Revised: April 23, 2024

New and Changed Information

The following table provides an overview of the significant changes up to this current release. The table does not provide an exhaustive list of all changes or of the new features up to this release.

Cisco ACI CNI plug-in Release Version	Feature
6.0(4)	Support for Red Hat OpenShift 4.14 on VMware vSphere 7 User-Provisioned Infrastructure (UPI).

Openshift 4.14 on VMware vSphere

Cisco ACI supports Red Hat OpenShift 4.14 on VMware vSphere 7 User-Provisioned Infrastructure (UPI). This document provides the instructions on using Ansible playbooks to provision OpenShift 4.14 on VMware vSphere with the Container Network Interface (CNI) plug-in.

The Ansible playbooks provision virtual machines (VMs) with the needed interface configuration and generate the ignition configuration files. You must deploy your own DHCP, DNS, and load-balancing infrastructure following high-availability best practices.

The Ansible playbooks are available on Github.

The following are the Ansible playbooks:

- asserts.yml: This playbook performs basic validations of variable declarations in the all.yml file.
- setup.yml: This playbook performs the following tasks:
 - Configures the orchestrator node:
 - Installs Terraform, the OpenShift client, and the OpenShift installer. It creates the following: Terraform variables for the bootstrap, master, and worker nodes; the master and worker machine-config operator; the OpenShift install config file.
 - Configures load balancer node: It disables Security-Enhanced Linux (SELinux), configures HAProxy, sets up DHCP and DNS if selected.

This optional step configures these three components only if you set the provision_dhcp, provision_dns, and provision_lb variables to true.

• oshift_prep.yml:

- Sets up the install and bootstrap directories.
- · Generates manifests using openshift-install.
- · Adds the additional machine-config operator manifests.
- Adds the Cisco ACI-CNI manifests.
- · Creates a backup of the manifests.
- Sets up the bootstrap, master, and worker nodes ignition files.
- Copies the bootstrap ignition file to the loadbalancer node.

- create_nodes.yml:
 - Provisions the bootstrap, master, and worker nodes, using Terraform.
 - Sets up a cron job to approve Cisco Certificate Signing Requests (CSRs), if selected.
- delete nodes.yml: Deletes all master and worker nodes.

Prerequisites for Installing OpenShift 4.14 on VMware vSphere

To install OpenShift Container Platform (OCP) 4.14 on VMware vSphere, fulfill the following prerequisites:

Cisco ACI

• Download the acc-provision tool version 6.0.4.1.post1 or later.

Specify the "--flavor" option value as "openshift-4.14-esx," and use the "-z" option. The tool creates a .tar archive file as specified by the "-z" option value. You need this archive file during installation.

Make sure that the Cisco ACI container images that are specified as input to the acc-provision tool are version 6.0.4.1.post1 or later.

VMware vSphere

Obtain user credentials with privileges to create virtual machines (VMs).

OpenShift

Obtain the following from the Red Hat website:

- The OCP4 Open Virtualization Appliance (OVA) ensure to download the relevant release of the OVA image. Navigate to the *mirror* page on the OpenShift website where all the RHCOS versions are listed, and select the required version. Download the rhcos-vmware.x86 64.ova file.
- OCP4 client tools navigate to the *mirror* page on the OpenShift website where the installation and client tool versions are listed, and select the required version. Download the openshift-client-linux.tar.gz and openshift-install-linux.tar.gz files.
- Pull Secret

Installing OpenShift 4.14 on VMware vSphere

Note See the Sample Ansible group_vars/all.yml File, on page 12 section.

Before you begin

Complete the tasks in the *Prerequisites* section, described above.

It is recommended to see the *RedHat OpenShift documentation* for prerequisites and other details about Installing a Cluster on vSphere.

Procedure

Step 1 Provision the Cisco ACI fabric using the acc-provision utility:
acc-provision -a -c acc_provision_input.yaml -u admin -p ### -f openshift-4.14-esx -z manifests.tar.gz
See the Sample acc-provision-input file, on page 11 section.
Note Due to Python 3 dependencies that are currently available only on RHEL8, acc-provision tool is supported to only run on RHEL8 operating system.
Step 2 After the Cisco ACI fabric is provisioned, verify that a port group with the name system_id_vlan_kubeapi_vlan is created under distributed switch.
This document refers to this port group as api-vlan-portgroup.
Note api-vlan-progroup port-group in VMware Distributed Virtual Switch is created using custom VLAN ID provided in the acc_provision_input file as kubeapi_vlan.
Figure 1: VMM VMware domain association with aci-containers-node EPG

