp_Follow_Up
0 Misc error 0 Rogue master Sync
0 Rogue master Follow_Up 0 Ro
```

Note
You can use the following command to reset the counters: **`clear ptp all all-clocks`**

Debugging Commands

The debugging feature collects logs that can be analyzed to resolve any issues on the switch. You can enable debugging on the switch, which logs debugging lists to a file on the switch or to a boot device.

Note

- We recommend that you save the debugging information to a boot device rather than to an internal file.

  Make sure that you have enough space on the boot device for the debugging logs.

- Enable debugging only when you are troubleshooting and disable debugging when you finish. Disabling debugging when not troubleshooting reduces CPU overhead.

Enabling Debugging

Enter both of the following commands to enable debugging on the switch:

- `switch# set platform software trace timingd switch active R0 iot-ptp debug`
- `switch# set platform software trace timingd switch active R0 timingd debug`

Note When you use the preceding commands, debugging information is not printed on the screen and will be logged to an internal file. You cannot access the file directly, but you can store the debugging information to a boot device, which you can access.

Storing Debugging Information on a Boot Device

Use the following command to store the debugging information in the internal file to a boot device:

Note You can give the debug file any name you choose. The following example uses `timing-logs` as the filename.

```
Switch# show log process timingd internal to-file bootflash:timing-logs
```

When you use the preceding command, the debugging information is printed on the screen in addition to being saved to the boot device.

Checking Debugging

Enter both of the following commands to see if debugging information is being collected:

```
switch#sh platform software trace level timingd switch active R0  | inc iot-ptp
iot-ptp                         Debug
```

```
switch#sh platform software trace level timingd switch active R0  | inc timingd
timingd                         Debug
```

Disabling Debugging

Enter both of the following commands to disable debugging on the switch:

- `switch# set platform software trace timingd switch active R0 iot-ptp notice`
- `switch# set platform software trace timingd switch active R0 timingd notice`

Feature History

Table 192: Feature history

Feature Name	Releases	Description
PTP over MACsec	Cisco IOS XE 26.1.1	This feature allows highly accurate time synchronization between devices, even when MACsec encrypts Ethernet traffic for security. This ensures industrial, utility, or automation networks can maintain precise timing and robust data protection on the same infrastructure.

CHAPTER 176

NTP Timing Based on PTP Clock

- PTP as a Reference Clock for NTP, on page 2551
- Enabling PTP as a Reference Clock for NTP, on page 2551
- Validate the PTP Reference Clock, on page 2552
- Troubleshooting PTP as an NTP Reference Clock, on page 2553

PTP as a Reference Clock for NTP

You can configure Precision Timing Protocol (PTP) time as the reference clock for Network Time Protocol (NTP).

PTP time acts as a stratum 0 source, and the Cisco IOS NTP server acts as a stratum 1 device. The server then provides clock information to its NTP clients (strata 2 and 3).

A Network Essentials or Network Advantage license is required.

Enabling PTP as a Reference Clock for NTP

The PTP reference clock feature is disabled by default. You enable it by entering a CLI command.

Before you begin

- Configure PTP and ensure that it is in slave mode.

  See the chapter *Precision Time Protocol* in this guide for configuration instructions.

Procedure

To enable PTP as a reference clock for NTP, enter the following command:**ntp refclock ptp**.

You disable the PTP reference clock feature by entering the following command: **no ntp refclock ptp**.

What to do next

Validate the PTP reference clock feature on the switch. See *Validate the PTP Reference Clock*.

Validate the PTP Reference Clock

After you enable PTP as the reference clock for NTP, you can enter CLI commands to validate the configuration.

Procedure

Step 1 Check that the PTP reference clock configuration is correct and that the feature is running.

Example:

```
#show run | sec ptp|ntp
ntp refclock ptp
ptp clock boundary domain 0  profile power
 clock-port 1
  transport ethernet multicast interface Gi1/1
```

Step 2 Check that PTP is in slave mode; that is PTP is in phase aligned state, which means it is locked to a master clock.

Example:

```
#sh ptp clock running
                      PTP Boundary Clock [Domain 0]  [Profile: power]
         State          Ports          Pkts sent      Pkts rcvd      Redundancy Mode
         PHASE_ALIGNED  1              629978         633            Hot standby
                                PORT SUMMARY
                                                                          PTP Master
Name  Tx Mode      Role         Transport    State         Sessions     Port Addr
1     mcast        negotiated   Ethernet     Slave         1            UNKNOWN
```

Step 3 Check that NTP is using PTP. as its reference clock.

Example:

```
#show ntp status
Clock is synchronized, stratum 1, reference is .PTP.
nominal freq is 250.0000 Hz, actual freq is 249.9998 Hz, precision is 2**10
ntp uptime is 28233900 (1/100 of seconds), resolution is 4016
reference time is E6161FA8.FFBE7988 (08:26:16.999 UTC Fri Apr 29 2022)
clock offset is 0.9998 msec, root delay is 0.00 msec
root dispersion is 3940.49 msec, peer dispersion is 3938.47 msec
loopfilter state is 'CTRL' (Normal Controlled Loop), drift is 0.000000856 s/s
system poll interval is 64, last update was 4 sec ago.
```

Troubleshooting PTP as an NTP Reference Clock

Checking PTP-NTP Synchronization

You can check the time on the PTP and NTP cocks to ensure that they are synchronized, as shown in the following example.

```
#show ptp lan clock | inc time
 Local clock time: 2022-4-29 8:48:39 UTC
#
#show clock detail
08:48:39.278 UTC Fri Apr 29 2022
Time source is NTP
#
```

Troubleshooting Commands

Table 193:

Command	Description
`ntp logging`	Enables syslogs from NTP.
`debug ntp all`	Provides the complete debugging logs for NTP processes.
`debug platform software pd-ptp all`	Provides debugging logs on the switch relating to PTP as a reference clock.
`show ntp status`	Shows detailed NTP status, including whether NTP is using PTP as its reference clock.
`show ntp association detail`	Shows detailed information about NTP peering.
`show ptp clock running`	Check that PTP is in slave mode; that is PTP is in phase aligned state, which means it is locked to a master clock.

Viewing Peering Details

The command output shows detailed information about NTP peering. You can use the command to check the amount of time the platform takes to switch to the next available timing source after the initial timing source goes down. In the following example, NTP waits 8x256 seconds to switch over to the next source .

```
#show ntp assoc deta
127.127.6.1 configured, ipv4, our_master, sane, valid, stratum 0
ref ID .PTP., time E61622E9.00000000 (08:40:09.000 UTC Fri Apr 29 2022)
our mode active, peer mode passive, our poll intvl 256, peer poll intvl 1024
root delay 0.00 msec, root disp 0.00, reach 377, sync dist 4.62
delay 0.00 msec, offset 0.9998 msec, dispersion 2.81, jitter 0.97 msec
precision 2**10, version 4
assoc id 63756, assoc name 127.127.6.1
assoc in packets 11, assoc out packets 17652, assoc error packets 0
org time E61622E8.FFBE7988 (08:40:08.999 UTC Fri Apr 29 2022)
rec time 00000000.00000000 (00:00:00.000 UTC Mon Jan 1 1900)
```

```
xmt time E61622E8.FFBE7988 (08:40:08.999 UTC Fri Apr 29 2022)
filtdelay =     0.00    0.00    0.00    0.00    0.00    0.00    0.00    0.00
filtoffset =    0.99    1.99    0.99    0.99    0.99    0.99    1.99    0.99
filterror =     0.97    2.89    4.81    6.73    8.65   10.57   11.53   12.49
minpoll = 4, maxpoll = 10
```

CHAPTER 177

MODBUS

- MODBUS Protocol, on page 2555
- MODBUS TCP Registers, on page 2555
- Interpreting the Port State Value, on page 2585
- Configure MODBUS, on page 2585
- Displaying MODBUS Commands, on page 2587

MODBUS Protocol

Modicon Communication Bus (MODBUS) is an application layer protocol for client-server communication between a switch (server) and a device in the network running MODBUS client software (client). You can use MODBUS over a serial line to connect a computer to a remote terminal unit (RTU) in supervisory control and data acquisition (SCADA) systems.

MODBUS also runs on Ethernet TCP/IP networks. Use MODBUS TCP over an Ethernet network when connecting the switch to devices such as intelligent electronic devices (IEDs), distributed controllers, substation routers, IP phones, Wireless Access Points, and other network devices such as redundant substation switches.

The client can be an IED or a human machine interface (HMI) application that remotely configures and manages devices running MODBUS TCP. The switch functions as the server.

The switch encapsulates a request or response message in a MODBUS TCP application data unit (ADU). A client sends a message to a TCP port on the switch.

MODBUS TCP Registers

This document lists the read-only registers for switches. MODBUS clients use them to communicate with a MODBUS server (the switch). There are no writable registers.

System Information Registers

Address spaces 0x0800 through 0x0FFF are system information read-only registers. These 2048 registers are accessible by MODBUS function code 0x03 `Read Multiple Registers`.

Table 194: System Information Registers

Address	Number of Registers	Description	R/W	Format	Value
0x0800	64	Product ID	R	Text	
0x0840	64	Software image name	R	Text	
0x0880	64	Software image version	R	Text	
0x08C0	64	Host Name	R	Text	
0x0900	1	Number of Gigabit Ethernet ports	R	Uint 16	
0x0901	1	Number of 10 Gigabit Ethernet ports	R	Uint 16	
0x0902	1	Number of mgig Ethernet ports	R	Uint 16	
0x0903	1	Number of power supplies	R	Uint 16	
0x0904	1	Power supply 1 status	R	Uint 16	0 – Not present 1 – Present
0x0905	1	Power supply 2 status	R	Uint 16	0 – Not present 1 – Present
0x0906	1	System or sensor ID 0 temperature	R	Uint 16	
0x0907	1	Alarm 1 – Description	R	Uint 16

0x0987	1	Number of Alarms	R	Uint 16	
0x0988	1	Alarm 1 Status	R	Uint 16	0 – Alarm off 1 – Alarm on
0x0989	2	Alarm 2 Status	R	Uint 16	0 – Alarm off 1 – Alarm on

Address	Number of Registers	Description	R/W	Format	Value
0x098A	64	Alarm 3 Description	R	Text	
0x09CA	64	Alarm 4 Description	R	Text	
0x0A0A	1	Alarm 3 Status	R	Uint16	0 – Alarm off 1 – Alarm on
0x0A0B	1	Alarm 4 Status	R	Uint16	0 – Alarm off 1 – Alarm on

Port Information Registers

Address spaces 0x1000 through 0x3FFF are port information read-only registers. These 12,000 registers are accessible by MODBUS function code 0x03 `Read Multiple Registers`. They are updated every time upon receiving a read request to the register(s).

The following table shows the memory map for all interface registers, with 64-bit counters (Address space 0x1000 through 0x2FFF, 8,000 registers).

Table 195: 11 Port Registers

Address	Number of Registers	Description	R/W	Format

Interpreting the Port State Value

This section provides information for determining the port state.

In the following table, the upper byte repressents the interface state, and the lower byte represents the line protocol state.

Address	Description	Value
0x1700 to 0x171B	Port state information	Upper byte: • 0x0: Interface is down • 0x1: Interface is going down • 0x2: Interface is in the initializing state • 0x3: Interface is coming up • 0x4: Interface is up and running • 0x5: Interface is reset by the user • 0x6: Interface is shut down by the user • 0x7: Interface is being deleted
		The lower byte: • 0x0: Line protocol state is down • 0x1: Line protocol state is up

Configure MODBUS

The MODBUS TCP server listens for MODBUS client requests on TCP port 502 by default. Port 502 is enabled when MODBUS server is started unless you configure a different port for MODBUS communications. The MODBUS server is disabled by default.

Note MODBUS is supported only on standalone .

To configure MODBUS:

Before you begin

If a firewall or other security services are enabled, the switch TCP port might be blocked, and the switch and the client cannot communicate. If a firewall and other security services are disabled, a denial-of-service attack might occur on the switch. To add security when using MODBUS TCP, configure an ACL to permit traffic from specific clients or configure QoS to rate-limit traffic.

Procedure

Step 1 Enter global configuration mode:

configure terminal

Step 2 Enable MODBUS TCP on the switch:

scada modbus tcp server

To disable MODBUS on the switch and return to the default settings, enter the **no scada modbus tcp server** global configuration command.

The system displays a message to warn you that starting the MODBUS TCP server is a security risk:

WARNING: Starting Modbus TCP server is a security risk. Please understand the security issues involved before proceeding further. Do you still want to start the server? [yes/no]:

Step 3 Enter **yes** to confirm that you understand the security issues and to proceed with starting the server.

Step 4 (Optional) Set the TCP port to which clients send messages:

scada modbus tcp server port *tcp-port-number*

The range for *tcp-port-number* is 1 to 65535. The default is 502.

Step 5 (Optional) Set the number of simultaneous connection requests sent to the switch:

scada modbus tcp server connection *connection-requests*

The range for *connection-requests* is 1 to 5. The default is 1.

Step 6 Return to privileged EXEC mode:

end

Example

```
Switch# configure terminal
Switch(config)# scada modbus tcp server
WARNING: Starting Modbus TCP server is a security risk. Please understand the security
issues involved
before proceeding further. Do you still want to start the server? [yes/no]: y
Switch(config)# end
```

Displaying MODBUS Commands

Use the commands listed below to display information for MODBUS TCP.

Command	Purpose
show scada modbus tcp server	Displays the server information and statistics
show scada modbus tcp server connections	Shows information and statistics for each client connection
clear scada modbus tcp server statistics	Clears all the statistics for the Modbus server, including statistics for each client connection

The following is an example of the **show scada modbus tcp server** command and its output:

```
Switch# show scada modbus tcp server
Summary: enabled, running, process id 142
Conn Stats: listening on port 801, 4 max simultaneous connections
    0 current client connections
    0 total accepted connections, 0 accept connection errors
    0 closed connections, 0 close connection errors
Send Stats: 0 tcp msgs sent, 0 tcp bytes sent, 0 tcp errors
    0 responses sent, 0 exceptions sent, 0 send errors
Recv Stats: 0 tcp msgs received, 0 tcp bytes received, 0 tcp errors
    0 requests received, 0 receive errors
```

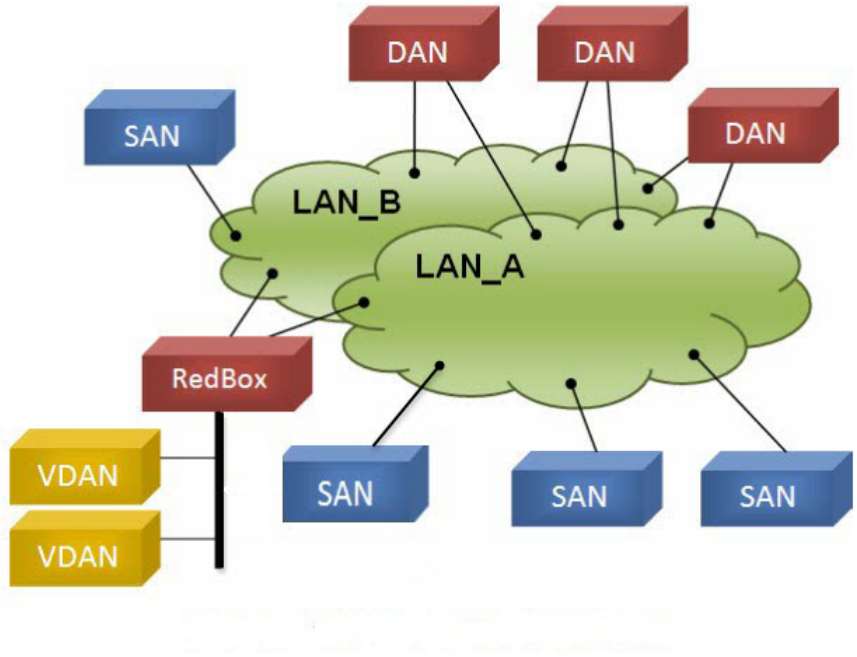
Information About PRP

From Release 17.17.1, the Cisco IE3505 Rugged Series Switches and IE3505 Heavy-Duty Series Switches supports Parallel Redundancy Protocol (PRP).

Parallel Redundancy Protocol overview

PRP is defined in the International Standard IEC 62439-3. PRP is designed to provide hitless redundancy (zero recovery time after failures) in Ethernet networks.

To recover from network failures, redundancy can be provided by network elements connected in mesh or ring topologies using protocols like RSTP, REP, or MRP, where a network failure causes some reconfiguration in the network to allow traffic to flow again (typically by opening a blocked port). These schemes for redundancy can take between a few milliseconds to a few seconds for the network to recover and traffic to flow again.



PRP uses a different scheme, where the end nodes implement redundancy (instead of network elements) by connecting two network interfaces to two independent, disjointed, parallel networks (LAN-A and LAN-B). Each of these Dually Attached Nodes (DANs) then have redundant paths to all other DANs in the network.

The DAN sends two packets simultaneously through its two network interfaces to the destination node. A redundancy control trailer (RCT), which includes a sequence number, is added to each frame to help the destination node distinguish between duplicate packets. When the destination DAN receives the first packet successfully, it removes the RCT and consumes the packet. If the second packet arrives successfully, it is discarded. If a failure occurs in one of the paths, traffic continues to flow over the other path uninterrupted, and zero recovery time is required.

Non-redundant endpoints in the network that attach only to either LAN-A or LAN-B are known as Singly Attached Nodes (SANs).

A Redundancy Box (RedBox) is used when an end node that does not have two network ports and does not implement PRP needs to implement redundancy. Such an end node can connect to a RedBox, which provides connectivity to the two different networks on behalf of the device. Because a node behind a RedBox appears for other nodes like a DAN, it is called a Virtual DAN (VDAN). The RedBox itself is a DAN and acts as a proxy on behalf of its VDANs.

Figure 164: PRP Redundant Network

To manage redundancy and check the presence of other DANs, a DAN periodically sends Supervision frames and can evaluate the Supervision frames sent by other DANs.

Switches that Support PRP

Table 199: The following Advanced base modules SKUs (PIDs) supports PRP.

Switch	PID
Cisco IE3505 Rugged Series Switch	IE-3505-8P3S
	IE-3505-8T3S

Switch	PID
Cisco IE3505 Heavy-Duty Series Switch	IE-3505H-16T

Table 200: The following Expansion modules PIDs include PRP support when installed on one of the above advanced base modules

Switch	Expansion modules PID
Cisco IE3505 Rugged Series Switch	IEM-3500-14T2S
	IEM-3500-6T2S
	IEM-3500-16P
	IEM-3500-16T
	IEM-3500-8P
	IEM-3500-8S
	IEM-3500-8T

Support for PRP is available on Network Essentials and Network Advantage licenses.

Supported PRP Features

IE-3505-8P3S, IE-3505-8T3S, and IE-3505H-16T switches support the following PRP features.

PRP supports maximum of two channel instance as shown in the following table:

Table 201: PRP Support for Cisco IE3505 Series Switch and Expansion Models

Switch	FPGA Profile	Number of PRP Instance
Cisco IE3505 Rugged Series without expansion module	Default	1
	Redundancy	2
Cisco IE3505 Rugged Series with expansion module	Default	1
	Redundancy	2
IE-3505H-16T	Default	1
	Redundancy	2

Role of the Switch

The switches implement RedBox functionality using Gigabit Ethernet port connections to each of the two LANs.

PRP Channels

PRP channel or channel group is a logical interface that aggregates two Gigabit Ethernet interfaces (access, trunk, or routed) into a single link. In the channel group, the lower numbered Gigabit Ethernet member port is the primary port and connects to LAN-A. The higher numbered port is the secondary port and connects to LAN-B.

The PRP channel remains up as long as at least one of these member ports remains up and sends traffic. When both member ports are down, the channel is down. The maximum number of supported PRP channel groups per switch is 2, depending on the configured FPGA profile. For information about FPGA profile, see Configure FPGA Profile, on page 2289.

The interfaces that you can use for each group on each switch series are fixed, as shown in the following table.

Table 202: The supported PRP channel interfaces for IE3505 Rugged Series Switch

PRP Channel Number	Module	Ports Interface
PRP Channel 1	Base module with SFP ports	GigabitEthernet1/1 and 1/2
PRP Channel 1	Base module with Copper (CU) ports	GigabitEthernet1/4 and 1/5
PRP Channel 2	Base module with CU ports	GigabitEthernet1/6 and 1/7
PRP Channel 2	8 port CU expansion module	GigabitEthernet2/1 and 2/2
PRP Channel 2	8 port SFP expansion module	GigabitEthernet2/1 and 2/2
PRP Channel 2	16 port CU expansion module	GigabitEthernet2/1 and 2/2
PRP Channel 2	8 port Mix expansion module	GigabitEthernet2/7 and 2/8
PRP Channel 2	16 port Mix expansion module	GigabitEthernet2/15 and 2/16

Table 203: The supported PRP channel interfaces for advanced IE3505 Heavy Duty Series Switch

PRP Channel Number	Module	
PRP Channel 1	Base module with CU ports	GigabitEthernet1/1 and 1/2
PRP Channel 1	Base module with CU ports	GigabitEthernet1/4 and 1/5
PRP Channel 2	Base module with CU ports	GigabitEthernet1/6 and 1/7

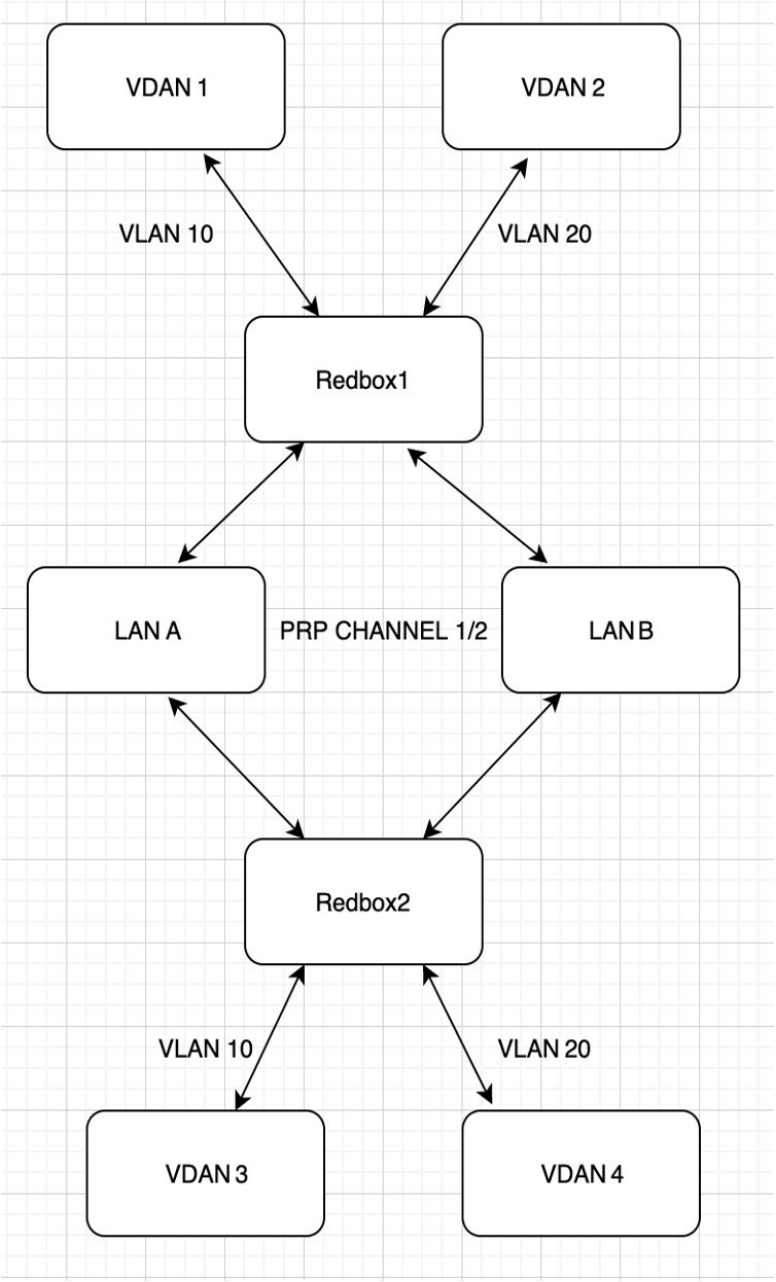
Mixed Traffic and Supervision Frames

Traffic egressing the RedBox PRP channel group can be mixed, that is, destined to either SANs (connected only on either LAN-A or LAN-B) or DANs. To avoid duplication of packets for SANs, the switch learns source MAC addresses from received supervision frames for DAN entries and source MAC addresses from non-PRP (regular traffic) frames for SAN entries and maintains these addresses in the node table. When forwarding packets out the PRP channel to SAN MAC addresses, the switch looks up the entry and determines which LAN to send to rather than duplicating the packet.

A RedBox with VDANs needs to send supervision frames on behalf of those VDANs. For traffic coming in on all other ports and going out PRP channel ports, the switch learns source MAC addresses, adds them to the VDAN table, and starts sending supervision frames for these addresses. Learned VDAN entries are subject to aging.

You can add static entries to the node and VDAN tables as described in x. You can also display the node and VDAN tables and clear entries. See y and z.

VLAN Tag in Supervision Frame



Switches support VLAN tagging for supervision frames. PRP VLAN tagging requires that PRP interfaces be configured in trunk mode. This feature allows you to specify a VLAN ID in the supervision frames for a PRP channel.

Note The IE3505 Series Switches support 512 VDAN/Node MAC addresses.

The PRP Supervision VLAN-aware feature is not supported in the IE3505 Series Switches.

For information on configuring the VLANs, see Configuring PRP Channel with Supervision Frame VLAN Tagging, on page 2614.

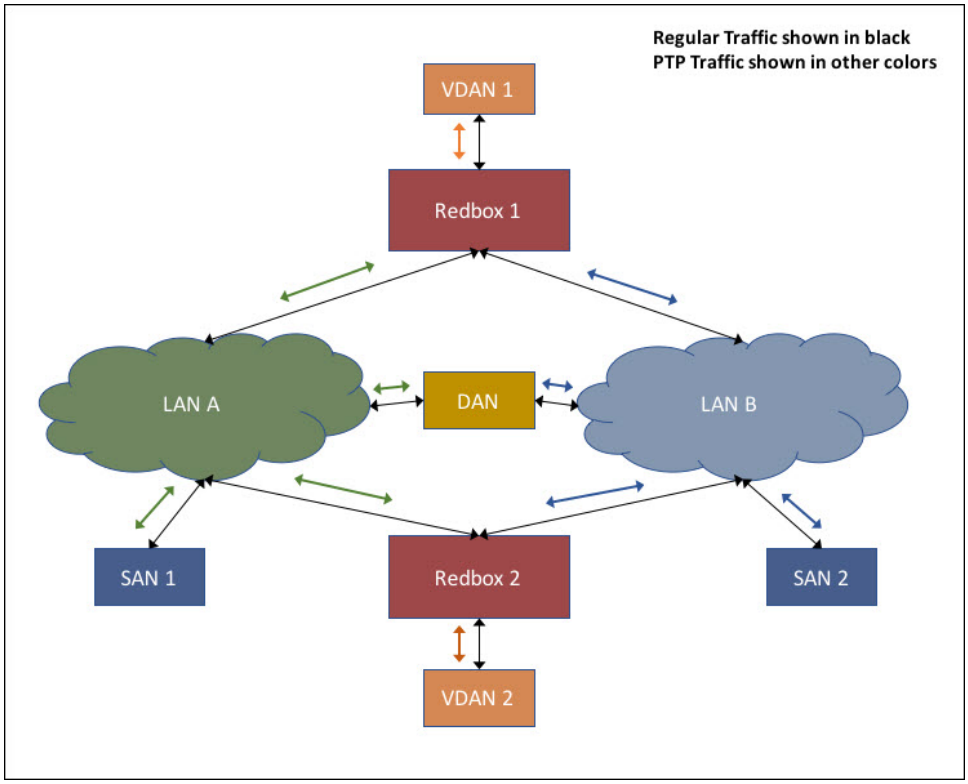
PTP over PRP

PRP provides high availability through redundancy for PTP. For a description of PTP, see *Precision Time Protocol*.

The PRP method of achieving redundancy by parallel transmission over two independent paths does not work for PTP as it does for other traffic. The delay that a frame experiences is not the same in the two LANs, and some frames are modified in the transparent clocks (TCs) while transiting through the LAN. A Dually Attached

Node (DAN) does not receive the same PTP message from both ports even when the source is the same. Specifically:

- Sync/Follow_Up messages are modified by TCs to adjust the correction field.
- Boundary Clocks (BCs) present in the LAN are not PRP-aware and generate their own Announce and Sync frames with no Redundancy Control Trailer (RCT) appended.
- Follow_Up frames are generated by every 2-step clock and carry no RCT.
- TCs are not PRP-aware and not obliged to forward the RCT, which is a message part that comes after the payload.



Before support of PTP over LAN-A and LAN-B, PTP traffic was allowed only on LAN-A to avoid the issues with PTP and parallel transmission described earlier. However, if LAN-A went down, PTP synchronization was lost. To enable PTP to leverage the benefit of redundancy offered by the underlying PRP infrastructure, PTP packets over PRP networks are handled differently than other types of traffic.

The implementation of the PTP over PRP feature is based on the PTP over PRP operation that is detailed in IEC 62439-3:2016, *Industrial communication networks - High availability automation networks - Part 3: Parallel Redundancy Protocol (PRP) and High-availability Seamless Redundancy (HSR)*. This approach overcomes the problems mentioned earlier by not appending an RCT to PTP packets and bypassing the PRP duplicate/discard logic for PTP packets.

PTP over PRP Packet Flow

The following figure illustrates the operation of PTP over PRP.

Figure 165: PTP over PRP Packet Flow

In the figure, VDAN 1 is the grandmaster clock (GMC). Dually attached devices receive PTP synchronization information over both their PRP ports. The LAN-A port and LAN-B port use a different virtual clock that is synchronized to the GMC. However, only one of the ports (referred to as time recipient) is used to synchronize the local clock (VDAN 2 in the figure). While the LAN-A port is the time recipient, the LAN-A port's virtual clock is used to synchronize VDAN-2. The other PRP port, LAN-B, is referred to as PASSIVE. The LAN-B port's virtual clock is still synchronized to the same GMC, but is not used to synchronize VDAN 2.

If LAN-A goes down, the LAN-B port takes over as the time recipient and is used to continue synchronizing the local clock on RedBox 2. VDAN 2 attached to RedBox 2 continues to receive PTP synchronization from RedBox 2 as before. Similarly, all DANs, VDANs, and RedBoxes shown in the figure continue to remain synchronized. For SANs, redundancy is not available, and in this example, SAN 1 loses synchronization if LAN-A goes down.

Due to the change, VDAN 2 may experience an instantaneous shift in its clock due to the offset between the LAN-A port's virtual clock and the LAN-B port's virtual clock. The magnitude of the shift should only be a few microseconds at the most, because both clocks are synchronized to the same GMC. The shift also occurs when the LAN-A port comes back as time recipient and the LAN-B port becomes PASSIVE.

Note Cisco is moving from the traditional Master/Slave nomenclature. In this document, the terms Grandmaster clock (GMC) or time source and time recipient are used instead, where possible. Exceptions may be present due to language that is hard-coded in the user interfaces of the product software, language used based on RFP documentation, or language that is used by a referenced third-party product.

Supported Location of GMC

The GMC can be located in a PTP over PRP topology as one of the following:

- A RedBox that is connected to both LAN A and LAN B (for example, RedBox 1 in the preceding diagram).
- A VDAN (for example, VDAN 1 in the preceding diagram).
- A DAN (for example, the DAN in the preceding diagram).

The GMC cannot be a SAN attached to LAN-A or LAN-B, because only the devices in LAN-A or LAN-B will be synchronized to the GMC.

Configuration

PTP over PRP does not require configuration beyond how you would normally configure PTP and PRP separately, and there is no user interface added for this feature. The difference is that before the PTP over PRP feature, PTP worked over LAN-A only; now it works over both LANs. Before implementing PTP over PRP, refer to Guidelines and Limitations.

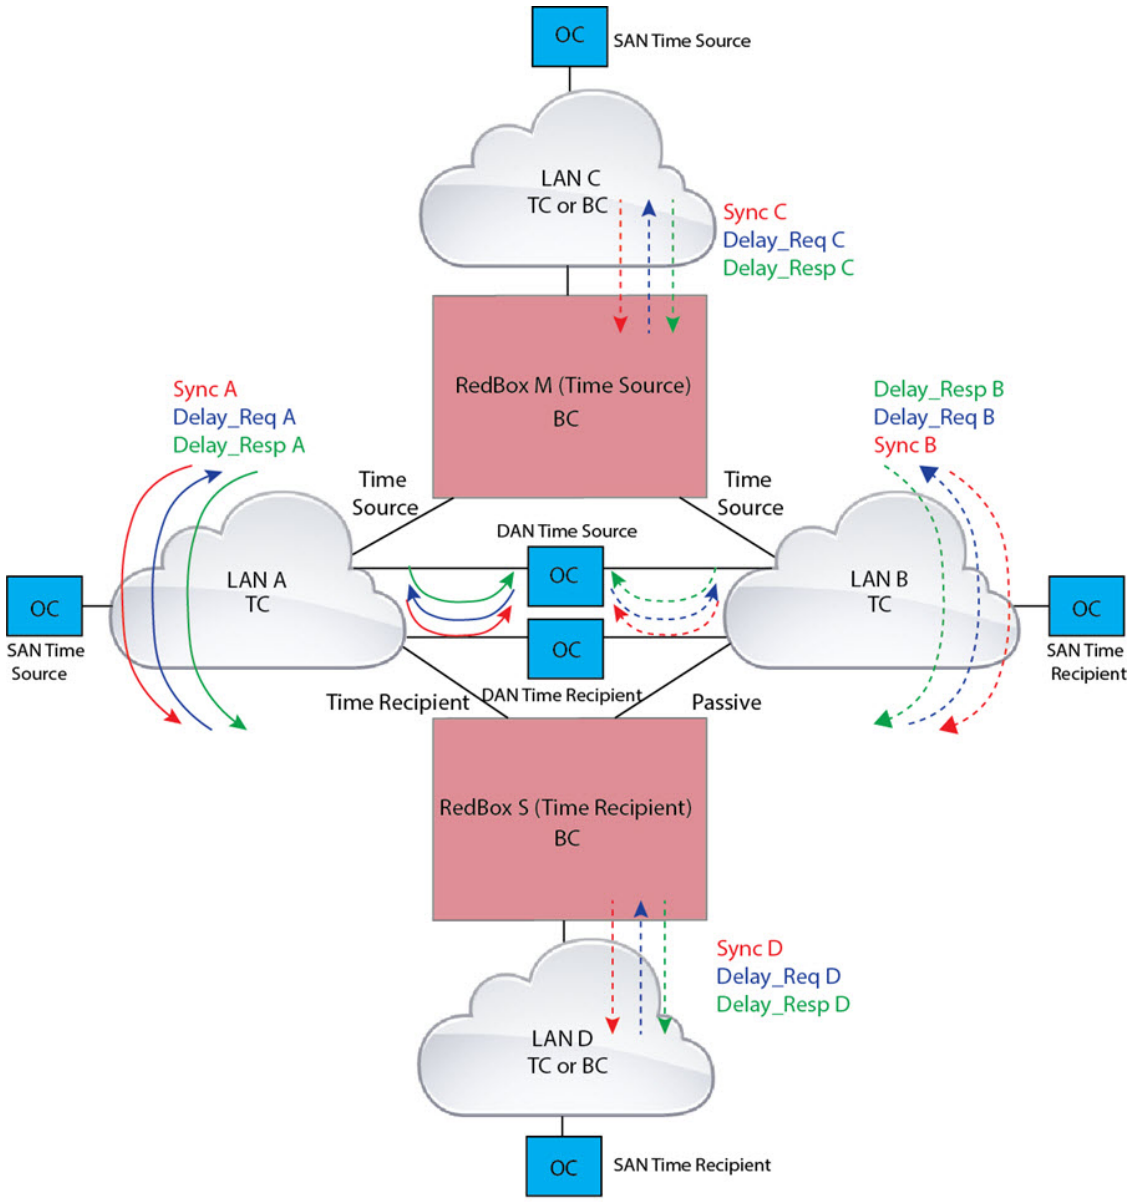
The high-level workflow to implement PTP over PRP in your network is as follows:

1. Refer to the section RedBox Types in this guide to determine the location of the PRP RedBox. Refer to *Precision Time Protocol* to determine the PTP mode and profile.
2. Configure PTP as described in *Precision Time Protocol* and follow the procedure for the PTP profile determined in step 1.
3. Configure PRP as described in Create a PRP Channel and Group.

Supported PTP Profiles and Clock Modes

The following table summarizes PTP over PRP support for the various PTP profiles and clock modes. In unsupported PTP profile/clock mode combinations, PTP traffic flows over LAN-A only. LAN-A is the lower numbered interface. See PRP Channels for PRP interface numbers.

PTP Profile	Clock Mode	Supported?	PRP RedBox type as per IEC 62439-3
End-to-End Delay Request-Response default profile	BC	Yes	PRP RedBox as doubly attached BC (DABC) with E2E
	E2E TC	No	PRP RedBox as doubly attached TC (DATC) with E2E
Power Profile	BC	Yes	PRP RedBox as doubly attached BC (DABC) with P2P
	P2P TC	Yes	PRP RedBox as doubly attached TC (DATC) with P2P



PRP RedBox Types

The switch plays the role of a RedBox in PRP networks. This section describes the types of PRP RedBoxes supported for PTP over PRP as defined in IEC 62439-3.

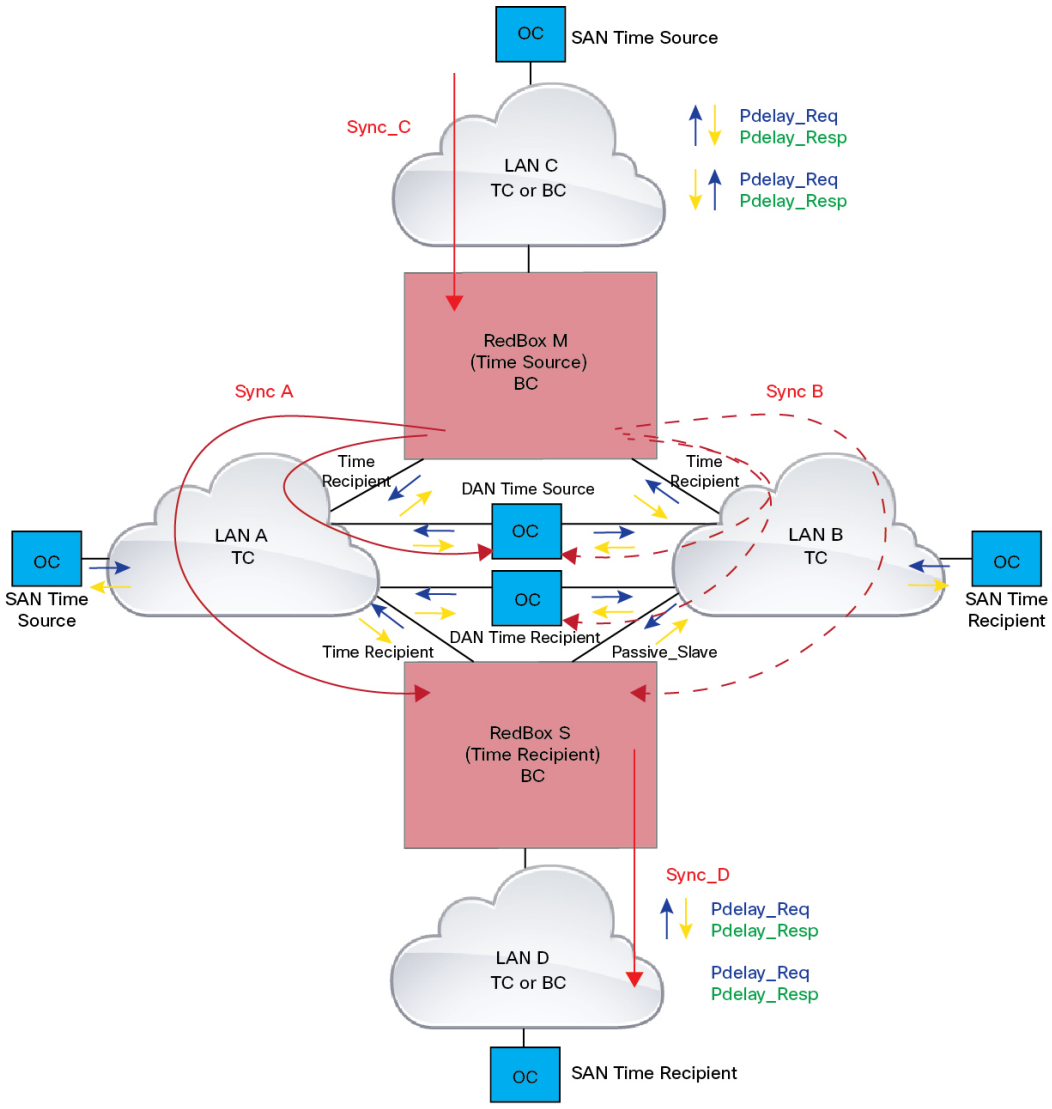
PRP RedBox as a Doubly Attached BC (DABC) with E2E

In the configuration shown below, two RedBoxes (for example, M and S) are configured as Boundary Clocks (BCs) that use the End-to-End delay measurement mechanism and IEEE1588v2 Default Profile. The Best Master Clock Algorithm (BMCA) on RedBox M determines port A and port B to be connected to the time source. The PTP protocol running on Redbox M treats both ports A and B individually as time source ports and sends out Sync and Follow_Up messages individually on both the ports.

Figure 166: PRP Redbox as DABC with E2E

On Redbox S, the regular BMCA operation determines port A to be a time recipient and port B to be PASSIVE. However, with the knowledge that ports A and B are part of the same PRP channel, port B is forced into PASSIVE_SLAVE state. Port A and Port B on Redbox S operate as follows:

- Port A works as a regular time recipient port. It uses the end-to-end delay measurement mechanism to calculate delay and offset from the time source. Using the calculated delay and offset, it synchronizes the local clock.
- Port B is in PASSIVE_SLAVE state. It uses the end-to-end delay measurement mechanism to calculate delay and offset from the time source.



It is passive in the sense that it maintains the calculated delay and offset, but does not perform any operation on the local clock. Having the delay and offset information readily available equips it to seamlessly change its role to time recipient if there is loss of connectivity to the time source on port A.

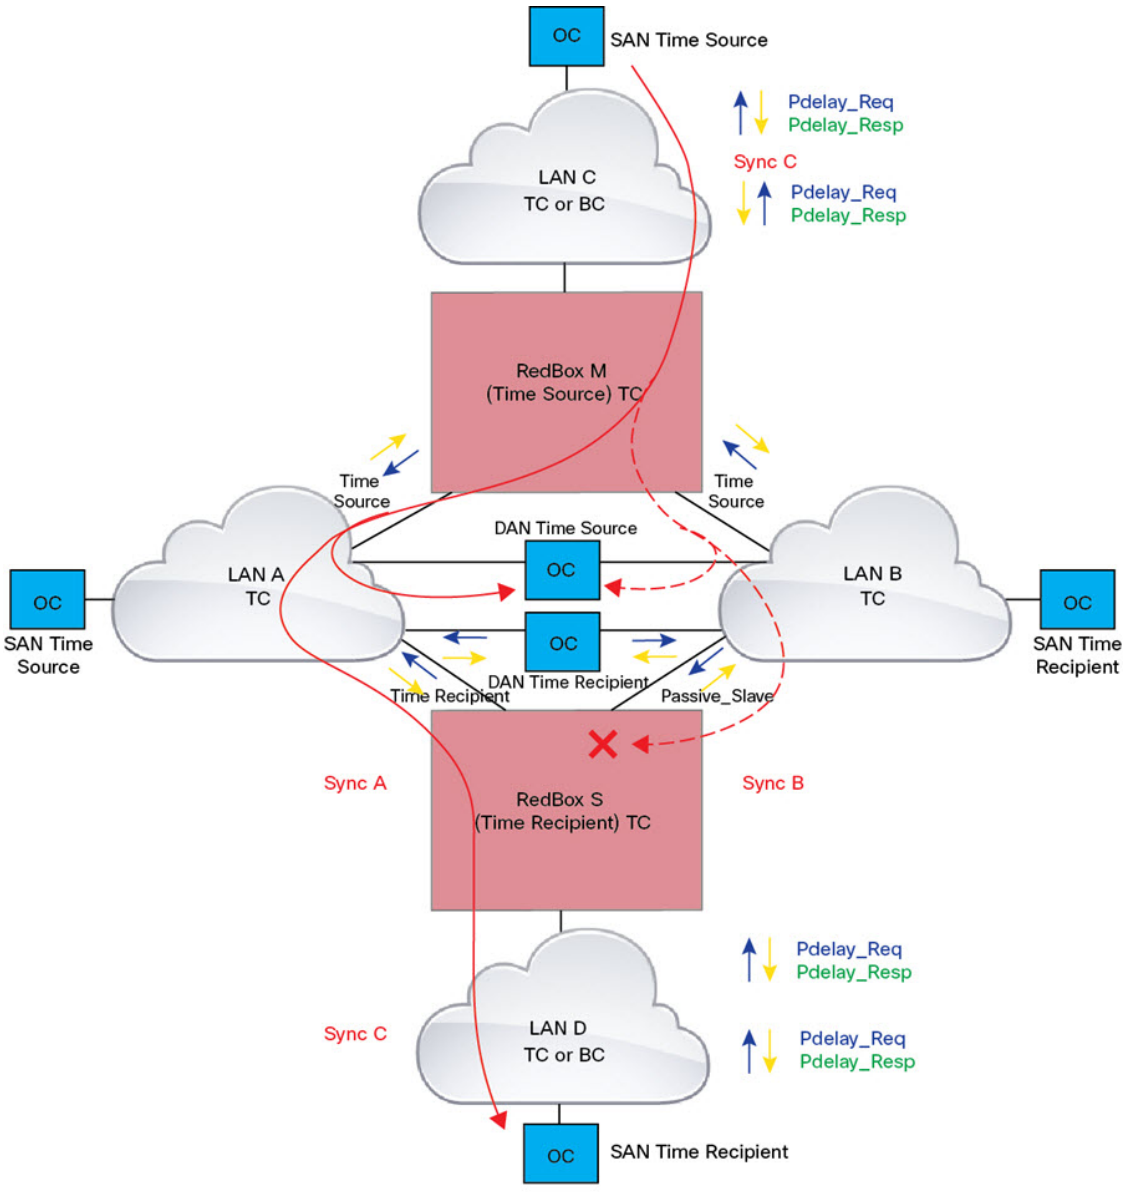
PRP RedBox as Doubly Attached BC (DABC) with P2P

The following figure shows an example where Redbox M and Redbox S are configured to run in Power Profile as Boundary Clocks that use Peer-to-Peer (P2P) delay measurement mechanism. In this example, the GMC is the ordinary clock attached through LAN C. All the clocks are configured to run Peer-to-Peer Delay measurement and the peer delay is regularly calculated and maintained on every link shown in the figure.

The BMCA on Redbox M determines ports A and B to be connected to the time source. The PTP protocol running on Redbox M treats both ports A and B individually as time source ports and sends out Sync and Follow_Up messages individually on both the ports.

Figure 167: PRP Redbox as DABC with P2P

On Redbox S, the regular BMCA operation determines port A to be time recipient and port B to be PASSIVE. However, with the knowledge that ports A and B are part of the same PRP channel, port B is forced into PASSIVE_SLAVE state. Port A and Port B on Redbox S operate as follows:



- Port A works as a regular time recipient port. It uses the Sync and Follow_Up messages along with their correction field to calculate the delay and offset from time source and synchronize the local clock. (Unlike an E2E BC, it does not need to generate Delay_Req messages because all the link delays and residence times along the PTP path are accumulated in the correction field of the Follow_Up messages).
- Port B is in PASSIVE_SLAVE state. Like port A, it maintains the delay and offset from time source, but does not perform any operation on the local clock. Having all the synchronization information available enables it to seamlessly take over as the new time recipient in case port A loses communication with the GM.

PRP RedBox as Doubly Attached TC (DATC) with P2P

The following figure shows an example where Redbox M and Redbox S are configured to run in Power Profile mode as Transparent Clocks. In this example, the GMC is the ordinary clock attached through LAN C. All the clocks are configured to run Peer-to-Peer Delay measurement and the peer delay is regularly calculated and maintained on every link shown in the figure.

Redbox M and Redbox S run BMCA even though it is not mandatory for a P2P TC to run BMCA. On Redbox M, the BMCA determines ports A and B to be connected to the time source. Redbox M forwards all Sync and Follow_Up messages received on port C out of ports A and B.

Figure 168: PRP Redbox as DATC with P2P

On Redbox S, port A is determined to be time recipient and port B to be PASSIVE_SLAVE as described earlier. Port A and Port B on Redbox S operate as follows:

- Port A works as a regular time recipient port. It uses the Sync and Follow_Up messages along with their correction field to calculate the delay and offset from time source and synchronize the local clock. (Unlike an E2E BC, it does not need to generate Delay_Req messages since all the link delays and residence times along the PTP path are accumulated in the correction field of the Follow_Up messages).
- Like port A, port B maintains the delay and offset from time source, but does not perform any operation on the local clock. Having all the synchronization information available enables it to seamlessly take over as the new time recipient in case port A loses communication with the GMC.

LAN-A and LAN-B Failure Detection and Handling

Failures in LAN-A and LAN-B are detected and handled in the same way for all RedBox types that are described in PRP RedBox Types.

Using the example that is shown in PRP RedBox as DATC with P2P with the GMC as a SAN in LAN C, a failure in LAN-A or LAN-B pertaining to PTP can occur due to the following reasons:

- A device within the LAN goes down.
- A link within the LAN goes down resulting in loss of connectivity.
- PTP messages are dropped within the LAN.

These events result in PTP Announce Receipt Timeout on RedBox S, which triggers the BMCA calculation. Refer to section 7.7.3.1 of the IEEE 1588v2 standard for details on Announce Receipt Timeout.

The BMCA, once invoked, changes the state of the PASSIVE_SLAVE port to time recipient and time recipient to PASSIVE_SLAVE or PASSIVE or FAULTY. The state changes are done atomically to avoid transient cases where there are two time recipient ports or two PASSIVE_SLAVE ports.

RedBox S now synchronizes to the GMC over the new time recipient port. The change to synchronization should be quick and seamless, unless the delays experienced by PTP packets on the two LANs are very different or if there are some non-PTP devices in the LANs.

The SAN time recipient in LAN D also sees this shift in the timing from RedBox S and must converge to the new clock. This is similar to a GMC change event for this clock, but as mentioned earlier, the change is usually seamless.

TrustSec on a PRP Interface

You can configure Cisco TrustSec (CTS) on member interfaces of a PRP channel.

Because TrustSec is supported only on physical interfaces, you cannot configure TrustSec on the logical PRP channel interface. A PRP channel includes two interfaces, for example, Gi1/1 and Gi1/2. To configure TrustSec on interfaces that are members of a PRP channel, ensure that the following conditions are met:

- The Network Advantage license is required to use TrustSec.
- Configure TrustSec on each interface first, before it is part of the PRP channel.
- The TrustSec configuration on both PRP channel interfaces must be the same to allow inline tagging and propagation with LAN-A and LAN-B as expected.

Note CTS + Security Association Protocol (SAP) and CTS + MACsec Key Agreement (MKA) methods are not supported over PRP interface.

Configuring TrustSec on a PRP Interface

This section provides examples for configuring TrustSec on a PRP interface. You can configure the PRP channel interfaces by configuring each individual interface or by using the **interface range** <>.

Valid Configuration

The following example shows configuring TrustSec on each interface, one at a time, and then making that individual interface part of a PRP channel.

```
switch#configure terminal
switch(config)#int gi1/1
switch(config-if)#switchport mode access
switch(config-if)#switchport access vlan 30
switch(config-if)#cts manual
switch(config-if-cts-manual)#policy static sgt 1000 trusted
switch(config-if-cts-manual)#exit
switch(config-if)#prp-channel-group 1
Creating a PRP-channel interface PRP-channel 1

switch(config-if)#
switch(config-if)#int gi1/2
switch(config-if)#switchport mode access
switch(config-if)#switchport access vlan 30
switch(config-if)#cts manual
switch(config-if-cts-manual)#policy static sgt 1000 trusted
switch(config-if-cts-manual)#exit
switch(config-if)#prp-channel-group 1
switch(config-if)#end
```

The following example shows configuring TrustSec on a range of interfaces and then making the interfaces part of a PRP channel.

```
switch#configure terminal
switch(config)#int range gi1/1-2
switch(config-if-range)#switchport mode access switch
switch(config-if-range)#switchport access vlan 30
switch(config-if-range)#cts manual
switch(config-if-cts-manual)#policy static sgt 1000 trusted
switch(config-if-cts-manual)#exit
switch(config-if-range)#prp-channel-group 1
Creating a PRP-channel interface PRP-channel 1
```

CTS and PRP Show Commands

This section lists **show** commands that you can use when configuring TrustSec on PRP member interfaces and examples of some command outputs:

- **show cts interface summary**
- **show cts pacs**

- **show cts interface <>**
- **show cts role-based counters**
- **show prp channel detail**
- **show prp statistics ingressPacketStatistics**
- **show prp statistics egressPacketStatistics**

The following example show the output of the **show cts interface summary** command:

```
switch#show cts interface summary
CTS Interfaces
----------------------
Interface                       Mode    IFC-state dot1x-role peer-id    IFC-cache

overrun pkt: 0
overrun pkt drop: 0
```

TrustSec Debugging Commands

This section lists **debug** commands that you can use when troubleshooting TrustSec on PRP member interfaces.

- **debug prp errors**
- **debug prp events**
- **debug prp detail**
- **debug cts error**
- **debug cts aaa**
- **debug cts all**

Prerequisites

Network Essentials or Network Advantage License

Guidelines and Limitations

Guidelines

- Because PRP DANs and RedBoxes add a 6-byte PRP trailer to the packet, PRP packets can be dropped by some switches with a maximum transmission unit (MTU) size of 1500. To ensure that all packets can flow through the PRP network, increase the MTU size for switches within the PRP LAN-A and LAN-B network to 1506 as follows: **system mtu 1506**.
- To configure supervision frame VLAN tagging, you must configure interfaces in trunk mode.

Note You cannot configure access mode on PRP interfaces when supervision frame vlan tag configuration exists. If you attempt to configure access mode on a PRP interface with supervision frame VLAN tagging, the system displays this message:

```
%PRP_MSG-4-PRP_VLANTAG: Warning: Do not configure access
mode for PRP interfaces with tagged supervision frames.
```

- A PRP channel must have two active ports that are configured within a channel to remain active and maintain redundancy.
- Both interfaces within a channel group must have the same configuration.

- For Layer 3, you must configure the IP address on the PRP channel interface.
- LLDP and CDP must be disabled on interfaces where PRP is enabled.
- UDLD must be disabled on interfaces where PRP is enabled, especially if the interfaces have media-type sfp.
- The **spanning-tree bpdufilter enable** command is required on the prp-channel interface. Spanning-tree BPDU filter drops all ingress/egress BPDU traffic. This command is required to create independent spanning-tree domains (zones) in the network.
- The **spanning-tree portfast edge trunk** command is optional on the prp-channel interface but highly recommended. It improves the spanning-tree converge time in PRP LAN-A and LAN-B.
- For PRP statistics, use the **show interface prp-channel** [**1** | **2**] command. Physical interface show commands, such as **show interface gi1/1**, do not provide PRP statistics information.
- For switches, use the **int Gi1/1** or **int Gi1/2**, as shown in the following example:

```
switch(config)#int Gi1/1
switch(config-if)#shut
%Interface GigabitEthernet1/1 is configured in PRP-channel group, shutdown not permitted!
```

- PRP functionality can be managed using the CIP protocol. The following CIP commands for PRP are available on:
  - show cip object prp <*0-2*>
  - show cip object nodetable <*0-2*>

Limitations

- PRP traffic load cannot exceed 90 percent bandwidth of the Gigabit Ethernet interface channels.
- Load-balancing is not supported.
- The Protocol status displays incorrectly for the Layer type = L3 section when you enter the **show prp channel detail** command. Refer to the Ports in the group section of the output for the correct Protocol status.

```
show prp channel detail
PRP-channel listing:
                ---------------------

PRP-channel: PR1
------------
 Layer type = L2
 Ports: 2       Maxports = 2
 Port state = prp-channel is Inuse
 Protocol = Enabled
Ports in the group:
  1) Port: Gi1/1
   Logical slot/port = 1/1      Port state = Inuse
        Protocol = Enabled
  2) Port: Gi1/2
   Logical slot/port = 1/2      Port state = Inuse
        Protocol = Enabled

PRP-channel: PR2
```

```
------------
 Layer type = L2
 Ports: 2       Maxports = 2
 Port state = prp-channel is Inuse
 Protocol = Enabled
Ports in the group:
  1) Port: Gi1/6
   Logical slot/port = 1/6      Port state = Inuse
        Protocol = Enabled
  2) Port: Gi1/7
   Logical slot/port = 1/7      Port state = Inuse
        Protocol = Enabled
```

- When an individual PRP interface goes down, **show interface status** continues to show a status of UP for the link. This is because the port status is controlled by the PRP module. Use the **show prp channel** command to confirm the status of the links, which will indicate if a link is down.

  The following example shows the output for the **show prp channel** command:

```
show prp channel 1 detail

PRP-channel: PR1
------------
 Layer type = L2
 Ports: 2       Maxports = 2
 Port state = prp-channel is Inuse
 Protocol = Enabled
Ports in the group:
  1) Port: Gi1/1
   Logical slot/port = 1/1      Port state = Inuse
        Protocol = Enabled
  2) Port: Gi1/2
   Logical slot/port = 1/2      Port state = Inuse
        Protocol = Enabled
```

Node and VDAN Tables

- The switch supports up to 512 (SAN+DANP) entries in the node table.
- The maximum static Node/VDAN count is 16.
- Hash collisions can limit the number of MAC addresses. If the node table is out of resources for learning a MAC address from a node, the switch will default to treating that node as a DAN.
- After reload (before any MAC address is learned), the switch will temporarily treat the unlearned node as a DAN and duplicate the egress packets until an ingress packet or supervision frame is received from the node to populate an entry into the node table.
- The switch supports up to 512 VDAN entries in the VDAN table. If the VDAN table is full, the switch cannot send supervision frames for new VDANS.

Default Settings

By default, no PRP channel exists on the switch until you create it. Interfaces that can be configured for PRP are fixed, as described in PRP Channels, on page 2594.

Create a PRP Channel and Group

To create and enable a PRP channel and group on the switch, follow these steps:

Before you begin

- Review the specific interfaces supported for each switch type, described in PRP Channels, on page 2594.
- Review the Prerequisites, on page 2609 and Guidelines and Limitations, on page 2609.
- Ensure that the member interfaces of a PRP channel are not participating in any redundancy protocols such as FlexLinks, EtherChannel, or REP, before creating a PRP channel.

Procedure

Step 1 Enter global configuration mode:

configure terminal

Step 2 Assign two Gigabit Ethernet interfaces to the PRP channel group. For channel 1, enter:

interface range gigabitethernet 1/1-2

For channel 2, enter:

interface range gigabitethernet 1/6-7

Use the **no interface prp-channel 1|2** command to disable PRP on the defined interfaces and shut down the interfaces.

Note
You must apply the Gi1/1 interface before the Gi1/2 interface. We recommend using the **interface range** command. Similarly, you must apply the Gi1/6 interface before the Gi1/7 for PRP channel 2.

Step 3 (Optional) For Layer 2 traffic, enter **switchport**. (Default):

switchport

Note
For Layer 3 traffic, enter **no switchport**.

Step 4 (Optional) Set a nontrunking, nontagged single VLAN Layer 2 (access) interface:

switchport mode access

Step 5 (Optional) Create a VLAN for the Gigabit Ethernet interfaces:

switchport access vlan <*value*>

Note
This step is required only for Layer 2 traffic.

Step 6 (Optional) Disable Precision Time Protocol (PTP) on the switch:

no ptp enable

PTP is enabled by default. You can disable it if you do not need to run PTP.

Step 7 Disable loop detection for the redundancy channel:

no keepalive

Step 8 Disable UDLD for the redundancy channel:

udld port disable

Step 9 Enter subinterface mode and create a PRP channel group:

prp-channel-group *prp-channel group*

prp-channel group: Value of 1 or 2

The two interfaces that you assigned in step 2 are assigned to this channel group.

The **no** form of this command is not supported.

Step 10 Bring up the PRP channel:

no shutdown

Step 11 Specify the PRP interface and enter interface mode:

interface prp-channel *prp-channel-number*

prp-channel-number: Value of 1 or 2

Step 12 Configure bpdufilter on the prp-channel interface:

spanning-tree bpdufilter enable

The spanning-tree BPDU filter drops all ingress and egress BPDU traffic. This command is required to create independent spanning-tree domains (zones) in the network.

Step 13 (Optional) Configure LAN-A/B ports to quickly get to FORWARD mode:

spanning-tree portfast edge trunk

This command is optional but highly recommended. It improves the spanning-tree convergence time on PRP RedBoxes and LAN-A and LAN-B switch edge ports. It is also highly recommended to configure this command on the LAN_A/LAN_B ports that are directly connected to a RedBox PRP interface.

Examples

The following example shows how to create a PRP channel, create a PRP channel group, and assign two ports to that group.

```
switch# configure terminal
switch(config)# interface range GigabitEthernet1/1-2
switch(config-if)# no keepalive
switch(config-if)# prp-channel-group 1
switch(config-if)# no shutdown
switch(config-if)# exit
```

```
switch(config)# interface prp-channel 1
switch(config)# spanning-tree bpdufilter enable
```

This example shows how to create a PRP channel with a VLAN ID of 2.

```
switch# configure terminal
switch(config)# interface range GigabitEthernet1/1-2
switch(config-if)# switchport
switch(config-if)# switchport mode access
switch(config-if)# switchport access vlan 2
switch(config-if)# no ptp enable
switch(config-if)# no keepalive
switch(config-if)# udld port disable
switch(config-if)# prp-channel-group 1
switch(config-if)# no shutdown
switch(config-if)# exit
switch(config)# interface prp-channel 1
switch(config)# spanning-tree bpdufilter enable
```

This example shows how to create a PRP channel on a switch configured with Layer 3.

