MLDP-Based MVPN

The MLDP-based MVPN feature provides extensions to Label Distribution Protocol (LDP) for the setup of point-to-multipoint (P2MP) and multipoint-to-multipoint (MP2MP) label switched paths (LSPs) for transport in the Multicast Virtual Private Network (MVPN) core network.

• Initial Deployment of an MLDP-Based MVPN, page 4

Overview of MLDP-Based MVPN

MVPN allows a service provider to configure and support multicast traffic in an MPLS VPN environment. This feature supports routing and forwarding of multicast packets for each individual VPN routing and forwarding (VRF) instance, and it also provides a mechanism to transport VPN multicast packets across the service provider backbone.

A VPN is network connectivity across a shared infrastructure, such as an Internet service provider (ISP). Its function is to provide the same policies and performance as a private network, at a reduced cost of ownership, thus creating many opportunities for cost savings through operations and infrastructure.
An MVPN allows an enterprise to transparently interconnect its private network across the network backbone of a service provider. The use of an MVPN to interconnect an enterprise network in this way does not change the way that the enterprise network is administered, nor does it change general enterprise connectivity.

As shown in the figure, in an MLDP-based MVPN, a static default multicast distribution tree (MDT) is established for each multicast domain. The default MDT defines the path used by provider edge (PE) devices to send multicast data and control messages to every other PE device in the multicast domain. A default MDT is created in the core network using a single MP2MP LSP. The default MDT behaves like a virtual LAN.

As shown in the figure, an MLDP-based MVPN also supports the dynamic creation of data MDTs for high-bandwidth transmission. For high-rate data sources, a data MDT is created using P2MP LSPs to off-load traffic from the default MDT to avoid unnecessary waste of bandwidth to PEs that did not join the stream. The creation of the data MDT is signaled dynamically using MDT Join TLV messages. Data MDTs are a feature unique to Cisco IOS software. Data MDTs are intended for high-bandwidth sources such as full-motion video inside the VPN to ensure optimal traffic forwarding in the MPLS VPN core. The threshold at which the data MDT is created can be configured on a per-device or a per-VRF basis. When the multicast transmission exceeds the defined threshold, the sending PE device creates the data MDT and sends a User
Datagram Protocol (UDP) message, which contains information about the data MDT to all devices on the default MDT.

**Figure 2**  
*MLDP with the Data MDT Scenario*

Data MDTs are created only for (S, G) multicast route entries within the VRF multicast routing table. They are not created for (*, G) entries regardless of the value of the individual source data rate.

The only transport mechanism previously available was Protocol Independent Multicast (PIM) with Multipoint Generic Routing Encapsulation (mGRE) over an IP core network. The introduction of Multicast Label Distribution Protocol (MLDP) provides transport by using MLDP with label encapsulation over an MPLS core network.

MLDP creates the MDTs as follows:

- The default MDT uses MP2MP LSPs.
  - Supports low bandwidth and control traffic between VRFs.
- The data MDT uses P2MP LSPs.
  - Supports a single high-bandwidth source stream from a VRF.

All other operations of MVPN remain the same regardless of the tunneling mechanism:

- PIM neighbors in a VRF are seen across a Label Switched Path virtual interface (LSP-VIF).
- The VPN multicast state is signaled by PIM.

The only other difference when using MLDP is that the MDT group address used in the mGRE solution is replaced with a VPN ID.

---

**Benefits of MLDP-Based MVPN**

- Enables the use of a single MPLS forwarding plane for both unicast and multicast traffic.
- Enables existing MPLS protection (for example, MPLS Traffic Engineering/Resource Reservation Protocol (TE/RSVP link protection) and MPLS Operations Administration and Maintenance (OAM) mechanisms to be used for multicast traffic.
- Reduces operational complexity due to the elimination of the need for PIM in the MPLS core network.

**Initial Deployment of an MLDP-Based MVPN**

Initial deployment of an MLDP-based MVPN involves the configuration of a default MDT and one or more data MDTs.

A static default MDT is established for each multicast domain. The default MDT defines the path used by PE devices to send multicast data and control messages to every other PE device in the multicast domain. A default MDT is created in the core network using a single MP2MP LSP.

An MLDP-based MVPN also supports the dynamic creation of data MDTs for high-bandwidth transmission.

- Default MDT Creation, page 4
- Data MDT Scenario, page 10

**Default MDT Creation**

The figure shows the default MDT scenario. The Opaque value used to signal a default MDT consists of two parameters: the VPN ID and the MDT number for the VPN in the format (vpn-id, 0) where vpn-id is a manually configured 7-byte number that uniquely identifies this VPN. The default MDT is set to zero.

In this scenario, each of the three PE devices belong to the VRF called VRF and they have the same VPN ID. Each PE device with the same VPN ID will join the same MP2MP tree. The PE devices have created a primary MP2MP tree rooted at P-Central (Root 1) and a backup MP2MP tree rooted at PE-North (Root 2). There are two sources at PE-West and interested receivers at both PE-North and PE-East. PE-West will
choose one of the MP2MP trees to transmit the customer VPN traffic, but all PE devices can receive traffic on either of the MP2MP trees.

**Figure 3  Default MDT Scenario**

- LSP Downstream Default MDT Creation, page 5
- LSP Upstream Default MDT Creation, page 7
- PIM Overlay Signaling of VPN Multicast State, page 9

**LSP Downstream Default MDT Creation**

The figures show the downstream tree creation for each of the roots. Each PE device configured with VPN ID 100:2 creates the same Forwarding Equivalence Class (FEC) Type Length Value (TLV), but with a different root and downstream labels per MP2MP tree. The FEC type will be MP2MP Down, which
prompts the receiving Label Switched Route (LSR) to respond with an upstream label mapping message to create the upstream path.

Figure 4  Default MDT Downstream--Root 1
LSP Upstream Default MDT Creation

The figures show the upstream LSP creation for the default MDTs. For each downstream label received, a corresponding upstream label is sent. In the first figure, P-Central sends out three upstream labels (111, 109, and 105) to each downstream directly connected neighbor (downstream is away from the root). The
process for PE-North is the same except that it only sends a single upstream label (313) as there is only one directly connected downstream neighbor, as shown in the second figure.

