

Configuring Layer 4 - Layer 7 Services

This chapter contains the following sections:

- About VXLAN Layer 4 Layer 7 Services, on page 1
- Integrating Layer 3 Firewalls in VXLAN Fabrics, on page 1
- Firewall as Default Gateway, on page 15
- Transparent Firewall Insertion, on page 16
- Firewall Clustering with VXLAN BGP EVPN, on page 22
- Service Redirection in VXLAN EVPN Fabrics, on page 25

About VXLAN Layer 4 - Layer 7 Services

This chapter covers insertion of Layer 4 – Layer 7 services (firewall, load balancer, and so on) in a VXLAN fabric.

As opposed to traditional 3-tier network topologies, in which L4-L7 services are connected to the switches hosting the default gateway (aggregation/distribution), L4-L7 services in VXLAN fabrics are typically connected to the leaf or border switches, often referred to as *services leafs*.

You can attach a L4-L7 services device to a VXLAN fabric in various ways. This chapter addresses the considerations you must take depending on how the L4-L7 services device is attached and the requirements of the device and the network.

Integrating Layer 3 Firewalls in VXLAN Fabrics

This section provides details on how to integrate a firewall within a VXLAN EVPN fabric. A Layer-3 firewall involves separating different security zones.

When integrating a Layer-3 firewall in a VXLAN EVPN fabric with a distributed Anycast Gateway, each of these zones must correspond to a VRF/tenant on the fabric. The traffic within a tenant is routed by the fabric. Traffic between the tenants is routed by the firewall. This scenario often refers to an inter-tenant or tenant edge firewall.

Consider two zones: an inside zone and an outside zone. This scenario requires a VRF definition on the fabric. You can call the VRFs the inside VRF and the outside VRF. Traffic between subnets within the same VRF is routed on the VXLAN fabric using the distributed gateway. Traffic between VRFs is routed by the firewall where the rules are applied.

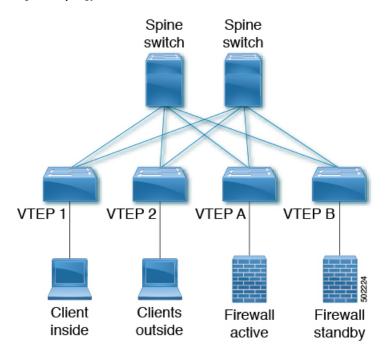

Figure 1: Topology Overview with Firewall Attachment

Single-Attached Firewall with Static Routing

If the firewall does not support running a routing protocol, you must have static routes on each VTEP pointing to the firewall as the next hop. The firewall also has static routes pointing to the Anycast Gateway IP as the next hop. The challenge with a static route is that the VTEP with an active firewall must be the one advertising the routes to the fabric. One way to accomplish this is to track the active firewall reachability via HMM and use this tracking to advertise routes into the fabric. When the active firewall is connected to VTEP A, VTEP A has a static route that tracks where the route is advertised if the firewall IP is learned as the HMM route. When the firewall fails and the standby firewall takes over, VTEP A learns the firewall IP using BGP, and VTEP B learns the firewall IP using HMM. VTEP A withdraws the route, and VTEP B advertises the route into the fabric. See the following example.

VTEP A and VTEP B:

Vlan 10

Route not found
```

Recursive Static Routes Distributed to the Rest of the Fabric

With this approach, the static routes are configured wherever the inside or outside VRF exists. As the next-hop is reachable through host routes (EVPN Route-Type2), the change of the active firewall to standby and vice versa is only seen locally and doesn't introduce any churn to the other VXLAN fabric. This approach can help to better scale and improve convergence.

Any VTEP:

```
VRF context OUTSIDE
Vni 1002000
IP route 10.1.1.0/24 20.1.1.1
! static route on VTEP pointing to Firewall next hop
! firewall VIP 20.1.1.1

VRF context INSIDE
Vni 1001000
IP route 20.1.1.0/24 10.1.1.1
! static route on VTEP pointing to Firewall next hop
! firewall VIP 10.1.1.1
```

Redistribute Static Routes into BGP and Advertise to the Rest of the Fabric

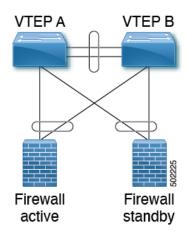

Through redistribution, we make the route toward the active firewall shown to the VTEP where it resides. The route is seen as a prefix route (EVPN Route-Type5), and as such, only the route toward the VTEP with the active firewall is seen. In the case of a firewall active/standby change, the tracking needs to detect the change and inform all of the remote VTEPs of this change. This behavior is equal to a route "delete" followed by an "add." This approach needs to notify all VTEPs with the VRF, and hence a wider churn can be seen.

VTEP A and VTEP B:

```
router bgp 65000
vrf OUTSIDE
address-family ipv4 unicast
redistribute static route-map Static-to-BGP
```

Single-Attached Firewall with eBGP Routing

If the firewall supports BGP, one option is to use BGP as a protocol between the firewall and the service VTEP. Peering using the anycast IP is not supported. The recommended design is to use dedicated loopback IPs on each VTEP and peer using the loopback. As long as the loopback interfaces are not advertised via

EVPN, the same IP address could be used on all of the belonging VTEPs. We recommend using individual IP addresses on a per-VTEP basis.

Reachability to the loopback from the firewall can be configured using a static route on the firewall, pointing to the Anycast Gateway IP on the VTEPs.

In the following example, an eBGP peering is established from the VTEPs, which are in AS 65000, and the firewall in AS 65002. The BGP peering with iBGP is not supported.

Note

When having eBGP peering to active/standby firewalls connected to different VTEPs, **export-gateway-ip** must be enabled.

Do not use Anycast Gateway for BGP peerings.

```

With the VXLAN fabric generally being in a single BGP Autonomous System (AS), the AS of the inside VRF and the outside VRF is the same. BGP does not install routes that are received from its own AS. Therefore, we need to adjust the AS-path to override this rule. Various approaches exist, including disabling the rule that BGP drops routes from its own AS, which has further implications to the network. To keep all of the BGP protection mechanics in place, the "local-as" approach allows you to mimic routes being originated from a different AS. We recommend inserting the "local-as #ASN# no-prepend replace-as" on each firewall peering with different "local-as" per VRF.

Figure 3: eBGP AS-Path Check

Dual-Attached Firewall with eBGP Routing

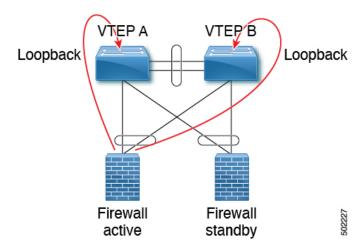

If the firewall supports BGP, one option is to use BGP as a protocol between the firewall and the service VTEP. Peering using the anycast IP is not supported. The recommended design is to use dedicated loopback IPs on each VTEP and peer using the loopback. As long as the loopback interfaces are not advertised via EVPN, the same IP address could be used on all of the belonging VTEPs. We recommend using individual IP addresses on a per-VTEP basis. For vPC environments, it is required.

Reachability to the loopback from the firewall can be configured using a static route on the firewall, pointing to the Anycast Gateway IP on the VTEPs.

In vPC deployments, you must have a per-VRF peering via a vPC peer-link. In addition to the per-VRF peering, you can enable the advertisement of prefix routes (EVPN Route-Type 5) using the **advertise-pip** command. For vPC with fabric peering, the per-VRF peering is not necessary, and the advertisement of prefix routes (EVPN Route-Type5) is required.

In the following example, an eBGP peering is established from the VTEPs, which are in AS 65000, and the firewall in AS 65002. The BGP peering with iBGP is not supported.

Figure 4: Dual-Attached Firewall with eBGP

Note

When having eBGP peering to active/standby firewalls connected to different VTEPs, **export-gateway-ip** must be enabled.

Do not use Anycast Gateway for BGP peerings.

address-family ipv4 unicast
vrf OUTSIDE
neighbor 100.1.2.0 remote-as 65000
 update-source vlan 3967
next-hop self
address-family ipv4 unicast
```

The routes learned in each VRF are advertised to the rest of the fabric via BGP EVPN updates.

Single-Attached Firewall with OSPF

The following example shows a configuration snippet from VTEP A running OSPF peering with the firewall.

SVIs are defined on the VTEP for both inside and outside VRFs. The VTEP peers with the firewall on each of these VRFs dynamically learn routing information to go from one VRF to the other.

VTEP A and VTEP B:

```
vlan 10
name inside
vn-segment 10010

vlan 20
name outside
vn-segment 10020

interface VLAN 10
Description inside_vlan
VRF member INSIDE
IP address 10.1.1.254/24
IP router ospf 1 area 0
fabric forwarding mode anycast-gateway