```
switch# configure terminal
switch(config)# interface range GigabitEthernet1/1-2
switch(config-if)# no switchport
switch(config-if)# no ptp enable
switch(config-if)# no keepalive
switch(config-if)# udld port disable
switch(config-if)# prp-channel-group 1
switch(config-if)# no shutdown
switch(config-if)# exit
switch(config)# interface prp-channel 1
switch(config)# spanning-tree bpdufilter enable
switch(config)# ip address 192.0.2.10 255.255.255.0
```

Configuring PRP Channel with Supervision Frame VLAN Tagging

To create and enable a PRP channel and group on the switch with VLAN-tagged supervision frames, follow these steps:

Before you begin

- Review the specific interfaces supported for each switch type, as described in PRP Channels, on page 2594.
- Review the Prerequisites, on page 2609 and Guidelines and Limitations, on page 2609.
- Ensure that the member interfaces of a PRP channel are not participating in any redundancy protocols such as FlexLinks, EtherChannel, REP, and so on before creating a PRP channel.

Procedure

Step 1 Enter global configuration mode:

configure terminal

Step 2 Assign two Gigabit Ethernet interfaces to the PRP channel group. For channel 1, enter:

interface gigabitethernet 1/1-2

For channel 2, enter:

interface gigabitethernet 1/6-7

Use the **no interface prp-channel 1|2** command to disable PRP on the defined interfaces and shut down the interfaces.

Note
You must apply the Gi1/1 interface before the Gi1/2 interface. So, we recommend using the **interface range** command.

Step 3 Configure the PRP interface for trunk administrative mode, to allow the interface to carry traffic for more than one VLAN.

switchport mode trunk

Step 4 Specify the allowed VLANS for the trunk interface:

switchport trunk allowed vlan *value*

value: Allowed VLAN number from 0 to 4095 or list of VLANs separated by commas.

Step 5 (Optional) Disable Precision Time Protocol (PTP) on the switch:

no ptp enable

PTP is enabled by default. You can disable it if you do not need to run PTP.

Step 6 Disable loop detection for the redundancy channel:

no keepalive

Step 7 Disable UDLD for the redundancy channel:

udld port disable

Step 8 Enter sub-interface mode and create a PRP channel group:

prp-channel-group *prp-channel group*

prp-channel group: Value of 1 or 2

The two interfaces that you assigned in step 2 are assigned to this channel group.

The **no** form of this command is not supported.

Step 9 Bring up the PRP channel:

no shutdown

Step 10 Specify the PRP interface and enter interface mode:

interface prp-channel *prp-channel-number*

prp-channel-number: Value of 1 or 2

Step 11 Configure bpdufilter on the prp-channel interface:

spanning-tree bpdufilter enable

Spanning-tree BPDU filter drops all ingress/egress BPDU traffic. This command is required to create independent spanning-tree domains (zones) in the network.

Step 12 Set the VLAN ID to be used in VLAN tags for supervision frames:

prp channel-group *prp-channel-number* **supervisionFrameOption vlan-id** *value*

prp-channel-number: Value of 1 or 2

value: VLAN number from 0 to 4095

Step 13 (Optional) Configure the Class of Service (COS) value to be set in the VLAN tag of the Supervision frame:

prp channel-group *prp-channel-number* **supervisionFrameOption vlan-cos** *value*

value: Range is 1 to 7. The default is 1.

Step 14 Enable VLAN tagging on the interface:

prp channel-group *prp-channel-number* **supervisionFrameOption vlan-tagged** *value*

prp-channel-number: Value of 1 or 2

Step 15 (Optional) Configure LAN-A/B ports to quickly get to FORWARD mode:

spanning-tree portfast edge trunk

This command is optional but highly recommended. It improves the spanning-tree convergence time on PRP RedBoxes and LAN-A and LAN-B switch edge ports. It is also highly recommended to configure this command on the LAN_A/LAN_B ports directly connected to a RedBox PRP interface.

Example

```
REDBOX1# configure terminal
REDBOX1(config)#int range GigabitEthernet1/1-2
REDBOX1(config-if-range)#switchport mode trunk
REDBOX1(config-if-range)#switchport trunk allowed vlan 10,20
REDBOX1(config-if-range)#no ptp enable
REDBOX1(config-if-range)#no keepalive
REDBOX1(config-if-range)#udld port disable
REDBOX1(config-if-range)#no shutdown
REDBOX1(config-if-range)#prp-channel-group 1
REDBOX1(config-if-range)#exit
REDBOX1(config)#prp channel-group 1 supervisionFrameOption vlan-tagged
REDBOX1(config)#prp channel-group 1 supervisionFrameOption vlan-id 10
REDBOX1(config)# spanning-tree bpdufilter enable
REDBOX1(config-if)#spanning-tree portfast edge trunk
```

Add Static Entries to the Node and VDAN Tables

Follow the steps in this section to add a static entry to the node or VDAN table.

Procedure

Step 1 Enter global configuration mode:

configure terminal

Example:

```
switch# configure terminal
switch(config-if)# prp channel-group 1 nodeTableMacaddress 0000.0000.0001 lan-a
```

Step 2 Specify the MAC address to add to the node table for the channel group and specify whether the node is a DAN or a SAN (attached to either LAN-A or LAN-B):

prp channel-group *prp-channel group* **nodeTableMacaddress** *mac-address* {dan | lan-a | lan-b}

prp-channel group: Value of 1 or 2

mac-address: MAC address of the node

Note
Use the **no** form of the command to remove the entry.

Step 3 Specify the MAC address to add to the VDAN table:

prp channel-group *prp-channel group* **vdanTableMacaddress** *mac-address*

prp-channel group: Value of 1 or 2

mac-address: MAC address of the node or VDAN

Note
Use the **no** form of the command to remove the entry.

Clearing All Node Table and VDAN Table Dynamic Entries

Procedure

Step 1 Clear all dynamic entries in the node table by entering the following command:

clear prp node-table [**channel-group** *group*]

Step 2 Clear all dynamic entries in the VDAN table by entering the following command:
clear prp vdan-table [**channel-group** *group*]

If you do not specify a channel group, the dynamic entries are cleared for all PRP channel groups.

Note

The **clear prp node-table** and **clear prp vdan-table** commands clear only dynamic entries. To clear static entries, use the **no** form of the **nodeTableMacaddress** or **vdanTableMacaddress** command shown in Add Static Entries to the Node and VDAN Tables, on page 2616.

Disabling the PRP Channel and Group

Procedure

Step 1 Enter global configuration mode:

configure terminal

Step 2 Disable the PRP channel:

no interface prp-channel *prp-channel-number*

prp-channel number: Value of 1 or 2

Step 3 Exit interface mode:

exit

Errors and Warnings as Syslog Messages

You can configure switches so that errors and warnings become syslogs. Doing so enables you to turn the syslogs into Simple Network Management Protocol (SNMP) traps for proper alerting and maintenance.

The following errors and warnings can be configured to become syslogs:

- Wrong LAN ID A

  The number of frames with a wrong LAN identifier received on port A.

- Wrong LAN ID B

  The number of frames with a wrong LAN identifier received on port B.

- Warning LAN A

  There is a potential problem with the PRP ports for LAN A. (Packet loss condition/Wrong LAN packet counter incremented)

- Warning LAN B

  There is a potential problem with the PRP ports for LAN B. (Packet loss condition/Wrong LAN packet counter incremented)

- Oversize packet A

- Oversize packet B

The parameters in the procedure list are captured from the output of the CLI command **sh prp statistics ingressPacketStatistics**.

You use CLI commands to configure the interval that syslogs are generated, from 60 seconds to 84,400 seconds. The default is 300 seconds. See the section Configure the PRP Logging Interval, on page 2619 in this guide for more information.

Configure the PRP Logging Interval

Complete the following steps to configure a logging interval for the creation of PRP syslogs from errors and warnings. The default is 300 seconds; however, you can choose a value from 60 seconds to 84,400 seconds.

Procedure

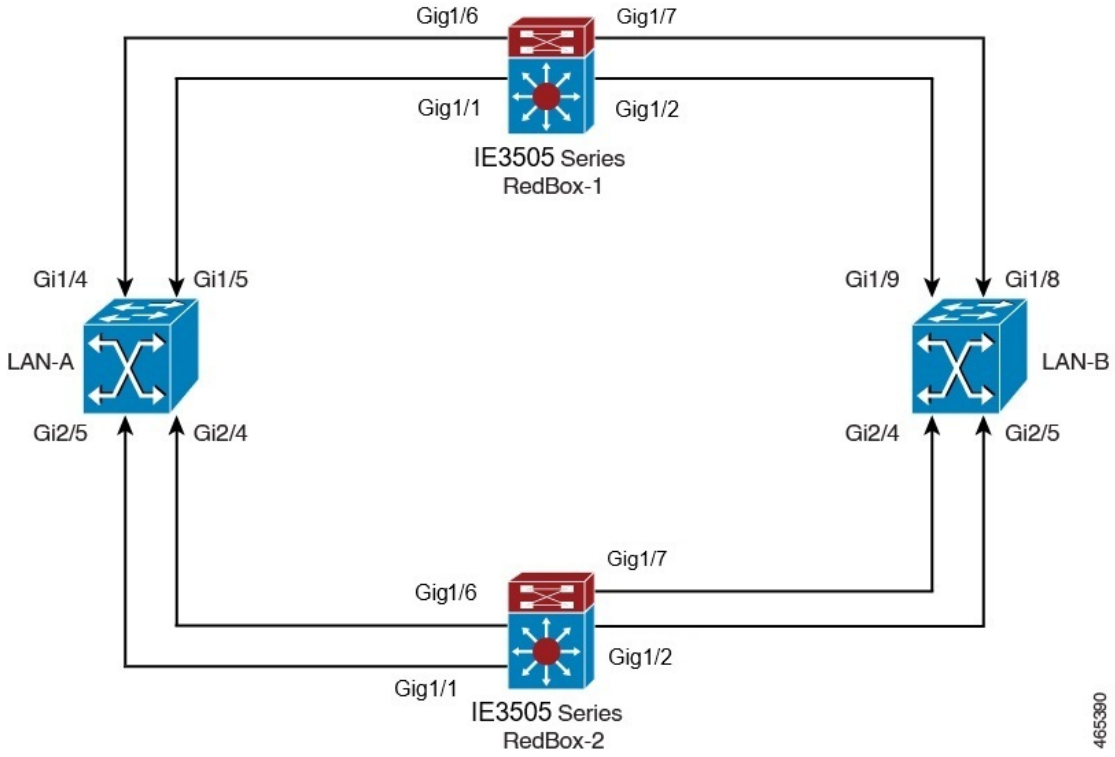
At the configuration prompt, enter the following command: **prp logging-interval** ***interval_in_seconds***

To choose the default interval of 300 seconds, do not enter a value. Enter one only to specify a logging inteval other than the 300-second default.

Example:

```
cl_2011#conf t
Enter configuration commands, one per line.  End with CNTL/Z.
cl_2011(config)#prp logging-interval 120
```

The switch generates syslogs from the PRP errors and warnings listed in the section Errors and Warnings as Syslog Messages , on page 2618.



Example

The following text shows sample output resulting from the configuring the logging interval.

```
*Sep 28 13:18:27.623: %PRP_WRONG_LAN-5-WRONG_LAN: PRP channel 2, LAN A is connected to LAN
 B on its peer
*Sep 28 13:18:27.623: %PRP_WRONG_LAN-5-WRONG_LAN: PRP channel 2, LAN B is connected to LAN
 A on its peer
*Sep 28 13:18:27.623: %PRP_WARN_LAN-5-WARN_LAN: PRP channel 2, PRP LAN warning is set on
LAN B
*Sep 28 13:18:27.623: %PRP_OVERSIZE_PKT-5-OVERSIZE_LAN: PRP channel 2, PRP oversize packet
 warning is set on LAN A
```

Configuration Examples

The following diagram shows a network configuration in which the switches might operate. The commands in this example highlight the configuration of features and switches to support that configuration.

In this example, the configuration establishes two LANs, LAN-A and LAN-B, and two PRP channels. Within the topology, a Switch is identified as RedBox-1 and another one is identified as RedBox-2.

Following is the configuration for LAN-A:

```
diagnostic bootup level minimal
!
!
!
spanning-tree mode rapid-pvst
spanning-tree extend system-id
memory free low-watermark processor 88589
!
!

Verify Configuration

This section lists commands that you can use to verify PRP configuration and examples of those commands.

Command	Purpose
show prp channel {**1** | **2** [**detail** | **status** | **summary**] | **detail** | **status** | **summary**}	Displays configuration details for a specified PRP channel.
show prp control {**VdanTableInfo** | **ptpLanOption** | **ptpProfile** | **supervisionFrameLifeCheckInterval** | **supervisionFrameOption** | **supervisionFrameRedboxMacaddress** | **supervisionFrameTime**}	Displays PRP control information, VDAN table, and supervision frame information.
show prp node-table [**channel-group** <**group**> | **detail**]	Displays PRP node table.

Command	Purpose
show prp statistics {**egressPacketStatistics** | **ingressPacketStatistics** | **nodeTableStatistics** | **pauseFrameStatistics** | **ptpPacketStatistics**}	Displays statistics for PRP components.
show prp vdan-table [**channel-group** <**group**> | **detail**]	Displays PRP VDAN table.
show interface prp-channel {**1** | **2**}	Displays information about PRP member interfaces.

Note The **show interface G1/1** or **show interface G1/2** command should not be used to read PRP statistics if these interfaces are PRP channel members because the counter information can be misleading. Use the **show interface prp-channel** [**1** | **2**] command instead.

The following example shows the output for **show prp channel** when one of the interfaces in the PRP channel is down.

```
show prp channel 1 detail
PRP-channel: PR1
------------
 Layer type = L2
 Ports: 2       Maxports = 2
 Port state = prp-channel is Inuse
 Protocol = Enabled
Ports in the group:
  1) Port: Gi1/1
   Logical slot/port = 1/1      Port state = Inuse
        Protocol = Enabled
  2) Port: Gi1/2
   Logical slot/port = 1/2      Port state = Inuse
        Protocol = Enabled
```

The following example shows how to display the PRP node table and PRP VDAN table.

```
Switch#show prp node-table
PRP Channel 1 Node Table
==================================
   Mac Address   Type  Dyn   TTL
---------------- ----- --- -------
 B0AA.7786.6781  lan-a  Y     59
 F454.3317.DC91  dan    Y     60
==================================
Channel 1 Total Entries: 2
Switch#show prp vdan-table
PRP Channel 1 VDAN Table
============================
   Mac Address   Dyn   TTL
---------------- --- -------
 F44E.05B4.9C81   Y     60
============================
Channel 1 Total Entries: 1
```

The following example shows output for the **show prp control supervisionFrameOption** command with and without VLAN tagging added to the PRP channel. A `VLAN value` field of 1 means that VLAN tagging is enabled, and a value of 0 means that VLAN tagging is disabled.

```
REDBOX1#show prp control supervisionFrameoption
 PRP channel-group 1 Super Frame Option
  COS value is 7
  CFI value is 0
  VLAN value is 1
  MacDA value is 200
  VLAN id value is 30
PRP channel-group 2 Super Frame Option
  COS value is 0
  CFI value is 0
  VLAN value is 0
  MacDA value is 0
  VLAN id value is 0

REDBOX1#
```

The following example shows the command to determine if the switch has been configured so that errors and warnings to become syslogs:

```
switch #sh prp control logging-interval
 PRP syslog logging interval is not configured
```

The following example shows the command for configuring the logging interval to the default, 300 seconds.

```
switch #conf t
Enter configuration commands, one per line.  End with CNTL/Z.
switch(config)#prp logging-interval
switch(config)#do sh prp control logging-interval
 PRP syslog logging interval is 300 in seconds
```

The following example shows the command for configuring the logging interval to 600 seconds.

```
switch(config)#prp logging-interval 600
 PRP syslog logging interval is 600 in seconds

switch(config)#
```

Resilient Ethernet Protocol

Resilient Ethernet Protocol (REP) is a Cisco proprietary protocol that provides an alternative to Spanning Tree Protocol (STP) to control network loops, handle link failures, and improve convergence time. REP controls a group of ports that are connected in a segment, ensures that the segment does not create any bridging loops, and responds to link failures within the segment. REP provides a basis for constructing more complex networks and supports VLAN load balancing.

REP segment is a chain of ports that are connected to each other and configured with a segment ID. Each segment consists of standard (nonedge) segment ports and two user-configured edge ports. A switch can have no more than two ports that belong to the same segment, and each segment port can have only one external neighbor. A segment can go through a shared medium, but on any link, only two ports can belong to the same segment. **REP is supported only on Trunk ports**.

The following figure shows an example of a segment consisting of six ports spread across four switches. Ports E1 and E2 are configured as edge ports. When all ports are operational (as in the segment on the left), a single port is blocked, shown by the diagonal line. This blocked port is also known as the Alternate port (ALT port). When there is a failure in the network, the blocked port returns to the forwarding state to minimize network disruption.

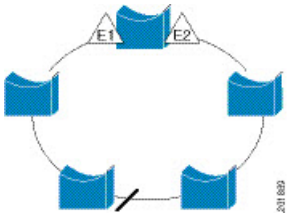

Figure 169: REP Open Segment

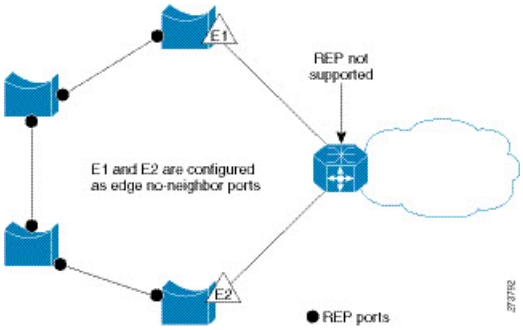
The segment shown in the preceding figure is an open segment; there is no connectivity between the two edge ports. The REP segment cannot cause a bridging loop, and you can safely connect the segment edges to any network. All hosts connected to switches inside the segment have two possible connections to the rest of the network through the edge ports, but only one connection is accessible at any time. If a failure occurs on any segment or on any port on a REP segment, REP unblocks the ALT port to ensure that connectivity is available through the other gateway.

The segment in the following figure is a closed segment, also known as Ring Segment, with both edge ports located on the same router. With this configuration, you can create a redundant connection between any two routers in the segment.

Figure 170: REP Ring Segment



REP segments have the following characteristics:

- If all ports in a segment are operational, one port (referred to as the ALT port) is in the blocked state for each VLAN. If VLAN load balancing is configured, two ALT ports in the segment control the blocked state of VLANs.
- If a port is not operational, and causes a link failure, all ports forward traffic on all VLANs to ensure connectivity.
- In case of a link failure, alternate ports are unblocked as quickly as possible. When the failed link is restored, a logically blocked port per VLAN is selected with minimal disruption to the network.

You can construct almost any type of network that is based on REP segments.

In access ring topologies, the neighboring switch might not support REP as shown in the following figure. In this case, you can configure the non-REP facing ports (E1 and E2) as edge no-neighbor ports. The edge no-neighbor port can be configured to send an STP topology change notice (TCN) towards the aggregation switch.

Figure 171: Edge No-Neighbor Ports

REP has these limitations:

- You must configure each segment port; an incorrect configuration can cause forwarding loops in the networks.
- REP can manage only a single failed port within the segment; multiple port failures within the REP segment cause loss of network connectivity.
- You should configure REP only in networks with redundancy. Configuring REP in a network without redundancy causes loss of connectivity.

Link Integrity

REP does not use an end-to-end polling function between edge ports to verify link integrity. It implements local link failure detection. The REP Link Status Layer (LSL) detects its REP-aware neighbor and establishes connectivity within the segment. All the VLANs are blocked on an interface until the neighbor is detected. After the neighbor is identified, REP determines which neighbor port should become the alternate port and which ports should forward traffic.

Each port in a segment has a unique port ID. The port ID format is similar to that used by the spanning tree algorithm: a port number (unique on the bridge) associated to a MAC address (unique in the network). When a segment port is coming up, its LSL starts sending packets that include the segment ID and the port ID. The port is declared as operational after it performs a three-way handshake with a neighbor in the same segment.

A segment port does not become operational if:

- No neighbor has the same segment ID.
- More than one neighbor has the same segment ID.
- A neighbor does not acknowledge a local port as a peer.

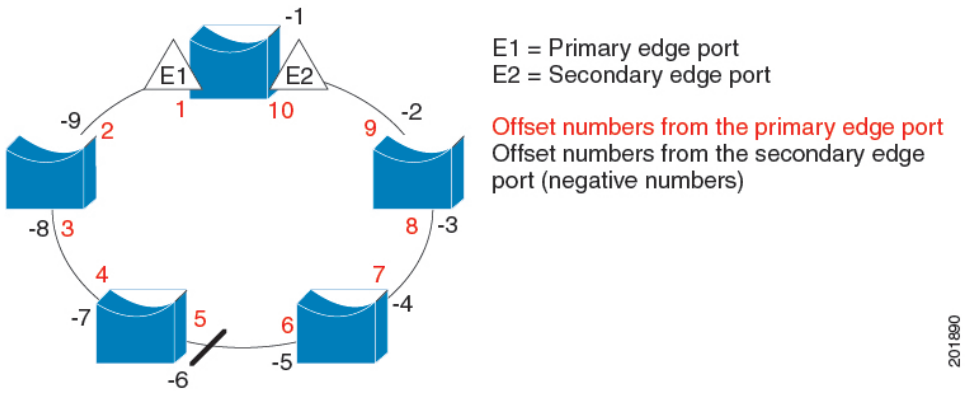
Each port creates an adjacency with its immediate neighbor. After the neighbor adjacencies are created, the ports negotiate with each other to determine the blocked port for the segment, which will function as the alternate port. All the other ports become unblocked. By default, REP packets are sent to a bridge protocol data unit-class MAC address. The packets can also be sent to a Cisco multicast address, which is used only to send blocked port advertisement (BPA) messages when there is a failure in the segment. The packets are dropped by the devices not running REP.

Fast Convergence

REP runs on a physical link basis and not on a per-VLAN basis. Only one hello message is required for all the VLANs, and this reduces the load on the protocol. We recommend that you create VLANs consistently on all the switches in a given segment and configure the same allowed VLANs on the REP trunk ports. To avoid the delay introduced by relaying messages in software, REP also allows some packets to be flooded to a regular multicast address. These messages operate at the hardware flood layer (HFL) and are flooded to the entire network, not just the REP segment. Switches that do not belong to the segment treat them as data traffic. You can control flooding of these messages by configuring an administrative VLAN for the entire domain or for a particular segment.

VLAN Load Balancing

One edge port in the REP segment acts as the primary edge port; and another as the secondary edge port. It is the primary edge port that always participates in VLAN load balancing in the segment. REP VLAN balancing is achieved by blocking some VLANs at a configured alternate port and all the other VLANs at the primary edge port. When you configure VLAN load balancing, you can specify the alternate port in one of three ways:



- By entering the port ID of the interface. To identify the port ID of a port in the segment, enter the **show interface rep detail** interface configuration command for the port.
- By entering the **preferred** keyword to select the port that you previously configured as the preferred alternate port with the **rep segment** *segment-id* **preferred** interface configuration command.
- By entering the neighbor offset number of a port in the segment, which identifies the downstream neighbor port of an edge port. The neighbor offset number range is –256 to +256; a value of 0 is invalid. The primary edge port has an offset number of 1; positive numbers above 1 identify downstream neighbors of the primary edge port. Negative numbers indicate the secondary edge port (offset number -1) and its downstream neighbors.

Note Configure offset numbers on the primary edge port by identifying a port's downstream position from the primary (or secondary) edge port. Never enter an offset value of 1 because that is the offset number of the primary edge port.

The following figure shows neighbor offset numbers for a segment, where E1 is the primary edge port and E2 is the secondary edge port. The red numbers inside the ring are numbers offset from the primary edge port; the black numbers outside of the ring show the offset numbers from the secondary edge port. Note that you can identify all the ports (except the primary edge port) by either a positive offset number (downstream position from the primary edge port) or a negative offset number (downstream position from the secondary edge port). If E2 became the primary edge port, its offset number would then be 1 and E1 would be -1.

Figure 172: Neighbor Offset Numbers in a Segment

When the REP segment is complete, all the VLANs are blocked. When you configure VLAN load balancing, you must also configure triggers in one of two ways:

- Manually trigger VLAN load balancing at any time by entering the **rep preempt segment** *segment-id* privileged EXEC command on the switch that has the primary edge port.
- Configure a preempt delay time by entering the **rep preempt delay** *seconds* interface configuration command. After a link failure and recovery, VLAN load balancing begins after the configured preemption time period elapses. Note that the delay timer restarts if another port fails before the time has elapsed.

Note When VLAN load balancing is configured, it does not start working until triggered by either manual intervention or a link failure and recovery.

When VLAN load balancing is triggered, the primary edge port sends out a message to alert all the interfaces in the segment about the preemption. When the secondary port receives the message, the message is sent to the network to notify the alternate port to block the set of VLANs specified in the message and to notify the primary edge port to block the remaining VLANs.

You can also configure a particular port in the segment to block all the VLANs. Only the primary edge port initiates VLAN load balancing, which is not possible if the segment is not terminated by an edge port on each end. The primary edge port determines the local VLAN load-balancing configuration.

Reconfigure the primary edge port to reconfigure load balancing. When you change the load-balancing configuration, the primary edge port waits for the **rep preempt segment** command or for the configured preempt delay period after a port failure and recovery, before executing the new configuration. If you change an edge port to a regular segment port, the existing VLAN load-balancing status does not change. Configuring a new edge port might cause a new topology configuration.

Spanning Tree Interaction

REP does not interact with STP, but it can coexist. A port that belongs to a segment is removed from spanning tree control and STP BPDUs are not accepted or sent from segment ports. Therefore, STP cannot run on a REP segment.

To migrate from an STP ring configuration to REP segment configuration, begin by shutdown the interface and proceed with configuring a single port in the ring as part of the segment and continue by configuring contiguous ports to minimize the number of segments.

Each segment always contains a blocked port, so multiple segments means multiple blocked ports and a potential loss of connectivity. When the segment has been configured in both directions up to the location of the edge ports, you then configure the edge ports. After the configuration, enable or unshut the ports.

REP Ports

REP segments consist of Failed, Open, or Alternate ports:

- A port configured as a regular segment port starts as a failed port.
- After the neighbor adjacencies are determined, the port transitions to alternate port state, blocking all the VLANs on the interface. Blocked-port negotiations occur, and when the segment settles, one blocked port remains in the alternate role and all the other ports become open ports.
- When link flap is triggered, only the link that is shut moves to Failed state. When the Alternate port receives the failure notification, it changes to the Open state, forwarding all the VLANs.

A regular segment port converted to an edge port, or an edge port converted to a regular segment port, does not always result in a topology change. If you convert an edge port into a regular segment port, VLAN load balancing is not implemented unless it has been configured. **For VLAN load balancing, you must configure two edge ports in the segment.**

A segment port that is reconfigured as a spanning tree port restarts according to the spanning tree configuration. By default, this is a designated blocking port. If PortFast is configured or if STP is disabled, the port goes into the forwarding state.

Resilient Ethernet Protocol Fast

The Resilient Ethernet Protocol (REP) Fast feature allows faster link failure detection and convergence on the switch copper Gigabit Ethernet (GE) ports.

On Fiber GE ports, link down detection time is also 10 ms, but on GE copper interfaces, the link drop detection and recovery times are between 750 ms and 350 ms. As a result, link loss and recovery can be detected a lot more quickly on GE fiber interfaces than on corresponding copper interfaces. This in turn means that the convergence time for REP is a lot higher when using GE copper interfaces.

To improve link down detection time, a beacon mechanism is implemented to trigger faster link failure detection when a REP interface is configured for REP Fast mode. The switch has two timers for each REP interface. The first timer is triggered every 3 ms to transmit the beacon frame to the neighbor node. After successful transmission and reception of the frame, both the timers are reset. If the packet is not received after the transmission, then the second timer is triggered to check the reception within 10 ms. If the packet is not received, upon the timer expiry, a link down message is sent to the switch.

REP Fast works on an individual link basis. It does not impact the REP Protocol. REP Fast requires both ends of the link to support REP Fast to work. REP Fast can be used on any interface link pair that is configured for REP, but it was created to solve an issue on Gigabit copper links. REP Fast speeds up detection of the link failure on Gigabit copper interfaces.

A switch can have a combination of REP rings and REP Fast rings, with each configured as a separate segment. REP Fast enablement does not impact REP ring size since it operates only on the pair of interfaces that are configured for it. Because REP Fast has to generate Beacon frames, only six interfaces on a single REP node can be configured for REP Fast at a time.

Note It is recommended to not have a mix of REP and REP Fast on a single ring.

If the neighbor acknowledges and is configured for REP Fast mode, convergence occurs within 50 ms. If a neighbor switch does not support the REP Fast feature, normal REP mode must be used for link up/down detection. In this case, you must disable fast mode on both ends of the link.

For information about configuring REP Fast, see Configure REP Fast in this guide.

REP fast configuration guidelines and limitations

Follow these guidelines when configuring REP fast:

- REP fast must be configured on all ports involved in the REP ring for proper operation.
- REP fast segments can be fiber, copper, or a combination, enabling convergence within 50 ms from a single failure.
- It is recommended not to mix REP and REP fast on the same ring.
- A maximum of three REP segments can have REP Fast enabled simultaneously on a switch.
- REP fast over EtherChannel is not supported.
- Switch supports a maximum of 3 REP fast segments.

Configure REP Fast

Follow these steps to configure REP Fast:

Before you begin

Enable REP on the switch and configure the REP topology as described in Configuring REP.

Procedure

Step 1 Enter global configuration mode:

configure terminal

Step 2 Specify the interface and enter interface configuration mode:

interface *interface-id*

Step 3 Enable REP Fast:

REP fastmode

Step 4 Return to privileged exec mode:

end

Example

```
gigabitethernet1/1
switch(config-if)#rep seg
switch(config-if)#rep segment ?
<1-1024> Between 1 and 1024

switch(config-if)#rep segment 10
switch(config-if)#rep fastmode
switch(config)#int <interface number>
switch(config-if)#
switch(config-if)#rep ?
  fastmode       REP fastmode

interface <interface number>
 switchport mode trunk
 rep segment <segment id>
 rep fastmode
end
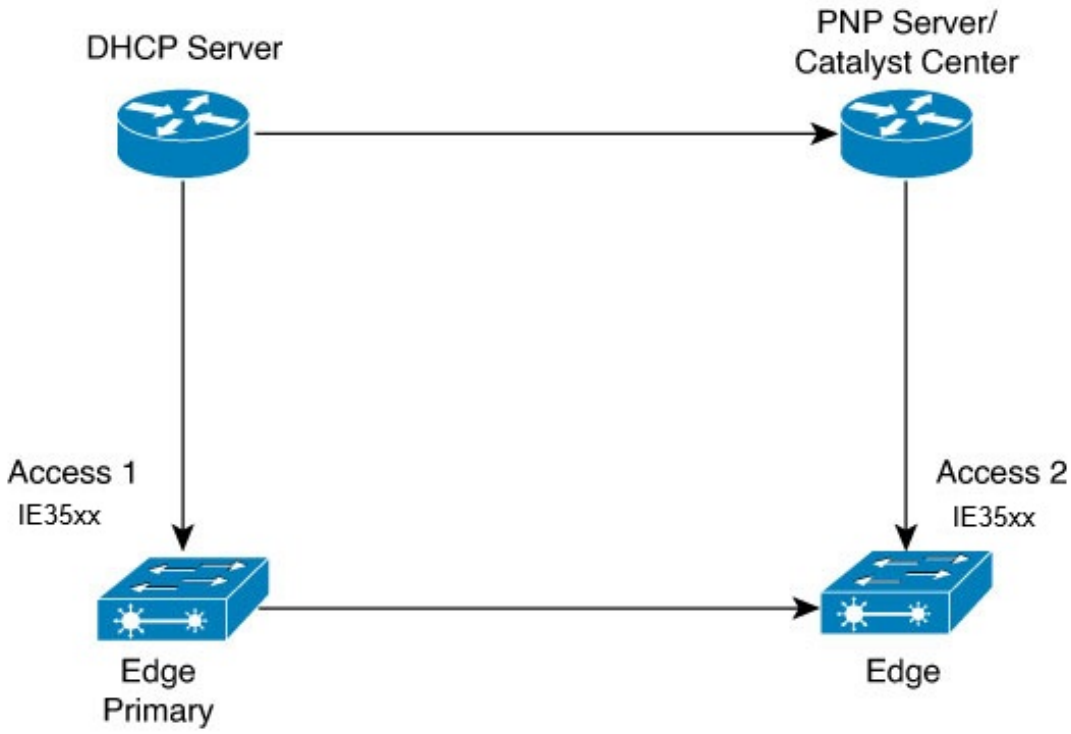
```

REP Zero Touch Provisioning



Before a network device such as a router or a switch is deployed online and fully functional, a fair amount of manual configuration is required. Zero Touch Provisioning (ZTP) technologies automate these processes, bringing up network devices into a functional state with minimal to no manual configuration. The Cisco Network Plug and Play (PnP) and Autoinstall Day Zero solutions provide a simple, secure, unified, and integrated offering for enterprise and industrial network customers to ease device rollouts for provisioning updates to an existing network. However, PnP does not support Resilient Ethernet Protocol (REP) due to the way REP is designed. Prior to the REP ZTP feature, REP ring provisioning for Day Zero required manual intervention. The REP ZTP feature introduces a new type-length-value (TLV) extension into the REP LSL packets to support configuring REP rings with zero-touch technologies.

REP and Day Zero

In a typical switch deployment using ZTP, the switch, with no startup configuration in the NVRAM, triggers the Cisco Open Plug-n-Play (PnP) agent to initiate a DHCP discovery process. This process acquires the IP configuration required for the switch from the DHCP server. The DHCP server can be configured to insert additional information in a DHCP message using vendor specific option 43. After the DHCP server receives a DHCP DISCOVER message with option 60 and the string "cisco pnp" from the switch, the DHCP server sends the IP address or hostname of the PnP server to the requesting switch. When the switch receives the DHCP response, the PnP agent extracts the option 43 from the response to get the IP address or the hostname of the PnP server. The PnP agent on the switch then uses this IP address or hostname to communicate with the PnP server. Finally, the PnP server downloads the required Day Zero configuration to the switch to complete the provisioning.

The example shown in the following diagrams illustrates REP ring provisioning on Day Zero, prior to the introduction of REP ZTP.

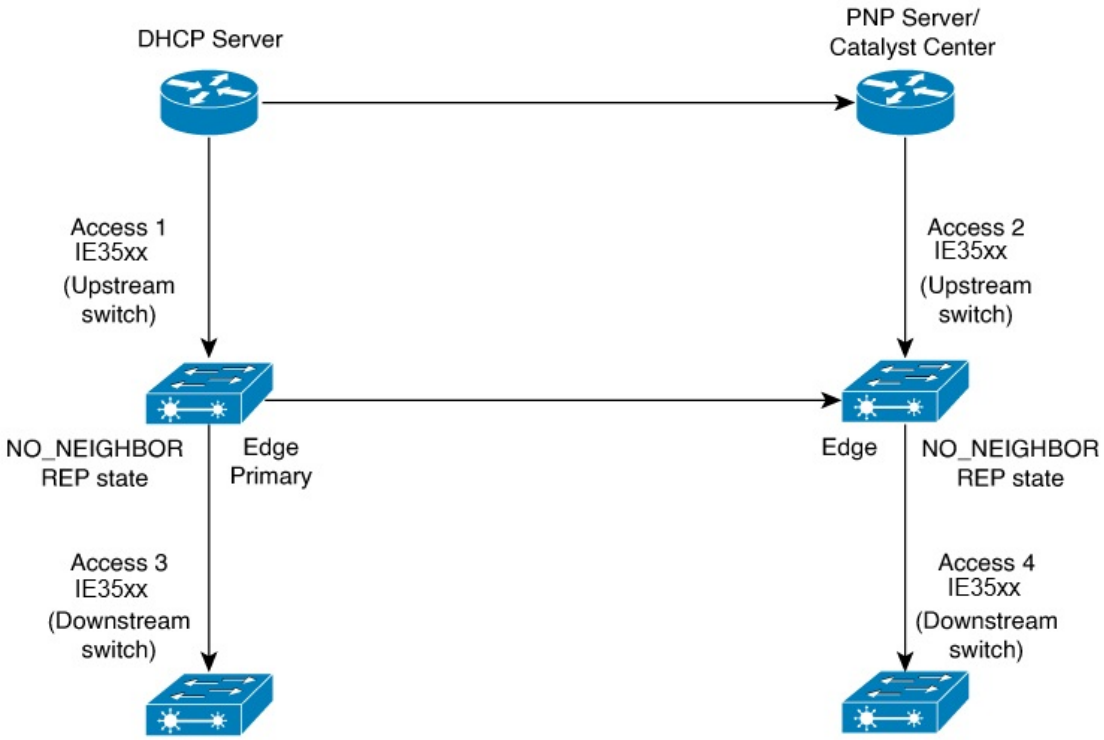


Figure 173: Adding Edge Nodes to the REP Ring

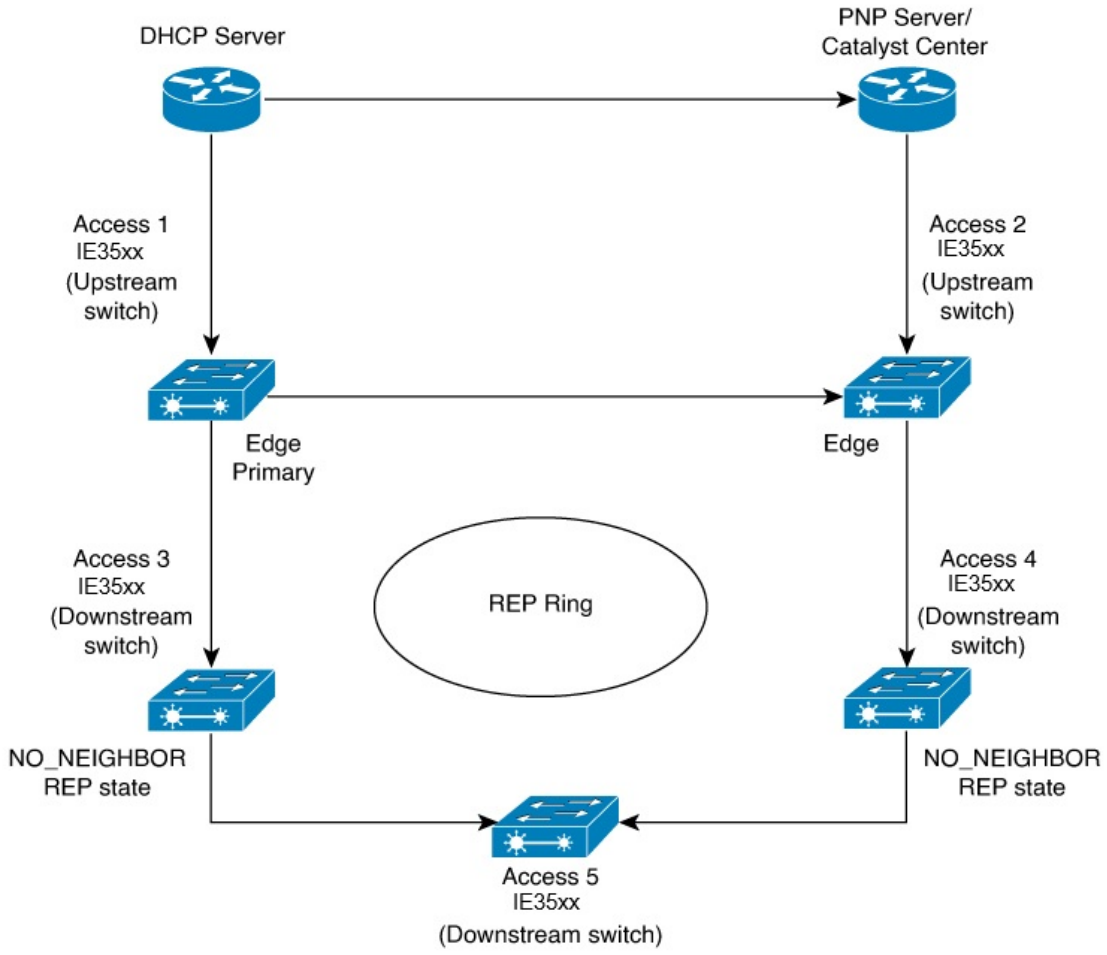
Note The DHCP Server and the PnP Server/Cisco Catalyst Center are not part of the REP ring.



The first set of nodes to be provisioned are Access 1 and Access 2 in the diagram. These are the 2 edge nodes of the REP ring. Note that PnP has configured the downlink port as primary edge on Access 1 and secondary edge on Access 2.

Figure 174: Adding Downstream Nodes

When either Access 3 or Access 4 are powered on, the REP edge primary port starts the REP protocol negotiation and discovers that the neighbor port is not a REP enabled port. (Recall that the switch will be added to the REP ring only after PnP provisioning, for which it needs to first contact the DHCP server as explained earlier.) When an upstream switch port has REP configured and a downstream switch is getting on-boarded with PnP, the REP port goes into the NO_NEIGHBOR state because it is not able to discover its REP peer. In the NO_NEIGHBOR state, REP blocks all the VLANs on that port. This means that the DHCP discovery message from the new switch on the PnP startup VLAN is dropped by the upstream switch because its REP state is NO_NEIGHBOR. The same sequence of blocked ports continues for all new switches added to the REP ring (see Access 5 in figure below).

Figure 175: NO_NEIGHBOR REP State

REP ZTP Overview

The REP ZTP enhancements require that both the upstream and the downstream switches support the feature. When the new downstream switch is powered on, it initiates PNP/autoinstall. The upstream switch's interface is configured for REP and blocks the interface to the downstream switch because the downstream switch is not REP by default (the upstream switch is in REP_NO_NEIGHBOR state).

Even though the interface on the upstream switch is blocked, it will transmit REP LSL packets to the downstream switch. This is normal. With the enhancement of the REP ZTP feature, the downstream switch will start transmitting REP LSL packets with a new TLV to inform the upstream switch that its neighbor is attempting PNP provisioning.

When the upstream switch reads this REP LSL with the new TLV, it will unblock the interface for the PNP startup VLAN only. All other VLANs for which the upstream interface is a member continue to be blocked. Because the upstream switch is forwarding packets on the PNP startup VLAN for this interface, the downstream switch can complete the PNP process.

The intent of this feature is to allow new switches to join a REP ring with no manual intervention. The interface on the upstream switch keeps the startup VLAN unblocked until the downstream switch has received its

configuration and has configured its own interface for REP. If there's a failure in the PNP proccess, the interface on the upstream switch reverts to blocking on the PNP startup VLAN. If the configuration received by the downstream switch does configure the interface for REP, the upstream switch reverts to blocking the PNP startup VLAN.

The downstream behavior to transmit the REP LSL with new TLV to request the PnP startup VLAN be unblocked is the default behavior for switches with no startup configuration. For security purposes, the upstream switch must have the interface to the downstream switch explicitly enabled to put the PnP startup VLAN into unblocked state. The interface level command is **rep ztp-enable**. See Configuring REP ZTP , on page 2654.

Note The upstream switch can be part of multiple REP rings and thereby connected to multiple downstream neighbours. The PnP startup VLAN is unblocked only on the interfaces to which the downstream switch is connected.

REP segment ID auto-discovery

A REP segment ID auto-discovery feature is a network feature that

- automatically configures and retains segment IDs in REP segments,
- allows switches to learn and store segment ID information through dedicated CLI commands, and
- supports both standard REP and REP Fast protocols starting with Cisco IOS XE 26.1.x or later.

REP segment ID auto-discovery reference information

REP segment ID auto-discovery reduces manual configuration errors and supports deployments with multiple REP rings by automating segment ID assignment and retention. This feature simplifies the process of adding switches to existing REP segments or creating new ones without manual intervention.

Table 204: Feature history for REP Segment ID auto discovery

Feature name	Release	Description
REP Segment ID auto discovery	Cisco IOS XE 26.1.1	REP segment ID auto-discovery was introduced in Cisco IOS XE 26.1.x to automate segment ID configuration, reduce manual errors, and simplify deployment in REP networks.

REP segment ID auto-discovery deployment

You can configure REP Segment-ID auto-discovery when you add a switch to a REP segment or when you create a REP segment. In both situations, manual configuration is reduced.

This section explains the recommended deployment order for configuring and expanding REP segments in industrial networks.

Add new switch to an REP segment

Build new REP segment

Build a REP segment with uplinks (daisy-chain)

Add new switch to an REP segment

- When you add a switch to an existing REP segment, use the **rep autodisc** command on the switches connected to the upstream and downstream devices to enable auto-discovery.
- After connecting the new switch, the upstream and downstream switches send Cisco Discovery Protocol (CDP) packets with REP segment ID information to the new switch interfaces.
- Use the **rep segment auto** command on the new switch interfaces. This action allows the interfaces to learn the segment ID.

Build new REP segment

- When you build a closed REP segment, you must start with a static REP segment ID configuration from an edge device. The primary and secondary edge devices in a closed segment are on the same switch.
- When you build an open REP segment, you must start a static REP segment ID configuration from both primary and secondary edge devices.
- The remaining steps apply to both closed and open REP segments. Begin by bringing up the next node in the REP ring. Then, add a new node between the two switches to enable auto-discovery.

Build REP segment with uplinks (daisy-chain)

- When you build a ring segment with uplinks (daisy chain), you must start with a static REP Segment ID configuration from the REP edge node. Connect the next device to one of the uplinks to the edge node and enable auto-discovery on the connected uplink. Port pairing support duplicates the REP configuration on the paired uplink port.
- After connecting each device to the uplink, the process repeats to bring the REP segment in a daisy chain manner. Each new REP node joins the ring automatically by learning the REP Segment ID from its connected node. In an REP open ring, the last device on the segment acts as an edge device with static REP configuration.

REP segment ID auto-discovery limitations

- The only supported port-pairing is uplinks Gi1/1 and Gi1/2. The same port pairing is applicable for Ten Gigabit Ethernet (Te) ports.
- If you configure a REP segment on a downlink port, the switch receives the segment ID from the upstream switch and connects the partner downlink port to the same segment. The switch does not pass the segment ID to its partner port. As a result, you must explicitly configure the partner port of the downlink pair.
- This feature does not support the insertion of an edge node into an existing segment. Configure static or manual REP segment IDs on both the primary and secondary edge devices.
- When inserting a new switch between two existing segment switches, connect the interface of the new switch to the corresponding interfaces on the existing switches that transmit the same segment ID.

Incorrect connections cause segment failure. This requirement also applies when you remove a node between two others.

For example, if Gi1/1 of switch1 and Gi1/2 of switch2 are part of an existing segment, and you insert switch3 between them, ensure that the interfaces connect to Gi1/1 of switch1 and Gi1/2 of switch2. This approach includes switch3 in the same segment.

- If you configure REP automatically on an interface using the **rep segment auto** command, and later remove the REP configuration with the **no rep segment** command or overwrite it with the **rep segment** <> command, you cannot configure REP automatically again by using the **rep segment auto** command. To restore automatic configuration, shut down the interface, bring it up, and enter the **rep segment** auto command again.
- REP segment ID auto-discovery depends on the CDP protocol. It does not support EtherChannel links.

Configuring Resilient Ethernet Protocol

A segment is a collection of ports that are connected to one another in a chain and configured with a segment ID. To configure REP segments, configure the REP administrative VLAN (or use the default VLAN 1) and then add the ports to the segment, using interface configuration mode. You should configure two edge ports in a segment, with one of them being the primary edge port and the other the secondary edge port by default. A segment should have only one primary edge port. If you configure two ports in a segment as primary edge ports, for example, ports on different switches, the REP selects one of them to serve as the segment's primary edge port. If necessary, you can configure the location to which segment topology change notices (STCNs) and VLAN load balancing are to be sent.

Default REP Configuration

- REP is disabled on all the interfaces. When enabled, the interface is a regular segment port unless it is configured as an edge port.
- When REP is enabled, the task of sending segment topology change notices (STCNs) is disabled, all the VLANs are blocked, and the administrative VLAN is VLAN 1.
- When VLAN load balancing is enabled, the default is manual preemption with the delay timer disabled. If VLAN load balancing is not configured, the default after manual preemption is to block all the VLANs in the primary edge port.
- REP Fast is disabled by default.
- REP Zero Touch Provisioning is enabled by default at the global level and disabled at the interface level.

REP configuration guidelines and limitations

Follow these guidelines when configuring REP:

- Begin by configuring one port, then contiguous ports to minimize the number of segments and blocked ports.
- If more than two ports in a segment fail without external neighbors, one port transitions to a forwarding state to maintain connectivity.

- In the **show interfaces rep** command output, failed ports show roles as Fail Logical Open and Fail No Ext Neighbor. When external neighbors are configured, ports transition through alternate states to open or remain alternate.
- REP ports must be Layer 2 IEEE 802.1Q or trunk ports.
- Configure all trunk ports in the segment with the same allowed VLANs.
- Avoid enabling REP through a SSH or Telnet on the same interface used for the session, as REP blocks all VLANs until unblocked by another REP interface, risking loss of connectivity.
- For configuration changes, shut down or disable the interface, apply changes, then enable or unshut the interface
- REP and STP cannot run on the same segment or interface.
- STP connections to REP segments must be at the segment edge to avoid bridging loops; all STP BPDUs are dropped at REP interfaces.
- The **rep stcn** command is mandatory at REP-STP boundaries where ENN is configured to allow status change notifications.
- On a switch, if REP is enabled on two ports, both must be either regular segment ports or edge ports:
  - Only two ports per switch can belong to the same REP segment.
  - If one port is configured, it should be an edge port.
  - Two ports in the same segment must be both edge, both regular, or one regular and one edge no-neighbor port.
  - Misconfiguration treating an edge port and regular segment port on the same switch results in the edge port being treated as regular.
- REP interfaces start and remain blocked until safe to unblock; monitor status to avoid connection loss.
- REP sends all LSL PDUs untagged on the native VLAN; BPA messages use the administration VLAN (default VLAN 1).
- The **rep lsl-age-timer** command configures how long a REP interface stays up without receiving a hello (120 ms to 10,000 ms). The LSL hello timer is age-timer divided by three.
  - Use **rep lsl-age-timer** only for non-REP fast copper Gigabit interfaces.
  - EtherChannel port channels do not support values less than 1000 ms; attempts to configure lower values are rejected.
  - The **rep lsl-age-timer** command is intended for scenarios where normal link down detection is too slow.
- FastEthernet and fiber connections do not require **lsl-age-timer**. Gigabit copper can use REP fast instead of **lsl-age-timer**.
- REP ports cannot be configured as:
  - Switched Port Analyzer (SPAN) destination port
  - Tunnel port

- Access port

- REP is supported on EtherChannels but not on individual ports within an EtherChannel.
- Switch supports a maximum of 26 open REP segments or 3 REP fast segments.

Note To increase the number of REP segments, an expansion module can be attached to the base module.

- REP ring size is unlimited, but rings larger than 20 nodes may not achieve desired convergence.

REP ZTP Configuration Guidelines

- REP ZTP requires the PnP feature to be present on the switches.
- This transient state change in port forwarding behavior in NO_NEIGHBOR state allows a DHCP request message to reach a DHCP server and unblock PnP provisioning of a new switch. There should not be any impact to the REP state machine after PnP completion.
- The changes in REP behavior during the NO_NEIGHBOR state apply only to REP Zero Touch Provisioning (ZTP). If the PnP feature is not present, normal REP functionality should work as expected.
- REP ZTP is supported on physical and EtherChannel interfaces.
- REP ZTP is supported on both copper (downlink) and fiber (uplink) interfaces.
- REP ZTP is interoperable only with other IE switching products running IOS XE that claim REP ZTP support.

Configure REP Administrative VLAN

To avoid the delay created by link-failure messages, and VLAN-blocking notifications during load balancing, REP floods packets to a regular multicast address at the hardware flood layer (HFL). These messages are flooded to the whole network, and not just the REP segment. You can control the flooding of these messages by configuring an administrative VLAN.

Follow these guidelines when configuring the REP administrative VLAN:

- If you do not configure an administrative VLAN, the default is VLAN 1.
- You can configure one admin VLAN on the switch for all segments.
- The administrative VLAN cannot be the RSPAN VLAN.

To configure the REP administrative VLAN, follow these steps, beginning in privileged EXEC mode:

Procedure

	Command or Action	Purpose
Step 1	**enable**	Enables privileged EXEC mode.

	Command or Action	Purpose
	Example: `Device> enable`	Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**rep admin vlan** *vlan-id* **Example:** `Device(config)# rep admin vlan 2`	Specifies the administrative VLAN. The range is from 2 to 4094. To set the admin VLAN to 1, which is the default, enter the **no rep admin vlan** global configuration command.
Step 4	**end** **Example:** `Device(config)# end`	Exits global configuration mode and returns to privileged EXEC mode.
Step 5	**show interface** [*interface-id*] **rep detail** **Example:** `Device# show interface gigabitethernet1/1 rep detail`	(Optional) Verifies the configuration on a REP interface.
Step 6	**copy running-config startup config** **Example:** `Device# copy running-config startup config`	(Optional) Saves your entries in the switch startup configuration file.

Configure a REP Interface

To configure REP, enable REP on each segment interface and identify the segment ID. This task is mandatory, and must be done before other REP configurations. You must also configure a primary and secondary edge port on each segment. All the other steps are optional.

Follow these steps to enable and configure REP on an interface:

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.

	Command or Action	Purpose
Step 3	**interface** *interface-id* **Example:** `Device(config)# interface gigabitethernet1/1`	Specifies the interface, and enters interface configuration mode. The interface can be a physical Layer 2 interface or a port channel (logical interface).
Step 4	**switchport mode trunk** **Example:** `Device(config-if)# switchport mode trunk`	Configures the interface as a Layer 2 trunk port.
Step 5	**rep segment** *segment-id* [**edge** [**no-neighbor**] [**primary**]] [**preferred**] **Example:** `Device(config-if)# rep segment 1 edge no-neighbor primary`	Enables REP on the interface and identifies a segment number. The segment ID range is from 1 to 1024. **Note** You must configure two edge ports, including one primary edge port, for each segment. These optional keywords are available: • (Optional) **edge**: Configures the port as an edge port. Each segment has only two edge ports. Entering the keyword **edge** without the keyword **primary** configures the port as the secondary edge port. • (Optional) **primary**: Configures the port as the primary edge port, the port on which you can configure VLAN load balancing. • (Optional) **no-neighbor**: Configures a port with no external REP neighbors as an edge port. The port inherits all the properties of an edge port, and you can configure the properties the same way you do for an edge port. **Note** Although each segment can have only one primary edge port, if you configure edge ports on two different switches and enter the keyword **primary** on both the switches, the configuration is valid. However, REP selects only one of these ports as the segment primary edge port. You can identify the primary edge port for a segment by entering the **show rep topology** command in privileged EXEC mode. • (Optional) **preferred**: Indicates that the port is the preferred alternate port or the preferred port for VLAN load balancing.

	Command or Action	Purpose
		Note Configuring a port as preferred does not guarantee that it becomes the alternate port; it merely gives the port a slight edge over equal contenders. The alternate port is usually a previously failed port.
Step 6	**rep stcn** {**interface** *interface id* | **segment** *id-list* | **stp**} **Example:** `Device(config-if)# rep stcn segment 25-50`	(Optional) Configures the edge port to send segment topology change notices (STCNs). • **interface** *interface-id*: Designates a physical interface or port channel to receive STCNs. • **segment** *id-list*: Identifies one or more segments to receive STCNs. The range is from 1 to 1024. • **stp**: Sends STCNs to STP networks. **Note** Spanning Tree (MST) mode is required on edge no-neighbor nodes when **rep stcn stp** command is configured for sending STCNs to STP networks. **Note** The incorrect configuration of STCN on the edge leads to a loop in the network topology.
Step 7	**rep block port** {**id** *port-id* | *neighbor-offset* | **preferred**} **vlan** {*vlan-list* | **all**} **Example:** `Device(config-if)# rep block port id 0009001818D68700 vlan 1-100`	(Optional) Configures VLAN load balancing on the primary edge port, identifies the REP alternate port in one of three ways (**id** *port-id*, *neighbor_offset*, **preferred**), and configures the VLANs to be blocked on the alternate port. • **id** *port-id*: Identifies the alternate port by port ID. The port ID is automatically generated for each port in the segment. You can view interface port IDs by entering the **show interface** *type number* **rep** [**detail**] privileged EXEC command. • *neighbor_offset*: Number to identify the alternate port as a downstream neighbor from an edge port. The range is from -256 to 256, with negative numbers indicating the downstream neighbor from the secondary edge port. A value of **0** is invalid. Enter **-1** to identify the secondary edge port as the alternate port.

	Command or Action	Purpose
		Note Because you enter the **rep block port** command at the primary edge port (offset number 1), you cannot enter an offset value of 1 to identify an alternate port. • **preferred**: Selects the regular segment port previously identified as the preferred alternate port for VLAN load balancing. • **vlan** *vlan-list*: Blocks one VLAN or a range of VLANs. • **vlan all**: Blocks all the VLANs. **Note** Enter this command only on the REP primary edge port.
Step 8	**rep preempt delay** *seconds* **Example:** `Device(config-if)# rep preempt delay 100`	(Optional) Configures a pre-empt time delay. • Use this command if you want VLAN load balancing to be automatically triggered after a link failure and recovery. • The time delay range is between 15 to 300 seconds. The default is manual pre-emption with no time delay. **Note** Enter this command only on the REP primary edge port.
Step 9	**rep lsl-age-timer** *value* **Example:** `Device(config-if)# rep lsl-age-timer 2000`	(Optional) Configures a time (in milliseconds) for which the REP interface remains up without receiving a hello from a neighbor. The range is from 120 to 10,000 ms in 40-ms increments. The default is 5000 ms (5 seconds). **Note** • EtherChannel port channel interfaces do not support LSL age-timer values that are less than 1000 ms. • Ensure that both the ports on the link have the same LSL age configured in order to avoid link flaps.

	Command or Action	Purpose
Step 10	**end** **Example:** `Device(config-if)# end`	Exits global configuration mode and returns to privileged EXEC mode.
Step 11	**show interface** [*interface-id*] **rep** [**detail**] **Example:** `Device# show interface gigabitethernet1/1 rep detail`	(Optional) Displays the REP interface configuration.
Step 12	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the router startup configuration file.

Setting Manual Preemption for VLAN Load Balancing

If you do not enter the **rep preempt delay** *seconds* interface configuration command on the primary edge port to configure a preemption time delay, the default is to manually trigger VLAN load balancing on the segment. Be sure that all the other segment configurations have been completed before manually preempting VLAN load balancing. When you enter the **rep preempt delay segment** *segment-id* command, a confirmation message is displayed before the command is executed because preemption might cause network disruption.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.

Step 2	**rep preempt segment** *segment-id*
	Example:
	`Device# rep preempt segment 100`
	`The command will cause a momentary traffic disruption.`
	`Do you still want to continue? [confirm]`
		Manually triggers VLAN load balancing on the segment.
		You need to confirm the command before it is executed.

Step 3	**show rep topology segment** *segment-id* **Example:** `Device# show rep topology segment 100`	(Optional) Displays REP topology information.
Step 4	**end** **Example:** `Device# end`	Exits privileged EXEC mode.

Configuring SNMP Traps for REP

You can configure a router to send REP-specific traps to notify the Simple Network Management Protocol (SNMP) server of link-operational status changes and port role changes.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**snmp mib rep trap-rate** *value* **Example:** `Device(config)# snmp mib rep trap-rate 500`	Enables the switch to send REP traps, and sets the number of traps sent per second. • Enter the number of traps sent per second. The range is from 0 to 1000. The default is 0 (no limit is imposed; a trap is sent at every occurrence).
Step 4	**end** **Example:** `Device(config)# end`	Returns to privileged EXEC mode.
Step 5	**show running-config** **Example:** `Device# show running-config`	(Optional) Displays the running configuration, which can be used to verify the REP trap configuration.
Step 6	**copy running-config startup-config** **Example:** `Device# copy running-config startup-config`	(Optional) Saves your entries in the switch startup configuration file.

Configuring REP ZTP

To configure REP ZTP, you enable or disable it at the global level and the interface level. The default states are:

- Global level: Enabled
- Interface level: Disabled

You must explicitly enable the feature at the interface level on the upstream device interface connected to the downstream device. When enabled, only that interface will receive notification from the downstream switch to block or unblock the PnP startup VLAN.

Procedure

Step 1 Enter global configuration mode:

```
Switch# configure terminal
```

Step 2 Globally enable REP ZTP:

```
Switch(config)# rep ztp
```

Use the no form of the command to disable REP ZTP: `Switch(config)# no rep ztp`

Step 3 Enter interface configuration mode on the upstream device interface that is connected to the downstream device:

```
Switch(config)# interface <interface-name>
```

Step 4 Enable REP ZTP on the interface:

```
Switch(config-if)#rep ztp-enable
```

Use the no form of the command to disable REP ZTP on the interface: `Switch(config-if)#no rep ztp-enable`

Example

The following example shows the minimum configuration required to enable the REP ZTP feature on the upstream device interface that is connected to a downstream device.

```
Switch#show running-config interface gigabitEthernet 1/1
Building configuration...

Current configuration : 93 bytes
!
interface GigabitEthernet1/1
 switchport mode trunk
 rep segment 100
 rep ztp-enable
end
```

Configure REP segment ID auto-discovery

Use this configuration during new REP ring deployments, ring expansions, or when you want to minimize manual configuration steps. This process simplifies and accelerates ring deployments.

Before you begin

- Verify that your switch model and software version support REP segment ID auto-discovery.
- Identify which devices will be configured as edge nodes (these require static configuration).

- Ensure that CDP is enabled on all devices.

Perform these steps to configure REP segment ID auto-discovery:

Procedure

Step 1 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Device# configure terminal
```

Step 2 Use the **rep autodisc** command to configure REP auto discovery.

Example:

```
Device(config)# rep autodisc
```

Use **no rep autodisc** command to disable the REP auto discovery.

Step 3 Use the **interface** *interfacename interface-id* command to enter the interface configuration mode.

Example:

```
Device(config)# interface GigabitEthernet1/3
```

Step 4 Use the **rep segment auto** command to enable auto-discovery on an interface that participates in the REP ring.

Example:

```
Device(config-if)# rep segment auto
```

Use **no rep segment** command to disable auto-discovery.

Step 5 Use the **rep segment** *segment-id* **edge** command to configure static REP on edge nodes with static REP segment ID.

Example:

```
Device(config-if)# rep segment 100 edge
```

Step 6 (Optional) Use the **show interfaces rep detail** command to check the status of REP segment ID auto-discovery on the segment.

Example:

This example shows that the REP segment ID auto-discovery is globally enabled on a device.