Edit VMM Domain Association - VMware/hypflex-vswitch

	Delimiter:				
Enhance	d Lag Policy:	select an option		~	
Allow Micro-S	egmentation:				
Untagged V	LAN Access:				
	VLAN Mode:	Dynamic Stati	c		
P	rimary VLAN:	For example, vlan-1			
	Port Encap:	vlan-35 For example, vlan-1

Active U	plinks Order:				
0		Enter IDs of uplinks separate	ed by comma		
Star	ndby Uplinks:	Enter IDs of uplinks separate	ed by comma		
Custon	n EPG Name:	ocp48_vlan_35			

Kube_api VLAN is added to the dynamic VLAN pool associated with the VMware VMM Domain. Allocation mode will be set to Static.

Figure 2: VLAN Pool used for VMM VMware domain

Allocation Mode:	Dynamic Allocation				
Encap Blocks:					+
	VLAN Range	Description	Allocation Mode	Role	
	[20-25]		Inherit allocMode from parent	External or On the wire encapsulations	
[[35]		Static Allocation	External or On the wire encapsulations	

Step 3 In VMware vSphere, import the OpenShift Container Platform 4 (OCP4)Open Virtual Appliance (OVA) image.

Specify api-vlan-portgroup as the port group for the network interface.

Step 4 Provision a Red Hat Enterprise load balancer virtual machine (VM) with the network interface that is connected to the api-vlan-portgroup.

The Ansible playbooks optionally configure this VM as a load balancer, DNS server, and DHCP server for the OpenShift cluster.

Step 5 Provision a Red Hat Enterprise orchestrator VM with the network interface that is connected to the api-vlan-portgroup.

The Ansible playbooks play from the orchestrator VM.

- **Step 6** Perform the following tasks on the orchestrator VM:
 - a) Clone the Git repository on GitHub: https://github.com/noironetworks/openshift_vsphere_upi.
 - b) Checkout the "ocp414" branch.
 - c) Generate Secure Shell (SSH) keys and copy them to the load balancer VM.
 - d) Enable the ansible-2.9-for-rhel-8-x86 64-rpms repository.
 - e) Update the Ansible package to the latest version.
 - f) Change the directory to the Git-cloned directory.
 - g) Install the Ansible module requirements:

```
ansible-galaxy install -r requirements.yaml
```

h) Edit the groups/all.yml and hosts.ini files and set the values that your site requires.

See the Sample hosts.ini file, on page 14 section.

i) Perform basic validation of variable values using the asserts.yml playbook:

ansible-playbook asserts.yml

- j) Copy the archive file that was created by the acc-provision utility to the files directory, giving it the name aci_manifests.tar.gz.
- k) Run the Ansible setup playbook:

```
ansible-playbook setup.yml
```

Running the setup playbook configures the orchestrator and load balancer VMs.

1) Run the Ansible oshift prep playbook:

ansible-playbook oshift_prep.yml

Running the oshift_prep generates the OpenShift manifests and ignition files.

m) Run the Ansible create_nodes playbook:

ansible-playbook create nodes.yml

The create_nodes playbook creates the VMs. After the VMs are created, the OCP4 installation process starts in the background. At this stage, you should be able to access the cluster APIs by using the kubeconfig files created by the installer.

The kubeconfig files are located at *base_dir*/bootstrap/auth directory. The base_dir is set in group vars/all.yml file, and the default value is/root/ocpinstall.

What to do next

You can use the commands openshift-install wait-for bootstrap-complete and openshift-install wait-for install-complete to check the progress of the installation. Execute the commands from the bootstrap directory.

Updating the Default Ingress Controller

For updating the default Ingress Controller publish strategy to use the ACI Loadbalancer, log in as a user with cluster-admin privileges and run the following:

```
oc replace --force --wait --filename - <<EOF
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
   namespace: openshift-ingress-operator
   name: default
spec:
   endpointPublishingStrategy:
    type: LoadBalancerService
   loadBalancer:
        scope: External
EOF</pre>
```

For more details, see the Configuring the default Ingress Controller for your cluster to be internal section in the Ingress Operator in OpenShift Container Platform Red Hat guide.

Configuring MachineSets with ACI CNI

The Machine API is a combination of primary resources that are based on the upstream Cluster API project and custom OpenShift Container Platform resources.

For OpenShift Container Platform 4.14 clusters, the Machine API performs all node host provisioning management actions after the cluster installation is completed. OpenShift Container Platform 4.14 offers an elastic, dynamic provisioning method on top of public or private cloud infrastructure because of the Machine API.