![Default MDT Upstream -- Root 1](image-url)
PIM Overlay Signaling of VPN Multicast State

The signaling of the multicast state within a VPN is via PIM. It is called overlay signaling because the PIM session runs over the multipoint LSP and maps the VPN multicast flow to the LSP. In an MVPN, the operation of PIM is independent of the underlying tunnel technology. In the MVPN solution, a PIM adjacency is created between PE devices, and the multicast states within a VRF are populated over the PIM sessions. When using MLDP, the PIM session runs over an LSP-VIF interface. The figure shows PIM signaling running over the default MDT MP2MP LSP. Access to the MP2MP LSP is via the LSP-VIF, which can see all the leaf PE devices at the end of branches, much like a LAN interface. In the figure, PE-East sends a downstream label mapping message to the root, P-Central, which in turn sends an upstream label mapping message to PE-West. These messages result in the creation of the LSP between the two leaf PE devices. A PIM session can then be activated over the top of the LSP allowing the (S, G) states and control messages to be signaled between PE-West and PE-East. In this case, PE-East receives a Join TLV message for (10.5.200.3, 238.1.200.2) within VRF, which it inserts into the mroute table. The Join TLV
message is then sent via the PIM session to PE-West (BGP next-hop of 10.5.200.3), which populates its VRF mroute table. This procedure is identical to the procedure using an mGRE tunnel.

**Figure 8  PIM Signaling over LSP**

![Diagram of PIM Signaling over LSP]

### Data MDT Scenario

In an MVPN, traffic that exceeds a certain threshold can move off the default MDT onto a data MDT.

The figure shows the data MDT scenario. The Opaque value used to signal a data MDT consists of two parameters: the VPN ID and the MDT number in the format (vpn-id, MDT# > 0) where vpn-id is a manually configured 7-byte number that uniquely identifies this VPN. The second parameter is the unique data MDT number for this VPN, which is a number greater than zero.

In the scenario, two receivers at PE-North and PE-East are interested in two sources at PE-West. If the source 10.5.200.3 exceeds the threshold on the default MDT, PE-West will issue an MDT Join TLV message over the default MDT MP2MP LSP advising all PE devices that a new data MDT is being created.
Because PE-East has an interested receiver in VRF, it will build a multipoint LSP using P2MP back to PE-West, which will be the root of the tree. PE-North does not have a receiver for 10.5.200.3, therefore it will just cache the Join TLV message.

**Figure 9 Data MDT Scenario**

### Configuring an MLDP-Based MVPN

Perform this task to configure an MLDP-based MVPN.

**SUMMARY STEPS**

1. `enable`  
2. `configure terminal`  
3. `ip multicast-routing`  
4. `ip multicast-routing vrf vrf-name`  
5. `ip vrf vrf-name`  
6. `rd route-distinguisher`  
7. `vpn id oui vpn-index`  
8. `route target export route-target-ext-community`  
9. `route target import route-target-ext-community`  
10. `mdt preference / mldp | pim /`  
11. `mdt default mpls mldp group-address`  
12. `mdt data mpls mldp number-of-data-mdt`  
13. `mdt data threshold kb/s list access-list`  
14. `end`

</table>
|      | **Example:**  
Device(config)# ip multicast-routing | |
| 4    | `ip multicast-routing vrf vrf-name` | Enables IP multicast routing for the MVPN VRF specified for the `vrf-name` argument. |
|      | **Example:**  
Device(config)# ip multicast-routing vrf VRF | |
| 5    | `ip vrf vrf-name` | Defines a VRF instance and enters VRF configuration mode. |
|      | **Example:**  
Device(config-vrf)# ip vrf VRF | |
| 6    | `rd route-distinguisher` | Creates a route distinguisher (RD) (in order to make the VRF functional). Creates the routing and forwarding tables, associates the RD with the VRF instance, and specifies the default RD for a VPN. |
|      | **Example:**  
Device(config-vrf)# rd 50:11 | |
| 7    | `vpn id oui:vpn-index` | Sets or updates the VPN ID on a VRF instance. |
|      | **Example:**  
Device(config-vrf)# vpn id 50:10 | |
| 8    | `route target export route-target-ext-community` | Creates an export route target extended community for the specified VRF. |
|      | **Example:**  
Device(config-vrf)# route target export 100:100 | |
| 9    | `route target import route-target-ext-community` | Creates an import route target extended community for the specified VRF. |
|      | **Example:**  
Device(config-vrf)# route target import 100:100 | |
### Command or Action | Purpose
---|---
**Step 10** &mdash; `mdt preference mldp | pim` | Specifies a preference for a particular MDT type (MLDP or PIM).

**Example:**

```
Device(config-vrf)# mdt preference mldp
```

**Step 11** &mdash; `mdt default mpls mldp group-address` | Configures a default MDT group for a VPN VRF instance.

**Example:**

```
Device(config-vrf)# mdt default mpls mldp 172.30.20.1
```

**Step 12** &mdash; `mdt data mpls mldp number-of-data-mdt` | Specifies a range of addresses to be used in the data MDT pool.

**Example:**

```
Device(config-vrf)# mdt data mpls mldp 255
```

**Step 13** &mdash; `mdt data threshold kb/s list access-list` | Defines the bandwidth threshold value in kilobits per second.

**Example:**

```
Device(config-vrf)# mdt data threshold 40 list 1
```

**Step 14** &mdash; `end` | Ends the current configuration session and returns to privileged EXEC mode.

**Example:**

```
Device(config)# end
```

### Verifying the Configuration of an MLDP-Based MVPN

Perform this task in privileged EXEC mode to verify the configuration of an MLDP-based MVPN.
SUMMARY STEPS

1. show mpls mldp database
2. show ip pim neighbor [vrf vrf-name] neighbor [interface-type interface-number]
3. show ip mroute [vrf vrf-name] [active [kbps] [interface type number] bidirectional count [terse] dense [interface type number] proxy pruned sparse ssd | static | summary] [source-address] [count [terse] interface type number proxy pruned summary] [group-address address-group-address] [count [terse] interface type number proxy pruned summary] [group-address] active [kbps] [interface type number] [verbose]
4. show mpls forwarding-table network [mask | length] | labels label [- label] [interface interface] | next-hop address | lsp-tunnel [tunnel-id] [vrf vrf-name] [detail]
5. show adjacency [ip-address] [interface-type interface-number] null number | port-channel number | sysclock number | vlan number | ipv6-address | fcpa number | serial number [connectionid number] [link {ipv4 | ipv6 | mpls}] [detail | encapsulation]

DETAILED STEPS

Step 1
show mpls mldp database
Enter the show mpls mldp database command to display information in the MLDP database. It shows the FEC, the Opaque value of the FEC decoded, and the replication clients associated with it:

Example:

```
Device# show mpls mldp database
* Indicates MLDP recursive forwarding is enabled
LSM ID : D3000001 (RNR LSM ID: 8A000002) Type: MP2MP Uptime : 00:04:54
FEC Root : 172.30.20.1
Opaque decoded : [mdt 100:2 0]
Opaque length : 11 bytes
Opaque value : 07 000B 00000100000001000000000
RNR active LSP : (this entry)
Upstream client(s) :
172.30.20.1:0 [Active]
Expires : Never Path Set ID : 99000001
Out Label (U) : 32 Interface : Ethernet1/0*
Local Label (D) : 30 Next Hop : 10.0.1.7
Replication client(s):
MDT (VRF VRF)
Uptime : 00:04:54 Path Set ID : 5000002
Interface : Lspvif0
```

Step 2
show ip pim neighbor [vrf vrf-name] neighbor [interface-type interface-number]
Enter the show ip pim neighbor command to display PIM adjacencies information:

Example:

```
Device# show ip pim vrf VRF neighbor
192.168.10.18 Serial6/0 04:53:19/00:01:18 v2 1 / G
172.30.20.3 Lspvif0 04:52:32/00:01:28 v2 1 / B S P G
172.30.20.2 Lspvif0 04:52:32/00:01:17 v2 1 / B S P G
```

Step 3
show ip mroute [vrf vrf-name] [active [kbps] [interface type number] bidirectional count [terse] dense [interface type number] proxy pruned sparse ssd | static | summary] [source-address] [count [terse] interface type number proxy pruned summary] [group-address] [source-address group-address] [count [terse] interface type number proxy pruned summary] [group-address] active [kbps] [interface type number] [verbose]
Enter the `show ip mroute` command to display the contents of the multicast routing (mroute) table:

Example:

```
Device# show ip mroute vrf VRF 238.1.200.2 10.5.200.3
(10.5.200.3, 238.1.200.2), 04:54:18/00:02:40, flags: sT
Incoming interface: Lspvif0, RPF nbr 172.30.20.2
Outgoing interface list:
Serial6/0, Forward/Sparse-Dense, 04:54:18/00:02:40
```

Step 4 Enter the `show mpls forwarding-table` command to display the contents of the MPLS Label Forwarding Information Base (LFIB):

Example:

```
Device# show mpls forwarding-table | inc 1F000001
105    307       mLDP:1F000001    38468   Se5/0      point2point
208      307       mLDP:1F000001    38468   Se4/0      point2point
109      307       mLDP:1F000001    34738   Se5/0      point2point
408      307       mLDP:1F000001    34738   Se6/0      point2point
111      408       mLDP:1F000001    282     Se6/0      point2point
208      408       mLDP:1F000001    282     Se4/0      point2point
```

Step 5 Enter the `show adjacency` command to display adjacency information for the specified LSP-VIF interface:

Example:

```
Device# show adjacency lspvif0
105      307       mLDP:1F000001    38468   Se5/0      point2point
208      307       mLDP:1F000001    38468   Se4/0      point2point
109      307       mLDP:1F000001    34738   Se5/0      point2point
408      307       mLDP:1F000001    34738   Se6/0      point2point
111      408       mLDP:1F000001    282     Se6/0      point2point
208      408       mLDP:1F000001    282     Se4/0      point2point
```

Configuration Examples for MLDP-Based MVPN

- Example Initial Deployment of an MLDP-Based MVPN, page 18
- Example Migration from a PIM with mGRE-Based MVPN to an MLDP-Based MPVN, page 25
Example Initial Deployment of an MLDP-Based MVPN

Initial deployment of an MLDP-based MVPN involves the configuration of a default MDT and one or more data MDTs.

- Default MDT Configuration, page 18
- Data MDT Configuration, page 21

Default MDT Configuration

The following example shows how to configure the default MDT for an MLDP-based MVPN. This configuration is based on the sample topology illustrated in the figure.

Figure 10  Default MDT Example

This configuration is consistent for every PE device participating in the same VPN ID. The `vpn id 100:2` command replaces the MDT group address used with the mGRE transport method. To provide redundancy, two default MDT trees are statically configured, rooted at P-Central and PE-North. The selection as to
which MP2MP tree the default MDT will use at a particular PE device is determined by Interior Gateway Protocol (IGP) metrics. An MP2MP LSP is implicit for the default MDT.

```
ip pim mpls source Loopback0
ip multicast-routing
ip multicast-routing vrf VRF
!
ip vrf VRF
er 100:2
vpn id 100:2
route-target export 200:2
route-target import 200:2
mdt default mpls mldp 172.30.20.1 (P-Central)
mdt default mpls mldp 172.30.20.3 (PE-North)
```

- PIM Adjacencies, page 19
- MLDP Database Entry--PE-East, page 19
- Label Forwarding Entry--P-Central (Root 1), page 20

**PIM Adjacencies**

PIM operates over the LSP-VIF as if it were a regular tunnel interface. That means PIM hellos are exchanged over the LSP-VIF to establish PIM adjacencies over the default MDT. The sample output in this section displays the three PIM adjacencies in VRF of PE-East. The first is the adjacency to the receiver network over serial interface 6/0, and the next two are the adjacencies to PE-West and PE-North over the MP2MP LSP via LSP-VIF interface 0.

```
PE-East# show ip pim vrf VRF neighbor
192.168.10.18     Serial6/0            04:53:19/00:01:18 v2 1 / G
172.30.20.3       Lspvif0              04:52:32/00:01:28 v2 1 / B S P G
172.30.20.2       Lspvif0              04:52:32/00:01:17 v2 1 / B S P G
```

The output from the `show ip mroute` command also shows the (S, G) entry for VRF. The stream 238.1.200.2 has the Reverse Path Forwarding (RPF) interface of LSP-VIF interface 0 and the neighbor 172.30.20.2, which is PE-West.

```
PE-East# show ip mroute vrf VRF 238.1.200.2 10.5.200.3
(10.5.200.3, 238.1.200.2), 04:54:18/00:02:40, flags: sT
Incoming interface: Lspvif0, RPF nbr 172.30.20.2
Outgoing interface list: Serial6/0, Forward/Sparse-Dense, 04:54:18/00:02:40
```

**MLDP Database Entry--PE-East**

The sample output in this section displays the database entries for the MP2MP trees supporting the default MDT at PE-East. The database is searched by Opaque value MDT 100:2, which results in information for two MP2MP trees (one for each root) being returned. Both trees have different system IDs (2E000001, F2000005) and use the same Opaque value ([mdt 100:2 0]), but with different roots. The last 0 in the Opaque value indicates this tree is a default MDT. Entry 79000004 shows it is the primary MP2MP tree, therefore PE-East will transmit all source multicast traffic on this LSP, and B2000006 will be the backup root. Note that interface LSP-VIF interface 0 represents both MP2MP LSPs. The Local Label (D) is the downstream label allocated by PE-East for this tree. In other words, traffic from the root will be received with either label 408 (Primary Tree) or 407 (Backup Tree). The Out Label (U) is the label that PE-East will use to send traffic into the tree; upstream towards the root, either 105 for the Primary Tree or 108 for the Backup Tree. Both these labels were received from P-Central.

```
PE-East# show mpls mldp database opaque_type mdt 100:2
* Indicates MLDP recursive forwarding is enabled
LSM ID : 79000004 (RNR LSM ID: 8A000002) Type: MP2MP Uptime : 00:04:54
```
Label Forwarding Entry--P-Central (Root 1)

