Configuring IP Routing Protocol-Independent Features

This module describes how to configure IP routing protocol-independent features. Some of the features discussed in this module include the Default Passive Interface, Fast-Switched Policy Routing, and Policy-Based Routing.

- Finding Feature Information, on page 1
- Information About Basic IP Routing, on page 1
- How to Configure Basic IP Routing, on page 14

- Additional References, on page 45
- Feature Information for Configuring IP Routing Protocol-Independent Features, on page 46

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Basic IP Routing

Variable-Length Subnet Masks

Dynamic routing protocols, such as the Enhanced Interior Gateway Routing Protocol (EIGRP), Intermediate System-to-Intermediate System (IS-IS), Open Shortest Path First (OSPF), and Routing Information Protocol (RIP) Version 2, and static routes support variable-length subnet masks (VLSMs). VLSM enables an organization to use more than one subnet mask within the same network address space. VLSM allows you to conserve IP addresses and efficiently use the available address space. Implementing VLSM is often referred to as “subnetting a subnet.”
You may want to carefully consider the use of VLSMs. It is easy to make mistakes during address assignments and difficult to monitor networks that use VLSMs. The best way to implement VLSMs is to keep your existing addressing plan in place and gradually migrate some networks to VLSMs to recover address space.

The following example uses two different subnet masks for the class B network address of 172.16.0.0. A subnet mask of /24 is used for LAN interfaces. The /24 mask allows 256 subnets with 254 host IP addresses on each subnet. The final subnet of the range of possible subnets using a /24 subnet mask (172.16.255.0) is reserved for use on point-to-point interfaces and assigned a longer mask of /30. The use of a /30 mask on 172.16.255.0 creates 64 subnets (172.16.255.0–72.16.255.252) with 2 host addresses on each subnet.

To ensure unambiguous routing, you must not assign 172.16.255.0/24 to a LAN interface in your network.

```
Router(config)# interface Ethernet 0/0
Router(config-if)# ip address 172.16.1.1 255.255.255.0
Router(config-if)# exit
Router(config)# interface Serial 0/0
Router(config-if)# ip address 172.16.255.5 255.255.255.252
Router(config-if)# exit
Router(config)# router rip
Router(config-router)# network 172.16.0.0
```

### Static Routes

Static routes are user-defined routes that cause packets moving between a source and a destination to take a specified path. Static routes can be important if the router cannot build a route to a particular destination. They are also useful in specifying a gateway of last resort to which all unroutable packets will be sent.

To configure a static route, use the `ip route` command in global configuration mode.

Static routes remain in the router configuration until you remove them (by using the `no` form of the `ip route` command). However, you can override static routes with dynamic routing information through the assignment of administrative distance values. An administrative distance is a rating of the trustworthiness of a routing information source, such as an individual router or a group of routers.

Each dynamic routing protocol has a default administrative distance, as listed in the table below. For a configured static route to be overridden, the administrative distance of the static route should be higher than that of the dynamic routing protocol.

#### Table 1: Default Administrative Distances

<table>
<thead>
<tr>
<th>Route Source</th>
<th>Default Administrative Distance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connected interface</td>
<td>0</td>
</tr>
<tr>
<td>Static route</td>
<td>1</td>
</tr>
<tr>
<td>EIGRP summary route</td>
<td>5</td>
</tr>
<tr>
<td>External Border Gateway Protocol (BGP)</td>
<td>20</td>
</tr>
</tbody>
</table>
Static routes that point to an interface are advertised through dynamic routing protocols, regardless of whether redistribute static router configuration commands were specified for those routing protocols. Static routes that point to an interface are advertised because the routing table considers these routes as connected routes and hence, these routes lose their static nature. However, if you define a static route to an interface that is not connected to one of the networks defined by a network command, no dynamic routing protocol will advertise the route unless a redistribute static command is specified for the protocols.

When an interface goes down, all static routes associated with that interface are removed from the IP routing table. Also, when the software can no longer find a valid next hop for the address specified as the address of the forwarding router in a static route, the static route is removed from the IP routing table.

### Default Routes

Default routes, also known as gateways of last resort, are used to route packets that are addressed to networks not explicitly listed in the routing table. A device might not be able to determine routes to all networks. To provide complete routing capability, network administrators use some devices as smart devices and give the remaining devices default routes to the smart device. (Smart devices have routing table information for the entire internetwork.) Default routes can be either passed along dynamically or configured manually into individual devices.

Most dynamic interior routing protocols include a mechanism for causing a smart device to generate dynamic default information, which is then passed along to other devices.

You can configure a default route by using the following commands:

- **ip default-gateway**
- **ip default-network**
- **ip route 0.0.0.0 0.0.0.0**

You can use the **ip default-gateway** global configuration command to define a default gateway when IP routing is disabled on a device. For instance, if a device is a host, you can use this command to define a default gateway.
gateway for the device. You can also use this command to transfer a Cisco software image to a device when the device is in boot mode. In boot mode, IP routing is not enabled on the device.

Unlike the `ip default-gateway` command, the `ip default-network` command can be used when IP routing is enabled on a device. When you specify a network by using the `ip default-network` command, the device considers routes to that network for installation as the gateway of last resort on the device.

Gateways of last resort configured by using the `ip default-network` command are propagated differently depending on which routing protocol is propagating the default route. For Interior Gateway Routing Protocol (IGRP) and Enhanced Interior Gateway Routing Protocol (EIGRP) to propagate the default route, the network specified by the `ip default-network` command must be known to IGRP or EIGRP. The network must be an IGRP- or EIGRP-derived network in the routing table, or the static route used to generate the route to the network must be redistributed into IGRP or EIGRP or advertised into these protocols by using the `network` command. The Routing Information Protocol (RIP) advertises a route to network 0.0.0.0 if a gateway of last resort is configured by using the `ip default-network` command. The network specified in the `ip default-network` command need not be explicitly advertised under RIP.

Creating a static route to network 0.0.0.0 0.0.0.0 by using the `ip route 0.0.0.0 0.0.0.0` command is another way to set the gateway of last resort on a device. As with the `ip default-network` command, using the static route to 0.0.0.0 is not dependent on any routing protocols. However, IP routing must be enabled on the device. IGRP does not recognize a route to network 0.0.0.0. Therefore, it cannot propagate default routes created by using the `ip route 0.0.0.0 0.0.0.0` command. Use the `ip default-network` command to have IGRP propagate a default route.

EIGRP propagates a route to network 0.0.0.0, but the static route must be redistributed into the routing protocol.

Depending on your release of the Cisco software, the default route created by using the `ip route 0.0.0.0 0.0.0.0` command is automatically advertised by RIP devices. In some releases, RIP does not advertise the default route if the route is not learned via RIP. You might have to redistribute the route into RIP by using the `redistribute` command.

Default routes created using the `ip route 0.0.0.0 0.0.0.0` command are not propagated by Open Shortest Path First (OSPF) and Intermediate System to Intermediate System (IS-IS). Additionally, these default routes cannot be redistributed into OSPF or IS-IS by using the `redistribute` command. Use the `default-information originate` command to generate a default route into an OSPF or IS-IS routing domain.

### Subnet Zero and All-Ones Subnet IP Addressing

When a network address is subnetted, the first subnet obtained is called subnet zero.

Consider a Class B address 172.16.0.0. By default, a Class B address has 16 bits reserved for representing the host portion, thus allowing 65534 ($2^{16} - 2$) valid host addresses. If network 172.16.0.0/16 is subnetted by borrowing three bits from the host portion, eight ($2^3$) subnets are obtained. The table below shows the subnets obtained by subnetting the address 172.16.0.0, the resulting subnet mask, the corresponding broadcast address, and the range of valid host addresses.

<table>
<thead>
<tr>
<th>Subnet Address</th>

<td>255.255.224.0</td>
<td>172.16.159.255</td>
<td>172.16.128.1 to 172.16.159.254</td>
</tr>
<tr>
<td>172.16.160.0</td>
<td>255.255.224.0</td>
<td>172.16.191.255</td>
<td>172.16.160.1 to 172.16.191.254</td>
</tr>
<tr>
<td>172.16.192.0</td>
<td>255.255.224.0</td>
<td>172.16.223.255</td>
<td>172.16.192.1 to 172.16.223.254</td>
</tr>
<tr>
<td>172.16.224.0</td>
<td>255.255.224.0</td>
<td>172.16.255.255</td>
<td>172.16.224.1 to 172.16.255.254</td>
</tr>
</tbody>
</table>

In the above table, the first subnet (subnet 172.16.0.0) is called subnet zero.

The class of the network subnetted and the number of subnets obtained after subnetting have no role in determining subnet zero. It is the first subnet obtained when subnetting the network address. Also, when you write the binary equivalent of the subnet zero address, all the subnet bits (bits 17, 18, and 19 in this case) are zeros. Subnet zero is also known as the all-zeros subnet.

When a network address is subnetted, the last subnet obtained is called the all-ones subnet.

With reference to the above table, the last subnet obtained when you subnet network 172.16.0.0 (subnet 172.16.224.0/19) is called the all-ones subnet.

The class of the network subnetted and the number of subnets obtained after subnetting have no role in determining the all-ones subnet. Also, when you write the binary equivalent of the all-ones subnet, all the subnet bits (bits 17, 18, and 19 in this case) are ones, hence the name.

**Problems with Subnet Zero and the All-Ones Subnet**

According to RFC 950, “It is useful to preserve and extend the interpretation of these special (network and broadcast) addresses in subnetted networks. This means the values of all zeros and all ones in the subnet field should not be assigned to actual (physical) subnets.” Therefore, network engineers who had to calculate the number of subnets obtained by borrowing three bits would calculate $2^3 - 2$ (6) and not $2^3$ (8). The –2 ensures that subnet zero and the all-ones subnet are not used.

**Subnet Zero**

Using subnet zero may lead to the creation of a network and a subnet with indistinguishable addresses.

With reference to the above table, if you calculate the subnet address for 172.16.1.10, the answer you arrive at is subnet 172.16.0.0 (subnet zero). Note that this subnet address is identical to the network address 172.16.0.0, which was subnetted in the first place. So whenever you perform subnetting, you get a network and a subnet (subnet zero) with indistinguishable addresses.

Depending on the release, your Cisco IOS software, by default, may not allow an IP address belonging to subnet zero to be configured on an interface. However, some releases allow the use of the `ip subnet-zero` command in global configuration mode to overcome this restriction. Some releases have the `ip subnet-zero` command enabled by default, and these releases allow you to configure the `no ip subnet-zero` command to restrict the use of subnet zero addresses.
All-Ones

The use of the all-ones subnet for addressing may lead to the creation of a network and a subnet with identical broadcast addresses.

With reference to above table, the broadcast address for the last subnet (subnet 172.16.224.0) is 172.16.255.255. This address is identical to the broadcast address of the network 172.16.0.0, which was subnetted in the first place. So whenever you perform subnetting, you get a network and a subnet (all-ones subnet) with identical broadcast addresses. You can configure the address 172.16.230.1/19 on a router, but if that is done, you can no longer differentiate between a local subnet broadcast (172.16.255.255 [/19]) and the Class B broadcast (172.16.255.255[/16]).

Despite the inherent confusion created by the use of subnet zero and all-ones subnet, the entire address space including subnet zero and the all-ones subnet have always been usable. The use of subnet zero is allowed in some Cisco IOS software releases. You can use subnet zero in these releases by entering the `ip subnet-zero` global configuration command. Today, the use of subnet zero and the all-ones subnet is generally accepted and most vendors support their use. However, on certain networks, particularly the ones using legacy software, the use of subnet zero and the all-ones subnet can lead to problems.

Maximum Number of Paths

By default, most IP routing protocols install a maximum of four parallel paths in a routing table. Static routes always install six paths. The exception is BGP, which by default allows only one path (the best path) to the destination. However, BGP can be configured to use equal and unequal cost multipath load sharing. See the "BGP Multipath Load Sharing for Both eBGP and iBGP in an MPLS-VPN" feature in the BGP Configuration Guide for more information.

The number of parallel paths that you can configure to be installed in the routing table is dependent on the installed version of the Cisco IOS software. To change the maximum number of parallel paths allowed, use the `maximum-paths` command in router configuration mode.

Multi-Interface Load Splitting

Multi-interface load splitting allows you to efficiently control traffic that travels across multiple interfaces to the same destination. The `traffic-share min` router configuration command specifies that if multiple paths are available to the same destination, only paths with the minimum metric will be installed in the routing table. The number of paths allowed is never more than six. For dynamic routing protocols, the number of paths is controlled by the `maximum-paths` router configuration command. The static route source can install six paths. If more paths are available, the extra paths are discarded. If some installed paths are removed from the routing table, pending routes are added automatically.

Routing Information Redistribution

You can configure the Cisco IOS software to redistribute information from one routing protocol to another. For example, you can configure a device to readvertise EIGRP-derived routes using RIP or to readvertise static routes using EIGRP. Redistribution from one routing protocol to another can be configured in all IP-based routing protocols.

You can also conditionally control the redistribution of routes between routing domains by configuring route maps between two domains. A route map is a route filter that is configured with permit and deny statements, match and set clauses, and sequence numbers. To define a route map for redistribution, use the `route-map` command in global configuration mode.
The metrics of one routing protocol do not necessarily translate into the metrics of another. For example, the RIP metric is hop count and the EIGRP metric is a combination of five metric values. In such situations, a dynamic metric is assigned to the redistributed route. Redistribution in these cases should be applied consistently and carefully in conjunction with inbound filtering to avoid the creation of routing loops.

The following examples illustrate the use of redistribution with and without route maps. The following example shows how to redistribute all OSPF routes into EIGRP:

```plaintext
Router(config)# router eigrp 1
Router(config-router)# redistribute ospf 101
Router(config-router)# exit
```

The following example shows how to redistribute RIP routes, with a hop count equal to 1, into OSPF. These routes will be redistributed into OSPF as external LSAs with a metric of 5, metric-type of type 1, and a tag equal to 1.

```plaintext
Router(config)# router ospf 1
Router(config-router)# redistribute rip route-map rip-to-ospf
Router(config-router)# exit

Router(config)# route-map rip-to-ospf permit
Router(config-route-map)# match metric 1
Router(config-route-map)# set metric 5
Router(config-route-map)# set metric-type type 1
Router(config-route-map)# set tag 1
Router(config-route-map)# exit
```

The following example shows how to redistribute OSPF learned routes with tag 7 as a RIP metric of 15:

```plaintext
Router(config)# router rip
Router(config-router)# redistribute ospf 1 route-map 5
Router(config-router)# exit

Router(config)# route-map 5 permit
Router(config-route-map)# match route-type external
Router(config-route-map)# set metric 15
```

The following example shows how to redistribute OSPF intra-area and inter-area routes with next-hop routers on serial interface 0/0 into BGP with a metric of 5:

```plaintext
Router(config)# router bgp 50000
Router(config-router)# redistribute ospf 1 route-map 10
Router(config-router)# exit

Router(config)# route-map 10 permit
Router(config-route-map)# match route-type internal
Router(config-route-map)# match interface serial 0
Router(config-route-map)# set metric 5
```

The following example redistributes two types of routes into the integrated IS-IS routing table (supporting both IP and CLNS). The first type is OSPF external IP routes with tag 5; these routes are inserted into Level 2 IS-IS link-state packets (LSPs) with a metric of 5. The second type is ISO-IGRP-derived CLNS prefix routes that match CLNS access list 2000; these routes are redistributed into IS-IS as Level 2 LSPs with a metric of 30.

```plaintext
Router(config)# router isis
Router(config-router)# redistribute ospf 1 route-map 2
Router(config-router)# redistribute iso-igrp nsfnet route-map 3
Router(config-router)# exit

Router(config)# route-map 2 permit
Router(config-route-map)# match route-type external
```
In the following example, OSPF external routes with tags 1, 2, 3, and 5 are redistributed into RIP with metrics of 1, 1, 5, and 5, respectively. The OSPF routes with a tag of 4 are not redistributed.

The following example shows how a route map is referenced by using the `default-information` router configuration command. Such referencing is called conditional default origination. OSPF will generate the default route (network 0.0.0.0) with a type 2 metric of 5 if 172.16.0.0 is in the routing table.

```
Supported Automatic Metric Translations

This section describes supported automatic metric translations between routing protocols. The following points are based on the assumption that you have not defined a default redistribution metric that replaces metric conversions:

- RIP can automatically redistribute static routes. It assigns static routes a metric of 1 (directly connected).
- BGP does not send metrics in its routing updates.
- EIGRP can automatically redistribute static routes from other EIGRP-routed autonomous systems as long as the static route and any associated interfaces are covered by an EIGRP network statement. EIGRP assigns static routes a metric that identifies them as directly connected. EIGRP does not change the metrics of routes derived from EIGRP updates from other autonomous systems.

Supported Automatic Metric Translations

This section describes supported automatic metric translations between routing protocols. The following points are based on the assumption that you have not defined a default redistribution metric that replaces metric conversions:

- RIP can automatically redistribute static routes. It assigns static routes a metric of 1 (directly connected).
- BGP does not send metrics in its routing updates.
- EIGRP can automatically redistribute static routes from other EIGRP-routed autonomous systems as long as the static route and any associated interfaces are covered by an EIGRP network statement. EIGRP assigns static routes a metric that identifies them as directly connected. EIGRP does not change the metrics of routes derived from EIGRP updates from other autonomous systems.
```
Any protocol can redistribute routes from other routing protocols as long as a default metric is configured.

**Protocol Differences in Implementing the no redistribute Command**

**Caution**
Removing options that you have configured for the `redistribute` command requires careful use of the `no redistribute` command to ensure that you obtain the result that you are expecting. In most cases, changing or disabling any keyword will not affect the state of other keywords.

Different protocols implement the `no redistribute` command differently as follows:

- In Border Gateway Protocol (BGP), Open Shortest Path First (OSPF), and Routing Information Protocol (RIP) configurations, the `no redistribute` command removes only the specified keywords from the `redistribute` commands in the running configuration. They use the *subtractive keyword* method when redistributing from other protocols. For example, in the case of BGP, if you configure `no redistribute static route-map interior`, only the route map is removed from the redistribution, leaving `redistribute static` in place with no filter.

- The `no redistribute isis` command removes the Intermediate System to Intermediate System (IS-IS) redistribution from the running configuration. IS-IS removes the entire command, regardless of whether IS-IS is the redistributed or redistributing protocol.

- The Enhanced Interior Gateway Routing Protocol (EIGRP) used the subtractive keyword method prior to EIGRP component version rel5. Starting with EIGRP component version rel5, the `no redistribute` command removes the entire `redistribute` command when redistributing from any other protocol.

**Default Passive Interfaces**

The Default Passive Interfaces feature simplifies the configuration of distribution devices by allowing all interfaces to be set as passive by default. In ISPs and large enterprise networks, many distribution devices have more than 200 interfaces. Obtaining routing information from these interfaces requires configuration of the routing protocol on all interfaces and manual configuration of the `passive-interface` command on interfaces where adjacencies were not desired.

**Sources of Routing Information Filtering**

Filtering sources of routing information prioritizes routing information gathered from different sources because some pieces of routing information may be more accurate than others. An administrative distance is a rating of the trustworthiness of a routing information source, such as an individual router or a group of routers. Numerically, an administrative distance is an integer from 0 to 255. In general, the higher the value the lower the trust rating. An administrative distance of 255 means that the routing information source cannot be trusted at all and should be ignored.

In a large network, some routing protocols and some routers can be more reliable than others as sources of routing information. Also, when multiple routing processes are running on the same router for IP, the same route may be advertised by more than one routing process. By specifying administrative distance values, you
enable a router to intelligently discriminate between sources of routing information. The router will always pick the route whose routing protocol has the lowest administrative distance.

There are no guidelines for assigning administrative distances because each network has its own requirements. You must determine a reasonable matrix of administrative distances for a network as a whole.

---

**Note**

You can use the administrative distance to rate the routing information from routers that are running the same routing protocol. However, using the administrative distance for this purpose can result in inconsistent routing information and forwarding loops.