```
Device# show interfaces rep detail
REP Segment Id Auto Discovery Status: Enabled
```

This example shows that the REP segment ID auto-discovery is globally disabled on a device.

```
Device# show interfaces rep detail
REP Segment Id Auto Discovery Status: Disabled
```

This example shows that the REP segment ID on the interface is configured automatically.

```
Device# show interfaces rep detail
REP Segment Id Type: Auto
```

This example shows that the REP segment ID on the interface is configured manually.

```
Device# show interfaces rep detail
REP Segment Id Type: Manual
```

Preventive best practices

Control-plane load governance

Ensure overall control-plane load is kept within safe limits to avoid interference with critical protocols such as REP, BFD, and PTP.

- Configure monitoring tools and SNMP polling intervals conservatively to prevent excessive CPU utilization.
- Account for concurrent CPU-intensive features, such as high-frequency SNMP polling, PTP traffic bursts, and BFD sessions, especially during topology changes or reconvergence events.
- Operate devices on stable and recommended software releases to benefit from validated fixes, performance improvements, and resiliency enhancements.

PTP and topology change stabilization

- Reduce transient CPU spikes that timing and topology adjustments can cause.
- Allow sufficient stabilization time for PTP after topology changes to reduce short-term CPU utilization increases.
- Avoid overlapping PTP adjustments with REP reconvergence or other CPU-intensive events.

REP design and operational planning

Design and operate REP with simplicity and predictability to minimize control-plane impact.

- Design REP rings only when operationally necessary. Avoid excessive, overlapping, or unnecessary rings that can increase reconvergence time and CPU load.
- Review and tune REP timing parameters, such as **rep preempt delay**, to align with resiliency goals and operational requirements.
- Plan configuration changes, maintenance windows, and REP topology modifications carefully to avoid multiple simultaneous control-plane events.

CPU monitoring and diagnostics

Continuously monitor system health to detect and mitigate CPU stress early.

- Monitor CPU utilization trends, particularly during REP convergence, power events, and maintenance activities.
- Periodically review system logs and resource utilization for recurring or sustained CPUHOG events linked to REP or other control-plane processes.

- Enable and retain sufficient logging and diagnostic data to support effective troubleshooting during abnormal conditions.

Recommended operational checks

Use these commands to monitor system state and collect diagnostic information.

- **show processes cpu sorted**
- **show platform resource**
- **show rep topology**
- **show logging**
- **show tech-support**

Monitoring Resilient Ethernet Protocol Configurations

This is an example of the output for the **show interface** [*interface-id*] **rep** [**detail**] command. This output shows the REP configuration and status on an uplink port.

```
Device# show interfaces GigabitEthernet1/1 rep detail

GigabitEthernet1/1 REP enabled
Segment-id: 3 (Primary Edge)
PortID: 03010015FA66FF80
Preferred flag: No
Operational Link Status: TWO_WAY
Current Key: 02040015FA66FF804050
Port Role: Open
Blocked VLAN: <empty>
Admin-vlan: 1
REP-ZTP Status: Disabled
Preempt Delay Timer: disabled
Configured Load-balancing Block Port: none
Configured Load-balancing Block VLAN: none

SVT_3400_2       Gi1/4             Open
10.64.106.68     Gi1/2             Open
10.64.106.68     Gi1/1             Open
10.64.106.63     Gi1/2        Sec  Alt
```

Displaying REP ZTP Status

Use the **show** command to identify the state of REP ZTP on an interface. In the following example, the feature is disabled on interface GigabitEthernet 1/1 and it is enabled on interface GigabitEthernet 1/1. The status of **pnp_startup_vlan** is "Blocked".

Procedure

Step 1 In priviledged exec mode, enter:

show interfaces rep detail

Example:

```
GigabitEthernet1/1   REP enabled
Segment-id: 100 (Segment)
PortID: 00016C13D5AC4320
Preferred flag: No
Operational Link Status: TWO_WAY
Current Key: 00026C13D5AC43209DAB
Port Role: Open
Blocked VLAN: <empty>
Admin-vlan: 1
REP-ZTP Status: Disabled
REP Segment Id Auto Discovery Status: Enabled
REP Segment Id Type: Manual
Preempt Delay Timer: disabled
LSL Ageout Timer: 5000 ms
LSL Ageout Retries: 5
Configured Load-balancing Block Port: none
Configured Load-balancing Block VLAN: none
STCN Propagate to: none
LSL PDU rx: 382, tx: 297
HFL PDU rx: 0, tx: 0
BPA TLV rx: 1, tx: 19
BPA (STCN, LSL) TLV rx: 0, tx: 0
BPA (STCN, HFL) TLV rx: 0, tx: 0
EPA-ELECTION TLV rx: 95, tx: 0
EPA-COMMAND TLV rx: 0, tx: 0
EPA-INFO TLV rx: 95, tx: 95

GigabitEthernet1/1   REP enabled
Segment-id: 100 (Segment)
PortID: 00026C13D5AC4320
Preferred flag: No
Operational Link Status: NO_NEIGHBOR
Current Key: 00026C13D5AC43209DAB
Port Role: Fail No Ext Neighbor
Blocked VLAN: 1-4094
Admin-vlan: 1
REP-ZTP Status: Enabled
REP-ZTP PnP Status: Unknown
REP-ZTP PnP Vlan: 1
REP-ZTP Port Status: Blocked
REP Segment Id Auto Discovery Status: Enabled
REP Segment Id Type: Manual
Preempt Delay Timer: disabled
LSL Ageout Timer: 5000 ms
LSL Ageout Retries: 5
Configured Load-balancing Block Port: none
Configured Load-balancing Block VLAN: none
STCN Propagate to: none
LSL PDU rx: 11, tx: 11
HFL PDU rx: 0, tx: 0
BPA TLV rx: 0, tx: 0
BPA (STCN, LSL) TLV rx: 0, tx: 0
BPA (STCN, HFL) TLV rx: 0, tx: 0
EPA-ELECTION TLV rx: 0, tx: 0
EPA-COMMAND TLV rx: 0, tx: 0
EPA-INFO TLV rx: 0, tx: 0
```

Step 2 Use the show command again to display the status of **pnp_startup_vlan**.

When the downstream device is booted up, it sends notification to the connected upstream switch interface to unblock the **pnp_startup_vlan** for it to get the DHCP IP address and further establish communication with the PNP server or Cisco Catalyst Center. The show command indicates the status as "Unblocked".

The following syslogs on the upstream switch notify you about FWD and BLK of ports. There are no syslogs in the downstream switch as PnP takes control of the console and no syslogs can be printed on the console.

```
REP-6-ZTPPORTFWD: Interface GigabitEthernet1/1 moved to forwarding on ZTP
notification
```

```
REP-6-ZTPPORTBLK: Interface GigabitEthernet1/1 moved to blocking on ZTP
notification
```

Example:

```
Switch#show interfaces rep detail
GigabitEthernet1/1   REP enabled
Segment-id: 100 (Segment)
PortID: 00016C13D5AC4320
Preferred flag: No
Operational Link Status: TWO_WAY
Current Key: 00026C13D5AC43209DAB
Port Role: Open
Blocked VLAN: <empty>
Admin-vlan: 1
REP-ZTP Status: Disabled
REP Segment Id Auto Discovery Status: Enabled
REP Segment Id Type: Manual
Preempt Delay Timer: disabled
LSL Ageout Timer: 5000 ms
LSL Ageout Retries: 5
Configured Load-balancing Block Port: none
Configured Load-balancing Block VLAN: none
STCN Propagate to: none
LSL PDU rx: 430, tx: 358
HFL PDU rx: 0, tx: 0
BPA TLV rx: 1, tx: 67
BPA (STCN, LSL) TLV rx: 0, tx: 0
BPA (STCN, HFL) TLV rx: 0, tx: 0
EPA-ELECTION TLV rx: 107, tx: 0
EPA-COMMAND TLV rx: 0, tx: 0
EPA-INFO TLV rx: 107, tx: 108

GigabitEthernet1/1   REP enabled
Segment-id: 100 (Segment)
PortID: 00026C13D5AC4320
Preferred flag: No
Operational Link Status: NO_NEIGHBOR
Current Key: 00026C13D5AC43209DAB
Port Role: Fail No Ext Neighbor
Blocked VLAN: 1-4094
Admin-vlan: 1
REP-ZTP Status: Enabled
REP-ZTP PnP Status: In-Progress
REP-ZTP PnP Vlan: 69
REP-ZTP Port Status: Unblocked
REP Segment Id Auto Discovery Status: Enabled
REP Segment Id Type: Manual
Preempt Delay Timer: disabled
LSL Ageout Timer: 5000 ms
LSL Ageout Retries: 5
Configured Load-balancing Block Port: none
Configured Load-balancing Block VLAN: none
STCN Propagate to: none
LSL PDU rx: 32, tx: 40
HFL PDU rx: 0, tx: 0
```

```
BPA TLV rx: 0, tx: 0
BPA (STCN, LSL) TLV rx: 0, tx: 0
BPA (STCN, HFL) TLV rx: 0, tx: 0
EPA-ELECTION TLV rx: 0, tx: 0
EPA-COMMAND TLV rx: 0, tx: 0
EPA-INFO TLV rx: 0, tx: 0
```

Step 3 Use the **show platform hardware fed switch active vlan** *vlan-id* command to check the interface state of the PnP startup VLAN:

Example:

```
Switch#show platform hardware fed switch active vlan 901
vlan id is:: 901
Interfaces in forwarding state: : Gig1/1(Untagged), Gig1/2(Untagged)
flood list: : Gig1/1, Gig1/2
```

Step 4 (Optional) Use the following debug commands to troubleshoot REP ZTP:

- **debug rep lslsm**: This command helps you understand LSL state machine events in the NO_NEIGHBOR state.
- **debug rep packet**: Use this command to dump LSL packets with the REP ZTP LSL TLV to check the PnP status on the peer client node.

PTP over REP

PTP over REP is a time synchronization solution that:

- combines Precision Time Protocol (PTP) with Resilient Ethernet Protocol (REP),
- provides accurate and predictable time synchronization in ring and linear Layer 2 topologies, and
- maintains timing continuity during link or node failures in industrial networks.

PTP over REP is essential for environments that require accurate timing for applications such as motion control, protection relays, and distributed control systems. It also ensures that network resiliency does not cause timing reconvergence events that disrupt these applications.

REP ensures rapid topology recovery, while PTP maintains synchronization accuracy across the restored topology.

Use cases

Common PTP over REP use cases include:

- An industrial ring network that uses REP for fast failover and PTP to synchronize controllers and field devices.
- A linear REP topology that connects network nodes in industrial environments where precise time alignment is required for monitoring and protection applications.

Guidelines for PTP over REP

- Each Boundary Clock (BC) introduces additional delay at every hop.
- Transparent Clock (TC) deployments minimize per-hop delay contribution. TCs are limited to a single VLAN.
- PTP over REP supports both standard REP and REP Fast. When using REP Fast, configure REP Fast on all ports in the ring. Do not mix standard REP and REP Fast within the same ring.

PTP clock types profiles and their accuracy

Table 205: PTP clock types, profiles, and their accuracy

Platforms	PTP clock type	PTP profile	PTP accuracy	Number of REP rings
Cisco Catalyst IE9300 Rugged Series Switch	• Boundary Clock • Grandmaster Boundary Clock • Transparent Clock	Default (IEEE 1588 v2), Power 2011/2017	Boundary Clock (BC): ~200 ns per hop Transparent Clock (TC): ~50 ns per hop	Up to 26 open REP segments
Cisco IE3500 Rugged Series Switch	• Boundary Clock • Grandmaster Boundary Clock • Transparent Clock	Default Profile (IEEE 1588 v2), Power Profile 2011/2017	Boundary Clock (BC): ~200 ns per hop Transparent Clock (TC): < 200 ns per hop	Up to 26 open REP segments or 3 REP Fast segments

Note

- End-to-end accuracy depends on the cumulative delay introduced by the number of BCs and TCs in the network path.
- The stated PTP accuracy values do not apply when GLC-T copper SFP transceivers are used in the timing path because these transceivers can reduce PTP timing accuracy.

Table 206: PTP over REP capabilities

Category	Support
PTP clocks	• Boundary Clock • Grandmaster Clock • Transparent Clock

Category	Support
PTP profiles	• Default (IEEE 1588 v2) • Power Profile 2011/2017 (platform-dependent)
Media	• Copper ports • SFP-based fiber ports
REP topology	• Ring topologies • Linear topologies • Up to 26 REP rings
VLAN behavior	• Boundary Clocks support multiple VLANs. • Transparent Clocks support a single VLAN.

Configure PTP over REP

You can configure PTP over REP using either of the following profiles:

- Configure PTP over REP using default profile
- Configure PTP over REP using power profile

Configure REP

Configures REP on switch interfaces to enable ring topology and PTP packet transport by setting the administrative VLAN and segment membership for ring ports.

Procedure

Step 1 Create and activate VLAN:

a) Use the **configure terminal** command to enter global configuration mode.

Example:

```
Switch# configure terminal
```

b) Use the **vlan** *vlan-id* command to create VLAN configuration on the switch, which serves as both the REP administrative VLAN and the PTP transport VLAN.

Example:

```
Switch(config)# vlan 100
```

c) (Optional) Use the **no shutdown** command in VLAN configuration mode to ensure that VLAN is administratively enabled.

Example:

```
Switch(config-vlan)# no shutdown
```

Note
This command applies to the Layer 2 VLAN and not an SVI. It helps clear an existing `lshut` state in a brownfield network.

The **lshut** status means that the VLAN is locally shut down.

d) Use the **exit** command to return to global configuration mode.

Example:

```
Switch(config-vlan)# exit
```

Step 2 Configure REP on interface:

a) Use the **interface** *interface-id* command to configure the interface.

Example:

```
Switch(config)# interface GigabitEthernet1/3
```

b) Use the **switchport mode trunk** command on the interface to set the first ring-facing port to trunk mode, allowing VLAN-tagged traffic including PTP packets to pass through.

Example:

```
Switch(config-if)# switchport mode trunk
```

c) Use the **switchport trunk allowed vlan** *vlan-id* command to explicitly permit VLAN on the trunk, ensuring PTP messages are not blocked by VLAN filtering.

Example:

```
Switch(config-if)# switchport trunk allowed vlan 100
```

d) Use the **rep segment** *segment-id* command to add interface as a non-edge member, enabling it to participate in the resilient ring topology and carry PTP packets.

Example:

```
Switch(config-if)# rep segment 10
```

e) Use the **no shutdown** command to enable the interface.

Example:

```
Switch(config-if)# rep segment 10
```

f) Use the **exit** command to return to global configuration mode.

Example:

```
Switch(config-if)# exit
```

g) Use the **rep admin vlan** *vlan-id* command to configure VLAN as the REP administrative VLAN to ensure REP control messages and PTP packets share the same VLAN and are not filtered.

Example:

```
Switch(config)# rep admin vlan 100
```

Repeat step 2 to configure REP on the second interface.

Step 3 (Optional) Use the **show rep topology** command to verify that the switch ports appear in REP segmen topology with `Open` state before proceeding with PTP configuration.

Example:

```
Switch# show rep topology
REP Segment 10

BridgeName       PortName   Edge Role
---------------- ---------- ---- ----
RB1              Gi4/0/7    Pri  Open
Switch           Gi1/3           Open
Switch           Gi1/4           Open
RB2              Gi2/0/7         Open
RB2              Gi2/0/8         Alt
LANB-1           Gi1/4           Open
LANB-1           Gi1/3           Open
RB1              Gi4/0/8    Sec  Open
```

Configure PTP over REP using power profile

Configure PTP over REP using the power profile to enable precise time synchronization across industrial ring topologies.

Before you begin

Ensure REP is configured.

Procedure

Step 1 Clear the existing PTP configuration.

a) Use the **configure terminal** command to enter global configuration mode.

Example:

```
Switch# configure terminal
```

b) Use the **no ptp profile** command to remove any existing PTP profile configuration before applying a new one.

Example:

```
Switch(config)# no ptp profile
```

c) Use the **no ptp mode** command to remove any existing PTP mode configuration on the switch.

Example:

```
Switch(config)# no ptp mode
```

d) Use the **no ptp domain** command to remove any existing PTP domain configuration on the switch.

Example:

```
Switch(config)# no ptp domain
```

Step 2 Configure REP on an interface.

a) Use the **interface** *interface-id* command to configure the interface.

Example:

```
Switch(config)# interface GigabitEthernet1/3
```

b) Use the **rep segment** *segment-id* command to add the interface as a non-edge member, enabling it to participate in the resilient ring topology and carry PTP packets.

Example:

```
Switch(config-if)# rep segment 10
```

c) Use the **exit** command to return to global configuration mode.

Example:

```
Switch(config-if)# exit
```

Repeat step 2 to configure REP on the second interface.

Step 3 Configure PTP power profile, mode, and domain.

a) Use the **ptp profile power** command to configure the power profile on the switch.

Example:

```
Switch(config)# ptp profile power
```

b) Use the **ptp mode p2ptransparent** command to configure the switch as a peer-to-peer Transparent Clock (TC) under the power profile.

Example:

```
Switch(config)# ptp mode p2ptransparent
```

c) Use the **ptp domain** *domain-number* command to assign the switch to PTP domain, ensuring it participates in the correct PTP synchronization domain.

Example:

```
Switch(config)# ptp domain 100
```

Step 4 Use the **interface** *interface-id* command to configure the first REP ring-facing interface and enter interface configuration mode.

Example:

```
Switch(config)# interface GigabitEthernet1/3
```

Step 5 Use the **ptp vlan** *vlan-id* command on the interface to bind PTP operation to VLAN on the first REP ring-facing interface.

Example:

```
Switch(config-if)# ptp vlan 100
```

Step 6 Use the **exit** command to return to global configuration mode.

Example:

```
Switch(config-if)# exit
```

Repeat steps 4 to 6 to configure PTP VLAN on the other ring-facing interface.

Step 7 Verify the REP configuration.

Example:

```
Switch# show rep topology
REP Segment 10

BridgeName       PortName   Edge Role
---------------- ---------- ---- ----
```

```
RB1             Gi4/0/7    Pri  Open
Switch          Gi1/3           Open
Switch          Gi1/4           Open
RB2             Gi2/0/7         Open
RB2             Gi2/0/8         Alt
LANB-1          Gi1/4           Open
LANB-1          Gi1/3           Open
RB1             Gi4/0/8    Sec  Open
```

Configure PTP over REP using default profile

Configure PTP over REP using the default profile to enable precise time synchronization across industrial ring topologies.

Before you begin

Ensure REP is configured.

Procedure

Step 1 Use these commands to clear the existing PTP configuration:

a) Use the **configure terminal** command to enter global configuration mode.

Example:

```
Switch# configure terminal
```

b) Use the **no ptp profile** command to remove any existing PTP profile configuration before applying a new one.

Example:

```
Switch(config)# no ptp profile
```

c) Use the **no ptp mode** command to remove any existing PTP mode configuration on the switch.

Example:

```
Switch(config)# no ptp mode
```

d) Use the **no ptp domain** command to remove any existing PTP domain configuration on the switch.

Example:

```
Switch(config)# no ptp domain
```

Step 2 Configure REP on an interface:

a) Use the **interface** *interface-id* command to select the interface and enter interface configuration mode.

Example:

```
Switch(config)# interface GigabitEthernet1/3
```

b) Use the **rep segment** *segment-id* command to add the interface as a nonedge member, enabling it to participate in the resilient ring topology and carry PTP packets.

Example:

```
Switch(config-if)# rep segment 10
```

c) Use the **exit** command to return to global configuration mode.

Example:

```
Switch(config-if)# exit
```

Repeat step 2 to configure REP on the second interface.

Step 3 Configure PTP mode and domain:

a) Use the **ptp mode e2etransparent** command to configure the switch as an end-to-end Transparent Clock (TC).

Example:

```
Switch(config)# ptp mode e2etransparent
```

b) Use the **ptp domain** *domain-number* command to assign the switch to PTP domain, ensuring it participates in the correct PTP synchronization domain.

Example:

```
Switch(config)# ptp domain 100
```

c) Use the **end** command to return to privileged EXEC mode.

Example:

```
Switch(config)# end
```

Step 4 (Optional) Use the **show rep topology** command to verify the REP configuration.

Example:

```
Switch# show rep topology
REP Segment 10
BridgeName   PortName   Edge   Role
------------ ---------- ----   ----
RB1          Gi4/0/7    Pri    Open
Switch       Gi1/3              Open
Switch       Gi1/4              Open
RB2          Gi2/0/7            Open
RB2          Gi2/0/8            Alt
LANB-1       Gi1/4              Open
LANB-1       Gi1/3              Open
RB1          Gi4/0/8    Sec    Open
```

Media Redundancy Protocol

Media Redundancy Protocol (MRP), defined in International Electrotechnical Commission (IEC) standard 62439-2, provides fast convergence in a ring network topology for Industrial Automation networks. MRP Media Redundancy Manager (MRM) defines its maximum recovery times for a ring in the following range: 200 ms and 500 ms.

Note The default maximum recovery time on the Cisco IE switch is 200 ms for a ring composed of up to 50 nodes. You can configure the switch to use the 500 ms recovery time profile as described in Configure MRP Auto-Manager, on page 2686. The 10 ms and 30 ms recovery time profiles are not supported.

MRP operates at the MAC layer and is commonly used in conjunction with the PROFINET standard for industrial networking in manufacturing.

MRP Mode

MRP is supported on the switches.

MRP CLI mode is managed by the Cisco IOS XE CLI and WebUI, a web-based user interface (UI).

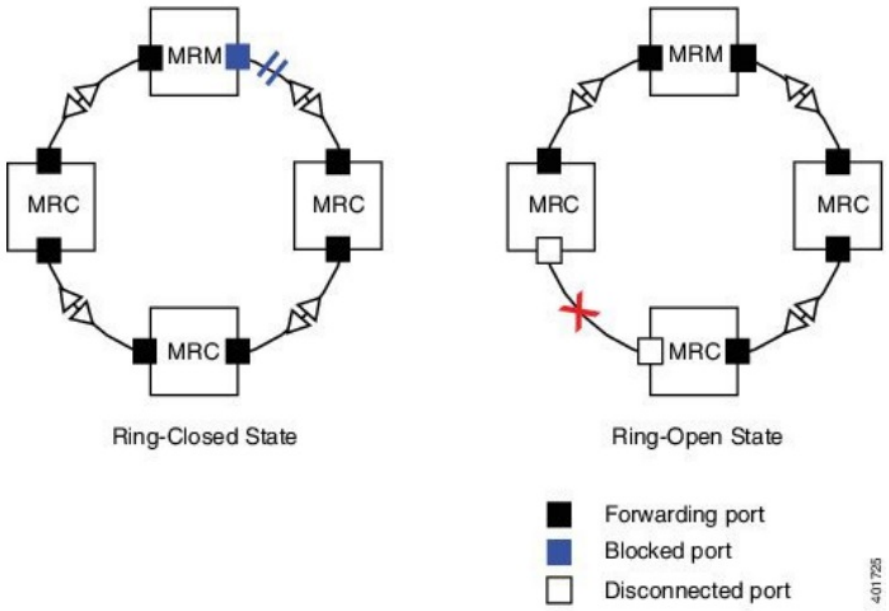
Note When managing the switch in MRP CLI mode, you cannot download the MRP configuration from Siemens STEP7/TIA.

Protocol Operation

In an MRP ring, the MRM serves as the ring manager, while the Media Redundancy Clients (MRCs) act as member nodes of the ring. Each node (MRM or MRC) has a pair of ports to participate in the ring. The MRM initiates and controls the ring topology to react to network faults by sending control frames on one ring port over the ring and receiving them from the ring over its other ring port, and conversely in the other direction. An MRC reacts to received reconfiguration frames from the MRM and can detect and signal link changes on its ring ports.

On the switch, certain nodes or all nodes in the ring can also be configured to start as a Media Redundancy Automanager (MRA). MRAs select one MRM among each other by using a voting protocol and a configured priority value. The remaining MRAs transition to the MRC role.

All MRM and MRC ring ports support the following states:



- Disabled: Ring ports drop all received frames.
- Blocked: Ring ports drop all received frames except MRP control frames and some standard frames, for example, LLDP.
- Forwarding: Ring ports forward all received frames.
- Not Connected: The link is physically down or disconnected. (This state differs from the Disabled state, in which the MRP Port is manually disabled through software.)

During normal operation, the network operates in the Ring-Closed state (see figure below). To prevent a loop, one of the MRM ring ports is blocked, while the other port is forwarding. Most of the time, both ring ports of all MRCs are in the forwarding state. With this loop avoidance, the physical ring topology becomes a logical stub topology.

In the figure, note the following details about the two rings, left and right:

- Left Ring: The connection (small blue square, top) on the MRM is in a blocked state (as shown by the two parallel lines) because no ports are disconnected.
- Right Ring: Two MRC connections (left and center small white squares) are in the disabled state because the link between them is broken, as marked by a red “x”.

Figure 176: MRP Ring States

If a network failure occurs:

- The network shifts into the Ring-Open state.
- In the case of failure of a link connecting two MRCs, both ring ports of the MRM change to the forwarding state, the MRCs adjacent to the failure have a disabled and a forwarding ring port, and the other MRCs have both ring ports forwarding.

In the Ring-Open state, the network logical topology becomes a stub.

Layer 2 Ethernet frames will be lost during the time required for the transition between these two ring states. The MRP protocol defines the procedures to automatically manage the switchover to minimize the switchover time. A recovery time profile, composed of various parameters, drives the MRP topology convergence performance. The 200 ms profile supports a maximum recovery time of 200 ms.

MRP uses three types of control frames:

- To monitor the ring status, MRM regularly sends test frames on both ring ports.
- When MRM detects failure or recovery, it sends TopoChange frames on both ring ports.
- When MRC detects failure or recovery on a local port, it sends LinkChange subtype frames, Linkdown and Linkup, to the MRM.

Media Redundancy Automanager

If configured to start as a Media Redundancy Automanager (MRA), the node or nodes select an MRM using a voting protocol and configured priority value. The remaining MRAs transition to the MRC role. All nodes must be configured as MRA. A manually configured MRM and MRA in the same ring is not supported.

Note

- You can activate MRA through the CLI. See the section Configuring MRP CLI Mode, on page 2686 in this guide.
- Although MRAs transition to the MRC role after an MRM is selected, you cannot explicitly configure an MRC.

The MRA role is not an operational MRP role like MRM or MRC. It is only an administrative, temporary role at device startup, and a node must transition to the MRM role or the MRC role after startup and the MRM is selected though the manager voting process.

MRA functions as follows:

1. At power on, all MRAs begin the manager voting process. Each MRA begins to send MRP_Test frames on both ring ports. The MRP_Test frame contains the MRA's priority value. The remote manager's priority value contained in the received MRP_Test frames are compared with the MRA's own priority. If its own priority is higher than the received priority, the MRA sends a negative test manager acknowledgment (MRP_TestMgrNAck) frame, along with the remote manager's MAC address.
2. If the receiving MRA receives an MRP_TestMgrNAck with its own MAC address, the receiving MRA initiates the transition into the client (MRC) role.
3. The MRP_TestPropagate frame informs other MRA devices in the client role about the role change and the new higher priority manager. The clients receiving this frame update their higher priority manager information accordingly. This ensures that clients remain in the client role if the monitored higher priority manager role changes.

Licensing

You do not need a feature license to use MRP with Switches. MRP works with either base license—Network Essentials or Network Advantage.

To find information about platform support and to know which license levels a feature is available with, use Cisco Feature Navigator. To access Cisco Feature Navigator, go to https://www.cisco.com/go/cfn. An account on cisco.com is not required.

Multiple MRP Rings

In an Industrial Ethernet network, an MRP ring in a cell/area is a sub-ring of the access layer. You can connect multiple MRP rings, which you can then aggregate into the distribution layer.

You can configure up to 3 rings. The MRP switch can be configured only as an auto-manager.

MRP-STP Interoperability

MRP works with Spanning Tree Protocol (STP) to prevent unwanted broadcast loops in the event that a user accidentally connects a device that does not participate in the MRP ring. In a network operating with MRP

and STP, spanning tree bridge protocol data units (BPDUs) are not sent on MRP-enabled ports. If ports are unconfigured from an MRP ring, then the ports are added to the spanning tree.

MRP-STP interoperability is supported in MRP CLI mode, and functions without additional CLI configuration.

Prerequisites

- Because MRP is deployed in a physical Ring topology, before configuring or unconfiguring the MRP feature, it is advised to leave one physical connection between two nodes in each ring open by either issuing a **shut** command on the connecting interfaces or physically removing the cable to avoid any network storms. After you have properly configured all MRMs, issue a **no shut** command on the port or re-connect the cable between the nodes.
- The use of extended VLANs is permitted in VTP mode 3.
- VLAN-specific restrictions apply when configuring the ring.
- The VLAN must be configured before setting up the ring.
- The VLAN range should align with platform-level limitations.

Guidelines and Limitations

General Guidelines and Limitations

- To avoid Smart License registration failure, ensure that the NTP configuration and the device clock are in sync.
- Support for multiple MRP rings is available only through the CLI or WebUI.
- The switch supports up to 50 MRCs per ring.
- MRP cannot run on the same interface (port) as Resilient Ethernet Protocol (REP), Device Level Ring (DLR), Spanning Tree Protocol (STP), Flex Links, macsec, or Dot1x.
- For access ports, you must specifically configure **switchport mode access** and **switchport access vlan** *x* commands in the MRP interface.
- MRP interfaces come up in a forwarding state and remain in a forwarding state until notified that it is safe to block. The MRP ring state changes to Ring-Closed.
- MRP ports cannot be configured as any of these port types: SPAN destination port, Private VLAN port, or Tunnel port.
- MRP is not supported on EtherChannels or on an individual port that belongs to an EtherChannel.
- Each MRP ring can have one MRP VLAN. The VLAN must be different for each ring in a device to avoid traffic flooding.

MRP CLI Mode Guidelines and Limitations

- After using the CLI to configure the MRP ring, you must attach the MRP ring to a pair of ports that support MRP.
- Both MRP ports must have the same interface mode (access or trunk).
- To change an existing MRP ring's configuration (mode), or to change the interface mode of the ring ports between access and trunk, you must first delete the ring and then recreate it with the new configuration.
- When both MRP ports are in access mode, the access VLANs should match. If the configured MRP VLAN does not match the ports' access VLAN, the MRP VLAN is automatically changed to the MRP ports' access VLAN.
- In an MRP ring with two access ports, if the ports do not belong to the same access VLAN when you create the MRP ring or you change the access VLAN for only one of the ports after the MRP ring is created, the MRP ring operation is suspended and a message similar to the following is displayed:

  ```
  ERROR% The ring 1 ports don't belong to the same access VLAN. The MRP ring will not
  function until the issue has been fixed
  ```

  Resolve the issue by configuring the access VLAN to be the same for the two ring ports.
- The 200 ms standard profile and 500 ms profile are supported. The 10 ms profile and 30 ms profile are not supported.
- You can activate MRA through the CLI.
- Although MRAs transition to the MRC role after an MRM is selected, you cannot explicitly configure an MRC.

Default Settings

- MRP is disabled by default; MRP CLI is the default mode when MRP is enabled.
- The default VLAN is 1.

Note Create the non-default VLAN before you assign it to MRP ring 1.

Fast MRP

Fast Media Redundancy Protocol (Fast MRP) is a layer 2 redundancy capability that

- supports industrial Ethernet ring topologies that require fast recovery
- provide high availability in ring topologies by enabling rapid recovery from link or node failures, and
- provides fast convergence using the 30 ms traffic profile

Starting from Cisco IOS XE release 26.2.1, switch supports 12 MRP rings.

Table 207: Feature history

Feature name	Release information	Description
Fast MRP	26.2.1	This feature expands Fast MRP support on IE3500 from 3 to 12 rings with 30ms convergence and up to 50 nodes per ring. It enables you to build larger, more scalable industrial networks with near-zero downtime during failures, reducing infrastructure costs while maintaining continuous operation of critical manufacturing and automation systems.

Guidelines and limitations of Fast MRP

Guidelines

- Ensure the number of rings does not exceed 12.
- Ensure the number of nodes per ring does not exceed 50.
- Use the 30 ms traffic profile for Fast MRP deployments.

Limitations

Table 208: Fast MRP supported parameters and their value

Paramater	Description or supported value
Maximum number of rings	12
Traffic profiles	30 ms
Convergence behavior	Convergence to all traffic profiles within the 30 ms profile requirement
Maximum nodes per ring	50
Maximum multicast groups	128, spread across multiple rings or VLANs
Maximum MAC addresses:	12,000 per node
Maximum VLANs	Same as the system supported VLAN limit, as defined in the platform configuration guide

Configure fast MRP

To configure Fast MRP, configure the 30 ms profile at the Configure the Switch as MRA in MRP CLI mode

Guidelines and limitations to PROFINET MRP mode

Before configuring the Cisco switch with PROFINET MRP through Siemens TIA or STEP7, ensure the following:

- The PROFINET MRP feature does not support the MRC role.
- Use the TIA portal to configure or modify the MRA role.
- Avoid using the CLI for configuration when TIA is in use. MRP CLI mode and PROFINET MRP mode are mutually exclusive.
- If the switch is connected to the PROFINET PLC, the output of **show profinet status | include Connected** should appear **Yes** . If it shows **No** , the switch is not connected to the PROFINET PLC.
- Ensure that the GSD file version matches the Cisco IOS release to avoid compatibility issues. Refer to the PROFINET Protocol Configuration Guide for detailed configuration instructions.

Install the PROFINET GSD File

The PROFINET MRP GSD file is bundled with the Cisco IOS XE software release. After the switch boots at least one time, the GSD files for the switch are located in a directory called "ProfinetGSD". In this directory, there is a zip file containing all the GSDs for all the switch SKUs. Use the GSD file bundled with the release and included in the ProfinetGSD directory.

Note Remove the older GSD XML file from TIA 15 or STEP 7 to ensure compatibility with the Cisco IOS software.

Configure PROFINET MRP

This task guides you through configuring PROFINET MRP to ensure proper network operation and redundancy.

Before you begin

Disconnect an MRP Ethernet port from the ring (open ring) to discover all neighboring devices using the LLDP protocol. Perform this step before deploying PROFINET MRP to the network. This approach prevents unnecessary flooding if configuration issues occur.

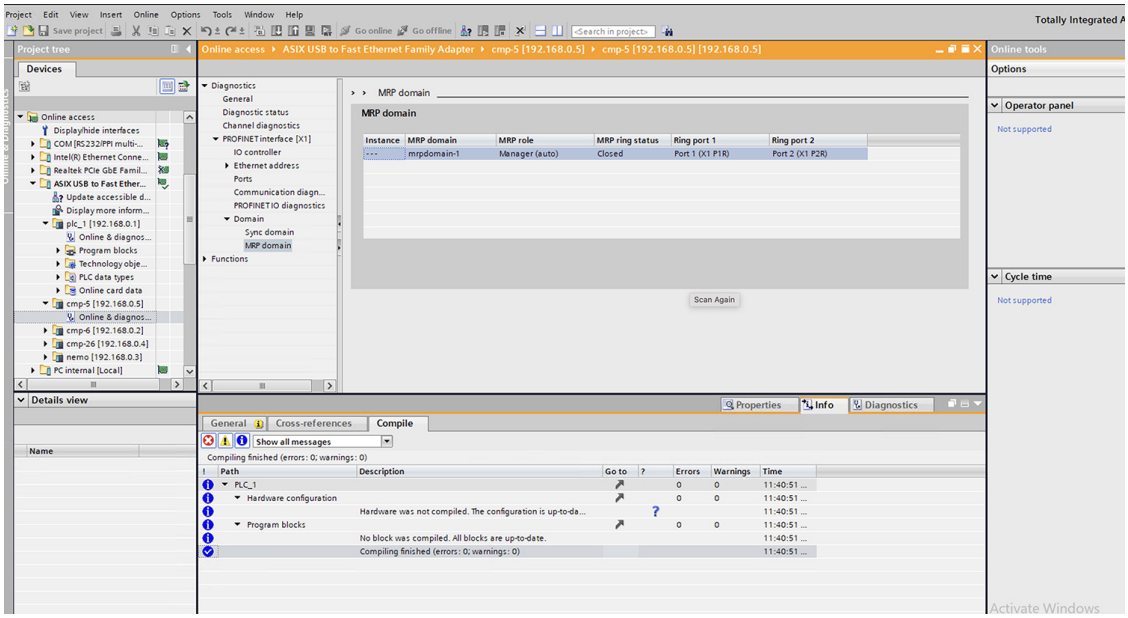
- (Optional) Verify **Neighbor Discovery** with LLDP.

  Use the command **show lldp neighbor** to confirm all neighbor devices are correctly discovered before continuing with PROFINET MRP setup.
- Check that the PROFINET status indicates a **connected-state**.
- Inspect the MRP ring port status:

  Use the **profinet mrp ring 1** command.

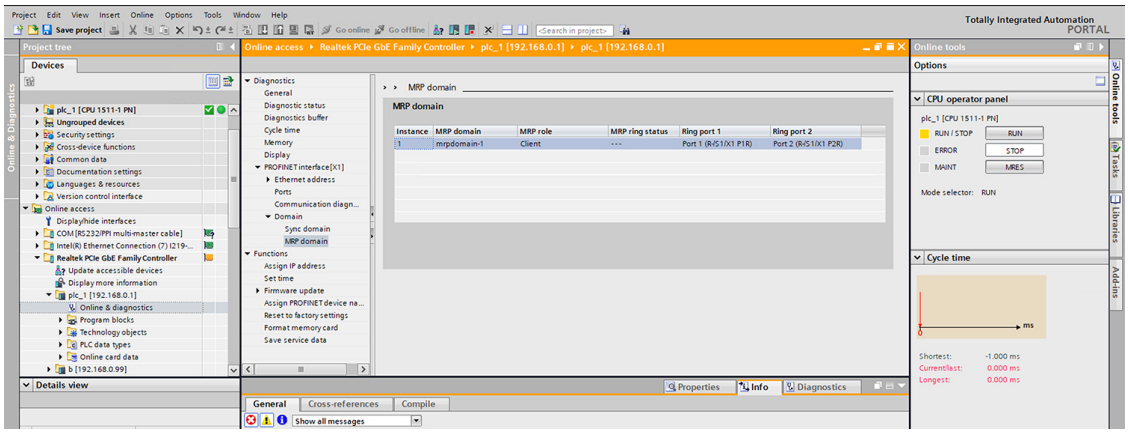
Procedure

Step 1 Access the PROFINET Device Discovery (DCP) window.



Open the PROFINET DCP window to identify and manage devices in the network.

Figure 177: PROFINET Device Discovery (DCP) window before configuring MRP



Step 2 Assign PROFINET MRP Manager role and domain name on MRM device.

Figure 178: PROFINET MRP Manager role and MRP domain name

Step 3 Define the PROFINET MRP client and MRP domain name on client devices.

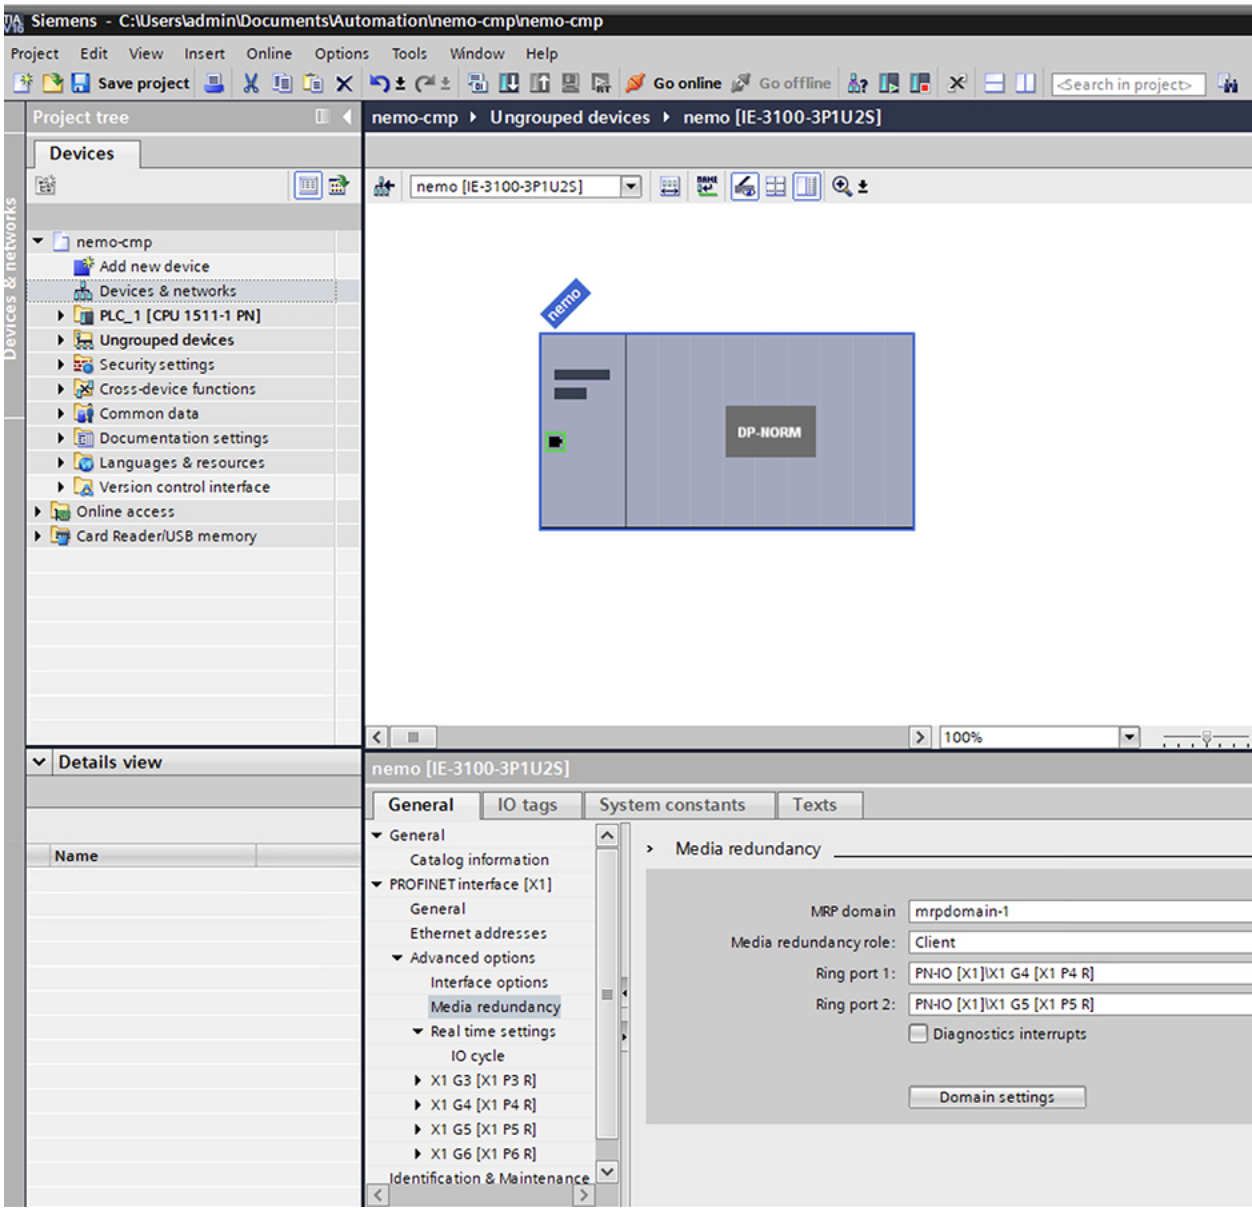


Figure 179: PROFINET MRP and MRP domain on client

Step 4 When using MRA mode, configure all devices and domain details.

Step 5 Configure the PROFINET MRP interfaces on all devices participating in the ring.

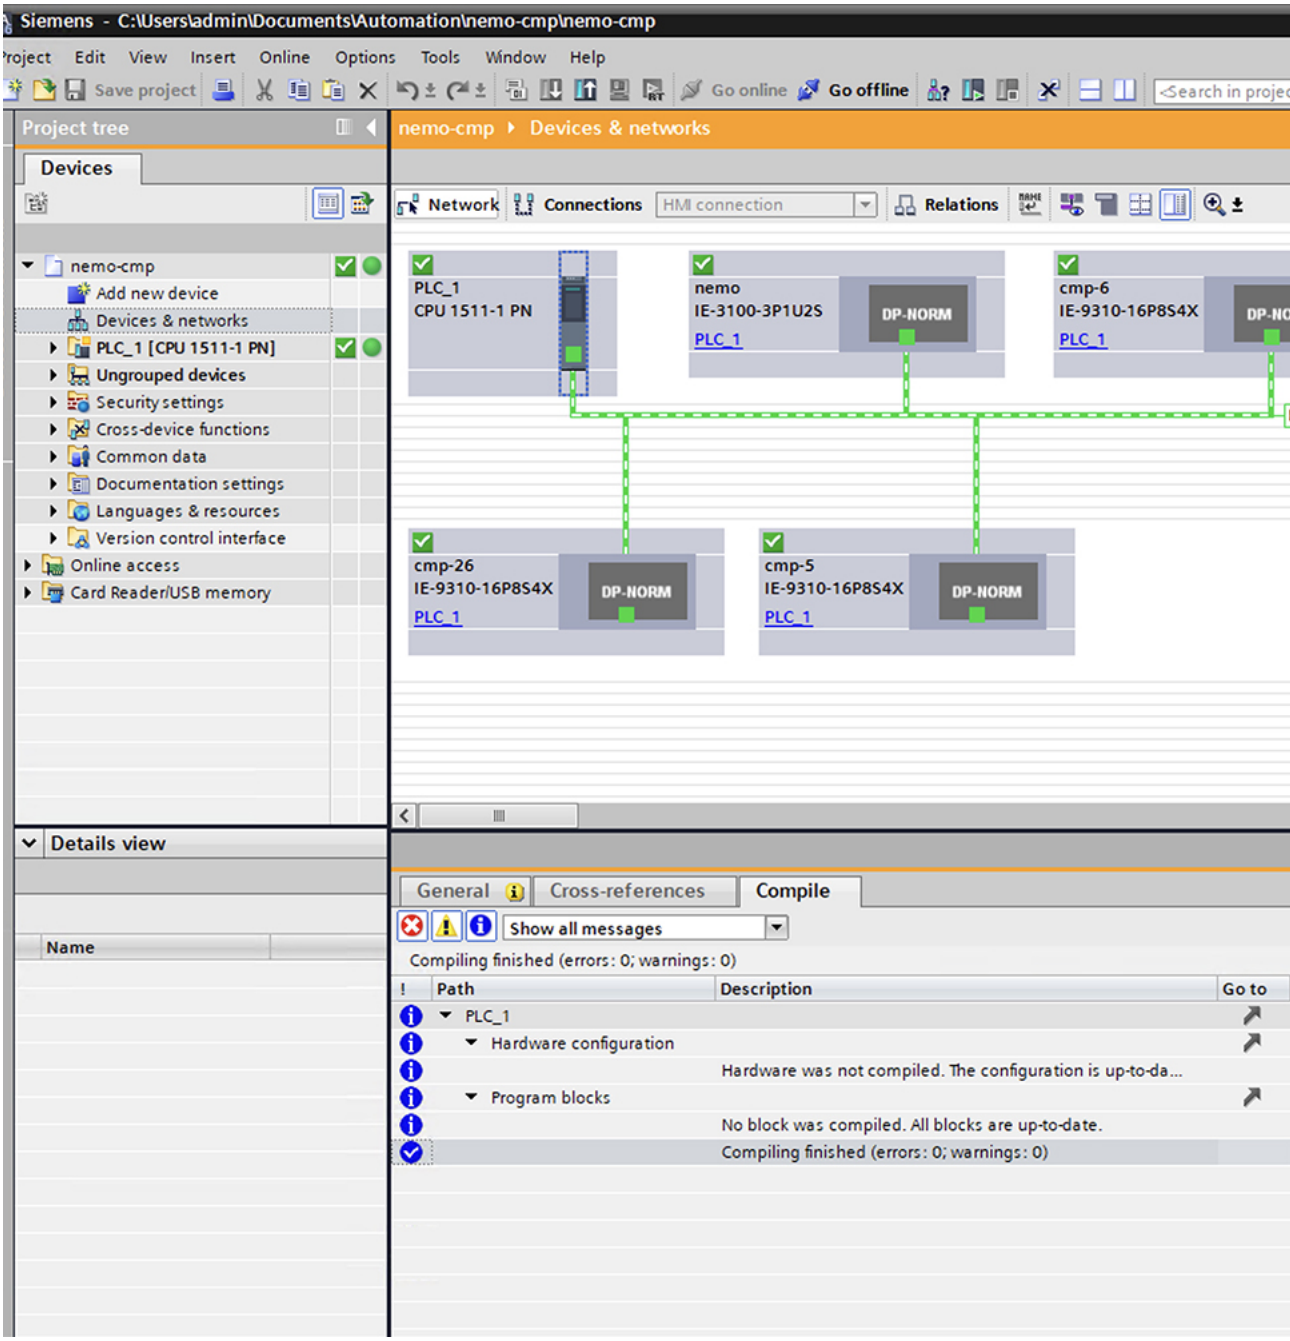

Figure 180: PROFINET MRP inerfaces

Step 6 Compile the configuration, and then download it to the PLC device.

Step 7 Verify that all devices are connected and the MRP ring is closed.

Figure 181: PROFINET MRP network configuration diagram

Step 8 Verify on the devices that the MRP ring is closed by using the **show profinet mrp ring 1** command:

Ensure that one port is in the **Blocked** state and the other port is in the **Forwarding** state.

Managing PROFINET Using Simatic Step 7 or TIA 15 Portal

This section provides an overview of key screens within the TIA portal. It does not provide any configuration details. For details on using the TIA portal, refer to the Siemens Simatic STEP7 user documentation.

Note MRP automanager in PROFINET mode is supported only in TIA V15.

Figure 182: PROFINET Device Discovery (DCP) Window Before Configuring MRP

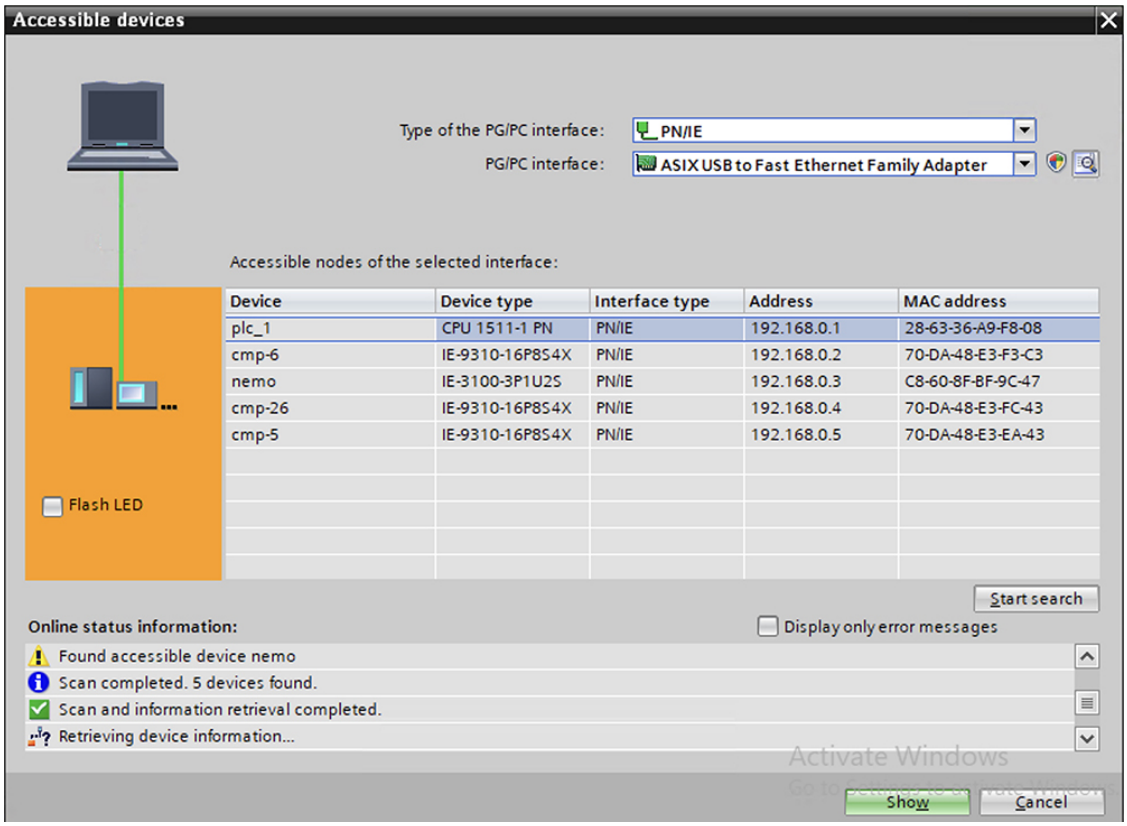

Figure 183: Define PROFINET MRP Manager and MRP domain

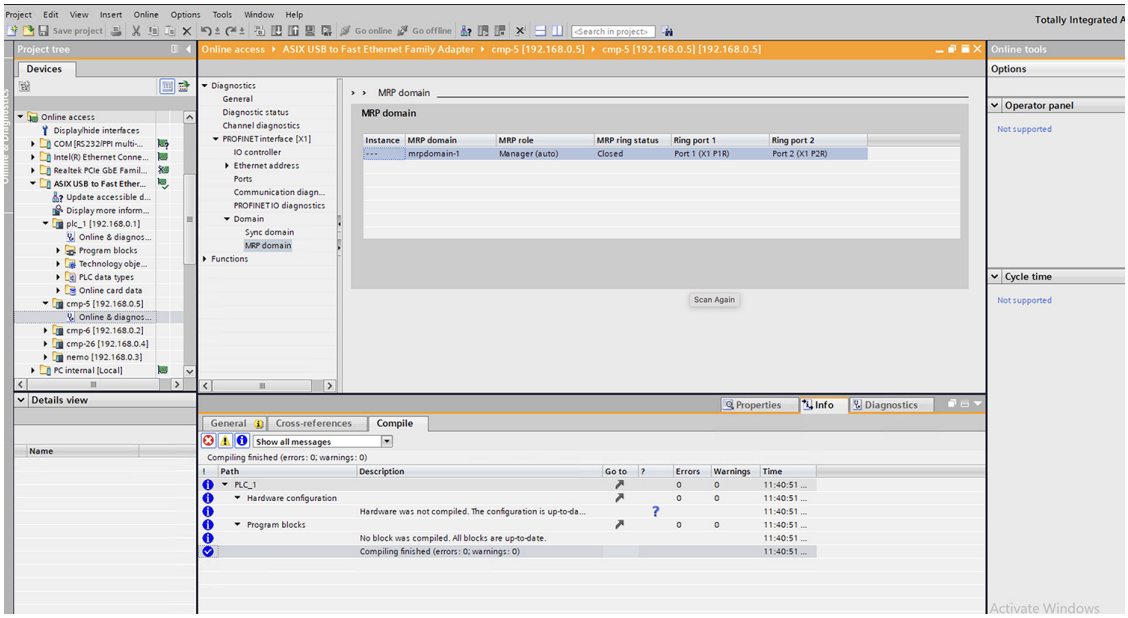

Figure 184: Define PROFINET MRP Client and MRP Domain

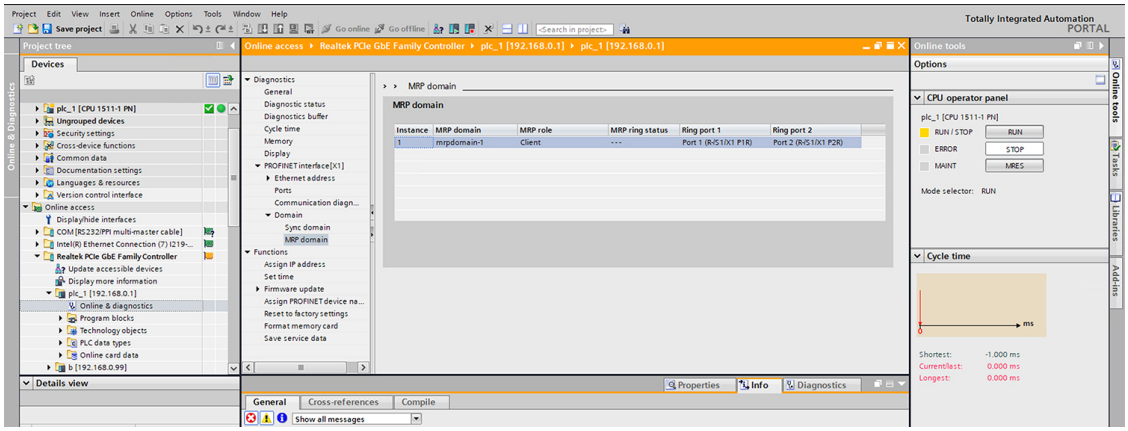

Figure 185: Define PROFINET MRP Interfaces

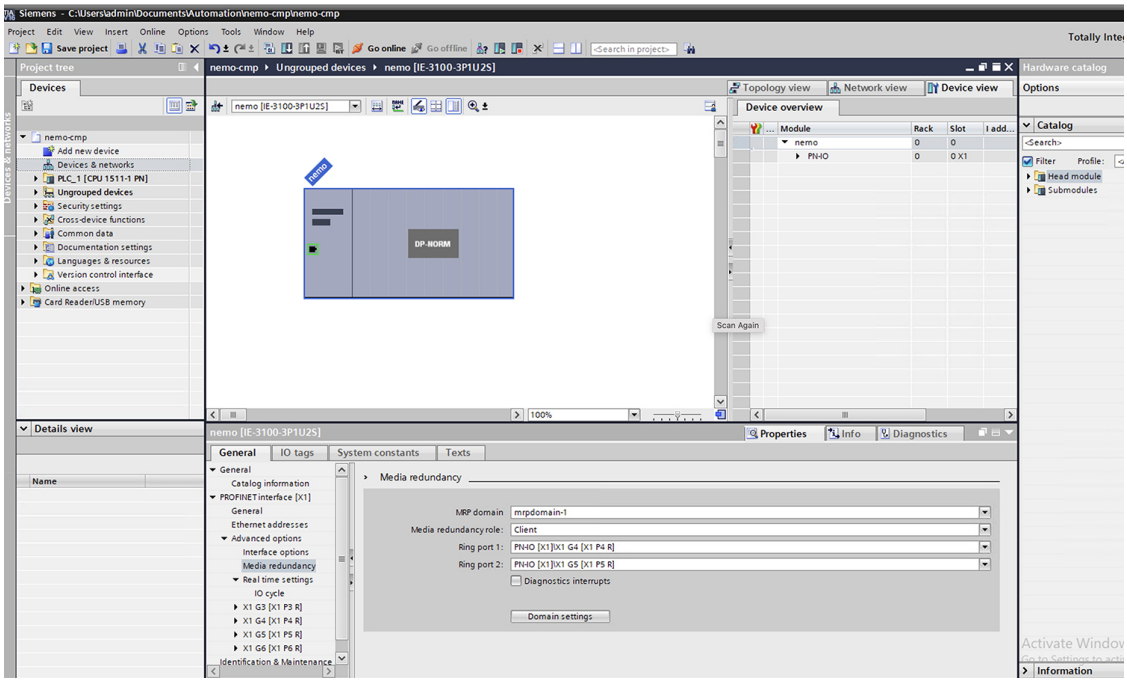

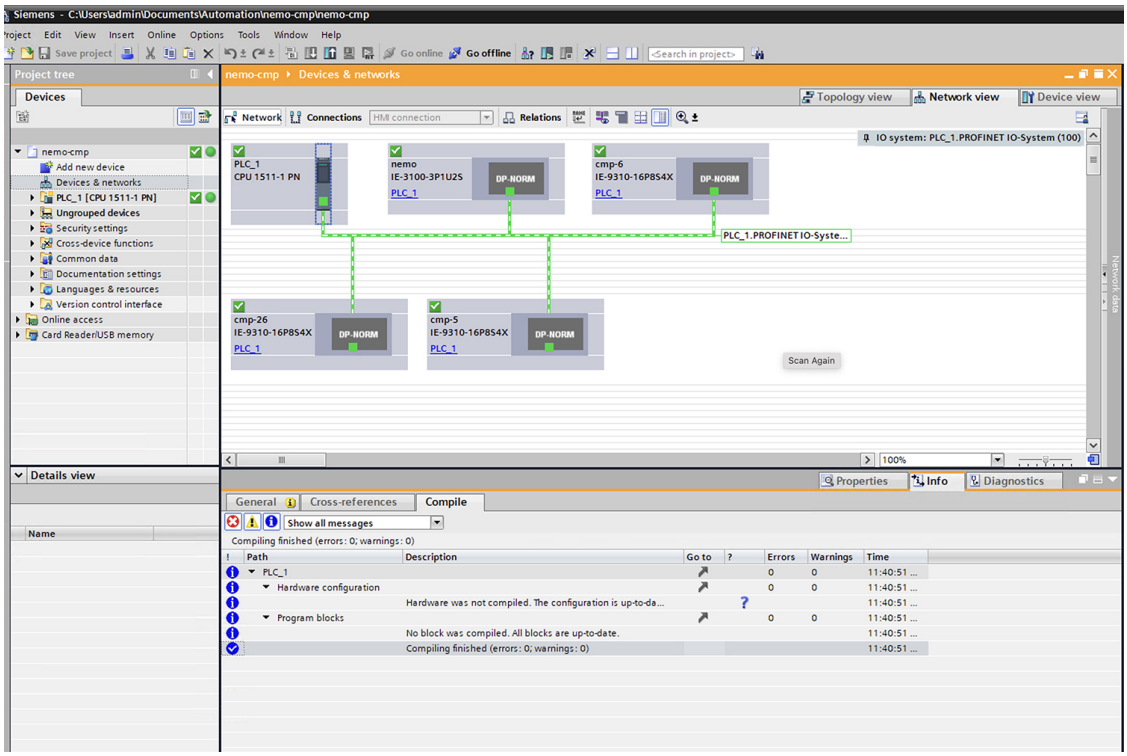

Figure 186: PROFINET MRP Network Configuration Diagram

Configuring MRP CLI Mode

To configure MRP, configure the node as MRA and specify the two MRP ports. Starting with Cisco IOS XE release 26.2.1, you can configure up to 12 rings on the device (the device can be manager or client) with a manager instance for each ring and one manager per device.

These MRP configuration parameters are optional:

- domain-id: A unique ID that represents the MRP ring.
- domain-name: Logical name of the configured MRP domain-ID.
- profile: 200 ms (the default)
- vlan-id: VLAN for sending MRP frames.

Configure MRP Auto-Manager

Perform this procedure to configure the switch as MRA in MRP CLI mode, which is the default.

Note If the device is connected to a PLC module, ensure **no device in the ring** is selected for MRP.

Procedure

Step 1 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Switch# configure terminal
```

Step 2 Configure MRP

a) Use the **no profinet mrp** command to disable PROFINET MRP.

