Optimizing PIM Sparse Mode in a Large IP Multicast Deployment

This module describes how to optimize Protocol Independent Multicast (PIM) sparse mode for a large deployment of IP multicast. You can set a limit on the rate of PIM register messages sent in order to limit the load on the designated router and RP, you can reduce the PIM router query message interval to achieve faster convergence, and you can delay or prevent the use of the shortest path tree.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Optimizing PIM Sparse Mode in a Large IP Multicast Deployment

- You must have PIM sparse mode running in your network.
- If you plan to use a group list to control to which groups the shortest-path tree (SPT) threshold applies, you must have configured your access list before performing the task.
Information About Optimizing PIM Sparse Mode in a Large IP Multicast Deployment

• PIM Registering Process, page 2
• PIM Designated Router, page 3
• PIM Sparse-Mode Register Messages, page 3
• Preventing Use of Shortest-Path Tree to Reduce Memory Requirement, page 3

PIM Registering Process

IP multicast sources do not use a signaling mechanism to announce their presence. Sources just send their data into the attached network, as opposed to receivers that use Internet Group Management Protocol (IGMP) to announce their presence. If a source sends traffic to a multicast group configured in PIM sparse mode (PIM-SM), the Designated Router (DR) leading toward the source must inform the rendezvous point (RP) about the presence of this source. If the RP has downstream receivers that want to receive the multicast traffic (natively) from this source and has not joined the shortest path leading toward the source, then the DR must send the traffic from the source to the RP. The PIM registering process, which is individually run for each (S, G) entry, accomplishes these tasks between the DR and RP.

The registering process begins when a DR creates a new (S, G) state. The DR encapsulates all the data packets that match the (S, G) state into PIM register messages and unicasts those register messages to the RP.

If an RP has downstream receivers that want to receive register messages from a new source, the RP can either continue to receive the register messages through the DR or join the shortest path leading toward the source. By default, the RP will join the shortest path, because delivery of native multicast traffic provides the highest throughput. Upon receipt of the first packet that arrives natively through the shortest path, the RP will send a register-stop message back to the DR. When the DR receives this register-stop message, it will stop sending register messages to the RP.

If an RP has no downstream receivers that want to receive register messages from a new source, the RP will not join the shortest path. Instead, the RP will immediately send a register-stop message back to the DR. When the DR receives this register-stop message, it will stop sending register messages to the RP.

Once a routing entry is established for a source, a periodic reregistering takes place between the DR and RP. One minute before the multicast routing table state times out, the DR will send one dataless register message to the RP each second that the source is active until the DR receives a register-stop message from the RP. This action restarts the timeout time of the multicast routing table entry, typically resulting in one reregistering exchange every 2 minutes. Reregistering is necessary to maintain state, to recover from lost state, and to keep track of sources on the RP. It will take place independently of the RP joining the shortest path.

• PIM Version 1 Compatibility, page 2

PIM Version 1 Compatibility

If an RP is running PIM Version 1, it will not understand dataless register messages. In this case, the DR will not send dataless register messages to the RP. Instead, approximately every 3 minutes after receipt of a register-stop message from the RP, the DR encapsulates the incoming data packets from the source into register messages and sends them to the RP. The DR continues to send register messages until it receives another register-stop message from the RP. The same behavior occurs if the DR is running PIM Version 1.
When a DR running PIM Version 1 encapsulates data packets into register messages for a specific (S, G) entry, the entry is process-switched, not fast-switched or hardware-switched. On platforms that support these faster paths, the PIM registering process for an RP or DR running PIM Version 1 may lead to periodic out-of-order packet delivery. For this reason, we recommend upgrading your network from PIM Version 1 to PIM Version 2.

**PIM Designated Router**

Devices configured for IP multicast send PIM hello messages to determine which device will be the designated router (DR) for each LAN segment (subnet). The hello messages contain the device’s IP address, and the device with the highest IP address becomes the DR.

The DR sends Internet Group Management Protocol (IGMP) host query messages to all hosts on the directly connected LAN. When operating in sparse mode, the DR sends source registration messages to the rendezvous point (RP).

By default, multicast devices send PIM router query messages every 30 seconds. By enabling a device to send PIM hello messages more often, the device can discover unresponsive neighbors more quickly. As a result, the device can implement failover or recovery procedures more efficiently. It is appropriate to make this change only on redundant devices on the edge of the network.

**PIM Sparse-Mode Register Messages**

Dataless register messages are sent at a rate of one message per second. Continuous high rates of register messages might occur if a DR is registering bursty sources (sources with high data rates) and if the RP is not running PIM Version 2.

By default, PIM sparse-mode register messages are sent without limiting their rate. Limiting the rate of register messages will limit the load on the DR and RP, at the expense of dropping those register messages that exceed the set limit. Receivers may experience data packet loss within the first second in which packets are sent from bursty sources.

**Preventing Use of Shortest-Path Tree to Reduce Memory Requirement**

Understanding PIM shared tree and source tree will help you understand how preventing the use of the shortest-path tree can reduce memory requirements.

- PIM Shared Tree and Source Tree - Shortest-Path Tree, page 3
- Benefit of Preventing or Delaying the Use of the Shortest-Path Tree, page 4

**PIM Shared Tree and Source Tree - Shortest-Path Tree**

By default, members of a multicast group receive data from senders to the group across a single data distribution tree rooted at the rendezvous point (RP). This type of distribution tree is called shared tree, as
shown in the figure. Data from senders is delivered to the RP for distribution to group members joined to
the shared tree.

**Figure 1**  *Shared Tree versus Source Tree (Shortest-Path Tree)*

If the data rate warrants, leaf devices on the shared tree may initiate a switch to the data distribution tree
rooted at the source. This type of distribution tree is called a shortest-path tree (SPT) or source tree. By
default, the software switches to a source tree upon receiving the first data packet from a source.

The following process describes the move from shared tree to source tree in more detail:

1. Receiver joins a group; leaf Device C sends a Join message toward the RP.
2. The RP puts the link to Device C in its outgoing interface list.
3. Source sends data; Device A encapsulates data in a register message and sends it to the RP.
4. The RP forwards data down the shared tree to Device C and sends a Join message toward the source. At
   this point, data may arrive twice at Device C, once encapsulated and once natively.
5. When data arrives natively (through multicast) at the RP, the RP sends a register-stop message to
   Device A.
6. By default, reception of the first data packet prompts Device C to send a Join message toward the
   source.
7. When Device C receives data on (S, G), it sends a Prune message for the source up the shared tree.
8. The RP deletes the link to Device C from the outgoing interface of (S, G). The RP triggers a Prune
   message toward the source.

Join and Prune messages are sent for sources and RPs. They are sent hop-by-hop and are processed by each
PIM device along the path to the source or RP. Register and register-stop messages are not sent hop-by-
hop. They are sent by the designated router that is directly connected to a source and are received by the RP
for the group.

Multiple sources sending to groups use the shared tree.

**Benefit of Preventing or Delaying the Use of the Shortest-Path Tree**
The switch from shared to source tree happens upon the arrival of the first data packet at the last hop device (Router C in Benefit of Preventing or Delaying the Use of the Shortest-Path Tree, page 4). This switch occurs because the `ip pim spt-threshold` command controls that timing, and its default setting is 0 kbps.

The shortest-path tree requires more memory than the shared tree, but reduces delay. You might want to prevent or delay its use to reduce memory requirements. Instead of allowing the leaf device to move to the shortest-path tree immediately, you can prevent use of the SPT or specify that the traffic must first reach a threshold.

You can configure when a PIM leaf device should join the shortest-path tree for a specified group. If a source sends at a rate greater than or equal to the specified kbps rate, the device triggers a PIM Join message toward the source to construct a source tree (shortest-path tree). If the `infinity` keyword is specified, all sources for the specified group use the shared tree, never switching to the source tree.

### How to Optimize PIM Sparse Mode in a Large IP Multicast Deployment

- Optimizing PIM Sparse Mode in a Large Deployment, page 5

### Optimizing PIM Sparse Mode in a Large Deployment

Consider performing this task if your deployment of IP multicast is large.

Steps 3, 5, and 6 in this task are independent of each other and are therefore considered optional. Any one of these steps will help optimize PIM sparse mode. If you are going to perform Step 5 or 6, you must perform Step 4. Step 6 applies only to a designated router; changing the PIM query interval is only appropriate on redundant devices on the edge of the PIM domain.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `ip pim register-rate-limit rate`
4. `ip pim spt-threshold {kbps|infinity}[group-list access-list]`
5. `interface type number`
6. `ip pim query-interval period [msec]`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip pim register-rate-limit <code>rate</code></td>
<td>(Optional) Sets a limit on the maximum number of PIM sparse mode register messages sent per second for each (S, G) routing entry.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
</tbody>
</table>
| Device(config)# ip pim register-rate-limit 10 | • Use this command to limit the number of register messages that the designated router (DR) will allow for each (S, G) entry.  
• By default, there is no maximum rate set.  
• Configuring this command will limit the load on the DR and RP at the expense of dropping those register messages that exceed the set limit.  
• Receivers may experience data packet loss within the first second in which register messages are sent from bursty sources. |
| **Step 4** ip pim spt-threshold `{kbps|infinity}|[group-list access-list]` | (Optional) Specifies the threshold that must be reached before moving to the shortest-path tree. |
| **Example:** | |
| Device(config)# ip pim spt-threshold infinity group-list 5 | • The default value is 0, which causes the device to join the SPT immediately upon the first data packet it receives.  
• Specifying the `infinity` keyword causes the device never to move to the shortest-path tree; it remains on the shared tree. This keyword applies to a multicast environment of “many-to-many” communication.  
• The group list is a standard access list that controls which groups the SPT threshold applies to. If a value of 0 is specified or the group list is not used, the threshold applies to all groups.  
• In the example, group-list 5 is already configured to permit the multicast groups 239.254.2.0 and 239.254.3.0: access-list 5 permit 239.254.2.0 0.0.0.255 access-list 5 permit 239.254.3.0 0.0.0.255 |
| **Step 5** interface `type number` | Configures an interface. |
| **Example:** | |
| Device(config)# interface gigabitethernet 0/0/0 | • If you do not want to change the default values of the PIM SPT threshold or the PIM query interval, do not perform this step; you are done with this task. |
| **Step 6** ip pim query-interval `period [msec]` | (Optional) Configures the frequency at which multicast devices send PIM router query messages. |
| **Example:** | |
| Device(config-if)# ip pim query-interval 1 | • Perform this step only on redundant devices on the edge of a PIM domain.  
• The default query interval is 30 seconds.  
• The `period` argument is in seconds unless the `msec` keyword is specified.  
• Set the query interval to a smaller number of seconds for faster convergence, but keep in mind the trade-off between faster convergence and higher CPU and bandwidth usage. |
Configuration Examples for Optimizing PIM Sparse Mode in a Large IP Multicast Deployment

- Optimizing PIM Sparse Mode in a Large IP Multicast Deployment Example, page 7

Optimizing PIM Sparse Mode in a Large IP Multicast Deployment Example

The following example shows how to:

- Set the query interval to 1 second for faster convergence.
- Configure the device to never move to the SPT but to remain on the shared tree.
- Set a limit of 10 PIM sparse mode register messages sent per second for each (S, G) routing entry.

```
interface gigabitethernet 0/0/0
ip pim query-interval 1

ip pim spt-threshold infinity
ip pim register-rate-limit 10
```

Multicast Subsecond Convergence

The Multicast Subsecond Convergence feature comprises a comprehensive set of features and protocol enhancements that provide for improved scalability and convergence in multicast-based services. This feature set provides for the ability to scale to larger services levels and to recover multicast forwarding after service failure in subsecond time frames.

- Finding Feature Information, page 11

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Multicast Subsecond Convergence

Service providers must have a multicast-enabled core in order to use the Cisco Multicast Subsecond Convergence feature.

Restrictions for Multicast Subsecond Convergence

Devices that use the subsecond designated router (DR) failover enhancement must be able to process hello interval information arriving in milliseconds. Devices that are congested or do not have enough CPU cycles to process the hello interval can assume that the Protocol Independent Multicast (PIM) neighbor is disconnected, although this may not be the case.
Information About Multicast Subsecond Convergence

- Benefits of Multicast Subsecond Convergence, page 12
- Multicast Subsecond Convergence Scalability Enhancements, page 12
- PIM Router Query Messages, page 12
- Reverse Path Forwarding, page 12
- RPF Checks, page 13
- Triggered RPF Checks, page 13
- Topology Changes and Multicast Routing Recovery, page 13

Benefits of Multicast Subsecond Convergence

- The scalability components improve on the efficiency of handling increases (or decreases) in service users (receivers) and service load (sources or content).
- New algorithms and processes (such as aggregated join messages, which deliver up to 1000 individual messages in a single packet) reduce the time to reach convergence by a factor of 10.
- Multicast subsecond convergence improves service availability for large multicast networks.
- Multicast users such as financial services firms and brokerages receive better quality of service (QoS), because multicast functionality is restored in a fraction of the time previously required.

Multicast Subsecond Convergence Scalability Enhancements

The Multicast Subsecond Convergence feature provides scalability enhancements that improve on the efficiency of handling increases (or decreases) in service users (receivers) and service load (sources or content). Scalability enhancements in this release include the following:

- Improved Internet Group Management Protocol (IGMP) and PIM state maintenance through new timer management techniques
- Improved scaling of the Multicast Source Discovery Protocol (MSDP) Source-Active (SA) cache

The scalability enhancements provide the following benefits:

- Increased potential PIM multicast route (mroute), IGMP, and MSDP SA cache state capacity
- Decreased CPU usage

PIM Router Query Messages

Multicast subsecond convergence allows you to send PIM router query messages (PIM hellos) every few milliseconds. The PIM hello message is used to locate neighboring PIM devices. Before the introduction of this feature, the device could send the PIM hellos only every few seconds. By enabling a device to send PIM hello messages more often, this feature allows the device to discover unresponsive neighbors more quickly. As a result, the device can implement failover or recovery procedures more efficiently.

Reverse Path Forwarding

Unicast Reverse Path Forwarding (RPF) helps to mitigate problems caused by the introduction of malformed or forged IP source addresses into a network by discarding IP packets that lack a verifiable IP
source address. Malformed or forged source addresses can indicate denial-of-service (DoS) attacks based on source IP address spoofing.