In the following example, the `router eigrp` global configuration command configures EIGRP routing in autonomous system 1. The `network` command specifies EIGRP routing on networks 192.0.2.16 and 172.16.0.0. The first `distance` router configuration command sets the default administrative distance to 255, which instructs the router to ignore all routing updates from routers for which an explicit distance has not been set. The second `distance` command sets the administrative distance to 80 for internal EIGRP routes and to 100 for external EIGRP routes. The third `distance` command sets the administrative distance to 120 for the router with the address 172.16.1.3.

```
Router(config)# router eigrp 1
Router(config-router)# network 192.0.2.16
Router(config-router)# network 172.16.0.0
Router(config-router)# distance 255
Router(config-router)# distance eigrp 80 100
Router(config-router)# distance 120 172.16.1.3 0.0.0.0
```

The `distance eigrp` command must be used to set the administrative distance for EIGRP-derived routes.

The following example assigns the router with the address 192.0.2.1 an administrative distance of 100 and all other routers on subnet 192.0.2.0 an administrative distance of 200:

```
Router(config-router)# distance 100 192.0.2.1 0.0.0.0
Router(config-router)# distance 200 192.0.2.0 0.0.0.255
```

However, if you reverse the order of these two commands, all routers on subnet 192.0.2.0 are assigned an administrative distance of 200, including the router at address 192.0.2.1:

```
Router(config-router)# distance 200 192.0.2.0 0.0.0.255
Router(config-router)# distance 100 192.0.2.1 0.0.0.0
```

---

**Note**

Administrative distances should be applied carefully and consistently to avoid the creation of routing loops or other network failures.

In the following example, the administrative distance value for learned IP routes is 90. Preference is given to these IP routes rather than routes with the default administrative distance value of 110.

```
Router(config)# router isis
Router(config-router)# distance 90 ip
```
Policy-Based Routing

Policy-based routing (PBR) is a more flexible mechanism than destination routing for routing packets. It is a process whereby a router puts packets through a route map before routing them. The route map determines which packets are routed to which router next. You can enable PBR if you want certain packets to be routed some way other than the obvious shortest path. Possible applications for policy-based routing include protocol-sensitive routing, source-sensitive routing, routing based on interactive versus batch traffic, and routing based on dedicated links.

To enable PBR, you must identify the route map to be used for PBR and create the route map. The route map specifies the match criteria and the resulting action if all match clauses are met.

A packet arriving on a specified interface will be subject to PBR, except when its destination IP address is the same as the IP address of the router’s interface. To disable fast switching of all packets arriving on this interface, use the `ip policy route-map` command in interface configuration mode.

To define the route map to be used for PBR, use the `route-map` command in global configuration mode.

To define the criteria by which packets are examined to learn if they will follow PBR, use either the `match length` command or the `match ip address` command or both in route map configuration mode. The `match length` command allows you to configure policy routing based on the Level 3 length of the packet, and the `match ip address` command allows you to policy route packets based on the criteria that can be matched with an extended access list.

The following example provides two sources with equal access to two different service providers. Packets that arrive on asynchronous interface 1 from the source 10.1.1.1 are sent to the router at 172.16.6.6 if the router has no explicit route for the destination of the packets. Packets that arrive from the source 172.17.2.2 are sent to the router at 192.168.7.7 if the router has no explicit route for the destination of the packets. All other packets for which the router has no explicit route to the destination are discarded.

```
Router(config)# access-list 1 permit ip 10.1.1.1
Router(config)# access-list 2 permit ip 172.17.2.2
Router(config)# interface async 1
Router(config-if)# ip policy route-map equal-access
Router(config-if)# exit
Router(config)# route-map equal-access permit 10
Router(config-route-map)# match ip address 1
Router(config-route-map)# set ip default next-hop 172.16.6.6
Router(config-route-map)# exit
Router(config)# route-map equal-access permit 20
Router(config-route-map)# match ip address 2
Router(config-route-map)# set ip default next-hop 192.168.7.7
Router(config-route-map)# exit
Router(config)# route-map equal-access permit 30
Router(config-route-map)# set default interface null 0
Router(config-route-map)# exit
```

You can set IP header precedence bits in the router when PBR is enabled. The precedence setting in the IP header determines how packets are treated during times of high traffic. When packets containing these headers arrive at another router, the packets are ordered for transmission according to the precedence set if the queuing feature is enabled. The router does not honor the precedence bits if queuing is not enabled, and the packets are sent in FIFO order. You can change the precedence setting by using either a number or a name.

The table below lists the possible IP Precedence values (numbers and their corresponding names), from the least important to the most important.
### Fast-Switched Policy Routing

IP policy routing can be fast-switched. Prior to fast-switched policy routing, policy routing could only be process-switched, which meant that on most platforms, the switching rate was approximately 1000 to 10,000 packets per second. Such rates were not fast enough for many applications. With fast-switched policy routing, users who need policy routing to occur at faster speeds can implement policy routing without slowing down the device.

Fast-switched policy routing supports all `match` commands and most `set` commands, except for the following:

- `set ip default`
- `set interface`

The `set interface` command is supported only over point-to-point links, unless there is a route cache entry that uses the same interface that is specified in the command in the route map.

To configure fast-switched policy routing, use the `ip route-cache policy` interface configuration command.

### Local Policy Routing

Packets that are generated by the router are not normally policy-routed. To enable local policy routing for such packets, you must indicate which route map the router should use. All packets originating on the router will then be subject to local policy routing. To identify the route map to be used for local policy routing, use the `ip local policy route-map` command in global configuration mode.

Use the `show ip local policy` command to display the route map used for local policy routing, if one exists.

### NetFlow Policy Routing

NetFlow policy routing (NPR) integrates policy routing, which enables traffic engineering and traffic classification, with NetFlow services, which provide billing, capacity planning, and information monitoring on real-time traffic flows. IP policy routing works with Cisco Express Forwarding (formerly known as CEF), distributed Cisco Express Forwarding (formerly known as dCEF), and NetFlow.

NetFlow policy routing leverages the following technologies:

---

### Table 3: IP Precedence Values

<table>
<thead>

</tr>
</tbody>
</table>
• Cisco Express Forwarding, which looks at a Forwarding Information Base (FIB) instead of a routing table when switching packets, to address maintenance problems of a demand caching scheme.

• Distributed Cisco Express Forwarding, which addresses the scalability and maintenance problems of a demand caching scheme.

• NetFlow, which provides accounting, capacity planning, and traffic monitoring capabilities.

The following are the benefits of NPR:

• NPR takes advantage of new switching services. Cisco Express Forwarding, distributed Cisco Express Forwarding, and NetFlow can now use policy routing.

• Policy routing can be deployed on a wide scale and on high-speed interfaces.

NPR is the default policy routing mode. No additional configuration tasks are required to enable policy routing with Cisco Express Forwarding, distributed Cisco Express Forwarding, or NetFlow. As soon as one of these features is turned on, packets are automatically subjected to policy routing in the appropriate switching path.

The following example shows how to configure policy routing with Cisco Express Forwarding. The route is configured to verify that the next hop 10.0.0.8 of the route map named test is a Cisco Discovery Protocol neighbor before the device tries to policy-routing to it.

```
Device(config)# ip cef
Device(config)# interface GigabitEthernet 0/0/1
Device(config-if)# ip route-cache flow
Device(config-if)# ip policy route-map test
Device(config-if)# exit
Device(config)# route-map test permit 10
Device(config-route-map)# match ip address 1
Device(config-route-map)# set ip precedence priority
Device(config-route-map)# set ip next-hop 10.0.0.8
Device(config-route-map)# set ip next-hop verify-availability
Device(config-route-map)# exit
Device(config)# route-map test permit 20
Device(config-route-map)# match ip address 101
Device(config-route-map)# set interface Ethernet 0/0/3
Device(config-route-map)# set ip tos max-throughput
Device(config-route-map)# exit
```

**QoS Policy Propogation via BGP**

The QoS Policy Propagation via BGP feature allows you to classify packets by IP precedence based on BGP community lists, BGP autonomous system paths, and access lists. After a packet has been classified, you can use other Quality of Service features such as committed access rate (CAR) and Weighted Random Early Detection (WRED) to specify and enforce policies to fit your business model.

Before you configure policy propagation via BGP, perform the following basic tasks:

• Configure BGP and Cisco Express Forwarding or distributed Cisco Express Forwarding. To configure BGP, refer to the *BGP Configuration Guide*. To configure Cisco Express Forwarding and distributed Cisco Express Forwarding, refer to the *Cisco Express Forwarding Configuration Guide*.

• Define a policy.

• Apply the policy through BGP.
• Configure the BGP community list, BGP autonomous system path, or an access list and enable the policy on an interface.

• Enable CAR or WRED to use the policy. To enable CAR, see the chapter “Configuring Committed Access Rate” in the Quality of Service Solutions Configuration Guide. To configure WRED, see the chapter “Configuring Weighted Random Early Detection” in the Quality of Service Solutions Configuration Guide.

Before the QoS Policy Propagation via BGP feature can work, you must enable BGP and Cisco Express Forwarding or distributed Cisco Express Forwarding on the router. Subinterfaces on ATM interfaces that have the `bgp-policy` command enabled must use Cisco Express Forwarding because distributed Cisco Express Forwarding is not supported. Distributed Cisco Express Forwarding uses the Versatile Interface Processor (VIP) rather than the Route Switch Processor (RSP) to perform forwarding functions.

**Authentication Key Management and Supported Protocols**

Key management is a method of controlling the authentication keys used by routing protocols. Not all protocols support key management. Authentication keys are available for Director Response Protocol (DRP) Agent, Enhanced Interior Gateway Routing Protocol (EIGRP), and Routing Information Protocol (RIP) Version 2.

You can manage authentication keys by defining key chains, identifying the keys that belong to the key chain, and specifying how long each key is valid. Each key has its own key identifier (specified using the `key chain` configuration command), which is stored locally. The combination of the key identifier and the interface associated with the message uniquely identifies the authentication algorithm and the message digest algorithm 5 (MD5) authentication key in use.

You can configure multiple keys with lifetimes. Only one authentication packet is sent, regardless of how many valid keys exist. The software examines the key numbers in ascending order and uses the first valid key it encounters. The lifetimes allow for overlap during key changes.

**How to Configure Basic IP Routing**

**Redistributing Routing Information**

You can redistribute routes from one routing domain into another, with or without controlling the redistribution with a route map. To control which routes are redistributed, configure a route map and reference the route map from the `redistribute` command.

The tasks in this section describe how to define the conditions for redistributing routes (a route map), how to redistribute routes, and how to remove options for redistributing routes, depending on the protocol being used.

**Defining Conditions for Redistributing Routes**

Route maps can be used to control route redistribution (or to implement policy-based routing). To define conditions for redistributing routes from one routing protocol into another, configure the `route-map` command. Then use at least one `match` command in route map configuration mode, as needed. At least one `match`
command is used in this task because the purpose of the task is to illustrate how to define one or more conditions on which to base redistribution.

**Note**
A route map is not required to have **match** commands; it can have only **set** commands. If there are no **match** commands, everything matches the route map.

**Note**
There are many more **match** commands not shown in this table. For additional **match** commands, see the *Cisco IOS Master Command List*.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>match as-path</strong> path-list-number</td>
<td>Matches a BGP autonomous system path access list.</td>
</tr>
<tr>
<td><strong>match community</strong> {standard-list-number</td>
<td>expanded-list-number</td>
</tr>
<tr>
<td><strong>match community</strong> {standard-list-number</td>
<td>expanded-list-number</td>
</tr>
<tr>
<td><strong>match ip address</strong> {access-list-number</td>
<td>access-list-name...</td>
</tr>
<tr>
<td><strong>match ip address</strong> {access-list-number</td>
<td>access-list-name...</td>
</tr>
<tr>
<td><strong>match ip address</strong> {access-list-number</td>
<td>access-list-name...</td>
</tr>
<tr>
<td><strong>match ip route-source</strong> {access-list-number</td>
<td>access-list-name...</td>
</tr>
<tr>
<td><strong>match route-type</strong> {local</td>
<td>internal</td>
</tr>
<tr>
<td><strong>match metric</strong> metric-value</td>
<td>Matches routes with the specified metric.</td>
</tr>
<tr>
<td><strong>match ip next-hop</strong> {access-list-number</td>
<td>access-list-name...</td>
</tr>
<tr>
<td><strong>match ip next-hop</strong> {access-list-number</td>
<td>access-list-name...</td>
</tr>
<tr>
<td><strong>match tag</strong> tag-value [tag-value]</td>
<td>Matches the specified tag value.</td>
</tr>
<tr>
<td><strong>match interface</strong> type number [type number]</td>
<td>Matches routes that use the specified interface as the next hop.</td>
</tr>
<tr>
<td><strong>match ip route-source</strong> {access-list-number</td>
<td>access-list-name...</td>
</tr>
<tr>
<td><strong>match ip route-source</strong> {access-list-number</td>
<td>access-list-name...</td>
</tr>
<tr>
<td><strong>match route-type</strong> {local</td>
<td>internal</td>
</tr>
</tbody>
</table>
To optionally specify the routing actions for the system to perform if the match criteria are met (for routes that are being redistributed by the route map), use one or more `set` commands in route map configuration mode, as needed.

**Note**
A route map is not required to have `set` commands; it can have only `match` commands.

**Note**
There are more `set` commands not shown in this table. For additional `set` commands, see the *Cisco IOS Master Command List*.

<table>

Removing Options for Redistribution Routes

Removing options that you have configured for the redistribute command requires careful use of the no redistribute command to ensure that you obtain the result that you are expecting.

Different protocols implement the no redistribute command differently as follows:

- In BGP, OSPF, and RIP configurations, the no redistribute command removes only the specified keywords from the redistribute commands in the running configuration. They use the subtractive keyword method when redistributing from other protocols. For example, in the case of BGP, if you configure no redistribute static route-map interior, only the route map is removed from the redistribution, leaving redistribute static in place with no filter.

- The no redistribute isis command removes the IS-IS redistribution from the running configuration. IS-IS removes the entire command, regardless of whether IS-IS is the redistributed or redistributing protocol.

- EIGRP used the subtractive keyword method prior to EIGRP component version rel5. Starting with EIGRP component version rel5, the no redistribute command removes the entire redistribute command when redistributing from any other protocol.

- For the no redistribute connected command, the behavior is subtractive if the redistribute command is configured under the router bgp or the router ospf command. The behavior is complete removal of the command if it is configured under the router isis or the router eigrp command.

The following OSPF commands illustrate how various options are removed from the redistribution in router configuration mode.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>no redistribute connected metric 1000 subnets</td>
<td>Removes the configured metric value of 1000 and the configured subnets and retains the redistribute connected command in the configuration.</td>
</tr>
</tbody>
</table>
Configuring Routing Information Filtering

To filter routing protocol information, perform the tasks in this section.

**Note**  
When routes are redistributed between OSPF processes, no OSPF metric is preserved.

Preventing Routing Updates Through an Interface

To prevent other routers on a local network from dynamically learning routes, you can keep routing update messages from being sent through a router interface. To prevent routing updates through a specified interface, use the `passive-interface` command in router configuration mode. This command is supported in all IP-based routing protocols, except BGP.

OSPF and IS-IS behave differently. In OSPF, the interface address that you specify as passive appears as a stub network in the OSPF domain. OSPF routing information is neither sent nor received through the specified router interface. In IS-IS, the specified IP addresses are advertised without actually running IS-IS on those interfaces.

Configuring Default Passive Interfaces

Perform this task to set all interfaces on a device, in an Enhanced Interior Gateway Routing Protocol (EIGRP) environment, as passive by default, and then activate only those interfaces where adjacencies are desired.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. router eigrp {autonomous-system-number | virtual-instance-number}
4. passive-interface [default] [type number]
5. no passive-interface [default] [type number]
### Configuring Default Passive Interfaces

6. `network network-address [options]`
7. `end`
8. `show ip eigrp interfaces`
9. `show ip interface`

## Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  * Example:  
  Device> enable |
| **Step 2** configure terminal | Enters global configuration mode.  
  * Example:  
  Device# configure terminal |
| **Step 3** router eigrp `{autonomous-system-number | virtual-instance-number}` | Configures an EIGRP process and enters router configuration mode.  
  * `autonomous-system-number`—Autonomous system number that identifies the services to the other EIGRP address-family devices. It is also used to tag routing information. The range is 1 to 65535.  
  * `virtual-instance-number`—EIGRP virtual instance name. This name must be unique among all address-family router processes on a single device, but need not be unique among devices  
  * Example:  
  Device(config)# router eigrp 1 |
| **Step 4** passive-interface [default] [type number] | Sets all interfaces as passive by default.  
  * Example:  
  Device(config-router)# passive-interface default |
| **Step 5** no passive-interface [default] [type number] | Activates only those interfaces that need adjacencies.  
  * Example:  
  Device(config-router)# no passive-interface gigabitethernet 0/0/0 |
| **Step 6** network network-address [options] | Specifies the list of networks to be advertised by routing protocols.  
  * Example:  
  Device(config-router)# network 192.0.2.0 |
| **Step 7** end | Exits router configuration mode and returns to privileged EXEC mode.  
  * Example: |
### Controlling the Advertising of Routes in Routing Updates

To prevent other devices from learning one or more routes, you can suppress routes from being advertised in routing updates. To suppress routes from being advertised in routing updates, use the `distribute-list {access-list-number | access-list-name} out [interface-name | routing-process | as-number]` command in router configuration mode.

You cannot specify an interface name in Open Shortest Path First (OSPF). When used for OSPF, this feature applies only to external routes.

### Controlling the Processing of Routing Updates

You might want to avoid processing certain routes listed in incoming updates. This feature does not apply to OSPF or IS-IS. To suppress routes in incoming updates, use the `distribute-list {access-list-number | access-list-name} in [interface-type interface-number]` command in router configuration mode.

### Filtering Sources of Routing Information

To filter sources of routing information, use the `distance ip-address wildcard-mask [ip-standard-acl | ip-extended-acl | access-list-name]` command in router configuration mode.

### Configuring Precedence for Policy-Based Routing Default Next-Hop Routes

Perform this task to configure the precedence of packets and specify where packets that pass the match criteria are output.

#### Note

The `set ip next-hop` and `set ip default next-hop` commands are similar but have a different order of operation. Configuring the `set ip next-hop` command causes the system to first use policy routing and then use the routing table. Configuring the `set ip default next-hop` command causes the system to first use the routing table and then the policy-route-specified next hop.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `route-map map-tag [permit | deny] [sequence-number] [```
4. set ip precedence {number | name}
5. set ip next-hop ip-address [ip-address]
6. set interface type number [...type number]
7. set ip default next-hop ip-address [ip-address]
8. set default interface type number [...type number]
9. end

<td><strong>Example:</strong> Device(config)# route-map alpha permit ordering-seq</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> set ip precedence {number</td>
<td>name}</td>
</tr>
<tr>
<td><strong>Note</strong> You can specify either a precedence number or a precedence name.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-route-map)# set ip precedence 5</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> set ip next-hop ip-address [ip-address]</td>
<td>Specifies the next hop for routing packets.</td>
</tr>
<tr>
<td><strong>Note</strong> The next hop must be an adjacent device.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-route-map)# set ip next-hop 192.0.2.1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> set interface type number [...type number]</td>
<td>Specifies the output interface for the packet.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-route-map)# set interface gigabitethernet 0/0/0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> set ip default next-hop ip-address [ip-address]</td>
<td>Specifies the next hop for routing packets if there is no explicit route for this destination.</td>
</tr>
<tr>
<td><strong>Note</strong> Like the <strong>set ip next-hop</strong> command, the <strong>set ip default next-hop</strong> command must specify an adjacent device.</td>
<td></td>
</tr>

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 1    | enable            | Enables privileged EXEC mode.  
|      | **Example:**      |         |
|      | Device> enable    |         |
| 2    | configure terminal | Enters global configuration mode. |
|      | **Example:**      |         |
|      | Device# configure terminal | |
| 3    | named-ordering-route-map enable | Enables ordering of route-maps based on a string provided by the user. |
|      | **Example:**      |         |
|      | Device(config)# named-ordering-route-map enable | |
| 4    | route-map map-tag [permit | deny] [sequence-number] [ordering-seq sequence-name] | Configures a route map and specifies how the packets are to be distributed. *ordering-seq* indicates the sequence that is to be used for ordering of route-maps. |
|      | **Example:**      |         |
|      | Device(config)# route-map alpha permit ordering-seq sequence1 | |
| 5    | match as-path path-list-number | Matches a Border Gateway Protocol (BGP) autonomous system path access list. |
|      | **Example:**      |         |
|      | Device(config-route-map)# match as-path 2 | |
| 6    | set ip precedence [number | name] | Sets the IP Precedence field when the autonomous-system path matches.  
|      | **Note**: You can specify either a precedence number or a precedence name. |
|      | **Example:**      |         |
|      | Device(config-route-map)# set ip precedence 5 | |
| 7    | exit              | Exits route-map configuration mode and returns to global configuration mode. |
|      | **Example:**      |         |
|      | Device(config-route-map)# exit | |
| 8    | router bgp autonomous-system | Enables a BGP process and enters router configuration mode. |
|      | **Example:**      |         |
|      | Device(config)# router bgp 45000 | |
| 9    | table-map route-map-name | Modifies the metric and tag values when the IP routing table is updated with BGP learned routes. |
|      | **Example:**      |         |
|      | Device(config-router)# table-map rm1 | |

**Configuring QoS Policy Propagation Based on an Access List**

This section describes how to configure the QoS Policy Propagation via BGP feature based on an access list. This section assumes that you have already configured Cisco Express Forwarding or distributed Cisco Express Forwarding and BGP on your router.