Example:

```
Switch# no profinet mrp
```

b) Use the **mrp ring** *mrp_id* command to enable MRP.

Example:

```
Switch(config)# mrp ring 1
```

Starting from Cisco IOS XE release 26.1.1, MRP supports up to 12 rings.

Step 3 Configure Auto-Manager mode and domain parameters

a) Use the **mode auto-manager** command to configure MRP auto-manager mode on the switch.

Example:

```
Switch(config-mrp)# mode auto-manager
```

b) (Optional for single MRP ring) Use the **domain-id** *domain_value* command to configure the domain ID.

Example:

```
Switch(config-mrp-auto-manager)# domain-id FFFFFFFF-FFFF-FFFF-FFFF-FFFFFFFFFFFF
```

domain_value : UUID string of 32 hexadecimal digits in five groups separated by hyphens.

Example: 550e8400-e29b-41d4-a716-446655440000

The default domain ID for ring 1 is FFFFFFFF-FFFF-FFFF-FFFF-FFFFFFFFFFFF.

The default domain ID for ring 2 is FFFFFFFF-FFFF-FFFF-FFFF-FFFFFFFFFFFE and so on for other rings.

Note
Only change the domain-ID from the default when required. Each ring should have its own domain ID. No two rings share the same domain ID.

c) (Optional for single MRP ring) Use the **domain-name** *name* command to configure the domain name.

Example:

```
Switch(config-mrp-auto-manager)# domain-name cisco
```

name : String of up to 32 characters.

d) (Optional) Use the **vlan-id** *vlan* command to configure the VLAN ID.

Example:

```
Switch(config-mrp-auto-manager)# vlan-id 10
```

Step 4 Configure Recovery Profile, Priority, and Interval

a) (Optional) Use the **profile** { **30** | **200** | **500** } command to configure the recovery profile.

Example:

```
Switch(config-mrp-auto-manager)# profile 30
```

- 30: Maximum recovery time 30 milliseconds.
- 200: Maximum recovery time 200 milliseconds.
- 500: Maximum recovery time 500 milliseconds.

Starting from Cisco IOS XE release 26.1.1, MRP profile supports 30 ms also.

b) (Optional) Use the **priority** *value* command to configure the MRA priority.

Example:

```
Switch(config-mrp-auto-manager)# priority 40960
```

value : Range <36864 – 61440>, lowest: 65535.

The default priority is 40960.

c) (Optional) Use the **interval** *interval* command to configure the interval.

Example:

```
Switch(config-mrp-auto-manager)# interval 3
```

- 3: 3 milliseconds MRP_Test default interval for 30 ms profile.

- 20: 20 milliseconds MRP_Test default interval for 200 ms profile.
- 50: 50 milliseconds MRP_Test default interval for 500 ms profile.
- <3-10>: Optional faster MRP_Test interval in milliseconds.

Note
The `Interval` field is not displayed in WebUI for MRP.

The optional faster MRP_Test interval can be configured only when the ring is formed with IE3500 devices.

d) Use the **exit** command to return to global configuration mode.

Example:

```
Switch(config-mrp-auto-manager)# exit
```

Step 5 Configure the ring ports

a) Use the **interface** *interface-id* command to specify the ID of the port that serves as the first ring port.

Example:

```
Switch(config)# interface GigabitEthernet1/1
```

b) Use the **switchport mode** { **access** | **trunk** } command to configure the interface mode.

Example:

```
Switch(config-if)# switchport mode access
```

You must specify **switchport mode access** when configuring MRP in access mode.

c) Use the **mrp ring** *ring_id* command to associate the interface to the MRP ring.

Example:

```
Switch(config-if)# mrp ring 1
```

Step 6 Use the **end** command to return to privileged EXEC mode.

Example:

```
Switch(config-mrp-auto-manager)# end
```

Step 7 (Optional) Use the **show mrp ring** *ring_id* command to monitor the MRP ring configuration.

Example:

```
Switch# show mrp ring 1
MRP ring 1
Profile : 30 ms
Mode : Auto-Manager
Priority : 40960
Operational Mode: manager
From : CLI
License : Active

Test Monitoring Extended Interval Count : N/A
```

Note
When the switch is operating in `CLI mode and PROFINET mode`, the **show mrp ring** output shows `License: Not Applicable`

Step 8 Use the **show mrp ports** command to monitor MRP port status.

Example:

```
Switch# show mrp ports
Ring ID : 1
PortName                Status
--------------------------------------
GigabitEthernet1/1         Forwarding
GigabitEthernet1/2         Blocked
```

Configuration Example

The following example shows the MRP switch configured as automanager:

```
Switch# configure terminal
Switch# no profinet mrp
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# mrp ring 1
Switch(config-mrp)# mode auto-manager
Switch(config-mrp-auto-manager)# priority 36864
Switch(config-mrp-auto-manager)# profile 30
Switch(config-mrp-auto-manager)# end
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gi1/1
Switch(config-if)# switchport mode trunk
Switch(config-if)# mrp ring 1

Verifying the Configuration

You can use the following commands to verify the MRP configuration.

Command	Description
show mrp ring? {**1 - 22**}	Display details about the MRP ring configuration.
show mrp ports	Display details about the MRP port states. If MRP is not configured on any ports, display shows N/A.
show mrp ring {**1 - 22**} **statistics** [**all** | **event** | **hardware** | **packet** | **platform**]	Display details about the MRP ring operation.
debug mrp-ring [**alarm**|**cli** | **client** | **license** | **manager** | **packet** | **platform**]	Trace MRP events. **Note** **manager** is available only when the switch is configured as manager or automanager.
show tech-supportmrp	Display all MRP details.

Media Redundancy Client

Media Redundancy Client (MRC) is a network redundancy capability that:

- enables Cisco switches to participate as client nodes in a Media Redundancy Protocol (MRP) ring,
- allows devices to react to ring topology changes and redundancy management controlled by an MRP manager, and
- provides rapid recovery from link or node failures by quickly unblocking ports to maintain connectivity.

MRP supports seamless redundancy and fault tolerance, which are critical for industrial automation. It enables industrial switches to join existing MRP rings, ensuring high network availability. For example, switches can be added to a plant floor MRP ring and configured as clients to participate in redundancy without managing the ring.

In an MRP ring network, a designated Media Ring Manager (MRM) actively monitors the ring's health. All other switches act as Media Ring Clients (MRCs), listening for instructions from the MRM. When a link or node fails, the MRM detects the issue and immediately coordinates a recovery by instructing all MRCs to update their forwarding tables and reroute traffic around the failure.

Starting with Cisco IOS XE release 26.1.1, MRC mode is supported.

There are two modes to configure a node in an MRP ring:

- Auto-manager mode: The node participates in the manager election process. The node with the lowest priority becomes the manager (MRA-M), and the others become clients (MRA-C).
- Client mode (MRC): The node does not participate in the manager election process and always remains a client. This mode is essential for networks requiring Process Field Net (PROFINET) certification, which mandates client mode.

MRC mode functionality

- MRC forwards the test frames.
- MRC responds to Media Redundancy Manager's (MRM's) instructions.
- MRCs do not supervise the ring.
- An MRP ring should consist of at least one Media Redundancy Manager (MRM) to achieve redundancy, as MRCs alone do not provide redundancy.

Configure MRC

You can set up a switch to operate in MRC mode within an MRP ring for increased network redundancy.

Use this task when you need a switch to join an MRP ring as a client node, not as a manager.

Perform these steps to configure MRC.

Procedure

Step 1 Use the **configure terminal** command to enter configuration mode.

Example:

```
Switch# configure terminal
```

Step 2 Use the **mrp ring** *ring_number* command to configure MRP for the specified ring ID.

Example:

```
Switch(config)# mrp ring 1
```

Step 3 Use the **mode client** command to enable client mode for the ring.

Example:

```
Switch(config-mrp-ring)# mode client
```

The MRC mode ensures that the switch does not participate in the ring manager election.

Step 4 Use the **exit** command to exit from the configuration mode and return to EXEC mode.

Example:

```
Switch(config-mrp-ring)# exit
```

Step 5 (Optional) Use the **show mrp ring** *1* command to monitor the MRP ring 1 details.

Example:

```
Switch# show mrp ring 1
MRP ring 1
Mode : Client

Feature History

Table 209: Feature history

Feature Name	Releases	Description
Media Redundancy Client	Cisco IOS XE 26.1.1	This feature enables configuring Cisco switches as Media Redundancy Clients (MRC) within an MRP ring, allowing them to participate in network redundancy and respond to topology changes without acting as the ring manager. This approach enhances network resiliency and simplifies deployment, supporting rapid failover and compliance with industrial certification requirements.

High-availability Seamless Redundancy

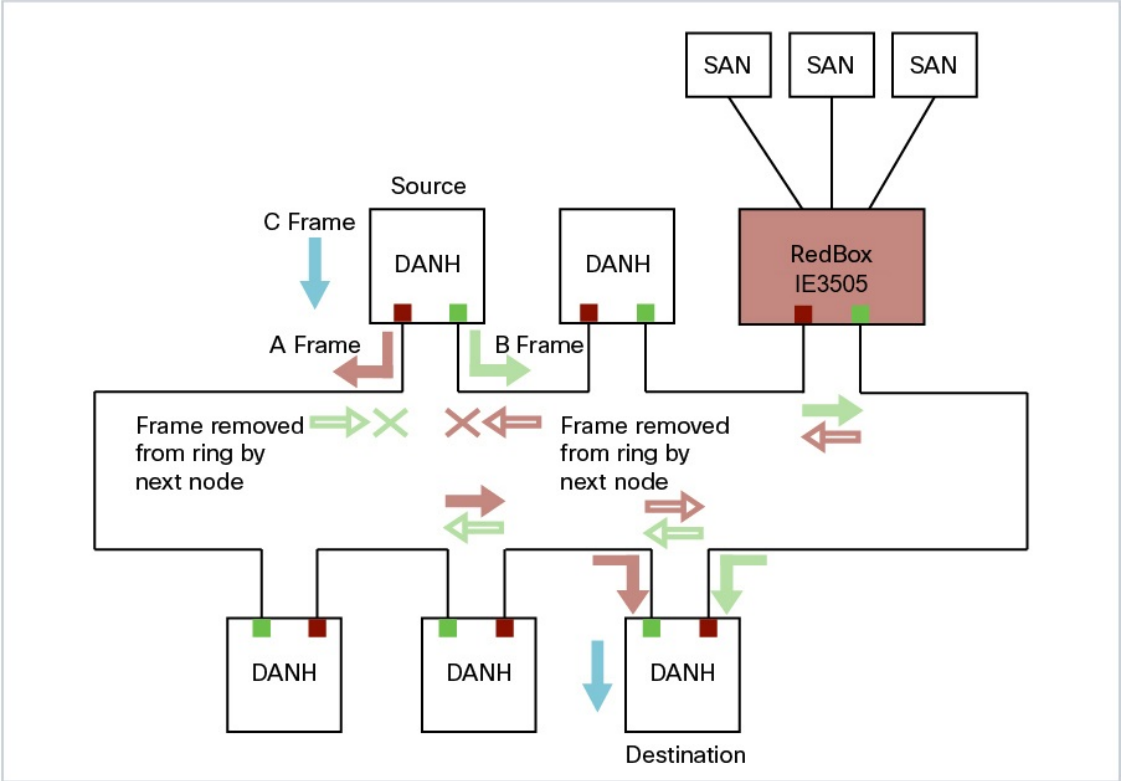
High-availability Seamless Redundancy overview

HSR is defined in International Standard IEC 62439-3-2016 clause 5. HSR is similar to Parallel Redundancy Protocol (PRP) but is designed to work in a ring topology. Instead of two parallel independent networks of any topology (LAN-A and LAN-B), HSR defines a ring with traffic in opposite directions. Port-A sends traffic counter clockwise in the ring, and Port-B sends traffic clockwise in the ring.



The HSR packet format is also different from PRP. To allow the switch to determine and discard duplicate packets, additional protocol specific information is sent with the data frame. For PRP, this is sent as part of a trailer called the redundancy control trailer (RCT), whereas for HSR this is sent as part of the header called the HSR header. Both the RCT and HSR header contain a sequence number, which is the primary data used to determine if the received frame is the first instance or a duplicate instance.

In this release, the switch supports only HSR-singly attached node (SAN) and only one HSR instance. If you have created a PRP instance, no HSR instance can be created.

The non-switching nodes with two interfaces attached to the HSR ring are referred to as Doubly Attached Nodes implementing HSR (DANHs). Similar to PRP, Singly Attached Nodes (SANs) are attached to the HSR ring through a device called a RedBox (Redundancy Box). The RedBox acts as a DANH for all traffic for which it is the source or the destination. The switch implements RedBox functionality using Gigabit Ethernet port connections to the HSR ring.

The following figure shows an example of an HSR ring as described in IEC 62439-3.

Figure 187: Example of HSR Ring Carrying Unicast Traffic

Devices that do not support HSR out of the box (for example, laptops and printers) cannot be attached to the HSR ring directly because all HSR capable devices must be able to process the HSR header on packets received from the ring and add the HSR header to all packets sent into the ring. These nodes are attached to the HSR ring through a RedBox. As shown in the figure above, the RedBox has two ports on the DANH side. Non-HSR SAN devices are attached to the upstream switch ports. The RedBox generates the supervision frames on behalf of these devices so that they are seen as DANH devices on the ring. Because the RedBox emulates these as DANH, they are called Virtual Doubly Attached Nodes (VDAN).

Switches that Support HSR

Table 210: The following Advanced base modules SKUs (PIDs) supports HSR.

Switch	PID
Cisco IE3505 Rugged Series Switch	IE-3505-8P3S
	IE-3505-8T3S
Cisco IE3505 Heavy-Duty Series Switch	IE-3505H-16T

Support for HSR is available on Network Essentials and Network Advantage licenses.

Supported HSR Features

IE-3505-8P3S, IE-3505-8T3S, and IE-3505H-16T switches support the following HSR features.

Maximum of one HSR ring is supported as shown in the following table:

Table 211: HSR Support for Cisco IE3505 Series Switch and Expansion Models

Switch	FPGA Profile	Number of Rings
Cisco IE3505 Rugged Series without expansion module	Default	1
	Redundancy	1
Cisco IE3505 Rugged Series with expansion module	Default	1
	Redundancy	1
IE-3505H-16T	Default	1
	Redundancy	1

Loop Avoidance

Each node in the HSR ring forwards frames received from one port to the other port of the HSR pair. To avoid loops and use network bandwidth effectively, the RedBox does not transmit frames that are already transmitted in same direction. When a node injects a packet into the ring, the packet is handled as follows to avoid loops:

- Unicast packet with destination inside the ring: When the unicast packet reaches the destination node, the packet is consumed by the respective node and is not forwarded.
- Unicast packet with destination not inside the ring: Because this packet does not have a destination node in the ring, it is forwarded by every node in the ring until it reaches the originating node. Because every node has a record of the packet it sent, along with the direction in which it was sent, the originating node detects that packet has completed the loop and drops the packet.
- Multicast packet: A multicast packet is forwarded by each node because there can be more than one consumer of this packet. For this reason a multicast packet always reaches the originating node. However, every node will check whether it has already forwarded the received packet through its outgoing interface. Once the packet reaches the originating node, the originating node determines that it already forwarded this packet and drops the packet instead of forwarding it again.

HSR RedBox Modes of Operation

The most basic mode of operation is HSR-SAN mode (single RedBox mode). In this mode, the RedBox is used to connect SAN devices to the HSR ring. The Redbox's responsibility in this mode is to represent SAN devices as VDANs on the ring.

HSR SAN Mode

In HSR-SAN mode, the RedBox inserts the HSR tag on behalf of the host and forwards the ring traffic, except for frames sent by the node itself, duplicate frames, and frames for which the node is the unique destination. In this mode, packets are handled as follows:

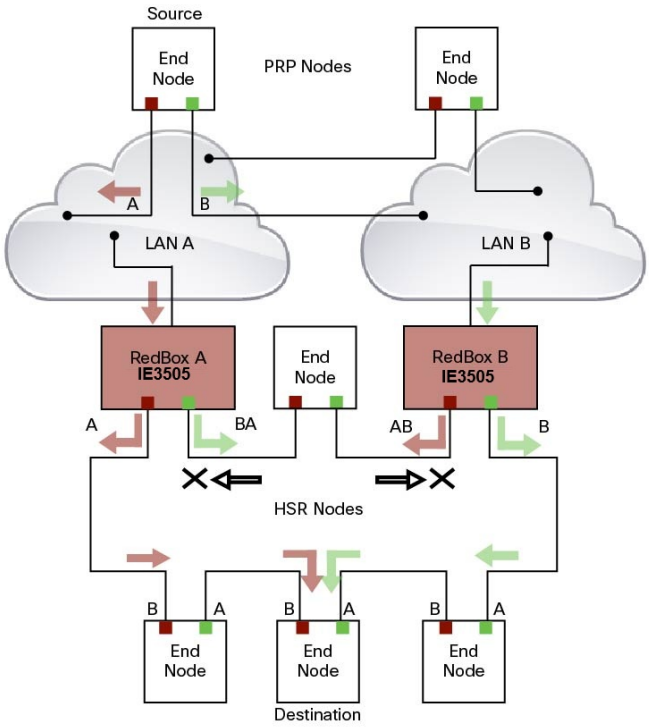
- A source DANH sends a frame passed from its upper layers (C frame), prefixes it with an HSR tag to identify frame duplicates, and sends the frame over each port (A frame and B frame).

- A destination DANH receives two identical frames from each port within a certain interval. The destination DANH removes the HSR tag of the first frame before passing it to its upper layers and discards any duplicate.
- Each node in the HSR ring forwards frames received from one port to the other port of the HSR pair. A node will not forward frames received on one port to the other under the following conditions:
  - The received frame returns to the originating node in the ring.
  - The frame is a unicast frame with a destination MAC address of a node upstream of the receiving node.
  - The node had already sent the same frame in the same direction. This rule prevents a frame from spinning in the ring in an infinite loop.

HSR-SAN interfaces

HSR-SAN mode is supported on interfaces GigabitEthernet 1/1-2 and GigabitEthernet 1/4-5. HSR ring 1 is configured as a pair of ports: Gi1/1 and Gi1/2 or Gi1/4 and Gi1/5.

Table 212: The supported HSR-SAN channel interfaces for IE3505 Rugged Series Switch



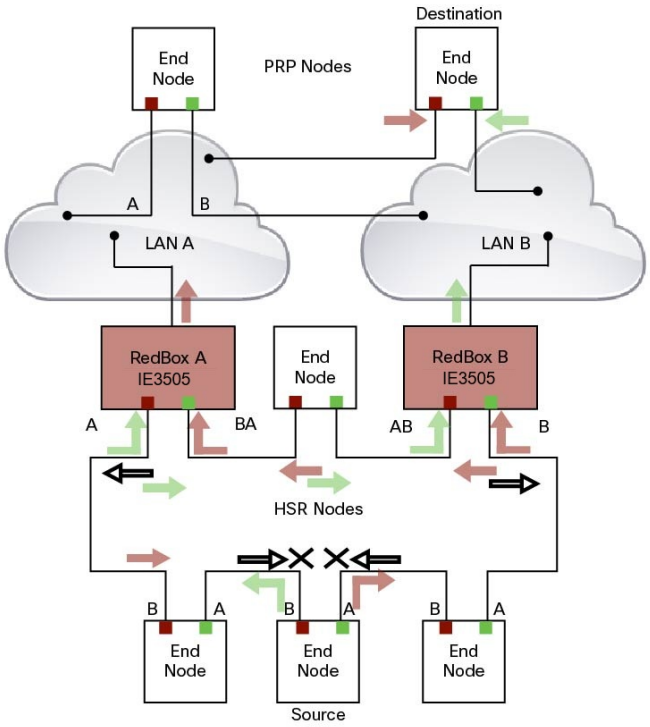
Mode	Module	Port Interface
HSR-SAN ring 1	Base Module	GigabitEthernet1/1 and 1/2 or GigabitEthernet1/4 and 1/5

HSR-PRP (Dual RedBox Mode)

HSR-PRP mode, also called Dual RedBox mode, is used to bridge HSR and PRP networks. Dual RedBox mode is supported on the Cisco IE3505 Series Switch.

In this mode, two different RedBoxes connect to LAN A and LAN B of the PRP network. Two ports connect to the HSR ring and one port connects to one of the two PRP LANs. The traffic on the upstream interlink port connecting the RedBox to the PRP network is PRP-tagged. In HSR-PRP mode, the RedBox extracts data from the PRP frame and generates the HSR frame using this data, and performs the reverse in the opposite direction. To avoid loops and use network bandwidth effectively, the RedBox does not transmit frames already transmitted in same direction (see Loop Avoidance, on page 2697).

The following figure shows an HSR ring connected to a PRP network through two RedBoxes, one for each LAN. In this example, the source frame originates in the PRP network. RedBoxes are configured to support PRP traffic on the interlink ports and HSR traffic on the ring ports. Nodes connected to the HSR-PRP Redbox act as a SAN to the PRP Redbox and a VDAN to the HSR-PRP Dual Redbox.



The sequence number from the PRP RCT is reused for the HSR tag and vice versa to allow frame identification from one redundancy network to the other and to identify the pairs and duplicates on either network. In the figure above, RedBox A and RedBox B send the same frame (A and AB and B and BA, respectively), but a RedBox does not transmit a frame that it already received.

Every DANH device generates its own sequence number, which is incremented for each outgoing frame. When a packet is switched from HSR to PRP or PRP to HSR, the sequence number is taken from the incoming packet so the same sequence number is used. Any node, whether it is an intermediate or final destination in the HSR or PRP network, uses the source MAC address and sequence number as the key for duplicate packet detection. Because the source address is expected to be unique for each node, there are no overlapping sequence numbers between different nodes.

Multicast frames or unicast frames without a receiver in the ring (arrows with the black outline in the figure) are removed by the RedBox that inserted them into the ring, if they originated from outside the ring. For this purpose, the frames carry a LAN identifier that is also the RedBox identifier.

The following figure shows an HSR ring coupled to a PRP network, where the source frame originates in the HSR ring.

To prevent frames from being reinjected into the PRP network through the other RedBox, each HSR frame carries the 4-bit PathId, which identifies the PRP network from which the frame came originally. RedBoxes are configured and identified by the PathId of the PRP LAN to which they are attached.

Different PathIds can be used to bridge more than one PRP network to an HSR ring. Likewise, more than one HSR ring can be bridged to a PRP network.

PRP is not needed for HSR-PRP to function in the IE3500 Rugged Series Switches. Any third port can be connected to PRP LAN A or LAN B network without PRP or any specific configurations.

PRP Supervision frames are sent toward PRP LAN A or LAN B from conversion of HSR Supervision Frames originated from DANHs and VDANs of HSR RedBoxes in the HSR ring. The HSR-PRP Redbox does not generate them but passes them along.

Packet flow in HSR-PRP

Packets coming from PRP network in the coupled PRP LAN-A or LAN-B are expected to have an RCT (Redundancy Control Trailer) tag. The switch removes the RCT and transfers the information to the HSR header using the programmed Net ID and LAN ID, recalculates the CRC, and sends the modified packet out to both ring A and ring B. If the packets originate from a SAN in the coupled PRP network, the switch treats it similarly as a VDAN to the HSR ring.

Egress Data Path—Packets coming from a SAN or PRP LAN A or LAN B to the HSR ring:

- For PRP packets, the switch converts the PRP RCT to an HSR tag for all packets (transfers Sequence Number and LAN ID from PRP to HSR).
- For SAN packets, the switch just inserts the HSR tag as is done in HSR-SAN RedBox mode.

- The switch needs to learn the MAC source address and add it to the Proxy Node table (VDAN table) with a new additional bit that allows the switch to distinguish between DANP or SAN. This allows the ingress path to determine whether to include the RCT trailer or not.

Ingress Data Path—Packets coming from the HSR ring to a SAN or PRP LAN A or LAN B:

- If the Proxy Node table or VDAN table lookup of the MAC destination address returns DANP, the switch converts the HSR tag to PRP RCT for accepted packets (transfers Sequence Number and LAN ID from HSR to PRP RCT).
- If the Proxy Node table or VDAN table lookup of the MAC destination address returns SAN, the switch strips the HSR tag and sends the packet without the RCT.

HSR-PRP Interfaces

In HSR-PRP Dual RedBox mode, two ports are connected to the HSR ring, and one port is connected to the PRP LAN A or LAN B network. The two ports that connect to the HSR ring are fixed (Gi1/1 and Gi1/2). When set to HSR-PRP mode, the two ports that connect to the HSR ring (Gi1/1 and Gi1/2) are automatically configured to HSR.

Table 213: The supported HSR-PRP channel interfaces for IE3505 Rugged Series Switch

Mode	Module	Port Interface
HSR-PRP	Base Module	GigabitEthernet1/1 and 1/2

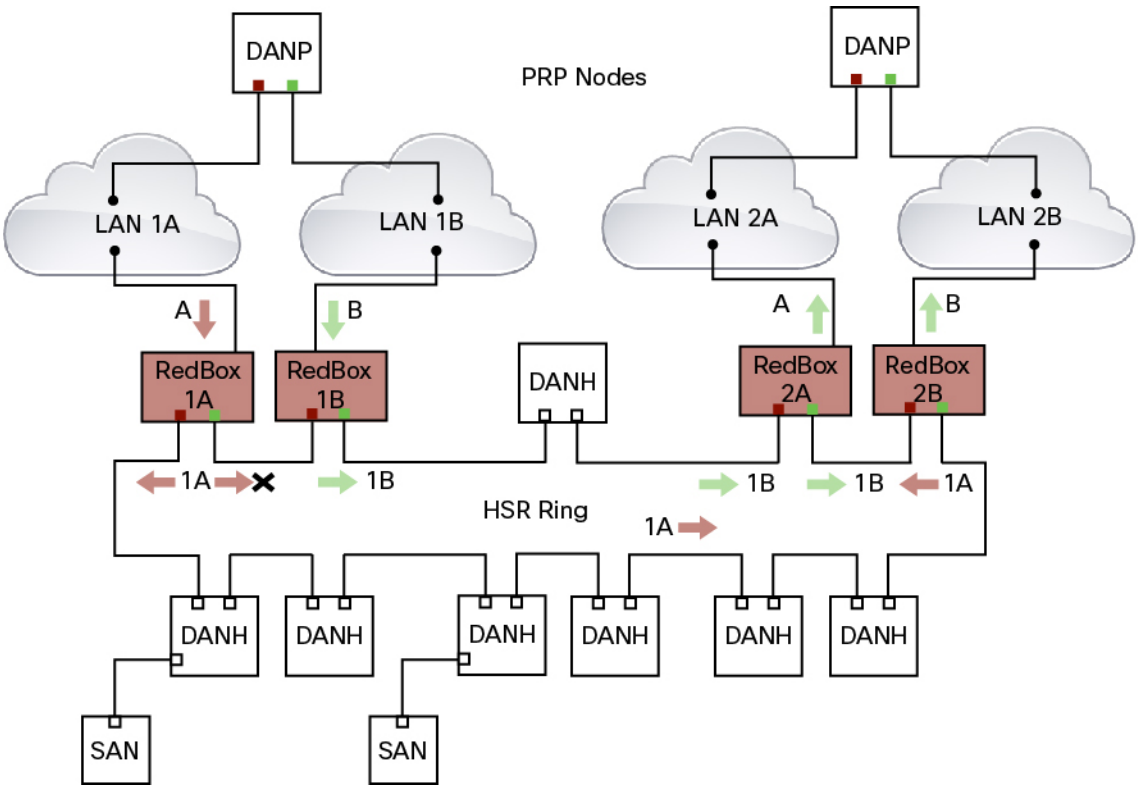
The port connected to PRP LAN A or LAN B can be any other port from the base module or expansion module. All remaining ports of the HSR-PRP RedBox (base module or expansion module ports) can be used for any other purpose, for example, to connect a DHCP server.

These ports act as non-HSR/PRP nodes (SANs/VDANs) in the topology. The HSR-PRP RedBox can use all remaining ports (base module or expansion module ports) for other purposes, such as connecting a DHCP server. These non-PRP and non-HSR ports must be in the same VLAN as the HSR and PRP ports to achieve SAN/VDAN behavior.

Connecting Multiple PRP Networks to an HSR Ring

A maximum of six PRP networks, identified by the PathId, can be connected to the same HSR ring. The 4-bit PathId consists of the following:

- The 3-bit NetId (1 to 6), which identifies a PRP network and the two RedBoxes that connect the PRP network to an HSR ring.
- The 1-bit LanId (LAN A = 0 and LAN B = 1)



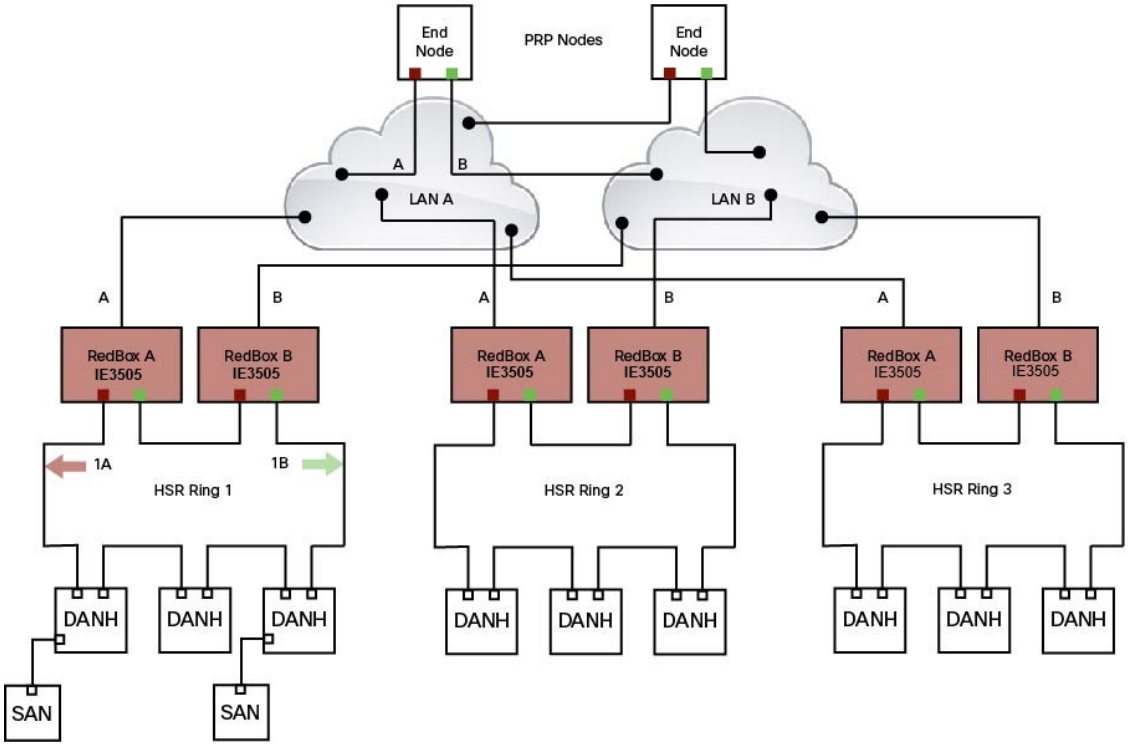
NetId values are as follows:

- 0 for regular HSR frames
- 1 to 6 for frames originating from a PRP network
- 7 is reserved

The following table lists the combinations of NetIds and LanIds for Redbox-A and Redbox-B.

PathId		
NetId	**LanId**	
	RedBox-A	**RedBox-B**
001	0	1
010	0	1
011	0	1
100	0	1
101	0	1
110	0	1
000	**Used for Local HSR Ring**	
111	**Reserved**	

The following figure shows an example of an HSR ring connected to two PRP networks.



To prevent reinjection of frames coming from one PRP network into another PRP network or from the other LAN of the same PRP network, a RedBox only forwards frames that do not carry its own PathId from the HSR ring.

When a PRP frame from LAN A or from LAN B of a PRP network with a given NetId is inserted to the HSR ring, a RedBox inserts its own NetId and the LanId “A” or ”B” into the PathId of the HSR tag.

When forwarding a frame from the HSR ring to a PRP network, the RedBox inserts the LanId “A” or ”B” into the RCT.

Connecting Multiple HSR Rings to a PRP Network

A PRP network can be connected to any number of HSR rings, but these rings cannot be connected to each other because this would create loops. The following figure shows an example of three HSR rings connected to one PRP LAN.

HSR Alarms

An HSR ring can generate the following two alarms:

- Partial Ring Fault: This fault is generated by an HSR RedBox when one of its physical ring ports/links is down. Because the packets can be sent using the redundant path, this is considered as a partial fault. However, this fault still requires user intervention to restore the ring. This is a minor fault and cannot be associated with an external hardware alarm relay.
- Full Ring Fault: This fault is generated by an HSR RedBox when both of its physical ring ports/links are down. This is a catastrophic failure and needs immediate attention. This is a major fault and can be associated with an external hardware alarm relay.

When an event that raises an alarm is generated, it can be associated with one or more of the following actions to notify the user:

- Syslog: A syslog is generated when the Alarm is raised/cleared.
- SNMP Notification: SNMP notification is sent when the alarm is raised/cleared.
- Relay output: External relay contacts can be asserted/de-asserted in response to the alarm. Relays are activated by major faults only.

See Enabling HSR Alarms, on page 2719 for steps to configure HSR alarms.

The following table lists the HSR events and their representations.

Event Number	Event Description	System Log (Level)	Alert/Alarm Log	Alarm LED and Output relay
1	Ring goes from UP to DOWN state.	2	2	Major Alarm/Assert
2	Ring goes from DOWN to UP state.	6	6	De-assert
3	One ring port goes DOWN, the other ring port and the ring itself is UP.	3	3	
4	Both ring ports are UP again.	6	6	

You can view currently active alarms using the **show facility alarm status** command. The following example shows alarm status for minor and major HSR alarms:

```
Switch#show facility-alarm status
Source          Severity    Description                      Relay   Time
Switch            MINOR    34 HSR ring is partially down       MAJ    Oct 24 2017 10:16:10

-------
Switch# show facility-alarm status
Source          Severity    Description                  Relay     Time
Switch            MAJOR    33 HSR ring is down             MAJ      Oct 24 2017 10:17:07
```

The following examples show the syslog entries that are generated for each HSR alarm event assertion and clear event (if configured):

- Syslog generated on occurrence of Partial fault:

```
Oct 24 11:07:13.952 IST: %HSR_ALARM-3-HSR_PARTIALFAULT: The HSR ring in now in PARTIAL
 FAULT state
```

- Syslog generated when the Partial fault is cleared:

```
Oct 24 11:07:38.032 IST: %HSR_ALARM-3-HSR_PARTIALFAULT: The HSR ring in now in PARTIAL
 FAULT state - event cleared
```

- Syslog generated on occurrence of Full fault:

```
Oct 24 11:07:38.036 IST: %HSR_ALARM-2-HSR_RINGFAULT: The HSR ring in now in FAULT state
```

- Syslog generated when the Full fault is cleared:

```
Oct 24 11:08:19.082 IST: %HSR_ALARM-2-HSR_RINGFAULT: The HSR ring in now in FAULT state
 - event cleared
```

CDP and LLDP for HSR

HSR supports the Cisco Discovery Protocol (CDP) and Link Layer Discovery Protocol (LLDP). CDP and LLDP are Layer 2 neighbor discovery protocols. Both CDP and LLDP can provide information about nodes directly connected to the device. They also provide additional information such as the local and remote interface and device names.

When CDP or LLDP is enabled, you can use the CDP or LLDP information to find the adjacent nodes on an HSR ring and their status. You can then use the neighbor information from each node to determine the complete HSR network topology and debug and locate ring faults.

CDP and LLDP are configured on physical interfaces only.

For more information, see Configuring an HSR Ring and Verifying Configuration.

PTP over HSR

PTP over HSR is a network synchronization capability that allows PTP packets to bypass standard HSR duplicate or discard logic to maintain timing accuracy across redundant paths.

PTP over HSR:

- Supports the PTP Power profile on Cisco Catalyst IE9300 Rugged, IE3500 Rugged and IE3500H Heavy Duty Series Switches.
- Utilizes a designated time recipient port for synchronization while maintaining a passive port for redundancy.
- Operates automatically without requiring additional interface-specific PTP configuration.

PTP over HSR operational details

The PTP grandmaster in an HSR network can be a RedBox, a VDAN, a SAN, or a DANH. Because the PTP 1588 standard does not account for clocks synchronized over redundant, simultaneously active paths, HSR handles PTP packets differently than other traffic types.

Supported PTP profiles and modes

This reference provides the HSR support matrix for PTP profiles, clock modes, and RedBox types as defined by IEC 62439-3.

PTP over HSR is supported only for the PTP Power Profile. For unsupported PTP profiles, PTP traffic flows over HSR port-A only.

Table 214: HSR support for PTP profiles

PTP Profile	Clock Mode	Supported	HSR RedBox Type as per IEC 62439-3
Power Profile	Boundary Clock (BC)	Yes	HSR RedBox as doubly attached BC (DABC) with P2P
	P2P Transparent Clock (TC)	Yes	HSR RedBox as doubly attached TC (DATC) with P2P
	Grandmaster Clock (GMC)-BC	No	Not applicable
	Forward	No	Not applicable
Default Profile	BC	No	Not applicable
	End-to-End (E2E) TC	No	Not applicable

Operating HSR RedBox as Doubly Attached BC (DABC) with P2P

This section describes the operation of PTP over HSR using an example where RedBox Primary and RedBox Secondary are configured to run in Power Profile as Boundary Clocks that use the Peer-to-Peer delay measurement mechanism.

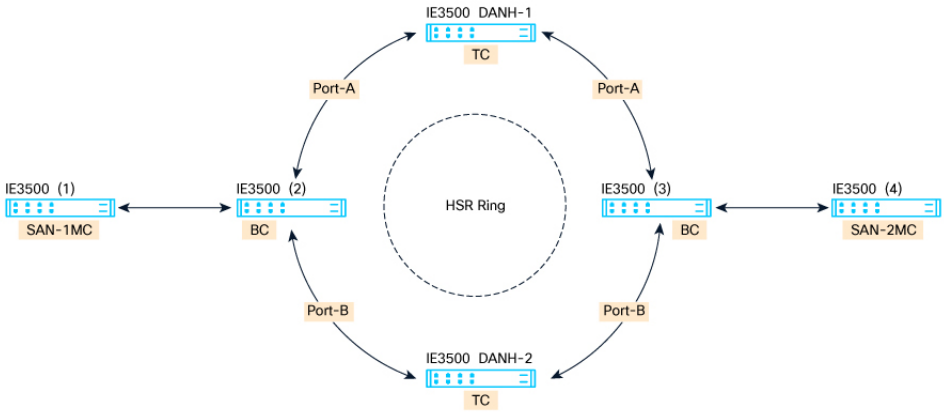
Summary

Assume for this example that SAN-1 is the GMC. All the clocks are configured to run Peer-to-Peer Delay measurement and the peer delay is regularly calculated and maintained on every link shown in the figure. The BMCA on RedBox Primary determines the port to SAN-1 to be connected to the time source. The PTP protocol running on RedBox Primary will forward Sync and Follow_Up messages on ports RedBox Primary A and B.

On RedBox Secondary, the regular BMCA operation determines RedBox Secondary port A to be time recipient and RedBox Secondary port B to be `PASSIVE`. However, with the knowledge that ports RedBox Secondary A and B are part of the same HSR ring, RedBox Secondary port B is forced into `PASSIVE_SLAVE` state and RedBox Secondary port A becomes active for PTP.

RedBox Secondary port A works as a regular time recipient port. It uses the Sync and Follow_Up messages along with their correction field to calculate the delay and offset from time source and synchronize the local clock.

RedBox Secondary port B, which is in `PASSIVE_SLAVE` state operates in this way:



Just like RedBox Secondary port A, it maintains the delay and offset from time source, but does not perform any operation on the local clock. Having all the synchronization information available enables it to seamlessly take over as the new time recipient in case RedBox Secondary port A loses communication with the GMC.

The given image uses these device mappings:

- SAN-1MC: IE3500 (1)
- RedBox Primary: IE3500 (2)

- RedBox Secondary: IE3500 (3)
- SAN-2MC: IE3500 (4)
- DANH-1: IE3500 configured as a Transparent Clock
- DANH-2: IE3500 configured as a Transparent Clock

Workflow

These stages describe the PTP operation and synchronization logic for RedBox Primary (IE3500 (2)) and RedBox Secondary (IE3500 (3)).

1. RedBox Primary (IE3500 (2)) performs BMCA to identify the time source and distribute synchronization messages.
   - BMCA identifies the port connected to SAN-1MC (IE3500 (1)) as the time-receiver port.
   - Sync and Follow_Up messages are forwarded through RedBox Primary Port A toward DANH-1 and through RedBox Primary Port B toward DANH-2.
2. RedBox Secondary (IE3500 (3)) manages its port states to maintain synchronization and redundancy.
   - RedBox Secondary Port A, connected to DANH-1, functions as the active time-receiver port.
   - RedBox Secondary Port B, connected to DANH-2, remains in the `PASSIVE_SLAVE` state while maintaining synchronization information for failover.

Configure HSR RedBox as DABC with P2P

Configure the PTP power profile on SAN, RedBox, and DANH nodes in an HSR doubly attached boundary clock topology with P2P delay measurement.

This procedure applies to resilient industrial Ethernet deployments that use SAN or RedBox boundary clocks and DANH transparent clocks. These clocks must synchronize with the same grandmaster while maintaining redundancy and accurate peer-delay measurements.

Procedure

Step 1 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Switch# configure terminal
```

Step 2 Use the **interface range** *interface-id* command to create the HSR ring interface and assign the ports to the HSR ring.

Example:

```
Switch(config)# interface range GigabitEthernet 1/1-2
```

Note
Select the pair that matches the physical ring connections in your deployment. Both interfaces in the selected pair must use the same settings and VLAN configuration. Configure these settings before assigning the interfaces to the HSR ring.

For channel and interface details, see HSR-Ring 1

Step 3 Use the **hsr-ring** *ring-id* command to create an HSR ring.

Example:

```
Switch(config-if-range)# hsr-ring 1
```

Step 4 Use the **no shutdown** command to turn on the HSR interface.

Example:

```
Switch(config-if-range)# no shutdown
```

For more details on the HSR ring configuration, see HSR Ring Configuration

Step 5 Use the **exit** command to return to global configuration mode.

Example:

```
Switch(config-if-range)# exit
```

Step 6 Configure PTP

a) Use the **ptp clock boundary domain** *domain-number* **profile power** command to configure the boundary type PTP clock, which stops the PTP session from the grandmaster clock and acts as a PTP server or client clock downstream.

Example:

```
Switch(config)# ptp clock boundary domain 0 profile power
```

b) Use the **allow-without-tlv** command to permit PTP message processing without TLVs.

Example:

```
Switch(config-ptp-clk)# allow-without-tlv
```

c) Use the **clock-port** *port-name* command to define a new clock port for ethernet multicast interface Gi1/0/21.

Example:

```
Switch(config-ptp-clk)# clock-port dyn1
```

d) Use the **transport ethernet multicast interface** *interface-id* command to specify the transport method for clocking traffic.

Example:

```
Switch(config-ptp-port)# transport ethernet multicast interface Gi1/0/21
```

e) Use the **clock-port** *port-name* command to define a new clock port for ethernet multicast interface Gi1/0/22.

Example:

```
Switch(config-ptp-clk)# clock-port dyn2
```

f) Use the **transport ethernet multicast interface** *interface-id* command to specify the transport method for clocking traffic.

Example:

```
Switch(config-ptp-port)# transport ethernet multicast interface Gi1/0/22
```

g) (Optional) Use the **vlan** *vlan-id* command to configure VLAN for tagged packets.

Example:

```
Switch(config-ptp-port)# vlan 100
```

Step 7 Configure Configure DANH-1 as a TC

In this example, DANH-1 is an IE3500 and IE3500H switch configured as a TC. The PTP commands apply to supported switches. HSR interface assignments are platform-specific so you can use the supported interface pair for your switch model.

a) Use the **configure terminal** command to enter global configuration mode of the switch that operates as DANH-1.

Example:

```
DANH-1# configure terminal
```

b) Use the **ptp clock transparent domain** *domain-number* **profile power** command to configure the device as a Transparent Clock, which accounts for packet residence time to maintain PTP synchronization accuracy without terminating the PTP session.

Example:

```
DANH-1(config)# ptp clock transparent domain 0 profile power
```

c) Use the **allow-without-tlv** command to permit PTP message processing without TLVs.

Example:

```
DANH-1(config)# allow-without-tlv
```

See Step 8a to 8c to configure DANH-2.

See Verification commands to verify the configuration.

Note
When RedBox Primary and RedBox Secondary are configured for HSR, Boundary Clock (BC) must be enabled on both the HSR-capable ring ports and the ports connected to SANH devices.

HSR RedBox as Doubly Attached TC (DATC) with P2P

This process assumes SAN-1 functions as the Grandmaster Clock (GMC). All clocks are configured to run Peer-to-Peer Delay measurement, with peer delay regularly calculated and maintained on every link.

Summary

These components participate in the synchronization process:

- RedBox Primary: Performs BMCA to determine the time source connection and forwards Sync and Follow_Up messages.
- RedBox Secondary: Operates with one port as the time recipient and the other as a passive slave to ensure seamless failover.

Workflow

These stages describe the operational behavior of the RedBox devices during PTP synchronization.

1. RedBox Primary determines the time source and manages message forwarding.
   - The BMCA on RedBox Primary identifies the port connected to SAN-1 as the time source.
   - RedBox Primary forwards all Sync and Follow_Up messages received on port C out of ports A and B.
2. RedBox Secondary manages port roles to maintain synchronization and redundancy.

When	And	Then	And
Port A receives Sync/Follow_Up	Active state	Calculate delay and offset	Forward messages out of port C
Port B receives Sync/Follow_Up	Passive state	Maintain delay and offset	Drop messages

Result

The network maintains synchronization information, allowing port B to seamlessly take over as the time recipient if port A loses communication with the GMC.

Configure HSR RedBox as DATC with P2P

Configure PTP power profile and clock modes across SAN, RedBox, and DANH nodes to establish deterministic time synchronization in an HSR DATC topology using P2P delay measurement.

This procedure applies to resilient industrial Ethernet deployments where SAN or RedBox TCs and DANH TCs must converge to the same grandmaster with redundancy and accurate peer-delay timing.

Procedure

Step 1 To configure SAN-1, SAN-2, RedBox with PTP, see PTP configuration.

Step 2 Use the **interface range** *interface-id* command to create the HSR ring interface and assign ports to the HSR ring.

Example:

```
Switch(config)# interface range GigabitEthernet 1/1/1-2
```

For channel and interface details, see HSR-Ring 1 .

Step 3 Use the **hsr-ring** *ring-id* command to create HSR ring.

Example:

```
Switch(config-if-range)# hsr-ring 1
```

Step 4 Use the **no shutdown** command to turn on the HSR interface.

Example:

```
Switch(config-if-range)# no shutdown
Swotch(config-if-range)# exit
```

For more details on the HSR ring configuration, see HSR Ring Configuration.

Step 5 Configure DANH-1 as a TC

In this example, DANH-1 is an IE3500 and IE3500H switch configured as a TC. The PTP commands also apply to supported switches. HSR interface assignments are platform-specific so you can use the supported interface pair for your switch model.

a) Use the **configure terminal** command to enter global configuration mode of the switch that operates as DANH-1.

Example:

```
DANH-1# configure terminal
```

b) Use the **ptp clock transparent domain** *domain-number* **profile power** command to configure the device as a TC, which accounts for packet residence time to maintain PTP synchronization accuracy without terminating the PTP session.

Example:

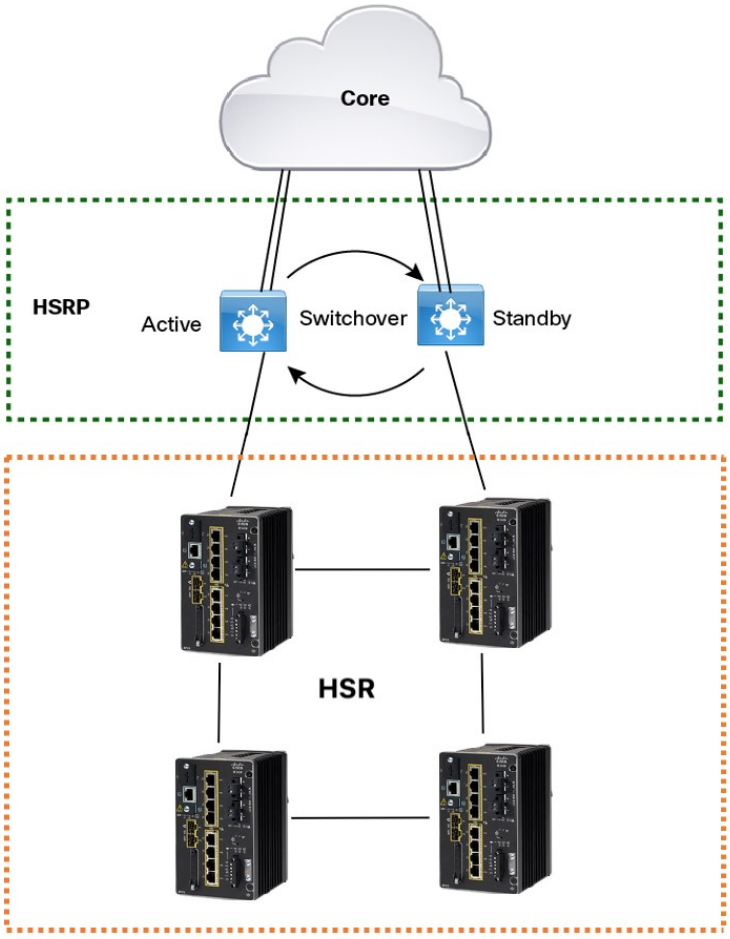
```
DANH-1(config)# ptp clock transparent domain 0 profile power
```

c) Use the **allow-without-tlv** command to permit PTP message processing without TLVs.

Example:

```
DANH-1(config)# allow-without-tlv
```

See Step 5a to 5c to configure TC for DANH-2, RedBox Primary, and RedBox Secondary.



See Verification commands to verify the configuration.

Note
On each RedBox, verify that PTP is enabled on both HSR ring interfaces and on the interfaces connected to singly attached nodes (SANs). Apply the same PTP settings to both HSR ring interfaces to support uninterrupted synchronization if the active timing path changes.

HSR Uplink Redundancy Enhancement

The HSR Uplink Redundancy Enhancement feature allows for flexible designs that enable two separate interfaces to connect upstream from the HSR ring through two separate HSR RedBoxes. This ensures there is no single point of failure exiting the HSR ring. Examples of protocols that can leverage this feature to improve high availability include HSRP, VRRP and REP. Prior to this enhancement, if these protocols were utilized on redundant uplinks, undesirable results could occur, such as next-hop split-brain conditions or slow REP failover times.

The following diagram shows an example network with HSR and HSRP that allows uplink next-hop gateway redundancy out of the HSR ring.

To implement HSR Uplink Redundancy, ensure that the **fpgamode-DualUplinkEnhancement** feature is not disabled. This feature is required to support the connectivity to a dual router (HSRP in this case) on the distribution layer:

```
Switch#show hsr ring 1 detail | include fpgamode
 fpgamode-DualUplinkEnhancement: Enabled
```

If the output shows *fpgamode-DualUplinkEnhancement,:Disabled* issue the following command:

```
Switch# conf t
Enter configuration commands, one per line.  End with CNTL/Z.
```

```
Switch(config)# hsr-ring 1 fpgamode-DualUplinkEnhancement
Switch(config)# end
```

HSRP Configuration

The following example HSRP configuration applies to the two distribution switches Active & Standby in the above figure. In the following configuration, HSRP is configured in a Switch Virtual Interface (SVI).

```
Active# conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Active(config)# interface vlan 10
Active(config-if)# ip address 30.30.30.2 255.255.255.0
Active(config-if)# standby 1 ip 30.30.30.1
Active(config-if)# standby 1 priority 120
Active(config-if)# end

Standby# conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Standby(config)# interface Vlan10
Standby(config-if)# ip address 30.30.30.4 255.255.255.0
Standby(config-if)# standby 1 ip 30.30.30.1
Standby(config-if)# end

Active# show standby
Vlan10 - Group 1
  State is Active
    8 state changes, last state change 00:03:55
    Track object 1 (unknown)

```

Guidelines and Limitations

- HSR is supported only in a standalone deployment.
- Only one HSR instance is supported. Note that the switch supports only one HSR or one PRP instance, so if a PRP instance has been created, no HSR instance can be created.
- HSR ring 1 can only be configured as a pair of ports: Gi1/1 and Gi1/2 or Gi1/4 and Gi1/5. Using these port pairs, you can configure 1 HSR ring.
- The HSR feature requires the Network Essentials license.
- The HSR feature is not enabled by default and you must explicitly configure the HSR rings.
- HSR is disabled automatically if the required firmware image is not available on the system.
- Once a port is part of a ring, the media-type, speed, and duplex settings of the port cannot be changed. We recommend that you apply those settings before configuring ring membership.
- If mode of HSR interfaces is changed from access to trunk mode or vice-versa after configuring the ring,we recommended that you flap the HSR ring.
- The recommended maximum number of nodes in the node table is 512. Nodes are all the DANH and VDAN devices that can be connected to the ring at same time. This number is not an absolute limit, but higher numbers of entries may increase the number of duplicate packets received by the end devices.
- HSR ring ports can only be configured in L2 mode.
- HSR is supported on following port types:
  - 100 mbps, Full Duplex. Half duplex is not supported.
  - 1000 mbps, Full Duplex. Half duplex is not supported.
  - HSR is not supported on the uplink ports.
- Both ports of one ring must be of same speed and type (that is, both can be SFPs or both can be copper)
- The following protocols and features are mutually exclusive with HSR on the same port:
  - PRP
  - EtherChannels
  - Link Aggregation Control Protocol (LACP)
  - Port Aggregation Protocol (PAgP)
  - Resilient Ethernet Protocol (REP)
- MACsec, HSR, and PRP are not allowed together.
- HSR supports an MTU size of up to 1998 bytes of Ethernet payload.

- STP is not supported on the HSR ring. By default, all modes of Spanning Tree Protocol (STP) will be disabled on the ring ports.
- Switched Port Analyzer (SPAN) and Remote SPAN (RSPAN) are not supported on HSR. That is, SPAN and RSPAN should not be used to monitor the traffic on an HSR ring. In addition, traffic that has been monitored using RSPAN should not be transferred over an HSR ring.
- It is important for all interfaces in an HSR ring to have the same speed and duplex settings. It is recommended to apply those settings before configuring ring membership.
- Once a port is part of ring, the port cannot be shut down.

  For example, if Gi1/4 and Gi1/5 are part of an HSR ring and you try to shut down Gi1/4 or Gi1/5, the operation will not be permitted:

```
Switch(config)# interface gi1/4
Switch(config-if)#shutdown
 %Interface GigabitEthernet1/4 is configured in a HSR ring shutdown not permitted!
Switch(config-if)#
```

  You can perform a shutdown of the HSR ring. For example:

```
Switch# conf t
Switch(config)#int hs1
Switch(config-if)#shut
```

- VLAN configuration such as trunk and access mode must be the same on both the ports participating in the ring. For example, if Gi1/4 and Gi1/5 in an HSR ring are in trunk mode and you attempt to change the mode of one port to access, the ports in the ring will not be bundled:

```
Switch(config)#interface range gi1/4
Switch(config-if)#switchport mode  access
Jul 27 22:00:27.809 IST: %EC-5-CANNOT_BUNDLE2: Gi1/4 is not compatible with Gi1/5 and
will be suspended (trunk mode of Gi1/4 is access, Gi1/5 is dynamic)
```

- After an interface is added in the HSR ring, only the primary interface counters are updated. You should not need to configure and check the status of individual physical interfaces after they are added to the HSR ring.
- As soon as you configure an HSR ring on two ports of a switch, MAC flaps will be observed on other switches where the HSR configuration is yet to be applied. We recommend that you shut down the newly created HSR ring on the switch before configuring the ring on all switches, and then re-enable them one by one as shown below. For example, if there are four switches in the ring, disable the HSR ring interfaces on each switch:

```
Switch1(config)#interface range gi1/1-2
Switch1(config-if)#shutdown
Switch1(config-if)#hsr-ring hs1
Creating a HSR-ring interface hs1
Switch1(config-if)#int hs1
Switch1(config-if)#shutdown
Switch1(config-if)#end
```

  After all four switches are configured with the ring, re-enable the HSR ports on each switch:

```
Switch1#conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch1(config)#int hs1
Switch1(config-if)#no shutdown
Switch1(config-if)#end
Switch1#
```

This prevents interim MAC flapping during HSR ring configuration in member switches.

Default Settings

Table 215: HSR Ring Parameters

Parameter	Description	Range	Default Value
entryForgetTime	Time for clearing an inactive entry from duplicate discard table.	0-65535	400 ms
fpgamode-DualUplinkEnhancement	Set FPGA register for source mac filtering.	enable or disable	enable
nodeForgetTime	Time to clear an inactive entry from the node table.	0-65535	60000 ms
nodeRebootInterval	Time after which the RedBox must start sending supervision frames after bootup.	0-65535	500 ms
pauseFrameTime	Time interval between HSR pause frames.	0-65535	25 ms
proxyNodeTableForgetTime	Time to clear an inactive entry from the proxy node table or vdan table.	0-65535	60000 ms
supervisionFrameLifeCheckInterval	Life check interval value for supervision frames.	0-65535	1600 ms
supervisionFrameOption			
mac-da	The last bytes of the destination MAC address of supervision frames (01:15:4E:00:01:00). The last 00 is replaced by the value of this parameter.	1-255 MAC DA last eight bits option value	No default
vlan-cfi	Enable Canonical Format Indicator (CFI) for the VLAN tagged frame.	enable or disable	disable
vlan-cos	Class of Service (COS) value to be set in the VLAN tag of the Supervision frame.	0-7	0

Parameter	Description	Range	Default Value
vlan-id	The VLAN tag of the supervision frame.	0-4095	0
vlan-tagged	Set VLAN tagging option.	enable or disable	disable
supervisionFrameRedboxMacaddress	The RedBox MAC address in the supervision frames.	48-bit RedBox MAC address	The interface HSR ring MAC address
supervisionFrameTime	Time interval between supervision frames.	0-65535	3 ms

Configure an HSR Ring

Follow these steps to configure an HSR ring:

Before you begin

- Read and understand the Guidelines and Limitations, on page 2714 section of this chapter.
- Ensure that the member interfaces of a HSR ring are not participating in any redundancy protocols such as FlexLinks, EtherChannel, REP, and so on before configuring a HSR ring.

Procedure

Step 1 Enter global configuration mode:

```
Switch# configure terminal
```

Step 2 (Optional) Globally enable CDP to provide information about HSR ring nodes:

```
Switch(config)# cdp run
```

Step 3 (Optional) Globally enable LLDP to provide information about HSR ring nodes:

```
Switch(config)# lldp run
```

Step 4 Enter interface configuration mode and disable PTP on the ports to be assigned to the HSR ring:

```
Switch(config)# interface range gi1/1-2
Switch(config-if-range)# no ptp enable
```

Step 5 (Optional) Enable CDP on the ports to be assigned to the HSR ring:

```
Switch(config-if-range)#cdp enable
```

Step 6 (Optional) Enable LLDP on the ports to be assigned to the HSR ring:

```
Switch(config-if-range)#lldp transmit
Switch(config-if-range)#lldp receive
```

Step 7 Shut down the ports before configuring the HSR ring:

```
Switch(config-if-range)# shutdown
```

Step 8 Create the HSR ring interface and assign the ports to the HSR ring:

```
Switch(config)# interface range gigabitEthernet 1/1-2
Switch(config-if-range)# hsr-ring 1
```

Step 9 (Optional) If required, configure HSR ring optional parameters. See the Default Settings section for the parameter descriptions, ranges and default values.