Interface VLAN 20
Description outside_vlan
VRF member OUTSIDE
```

```
IP address 20.1.1.254/24
IP router ospf 1 area 0
fabric forwarding mode anycast-gateway
interface nvel
 no shutdown
host-reachability protocol bgp
source-interface loopback1
member vni 10010
 mcastgroup 239.1.1.1
member vni 10020
 mcastgroup 239.1.1.1
member vni 1001000 associate-vrf
member vni 1002000 associate-vrf
router ospf 1
router-id 192.168.1.1
  vrf INSIDE
 VRF OUTSIDE
VTEPA# show ip route ospf-1 vrf OUTSIDE
IP Route Table for VRF "OUTSIDE"
'*' denotes best ucast next-hop
'**' denotes best mcast next-hop
'[x/y]' denotes [preference/metric]
'%<string>' in via output denotes VRF <string>
10.1.1.0/24, ubest/mbest: 1/0
  *via 20.1.1.1 Vlan20, [110/41], 1w5d, ospf-1, intra
VTEPA# show ip route ospf-1 vrf INSIDE
IP Route Table for VRF "INSIDE"
'*' denotes best ucast next-hop
'**' denotes best mcast next-hop
'[x/y]' denotes [preference/metric]
'%<string>' in via output denotes VRF <string>
20.1.1.0/24, ubest/mbest: 1/0
  *via 10.1.1.1 Vlan10, [110/41], 1w5d, ospf-1, intra
```

This route is then redistributed into BGP and advertised through the EVPN fabric so that all other VTEPs have all routes in each VRF pointing to VTEP A as the next hop.

Redistribute OSPF Routes into BGP and Advertise to the Rest of the Fabric

VTEP A and VTEP B:

```
router bgp 65000
vrf OUTSIDE
address-family ipv4 unicast
  redistribute ospf 1 route-map OUTSIDEOSPF-to-BGP
vrf INSIDE
  address-family ipv4 unicast
  redistribute ospf 1 route-map INSIDEOSPF-to-BGP

VTEPA# show ip route 10.1.1.0/24 vrf OUTSIDE

10.1.1.0/24 ubest/mbest: 1/0
  *via 10.1.1.18%default, [200/41], 1w1d, bgp-65000, internal, tag 65000 (evpn) segid:
200100 tunnelid: 0xa010112 encap: VXLAN
```

Traffic is VXLAN encapsulated from VTEP to services VTEP and decapsulated and sent to the firewall. The firewall enforces the rules and sends the traffic to the services VTEP on the inside VRF. This traffic is then VXLAN encapsulated and sent to the destination VTEP where traffic is decapsulated and sent to the end client.

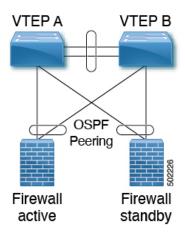

Firewall Failover

When the active firewall fails and the standby firewall takes over, routes are withdrawn from service VTEP A and advertised to the fabric by service VTEP B.

Dual-Attached Firewall with OSPF

Cisco NX-OS supports dynamic OSPF peering over vPC using Layer 3, which enables firewall connectivity using vPC and establishes OSPF peering over this link. The VLAN used to establish peering between the Cisco Nexus 9000 switches and the firewall must be a non-VXLAN-enabled VLAN.

Figure 5: Dual-Attached Firewall with OSPF

Note

Do not use Anycast Gateway for OSPF adjacencies.

```

Redistribute OSPF Routes into BGP and Advertise to the Rest of the Fabric

VTEP A and VTEP B:

```
router bgp 65000
vrf OUTSIDE
  address-family ipv4 unicast
  redistribute ospf 1 route-map OUTSIDEOSPF-to-BGP
vrf INSIDE
  address-family ipv4 unicast
  redistribute ospf 1 route-map INSIDEOSPF-to-BGP
```

Firewall as Default Gateway

In this deployment model, the VXLAN fabric is a Layer 2 fabric, and the default gateway resides on the firewall.

