Configuring Basic IP Multicast

IP multicast is a bandwidth-conserving technology that reduces traffic by delivering a single stream of information simultaneously to potentially thousands of corporate businesses and homes. Applications that take advantage of multicast include video conferencing, corporate communications, distance learning, and distribution of software, stock quotes, and news. This module describes the tasks used to configure basic IP multicast.

- Prerequisites for Configuring Basic IP Multicast, on page 1
- Restrictions for Configuring Basic IP Multicast, on page 1
- Information About Configuring Basic IP Multicast, on page 2
- How to Configure Basic IP Multicast, on page 6
- Configuration Examples for Basic IP Multicast, on page 16

Prerequisites for Configuring Basic IP Multicast

- To determine which of the tasks contained in this module you will have to perform, you must decide which Protocol Independent Multicast (PIM) mode will be used. This determination is based on the applications you intend to support on your network.
- All access lists to be used with the tasks in this module should be configured prior to beginning the configuration task. For information about how to configure an access list, see the “Creating an IP Access List and Applying It to an Interface” module of the Security Configuration Guide: Access Control Lists guide.

Restrictions for Configuring Basic IP Multicast

HSRP/GLBP aware PIM is not supported.
Information About Configuring Basic IP Multicast

Auto-RP Overview

The Role of Auto-RP in a PIM Network

Auto-RP automates the distribution of group-to-rendezvous point (RP) mappings in a PIM network. To make Auto-RP work, a device must be designated as an RP mapping agent, which receives the RP announcement messages from the RPs and arbitrates conflicts. The RP mapping agent then sends the consistent group-to-RP mappings to all other devices.

Thus, all routers automatically discover which RP to use for the groups they support. The Internet Assigned Numbers Authority (IANA) has assigned two group addresses, 224.0.1.39 and 224.0.1.40, for Auto-RP.

The mapping agent receives announcements of intention to become the RP from Candidate-RPs. The mapping agent then announces the winner of the RP election. This announcement is made independently of the decisions by the other mapping agents.

IP Multicast Boundary

As shown in the figure, address scoping defines domain boundaries so that domains with RPs that have the same IP address do not leak into each other. Scoping is performed on the subnet boundaries within large domains and on the boundaries between the domain and the Internet.

You can set up an administratively scoped boundary on an interface for multicast group addresses using the `ip multicast boundary` command with the `access-list` argument. A standard access list defines the range of addresses affected. When a boundary is set up, no multicast data packets are allowed to flow across the boundary from either direction. The boundary allows the same multicast group address to be reused in different administrative domains.

The Internet Assigned Numbers Authority (IANA) has designated the multicast address range 239.0.0.0 to 239.255.255.255 as the administratively scoped addresses. This range of addresses can be reused in domains administered by different organizations. They would be considered local, not globally unique.

You can configure the `filter-autorp` keyword to examine and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary access control list (ACL) are removed. An Auto-RP group...
range announcement is permitted and passed by the boundary only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

Benefits of Auto-RP in a PIM Network

- Auto-RP allows any change to the RP designation to be configured only on the devices that are RPs, not on the leaf routers.
- Auto-RP offers the ability to scope the RP address within a domain.

Static RP Overview

If you are configuring PIM sparse mode, you must configure a PIM RP for a multicast group. An RP can either be configured statically in each device, or learned through a dynamic mechanism. This task explains how to statically configure an RP, as opposed to the router learning the RP through a dynamic mechanism such as Auto-RP.

PIM designated routers (DRs) forward data from directly connected multicast sources to the RP for distribution down the shared tree. Data is forwarded to the RP in one of two ways. It is encapsulated in register packets and unicast directly to the RP, or, if the RP has itself joined the source tree, it is multicast forwarded per the RPF forwarding algorithm. Last hop routers directly connected to receivers may, at their discretion, join themselves to the source tree and prune themselves from the shared tree.

A single RP can be configured for multiple groups that are defined by an access list. If no RP is configured for a group, the router treats the group as dense using the PIM sparse-dense mode techniques. (You can prevent this occurrence by configuring the `no ip pim dm-fallback` command.)