RPF uses access control lists (ACLs) in determining whether to drop or forward data packets that have malformed or forged IP source addresses. An option in the ACL commands allows system administrators to log information about dropped or forwarded packets. Logging information about forged packets can help in uncovering information about possible network attacks.

Per-interface statistics can help system administrators quickly discover the interface serving as the entry point for an attack on the network.

RPF Checks

PIM is designed to forward IP multicast traffic using the standard unicast routing table. PIM uses the unicast routing table to decide if the source of the IP multicast packet has arrived on the optimal path from the source. This process, the RPF check, is protocol-independent because it is based on the contents of the unicast routing table and not on any particular routing protocol.

Triggered RPF Checks

Multicast subsecond convergence provides the ability to trigger a check of RPF changes for mroute states. This check is triggered by unicast routing changes. By performing a triggered RPF check, users can set the periodic RPF check to a relatively high value (for example, 10 seconds) and still fail over quickly.

The triggered RPF check enhancement reduces the time needed for service to be restored after disruption, such as for single service events (for example, in a situation with one source and one receiver) or as the service scales along any parameter (for example, many sources, many receivers, and many interfaces). This enhancement decreases in time-to-converge PIM (mroute), IGMP, and MSDP (SA cache) states.

Topology Changes and Multicast Routing Recovery

The Multicast Subsecond Convergence feature set enhances both enterprise and service provider network backbones by providing almost instantaneous recovery of multicast paths after unicast routing recovery.

Because PIM relies on the unicast routing table to calculate its RPF when a change in the network topology occurs, unicast protocols first need to calculate options for the best paths for traffic, and then multicast can determine the best path.

Multicast subsecond convergence allows multicast protocol calculations to finish almost immediately after the unicast calculations are completed. As a result, multicast traffic forwarding is restored substantially faster after a topology change.

How to Configure Multicast Subsecond Convergence

• Modifying the PIM Router Query Message Interval, page 13
• Verifying Multicast Subsecond Convergence Configurations, page 14

Modifying the PIM Router Query Message Interval

Perform this task to modify the PIM router query message interval.
### SUMMARY STEPS
1. enable
2. configure terminal
3. interface type slot / subslot / port
4. ip pim query-interval period [msec]

### DETAILED STEPS

<table>
<thead>
<tr>

### What to Do Next
Proceed to the Verifying Multicast Subsecond Convergence Configurations, page 14 to display and verify information about the Multicast Subsecond Convergence feature.

### Verifying Multicast Subsecond Convergence Configurations
Perform this task to display detailed information about and to verify information regarding the Multicast Subsecond Convergence feature.
SUMMARY STEPS

1. enable
2. show ip pim interface type number
3. show ip pim neighbor

DETAILED STEPS

Step 1 enable

Example:

Device> enable
Enables privileged EXEC mode.
  • Enter your password if prompted.

Step 2 show ip pim interface type number
Use this command to display information about interfaces configured for PIM.

The following is sample output from the show ip pim interface command:

Example:

Device# show ip pim interface GigabitEthernet 1/0/0
Address          Interface                Ver/   Nbr    Query  DR     DR
Mode   Count  Intvl  Prior
172.16.1.4       GigabitEthernet1/0/0     v2/S   1      100 ms 1      172.16.1.4

Step 3 show ip pim neighbor
Use this command to display the PIM neighbors discovered by the Cisco IOS XE software.

The following is sample output from the show ip pim neighbor command:

Example:

Device# show ip pim neighbor
PIM Neighbor Table
Neighbor          Interface                Uptime/Expires    Ver   DR
Address                                                            Prio/Mode
172.16.1.3        GigabitEthernet1/0/0     00:03:41/250 msec v2    1 / S

Configuration Examples for Multicast Subsecond Convergence

• Modifying the PIM Router Query Message Interval Example, page 16
Modifying the PIM Router Query Message Interval Example

In the following example, the `ip pim query-interval` command has been set to 100 milliseconds. This command does not show up in `show running-config` command output unless the interval value has been configured to be the nondefault value.

```%
interface gigabitethernet0/0/1
ip address 172.16.2.1 255.255.255.0
ip pim query-interval 100 msec
ip pim sparse-mode
%
```

Feature Information for Multicast Subsecond Convergence

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

### Table 2 Feature Information for Multicast Subsecond Convergence

<table>
<thead>
<tr>
<th>Feature Name</th>
<th>Releases</th>
<th>Feature Information</th>
</tr>
</thead>
</table>
| Multicast Subsecond Convergence     | Cisco IOS XE Release 2.1  | The Multicast Subsecond Convergence feature comprises a comprehensive set of features and protocol enhancements that provide for improved scalability and convergence in multicast-based services. This feature set provides for the ability to scale to larger services levels and to recover multicast forwarding after service failure in subsecond time frames. The following commands were introduced or modified:  
  • debug ip mrouter
  • debug ip pim
  • ip pim query-interval
  • show ip pim interface
  • show ip pim neighbor |

Load Splitting IP Multicast Traffic over ECMP

This module describes how to load split IP multicast traffic over Equal Cost Multipath (ECMP). Multicast traffic from different sources or from different sources and groups are load split across equal-cost paths to take advantage of multiple paths through the network.

• Finding Feature Information, page 19
• Prerequisites for IP Multicast Load Splitting - ECMP, page 19

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for IP Multicast Load Splitting - ECMP

• You must have an adequate number of sources (at least more than two sources) to enable ECMP multicast load splitting based on source address.
• You must have multiple paths available to the RP to configure ECMP multicast load splitting.

Note

Use the show ip route command with either the IP address of the source for the ip-address argument or the IP address of the RP to validate that there are multiple paths available to the source or RP, respectively. If you do not see multiple paths in the output of the command, you will not be able to configure ECMP multicast load splitting.

• When using PIM-SM with shortest path tree (SPT) forwarding, the T-bit must be set for the forwarding of all (S, G) states.
Before configuring ECMP multicast load splitting, it is best practice to use the `show ip rpf` command to validate whether sources can take advantage of IP multicast multipath capabilities.

BGP does not install multiple equal-cost paths by default. Use the `maximum-paths` command to configure multipath (for example in BGP). For more information, see the Use of BGP with ECMP Multicast Load Splitting, page 28 section.

**Load Splitting Versus Load Balancing**

Load splitting and load balancing are not the same. Load splitting provides a means to randomly distribute (*, G) and (S, G) traffic streams across multiple equal-cost reverse path forwarding (RPF) paths, which does not necessarily result in a balanced IP multicast traffic load on those equal-cost RPF paths. By randomly distributing (*, G) and (S, G) traffic streams, the methods used for load splitting IP multicast traffic attempt to distribute an equal amount of traffic flows on each of the available RPF paths not by counting the flows, but, rather, by making a pseudorandom decision. These methods are collectively referred to as ECMP multicast load splitting methods. ECMP multicast load splitting methods, thus, result in better load-sharing in networks where there are many traffic streams that utilize approximately the same amount of bandwidth.

If there are just a few (S, G) or (*, G) states flowing across a set of equal-cost links, the chance that they are well balanced is quite low. To overcome this limitation, precalculated source addresses—for (S, G) states—or rendezvous point (RP) addresses—for (*, G) states—can be used to achieve a reasonable form of load balancing. This limitation applies equally to the per-flow load splitting in Cisco Express Forwarding (CEF) or with EtherChannels: As long as there are only a few flows, those methods of load splitting will not result in good load distribution without some form of manual engineering.

**Default Behavior for IP Multicast When Multiple Equal-Cost Paths Exist**

By default, for Protocol Independent Multicast sparse mode (PIM-SM), Source Specific Multicast (PIM-SSM), bidirectional PIM (bidir-PIM), and PIM dense mode (PIM-DM) groups, if multiple equal-cost paths are available, Reverse Path Forwarding (RPF) for IPv4 multicast traffic is based on the PIM neighbor with the highest IP address. This method is referred to as the highest PIM neighbor behavior. This behavior is in accordance with RFC 2362 for PIM-SM, but also applies to PIM-SSM, PIM-DM, and bidir-PIM.
The figure illustrates a sample topology that is used in this section to explain the default behavior for IP multicast when multiple equal-cost paths exist.

**Figure 2** Default Behavior for IP Multicast When Multiple Equal-Cost Paths Exist

In the figure, two sources, S1 and S2, are sending traffic to IPv4 multicast groups, G1 and G2. Either PIM-SM, PIM-SSM, or PIM-DM can be used in this topology. If PIM-SM is used, assume that the default interface 0 is being used on Device 2, that an Interior Gateway Protocol (IGP) is being run, and that the output of the `show ip route` command for S1 and for S2 (when entered on Device 2) displays serial interface 0 and serial interface 1 on Device 1 as equal-cost next-hop PIM neighbors of Device 2.

Without further configuration, IPv4 multicast traffic in the topology illustrated in the figure would always flow across one serial interface (either serial interface 0 or serial interface 1), depending on which interface has the higher IP address. For example, suppose that the IP addresses configured on serial interface 0 and serial interface 1 on Device 1 are 10.1.1.1 and 10.1.2.1, respectively. Given that scenario, in the case of PIM-SM and PIM-SSM, Device 2 would always send PIM join messages towards 10.1.2.1 and would always receive IPv4 multicast traffic on serial interface 1 for all sources and groups shown in the figure. In the case of PIM-DM, Device 2 would always receive IP multicast traffic on serial Interface 1, only that in this case, PIM join messages are not used in PIM-DM; instead Device 2 would prune the IP multicast traffic across serial interface 0 and would receive it through serial interface 1 because that interface has the higher IP address on Device 1.

IPv4 RPF lookups are performed by intermediate multicast device to determine the RPF interface and RPF neighbor for IPv4 (*,G) and (S, G) multicast routes (trees). An RPF lookup consists of RPF route-selection and route-path-selection. RPF route-selection operates solely on the IP unicast address to identify the root of the multicast tree. For (*, G) routes (PIM-SM and Bidir-PIM), the root of the multicast tree is the RP address for the group G; for (S, G) trees (PIM-SM, PIM-SSM and PIM-DM), the root of the multicast tree is the source S. RPF route-selection finds the best route towards the RP or source in the routing information base (RIB), and, if configured (or available), the Distance Vector Multicast Routing Protocol (DVMRP) routing table, the Multiprotocol Border Gateway Protocol (MBGP) routing table or configured static mroutes. If the resulting route has only one available path, then the RPF lookup is complete, and the next-hop device and interface of the route become the RPF neighbor and RPF interface of this multicast tree. If the route has more than one path available, then route-path-selection is used to determine which path to choose.

For IP multicast, the following route-path-selection methods are available:
Note

All methods but the default method of route-path-selection available in IP multicast enable some form of ECMP multicast load splitting.

- Highest PIM neighbor--This is the default method; thus, no configuration is required. If multiple equal-cost paths are available, RPF for IPv4 multicast traffic is based on the PIM neighbor with the highest IP address; as a result, without configuration, ECMP multicast load splitting is disabled by default.
- ECMP multicast load splitting method based on source address--Enables ECMP multicast load splitting based on source address using the S-hash algorithm.
- ECMP multicast load splitting method based on source and group address--Enables ECMP multicast load splitting based on source and group address using the basic S-G-hash algorithm.
- ECMP multicast load splitting method based on source, group, and next-hop address--Enables ECMP multicast load splitting based on source, group, and next-hop address using the next-hop-based S-G-hash algorithm.

The default behavior (the highest PIM neighbor behavior) does not result in any form of ECMP load-splitting in IP multicast, but instead selects the PIM neighbor that has the highest IP address among the next-hop PIM neighbors for the available paths. A next hop is considered to be a PIM neighbor when it displays in the output of the `show ip pim neighbor` command, which is the case when PIM hello messages have been received from it and have not timed out. If none of the available next hops are PIM neighbors, then simply the next hop with the highest IP address is chosen.

Methods to Load Split IP Multicast Traffic

In general, the following methods are available to load split IP multicast traffic:

- You can enable ECMP multicast load splitting based on source address, based on source and group address, or based on source, group, and next-hop address. After the equal-cost paths are recognized, ECMP multicast load splitting operates on a per (S, G) basis, rather than a per packet basis as in unicast traffic.
- Alternative methods to load split IP multicast are to consolidate two or more equal-cost paths into a generic routing encapsulation (GRE) tunnel and allow the unicast routing protocol to perform the load splitting, or to load split across bundle interfaces, such as Fast or Gigabit EtherChannel interfaces, Multilink PPP (MLPPP) link bundles, or Multilink Frame Relay (FR.16) link bundles.

Overview of ECMP Multicast Load Splitting

By default, ECMP multicast load splitting of IPv4 multicast traffic is disabled. ECMP multicast load splitting can be enabled using the `ip multicast multipath` command.

- ECMP Multicast Load Splitting Based on Source Address Using the S-Hash Algorithm, page 23
- ECMP Multicast Load Splitting Based on Source and Group Address Using the Basic S-G-Hash Algorithm, page 23
- Predictability As a By-Product of Using the S-Hash and Basic S-G-Hash Algorithms, page 23
- Polarization As a By-Product of Using the S-Hash and Basic S-G-Hash Algorithms, page 23
- ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address, page 24
ECMP Multicast Load Splitting Based on Source Address Using the S-Hash Algorithm

ECMP multicast load splitting traffic based on source address uses the S-hash algorithm, enabling the RPF interface for each (*, G) or (S, G) state to be selected among the available equal-cost paths, depending on the RPF address to which the state resolves. For an (S, G) state, the RPF address is the source address of the state; for a (*, G) state, the RPF address is the address of the RP associated with the group address of the state.

When ECMP multicast load splitting based on source address is configured, multicast traffic for different states can be received across more than just one of the equal-cost interfaces. The method applied by IPv4 multicast is quite similar in principle to the default per-flow load splitting in IPv4 CEF or the load splitting used with Fast and Gigabit EtherChannels. This method of ECMP multicast load splitting, however, is subject to polarization.

ECMP Multicast Load Splitting Based on Source and Group Address Using the Basic S-G-Hash Algorithm

ECMP multicast load splitting based on source and group address uses a simple hash, referred to as the basic S-G-hash algorithm, which is based on source and group address. The basic S-G-hash algorithm is predictable because no randomization is used in coming up with the hash value. The S-G-hash mechanism, however, is subject to polarization because for a given source and group, the same hash is always picked irrespective of the device this hash is being calculated on.