For example:

```
vlan 10
 name WEB
  vn-segment 10010
vlan 20
 name APPLICATION
  vn-segment 10020
vlan 30
 name DATABASE
  vn-segment 10030
interface nvel
 no shutdown
 host-reachability protocol bgp
  source-interface loopback1
 member vni 10010
  mcastgroup 239.1.1.1
 member vni 10020
  mcastgroup 239.1.1.1
  member vni 10030
   mcastgroup 239.1.1.1
```

The firewall has a logical interface in each VNI and is the default gateway for all endpoints. Every inter-VNI communication flows through the firewall. Take special care with the sizing of the firewall so that it does not become a bottleneck. Therefore, use this design in environments with low-bandwidth requirements.

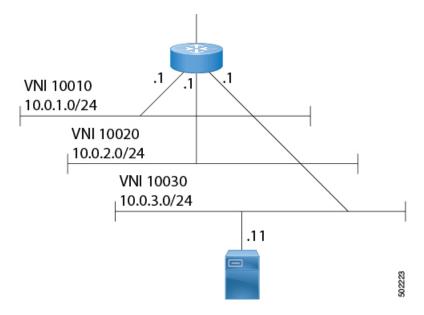

Figure 6: Firewall as Default Gateway with a Layer-2 VXLAN Fabric

Transparent Firewall Insertion

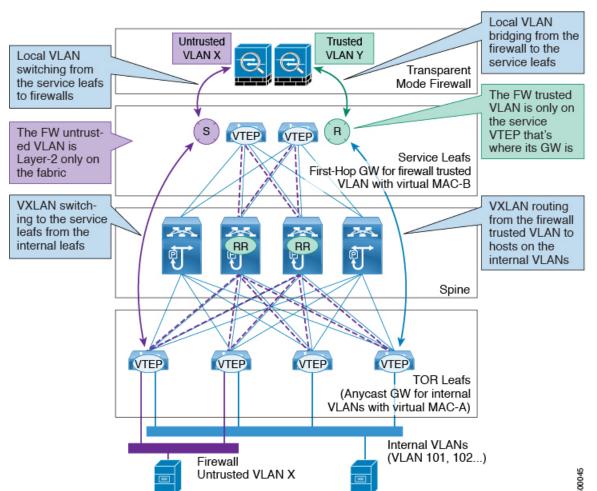

Transparent firewalls or Layer 2 firewalls (including IPS/IDS) typically bridge between an inside VLAN and outside VLAN and inspect traffic as it traverses through them. VLAN stitching is done by placing the default gateway for the service on the inside VLAN. The Layer 2 reachability to this gateway is done on the outside VLAN.

Overview of EVPN with Transparent Firewall Insertion

The topology contains the following types of VLANs:

- Internal VLAN (a regular VXLAN on ToR leafs with Anycast Gateway)
- Firewall untrusted VLAN X
- Firewall trusted VLAN Y

In this topology, the traffic that goes from VLAN X to other VLANs must go through a transparent Layer 2 firewall that is attached to the service leafs. This topology utilizes an approach of an untrusted VLAN X and a trusted VLAN Y. All ToR leafs have a Layer 2 VNI VLAN X. There is no SVI for VLAN X. The service leafs that are connected to the firewall have Layer 2 VNI VLAN X, non-VXLAN VLAN Y, and SVI Y with an HSRP gateway.

Overview of EVPN with Transparent Firewall Insertion

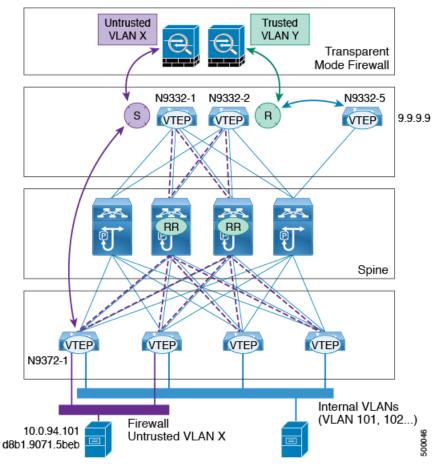

Note

For VXLAN EVPN, we recommend using the distributed Anycast Gateway with transparent firewall insertion. Doing so allows all VLANs to be VXLAN enabled. When using an HSRP/VRRP-based First-Hop Gateway, the VLAN for the SVI can't be VXLAN enabled and should reside on a vPC pair for redundancy.