Perform this task to configure the router to propagate the IP precedence based on an access list:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. route-map route-map-name [permit | deny [sequence-number]]
4. match ip address access-list-number
5. set ip precedence [number | name]
6. exit
7. router bgp autonomous-system
8. table-map route-map-name
9. exit
10. access-list access-list-number {permit | deny} source
11. interface type number
12. bgp-policy {source | destination} ip-prec-map
13. end
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | enable  
*Example:*  
Router> enable | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| **Step 2** | configure terminal  
*Example:*  
Router# configure terminal | Enters global configuration mode. |
| **Step 3** | route-map route-map-name [permit | deny  
[sequence-number]]  
*Example:*  
Router(config)# route-map rm1 | Defines a route map to control redistribution and enters route-map configuration mode. |
| **Step 4** | match ip address access-list-number  
*Example:*  
Router(config-route-map)# match ip address 3 | Matches routes that have a destination network address that is permitted by a standard or extended access list. |
| **Step 5** | set ip precedence [number | name]  
*Example:*  
Router(config-route-map)# set ip precedence 5 | Sets the IP Precedence field when the autonomous system path matches.  
**Note** You can specify either a precedence number or a precedence name. |
| **Step 6** | exit  
*Example:*  
Router(config-route-map)# exit | Exits route-map configuration mode and returns to global configuration mode. |
| **Step 7** | router bgp autonomous-system  
*Example:*  
Router(config)# router bgp 45000 | Enables a BGP routing process and enters router configuration mode. |
| **Step 8** | table-map route-map-name  
*Example:*  
Router(config-router)# table-map rm1 | Modifies the metric and tag values when the IP routing table is updated with BGP learned routes. |
| **Step 9** | exit  
*Example:*  
Router(config-router)# exit | Exits router configuration mode and returns to global configuration mode. |
| **Step 10** | access-list access-list-number {permit | deny} source  
*Example:*  
Router(config)# access-list 2 permit 172.16.0.2 | Defines an access list. |
### Purpose

**Command or Action**

**Step 11**

*interface type number*

*Example:*

Router(config)# interface ethernet 0/0

**Step 12**

*bgp-policy {source | destination} ip-prec-map*

*Example:*

Router(config-if)# bgp-policy source ip-prec-map

**Step 13**

*end*

*Example:*

Router(config-if)# end

### Monitoring QoS Policy Propagation via BGP

To monitor the QoS Policy Propagation via the BGP feature configuration, use the following optional commands.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>show ip bgp</strong></td>
<td>Displays entries in the Border Gateway Protocol (BGP) routing table to verify whether the correct community is set on the prefixes.</td>
</tr>
<tr>
<td><strong>show ip bgp community-list community-list-number</strong></td>
<td>Displays routes permitted by the BGP community to verify whether correct prefixes are selected.</td>
</tr>
<tr>
<td><strong>show ip cef network</strong></td>
<td>Displays entries in the forwarding information base (FIB) table based on the specified IP address to verify whether Cisco Express Forwarding has the correct precedence value for the prefix.</td>
</tr>
<tr>
<td><strong>show ip interface</strong></td>
<td>Displays information about the interface.</td>
</tr>
<tr>
<td><strong>show ip route prefix</strong></td>
<td>Displays the current status of the routing table to verify whether correct precedence values are set on the prefixes.</td>
</tr>
</tbody>
</table>
Managing Authentication Keys

SUMMARY STEPS
1. enable
2. configure terminal
3. key chain name-of-chain
4. key number
5. key-string text
6. accept-lifetime start-time \{infinite | end-time | duration seconds\}
7. send-lifetime start-time \{infinite | end-time | duration seconds\}
8. end
9. show key chain

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> You can configure multiple keys with lifetimes. Only one authentication packet is sent, regardless of how many valid keys exist. The software examines the key numbers in ascending order and uses the first valid key it encounters. The lifetimes allow for overlap during key changes.</td>
<td></td>
</tr>
<tr>
<td><strong>Device&gt; enable</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Device# configure terminal</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> key chain name-of-chain</td>
<td>Defines a key chain and enters key-chain configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Device(config)# key chain chain1</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> key number</td>
<td>Identifies number of an authentication key on a key chain. The range of keys is from 0 to 2147483647. The key identification numbers need not be consecutive.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Device(config-keychain)# key 1</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> key-string text</td>
<td>Identifies the key string.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Device(config-keychain-key)# key-string string1</strong></td>
<td></td>
</tr>
</tbody>
</table>
### Monitoring and Maintaining the IP Network

#### Clearing Routes from the IP Routing Table

You can remove all contents of a particular table. Clearing a table may become necessary when the contents of the particular structure have become, or are suspected to be, invalid.

To clear one or more routes from the IP routing table, use the `clear ip route` command in privileged EXEC mode.

#### Displaying System and Network Statistics

You can use the following `show` commands to display system and network statistics. You can display specific statistics such as contents of IP routing tables, caches, and databases. You can also display information about node reachability and discover the routing path that packets leaving your device are taking through the network. This information can be used to determine resource utilization and solve network problems.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip cache policy</code></td>
<td>Displays cache entries in the policy route cache.</td>
</tr>
<tr>
<td><code>show ip local policy</code></td>
<td>Displays the local policy route map if one exists.</td>
</tr>
<tr>
<td><code>show ip policy</code></td>
<td>Displays policy route maps.</td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip protocols</code></td>
<td>Displays the parameters and current state of the active routing protocols.</td>
</tr>
<tr>
<td>`show ip route [ip-address [mask] [longer-prefixes]</td>
<td>protocol [process-id]</td>
</tr>
<tr>
<td><code>show ip route summary</code></td>
<td>Displays the current state of the routing table in summary form.</td>
</tr>
<tr>
<td><code>show ip route supernets-only</code></td>
<td>Displays supernets.</td>
</tr>
<tr>
<td><code>show key chain [name-of-chain]</code></td>
<td>Displays authentication key information.</td>
</tr>
<tr>
<td><code>show route-map [map-name]</code></td>
<td>Displays all route maps configured or only the one specified.</td>
</tr>
</tbody>
</table>

## Configuration Examples for Basic IP Routing

### Example: Configuring Redistribution Routes

**Example: Static Routing Redistribution**

In the example that follows, three static routes are specified, two of which are to be advertised. The static routes are created by specifying the `redistribute static` router configuration command and then specifying an access list that allows only those two networks to be passed to the EIGRP process. Any redistributed static routes should be sourced by a single router to minimize the likelihood of creating a routing loop.

```
Router(config)# ip route 192.168.2.0 255.255.255.0 192.168.7.65
Router(config)# ip route 192.168.5.0 255.255.255.0 192.168.7.65
Router(config)# ip route 10.10.10.0 255.255.255.0 10.20.1.2
Router(config)# !
Router(config)# access-list 3 permit 192.168.2.0 0.0.255.255
Router(config)# access-list 3 permit 192.168.5.0 0.0.255.255
Router(config)# access-list 3 permit 10.10.10.0 0.0.0.255
Router(config)# !
Router(config)# router eigrp 1
Router(config-router)# network 192.168.0.0
Router(config-router)# network 10.10.10.0
Router(config-router)# redistribute static metric 10000 100 255 1 1500
Router(config-router)# distribute-list 3 out static
```
Example: EIGRP Redistribution

Each EIGRP routing process provides routing information to only one autonomous system. The Cisco IOS software must run a separate EIGRP process and maintain a separate routing database for each autonomous system that the software services. However, you can transfer routing information among routing databases.

In the following example, network 10.0.0.0 is configured under EIGRP autonomous system 1 and network 192.168.7.0 is configured under EIGRP autonomous system 101:

```bash
Router(config)# router eigrp 1
Router(config-router)# network 10.0.0.0
Router(config-router)# exit
Router(config)# router eigrp 101
Router(config-router)# network 192.168.7.0
```

In the following example, routes from the 192.168.7.0 network are redistributed into autonomous system 1 (without passing any other routing information from autonomous system 101):

```bash
Router(config)# access-list 3 permit 192.168.7.0
Router(config)# !
Router(config)# route-map 101-to-1 permit 10
Router(config-route-map)# match ip address 3
Router(config-route-map)# set metric 10000 100 1 255 1500
Router(config-route-map)# exit
Router(config)# router eigrp 1
Router(config-router)# redistribute eigrp 101 route-map 101-to-1
Router(config-router)#!
```

The following example is an alternative way to redistribute routes from the 192.168.7.0 network into autonomous system 1. This method does not allow you to set the metric for redistributed routes.

```bash
Router(config)# access-list 3 permit 192.168.7.0
Router(config)#!
Router(config)# router eigrp 1
Router(config-router)# redistribute eigrp 101
Router(config-router)# distribute-list 3 out eigrp 101
Router(config-router)#!
```

Example: Mutual Redistribution Between EIGRP and RIP

Consider a WAN at a university that uses the Routing Information Protocol (RIP) as an interior routing protocol. Assume that the university wants to connect its WAN to regional network 172.16.0.0, which uses the Enhanced Interior Gateway Routing Protocol (EIGRP) as the routing protocol. The goal in this case is to advertise the networks in the university network to devices in the regional network.

Mutual redistribution is configured between EIGRP and RIP in the following example:

```bash
Device(config)# access-list 10 permit 172.16.0.0
Device(config)#!
Device(config)# router eigrp 1
Device(config-router)# network 172.16.0.0
Device(config-router)# redistribute rip metric 10000 100 255 1 1500
Device(config-router)# default-metric 10
Device(config-router)# distribute-list 10 out rip
Device(config-router)# exit
Device(config)# router rip
Device(config-router)# redistribute eigrp 1
Device(config-router)#!
```
In this example, an EIGRP routing process is started. The network router configuration command specifies that network 172.16.0.0 (the regional network) is to send and receive EIGRP routing information. The redistribute router configuration command specifies that RIP-derived routing information be advertised in routing updates. The default-metric router configuration command assigns an EIGRP metric to all RIP-derived routes. The distribute-list router configuration command instructs the Cisco software to use access list 10 (not defined in this example) to limit the entries in each outgoing update. The access list prevents unauthorized advertising of university routes to the regional network.

**Example: Mutual Redistribution Between EIGRP and BGP**

In the following example, mutual redistribution is configured between the Enhanced Interior Gateway Routing Protocol (EIGRP) and the Border Gateway Protocol (BGP).

Routes from EIGRP routing process 101 are injected into BGP autonomous system 50000. A filter is configured to ensure that the correct routes are advertised, in this case, three networks. Routes from BGP autonomous system 50000 are injected into EIGRP routing process 101. The same filter is used.

```
Device(config)# ! All networks that should be advertised from R1 are controlled with ACLs:
Device(config)# access-list 1 permit 172.18.0.0 0.0.255.255
Device(config)# access-list 1 permit 172.16.0.0 0.0.255.255
Device(config)# access-list 1 permit 172.25.0.0 0.0.255.255
Device(config)# ! Configuration for router R1:
Device(config)# router bgp 50000
Device(config-router)# network 172.18.0.0
Device(config-router)# network 172.16.0.0
Device(config-router)# neighbor 192.168.10.1 remote-as 2
Device(config-router)# neighbor 192.168.10.15 remote-as 1
Device(config-router)# neighbor 192.168.10.24 remote-as 3
Device(config-router)# redistribute eigrp 101
Device(config-router)# distribute-list 1 out eigrp 101
Device(config-router)# exit
Device(config)# router eigrp 101
Device(config-router)# network 172.25.0.0
Device(config-router)# redistribute bgp 50000
Device(config-router)# distribute-list 1 out bgp 50000
Device(config-router)# !
```

**Caution**

BGP should be redistributed into an Interior Gateway Protocol (IGP) when there are no other suitable options. Redistribution from BGP into any IGP should be applied with proper filtering by using distribute lists, IP prefix lists, and route map statements to limit the number of prefixes.

**Examples: OSPF Routing and Route Redistribution**

OSPF typically requires coordination among many internal devices, area border routers (ABRs), and Autonomous System Boundary Routers (ASBRs). At a minimum, OSPF-based devices can be configured with all default parameter values, with no authentication, and with interfaces assigned to areas.

This section provides the following configuration examples:

- The first example shows simple configurations illustrating basic OSPF commands.
- The second example shows configurations for an internal device, ABR, and ASBR within a single, arbitrarily assigned OSPF autonomous system.
Example: Basic OSPF Configurations

The following example shows a simple OSPF configuration that enables OSPF routing process 1, attaches Ethernet interface 0/0 to Area 0.0.0.0, and redistributes RIP into OSPF and OSPF into RIP:

```
Router(config)# interface Ethernet 0/0
Router(config-if)# ip address 172.16.1.1 255.255.255.0
Router(config-if)# ip ospf cost 1
Router(config-if)# exit
Router(config)# interface Ethernet 1/0
Router(config-if)# ip address 172.17.1.1 255.255.255.0
Router(config-if)# exit
Router(config)# router ospf 1
Router(config-router)# network 172.18.0.0 0.0.255.255 area 0.0.0.0
Router(config-router)# redistribute rip metric 1 subnets
Router(config-router)# exit
Router(config)# router rip
Router(config-router)# network 172.17.0.0
Router(config-router)# redistribute ospf 1
Router(config-router)# default-metric 1
Router(config-router)# !
```

The following example shows the assignment of four area IDs to four IP address ranges. In the example, OSPF routing process 1 is initialized, and four OSPF areas are defined: 10.9.50.0, 2, 3, and 0. Areas 10.9.50.0, 2, and 3 mask specific address ranges, whereas Area 0 enables OSPF for all other networks.

```
Router(config)# router ospf 1
Router(config-router)# network 172.18.20.0 0.0.0.255 area 10.9.50.0
Router(config-router)# network 172.18.0.0 0.0.255.255 area 2
Router(config-router)# network 172.19.10.0 0.0.0.255 area 3
Router(config-router)# network 0.0.0.0 255.255.255.255 area 0
Router(config-router)# exit
Router(config)# ! Ethernet interface 0/0 is in area 10.9.50.0:
Router(config)# interface Ethernet 0/0
Router(config-if)# ip address 172.18.20.5 255.255.255.0
Router(config-if)# exit
Router(config)# ! Ethernet interface 1/0 is in area 2:
Router(config)# interface Ethernet 1/0
Router(config-if)# ip address 172.18.1.5 255.255.255.0
Router(config-if)# exit
Router(config)# ! Ethernet interface 2/0 is in area 2:
Router(config)# interface Ethernet 2/0
Router(config-if)# ip address 172.18.2.5 255.255.255.0
Router(config-if)# exit
Router(config)# ! Ethernet interface 3/0 is in area 3:
Router(config)# interface Ethernet 3/0
Router(config-if)# ip address 172.19.10.5 255.255.255.0
Router(config-if)# exit
Router(config)# ! Ethernet interface 4/0 is in area 0:

Router(config-if)# exit
Router(config)# ! Ethernet interface 5/0 is in area 0:
Router(config)# interface Ethernet 5/0
Router(config-if)# ip address 10.1.0.1 255.255.0.0
Router(config-if)# !
```
Each network router configuration command is evaluated sequentially, so the specific order of these commands in the configuration is important. The Cisco IOS software sequentially evaluates the address wildcard-mask pair for each interface. See the IP Routing: Protocol-Independent Command Reference for more information.

Consider the first network command. Area ID 10.9.50.0 is configured for the interface on which subnet 172.18.20.0 is located. Assume that a match is determined for Ethernet interface 0/0. Ethernet interface 0/0 is attached to Area 10.9.50.0 only.

The second network command is evaluated next. For Area 2, all interfaces (except Ethernet interface 0/0) are evaluated. Assume that a match is determined for Ethernet interface 1/0. OSPF is then enabled for that interface, and Ethernet 1/0 is attached to Area 2.

This process of attaching interfaces to OSPF areas continues for all network commands. Note that the last network command in this example is a special case. With this command, all available interfaces (not explicitly attached to another area) are attached to Area 0.

Example: Internal Router ABR and ASBR Configurations

The figure below provides a general network map that illustrates a sample configuration for several routers within a single OSPF autonomous system.
In this configuration, the following five routers are configured in OSPF autonomous system 1:

- Router A and Router B are both internal routers within area 1.
- Router C is an OSPF ABR. Note that for Router C, area 1 is assigned to E3 and Area 0 is assigned to S0.
- Router D is an internal router in Area 0 (backbone area). In this case, both `network` router configuration commands specify the same area (Area 0 or the backbone area).
- Router E is an OSPF ASBR. Note that BGP routes are redistributed into OSPF and that these routes are advertised by OSPF.
You don't have to include definitions of all areas in an OSPF autonomous system in the configuration of all routers in the autonomous system. You must define only the directly connected areas. In the example that follows, routes in Area 0 are learned by routers in area 1 (Router A and Router B) when the ABR (Router C) injects summary LSAs into Area 1.

Autonomous system 60000 is connected to the outside world via the BGP link to the external peer at IP address 172.16.1.6.

Here is an example configuration for the general network map shown in the figure above.

**Router A Configuration**—Internal Router

```
Router(config)# interface Ethernet 1/0
Router(config-if)# ip address 192.168.1.1 255.255.255.0
Router(config-if)# exit
Router(config)# router ospf 1
Router(config-router)# network 192.168.1.0 0.0.0.255 area 1
Router(config-router)# exit
```

**Router B Configuration**—Internal Router

```
Router(config)# interface Ethernet 2/0
Router(config-if)# ip address 192.168.1.2 255.255.255.0
Router(config-if)# exit
Router(config)# router ospf 1
Router(config-router)# network 192.168.1.0 0.0.0.255 area 1
Router(config-router)# exit
```

**Router C Configuration**—ABR

```
Router(config)# interface Ethernet 3/0
Router(config-if)# ip address 192.168.1.3 255.255.255.0
Router(config-if)# exit
Router(config)# interface Serial 0
Router(config-if)# ip address 192.168.2.3 255.255.255.0
Router(config-if)# exit
Router(config)# router ospf 1
Router(config-router)# network 192.168.1.0 0.0.0.255 area 1
Router(config-router)# network 192.168.2.0 0.0.0.255 area 0
Router(config-router)# exit
```

**Router D Configuration**—Internal Router

```
Router(config)# interface Ethernet 4/0
Router(config-if)# ip address 10.0.0.4 255.0.0.0
Router(config-if)# exit
Router(config)# interface Serial 1
Router(config-if)# ip address 192.168.2.4 255.255.255.0
Router(config-if)# exit
Router(config)# router ospf 1
Router(config-router)# network 192.168.2.0 0.0.0.255 area 0
Router(config-router)# network 10.0.0.0 0.255.255.255 area 0
Router(config-router)# exit
```
**Example: Complex OSPF Configuration**

The following example configuration accomplishes several tasks in setting up an ABR. These tasks can be split into the following two general categories:

- Basic OSPF configuration
- Route redistribution

The figure below illustrates the network address ranges and area assignments for interfaces.