The sample output shown in this section displays the VRF (MDT 100:2) MLDP database entry 1F000001 for the primary MP2MP LSP, which is P-Central. Because the local device P-Central is the root, there is no upstream peer ID, therefore no labels are allocated locally. However there are three replication clients, representing each of the three PE devices: PE-North, PE-West, and PE-East. These replication clients are the downstream nodes of the MP2MP LSP. These clients receive multipoint replicated traffic.

In the replication entry looking from the perspective of the root, there are two types of labels:

- Out label (D)--These are labels received from remote peers that are downstream to the root (remember traffic flows downstream away from the root).
- Local label (U)--These are labels provided by P-Central to its neighbors to be used as upstream labels (sending traffic to the root). It is easy to identify these labels as they all start in the 100 range, which we have configured for P-Central to use. P-Central sends these labels out when it receives a FEC with the type as MP2MP Down.

From the labels received and sent in the replication entries, the Label Forwarding Information Base (LFIB) is created. The LFIB has one entry per upstream path and one entry per downstream path. In this case because P-Central is the root, there are only upstream entries in the LFIB that have been merged with the corresponding downstream labels. For example, label 105 is the label P-Central sent to PE-East to send source traffic upstream. Traffic received from PE-East will then be replicated using the downstream labels 307 to PE-West and 208 to PE-North.
The sample output shown in this section displays the entry on P-Central for the MP2MP LSP rooted at PE-North (backup root). In this tree P-Central is a branch of the tree, not a root, therefore there are some minor differences to note:

- The upstream peer ID is PE-North, therefore P-Central has allocated label 104 in the downstream direction towards PE-North and subsequently PE-North has responded with an upstream label of 313.
- Two replication entries representing PE-East and PE-West are displayed.
- The merged LFIB shows three entries:
  - One downstream entry label 104 receiving traffic from Root 2 (PE-North), which is then directed further downstream using labels 207 PE-West and 407 PE-East.
  - Two upstream entries 108 and 115 receiving traffic from the leaves and directing it either downstream 207, 407 or upstream using label 313.
The following example shows how to configure the data MDT for an MLDP-based MVPN. This configuration is based on the sample topology illustrated in the figure.

**Figure 11  Data MDT Example**

The sample output in this section displays the data MDT configuration for all the PE devices. The `mdt data` commands are the only additional commands necessary. The first `mdt data` command allows a maximum of 60 data MDTs to be created, and the second `mdt data` command sets the threshold. If the number of data MDTs exceeds 60, then the data MDTs will be reused in the same way as they are for the mGRE tunnel method (the one with the lowest reference count).

```
ip pim vrf VRF mpls source Loopback0
ip vrf VRF
rd 100:2
vpn id 100:2
route-target export 200:2
route-target import 200:2
mdt default mpls mldp 172.30.20.1 (P-Central)
mdt default mpls mldp 172.30.20.3 (PE-North)
mdt data mpls mldp 60
dmt data threshold 1
```

- **VRF mroute Table--PE-West, page 23**
- **LSP-VIF Adjacencies--PE-West, page 23**
VRF mroute Table--PE-West

The sample output in this section displays the VRF mroute table on PE-West before the high-bandwidth source exceeds the threshold. At this point there are two streams, representing each of the two VPN sources at PE-West, on a single MP2MP LSP (System ID D8000000). The LSP represents the default MDT accessed via LSP-VIF interface 0.

```
PE-West# show ip mroute vrf VRF verbose
.
(10.5.200.2, 238.1.200.1), 00:00:25/00:03:29, flags: sT
  Incoming interface: Serial6/0, RPF nbr 192.168.10.6
  Outgoing interface list:
    Lspvif0, LSM MDT: D8000000 (default), Forward/Sparse-Dense,
    
(10.5.200.3, 238.1.200.2), 00:11:14/00:02:48, flags: sT
  Incoming interface: Serial6/0, RPF nbr 192.168.10.6
  Outgoing interface list:
    Lspvif0, LSM MDT: D8000000 (default), Forward/Sparse-Dense,
```

The sample output in this section displays the output after the source transmission exceeds the threshold. PE-West sends an MDT Join TLV message to signal the creation of a data MDT. In this case, the data MDT number is 1, therefore PE-East will send a label mapping message back to PE-West with a FEC TLV containing root=PE-West, Opaque value=(mdt vpn-id 1). The System ID is now changed to 4E000003 signaling a different LSP; however, the LSP-VIF is still LSP-VIF interface 0. The (S, G) entry also has the “y” flag set indicating this stream has switched to a data MDT.

```
PE-West# show ip mroute vrf VRF 10.5.200.3 238.1.200.2 verbose
.
(10.5.200.3, 238.1.200.2), 00:00:08/00:03:27, flags: sTy
  MDT TX nr: 1 LSM-ID 4E000003
  Incoming interface: Serial6/0, RPF nbr 192.168.10.6
  Outgoing interface list:
    Lspvif0, LSM MDT: 4E000003 (data) Forward/Sparse-Dense,
```

LSP-VIF Adjacencies--PE-West

For the interface LSP-VIF, each virtual circuit represents a unique multipoint LSP forwarding instance. The correct adjacency is selected when sending the multicast packet. The sample output in this section displays the application of that concept on PE-West. There is a single LSP-VIF interface 0 interface, but it has three adjacencies as follows:

- 4E000003 is the single data MDT created for (10.5.200.3, 238.1.200.2)
- 58000000 is the default MDT (backup root)
- D8000000 is the default MDT (primary root)

```
PE-West# show adjacency lspvif 0
Protocol Interface Address
IP Lspvif0 4E000003(S)
```
MLDP Database Entries

The sample output in this section displays the MLDP entry for the data MDT (4E000003) on the ingress device PE-West. The following points about this entry should be noted:

- The tree type is P2MP with PE-West (172.30.20.2) as the root.
- The Opaque value is [mdt 100:2 1] denoting the first data MDT.
- There are no labels allocated as it is the root.
- There are two replication client entries on this tree.
- Label 112 will be used to send the traffic downstream towards PE-East (via P-Central).
- The MDT entry is an internal construct.