Note

The basic S-G-hash algorithm ignores bidir-PIM groups.

Predictability As a By-Product of Using the S-Hash and Basic S-G-Hash Algorithms

The method used by ECMP multicast load splitting in IPv4 multicast allows for consistent load splitting in a network where the same number of equal-cost paths are present in multiple places in a topology. If an RP address or source addresses are calculated once to have flows split across N paths, then they will be split across those N paths in the same way in all places in the topology. Consistent load splitting allows for predictability, which, in turn, enables load splitting of IPv4 multicast traffic to be manually engineered.

Polarization As a By-Product of Using the S-Hash and Basic S-G-Hash Algorithms

The hash mechanism used in IPv4 multicast to load split multicast traffic by source address or by source and group address is subject to a problem usually referred to as polarization. A by-product of ECMP multicast load splitting based on source address or on source and group address, polarization is a problem that prevents devices in some topologies from effectively utilizing all available paths for load splitting.
The figure illustrates a sample topology that is used in this section to explain the problem of polarization when configuring ECMP multicast load splitting based on source address or on source and group address.

**Figure 3  Polarization Topology**

In the topology illustrated in the figure, notice that Device 7 has two equal-cost paths towards the sources, S1 to S10, through Device 5 and Device 6. For this topology, ECMP multicast load splitting is enabled on all of the devices in the topology. In this scenario, Device 7 would apply equal-cost load splitting to the 10 \((S, G)\) states. The problem of polarization in this scenario would affect Device 7 because that device would end up choosing serial interface 0 on Device 5 for sources S1 to S5 and serial interface 1 on Device 6 for sources S6 to S10. The problem of polarization, furthermore, would also affect Device 5 and Device 6 in this topology. Device 5 has two equal-cost paths for S1 to S5 through serial interface 0 on Device 1 and serial interface 1 on Device 2. Because Device 5 would apply the same hash algorithm to select which of the two paths to use, it would end up using just one of these two upstream paths for sources S1 to S5; that is, either all the traffic would flow across Device 1 and Device 5 or across Device 2 and Device 5. It would be impossible in this topology to utilize Device 1 and Device 5 and Device 2 and Device 5 for load splitting. Likewise, the polarization problem would apply to Device 3 and Device 6 and Device 4 and Device 6; that is, it would be impossible in this topology to utilize both Device 3 and Device 6 and Device 4 and Device 6 for load splitting.

**ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address**

Configuring ECMP multicast load splitting based on source, group, and next-hop address enables a more complex hash, the next-hop-based S-G-hash algorithm, which is based on source, group, and next-hop address. The next-hop-based S-G-hash algorithm is predictable because no randomization is used in calculating the hash value. Unlike the S-hash and basic S-G-hash algorithms, the hash mechanism used by the next-hop-based S-G-hash algorithm is not subject to polarization.

**Note**

The next-hop-based S-G-hash algorithm in IPv4 multicast is the same algorithm used in IPv6 ECMP multicast load splitting, which, in turn, utilizes the same hash function used for PIM-SM bootstrap device (BSR).

The next-hop-based hash mechanism does not produce polarization and also maintains better RPF stability when paths fail. These benefits come at the cost that the source or RP IP addresses cannot be used to reliably predict and engineer the outcome of load splitting when the next-hop-based S-G-hash algorithm is
used. Because many customer networks have implemented equal-cost multipath topologies, the manual engineering of load splitting, thus, is not a requirement in many cases. Rather, it is more of a requirement that the default behavior of IP multicast be similar to IP unicast; that is, it is expected that IP multicast use multiple equal-cost paths on a best-effort basis. Load splitting for IPv4 multicast, therefore, could not be enabled by default because of the anomaly of polarization.

**Note**
Load splitting for CEF unicast also uses a method that does not exhibit polarization and likewise cannot be used to predict the results of load splitting or engineer the outcome of load splitting.

The next-hop-based hash function avoids polarization because it introduces the actual next-hop IP address of PIM neighbors into the calculation, so the hash results are different for each device, and in effect, there is no problem of polarization. In addition to avoiding polarization, this hash mechanism also increases stability of the RPF paths chosen in the face of path failures. Consider a device with four equal-cost paths and a large number of states that are load split across these paths. Suppose that one of these paths fails, leaving only three available paths. With the hash mechanism used by the polarizing hash mechanisms (the hash mechanism used by the S-hash and basic S-G-hash algorithms), the RPF paths of all states would likely reconverge and thus change between those three paths, especially those paths that were already using one of those three paths. These states, therefore, may unnecessarily change their RPF interface and next-hop neighbor. This problem exists simply because the chosen path is determined by taking the total number of paths available into consideration by the algorithm, so once a path changes, the RPF selection for all states is subject to change too. For the next-hop-based hash mechanism, only the states that were using the changed path for RPF would need to reconverge onto one of the three remaining paths. The states that were already using one of those paths would not change. If the fourth path came back up, the states that initially used it would immediately reconverge back to that path without affecting the other states.

**Note**
The next-hop-based S-G-hash algorithm ignores bidir-PIM groups.

### Effect of ECMP Multicast Load Splitting on PIM Neighbor Query and Hello Messages for RPF Path Selection

If load splitting of IP multicast traffic over ECMP is not enabled and there are multiple equal-cost paths towards an RP or a source, IPv4 multicast will first elect the highest IP address PIM neighbor. A PIM neighbor is a device from which PIM hello (or PIMv1 query) messages are received. For example, consider a device that has two equal-cost paths learned by an IGP or configured through two static routes. The next hops of these two paths are 10.1.1.1 and 10.1.2.1. If both of these next-hop devices send PIM hello messages, then 10.1.2.1 would be selected as the highest IP address PIM neighbor. If only 10.1.1.1 sends PIM hello messages, then 10.1.1.1 would be selected. If neither of these devices sends PIM hello messages, then 10.1.2.1 would be selected. This deference to PIM hello messages allows the construction of certain types of dynamic failover scenarios with only static multicast routes (mroutes); it is otherwise not very useful.

**Note**
For more information about configuring static mroutes, see the Configuring Multiple Static Mroutes in Cisco IOS configuration note on the Cisco IOS IP multicast FTP site, which is available at: ftp://ftpeng.cisco.com/ipmulticast/config-notes/static-mroutes.txt.

When load splitting of IP multicast traffic over ECMP is enabled, the presence of PIM hello message from neighbors is not considered; that is, the chosen RPF neighbor does not depend on whether or not PIM hello
messages are received from that neighbor—it only depends on the presence or absence of an equal-cost route entry.

**Effect of ECMP Multicast Loading Splitting on Assert Processing in PIM-DM and DF Election in Bidir-PIM**

Enabling load splitting across ECMP changes only the RPF selection on the downstream device; it does not have an effect on designated forwarder (DF) election in bidir-PIM or the assert processing on upstream devices in PIM-DM.

The figure illustrates a sample topology that is used in this section to explain the effect of ECMP multicast load splitting on assert processing in PIM-DM and DF election in bidir-PIM.

**Figure 4** ECMP Multicast Load Splitting and Assert Processing in PIM-DM and DF Election in Bidir-PIM

In the figure, Device 2 has two equal-cost paths to S1 and S2 and the RP addresses on Device 1. Both paths are across Gigabit Ethernet interface 1/0/0: one path towards Device 3 and one path towards Device 4. For PIM-SM and PIM-SSM (*, G) and (S, G) RPF selection, there is no difference in the behavior of Device 2 in this topology versus Device 2 in the topology illustrated in the figure. There is, however, a difference when using PIM-DM or bidir-PIM.

If PIM-DM is used in the topology illustrated in the figure, Device 3 and Device 4 would start flooding traffic for the states onto Gigabit Ethernet interface 1/0/0 and would use the PIM assert process to elect one device among them to forward the traffic and to avoid traffic duplication. As both Device 3 and Device 4 would have the same route cost, the device with the higher IP address on Gigabit Ethernet interface 1/0/0 would always win the assert process. As a result, if PIM-DM is used in this topology, traffic would not be load split across Device 3 and Device 4.

If bidir-PIM is used in the topology illustrated in the figure, a process called DF election would take place between Device 2, Device 3, and Device 4 on Gigabit Ethernet interface 1/0/0. The process of DF election would elect one device for each RP to forward traffic across Gigabit Ethernet interface 1/0/0 for any groups using that particular RP, based on the device with the highest IP address configured for that interface. Even if multiple RPs are used (for example one for G1 and another one for G2), the DF election for those RPs would always be won by the device that has the higher IP address configured on Gigabit Ethernet interface 1/0/0 (either Device 3 or Device 4 in this topology). The election rules used for DF election are virtually the same as the election rules used for the PIM assert process, only the protocol mechanisms to negotiate them are more refined for DF election (in order to return the results more expeditiously). As a result, when
bidir-PIM is used in this topology, load splitting would always occur across Gigabit Ethernet interface 1/0/0.

The reason that ECMP multicast load splitting influences the RPF selection but not the assert process in PIM-DM or DF election in bidir-PIM is because both the assert process and DF election are cooperative processes that need to be implemented consistently between participating devices. Changing them would require some form of protocol change that would also need to be agreed upon by the participating devices. RPF selection is a purely device local policy and, thus, can be enabled or disabled without protocol changes individually on each device.

For PIM-DM and bidir-PIM, configuring ECMP multicast load splitting is effective only in topologies where the equal-cost paths are not upstream PIM neighbors on the same LAN, but rather neighbors on different LANs or point-to-point links.

### Effect of ECMP Multicast Load Splitting on the PIM Assert Process in PIM-SM and PIM-SSM

There are also cases where ECMP multicast load splitting can become ineffective due to the PIM assert process taking over, even when using PIM-SM with (*) or (S, G) forwarding or PIM-SSM with (S, G) forwarding.

The figure illustrates a sample topology that is used in this section to explain the effect of ECMP multicast load splitting on the PIM assert process in PIM-SM and PIM-SSM.

**Figure 5**  
ECMP Multicast Load Splitting and the PIM Assert Process in PIM-SM and PIM-SSM

In the topology illustrated in the figure, if both Device 2 and Device 5 are Cisco devices and are consistently configured for ECMP multicast load splitting, then load splitting would continue to work as expected; that is, both devices would have Device 3 and Device 4 as equal-cost next hops and would sort the list of equal-cost paths in the same way (by IP address). When applying the multipath hash function, for each (S, G) or (*) state, they would choose the same RPF neighbor (either Device 3 or Device 4) and send their PIM joins to this neighbor.

If Device 5 and Device 2 are inconsistently configured, or if Device 5 is a third-party device, then Device 2 and Device 5 may choose different RPF neighbors for some (*) or (S, G) states. For example Device 2 could choose Device 3 for a particular (S, G) state or Device 5 could choose Device 4 for a particular (S, G) state. In this scenario, Device 3 and Device 4 would both start to forward traffic for that state onto Gigabit Ethernet interface 1/0/0, see each other’s forwarded traffic, and—to avoid traffic duplication—start the assert process. As a result, for that (S, G) state, the device with the higher IP address for Gigabit Ethernet
interface 1/0/0 would forward the traffic. However, both Device 2 and Device 5 would be tracking the winner of the assert election and would send their PIM joins for that state to this assert winner, even if this assert winner is not the same device as the one that they calculated in their RPF selection. For PIM-SM and PIM-SSM, therefore, the operation of ECMP multicast load splitting can only be guaranteed when all downstream devices on a LAN are consistently configured Cisco devices.

**ECMP Multicast Load Splitting and Reconvergence When Unicast Routing Changes**

When unicast routing changes, all IP multicast routing states reconverge immediately based on the available unicast routing information. Specifically, if one path goes down, the remaining paths reconverge immediately, and if the path comes up again, multicast forwarding will subsequently reconverge to the same RPF paths that were used before the path failed. Reconvergence occurs whether load splitting of IP multicast traffic over ECMP is configured or not.

**Use of BGP with ECMP Multicast Load Splitting**

ECMP multicast load splitting works with RPF information learned through BGP in the same way as with RPF information learned from other protocols: It chooses one path out of the multiple paths installed by the protocol. The main difference with BGP is that it only installs a single path, by default. For example, when a BGP speaker learns two identical external BGP (eBGP) paths for a prefix, it will choose the path with the lowest device ID as the best path. The best path is then installed in the IP routing table. If BGP multipath support is enabled and the eBGP paths are learned from the same neighboring AS, instead of picking the single best path, BGP installs multiple paths in the IP routing table. By default, BGP will install only one path to the IP routing table.

To leverage ECMP multicast load splitting for BGP learned prefixes, you must enable BGP multipath. Once configured, when BGP installs the remote next-hop information, RPF lookups will execute recursively to find the best next hop towards that BGP next hop (as in unicast). If for example there is only a single BGP path for a given prefix, but there are two IGP paths to reach that BGP next hop, then multicast RPF will correctly load split between the two different IGP paths.

**Use of ECMP Multicast Load Splitting with Static Mroutes**

If it is not possible to use an IGP to install equal cost routes for certain sources or RPs, static routes can be configured to specify the equal-cost paths for load splitting. You cannot use static mroutes to configure equal-cost paths because the software does not support the configuration of one static mroute per prefix. There are some workarounds for this limitation using recursive route lookups but the workarounds cannot be applied to equal-cost multipath routing.

---

**Note**

For more information about configuring static mroutes, see the Configuring Multiple Static Mroutes in Cisco IOS configuration note on the Cisco IOS IP multicast FTP site at ftp://ftpeng.cisco.com/ipmulticast/config-notes/static-mroutes.txt.

You can specify only static mroutes for equal-cost multipaths in IPv4 multicast; however, those static mroutes would only apply to multicast, or you can specify that the equal-cost multipaths apply to both unicast and multicast routing. In IPv6 multicast, there is no such restriction. Equal-cost multipath mroutes can be configured for static IPv6 mroutes that apply to only unicast routing, only multicast routing, or both unicast and multicast routing.
Alternative Methods of Load Splitting IP Multicast Traffic

Load splitting of IP multicast traffic can also be achieved by consolidating multiple parallel links into a single tunnel over which the multicast traffic is then routed. This method of load splitting is more complex to configure than ECMP multicast load splitting. One such case where configuring load splitting across equal-cost paths using GRE links can be beneficial is the case where the total number of (S, G) or (*, G) states is so small and the bandwidth carried by each state so variable that even the manual engineering of the source or RP addresses cannot guarantee the appropriate load splitting of the traffic.