**Figure 2: Interface and Area Specifications for the OSPF Configuration**

- **Network address range:** 192.168.110.0 through 192.168.110.255
  - **Area ID:** 192.168.110.0

- **Network address range:** 10.56.0.0 through 10.56.255.255
  - **Area ID:** 10.0.0.0
  - Configured as stub area

- **Network address range:** 172.19.251.0 through 172.19.251.255
  - **Area ID:** 0
  - Configured as backbone area

- **Network address range:** 172.19.254.0 through 172.19.254.255
  - **Area ID:** 0
  - Configured as backbone area

The basic configuration tasks in this example are as follows:

- Configure address ranges for Ethernet interface 0 through Ethernet interface 3.
- Enable OSPF on each interface.
- Set up an OSPF authentication password for each area and network.
- Assign link-state metrics and other OSPF interface configuration options.
• Create a stub area with area ID 10.0.0.0. (Note that the authentication and stub options of the area router configuration command are specified with separate area command entries, but they can be merged into a single area command.)

• Specify the backbone area (Area 0).

Configuration tasks associated with route redistribution are as follows:

• Redistribute EIGRP and RIP into OSPF with various options set (including metric-type, metric, tag, and subnet).

• Redistribute EIGRP and OSPF into RIP.

The following is a sample OSPF configuration:

```
Router(config)# interface Ethernet 0/0
Router(config-if)# ip address 192.168.110.201 255.255.255.0
Router(config-if)# ip ospf authentication-key abcdefgh
Router(config-if)# ip ospf cost 10
Router(config-if)# exit
Router(config)# interface Ethernet 1/0
Router(config-if)# ip address 172.19.251.201 255.255.255.0
Router(config-if)# ip ospf authentication-key ijklnmop
Router(config-if)# ip ospf cost 20
Router(config-if)# ip ospf retransmit-interval 10
Router(config-if)# ip ospf transmit-delay 2
Router(config-if)# ip ospf priority 4
Router(config-if)# exit
Router(config)# interface Ethernet 2/0
Router(config-if)# ip address 10.56.0.201 255.255.255.0
Router(config-if)# ip ospf authentication-key ijklnmop
Router(config-if)# ip ospf cost 20
Router(config-if)# ip ospf dead-interval 80
Router(config-if)# exit
```

In the following configuration, OSPF is on network 172.19.0.0:

```
Router(config)# router ospf 1
Router(config-router)# network 10.0.0.0 0.255.255.255 area 10.0.0.0
Router(config-router)# network 192.168.110.0 0.0.0.255 area 192.68.110.0
Router(config-router)# network 172.19.0.0 0.0.0.255 area 0
Router(config-router)# area 0 authentication
Router(config-router)# area 10.0.0.0 stub
Router(config-router)# area 10.0.0.0 authentication
Router(config-router)# area 10.0.0.0 default-cost 20
Router(config-router)# area 192.168.110.0 authentication
Router(config-router)# area 10.0.0.0 range 10.0.0.0 255.0.0.0
Router(config-router)# area 192.168.110.0 range 192.168.110.0 255.255.255.0
Router(config-router)# area 0 range 172.19.251.0 255.255.255.0
Router(config-router)# area 0 range 172.19.254.0 255.255.255.0
Router(config-router)# redistribute eigrp 200 metric-type 2 metric 1 tag 200 subnets
Router(config-router)# redistribute rip metric-type 2 metric 1 tag 200
Router(config-router)# exit
```

In the following configuration, EIGRP autonomous system 1 is on 172.19.0.0:
Example: Default Metric Values Redistribution

The following example shows how a router in autonomous system 1 is configured to run both RIP and EIGRP. The example advertises EIGRP-derived routes using RIP and assigns the EIGRP-derived routes a RIP metric of 10.

```conf
Router(config)# router rip
Router(config-router)# default-metric 10
Router(config-router)# redistribute eigrp 1
Router(config-router)# exit
```

Example: Configuring Default Passive Interfaces

The following example shows how to configure network interfaces, set all interfaces that are running OSPF as passive, and then enable serial interface 0/0:

```conf
Router(config)# interface Ethernet 0/0
Router(config-if)# ip address 172.19.64.38 255.255.255.0 secondary
Router(config-if)# ip address 172.19.232.70 255.255.255.240
Router(config-if)# no ip directed-broadcast
Router(config-if)# exit
Router(config)# interface Serial 0/0
Router(config-if)# ip address 172.24.101.14 255.255.255.252
Router(config-if)# no ip directed-broadcast
Router(config-if)# no ip mroute-cache
Router(config-if)# exit
Router(config)# interface TokenRing 0
Router(config-if)# ip address 172.20.10.4 255.255.255.0
Router(config-if)# no ip directed-broadcast
Router(config-if)# no ip mroute-cache
Router(config-if)# ring-speed 16
Router(config-if)# exit
Router(config)# router ospf 1
Router(config-router)# passive-interface default
Router(config-router)# no passive-interface Serial 0/0
Router(config-router)# network 172.16.10.0 0.0.0.255 area 0
Router(config-router)# network 172.19.232.0 0.0.0.255 area 4
Router(config-router)# network 172.24.101.0 0.0.0.255 area 4
Router(config-router)# exit
```
Example: IP Default Gateway as a Static IP Next Hop When IP Routing Is Disabled

The following example shows how to configure IP address 172.16.5.4 as the default route when IP routing is disabled:

```
Device> enable
Device# configure terminal
Device(conf)# no ip routing
Device(conf)# ip default-gateway 172.16.15.4
```

Example: Configuring QoS Policy Propagation via BGP

The following example shows how to create route maps to match access lists, Border Gateway Protocol (BGP) community lists, and BGP autonomous system paths, and apply IP precedence to routes learned from neighbors.

In the figure below, Device A learns routes from autonomous system 10 and autonomous system 60. The quality of service (QoS) policy is applied to all packets that match defined route maps. Any packets from Device A to autonomous system 10 or autonomous system 60 are sent the appropriate QoS policy, as the numbered steps in the figure indicate.

![Figure 3: Device Learning Routes and Applying QoS Policy](image)

**Device A Configuration**

```
interface serial 5/0/0/1:0

ip as-path access-list 1 permit ^10_60
!
! Define the access list
access-list 69 permit 10.69.0.0

**Device B Configuration**

router bgp 10
 neighbor 10.30.30.1 remote-as 30
 neighbor 10.30.30.1 send-community
 neighbor 10.30.30.1 route-map send_community out
!
ip bgp-community new-format
Example: Managing Authentication Keys

The following example shows how to configure a key chain named kc1. In this example, the software will always accept and send ks1 as a valid key. The key ks2 will be accepted from 1:30 p.m. to 3:30 p.m. and be sent from 2:00 p.m. to 3:00 p.m. The overlap allows for migration of keys or discrepancy in the set time of the router.

```
Router(config)# interface Ethernet 0/0
Router(config-if)# ip rip authentication key-chain kc1
Router(config-if)# ip rip authentication mode md5
Router(config-if)# exit
Router(config)# router rip
```

Router(config-router)# network 172.19.0.0
Router(config-router)# version 2
Router(config-router)# exit
Router(config)# key chain kcl
Router(config-keychain)# key 1
Router(config-keychain-key)# key-string ks1
Router(config-keychain-key)# key 2
Router(config-keychain-key)# key-string ks2
Router(config-keychain-key)# accept-lifetime 13:30:00 Jan 25 2005 duration 7200
Router(config-keychain-key)# send-lifetime 14:00:00 Jan 25 2005 duration 3600
Router(config-keychain-key)# key 3
Router(config-keychain-key)# key-string ks3
Router(config-keychain-key)# accept-lifetime 14:30:00 Jan 25 2005 duration 7200
Router(config-keychain-key)# send-lifetime 15:00:00 Jan 25 2005 duration 3600
Router(config-keychain-key)# exit

Feature Information for Configuring IP Routing Protocol-Independent Features

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

<table>
<thead>
<tr>
<th>Feature Name</th>
<th>Releases</th>
<th>Feature Information</th>
</tr>
</thead>
</table>
| Default Passive Interface             | 12.0     | In ISPs and large enterprise networks, many distribution routers have more than 200 interfaces. Obtaining routing information from these interfaces requires configuration of the routing protocol on all interfaces and manual configuration of the `passive-interface` command on interfaces where adjacencies were not desired. The Default Passive Interface feature simplifies the configuration of distribution routers by allowing all interfaces to be set as passive by default.
|                                       |          | The following commands were introduced or modified: `no passive-interface`, `passive-interface default`. |
| Fast-Switched Policy Routing          | 11.3     | IP policy routing can be fast-switched. Prior to fast-switched policy routing, policy routing could only be process-switched, which meant that on most platforms, the switching rate was approximately 1000 to 10,000 packets per second. Such rates were not fast enough for many applications. Users who need policy routing to occur at faster speeds can implement policy routing without slowing down the router. |
| IP Routing                            | 11.0     | The IP Routing feature introduces basic IP routing features. |
| NetFlow Policy Routing                | 12.0(3)T | NetFlow policy routing (NPR) integrates policy routing, which enables traffic engineering and traffic classification, with NetFlow services, which provide billing, capacity planning, and monitoring information on real-time traffic flows. IP policy routing works with Cisco Express Forwarding, distributed Cisco Express Forwarding, and NetFlow. |
|                                       | 15.3(1)S |                                      |
The Policy-Based Routing feature introduces a more flexible mechanism than destination routing for routing packets. Policy-based routing (PBR) is a process where a router puts packets through a route map before routing the packets. The route map determines which packets are routed to which router next.

The following command was introduced by this feature: `ip policy route-map`.

The Policy-Based Routing Default Next-Hop Route feature introduces the ability for packets that are forwarded as a result of the `set ip default next-hop` command to be switched at the hardware level.

The following command was modified by this feature: `set ip default next-hop`.

The Policy Routing Infrastructure feature provides full support of IP policy-based routing in conjunction with Cisco Express Forwarding and NetFlow. When both policy routing and NetFlow are enabled, redundant processing is avoided.

The QoS Policy Propagation via BGP feature allows you to classify packets by IP precedence based on BGP community lists, BGP autonomous system paths, and access lists. After a packet has been classified, you can use other QoS features such as committed access rate (CAR) and Weighted Random Early Detection (WRED) to specify and enforce policies to fit your business model.
IPv6 Routing: Static Routing

This feature provides static routing for IPv6. Static routes are manually configured and define an explicit path between two networking devices.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for IPv6 Routing: Static Routing

Before configuring the device with a static IPv6 route, you must enable the forwarding of IPv6 packets using the `ipv6 unicast-routing` global configuration command, enable IPv6 on at least one interface, and configure an IPv6 address on that interface.

Restrictions for IPv6 Routing: Static Routing

You should not configure static configurations over dynamic interfaces, because static configurations will be lost during reboot or when the user disconnects and reconnects the device.
Information About IPv6 Routing: Static Routing

Static Routes

Networking devices forward packets using route information that is either manually configured or dynamically learned using a routing protocol. Static routes are manually configured and define an explicit path between two networking devices. Unlike a dynamic routing protocol, static routes are not automatically updated and must be manually reconfigured if the network topology changes. The benefits of using static routes include security and resource efficiency. Static routes use less bandwidth than dynamic routing protocols and no CPU cycles are used to calculate and communicate routes. The main disadvantage to using static routes is the lack of automatic reconfiguration if the network topology changes.

Static routes can be redistributed into dynamic routing protocols but routes generated by dynamic routing protocols cannot be redistributed into the static routing table. No algorithm exists to prevent the configuration of routing loops that use static routes.

Static routes are useful for smaller networks with only one path to an outside network and to provide security for a larger network for certain types of traffic or links to other networks that need more control. In general, most networks use dynamic routing protocols to communicate between networking devices but may have one or two static routes configured for special cases.

Directly Attached Static Routes

In directly attached static routes, only the output interface is specified. The destination is assumed to be directly attached to this interface, so the packet destination is used as the next-hop address. This example shows such a definition:

```
ipv6 route 2001:DB8::/32 ethernet1/0
```

The example specifies that all destinations with address prefix 2001:DB8::/32 are directly reachable through interface Ethernet1/0.

Directly attached static routes are candidates for insertion in the IPv6 routing table only if they refer to a valid IPv6 interface; that is, an interface that is both up and has IPv6 enabled on it.

Recursive Static Routes

In a recursive static route, only the next hop is specified. The output interface is derived from the next hop. This definition is shown in the following example:

```
ipv6 route 2001:DB8::/32 2001:DB8:3000:1
```

This example specifies that all destinations with address prefix 2001:DB8::/32 are reachable via the host with address 2001:DB8:3000:1.

A recursive static route is valid (that is, it is a candidate for insertion in the IPv6 routing table) only when the specified next hop resolves, either directly or indirectly, to a valid IPv6 output interface, provided the route does not self-recurse, and the recursion depth does not exceed the maximum IPv6 forwarding recursion depth.

A route self-recurses if it is itself used to resolve its own next hop. For example, suppose we have the following routes in the IPv6 routing table:
IPv6 Routing Table - 9 entries
Codes: C - Connected, L - Local, S - Static, R - RIP, B - BGP
U - Per-user Static route
I1 - ISIS L1, I2 - ISIS L2, IA - ISIS Interarea
O - OSPF intra, OI - OSPF inter, OE1 - OSPF ext 1, OE2 - OSPF ext 2
R 2001:DB8::/32 [130/0]
via ::, Serial2/0
B 2001:DB8:3000:0/16 [200/45]
Via 2001:DB8::0104

The following examples defines a recursive IPv6 static route:

ipv6 route 2001:DB8::/32 2001:DB8:3000:1
This static route will not be inserted into the IPv6 routing table because it is self-recursive. The next hop of
the static route, 2001:DB8:3000:1, resolves via the BGP route 2001:DB8:3000:0/16, which is itself a recursive
route (that is, it only specifies a next hop). The next hop of the BGP route, 2001:DB8::0104, resolves via the
static route. Therefore, the static route would be used to resolve its own next hop.

It is not normally useful to manually configure a self-recursive static route, although it is not prohibited.
However, a recursive static route that has been inserted in the IPv6 routing table may become self-recursive
as a result of some transient change in the network learned through a dynamic routing protocol. If this occurs,
the fact that the static route has become self-recursive will be detected and it will be removed from the IPv6
routing table, although not from the configuration. A subsequent network change may cause the static route
to no longer be self-recursive, in which case it will be reinserted in the IPv6 routing table.

Fully Specified Static Routes

In a fully specified static route, both the output interface and the next hop are specified. This form of static
route is used when the output interface is a multi-access one and it is necessary to explicitly identify the next
hop. The next hop must be directly attached to the specified output interface. The following example shows
a definition of a fully specified static route:

ipv6 route 2001:DB8::/32 ethernet1/0 2001:DB8:3000:1
A fully specified route is valid (that is, a candidate for insertion into the IPv6 routing table) when the specified
IPv6 interface is IPv6-enabled and up.

Floating Static Routes

Floating static routes are static routes that are used to back up dynamic routes learned through configured
routing protocols. A floating static route is configured with a higher administrative distance than the dynamic
routing protocol it is backing up. As a result, the dynamic route learned through the routing protocol is always
used in preference to the floating static route. If the dynamic route learned through the routing protocol is
lost, the floating static route will be used in its place. The following example defines a floating static route:

ipv6 route 2001:DB8::/32 ethernet1/0 2001:DB8:3000:1 210
Any of the three types of IPv6 static routes can be used as a floating static route. A floating static route must
be configured with an administrative distance that is greater than the administrative distance of the dynamic
routing protocol, because routes with smaller administrative distances are preferred.
How to Configure IPv6 Static Routing

Configuring a Static IPv6 Route

SUMMARY STEPS

1. enable
2. configure terminal
3. ipv6 route ipv6-prefix / prefix-length ipv6-address [interface-type interface-number ipv6-address]
   [administrative-distance] [administrative-multicast-distance | multicast] [tag tag]

DETAILED STEPS

</tbody>
</table>
### Command or Action

- **show ipv6 route** [ipv6-address | ipv6-prefix / prefix-length | protocol | interface-type interface-number]

**Example:**

Device# show ipv6 static

**Example:**

Device# show ipv6 route static

### Step 3

- **debug ipv6 routing**

**Example:**

Device# debug ipv6 routing

Displays debugging messages for IPv6 routing table updates and route cache updates.

---

### Configuration Examples for IPv6 Static Routing

Static routes may be used for a variety of purposes. Common usages include the following:

- Manual summarization
- Traffic discard
- Fixed default route
- Backup route

In many cases, alternative mechanisms exist within Cisco software to achieve the same objective. Whether to use static routes or one of the alternative mechanisms depends on local circumstances.

### Example: Configuring Manual Summarization

The following example shows a static route being used to summarize local interface prefixes advertised into RIP. The static route also serves as a discard route, discarding any packets received by the device to a 2001:DB8:1::/48 destination not covered by a more specific interface prefix.

```
Device> enable
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# interface ethernet0/0
Device(config-if)# ipv6 address 2001:DB8:2:1234/64
Device(config-if)# exit
Device(config)#
Device(config)# interface ethernet1/0
Device(config-if)# ipv6 address 2001:DB8:3:1234/64
Device(config-if)# exit
Device(config)# interface ethernet2/0
Device(config-if)# ipv6 address 2001:DB8:4:1234/64
Device(config-if)# exit
Device(config)# interface ethernet3/0
```
Example: Configuring Traffic Discard

Configuring a static route to point at interface null0 may be used for discarding traffic to a particular prefix. For example, if it is required to discard all traffic to prefix 2001:DB8:42:1/64, the following static route would be defined:

```
Device> enable
Device# configure terminal
Device(config)# ipv6 route 2001:DB8:42:1::/64 null0
Device(config)# end
```

Example: Configuring a Fixed Default Route

A default static route is often used in simple device topologies. In the following example, a device is connected to its local site via Ethernet0/0 and to the main corporate network via Serial2/0 and Serial3/0. All nonlocal traffic will be routed over the two serial interfaces.

```
Device(config)# interface ethernet0/0
Device(config-if)# ipv6 address 2001:DB8:17:1234/64
Device(config-if)# exit
Device(config)# interface Serial2/0
Device(config-if)# ipv6 address 2001:DB8:1:1234/64
Device(config-if)# exit
Device(config)# interface Serial3/0
Device(config-if)# ipv6 address 2001:DB8:2:124/64
Device(config-if)# exit
Device(config)# ipv6 route ::/0 Serial2/0
Device(config)# ipv6 route ::/0 Serial3/0
Device(config)# end
Device# 00:06:30: %SYS-5-CONFIG_I: Configured from console by console
Device# show ipv6 route static
IPv6 Routing Table - 7 entries
Codes: C - Connected, L - Local, S - Static, R - RIP, B - BGP
U - Per-user Static route
I1 - ISIS L1, I2 - ISIS L2, IA - ISIS interarea, IS - ISIS summary
O - OSPF intra, OI - OSPF inter, OE1 - OSPF ext 1, OE2 - OSPF ext 2
ON1 - OSPF NSSA ext 1, ON2 - OSPF NSSA ext 2
S  2001:DB8:1::/48 [1/0] via ::, Null0
```
Example: Configuring a Floating Static Route

A floating static route often is used to provide a backup path in the event of connectivity failure. In the following example, the device has connectivity to the network core via Serial2/0 and learns the route 2001:DB8:1:1/32 via IS-IS. If the Serial2/0 interface fails, or if route 2001:DB8:1:1/32 is no longer learned via IS-IS (indicating loss of connectivity elsewhere in the network), traffic is routed via the backup ISDN interface.