**PE-West# show mpls mldp database id 4E000003**

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About IPv6 Multicast Listener Discovery Protocol

- IPv6 Multicast Overview, page 29
- IPv6 Multicast Routing Implementation, page 30
- Multicast Listener Discovery Protocol for IPv6, page 31
- MLD Access Group, page 32

IPv6 Multicast Overview

An IPv6 multicast group is an arbitrary group of receivers that want to receive a particular data stream. This group has no physical or geographical boundaries—receivers can be located anywhere on the Internet or in any private network. Receivers that are interested in receiving data flowing to a particular group must join the group by signaling their local device. This signaling is achieved with the MLD protocol.

Devices use the MLD protocol to learn whether members of a group are present on their directly attached subnets. Hosts join multicast groups by sending MLD report messages. The network then delivers data to a potentially unlimited number of receivers, using only one copy of the multicast data on each subnet. IPv6 hosts that wish to receive the traffic are known as group members.
Packets delivered to group members are identified by a single multicast group address. Multicast packets are delivered to a group using best-effort reliability, just like IPv6 unicast packets.

The multicast environment consists of senders and receivers. Any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group receive the message.

A multicast address is chosen for the receivers in a multicast group. Senders use that address as the destination address of a datagram to reach all members of the group.

Membership in a multicast group is dynamic; hosts can join and leave at any time. There is no restriction on the location or number of members in a multicast group. A host can be a member of more than one multicast group at a time.

How active a multicast group is, its duration, and its membership can vary from group to group and from time to time. A group that has members may have no activity.

**IPv6 Multicast Routing Implementation**

Cisco software supports the following protocols to implement IPv6 multicast routing:

- MLD is used by IPv6 devices to discover multicast listeners (nodes that want to receive multicast packets destined for specific multicast addresses) on directly attached links. There are two versions of MLD:
  - MLD version 1 is based on version 2 of the Internet Group Management Protocol (IGMP) for IPv4.
  - MLD version 2 is based on version 3 of the IGMP for IPv4.
- IPv6 multicast for Cisco software uses both MLD version 2 and MLD version 1. MLD version 2 is fully backward-compatible with MLD version 1 (described in RFC 2710). Hosts that support only MLD version 1 will interoperate with a device running MLD version 2. Mixed LANs with both MLD version 1 and MLD version 2 hosts are likewise supported.
- PIM-SM is used between devices so that they can track which multicast packets to forward to each other and to their directly connected LANs.
- PIM in Source Specific Multicast (PIM-SSM) is similar to PIM-SM with the additional ability to report interest in receiving packets from specific source addresses (or from all but the specific source addresses) to an IP multicast address.

The figure below shows where MLD and PIM-SM operate within the IPv6 multicast environment.
Multicast Listener Discovery Protocol for IPv6

To start implementing multicasting in the campus network, users must first define who receives the multicast. The MLD protocol is used by IPv6 devices to discover the presence of multicast listeners (for example, nodes that want to receive multicast packets) on their directly attached links, and to discover specifically which multicast addresses are of interest to those neighboring nodes. It is used for discovering local group and source-specific group membership. The MLD protocol provides a means to automatically control and limit the flow of multicast traffic throughout your network with the use of special multicast queriers and hosts.

The difference between multicast queriers and hosts is as follows:

• A querier is a network device, such as a device, that sends query messages to discover which network devices are members of a given multicast group.
• A host is a receiver, including devices, that send report messages to inform the querier of a host membership.

A set of queriers and hosts that receive multicast data streams from the same source is called a multicast group. Queriers and hosts use MLD reports to join and leave multicast groups and to begin receiving group traffic.

MLD uses the Internet Control Message Protocol (ICMP) to carry its messages. All MLD messages are link-local with a hop limit of 1, and they all have the alert option set. The alert option implies an implementation of the hop-by-hop option header.

MLD has three types of messages:

• Query--General, group-specific, and multicast-address-specific. In a query message, the multicast address field is set to 0 when MLD sends a general query. The general query learns which multicast addresses have listeners on an attached link.

Group-specific and multicast-address-specific queries are the same. A group address is a multicast address.

• Report--In a report message, the multicast address field is that of the specific IPv6 multicast address to which the sender is listening.

• Done--In a done message, the multicast address field is that of the specific IPv6 multicast address to which the source of the MLD message is no longer listening.

An MLD report must be sent with a valid IPv6 link-local source address, or the unspecified address (::), if the sending interface has not yet acquired a valid link-local address. Sending reports with the unspecified address is allowed to support the use of IPv6 multicast in the Neighbor Discovery Protocol.

For stateless autoconfiguration, a node is required to join several IPv6 multicast groups in order to perform duplicate address detection (DAD). Prior to DAD, the only address the reporting node has for the sending interface is a tentative one, which cannot be used for communication. Therefore, the unspecified address must be used.

MLD states that result from MLD version 2 or MLD version 1 membership reports can be limited globally or by interface. The MLD group limits feature provides protection against denial of service (DoS) attacks caused by MLD packets. Membership reports in excess of the configured limits will not be entered in the MLD cache, and traffic for those excess membership reports will not be forwarded.

MLD provides support for source filtering. Source filtering allows a node to report interest in listening to packets only from specific source addresses (as required to support SSM), or from all addresses except specific source addresses sent to a particular multicast address.

When a host using MLD version 1 sends a leave message, the device needs to send query messages to reconfirm that this host was the last MLD version 1 host joined to the group before it can stop forwarding...
traffic. This function takes about 2 seconds. This "leave latency" is also present in IGMP version 2 for IPv4 multicast.

**MLD Access Group**

MLD access groups provide receiver access control in Cisco IPv6 multicast devices. This feature limits the list of groups a receiver can join, and it allows or denies sources used to join SSM channels.

**How to Configure IPv6 Multicast Listener Discovery Protocol**

- Enabling IPv6 Multicast Routing, page 32
- Customizing and Verifying MLD on an Interface, page 33
- Disabling MLD Device-Side Processing, page 35
- Resetting the MLD Traffic Counters, page 36
- Clearing the MLD Interface Counters, page 37

**Enabling IPv6 Multicast Routing**

IPv6 multicast uses MLD version 2. This version of MLD is fully backward-compatible with MLD version 1 (described in RFC 2710). Hosts that support only MLD version 1 will interoperate with a device running MLD version 2. Mixed LANs with both MLD version 1 and MLD version 2 hosts are likewise supported.

