Application Performance Monitoring Commands

Commands for application performance monitoring (APM) refer to Assurance-related metrics collected per network application, for flows forwarded through specific interfaces, to support Assurance monitoring by Cisco DNA Center.

APM Overview

Cisco DNA Assurance

Assurance collects and analyzes network data to help provide better and more consistent network performance. Cisco DNA Center uses Flexible NetFlow (FNF) to collect specific network metrics for Assurance, providing quantitative and qualitative information about devices in the network. The FNF records designed for Assurance-related metrics are specially optimized for improved performance.

FNF provides a pair of record types (for IPv4 and IPv6) to collect data for Assurance. Monitoring Assurance metrics using these dedicated record types is optimized to provide better performance, as compared with typical FNF monitors configured to collect the same metrics. (Modifying the records cancels the dedicated performance enhancements for Assurance, and may prevent attaching a monitor to an interface.)

Manual Configuration

In typical use, Cisco DNA Center configures the monitors to collect data for Assurance, without requiring user input. However, it is also possible to use these record types manually.

Metrics Collected for Assurance

Most of the metrics collected for Assurance are metrics that have been available through FNF and other monitor types, but when they are collected specifically for Assurance records, some metrics may behave slightly differently.

Table 1: Metrics

Metric	Information
match ipv4/ipv6 version	IPv4/IPv6 version from IPv4/IPv6 header. [1]
match ipv4/ipv6 protocol	Layer 4 protocol from the IPv4/IPv6 header.
match application name	Application ID.
match connection client ipv4/ipv6 address	Field name: clientIPv4/IPv6Address IPv4/IPv6 client address in the IP packet header. The client is the device that triggered the session creation, and remains the same for the life of the session. [2]
match connection server ipv4/ipv6 address	Field name: serverIPv4/IPv6Address IPv4/IPv6 server address in the IP packer header. The server is the device that replies to the client, and remains the same for the life of the session. [2]
match connection server transport port	Field name: serverTransportPort Server transport port identifier. This may be the source or destination transport port. The server is the device that replies to the client, and remains the same for the life of the session. [2]
match flow observation point	Field name: observationPointId Identifier of an observation point unique for each observation domain. [2]
collect connection initiator	Field name: biflowDirection By convention, this field is set to Initiator. [2]
collect flow direction	Direction (ingress/egress) of the initiator side of the flow (as is set by convention in the connection initiator field).

Metric	Information
collect routing vrf input	Field name: ingressVRFID (Applies only to routers, not wireless controllers) VRF ID from incoming packets on a router. If a packet arrives on an interface that does not belong to a VRF, a VRF ID of 0 is recorded.
collect wireless client mac address	(Applies only to wireless controllers) Field name: staMacAddress The IEEE 802 MAC address of a wireless station (STA).
collect timestamp absolute first	Field name: flowStartMilliseconds The absolute timestamp of the first packet of the flow.
collect timestamp absolute last	Field name: flowEndMilliseconds The absolute timestamp of the last packet of the flow.
collect connection new-connections	Field name: connectionCountNew This information element counts the number of TCP or UDP connections which were opened during the observation period. The observation period may be specified by the flow start and end timestamps. [2]
collect connection server counter packets long	Field name: serverPackets Number of layer 4 packets in a flow from the server. The server is the device that replies to the client, and remains the same for the life of the session. [2]
collect connection server counter bytes network long	Field name: serverOctets Overall IP packet bytes in a flow from the server. The server is the device that replies to the client, and remains the same for the life of the session. [2]
collect connection client counter packets long	Field name: clientPackets Number of layer 4 packets in a flow from the client. The client is the device that triggered the session creation, and remains the same for the life of the session. [2]
collect connection client counter bytes network long	Overall IP packet bytes from client to server. [2]