EVPN with Transparent Firewall Insertion Example

Example of EVPN with Transparent Firewall Insertion

• Host in VLAN X: 10.1.94.101

• ToR leaf: N9372-1

• Service leaf in vPC: N9332-1 and N9332-2

• Border leaf: N9332-5

```

Firewall Clustering with VXLAN BGP EVPN

This section provides details on how to configure a firewall cluster that spans across multiple sites running a VXLAN fabric with a BGP EVPN control plane.

The following topology illustrates the firewall clustering with VXLAN EVPN.

Figure 7: Firewall clustering with VXLAN EVPN

This topology covers the following:

- Firewall cluster consists of multiple instances that act as a single device.
- Routed Access to firewall can be through a different or same subnet.
- Firewall employs a L2 port-channel spanned across all instances.
- A common ESI represents all vPC port-channels that connect to the firewall cluster.
- Single VIP/VMAC is present across all instances.
- BGP-EVPN VXLAN overlay per site is stitched at Border Gateways.
- Anycast forwarding of Active-to-Active instances within the same site and Active-to-Backup access to firewall across sites for traffic flows is supported.
- Each site has a single vPC pair connected to the cluster with a port-channel interface assigned to it.
- The cluster VIP and cluster VMAC are advertised into the VXLAN EVPN fabric as BGP EVPN Route Target-2s (with the ESI set to the configured value on each vPC's port-channel interface). The next hop of the Route Target-2 is the vPC pair's VTEP VIP address.
- Each site may have multiple clusters. The clusters are attached to the vPC pair with their individual port-channels with unique ESIs.
- Each cluster has its own cVIP and cVMAC that are advertised into the VXLAN EVPN fabric as BGP EVPN Route Target -2s (with the ESI set to the configured value on its vPC's Port-channel interface).
- A cluster may have multiple VLANs on the port-channel connected to the vPC pair. Each cVIP/cVMAC learnt on a VLAN is advertised with its corresponding L2VNI as a Route T-2 EVPN route.
- VIP and VMAC (Firewall Hosts) are attached to a single spanned Ether-channel.
- Spanned Ether-channel extends across sites.
- Anycast forwarding to VIP is determined by leverage of existing BGP path attributes and best-path selection.

On the VTEP leafs attached to the firewall cluster, BGP uses a route-map to attach a community to firewall cluster-related EVPN EAD/ES (Type-1) and MAC/IP (Type-2) routes.

```
router bgp 12000
address-family 12vpn evpn
originate-map set_esi
template peer SITE-BGW
remote-as 12000
update-source loopback1
address-family 12vpn evpn
send-community
send-community extended
template peer VTEP-PEERS
remote-as 12000
update-source loopback1
address-family 12vpn evpn
send-community
send-community
```

On the border gateways, BGP uses a route-map to match the firewall clustering community attached to EVPN EAD/ES (Type-1) and MAC/IP (Type-2) routes.

```
router bgp 11000
```

```
bestpath as-path multipath-relax
neighbor 111.111.10.1 remote-as 12000
peer-type fabric-external
address-family 12vpn evpn
send-community
send-community extended
route-map preserve_esi out
rewrite-evpn-rt-asn
```

On the VTEP leafs attached to the firewall cluster, you need to configure a route-map to attach a community to firewall cluster-related EVPN EAD/ES (Type-1) and MAC/IP (Type-2) routes.

```
route-map set_esi permit 10
  match tag 100000
  match evpn route-type 1 2
  set community 23456:12345
route-map set esi permit 15
```

Caution

The **match tag** command in a route-map associated with route-map *<name>* out BGP command under neighbor address-family mode is only supported if configured under address-family l2vpn evpn.

On the border gateways, you need to configure separate route-maps for fabric-internal and fabric-external peers to match the firewall clustering community attached to EVPN EAD/ES (Type-1) and MAC/IP (Type-2) routes.

Matching outbound L2VPN/EVPN route-map to fabric-internal peers:

```
route-map preserve_esi permit 10
match community preserve_esi
match evpn route-type 2
set esi unchanged
route-map preserve_esi permit 15
route-map preserve esi permit 30
```

Matching outbound L2VPN/EVPN route-map to fabric-external peers:

```
route-map preserve_esi_external permit 10
match community preserve_esi
match evpn route-type 2
set esi unchanged
route-map preserve_esi_external permit 15
match community preserve_esi
match evpn route-type 1
route-map preserve_esi_external permit 20
match evpn route-type 1
match route-type local
route-map preserve_esi_external deny 25
match evpn route-type 1
route-map preserve_esi_external permit 30
```

The ethernet-segment can be configured only under vPC port-channel.