If dynamic and static group-to-RP mappings are used together and there is an RP address conflict, the RP address configured for a static group-to-RP mapping (with the `ip pim rp-address override` command) will take precedence.

---

**Note**

If the **override** keyword is not specified and there is RP address conflict, dynamic group-to-RP mappings will take precedence over static group-to-RP mappings.

SSM Overview

Source Specific Multicast (SSM). SSM is an extension of IP multicast where datagram traffic is forwarded to receivers from only those multicast sources that the receivers have explicitly joined. For multicast groups configured for SSM, only source-specific multicast distribution trees (not shared trees) are created.

SSM Components

Source Specific Multicast (SSM) is a datagram delivery model that best supports one-to-many applications, also known as broadcast applications. SSM is a core networking technology for the Cisco implementation of IP multicast solutions targeted for audio and video broadcast application environments and is described in RFC 3569. The following two components together support the implementation of SSM:

- Protocol Independent Multicast source-specific mode (PIM-SSM)
How SSM Differs from Internet Standard Multicast

The standard IP multicast infrastructure in the Internet and many enterprise intranets is based on the PIM-SM protocol and Multicast Source Discovery Protocol (MSDP). These protocols have proved to be reliable, extensive, and efficient. However, they are bound to the complexity and functionality limitations of the Internet Standard Multicast (ISM) service model. For example, with ISM, the network must maintain knowledge about which hosts in the network are actively sending multicast traffic. With SSM, this information is provided by receivers through the source addresses relayed to the last-hop devices by IGMPv3. SSM is an incremental response to the issues associated with ISM and is intended to coexist in the network with the protocols developed for ISM. In general, SSM provides IP multicast service for applications that utilize SSM.

ISM service is described in RFC 1112. This service consists of the delivery of IP datagrams from any source to a group of receivers called the multicast host group. The datagram traffic for the multicast host group consists of datagrams with an arbitrary IP unicast source address $S$ and the multicast group address $G$ as the IP destination address. Systems will receive this traffic by becoming members of the host group. Membership in a host group simply requires signaling the host group through IGMP Version 1, 2, or 3.

In SSM, delivery of datagrams is based on $(S, G)$ channels. Traffic for one $(S, G)$ channel consists of datagrams with an IP unicast source address $S$ and the multicast group address $G$ as the IP destination address. Systems will receive this traffic by becoming members of the $(S, G)$ channel. In both SSM and ISM, no signaling is required to become a source. However, in SSM, receivers must subscribe or unsubscribe to $(S, G)$ channels to receive or not receive traffic from specific sources. In other words, receivers can receive traffic only from $(S, G)$ channels to which they are subscribed, whereas in ISM, receivers need not know the IP addresses of sources from which they receive their traffic. The proposed standard approach for channel subscription signaling utilizes IGMP INCLUDE mode membership reports, which are supported only in IGMP Version 3.

SSM can coexist with the ISM service by applying the SSM delivery model to a configured subset of the IP multicast group address range. The Internet Assigned Numbers Authority (IANA) has reserved the address range from 232.0.0.0 through 232.255.255.255 for SSM applications and protocols. The software allows SSM configuration for an arbitrary subset of the IP multicast address range from 224.0.0.0 through 239.255.255.255. When an SSM range is defined, an existing IP multicast receiver application will not receive any traffic when it tries to use addresses in the SSM range unless the application is modified to use explicit $(S, G)$ channel subscription or is SSM-enabled.

SSM Operations

An established network in which IP multicast service is based on PIM-SM can support SSM services. SSM can also be deployed alone in a network without the full range of protocols that are required for interdomain PIM-SM. That is, SSM does not require an RP, so there is no need for an RP mechanism such as Auto-RP, MSDP, or bootstrap router (BSR).

If SSM is deployed in a network that is already configured for PIM-SM, then only the last-hop devices must be upgraded to a software image that supports SSM. Routers that are not directly connected to receivers do not have to upgrade to a software image that supports SSM. In general, these non-last-hop devices must only
run PIM-SM in the SSM range. They may need additional access control configuration to suppress MSDP signaling, registering, or PIM-SM shared-tree operations from occurring within the SSM range.