You must first enable IPv6 unicast routing on all interfaces of the device on which you want to enable IPv6 multicast routing.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ipv6 multicast-routing [vrf vrf-name]

### Customizing and Verifying MLD on an Interface

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ipv6 mld join-group [group-address] [[include | exclude] {source-address | source-list [acl]}}`
5. `ipv6 mld access-group access-list-name`
6. `ipv6 mld static-group [group-address] [[include | exclude] {source-address | source-list [acl]}}`
7. `ipv6 mld query-max-response-time seconds`
8. `ipv6 mld query-timeout seconds`
9. `ipv6 mld query-interval seconds`
10. `end`
11. `show ipv6 mld groups [link-local] [group-name | group-address] [interface-type interface-number] [detail | explicit]`
12. `show ipv6 mfib summary`
13. `show ipv6 mld interface [type number]`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>

</table>

### Example

- **Step 3**
  ```
  Device(config)# interface GigabitEthernet 1/0/0
  ```
- **Step 4**
  ```
  Device(config-if)# ipv6 mld join-group FF04::12 exclude 2001:DB8::10::11
  ```
- **Step 5**
  ```
  Device(config-if)# ipv6 mld access-list acc-grp-1
  ```
- **Step 6**
  ```
  Device(config-if)# ipv6 mld static-group ff04::10 include 100::1
  ```
- **Step 7**
  ```
  Device(config-if)# ipv6 mld query-max-response-time 20
  ```
- **Step 8**
  ```
  Device(config-if)# ipv6 mld query-timeout 130
  ```
- **Step 9**
  ```
  Device(config-if)# ipv6 mld query-interval 60
  ```
### Command or Action | Purpose
--- | ---
**Step 10** end | Exits to privileged EXEC mode.

**Example:**
```
Device(config-if)# end
```

**Step 11** show ipv6 mld groups [link-local] [group-name | group-address] [interface-type interface-number] [detail | explicit] | Displays the multicast groups that are directly connected to the device and that were learned through MLD.

**Example:**
```
Device# show ipv6 mld groups GigabitEthernet 2/1/0
```

**Step 12** show ipv6 mfib summary | Displays summary information about the number of IPv6 Multicast Forwarding Information Base (MFIB) entries (including link-local groups) and interfaces.

**Example:**
```
Device# show ipv6 mfib summary
```

**Step 13** show ipv6 mld interface [type number] | Displays multicast-related information about an interface.

**Example:**
```
Device# show ipv6 mld interface GigabitEthernet 2/1/0
```

---

### Disabling MLD Device-Side Processing

A user might only want specified interfaces to perform IPv6 multicast and will therefore want to turn off MLD device-side processing on a specified interface.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface type number
4. no ipv6 mld router
**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  • Enter your password if prompted. |
| **Example:** | |
| Device> enable | |
| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:** | |
| Device# configure terminal | |
| **Step 3** interface type number | Specifies an interface type and number, and places the device in interface configuration mode. |
| **Example:** | |
| Device(config)# interface GigabitEthernet 1/0/0 | |
| **Step 4** no ipv6 mld router | Disables MLD device-side processing on a specified interface. |
| **Example:** | |
| Device(config-if)# no ipv6 mld router | |

**Resetting the MLD Traffic Counters**

**SUMMARY STEPS**

1. enable  
2. clear ipv6 mld [vrf vrf-name] traffic  
3. show ipv6 mld [vrf vrf-name] traffic

**DETAILED STEPS**

**Configuration Examples for IPv6 Multicast Listener Discovery Protocol**

- Example: Enabling IPv6 Multicast Routing, page 38
- Example: Configuring the MLD Protocol, page 38
- Example: Disabling MLD Router-Side Processing, page 39
Example: Enabling IPv6 Multicast Routing

The following example enables multicast routing on all interfaces and also enables multicast forwarding for PIM and MLD on all enabled interfaces of the device.

```
Device> enable
Device# configure terminal
Device(config)# ipv6 multicast-routing
```

Example: Configuring the MLD Protocol

The following example shows how to configure the query maximum response time, the query timeout, and the query interval on GigabitEthernet interface 1/0/0:

```
Device> enable
Device# configure terminal
Device(config)# interface GigabitEthernet 1/0/0
Device(config-if)# ipv6 mld query-max-response-time 20
Device(config-if)# ipv6 mld query-timeout 130
Device(config-if)# ipv6 mld query-interval 60
```

The following example shows how to configure MLD reporting for a specified group and source, allows the user to perform IPv6 multicast receiver access control, and statically forwards traffic for the multicast group onto GigabitEthernet interface 1/0/0:

```
Device> enable
Device# configure terminal
Device(config)# interface GigabitEthernet 1/0/0
Device(config)# ipv6 mld join-group FF04::10
Device(config)# ipv6 mld static-group FF04::10 100::1
Device(config)# ipv6 mld access-group acc-grp-1
```

The following example shows information from the `show ipv6 mld interface` command for GigabitEthernet interface 2/1/0:

```
Device# show ipv6 mld interface GigabitEthernet 2/1/1
GigabitEthernet2/1/1 is up, line protocol is up
Internet address is FE80::205:5FFF:FEAF:2C39/10
MLD is enabled in interface
Current MLD version is 2
MLD query interval is 125 seconds
MLD querier timeout is 255 seconds
MLD max query response time is 10 seconds
Last member query response interval is 1 seconds
MLD activity: 25 joins, 17 leaves
MLD querying router is FE80::205:5FFF:FEAF:2C39 (this system)
```

The following example displays the MLD protocol messages received and sent:

```
Device# show ipv6 mld traffic
MLD Traffic Counters
Elapsed time since counters cleared:00:00:21

  Valid MLD Packets  Received   Sent
  Queries            1           0
  Reports            2           1
```
### Example: Disabling MLD Router-Side Processing

The following example turns off MLD device-side processing on GigabitEthernet interface 1/0/0:

```
Device> enable
Device# configure terminal
Device(config)# interface GigabitEthernet 1/0/0
Device(config-if)# no ipv6 mld router
```

MLDP Filtering

The MDLP Filtering feature adds filtering capabilities to the Cisco Multicast Label Distribution Protocol (MLDP) label-based Multicast Virtual Private Network (MVPN) solution.
Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.
Prerequisites for MLDP Filtering

- MDT must be configured.
- MLDP-based MVPN must be configured.
Information about MLDP Filtering

- MLDP Filtering, page 49
- MLDP Disable on an Interface, page 49

MLDP Filtering

MLDP Filtering prevents multicast traffic that is distributed to different sites via MVPNs from traveling on sections of the network by providing the following capabilities:

- Prevent MLDP traffic from traversing interconnections
- Map flows to MLDP data Multicast Distribution Tree (MDT) numbers
- Filter label mappings based on a particular range of MLDP tree numbers per VRF

The filtering feature uses FEC (Forward Equivalence Class) definitions to filter specified FECs on a per-peer basis. The list of peers for which a FEC is to be filtered is defined in an access control list (ACL). FEC-based filtering per peer is supported only for outbound filtering. If an MLDP stream is denied by the filter, then the router will not advertise label mappings to the filtered peer.