```
Switch(config-if-range)# hsr 1 supervisionFrameLifeCheckInterval 10000
```

Step 10 Turn on the HSR interface:

```
Switch(config-if-range)# no shutdown
Switch(config-if)# end
```

Example

```
Switch# conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch(config)# interface range gigabitEthernet 1/1-2
Switch(config-if-range)# no ptp enable
Switch(config-if-range)# shutdown
Switch(config-if-range)# hsr-ring 1
Switch(config-if-range)# hsr-ring 1 supervisionFrameLifeCheckInterval 10000
Switch(config-if-range)# no shutdown
Switch(config-if-range)# end
```

Configuring HSR-PRP

Follow these steps to enable HSR-PRP Redbox mode on the switch. Enabling HSR-PRP mode creates an HSR ring and bridges the the HSR ring to a PRP network.

Before you begin

- See Guidelines and Limitations, on page 2714.

Procedure

Step 1 Enter global configuration mode:

```
switch# configure terminal
```

Step 2 Enable HSR-PRP mode and select LAN A or LAN B and the optional PRP Net ID:

hsr-prp-mode enable {prp-lan-a | prp-lan-b} [1-6]

- prp-lan-a: Redbox is connected to LAN A.
- prp-lan-b: Redbox is connected to LAN B.
- 1-6: PRP Net ID value from 1 to 6.

The default is 1.

Note
Be sure to configure the same Net ID in Redbox A and B that is part of the same PRP network.

Example:

```
switch(config)#hsr-prp-mode enable prp-lan-a
```

To disable HSR-PRP Redbox mode, use the command **no hsr-prp-mode enable**.

Enabling HSR Alarms

To enable alarms for HSR, follow these steps:

Before you begin

Alarms and actions can be enabled/disabled at the facility level only. You cannot enable only partial faults or full faults; either all alarms for given facility are enabled or all are disabled.

See HSR Alarms, on page 2703 for details about HSR alarms.

Procedure

Step 1 Enter global configuration mode:

```
Switch# configure terminal
```

Step 2 Enable the HSR alarm facility:

```
Switch(config)# alarm facility hsr enable
```

To disable HSR alarms, enter **no alarm facility hsr enable**.

Step 3 (Optional) Enable SNMP notification for HSR alarms:

```
Switch(config)# alarm facility hsr notifies
```

Step 4 (Optional) Associate HSR alarms with the Major Relay:

```
Switch(config)# alarm facility hsr relay major
```

Step 5 (Optional) Send HSR alarms to a syslog server:

```
Switch(config)# alarm facility hsr syslog
```

Step 6 (Optional) Enable logging of informational HSR alarm messages:

```
Switch(config)# logging alarm informational
```

Step 7 Exit global configuration mode:

```
Switch(config)# end
```

Step 8 Verify the configuration:

```
Switch# show facility-alarm status
```

Clear All Node Table and VDAN Table Dynamic Entries

Procedure

Step 1 To clear all dynamic entries in the node table, enter the following command: **clear hsr node-table**

Step 2 To clear all dynamic entries in the VDAN table, enter the following command; **clear hsr vdan-table**

Verifying the Configuration

Command	Purpose
show hsr ring 1 [**detail**]	Displays configuration details for the specified HSR ring.
show hsr statistics {**egressPacketStatistics** | **ingressPacketStatistics** | **nodeTableStatistics** | **pauseFrameStatistics**}	Displays statistics for HSR components. **Note** To clear HSR statistics information, enter the command **clear hsr statistics**.
show hsr node-table	Displays HSR node table.
show hsr vdan-table	Displays HSR Virtual Doubly Attached Node (VDAN) table. **Note** The VDAN table and Proxy node table are the same.
show cdp neighbors	Displays CDP neighbor information for an HSR ring.
show lldp neighbors	Displays LLDP neighbor information for an HSR ring.

Configuration Examples

HSR-SAN

This example shows the configuration of an HSR ring (Ring 1) using Gi1/1 and Gi1/2 ports between four devices.

```
Switch-1# conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch-1(config)#interface range gigabitEthernet 1/1-2
Switch-1(config-if-range)#shutdown
Switch-1(config-if-range)#hsr-ring 1
Creating a HSR-ring interface HSR-ring 1

Switch-1(config-if-range)#no shutdown
Switch-1(config-if-range)#exit
Switch-1(config)#exit
Switch-1#
Switch-2# conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch-2(config)#interface range gigabitEthernet 1/1-2
Switch-2(config-if-range)#shutdown
Switch-2(config-if-range)#hsr-ring 1
Creating a HSR-ring interface HSR-ring 1

Switch-2(config-if-range)#no shutdown
Switch-2(config-if-range)#exit
Switch-2(config)#exit
Switch-2#
Switch-3# conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch-3(config)#interface range gigabitEthernet 1/1-2
Switch-3(config-if-range)#shutdown
Switch-3(config-if-range)#hsr-ring 1
Creating a HSR-ring interface HSR-ring 1

Switch-3(config-if-range)#no shutdown
Switch-3(config-if-range)#exit
Switch-3(config)#exit
Switch-3#
Switch-4# conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Switch-4(config)#interface range gigabitEthernet 1/1-2
Switch-4(config-if-range)#shutdown

HSR-HSR QuadBox

HSR-HSR QuadBox

High-availability Seamless Redundancy (HSR)-HSR QuadBox is a quadruple port specialized device used to interconnect two independent HSR networks. This network redundancy feature:

- provides enhanced protection against a failure on one QuadBox device,
- utilizes four specific ports to bridge traffic between two HSR domains for seamless failover, and
- ensures continuous network operation with minimal packet loss even during link or node failures.

The HSR-HSR QuadBox mode is a specialized configuration that enables the system to interconnect two independent HSR rings. This functionality explicitly supports HSR port assignments across both base and expansion modules, overriding general HSR limitations that typically restrict a system to a single HSR ring or HSR ports to base modules only.

The QuadBox connects multiple HSR rings by linking two rings through four dedicated ports without causing any learning or forwarding delays. It is designed for industrial networks that demand zero downtime, high fault tolerance, and reliability. The HSR-HSR QuadBox mode is a specialized switch configuration with fixed port assignments that vary based on the module type, ensuring seamless and efficient bridging of the two HSR rings.

Note The interface assignment for HSR-HSR QuadBox is fixed and cannot be changed.

Table 216: Interface assignment for HSR-HSR QuadBox

Port Pair	Module	Ring 1 ports	Ring 2 ports
Copper	Base Module	Gig1/4, Gig1/5	Gig1/6, Gig1/7
Mixed (SFP + Cu)	Base Module	Gig1/1, Gig1/2	Gig1/6, Gig1/7
SFP	Base + 8P SFP Expansion Module	Gig1/1, Gig1/2	Gig2/1, Gig2/2
	Base + 8P Mixed Expansion Module	Gig1/1, Gig1/2	Gig2/7, Gig2/8
	Base + 16P Mixed Expansion Module	Gig1/1, Gig1/2	Gig2/15, Gig2/16

The port pair option is chosen via CLI and in case of SFP, based on the expansion module attached too.

Guidelines and limitations for configuring HSR-HSR QuadBox

Activation, configuration, and management limitations and restrictions

- Activate a new FPGA profile and reload the box to enable HSR QuadBox.
- The feature is available in Network Essentials license.
- When you enable HSR-HSR QuadBox mode, only the four HSR-HSR ports stay active. All other ports shut down, and their features stop working. You receive a warning for this mode change.
- You can manage the switch through interfaces such as the device manager, CLI, or SNMP, using an in-band Switched Virtual Interface (SVI) over the HSR Ring, but expect a temporary loss of connection when you enable or disable QuadBox mode.

  So, we strongly recommend you to use a console connection when switching into or out of HSR-HSR mode.
- Disabling HSR-HSR mode resets all physical interfaces to their default configuration and erases settings on non-QuadBox ports.
- Set the same native VLAN on both QuadBox rings and all connected ports.

Functional limitations and restrictions

- QuadBox disables MAC address learning.
- When the topology has more than one QuadBox, the VLAN and multicast filter configuration must match on all the QuadBoxes and both the HSR rings.
- HSR-HSR mode restricts switchport access.
- HSR-HSR mode sets MTU to 2020 and you cannot change it.
- QuadBox disables PTP.
- HSR-HSR FPGA profile does not support show and clear commands for Node and VDAN tables, HSR ring proxyNodeTableForgetTime, HSR ring nodeforgetTime, or creation of independent HSR ring interfaces.
- Multicast filters drop only multicast MAC addresses. They do not drop unicast MAC addresses

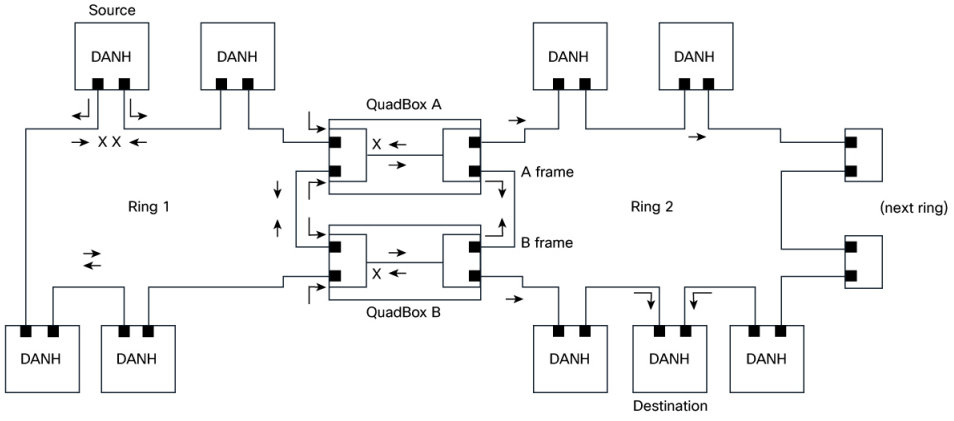
HSR-HSR QuadBox workflow

Summary

A HSR QuadBox, or quadruple port device, connects two HSR rings to each other. Two of these ports connect to the first ring, and the other two connect to the second ring, while any other ports on the device remain inactive.

To segregate traffic between the two rings, you can configure the QuadBox with VLAN and multicast filters. This allows you to restrict the specified VLAN and multicast groups from crossing the rings. VLAN filtering uses the VLAN allowed list to restrict VLANs. Multicast filtering matches packets with the same MAC

destination address (MACDA) and optional mask as configured in the filters. If there is a match, the packets are dropped.



A QuadBox manages duplicate information. If two QuadBoxes are on the same ring and both try to send the same data from the first ring to the second, the system prevents it. If a QuadBox receives a piece of information that it has already sent, or the another QuadBox on the same ring has already sent, it recognizes the duplicate and do not forward it further. This prevents four copies to be circulated on the second ring.

The key components involved in the process are:

- Doubly Attached Node for HSR (DANH) source node: Duplicates each outgoing frame and injects the copies into the ring in opposite directions.
- Ring 1: Redundant path that carries the two counter-rotating frame copies and continues service even when a link is broken.
- QuadBox A: Interconnect device that receives frames from Ring 1 and forwards a copy to Ring 2 or vice versa.
- QuadBox B: Interconnect device that receives frames from Ring 1 and forwards a copy to Ring 2 or vice versa.
- Ring 2: Second redundant ring that transports both frame copies (labeled as A frame and B Frame as per `HSR-HSR QuadBox workflow` figure) toward destination nodes and onward to the next ring if present.
- DANH destination node: Accepts the first-arriving frame and discards the duplicate to avoid loops and duplicates.
- Next ring: Downstream ring link that can receive forwarded traffic for extended topologies.

Workflow

Figure 188: HSR-HSR QuadBox workflow

The process involves these stages:

1. The DANH source node sends a data frame and immediately creates two copies, injecting those copies into Ring 1 in opposite directions.
2. The two frame copies propagate around Ring 1. If a link is broken (as indicated by the cross marks), the intact path still carries the frames to the interconnects.

3. QuadBox A receives the Ring 1 frame traveling in one direction (clockwise) and forwards a copy to Ring 2, preserving redundancy.
4. QuadBox B receives the Ring 1 frame traveling in the opposite direction (counter-clockwise) and forwards a copy to Ring 2, ensuring both directions of Ring 2 carry the duplicated frames.
5. On Ring 2, the A frame and B frame travel in opposite directions, so that all attached DANH nodes can receive at least one copy.
6. The DANH destination node takes the first-arriving frame, processes it, and discards the second copy to prevent duplicate delivery.
7. If the topology includes a downstream link, Ring 2 forwards traffic toward the next ring to extend connectivity.

Result

The switch provides seamless interconnection between two HSR rings, ensuring redundancy and network resilience in industrial environments.

Enable HSR-HSR QuadBox mode

You can activate HSR-HSR QuadBox mode to bridge two HSR rings using four dedicated ports on an IE3505 or IE3505H switch.

Use this task when you need to interconnect two HSR rings for redundancy.

Procedure

Step 1 Use the **fpga-profile activate hsr-quadbox** command to activate FPGA profile for QuadBox.

Example:

```
Switch# fpga-profile activate hsr-quadbox
```

Use the **reload** command to reload the device to apply the new profile.

Step 2 Use the **configure terminal** command to enter configuration mode.

Example:

```
Switch# configure terminal
```

Step 3 Use the **hsr-hsr-mode enable pair [copper | sfp | mixed]** command to enable HSR-HSR QuadBox based on the port pair option mentioned in the *Interface configuration for HSR-HSR QuadBox* table.

Example:

```
Switch(config)# hsr-hsr-mode enable pair sfp
PLEASE READ THE FOLLOWING INFORMATION ABOUT THE HSR-HSR MODE:

By enabling this mode, Ethernet ports that are not part of the feature will
no longer be operational.

When operating in this mode note the following:
        1. When this mode is configured and enabled, all other ports apart
           from the mode ports, will be shut down. Any feature running on these
           Ethernet ports will no longer function.
```

```
2. The only means to manage the Switch will be available through the Serial Console.

3. IP management of the Switch will be restored once "inband access via HTTP/HTTPS"

   is configured and Device Manager will be not be accessible until inband
   IP management is operational.

4. Make sure Native VLAN is same on both the Quadboxes.
5. Make sure Vlan allowed list configuration and Multicast
   filters configured are same on both quadboxes
6. The CLI switchport mode acess will be disabled
   when quadbox is enabled
7. Switchport access mode will be disabled when HSR-HSR is configured.
8. MTU size is restricted to 2020.

ACCEPT? (yes/[no]): yes
Creating a HSR-ring interface HSR-ring 1

Creating a HSR-ring interface HSR-ring 2

Interface GigabitEthernet1/1 set to default configuration
Interface GigabitEthernet1/2 set to default configuration
Interface GigabitEthernet1/3 set to default configuration
Interface GigabitEthernet1/8 set to default configuration
Interface GigabitEthernet1/9 set to default configuration
```

Confirm acceptance of the mode change and acknowledge the warning about port shutdown and management changes.

Table 217: Syntax description

Keyword	Description
copper	Configures both HSR rings to use built-in copper ports.
sfp	Configures both HSR rings to use SFP ports.
mixed	Configures one HSR ring to use SFP ports and the other to use copper ports.

Refer to *Interface assignment for HSR-HSR QuadBox* table for additional ports information.

Step 4 (Optional) Use the **hsr-ring** *ring_number* **multicast-filter deny group** *multicast_group_number_with_mask* **[** *multicast_group_number_without_mask***] address** *multicast address* **[mask** *multicast_address_mask***]** command to configure multicast filtering for the QuadBox.

Example:

```
Switch(config)# hsr-ring 1 multicast_filter_deny_group 1 0000.0100.0a00 ffff.ffff.ffff
Switch(config)# hsr-ring 2 multicast_filter_deny_group 5 0000.0100.0b00
```

Table 218: Syntax description

Keyword	Description
multicast_group_number_with_mask	The multicast group number configured with a mask. Configure the 48-bit multicast address and mask. The MAC destination address (MACDA) of a frame is matched with the configured 48-bit match-pattern up to the number of bits configured in the 48-bit mask. Once a match is found between the frame's MACDA and the mask/match-pattern setting, the frame is dropped and not forwarded from the QuadBox. It ranges from 1 to 4.
multicast_group_number_without_mask	The multicast group number configured without a mask. These 256 filters allow you to specify a single group that can be blocked. Because there is no mask, each filter can block only one multicast group. Any packets with a MACDA matching the configured MAC addresses are then dropped by the QuadBox. It ranges from 5 to 260.
multicast_address_mask	The 48-bit MAC destination address written as a dotted triple of four-digit hexadecimal numbers. The ones bits in the mask are the bits to be ignored in the MAC Address.

Step 5 (Optional) Perform these steps to configure VLAN filtering for HSR ring interface 1 or 2.

a) Use the **interface hsr-ring***ring_number* command to configure the interface for HSR ring.

Example:

```
Switch(config)# interface hsr-ring 1
```

b) Use the **switchport mode trunk allowed vlan** *vlan_num* command to configure the switch mode.

Example:

```
Switch(config-if)# switchport mode trunk allowed vlan 1
```

The allowed *vlan_num* value on the HSR ring ranges from 1 to 4096. All other VLANs are dropped.

c) Use the **exit** command to exit from the configuration mode.

Example:

```
Switch(config-if)# exit
```

Step 6 Use the **show hsr ring [multicast-filter | allowed-vlan | vlan-filter-drop-count | multicast-filter-drop]** command to monitor the information.

Example:

```
Switch# show hsr ring multicast-filter
                HSR-ring listing:
                --------------------
HSR-ring: HS1

Feature History

Table 219: Feature history

Feature Name	Releases	Description
HSR-HSR QuadBox	Cisco IOS XE 26.1.1	This feature enables you to interconnect two distinct High-availability Seamless Redundancy (HSR) rings, providing continuous, fault-tolerant communication between them. This capability is crucial in industrial and critical infrastructure environments where zero packet loss and high network availability are paramount. It allows for robust network segmentation and enhanced resilience on IE3505 and IE3505H platforms.

Device Level Ring

Device Level Ring overview

Device Level Ring (DLR) is a Layer 2 protocol that enables redundancy in a ring topology, providing fast network fault detection and reconfiguration for industrial networks. DLR is an EtherNet/IP™ protocol that is defined by the Open DeviceNet® Vendors' Association (ODVA).

DLR network includes at least one node configured to be a ring supervisor, and any number of normal ring nodes. All DLR ring nodes are required to have at least two Ethernet ports and incorporate embedded switch technology. Non-DLR multiport devices—switches or end devices—may be present in the ring, subject to certain implementation constraints. (No MAC table filtering is one example.) Non-DLR devices also affect the worst-case ring recovery time.

The DLR protocol supports a simple, single-ring topology. However, a network installation may use more than one DLR-based ring, so long as each ring is isolated so that DLR protocol messages from one ring are not present on another ring.

DLR supports redundant gateways for connecting with network infrastructure outside of the DLR network. The DLR redundant gateway feature provides mechanisms for automatically or manually selecting an active gateway. It also provides for automatic switchover to a backup gateway in the event of a connection failure.

A DLR ring can operate on access or trunk interfaces. A DLR ring configured with access ports can connect switches or end nodes. A DLR ring with trunk interfaces serves as an infrastructure that connects DLR-capable

switches and devices in multiple VLANs. All the interfaces on the ring should have the same VLAN membership.

Components of DLR

DLR Device Classes

DLR supports the given classes of devices:

- *Ring supervisor*: On every DLR network, you must configure at least one device as the ring supervisor. The ring supervisor verifies the integrity of the ring, reconfigures it when a fault occurs, and collects diagnostic information. The ring supervisor also sends and processes Beacon frames at the default beacon interval of 400 microseconds.

  We recommend that you make at least one other device on the DLR network available as a back-up ring supervisor. Each supervisor is configured with a precedence value; the device with the highest precedence value becomes the active ring supervisor.

- *Beacon-based ring node*: This class of device implements the DLR protocol, but lacks ring supervisor capability. The device must be able to process and act on the beacon frames that the ring supervisor sends.

- *Redundant Gateway*: In a DLR network, redundant gateway devices enable multiple connections to the network outside of the DLR network. They provide an alternate path for communication in case a gateway device or its connection to the outside network fails.

  For information about redundant gateways, see the sections Redundant Gateways, on page 2737 and Configure a Redundant Gateway, on page 2746.

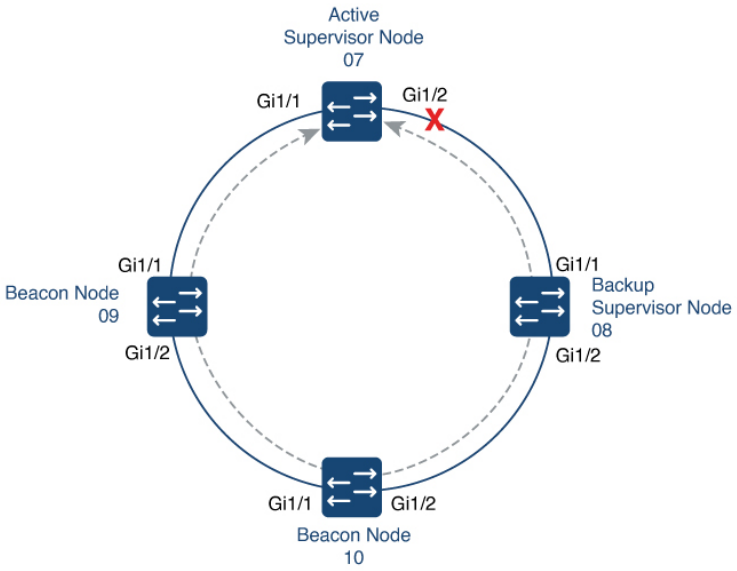
- *VLAN trunking*: VLAN trunking devices allow a DLR network to carry traffic through a trunk link. A trunk link connects switches that carry traffic from multiple VLANs, unlike an access link that can only carry a single VLAN.

  DLR VLAN trunking allows switches and star-connected devices in multiple VLANs to communicate through a DLR network. Traffic that passes from one switch to the next can either remain on the same VLAN or pass to a different VLAN through routing.

- *Multiple Rings support*: Cisco IE3500 Rugged Series Switches and Cisco IE3500 Heavy-Duty Series Switches support up to three rings.

FPGA Profiles

Because the DLR feature requires use of the Cisco IE3505 Series Switch FPGA, the number of DLR rings supported on the Cisco IE3505 Series Switch depends on the FPGA profile. For information about FPGA profile, see Configure FPGA Profile, on page 2289



The Cisco IE3505 Series Switch expansion modules have product ID prefix *IEM-3500*. The switch allow you to configure all DLR rings either on the base module, on the expansion module, or as a mix of both, without restrictions.

DLR Topology

The Cisco IE3505 Rugged Series Switches and Cisco IE3505 Heavy-Duty Series Switches can act as a DLR ring supervisor, backup supervisor, or regular DLR beacon node. This functionality helps other nodes that are connected in a DLR with Cisco IE3505 Rugged Series Switches and Cisco IE3505 Heavy-Duty Series Switches to recover from a ring fault within 3 milliseconds and resume communications.

The following illustration shows a DLR ring with Cisco IE3505 Rugged Series Switches and Cisco IE3505 Heavy-Duty Series Switches acting as the ring supervisor, backup supervisor, and beacon nodes. The solid blue line represents the ring over which Ethernet frames travel, and the dotted gray line represents the bidirectional beacon frames. The X in the illustration shows where the ring supervisor blocks an interface to prevent broadcast storms. If a failure occurs in the DLR ring, the supervisor will unblock the interface.

Figure 189: DLR Topology

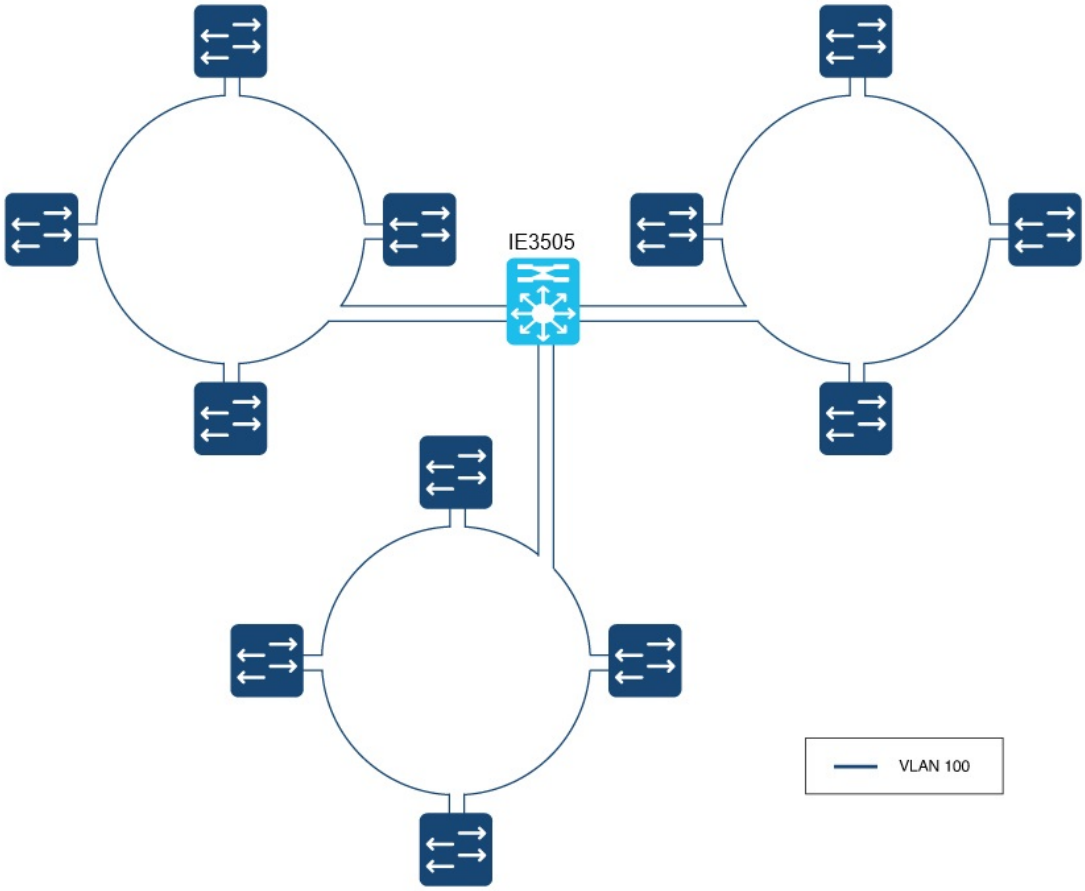
We recommend that you connect the interface with the higher number on the active supervisor node to the backup supervisor node.

Multiple Rings

The Cisco IE3505 Rugged Series Switches and IE3505 Heavy-Duty Series Switches support up to three rings.

Multiple Rings, Single Switch, Single VLAN

The following restrictions apply to multiple rings that are connected to one switch on one VLAN:



- Multiple rings cannot share the same ring ports.
- Ring ports supports access ports and trunk ports.

Note Ensure that all nodes in the same ring use the same access ports and trunk ports.

- All ports participating in the ring must have the same VLAN mode. If an access ring is configured, then all ports must be in the same access VLAN. For a trunk ring, all ports must be in trunk mode.

When only one node is a member of multiple rings, as in the example below, a VLAN can have ports in more than one ring.

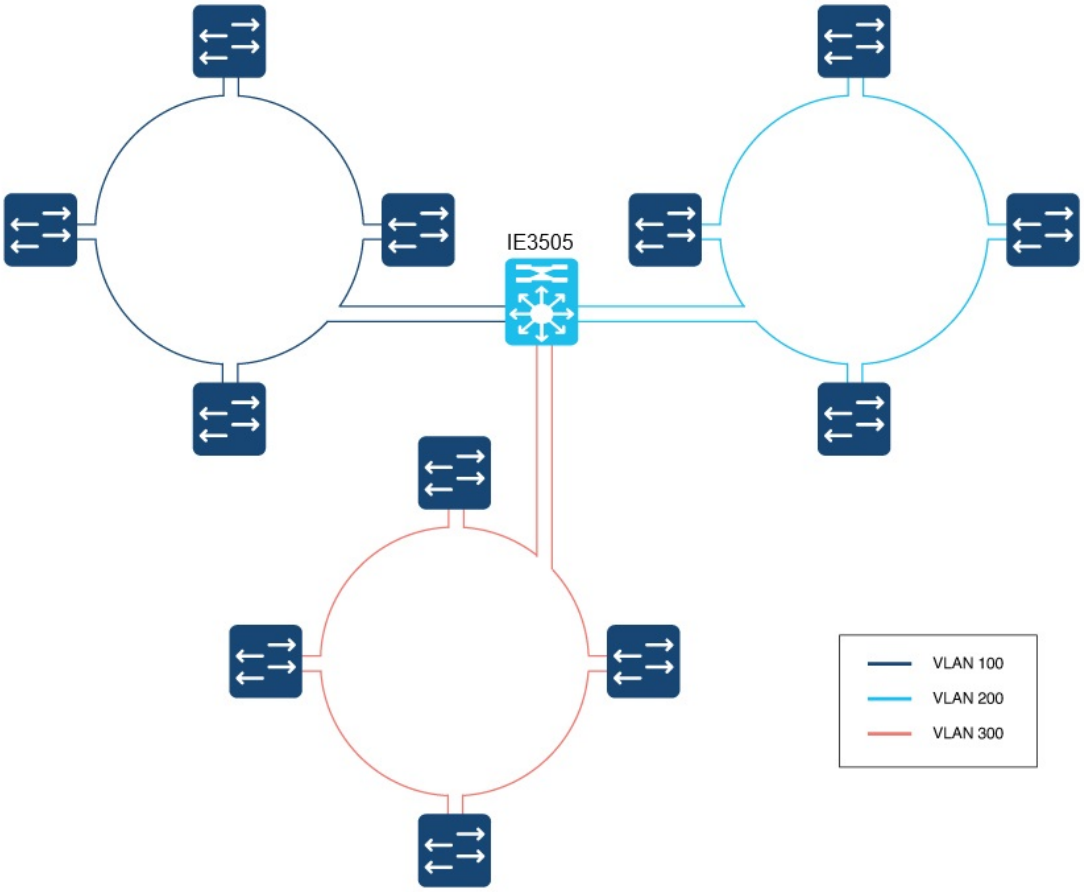


Figure 190: Multiple Rings, Single Switch, Single VLAN

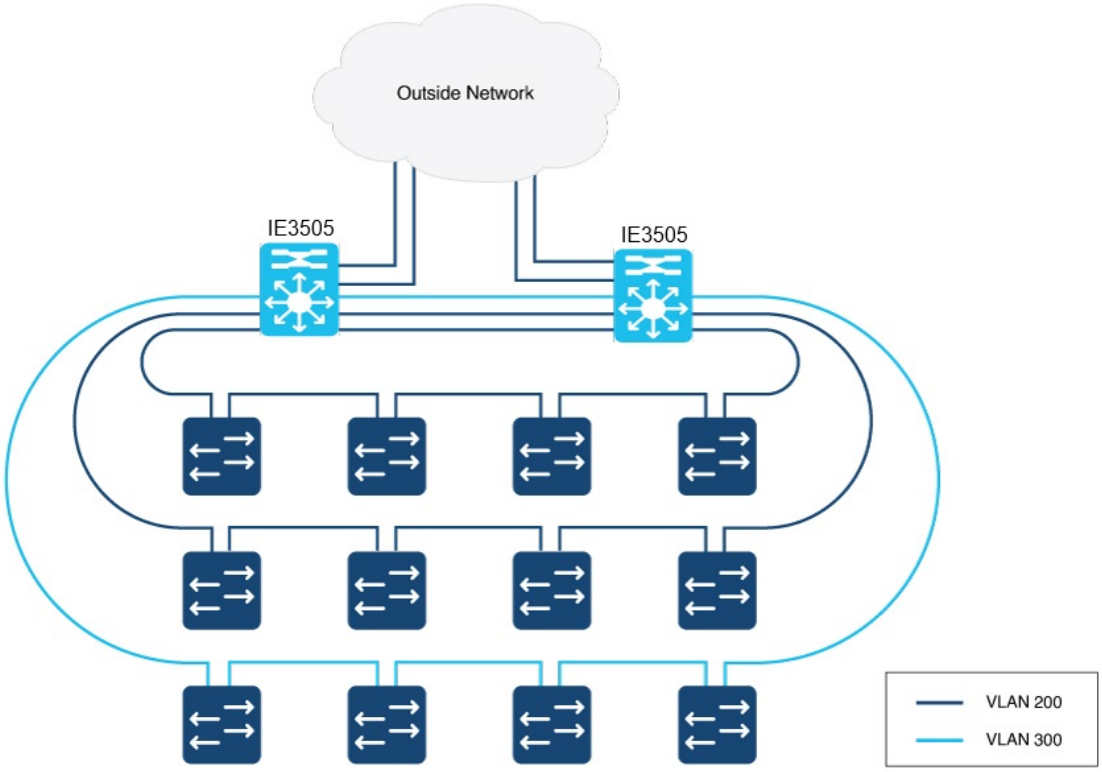
Multiple Rings, Single Switch, Multiple VLANs

The following illustration shows multiple rings sharing a common supervisor with unique VLANs for each ring. When each DLR ring operates in a different VLAN, there is no issue and this is a supported deployment.

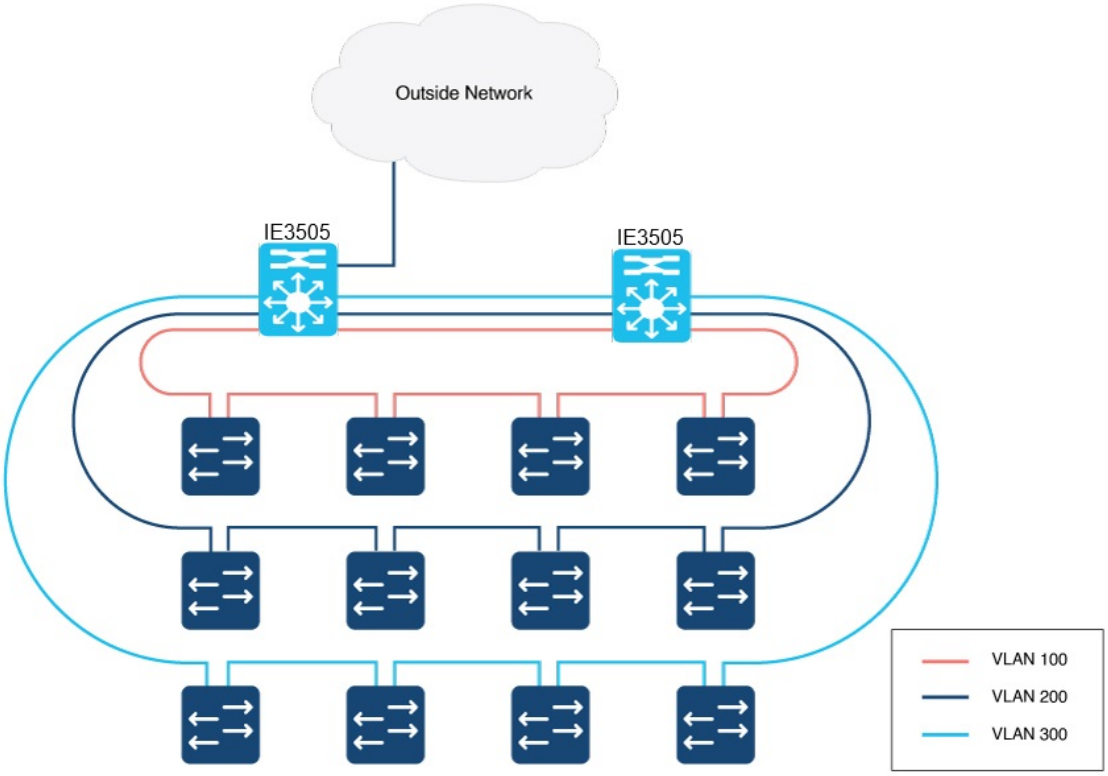
Figure 191: Multiple Rings, Single Switch, Multiple VLANs



Multiple Rings Connected to Multiple Switches

You can also use multiple rings with multiple Cisco IE3500 Series Switches, as shown in the illustration below. Depending on the configuration of the switches, VLAN restrictions can apply.

If the two switches are configured as redundant gateways for the same set of rings, there are no VLAN restrictions. The following example shows two rings on the same VLAN and one ring on a separate VLAN. However, because there are no VLAN restrictions, you can also configure all three rings on the same VLAN or all three on separate VLANs.



When there are two or more switches in same DLR, and they are not configured as redundant gateways, then each DLR ring must have a unique VLAN. VLANs and mutiple DLR rings need to be planned, especially when the VLAN or VLANs are present on more than one DLR ring. Configuring redundant gateways on the IE switches enables DLR deployments where a VLAN is present on multiple DLR rings. When the DLR gateway is not configured on the IE switch pair, then a VLAN cannot be shared across rings. Failure to adhere to this guidance will result in a Layer 2 loop. In example below, the two IE switches are configured for DLR gateway, thus a VLAN can be present across two or more DLR rings.

Figure 192: Multiple Rings, Multiple Switches, No VLAN Restrictions

If the two switches are not configured as redundant gateways, VLANs cannot be present on more than one ring, otherwise a Layer 2 loop becomes possible. The following illustration shows only one path out of the DLR ring, so DLR redundant gateways have not been configured.

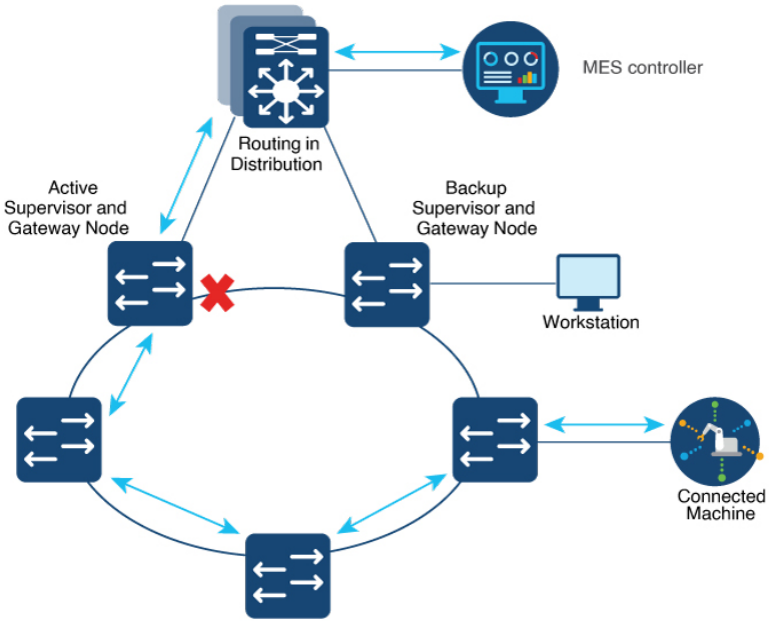
Figure 193: Vlans Not Shared Across DLR Rings

Redundant Gateways

A DLR network with redundant gateways uses multiple switches to provide multiple connections from a ring to the outside network. Redundant gateways are not essential if you need only one connection to the outside network, but they provide extra network resiliency if an uplink connection fails.

Either a ring supervisor or a ring participant can be a redundant gateway; however, you must enable and configure DLR on both gateway switches.

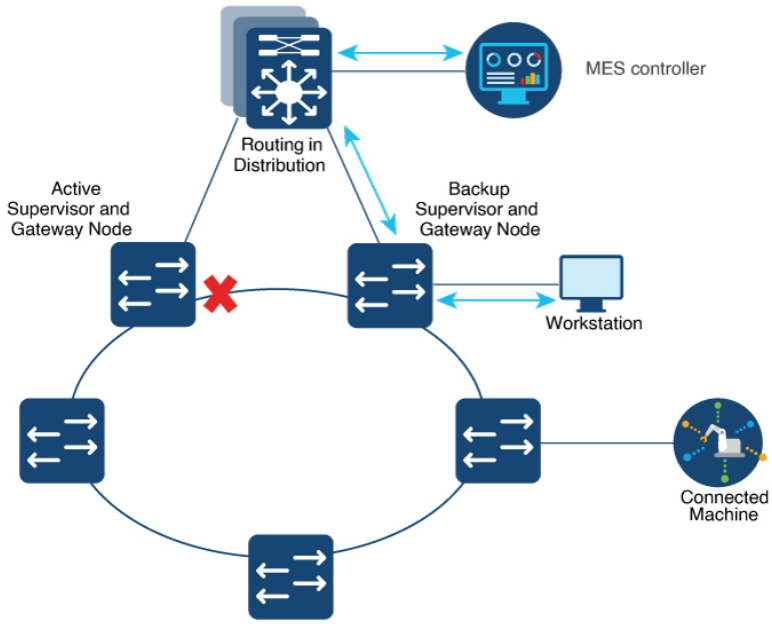
Redundant gateways enable you to automatically or manually chose an active gateway as well as for automatic switchover to a backup gateway in case of a connection failure. Gateway switchover times range from 14 ms to 6.1 seconds, depending on the uplink network resiliency protocol. DLR redundancy gateway performance applies to traffic sourced from inside the DLR destined to the outside network:



- Uplink connection failure detected by the active gateway at the physical layer is anywhere from 14 to 150 ms.
- Failure of the Active Gateway Node can take between 19 and 150 ms.

System performance, which applies to most applications, describes traffic sourced from the outside network destined to the DLR. Higher layer uplink fault detection is up to 6.1 seconds.

DLR gateway convergence depends on the redundancy protocol running on the gateway interfaces. STP and REP have different convergence times. Traffic in and out of the DLR ring to the outside network should converge on failure to match the protocol used.



The following illustration shows traffic flow in and out of a DLR ring through the active DLR gateway.

Figure 194: DLR Active Gateway Traffic Flow

The following illustration shows traffic flow in and out of a DLR ring through the backup DLR gateway for devices directly connected to the backup gateway node. It is important to understand the physical path devices take to communicate with other applications outside the ring. The devices attached to the configured backup gateway take a different path than devices attached to the active gateway or other nodes in the DLR ring.

Figure 195: DLR Backup Gateway Traffic Flow

For more information about redundant gateways, see *Guidelines for Using Device Level Ring (DLR) with Ethernet/IP*™ on the odva.org website.

Cisco IE Switch Support for DLR

The Cisco IE3505 Rugged Series Switches and IE3505 Heavy-Duty Series Switches support DLR.

Switches that Support DLR

Table 220: The following Advanced base modules SKUs (PIDs) supports DLR.

Switch	PID
Cisco IE3505 Rugged Series Switch	IE-3505-8P3S
	IE-3505-8T3S
Cisco IE3505 Heavy-Duty Series Switch	IE-3505H-16T

Table 221: The following Expansion modules PIDs include DLR support when installed on one of the above advanced base modules

Switch	Expansion modules PID
Cisco IE3500 Series Switch	IEM-3500-14T2S
	IEM-3500-6T2S
	IEM-3500-16P
	IEM-3500-16T
	IEM-3500-8P
	IEM-3500-8S
	IEM-3500-8T

Support for DLR is available on Network Essentials and Network Advantage licenses.

Supported DLR Features

IE-3505-8P3S, IE-3505-8T3S, and IE-3505H-16T switches support the following DLR features:

- The number of supported DLR rings varies by Cisco IOS XE release and FPGA profile, as shown in the table below.

Table 222: Ring Support for Cisco IE3505 Series Switch and Expansion Models

Switch	FPGA Profile	Cisco IOS XE Release 17.18.x	Cisco IOS XE Release 26.1.x
Cisco IE3505 Rugged Series without expansion module	Default	3	2
	Redundancy	2	0
	HSR-Quadbox	Not applicable	0
	DLR	Not applicable	3
Cisco IE3505 Rugged Series with expansion module	Default	3	2
	Redundancy	2	0
	HSR-Quadbox	Not applicable	0
	DLR	Not applicable	3
IE-3505H-16T	Default	3	2
	Redundancy	2	0
	HSR-Quadbox	Not applicable	0
	DLR	Not applicable	3

- Redundant gateway
- You can configure DLR by using the web user interface (WebUI).
- You can configure DLR by using Common Industrial Protocol (CIP).

Differences Between Switch Models When Using DLR

Port mapping for IE3505 Heavy-Duty Series Switches differs from port mapping for IE3505-8P3S and IE3505-8T3S Rugged Series Switches.

For IE3505-8P3S and IE3505-8T3S Rugged Series Switches, DLR is supported on the base system (Gi1/1, Gi1/2), (Gi1/4, Gi1/5), (Gi1/6, Gi1/7), (Gi1/8, Gi1/9), and (Gi1/10, Gi1/11), and on the expansion module Gi2/1 through Gi2/6.

Table 223: Cisco IE3505 Rugged Series Switch Port Pairing

Module	Valid DLR Ring Port Pairs
Base module	• [Gi1/1, Gi1/2] • [Gi1/4, Gi1/5] • [Gi1/6, Gi1/7] • [Gi1/8, Gi1/9] • [Gi1/10, Gi1/11]
Expansion module	• [Gi2/1, Gi2/2] • [Gi2/3, Gi2/4] • [Gi2/5, Gi2/6]

For Cisco IE3505 Heavy-Duty Series Switches, you must pair DLR ring ports with adjacent ports. The following table shows valid DLR ring port pairs:

Table 224: Cisco IE3505 Heavy-Duty Switch Port Pairing

Ports	Valid DLR Ring Port Pairs
Gi1/1 through Gi1/8	• [Gi1/1, Gi1/2] • [Gi1/3, Gi1/4] • [Gi1/5, Gi1/6] • [Gi1/7, Gi1/8]
Gi1/9 through Gi1/16	• [Gi1/9, Gi1/10] • [Gi1/11, Gi1/12] • [Gi1/13, Gi1/14] • [Gi1/15, Gi1/16]

DLR Feature Interactions

The following list contains features that cannot be configured on interfaces that are also configured as DLR ring ports..

- STP, RSTP, and MSTP
- 802.1x and Guest VLAN
- PVLAN and PVLAN Edge
- VLAN Routing and Bridging and MV

DLR does not interfere with the functionality of the following features. However, take care during configuration: The MAC or IP addresses of the DLR devices must be included in the allowable list.

- Port Security
- Unicast MAC filter
- DAI
- DHCP Snooping

For the following features, the ports forward IGMP packets between the two DLR ports but do not process them. Devices other than gateways and active redundant gateway devices are unaffected.

- Multicast
- IGMP Snooping

Guidelines and Limitations

The following restrictions apply to DLR configuration and operation:

- You can configure up to three DLR rings at the same time on each the Cisco IE3505 Rugged Series Switches and IE3505 Heavy-Duty Series Switches. See use cases in Multiple Rings, on page 2733 for guidance.
- When configuring DLR Gateways, for each node, you can configure two ports as an uplink. An uplink can belong to more than one ring.
- We recommend that you configure no more than one backup gateway for each ring.
- MAC learning for each ring is limited to 1024 unicast MAC addresses and 128 multicast MAC addresses for each he Cisco IE3505 Rugged Series Switches and IE3505 Heavy-Duty Series Switches.
- Multicast MAC learning through IGMP snooping is limited to 128 addresses.
- Duplicated packets may be observed during ring convergence.
- DLR is supported on 1 Gbps links and 100 Mbps interfaces with full duplex capability. DLR does not support half duplex links.

- On a given physical ring, all the nodes must be configured with same ring- ID If there is any mismatch in ring IDs between nodes (due to misconfiguration), the ring will still converge and may lead to unexpected behavior.

The following restrictions apply to configuring multiple DLR rings:

- Multiple rings cannot share the same ring ports.
- The switch cannot be configured as announce-based node.
- The default beacon interval is 400 usec. This is the recommended interval for 1 Gbps and 100 Mbps ring interface speeds. The default beacon timeout is 1960 usec. This is the recommended value.
- DLR ring ports are supported on IEM-3500 expansion modules. Check the Product ID (PID) of any expansion modules attached to the IE3505 before attempting to configure DLR rings on expansion module ports.

Note For information, including limitations, on DLR interactions with other features and protocols, see the section DLR Feature Interactions, on page 2742 in this guide.

Configuring DLR

The following sections provide information for configuring DLR on IE3505 Rugged Series Switches and IE3505 Heavy-Duty Series Switches. The supervisor node with the highest precedence value is elected to operate as DLR supervisor. You can use this feature to plan which node will be active and which will be backup supervisor.

Configure a Ring Supervisor

Complete the following procedure to configure the switch as a ring supervisor.

Before you begin

Refer to the parameters for configuring a DLR ring supervisor, which are shown in the following table.

Parameter	Range	Default
Beacon interval	200 to100,000 microseconds	400 microseconds
Beacon timeout	200 to 500,000 microseconds	1960 microseconds
Precedence	0 to 255	0
control-vlan-id	0 to 4095	0

Procedure

	Command or Action	Purpose
Step 1	**dlr ring** *ring_number* **Example:** `switch(config)#dlr ring 1`	Provide the unique DLR value identifying a ring.
Step 2	**mode** *device_role* **Example:** `switch(config)#mode supervisor`	Configure the DLR device as a ring supervisor.
Step 3	**beacon-interval** *microseconds* **Example:** `switch(config)#beacon-interval 500`	Set the beacon interval. **Note** You can set the beacon interval only for devices in supervisor mode.
Step 4	**beacon-timeout** *microseconds* **Example:** `switch(config)# beacon-timeout 2500`	Set the beacon timeout. **Note** You can set the beacon timeout only for devices in supervisor mode.
Step 5	**precedence** *rank* **Example:** `switch(config)#precedence 100`	Sets the precedence of the ring supervisor.
Step 6	**interface** *interface_name* **Example:** `switch(config)#interface gigabitEthernet 1/1`	Enter interface configuation submode for interface GigabitEthernet 1/1.

Step 7	**switchport mode access**
	Example:
	`switch(config-if)#switchport mode access`
	`switch(config-if)#switchport access vlan 33`
		Configure the interface to be a member of a single VLAN.

Step 8	**dlr ring 1** **Example:** `switch(config-if)#dlr ring 1`	Configure the interface to be a member of a DLR ring.
Step 9	**interface** **Example:** `switch(config)#interface gigabitEthernet 1/2`	Set the interface for the second DLR ring port. The second DLR ring port must be a valid port pair of the first DLR ring port. See the section Cisco IE Switch Support for DLR, on page 2739 in this guide for valid port pair combinations.

	Command or Action	Purpose

Step 10	**switchport mode access**
	Example:
	`switch(config-if)#switchport mode access`
	`switch(config-if)#switchport access vlan 33`
		Configure the interface to be a member of a single VLAN. The VLAN must be the same as the one used by the other interface to be a port on same DLR ring.

Step 11	**dlr ring 1** **Example:** `switch(config-if)#dlr ring 1`	Add interface for the DLR ring port.

What to do next

Verify that the ring supervisor is configured by entering the show command. The following example is output of the show command when the switch is configured as a ring supervisor:

```
Switch#sh dlr ring 1
DLR ring 1

mode: Active Supervisor
Network Topology:     Ring Network Status: Normal
IOS state: NORMAL_ACTIVE    Hardware State: NORMAL_ACTIVE
Transition bit = 0
Mac-Addr: 6C:13:D5:AC:3A:C3 IP-Addr: 0.0.0.0
Port1: GigabitEthernet1/1, vlan 33,   UP Port2: GigabitEthernet1/2, vlan 33, UP
LastBcnRcvPort: Port 1: Yes    Port 2: Yes

Active Supervisor Parameters:
Beacon Interval (usec): 500    Beacon Timeout (usec): 2500
DLR VLAN ID: 0      Precedence: 100
Mac-Addr: 6C:13:D5:AC:3A:C3    IP-Addr: 0.0.0.0

Locally Configured Supervisor Parameters:
Beacon Interval (usec): 500    Beacon Timeout (usec): 2500
DLR VLAN ID: 0      Precedence: 100
Port1: GigabitEthernet1/1    Port2: GigabitEthernet1/2
```

Configure a Beacon-Based Ring Node

Procedure

Complete the commands as shown in the following example to configure the switch as a beacon-based ring node.

Example:

```
…
dlr ring 2
   mode beacon-node
!
…
interface GigabitEthernet1/1
   switchport mode trunk
   dlr ring 2
```

```
!
interface GigabitEthernet1/2
   switchport mode trunk
   dlr ring 2
!
…
```

What to do next

Verify that the beacon-based ring node is configured by entering the show command. The following example is output of the show command when the switch is configured as a beacon-based ring node:

```
Switch#show dlr ring 2
DLR ring 2
mode: Beacon Node
Network Topology: Ring     Network Status: Normal
IOS state: NORMAL     Hardware State: NORMAL
Transition bit = 0
Mac-Addr: 6C:13:D5:AC:3C:03 IP-Addr: 0.0.0.0
Port1: GigabitEthernet1/1, vlan Trunk, UP  Port2: GigabitEthernet1/2, vlan Trunk, UP
LastBcnRcvPort: Port 1: Yes    Port 2: Yes

Active Supervisor Parameters:
Beacon Interval (usec): 400    Beacon Timeout (usec): 1960
DLR VLAN ID: 0 Precedence: 0
Mac-Addr: 6C:13:D5:AC:3A:C3    IP-Addr: 0.0.0.0

Locally Configured Beacon Node Parameters:
Port1: GigabitEthernet1/1    Port2: GigabitEthernet1/2
```

Configure a Redundant Gateway

You must configure DLR on both gateway switches.

Before you begin

Refer to the parameters for configuring a switch as a DLR redundant gateway node. The parameters are shown in the following table:

Parameter	Range	Default
Gateway enable	Enable-Disable	Disable
Precedence	0 to 255	0
Advertise interval	200 to 100,000 microseconds	2000 microseconds
Advertise timeout	500 to 500,000 microseconds	5000 microseconds
Learning-update	Supported	Enabled

Procedure

Complete the commands as shown in the following example to configure the switch as a redundant gateway node.

Example:

Switch A Configuration	Switch B Configuration
… dlr ring 1 mode supervisor dlr ring 1 gateway enable gateway-precedence 100 advertise-interval 3000 advertise-timeout 10000 interface GigabitEthernet1/9 switchport mode trunk dlr ring 1 uplink !…	… dlr ring 1 mode supervisor dlr ring 1 gateway enable gateway-precedence 255 advertise-interval 3000 advertise-timeout 10000 interface GigabitEthernet1/9 switch mode trunk dlr ring 1 uplink !…

What to do next

Verify that the redundant gateways are configured by entering the show command.

The following example is output of the show command when a switch is configured as the redundant gateway nodes:

```
Switch-a#sh dlr ring 1
DLR ring 1

mode: Active Supervisor
Network Topology: Ring    Network Status: Normal
IOS state: NORMAL_ACTIVE   Hardware State: NORMAL_ACTIVE
Transition bit = 0
Mac-Addr: 6C:13:D5:AC:3C:03 IP-Addr: 0.0.0.0
Port1: GigabitEthernet1/1, vlan Trunk, UP Port2: GigabitEthernet1/2, vlan Trunk, UP
LastBcnRcvPort: Port 1: Yes   Port 2: Yes

Active Supervisor Parameters:
Beacon Interval (usec): 400   Beacon Timeout (usec): 1960
DLR VLAN ID: 0     Precedence: 0
Mac-Addr: 6C:13:D5:AC:3C:03 IP-Addr: 0.0.0.0

Locally Configured Supervisor Parameters:
Beacon Interval (usec): 400   Beacon Timeout (usec): 1960
DLR VLAN ID: 0     Precedence: 0
Port1: GigabitEthernet1/1   Port2: GigabitEthernet1/2
…
…
…
Redundant Gateway Information:
Redundant Gateway Status: Active Gateway
Hardware State: ACTIVE NORMAL
Mac-Addr: 6C:13:D5:AC:3C:03 IP_addr:0.0.0.0
```

```
Uplink Port(s): GigabitEthernet1/9

Active Gateway Parameters:
Advertise Interval (usec): 3000  Advertise Timeout (usec): 10000
Precedence: 100    Learning Update Enable: yes
Mac-Addr: 6C:13:D5:AC:3C:03 IP-Addr:0.0.0.0

Fault Statistics:
Gateway Faults since power up: 0

Locally Configured Gateway Parameters:
Advertise Interval (usec): 3000  Advertise Timeout (usec): 10000
Precedence: 100    Learning Update Enable: yes
Uplink Port(s): GigabitEthernet1/9
switch-a#
```

The following example is output of the show command when a switch is configured as the backup gateway:

```
Switch-b#sh dlr ring 1
----------------------------------------
DLR ring 1

mode: Backup Supervisor
Network Topology: Ring    Network Status: Normal
IOS state: NORMAL_BACKUP   Hardware State: NORMAL_BACKUP
Transition bit = 0
Mac-Addr: 6C:13:D5:AC:3A:C3 IP-Addr: 0.0.0.0
Port1: GigabitEthernet1/1, vlan Trunk, UP Port2: GigabitEthernet1/2, vlan Trunk, UP
LastBcnRcvPort: Port 1:   Yes Port 2: Yes

Active Supervisor Parameters:
Beacon Interval (usec): 400   Beacon Timeout (usec): 1960
DLR VLAN ID: 0     Precedence: 0
Mac-Addr: 6C:13:D5:AC:3C:03 IP-Addr: 0.0.0.0

Locally Configured Supervisor Parameters:
Beacon Interval (usec): 400   Beacon Timeout (usec): 1960
DLR VLAN ID: 0     Precedence: 0
Port1: GigabitEthernet1/1   Port2: GigabitEthernet1/2
…
…
…
Backup Supervisor Precedence: 0

Redundant Gateway Information:
Redundant Gateway Status: Backup Gateway
Hardware State: BACKUP NORMAL
Mac-Addr: 6C:13:D5:AC:3A:C3 IP_addr:0.0.0.0
Uplink Port(s): GigabitEthernet1/9

Active Gateway Parameters:
Advertise Interval (usec): 3000  Advertise Timeout (usec): 10000
Precedence: 100    Learning Update Enable: yes
Mac-Addr: 6C:13:D5:AC:3C:03 IP-Addr:0.0.0.0

Fault Statistics:
Gateway Faults since power up: 0

Locally Configured Gateway Parameters:
Advertise Interval (usec): 3000  Advertise Timeout (usec): 10000
Precedence: 0     Learning Update Enable: yes
Uplink Port(s): GigabitEthernet1/9
```

Configure VLAN Trunking

Note When a node has two or more DLR rings configured, a VLAN can only be present on one ring. When configuring DLR ring ports in trunk mode, you must edit the trunk-allowed VLAN list to ensure unique VLAN membership across DLR rings.

Procedure

Complete the commands as shown in the following example to configure VLAN trunking for DLR.

Example:

```
switch(config)#dlr ring 1
switch(config-dlr)#mode supervisor
switch(config-dlr-supervisor)#end

switch(config)#int gi1/1
switch(config-if)#switchport mode trunk
switch(config-if)#switchport trunk allowed vlan 10,20
switch(config-if)#dlr ring 1

switch(config-if)#
switch(config-if)#int gi1/2
switch(config-if)#switchport mode trunk
switch(config-if)#switchport trunk allowed vlan 10,20
switch(config-if)#dlr ring 1
```

What to do next

Verify that VLAN trunking is configured by entering the show command. The following example is the output of the show command when VLAN trunking is configured:

```
switch#sh dlr ring
----------------------------------------
DLR ring 1

mode: Active Supervisor
Network Topology: Ring     Network Status: Normal
IOS state: NORMAL_ACTIVE    Hardware State: NORMAL_ACTIVE
Transition bit = 0
Mac-Addr: 6C:13:D5:AC:3A:C3 IP-Addr: 0.0.0.0
Port1: GigabitEthernet1/1, vlan Trunk, UP  Port2: GigabitEthernet1/2, vlan Trunk, UP
LastBcnRcvPort: Port 1: Yes    Port 2: Yes

Active Supervisor Parameters:
Beacon Interval (usec): 400    Beacon Timeout (usec): 1960
DLR VLAN ID: 0      Precedence: 0
Mac-Addr: 6C:13:D5:AC:3A:C3 IP-Addr: 0.0.0.0

Locally Configured Supervisor Parameters:
Beacon Interval (usec): 400    Beacon Timeout (usec): 1960
DLR VLAN ID: 0      Precedence: 0
Port1: GigabitEthernet1/1    Port2: GigabitEthernet1/2
```

```
Ring Protocol Participants Count: 3
No    Mac-Addr IP-Addr
1     6C:13:D5:AC:3A:C3 0.0.0.0
2     6C:13:D5:AC:3C:03 0.0.0.0
3     6C:13:D5:AC:37:03 0.0.0.0

Fault Statistics:CIP

Ring Faults since power up: 0
Ring Fault Location  Mac-Addr IP-Addr
Last Active Node on Port 1 00:00:00:00:00:000.0.0.0
Last Active Node on Port 2 00:00:00:00:00:000.0.0.0

Redundant Gateway Information:
Redundant Gateway Status: Gateway not enabled
---------------------------------------
DLR ring 2 not configured
```

Enabling CIP

You can enable Common Industrial Protocol (CIP) on a device by applying the `cip enable` command on one of the Layer-3 interfaces—a physical L3 interface or an SVI-interface.

Note Be aware of the following when enabling CIP:

- You must habve DLR rings configured on the switch before enabling CIP.
- You must enter the command in interface configuration mode.
- You enable CIP at the device level.
- You enable CIP only through one of the Layer-3 interfaces; if you try to enable CIP on another interface, an error occurs.

Enable CIP on the Layer 3 Interface

Complete the steps in this section to enable CIP on the Layer 3 interface.

Procedure

	Command or Action	Purpose
Step 1	**conf t**	Enter configuration mode.
Step 2	**interface** *interface_name* **Example:** `switch(config)#interface gigabitEthernet 1/10`	Specify the interface.

	Command or Action	Purpose
Step 3	**no switchport**	Prevent the interface from forwarding Ethernet frames based on MAC addresses. The interface is not operational until a valid IP address is assigned.
Step 4	**ip address** *IP_address subnet_address* **Example:** `switch(config-if)#ip address 192.168.1.10 255.255.255.0`	Set the IP address and subnet.
Step 5	**cip enable**	Enable CIP on the interface.
Step 6	**end**	Leave configuration mode.

What to do next

Verify that CIP is configured by entering the show command. The following example is output of the `show` command when CIP is configured:

```
DLR_node#show cip status
State : Enabled
Interface : Gi1/10
DLR_node#
```

Enable CIP on the SVI Interface

Complete the steps in this section to enable CIP on the SVI interface.

Before you begin

If the SVI is not vlan1, assign `switchport access vlan` *`vlan-id`* to the DLR ring.

Procedure

	Command or Action	Purpose
Step 1	**conf t**	Enter configuration mode.
Step 2	**vlan** *vlan_id* **Example:** `switch(config)#vlan 1`	Specify the VLAN.
Step 3	int vlan *vlan_id* **Example:** `switch(config-vlan)#int vlan 1`	Enter interface configuration mode.
Step 4	**ip address** *IP_address subnet_address* **Example:**	Specify an ID address and subnet.

	Command or Action	Purpose
	`switch(config-if)#ip address 192.168.1.10 255.255.255.0`	
Step 5	**cip enable** **Example:** `switch(config-if)# cip enable`	Enable CIP on the interface.
Step 6	**end** **Example:** `switch(config-if)# end`	Leave configuration mode.

What to do next

Verify that CIP is configured by entering the show command. The following example is output of the `show` command when CIP is configured:

```
DLR_node#show cip status
State : Enabled
Interface : Vlan 1
DLR_node#
```

PTP over DLR

Precision Time Protocol over Device Level Ring (PTP over DLR) is a time-synchronization capability that:

- maintains accurate clock synchronization across a DLR during link failures,
- prevents PTP re-convergence at endpoint devices during DLR fault and recovery events, and
- supports time-sensitive industrial applications.

PTP over DLR integrates IEEE 1588 time synchronization with DLR redundancy and it supports:

- up to three DLR simultaneously,
- up to 50 nodes per ring. and
- DLR-supported expansion module ports.

Guidelines for PTP over DLR

- Use multiple-VLAN transparent clock (TC) mode on the active and backup DLR supervisors or redundant gateways to prevent endpoint PTP reconvergence during DLR fault and recovery events.
- Maintain a single Grandmaster Clock (GMC) per DLR ring to avoid timing instability.
- Use compatible PTP clock modes across all DLR supervisors, gateways, and participating devices.
- Plan VLAN usage carefully and ensure PTP VLAN configuration is consistent across all ring interfaces.
- Although Boundary Clocks (BCs) are supported within a DLR ring, a BC terminates and re-originates PTP messages and selects one PTP port as its time-recipient port. During a DLR fault or recovery event,

the selected parent clock or timing path can change, causing endpoints to reconverge. To maintain continuous PTP operation without endpoint reconvergence, configure multiple-VLAN Transparent Clock (TC) mode on the active and backup DLR supervisors or redundant gateways.

- Do not mix other redundancy mechanisms; DLR must be the sole loop-prevention mechanism within the ring.
- Validate PTP synchronization after topology changes such as link failures or recoveries.
- Do not configure incompatible PTP clock modes within the same DLR ring, as this may cause synchronization loss and application level faults.

Limitations of PTP over DLR

- PTP over DLR supports the default PTP profile.
- End-to-end TC cannot be configured when a DLR supervisor or redundant gateway is configured on a switch.
- Using a BC inside a DLR ring can cause PTP parent clock changes during ring fault or recovery events.
- All devices participating in a DLR ring must use compatible PTP clock modes; mixing BCs and TCs can cause timing instability.
- A standard TC supports PTP traffic on only one VLAN. For DLR deployments that carry PTP traffic across multiple-VLANs, configure multiple-VLAN TC mode on the active and backup DLR supervisors or redundant gateways. Alternatively, use a single VLAN for PTP traffic or deploy devices that support multiple-VLAN TC.
- PTP over DLR supports up to three DLR rings simultaneously.
- Each DLR ring supports up to 50 nodes. Do not connect more than 50 nodes to a single ring. Configurations that exceed this limit are unsupported and may not provide the specified DLR fault-recovery or PTP synchronization behavior, potentially causing connectivity or timing disruptions.
- PTP over DLR is supported only on DLR supported models.

PTP over DLR reference information

PTP profiles and clock types

PTP over DLR supports default PTP profile.

Table 225: PTP types and modes for DLR

PTP clock type	Description
Boundary Clock (BC)	Terminates and regenerates PTP timing information.
Transparent Clock (TC)	Forwards PTP packets while correcting residence time.
Multiple-VLAN Transparent Clock	Provides TC operation for PTP traffic across multiple-VLANs.

PTP clock type	Description
Grandmaster Clock (GMC)	Serves as the primary source of time and reference for the PTP domain.
Forward mode	Forwards PTP packets without participating in clock selection.

Troubleshooting PTP over DLR

These are the PTP over DLR issues and their causes.

Table 226: PTP over DLR issues and causes

Issues	Description	Cause
PTP ordinary clock resynchronization during ring faults	A ring fault changes the PTP timing path, causing an endpoint to select a new parent clock and resynchronize. Synchronization may be temporarily interrupted.	BC is used where multiple-VLAN TC mode is required.
VLAN mismatch errors	PTP packets are received on a VLAN that does not match the configured PTP VLAN. The packets may not be processed, preventing synchronization.	Incorrect PTP VLAN configuration.
No PTP traffic	PTP Announce, Sync, and delay-measurement messages are not transmitted or received on the ring interfaces. As a result, the endpoint clocks cannot synchronize.	PTP is not enabled on ring interfaces.
Timing instability	Endpoint clocks receive inconsistent timing information or repeatedly switch between available time sources, causing clock-offset variations.	Multiple PTP time sources are configured in the DLR ring without a clearly defined preferred grandmaster clock.

These are the PTP over DLR error messages and their causes.

Table 227: Understanding PTP over DLR display messages

Message	Reason
`WARNING%% DLR supervisor/redundant gateway is configured, only PTP Boundary Clock or Transparent Clock (multiple VLAN) or Forward mode is allowed.`	This warning message is displayed when standard End-to-End TC mode, without multiple-VLAN support, is configured on a switch that is already configured as a DLR supervisor or redundant gateway. These DLR roles support BC, multiple-VLAN TC, or forward mode, but not standard End-to-End TC mode.

Message	Reason
`ERROR%% DLR Supervisor can be configured only with PTP Boundary Clock or Transparent Clock (multiple VLAN) or Forward mode.`	This error message is displayed when you attempt to configure the local switch as a DLR supervisor while standard End-to-End TC mode is already configured on that switch. Change the PTP mode to BC, multiple-VLAN TC, or forward mode before configuring the DLR supervisor role.
`ERROR%% DLR Redundant can be configured only with PTP Boundary Clock or Transparent Clock (multiple VLAN) or Forward mode.`	This error message is displayed when you attempt to configure the local switch as a DLR redundant gateway while standard End-to-End TC mode, without multiple-VLAN support, is already configured on that switch. Change the PTP mode to BC, multiple-VLAN TC, or forward mode before configuring the redundant gateway role.

Note

1. First message: The DLR role is configured first, followed by an incompatible PTP mode.
2. Second message: The incompatible PTP mode is configured first, followed by the DLR supervisor role.
3. Third message: The incompatible PTP mode is configured first, followed by the DLR redundant gateway role.

Use these commands at EXEC level to monitor PTP over statistics.

Table 228: PTP over DLR commands to monitor statistics

Command	Purpose
show ptp clock dataset default	Displays the configured PTP clock type.
show ptp clock dataset parent	Displays the parent clock information.
show ptp clock dataset time-properties	Displays the clock synchronization state.
show ptp lan clock	Displays the PTP LAN clock information.
show ptp lan port interface Gigabitethernet1/1 counters error	Provides PTP error counters.**show dlr ring** *ring-id*.
show ptp lan port interface Gigabitethernet1/1 counters messages	Provides PTP message counters.
show running-config interface Gigabitethernet1/1	Provides PTP VLAN configuration.
show dlr ring *ring-id*	Displays the specified DLR ring status.

Configure DLR

Configure PTP over DLR with multiple-VLANs

Enable PTP synchronization across multiple-VLANs within a DLR network.

This procedure configures a multiple-VLAN TC to support PTP timing distribution across DLR segments.

To configure PTP over DLR on a DLR supervisor or redundant gateway, use the following procedure.

Before you begin

Note A redundant gateway is optional and is not required for PTP over DLR. On other DLR nodes, configure multiple-VLAN TC mode only when the node operates as a transparent clock. Nodes operating in forward mode and PTP endpoints do not require the global multiple-VLAN TC command.

Procedure

Step 1 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Switch# configure terminal
```

Step 2 Use the **ptp clock transparent-mvlan domain** *domain-id* **profile default** command to configure multiple-VLAN TC.