Note

With the availability of ECMP multicast load splitting, tunnels typically only need to be used if per-packet load sharing is required.

IP multicast traffic can also be used to load split across bundle interfaces, such as Fast or Gigabit EtherChannel interfaces, MLPPP link bundles or Multilink Frame Relay (FRF.16) bundles. GRE or other type of tunnels can also constitute such forms of Layer 2 link bundles. Before using such an Layer 2 mechanism, it is necessary to understand how unicast and multicast traffic is load split.

Before load splitting IP multicast traffic across equal-cost paths over a tunnel, you must configure CEF per-packet load balancing or else the GRE packets will not be load balanced per packet.

How to Load Split IP Multicast Traffic over ECMP

- Restrictions, page 29
- Enabling ECMP Multicast Load Splitting Based on Source Address, page 29
- Enabling ECMP Multicast Load Splitting Based on Source and Group Address, page 31
- Enabling ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address, page 33

Restrictions

The ip multicast multipath command does not support configurations in which the same PIM neighbor IP address is reachable through multiple equal-cost paths. This situation typically occurs if unnumbered interfaces are used. Use different IP addresses for all interfaces when configuring the ip multicast multipath command.

Enabling ECMP Multicast Load Splitting Based on Source Address

Perform this task to enable ECMP multicast load splitting of multicast traffic based on source address (using the S-hash algorithm) to take advantage of multiple paths through the network. The S-hash algorithm is predictable because no randomization is used in calculating the hash value. The S-hash algorithm, however, is subject to polarization because for a given source, the same hash is always picked irrespective of the device on which the hash is being calculated.
Enable ECMP multicast load splitting on the device that is to be the receiver for traffic from more than one incoming interfaces, which is opposite to unicast routing. From the perspective of unicast, multicast is active on the sending device connecting to more than one outgoing interfaces.

### SUMMARY STEPS

1. enable
2. configure terminal
3. ip multicast multipath
4. Repeat step 3 on all the devices in a redundant topology.
5. exit
6. show ip rpf source-address [group-address]
7. show ip route ip-address

### Enabling ECMP Multicast Load Splitting Based on Source and Group Address

Perform this task to enable ECMP multicast load splitting of multicast traffic based on source and group address (using the basic S-G-hash algorithm) to take advantage of multiple paths through the network. The basic S-G-hash algorithm is predictable because no randomization is used in calculating the hash value. The basic S-G-hash algorithm, however, is subject to polarization because for a given source and group, the same hash is always picked irrespective of the device on which the hash is being calculated.

The basic S-G-hash algorithm provides more flexible support for ECMP multicast load splitting than the S-hash algorithm. Using the basic S-G-hash algorithm for load splitting, in particular, enables multicast traffic from devices that send many streams to groups or that broadcast many channels, such as IPTV servers or MPEG video servers, to be more effectively load split across equal-cost paths.

#### Note

Enable ECMP multicast load splitting on the device that is to be the receiver for traffic from more than one incoming interfaces, which is opposite to unicast routing. From the perspective of unicast, multicast is active on the sending device connecting to more than one outgoing interfaces.

### SUMMARY STEPS

1. enable
2. configure terminal

**Load Splitting IP Multicast Traffic over ECMP**

**How to Load Split IP Multicast Traffic over ECMP**

**IP Multicast: Multicast Optimization Configuration Guide, Cisco IOS XE Release 3S (Cisco ASR 1000)**
Enabling ECMP Multicast Load Splitting Based on Source Group and Next-Hop Address

Perform this task to enable ECMP multicast load splitting of multicast traffic based on source, group, and next-hop address (using the next-hop-based S-G-hash algorithm) to take advantage of multiple paths through the network. The next-hop-based S-G-hash algorithm is predictable because no randomization is used in calculating the hash value. Unlike the S-hash and basic S-G-hash algorithms, the hash mechanism used by the next-hop-based S-G-hash algorithm is not subject to polarization.

The next-hop-based S-G-hash algorithm provides more flexible support for ECMP multicast load splitting than S-hash algorithm and eliminates the polarization problem. Using the next-hop-based S-G-hash algorithm for ECMP multicast load splitting enables multicast traffic from devices that send many streams to groups or that broadcast many channels, such as IPTV servers or MPEG video servers, to be more effectively load split across equal-cost paths.

**Note**
Enable ECMP multicast load splitting on the device that is to be the receiver for traffic from more than one incoming interfaces, which is opposite to unicast routing. From the perspective of unicast, multicast is active on the sending device connecting to more than one outgoing interfaces.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip multicast multipath s-g-hash next-hop-based
4. Repeat Step 3 on all the devices in a redundant topology.
5. exit
6. show ip rpf source-address [group-address]
7. show ip route ip-address

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device&gt; enable</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Device# configure terminal</td>
</tr>
</tbody>
</table>
### Step 3
**Command or Action:**
```
ip multicast multipath s-g-hash next-hop-based
```

**Purpose:** Enables ECMP multicast load splitting based on source, group, and next-hop-address using the next-hop-based S-G-hash algorithm.

Example:
```
Device(config)# ip multicast multipath s-g-hash next-hop-based
```

- Because this command changes the way an RPF neighbor is selected, it must be configured consistently on all devices in a redundant topology to avoid looping.

### Step 4
Repeat Step 3 on all the devices in a redundant topology.

### Step 5
**Command or Action:**
```
exit
```

**Purpose:** Exits global configuration mode and returns to privileged EXEC mode.

Example:
```
Device(config)# exit
```

### Step 6
**Command or Action:**
```
show ip rpf source-address [group-address]
```

**Purpose:** (Optional) Displays the information that IP multicast routing uses to perform the RPF check.

Example:
```
Device# show ip rpf 10.1.1.2
```

- Use this command to verify RPF selection so as to ensure that IP multicast traffic is being properly load split.

### Step 7
**Command or Action:**
```
show ip route ip-address
```

**Purpose:** (Optional) Displays the current state of the IP routing table.

Example:
```
Device# show ip route 10.1.1.2
```

- Use this command to verify that there multiple paths available to a source or RP for ECMP multicast load splitting.
- For the `ip-address` argument, enter the IP address of a source to validate that there are multiple paths available to the source (for shortest path trees) or the IP address of an RP to validate that there are multiple paths available to the RP (for shared trees).

### Configuration Examples for Load Splitting IP Multicast Traffic over ECMP
- Example Enabling ECMP Multicast Load Splitting Based on Source Address, page 35

### Feature Information for Load Splitting IP Multicast Traffic - ECMP

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.
Table 3  Feature Information for Load Splitting IP Multicast Traffic--ECMP Using S, G and Next Hop

<table>
<thead>
<tr>
<th>Feature Name</th>
<th>Releases</th>
<th>Feature Information</th>

Configuring Multicast Admission Control

This module describes how to implement multicast admission control in an IP multicast network. Multicast admission control features are configured on multicast-enabled routers to prevent control plane overload, ensure proper resource allocation, and provide multicast Call Admission Control (CAC) capabilities.

- Finding Feature Information, page 39
- Prerequisites for Configuring Multicast Admission Control, page 39
- Information About Configuring Multicast Admission Control, page 39
- How to Configure Multicast Admission Control, page 47

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Configuring Multicast Admission Control

IP multicast is enabled and the Protocol Independent Multicast (PIM) interfaces are configured using the tasks described in the “Configuring Basic IP Multicast” module.

Information About Configuring Multicast Admission Control

- Multicast Admission Control, page 40
- Multicast Admission Control Features, page 40
- Global Mroute State Limit, page 41
- MSDP SA Limit, page 42
- IGMP State Limit, page 42
Multicast Admission Control

As the popularity of network video applications grows among consumers, admission control functions—which govern transmission and reception of multicast traffic based on available network resources—are vital. Without admission control, some users may receive degraded multicast streams, rendering programs unwatchable, and others may receive a “Network Busy” message or nothing at all as network resources are overtaxed. Network admission control is important in maintaining a high quality of experience for digital video consumers.

The goals of multicast admission control features, therefore, are as follows:

- Protect the router from control plane overload to ensure that memory and CPU resources on multicast-enabled routers are not overrun by multicast route (mroute) states or denial-of-service (DoS) attacks from multicast packets.
- Enable proper resource allocation (on a global or per interface basis) to ensure that multicast services are delivered to subscribers per their IP Service Level Agreements (SLAs) and to minimize the effects of DoS attacks on subscribers.
- Provide multicast CAC capabilities to prevent bandwidth resources (interfaces, subnetworks) from being congested and to enable service providers to offer more flexible and refined content and subscriber-based policies.

Multicast Admission Control Features

The Cisco IOS XE software supports the following multicast admission control features:

- Global Mroute State Limit

The `ip multicast route-limit` command allows for the configuration of global state limiters, which impose limits on the number of multicast routes (mroutes) that can be added to the global table.

- MSDP SA Limit

The `ip msdp sa-limit` command allows for the configuration of MSDP SA limiters, which impose limits on the number of Multicast Source Discovery Protocol (MSDP) Source Active (SA) messages that can be cached on a router.

For more information about MSDP, see the “Using MSDP to Interconnect Multiple PIM-SM Domains” module.

- IGMP State Limit

This feature allows for the configuration of IGMP state limiters, which impose limits on mroute states resulting from Internet Group Management Protocol (IGMP) membership reports (IGMP joins).

- Per Interface Mroute State Limit

This feature allows for the configuration of per interface mroute state limiters, which impose mroute state limits for different access control list (ACL)-classified sets of multicast traffic on an interface.

- Bandwidth-Based CAC for IP Multicast

This feature allows for the configuration of bandwidth-based multicast CAC policies, which allow for bandwidth-based CAC on a per interface basis.
These admission control features may be invoked by service providers and enterprise network administrators based on different criteria, including the service package an end user has purchased or the privileges an enterprise user is entitled to.

**Global Mroute State Limit**

The `ip multicast route-limit` command allows for the configuration of global mroute state limiters, which impose limits on the number of mroutes that can be added to the global table.

Global mroute state limiters are used to limit the number of mroutes that can be added to the global table on a router. Configuring a global mroute state limiter can protect a router in the event of a multicast DoS attack (by preventing mroutes from overrunning the router).

- Global Mroute State Limit Feature Design, page 41
- Mechanics of Global Mroute State Limiters, page 41

**Global Mroute State Limit Feature Design**

Global mroute state limiters are configured using the `ip multicast route-limit` command in global configuration mode. The syntax of the `ip multicast route-limit` command is as follows:

```
ip multicast route-limit limit [threshold]
```

---

**Note**

When configuring global mroute state limiters, you can only configure one limit for the global table.

The value specified for the required `limit` argument defines the maximum number of mroutes that can be added to the global table.

In addition, for global mroute state limiters, the optional `threshold` argument is available to set mroute threshold limits.

**Mechanics of Global Mroute State Limiters**

The mechanics of global mroute state limiters are as follows:

- Each time the state for an mroute is created on a router, the Cisco IOS XE software checks to see if the limit for the global mroute state limiter has been reached.
- States for mroutes that exceed the configured limit for the global mroute state limiter are not created on the router, and a warning message in the following format is generated:

```
% MROUTE-4-ROUTELIMIT : <current mroute count> exceeded multicast route-limit of <mroute limit value>
```

- When an mroute threshold limit is also configured for the global mroute state limiter, each time the state for an mroute is created on a router, the Cisco IOS XE software also checks to see if the mroute threshold limit has been reached. If the mroute threshold limit is exceeded, a warning message in the following format is generated:

```
% MROUTE-4-ROUTELIMITWARNING : multicast route-limit warning <current mroute count> threshold <mroute threshold value>
```

Warning messages continue to be generated until the number of mroutes exceeds the configured limit or until the number of mroute states falls below the configured mroute threshold limit.
MSDP SA Limit

The `ip msdp sa-limit` command allows for the configuration of MSDP SA limiters, which impose limits on the number of MSDP Source Active (SA) messages that an MSDP-enabled router can accept (can be cached) from an MSDP peer. This command provides a means to protect an MSDP-enabled router from denial of service (DoS) attacks.

- MSDP SA Limit Feature Design, page 42
- Mechanics of MSDP SA Limiters, page 42
- Tips for Configuring MSDP SA Limiters, page 42

MSDP SA Limit Feature Design

MSDP SA limiters are configured using the `ip msdp sa-limit` command in global configuration mode. The syntax of the `ip msdp sa-limit` command is as follows:

```
ip msdp sa-limit {peer-address | peer-name} sa-limit
```

For the required `peer-address` argument or `peer-name` argument, specify either the MSDP peer address or MSDP peer name of the peer to be limited.

For the required `sa-limit` argument, specify the maximum number of SA messages that can be accepted (cached) from the specified peer. The range is from 1 to 2147483646.

Mechanics of MSDP SA Limiters

- When MSDP SA limiters are configured, the router maintains a per-peer count of SA messages stored in the SA cache.
- SA messages that exceed the limit configured for an MSDP peer are ignored.
- If the router receives SA messages in excess of the configured limit from an MSDP peer, a warning in the following format is generated (once a minute) until the cache is cleared:

```
%MSDP-4-SA_LIMIT: SA from peer <peer address or name>, RP <RP address> for <mroute> exceeded sa-limit of <configured SA limit for MSDP peer>
```

Tips for Configuring MSDP SA Limiters

- We recommended that you configure MSDP SA limiters for all MSDP peerings on the router.
- An appropriately low MSDP SA limit should be configured on peerings with a stub MSDP region (an MSDP peer that may have some further downstream peers but does not act as a transit for SA messages across the rest of the Internet).
- An appropriately high SA limit should be configured for all MSDP peerings that act as transits for MSDP SA messages across the Internet.

IGMP State Limit

The IGMP State Limit feature allows for the configuration of IGMP state limiters, which impose limits on mroute states resulting from IGMP membership reports (IGMP joins) on a global or per interface basis. Membership reports exceeding the configured limits are not entered into the IGMP cache. This feature can be used to prevent DoS attacks or to provide a multicast CAC mechanism in network environments where all the multicast flows roughly utilize the same amount of bandwidth.
Note

IGMP state limiters impose limits on the number of mroute states resulting from IGMP, IGMP v3lite, and URL Rendezvous Directory (URD) membership reports on a global or per interface basis.