The two primary resources are:

- Machines-A fundamental unit that describes the host for a node. A machine has a providerSpec specification, which describes the types of compute nodes that are offered for different cloud platforms. For example, a machine type for a worker node on Amazon Web Services (AWS) might define a specific machine type and required metadata.
- MachineSet-MachineSet resources are groups of machines. Machine sets are to machines as replica sets are to pods. If you need
 more machines or must scale them down, you change the replicas field on the machineset to meet your compute need.

Changes to operating systems on OpenShift Container Platform nodes can be done by creating MachineConfig objects that are managed by the Machine Config Operator.

Creating a MachineConfiguration File

Use this procedure to create a MachineConfig file that will configure network interfaces for the new nodes with:

- ACI Infra interface (ens224)
- ACI Infra SubInterface (ens224. {InfraVlanID})
- Opflex-route for BUM traffic replication (224.0.0.0/4)

The required configurations (sample) are shown in the procedure below, however, they need to be customized to match your specific environment. In general the following changes are required:

- Replace every occurence of {InfraVLAN} with the ACI Infra VLAN for your fabric.
- Replace every occurence of {MTU} with the MTU you selected for your cluster.

Note Ensure that your network interface is *ens224* (not a different name).

Procedure

Step 1 Create an 80-opflex-route.

```
#!/bin/bash
if [ "$1" == "ens224.{InfraVLAN}" ] && [ "$2" == "up" ]; then
route add -net 224.0.0.0 netmask 240.0.0.0 dev ens224.{InfraVLAN}
fi
```

Step 2 Create an ens224.nmconnection.

```
[connection]
id=ens224
type=ethernet
interface-name=ens224
multi-connect=1
permissions=
[ethernet]
mac-address-blacklist=
mtu={MTU}
[ipv4]
dns-search=
method=disabled
```

[ipv6]
addr-gen-mode=eui64
dns-search=
method=disabled

[proxy]

Step 3 Create an ens224.{InfraVLAN}.nmconnection.

```
[connection]
id=ens224.{InfraVLAN}
type=vlan
interface-name=ens224.{InfraVLAN}
multi-connect=1
permissions=
[ethernet]
mac-address-blacklist=
[vlan]
egress-priority-map=
flags=1
id={InfraVLAN}
ingress-priority-map=
parent=ens224
[ipv4]
dns-search=
method=auto
[ipv6]
addr-gen-mode=eui64
dns-search=
method=auto
[proxy]
```

Step 4 Convert the above three configurations (steps 1,2,3) into *base64* encoded strings, and use it in the machineconfig (after base64) template, as shown below.

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
 labels:
   machineconfiguration.openshift.io/role: worker
 name: 00-worker-cni
spec:
 config:
   ignition:
     version: 3.2.0
   storage:
     files:
      - contents:
          source: data:text/plain;charset=utf-8;base64,
                  IyEvYmluL2Jhc2gKIGlmIFsgIiQxIiA9PSAiZW5zMjI0LjM0NTYiIF0gJiYgWyAi
                  JDIiID09ICJ1cCIqXTsqdGhlbqoqcm91dGUqYWRkIC1uZXQqMjI0LjAuMC4wIG51d
                  G1hc2sgMjQwLjAuMC4wIGRldiBlbnMyMjQuMzQ1NgogZmk=
       mode: 0755
       overwrite: true
       path: /etc/NetworkManager/dispatcher.d/80-opflex-route
      - contents:
          source: data:text/plain;charset=utf-8;base64,
                  W2Nvbm51Y3Rpb25dCmlkPWVuczIyNAp0eXB1PWV0aGVybmV0CmludGVyZmFjZS1uYW11PWVuczIy
                  NAptdWx0aS1jb25uZWN0PTEKcGVybWlzc2lvbnM9CgpbZXRoZXJuZXRdCm1hYy1hZGRyZXNzLWJs
                  YWNrbGlzdD0KbXR1PTkwMDAKCltpcHY0XQpkbnMtc2VhcmNoPQptZXRob2Q9ZGlzYWJsZWQKCltpc
                HY2XQphZGRyLWdlbiltb2RlPWV1aTY0CmRucy1zZWFyY2g9CmlldGhvZDlkaXNhYmxlZAoKW3Byb3h5XQ==
```

/etc/NetworkManager/system-connections/ens224.{InfraVLAN}.nmconnection (last line in the sample above). You may also customize the name of the MachineConfig. In the above example, the name is 00-worker-cni.

Step 5 Use the **oc create -f** command to create the MachineConfig for your cluster.

The machineconfig is applied to the pre-existing workers nodes (two) and replaces the three files already existing with identical copies. When you include the md5 configuration in the machine config, three files are created on the node. The pre-existing worker nodes will reboot one at a time.

Step 6 Get you cluster id using the oc get -o jsonpath='{.status.infrastructureName}{"\n"}' infrastructure cluster command.

Step 7 Create the machineset.

Note