The SSM mode of operation is enabled by configuring the SSM range using the `ip pim ssm` global configuration command. This configuration has the following effects:

- For groups within the SSM range, (S, G) channel subscriptions are accepted through IGMPv3 INCLUDE mode membership reports.
- PIM operations within the SSM range of addresses change to PIM-SSM, a mode derived from PIM-SM. In this mode, only PIM (S, G) Join and Prune messages are generated by the device. Incoming messages related to rendezvous point tree (RPT) operations are ignored or rejected, and incoming PIM register messages are immediately answered with Register-Stop messages. PIM-SSM is backward-compatible with PIM-SM unless a device is a last-hop device. Therefore, devices that are not last-hop devices can run PIM-SM for SSM groups (for example, if they do not yet support SSM).
- For groups within the SSM range, no MSDP Source-Active (SA) messages within the SSM range will be accepted, generated, or forwarded.

**IGMPv3 Host Signaling**

IGMPv3 is the third version of the IETF standards track protocol in which hosts signal membership to last-hop devices of multicast groups. IGMPv3 introduces the ability for hosts to signal group membership that allows filtering capabilities with respect to sources. A host can signal either that it wants to receive traffic from all sources sending to a group except for some specific sources (a mode called EXCLUDE) or that it wants to receive traffic only from some specific sources sending to the group (a mode called INCLUDE).

IGMPv3 can operate with both ISM and SSM. In ISM, both EXCLUDE and INCLUDE mode reports are accepted by the last-hop router. In SSM, only INCLUDE mode reports are accepted by the last-hop router.

**Benefits of Source Specific Multicast**

**IP Multicast Address Management Not Required**

In the ISM service, applications must acquire a unique IP multicast group address because traffic distribution is based only on the IP multicast group address used. If two applications with different sources and receivers use the same IP multicast group address, then receivers of both applications will receive traffic from the senders of both applications. Even though the receivers, if programmed appropriately, can filter out the unwanted traffic, this situation would cause generally unacceptable levels of unwanted traffic.

Allocating a unique IP multicast group address for an application is still a problem. Most short-lived applications use mechanisms like Session Description Protocol (SDP) and Session Announcement Protocol (SAP) to get a random address, a solution that does not work well with a rising number of applications in the Internet. The best current solution for long-lived applications is described in RFC 2770, but this solution suffers from the restriction that each autonomous system is limited to only 255 usable IP multicast addresses.

In SSM, traffic from each source is forwarded between devices in the network independent of traffic from other sources. Thus different sources can reuse multicast group addresses in the SSM range.

**Denial of Service Attacks from Unwanted Sources Inhibited**

In SSM, multicast traffic from each individual source will be transported across the network only if it was requested (through IGMPv3 or IGMP v3lite memberships) from a receiver. In contrast, ISM forwards traffic from any active source sending to a multicast group to all receivers requesting that multicast group. In Internet
broadcast applications, this ISM behavior is highly undesirable because it allows unwanted sources to easily disturb the actual Internet broadcast source by simply sending traffic to the same multicast group. This situation depletes bandwidth at the receiver side with unwanted traffic and thus disrupts the undisturbed reception of the Internet broadcast. In SSM, this type of denial of service (DoS) attack cannot be made by simply sending traffic to a multicast group.

**Easy to Install and Manage**

SSM is easy to install and provision in a network because it does not require the network to maintain which active sources are sending to multicast groups. This requirement exists in ISM (with IGMPv1, IGMPv2, or IGMPv3).

The current standard solutions for ISM service are PIM-SM and MSDP. Rendezvous point (RP) management in PIM-SM (including the necessity for Auto-RP or BSR) and MSDP is required only for the network to learn about active sources. This management is not necessary in SSM, which makes SSM easier than ISM to install and manage, and therefore easier than ISM to operationally scale in deployment. Another factor that contributes to the ease of installation of SSM is the fact that it can leverage preexisting PIM-SM networks and requires only the upgrade of last hop devices to support IGMPv3, or IGMP v3lite.