- IGMP State Limit Feature Design, page 43
- Mechanics of IGMP State Limiters, page 43

IGMP State Limit Feature Design

- Configuring IGMP state limiters in global configuration mode specifies a global limit on the number of IGMP membership reports that can be cached.
- Configuring IGMP state limiters in interface configuration mode specifies a limit on the number of IGMP membership reports on a per interface basis.
- Use ACLs to prevent groups or channels from being counted against the interface limit. A standard or an extended ACL can be specified. A standard ACL can be used to define the (*, G) state to be excluded from the limit on an interface. An extended ACLs can be used to define the (S, G) state to be excluded from the limit on an interface. An extended ACL also can be used to define the (*, G) state to be excluded from the limit on an interface, by specifying 0.0.0.0 for the source address and source wildcard--referred to as (0, G)--in the permit or deny statements that compose the extended access list.
- You can only configure one global limit per device and one limit per interface.

Mechanics of IGMP State Limiters

The mechanics of IGMP state limiters are as follows:

- Each time a router receives an IGMP membership report for a particular group or channel, the Cisco IOS software checks to see if either the limit for the global IGMP state limiter or the limit for the per interface IGMP state limiter has been reached.
- If only a global IGMP state limiter has been configured and the limit has not been reached, IGMP membership reports are honored. When the configured limit has been reached, subsequent IGMP membership reports are then ignored (dropped) and a warning message in one of the following formats is generated:
  - %IGMP-6-IGMP_GROUP_LIMIT: IGMP limit exceeded for <group (*, group address)> on <interface type number> by host <ip address>
  - %IGMP-6-IGMP_CHANNEL_LIMIT: IGMP limit exceeded for <channel (source address, group address)> on <interface type number> by host <ip address>
- If only per interface IGMP state limiters are configured, then each limit is only counted against the interface on which it was configured.
- If both a global IGMP state limiter and per interface IGMP state limiters are configured, the limits configured for the per interface IGMP state limiters are still enforced but are constrained by the global limit.

Per Interface Mroute State Limit

The Per Interface Mroute State Limit feature provides the capability to limit the number of mroute states on an interface for different ACL-classified sets of multicast traffic. This feature can be used to prevent DoS attacks or to provide a multicast CAC mechanism when all the multicast flows roughly utilize the same amount of bandwidth.
The Per Interface Mroute State Limit feature essentially is a complete superset of the IGMP State Limit feature (with the exception that it does not support a global limit). The Per Interface Mroute State Limit feature, moreover, is more flexible and powerful (albeit more complex) than the IGMP State Limit feature but is not intended to be a replacement for it because there are applications that suit both features.

The main differences between the Per Interface Mroute State Limit feature and the IGMP State Limit feature are as follows:

- The Per Interface Mroute State Limit feature allows multiple limits to be configured on an interface, whereas the IGMP State Limit feature allows only one limit to be configured on an interface. The Per Interface Mroute State Limit feature, thus, is more flexible than the IGMP State Limit feature in that it allows multiple limits to be configured for different sets of multicast traffic on an interface.

- The Per Interface Mroute State Limit feature can be used to limit both IGMP and PIM joins, whereas the IGMP State Limit feature can only be used to limit IGMP joins. The IGMP State Limit feature, thus, is more limited in application in that it is best suited to be configured on an edge router to limit the number of groups that receivers can join on an outgoing interface. The Per Interface Mroute State Limit feature has a wider application in that it can be configured to limit IGMP joins on an outgoing interface, to limit PIM joins (for Any Source Multicast [ASM] groups or Source Specific Multicast [SSM] channels) on an outgoing interface connected to other routers, to limit sources behind an incoming interface from sending multicast traffic, or to limit sources directly connected to an incoming interface from sending multicast traffic.

Note

Although the PIM Interface Mroute State Limit feature allows you to limit both IGMP and PIM joins, it does not provide the capability to limit PIM or IGMP joins separately because it does not take into account whether the state is created as a result of an IGMP or PIM join. As such, the IGMP State Limit feature is more specific in application because it specifically limits IGMP joins.

- The Per Interface Mroute State Limit feature allows you to specify limits according to the direction of traffic; that is, it allows you to specify limits for outgoing interfaces, incoming interfaces, and for incoming interfaces having directly connected multicast sources. The IGMP State Limit feature, however, only can be used to limit outgoing interfaces. The Per Interface State Mroute State Limit feature, thus, is wider in scope in that it can be used to limit mroute states for both incoming and outgoing interfaces from both sources and receivers, whereas the IGMP State Limit feature is more narrow in scope in that it can only be used to limit mroute states for receivers on an LAN by limiting the number of IGMP joins on an outgoing interface.

Both the IGMP State Limit and Per Interface Mroute State Limit features provide a rudimentary multicast CAC mechanism that can be used to provision bandwidth utilization on an interface when all multicast flows roughly utilize the same amount of bandwidth. The Bandwidth-Based CAC for IP Multicast feature, however, offers a more flexible and powerful alternative for providing multicast CAC in network environments where IP multicast flows utilize different amounts of bandwidth.

Note

For more information about the Bandwidth-Based CAC for IP Multicast feature, see the Bandwidth-Based CAC for IP Multicast, page 46.
Per Interface Mroute State Limit Feature Design

The Per Interface Mroute State Limit feature is configured using the `ip multicast limit` command in interface configuration mode. An `ip multicast limit` command configured on an interface is called an `per interfacemroute state limiter`. A per interface mroute state limiter is defined by direction, ACL, and maximum number of mroutes. Each per interface mroute state limiter maintains a counter to ensure that the maximum number of mroutes is not exceeded.

The following forms of the `ip multicast limit` command are available to configure per interface mroute state limiters:

- `ip multicast limit access-list max-entries`
  
  This command limits mroute state creation for an ACL-classified set of traffic on an interface when the interface is an outgoing (egress) interface, and limits mroute outgoing interface list (olist) membership when the interface is an incoming (ingress) Reverse Path Forwarding (RPF) interface.

  This type of per interface mroute state limiter limits mroute state creation--by accounting each time an mroute permitted by the ACL is created or deleted--and limits mroute olist membership--by accounting each time that an mroute olist member permitted by the ACL is added or removed.

  Entering this form of the command (that is, with no optional keywords) is equivalent to specifying the `ip multicast limit rpf` and `ip multicast limit out` forms of the command.

- `ip multicast limit connected access-list max-entries`
  
  This command limits mroute state creation for an ACL-classified set of multicast traffic on an incoming (RPF) interface that is directly connected to a multicast source by accounting each time that an mroute permitted by the ACL is created or deleted.

- `ip multicast limit out access-list max-entries`
  
  This command limits mroute olist membership on an outgoing interface for an ACL-classified set of multicast traffic by accounting each time that an mroute olist member permitted by the ACL is added or removed.

- `ip multicast limit rpf access-list max-entries`
  
  This command limits mroute state creation for an ACL-classified set of multicast traffic on an incoming (RPF) interface by accounting each time an mroute permitted by the ACL is created or deleted.

  For the required `access-list` argument, specify the ACL that defines the IP multicast traffic to be limited on an interface. A standard or extended ACL can be specified. Standard ACLs can be used to define the (*, G) state to be limited on an interface. Extended ACLs can be used to define the (S, G) state to be limited on an interface. Extended ACLs also can be used to define the (*, G) state to be limited on an interface, by specifying 0.0.0.0 for the source address and source wildcard--referred to as (0, G)--in the permit or deny statements that compose the extended access list.

Mechanics of Per Interface Mroute State Limiters

The mechanics of per interface mroute state limiters are as follows:

- Each time the state for an mroute is created or deleted and each time an olist member is added or removed, the Cisco IOS XE software searches for a corresponding per interface mroute state limiter that matches the mroute.

- In the case of the creation and deletion of mroutes, the Cisco IOS XE software searches for a per interface mroute state limiter configured on the incoming (RPF) interface that matches the mroute to
be created or deleted. In the case of olist member addition or removal, the Cisco IOS XE software searches for a per interface mroute state limiter configured on the outgoing interface that matches the mroute to be added or removed.

- The Cisco IOS XE software performs a top-down search from the list of configured per interface mroute state limiters. Only per interface mroute state limiters that match the direction of traffic are considered. The first per interface mroute state limiter that matches is used for limiting (sometimes referred to as accounting). A match is found when the ACL permits the mroute state.
- When a match is found, the counter of the per interface mroute state limiter is updated (increased or decreased). If no per interface mroute state limiter is found that matches an mroute, no accounting is performed for the mroute (because there is no counter to update).
- The amount to update the counter with is called the cost (sometimes referred to as the cost multiplier). The default cost is 1.

Notes
A per interface mroute state limiter always allows the deletion of an mroute or the removal of an interface from the olist. In those cases, the respective per interface mroute state limiter decreases the counter by the value of the cost multiplier. In addition, RPF changes to an existing mroute are always allowed (in order to not affect existing traffic). However, a per interface mroute state limiter only allows the creation of an mroute or the addition of an mroute olist member if adding the cost does not exceed the maximum number of mroutes permitted.

Tips for Configuring Per Interface Mroute State Limiters

- To ensure that all mroutes are accounted, you can configure a per interface mroute state limiter whose ACL contains a permit-any statement and set the value of zero (0) for maximum entries. Configuring an mroute state limiter in this manner effectively denies all fall through states, which may be a way to prevent a multicast DoS attack in and out of the interface.
- When creating an ACL, remember that, by default, the end of the ACL contains an implicit deny-any statement for everything if it did not find a match before reaching the end.
- An explicit deny statement for a specific mroute in an ACL can be used to specify the state that will not match the ACL which will prevent the ACL from being accounted. If an mroute matches a deny statement, the search immediately continues to the next configured mroute state limiter. Configuring an explicit deny statement in an ACL can be more efficient than forcing the mroute to fall through an ACL by using an implicit deny-any statement at the end of the ACL.

Bandwidth-Based CAC for IP Multicast

The Bandwidth-Based CAC for IP Multicast feature enhances the Per Interface Mroute State Limit feature by implementing a way to count per interface mroute state limiters using cost multipliers (referred to as bandwidth-based multicast CAC policies). This feature can be used to provide bandwidth-based multicast CAC on a per interface basis in network environments where the multicast flows utilize different amounts of bandwidth.

- Bandwidth-Based CAC for IP Multicast Feature Design, page 47
- Mechanics of the Bandwidth-Based Multicast CAC Policies, page 47
- Tips for Configuring Bandwidth-Based CAC Policies for IP Multicast, page 47
Bandwidth-Based CAC for IP Multicast Feature Design

Bandwidth-based multicast CAC policies are configured using the `ip multicast limit cost` command in global configuration mode. The syntax of the `ip multicast limit cost` command is as follows:

```plaintext
ip multicast limit cost access-list cost-multiplier
```

For the required `access-list` argument, specify the ACL that defines the IP multicast traffic for which to apply a cost. A standard or extended ACL can be specified. Standard ACLs can be used to define the (*, G) state. Extended ACLs can be used to define the (S, G) state. Extended ACLs also can be used to define the (*, G) state, by specifying 0.0.0.0 for the source address and source wildcard--referred to as (0, G)--in the permit or deny statements that compose the extended access list.

For the required `cost-multiplier` argument, specify the cost value to be applied to mroutes that match the ACL associated with the bandwidth-based multicast CAC policy. The range is 0 to 2147483647.

Mechanics of the Bandwidth-Based Multicast CAC Policies

The mechanics of bandwidth-based multicast CAC policies are as follows:

- Once an mroute matches an ACL configured for a per interface mroute state limiter, the Cisco IOS XE software performs a top-down search from the global list of configured bandwidth-based multicast CAC policies to determine if a cost should be applied to the mroute.
- A cost is applied to the first bandwidth-based CAC policy that matches the mroute. A match is found when the ACL applied to the bandwidth-based CAC policy permits the mroute state.
- The counter for the mroute state limiter either adds or subtracts the cost configured for the `cost-multiplier` argument. If no costs are configured or if the mroute does not match any of the configured bandwidth-based CAC policies, the default cost of 1 is used.

Tips for Configuring Bandwidth-Based CAC Policies for IP Multicast

- To ensure that a particular cost applies to all mroutes being limited, you can configure a bandwidth-based CAC policy whose ACL contains a `permit any` statement. Configuring a bandwidth-based CAC policy in this manner effectively ensures that the default cost is not applied to any mroutes being limited.
- Configuring a bandwidth-based CAC policy with a cost of 0 for the `cost-multiplier` argument can be used to skip the accounting of certain mroutes (for example, to prevent Auto-RP groups or a specific multicast channel from being accounted).
- An explicit deny statement for a specific mroute in an ACL can be used to specify the state that will not match the ACL (thus, preventing the ACL from being accounted). If an mroute matches a deny statement, the search immediately continues to the next configured bandwidth-based CAC policy. Configuring an explicit deny statement in an ACL can be more efficient than forcing the mroute to fall through an ACL (by means of the implicit `deny any` statement at the end of the ACL).

How to Configure Multicast Admission Control

- Configuring Global Mroute State Limiters, page 48
- Configuring MSDP SA Limiters, page 49
- Configuring IGMP State Limiters, page 51
Configuring Global Mroute State Limiters

Perform the following optional tasks to configure global mroute state limiters.

Global mroute state limiters are used to limit the number of mroutes that can be added to the global table on a router. Configuring a global mroute state limiter can protect a router in the event of a multicast DoS attack (by preventing mroutes from overrunning the router).

