

EEM Event Tcl Command Extensions

The following conventions are used for the syntax documented on the Tcl command extension pages:

• An optional argument is shown within square brackets, for example:

[type ?]

- A question mark? represents a variable to be entered.
- Choices between arguments are represented by pipes, for example:

priority low|normal|high

Note

For all EEM Tcl command extensions, if there is an error, the returned Tcl result string contains the error information.

Note

Arguments for which no numeric range is specified take an integer from -2147483648 to 2147483647, inclusive.

- event_completion, page 1
- event_completion_with_wait, page 2
- event_publish, page 3
- event_wait, page 6

event_completion

Sends a notification to the EEM server that the policy is done servicing the event that triggered it. The event only takes a single argument which is the **return_code** of this event instance.

Syntax

event_completion status ?

Arguments

status	(Mandatory) Exit status (return_code) of this event
	instance. A value of zero indicates no error and any other integer value indicates an error.

Result String

None

Set _cerrno

No

event_completion_with_wait

The **event_completion_with_wait** command combines the two commands **event_completion** and **event_wait** into a single command for ease of use.

The **event_completion** command sends a notification to the EEM server that the policy is done servicing the event that triggered it. The event only takes a single argument which is the **return_code** of this event instance.

The **event_wait** places the Tcl policy into a sleep state. When the Tcl policy receives a new signal announcing a new event, the policy is placed into a wake state and again returns to a sleep state. This loop continues. If **event_wait** policy is invoked before **event_completed** policy, an error results and the policy exits.

Syntax

event_completion_with_wait status ? [refresh_vars]

Arguments

status	(Mandatory) exit_status (return_code) of this event instance. A value of zero indicates no error. Any other integer value indicates an error.
refresh_vars	(Optional) Indicates whether built-in and environment variables should be updated (refreshed) from the EEM Policy Director during this event instance.

Result String

None

Set _cerrno

Yes

Sample Usage

Here is a similar example as above using this single command:

```
namespace import ::cisco::eem::*
namespace import ::cisco::lib::*
set i 1
while \{1 == 1\} { # Start high performance policy loop
  array set arr_einfo [event_reqinfo]
  if \{\$ \text{ cerrno } \overline{!} = 0\}
      set result [format "component=%s; subsys err=%s; posix err=%s;\n%s" \
      $ cerr sub num $ cerr sub err $ cerr posix err $ cerr str]
  action_syslog msg "event $i serviced" priority info
  if {$i == 5} {
      action syslog msg "Exiting after servicing 5 events" priority info
  incr i
   array set event state arr [event completion with wait status 0 refresh vars 1]
  if {$ event state arr(event state) != 0} {
      exit 0
```

The running configuration output is the same as the event publishTcl command.

event_publish

Publishes an application-specific event.

Syntax

```
event_publish sub_system ? type ? [arg1 ?] [arg2 ?] [arg3 ?] [arg4 ?]
```

Arguments

sub_system	(Mandatory) Number assigned to the EEM policy that published the application-specific event. Number is set to 798 because all other numbers are reserved for Cisco use.
type	(Mandatory) Event subtype within the specified component. The sub_system and type arguments uniquely identify an application event. Must be an integer between 1 and 4294967295, inclusive.

[arg1 ?]-[arg4 ?]	(Optional) Four pieces of application event publisher string data.
-------------------	--

Result String

None

Set _cerrno

Yes

```
( cerr sub err = 2) FH ESYSERR (generic/unknown error from OS/system)
```

This error means that the operating system reported an error. The POSIX error value that is reported with the error should be used to determine the cause of the operating system error.

Sample Usage

This example demonstrates how to use the **event_publish** Tcl command extension to execute a script *n* times repeatedly to perform some function (for example, to measure the amount of CPU time taken by a given group of Tcl statements). This example uses two Tcl scripts.

Script1 publishes a type 9999 EEM event to cause Script2 to run for the first time. Script1 is registered as a none event and is run using the Cisco IOS CLI **event manager run** command. Script2 is registered as an EEM application event of type 9999, and this script checks to see if the application publish arg1 data (the iteration number) exceeds the EEM environment variable test_iterations value. If the test_iterations value is exceeded, the script writes a message and exits; otherwise the script executes the remaining statements and reschedules another run. To measure the CPU utilization for Script2, use a value of test_iterations that is a multiple of 10 to calculate the amount of average CPU time used by Script2.

To run the Tcl scripts, enter the following Cisco IOS commands:

```
configure terminal
event manager environment test_iterations 100
event manager policy script1.tcl
event manager policy script2.tcl
end
event manager run script1.tcl
```

The Tcl script Script2 will be executed 100 times. If you execute the script without the extra processing and derive the average CPU utilization, and then add the extra processing and repeat the test, you can subtract the former CPU utilization from the later CPU utilization to determine the average for the extra processing.