**Ideal for Internet Broadcast Applications**

The three benefits previously described make SSM ideal for Internet broadcast-style applications for the following reasons:

- The ability to provide Internet broadcast services through SSM without the need for unique IP multicast addresses allows content providers to easily offer their service (IP multicast address allocation has been a serious problem for content providers in the past).

- The prevention against DoS attacks is an important factor for Internet broadcast services because, with their exposure to a large number of receivers, they are the most common targets for such attacks.

- The ease of installation and operation of SSM makes it ideal for network operators, especially in those cases where content needs to be forwarded between multiple independent PIM domains (because there is no need to manage MSDP for SSM between PIM domains).

**How to Configure Basic IP Multicast**

The tasks described in this section configure the basic IP multicast modes. No single task in this section is required; however, at least one of the tasks must be performed to configure IP multicast in a network. More than one of the tasks may be needed.

**Configuring Sparse Mode with Auto-RP**

**Before you begin**

- An interface configured in sparse-dense mode is treated in either sparse mode or dense mode of operation, depending on the mode in which the multicast group operates. You must decide how to configure your interfaces.

- All access lists that are needed when Auto-RP is configured should be configured prior to beginning the configuration task.
If a group has no known RP and the interface is configured to be sparse-dense mode, the interface is treated as if it were in dense mode, and data is flooded over the interface. To avoid this data flooding, configure the Auto-RP listener and then configure the interface as sparse mode.

When configuring Auto-RP, you must either configure the Auto-RP listener feature (Step 5) and specify sparse mode (Step 7) or specify sparse-dense mode (Step 8).

When you configure sparse-dense mode, dense mode failover may result in a network dense-mode flood. To avoid this condition, use PIM sparse mode with the Auto-RP listener feature.

Follow this procedure to configure auto-rendezvous point (Auto-RP). Auto-RP can also be optionally used with anycast RP.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip multicast-routing distributed`
4. Either perform Steps 5 through 7 or perform Steps 6 and 8.
5. `ip pim autorp listener`
6. `interface type number`
7. `ip pim sparse-mode`
8. `ip pim sparse-dense-mode`
9. `exit`
10. Repeat Steps 1 through 9 on all PIM interfaces.
11. `ip pim send-rp-announce` `{interface-type interface-number | ip-address} scope ttl-value [group-list access-list] [interval seconds] [bidir]`
12. `ip pim send-rp-discovery` `{interface-type interface-number} scope ttl-value [interval seconds]`
13. `ip pim rp-announce-filter rp-list access-list group-list access-list`
14. `no ip pim dm-fallback`
15. `interface type number`
16. `ip multicast boundary access-list [filter-autorp]`
17. `end`
18. `show ip pim autorp`
19. `show ip pim rp [mapping] [rp-address]`
20. `show ip igmp groups` `{group-name | group-address | interface-type interface-number} [detail]`
21. `show ip mroute` `{group-address | group-name | source-address | source-name | interface-type interface-number} [summary] [count] [active kbps]`

**Configuring Sparse Mode with Auto-RP**
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Device(config)# ip pim send-rp-announce loopback0 scope 31 group-list 5** | • Use the `interface-type` and `interface-number` arguments to define which IP address is to be used as the RP address.  
• Use the `ip-address` argument to specify a directly connected IP address as the RP address.  
**Note** If the `ip-address` argument is configured for this command, the RP-announce message will be sourced by the interface to which this IP address is connected (that is, the source address in the IP header of the RP-announce message is the IP address of that interface).  
• This example shows that the interface is enabled with a maximum of 31 hops. The IP address by which the device wants to be identified as RP is the IP address associated with loopback interface 0. Access list 5 describes the groups for which this device serves as RP. |