Metric	Information
collect connection delay network client-to-server sum	Field name: sumNwkTime Network delay is the round-trip time between the client and the server, as measured by the observation point, calculated once per session. The value of this information element is the sum of all network delays observed for the sessions of this flow. [2] [3]
collect connection delay network to-server sum	Field name: sumServerNwkTime Server network delay is the round-trip time between the observation point and the server, calculated once per session. The value of this information element is the sum of all server network delays observed for the sessions of this flow. [2] [3]
collect connection client counter packets retransmitted	Field name: retransClientPackets Number of packets retransmitted by the client. [2] [3]
collect connection server counter packets retransmitted	Field name: retransServerPackets Number of packets retransmitted by the server. [3]
collect connection delay application sum	Field name: sumServerRespTime The sum of all application delays observed for all responses of the flow. [2] [3]
collect connection server counter responses	Field name: numRespsCountDelta Total number of responses sent by the server. [2] [3]

Notes

- [1] See the Cisco IOS Flexible NetFlow Command Reference.
- [2] See the Cisco AVC Field Definition Guide.
- [3] This metric can be used in Cisco Performance Monitor record types. It can be used with FNF only as part of the specially optimized Assurance-related records. Attempting to use this metric in a different FNF record type causes the record to be rejected when attaching it to an interface.

Configure Assurance Monitors Outside of Cisco DNA Center

In typical use, Cisco DNA Center configures the monitors without requiring additional user input, but it is possible to configure monitors for Assurance-related metrics manually.

Method	Applicable to...	See section...
ezPM profile	Platforms that support ezPM Not wireless controllers	Configure Assurance Monitors Using ezPM, on page 7
Predefined FNF records for Assurance	Routers Wireless controllers	Configure Assurance Monitors Using Predefined FNF Records, on page 8

Configure Assurance Monitors Using ezPM

Applicable to: routers, not wireless controllers

The application-assurance ezPM profile makes use of the application performance monitoring (APM) FNF records designed for Assurance-related metrics. Configuring APM with ezPM simplifies the configuration as compared to working with the FNF records directly.

1. Configure the ezPM context.

   performance monitor context *context-name* **profile application-assurance**
   traffic-monitor assurance-monitor ipv4
   traffic-monitor assurance-monitor ipv6

2. Attach the context to an interface. The following command attaches the performance monitor to an interface, monitoring both input and output.

   interface *interface*
   performance monitor context *context-name*

Result

This attaches monitors to the interface to collect Assurance-related metrics.

Example

In the following example, a monitor called *apm* is attached to the Gigabit Ethernet 1 interface.

```
performance monitor context apm profile application-assurance
traffic-monitor assurance-monitor ipv4
traffic-monitor assurance-monitor ipv6

interface GigabitEthernet1
performance monitor context apm
```

Configure Assurance Monitors Using Predefined FNF Records

Applicable to: routers, wireless controllers

ezPM is the preferred method for configuring monitors for Assurance-related metrics, but it is also possible to use the FNF records predefined for these metrics. For platforms that do not support ezPM, predefined FNF records are the preferred method.

The FNF records designed for Assurance-related metrics are optimized for improved performance.

Routing Platforms

1. Define two flow monitors for assurance-related metrics, one for IPv4 and one for IPv6.

   ```
   flow monitor monitor-name-for-ipv4
   cache entries 100000 {Optional. Recommended value depends on platform.}
   record netflow ipv4 assurance
   flow monitor monitor-name-for-ipv6
   cache entries 100000 {Optional. Recommended value depends on platform.}
   record netflow ipv6 assurance
   ```

2. Attach the context to an interface. The following command attaches the performance monitor to an interface, monitoring both input and output.

   ```
   interface interface
   ip flow monitor monitor-name-for-ipv4 input
   ip flow monitor monitor-name-for-ipv4 output
   ipv6 flow monitor monitor-name-for-ipv6 input
   ipv6 flow monitor monitor-name-for-ipv6 output
   ```

Result

The preceding commands attach two IPv4 and two IPv6 monitors to the interface for collecting the metrics that are needed for Assurance.