**Note**
When configuring global mroute state limiters, you can only configure one limit for the global table.

- This task assumes that IP multicast has been enabled and that the PIM interfaces have been configured using the tasks described in the “Configuring Basic IP Multicast” module.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip multicast route-limit limit [threshold]`
4. `end`
5. `show ip mroute count`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip multicast route-limit <code>limit [threshold]</code></td>
<td>Limits the number of mroutes that can be added to the global table.</td>
</tr>
<tr>
<td>Example:</td>
<td>• For the required <code>limit</code> argument, specify the limit on the number of mroutes that can be added to the global table. The range is from 1 to 2147483647.</td>
</tr>
<tr>
<td>Router(config)# ip multicast route-limit 1500 1460</td>
<td>• Use the optional <code>threshold</code> argument to set an mroute threshold limit. The range is from 1 to 2147483647.</td>
</tr>
</tbody>
</table>
### Configuring MSDP SA Limiters

Perform this optional task to limit the overall number of SA messages that the router can accept from specified MSDP peers. Performing this task protects an MSDP-enabled router from distributed DoS attacks.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 4 end</td>
<td>Ends the current configuration session and returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config)# end</td>
</tr>
<tr>
<td>Step 5 show ip mroute count</td>
<td>(Optional) Displays mroute data and packet count statistics.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router# show ip mroute count</td>
</tr>
</tbody>
</table>

#### Note
We recommend that you perform this task for all MSDP peerings on the router.

This task assumes that you are running MSDP and have configured MSDP peers using the tasks described in the “Using MSDP to Interconnect Multiple PIM-SM Domains” module.

### SUMMARY STEPS

1. enable
2. configure terminal
3. ip msdp sa-limit \{peer-address | peer-name\} sa-limit
4. end
5. show ip msdp count
6. show ip msdp peer \{peer-address | peer-name\}
7. show ip msdp summary

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router&gt; enable</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
</tbody>
</table>
## Command or Action

### Step 2 configure terminal

**Example:**

```
Router# configure terminal
```

**Purpose:**
Enters global configuration mode.

### Step 3 ip msdp sa-limit {peer-address | peer-name} 

**Example:**

```
Router(config)# ip msdp sa-limit peer-address 192.168.10.1 100
```

**Purpose:**
Limits the number of SA messages allowed in the SA cache from the specified MSDP.

- For the required `peer-address` argument or `peer-name` argument, specify either the MSDP peer address or MSDP peer name of the peer to be limited.
- For the required `sa-limit` argument, specify the maximum number of SA messages that can be accepted (cached) from the specified peer. The range is from 1 to 2147483646.

### Step 4 end

**Example:**

```
Router(config)# end
```

**Purpose:**
Exits global configuration mode and returns to privileged EXEC mode.

### Step 5 show ip msdp count

**Example:**

```
Router# show ip msdp count
```

**Purpose:**
(Optional) Displays the number of sources and groups originated in MSDP SA messages and the number of SA messages from an MSDP peer in the SA cache.

### Step 6 show ip msdp peer [peer-address | peer-name]

**Example:**

```
Router# show ip msdp peer
```

**Purpose:**
(Optional) Displays detailed information about MSDP peers.

**Note:** The output of this command displays the number of SA messages received from MSDP peers that are stored in the cache.

### Step 7 show ip msdp summary

**Example:**

```
Router# show ip msdp summary
```

**Purpose:**
(Optional) Displays MSDP peer status.

**Note:** The output of this command displays a per-peer “SA Count” field that displays the number of SAs stored in the SA cache.
Configuring IGMP State Limiters

Note

IGMP state limiters impose limits on the number of mroute states resulting from IGMP, IGMP v3lite, and URD membership reports on a global or per interface basis.

Prerequisites

- Prerequisites, page 51
- Configuring Global IGMP State Limiters, page 51
- What to Do Next, page 52
- Configuring Per Interface IGMP State Limiters, page 52

Prerequisites

- These tasks assume that IP multicast has been enabled and that the PIM interfaces have been configured using the tasks described in the “Configuring Basic IP Multicast” module.
- All ACLs you intend to apply to per interface IGMP state limiters should be configured prior to beginning this configuration task; otherwise, IGMP membership reports for all groups and channels are counted against the configured limits. For information about how to configure ACLs, see the “Creating an IP Access List and Applying It to an Interface” module.

Configuring Global IGMP State Limiters

Perform this optional task to configure one global IGMP state limiter per device.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip igmp limit number
4. end
5. show ip igmp groups

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
</tbody>
</table>

Example:

Device> enable
### Command or Action | Purpose
--- | ---
**Step 2** configure terminal | Enters global configuration mode.

**Example:**
```
Device# configure terminal
```

**Step 3** ip igmp limit *number* | Configures a global limit on the number of mroute states resulting from IGMP membership reports (IGMP joins).

**Example:**
```
Device(config)# ip igmp limit 150
```

**Step 4** end | Ends the current configuration session and returns to privileged EXEC mode.

**Example:**
```
Device(config-if)# end
```

**Step 5** show ip igmp groups | (Optional) Displays the multicast groups with receivers that are directly connected to the device and that were learned through IGMP.

**Example:**
```
Device# show ip igmp groups
```

### What to Do Next
Proceed to the Configuring Per Interface IGMP State Limiters, page 52 task to configure per interface IGMP state limiters.

### Configuring Per Interface IGMP State Limiters
Perform this optional task to configure a per interface IGMP state limiter.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface *type number*
4. ip igmp limit *number [except access-list]*
5. • exit
   • end
6. show ip igmp interface [type number]
7. show ip igmp groups
## DETAILED STEPS

<table>
<thead>

| **Example:** | Device# show ip igmp groups |
Configuring Per Interface Mroute State Limiters

Perform this task to configure per interface mroute state limiters. Configuring per interface mroute state limiters can be used to prevent DoS attacks or to provide a multicast CAC mechanism to control bandwidth, when all the multicast flows roughly utilize the same amount of bandwidth.

- This task assumes that IP multicast has been enabled and that the PIM interfaces have been configured using the tasks described in the “Configuring Basic IP Multicast” module.
- All ACLs you intend to apply to per interface mroute state limiters should be configured prior to beginning this configuration task; otherwise, the limiters are ignored. For information about how to configure ACLs, see the “Creating an IP Access List and Applying It to an Interface” module.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface type number
4. ip multicast limit [connected | out | rpf] access-list max-entries
5. 
6. Repeat Step 4, if you want to configure additional per interface mroute state limiters on the interface.
7. Repeat Step 3 and Step 4 if you want to configure per interface mroute state limiters on additional interfaces.
8. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>

<td></td>
</tr>
</tbody>
</table>
### Command or Action
**Step 4**  
*ip multicast limit [connected | out | rpf] access-list max-entries*

### Purpose
Configures per interface mrout state limiters.

- Specify the **ip multicast limit** command with no optional keywords to limit mroute state creation for an ACL-classified set of traffic on an interface when the interface is an outgoing (egress) interface, and to limit mroute olist membership when the interface is an incoming (ingress) Reverse Path Forwarding (RPF) interface.
  - This type of per interface mroute state limiter limits mroute state creation by accounting each time an mroute permitted by the ACL is created or deleted and limits mroute olist membership by accounting each time that an mroute olist member permitted by the ACL is added or removed.
  - Entering this form of the command (that is, with no optional keywords) is equivalent to specifying the **ip multicast limit rpf** and **ip multicast limit out** forms of the command.
- Use the optional **connected** keyword to configure a per interface mroute state limiter that limits mroute states created for an ACL-classified set of multicast traffic on an incoming (RPF) interface that is directly connected to a multicast source by accounting each time that an mroute permitted by the ACL is created or deleted.
- Use the optional **out** keyword to configure a per interface mroute state limiter that limits mroute olist membership on an outgoing interface for an ACL-classified set of multicast traffic by accounting each time that an mroute olist member permitted by the ACL is added or removed.
- Use the optional **rpf** keyword to configure a per interface mroute state limiter that limits the number of mroute states created for an ACL-classified set of multicast traffic on an incoming (RPF) interface by accounting each time an mroute permitted by the ACL is created or deleted.

### Example:

```
Router(config-if)# ip multicast limit 15 100
```

### Step 5

- For the required **access-list** argument, specify the ACL that defines the IP multicast traffic to be limited on an interface.
  - Standard ACLs can be used to define the (*) G) state to be limited on an interface.
  - Extended ACLs can be used to define the (S, G) state to be limited on an interface. Extended ACLs also can be used to define the (*, G) state to be limited on an interface, by specifying 0.0.0.0 for the source address and source wildcard—referred to as (0, G)—in the permit or deny statements that compose the extended access list.
- For the required **max-entries** argument, specify the maximum number of mroutes permitted by the per interface mroute state limiter. The range is from 0 to 2^32.

### Step 6

Repeat Step 4, if you want to configure additional per interface mrout state limiters on the interface.
### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 7</strong> Repeat Step 3 and Step 4 if you want to configure per interface mroute state limiters on additional interfaces.</td>
<td>--</td>
</tr>
<tr>
<td><strong>Step 8</strong> end</td>
<td>Exits interface configuration mode, and enters privileged EXEC mode.</td>
</tr>
</tbody>
</table>

**Example:**

```
Router(config-if)# end
```

- What to Do Next, page 56

**What to Do Next**

Proceed to the Monitoring Per Interface Mroute State Limiters and Bandwidth-Based Multicast CAC Policies task to monitor per interface mroute state limiters.

**Configuring Bandwidth-Based Multicast CAC Policies**

Perform this optional task to configure bandwidth-based multicast CAC policies. Bandwidth-based multicast CAC policies provide the capability to assign costs to mroutes that are being limited by per interface mroute state limiters. This task can be used to provide bandwidth-based multicast CAC on a per interface basis in network environments where the multicast flows utilize different amounts of bandwidth. Bandwidth-based multicast CAC policies can be applied globally.

**Note**

You can omit Steps 3 to 7 if you have already configured the per interface mroute state limiters for which to apply costs.

- IP multicast is enabled and the Protocol Independent Multicast (PIM) interfaces are configured using the tasks described in the "Configuring Basic IP Multicast" module of the IP Multicast: PIM Configuration Guide.
- All ACLs to be applied to bandwidth-based multicast CAC policies must be configured prior to beginning this configuration task; otherwise, the limiters are ignored. For information about how to configure ACLs, see the “Creating an IP Access List and Applying It to an Interface” module of the Security Configuration Guide: Access Control Lists guide.
### SUMMARY STEPS

1. enable
2. configure terminal
3. interface type number
4. `ip multicast limit [connected | out | rpf] access-list max-entries`
5. Repeat Step 4 if you want to configure additional mroute state limiters on the interface. Repeat Step 3 and Step 4 if you want to configure mroute state limiters on additional interfaces.
6. exit
7. `ip multicast limit cost access-list cost-multiplier`
8. Repeat Step 7 if you want to apply additional costs to mroutes.
9. end

### DETAILED STEPS

</tr>
<tr>
<td><strong>Step 5</strong> Repeat Step 4 if you want to configure additional mroute state limiters on the interface. Repeat Step 3 and Step 4 if you want to configure mroute state limiters on additional interfaces.</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action | Purpose
--- | ---
**Step 6** exit | Exits interface configuration mode, and returns to global configuration mode.  
**Example:**  
Device(config-if)# exit

**Step 7** ip multicast limit cost access-list cost-multiplier | Applies costs to per interface mroute state limiters.  
| • Specify the ACL that defines the IP multicast traffic for which to apply a cost.  
| ◦ Standard ACLs can be used to define the (*, G) state.  
| ◦ Extended ACLs can be used to define the (S, G) state.  
| ◦ Extended ACLs also can be used to define the (*, G) state, by specifying 0.0.0.0 for the source address and source wildcard--referred to as (0, G)--in the permit or deny statements that compose the extended access list.  
| • Specify the cost value to be applied to mroutes that match the ACL associated with the bandwidth-based multicast CAC policy.  
**Example:**  
Device(config)# ip multicast limit cost acl-MP2SD-channels 4000

**Step 8** Repeat Step 7 if you want to apply additional costs to mroutes.  

**Step 9** end | Exits interface configuration mode, and enters privileged EXEC mode.  
**Example:**  
Device(config-if)# end

**What to Do Next**

Proceed to the Monitoring Per Interface Mroute State Limiters and Bandwidth-Based Multicast CAC Policies task to monitor bandwidth-based multicast CAC policies.

**Monitoring Per Interface Mroute State Limiters and Bandwidth-Based Multicast CAC Policies**

Perform this optional task to monitor per interface mroute state limiters and bandwidth-based multicast CAC policies.
SUMMARY STEPS

1. enable
2. debug ip mrouter limits [group-address]
3. show ip multicast limit type number
4. clear ip multicast limit [type number]

DETAILED STEPS

Step 1 enable
Enables privileged EXEC mode. Enter your password if prompted.

Example:

Router> enable

Step 2 debug ip mrouter limits [group-address]
Use this command to display debugging information about configured per interface mroute state limiters and bandwidth-based multicast CAC policies.

Specify the optional group-address argument to restrict the output to display only per interface mroute state limiter events related to a particular multicast group.

The following output is from the debug ip mrouter limits command. The output displays the following events:

- An mroute state being created and the corresponding per interface mroute state limiter counter being increased by the default cost of 1 on incoming Gigabit Ethernet interface 1/0/0.
- An mroute olist member being removed from the olist and the corresponding per interface mroute limiter being decreased by the default cost of 1 on outgoing Gigabit Ethernet interface 1/0/0.
- An mroute being denied by the per interface mroute state limiter because the maximum number of mroute states has been reached.
- An mroute state being created and the corresponding per interface mroute state limiter counter being increased by the cost of 2 on incoming Gigabit Ethernet interface 1/0/0.
- An mroute olist member being removed from the olist and the corresponding per interface mroute limiter being decreased by a cost of 2 on outgoing Gigabit Ethernet interface 1/0/0.

Example:

Router# debug ip mrouter limits
MRL(0): incr-ed acl 'rpf-list' to (13 < max 32), [n:0,p:0], (main) GigabitEthernet1/0/0, (10.41.0.41, 225.30.200.60)
MRL(0): decr-ed acl 'out-list' to (10 < max 32), [n:0,p:0], (main) GigabitEthernet1/0/0, (*, 225.40.202.60)
MRL(0): Add mroute (10.43.0.43, 225.30.200.60) denied for GigabitEthernet0/2/0, acl std-list, (16 = max 16)
MRL(0): incr-ed limit-acl 'rpf-list' to (12 < max 32), cost-acl 'cost-list' cost 2, [n:0,p:0], (main) GigabitEthernet1/0/0, (10.41.0.41, 225.30.200.60)
MRL(0): decr-ed limit-acl 'out-list' to (8 < max 32), cost-acl 'cost-list' cost 2, [n:0,p:0], (main) GigabitEthernet1/0/0, (*, 225.40.202.60)

Step 3 show ip multicast limit type number
Use this command to display counters related to mroute state limiters configured on the interfaces on the router.
Specify the optional type number arguments to restrict the output to displaying only statistics about per interface mroute state limiters configured on the specified interface.