MLDP Filtering also enables you to filter label mappings based on a particular range of MLDP tree numbers per VRF. If a source and group (S,G) MVPN entry matches more than one data MDT configuration, all data MDT configurations are examined and the first configuration that contains an ACL that matches the (S,G) is picked. If none of the ACLs match the (S,G), then the tree number with the lowest ref_count among all the remaining no-ACL data MDT configurations is selected. If an (S,G) flow in the vrf is on a data MDT without an ACL and a new data MDT configuration with a matching ACL is configured, the (S,G) flow will not switch to the newly configured scope. The (S,G) flows which are already on the data MDT will switch only if the vrf mroutes are cleared.

Traffic can flow on the default MDT or it can be switched immediately to the data MDT after the (S,G) state is created on the ingress Provider Edge (PE) router. Immediate switch works for source specific-multicast (SSM) groups in the VRF only if the MDT data threshold is 0. As long as the (S,G) SSM state exists on the ingress PE router, traffic will stay on the data MDT.

MLDP Disable on an Interface

Multicast Label Distribution Protocol (MLDP) is automatically enabled on all interfaces on which Multiprotocol Label Switching (MPLS) dynamic label switching is enabled. Disabling MLDP on an interface prevents that interface from being used in path selection even if it is advertised as a path by route watch. If the only path returned by route watch is one on which MLDP is disabled, then the route to that peer or root is considered unreachable. If a router receives a label mapping on a particular interface on which MLDP is disabled, the router installs the label mapping and builds a tree upstream.
If there are two links to a given peer and one of them is MLDP-disabled, it is possible that the MPLS Forwarding Infrastructure (MFI) will use the disabled link for forwarding if recursive forwarding is configured. To ensure that the MLDP-disabled interface is not used by MFI, you must disable recursive forwarding.
How to Configure MLDP Filtering

- Disabling MLDP on an Interface, page 51
- Filtering MLDP Traffic, page 52
- Mapping S and G Flows to MDT Trees, page 53
- Verifying MLDP Filtering, page 54

Disabling MLDP on an Interface

MLDP is enabled by default on all MPLS-enabled interfaces. Perform this task to disable MLDP on the specified interface. We recommend that you disable MLDP on both sides of a link.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **no mlps mldp**
5. **end**

Configuration Examples for MLDP Filtering

- Example: MLDP Filtering, page 57
- Example: S and G Mappings to Data MDT Tree Numbers, page 57

**Example: MLDP Filtering**

The following example configuration shows the following:

- Peer P4 will be denied for all FECs (matches FEC 1).
- For FECs having VPN id 1:1 and any scope, peers P4 (matches FEC 1) and P2 (matches FEC 2) will be denied. Additionally peer P3 will be denied if FEC VPN id is 1:1 and scope 2 (matches FEC 4).
- For FECs having VPN id 2:2 and scope 1, peers P4 (matches FEC 1) and P2 (matches FEC 3) will be denied. Additionally peer P3 will be denied if FEC VPN id is 2:2 and scope 2 (matches FEC 4).
- For FECs having any VPN id and scope 2, peers P4 (matches FEC 1) and P3 (matches FEC 4) will be denied.
- Peer P4 will be denied for FEC with VPN id 3:3 and scope 3.

```plaintext
access-list 50 deny 4.4.4.4
access-list 50 permit any
access-list 51 deny 2.2.2.2
access-list 51 permit any
access-list 52 deny 3.3.3.3
access-list 52 permit any

mpls mldp fec 1 opaque-type mdt vpn-id any scope any
mpls mldp fec 2 opaque-type mdt vpn-id 1:1 scope any
mpls mldp fec 3 opaque-type mdt vpn-id 2:2 scope 1
mpls mldp fec 4 opaque-type mdt vpn-id all scope 2

mpls mldp filter 1 peer-list 50
mpls mldp filter 2 peer-list 51
mpls mldp filter 3 peer-list 51
mpls mldp filter 4 peer-list 52
```

**Example: S and G Mappings to Data MDT Tree Numbers**

This example shows the (S,G) mappings on the ingress PE for a given VRF (blue). Group range 232.1.1.0/24 is confined within local scope 1 with traffic switching immediately to the data MDT. Group range 232.1.2.0/24 is confined to regional scope 2.

```plaintext
access-list 100 permit ip any 232.1.1.0 0.0.0.255
access-list 101 permit ip any 232.1.2.0 0.0.0.255
```
Example: S and G Mappings to Data MDT Tree Numbers

```
ip vrf blue
mtb data mpls mldp 100 list 100 scope 1 immediate-switch
mtb data mpls mldp 200 list 101 scope 2 immediate-switch
```

MLD Group Limits

The IPv6 Multicast Listener Discovery (MLD) group limits feature provides global and per-interface MLD join limits.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About MLD Group Limits

- Multicast Listener Discovery Protocol for IPv6, page 65

Multicast Listener Discovery Protocol for IPv6

To start implementing multicasting in the campus network, users must first define who receives the multicast. The MLD protocol is used by IPv6 devices to discover the presence of multicast listeners (for example, nodes that want to receive multicast packets) on their directly attached links, and to discover specifically which multicast addresses are of interest to those neighboring nodes. It is used for discovering local group and source-specific group membership. The MLD protocol provides a means to automatically control and limit the flow of multicast traffic throughout your network with the use of special multicast queriers and hosts.

The difference between multicast queriers and hosts is as follows:

- A querier is a network device, such as a device, that sends query messages to discover which network devices are members of a given multicast group.
A host is a receiver, including devices, that send report messages to inform the querier of a host membership.

A set of queriers and hosts that receive multicast data streams from the same source is called a multicast group. Queriers and hosts use MLD reports to join and leave multicast groups and to begin receiving group traffic.

MLD uses the Internet Control Message Protocol (ICMP) to carry its messages. All MLD messages are link-local with a hop limit of 1, and they all have the alert option set. The alert option implies an implementation of the hop-by-hop option header.

MLD has three types of messages:

- Query—General, group-specific, and multicast-address-specific. In a query message, the multicast address field is set to 0 when MLD sends a general query. The general query learns which multicast addresses have listeners on an attached link.

  Group-specific and multicast-address-specific queries are the same. A group address is a multicast address.