Example

This example defines monitors called assurance-ipv4 and assurance-ipv6, and attaches the monitors to the GigabitEthernet1 interface.

```
flow monitor assurance-ipv4
cache entries 100000
record netflow ipv4 assurance

flow monitor assurance-ipv6
cache entries 100000
record netflow ipv6 assurance

interface GigabitEthernet1
ip flow monitor assurance-ipv4 input
ip flow monitor assurance-ipv4 output
ipv6 flow monitor assurance-ipv6 input
ipv6 flow monitor assurance-ipv6 output
```

Wireless Platforms

1. Enter the configuration mode for the relevant wireless profile.

```
interface policy-name
```

2. Define two monitors for the wireless controller, one for IPv4 and one for IPv6.

```
flow monitor monitor-name-wlc-for-ipv4
cache entries 100000 {Optional. Recommended value depends on platform.}
record wireless avc ipv4 assurance
flow monitor monitor-name-wlc-for-ipv6
cache entries 100000 {Optional. Recommended value depends on platform.}
record wireless avc ipv6 assurance
```

3. Attach the two flow monitors to the wireless profile, including input and output traffic.

```
wireless profile policy policy-name
ip flow monitor monitor-name-for-wireless-ipv4 input
ip flow monitor monitor-name-for-wireless-ipv4 output
ipv6 flow monitor monitor-name-for-wireless-ipv6 input
ipv6 flow monitor monitor-name-for-wireless-ipv6 output
```

Example

This example defines monitors called *assurance-wlc-ipv4* and *assurance-wlc-ipv6*, and attaches the monitors to a wireless profile.

```
flow monitor assurance-wlc-ipv4
cache entries 100000
record wireless avc ipv4 assurance

flow monitor assurance-wlc-ipv6
cache entries 100000
record wireless avc ipv6 assurance

wireless profile policy AVC_POL
central association
central switching
ip flow monitor assurance-wlc-ipv4 input
ip flow monitor assurance-wlc-ipv4 output
ipv6 flow monitor assurance-wlc-ipv6 input
ipv6 flow monitor assurance-wlc-ipv6 output
no shutdown
```

About Attaching the Assurance Monitors to Interfaces

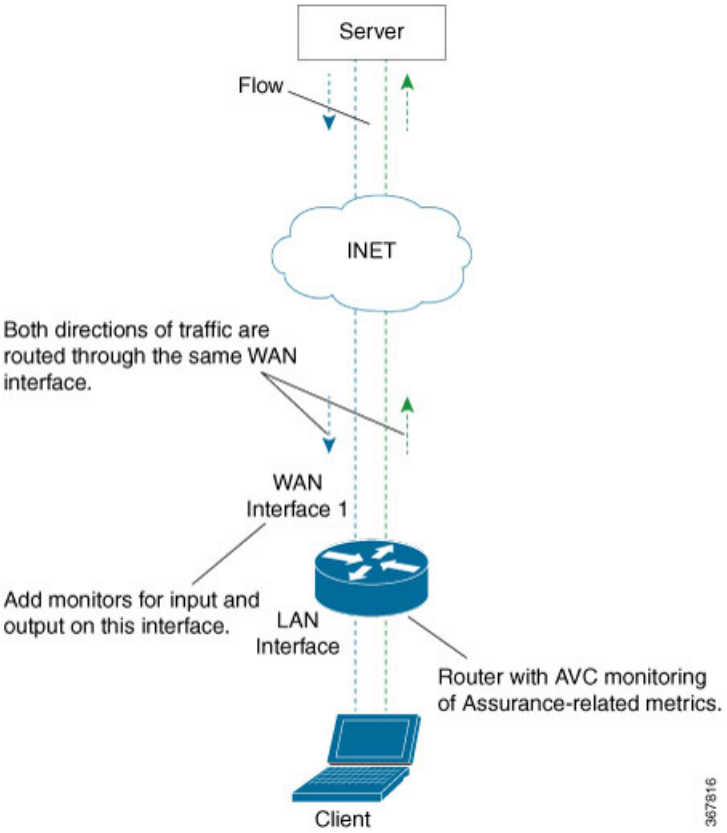
Monitor a Flow on Only One Interface

Monitors for Assurance-related metrics should only see a single flow one time. In the typical symmetric routing scenario, they should monitor the flow on only one interface.