```
Device> enable
Device# configure
   terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# interface ethernet0/0
Device(config-if)# ipv6 address 2001:DB8:17:1234/64
Device(config-if)# exit
Device(config)# interface Serial2/0
Device(config-if)# ipv6 address 2001:DB8:1:1234/64
Device(config-if)# ipv6 router isis
Device(config-if)# exit
Device(config)# router isis
Device(config-rtr)# net 42.0000.0000.0000.0001.00
Device(config-rtr)# exit
Device(config)# interface BRI1/0
Device(config-if)# encapsulation ppp
Device(config-if)# ipv6 enable
Device(config-if)# isdn switch-type basic-net3
Device(config-if)# ppp authentication chap optional
Device(config-if)# ppp multilink
Device(config-if)# exit
Device(config)# dialer-list 1 protocol ipv6 permit
Device(config)# ipv6 route 2001:DB8:1::/32 BRI1/0 200
Device(config)# end
Device# 00:03:07: %SYS-5-CONFIG_I: Configured from console by console
2001:DB8:5000:/16, interface Ethernet3/0, distance 1
```

Feature Information for IPv6 Routing: Static Routing

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

IP Event Dampening

The IP Event Dampening feature introduces a configurable exponential decay mechanism to suppress the effects of excessive interface flapping events on routing protocols and routing tables in the network. This feature allows the network operator to configure a router to automatically identify and selectively dampen a local interface that is flapping.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for IP Event Dampening

Subinterface Restrictions

Only primary interfaces can be configured with this feature. The primary interface configuration is applied to all subinterfaces by default. IP Event Dampening does not track the flapping of individual subinterfaces on an interface.
Virtual Templates Not Supported

Copying a dampening configuration from virtual templates to virtual access interfaces is not supported because dampening has limited usefulness to existing applications that use virtual templates. Virtual access interfaces are released when an interface flaps, and new connections and virtual access interfaces are acquired when the interface comes up and is made available to the network. Since dampening states are attached to the interface, the dampening states would not survive an interface flap.

IPX Routing Protocols Not Supported

Internetwork Packet Exchange (IPX) protocols are not supported by the IP Event Dampening feature. However, IPX variants of these protocols will still receive up and down state event information when this feature is enabled. This should not create any problems or routing issues.

Information About IP Event Dampening

IP Event Dampening Overview

Interface state changes occur when interfaces are administratively brought up or down or if an interface changes state. When an interface changes state or flaps, routing protocols are notified of the status of the routes that are affected by the change in state. Every interface state change requires all affected devices in the network to recalculate best paths, install or remove routes from the routing tables, and then advertise valid routes to peer routers. An unstable interface that flaps excessively can cause other devices in the network to consume substantial amounts of system processing resources and cause routing protocols to lose synchronization with the state of the flapping interface.

The IP Event Dampening feature introduces a configurable exponential decay mechanism to suppress the effects of excessive interface flapping events on routing protocols and routing tables in the network. This feature allows the network operator to configure a router to automatically identify and selectively dampen a local interface that is flapping. Dampening an interface removes the interface from the network until the interface stops flapping and becomes stable. Configuring the IP Event Dampening feature improves convergence times and stability throughout the network by isolating failures so that disturbances are not propagated. This, in turn, reduces the utilization of system processing resources by other devices in the network and improves overall network stability.

Interface State Change Events

This section describes the interface state change events of the IP Event Dampening feature. This feature employs a configurable exponential decay mechanism that is used to suppress the effects of excessive interface flapping or state changes. When the IP Event Dampening feature is enabled, flapping interfaces are dampened from the perspective of the routing protocol by filtering excessive route updates. Flapping interfaces are identified, assigned penalties, suppressed if necessary, and made available to the network when the interface stabilizes. Figure 1 displays interface state events as they are perceived by routing protocols.

Suppress Threshold

The suppress threshold is the value of the accumulated penalty that triggers the router to dampen a flapping interface. The flapping interface is identified by the router and assigned a penalty for each up and down state change, but the interface is not automatically dampened. The router tracks the penalties that a flapping interface
accumulates. When the accumulated penalty reaches the default or preconfigured suppress threshold, the interface is placed in a dampened state.

**Half-Life Period**

The half-life period determines how fast the accumulated penalty can decay exponentially. When an interface is placed in a dampened state, the router monitors the interface for additional up and down state changes. If the interface continues to accumulate penalties and the interface remains in the suppress threshold range, the interface will remain dampened. If the interface stabilizes and stops flapping, the penalty is reduced by half after each half-life period expires. The accumulated penalty will be reduced until the penalty drops to the reuse threshold. The configurable range of the half-life period timer is from 1 to 30 seconds. The default half-life period timer is 5 seconds.

**Reuse Threshold**

When the accumulated penalty decreases until the penalty drops to the reuse threshold, the route is unsuppressed and made available to other devices in the network. The range of the reuse value is from 1 to 20000 penalties. The default value is 1000 penalties.

**Maximum Suppress Time**

The maximum suppress time represents the maximum time an interface can remain dampened when a penalty is assigned to an interface. The maximum suppress time can be configured from 1 to 20000 seconds. The default maximum penalty timer is 20 seconds or four times the default half-life period (5 seconds). The maximum value of the accumulated penalty is calculated based on the maximum suppress time, reuse threshold, and half-life period.
Affected Components

When an interface is not configured with dampening, or when an interface is configured with dampening but is not suppressed, the routing protocol behavior as a result of interface state transitions is not changed by the IP Event Dampening feature. However, if an interface is suppressed, the routing protocols and routing tables are immune to any further state transitions of the interface until it is unsuppressed.

Route Types

The following interfaces are affected by the configuration of this feature:

- Connected routes:
  - The connected routes of dampened interfaces are not installed into the routing table.
  - When a dampened interface is unsuppressed, the connected routes will be installed into the routing table if the interface is up.

- Static routes:
  - Static routes assigned to a dampened interface are not installed into the routing table.
  - When a dampened interface is unsuppressed, the static route will be installed into the routing table if the interface is up.
Only the primary interface can be configured with this feature, and all subinterfaces are subject to the same dampening configuration as the primary interface. IP Event Dampening does not track the flapping of individual subinterfaces on an interface.

### Supported Protocols

The IP Event Dampening feature supports Border Gateway Protocol (BGP), Connectionless Network Services (CLNS), Enhanced Interior Gateway Routing Protocol (EIGRP), Intermediate System-to-Intermediate System (IS-IS), Hot Standby Routing Protocol (HSRP), Open Shortest Path First (OSPF), and Routing Information Protocol (RIP). The following list provides some general information about the operation of this feature with these protocols.

- **BGP, EIGRP, IS-IS, RIP, and OSPF:**
  - When an interface is dampened, the interface is considered to be down by the routing protocol. The routing protocol will not hold any adjacencies with this peer router over the dampened interface or generate advertisements of any routes related to this interface to other peer routers.
  - When the interface is unsuppressed and made available to the network, the interface will be considered by the routing protocols to be up. The routing protocols will be notified that the interface is in an up state and routing conditions will return to normal.

- **HSRP:**
  - When an interface is dampened, it is considered to be down by HSRP. HSRP will not generate HSRP messages out of the dampened interface or respond to any message received by the dampened interface. When the interface is unsuppressed and made available to the network, HSRP will be notified of the up state and will return to normal operations.

- **CLNS:**
  - When an interface is dampened, the interface is dampened to both IP and CLNS routing equally. The interface is dampened to both IP and CLNS because integrated routing protocols like IS-IS, IP, and CLNS routing are closely interconnected, so it is impossible to apply dampening separately.

The IP Event Dampening feature has no effect on any routing protocols if it is not enabled or an interface is not dampened.

### Network Deployments

In real network deployments, some routers may not be configured with interface dampening, and all routers may not even support this feature. No major routing issues are expected, even if the router at the other end of a point-to-point interface or routers of the same multicast LAN do not have interface dampening turned on or do not have this feature implemented. On the router, where the interface is dampened, routes associated with the interface will not be used. No packets will be sent out of this interface, and no routing protocol activity will be initiated with routers on the other side of the interface. However, routers on the other side can still install some routes, in their routing tables, that are associated with this subnet because the routers recognize that their own interfaces are up and can start forwarding packets to the dampened interface. In such situations,
the router with the dampened interface will start forwarding these packets, depending on the routes in its routing table.

The IP Event Dampening feature does not introduce new information into the network. In fact, the effect of dampening is to subtract a subset of routing information from the network. Therefore, looping should not occur as a result of dampening.

Benefits of IP Event Dampening

**Reduced Processing Load**

The IP Event Dampening Feature employs a configurable exponential decay mechanism to suppress the effects of excessive interface flapping events on routing protocols. Excessive interface up and down state changes that are received in a short period of time are not processed and do not consume system resources. Other routers in the network need not waste system resources because of a flapping route.

**Faster Convergence**

The IP Event Dampening feature improves convergence times and stability throughout the network by isolating failures so that disturbances are not propagated. Routers that are not experiencing link flap reach convergence sooner, because routing tables are not rebuilt each time the offending router leaves and enters the service.

**Improved Network Stability**

The IP Event Dampening feature provides increased network stability. A router with a flapping interface removes the flapping interface from the network until the interface stabilizes, so other routers simply redirect traffic around the affected router until the interface becomes stable, which ensures that the router loses no data packets.

How to Configure IP Event Dampening

**Enabling IP Event Dampening**

The `dampening` command is entered in interface configuration mode to enable the IP Event Dampening feature. If this command is applied to an interface that already has dampening configured, all dampening states are reset and the accumulated penalty will be set to 0. If the interface has been dampened, the accumulated penalty will fall into the reuse threshold range, and the dampened interface will be made available to the network. The flap counts, however, are retained.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface type number
4. dampening [half-life-period reuse-threshold] [suppress-threshold max-suppress [restart-penalty]]
5. end
DETAILED STEPS

<tr>
<td>Router(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>

Verifying IP Event Dampening

Use the **show dampening interface** or **show interface dampening** commands to verify the configuration of the IP Event Dampening feature.

Note

The **clear counters** command can be used to clear the flap count and reset it to zero. All other parameters and status, including dampening states and accumulated penalties, are not affected by this command.

SUMMARY STEPS

1. enable
2. show dampening interface
3. show interface dampening
### Configuration Examples for IP Event Dampening

#### Example: Enabling IP Event Dampening

The following example shows how to enable interface dampening on Ethernet interface 0/0 and sets the half life to 30 seconds, the reuse threshold to 1500, the suppress threshold to 10000, and the maximum suppress time to 120 seconds:

```plaintext
interface Ethernet 0/0
dampening 30 1500 10000 120
```

The following example shows how to enable interface dampening on ATM interface 6/0 and uses the default interface dampening values:

```plaintext
interface atm 6/0
dampening
```

The following example shows how to configure the router to apply a penalty of 500 on Ethernet interface 0/0 when the interface comes up for the first time after the router is reloaded:

```plaintext
interface Ethernet 0/0
dampening 5 500 1000 20 500
```

#### Example: Verifying IP Event Dampening

The following sample output from the `show dampening interface` command displays a summary of interface dampening:

```
Router# show dampening interface
3 interfaces are configured with dampening.
```
No interface is being suppressed.
Features that are using interface dampening:
  IP Routing
  CLNS Routing

The following sample output from the `show interface dampening` command displays the summary of the dampening parameters and the status of the interfaces on the local router:

```
Router# show interface dampening
FastEthernet0/0
  Flaps Penalty Supp ReuseTm HalfL ReuseV SuppV MaxSTm MaxP Restart
  0      0     FALSE  0    5    1000  2000   20   16000   0
ATM2/0
  Flaps Penalty Supp ReuseTm HalfL ReuseV SuppV MaxSTm MaxP Restart
  0      0     FALSE  0    5    1000  2000   20   16000   0
POS6/0
  Flaps Penalty Supp ReuseTm HalfL ReuseV SuppV MaxSTm MaxP Restart
  0      0     FALSE  0    5    1000  2000   20   16000   0
```

Feature Information for IP Event Dampening

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

<table>
<thead>
<tr>
<th>Feature Name</th>
<th>Releases</th>
<th>Feature Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP Event Dampening</td>
<td>12.0(22)S, 12.2(14)S, 12.2(13)T, 12.2(18)SXD, Cisco IOS XE 3.1.0SG</td>
<td>The IP Event Dampening feature introduces a configurable exponential decay mechanism to suppress the effects of excessive interface flapping events on routing protocols and routing tables in the network. This feature allows the network operator to configure a router to automatically identify and selectively dampen a local interface that is flapping. The following commands were introduced or modified: dampening, debug dampening, show dampening interface, show interface dampening.</td>
</tr>
</tbody>
</table>
Glossary

**event dampening**--The process in which a router dampens a flapping interface from the perspective of the routing tables and routing protocols of IP and CLNS by filtering the excessive route adjust message because of the interface state change.

**flap**--Rapid interface state changes from up to down and down to up within a short period of time.

**half life**--The rate of the exponential decay of the accumulated penalty is determined by this value.

**maximum penalty**--The maximum value beyond which the penalty assigned does not increase. It is derived from the maximum suppress time.

**maximum suppress time**--The maximum amount of time the interface can stay suppressed at the time a penalty is assigned.

**penalty**--A value assigned to an interface when it flaps. This value increases with each flap and decreases over time. The rate at which it decreases depends on the half life.

**reuse threshold**--The threshold value after which the interface will be unsuppressed and can be used again.

**suppress threshold**--Value of the accumulated penalty that triggers the router to dampen a flapping interface. When the accumulated penalty exceeds this value, the interface state is considered to be down from the perspective of the routing protocol.

**suppressed**--Suppressing an interface removes an interface from the network from the perspective of the routing protocol. An interface enters the suppressed state when it has flapped frequently enough for the penalty assigned to it to cross a threshold limit.
PBR Recursive Next Hop

The PBR Recursive Next Hop feature enhances route maps to enable configuration of a recursive next-hop IP address that is used by policy-based routing (PBR). The recursive next-hop IP address is installed in the routing table and can be a subnet that is not directly connected. If the recursive next-hop IP address is not available, packets are routed using a default route.

Because Cisco Express Forwarding (CEF) or process switching provides the infrastructure, the benefit of this feature is the CEF loadsharing.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.
How to Configure PBR Recursive Next Hop

Setting the Recursive Next-Hop IP Address

The infrastructure provided by CEF or process switching performs the recursion to the next-hop IP address. The configuration sequence, which affects routing, is as follows:

1. Next-hop
2. Next-hop recursive
3. Interface
4. Default next-hop
5. Default interface

If both a next-hop and a recursive next-hop IP address are present in the same route-map entry, the next-hop is used. If the next-hop is not available, the recursive next-hop is used. If the recursive next-hop is not available and no other IP address is present, the packet is routed using the default routing table; it is not dropped. If the packet is supposed to be dropped, use the set ip next-hop command with the recursive keyword followed by a set interface null0 configuration.

Note
Match interface is not supported on Cisco Catalyst 3750 series devices.

Perform this task to set the IP address for the recursive next-hop router.

Before you begin
If loadsharing is required, CEF loadsharing should be configured for per-packet or per-destination loadsharing. Loadbalancing should be done over all equal-cost routes to the subnet that have been configured by the set ip next-hop recursive command.

This functionality should be available in centralized and distributed systems.

Note
Only one recursive next-hop IP address is supported per route-map entry.

SUMMARY STEPS

1. enable
2. configure terminal
3. access-list permit source
4. route-map map-tag
5. set ip next-hop ip-address
6. set ip next-hop {ip-address [...ip-address] | recursive ip-address}
7. match ip address access-list-number
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | `enable` | Enables privileged EXEC mode.  
* Enter your password if prompted. |
|        | **Example:** | | Router> enable |
| Step 2 | `configure terminal` | Enters global configuration mode. |
|        | **Example:** | | Router# configure terminal |
| Step 3 | `access-list permit source` | Configures an access list. The example configuration permits any source IP address that falls within the 10.60.0.0.0.255.255 subnet. |
|        | **Example:** | | Router(config)# access-list 101 permit 10.60.0.0 0.0.255.255 |
| Step 4 | `route-map map-tag` | Enables policy routing and enters route-map configuration mode. |
|        | **Example:** | | Router(config)# route-map abccomp |
| Step 5 | `set ip next-hop ip-address` | Sets a next-hop router IP address.  
* Set this IP address separately from the next-hop recursive router configuration. |
|        | **Example:** | | Router(config-route-map)# set ip next-hop 10.10.1.1 |
| Step 6 | `set ip next-hop {ip-address [...ip-address] | recursive ip-address}` | Sets a recursive next-hop IP address.  
* This configuration does not ensure that packets get routed using the recursive IP address if an intermediate IP address is a shorter route to the destination. |
|        | **Example:** | | Router(config-route-map)# set ip next-hop recursive 10.20.3.3 |
| Step 7 | `match ip address access-list-number` | Sets an access list to be matched. |
|        | **Example:** | | Router(config-route-map)# match ip address 101 |
| Step 8 | `end` | Exits route-map configuration mode and returns to privileged EXEC mode. |
|        | **Example:** | | Router(config-route-map)# end |
Verifying the Recursive Next-Hop Configuration

To verify the recursive next-hop configuration, perform the following steps.

**SUMMARY STEPS**

1. `show running-config | begin abccomp`
2. `show route-map map-name`

**DETAILED STEPS**

**Step 1**

`show running-config | begin abccomp`

Use this command to verify the IP addresses for a next-hop and recursive next-hop IP address, for example:

**Example:**

```
Router# show running-config | begin abccomp
route-map abccomp permit 10
  match ip address 101 ! Defines the match criteria for an access list.
  set ip next-hop recursive 10.3.3.3 ! If the match criteria are met, the recursive IP address is set.
  set ip next-hop 10.1.1.1 10.2.2.2 10.4.4.4
```

**Step 2**

`show route-map map-name`

Use this command to display the route maps, for example:

**Example:**

```
Router# show route-map abccomp
route-map abccomp, permit, sequence 10
  Match clauses:
    ip address (access-lists): 101
  Set clauses:
    ip next-hop recursive 10.3.3.3
    ip next-hop 10.1.1.1 10.2.2.2 10.4.4.4
Policy routing matches: 0 packets, 0 bytes
```

**Configuration Examples for PBR Recursive Next Hop**

**Example: Recursive Next-Hop IP Address**

The following example shows the configuration of IP address 10.3.3.3 as the recursive next-hop router:

```
route-map abccomp
  set ip next-hop 10.1.1.1
  set ip next-hop 10.2.2.2
  set ip next-hop recursive 10.3.3.3
  set ip next-hop 10.4.4.4
```
The following example shows the configuration of IPv6 address 2001:DB8:2003:1::95 as the recursive next-hop router:

```
route-map abccomp
  set ipv6 next-hop 2001:DB8:2003:1::95
  set ipv6 next-hop 2001:DB8:2004:3::96
  set ipv6 next-hop recursive 2001:DB8:2005:2::95
  set ipv6 next-hop 2001:DB8:2006:1::95
```

Information About PBR Next-Hop Verify Availability for VRF

PBR Next-Hop Verify Availability for VRF Overview

Cisco IOS policy-based routing (PBR) defines packet matching and classification specifications, sets action policies, which can modify the attributes of IP packets, and overrides normal destination IP address-based routing and forwarding. PBR can be applied on global interfaces and under multiple routing instances. The PBR Next-Hop Verify Availability for VRF feature enables verification of next-hop availability for IPv4/IPv6 packets under virtual routing and forwarding (VRF) instances.

In case of an inherited VRF, the VRF instance is based on the ingress interface. Inter VRF refers to forwarding of packets from one VRF to another VRF; for example, from VRFx to VRFy. An IPv4/IPv6 packet received from VRFx is forwarded to VRFy and the availability of the next hop is verified in the VRFy instance.
How to Configure PBR Next-Hop Verify Availability for VRF

Configuring PBR Next-Hop Verify Availability for Inherited IP VRF

SUMMARY STEPS

1. enable
2. configure terminal
3. ip vrf vrf-name

### Configuring PBR Next-Hop Verify Availability for Inter VRF

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip vrf *vrf-name*
4. rd *vpn-route-distinguisher*
5. route-target export *route-target-ext-community*
6. ip vrf *vrf-name*
7. no rd *vpn-route-distinguisher*
8. rd *vpn-route-distinguisher*
9. route-target export *route-target-ext-community*
10. interface *type number*
11. `ip vrf forwarding vrf-name`
12. `ip address ip-address subnet-mask`
13. `ip policy route-map map-tag`
14. `interface type number`
15. `ip vrf forwarding vrf-name`
16. `ip address ip-address subnet-mask`
17. `exit`
18. `ip route vrf vrf-name prefix mask interface-type interface-number ip-address`
19. `ip route vrf vrf-name prefix mask ip-address`
20. Repeat Step 19 to establish additional static routes.
21. `route-map map-tag [permit | deny] [sequence-number] [sequence-name]
mapping interface-type interface-number`
22. `match interface interface-type interface-number`
23. `set ip vrf vrf-name next-hop verify-availability next-hop-address sequence track object`
24. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>* Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip vrf vrf-name</td>
<td>Configures an IP VPN routing and forwarding instance and enters VRF configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# ip vrf BLUE</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> rd vpn-route-distinguisher</td>
<td>Specifies the route distinguisher. The route distinguisher is either an autonomous system (AS) number or an IP address.</td>
</tr>
<tr>
<td>Example: Device(config-vrf)# rd 800:1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> route-target export route-target-ext-community</td>
<td>Creates a route-target extended community for a VRF and exports routing information from the target VPN extended community. The route-target-ext-community argument is either an AS number or an IP address.</td>

### Configuration Examples for PBR Next-Hop Verify Availability for VRF

#### Example: Configuring PBR Next-Hop Verify Availability for Inherited IP VRF