```
apiVersion: machine.openshift.io/v1beta1
kind: MachineSet
metadata:
 name: ocp4aci-jlff9-worker
  namespace: openshift-machine-api
  labels:
   machine.openshift.io/cluster-api-cluster: ocp4aci-jlff9
spec:
  replicas: 1
  selector:
   matchLabels:
     machine.openshift.io/cluster-api-cluster: ocp4aci-jlff9
     machine.openshift.io/cluster-api-machineset: ocp4aci-jlff9-worker
  template:
   metadata:
      labels:
        machine.openshift.io/cluster-api-cluster: ocp4aci-jlff9
       machine.openshift.io/cluster-api-machine-role: worker
       machine.openshift.io/cluster-api-machine-type: worker
       machine.openshift.io/cluster-api-machineset: ocp4aci-jlff9-worker
    spec:
      metadata: { }
      providerSpec:
        value:
          numCoresPerSocket: 1
          diskGiB: 120
          snapshot: ''
          userDataSecret:
```

```
name: worker-user-data
memoryMiB: 8192
credentialsSecret:
 name: vsphere-cloud-credentials
network:
 devices:
   - networkName: ocp4aci vlan 35
    - networkName: ocp4aci
metadata:
 creationTimestamp: null
numCPUs: 2
kind: VSphereMachineProviderSpec
workspace:
 datacenter: my-dc
  datastore: mydatastore
 folder: /mydatastore/vm/ocp4aci
  server: myvsphere.local.lab
template: RHCOS414
apiVersion: vsphereprovider.openshift.io/v1beta1
```

The above is a sample configuration, you may need to modify as below:

- Cluster ID is ocp4aci-jlff9. Replace it with the relevant cluster ID.
- Replace ocp4aci_vlan_35 and ocp4aci with your port-groups names (the order is important, ensure not to swap it).
- Set the replicas value to how many new workers you want on top of the one that were created during cluster bring up.
- Edit all the workspace parameters (such as, datacenter, datastore), to match your vSphere settings.
- Edit the VM specifications, if required (memoryMiB, numCPUs and diskGiB).
- **Note** The original workers are not managed by the MachineSet and you can choose to delete them. If you delete a worker, wait for the OCP routers to be started on the new node.

Scaling of Compute Nodes Using MachineSet

Use this procedure to scale compute nodes using MachineSet.

Procedure

Step 1	Create a VM folder - /DC name/vm/cluster name in vCenter; the <i>cluster name</i> is the OpenShift cluster ID. In the example, the folder has been named: /mydatastore/vm/ocp4aci.
Step 2	Create a Template in vCenter.
	Ensure that the <i>template name</i> matches the <i>cluster name</i> in the RHCOS414 template.
Step 3	Create a TAG category called <i>id</i> in vCenter.
Step 4	Configure the DHCP server to allocate IP addresses to the nodes.

Sample Files for Installing OpenShift 4.14 on VMware vSphere

This section contains sample files that you need for installing agent-based OpenShift 4.14 on VMware vSphere.

Sample acc-provision-input file

The following is a sample acc-provision-input.yaml. The highlighted or bold values are those that you must modify to meet your site requirements.

```
#

Sample hosts.ini file

The following is a sample hosts.ini. The highlighted or bold values are those that you must modify to meet your site requirements.

[orchestrator] 192.168.18.200 [lb] 192.168.18.201

Decommissioning OpenShift

Use this procedure to decommission OpenShift and remove the ACI-provisioned configuration from ACI.

Note Starting with Cisco APIC release 5.2, VMM domains for OpenShift cannot be removed from the APIC GUI. It is only possible using REST API, therefore, it is convenient to use the acc-provision tool to remove the VMM domain, and other related objects used by the decommissioned OpenShift cluster. Ensure you have the acc-input-config.yaml file and certificates used by the acc-provision tool to access APIC.

Before you begin

In case of decommissioning or removing Openshift cluster, ACI configuration provisioned for that cluster should be removed from ACI. The acc-provision tool can be used to remove that configuration.

Procedure

Use the following command from the machine and folder which was used to provision the ACI infrastructure, to delete the pre-provisioned configurations and the VMM domain.

acc-provision -d -f openshift-4.14-esx -c acc-input-file -u user -p password

Example:

acc-provision -d -f openshift-4.14-esx -c acc-input-config.yaml -u admin -p password