```
interface port-channel 100
  ethernet-segment vpc
  esi <esi> [ tag <uint >]
interface port-channel 200
  ethernet-segment vpc
  esi system-mac <system-mac> <local-identifier> [tag <uint>]
```

A common ESI represents all vPC port-channels that connect to the firewall cluster. You can configure ESI under a vPC port-channel.

```
evpn esi multihoming
port-channel 100
  ethernet-segment 1
    system-mac aa.bb.cc <anycast-host>
```

Keep the same system-mac for all vPC port-channels that host the same firewall cluster.

For more firewall information, see Integrating Layer 3 Firewalls in VXLAN Fabrics.

Service Redirection in VXLAN EVPN Fabrics

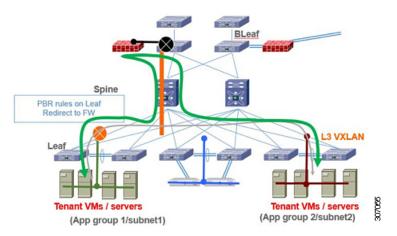

Today, insertion of service appliances (also referred to as service nodes or service endpoints) such as firewalls, load-balancers, etc are needed to secure and optimize applications within a data center. This section describes the Layer 4-Layer 7 service insertion and redirection features offered on VXLAN EVPN fabrics that provides sophisticated mechanisms to onboard and selectively redirect traffic to these services.

Use of Policy-Based Redirect for Services Insertion

Policy-based redirect (PBR) provides a mechanism to bypass a routing table lookup and redirect traffic to a next-hop IP reachable over VXLAN. The feature enables service redirection to Layer 4-Layer 7 devices such as firewalls and load balancers.

PBR involves configuring a route-map with rules that dictate where traffic must be forwarded. The route map is applied on the tenant SVI to influence traffic coming from the host-facing interfaces to a next hop reachable via the fabric.

In scenarios where traffic is coming to a VTEP from the overlay and needs to be redirected to another next hop, the PBR policy must be applied on the fabric facing Layer-3 VNI Interface.

In the previous figure, communication between App group 1 and App group 2 takes place via inter-VLAN/VNI routing in the tenant VRF by default. If there is a requirement where traffic from App group 1 to App group 2 must go through a firewall, a PBR policy can be used to redirect traffic. The example in section "Configuration Example for Policy-Based Redirect" provides the necessary configuration that redirects the traffic flow.

This VXLAN PBR functionality is very basic and lacks many of the required functionality for proper insertion of services in VXLAN fabric. Hence the recommendation is to instead look at ePBR for all the reasons explained in Enhanced-Policy Based Redirect (ePBR), on page 30 section.

Guidelines and Limitations for Policy-Based Redirect

The following guidelines and limitations apply to PBR over VXLAN.

- The following platforms support PBR over VXLAN:
 - Cisco Nexus 9332C and 9364C switches
 - Cisco Nexus 9300-EX switches
 - Cisco Nexus 9300-FX/FX2/FX3 switches
 - Cisco Nexus 9300-GX switches
 - Cisco Nexus 9300-GX2 switches
 - Cisco Nexus 9332D-H2R switches
 - Cisco Nexus 93400LD-H1 switches
 - Cisco Nexus 9364C-H1 switches
 - Cisco Nexus 9504 and 9508 switches with -EX/FX line cards
- Beginning with Cisco NX-OS Release 10.2(3)F, the VXLAN PBR feature is supported with VXLANv6 on all TOR switches.
- PBR over VXLAN doesn't support the following features: VTEP ECMP, and the **load-share** keyword in the **set {ip | ipv6} next-hop** *ip-address* command.

Enabling the Policy-Based Redirect Feature

To configure basic PBR, in cases where the advanced (and recommended) ePBR functions are not deployed, see the following sections:

- Enabling the Policy-Based Redirect Feature, on page 26
- Configuring a Route Policy, on page 27
- Verifying the Policy-Based Redirect Configuration, on page 28
- Configuration Example for Policy-Based Redirect, on page 29

Before you begin

Enable the policy-based redirect feature before you can configure a route policy.

SUMMARY STEPS

- 1. configure terminal
- 2. [no] feature pbr
- 3. (Optional) show feature
- 4. (Optional) copy running-config startup-config

DETAILED STEPS

	Command or Action	Purpose