```
Device> enable
Device# configure terminal
Device(config)# ip vrf RED
Device(config-vrf)# rd 100:1
Device(config-vrf)# route-target export 100:1
Device(config-vrf)# route-target import 100:1
Device(config-vrf)# exit
Device(config)# ip sla 1
Device(config-ip-sla)# icmp-echo 10.0.0.4
```
Example: Configuring PBR Next-Hop Verify Availability for Inherited IPv6 VRF

Device(config-ip-sla-echo)# vrf RED
Device(config-ip-sla-echo)# exit
Device(config)# ip sla schedule 1 life forever start-time now
Device(config)# track 1 ip sla 1
Device(config-track)# interface Ethernet0/0
Device(config-if)# ip vrf forwarding RED
Device(config-if)# ip address 10.0.0.2 255.0.0.0
Device(config-if)# exit
Device(config)# route-map test02 permit 10
Device(config-route-map)# set ip vrf RED next-hop verify-availability 192.168.23.2 1 track 1
Device(config-route-map)# interface Ethernet0/0
Device(config-if)# ip vrf forwarding RED
Device(config-if)# ip policy route-map test02
Device(config-if)# ip address 192.168.10.2 255.255.255.0
Device(config-if)# end

Example: Configuring PBR Next-Hop Verify Availability for Inter VRF

Device> enable
Device# configure terminal
Device(config)# ip vrf BLUE
Device(config-vrf)# rd 800:1
Device(config-vrf)# route-target export 800:1
Device(config-vrf)# ip vrf BLUE
Device(config-vrf)# no rd 800:1
Device(config-vrf)# rd 900:1
Device(config-vrf)# route-target export 900:1
Device(config-vrf)# interface Ethernet0/0
Device(config-if)# ip vrf forwarding RED
Device(config-if)# ip address 192.168.10.2 255.255.255.0
Device(config-if)# ip policy route-map test00
Device(config-if)# interface Ethernet0/1
Device(config-if)# ip vrf forwarding BLUE
Device(config-if)# ip address 192.168.21.1 255.255.255.0
Device(config-if)# exit
Device(config)# ip route vrf blue 192.168.10.1 255.255.255.255 Ethernet0/0 192.168.10.1
Device(config)# ip route vrf blue 192.168.23.0 255.255.255.0 192.168.21.2
Device(config)# route-map test00 permit 10
Device(config-route-map)# match interface Ethernet0/0
Device(config-route-map)# set ip vrf blue next-hop verify-availability 192.168.23.2 1 track 1
Device(config-route-map)# end

## Feature Information for PBR Next-Hop Verify Availability for VRF

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.
Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to [www.cisco.com/go/cfn](http://www.cisco.com/go/cfn). An account on Cisco.com is not required.

CHAPTER 6

PBR Support for Multiple Tracking Options

The PBR Support for Multiple Tracking Options feature extends the capabilities of object tracking using Cisco Discovery Protocol (CDP) to allow the policy-based routing (PBR) process to verify object availability by using additional methods. The verification method can be an Internet Control Message Protocol (ICMP) ping, a User Datagram Protocol (UDP) ping, or an HTTP GET request.

- Finding Feature Information, on page 93
- Information About PBR Support for Multiple Tracking Options, on page 93
- How to Configure PBR Support for Multiple Tracking Options, on page 94
- Configuration Examples for PBR Support for Multiple Tracking Options, on page 98

- Feature Information for PBR Support for Multiple Tracking Options, on page 99

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About PBR Support for Multiple Tracking Options

Object Tracking

Object tracking is an independent process that monitors objects such as the following:

- State of the line protocol of an interface
- Existence of an entry in the routing table
- Results of a Service Assurance Agent (SAA) operation, such as a ping
Clients such as Hot Standby Router Protocol (HSRP), Virtual Router Redundancy Protocol (VRRP), Gateway Load Balancing Protocol (GLBP), and (with this feature) PBR can register their interest in specific, tracked objects and then take action when the state of the objects changes.

**PBR Support for Multiple Tracking Options Feature Design**

The PBR Support for Multiple Tracking Options feature gives PBR access to all the objects that are available through the tracking process. The tracking process provides the ability to track individual objects—such as ICMP ping reachability, routing adjacency, an application running on a remote device, a route in the Routing Information Base (RIB)—or to track the state of an interface line protocol.

Object tracking functions in the following manner. PBR will inform the tracking process that a certain object should be tracked. The tracking process will in turn notify PBR when the state of that object changes.

**How to Configure PBR Support for Multiple Tracking Options**

The tasks in this section are divided according to the Cisco IOS release that you are running because Cisco IOS Release 12.3(14)T introduced new syntax for IP Service Level Agreements (SLAs). To use this feature, you must be running Cisco IOS Release 12.3(4)T, 12.2(25)S, or a later release. This section contains the following tasks:

**Configuring PBR Support for Multiple Tracking Options**

Perform this task to configure PBR support for multiple tracking options. In this task, a route map is created and configured to verify the reachability of the tracked object.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip sla monitor operation-number`
4. `type echo protocol ipIcmpEcho {destination-ip-address|destination-hostname}|source-ipaddr
   {ip-address|hostname}|source-interface interface-name`
5. `exit`
6. `ip sla monitor schedule operation-number [life {forever|seconds}] [start-time [hh:mm:ss]
   [month day|day month]|pending|now|after hh:mm:ss]} [ageout seconds] [recurring]`
7. `track object-number rtr entry-number [reachability|state]`
8. `delay {up seconds|down seconds}|[up seconds] down seconds}`
9. `exit`
10. `interface type number`
11. `ip address ip-address mask [secondary]`
12. `ip policy route-map map-tag`
13. `exit`
14. `route-map map-tag [permit|deny] [sequence-number] [```
15. `set ip next-hop verify-availability [next-hop-address sequence track object]`
16. `end`
17. `show track object-number`
## PBR Support for Multiple Tracking Options

### Configuring PBR Support for Multiple Tracking Options

#### 18.  `show route-map [map-name| all| dynamic]`

### Detailed Steps

<td></td>
</tr>
<tr>
<td><strong>Step 10</strong> interface type number</td>
<td>Specifies an interface type and number and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# interface serial 2/0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 11</strong> ip address ip-address mask [secondary]</td>
<td>Specifies a primary or secondary IP address for an interface.</td>
</tr>
</tbody>
</table>
| Example: Device(config-if)# ip address 192.168.1.1 255.255.255.0 | • See the "Configuring IPv4 Addresses" chapter of the Cisco IOS IP Addressing Services Configuration Guide for information on configuring IPv4 addresses.  
• In this example, the IP address of the incoming interface is specified. This is the interface on which policy routing is to be enabled. |
| **Step 12** ip policy route-map map-tag | Enables policy routing and identifies a route map to be used for policy routing. |
| Example: Device(config-if)# ip policy route-map alpha | |
| **Step 13** exit | Exits interface configuration mode and returns the device to global configuration mode. |
| Example: Device(config-if)# exit | |
| **Step 14** route-map map-tag [permit | deny] [sequence-number] | Configures a route map and specifies how the packets are to be distributed. |
| Example: Device(config)# route-map alpha permit ordering-seq | |
| **Step 15** set ip next-hop verify-availability [next-hop-address sequence track object] | Configures the route map to verify the reachability of the tracked object. |
| Example: | |
Purpose

Command or Action

Device(config-route-map)# set ip next-hop verify-availability 10.1.1.1 10 track 123

• In this example, the policy is configured to forward packets received on serial interface 2/0 to 10.1.1.1 if that device is reachable.

Step 16

end

Example:

Device(config-route-map)# end

Exits route-map configuration mode and returns the device to privileged EXEC mode.

Step 17

show track  object-number

Example:

Device# show track 123

(Optional) Displays tracking information.

• Use this command to verify the configuration. See the display output in the "Examples" section of this task.

Step 18

show route-map  [map-name| all| dynamic]

Example:

Device# show route-map alpha

(Optional) Displays route map information.

• In this example, information about the route map named alpha is displayed. See the display output in the "Examples" section of this task.

Examples

The following output from the show track command shows that the tracked object 123 is reachable.

Device# show track 123
Track 123
Response Time Reporter 1 reachability
Reachability is Up
  2 changes, last change 00:00:33
Delay up 60 secs, down 30 secs
Latest operation return code: OK
Latest RTT (milliseconds) 20
Tracked by:
 ROUTE-MAP 0

The following output from the show route-map command shows information about the route map named alpha that was configured in the task.

Device# show route-map alpha
route-map alpha, permit, sequence 10
Match clauses:
Set clauses:
 ip next-hop verify-availability 10.1.1.1 10 track 123 [up]
Policy routing matches: 0 packets, 0 bytes
Configuration Examples for PBR Support for Multiple Tracking Options

Example: Configuring PBR Support for Multiple Tracking Options

The following example shows how to configure PBR support for multiple tracking options.

The configured policy is that packets received on Ethernet interface 0, should be forwarded to 10.1.1.1 only if that device is reachable (responding to pings). If 10.1.1.1 is not up, then the packets should be forwarded to 10.2.2.2. If 10.2.2.2 is also not reachable, then the policy routing fails and the packets are routed according to the routing table.

Two RTRs are configured to ping the remote devices. The RTRs are then tracked. Policy routing will monitor the state of the tracked RTRs and make forwarding decisions based on their state.

! Define and start the RTRs.
ip sla monitor 1
  type echo protocol ipicmp 10.1.1.1
ip sla monitor schedule 1 start-time now life forever
!
ip sla monitor 2
  type echo protocol ipicmp 10.2.2.2
ip sla monitor schedule 2 start-time now life forever
!
! Track the RTRs.
track 123 rtr 1 reachability
track 124 rtr 2 reachability
!
! Enable policy routing on the incoming interface.
interface ethernet 0
  ip address 10.4.4.4 255.255.255.0
  ip policy route-map beta
!
! 10.1.1.1 is via this interface.
interface ethernet 1
  ip address 10.1.1.254 255.255.255.0
!
! 10.2.2.2 is via this interface.
interface ethernet 2
  ip address 10.2.2.254 255.255.255.0
!
! Define a route map to set the next-hop depending on the state of the tracked RTRs.
route-map beta

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for PBR Match Track Object

- You can use only one match track variable at a time in a route map sequence.
- You must remove the existing match track object configuration before configuring another match track object. The match track object is unregistered from the tracking component when you remove the match track object number configuration.
- Route-map for PBR, does not take ‘track-object’ into consideration when used under the ‘Match clause’. Match track-object is used for route distribution protocol (for example, BGP) only during the route distribution. Track object cannot be used in route-map, when that route-map is used in PBR.
Information About PBR Match Track Object

PBR Match Track Object Overview

You refer to the stub object that you track as the match track object. The device checks for the existence of the match track object and issues an error message if there is none. Then registration with the tracking component is done to track this object. The device issues an error in case the registration fails.

![Match track object registration](image)

During redistribution, the routing protocols check the route map for matches with existing routes. This provides an exact route map that corresponds to the specific match criteria. When you apply this route map with the match track object, the device checks the status of the match track object and provides a specific route map.

![Route map on redistribution using routing protocols](image)

The device uses Border Gateway Protocol (BGP) for route-filtering and distribution. The device uses the existing notification mechanism to notify the routing protocols about the new match clause and also notifies the routing protocols about any change in the match track object status depending upon the Policy-Based Routing (PBR) query on redistribution.
How to Configure PBR Match Track Object

Configuring PBR Match Track Object

**SUMMARY STEPS**

1. enable
2. configure terminal
3. route-map map-tag
4. match track track-object-number
5. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Device&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        | Enters global configuration mode. |
| configure terminal|         |
| Example:          |         |
| Device# configure terminal | |

| **Step 3**        | Enables policy routing and enters route-map configuration mode. |
| route-map map-tag |         |
| Example:          |         |
| Device(config)# route-map abc | |

| **Step 4**        | Tracks the stub object. Value ranges from 1 to 1000. |
| match track track-object-number |         |
| Example:          |         |
| Device(config-route-map)# match track 2 | |

| **Step 5**        | Returns to privileged EXEC mode. |
| end               |         |
| Example:          |         |
| Device(config-route-map)# end | |

Verifying PBR Match Track Object

**SUMMARY STEPS**

1. enable
2. show route-map map-name
**Detailed Steps**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>

<td></td>
</tr>
</tbody>
</table>

**Configuration Examples for PBR Match Track Object**

**Example: PBR Match Track Object Configuration**

Device> enable
Device# configure terminal
Device(config)# route-map abc
Device(config-route-map)# match track 2
Device(config-route-map)# end

**Example: Verifying PBR Match Track Object**

**Sample output for the show route-map map-name command**

To display information about a specific route-map, use the `show route-map map-name` command in privileged EXEC mode.

Device> enable
Device# show route-map abc
route-map abc, permit, sequence 10
  Match clauses:
  track-object 2
  Set clauses:
  Policy routing matches: 0 packets, 0 bytes

Feature Information for PBR Match Track Object
 IPv6 Policy-Based Routing

Policy-based routing (PBR) in both IPv6 and IPv4 allows a user to manually configure how received packets should be routed. PBR allows the user to identify packets by using several attributes and to specify the next hop or the output interface to which the packet should be sent. PBR also provides a basic packet-marking capability.

- Finding Feature Information, on page 107
- Information About IPv6 Policy-Based Routing, on page 107
- How to Enable IPv6 Policy-Based Routing, on page 110
- Configuration Examples for IPv6 Policy-Based Routing, on page 114
- Additional References, on page 115
- Feature Information for IPv6 Policy-Based Routing, on page 116

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About IPv6 Policy-Based Routing

Policy-Based Routing Overview

Policy-based routing (PBR) gives you a flexible means of routing packets by allowing you to configure a defined policy for traffic flows, which lessens reliance on routes derived from routing protocols. Therefore, PBR gives you more control over routing by extending and complementing the existing mechanisms provided by routing protocols. PBR allows you to set the IPv6 precedence. For a simple policy, you can use any one of these tasks; for a complex policy, you can use all of them. It also allows you to specify a path for certain traffic, such as priority traffic over a high-cost link. IPv6 PBR is supported on Cisco ASR 1000 Series platform.

PBR for IPv6 may be applied to both forwarded and originated IPv6 packets. For forwarded packets, PBR for IPv6 will be implemented as an IPv6 input interface feature, supported in the following forwarding paths:
How Policy-Based Routing Works

All packets received on an interface with policy-based routing (PBR) enabled are passed through enhanced packet filters called route maps. The route maps used by PBR dictate the policy, determining where to forward packets.

Route maps are composed of statements. The route map statements can be marked as permit or deny, and they are interpreted in the following ways:

- If a packet matches all match statements for a route map that is marked as permit, the device attempts to policy route the packet using the set statements. Otherwise, the packet is forwarded normally.
- If the packet matches any match statements for a route map that is marked as deny, the packet is not subject to PBR and is forwarded normally.
- If the statement is marked as permit and the packets do not match any route map statements, the packets are sent back through normal forwarding channels and destination-based routing is performed.

You must configure policy-based routing (PBR) on the interface that receives the packet, and not on the interface from which the packet is sent.

Packet Matching

Policy-based routing (PBR) for IPv6 will match packets using the `match ipv6 address` command in the associated PBR route map. Packet match criteria are those criteria supported by IPv6 access lists, as follows:

- Input interface
- Source IPv6 address (standard or extended access control list [ACL])
- Destination IPv6 address (standard or extended ACL)
- Protocol (extended ACL)
- Source port and destination port (extended ACL)
• DSCP (extended ACL)
• Flow-label (extended ACL)
• Fragment (extended ACL)

Packets may also be matched by length using the `match length` command in the PBR route map.

Match statements are evaluated first by the criteria specified in the `match ipv6 address` command and then by the criteria specified in the `match length` command. Therefore, if both an ACL and a length statement are used, a packet will first be subject to an ACL match. Only packets that pass the ACL match will be subject to the length match. Finally, only packets that pass both the ACL and the length statement will be policy routed.

**Packet Forwarding Using Set Statements**

Policy-based routing (PBR) for IPv6 packet forwarding is controlled by using a number of set statements in the PBR route map. These set statements are evaluated individually in the order shown, and PBR will attempt to forward the packet using each of the set statements in turn. PBR evaluates each set statement individually, without reference to any prior or subsequent set statement.

You may set multiple forwarding statements in the PBR for IPv6 route map. The following set statements may be specified:

• IPv6 next hop. The next hop to which the packet should be sent. The next hop must be present in the Routing Information Base (RIB), it must be directly connected, and it must be a global IPv6 address. If the next hop is invalid, the set statement is ignored.

• Output interface. A packet is forwarded out of a specified interface. An entry for the packet destination address must exist in the IPv6 RIB, and the specified output interface must be in the set path. If the interface is invalid, the statement is ignored.

• Default IPv6 next hop. The next hop to which the packet should be sent. It must be a global IPv6 address. This set statement is used only when there is no explicit entry for the packet destination in the IPv6 RIB.

• Default output interface. The packet is forwarded out of a specified interface. This set statement is used only when there is no explicit entry for the packet destination in the IPv6 RIB.

---

**Note**

The order in which PBR evaluates the set statements is the order in which they are listed above. This order may differ from the order in which route-map set statements are listed by `show` commands.

**When to Use Policy-Based Routing**

Policy-based routing (PBR) can be used if you want certain packets to be routed some way other than the obvious shortest path. For example, PBR can be used to provide the following functionality:

• Equal access
• Protocol-sensitive routing
• Source-sensitive routing
• Routing based on interactive traffic versus batch traffic
• Routing based on dedicated links

Some applications or traffic can benefit from Quality of Service (QoS)-specific routing; for example, you could transfer stock records to a corporate office on a higher-bandwidth, higher-cost link for a short time while sending routine application data such as e-mail over a lower-bandwidth, lower-cost link.

**How to Enable IPv6 Policy-Based Routing**

**Enabling PBR on an Interface**

To enable PBR for IPv6, create a route map that specifies the packet match criteria and the desired policy-route action. Then, associate the route map on the required interface. All packets arriving on the specified interface that match the match clauses will be subject to PBR.

Depending on your release, IPv6 PBR allows users to override normal destination IPv6 address-based routing and forwarding results. VPN routing and forwarding (VRF) allows multiple routing instances in Cisco software. The PBR feature is VRF-aware, which means that it works under multiple routing instances, beyond the default or global routing table.

In PBR, the `set vrf` command decouples the VRF and interface association and allows the selection of a VRF based on ACL-based classification using existing PBR or route-map configurations. PBR, through the `set vrf` command, provides a single device with multiple routing tables and the ability to select routes based on ACL classification. The device classifies packets based on ACL, selects a routing table, looks up the destination address, and then routes the packet.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `route-map map-tag [permit | deny] [sequence-number]`
4. Enter one of the following commands:
   - `match length minimum-length maximum-length`
   - `match ipv6 address {prefix-list prefix-list-name | access-list-name}`
5. Enter one of the following commands:
   - `set ipv6 precedence precedence-value`
   - `set ipv6 next-hop global-ipv6-address [global-ipv6-address...]`
   - `set interface type number [...type number]`
   - `set ipv6 default next-hop global-ipv6-address [global-ipv6-address...]`
   - `set default interface type number [...type number]`
   - `set vrf vrf-name`
6. `exit`
7. `interface type number`
8. `ipv6 policy route-map route-map-name`
9. `end`
## IPv6 Policy-Based Routing
### Enabling PBR on an Interface

#### Detailed Steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | enable | Enables privileged EXEC mode.  
  - Enter your password if prompted. |
| Example: | Device> enable | |
| **Step 2** | configure terminal | Enters global configuration mode. |
| Example: | Device# configure terminal | |
| **Step 3** | route-map map-tag [permit | deny] [sequence-number] | Enters route-map configuration mode and defines conditions for redistributing routes from one routing protocol into another or enables policy routing. |
| Example: | Device(config)# route-map rip-to-ospf permit | |
| **Step 4** | Enter one of the following commands:  
- match length minimum-length maximum-length  
- match ipv6 address {prefix-list prefix-list-name | access-list-name} | Specifies the match criteria.  
- You can specify any or all of the following:  
  - Match the Level 3 length of the packet.  
  - Match a specified IPv6 access list.  
  - If you do not specify a match command, the route map applies to all packets. |
| Example: | Device(config-route-map)# match length 3 200  
Device(config-route-map)# match ipv6 address marketing | |
| **Step 5** | Enter one of the following commands:  
- set ipv6 precedence precedence-value  
- set ipv6 next-hop global-ipv6-address  
  [global-ipv6-address...]  
- set interface type number [...type number]  
- set ipv6 default next-hop global-ipv6-address  
  [global-ipv6-address...]  
- set default interface type number [...type number]  
- set vrf vrf-name | Specifies the action or actions to be taken on the packets that match the criteria.  
- You can specify any or all of the following actions:  
  - Set the precedence value in the IPv6 header.  
  - Set the next hop for the packet (the next hop must be an adjacent device).  
  - Set output interface for the packet.  
  - Set the next hop for the packet, if there is no explicit route for this destination.  
  - Set the output interface for the packet, if there is no explicit route for this destination.  
  - Set VRF instance selection within a route map for a policy-based routing VRF selection. |
| Example: | Device(config-route-map)# set ipv6 precedence 1  
Device(config-route-map)# set ipv6 next-hop  
2001:DB8:2003:1::95  
Device(config-route-map)# set interface serial 0/0  
Device(config-route-map)# set ipv6 default next-hop  
2001:DB8:2003:1::95 | |

### Enabling Local PBR for IPv6

Packets that are generated by the device are not normally policy routed. Perform this task to enable local IPv6 policy-based routing (PBR) for such packets, indicating which route map the device should use.

### SUMMARY STEPS

1. enable
2. configure terminal
3. ipv6 local policy route-map route-map-name
4. end

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1 enable</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Example:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device&gt; enable</td>
</tr>
</tbody>
</table>

- Enter your password if prompted.
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 2**
  configure terminal
  Example:
  Device# configure terminal | Enters global configuration mode. |
| **Step 3**
  ipv6 local policy route-map route-map-name
  Example:
  Device(config)# ipv6 local policy route-map pbr-src-90 | Configures IPv6 PBR for packets generated by the device. |
| **Step 4**
  end
  Example:
  Device(config)# end | Returns to privileged EXEC mode. |

**Verifying the Configuration and Operation of PBR for IPv6**

**SUMMARY STEPS**

1. enable
2. show ipv6 policy

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  enable
  Example:
  Device> enable | Enables privileged EXEC mode.
  * Enter your password if prompted. |
| **Step 2**
  show ipv6 policy
  Example:
  Device# show ipv6 policy | Displays IPv6 policy routing packet activity. |

**Troubleshooting PBR for IPv6**

Policy routing analyzes various parts of the packet and then routes the packet based on certain user-defined attributes in the packet.

**SUMMARY STEPS**

1. enable
2. `show route-map [map-name | dynamic [dynamic-map-name | application [application-name]] | all] [detailed]`

3. `debug ipv6 policy [access-list-name]`

## Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>

<td></td>
</tr>
</tbody>
</table>

## Configuration Examples for IPv6 Policy-Based Routing

### Example: Enabling PBR on an Interface

In the following example, a route map named pbr-dest-1 is created and configured. The route map specifies the packet match criteria and the desired policy-route action. PBR is then enabled on Ethernet interface 0/0.