- Report--In a report message, the multicast address field is that of the specific IPv6 multicast address to which the sender is listening.

- Done--In a done message, the multicast address field is that of the specific IPv6 multicast address to which the source of the MLD message is no longer listening.

An MLD report must be sent with a valid IPv6 link-local source address, or the unspecified address (::), if the sending interface has not yet acquired a valid link-local address. Sending reports with the unspecified address is allowed to support the use of IPv6 multicast in the Neighbor Discovery Protocol.

For stateless autoconfiguration, a node is required to join several IPv6 multicast groups in order to perform duplicate address detection (DAD). Prior to DAD, the only address the reporting node has for the sending interface is a tentative one, which cannot be used for communication. Therefore, the unspecified address must be used.

MLD states that result from MLD version 2 or MLD version 1 membership reports can be limited globally or by interface. The MLD group limits feature provides protection against denial of service (DoS) attacks caused by MLD packets. Membership reports in excess of the configured limits will not be entered in the MLD cache, and traffic for those excess membership reports will not be forwarded.

MLD provides support for source filtering. Source filtering allows a node to report interest in listening to packets only from specific source addresses (as required to support SSM), or from all addresses except specific source addresses sent to a particular multicast address.

When a host using MLD version 1 sends a leave message, the device needs to send query messages to reconfirm that this host was the last MLD version 1 host joined to the group before it can stop forwarding traffic. This function takes about 2 seconds. This "leave latency" is also present in IGMP version 2 for IPv4 multicast.

How to Implement MLD Group Limits

- Implementing MLD Group Limits Globally, page 67
- Implementing MLD Group Limits per Interface, page 67
Implementing MLD Group Limits Globally

SUMMARY STEPS

1. enable
2. configure terminal
3. ipv6 mld [vrf vrf-name] state-limit number

DETAILED STEPS

**Configuration Examples for MLD Group Limits**

- Example: Implementing MLD Group Limits, page 68

**Example: Implementing MLD Group Limits**

This example shows the groups and channels that are being accounted when the MLD group limit function is active:

Device# show ipv6 mld groups FF03::1 detail

<table>
<thead>
<tr>
<th>Interface:</th>
<th>FastEthernet5/1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group:</td>
<td>FF03::1</td>
</tr>
<tr>
<td>Uptime:</td>
<td>00:00:05</td>
</tr>
<tr>
<td>Router mode:</td>
<td>EXCLUDE (Expires: 00:04:14)</td>
</tr>
<tr>
<td>Host mode:</td>
<td>INCLUDE</td>
</tr>
<tr>
<td>Last reporter</td>
<td>FE80::20A:8BFF:FE4D:6039</td>
</tr>
<tr>
<td>State accounted</td>
<td></td>
</tr>
<tr>
<td>Source list is empty</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Interface:</th>
<th>FastEthernet5/1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group:</td>
<td>FF33::1</td>
</tr>
<tr>
<td>Uptime:</td>
<td>00:00:03</td>
</tr>
<tr>
<td>Router mode:</td>
<td>INCLUDE</td>
</tr>
</tbody>
</table>
Host mode: INCLUDE
Last reporter: FE80::20A:8BFF:FE4D:6039
Group source list:
Source Address                          Uptime    Expires   Fwd  Flags
2001:DB8:0::1                                   00:00:03  00:04:16  Yes  Remote Ac 4

The following example shows all of the groups joined by Fast Ethernet interface 2/1, including link-local groups used by network protocols.

Device# show ipv6 mld groups FastEthernet 2/1

MLD Connected Group Membership
Group Address          Interface           Uptime        Expires
FF02::2                FastEthernet2/1     3d18h         never
FF02::D                FastEthernet2/1     3d18h         never
FF02::16               FastEthernet2/1     3d18h         never
FF02::1:FF00:1         FastEthernet2/1     3d18h         00:00:27
FF02::1:FF00:79        FastEthernet2/1     3d18h         never
FF02::1:FF23:83C2      FastEthernet2/1     3d18h         00:00:22
FF02::1:FFAF:2C39      FastEthernet2/1     3d18h         never
FF06:7777::1           FastEthernet2/1     3d18h         00:00:26

The following is sample output from the show ipv6 mld groups summary command:

Device# show ipv6 mld groups summary

MLD Route Summary
No. of (*,G) routes = 5
No. of (S,G) routes = 0

HA Support for MLDP

The HA Support for MLDP feature enables Cisco Multicast Label Distribution Protocol (MLDP) to checkpoint sufficient signaling and forwarding information for repopulating the necessary database on a dual Route Processor (RP) platform on which Stateful Switchover/Nonstop Forwarding (SSO/NSF) and Label Distribution Protocol (LDP) Graceful Restart are configured, after a switchover.
Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.
Prerequisites for HA Support for MLDP

- Stateful Switchover/Nonstop Forwarding (SSO/NSF) and LDP Graceful Restart must be configured on the dual Route Processor (RP) platform.
- LDP Graceful Restart must be configured on the NSF router peers.
- The Cisco IOS release software installed on the active and standby RPs must support MLDP-based MVPN and HA Support for MLDP.
Restrictions for HA Support for MLDP

- If Label Distribution Protocol (LDP) Graceful Restart is not enabled on the dual Route Processor (RP) platform, Nonstop Forwarding (NSF) peers will remove existing forwarding and label information from their Multicast Label Distribution Protocol (MLDP) database entries immediately following a switchover.
Information About HA Support for MLDP

The HA Support for MLDP feature enables MLDP to checkpoint label forwarding or path set information. To support NSF, MLDP uses existing PIM HA architecture to checkpoint the information to the standby RP.

MDT data group creation is a dynamic event triggered by traffic exceeding a specified threshold. When the threshold is exceeded (requiring an MDT data group to be created) or when traffic falls below the threshold (requiring the MDT data group to be deleted), the router detecting the event creates, deletes, or updates an MDT data "send" entry, creates the corresponding (S,G) state, if necessary, and sends a message to PE peers to create, delete, or update a corresponding MDT data "receive" entry and the corresponding (S,G) state.

The active RP will checkpoint the current state of the MLDP peer, paths to peers, root, paths to root, and the database and replication/branch entry onto the standby RP and use this state to recreate the MLDP state after a switchover.
How to Monitor HA Support for MLDP

• Displaying Check Pointed Information, page 83
• Displaying Data MDT Mappings for MLDP on Standby Device, page 84

Displaying Check Pointed Information

SUMMARY STEPS

1. enable
2. show mpls mldp ha database
3. show mpls mldp ha database summary
4. show mpls mldp ha neighbor
5. show mpls mldp ha root
6. show mpls mldp ha count

DETAILED STEPS

<table>