Step 1	configure terminal	Enters global configuration mode.
	Example:	
	switch# configure terminal	
Step 2	[no] feature pbr	Enables the policy-based routing feature.
	Example:	
	switch(config)# feature pbr	
Step 3	(Optional) show feature	Displays enabled and disabled features.
	Example:	
	switch(config)# show feature	
Step 4	(Optional) copy running-config startup-config	Saves this configuration change.
	Example:	
	switch(config)# copy running-config startup-config	

Configuring a Route Policy

You can use route maps in policy-based routing to assign routing policies to the inbound interface. Cisco NX-OS routes the packets when it finds a next hop and an interface.

Note

The switch has a RACL TCAM region by default for IPv4 traffic.

Before you begin

Configure the RACL TCAM region (using TCAM carving) before you apply the policy-based routing policy. For instructions, see the "Configuring ACL TCAM Region Sizes" section in the Cisco Nexus 9000 Series NX-OS Security Configuration Guide, Release 9.2(x).

SUMMARY STEPS

- 1. configure terminal
- 2. interface type slot/port
- 3. {ip | ipv6} policy route-map map-name
- **4.** route-map map-name [permit | deny] [seq]
- 5. match {ip | ipv6} address access-list-name name [name...]
- **6. set ip next-hop** *address1*
- 7. set ipv6 next-hop address1
- 8. (Optional) set interface null0
- 9. (Optional) copy running-config startup-config

DETAILED STEPS

	Command or Action	Purpose
ep 1	configure terminal	Enters global configuration mode.
	Example:	
	switch# configure terminal	
ep 2	interface type slot/port	Enters interface configuration mode.
	Example:	
	<pre>switch(config)# interface ethernet 1/2</pre>	
ер 3	{ip ipv6} policy route-map map-name	Assigns a route map for IPv4 or IPv6 policy-based routing to the interface.
	Example:	
	<pre>switch(config-inf) # ip policy route-map Testmap</pre>	
ep 4	route-map map-name [permit deny] [seq]	Creates a route map or enters route-map configuration mode for an existing route map. Use <i>seq</i> to order the entries in a route map.
	Example:	
	<pre>switch(config-inf)# route-map Testmap</pre>	
ep 5	$\mathbf{match} \ \{\mathbf{ip} \ \ \mathbf{ipv6}\} \ \mathbf{address} \ \mathbf{access\text{-}list\text{-}name} \ \mathit{name} \ [\mathit{name}]$	Matches an IPv4 or IPv6 address against one or more IPv4 or IPv6 access control lists (ACLs). This command is used for policy-based routing and is ignored by route filtering or redistribution.
	Example:	
I	<pre>switch(config-route-map)# match ip address</pre>	
	access-list-name ACL1	
·	set ip next-hop address1	Sets the IPv4 next-hop address for policy-based routing.
	Example:	
	<pre>switch(config-route-map)# set ip next-hop 192.0.2.1</pre>	
·	set ipv6 next-hop address1	Sets the IPv6 next-hop address for policy-based routing.
	Example:	
I	<pre>switch(config-route-map) # set ipv6 next-hop 2001:0DB8::1</pre>	
ep 8	(Optional) set interface null0	Sets the interface that is used for routing. Use the null0 interface to drop packets.
	Example:	
	<pre>switch(config-route-map) # set interface null0</pre>	
ep 9	(Optional) copy running-config startup-config	Saves this configuration change.
	Example:	
I	<pre>switch(config-route-map) # copy running-config startup-config</pre>	
ep 9	(Optional) copy running-config startup-config Example: switch(config-route-map) # copy running-config	Saves this configuration change.

Verifying the Policy-Based Redirect Configuration

To display the policy-based redirect configuration information, perform one of the following tasks:

Command	Purpose
show [ip ipv6] policy [name]	Displays information about an IPv4 or IPv6 policy.
show route-map [name] pbr-statistics	Displays policy statistics.

Use the **route-map** *map-name* **pbr-statistics** command to enable policy statistics. Use the **clear route-map** *map-name* **pbr-statistics** command to clear these policy statistics.

Configuration Example for Policy-Based Redirect

Perform the following configuration on all tenant VTEPs, excluding the service VTEP.

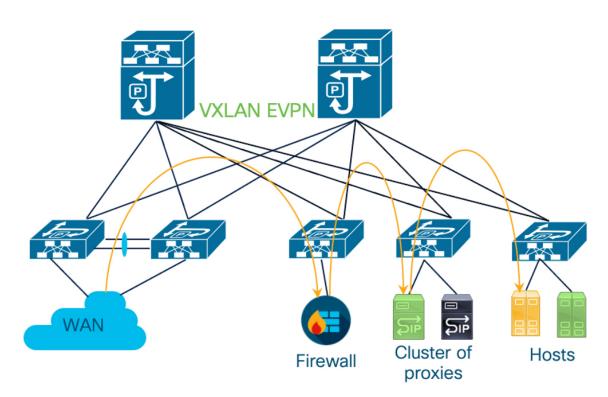