Script1 (script1.tcl)

```
$ cerr sub num $ cerr sub err $ cerr posix err $ cerr str]
    error $result
# Cause the first iteration to run.
event_publish sub_system 798 type 9999 arg1 0
if {$ cerrno != 0} {
    set result [format \
          "component=%s; subsys err=%s; posix err=%s; \n%s" \
          $ cerr sub_num $_cerr_sub_err $_cerr_posix_err $_cerr_str]
    error $result
Script2 (script2.tcl)
::cisco::eem::event register appl sub system 798 type 9999
# Check if all the required environment variables exist.
# If any required environment variable does not exist, print out an error msg and quit.
if {![info exists test iterations]} {
    set result \
      "Policy cannot be run: variable test iterations has not been set"
    error $result $errorInfo
namespace import ::cisco::eem::*
namespace import ::cisco::lib::*
# Query the event info.
array set arr_einfo [event_reqinfo]
if \{\$ \text{ cerrno } \overline{!} = 0\}
    set result [format "component=%s; subsys err=%s; posix err=%s; \n%s" \
        $_cerr_sub_num $_cerr_sub_err $_cerr_posix_err $_cerr_str]
    error $result
# Datal contains the arg1 value used to publish this event.
set iter $arr einfo(data1)
# Use the argl info from the previous run to determine when to end.
if {$iter >= $test iterations} {
    # Log a message.
    action_syslog priority info msg "EEM application publish test end"
    if {$_cerrno != 0} {
      set result [format \
             "component=%s; subsys err=%s; posix err=%s; \n%s" \
             $ cerr sub num $ cerr sub err $ cerr posix err $ cerr str]
      error $result
    exit 0
set iter [expr $iter + 1]
# Log a message.
set msg [format "EEM application_publish test iteration %s" $iter]
action syslog priority info msg ₹msg
if {$ cerrno != 0} {
    \bar{\text{set}} result [format "component=%s; subsys err=%s; posix err=%s; \n%s" \
      $_cerr_sub_num $_cerr_sub_err $_cerr_posix_err $_cerr_str]
    error $result
# Do whatever processing that you want to measure here.
# Cause the next iteration to run. Note that the iteration is passed to the
# next operation as arg1.
event_publish sub_system 798 type 9999 arg1 $iter if \{\$\_cerrno != 0\} {
    set result [format \
          "component=%s; subsys err=%s; posix err=%s; \n%s" \
          $ cerr sub num $ cerr sub err $ cerr posix err $ cerr str]
    error $result
}
```

event_wait

Places the Tcl policy into a sleep state. When the Tcl policy receives a new signal announcing a new event, the policy is placed into a wake state and again returns to a sleep state. This loop continues. If **event_wait** policy is invoked before **event completed** policy, an error results and the policy exits.

Syntax

```
event_wait [refresh_vars]
```

Arguments

refresh_vars	(Optional) Indicates whether built-in and environment
	variables should be updated (refreshed) from the EEM
	Policy Director during this event instance.

Result String

None

Set cerrno

No

Sample Usage

The **event_wait** event detector returns an array type value with a single element named **event_state**. Event_state is a value sent back from the EEM Server indicating whether or not an error has occurred in processing the event. An example of an error here would be if the user configured **event_wait** before configuring **event_completion** when handling the event instance.

The following sample output shows the use of both **event_completion** and **event_wait**Tcl commands:

```
::cisco::eem::event register syslog tag e1 occurs 1 pattern CLEAR maxrun 0
namespace import ::cisco::eem::*
namespace import ::cisco::lib::*
while \{1 == 1\} { \# Start high performance policy loop
   array set arr_einfo [event_reqinfo]
   if \{\$ \text{ cerrno } \overline{!} = 0\}
       set result [format "component=%s; subsys err=%s; posix err=%s;\n%s" \
       $_cerr_sub_num $_cerr_sub_err $_cerr_posix_err $_cerr_str]
      error $result
   action syslog msg "event $i serviced" priority info
       action syslog msg "Exiting after servicing 5 events" priority info
      exit 0
   incr i
   event completion status 0
   array set _event_state arr [event_wait refresh_vars 0]
if {$_event_state_arr(event_state) != 0} {
      exit 0
```

.

Here is an example of the running configuration:

```
Router#
01:00:44: %SYS-5-CONFIG I: Configured from console by consoleclear counters

Router#
Router#
01:02:36: %CLEAR-5-COUNTERS: Clear counter on all interfaces by console
01:02:36: %HA_EM-6-LOG: high_perf_example.tcl: event 5 serviced
01:02:36: %HA_EM-6-LOG: high_perf_example.tcl: Exiting after servicing 5 events
```

Also while an event has been serviced and is waiting for the next event to come in **show event manager policy active** command will display the following output:

```
Router#show event manager policy active

Key: p - Priority :L - Low, H - High, N - Normal, Z - Last
s - Scheduling node: A - Active, S - Standby

default class - 1 script event
no. job id ps status time of event event type name
1 11 N A wait Mon Oct20 14:15:24 2008 syslog

high perf example.tcl
```

In the above example the status is wait. This indicates that the policy is waiting for the next event to come in.