**Step 12**  
**ip pim send-rp-discovery** [`interface-type interface-number`] **scope ttl-value** [`interval seconds`]  
**Example:**  
Device(config)# ip pim send-rp-discovery loopback 1 scope 31  
**Configures the device to be an RP mapping agent.**  
• Perform this step on RP mapping agent devices or on combined RP/RP mapping agent devices.  
**Note** Auto-RP allows the RP function to run separately on one device and the RP mapping agent to run on one or multiple devices. It is possible to deploy the RP and the RP mapping agent on a combined RP/RP mapping agent device.  
• Use the optional `interface-type` and `interface-number` arguments to define which IP address is to be used as the source address of the RP mapping agent.  
• Use the `scope` keyword and `ttl-value` argument to specify the Time-to-Live (TTL) value in the IP header of Auto-RP discovery messages.  
• Use the optional `interval` keyword and `seconds` argument to specify the interval at which Auto-RP discovery messages are sent.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 13** ip pim rp-announce-filter rp-list access-list group-list access-list | Filters incoming RP announcement messages sent from candidate RPs (C-RPs) to the RP mapping agent.  
- Perform this step on the RP mapping agent only. |
| **Example:** | 
Device(config)# ip pim rp-announce-filter rp-list 1 group-list 2 |
| **Step 14** no ip pim dm-fallback | (Optional) Prevents PIM dense mode fallback.  
- Skip this step if all interfaces have been configured to operate in PIM sparse mode. |
| **Example:** | 
Device(config)# no ip pim dm-fallback |
| **Step 15** interface type number | Selects an interface that is connected to hosts on which PIM can be enabled. |
| **Example:** | 
Device(config)# interface gigabitethernet 1/0/0 |
| **Step 16** ip multicast boundary access-list [filter-autorp] | Configures an administratively scoped boundary.  
- Perform this step on the interfaces that are boundaries to other devices.  
- The access list is not shown in this task.  
- An access list entry that uses the deny keyword creates a multicast boundary for packets that match that entry. |
| **Example:** | 
Device(config-if)# ip multicast boundary 10 filter-autorp |
| **Step 17** end | Returns to global configuration mode. |
| **Example:** | 
Device(config-if)# end |

### What to Do Next

Proceed to the “Verifying IP Multicast Operation” module.

### Configuring Sparse Mode with a Single Static RP

A rendezvous point (RP) is required in networks running Protocol Independent Multicast sparse mode (PIM-SM). In PIM-SM, traffic will be forwarded only to network segments with active receivers that have explicitly requested multicast data.

This section describes how to configure sparse mode with a single static RP.

### Before you begin

All access lists that are needed when sparse mode is configured with a single static RP should be configured prior to beginning the configuration task.

### Note

The same RP address cannot be used for both bidirectional and sparse mode PIM groups.
SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip multicast-routing distributed**
4. **interface type number**
5. **ip pim sparse-mode**
6. Repeat Steps 1 through 5 on every interface that uses IP multicast.
7. **exit**
8. **ip pim rp-address rp-address [access-list] [override]**
9. **end**
10. **show ip pim rp [mapping] [rp-address]**
11. **show ip igmp groups [group-name | group-address | interface-type interface-number] [detail]**
12. **show ip mroute**

Configuring Source Specific Multicast

This section describes how to configure Source Specific Multicast (SSM).

Before you begin

If you want to use an access list to define the SSM range, configure the access list before you reference the access list in the `ip pim ssm` command.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip multicast-routing distributed`
4. `ip pim ssm {default | range access-list}`
5. `interface type number`
6. `ip pim sparse-mode`
7. Repeat Steps 1 through 6 on every interface that uses IP multicast.
8. `ip igmp version 3`
9. Repeat Step 8 on all host-facing interfaces.
10. `end`
11. `show ip igmp groups [group-name | group-address | interface-type interface-number] [detail]`
12. `show ip mroute`

</tbody>
</table>
| Device(config)# ip pim ssm default | - The **default** keyword defines the SSM range access list as 232/8.  
- The **range** keyword specifies the standard IP access list number or name that defines the SSM range. |

### Step 5
**interface** *type number*
**Example:**
Device(config)# interface gigabitethernet 1/0/0

Selects an interface that is connected to hosts on which IGMPv3 can be enabled.

### Step 6
**ip pim sparse-mode**
**Example:**
Device(config-if)# ip pim sparse-mode

Enables PIM on an interface. You must use sparse mode.

### Step 7
Repeat Steps 1 through 6 on every interface that uses IP multicast.

### Step 8
**ip igmp version 3**
**Example:**
Device(config-if)# ip igmp version 3

Enables IGMPv3 on this interface. The default version of IGMP is set to Version 2. Version 3 is required by SSM.