Do not attach monitors for Assurance-related metrics to two separate interfaces that handle both directions of the same flow. Doing so will cause incorrect traffic metrics to be reported. For example, if traffic enters a device on interface A and leaves on interface B, do not attach monitors for Assurance-related metrics to both interfaces A and B.

The following figure shows the typical symmetric routing, with monitors for input and output on the same interface.

Figure 1: Symmetric Routing

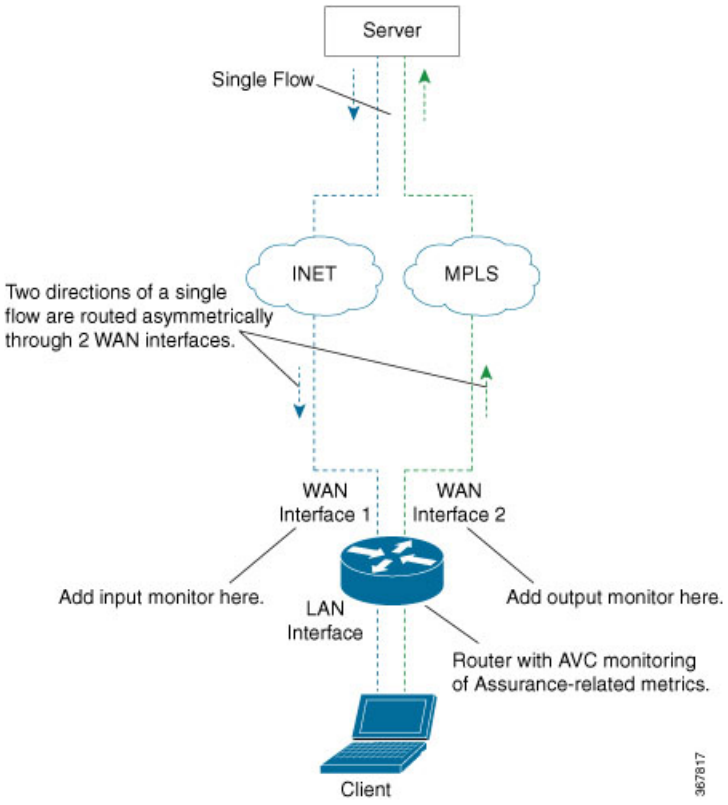


Asymmetric Routing

In some cases, such as for asymmetric routing, it might be necessary to attach a monitor for input on one interface, and a monitor for output on another interface.

In some scenarios, a single flow may be routed asymmetrically, with upstream and downstream traffic for the flow occurring on two different interfaces. In this case, place monitors for input and output on two separate interfaces to monitor the complete flow.

Figure 2: Asymmetric Routing



View Details of Assurance Records and Contexts

After you attach a context to an interface, two **show** commands can be used to display information about Assurance records or about contexts.

Displaying Structure of the Assurance Record

The following command displays the structure of the predefined Assurance records (IPv4 and IPv6).

show flow record netflow {ipv4 | ipv6} assurance

Displaying Configuration of a Context

The following command displays the full configuration of a specified context.

show performance monitor context *context-name* **configuration**

The following output shows the Assurance-related monitoring through an ezPM context, called ApmContext, attached to a router interface.

```
Device#show performance monitor context ApmContext configuration

Assurance-Related Metrics and Elephant Flows

In networking, especially long flows are called *elephant flows* and can pose a challenge to networking resources.

In a case where a single high-burst flow consumes too many QFP resources, the monitor collecting Assurance metrics might stop collecting qualitative metrics for the flow, to preserve resources for other traffic. No other traffic is affected.

Quantitative metrics are collected fully:

- Flow packets start time
- Flow packets end time
- Packets
- Bytes

Qualitative metrics are not collected fully:

- Total network delay sum (in the TCP handshake)
- Network to-server delay sum (in the TCP handshake)
- Client packets retransmitted
- Server packets retransmitted
- Application delay sum
- Number of server application responses