For each per interface mroute state limiter shown in the output, the following information is displayed:

- The direction of traffic that the per mroute state limiter is limiting.
- The ACL referenced by the per interface mroute state limiter that defines the IP multicast traffic being limited.
- Statistics, enclosed in parenthesis, which track the current number of mroutes being limited less the configured limit. Each time the state for an mroute is created or deleted and each time an outgoing interface list (olist) member is added or removed, the counters for matching per interface mroute state limiters are increased or decreased accordingly.
- The exceeded counter, which tracks the total number of times that the limit configured for the per interface mroute state limiter has been exceeded. Each time an mroute is denied due to the configured limit being reached, the exceeded counter is increased by a value of 1.

The following is sample output from the show ip multicast limit command with the type number arguments. In this example, information about mroute state limiters configured on Gigabit Ethernet interface 0/0 is displayed.

Example:

Router# show ip multicast limit GigabitEthernet 0/0/0
Interface GigabitEthernet 0/0/0
Multicast Access Limits
out acl out-list (1 < max 32) exceeded 0
rpf acl rpf-list (6 < max 32) exceeded 0
con acl conn-list (0 < max 32) exceeded 0

Step 4 clear ip multicast limit [type number]
Use this command to reset the exceeded counter for per interface mroute state limiters.

The exceeded counter is displayed in the output of the show ip multicast limit command. This counter tracks the total number of times that the limit configured for the per interface mroute state limiter has been exceeded. Each time an mroute is denied due to the configured limit being reached, the exceeded counter is increased by a value of 1.

Specify the optional type number arguments to reset the exceeded counter for only per interface mroute state limiters configured on the specified interface.

The following example shows how to reset exceeded counters for per interface mroute state limiters configured on Gigabit Ethernet interface 0/0/0:

Example:

clear ip multicast limit interface GigabitEthernet 0/0/0

---

Configuration Examples for Configuring Multicast Admission Control

- Configuring Global Mroute State Limiters Example, page 61
- Configuring MSDP SA Limiters Example, page 61
Configuring Global Mroute State Limiters Example

The following example shows how to configure a global mroute state limiter. In this example, a global mroute state limiter is configured with an mroute limit of 1500 and an mroute threshold limit of 1460.

```plaintext
ip multicast route-limit 1500 1460
```

The following is a sample mroute threshold warning message. The output shows that the configured mroute threshold limit of 1460 has been exceeded by one mroute.

```
%MROUTE-4-ROUTELIMITWARNING : multicast route-limit warning 1461 threshold 1460
```

The following is a sample mroute exceeded warning message. The output shows that the configured mroute limit of 1500 has been exceeded by one mroute. States for mroutes that exceed the configured limit for the global mroute state limiter are not created on the router.

```
%MROUTE-4-ROUTELIMIT : 1501 routes exceeded multicast route-limit of 1500
```

Configuring MSDP SA Limiters Example

The following example shows how to configure an MSDP SA limiter. In this example, an MSDP SA limiter is configured that imposes a limit of 100 SA messages from the MSDP peer at 192.168.10.1.

```plaintext
ip msdp sa-limit 192.168.10.1 100
```

Configuring IGMP State Limiters Example

The following example shows how to configure IGMP state limiters to provide multicast CAC in a network environment where all the multicast flows roughly utilize the same amount of bandwidth. This example uses the topology illustrated in the figure.

![IGMP State Limit Example Topology](image)
In this example, a service provider is offering 300 Standard Definition (SD) TV channels. Each SD channel utilizes approximately 4 Mbps.

The service provider must provision the Gigabit Ethernet interfaces on the PE router connected to the Digital Subscriber Line Access Multiplexers (DSLAMs) as follows: 50% of the link’s bandwidth (500 Mbps) must be available to subscribers of the Internet, voice, and video on demand (VoD) service offerings while the remaining 50% (500 Mbps) of the link’s bandwidth must be available to subscribers of the SD channel offerings.

Because each SD channel utilizes the same amount of bandwidth (4 Mbps), per interface IGMP state limiters can be used to provide the necessary CAC to provision the services being offered by the service provider. To determine the required CAC needed per interface, the total number of channels is divided by 4 (because each channel utilizes 4 Mbps of bandwidth). The required CAC needed per interface, therefore, is as follows:

\[
\frac{500\text{Mbps}}{4\text{Mbps}} = 125 \text{ mroutes}
\]

Once the required CAC is determined, the service provider uses the results to configure the per IGMP state limiters required to provision the Gigabit Ethernet interfaces on the PE router. Based on the network’s CAC requirements, the service provider must limit the SD channels that can be transmitted out a Gigabit Ethernet interface (at any given time) to 125. Configuring a per interface IGMP state limit of 125 for the SD channels provisions the interface for 500 Mbps of bandwidth, the 50% of the link’s bandwidth that must always be available (but never exceeded) for the SD channel offerings.

The following configuration shows how the service provider uses a per interface mroute state limiter to provision interface Gigabit Ethernet 0/0/0 for the SD channels and Internet, Voice, and VoD services being offered to subscribers:

```config
interface GigabitEthernet0/0/0
description --- Interface towards the DSLAM ---
    ip igmp limit 125
```

### Configuring Per Interface Mroute State Limiters Example

The following example shows how to configure per interface mroute state limiters to provide multicast CAC in a network environment where all the multicast flows roughly utilize the same amount of bandwidth.
This example uses the topology illustrated in the figure.

**Figure 7  Per Interface Mroute State Limit Example Topology**

In this example, a service provider is offering 300 SD TV channels. The SD channels are being offered to customers in three service bundles (Basic, Premium, and Gold), which are available to customers on a subscription basis. Each bundle offers 100 channels to subscribers, and each channel utilizes approximately 4 Mbps of bandwidth.

The service provider must provision the Gigabit Ethernet interfaces on the PE router connected to DSLAMs as follows: 50% of the link’s bandwidth (500 Mbps) must be available to subscribers of their Internet, voice, and VoD service offerings while the remaining 50% (500 Mbps) of the link’s bandwidth must be available to subscribers of their SD channel bundle service offerings.

For the 500 Mbps of the link’s bandwidth that must always be available to (but must never be exceeded by) the subscribers of the SD channel bundles, the interface must be further provisioned as follows:

- 60% of the bandwidth must be available to subscribers of the basic service (300 Mbps).
- 20% of the bandwidth must be available to subscribers of the premium service (100 Mbps).
- 20% of the bandwidth must be available to subscribers of the gold service (100 Mbps).

Because each SD channel utilizes the same amount of bandwidth (4 Mbps), per interface mroute state limiters can be used to provide the necessary CAC to provision the services being offered by the service provider. To determine the required CAC needed per interface, the number of channels for each bundle is divided by 4 (because each channel utilizes 4 Mbps of bandwidth). The required CAC needed per interface, therefore, is as follows:

- Basic Services: $300 / 4 = 75$
- Premium Services: $100 / 4 = 25$
- Gold Services: $100 / 4 = 25$

Once the required CAC required per SD channel bundle is determined, the service provider uses the results to configure the mroute state limiters required to provision the Gigabit Ethernet interfaces on the PE router for the services being offered to subscribers behind the DSLAMs:

- For the Basic Services bundle, the service provider must limit the number of Basic Service SD channels that can be transmitted out a Gigabit Ethernet interface (at any given time) to 75. Configuring
an mroute state limit of 75 for the SD channels offered in the Basic Service bundle provisions the interface for 300 Mbps of bandwidth (the 60% of the link’s bandwidth that must always be available to [but never exceeded by] the subscribers of the Basic Services bundle).

- For the Premium Services bundle, the service provider must limit the number of Premium Service SD channels that can be transmitted out a Gigabit Ethernet interface (at any given time) to 25. Configuring an mroute state limit of 25 for the SD channels offered in the Premium Service bundle provisions the interface for 100 Mbps of bandwidth (the 20% of the link’s bandwidth that must always be available to [but never exceeded by] the subscribers of the Premium Service bundle).

- For the Gold Services bundle, the service provider must limit the number of Gold Service SD channels that can be transmitted out a Gigabit Ethernet interface (at any given time) to 25. Configuring an mroute state limit of 25 for the SD channels offered in the Gold Service bundle provisions the interface for 100 Mbps of bandwidth (the 20% of the link’s bandwidth that must always be available to [but never exceeded by] the subscribers of the Gold Service bundle).

The service provider then configures three ACLs to be applied to per interface mroute state limiters. Each ACL defines the SD channels for each SD channel bundle to be limited on an interface:

- acl-basic--The ACL that defines the SD channels offered in the basic service.
- acl-premium--The ACL that defines the SD channels offered in the premium service.
- acl-gold--The ACL that defines the SD channels offered in the gold service.

These ACLs are then applied to per interface mroute state limiters configured on the PE router’s Gigabit Ethernet interfaces.

For this example, three per interface mroute state limiters are configured on Gigabit Ethernet interface 0/0/0 to provide the multicast CAC needed to provision the interface for the SD channel bundles being offered to subscribers:

- An mroute state limit of 75 for the SD channels that match acl-basic.
- An mroute state limit of 25 for the SD channels that match acl-premium.
- An mroute state limit of 25 for the SD channels that match acl-gold.

The following configuration shows how the service provider uses per interface mroute state limiters to provision Gigabit Ethernet interface 0/0/0 for the SD channel bundles and Internet, Voice, and VoD services being offered to subscribers:

```plaintext
interface GigabitEthernet0/0/0
description --- Interface towards the DSLAM ---

ip multicast limit out acl-basic 75
ip multicast limit out acl-premium 25
ip multicast limit out acl-gold 25
```

### Configuring Bandwidth-Based Multicast CAC Policies Example

The following example shows how to configure bandwidth-based multicast CAC policies to provide multicast CAC in a network environment where the multicast flows utilize different amounts of bandwidth.
This example uses the topology illustrated in the figure.

**Figure 8** Bandwidth-Based CAC for IP Multicast Example Topology

In this example, three content providers are providing TV services across a service provider core. The content providers are broadcasting TV channels that utilize different amounts of bandwidth:

- MPEG-2 SDTV channels—4 Mbps per channel.
- MPEG-2 HDTV channels—18 Mbps per channel.
- MPEG-4 SDTV channels—1.6 Mbps per channel.
- MPEG-4 HDTV channels—6 Mbps per channel.

The service provider needs to provision the fair sharing of bandwidth between these three content providers to its subscribers across Gigabit Ethernet interfaces. The service provider, thus, determines that it needs to provision each Gigabit Ethernet interface on the PE router connected to the DSLAMs as follows:

- 250 Mbps per content provider.
- 250 Mbps for Internet, voice, and VoD services.

The service provider then configures three ACLs:

- acl-CP1-channels—The ACL that defines the channels being offered by the content provider CP1.
- acl-CP2-channels—The ACL that defines the channels being offered by the content provider CP2.
- acl-CP3-channels—The ACL that defines the channels being offered by the content provider CP3.

Because the content providers are broadcasting TV channels that utilize different amounts of bandwidth, the service provider needs to determine the values that need to be configured for the per interface mroute state limiters and bandwidth-based multicast CAC policies to provide the fair sharing of bandwidth required between the content providers.

Prior to the introduction of the Bandwidth-Based CAC for IP Multicast feature, per interface mroute state limiters were based strictly on the number of flows. The introduction of cost multipliers by the Bandwidth-Based CAC for IP Multicast feature expands how per interface mroute state limiters can be defined. Instead
of defining the per interface mroute state limiters based on the number of multicast flows, the service provider looks for a common unit of measure and decides to represent the per interface mroute state limiters in kilobits per second (Kbps). The service provider then configures three per interface mroute state limiters, one per content provider. Because the link is a Gigabit, the service provider sets each limit to 250000 (because 250000 Kbps equals 250 Mbps, the number of bits that service provider needs to provision per content provider).

The service provider needs to further provision the fair sharing of bandwidth between the content providers, which can be achieved by configuring bandwidth-based multicast CAC policies. The service provider decides to create four bandwidth-based CAC policies, one policy per channel based on bandwidth. For these policies, the service provider configures the following ACLs:

- acl-MP2SD-channels--Defines all the MPEG-2 SD channels offered by the three content providers.
- acl-MP2HD-channels--Defines all the MPEG-2 HD channels offered by the three content providers.
- acl-MP4SD-channels--Defines all the MPEG-4 SD channels offered by the three content providers.
- acl-MP4HD-channels--Defines all the MPEG-4 HD channels offered by the three content providers.

For each policy, a cost multiplier (represented in Kbps) is defined for each ACL that is based on the bandwidth of the channels defined in the ACL:

- 4000--Represents the 4 Mbps MPEG-2 SD channels.
- 18000--Represents the 18 Mbps MPEG-2 HD channels.
- 1600--Represents the 1.6 Mbps MPEG-4 SD channels.
- 6000--Represents the 6 Mbps MPEG-4 HD channels.

The following configuration example shows how the service provider used per interface mroute state limiters with bandwidth-based multicast CAC policies to provision Gigabit Ethernet interface 0/0/0 for the fair sharing of bandwidth required between the three content providers:

```
! ip multicast limit cost acl-MP2SD-channels 4000
ip multicast limit cost acl-MP2HD-channels 18000
ip multicast limit cost acl-MP4SD-channels 1600
ip multicast limit cost acl-MP4HD-channels 6000
!
!
interface GigabitEthernet0/0/0
  ip multicast limit out acl-CP1-channels 250000
  ip multicast limit out acl-CP2-channels 250000
  ip multicast limit out acl-CP3-channels 250000
!
```

SSM Channel Based Filtering for Multicast Boundaries

The SSM Channel Based Filtering for Multicast Boundaries feature enables the user to apply filtering policies based on Source Specific Multicast (SSM) channels for Source and Group (S,G) addresses, which is a combination of source and destination IP addresses.

- Finding Feature Information, page 71
- Prerequisites for SSM Channel Based Filtering for Multicast Boundaries, page 71

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for SSM Channel Based Filtering for Multicast Boundaries

- IP multicast needs to be configured on the router.
Restrictions for SSM Channel Based Filtering for Multicast Boundaries

- The `filter-autorp` keyword does not support extended access lists.