Example:

```
Switch(config)# ptp clock transparent-mvlan domain 10 profile default
```

Step 3 Enable PTP and associate a VLAN on the DLR ring interface if the interface is a trunk port

a) Use the **interface** *interface-name* command to specify the interface.

Example:

```
Switch(config)# interface GigabitEthernet1/2
```

b) Use the **ptp vlan** *vlan-id* command to associate PTP operation with the specified VLAN if the interface is a trunk port.

Example:

```
Switch(config-if)# ptp vlan 100
```

If the interface is an access port, do not configure the **ptp vlan** command.

c) Use the **exit** command to return to global configuration mode.

Example:

```
Switch(config-if)# exit
```

Note
Repeat step 3 to enable PTP and associate a VLAN on all other applicable DLR ring interfaces.

Step 4 (Optional) Use the **show running-config | include ptp** command to display the PTP information along with the other commands as given in the example.

Example:

```
Switch# show running-config | include ptp
ptp clock transparent domain 10  profile default

Switch# show ptp clock dataset default
CLOCK [multi-VLAN Transparent Clock, domain 10]

  Profile: default

```

Configure PTP over DLR using BC

Enable PTP timing distribution across a DLR ring using BC functionality.

This procedure allows for the regeneration and distribution of PTP timing information within a DLR deployment.

Before you begin

Ensure that only one time source exists in the DLR ring and that all devices support PTP.

Procedure

Step 1 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Switch# configure terminal
```

Step 2 Use the **ptp clock boundary domain** *domain-number* **profile default** command to configure the BC.

Example:

```
Switch(config)# ptp clock boundary domain 10 profile default
```

Step 3 Use the **clock-port** *port-name* command to configure a clock port.

Example:

```
Switch(config-ptp-clk)# clock-port ptp1
```

Step 4 Use the **transport ipv4 multicast interface** *interface-id* command to specify the interface.

Example:

```
Switch(config-ptp-port)# transport ipv4 multicast interface GigabitEthernet1/2
```

a) Use the **ptp vlan** *vlan-id* command to specify PTP VLAN for a trunk port.

Example:

```
Switch(config-ptp-port)# ptp vlan 10
```

Configure PTP VLAN as per trunk allowed VLAN list on the interface.

b) Use the **exit** command to return to global configuration mode.

Example:

```
Switch(config-ptp-port)# exit
```

Configure PTP over DLR using TC

Maintain stable time synchronization across a DLR network during link failures. These configurations are done on DLR beacon nodes. For more details, refer to Configure a Beacon-based ring node.

This procedure configures PTP over DLR using TC to ensure consistent PTP timing distribution within a DLR environment.

Before you begin

Ensure that DLR is configured and operational, and a PTP grandmaster exists in the network.

Procedure

Step 1 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Switch# configure terminal
```

Step 2 Use the **ptp clock transparent domain** *domain-number* **profile default** command to configure the TC.

Example:

```
Switch(config)# ptp clock transparent domain 10 profile default
```

You must configure the global PTP VLAN if DLR ring interfaces on beacon nodes are trunk ports. If you do not configure a PTP VLAN, PTP packets use the trunk's native VLAN and are sent untagged. Synchronization may fail if the connected devices expect tagged PTP packets.

Step 3 Use the **vlan** *vlan-id* command to configure the global PTP VLAN for PTP traffic on this clock instance.

Example:

```
Switch(config-ptp-clk)# vlan 10
```

This is applicable for all DLR ring interfaces which are configured as trunk ports with allowed VLAN list on beacon node.

Step 4 (Optional) Use the **show running-config | include ptp** command to verify the PTP information.

Refer to Step 4 of Configure PTP over DLR with multiple-VLANs.

PART XI

Common Industrial Protocol

- Common Industrial Protocol, on page 2765

CHAPTER 183

Common Industrial Protocol

- Information about CIP, on page 2765
- CIP restrictions, on page 2765
- Enabling CIP, on page 2765
- CIP password encryption, on page 2766
- Additional references, on page 2768

Information about CIP

The Common Industrial Protocol (CIP) is an industrial protocol for industrial automation applications.Previously known as Control and Information Protocol, CIP encompasses a comprehensive suite of messages and services for the collection of manufacturing automation applications - control, safety, synchronization,motion, configuration and information.

It is supported by Open DeviceNet Vendors Association (ODVA), an organization that supports network technologies based upon CIP such as DeviceNet, EtherNet/IP, CIP Safety and CIP Sync. CIP allows users to integrate these manufacturing applications with enterprise-level Ethernet networks and the Internet.

CIP restrictions

CIP can be enabled on only one VLAN on the switch.

Enabling CIP

Before you begin

By default, CIP is not enabled

Procedure

Step 1 Enters global configuration mode.

```
Configure Terminal
```

Step 2 Sets CIP security options on the switch.

```
cip security { password password | window timeout value }
```

Step 3 Enters interface configuration mode.

```
interface vlan 20
```

Step 4 Enables CIP on a VLAN.

```
cip enable
```

Step 5 Returns to privileged EXEC mode.

```
end
```

Step 6 Verifies your entries.

```
show running-config
```

Step 7 (Optional) Saves your entries in the configuration file.

```
copy running-config startup-config
```

Step 8 (Optional) Displays information about the CIP subsystem.

```
show cip { connection | faults | file | miscellaneous |
object | security | session | status }
```

Step 9 (Optional) Enables debugging of the CIP subsystem.

```
debug cip {assembly | connection manager | dlr | errors
| event | file | io | packet | infra | security | session | socket}
```

CIP password encryption

Common Industrial Protocol (CIP) password encryption is a security feature for industrial environments that

- protects CIP credentials within device configuration files,
- uses the Type 8 (SHA256) hashing algorithm to meet modern security standards, and
- ensures that stored credentials are irreversible and resistant to cryptographic attacks.

Type 8 encryption is a strong, irreversible hashing method that replaces the legacy Type 7 encryption to improve the security posture of industrial deployments.

Table 229: Feature history table

Feature name	Release information	Description
CIP password encryption	26.2.1	This feature provides enhanced security by converting legacy CIP passwords to the irreversible Type 8 (SHA256) algorithm to resist cryptographic attacks. It ensures credential integrity and uninterrupted authentication across industrial deployments.

Type 8 password encryption advantages

Type 8 password encryption provides security and operational advantages by automatically converting legacy passwords during the Cisco IOS XE software upgrade. This irreversible method reinforces credential security by preventing the system from converting passwords back to plaintext. During migration, the system handles invalid or corrupted data gracefully to ensure data integrity. By storing these passwords in the configuration file, the system maintains consistency across reboots and device transfers. It also integrates with the CIP module to provide uninterrupted authentication and communication.

CIP password encryption transitions

When you upgrade the software image to release 26.2.1 or later, the system automatically detects existing CIP passwords stored with Type 7 encryption. The system converts these passwords to the strong, irreversible Type 8 hashing algorithm and saves them into the device configuration file.

Guidelines and restrictions of CIP

Guidelines

- Downgrading to a software version earlier than 26.2.1 removes the CIP password from the configuration.
- Plaintext passwords must be stored externally as they cannot be retrieved once encrypted.
- Manual configuration transfers preserve CIP password.

Restrictions

Type 8 encryption is irreversible, and the original plaintext password cannot be recovered from the device.

Configure CIP password encryption

Set a password to secure CIP communications.

You can enter a plaintext password, which the system automatically converts to Type 8 encryption in the configuration file, or you can manually enter a pre-encrypted Type 8 (SHA256) hash.

Before you begin

Ensure the device is running release 26.2.1 or later to support Type 8 encryption.

Procedure

Step 1 Use the `configure terminal` command to enter global configuration mode.

Example:

```
Switch# configure terminal
```

Step 2 Use the **cip security { password** <*pass_word*> **| password 8** < *SHA256-encrypted-password*> } command to configure the password based on your available credential format.

Example:

```
Switch(config)# cip security password cisco
```

Use the **cip security password 8** < *SHA256-encrypted-password*> command to enter a pre-encrypted Type 8 hash.

Step 3 Use the **exit** command to return to privileged EXEC mode.

Example:

```
Switch(config)# exit
```

Step 4 Use the **copy running-config startup-config** command to copy the running configuration to NVRAM.

Example:

```
Switch# copy running-config startup-config
Destination filename [startup-config]?
Building configuration...
[OK]
```

- Feature history for Read-only PROFINET, on page 2796

Information About Configuring PROFINET

PROFINET is the leading Industrial Ethernet standard that uses TCP/IP and IT standards to connect and control machines in real time. It is widely used in industrial automation and process control networks, especially for motion control and precision instrumentation. PROFINET emphasizes fast, reliable data exchange and defines communication paths to meet different speed requirements.

Communication Levels: PROFINET communication is scalable across three levels:

- **Non-Real-Time (NRT):** Uses TCP/IP with bus cycle times around 100 ms.
- **Real-Time (RT):** Enables faster cycle times, approximately 10 ms.
- **Isochronous Real-Time (IRT):** Achieves highly precise synchronization with cycle times as low as 1 ms (not supported in Class B).

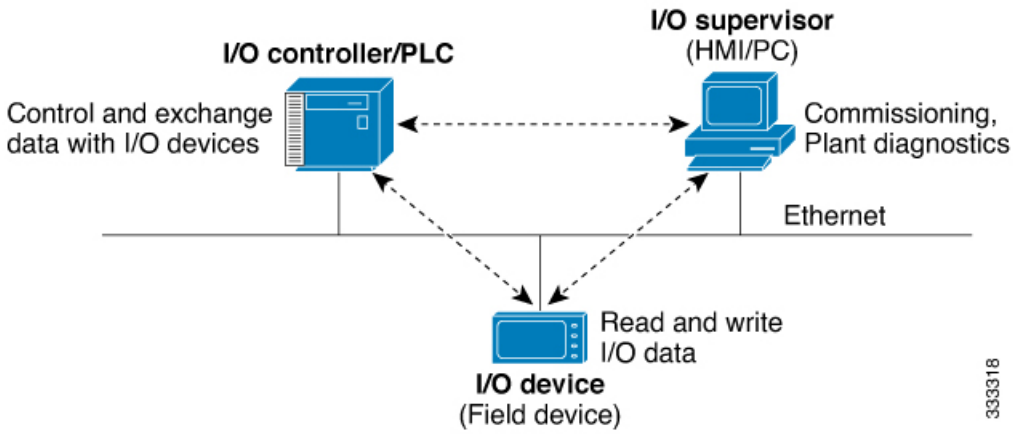
PROFINET I/O System: PROFINET I/O is a flexible communication framework for distributed automation. It uses cyclic data transfer to exchange information, alarms, and diagnostics between controllers, I/O devices, and automation systems like motion controllers.

PROFINET Conformance Class B Support

All Cisco IE switches support PROFINET Conformance Class B.

Conformance Classes: PROFINET has different conformance classes that define supported features.

- **Class B:** Common in factory automation, it supports fast, real-time communication and diagnostics — ideal for applications like production lines and equipment monitoring. Class B includes **PROFINET Real Time (RT)**, which prioritizes important data to reduce delays, with cycle times around 10 ms. This makes RT suitable for tasks like conveyor belt and packaging machine control. However, the switches do not support **Isochronous Real Time (IRT)**, which is required for ultra-precise synchronization.



PROFINET Device Roles

An I/O controller is a programmable logic controller (PLC) that controls I/O devices and exchanges data such as configuration, alarms, and I/O data through an automation program. The I/O controller and the I/O supervisor exchange diagnostic information. The I/O controller shares configuration and I/O information with an I/O device and receives alarms from the I/O device.

A PROFINET I/O system includes three device roles:

- **I/O Devices:** Field devices connected to controllers.
- **I/O Controllers:** Manage and control field devices.
- **I/O Supervisors:** Tools for diagnostics and configuration.

Figure 196: PROFINET Device Roles

Basic PROFINET parameters can be assigned through the controller environment, while Cisco IOS XE or Cisco Catalyst Center can manage other configuration depending on the deployment.

Automatic Device Detection and Configuration: The I/O controller automatically detects switches using the Discovery and Configuration Protocol (DCP). It sets the device name and IP address, so you don’t need to enter Cisco IOS commands for basic configurations.

Advanced Configuration with Cisco IOS: For advanced features, like Quality of Service (QoS), DHCP, and similar capabilities, you’ll need to configure the switch using Cisco IOS commands. These advanced settings cannot be managed directly through PROFINET.

An I/O supervisor is an engineering station, such as a human machine interface (HMI) or PC, used for commissioning, monitoring, and diagnostic analysis. The I/O supervisor exchanges diagnostic, status, control, and parameter information with the I/O device.

An I/O device is a distributed I/O device such as a sensor, an actuator, or a motion controller.

Note If Profinet DCP cannot detect the switch, PLC, or IO mac addresses, temporarily disable the firewall or virus scan from the Windows PC that installed the Siemens STEP7 or TIA Portal Automation application.

In a PROFINET I/O system, all the I/O devices communicate over an Ethernet communication network to meet the automation industry requirement for bus cycle times of less than 100 ms. The network uses switches and full-duplex data exchange to avoid data collisions. The switches play the role of I/O device in Figure 196: PROFINET Device Roles, on page 2774.

PROFINET Device Data Exchange

After PROFINET uses DCP to discover devices, including the switch, the devices establish application relationships (ARs) and communication relationships (CRs). After a connection is established and information about device parameters is exchanged, I/O data is exchanged. The switch uses non-real-time CRs to exchange the data attributes listed below.

Table 230: PROFINET I/O Switch Attributes

PROFINET I/O Switch Configuration Attributes	Value or Action
Device name	Configures a name for the device.
TCP/IP	IP address, subnet mask, default gateway, and switch virtual interface (SVI).
Primary temperature alarm	Enables or disables monitoring for the specified alarm.
Secondary temperature alarm	Enables or disables monitoring for the specified alarm.
SD card alarm	Enables or disables monitoring for the specified alarm.
RPS failed alarm	Enables or disables monitoring for the redundant power supply alarm. **Note** Before enabling monitoring for the RPS failed alarm, the user must configure the command "power-supply dual" in CLI to trigger an alarm when one of the power supplies is missing or inoperable.
Relay major alarm	Enables or disables monitoring for the specified alarm.

PROFINET I/O Switch Configuration Attributes	Value or Action
Reset to factory	Reset to factory (Mode 2: Communication parameter) Uses the PROFINET I/O controller to reset the switch communication parameter. This action removes the Profinet device ID, IP address, and configured SNMP writable MIBs.
Relay major configuration	Specifies the type of port alarm, for example, link fault, that triggers the major relay. Any port configured with the specified alarm type can trigger the major relay.

Table 231: PROFINET I/O Port Attributes

PROFINET I/O Port Configuration Attributes	Value or Action
Speed	10, 100, 1000, or auto.
Duplex	half, full, or auto.
Port mode	access or trunk.
Link status	shut down or no shut down.
Configure rate limiting	Broadcast, unicast, or multicast threshold exceeds configured levels.
Port link fault alarm	Enables or disables monitoring for specified alarm.
Port not forwarding alarm	Enables or disables monitoring for specified alarm.
Port not operating alarm	Enables or disables monitoring for specified alarm.
Port FCS threshold alarm	Enables or disables monitoring for specified alarm.

General Station Description File

PROFINET devices are integrated by using a general station description (GSD) file that contains the data for engineering and data exchange between the I/O controller, the I/O supervisor, and the I/O devices, including the switch. Each PROFINET I/O field device must have an associated GSD file that describes the properties of the device and contains all this information required for configuration:

- Device identification information (device ID, vendor ID and name, product family, number of ports)
- Number and types of pluggable modules
- Error text for diagnostic information
- Communication parameters for I/O devices, including the minimum cycle time, the reduction ratio, and the watch dog time
- Configuration data for the I/O device modules, including speed, duplex, VLAN, port security information, alarms, and broadcast rate limiting thresholds

- Parameters configured for I/O device modules for the attributes listed above

The PROFINET GSD file is bundled with the Cisco IOS release. After the switch boots at least one time, the GSD files for the switch are located in a directory called ProfinetGSD. In this directory, there is a zip file containing all the GSDs for all Cisco IE3500 Series Switch SKUs. The file is called CISCO_*product_id*.zip, for example, CISCO_IE35xx.zip.

The GSD file is in the switch and the I/O supervisor uses this file to manage the switch. For IOS XE-based platforms, the GSD file can be found in the Flash: or SDFlash: file system. If you want to load the GSD file for the Cisco IOS XE platform into the I/O supervisor, you need to copy it from the switch.

Note You must use the GSD file that is associated with the Cisco IOS release on the switch to manage your PROFINET network. Both the I/O supervisor and the Cisco IOS software alert you to a mismatch between the GSD file and the switch's Cisco IOS software version.

The status of GSD match or mismatch can be determined using the **show profinet status** command.

Configuring PROFINET

You can use either the SIMATIC STEP7 or TIA Portal Automation application on the I/O supervisor, or you can use the Cisco IOS software to configure PROFINET on the switch.

After you enable PROFINET, Link Layer Discovery Protocol (LLDP) is automatically enabled on the switch because PROFINET relies on LLDP to fully function. If you disable PROFINET, you can enable or disable LLDP as needed.

Table 232: Feature history table

Feature	Release information	Feature description
VLAN 0 Priority Tagging	Release 17.18.1	This feature enables prioritization of critical traffic using 802.1Q frames with a VLAN ID of zero, ensuring higher processing priority without VLAN assignment.

VLAN 0 priority tagging

You can prioritize traffic without assigning it to a specific VLAN.

Starting with Cisco IOS XE Release 17.18.1, the VLAN 0 priority tagging feature allows you to prioritize traffic without assigning it to a specific VLAN. This feature enables the transmission and reception of 802.1Q Ethernet frames with the VLAN ID set to zero, by retaining the 802.1P priority bits of the VLAN 0 Ethernet packets. These Ethernet frames are known as **priority tagged** frames. As a result, critical traffic receives higher processing priority.

Perform these steps to configure the default PROFINET settings on a switch:

Procedure

Step 1 Use the **configure terminal** command to enter global configuration mode.

Example:

```
Switch# configure terminal
```

Step 2 Use the **interface vlan 1** command to access the VLAN 1 interface.

Example:

```
Switch(config)# interface vlan 1
```

Step 3 Use the **no shut** command to enable VLAN 1.

Example:

```
Switch(config-if)# no shut
```

Step 4 Use the **end** command to exit the configuration mode.

Example:

```
Switch(config-if)#end
```

Step 5 To enable PROFINET on the switch, refer to Enable PROFINET.

Note
Cisco devices undergo the Profinet Certification process to ensure compliance with industrial automation standards. During this process, the use of non-standard protocols such as CDP results in test failures, preventing certification. As a result, Cisco devices intended for Profinet environments must use IEEE standard LLDP instead of CDP.

Enabling PROFINET

To enable PROFINET, follow these steps:

Procedure

Step 1 Enter global configuration mode:

```
Switch# configure terminal
```

Step 2 Enable PROFINET on the switch:

```
Switch(config)# profinet
```

After PROFINET is enabled, you can configure the device as described in Configuring the Switch with STEP7/TIA, on page 2779 (recommended) or by using the Cisco IOS commands provided in the subsequent steps.

Step 3 (Optional) Set the PROFINET device identifier (ID) by using the Cisco IOS software:

```
Switch(config)# profinet id line
```

The maximum length of the ID string can be 240 characters. The only special characters allowed are period (.) and hyphen (-), and they are allowed only in specific positions within the ID string. The ID can have multiple labels within the string. Each label can be from 1 to 63 characters, and labels must be separated by a period (.). The final character in the string must not be zero (0).

For more details about configuring the PROFINET ID, see the PROFINET specification, document number TC2-06-0007a, filename PN-AL-protocol_2722_V22_Oct07, available at PROFIBUS.

This step is optional and can be done through STEP7 or TIA PORTAL STEP 7 or the TIA Portal Automation application installed on the Supervisor (recommended).

Step 4 (Optional) Change the VLAN number. The default VLAN number is 1. The VLAN ID range is from 1 to 4096. One PROFINET VLAN is supported per switch.

```
Switch(config)# profinet vlan vlan_id
```

Note
You must create a VLAN before assigning a new VLAN to PROFINET if you are using a nondefault VLAN.

Step 5 Return to privileged EXEC mode:

```
Switch(config)# end
```

Step 6 Verify your entries:

```
Switch# show running-config
```

Step 7 (Optional) Save your entries in the configuration file:

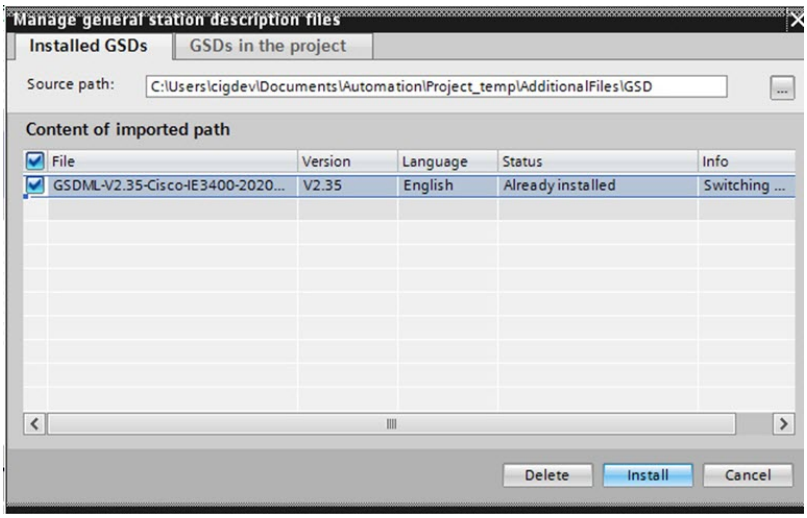
```
Switch# copy running-config startup-config
```

Configuring the Switch with STEP7/TIA

Complete the following steps to configure the switch with STEP7/TIA. TIA v15.1 is used in the following example. Ensure that you do not use the CLI to configure or modify the switch configuration when PROFINET and TIA are in use.

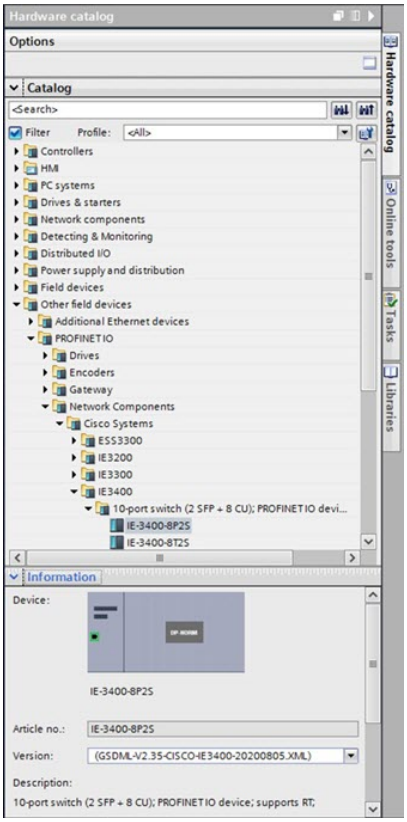
Procedure

Step 1 Check the availability of the GSD file on the switch. You must use the same version that matches the GSD file bundled with the Cisco IOS release image.



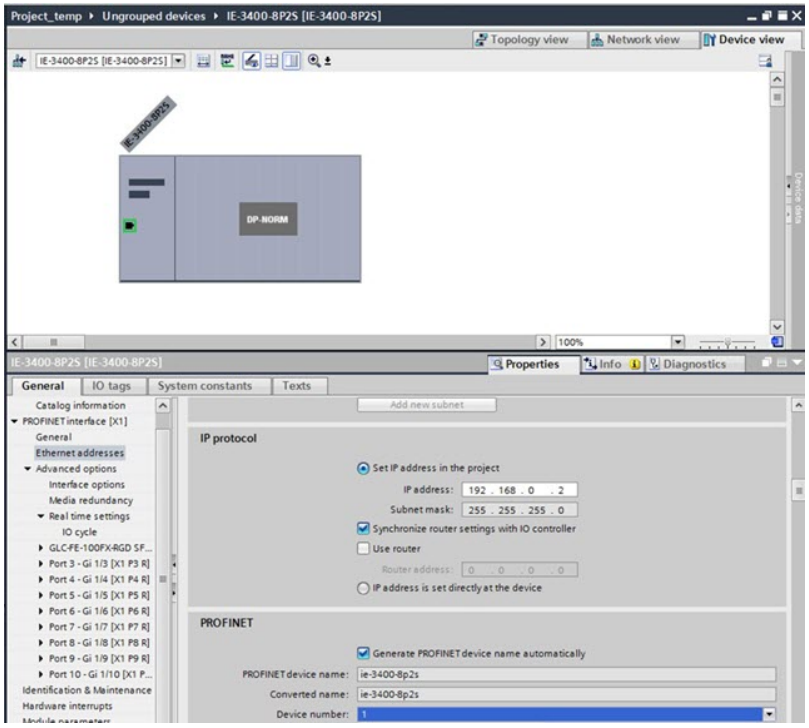
See General Station Description File, on page 2776 for more information.

Step 2 Install the GSD file in STEP7/ TIA:

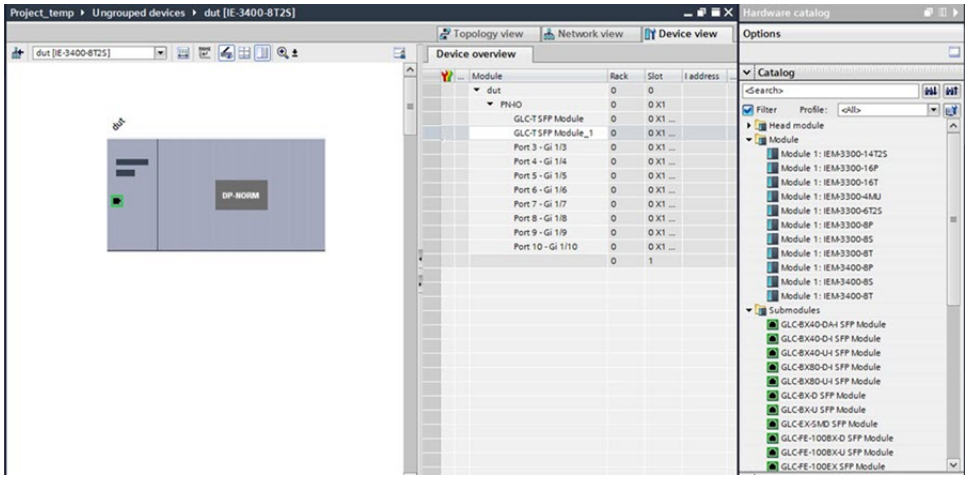


a) In STEP7/TIA, choose **Options** > **Manage general stations description files**, and browse to the location of the GSD file on the PC through source path.

The tool displays all the available GSD files.

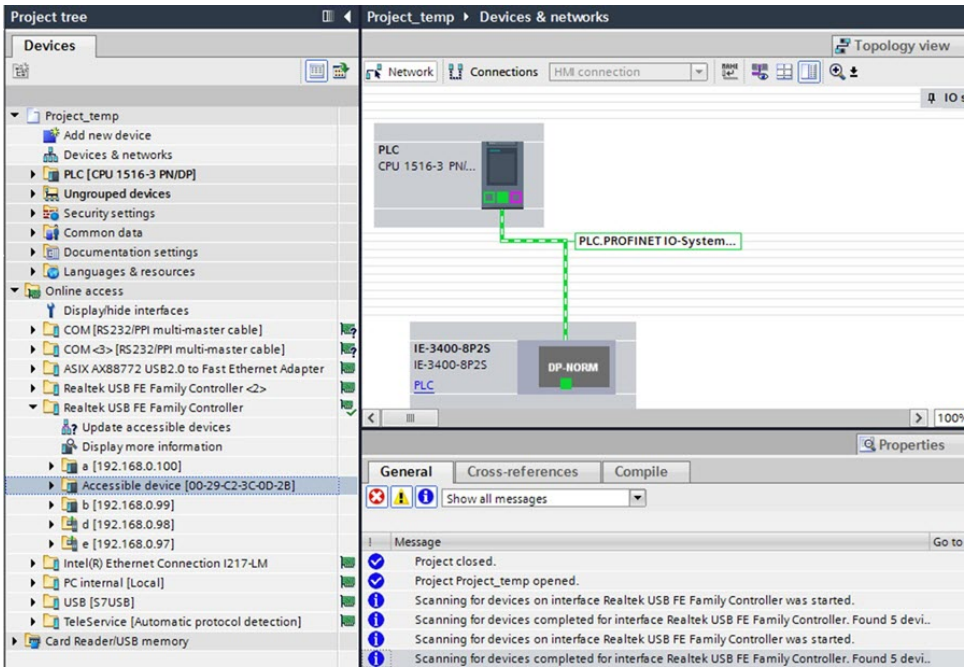


b) Check the check box adjacent to the appropriate the desired GSD file and click **Install**.

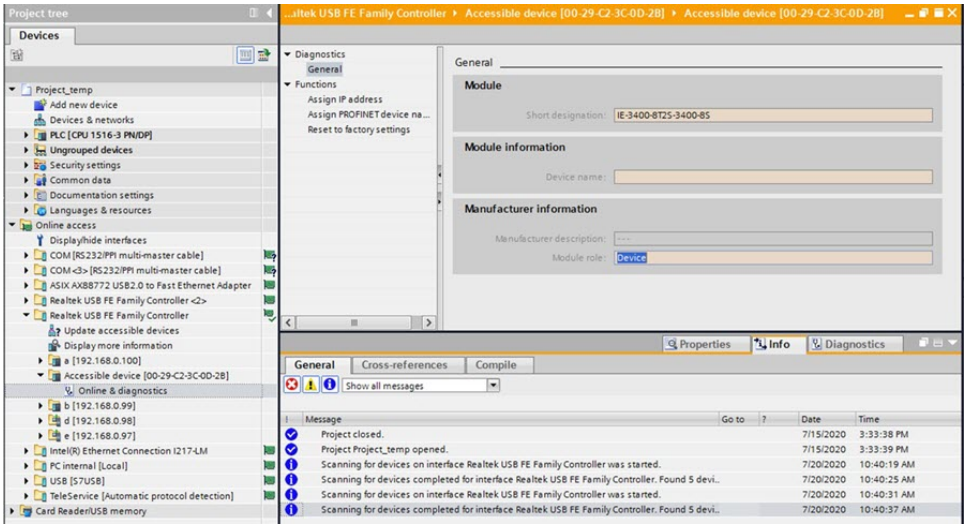


Step 3 After the installation is completed, give it a few seconds to update the **Hardware catalog**. Add the switch from the **Hardware catalog**:

a) In the Device view, configure **IP address** and **PROFINET device name** and save the configuration. These settings are for STEP7/TIA only; the switch is actually configured later during discovery steps.

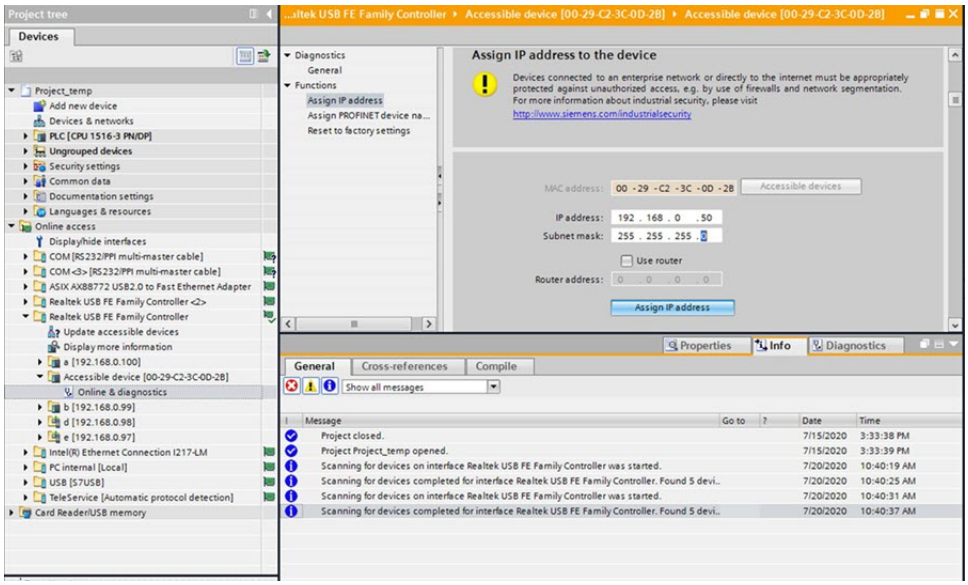


b) Configure the required expansion module or pluggable modules in Device view.

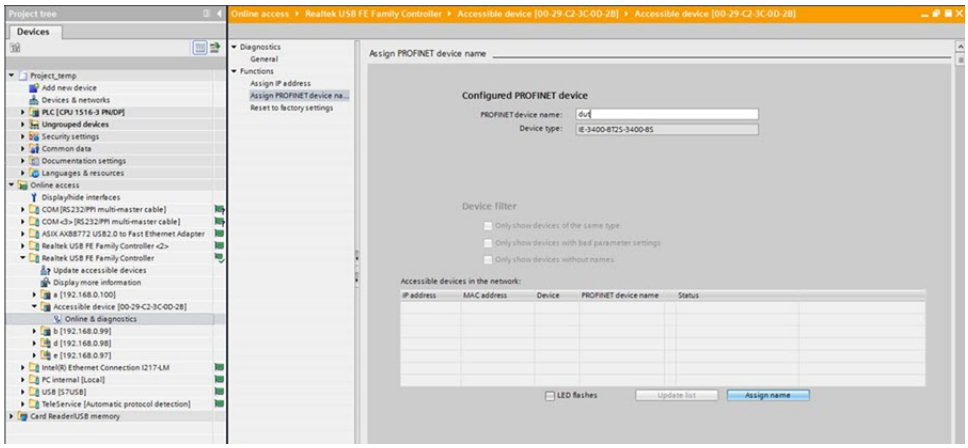


Step 4 After the device is added in the program, discover the device through the interface of the PC connected to the PROFINET topology.

Topology discovery uses LLDP for discovery. LLDP is enabled by default on the switch. You will see the new device listed as **Accessible device** followed by the MAC address under the network card of the PC.

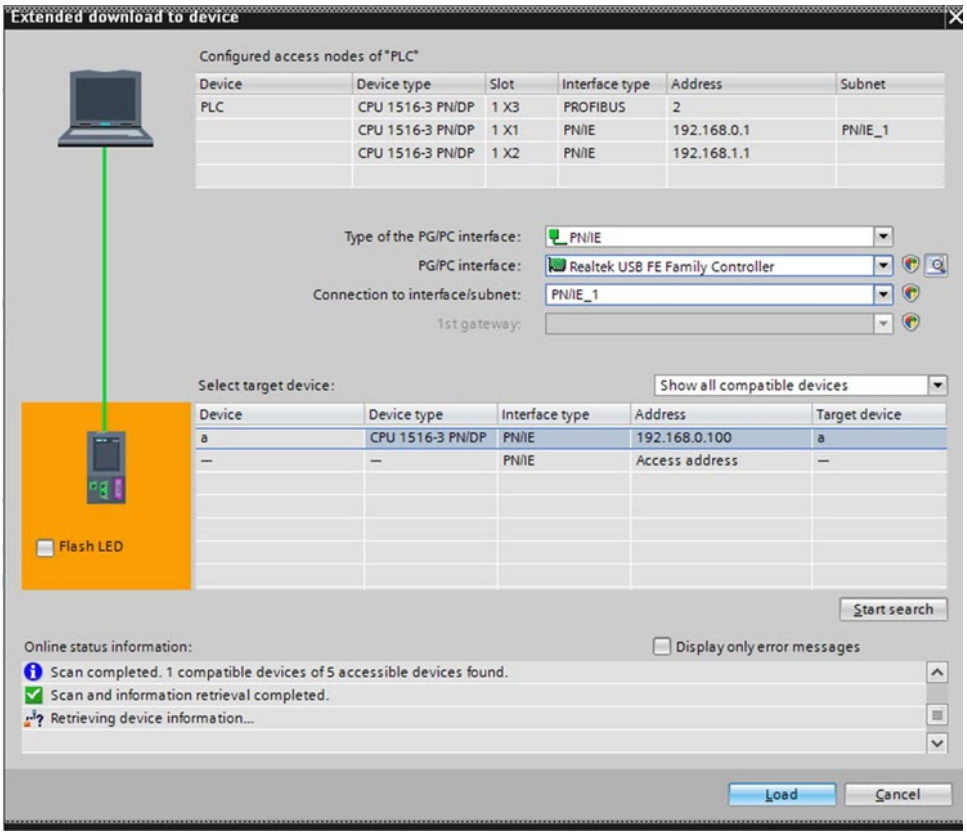


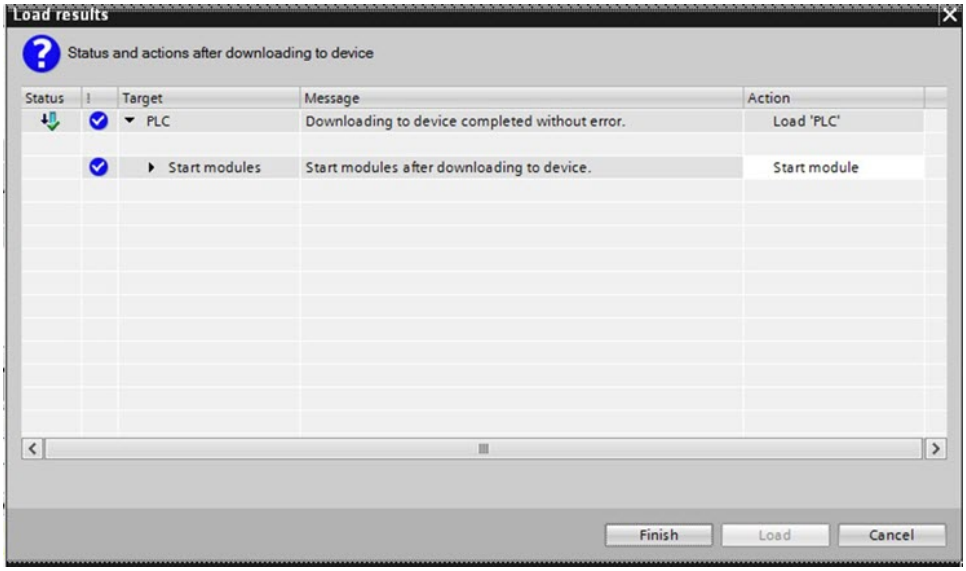
In the **Devices** pane on the left, under **Online access**, find the PC network card and click **Update accessible device**. This initiates the discovery of all the devices in the network.



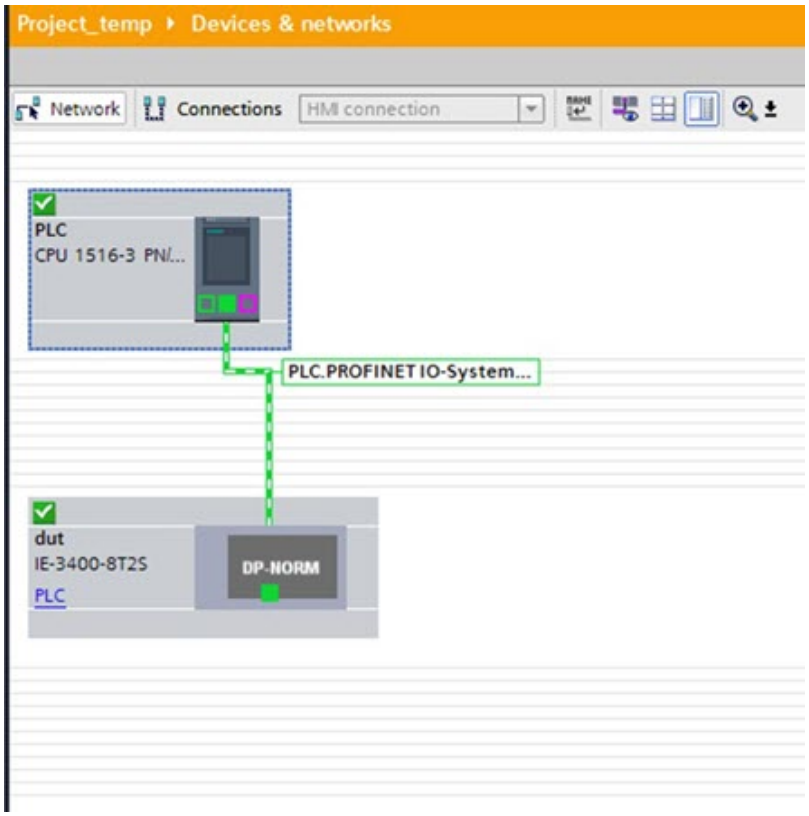
Step 5 In the **Devices** pane, expand the **Accessible device** folder, and click **Online & diagnostics** to further configure the device.

a) In the **IP address** field, enter the IP address and click **Assign IP address** to push the IP address configuration to the switch.





b) In the **PROFINET device name** field, enter the device name and click **Assign name** to push the device name configuration to the switch.



Step 6 Download the project from STEP7/TIA and go online.

a) Compile, download, and load the project to the PLC (I/O Controller).

PROFINET Subsystem

The switch enables the PROFINET subsystem. By default, the switch automatically configures its interfaces to manage PROFINET frames with priority tagging. When the IOSd detects PROFINET traffic, it automatically applies the configuration at runtime, using the **switchport voice vlan dot1p** command on each active interface. This runtime configuration ensures the switch receives the priority-tagged PROFINET frames from the LAN.

```
!
interface GigabitEthernet1/1
switchport voice vlan dot1p
!
```

PROFINET Netload-3 Robustness

PROFINET Netload-3 Robustness is an automatic, built-in traffic-protection feature. When PROFINET is enabled, the system automatically applies the protection mechanisms required to help maintain PROFINET communication during abnormal network-load conditions.

You do not configure or enable this feature separately. The system determines the applicable protection policy and automatically applies it to eligible interfaces associated with the PROFINET VLAN.

Netload-3 is different from PROFINET Conformance Class B. Netload-3 describes resistance to network load. Conformance Class B describes the PROFINET functions supported by a device.

The feature operates automatically when the PROFINET subsystem is enabled. No additional netload-specific commands or configurable thresholds are provided.

The switch performs the following functions:

- Examines incoming PROFINET packets to determine the Frame ID and traffic classification.
- Allows valid traffic associated with the expected Application Relationship (AR) to continue without invoking netload protection.
- Detects unexpected PROFINET Real-Time (RT) frames received from a source other than the expected I/O controller.
- Invokes dynamic MAC access control list processing to block the offending Layer 2 source.
- Applies a system-defined policing policy to incoming IP traffic directed to the PROFINET VLAN IP address.
- Applies the policing policy to eligible physical interfaces when the platform does not support policing directly on a switched virtual interface.

This feature is supported on the these switches from IOS XE 26.2.1:

- Cisco Catalyst IE3500 Rugged Series and Heavy Duty Series Switches

Packet-handling behavior

The switch performs the actions given in the table automatically.

Table 233: Packet-handling behavior

Traffic condition	Switch action
Valid traffic associated with the expected AR.	Forwards the traffic without invoking netload blocking.
Unexpected PROFINET RT traffic from a source other than the expected I/O controller	Identifies the ingress interface, invokes dynamic MAC ACL processing for the source, and generates diagnostic information.
Incoming IP traffic directed to the PROFINET VLAN IP address	Applies a fixed, system-defined policing policy.
SVI policing is not supported by the platform	Applies the policing policy to eligible physical interfaces that carry the PROFINET VLAN.

Eligible physical interfaces

When protection must be applied at the physical-interface level, the system identifies eligible interfaces automatically. No netload-specific user configuration is required. An eligible interface must meet all the following conditions:

- The interface is associated with the PROFINET VLAN.

- The interface is operationally up.
- The interface is an access port in the PROFINET VLAN or a trunk port that allows the PROFINET VLAN.

A MAC ACL or Layer 3 ACL is applied to the interface when the specified conditions are met.

Restrictions for PROFINET Netload-3 Robustness

The following restrictions and guidelines apply to this feature:

- The feature operates only when the PROFINET subsystem is enabled.
- Only interfaces associated with the configured PROFINET VLAN are eligible for netload policing.
- The policing rate is system defined and is not user-configurable.
- If the platform does not support policing on the PROFINET SVI, the switch applies policing to eligible physical interfaces.
- This feature does not add support for Isochronous Real-Time communication.

Profinet connection configuration

When a Profinet connection/session is established, the network device automatically applies and saves the CLI configurations (including SNMP) given in the table below.

Table 234: CLI for the PROFINET Configuration

CLI	Purpose
snmp-server community private RW **snmp-server community public RO**	Configure two Simple Network Management Protocol (SNMP) community strings, each with a read-write and read-only access.
LLDP **lldp timer 5** **lldp holdtime 20** **lldp run**	Enable the Link Layer Discovery Protocol (LLDP) with a frame transmission interval of 5 seconds and a holdtime of 20 seconds.
CDP **no cdp run**	Disable the Cisco Discovery Protocol (CDP).
Power-supply **power-supply dual**	Set up the device to manage dual power supplies, ensuring it can operate redundantly if one power supply fails.

Note CDP is enabled by default in IOS XE 17.18.2 and later releases.

Preventing Default Gateway and CDP Loss During Reloads and Upgrades

Cisco IE switches have Profinet (PN) enabled by default to facilitate management through the Siemens TIA application portal, similar to other I/O devices, Programmable Logic Controllers (PLCs), and I/O devices within the Local Area Network (LAN).

Upon reloading an Industrial Ethernet (IE) switch operating on Cisco IOS XE 17.x or performing an upgrade from version 16.x, you may experience unexpected network connectivity disruptions. This phenomenon arises because the default gateway configuration fails to persist in the running configuration, resulting in its silent disappearance. Moreover, the Cisco Discovery Protocol (CDP) may also be disabled during this process. To rectify the loss of default gateway and CDP configurations, see the *Recommended Solution* section. While both the default gateway and CDP configurations are retained in the startup configuration, they do not appear in the running configuration post-reload or upgrade.

Technical Evaluation

When the Profinet feature is active, the Profinet subsystem conducts several critical checks to ensure proper configuration:

- Non-Zero Values: The switch IP address configured on the Profinet VLAN, gateway address, and netmask must all be non-zero.
- Subnet Consistency: The IP address and gateway address must reside within the same subnet.
- Uniqueness: The IP address and gateway address must not be identical.

If any of these conditions are not met while the Profinet feature is enabled, the default gateway configuration is removed from the running configuration. Additionally, if you save this incomplete configuration to the startup configuration using the **write mem** command, the erroneous settings will persist through power cycles.

Recommended Solution

To rectify the loss of default gateway and CDP configurations, execute the following steps:

1. Disable Profinet.

   Enter the **no profinet** command to disable the Profinet feature.

2. Reconfigure settings.

   Manually re-enter the CDP and default gateway configurations.

3. Save configuration.

   Use the **write mem** command to save the updated configuration.

4. Verify configuration.

Optionally, reload the switch to confirm that the configurations are correctly reflected in the running configuration post-reload.

5. Check Profinet status.

   Use the **show profinet status** to ensure that Profinet is disabled.

Gateway IP address configuration scenarios

The configuration and persistence of the IP address, subnet mask, and default gateway depend on how PROFINET and the management system control the device.

Scenario 1: The device is managed by a PROFINET controller

When PROFINET is enabled and the device is actively managed by a PROFINET controller, such as a PLC or TIA Portal, the controller configures the IP address, subnet mask, and default gateway. The device receives these parameters after it connects to the controller.

The device does not retain these parameters across a software upgrade or reload. After the device reconnects to the PROFINET controller, the controller configures the parameters again. This behavior complies with the PROFINET specification.

The PROFINET requirements related to the IP address, subnet mask, and default gateway remain enforced.

Scenario 2: PROFINET is enabled, but the device is not managed by a PROFINET controller

When PROFINET is enabled but the device is not actively managed by a PROFINET controller, you can configure the IP address, subnet mask, and default gateway by using the CLI or another management application, such as Cisco Catalyst Center.

To prevent PROFINET from affecting the IP address, subnet mask, or default gateway configuration, disable PROFINET, save the running configuration, and reload the device:

```
Switch# configure terminal
Switch(config)# no profinet
Switch(config)# end
Switch# write memory
Switch# reload
```

After the device reloads, PROFINET no longer controls these parameters.

Scenario 3: The device is managed by both a PROFINET controller and Cisco Catalyst Center

In a converged network, the device may connect to an active PROFINET controller, and Cisco Catalyst Center or the CLI may manage its IP configuration. The IP address, subnet mask, and gateway information is not sourced from the PROFINET controller in this scenario.

Guidelines for managing IP configuration:

- Configure a default route instead of a default gateway to maintain gateway connectivity.

  ```
  Switch# configure terminal
  Switch(config)# ip routing
  Switch(config)# ip route 0.0.0.0 0.0.0.0 192.168.1.254
  ```

- The PROFINET requirements related to the IP address, subnet mask, and gateway remain enforced because PROFINET is active.

- After a software upgrade or reload, the PROFINET module clears the IP address, subnet mask, and gateway information unless they are provided by the PROFINET controller or TIA Portal. If the PROFINET controller or TIA Portal does not supply these parameters, Cisco Catalyst Center or another management application must reconfigure them.

Monitoring and Maintaining PROFINET

Table 235: Commands for Displaying the PROFINET Configuration

Command	Purpose
show profinet alarm	Displays all the alarms supported by PROFINET.
show profinet lldp	Displays whether LLDP is active or inactive on the ports.
show profinet session	Displays the currently connected PROFINET sessions.
show profinet status	Displays the status of the PROFINET subsystem.
show profinet mrp ring 1	Displays the status of the MRP ring.
show lldp neighbor interface *interface_id* **detail**	Displays information about the adjacent interface.