```
feature pbr
ipv6 access-list IPV6 App group 1
10 permit ipv6 any 2001:10:1:1::0/64
ip access-list IPV4 App group 1
10 permit ip any 10.1.1.0/24
ipv6 access-list IPV6 App group 2
10 permit ipv6 any 2001:20:1:1::0/64
ip access-list IPV4_App_group_2
10 permit ip any 20.1.1.0/24
route-map IPV6_PBR_Appgroup1 permit 10
 match ipv6 address IPV6 App group 2
  set ipv6 next-hop 2001:100:1:1::20 (next hop is that of the firewall)
route-map IPV4 PBR Appgroup1 permit 10
  match ip address IPV4 App group 2
  set ip next-hop 10.100.1.20 (next hop is that of the firewall)
route-map IPV6 PBR Appgroup2 permit 10
 match ipv6 address IPV6 App group1
  set ipv6 next-hop 2001:100:1:1::20 (next hop is that of the firewall)
route-map IPV4 PBR Appgroup2 permit 10
  match ip address IPV4_App_group_1
  set ip next-hop 10.10\overline{0.1.20} (next hop is that of the firewall)
interface Vlan10
! tenant SVI appgroup 1
vrf member appgroup
ip address 10.1.1.1/24
no ip redirect
ipv6 address 2001:10:1:1::1/64
no ipv6 redirects
 fabric forwarding mode anycast-gateway
ip policy route-map IPV4 PBR Appgroup1
ipv6 policy route-map IPV6 PBR Appgroup1
interface Vlan20
! tenant SVI appgroup 2
vrf member appgroup
ip address 20.1.1.1/24
no ip redirect
ipv6 address 2001:20:1:1::1/64
no ipv6 redirects
 fabric forwarding mode anycast-gateway
```

```
ip policy route-map IPV4 PBR Appgroup2
ipv6 policy route-map IPV6 PBR Appgroup2
On the service VTEP, the PBR policy is applied on the tenant VRF SVI. This ensures the
traffic post decapsulation will be redirected to firewall.
feature pbr
ipv6 access-list IPV6 App group 1
10 permit ipv6 any 2001:10:1:1::0/64

ipv6 policy route-map IPV6 PBR Appgroup
```

Enhanced-Policy Based Redirect (ePBR)

VXLAN PBR as a solution to selectively redirect traffic can only cater to simple traffic redirection requirements. For more complex use cases like service chaining, symmetric load-balancing, or tracking health of service appliances, usage of PBR becomes difficult. The challenge with service chaining using PBR is that it requires the user to create unique policies per node and manage the redirection rules manually across all the nodes in the chain. Also, given the stateful nature of the service nodes, the PBR rules must ensure symmetry for the reverse traffic, and this adds additional complexity to the configuration and management of the PBR policies.

Enhanced Policy-Based Redirect (ePBR) provides a comprehensive solution to insert service nodes, selectively redirect and load-balance traffic. ePBR provides a simplified workflow to create traffic chains and load-balancing rules along with providing options for probing/monitoring the health of service appliances and taking corrective action in the event of failure. ePBR is supported in both single and multi-site VXLAN EVPN deployments.

In this Figure, selective traffic originating from WAN is chained to a firewall and then the traffic is load-balanced across a cluster of proxies before forwarding toward the destination hosts. ePBR ensures symmetry is maintained for a given flow by making sure that traffic in both forward and reverse direction is redirected to the same service endpoint in the cluster of TCP proxies.

For more detailed information, guidelines and configuration examples on ePBR, see Cisco Nexus 9000 Series NX-OS ePBR Configuration Guide and Layer 4 to Layer 7 Service Redirection with Enhanced Policy-Based Redirect White Paper.

Enhanced-Policy Based Redirect (ePBR)