### Step 9
Repeat Step 8 on all host-facing interfaces.

### Step 10
**end**
**Example:**
Device(config-if)# end

Ends the current configuration session and returns to privileged EXEC mode.

### Step 11
**show ip igmp groups** [*group-name | group-address| interface-type interface-number] [detail]
**Example:**
Device# show ip igmp groups

(Optional) Displays the multicast groups having receivers that are directly connected to the device and that were learned through IGMP.  
- A receiver must be active on the network at the time that this command is issued in order for receiver information to be present on the resulting display.

### Step 12
**show ip mroute**
**Example:**
Device# show ip mroute

(Optional) Displays the contents of the IP mroute table.  
- This command displays whether a multicast group is configured for SSM service or a source-specific host report has been received.

**What to Do Next**

Proceed to the “Verifying IP Multicast Operation” module.
Configuration Examples for Basic IP Multicast

Example: Sparse Mode with Auto-RP

The following example configures sparse mode with Auto-RP:

```plaintext
ip multicast-routing
ip pim autorp listener
ip pim send-rp-announce Loopback0 scope 16 group-list 1
ip pim send-rp-discovery Loopback1 scope 16
no ip pim dm-fallback
access-list 1 permit 239.254.2.0 0.0.0.255
access-list 1 permit 239.254.3.0 0.0.0.255
.
.
access-list 10 permit 224.0.1.39
access-list 10 permit 224.0.1.40
access-list 10 permit 239.254.2.0 0.0.0.255
access-list 10 permit 239.254.3.0 0.0.0.255
```

Example: Sparse Mode with a Single Static RP

The following example sets the PIM RP address to 192.168.1.1 for all multicast groups and defines all groups to operate in sparse mode:

```plaintext
ip multicast-routing
interface gigabitethernet 1/0/0
  ip pim sparse-mode
ip pim rp-address 192.168.1.1
```

**Note**
The same RP cannot be used for both bidirectional and sparse mode groups.

The following example sets the PIM RP address to 172.16.1.1 for the multicast group 225.2.2.2 only:

```plaintext
access list 1 225.2.2.2 0.0.0.0
ip pim rp-address 172.17.1.1
```

SSM with IGMPv3 Example

The following example shows how to configure a device (running IGMPv3) for SSM:

```plaintext
ip multicast-routing
!
interface GigabitEthernet3/1/0
  ip address 172.21.200.203 255.255.255.0
  description backbone interface
  ip pim sparse-mode
!
interface GigabitEthernet3/2/0
  ip address 131.108.1.2 255.255.255.0
  ip pim sparse-mode
```
SSM Filtering Example

The following example shows how to configure filtering on legacy RP routers running software releases that do not support SSM routing. This filtering will suppress all unwanted PIM-SM and MSDP traffic in the SSM range. Without this filtering, SSM will still operate, but there may be additional RPT traffic if legacy first hop and last hop routers exist in the network.

```
description ethernet connected to hosts
ip igmp version 3
!
ip pim ssm default

ip access-list extended no-ssm-range
deny ip any 232.0.0.0 0.255.255.255 ! SSM range
permit ip any any
!
Deny registering in SSM range
ip pim accept-register list no-ssm-range
ip access-list extended msdp-nono-list
deny ip any 232.0.0.0 0.255.255.255 ! SSM Range
!
!
!
See ftp://ftpeng.cisco.com/ipmulticast/config-notes/msdp-sa-filter.txt for other SA messages that typically need to be filtered.
permit ip any any
!
Filter generated SA messages in SSM range. This configuration is only needed if there are directly connected sources to this router. The “ip pim accept-register” command filters remote sources.
ip msdp redistribute list msdp-nono-list
!
Filter received SA messages in SSM range. “Filtered on receipt” means messages are neither processed or forwarded. Needs to be configured for each MSDP peer.
ip msdp sa-filter in msdp-peer1 list msdp-nono-list
!
!
ip msdp sa-filter in msdp-peerN list msdp-nono-list
```