The following example displays the PROFINET status and currently connected PROFINET sessions.

```
Switch#sh profinet status
Profinet                        : Enabled
Connection Status               : Connected

Monitoring Configuration Changes in PROFINET Sub-Systems

The PROFINET sub-system operates in real-time and adjusts the configuration of the device based on provisions made by remote engineering tools such as TIA Portal or in response to incoming network traffic. These dynamic updates to the running configuration often occur without your awareness. As a result, this can potentially lead to unexpected changes in system behavior.

To enhance user awareness and system transparency, syslog messages are generated whenever modifications occur in critical configuration fields. By monitoring these syslog messages, you can stay informed about real-time changes to the system configuration, ensuring better management and understanding of the PROFINET environment.

The following fields or protocols generate syslogs:

- Link Layer Discovery Protocol (LLDP)
- Cisco Discovery Protocol (CDP)
- Simple Network Management Protocol (SNMP)
- IP address and gateway configurations

Example of the syslog messages:

```
*Jun 19 14:41:11.247: %PROFINET_MODULE-6-PN_RUNNING_CONFIG: IP / netmask: persistent
configuration applied
*Jun 19 14:41:11.248: %PROFINET_MODULE-6-PN_RUNNING_CONFIG: Gateway IP criteria met,
configuring default gateway
*Jun 19 14:41:11.260: %SYS-5-CONFIG_I: Configured from console by vty0
*Jun 19 14:41:11.260: %PROFINET_MODULE-6-PN_RUNNING_CONFIG: CDP Global: service stopped
*Jun 19 14:41:11.276: %SYS-5-CONFIG_I: Configured from console by vty0
*Jun 19 14:41:11.280: %SYS-5-CONFIG_I: Configured from console by vty0
*Jun 19 14:41:11.280: %PROFINET_MODULE-6-PN_RUNNING_CONFIG: SNMP Global: service started
%PROFINET_MODULE-6-PN_RUNNING_CONFIG: LLDP Global: Tx Freq = 5 secs & Holdtime = 20 secs
*Jun 19 14:41:44.283: %PROFINET_MODULE-6-PN_RUNNING_CONFIG: Applying dot1p config on one
or more interfaces
```

Troubleshooting PROFINET

The PLC has LEDs that display red for alarms. The I/O supervisor software monitors those alarms.

To troubleshoot PROFINET, use the **debug profinet** privileged EXEC command with the keywords listed in the following table.

Caution Be aware that the output of a **debug** command might cause a Telnet connection to fail due to long debug outputs. When you use this command, use the serial or console port rather than Telnet using Ethernet to access the Cisco IOS CLI. You should use these commands only under the guidance of a Cisco Technical Support engineer.

Table 236: Commands for Troubleshooting the PROFINET Configuration

Command	Purpose
debug profinet alarm	Displays the alarm status (on or off) and content of the PROFINET alarms.
debug profinet cyclic	Displays information about the time-cycle-based PROFINET Ethernet frames.
debug profinet error	Displays the PROFINET session errors.
debug profinet packet ethernet	Displays information about the PROFINET Ethernet packets.
debug profinet packet udp	Displays information about the PROFINET User Datagram Protocol (UDP) packets.
debug profinet platform	Displays information about the interaction between the Cisco IOS software and PROFINET.
debug profinet topology	Displays the PROFINET topology packets received.
debug profinet trace	Displays a group of traced debug output logs.

PROFINET system redundancy

A PROFINET system redundancy is a communication architecture that

- allows IO devices and IO controllers to maintain communication in the event of device or connection failure, and
- ensures higher availability and reliability in industrial automation networks.

Starting from 26.1.1, Cisco Industrial Ethernet (IE) switches support only S2 controller redundancy as per the *PN-AL-Protocol_2722_V24MU5* and *PN-AL-Services_2712_V24Mu5* specifications.

Note After you upgrade the software, download and install the updated Generic Station Description Markup Language (GSDML) configuration files to enable S2 redundancy.

Prerequisites to PROFINET system Reduncandy modes opration

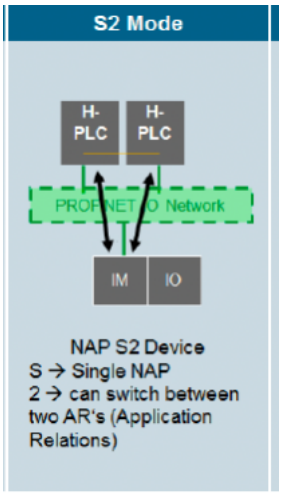
- Enable S2 mode so that each PROFINET device forms two communication relationships (Application Relationships (ARs)) with two controllers.
- Ensure both the IO device and the controllers support S2 redundancy features.
- Ensure that the device is connected to both controllers through a single PROFINET interface (NAP).
- Maintain only one active controller connection at a time.

Restrictions for PROFINET system redundancy

- Only S2 PROFINET redudandcy is supported. R1 and R2 PROFINET redudandcy modes are not supported.

How PROFINET system redundancy modes work

Summary



PROFINET system redundancy modes ensure continuous communication between IO controllers and IO devices. This increases system availability by enabling failover paths if a controller or network component fails.

Table 237: key components of PROFINET system redundancy workflflow

Component	Function
PLC (Programmable Logic Controller)	Acts as the IO controller, managing the communication and control logic for the automation system.
IO device (IOD)	The field device (such as ET 200SP, Cisco IE switches) that connects to the controller and exchanges process data.
Network Access Point (NAP)	The PROFINET interface on the IO device, which may be single or provide redundancy.
Application Relationship (AR)	The logical connection for data exchange between a controller and an IO device.

Workflow

Figure 197: PROFINET system redundancy in S2 mode

The process involves these stages:

1. The IO device supports two ARs, each with a separate PLC, but has only a single NAP.
2. Only one AR is active for IO data exchange and the other AR is in standby.
3. If the primary connection fails, the IO device quickly switches to the backup AR, minimizing downtime.

Result

PROFINET system redundancy modes provide graded levels of redundancy to maintain process continuity in industrial networks. These modes range from no failover (S1 redundancy mode) to controller failover (S2 redundancy mode).

Feature history for PROFINET System Redundancy

Table 238: Feature history

Feature Name	Releases	Description
PROFINET system redundancy	Cisco IOS XE 26.1.1	This feature enables Cisco Industrial Ethernet (IE) switches to interoperate with existing high available systems by providing robust controller failover using PROFINET S2 controller redundancy mode. It aims to minimize potential issues and downtime in the event of network or controller failures.

Read-only PROFINET

The read-only PROFINET feature is a configuration mode that prevents modifications to critical network parameters, including IP address, subnet mask, gateway, device name, and factory reset settings. While write operations are restricted, the feature still allows read and identification functions. Additionally, it preserves existing configurations for LLDP, SNMP, and CDP, ensuring these services remain fully operational.

Configure read-only PROFINET

Enable read-only PROFINET.

Procedure

Step 1 Use the **configure terminal** command to enter configuration mode.

Example:

```
Switch# configure terminal
```

Step 2 Use the **profinet read-only** command to enable PROFINET as read-only.

Example:

```
Switch(config)# profinet read-only
```

Use the **no profinet read-only** command to disable this feature.

Step 3 (Optional) Use the **Show profinet status** command to monitor PROFINET status.

Example:

```
Switch# show profinet status
Profinet                        : Enabled
Connection Status               : Disconnected
Vlan                            : 1
Profinet ID                     :
GSD version                     : Unknown
Reduct Ratio                    : 128
MRP                             : Enabled
MRP License Status              : Not Applicable
MRP Max Rings Allowed           : 3
Profinet read-only              : Enabled
```

Feature history for Read-only PROFINET

Table 239: Feature history

Feature Name	Releases	Description
Read-only PROFINET	Cisco IOS XE 26.1.1	This feature increases device security and network flexibility by placing Discovery and Configuration Protocol (DCP) operations in read-only mode. It: • Protects the IP address, gateway, and device name from changes. • Protects critical network settings and prevents unexpected loss of connectivity. • Maintains compatibility with LLDP, SNMP, and CDP. • Allows devices to perform identification and basic network discovery.

CHAPTER 185

Adding SFP Modules to Step 7TIA

•
• Supported Small Form-Factor Pluggables, on page 2797
• Adding SFPs to the Hardware Configuration in SS7/TIA, on page 2798

Supported Small Form-Factor Pluggables

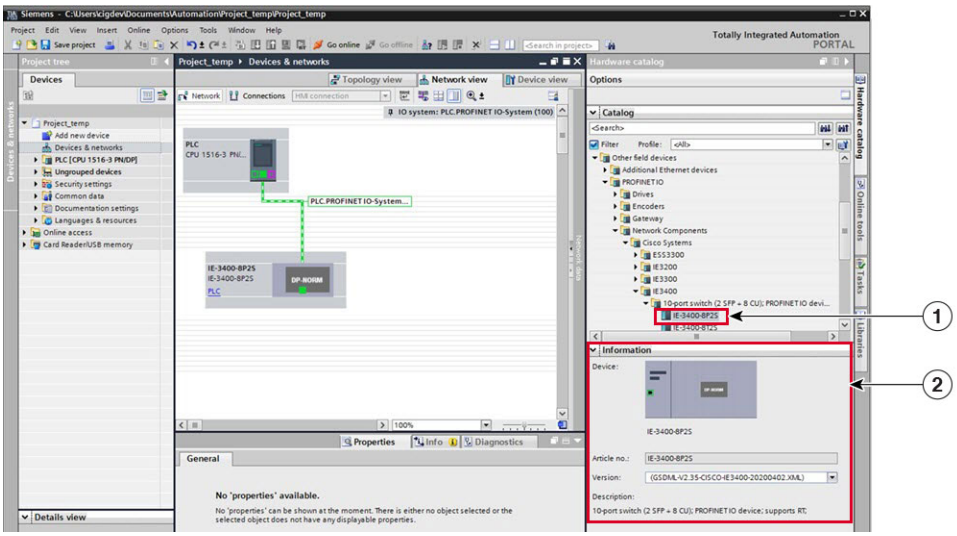
This document describes how to add Small Form-Factor Pluggable (SFP) modules to the SIMATIC STEP7 or TIA Portal automation applications to enable these applications to recognize the SFP modules in the PROFINET environment.

The following SFPs are supported for the switch and the fiber ports expansion module and can be added to the STEP 7 or TIA Portal Automation application installed on the supervisor:

- GLC-T
- GLC-TE
- GLC-T-RGD
- GLC-FE-100FX-RGD
- GLC-FE-100LX-RGD
- GLC-SX-MM-RGD
- GLC-LX-SM-RGD
- GLC-FE-100FX
- GLC-FE-100LX
- GLC-SX-MMD
- GLC-LH-SMD
- GLC-SX-MM
- GLC-LH-SM

Adding SFPs to the Hardware Configuration in SS7/TIA

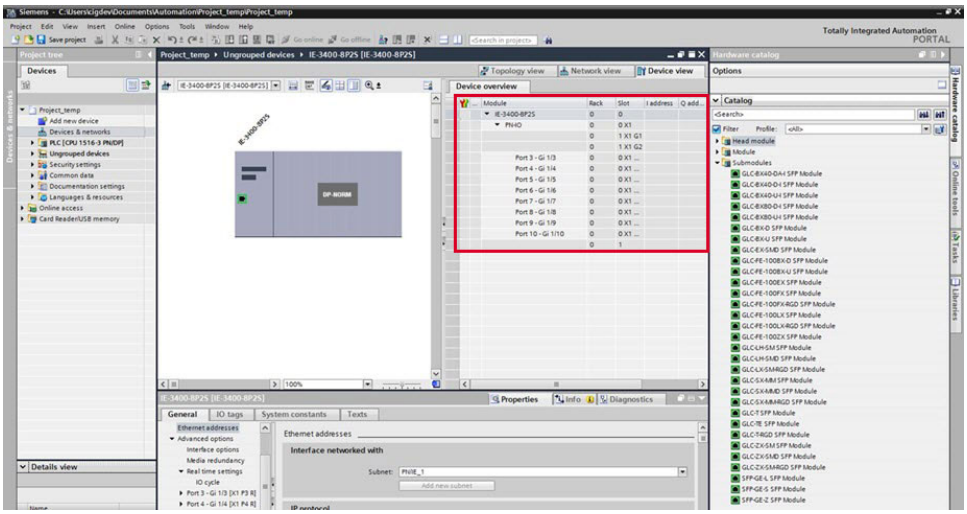
Follow this procedure to add SFPs to the hardware configuration in STEP7 or TIA.



Before you begin

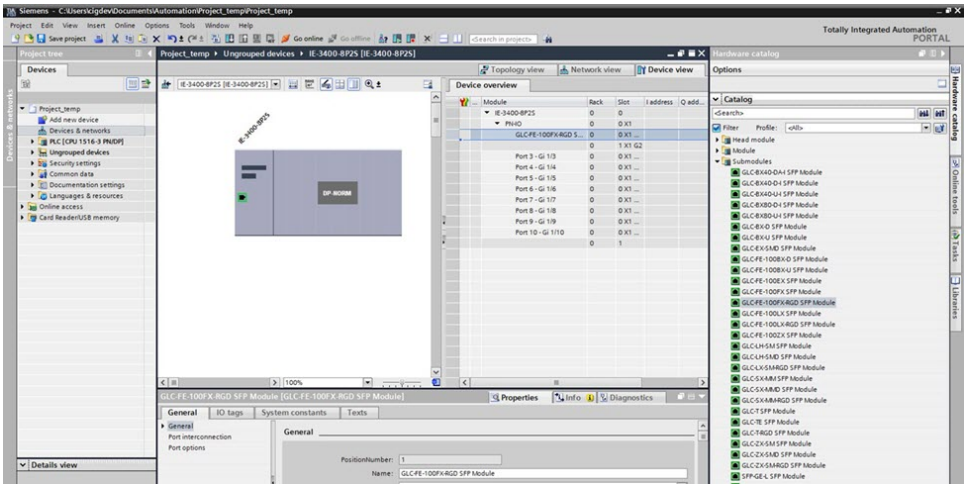
Install the latest GSD file for your IE switches in STEP7 or TIA (see Configuring the Switch with STEP7/TIA, on page 2779 for more information). The GSD file is not backward compatible. Combination ports do not have defaults and must be re-created in STEP7 or TIA with the new GSD file.

Procedure



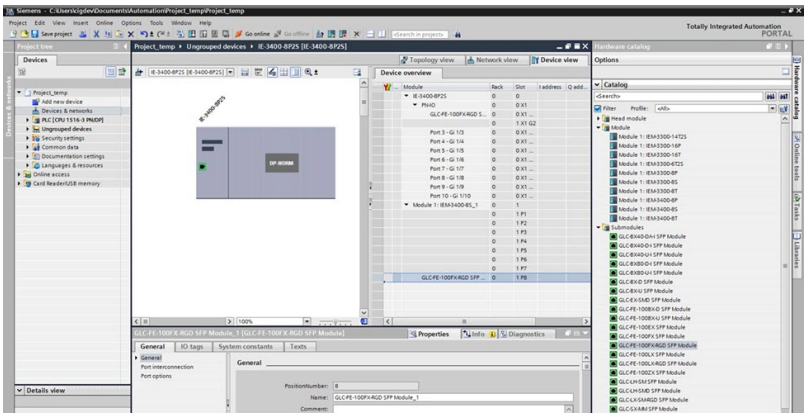
Step 1 In STEP7 or TIA, open the project containing the Cisco IE switch, and double-click **Devices & networks** in the **Project tree**.

Step 2 From the **Hardware catalog** in the devices and network editor, select the Device Access Point (DAP) name for your switch.



Step 3 Double-click the DAP name to go to **Device view** tab (see callout 1).

Step 4 Expand the PN-IO row (see callout 2) in Device overview section if the port list is not displayed.



Step 5 Select the modules that you have installed in the switch from the **Hardware catalog** and drag them to the appropriate rows in the table area of **Device view**: Appropriate SFP module for port type (combo port or fiber-only port)

The following figure shows the **Device view** and **Hardware catalog** with SFP modules. There is an uplink module for Gi SFP. The device in TIA is now ready to compile and download.

The following figure shows the **Device view** and **Hardware catalog** with SFP modules for IE3400 with the Fiber expansion module that has downlink SFP port Gi2/1-8, and where SFP GLC-FE-100FX-RGD is dragged to uplink port Gi2/8. The device in TIA is now ready to compile and download.

PART XIII

EVPN Multihoming: All-Active Mode

- All-Active Mode, on page 2803
- Overlay: Routed, on page 2815
- Overlay: Distributed Anycast Bridged, on page 2839
- Overlay:Distributed Anycast Gateway Routed, on page 2873

CHAPTER 186

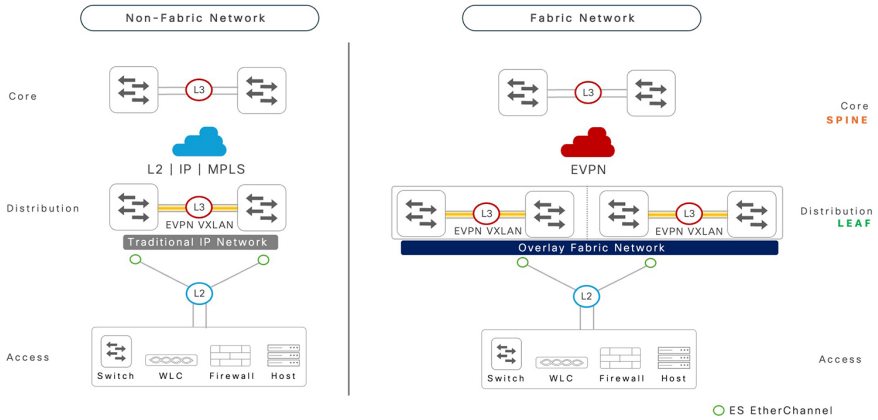
All-Active Mode

The Ethernet VPN (EVPN) multihoming is RFC 7432, RFC 8365 based industry-standard Layer 2 multipath solution solving various traditional networking protocol challenges impacting scale, performance and resiliency. It is an advanced networking technology designed to provide high availability, Border Gateway Protocol (BGP) based Layer 2 loop-free network, and efficient load balancing in modern enterprise campus networks.

A pair of switches can connect to downstream Layer 2 or Layer 3 network device with local physical connection binding into single logical EtherChannel configured in Layer 2 trunk or access mode. With industry-standard non-blocking architecture, any downstream networking devices such as, Ethernet Switch, Wireless LAN Controller (WLC), firewalls, servers and hosts can be dual-homed.

Note All-active mode is enabled by default. To configure single-active mode, see Configuring Multihoming in a BGP EVPN VXLAN Fabric.

- EVPN multihoming key benefits, on page 2803
- Restrictions for EVPN multihoming in all-active mode, on page 2804
- EVPN multihoming technology overview, on page 2805
- EVPN multihoming for non-fabric networks, on page 2808
- EVPN multihoming in fabric networks, on page 2809



EVPN multihoming key benefits

EVPN multihoming technology was introduced on switches in Cisco IOS XE 26.2.1, delivering a highly flexible and extensible deployment solution for global enterprise customers.

The key technology architecture benefits provided by switches, combined with the advanced Cisco IOS XE software capabilities, enable the best of both worlds. Enterprise network administrators can implement EVPN multihoming within their existing traditional Layer 2 or Layer 3 network designs while laying a practical and gradual foundation for evolving towards modern, secure, fabric-based virtual networks.

The following illustration shows the EVPN multihoming solution for switches in two key flexible deployment models.

Figure 198: EVPN multihoming enterprise campus deployment model

With flexible deployment model support, EVPN multihoming provides significant technological benefits to support enterprise-grade networking requirements.

- **Industry-standard Layer 2 multipath**: RFC 7432 and RFC 8365-defined Layer 2 multipath technology with BGP control-plane eliminates the vendor proprietary complex solutions.
- **Flexible architecture**: Purpose-built solution supports a wide range of networking use-cases for traditional Layer 2 and Layer 3, to modernized secure campus fabrics enabling network-wide, two-tier virtual network segmentation and extensions.
- **Distributed planes**: A fully distributed architecture where each system maintains its own scalable and resilient control plane, independent management plane configuration, and software versions provide more resilience with synchronized data-plane between paired systems.
- **Increased performance**: Non-blocking Spanning Tree Protocol (STP), Layer 2 loop-free network combined with advanced load-sharing technique assist in increasing forwarding capacity and improving application experience.
- **Seamless integration**: Least disruptive integration in classic Layer 2 networks with a wide range of networking device types that support link-bundling capabilities. Flexible and seamless integration with existing core network system without a forklift architecture change.
- **Resilient**: Deterministic fault detection and recovery technique during various types of planned and unplanned failure conditions, which reduces the Mean Time to Repair (MTTR) and increases the network reliability with a higher Mean Time Between Failure (MTBF).

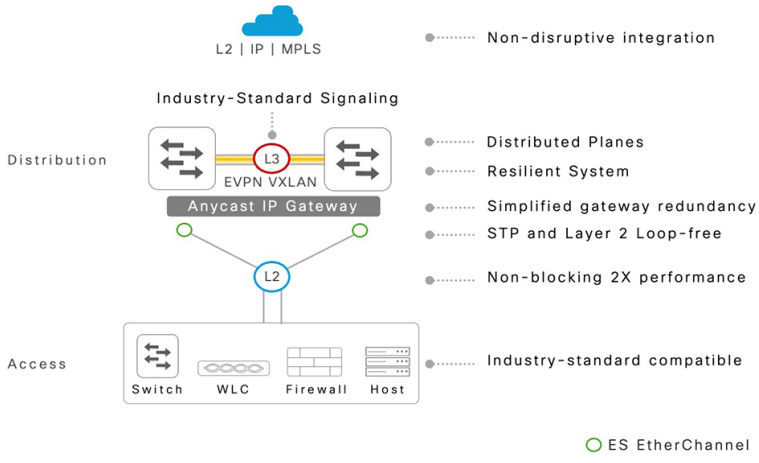
Restrictions for EVPN multihoming in all-active mode

This section lists the deployment restrictions for multihoming in all-active mode.

- EVPN multihoming for non-fabric and fabric networks with IPv6-only underlay network is not supported.
- EVPN multihoming in all-active mode is not supported on stacked switches.
- EVPN multihoming is not supported with Layer 2 leaf mode in centralized gateway mode fabric deployments.

- Anycast gateway (global or VRF-enabled) SVI with First Hop Redundancy Protocol (FHRP) protocol is not supported.
- Resilient Ethernet Protocol (REP) on Layer 2 Ethernet segment ports is not supported.
- Private VLAN (PVLAN) on Layer 2 Ethernet segment ports is not supported.
- DHCP snooping and ARP inspection on VLAN IDs mapped on logical Ethernet Segment EtherChannel trunk port is not supported.

EVPN multihoming technology overview



The legacy networking protocols in enterprise campus networks have been a challenge for IT organizations.

The challenges include difficulty in eliminating Spanning Tree Protocol (STP) that can lead to inefficient network topologies, restrictions in traditional Layer 2 designs that limit the network switching capacity, lack of deterministic reliability that makes it a challenge to support real-time mission-critical applications, insufficient support for mobility in wireless and legacy application environments, and increased complexity in network management and troubleshooting.

This section provides a brief overview of the advanced industry-standard EVPN multihoming technology for traditional Layer 2 and Layer 3 networks. Each subsection focuses on various technology components enabling loop-free, high-performance and resilient Layer 2 networking solutions.

The following illustration captures the key benefits of EVPN multihoming technology for simplified and resilient enterprise campus networks.

Figure 199: EVPN multihoming technology benefits

Refer to the *Terms and definitions* section for the description and purpose of acronyms.

Network system components

The EVPN multihoming technology comprises directly attached networking systems through traditional Layer 2 ports in trunk or access mode. The switches are required to be provisioned in EVPN multihoming mode to provide a loop-free Layer 2 multipath EtherChannel to any type of downstream network device.

Ethernet segment redundancy group

An Ethernet segment redundancy group is a physical grouping of network devices that form an EVPN multihoming network, enabling an all-active Layer 2 multipath solution.

The EVPN multihoming redundancy group consists of a single pair of switches, which provide physical connectivity and system-level redundancy. This architecture ensures continuous communication during both planned and unplanned failure events.

Ethernet segment switch

An Ethernet segment switch is a typical switch in core or distribution system configured to support the Layer 2 multihomed network with directly attached various types of Layer 2 systems.

The Ethernet Segment (ES) system can support multifunctional Layer 2 and Layer 3 networks for enterprise campus networks in classic and traditional non-fabric or modern fabric network roles. As a result, the ES switch is also known as a Provider Edge (PE) or Leaf or VTEP. Each ES switch operates and maintains fully distributed control, management, and data planes while solving legacy protocol challenges with industry-standard Layer 2 multipath solutions.

Ethernet segment switch platform and software

The EVPN multihoming technology operation between ES network devices—fixed or modular models, is no different from any of the other industry-standard networking protocols, like OSPF and BGP. A pair of ES switches can have different platform types, modules, interfaces, and so on. The ES pair switches can also have different Cisco IOS XE software versions to address stage upgrades and other conditions.

While the technology permits asymmetric platform and software versions on an ES pair, Cisco recommends a common platform and software version to deliver consistent performance and resiliency for non-disruptive business continuity during planned and unplanned failure conditions.

Ethernet segment client

The Layer 2 system is a directly attached single, dual, or multihomed connection to a pair of switches in an ES system. The Layer 2 ES client network can be of any device type but must follow the industry-standard Layer 2 networking technologies.

EVPN multihoming control plane

The EVPN multihoming technology is built on industry-standard, highly flexible, and proven BGP routing protocol. The BGP control plane replaces legacy STP for Layer 2 loop detection and prevention techniques.

The L2VPN EVPN address-family is a multiprotocol extension that enables a network-agnostic multihoming solution. The BGP protocol provides four key functions: discover remote neighbor and ES ID, real-time synchronization of network states, distributed forwarding rule to select local-bias rules for optimal performance, and resiliency for deterministic and efficient rapid fault-detection and recovery.

Ethernet segment

Ethernet segment (ES) is a pair of switches in the aggregation layer with a Layer 2 physical port that directly connects to an ES client device. It represents a single logical entity to enable loop-free, non-blocking all-active Layer 2 network connectivity.

An STP-Bridge Protocol Data Unit (BPDU) free Layer 2 network dynamically supports per-VLAN loop prevention while maximizing the network throughput to support accelerated application performance and resiliency.

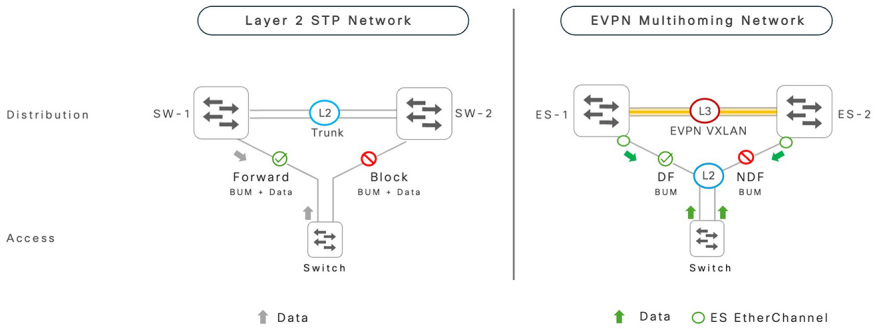
Ethernet segment ID

An Ethernet segment ID is a 10-byte (00:01:01:01:01:01:01:01:01:01) identifier for each Layer 2 port that is connected to an ES client device. A common ES ID is assigned to a pair of ES systems on the Layer 2 physical port that connects to the same Layer 2 ES client device to enable all-active EVPN multihoming.

switches support 3 types of industry-standard ESI ID that is either auto-generated or IT-defined and manually configured.

Anycast gateway MAC and IP addresses

An SVI interface on a switch with anycast gateway is provisioned with a shared virtual IP address and an auto-derived shared virtual MAC address with **anycast-gateway mac auto** command in the global settings, on pair of EVPN multihoming switches. The unified, resolved ARP and ND addresses between the distributed IP gateway switches support optimal data load-balancing across all available bundled links and resilient networks during planned or unplanned failures for wired and wireless endpoints.



Designated forwarder and non-designated forwarder roles

Traditionally, in Layer 2 STP-enabled networks, loop detection is achieved through a blocking link to transmit broadcast and business application data traffic. As a result, the network operates inefficiently at reduced bandwidth capacity. Additionally, protocol-based fault detection and recovery increase the network convergence time, which impacts the reliability of mission-critical applications during faults.

In EVPN multihoming-based campus networks, the same result is obtained using a very different logic. Instead of blocking links, the EVPN distinctly decouples network traffic types between broadcast categories and business applications. On a per ES port and VLAN basis, the pair of switches dynamically assign specific roles to forward BUM (Broadcast, Unknown Unicast, and Multicast) traffic in active and passive modes. However, business application forwarding traffic is unblocked in active-active mode.

The switch elected to actively forward the BUM traffic on a shared ES EtherChannel interface is known as designated forwarder (DF). The switch elected to block the forwarding of the BUM traffic on a shared ES EtherChannel interface is known as non-designated forwarder (non-DF). The dynamic DF and non-DF role assignment is automatically derived based on the internal system modulo hash algorithm, which enables auto load balancing of the BUM traffic between a pair of switches connected to same downstream Layer 2 network access devices.

Figure 200: Designated forwarder and non-designated forwarder roles

Dynamic MAC and IP learning and synchronization

EVPN multihoming networks build and maintain the Layer 2 and Layer 3 network information using the control plane, between a pair of ES switches.

The upstream data towards the IP core network is hashed from Layer 2 network devices, the dynamic MAC, IPv4, and IPv6 host addresses synchronized using the BGP control plane in real time between both the ES switches.

The common MAC or IP forwarding tables enable high performance and fully-distributed local forwarding while pre-programming the inter-ES Layer 2 VXLAN tunnel to bridge the downstream Layer 2 network traffic as the last-resort interface to reroute the data plane rapidly, upon local path failure, without relying on data-plane flooding.

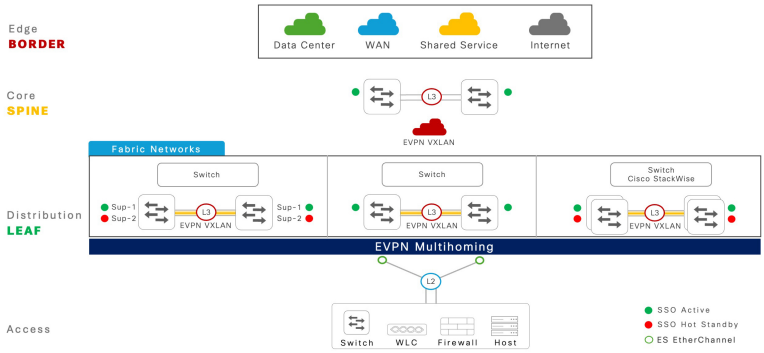
IGMP join and leave synchronization

The incoming Internet Group Management Protocol (IGMP) messages from multicast host receivers are locally processed by the connected ES switches. The IPv4 or IPv6 multicast group-to-IP membership information is synchronized between the ES switches by using an extended BGP control plane that supports consistent multicast state across the multihomed Ethernet segments.

The ES switch with a VLAN in the DF role transmits egress multicast traffic towards the receiver. The peer non-DF ES switch suppresses duplicate multicast frames to prevent loops and undesired multicast replication. This enables EVPN multihoming to support symmetric unicast or multicast application performance and resiliency during planned or unplanned failure events.

EVPN multihoming for non-fabric networks

EVPN multihoming in switches provides a flexible deployment solution for global enterprise customers to retain their traditional Layer 2 or Layer 3 networks in upstream core networks. Such network deployment option is also known as non-fabric network.



EVPN multihoming in fabric networks

Modern enterprise campuses require a secure fabric networking solution that seamlessly supports large-scale virtual and logical networks over a robust physical network infrastructure. EVPN multihoming-based networks offer a simplified and resilient architecture evolving from legacy STP protocol-based enterprise campus networks to a non-blocking Layer 2 fabric.

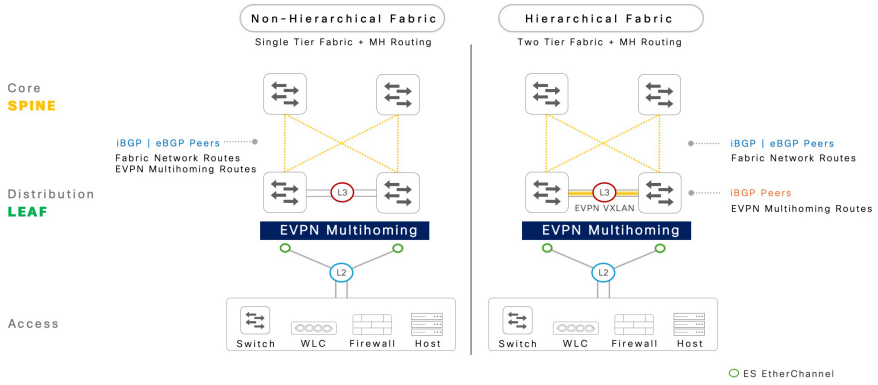
The EVPN VXLAN-enabled fabric core networks introduce new possibilities for EVPN multihomed Layer 2 networks by enabling secured wired and wireless segmented and extended networks that address critical technical and business requirements.

The following illustration displays EVPN multihoming in fabric networks

Figure 201: EVPN multihoming in fabric networks

Single unified BGP control plane

Enterprise campuses can be designed and deployed using a single unified BGP control plane that addresses the traditional Layer 2 and Layer 3 networking requirements at the access layer while supporting a modern fabric network at the core. The unified BGP control plane simplifies network operations by distinctly managing multi-domain routing and bridging functions, enabling seamless integration of the access and core networks.



BGP EVPN multihoming-based networks represents a shift from the traditional flood-based networks to control-plane driven architecture that supports non-blocking and resilient enterprise campus networks. Host addresses—including the MAC, IPv4 or IPv6, multicast—are statefully discovered and synchronized across peer systems, enabling all-active data forwarding in BGP EVPN multihoming networks.

As the BGP control plane role expands into traditional networks, processing demands may increase due to additional BGP prefix tables supporting EVPN multihoming auto-generated prefixes.

switches support both standard non-hierarchical and hierarchical BGP peering mode between leaf and spine devices, facilitating the exchange of fabric and EVPN multihoming network prefixes.

To address scalability and performance requirements, switches can implement a two-tier hierarchical control-plane network in large deployments.

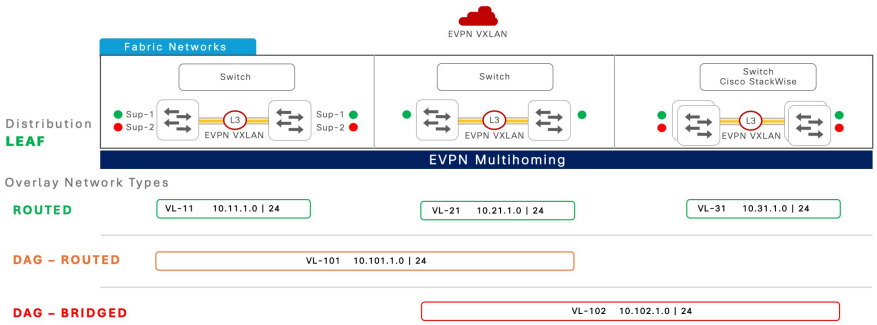
Figure 202: BGP peering alternatives for fabric networks

Non-hierarchical fabric networks

The general non-hierarchical BGP EVPN VXLAN network implementation follows a standard single tier BGP peering model where all fabric devices peer directly with each other to dynamically exchange routes and build the VXLAN forwarding tunnels.

The EVPN multihoming-enabled non-hierarchical fabric network implementation follows a standard iBGP or eBGP peering model between the spine and EVPN multihoming-enabled leaf or border system.

In large scale enterprise campus network environments, spine layer devices require additional resources such as processing power and memory to handle standard fabric host information, such as MAC addresses, MAC/IP bindings and network prefixes (IPv4/IPv6) along with EVPN multihoming auto-generated routes received from each leaf or border system.



EVPN fabric overlay network types overview

BGP EVPN VXLAN provides a flexible, virtual networking solution that addresses key networking use cases by combining a wide range of overlay architectures.

Such business-driven network architectures enable multidimensional benefits for scalable and secure segmented overlay networks in EVPN multihoming networks. Network administrators can build overlay networks with a “route first” mindset that can conditionally extend IP or VLAN networks between targeted Ethernet segment network devices to meet application requirements.

The following figure illustrates three overlay network types in EVPN multihoming networks.

Figure 203: BGP EVPN fabric overlay network types

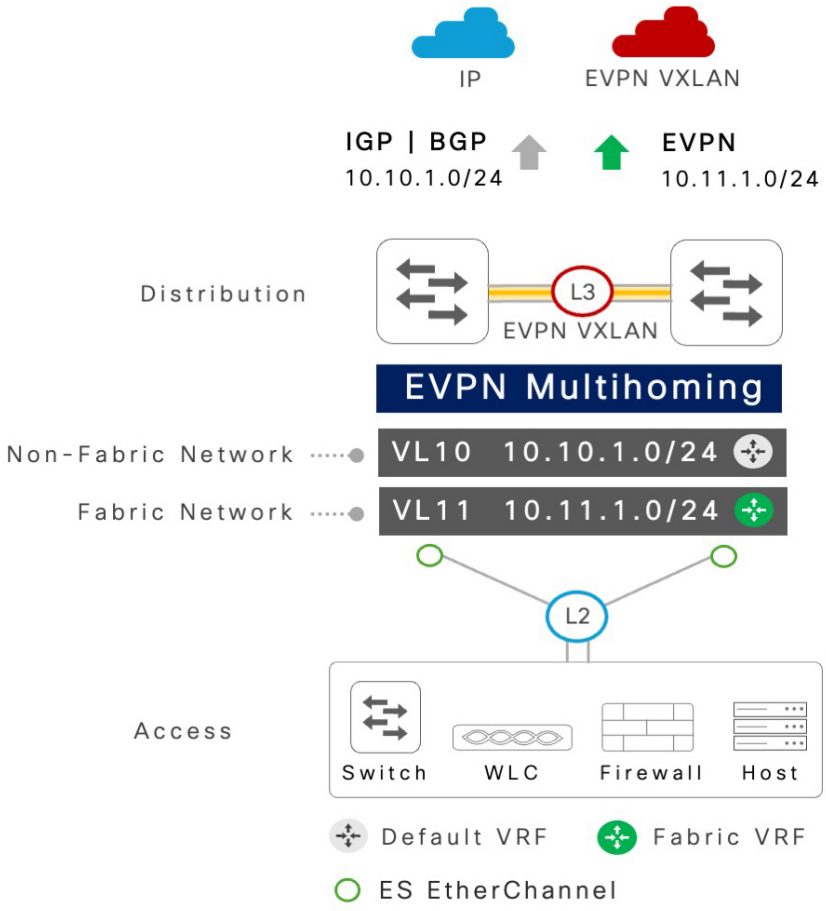
Network administrators decide on the type of overlay networks to deploy across the fabric core based on the specific application requirements to achieve better scale and resiliency in EVPN multihoming networks.

switches provide a flexible solution that supports coexistence of all overlay network types within a single system. Based on technical requirements, each VLAN from an Ethernet segment EtherChannel on switches can be configured to support IP-routed network segmentation, conditionally stretch IP subnets, or bridge VLANs using Layer 2 flood mechanisms selectively between VLANs.

Table 240: Comparison of EVPN overlay network types

	EVPN overlay network types		
	Routed	**DAG routed**	**DAG bridged**
Function	IP routing in core and Layer 3 segmented overlay.	Flood-free IP subnet stretch and Layer 3 segmented overlay.	Layer 2 flood stretch and Layer 3 segmented overlay.
Use case	Wired or wireless data. IT or OT endpoints	Wired or wireless data. IT or OT endpoints	Wired or wireless data. IT or OT endpoints. Non-IP endpoints
VLAN/subnet	One VLAN or subnet per distribution block	Stretched IP subnets between targeted distribution blocks	Stretched VLANs or subnets between targeted distribution blocks
Layer 2 flood boundary	Within the local Layer 2 network	Within the local Layer 2 network	Within the local Layer 2 network and across the fabric core
IP gateway	Anycast gateway per distribution block	Anycast gateway between targeted distribution blocks	Anycast gateway between targeted distribution blocks
IP subnet stretch	Not applicable	Yes—flood-free	Yes—flood-based
Seamless distributed wireless mobility	Within the local distribution block	Within the local distribution block and across targeted destination blocks	Within the local distribution block and across targeted destination blocks

	EVPN overlay network types		
	Routed	**DAG routed**	**DAG bridged**
Non-IP/silent host support	Within the local distribution block	Within the local distribution block	Within the local distribution block and across targeted destination blocks
Recommendation	Best scalable solution	Extends IP subnet selectively; use only if required	Extends Layer 2 flood selectively; use only if required



EVPN fabric and non-fabric network co-existence

Enterprise campuses require flexible networking solutions that support both modern secure fabric networks and backward-compatible traditional Layer 2 or Layer 3 networks. switches with EVPN multihoming-enabled EtherChannel trunk interfaces provide this flexibility by bundling multiple VLANs, each delivering distinct networking services.

Network administrators can program some VLANs to operate traditional IP-based networks in the underlay, while mapping other VLANs to IP VRFs or MAC VRFs to route and bridge over the VXLAN fabric.

The following illustration shows a network deployment scenario with both fabric and non-fabric VLANs on EVPN multihoming-enabled networks.

Figure 204: EVPN multihoming: fabric and non-fabric network co-existence

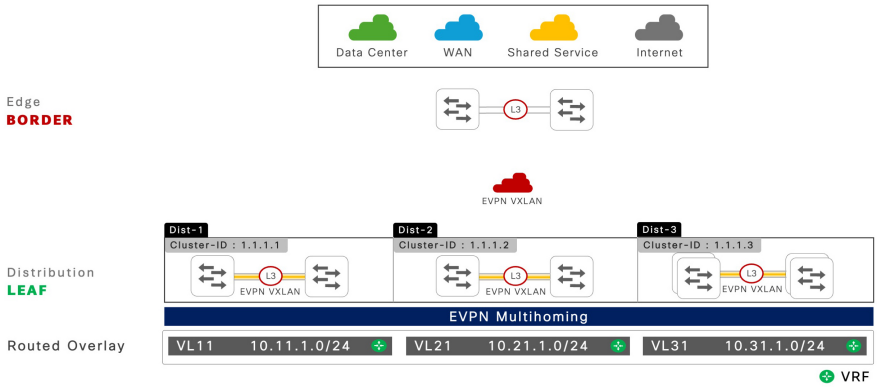
CHAPTER 187

Overlay: Routed

Routed overlays enable the separation of underlay and overlay routing, allowing for flexible and scalable network designs.

- Routed overlay network overview, on page 2815
- Understanding routed overlay networks, on page 2816
- Configure routed overlay networks, on page 2817
- Verify the routed overlay network configuration, on page 2825
- Reference routed overlay network configuration, on page 2827

Routed overlay network overview



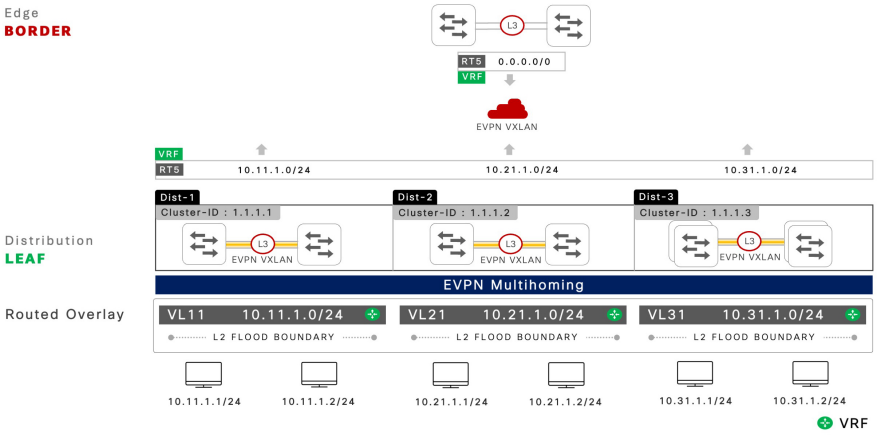
In multilayer campus networks, the traditional IP addressing plan follows a VLAN-to-subnet approach on a per distribution block basis.

The networking requirements and use cases for business applications typically remain within a single Layer 2 or Layer 3 network. The unique IPv4 or IPv6 subnet from each distribution network can be IP-routed in the default routing space using traditional Interior Gateway Protocols (IGPs) or BGP protocols in the underlay network, or the subnet can be logically segmented and routed in the overlay VXLAN fabric network.

The BGP EVPN VXLAN fabric routed overlay is highly relevant when deploying switches in the leaf role at the campus distribution layer. The unified and structured IP addressing plan between the underlay and overlay networks provides a congruent design, deployment, and operational experience across the enterprise network.

The following figure shows a reference EVPN multihoming network with a routed overlay deployment scenario.

Figure 205: EVPN multihoming with routed overlay fabric network



Understanding routed overlay networks

The fundamentals of Layer 2 and Layer 3 networking with routed overlay in BGP EVPN VXLAN-based fabric networks remain unchanged from the traditional campus network deployment models. This section provides the key functional and operational components for building scalable BGP EVPN VXLAN fabric networks with EVPN multihoming.

The following figure shows the characteristics of an EVPN multihoming network with routed overlay fabric.

Figure 206: Key fabric network characteristics of a routed overlay network

Hierarchical BGP control plane

In large-scale campus networks, the recommended deployment approach for controlled route management between EVPN multihoming peers and spines is a two-tier hierarchical BGP control plane. This design enables each BGP peering layer to manage domain-specific EVPN routes to support downstream non-blocking and all-active Layer 2 multipath network, and manage the advertisement of fabric network prefixes to enable secure global network access connectivity.

EVPN multihoming

The Layer 2 network with EVPN multihoming operation functions independently from the EVPN fabric core network. The pair of switches at each distribution layer form and manage EVPN multihoming within their respective redundancy group. These switches use a unified Layer 2 Ethernet Segment (ES) EtherChannel connection to downstream network devices. The EtherChannel connection can carry VLANs that are either mapped to routed overlay and advertised within the fabric core or continue to operate within the traditional underlay IP network.

Layer 2 broadcast network boundary

The EVPN fabric routed overlay networks provide a unified Layer 2 or Layer 3 network boundary similar to the traditional underlay campus networks. The Layer 2 bridge-domain and blast radius are contained between the Layer 2 access layer and directly attached EVPN multihoming-enabled distribution layer systems.

The pair of switches in the distribution layer network dynamically builds a Layer 2 VXLAN tunnel using ingress replication mode to extend Broadcast, Unknown Unicast and Multicast (BUM) traffic. With inbuilt loop detection and fast convergence techniques, the EVPN multihoming-enabled networks support secure and scalable Layer 2 networks over traditional STP-based networks.

Structured IP subnet and gateway redundancy

The Distributed Anycast Gateway (DAG) routed overlay networks follow the standard enterprise campus design principles with a VLAN or subnet per distribution block. Network administrators can define a structured IPv4 or IPv6 addressing plan to build scalable overlay networks.

A pair of switches operating in EVPN multihoming mode provides IP gateway redundancy by implementing a built-in gateway function for both IPv4 or IPv6 in each distribution block.

Spine-route policy

In large scale EVPN multihoming enabled fabric networks, controlled route management is enforced through route policies on leaf switches that are attached to spine switches. The iBGP or eBGP prefix advertisement to spine switches in the fabric core limits the advertising of IPv4 or IPv6 network prefixes, specifically EVPN route type 5 prefixes, while retaining unfiltered routing with iBGP peering sessions between leaf switches and remote ES switches. This design supports a non-blocking Layer 2 multipath EtherChannel that ensures scalability and efficient route distribution.

Note EVPN multihoming-enabled networks support additional overlay network types to stretch the IP subnets or Layer 2 flood-domains beyond a single distribution block by using the DAG technology. Routed overlay networks are recommended for better scale, performance, and resiliency.

Configure routed overlay networks

This section lists the tasks to configure a routed overlay network.

Prerequisites to configure routed overlay networks

A reliable underlay IP network and a Layer 2 EVPN multihoming network are prerequisites for configuring a BGP EVPN VXLAN-enabled fabric core network.

Configure IP VRFs

Perform this task to configure a logically segmented virtual network with an IP VRF to exchange IPv4 or IPv6 network prefixes across all the VTEPs in the fabric core network.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**vrf definition** *vrf-name* **Example:** `Device(config)# vrf definition green`	Configures a new Virtual Routing and Forwarding (VRF) instance and enters VRF configuration mode.
Step 4	**rd** *route distinguisher* **Example:** `Device(config-vrf)# rd 10.200.255.101:101`	Configures a route distinguisher with distinct values across all fabric devices.
Step 5	**address-family ipv4** [**multicast** | **unicast**] **Example:** `Device(config-vrf)# address-family ipv4 unicast`	Enters IPv4 unicast address-family configuration mode.
Step 6	**route-target** [**both** | **export** | **import**] *route-target-ext-community* **Example:** `Device(config-vrf-af)# route-target 65101:101`	Configures overlay IPv4 routing import or export policies that match extended community values. • The default **both** keyword will auto-generate the import and export command-line with the configured community value.
Step 7	**route-target** [**both** | **export** | **import**] *route-target-ext-community* **stitching** **Example:** `Device(config-vrf-af)# route-target 65101:101 stitching`	Configures overlay IPv4 routing import or export policies that match the extended community values to enable extended Network Layer Reachability Information (NLRI) types for BGP EVPN VXLAN enabled networks. The default value is **both**.

	Command or Action	Purpose
Step 8	**exit** **Example:** `Device(config-vrf-af)# exit`	Exits IPv4 unicast address-family configuration mode and returns to VRF configuration mode.
Step 9	**address-family ipv6** [**multicast** | **unicast**] **Example:** `Device(config-vrf)# address-family ipv6 unicast`	Enters IPv6 unicast address-family configuration mode.
Step 10	**route-target** [**both** | **export** | **import**] *route-target-ext-community* **Example:** `Device(config-vrf-af)# route-target 65101:101`	Configures overlay IPv6 routing import and export policies that match the extended community value. • The default **both** keyword will auto-generate the import and export command-line with the configured community value.
Step 11	**route-target** [**both** | **export** | **import**] *route-target-ext-community* **stitching** **Example:** `Device(config-vrf-af)# route-target 65101:101 stitching`	Configures the overlay IPv6 routing import and export policies that match the extended community values to enable extended NLRI types for BGP EVPN VXLAN enabled networks. The default value is **both**.
Step 12	**end** **Example:** `Device(config-vrf-af)# end`	Exits IPv6 unicast address-family configuration mode and returns to privileged EXEC mode.

Configure core VLAN and SVI interfaces

Perform this task to configure core VLAN and SVI interfaces for each IP VRF to enable VXLAN encapsulation and decapsulation functions between downstream non-VXLAN network and remote VXLAN-enabled VTEPs.

Note Configure a Network Virtualization Endpoint (NVE) interface and bind the L3VNI ID to a logical interface.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**vlan** *id* **Example:** `Device(config)# vlan 101`	Configures a dedicated VLAN ID for IP VRF core routing and enters VLAN configuration mode. • This VLAN must be pruned from Layer 2 trunk ports and cannot be used for any other purpose.
Step 4	**vlan configuration** *id* **Example:** `Device(config-vlan)# vlan configuration 101`	Configures a core VLAN to assign the Layer 3 VXLAN network (VNI) ID.
Step 5	**member vni** *l3vni-id* **Example:** `Device(config-vlan)# member vni 11101`	Configures a unique Layer 3 VNI ID for an IP VRF. • For example, VRF Green will have VLAN 101 as the dedicated VLAN and Layer 3 VNI, and this VNI ID must not be shared with other IP VRFs on the same system.
Step 6	**exit** **Example:** `Device(config-vlan)# exit`	Exits VLAN configuration mode and returns to global configuration mode.
Step 7	**interface vlan** *id* **Example:** `Device(config-vlan)# interface vlan 101`	Configures a core VLAN SVI interface and assigns it to an IP VRF and enters interface configuration mode. • The core VLAN SVI MAC address is used to support routed MAC address for Layer 3 overlay networks.
Step 8	**vrf forwarding** *vrf-name* **Example:** `Device(config-if)# vrf forwarding green`	Maps IP VRF to a core VLAN SVI interface.
Step 9	**ip unnumbered** *interface-type interface-number* **Example:** `Device(config-if)# ip unnumbered Loopback0`	Configures unnumbered IPv4 address from an underlay logical interface.

	Command or Action	Purpose
Step 10	**no autostate** **Example:** `Device(config-if)# no autostate`	Disables autostate on the interface. • In EVPN deployments, a VLAN used for a core-facing SVI should not be allowed in any trunk ports. For a core-facing SVI to function properly, the **no autostate** command must be configured under the SVI.
Step 11	**exit** **Example:** `Device(config-if)# exit`	Exits interface configuration mode and returns to global configuration mode.
Step 12	**interface nve** *id* **Example:** `Device(config)# interface nve 1`	Configures a virtual NVE interface to bind one or more L2VNIs and L3VNIs to enable the system-wide VXLAN forwarding function • Enters NVE interface configuration mode.
Step 13	**source-interface** *id* **Example:** `Device(config-if-nve)# source-interface Loopback0`	Configures the loopback interface as the source address to enable data communication over a VXLAN tunnel.
Step 14	**host-reachability protocol bgp** **Example:** `Device(config-if-nve)# host-reachability protocol bgp`	Configures BGP as the host reachability control plane protocol on the interface.
Step 15	**member vni** *l3vni-id* **vrf** *vrf-name* **Example:** `Device(config-if-nve)# member vni 11101 vrf green`	Binds the L3VNI and IP VRF under the NVE interface.
Step 16	**end** **Example:** `Device(config-if-nve)# end`	Exits NVE interface configuration mode and returns to privileged EXEC mode.

Configure access SVI interfaces

This section provides step-by-step instructions to configure two Ethernet Segment (ES) systems as a single logical IP gateway with the network edge SVI interface sharing a common IP address.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface vlan** *id* **Example:** `Device(config)# interface vlan 11`	Configures a Layer 3 access SVI interface ID and enters interface configuration mode.
Step 4	**ip address** *ip-address mask* **Example:** `Device(config-if)# ip address 10.11.1.254 255.255.255.0`	Assigns an IPv4 gateway address and mask for the selected VLAN. Anycast gateway is auto-enabled with a common IP address between the ES systems.
Step 5	**ipv6 address** *ipv6-address mask* **Example:** `Device(config-if)# ipv6 address 2001:10:11:1::f/64`	Assigns an IPv6 gateway address and prefix for the selected VLAN. Anycast gateway is auto-enabled with a common address between the ES systems.
Step 6	**end** **Example:** `Device(config-if)# end`	Exits interface configuration mode and returns to privileged EXEC mode.

Configure spine EVPN route policies

This section provides step-by-step instructions to configure two switches that act as a pair of ES systems with an outbound spine EVPN route policy. The route policy controls the advertisement of EVPN routes by the ES systems for a scalable routed overlay network, independent of iBGP or eBGP spine peering session type.

The route policy limits the advertisement of route type 5 (RT-5) prefixes to spine switches for network-wide route propagation. iBGP peering with EVPN multihoming system maintains unfiltered EVPN route exchange to build and maintain a non-blocking Layer 2 multipath network.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode • Enter your password if prompted.

	Command or Action	Purpose
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**route-map** *name* [**permit** | **deny**] *sequence-number* **Example:** `Device(config)# route-map SPINE-ROUTE-POLICY-OUT permit 10`	Creates a route-map rule with permit or deny match criteria for filtering or modifying routing information. The optional *sequence-number* argument indicates the order of route-map rule processing. • Enters route-map configuration mode.
Step 4	**description** *description* **Example:** `Device(config-route-map)# description ROUTED OVERLAY – VL11`	(Optional) Configures a description for the route-map sequence.
Step 5	**match evpn route-type** [**1-8** | **2-mac-ip** | **2-mac-only**] **Example:** `Device(config-route-map)# match evpn route-type 5`	Configures an EVPN route policy sequence to permit the advertisement of local IPv4 or IPv6 RT-5 network prefixes to any IP VRF.
Step 6	**exit** **Example:** `Device(config-route-map)# exit`	Exits route-map configuration mode and returns to global configuration mode.
Step 7	**router bgp** *autonomous-system-number* **Example:** `Device(config)# router bgp 65101`	Configures a BGP Autonomous System Number (ASN) using 2-bytes or 4-bytes in asplain and asdot formats and enters router configuration mode.
Step 8	**address-family l2vpn evpn** **Example:** `Device(config-router)# address-family l2vpn evpn`	Enters BGP L2VPN address-family configuration mode.
Step 9	**neighbor** *spine-loopback-address* **route-map** *name* **out** **Example:** `Device(config-router-af)# neighbor 10.200.255.3 route-map SPINE-ROUTE-POLICY-OUT out`	Applies the outbound route-map policy to each spine peer to limit advertising the RT-5 prefix.
Step 10	**end** **Example:** `Device(config-router-af)# end`	Exits BGP L2VPN address-family configuration mode and returns to privileged EXEC mode.

Configure IP VRF address family routing

Perform this task to advertise network prefixes in IPv4 and IPv6 address family in overlay networks.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**router bgp** *autonomous-system-number* **Example:** `Device(config)# router bgp 65101`	Configures a BGP ASN using 2-bytes or 4-bytes in asplain and asdot formats and enters router configuration mode.
Step 4	**address-family** [**ipv4** | **ipv6**] **vrf** *vrf-name* **Example:** `Device(config-router)# address-family ipv4 vrf green`	Enables IPv4 address-family for a VRF instance to enable IPv4 network prefix routing in overlay networks.
Step 5	**advertise l2vpn evpn** **Example:** `Device(config-router-af)# advertise l2vpn evpn`	Enables the advertising of the IPv4 network prefix routing between an IPv4 VRF instance and an EVPN fabric core network.
Step 6	**redistribute connected** [**metric** | **route-map** *name*] **Example:** `Device(config-router-af)# redistribute connected`	Configures an IPv4 address family to advertise all locally connected IPv4 network prefixes in the EVPN fabric network. • You can also advertise the network prefix using the **network** command.
Step 7	**exit** **Example:** `Device(config-router-af)# exit`	Exits IPv4 address-family configuration mode and returns to router configuration mode.
Step 8	**address-family** [**ipv4** | **ipv6**] **vrf** *vrf-name* **Example:** `Device(config-router)# address-family ipv6 vrf green`	Enables IPv6 address family for a VRF instance to enable IPv6 network prefix routing in overlay networks.

	Command or Action	Purpose
Step 9	**advertise l2vpn evpn** **Example:** `Device(config-router-af)# advertise l2vpn evpn`	Enables IPv6 network prefix routing between an IPv6 VRF instance and the EVPN fabric core network.
Step 10	**redistribute connected** [**metric** | **route-map**] *name* **Example:** `Device(config-router-af)# redistribute connected`	Configures an IPv6 address family to advertise all locally connected IPv6 network prefixes in the EVPN fabric network. • You also can use the **network** command to advertise the network prefix.
Step 11	**end** **Example:** `Device(config-router-af)# end`	Exits IPv6 address family configuration mode and returns to privileged EXEC mode.

Verify the routed overlay network configuration

This section lists the commands and the output of these commands to verify the routed overlay network configuration and the states of the VTEPs.

The command output may be truncated to focus on critical information useful for Day Two operations and troubleshooting.

IP VRF networks: Verifies the locally configured IP VRFs and the associated physical or logical interface bindings to a virtual network on VTEPs, including leaf and border devices.

The interface bindings displayed in this command output include the network edge VLANs connecting to endpoints, network devices along with a single core VLAN (VLAN 101) of an IP VRF.

```
ES-1# show vrf green

  Name          Default RD            Protocols Interfaces
  green         10.200.255.103:101     ipv4  Vl11
                                                 Vl101

BORDER-1# show vrf green

  Name           Default RD            Protocols Interfaces
  green          10.200.255.1:101 ipv4  Vl101
                                                  Vl1101
```

BGP L2VPN EVPN neighbors: Verifies that the two-tier hierarchical iBGP session between a pair of switches in EVPN multihoming mode and the iBGP peering to a pair of spine systems are operational.

The following output displays iBGP peering between a pair of spine switches, 10.100.255.3 and 10.100.255.4 and direct iBGP peering between ES-1 local 10.100.255.101 and ES-2 10.100.255.102 switches are operational and in EVPN multihoming mode.

```
ES-1# show bgp l2vpn evpn all summary
```

```
BGP router identifier 10.100.255.101, local AS number 65101
<snip>

Neighbor           V        AS      MsgRcvd MsgSent   TblVer  InQ     OutQ    Up/Down

    28
```

Spine policy: Verifies that a VTEP in leaf or border roles implemented in EVPN multihoming mode is configured with a route map and has an outbound policy applied to each spine, such as 10.200.255.3. The spine policy configuration on the border switch is optional and not required if the switch is not implemented in EVPN multihoming mode to connect to external network devices, such as firewalls.

```
ES-1# show bgp l2vpn evpn neighbor 10.200.255.3 policy

 Neighbor: 10.200.255.3, Address-Family: L2VPN E-VPN
 Locally configured policies:
  send-community extended
 Inherited polices:
  route-map EVPN-SPINE-ROUTE-POLICY-OUT out
```

L2VPN advertised routes: Verifies that a VTEP in leaf or border roles implemented in EVPN multihoming mode is advertising EVPN prefixes to the spine (10.200.255.3) based on the applied route-map policy.

The following output shows that the RT-5 EVPN prefix is advertised, and no additional EVPN route-types are advertised to the spine switches.

```
ES-1# show bgp l2vpn evpn neighbor 10.200.255.3 advertised-route

BGP table version is 7179, local router ID is 10.200.255.101

Reference routed overlay network configuration

This section provides a reference network design to implement an end-to-end routed overlay fabric network.

The following figure illustrates an EVPN multihoming network with hierarchical BGP peering that involves the spine and leaf architecture.

Figure 207: EVPN multihoming: Routed overlay fabric network design

Layer 2 EVPN multihoming

This step-by-step configuration shows how to build a non-blocking all-active Layer 2 network with EVPN multihoming technology on a pair of switches, starting from a Layer 2 campus network.

Step	ES-1	ES-2
1: Inter-ES Layer 3 EtherChannel	! interface Port-Channel 128 description CONNECTED TO EVPN MH SW-2 no switchport ip address 10.0.0.0 255.255.255.254 ip ospf network point-to-point ip ospf multi-area 0 ip ospf 100 area 101 ip ospf cost 10 carrier-delay msec 0 hold-queue 4094 in hold-queue 4094 out evpn multihoming core-tracking !	! interface Port-Channel 128 description CONNECTED TO EVPN MH SW-1 no switchport ip address 10.0.0.1 255.255.255.254 ip ospf network point-to-point ip ospf multi-area 0 ip ospf 100 area 101 ip ospf cost 10 carrier-delay msec 0 hold-queue 4094 in hold-queue 4094 out evpn multihoming core-tracking !

Step	ES-1	ES-2

Underlay: fabric core and BGP peering

Enterprise campus core networks with a solid underlay network foundation is essential to build highly scalable and resilient BGP EVPN VXLAN fabrics. This section is the second step to build a reliable underlay core network and establish hierarchical iBGP peering among targeted network devices with specific roles.

Note The table is divided into two fabric roles with each step either sharing a common configuration or a unique per-device configuration with a common role.

Step	ES-1 and ES-2	Spine-1 and Spine-2	Border-1 and Border-2
1: Global best practices	! system mtu 9100 ! port-channel load-balance vlan-src-dst-mixed-ip-port ip cef load-sharing algorithm include-ports source destination protocol ! ip tcp mss 8000 ip tcp window-size 262144 ip tcp path-mtu-discovery !	! system mtu 9100 ! port-channel load-balance vlan-src-dst-mixed-ip-port ip cef load-sharing algorithm include-ports source destination protocol ! ip tcp mss 8000 ip tcp window-size 262144 ip tcp path-mtu-discovery !	! system mtu 9100 ! port-channel load-balance vlan-src-dst-mixed-ip-port ip cef load-sharing algorithm include-ports source destination protocol ! ip tcp mss 8000 ip tcp window-size 262144 ip tcp path-mtu-discovery !
2: Underlay interface configuration and best practices	! interface range HundredGig1/0/49-50 description CONNECTED TO SPINE ip ospf 100 area 0 ip ospf network point-to-point carrier-delay msec 0 hold-queue 4094 in hold-queue 4094 out evpn multihoming core-tracking !	! interface range HundredGig1/0/1-4 description CONNECTED TO CAMPUS CORE NETWORK ip ospf 100 area 0 ip ospf network point-to-point carrier-delay msec 0 hold-queue 4094 in hold-queue 4094 out !	! interface range HundredGig1/0/49-50 description CONNECTED TO SPINE ip ospf 100 area 0 ip ospf network point-to-point carrier-delay msec 0 hold-queue 4094 in hold-queue 4094 out !

Step	ES-1 and ES-2	Spine-1 and Spine-2	Border-1 and Border-2

Overlay routed networks

The overlay network configuration is the final step to enable the fabric in an enterprise campus. This step-by-step procedure shows VTEPs configured in a routed overlay network that exchanges IP prefixes between external and internal network domains.

On switches, the routed overlay configuration is implemented within EVPN multihoming-based networks. The configuration example also shows the standard procedure to implement and manage the overlay network in other system configuration modes such as routed access, Cisco StackWise Virtual, and First Hop Redundancy Protocol (FHRP).

CHAPTER 188

Overlay: Distributed Anycast Bridged

The distributed anycast bridged overlay enables efficient Layer 2 connectivity across network segments by using anycast gateway addresses, allowing seamless host mobility and redundancy.

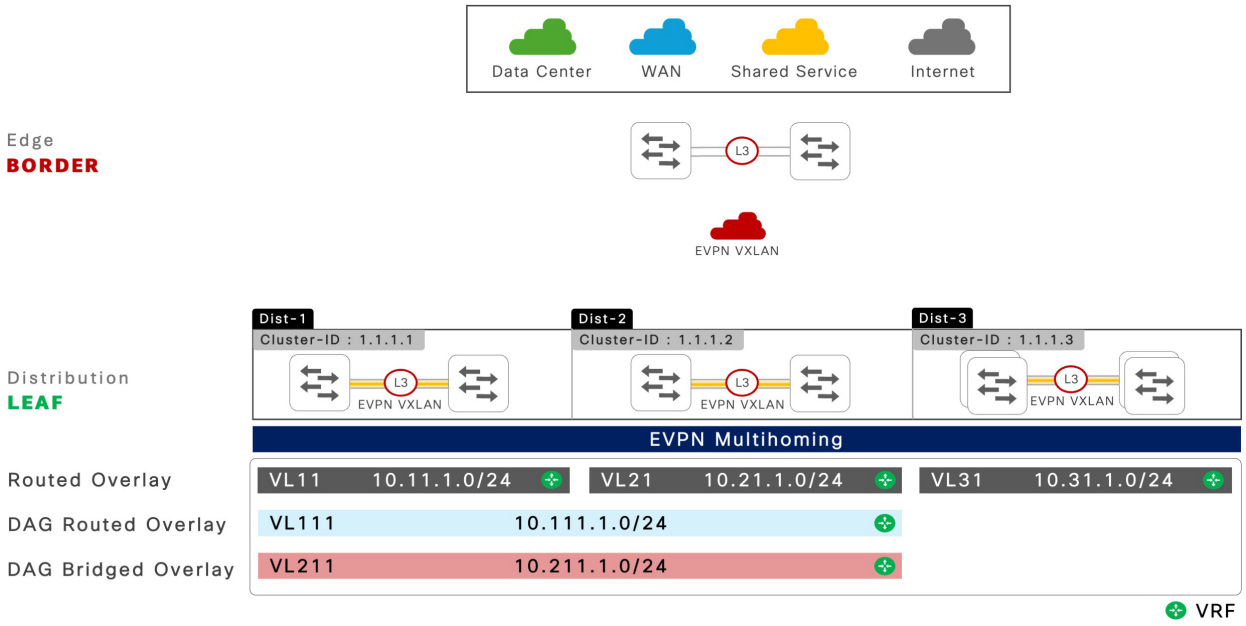
Overview: Distributed Anycast Gateway bridged overlay networks

In modern enterprise campus environments, most application traffic flows between wired and wireless users and between resources that are hosted within on-premises data centers or across cloud. Network administrators build structured IP addressing plans with VLAN and subnet on a per-distribution block and enable segmentation through routed overlay or selectively stretching flood-free IP subnets with Distributed Anycast Gateway Routed VXLAN fabric network.