Information About the SSM Channel Based Filtering for Multicast Boundaries Feature

- Rules for Multicast Boundaries, page 72
- Benefits of SSM Channel Based Filtering for Multicast Boundaries, page 72

Rules for Multicast Boundaries

The SSM Channel Based Filtering for Multicast Boundaries feature expands the `ip multicast boundary` command for control plane filtering support. More than one `ip multicast boundary` command can be applied to an interface.

The following rules govern the `ip multicast boundary` command:

- One instance of the `in` and `out` keywords can be configured on an interface.
- The `in` and `out` keywords can be used for standard or extended access lists.
- Only standard access lists are permitted with the use of the `filter-autorp` keyword or no keyword.
- A maximum of three instances of a command will be allowed on an interface: one instance of `in`, one instance of `out`, and one instance of `filter-autorp` or no keyword.
- When multiple instances of the command are used, the filtering will be cumulative. If a boundary statement with no keyword exists with a boundary statement with the `in` keyword, both access lists will be applied on the in direction and a match on either one will be sufficient.
- All instances of the command apply to both control and data plane traffic.
- Protocol information on the extended access list is parsed to allow reuse and filtering for Cisco IOS XE consistency. An (S,G) operation will be filtered by an extended access list under all conditions stated above for keywords if the access list filters (S,G) traffic for all protocols.

Benefits of SSM Channel Based Filtering for Multicast Boundaries

- This feature allows input on the source interface.
- The access control capabilities are the same for SSM and Any Source Multicast (ASM).

How to Configure SSM Channel Based Filtering for Multicast Boundaries

- Configuring the Multicast Boundaries, page 73
Configuring the Multicast Boundaries

Perform this task to configure the multicast boundary.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip access-list {standard|extended} access-list-name
4. permit protocol host address host address
5. deny protocol host address host address
6. Repeat Step 4 or Step 5 as needed.
7. interface type interface-number port-number
8. ip multicast boundary access-list-name [in|out | filter-autorp]

DETAILED STEPS

- Configuring the Multicast Boundaries Denying Traffic Example, page 75

**Configuring the Multicast Boundaries Permitting and Denying Traffic Example**

The following example permits outgoing traffic for (181.1.2.201, 232.1.1.1) and (181.1.2.202, 232.1.1.1) and denies all other (S,G)s.

```
configure terminal
ip access-list extended acc_grp1
permit ip host 0.0.0.0 232.1.1.1 0.0.0.255
permit ip host 181.1.2.201 host 232.1.1.1
permit udp host 181.1.2.202 host 232.1.1.1
permit ip host 181.1.2.202 host 232.1.1.1
deny igmp host 181.2.3.303 host 232.1.1.1
interface gigabitethernet 2/3/0
ip multicast boundary acc_grp1 out
```
Configuring the Multicast Boundaries Permitting Traffic Example

The following example permits outgoing traffic for (192.168.2.201, 232.1.1.5) and 192.168.2.202, 232.1.1.5).

```
configure terminal
ip access-list extended acc_grp6
  permit ip host 0.0.0.0 232.1.1.1 5.0.0.255
  deny udp host 192.168.2.201 host 232.1.1.5
  permit ip host 192.168.2.201 host 232.1.1.5
  deny pim host 192.168.2.201 host 232.1.1.5
  permit ip host 192.168.2.202 host 232.1.1.5
  deny igmp host 192.2.3.303 host 232.1.1.1
interface gigabitethernet 2/3/0
  ip multicast boundary acc_grp6 out
```

Configuring the Multicast Boundaries Denying Traffic Example

The following example denies a group-range that is being announced by the candidate RP. Since the group range is denied, there will be no pim auto-rp mappings created.

```
configure terminal
ip access-list standard acc_grp10
deny 225.0.0.0 0.255.255.255
permit any
access-list extended acc_grp12
  permit pim host 181.1.2.201 host 232.1.1.8
  deny udp host 181.1.2.201 host 232.1.1.8
  permit pim host 181.1.2.203 0.0.0.255 host 227.7.7.7
  permit ip host 0.0.0.0 host 227.7.7.7
  permit ip 181.1.2.203 0.0.0.255 host 227.7.7.7
  permit ip host 181.1.2.201 host 232.1.1.7
ip access-list extended acc_grp13
  deny ip host 181.1.2.201 host 232.1.1.8
  permit ip any any
interface gigabitethernet 2/3/0
  ip multicast boundary acc_grp10 filter-autorp
  ip multicast boundary acc_grp12 out
  ip multicast boundary acc_grp13 in
```

### Feature Information for SSM Channel Based Filtering for Multicast Boundaries

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to [www.cisco.com/go/cfn](http://www.cisco.com/go/cfn). An account on Cisco.com is not required.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About IPv6 Multicast: Bandwidth-Based Call Admission Control

- Bandwidth-Based CAC for IPv6 Multicast, page 79
- Threshold Notification for mCAC Limit, page 80

Bandwidth-Based CAC for IPv6 Multicast

The bandwidth-based call admission control (CAC) for IPv6 multicast feature implements a way to count per-interface mroute state limiters using cost multipliers. This feature can be used to provide bandwidth-based CAC on a per-interface basis in network environments where the multicast flows use different amounts of bandwidth.

This feature limits and accounts for IPv6 multicast state in detail. When this feature is configured, interfaces can be limited to the number of times they may be used as incoming or outgoing interfaces in the IPv6 multicast PIM topology.
With this feature, device administrators can configure global limit cost commands for state matching access lists and specify which cost multiplier to use when accounting such state against the interface limits. This feature provides the required flexibility to implement bandwidth-based local CAC policy by tuning appropriate cost multipliers for different bandwidth requirements.

**Threshold Notification for mCAC Limit**

The threshold notification for mCAC limit feature notifies the user when actual simultaneous multicast channel numbers exceed or fall below a specified threshold percentage. For example, if the mCAC rate limit is set to 50,000,000 and the configured threshold percentage is 80 percent, then the user is notified if the limit exceeds 10,000,000.

PIM Dense Mode State Refresh

This feature module describes the Protocol Independent Multicast (PIM) Dense Mode (DM) State Refresh feature, which is an extension to the dense operational mode of the PIM Version 2 multicast routing architecture.

- Finding Feature Information, page 89
- Prerequisite for PIM Dense Mode State Refresh, page 89
- Restrictions on PIM Dense Mode State Refresh, page 89
- Information About PIM Dense Mode State Refresh, page 90
- How to Configure PIM Dense Mode State Refresh, page 90
- Configuration Examples for PIM Dense Mode State Refresh, page 92
- Additional References, page 93
- Feature Information for PIM Dense Mode State Refresh, page 94

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisite for PIM Dense Mode State Refresh

- You must have PIM dense mode enabled on an interface before configuring the PIM Dense Mode State Refresh feature.

Restrictions on PIM Dense Mode State Refresh

- All routers in a PIM dense mode network must run a software release that supports the PIM Dense Mode State Refresh feature to process and forward state refresh control messages.
- The origination interval for the state refresh control message must be the same for all PIM routers on the same LAN. Specifically, the same origination interval must be configured on each router interface that is directly connected to the LAN.
PIM Dense Mode State Refresh Overview

The PIM Dense Mode State Refresh feature is an extension of the PIM Version 2 multicast routing architecture.

PIM dense mode builds source-based multicast distribution trees that operate on a flood and prune principle. Multicast packets from a source are flooded to all areas of a PIM dense mode network. PIM routers that receive multicast packets and have no directly connected multicast group members or PIM neighbors send a prune message back up the source-based distribution tree toward the source of the packets. As a result, subsequent multicast packets are not flooded to pruned branches of the distribution tree. However, the pruned state in PIM dense mode times out approximately every 3 minutes and the entire PIM dense mode network is reflooded with multicast packets and prune messages. This reflooding of unwanted traffic throughout the PIM dense mode network consumes network bandwidth.

The PIM Dense Mode State Refresh feature keeps the pruned state in PIM dense mode from timing out by periodically forwarding a control message down the source-based distribution tree. The control message refreshes the prune state on the outgoing interfaces of each router in the distribution tree.

Benefits of PIM Dense Mode State Refresh

The PIM Dense Mode State Refresh feature keeps the pruned state in PIM dense mode from timing out, which saves network bandwidth by greatly reducing the reflooding of unwanted multicast traffic to pruned branches of the PIM dense mode network. This feature also enables PIM routers in a PIM dense mode multicast network to recognize topology changes (sources joining or leaving a multicast group) before the default 3-minute state refresh timeout period.

How to Configure PIM Dense Mode State Refresh

Configuring PIM Dense Mode State Refresh

There are no configuration tasks for enabling the PIM Dense Mode State Refresh feature. By default, all PIM routers that are running a Cisco IOS XE software release that supports the PIM Dense Mode State Refresh feature automatically process and forward state refresh control messages.

To disable the processing and forwarding of state refresh control messages on a PIM router, use the `ip pim state-refresh disable` global configuration command. To enable state refresh again if it has been disabled, use the `no ip pim state-refresh disable` global configuration command.
The origination of state refresh control messages is disabled by default. To configure the origination of the control messages on a PIM router, use the following commands beginning in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# interface type number</td>
<td>Specifies an interface and places the router in interface configuration mode.</td>
</tr>
<tr>
<td>Router(config-if)# ip pim state-refresh origination-interval [interval]</td>
<td>Configures the origination of the PIM Dense Mode State Refresh control message. Optionally, you can configure the number of seconds between control messages by using the interval argument. The default interval is 60 seconds. The interval range is 1 second to 100 seconds.</td>
</tr>
</tbody>
</table>

**Verifying PIM Dense Mode State Refresh Configuration**

Use the `show ip pim interface [type number] detail` and the `show ip pim neighbor [interface]` commands to verify that the PIM Dense Mode State Refresh feature is configured correctly. The following output of the `show ip pim interface [type number] detail` command indicates that processing, forwarding, and origination of state refresh control messages is enabled.

```
Router# show ip pim interface fastethernet 0/1/0 detail
FastEthernet0/1/0 is up, line protocol is up
Internet address is 172.16.8.1/24
Multicast switching:process
Multicast packets in/out:0/0
Multicast boundary:not set
Multicast TTL threshold:0
PIM:enabled
PIM version:2, mode:dense
PIM DR:172.16.8.1 (this system)
PIM neighbor count:0
PIM Hello/Query interval:30 seconds
PIM State-Refresh processing:enabled
PIM State-Refresh origination:enabled, interval:60 seconds
PIM NBMA mode:disabled
PIM ATM multipoint signalling:disabled
PIM domain border:disabled
Multicast Tagswitching:disabled
```

The S in the Mode field of the following `show ip pim neighbor [interface]` command output indicates that the neighbor has the PIM Dense Mode State Refresh feature configured.

```
Router# show ip pim neighbor
PIM Neighbor Table
Neighbor          Interface          Uptime/Expires    Ver   DR
Address                                                      Priority/Mode
172.16.5.1        Ethernet1/1        00:09:03/00:01:41 v2    1 / B S
```

**Monitoring and Maintaining PIM DM State Refresh**

Following are the PIM Dense Mode State Refresh control messages that are sent and received by a PIM router after the `debug ip pim` privileged EXEC command is configured for multicast group 239.0.0.1:

```
Router# debug ip pim 239.0.0.1
*Mar 1 00:25:10.416: PIM: Originating refresh message for (172.16.8.3,239.0.0.1)
*Mar 1 00:25:10.416: PIM: Send SR on GigabitEthernet1/1/0 for (172.16.8.3,239.0.0.1)
TTL=9
```
The following output from the `show ip mroute` command displays are the resulting prune timer changes for GigabitEthernet interface 1/0/0 and multicast group 239.0.0.1. (The following output assumes that the `debug ip pim` privileged EXEC command has already been configured on the router.) In the first output from the `show ip mroute` command, the prune timer reads 00:02:06. The debug messages indicate that a PIM Dense Mode State Refresh control message is received and sent on Ethernet interface 1/0, and that other PIM Dense Mode State Refresh routers were discovered. In the second output from the `show ip mroute` command, the prune timer has been reset to 00:02:55.

Router# show ip mroute 239.0.0.1 (172.16.8.3, 239.0.0.1), 00:09:50/00:02:06, flags:PT
   Incoming interface: GigabitEthernet1/1/0, RPF nbr 172.16.5.2
   Outgoing interface list: GigabitEthernet1/0/0, Prune/Dense, 00:09:43/00:02:06
Router# *Mar 1 00:32:06.657:PIM:SR on iif from 172.16.5.2 orig 172.16.8.1 for (172.16.8.3,239.0.0.1)
   flags:prune-indicator
   *Mar 1 00:32:06.661:PIM:Cached metric is [0/0]
   *Mar 1 00:32:06.661:PIM:Send SR on Ethernet1/0 for (172.16.8.3,239.0.0.1)
   TTL=8
   *Mar 1 00:32:06.661: flags:prune-indicator
Router# show ip mroute 239.0.0.1 (172.16.8.3, 239.0.0.1), 00:10:01/00:02:55, flags:PT
   Incoming interface: GigabitEthernet1/1/0, RPF nbr 172.16.5.2
   Outgoing interface list: GigabitEthernet1/0/0, Prune/Dense, 00:09:55/00:02:55

Configuration Examples for PIM Dense Mode State Refresh

- Originating Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example, page 92
- Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example, page 92

Originating Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example

The following example is for a PIM router that is originating, processing, and forwarding PIM Dense Mode State Refresh control messages on Fast Ethernet interface 0/1/0 every 60 seconds:

```
ip multicast-routing distributed
interface FastEthernet0/1/0
ip address 172.16.8.1 255.255.255.0
ip pim state-refresh origination-interval 60
ip pim dense-mode
```

Processing and Forwarding PIM Dense Mode State Refresh Control Messages Example

The following example is for a PIM router that is just processing and forwarding PIM Dense Mode State Refresh control messages on Fast Ethernet interface 1/1/0:

```
ip multicast-routing
interface FastEthernet1/1/0
```
ip address 172.16.7.3 255.255.255.0
ip pim dense-mode

Feature Information for PIM Dense Mode State Refresh

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.