With the digitally evolving IP-everywhere networks, in some scenarios network administrators are mandated to maintain modern fabric networks, while supporting scarce VLAN segments with legacy enterprise network applications and endpoints operating at link-layer without IP addresses. The Distributed Anycast Gateway (DAG) technology supports classic methods to extend the Layer 2 flood-boundary for selective VLANs over the dynamic Layer 2 VXLAN tunnels.

The DAG-bridged overlay networks stretch IP subnets and the Layer 2 VLAN flood-boundary with traditional Integrated Routing and Bridging (IRB) function between targeted switches implemented in EVPN multihoming fabric mode. The DAG-bridged overlay networks extend the Layer 2 flood boundary across fabric networks for all endpoints including hosts with and without IP addresses.

Switches support the coexistence of routed, DAG-routed and DAG-bridged overlay networks that provide the flexibility to scale fabric networks while enabling enterprise application requirements.

The following figure shows a reference EVPN multihoming network with DAG-bridged overlay for extending Layer 2 flood-boundary for a specific VLAN or IP subnet between pairs of switches.

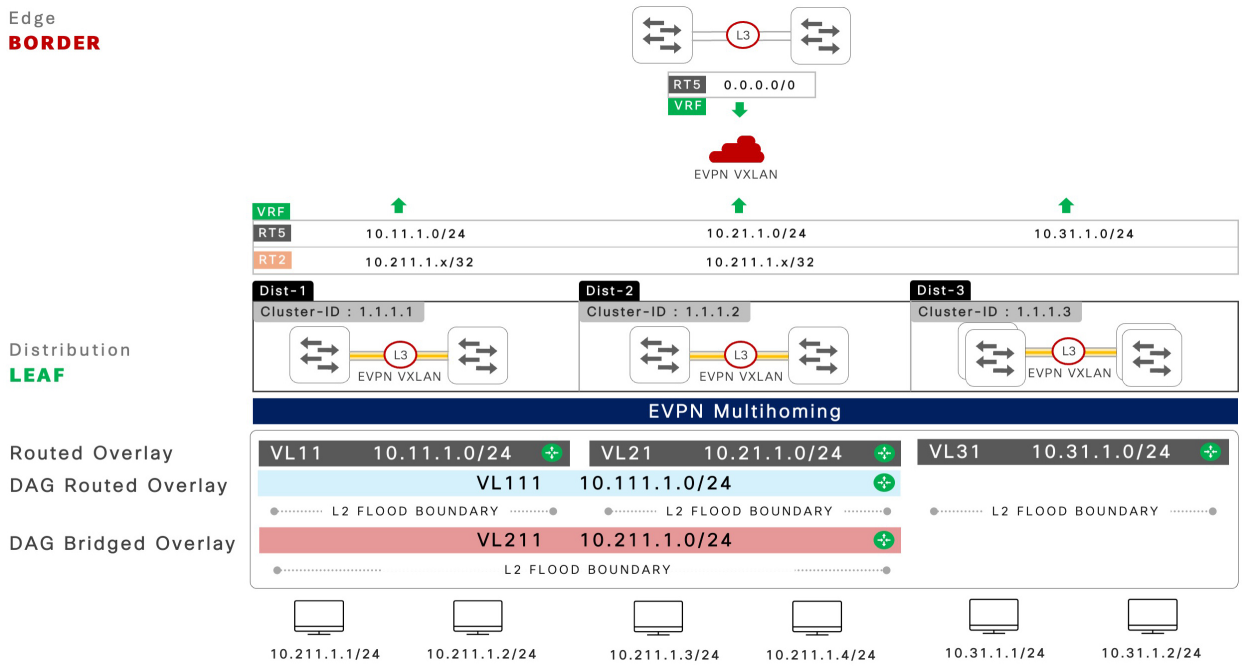
Figure 208: EVPN multihoming with DAG-bridged overlay fabric network

Guidelines for DAG bridged overlay networks

Follow these guidelines when planning for DAG bridged overlay networks.

- Extended bridge-domain boundaries build larger Layer 2 flood domains.
- The DAG bridge mode is suggested for the deployment of selective VLANs or subnets based on technical requirements, such as non-IP and silent hosts.

Refer to the downstream Layer 2 network access device product datasheet to determine the MAC address scale numbers.



Understanding DAG bridged overlay networks

Based on business requirements, enterprise networks have the flexibility to support unique per-VLAN basis overlay functions. Routed overlay is proven and recommended for the large-scale overlay networks, DAG-routed overlay provides flexible Layer 2 flood-free IP subnet stretch for selective networks, and the DAG bridge overlay addresses non-routable legacy endpoints and applications by extending the Layer 2 network across the fabric.

Switches support the coexistence of routed, Distributed Anycast Gateway-routed, and Distributed Anycast Gateway-bridged overlay networking options within the same macro-segmented IP VRF and the micro-segmented VXLAN GPO-enabled environment.

The following figure illustrates the characteristics of an EVPN multihoming network with DAG bridged overlay fabric.

Figure 209: Key characteristics of a DAG bridged fabric overlay network

Hierarchical BGP control plane

The recommended deployment consideration to support controlled route management between EVPN multihoming peers and spine switches in large-scale campus networks is the two-tier hierarchical BGP control plane. Each BGP peering layer manages domain-specific EVPN routes to enable downstream non-blocking and all-active Layer 2 multipath networks, and manages the advertising of fabric network prefixes to enable secure global network access connectivity in core networks.

EVPN multihoming

Layer 2 networks with EVPN multihoming functions independent of the fabric core EVPN fabric network. A pair of switches in each distribution layer builds and manages EVPN multihoming in each redundancy group.

The unified Layer 2 Ethernet Segment (ES) EtherChannel connection to downstream network device can carry VLANs that are mapped to routed, selective-stretched subnets with DAG-routed overlay and advertised in the fabric core or can continue to be traditional underlay IP networks.

Layer 2 broadcast network boundary

The DAG-bridged overlay networks provide unified Layer 2 or Layer 3 network boundary as the routed overlay and the traditional underlay campus network. The Layer 2 bridge domain and the blast radius remain contained between Layer 2 access and EVPN multihoming-enabled distribution layer systems.

A pair of switches in the distribution layer network dynamically builds the Layer 2 VXLAN tunnel using ingress replication mode to extend Broadcast, Unknown Unicast and Multicast (BUM) traffic. With built-in

loop-detection and prevention techniques, EVPN multihoming-enabled networks support a secure and scalable Layer 2 network over traditional STP based networks.

Stretched IP subnet and gateway redundancy

The DAG routed overlay network enables stretching an IP subnet between targeted EVPN multihoming network devices that support distributed connected IP or non-IP reachability across fabric networks. The selective group of switches in EVPN multihoming mode shares common IPv4 or IPv6 subnet function to support intra-subnet host communication based on the fabric host-routing or MAC address tables while providing load-sharing and gateway redundancy with Anycast gateway as a routed overlay.

Spine route policy

The IPv4 or IPv6 subnets and Layer 2 flood domains stretch across multiple IP gateway systems and demand a non-condensed host-level MAC-only or MAC-IP prefix to support seamless data communication across fabrics and beyond.

Large scale EVPN multihoming-enabled fabric networks benefit from the enforcement of the route policy on leaf switches towards the spine switches.

The iBGP or eBGP prefix advertisement to spine switches in the fabric core is limited to the advertising of RT-2 host prefixes and RT-5 network prefixes along with EAD per-ES RT-1 routes. Switches in EVPN multihoming mode retain unfiltered routing with an iBGP peering session with remote ES switches for non-blocking Layer 2 multipath EtherChannel.

Note Routed overlay networks are recommended for better scale, performance, and resiliency.

Configure DAG bridged overlay networks

This section provides sequential configuration tasks to successfully implement a DAG bridged overlay fabric network.

The BGP EVPN VXLAN-enabled fabric core network must be built with a reliable underlay IP and Layer 2 EVPN multihoming network as prerequisites.

Configure IP VRFs

This task shows how to configure a logically segmented virtual network with an IP VRF to exchange IPv4 or IPv6 network prefixes across all VTEPs in the fabric core network.

Note This configuration task is optional if IP VRFs are already configured on switches as part of the routed overlay network configuration.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**vrf definition** *vrf-name* **Example:** `Device(config)# vrf definition green`	Configures a new virtual routing and forwarding (VRF) instance and enters VRF configuration mode.
Step 4	**rd** *vpn-route-distinguisher* **Example:** `Device(config-vrf)# rd 10.200.255.101:101`	Configures a route distinguisher with a distinct value across all fabric devices.
Step 5	**address-family ipv4** [**multicast** | **unicast**] **Example:** `Device(config-vrf-af)# address-family ipv4 unicast`	Enters IPv4 unicast address-family configuration mode.
Step 6	**route-target** [**both** | **export** | **import**] *route-target-ext-community* **Example:** `Device(config- vrf-af)# route-target 65101:101`	Configures an overlay IPv4 import and export routing policy that matches the extended community value. • The default is **both** and will auto-generate both import and export command line with the configured community value.
Step 7	**route-target** [**both** | **export** | **import**] *route-target-ext-community* **stitching** **Example:** `Device(config- vrf-af)# route-target 65101:101 stitching`	Configures an IPv4 routing import and export overlay policy that matches the extended community value and enables extended NLRI types for BGP EVPN VXLAN-enabled networks. • The default is **both**
Step 8	**address-family ipv6** [**multicast** | **unicast**] **Example:** `Device(config- vrf-af)# address-family ipv6 unicast`	Enters IPv6 unicast address-family configuration mode.

	Command or Action	Purpose
Step 9	**route-target** [**both** | **export** | **import**] *route-target-ext-community* **Example:** `Device(config- vrf-af)# route-target 65101:101`	Configures an IPv6 routing import and export overlay policy that matches the extended community value. • The default is **both** and will auto-generate both import and export command line with the configured community value.
Step 10	**route-target** [**both** | **export** | **import**] *route-target-ext-community* **stitching** **Example:** `Device(config- vrf-af)# route-target 65101:101 stitching`	Configures an IPv6 routing import and export overlay policy that matches the extended community value and enables extended NLRI types for BGP EVPN VXLAN-enabled networks. • The default is **both**.
Step 11	**end** **Example:** `Device(config- vrf-af)# end`	Exits IPv6 unicast address-family configuration mode and returns to privileged EXEC mode.

Configure core VLAN and SVI interfaces

This task shows how to configure core VLAN and SVI interfaces for each of the IP VRFs used for VXLAN encapsulation and decapsulation functions between the downstream non-VXLAN network and remote VXLAN-enabled VTEPs. The task also shows how to configure the NVE interface and bind the L3VNI ID to a logical interface.

Note Skip this task if you have already configured core VLAN and SVI interfaces as part of the routed overlay network configuration.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**vlan** *id* **Example:**	Configures a dedicated VLAN ID for IP VRF core routing. This VLAN must not be used for

	Command or Action	Purpose
	`Device(config)# vlan 101`	any other purpose, and it is recommended to be pruned from Layer 2 trunk ports.
Step 4	**vlan configuration** *id* **Example:** `Device(config)# vlan configuration 101`	Configures a core VLAN to assign the Layer 3 VNI ID and enters VLAN configuration mode.
Step 5	**member vni** *l3vni-id* **Example:** `Device(config-vlan)# member vni 11101`	Configures a unique Layer 3 VNI ID for a specific IP VRF. For example, VRF green has the dedicated VLAN, 101 and Layer 3 VNI, and these IDs must not be shared with other IP VRFs on the same system. • It is recommended that all other VTEPs must have a Layer 3 VNI ID for the same IP VRF.
Step 6	**exit** **Example:** `Device(config-vlan)# exit`	Exits VLAN configuration mode and returns to global configuration mode
Step 7	**interface vlan** *id* **Example:** `Device(config)# interface vlan 101`	Configures a core VLAN SVI interface and assigns it to an IP VRF. • The core VLAN SVI MAC address is used to support routed MAC (RMAC) for Layer 3 overlays.
Step 8	**vrf forwarding** *vrf-name* **Example:** `Device(config-if)# vrf forwarding green`	Maps the IP VRF to a core VLAN SVI interface.
Step 9	**ip unnumbered** *id* **Example:** `Device(config-if)# ip unnumbered Loopback0`	Configures an unnumbered IPv4 address from an underlay logical interface, for example, Loopback0.
Step 10	**no autostate** **Example:** `Device(config-if)# no autostate`	Disables autostate on the interface. • In EVPN deployments, a VLAN used for a core-facing SVI, should not be allowed in any trunks. For a core-facing SVI to function correctly, the **no autostate** command must be configured for the SVI.

	Command or Action	Purpose
Step 11	**exit** **Example:** `Device(config-if)# exit`	Exits interface configuration mode and returns to global configuration mode.
Step 12	**interface nve** *id* **Example:** `Device(config)# interface nve 1`	Configures a virtual NVE interface to bind one or more L2VNIs and enables system-wide VXLAN forwarding function from the L3VNIs. • Enters interface configuration mode.
Step 13	**source-interface** *id* **Example:** `Device(config-if)# source-interface Loopback0`	Configures a Loopback interface as the source to enable data communication over a VXLAN tunnel.
Step 14	**host-reachability protocol bgp** **Example:** `Device(config-if)# host-reachability protocol bgp`	Configures BGP as the host-reachability control plane protocol on this interface.
Step 15	**member vni** *l3vni-id* **vrf** *vrf-name* **Example:** `Device(config-if)# member vni 11101 vrf green`	Binds the L3VNI to the IP VRF under the NVE interface.
Step 16	**end** **Example:** `Device(config-if)# end`	Exits interface configuration mode and returns to privileged EXEC mode.

Configure a DAG bridged overlay MAC-VRF

This task shows how to configure a MAC VRF and route-target policy to selectively exchange prefixes between a pair of EVPN multihoming-enabled switches in a single cluster.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:**	Enters global configuration mode.

	Command or Action	Purpose
	`Device# configure terminal`	
Step 3	**l2vpn evpn instance** *id* **vlan-based** **Example:** `Device(config)# l2vpn evpn instance 211 vlan-based`	Configures a L2VPN EVPN virtual instance with a unique ID. Typically, the ID value is the same as the VLAN ID, for example, data VLAN ID 211. • Enters EVPN instance configuration mode.
Step 4	**encapsulation vxlan** **Example:** `Device(config-evpn-evi)# encapsulation vxlan`	Enables VXLAN encapsulation to bridge inter-ES data between two systems.
Step 5	**route-target** {**export** | **import** | **both**} *route-target-ext-community* **Example:** `Device(config-evpn-evi)# route-target both 1.1.1.1:211`	Configures a MAC or IP routing import and export policy that matches the extended community value. • The recommended format for EVPN multihoming cluster VLAN ID is Cluster-1 ID with 1.1.1.1 and DAG-routed VLAN ID 211 can result in the MAC VRF route-target 1.1.1.1:211. The default is **both** and it auto-generates the import and export command lines with the configured community value.
Step 6	**route-target** {**export** | **import** | **both**} *route-target-ext-community* **Example:** `Device(config-evpn-evi)# route-target import 1.1.1.2:211`	Configures inter-cluster DAG bridging with a MAC or IP routing import-only policy that matches the extended community value. • The recommended format for EVPN multihoming cluster VLAN ID is Cluster-1 ID with 1.1.1.2 and DAG-routed VLAN ID 211 can result in the MAC VRF route-target 1.1.1.2:211.
Step 7	**no auto-route-target** **Example:** `Device(config-evpn-evi)# no auto-route-target`	Disables auto route target with the manual route target configured in Step 5 for the DAG-routed overlay MAC VRF. • The default is auto-generated route target in ASN:L2VPN instance ID format. Default enabled with auto-generated RT in ASN:L2VPN Instance ID format.

	Command or Action	Purpose
Step 8	**advertise mac enable** **Example:** `Device(config-evpn-evi)# advertise mac enable`	Enables the originating and advertising of the MAC-only route to enable non-IP data communication.
Step 9	**replication-type** {**ingress** | **static**} **Example:** `Device(config-evpn-evi)# replication-type static`	Enables underlay BUM replication type with multicast for scalable fabric networks.
Step 10	**end** **Example:** `Device(config-evpn-evi)# end`	Exits EVPN instance configuration mode and returns to privileged EXEC mode.

Configure access SVI interfaces

This section provides step-by-step instructions to configure switches in EVPN multihoming mode.

The DAG bridge mode provides a single-unified IP gateway system through multiple leaf network devices. The intra subnet IP or non-IP host communication follows standard remote MAC-to-IP binding resolution, while all inter subnet IP communication is routed through the anycast gateway IP address.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface vlan** *id* **Example:** `Device(config)# interface Vlan 211`	Configures a Layer 3 SVI interface ID and enters interface configuration mode.
Step 4	**vrf forwarding** *vrf-name* **Example:** `Device(config-if)# vrf forwarding green`	Maps the IP VRF to a core VLAN SVI interface.
Step 5	**ip address** *ip-address mask* **Example:**	Assigns an IPv4 gateway address and mask for selected VLANs.

	Command or Action	Purpose
	`Device(config-if)# ip address 10.211.1.254 255.255.255.0`	• The anycast gateway is auto enabled with common addresses between ES systems.
Step 6	**ipv6 address** *ipv6-address mask* **Example:** `Device(config-if)# ipv6 address 2001:10:211:1::f/64`	Assigns an IPv6 gateway address and prefix for selected VLANs. • The anycast gateway is auto enabled with common addresses between ES systems.
Step 7	**end** **Example:** `Device(config-if)# end`	Exits interface configuration mode and returns to privileged EXEC mode.

Configure a spine policy for DAG bridged overlay networks

This task provides step-by-step instructions to configure a pair of ES switches with an outbound spine EVPN route policy. The route policy enables controlled EVPN route advertisement by a pair of ES switches, independent of iBGP or eBGP spine-peering session type.

The spine route-map policy to permit RT-5 prefix for routed overlay can be expanded with a new sequence to limit switches advertising the Route-Type 1 and Route-Type 2 (that includes MAC-only and MAC-IP) prefixes for network-wide host route propagation based on DAG MAC VRF route target values.

The iBGP peering with EVPN multihoming system unfiltered EVPN route exchange to build and maintain non-blocking Layer 2 multipath network.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**ip extcommunity-list** [**expanded** *list-name* {**permit** | **deny**} [*regular-expression*] | **standard-lit-number** *standard-list-name* {**permit** | **deny**} [**rt** *extended-community-value*] [**soo** *extended-community-value*] **Example:**	Configures an extended IP community list to permit the DAG-bridge MAC VRF route-target values. • A single IP extended community can be configured with a single RT value or can be configured through regular expressions that match multiples. For example, 21[1-9] for 211-219 DAG-bridged VLAN ID range.

	Command or Action	Purpose
	`Device(config)# ip extcommunity-list expanded DAG-BRIDGED-OVERLAY-EXTCOMM permit 1.1.1.1:211`	
Step 4	**route-map** *name* [**permit** | **deny**] *sequence-number* **Example:** `Device(config)# route-map SPINE-ROUTE-POLICY-OUT permit 30`	Creates a route-map rule with permit or deny match criteria and enters route-map configuration mode. • The optional *sequence-number* argument indicates the order of processing of the route-map rule.
Step 5	**description** *description* **Example:** `Device(config-route-map)# description DAG BRIDGED OVERLAY – VL211`	(Optional) Adds a description for the route-map sequence.
Step 6	**match evpn route-type** [**1-8** | **2-mac-ip** | **2-mac-only**] **Example:** `Device(config-route-map)# match evpn route-type 1`	Configures an EVPN route policy sequence to permit advertising the local EAD per Ethernet Segment (ES) prefixes RT-1) for each local ES.
Step 7	**match evpn route-type** [**1-8** | **2-mac-ip** | **2-mac-only**] **Example:** `Device(config-route-map)# match evpn route-type 2`	Configures an EVPN route policy sequence to permit advertising the local IPv4 or IPv6 host and MAC prefixes (RT-2) mapped to any IP VRF.
Step 8	**exit** **Example:** `Device(config-route-map)# exit`	Exits route-map configuration mode and returns to global configuration mode.
Step 9	**router bgp** *autonomous-system-number* **Example:** `Device(config)# router bgp 65101`	Configures BGP autonomous system numbers using 2-bytes or 4-bytes in asplain and asdot formats and enters router configuration mode.
Step 10	**address-family l2vpn evpn** **Example:** `Device(config-router)# address-family l2vpn evpn`	Enters BGP L2VPN address-family configuration mode.
Step 11	**neighbor** *spine-loopback-address* **route-map** *name* **out** **Example:** `Device(config-router-af)# neighbor 10.200.255.3 route-map SPINE-ROUTE-POLICY-OUT out`	Applies outbound route-map policy to each spine peer to limit the advertising of the RT-5 prefix.

	Command or Action	Purpose
Step 12	**end** **Example:** `Device(config-router-af)# end`	Exits BGP L2VPN address-family configuration mode and returns to privileged EXEC mode.

Configure IP VRF address family routing under BGP

This task shows how to advertise network prefixes in IPv4 and IPv6 address-family configurations.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**router bgp** *autonomous-system-number* **Example:** `Device(config)# router bgp 65101`	Configures BGP autonomous system numbers using 2-bytes or 4-bytes in asplain and asdot formats and enters router configuration mode.
Step 4	**address-family ipv4 vrf** *vrf-name* **Example:** `Device(config-router)# address-family ipv4 vrf green`	Enables IPv4 address-family for a VRF instance to enable IPv4 network prefix routing in overlay.
Step 5	**advertise l2vpn evpn** **Example:** `Device(config-route-af)# advertise l2vpn evpn`	Enables advertising the IPv4 network prefix routing between IPv4 VRF instances and EVPN fabric core networks.
Step 6	**redistribute connected** [**metric** |**route-map**] *name* **Example:** `Device(config-route-af)# redistribute connected`	Configures IPv4 address-family to advertise all local connected IPv4 network prefixes in EVPN fabric network. • Network prefixes can be advertised by the **network** command as an alternative.
Step 7	**exit** **Example:** `Device(config-route-af)# exit`	Exits IPv4 address-family configuration mode and returns to router configuration mode

	Command or Action	Purpose
Step 8	**address-family ipv6 vrf** *vrf-name* **Example:** `Device(config-router)# address-family ipv6 vrf green`	Enables IPv6 address-family for a VRF instance to enable IPv6 network prefix routing in overlay.
Step 9	**advertise l2vpn evpn** **Example:** `Device(config-route-af)# advertise l2vpn evpn`	Enables IPv6 network prefix routing between IPv6 VRF instances and EVPN fabric core networks.
Step 10	**redistribute connected** [**metric** |**route-map**] *name* **Example:** `Device(config-route-af)# redistribute connected`	Configures an IPv6 address-family to advertise all local connected IPv6 network prefixes in EVPN fabric network. • Network prefixes can be advertised by the **network** command, as an alternative.
Step 11	**end** **Example:** `Device(config-route-af)# end`	Exits IPv6 address-family configuration mode and returns to privileged EXEC mode.

Verify the DAG bridged overlay network configuration

This section provides examples to verify the DAG-bridged overlay network configuration and states of VTEPs.

The command output may be truncated to focus on critical information for a Day-2 operation and troubleshooting.

IP VRF networks: Verifies the locally configured IP VRF and the associated physical or logical interface bindings to a virtual network on VTEPs including leaf and border devices. The interface binding includes the network edge VLANs connecting to endpoints, and network devices, along with a single core VLAN (VLAN 101) of an IP VRF.

```
ES-1# show vrf green

  Name      Default RD               Protocols     Interfaces
  green     10.200.255.101:101 ipv4     Vl111
                                                   Vl211
                                                   Vl101
BORDER-1# show vrf green

  Name     Default RD              Protocols Interfaces
  green    10.200.255.1:101  ipv4       Vl101
                                                   Vl1101
```

BGP L2VPN EVPN neighbors: Verifies that the two-tier hierarchical iBGP sessions between switches in EVPN multihoming mode, and iBGP peering to a pair of spine systems are operational.

The following command output shows iBGP peering with a pair of spines switches, 10.100.255.3 and 10.100.255.4 and direct iBGP peering between ES-1, local 10.100.255.101 and ES-2, 10.100.255.102 switches in EVPN multihoming mode is operational.

```
ES-1# show bgp l2vpn evpn all summary

BGP router identifier 10.100.255.101, local AS number 65101
<snip>

Neighbor        V    AS     MsgRcvd  MsgSent   TblVer  InQ   OutQ    Up/Down    State/PfxRcd

10.100.255.3     4    65101    18        20      104     0      0     00:04:35         2
10.100.255.4     4    65101    23        25      106     0      0     00:05:19         2
10.100.255.102   4    65101    51        65      104     0      0     00:04:26         28
```

Spine policy: Verifies the VTEP in leaf or border roles implemented in EVPN multihoming mode is configured with a route-map and an outbound policy is applied to each spine, 10.200.255.3.

The spine policy configuration on border switches is optional and not required if the switches are not implemented in EVPN multihoming mode to connect to external network devices, such as firewalls.

```
ES-1# show bgp l2vpn evpn neighbor 10.200.255.3 policy

Neighbor: 10.200.255.3, Address-Family: L2VPN E-VPN
 Locally configured policies:
  send-community extended
 Inherited polices:
  route-map EVPN-SPINE-ROUTE-POLICY-OUT out
```

L2VPN advertised routes: Verifies the VTEP in leaf or border roles implemented in EVPN multihoming mode is advertising the EVPN prefixes to the spine, 10.200.255.3, based on the applied route-map policy.

The following command output from leaf and border switches confirms the advertising of RT-2-MAC-IP EVPN prefixes, and that no additional EVPN route-types are advertised to the spine switches.

```
ES-1# show bgp l2vpn evpn neighbor 10.200.255.3 advertised-route

BGP table version is 7179, local router ID is 10.200.255.101

                       0.0.0.0                        32768     ?

Border-1# show bgp l2vpn evpn neighbors 10.200.255.3 advertised-routes

BGP table version is 2895, local router ID is 10.200.255.1
<snip>
     Network          Next Hop            Metric    LocPrf     Weight   Path
Route Distinguisher: 10.100.255.1:101 (default for vrf green)
 *>   [5][10.100.255.1:101][0][0][0.0.0.0]/17
                       21.1.1.1              0          0      65001      ?
 *>   [5][10.100.255.1:101][0][16][111.1.0.0]/17
```

```
                    21.1.1.1              0          0       65001       ?
```

MAC-VRF manual route-target: Verifies that the stretched IP-subnet VLAN is limited to import and export of the MAC or IP route matching the local cluster EVPN multihoming peer switch. With auto route-target disabled, the import and export route-target only lists the manual configuration settings.

The following command output confirms that the bidirectional MAC route policy with route-target 1.1.1.1:12 and the default auto-generated ASN instance ID 65101:211 is not listed along with the manual configuration.

```
ES-1# show l2vpn evpn evi 211 detail

EVPN instance:           211 (VLAN Based)
  RD:                    10.200.255.101:211 (auto)
  Import-RTs:            1.1.1.1:211   1.1.1.2:211
  Export-RTs:            1.1.1.1:211
  Per-EVI Label:         none
  State:                 Established
  Replication Type:      Static
 <snip>
```

VRF IP routing table: Verifies that the leaf implemented in EVPN multihoming mode is advertising the EVPN prefixes to the spine switch 10.200.255.3 based on the applied route-map policy.

The following command output from the border switch confirms that the pair of EVPN multihoming leaf systems configured in DAG routed overlay, each with two hosts are advertising RT2-MAC-IP. Border switches have a dual-path ECMP to each host to support load-sharing and redundancy for overlay network prefixes. And leaf switches receive the RT-5 network prefix from the IP routing table of IP VRFs in the border systems that confirm the advertising of RT-5 EVPN prefixes.

```

Reference configuration for DAG bridged overlay networks

This section provides a reference network design and configuration to implement a DAG bridged overlay fabric network.

This following figure illustrates a reference network design to support scalable EVPN multihoming and fabric core with hierarchical BGP peering, control-plane peering, and selective stretching of an IP subnet between a pair of switches deployed in the distribution block with overlay fabric network.

Figure 210: EVPN multihoming: DAG-bridged overlay fabric network

This reference configuration shows a three-step process, from the initial network setup to the successful fabric deployment. Network administrators can follow these steps sequentially for initial deployment and to increment the overlay network configuration as the network demands increase.

Layer 2 EVPN multihoming

The base configuration to build a fabric begins with Layer 2 campus networks using EVPN multihoming technology. This section provides the step-by-step configuration on a pair of switches to successfully build a non-blocking all-active Layer 2 network with EVPN multihoming.

Step	ES-1 and ES-2	ES-3 and ES-4
1: Inter-ES Layer 3 EtherChannel	ES-1 ! interface Port-Channel 128 description CONNECTED TO ES PEER no switchport ip address 10.0.0.0 255.255.255.254 ip ospf network point-to-point ip ospf multi-area 0 ip ospf 100 area 101 ip ospf 100 cost 10 carrier-delay msec 0 hold-queue 4094 in hold-queue 4094 out evpn multihoming core-tracking ! Underlay: fabric core and BGP peering

Enterprise campus core networks with solid underlay network foundation is the key for highly scalable, resilient BGP EVPN VXLAN fabric networks. This section is the second step to build a reliable underlay core network for fabric and hierarchical BGP peering on targeted network devices with specific roles.

Note The table is subdivided into two fabric roles with each step either sharing common configuration or a unique per-device with a common role.

Step	ES-1, ES-2, ES-3 and ES-4	Spine-1 and Spine-2	Border-1 and Border-2
1: Global best practices	! system mtu 9100 ! port-channel load-balance vlan-src-dst-mixed-ip-port ip cef load-sharing algorithm include-ports source destination protocol ! ip tcp mss 8000 ip tcp window-size 262144 ip tcp path-mtu-discovery !	! system mtu 9100 ! port-channel load-balance vlan-src-dst-mixed-ip-port ip cef load-sharing algorithm include-ports source destination protocol ! ip tcp mss 8000 ip tcp window-size 262144 ip tcp path-mtu-discovery !	! system mtu 9100 ! port-channel load-balance vlan-src-dst-mixed-ip-port ip cef load-sharing algorithm include-ports source destination protocol ! ip tcp mss 8000 ip tcp window-size 262144 ip tcp path-mtu-discovery !

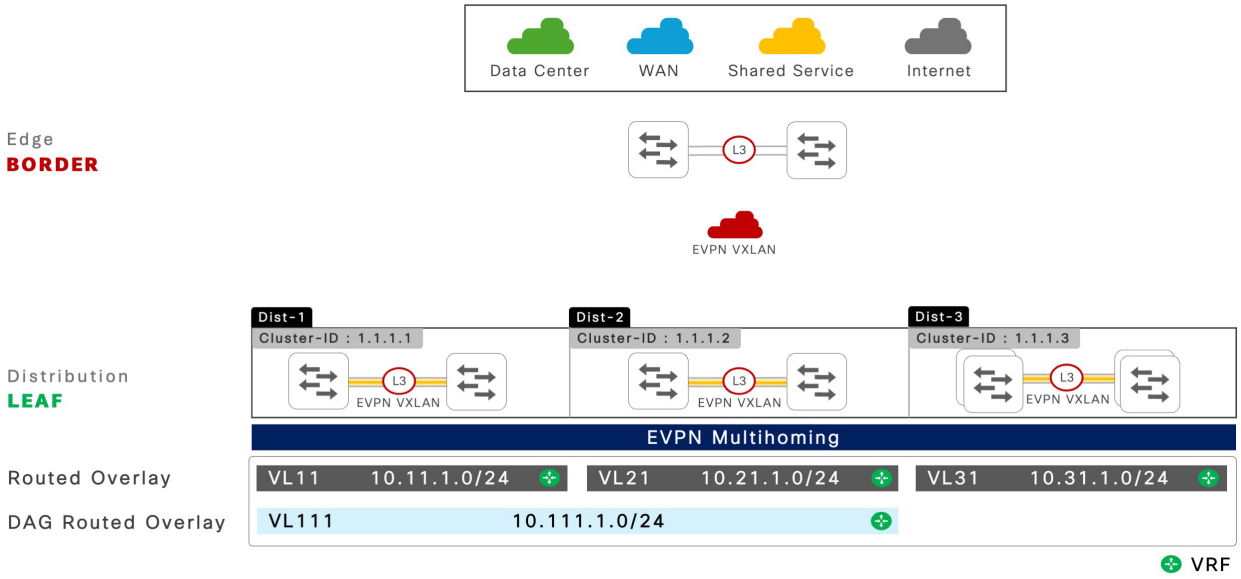
- Reference configuration for DAG routed overlay networks, on page 2888

Distributed Anycast Gateway: routed overlay network overview



In modern enterprise campus environments, application traffic typically flows between wired and wireless users, and resources hosted either on-premises or across cloud environments. To manage this efficiently, network administrators implement a structured IP addressing plan with VLANs and subnets organized per distribution block. This approach enables segmentation through a routed overlay VXLAN fabric network, which provides scalable, flexible, and secure network segmentation.

In certain cases, the VLAN or subnet networks may require stretching beyond a single IP gateway boundary to support latency-sensitive or legacy enterprise applications. The Distributed Anycast Gateway (DAG) technology enables this by allowing secure and segmented communication between IP endpoints over a dynamic VXLAN tunnel.

With a Layer 2 flood-free network, the DAG-routed overlay network enables the stretching of IP subnets across switches implemented in EVPN multihoming fabric mode across targeted leaf switches. This approach supports scalable and secure network segmentation tailored to enterprise application requirements. Switches support the co-existence of routed and DAG routed overlay networks.

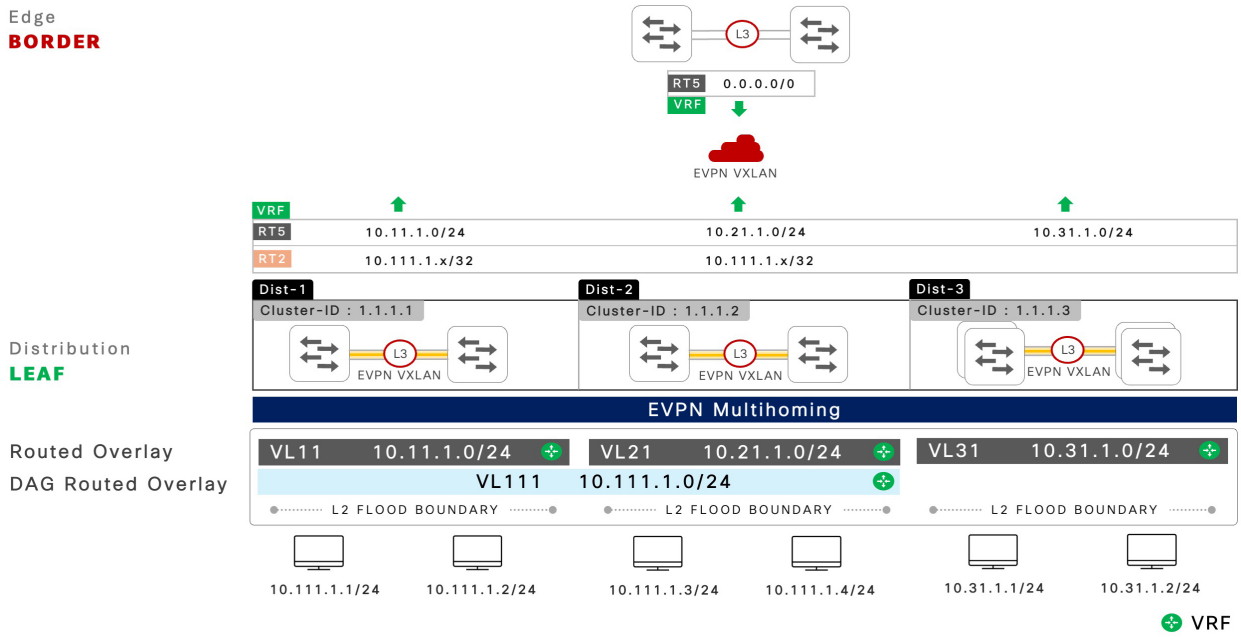
The following illustration shows a deployment scenario for an EVPN multihoming network with the co-existence of routed and DAG-routed overlay networks. The illustration also shows the stretching of a specific IP subnet, VLAN-111 between two targeted switches, one in network distribution Block 1 and the other in Block 2.

Figure 211: EVPN multihoming with DAG-routed overlay fabric network

Restrictions for DAG routed overlay networks

The following restrictions apply to the DAG Routed Overlay feature.

- Non-IP endpoint communication beyond local EVPN multihoming network devices is not supported.
- Silent-host endpoint communication beyond local EVPN multihoming network devices is not supported.



Understanding DAG routed overlay networks

Enterprise networks require flexibility to support unique per-VLAN overlay functions that are tailored to business requirements. Routed overlay is a proven and recommended approach for large-scale overlay networks, which can implement DAG-routed overlay to selectively stretch IP subnets without extending the Layer 2 flood boundary. Network administrators can implement the DAG-routed overlay to stretch an IP subnet across targeted leaf switches without extending the Layer 2 flood boundary.

Switches support the multiple flexible co-existence of routed and distributed Anycast gateway routed overlay networking options within the same macro-segmented IP VRF, and the micro-segmented VXLAN-GPO enabled environment.

The following figure displays the characteristics of an EVPN multihoming network with a DAG-routed overlay fabric.

Figure 212: Key network characteristics of a DAG-routed overlay fabric

Hierarchical BGP control plane

The recommended deployment consideration to support controlled route management between EVPN multihoming peers and spine switches in large-scale campus networks is the two-tier hierarchical BGP control plane. Each BGP peering layer manages domain-specific EVPN routes to enable downstream non-blocking and all-active Layer 2 multipath networks, and manages the advertising of fabric network prefixes to enable secure global network access connectivity in core networks.

EVPN multihoming

Layer 2 networks with EVPN multihoming functions independent of the fabric core EVPN fabric network. A pair of switches in each distribution layer builds and manages EVPN multihoming in each redundancy group.

The unified Layer 2 Ethernet Segment (ES) EtherChannel connection to downstream network device can carry VLANs that are mapped to routed, selective-stretched subnets with DAG-routed overlay and advertised in the fabric core or can continue to be traditional underlay IP networks.

Layer 2 broadcast network boundary

DAG routed overlay networks provide unified Layer 2 or Layer 3 network boundary as the routed overlay and the traditional underlay campus network. The Layer 2 bridge domain and the blast-radius remain contained between Layer 2 access and EVPN multihoming-enabled distribution layer systems.

A pair of switches in the distribution layer network dynamically builds the Layer 2 VXLAN tunnel using ingress replication mode to extend Broadcast, Unknown Unicast and Multicast (BUM) traffic. With built-in loop-detection and prevention techniques, EVPN multihoming-enabled networks support a secure and scalable Layer 2 network over traditional STP based networks.

IPv4 ARP and IPv6 proxy

Switches support IPv4 ARP and IPv6 Neighbor Discovery (ND) and Duplicate Address Detection (DAD) proxy functions on a per VLAN or subnet basis.

The intended, stretched IP subnet interface is configured with local proxy functions on anycast gateway switches. The incoming IPv4 ARP request and IPv6 ND/DAD messages are intercepted, processed, and responded to by the anycast gateway switch with the local anycast MAC address (00:00:5e:00:01:01). As a result, the IP subnet with IPv4 or IPv6 endpoints can be selectively stretched between EVPN multihoming network devices without extending the Layer 2 flood boundary that can impact scale, performance, and security in large scale environments.

Structured IP subnet with proxy and gateway redundancy

The DAG routed overlay network enables stretching an IP subnet between targeted EVPN multihoming network devices supporting scalable and secure overlay network. The selective group of switches in EVPN multihoming mode shares common IPv4/IPv6 subnet with IP proxy function enable to support intra-subnet host communication based on fabric host-routing table while providing load-sharing and gateway redundancy with anycast gateway as routed overlay.

Spine route policy

The IPv4 or IPv6 subnet stretch across multiple IP gateway systems demand a non-condensed host-level prefix announcement in fabric core to support end-to-end seamless data communication. Switches that stretch the IPv4 or IPv6 subnets require the advertisement of the host-route to the fabric.

The iBGP or eBGP prefix advertisement to spine switches in fabric core limits advertising the IPv4 or IPv6 RT-2-MAC-IP host prefixes along with RT-5 network prefixes. The switches in EVPN multihoming mode retain unfiltered routing with iBGP peering session with the remote ES switch for non-blocking the Layer 2 multipath EtherChannel.

Note EVPN multihoming-enabled networks support additional overlay network types to stretch IP subnets or Layer 2 flood-domain beyond a single distribution block using Distributed Anycast Gateway (DAG) bridged technology. For better scale, performance, and resiliency, we recommend the routed overlay network.

Configure DAG routed overlay networks

This section provides step-by-step configuration guidelines to implement DAG routed overlay networks.

Configure IP VRFs

This task shows how to configure a logically segmented virtual network with an IP VRF to exchange IPv4 or IPv6 network prefixes across all VTEPs in the fabric core network.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**vrf definition** *vrf-name* **Example:** `Device(config)# vrf definition green`	Configures a new virtual routing and forwarding (VRF) instance and enters VRF configuration mode.
Step 4	**rd** *vpn-route-distinguisher* **Example:** `Device(config-vrf)# rd 10.200.255.101:101`	Configures a route distinguisher with a distinct value across all fabric devices.
Step 5	**address-family ipv4** [**multicast** | **unicast**] **Example:** `Device(config-vrf-af)# address-family ipv4 unicast`	Enters IPv4 unicast address-family configuration mode.
Step 6	**route-target** [**both** | **export** | **import**] *route-target-ext-community* **Example:** `Device(config- vrf-af)# route-target 65101:101`	Configures an overlay IPv4 import and export routing policy that matches the extended community value. • The default is **both** and will auto-generate both import and export command line with the configured community value.
Step 7	**route-target** [**both** | **export** | **import**] *route-target-ext-community* **stitching** **Example:** `Device(config- vrf-af)# route-target 65101:101 stitching`	Configures an IPv4 routing import and export overlay policy that matches the extended community value and enables extended NLRI types for BGP EVPN VXLAN-enabled networks. • The default is **both**
Step 8	**address-family ipv6** [**multicast** | **unicast**] **Example:** `Device(config- vrf-af)# address-family ipv6 unicast`	Enters IPv6 unicast address-family configuration mode.

	Command or Action	Purpose
Step 9	**route-target** [**both** | **export** | **import**] *route-target-ext-community* **Example:** `Device(config- vrf-af)# route-target 65101:101`	Configures an IPv6 routing import and export overlay policy that matches the extended community value. • The default is **both** and will auto-generate both import and export command line with the configured community value.
Step 10	**route-target** [**both** | **export** | **import**] *route-target-ext-community* **stitching** **Example:** `Device(config- vrf-af)# route-target 65101:101 stitching`	Configures an IPv6 routing import and export overlay policy that matches the extended community value and enables extended NLRI types for BGP EVPN VXLAN-enabled networks. • The default is **both**.
Step 11	**end** **Example:** `Device(config- vrf-af)# end`	Exits IPv6 unicast address-family configuration mode and returns to privileged EXEC mode.

Configure core VLAN and SVI interfaces

This task shows how to configure core VLAN and SVI interfaces for each of the IP VRFs used for VXLAN encapsulation and decapsulation functions between the downstream non-VXLAN network and remote VXLAN-enabled VTEPs. The task also shows how to configure the NVE interface and bind the L3VNI ID to a logical interface.

Note Skip this task if you have already configured core VLAN and SVI interfaces as part of the routed overlay network configuration.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**vlan** *id* **Example:**	Configures a dedicated VLAN ID for IP VRF core routing. This VLAN must not be used for

	Command or Action	Purpose
	`Device(config)# vlan 101`	any other purpose, and it is recommended to be pruned from Layer 2 trunk ports.
Step 4	**vlan configuration** *id* **Example:** `Device(config)# vlan configuration 101`	Configures a core VLAN to assign the Layer 3 VNI ID and enters VLAN configuration mode.
Step 5	**member vni** *l3vni-id* **Example:** `Device(config-vlan)# member vni 11101`	Configures a unique Layer 3 VNI ID for a specific IP VRF. For example, VRF green has the dedicated VLAN 101 and Layer 3 VNI, and these IDs must not be shared with other IP VRFs on the same system. All other VTEPs are recommended to have a Layer 3 VNI ID for the same IP VRF.
Step 6	**exit** **Example:** `Device(config-vlan)# exit`	Exits VLAN configuration mode and returns to global configuration mode
Step 7	**interface vlan** *id* **Example:** `Device(config)# interface vlan 101`	Configures a core VLAN SVI interface and assigns it to an IP VRF. The core VLAN SVI MAC address supports routed MAC (RMAC) for Layer 3 overlays.
Step 8	**vrf forwarding** *vrf-name* **Example:** `Device(config-if)# vrf forwarding green`	Maps the IP VRF to a core VLAN SVI interface.
Step 9	**ip unnumbered** *id* **Example:** `Device(config-if)# ip unnumbered Loopback0`	Configures an unnumbered IPv4 address from an underlay logical interface, for example, Loopback0.
Step 10	**no autostate** **Example:** `Device(config-if)# no autostate`	Disables autostate on the interface. • In EVPN deployments, a VLAN used for a core-facing SVI, should not be allowed in any trunks. For a core-facing SVI to function correctly, the **no autostate** command must be configured for the SVI.
Step 11	**exit** **Example:** `Device(config-if)# exit`	Exits interface configuration mode and returns to global configuration mode.

	Command or Action	Purpose
Step 12	**interface nve** *id* **Example:** `Device(config)# interface nve`	Configures a virtual NVE interface to bind one or more L2VNIs and enables system-wide VXLAN forwarding function from the L3VNIs. • Enters interface configuration mode.
Step 13	**source-interface** *id* **Example:** `Device(config-if)# source-interface Loopback0`	Configures a Loopback interface as the source to enable data communication over a VXLAN tunnel.
Step 14	**host-reachability protocol bgp** **Example:** `Device(config-if)# host-reachability protocol bgp`	Configures BGP as the host-reachability control plane protocol on this interface.
Step 15	**member vni** *l3vni-id* **vrf** *vrf-name* **Example:** `Device(config-if)# member vni 11101 vrf green`	Binds the L3VNI to the IP VRF under the NVE interface.
Step 16	**end** **Example:** `Device(config-if)# end`	Exits interface configuration mode and returns to privileged EXEC mode.

Configure DAG routed MAC VRFs

This task shows how to configure a MAC VRF and route-target policy to selectively exchange prefixes between a pair of EVPN multihoming-enabled switches in a single cluster.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**l2vpn evpn instance** *id* **vlan-based** **Example:**	Configures a L2VPN EVPN virtual instance with a unique ID. Typically, the ID value is the

	Command or Action	Purpose
	`Device(config)# l2vpn evpn instance 111 vlan-based`	same as the VLAN ID, for example, data VLAN ID 111. • Enters EVPN instance configuration mode.
Step 4	**encapsulation vxlan** **Example:** `Device(config-evpn-evi)# encapsulation vxlan`	Enables VXLAN encapsulation to bridge inter-ES data between two systems.
Step 5	**route-target** {**export** | **import** | **both**} *route-target-ext-community* **Example:** `Device(config-evpn-evi)# route-target both 1.1.1.1:111`	Configures a MAC or IP routing import and export policy that matches the extended community value. • The recommended format for EVPN multihoming cluster VLAN ID is Cluster-1 ID with 1.1.1.1 and DAG-routed VLAN ID 111 can result in the MAC VRF route-target 1.1.1.1:111. The default is **both** and it auto-generates the import and export command-line with the configured community value.
Step 6	**no auto-route-target** **Example:** `Device(config-evpn-evi)# no auto-route-target`	Disables auto route-target with the manual route-target configured in Step-5 for the DAG-routed overlay MAC VRF. • The default is auto-generated route-target in ASN:L2VPN instance ID format.
Step 7	**end** **Example:** `Device end`	Exits EVPN instance configuration mode and returns to privileged EXEC mode.

Configure IPv4 ARP and IPv6 ND/DAD proxy

Configures IPv4 Address Resolution Protocol (ARP) and IPv6 Neighbor Discovery (ND) or Duplicate Address Detection (DAD) proxy on switches to provide local anycast interface MAC response after receiving requests or queries from local endpoints connected to the downstream Layer 2 network.

This configuration is required only on access-facing VLAN or SVI interfaces that are implemented in distributed anycast gateway routed overlay mode

Procedure

	Command or Action	Purpose
Step 1	**enable**	Enables privileged EXEC mode.

	Command or Action	Purpose
	Example: `Device> enable`	• Enter your password if prompted
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**interface vlan** *id* **Example:** `Device(config)# interface vlan 111`	Configures a Layer 3 SVI interface ID and enters interface configuration mode.
Step 4	**ip address** *address mask* **Example:** `Device(config-if)# ip address 10.111.1.254 255.255.255.0`	Assigns IPv4 gateway address and mask for selected VLANs. • Anycast gateway address is auto enabled with a common address between ES systems.
Step 5	**ip local-proxy-arp** **Example:** `Device(config-if)# ip local-proxy-arp`	Configures a gateway to send proxy responses with the local interface MAC address when receiving IPv4 ARP requests from local hosts.
Step 6	**ipv6 address** *address mask* **Example:** `Device(config-if)# ipv6 address 2001:10:111:1::f/64`	Assigns IPv6 gateway address and prefix for selected VLANs. • Anycast gateway address is auto-enabled with a common address between ES systems.
Step 7	**exit** **Example:** `Device(config-if)# exit`	Exits interfaced configuration mode and returns to privileged EXEC mode.
Step 8	**vlan configuration** *id* **Example:** `Device(config)# vlan configuration 111`	Enters VLAN configuration mode
Step 9	**ipv6 nd routing proxy** **Example:** `Device(config-vlan)# ipv6 nd routing proxy`	Configures a gateway switch to send proxy responses with the local interface MAC address when receiving IPv6 ND requests from local hosts.
Step 10	**ipv6 nd dad-proxy** **Example:** `Device(config-vlan)# ipv6 nd dad-proxy`	Configures the gateway switch to send DAD proxy response to local hosts with the local interface MAC address when receiving IPv6 ND DAD messages for the IPv6 address owned by another host.

	Command or Action	Purpose
Step 11	**end** **Example:** `Device(config-vlan)# end`	Exits VLAN configuration mode and returns to privileged EXEC mode.

Configure spine policies for DAG routed overlay networks

This task provides step-by-step instructions to configure a pair of ES switches with an outbound spine EVPN route policy. The route policy enables controlled EVPN route advertisement by the pair of ES switches, independent of iBGP or eBGP spine-peering session type.

The spine route-map policy to permit RT-5 prefix for routed overlay can be expanded with a new sequence to limit the switches advertising the RT-2 with combined MAC and IP (RT-2-MAC-IP) prefix for network-wide host route with IPv4 or IPv6 address propagation.

The iBGP peering with EVPN multihoming system unfiltered EVPN route exchange to build and maintain non-blocking Layer 2 multipath network.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**route-map** *name* [**permit** | **deny**] *sequence-number* **Example:** `Device(config)# route-map SPINE-ROUTE-POLICY-OUT permit 20`	Creates a route-map rule with permit or deny match criteria and enters route-map configuration mode. • The optional *sequence-number* argument indicates the order of processing of the route-map rule.
Step 4	**description** *description* **Example:** `Device(config-route-map)# description DAG ROUTED OVERLAY – VL111`	(Optional) Adds a description for the route-map sequence.
Step 5	**match evpn route-type** [**1-8** | **2-mac-ip** | **2-mac-only**] **Example:** `Device(config-route-map)# match evpn route-type 2-mac-ip`	Configures an EVPN route-policy sequence to permit advertising the local IPv4 or IPv6 hosts prefixes (RT-2-MAC-IP) mapped to any IP VRF.

	Command or Action	Purpose
Step 6	**exit** **Example:** `Device(config-route-map)# exit`	Exits route-map configuration mode and returns to global configuration mode.
Step 7	**router bgp** *autonomous-system-number* **Example:** `Device(config)# router bgp 65101`	Configures BGP autonomous system numbers using 2-bytes or 4-bytes in asplain and asdot formats and enters router configuration mode.
Step 8	**address-family l2vpn evpn** **Example:** `Device(config-router)# address-family l2vpn evpn`	Enters BGP L2VPN address-family configuration mode.
Step 9	**neighbor** *spine-loopback-address* **route-map** *name* **out** **Example:** `Device(config-router-af)# neighbor 10.200.255.3 route-map SPINE-ROUTE-POLICY-OUT out`	Applies outbound route-map policy to each spine peer to limit the advertising of the RT-5 prefix.
Step 10	**end** **Example:** `Device(config-router-af)# end`	Exits router configuration mode and returns to privileged EXEC mode.

Configure IP VRF address family routing under BGP

This task shows how to advertise network prefixes in IPv4 and IPv6 address-family configuration.

Procedure

	Command or Action	Purpose
Step 1	**enable** **Example:** `Device> enable`	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	**configure terminal** **Example:** `Device# configure terminal`	Enters global configuration mode.
Step 3	**router bgp** *autonomous-system-number* **Example:** `Device(config)# router bgp 65101`	Configures BGP autonomous system numbers using 2-bytes or 4-bytes in asplain and asdot formats and enters router configuration mode.

	Command or Action	Purpose
Step 4	**address-family ipv4 vrf** *vrf-name* **Example:** `Device(config-router)# address-family ipv4 vrf green`	Enables IPv4 address-family for a VRF instance to enable IPv4 network prefix routing in overlay.
Step 5	**advertise l2vpn evpn** **Example:** `Device(config-route-af)# advertise l2vpn evpn`	Enables advertising the IPv4 network prefix routing between IPv4 VRF instances and EVPN fabric core networks.
Step 6	**redistribute connected** [**metric** |**route-map**] *name* **Example:** `Device(config-route-af)# redistribute connected`	Configures IPv4 address-family to advertise all local connected IPv4 network prefixes in EVPN fabric network. • The network prefix can be advertised with network command-line as an alternative.
Step 7	**exit** **Example:** `Device(config-route-af)# exit`	Exits IPv4 address-family configuration mode and returns to router configuration mode
Step 8	**address-family ipv6 vrf** *vrf-name* **Example:** `Device(config-router)# address-family ipv6 vrf green`	Enables IPv6 address-family for a VRF instance to enable IPv6 network prefix routing in overlay.
Step 9	**advertise l2vpn evpn** **Example:** `Device(config-route-af)# advertise l2vpn evpn`	Enables IPv6 network prefix routing between IPv6 VRF instances and EVPN fabric core networks.
Step 10	**redistribute connected** [**metric** |**route-map**] *name* **Example:** `Device(config-route-af)# redistribute connected`	Configures an IPv6 address-family to advertise all local connected IPv6 network prefixes in EVPN fabric network. • The network prefix can be advertised with network command-line as an alternative.
Step 11	**end** **Example:** `Device(config-route-af)# end`	Exits IPv6 address-family configuration mode and returns to privileged EXEC mode.

Verify the DAG routed overlay configuration

This section provides examples to verify the DAG routed overlay network configuration and states of VTEPs.

The command output may be truncated to focus on critical information for a Day-2 operation and troubleshooting.

IP VRF networks: Verifies the locally configured IP VRF and the associated physical or logical interface bindings to a virtual network on VTEPs including leaf and border devices. The interface binding includes the network edge VLANs connecting to endpoints, and network devices, along with a single core VLAN (VLAN 101) of an IP VRF.

```
ES-1# show vrf green

  Name      Default RD            Protocols   Interfaces
  green     10.200.255.101:101    ipv4   Vl11
                                             Vl111
                                             Vl101

BORDER-1# show vrf green

  Name      Default RD            Protocols    Interfaces
  green     10.200.255.1:101      ipv4    Vl101
                                              Vl1101
```

BGP L2VPN EVPN neighbors: Verifies that the two-tier hierarchical iBGP sessions between switches in EVPN multihoming mode and iBGP peering to a pair of spine systems are in operational state.

The following command output shows iBGP peering with a pair of spines switches, 10.100.255.3 and 10.100.255.4 and direct iBGP peering between ES-1, local 10.100.255.101 and ES-2, 10.100.255.102 switches in EVPN multihoming mode is operational.

```
ES-1# show bgp l2vpn evpn all summary

BGP router identifier 10.100.255.101, local AS number 65101
<snip>

Neighbor        V    AS     MsgRcvd  MsgSent   TblVer  InQ   OutQ    Up/Down    State/PfxRcd

10.100.255.3     4    65101    18        20      104     0      0     00:04:35         2
10.100.255.4     4    65101    23        25      106     0      0     00:05:19         2
10.100.255.102   4    65101    51        65      104     0      0     00:04:26         28
```

Spine policy: Verifies the VTEP in leaf or border roles implemented in EVPN multihoming mode is configured with a route-map and an outbound policy is applied to each spine, 10.200.255.3.

The spine policy configuration on border switches is optional and not required if the switches are not implemented in EVPN multihoming mode to connect to external network devices, such as firewalls.

```
ES-1# show bgp l2vpn evpn neighbor 10.200.255.3 policy

Neighbor: 10.200.255.3, Address-Family: L2VPN E-VPN
 Locally configured policies:
  send-community extended
 Inherited polices:
  route-map EVPN-SPINE-ROUTE-POLICY-OUT out
```

L2VPN advertised routes: Verifies the VTEP in leaf or border roles implemented in EVPN multihoming mode is advertising the EVPN prefixes to the spine, 10.200.255.3, based on the applied route-map policy.

The following command output from leaf and border switches confirms the advertising of RT-2-MAC-IP EVPN prefixes, and that no additional EVPN route-types are advertised to the spine switches.

```
ES-1# show bgp l2vpn evpn neighbor 10.200.255.3 advertised-route

BGP table version is 7179, local router ID is 10.200.255.101

                      21.1.1.1               0          0      65001      ?
 *>   [5][10.100.255.1:101][0][16][111.1.0.0]/17
                      21.1.1.1               0          0      65001      ?
```

MAC-VRF manual route-target: Verifies that the stretched IP-subnet VLAN is limited to import and export of the MAC or IP route matching the local cluster EVPN multihoming peer switch. With auto-route-target disabled, the import and export route-target only lists the manual configuration settings.

The following command output confirms that the bidirectional MAC route policy with route-target 1.1.1.1:111 and the default auto-generated ASN:Instance ID 65101:111 is not listed along with the manual configuration.

```
ES-1# show l2vpn evpn evi 111 detail

EVPN instance:           111 (VLAN Based)
  RD:                    10.200.255.101:111 (auto)
  Import-RTs:            1.1.1.1:111
  Export-RTs:            1.1.1.1:111
  Per-EVI Label:         none
  State:                 Established
  Replication Type:      Ingress (global)
 <snip>
```

IP local proxy: Verifies the stretched IP-subnet SVI interface configured to support the IPv4 ARP local proxy function.

Use the **show ip interface vlan** command to verify the Anycast Gateway SVI interface. Network administrators can verify the ARP entries on local hosts to confirm the common IP gateway and the remote host IP-to-MAC binding entries.

```
ES-1# show ip interface vlan111

Vlan111 is up, line protocol is up
  Internet address is 10.111.1.254/24
  Broadcast address is 255.255.255.255
  Address determined by non-volatile memory
```

```
  MTU is 9100 bytes
 <snip>
  Proxy ARP is enabled
  Local Proxy ARP is enabled
<snip>
```

VRF IP routing table: Verifies that the leaf implemented in EVPN multihoming mode is advertising the EVPN prefixes to the spine switch 10.200.255.3 based on the applied route-map policy.

The following command output from the border switch confirms that the pair of EVPN multihoming leaf systems configured in DAG routed overlay, each with two hosts are advertising RT2-MAC-IP. Border switches have a dual-path ECMP for each host to support load-sharing and redundancy for overlay network prefixes. And leaf switches receive RT-5 network prefix from the IP routing table of IP VRFs in the border systems that confirm the advertising of RT-5 EVPN prefixes.

```

Reference configuration for DAG routed overlay networks

This section provides a reference network design and configuration to implement end-to-end Layer 2 flood-free DAG routed overlay fabric network.

This following figure illustrates a reference network design to support scalable EVPN multihoming and fabric core with hierarchical BGP peering, control-plane peering, and selective stretching of an IP subnet between a pair of switches deployed in the distribution block with overlay fabric network.

Figure 213: EVPN multihoming: DAG routed overlay fabric network

This reference configuration shows a three-step process, from the initial network setup to the successful fabric deployment. Network administrators can follow these steps sequentially for initial deployment and to increment the overlay network configuration as the network demands increase.

Layer 2 EVPN multihoming

The base configuration to build a fabric begins with Layer 2 campus networks using EVPN multihoming technology. This section provides the step-by-step configuration on a pair of switches to successfully build a non-blocking all-active Layer 2 network with EVPN multihoming.

Step	ES-1 and ES-2	ES-3 and ES-4

Underlay: fabric core and BGP peering

Enterprise campus core networks with solid underlay network foundation are the key for highly scalable, resilient BGP EVPN VXLAN fabric networks. This section is the second step to build a reliable underlay core network for fabric and hierarchical BGP peering on targeted network devices with specific roles.

Note The table is subdivided into two fabric roles with each step either sharing common configuration or a unique per-device with a common role.

Step	ES-1, ES-2, ES-3 and ES-4	Spine-1 and Spine-2	Border-1 and Border-2
1: Global best practices	! system mtu 9100 ! port-channel load-balance vlan-src-dst-mixed-ip-port ip cef load-sharing algorithm include-ports source destination protocol ! ip tcp mss 8000 ip tcp window-size 262144 ip tcp path-mtu-discovery !	! system mtu 9100 ! port-channel load-balance vlan-src-dst-mixed-ip-port ip cef load-sharing algorithm include-ports source destination protocol ! ip tcp mss 8000 ip tcp window-size 262144 ip tcp path-mtu-discovery !	! system mtu 9100 ! port-channel load-balance vlan-src-dst-mixed-ip-port ip cef load-sharing algorithm include-ports source destination protocol ! ip tcp mss 8000 ip tcp window-size 262144 ip tcp path-mtu-discovery !