```
ipv6 access-list match-dest-1
  permit ipv6 any 2001:DB8:2001:1760::/32
route-map pbr-dest-1 permit 10
  match ipv6 address match-dest-1
  set interface serial 0/0
interface Ethernet0/0
ipv6 policy route-map interactive
```

### Example: Enabling Local PBR for IPv6

In the following example, packets with a destination IPv6 address that match the IPv6 address range allowed by access list pbr-src-90 are sent to the device at IPv6 address 2001:DB8:2003:1::95:

```
ipv6 access-list src-90
  permit ipv6 host 2001:DB8:2003::90 2001:DB8:2003:1000::/64
route-map pbr-src-90 permit 10
```
match ipv6 address src-90
set ipv6 next-hop 2001:DB8:2003:1::95
ipv6 local policy route-map pbr-src-90

Example: Verifying IPv6 PBR Configuration

The following sample output from the `show ipv6 policy` command displays the IPv6 PBR configuration enabled on interface Ethernet interface 0/0:

```
Device# show ipv6 policy
Interface          Routemap
Ethernet0/0         src-1
```

Example: Verifying Route-Map Information

The following sample output from the `show route-map` command displays specific route-map information, such as a count of policy matches:

```
Device# show route-map
route-map bill, permit, sequence 10
Match clauses:
Set clauses:
Policy routing matches:0 packets, 0 bytes
```

CHAPTER 9

Multi-VRF Selection Using Policy-Based Routing

The Multi-VRF Selection Using Policy-Based Routing (PBR) feature allows a specified interface on a provider edge (PE) device to route packets to Virtual Private Networks (VPNs) based on packet length or match criteria defined in an IP access list.

You can enable VPN routing and forwarding (VRF) selection by policy routing packets through a route map, through the global routing table, or to a specified VRF.

You can enable policy-routing packets for VRF instances by using route map commands with set commands.

On supported hardware, you can configure both the Multi-VRF Selection Using Policy-Based Routing feature and the MPLS VPN VRF Selection Based on a Source IP Address feature on the same interface.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.
Prerequisites for Multi-VRF Selection Using Policy-Based Routing

• The device must support policy-based routing (PBR) in order for you to configure this feature. For platforms that do not support PBR, use the MPLS VPN VRF Selection Based on a Source IP Address feature.

• A Virtual Private Network (VPN) virtual routing and forwarding (VRF) instance must be defined before you configure this feature. An error message is displayed on the console if no VRF exists.

Restrictions for Multi-VRF Selection Using Policy-Based Routing

• All commands that aid in routing also support hardware switching, except for the set ip next-hop verify availability command because Cisco Discovery Protocol information is not available in the line cards.

• Protocol Independent Multicast (PIM) and multicast packets do not support policy-based routing (PBR) and cannot be configured for a source IP address that is a match criterion for this feature.

• The set vrf and set ip global next-hop commands can be configured with the set default interface, set interface, set ip default next-hop, and set ip next-hop commands. But the set vrf and set ip global next-hop commands take precedence over the set default interface, set interface, set ip default next-hop, and set ip next-hop commands. No error message is displayed if you attempt to configure the set vrf command with any of these three set commands.

• The Multi-VRF Selection Using Policy-Based Routing feature cannot be configured with IP prefix lists.

• The set global and set vrf commands cannot be simultaneously applied to a route map.

• The Multi-VRF Selection Using Policy-Based Routing feature supports VRF-lite; that is, only IP routing protocols run on the device. Multiprotocol Label Switching (MPLS) and Virtual Private Networks (VPNs) cannot be configured. However, the set vrf command will work in MPLS VPN scenarios.

• If you delete one VRF using no vrf definition vrf-name command, then other VRFs in the VRF routing table are also removed unexpectedly; when ip vrf receive command is configured with receive entries above 400, and IPv4 and IPv6 routes above 2000. This is applicable only for Cisco ASR 1000 platform.

• In a VRF receive scenario, the memory requirements are proportional to the number of VRF receives that are configured multiplied by the number of directly connected neighbours (Cisco Express Forwarding adjacencies). When the ip vrf receive command is configured, Cisco Express Forwarding adjacency prefixes are copied to the VRF. Network resources might be exhausted based on number of bytes per each adjacency prefix, number of adjacency prefixes, number of VRF receives configured, and the platform-specific route processor memory restrictions applicable to Cisco Express Forwarding entries.
Information About Multi-VRF Selection Using Policy-Based Routing

Policy Routing of VPN Traffic Based on Match Criteria

The Multi-VRF Selection Using Policy-Based Routing feature is an extension of the MPLS VPN VRF Selection Based on a Source IP Address feature. The Multi-VRF Selection Using Policy-Based Routing feature allows you to policy route Virtual Private Network (VPN) traffic based on match criteria. Match criteria are defined in an IP access list and/or are based on packet length. The following match criteria are supported in Cisco software:

- IP access lists—Define match criteria based on IP addresses, IP address ranges, and other IP packet access list filtering options. Named, numbered, standard, and extended access lists are supported. All IP access list configuration options in Cisco software can be used to define match criteria.

- Packet lengths—Define match criteria based on the length of a packet, in bytes. The packet length filter is defined in a route map with the `match length` route-map configuration command.

Policy routing is defined in the route map. The route map is applied to the incoming interface with the `ip policy route-map` interface configuration command. An IP access list is applied to the route map with the `match ip address` route-map configuration command. Packet length match criteria are applied to the route map with the `match length` route-map configuration command. The `set` action is defined with the `set vrf` route-map configuration command. The match criteria are evaluated, and the appropriate VRF is selected by the `set` command. This combination allows you to define match criteria for incoming VPN traffic and policy route VPN packets out to the appropriate virtual routing and forwarding (VRF) instance.

Policy-Based Routing set Commands

Policy-routing Packets for VRF Instances

To enable policy-routing packets for virtual routing and forwarding (VRF) instances, you can use route map commands with the following `set` commands. They are listed in the order in which the device uses them during the routing of packets.

- `set tos`—Sets the Type of Service (TOS) bits in the header of an IP packet.
- `set df`—Sets the Don’t Fragment (DF) bit in the header of an IP packet.
- `set vrf`—Routes packets through the specified interface. The destination interface can belong only to a VRF instance.
- `set global`—Routes packets through the global routing table. This command is useful for routing ingress packets belonging to a specific VRF through the global routing table.
- `set ip vrf next-hop`—Indicates where to output IPv4 packets that pass a match criteria of a route map for policy routing when the IPv4 next hop must be under a specified VRF.
- `set ipv6 vrf next-hop`—Indicates where to output IPv6 packets that pass a match criteria of a route map for policy routing when the IPv6 next hop must be under a specified VRF.
Change of Normal Routing and Forwarding Behavior

When you configure policy-based routing (PBR), you can use the following six set commands to change normal routing and forwarding behavior. Configuring any of these set commands, with the potential exception of the set ip next-hop command, overrides the routing behavior of packets entering the interface if the packets do not belong to a virtual routing and forwarding (VRF) instance. The packets are routed from the egress interface across the global routing table.

- set default interface—Indicates where to output packets that pass a match criterion of a route map for policy routing and have no explicit route to the destination. The interface can belong to any VRF.

- set interface—When packets enter a VRF interface, routes the packets out of the egress interface under the same VRF according to the set interface policy, provided that the Layer 2 rewrite information is available.

- set default next-hop—Indicates where to output IPv4 packets that pass a match criterion of a route map for policy routing and for which the Cisco software has no explicit route to a destination.

- set ipv6 default next-hop—Indicates where to IPv6 output packets that pass a match criterion of a route map for policy routing and for which the Cisco software has no explicit route to a destination.

- set default interface—Indicates where to output packets that pass a match criterion of a route map for policy routing and have no explicit route to the destination.

- set interface—When packets enter a VRF interface, routes the packets out of the egress interface under the same VRF according to the set interface policy, provided that the Layer 2 rewrite information is available.

Note
The interface must be a peer-to-peer (P2P) interface.

- set ip default next-hop—Indicates where to output IPv4 packets that pass a match criterion of a route map for policy routing and for which the Cisco software has no explicit route to a destination.
• **set ipv6 default next-hop**—Indicates where to output IPv6 packets that pass a match criterion of a route map for policy routing and for which the Cisco software has no explicit route to a destination.

• **set ip next-hop**—Indicates where to output IPv4 packets that pass a match criterion of a route map for policy routing. If an IPv4 packet is received on a VRF interface and is transmitted from another interface within the same VPN, the VRF context of the incoming packet is inherited from the interface.

• **set ipv6 next-hop**—Indicates where to output IPv6 packets that pass a match criterion of a route map for policy routing. If an IPv6 packet is received on a VRF interface and is transmitted from another interface within the same Virtual Private Network (VPN), the VRF context of the incoming packet is inherited from the interface.

### Support of Inherit-VRF Inter-VRF and VRF-to-Global Routing

The Multi-VRF Selection Using Policy-Based Routing (PBR) feature supports inherit-VRF and inter-VRF. With inherit-VRF routing, packets arriving at a virtual routing and forwarding (VRF) interface are routed by the same outgoing VRF interface. With inter-VRF routing, packets arriving at a VRF interface are routed through any other outgoing VRF interface.

VRF-to-global routing causes packets that enter any VRF interface to be routed through the global routing table. When a packet arrives on a VRF interface, the destination lookup normally is done only in the corresponding VRF table. If a packet arrives on a global interface, the destination lookup is done in the global routing table.

The Multi-VRF Selection Using Policy-Based Routing feature modifies the following *set* commands to support inherit-VRF, inter-VRF, and VRF-to-global routing. The commands are listed in the order in which the device uses them during the routing of packets.

• **set global**—Routes packets through the global routing table. This command is useful for routing ingress packets belonging to a specific VRF through the global routing table.

• **set ip global next-hop**—Indicates where to forward IPv4 packets that pass a match criterion of a route map for policy routing and for which the Cisco software uses the global routing table.

• **set ipv6 global next-hop**—Indicates where to forward IPv6 packets that pass a match criterion of a route map for policy routing and for which the Cisco software uses the global routing table.

• **set ip vrf next-hop**—Causes the device to look up the IPv4 next hop in the VRF table. If an IPv4 packet arrives on an interface that belongs to a VRF and the packet needs to be routed through a different VRF, you can use the *set ip vrf next-hop* command.

• **set ipv6 vrf next-hop**—Causes the device to look up the IPv6 next hop in the VRF table. If an IPv6 packet arrives on an interface that belongs to a VRF and the packet needs to be routed through a different VRF, you can use the *set ipv6 vrf next-hop* command.

• **set ip default vrf**—Provides IPv4 inherit-VRF and inter-VRF routing. With IPv4 inherit-VRF routing, IPv4 packets arriving at a VRF interface are routed by the same outgoing VRF interface. With inter-VRF routing, IPv4 packets arriving at a VRF interface are routed through any other outgoing VRF interface.

• **set ipv6 default vrf**—Provides IPv6 inherit-VRF and inter-VRF routing. With IPv6 inherit-VRF routing, IPv6 packets arriving at a VRF interface are routed by the same outgoing VRF interface. With inter-VRF routing, IPv6 packets arriving at a VRF interface are routed through any other outgoing VRF interface.

• **set interface**—When packets enter a VRF, routes the packets out of the egress interface under the same VRF, according to the set interface policy, provided that the Layer 2 rewrite information is available.
• **set default interface**—Indicates where to output packets that pass a match criterion of a route map for policy routing and have no explicit route to the destination. The interface can belong to any VRF.

• **set ip next-hop**—Routes IPv4 packets through the global routing table in an IPv4-to-IPv4 routing and forwarding environment.

• **set ipv6 next-hop**—Routes IPv6 packets through the global routing table in an IPv6-to-IPv6 routing and forwarding environment.

• **set vrf**—Selects the appropriate VRF after a successful match occurs in the route map. VRS-aware PSV allows only inter-VRF (or VRF-to-VRF) switching.

## How to Configure Multi-VRF Selection Using Policy-Based Routing

### Defining the Match Criteria for Multi-VRF Selection Using Policy-Based Routing

Define the match criteria for the Multi-VRF Selection using Policy-Based Routing (PBR) feature so that you can selectively route the packets instead of using their default routing and forwarding.

The match criteria for the Multi-VRF Selection using Policy-Based Routing are defined in an access list. Standard, named, and extended access lists are supported.

You can define the match criteria based on the packet length by configuring the `match length` route-map configuration command. This configuration option is defined entirely within a route map.

The following sections explain how to configure PBR route selection:

### Configuring Multi-VRF Selection Using Policy-Based Routing with a Standard Access List

#### Before you begin

The tasks in the following sections assume that the virtual routing and forwarding (VRF) instance and associated IP address are already defined.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `access-list access-list-number {deny | permit} [source source-wildcard] [log]`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td></td>
</tr>
<tr>

</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
</tbody>
</table>
Configuring Multi-VRF Selection Using Policy-Based Routing with a Named Extended Access List

To configure Multi-VRF Selection using Policy-Based Routing (PBR) with a named extended access list, complete the following steps.

Before you begin

The tasks in the following sections assume that the virtual routing and forwarding (VRF) instance and associated IP address are already defined.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip access-list {standard | extended} [access-list-name | access-list-number]
4. [sequence-number] {permit | deny} protocol source source-wildcard destination destination-wildcard [option option-value] [precedence precedence] [tos tos] [ttl operator-value] [log] [time-range time-range-name] [fragments]

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>

Example:

```
Device> enable
Device# configure terminal
Device(config)# access-list 40 permit source 10.1.1.0/24 0.0.0.255
```
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
<td>Specifies the IP access list type and enters the corresponding access list configuration mode.</td>
</tr>
</tbody>
</table>

**Step 3**

`ip access-list {standard | extended} [access-list-name | access-list-number]`  
Example:  
Device(config)# ip access-list extended NAMEDACL

**Step 4**

`[sequence-number] {permit | deny} protocol source source-wildcard destination destination-wildcard [option option-value] [precedence precedence] [tos] [ttl] [operator-value] [log] [time-range time-range-name] [fragments]`  
Example:  
Device(config-ext-nacl)# permit ip any any option any-options

---

**Configuring Multi-VRF Selection in a Route Map**

Incoming packets are filtered through the match criteria that are defined in the route map. After a successful match occurs, the `set` command configuration determines the VRF through which the outbound Virtual Private Network (VPN) packets will be policy routed.

**Before you begin**

You must define the virtual routing and forwarding (VRF) instance before you configure the route map; otherwise an error message appears on the console.

A receive entry must be added to the VRF selection table with the `ip vrf receive` command. If a match and set operation occurs in the route map but there is no receive entry in the local VRF table, the packet will be dropped if the packet destination is local.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. named-ordering-route-map enable
4. route-map map-tag [permit | deny] [sequence-number] [  
5. Do one of the following :  
   • set ip vrf vrf-name next-hop global-ipv4-address [...global-ipv4-address]  
   • set ipv6 vrf vrf-name next-hop global-ipv6-address [...global-ipv6-address]  
   • set ip next-hop recursive vrf global-ipv4-address [...global-ipv4-address]  
   • set ip global next-hop global-ipv4-address [...global-ipv4-address]  
   • set ipv6 global next-hop global-ipv6-address [...global-ipv6-address]
6. Do one of the following:
   • **match ip address** `{acl-number [acl-name | acl-number]}
   • **match length** minimum-lengthmaximum-length

7. end

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | enable | Enables privileged EXEC mode.  
Example:  
Device> enable |  |
| **Step 2** | configure terminal | Enters global configuration mode. |
Example:  
Device# configure terminal |  |
| **Step 3** | named-ordering-route-map enable | Enables ordering of route-maps based on a string provided by the user.  
Example:  
Device(config)# named-ordering-route-map enable |  |
| **Step 4** | route-map `map-tag [permit | deny] [sequence-number]` | Configures a route map and specifies how the packets are to be distributed. |
Example:  
Device(config)# route-map alpha permit ordering-seq |  |
| **Step 5** | Do one of the following :  
• set ip vrf `vrf-name next-hop global-ipv4-address`  
• set ipv6 vrf `vrf-name next-hop global-ipv6-address`  
• set ip next-hop recursive vrf `global-ipv4-address`  
• set ip global next-hop `global-ipv4-address`  
• set ipv6 global next-hop `global-ipv6-address`  
Example:  
Device(config-route-map)# set ip vrf myvrf next-hop 10.0.0.0 | Indicates where to forward packets that pass a match criterion of a route map for policy routing when the IPv4 next hop must be under a specified VRF.  
Indicates where to forward packets that pass a match criterion of a route map for policy routing when the IPv6 next hop must be under a specified VRF.  
Indicates the IPv4 address to which destination or next hop is used for packets that pass the match criterion configured in the route map.  
Indicates the IPv4 address to forward packets that pass a match criterion of a route map for policy routing and for which the software uses the global routing table.  
Indicates the IPv6 address to forward packets that pass a match criterion of a route map for policy routing and for which the software uses the global routing table. |
Configuring Multi-VRF Selection Using Policy-Based Routing and IP VRF
Receive on the Interface

The route map is attached to the incoming interface with the `ip policy route-map` interface configuration command.

The source IP address must be added to the virtual routing and forwarding (VRF) selection table. VRF selection is a one-way (unidirectional) feature. It is applied to the incoming interface. If a `match` and `set` operation occurs in the route map but there is no receive entry in the local VRF table, the packet is dropped if the packet destination is local.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface type number [name-tag]`
4. `ip policy route-map map-tag`
5. `ip vrf receive vrf-name`
6. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable Example: Device> enable | Enables privileged EXEC mode.  
• Enter your password if prompted. |
| **Step 2** configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| **Step 3** interface type number [name-tag] Example: Device(config)# interface FastEthernet 0/1/0 | Configures an interface and enters interface configuration mode. |
| **Step 4** ip policy route-map map-tag Example: Device(config-if)# ip policy route-map map1 | Identifies a route map to use for policy routing on an interface.  
• The configuration example attaches the route map named map1 to the interface. |
| **Step 5** ip vrf receive vrf-name Example: Device(config-if)# ip vrf receive VRF-1 | Adds the IP addresses that are associated with an interface into the VRF table.  
• This command must be configured for each VRF that will be used for VRF selection. |
| **Step 6** end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

### Verifying the Configuration of Multi-VRF Selection Using Policy-Based Routing

To verify the configuration of the Multi-VRF Selection Using Policy-Based Routing (PBR) feature, perform the following steps. You can enter the commands in any order.
Verifying the Configuration of Multi-VRF Selection Using Policy-Based Routing

SUMMARY STEPS

1. `show ip access-list [access-list-number | access-list-name]`
2. `show route-map [map-name]`
3. `show ip policy`

DETAILED STEPS

Step 1  
`show ip access-list [access-list-number | access-list-name]`
Verifies the configuration of match criteria for Multi-VRF Selection Using Policy-Based Routing. The command output displays three subnet ranges defined as match criteria in three standard access lists:

Example:

Device# show ip access-list

Standard IP access list 40
  10 permit 10.1.0.0, wildcard bits 0.0.255.255
Standard IP access list 50
  10 permit 10.2.0.0, wildcard bits 0.0.255.255
Standard IP access list 60
  10 permit 10.3.0.0, wildcard bits 0.0.255.255

Step 2  
`show route-map [map-name]`
Verifies match and set commands within the route map:

Example:

Device# show route-map

The output displays the match criteria and set action for each route-map sequence. The output also displays the number of packets and bytes that have been policy routed per each route-map sequence.

Example:

Device# show route-map map1

route-map map1, permit, sequence 10
Match clauses:
Set clauses:
  ip next-hop vrf myvrf 10.5.5.5 10.6.6.6 10.7.7.7
  ip next-hop global 10.8.8.8 10.9.9.9
Policy routing matches: 0 packets, 0 bytes
Device# show route-map map2
route-map map2, permit, sequence 10
Match clauses:
Set clauses:
  vrf myvrf
Policy routing matches: 0 packets, 0 bytes
Device# show route-map map3
route-map map3, permit, sequence 10
Match clauses:
Set clauses:
  global
Policy routing matches: 0 packets, 0 bytes

The following `show route-map` command displays output from the `set ip vrf next-hop` command:
Example:

Device(config)# route-map test
Device(config-route-map)# set ip vrf myvrf next-hop
Device(config-route-map)# set ip vrf myvrf next-hop 192.168.3.2
Device(config-route-map)# match ip address 255 101
Device(config-route-map)# end
Device# show route-map

route-map test, permit, sequence 10
  Match clauses:
  ip address (access-lists): 101
  Set clauses:
  ip vrf myvrf next-hop 192.168.3.2
Policy routing matches: 0 packets, 0 bytes

The following show route-map command displays output from the set ip global command:

Example:

Device(config)# route-map test
Device(config-route-map)# match ip address 255 101
Device(config-route-map)# set ip global next-hop 192.168.4.2
Device(config-route-map)# end
Device# show route-map

*May 25 13:45:55.551: %SYS-5-CONFIG_I: Configured from console by consoleout-map
route-map test, permit, sequence 10
  Match clauses:
  ip address (access-lists): 101
  Set clauses:
  ip global next-hop 192.168.4.2
Policy routing matches: 0 packets, 0 bytes

Step 3  show ip policy

Verifies the Multi-VRF Selection Using Policy-Based Routing policy.

Example:

Device# show ip policy

The following show ip policy command output displays the interface and associated route map that is configured for policy routing:

Example:

Device# show ip policy

<table>

<tbody>
<tr>
<td>FastEthernet0/1/0</td>
<td>PBR-VRF-Selection</td>
</tr>
</tbody>
</table>
Configuration Examples for Multi-VRF Selection Using Policy-Based Routing

Example: Defining the Match Criteria for Multi-VRF Selection Using Policy-Based Routing

In the following example, three standard access lists are created to define match criteria for three different subnetworks. Any packets received on FastEthernet interface 0/1/0 will be policy routed through the PBR-VRF-Selection route map to the virtual routing and forwarding (VRF) that is matched in the same route-map sequence. If the source IP address of the packet is part of the 10.1.0.0/24 subnet, VRF1 will be used for routing and forwarding.

access-list 40 permit source 10.1.0.0 0.0.255.255
access-list 50 permit source 10.2.0.0 0.0.255.255
access-list 60 permit source 10.3.0.0 0.0.255.255
route-map PBR-VRF-Selection permit 10
match ip address 40
set vrf VRF1
!
route-map PBR-VRF-Selection permit 20
match ip address 50
set vrf VRF2
!
route-map PBR-VRF-Selection permit 30
match ip address 60
set vrf VRF3
!
interface FastEthernet 0/1/0
ip address 192.168.1.6 255.255.255.252
ip policy route-map PBR-VRF-Selection
ip vrf receive VRF1
ip vrf receive VRF2
ip vrf receive VRF3

Example: Configuring Multi-VRF Selection in a Route Map

The following example shows a `set ip vrf next-hop` command that applies policy-based routing to the virtual routing and forwarding (VRF) interface named myvrf and specifies that the IP address of the next hop is 10.0.0.2:

```
Device(config)# route-map map1 permit
Device(config)# set vrf myvrf
Device(config-route-map)# set ip vrf myvrf next-hop 10.0.0.2
Device(config-route-map)# match ip address 101
Device(config-route-map)# end
```

The following example shows a `set ip global` command that specifies that the device should use the next hop address 10.0.0.1 in the global routing table:

```
Device(config-route-map)# set ip global next-hop 10.0.0.1
```

Feature Information for Multi-VRF Selection Using Policy-Based Routing

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Glossary

**CE device**—customer edge device. A device that is part of a customer network and that interfaces to a provider edge (PE) device.

**Inherit-VRF routing**—Packets arriving at a VRF interface are routed by the same outgoing VRF interface.
**Inter-VRF routing**—Packets arriving at a VRF interface are routed via any other outgoing VRF interface.

**IP**—Internet Protocol. Network layer protocol in the TCP/IP stack offering a connectionless internetwork service. IP provides features for addressing, type-of-service specification, fragmentation and reassembly, and security. Defined in RFC 791.

**PBR**—policy-based routing. PBR allows a user to manually configure how received packets should be routed.

**PE device**—provider edge device. A device that is part of a service provider’s network and that is connected to a CE device. It exchanges routing information with CE devices by using static routing or a routing protocol such as BGP, RIPv1, or RIPv2.

**VPN**—Virtual Private Network. A collection of sites sharing a common routing table. A VPN provides a secure way for customers to share bandwidth over an ISP backbone network.

**VRF**—A VPN routing and forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table.

**VRF-lite**—A feature that enables a service provider to support two or more VPNs, where IP addresses can be overlapped among the VPNs.
Basic IP Routing

This module describes how to configure basic IP routing. The Internet Protocol (IP) is a network layer (Layer 3) protocol that contains addressing information and some control information that enables packets to be routed. IP is documented in RFC 791 and is the primary network layer protocol in the Internet protocol suite.

- Information About Basic IP Routing, on page 135
- How to Configure Basic IP Routing, on page 142
- Configuration Examples for Basic IP Routing, on page 149
- Additional References, on page 163
- Feature Information for Basic IP Routing, on page 164

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Basic IP Routing

Variable-Length Subnet Masks

Enhanced Interior Gateway Routing Protocol (EIGRP), Intermediate System-to-Intermediate System (IS-IS), Open Shortest Path First (OSPF), Routing Information Protocol (RIP) Version 2, and static routes support variable-length subnet masks (VLSMs). With VLSMs, you can use different masks for the same network number on different interfaces, which allows you to conserve IP addresses and more efficiently use available address space. However, using VLSMs also presents address assignment challenges for the network administrator and ongoing administrative challenges.

Refer to RFC 1219 for detailed information about VLSMs and how to correctly assign addresses.
Consider your decision to use VLSMs carefully. You can easily make mistakes in address assignments and you will generally find that the network is more difficult to monitor using VLSMs.

The best way to implement VLSMs is to keep your existing addressing plan in place and gradually migrate some networks to VLSMs to recover address space.

**Static Routes**

Static routes are user-defined routes that cause packets moving between a source and a destination to take a specified path. Static routes can be important if the device cannot build a route to a particular destination. They are also useful for specifying a gateway of last resort to which all unroutable packets will be sent.

To configure a static route, use the `ip route prefix mask [ip-address | interface-type interface-number [ip-address]] [distance] [name] [permanent | track number] [tag tag]` global configuration command.

Static routes remain in the device configuration until you remove them (using the `no ip route` global configuration command). However, you can override static routes with dynamic routing information through prudent assignment of administrative distance values. An administrative distance is a rating of the trustworthiness of a routing information source, such as an individual router or a group of routers. Numerically, an administrative distance is an integer from 0 to 255. In general, the higher the value, the lower the trust rating. An administrative distance of 255 means the routing information source cannot be trusted at all and should be ignored.

Each dynamic routing protocol has a default administrative distance, as listed in the table below. If you want a static route to be overridden by information from a dynamic routing protocol, simply ensure that the administrative distance of the static route is higher than that of the dynamic protocol.

### Table 10: Default Administrative Distances for Dynamic Routing Protocols

</table>
Static routes that point to an interface are advertised via RIP, EIGRP, and other dynamic routing protocols, regardless of whether `redistribute static` router configuration commands are specified for those routing protocols. These static routes are advertised because static routes that point to an interface are considered in the routing table to be connected and hence lose their static nature. However, if you define a static route to an interface that is not one of the networks defined in a `network` command, no dynamic routing protocols will advertise the route unless a `redistribute static` command is specified for these protocols.

When an interface goes down, all static routes through that interface are removed from the IP routing table. Also, when the software can no longer find a valid next hop for the address specified as the address of the forwarding device in a static route, the static route is removed from the IP routing table.

A packet with an E-class source address (240.0.0.0/4) gets dropped on Cisco ASR 1000 Series Aggregation Services Routers, although RFC 1812 (Requirements for IP Version 4 Routers) defines this behavior only for destination addresses and not specifically for source addresses.

### Default Routes

Default routes, also known as gateways of last resort, are used to route packets that are addressed to networks not explicitly listed in the routing table. A device might not be able to determine routes to all networks. To provide complete routing capability, network administrators use some devices as smart devices and give the remaining devices default routes to the smart device. (Smart devices have routing table information for the entire internetwork.) Default routes can be either passed along dynamically or configured manually into individual devices.

Most dynamic interior routing protocols include a mechanism for causing a smart device to generate dynamic default information, which is then passed along to other devices.

You can configure a default route by using the following commands:

- `ip default-gateway`
- `ip default-network`
- `ip route 0.0.0.0 0.0.0.0`

You can use the `ip default-gateway` global configuration command to define a default gateway when IP routing is disabled on a device. For instance, if a device is a host, you can use this command to define a default gateway for the device. You can also use this command to transfer a Cisco software image to a device when the device is in boot mode. In boot mode, IP routing is not enabled on the device.

Unlike the `ip default-gateway` command, the `ip default-network` command can be used when IP routing is enabled on a device. When you specify a network by using the `ip default-network` command, the device considers routes to that network for installation as the gateway of last resort on the device.
Gateways of last resort configured by using the `ip default-network` command are propagated differently depending on which routing protocol is propagating the default route. For Interior Gateway Routing Protocol (IGRP) and Enhanced Interior Gateway Routing Protocol (EIGRP) to propagate the default route, the network specified by the `ip default-network` command must be known to IGRP or EIGRP. The network must be an IGRP- or EIGRP-derived network in the routing table, or the static route used to generate the route to the network must be redistributed into IGRP or EIGRP or advertised into these protocols by using the `network` command. The Routing Information Protocol (RIP) advertises a route to network 0.0.0.0 if a gateway of last resort is configured by using the `ip default-network` command. The network specified in the `ip default-network` command need not be explicitly advertised under RIP.

Creating a static route to network 0.0.0.0 0.0.0.0 by using the `ip route 0.0.0.0 0.0.0.0` command is another way to set the gateway of last resort on a device. As with the `ip default-network` command, using the static route to 0.0.0.0 is not dependent on any routing protocols. However, IP routing must be enabled on the device. IGRP does not recognize a route to network 0.0.0.0. Therefore, it cannot propagate default routes created by using the `ip route 0.0.0.0 0.0.0.0` command. Use the `ip default-network` command to have IGRP propagate a default route.

EIGRP propagates a route to network 0.0.0.0, but the static route must be redistributed into the routing protocol. Depending on your release of the Cisco software, the default route created by using the `ip route 0.0.0.0 0.0.0.0` command is automatically advertised by RIP devices. In some releases, RIP does not advertise the default route if the route is not learned via RIP. You might have to redistribute the route into RIP by using the `redistribute` command.

Default routes created using the `ip route 0.0.0.0 0.0.0.0` command are not propagated by Open Shortest Path First (OSPF) and Intermediate System to Intermediate System (IS-IS). Additionally, these default routes cannot be redistributed into OSPF or IS-IS by using the `redistribute` command. Use the `default-information originate` command to generate a default route into an OSPF or IS-IS routing domain.

### Default Network

Default networks are used to route packets to destinations not established in the routing table. You can use the `ip default-network network-number` global configuration command to configure a default network when IP routing is enabled on the device. When you configure a default network, the device considers routes to that network for installation as the gateway of last resort on the device.

### Gateway of Last Resort

When default information is being passed along through a dynamic routing protocol, no further configuration is required. The system periodically scans its routing table to choose the optimal default network as its default route. In the case of the Routing Information Protocol (RIP), there is only one choice, network 0.0.0.0. In the case of Enhanced Interior Gateway Routing Protocol (EIGRP), there might be several networks that can be candidates for the system default. Cisco software uses both administrative distance and metric information to determine the default route (gateway of last resort). The selected default route appears in the gateway of last resort display of the `show ip route` privileged EXEC command.

If dynamic default information is not being passed to the software, candidates for the default route are specified with the `ip default-network` global configuration command. In this usage, the `ip default-network` command takes an unconnected network as an argument. If this network appears in the routing table from any source (dynamic or static), it is flagged as a candidate default route and is a possible choice as the default route.

If the device has no interface on the default network, but does have a route to it, it considers this network as a candidate default path. The route candidates are examined and the best one is chosen, based on administrative distance and metric. The gateway to the best default path becomes the gateway of last resort.
Maximum Number of Paths

By default, most IP routing protocols install a maximum of four parallel routes in a routing table. Static routes always install six routes. The exception is Border Gateway Protocol (BGP), which by default allows only one path (the best path) to a destination. However, BGP can be configured to use equal and unequal cost multipath load sharing.

The number of parallel routes that you can configure to be installed in the routing table is dependent on the installed version of Cisco software. To change the maximum number of parallel paths allowed, use the `maximum-paths number-paths` command in router configuration mode.

Multi-Interface Load Splitting

Multi-interface load splitting allows you to efficiently control traffic that travels across multiple interfaces to the same destination. The `traffic-share min` router configuration command specifies that if multiple paths are available to the same destination, only paths with the minimum metric will be installed in the routing table. The number of paths allowed is never more than six. For dynamic routing protocols, the number of paths is controlled by the `maximum-paths` router configuration command. The static route source can install six paths. If more paths are available, the extra paths are discarded. If some installed paths are removed from the routing table, pending routes are added automatically.

Routing Information Redistribution

In addition to running multiple routing protocols simultaneously, Cisco software can be configured to redistribute information from one routing protocol to another. For example, you can configure a device to readvertise Enhanced Interior Gateway Routing Protocol (EIGRP)-derived routes using the Routing Information Protocol (RIP), or to readvertise static routes using the EIGRP protocol. Redistribution from one routing protocol to another can be configured in all of the IP-based routing protocols.

You also can conditionally control the redistribution of routes between routing domains by configuring route maps between the two domains. A route map is a route/packet filter that is configured with permit and deny statements, match and set clauses, and sequence numbers.

Although redistribution is a protocol-independent feature, some of the `match` and `set` commands are specific to a particular protocol.

One or more `match` commands and one or more `set` commands are configured in route map configuration mode. If there are no `match` commands, then everything matches. If there are no `set` commands, then no set action is performed.

To define a route map for redistribution, use the `route-map map-tag [permit | deny] [sequence-number]` global configuration command.

The metrics of one routing protocol do not necessarily translate into the metrics of another. For example, the RIP metric is a hop count and the EIGRP metric is a combination of five metric values. In such situations, a dynamic metric is assigned to the redistributed route. Redistribution in these cases should be applied consistently and carefully with inbound filtering to avoid routing loops.

Removing options that you have configured for the `redistribute` command requires careful use of the `no redistribute` command to ensure that you obtain the result that you are expecting.
Supported Metric Translations

This section describes supported automatic metric translations between the routing protocols. The following descriptions assume that you have not defined a default redistribution metric that replaces metric conversions:

- The Routing Information Protocol (RIP) can automatically redistribute static routes. It assigns static routes a metric of 1 (directly connected).
- The Border Gateway Protocol (BGP) does not normally send metrics in its routing updates.
- The Enhanced Interior Gateway Routing Protocol (EIGRP) can automatically redistribute static routes from other EIGRP-routed autonomous systems as long as the static route and any associated interfaces are covered by an EIGRP network statement. EIGRP assigns static routes a metric that identifies them as directly connected. EIGRP does not change the metrics of routes derived from EIGRP updates from other autonomous systems.

**Note**

Note that any protocol can redistribute routes from other routing protocols as long as a default metric is configured.

Protocol Differences in Implementing the `no redistribute` Command

**Caution**

Removing options that you have configured for the `redistribute` command requires careful use of the `no redistribute` command to ensure that you obtain the result that you are expecting. In most cases, changing or disabling any keyword will not affect the state of other keywords.

Different protocols implement the `no redistribute` command differently as follows:

- In Border Gateway Protocol (BGP), Open Shortest Path First (OSPF), and Routing Information Protocol (RIP) configurations, the `no redistribute` command removes only the specified keywords from the `redistribute` commands in the running configuration. They use the subtractive keyword method when redistributing from other protocols. For example, in the case of BGP, if you configure `no redistribute static route-map interior`, only the route map is removed from the redistribution, leaving `redistribute static` in place with no filter.

- The `no redistribute isis` command removes the Intermediate System to Intermediate System (IS-IS) redistribution from the running configuration. IS-IS removes the entire command, regardless of whether IS-IS is the redistributed or redistributing protocol.

- The Enhanced Interior Gateway Routing Protocol (EIGRP) used the subtractive keyword method prior to EIGRP component version rel5. Starting with EIGRP component version rel5, the `no redistribute` command removes the entire `redistribute` command when redistributing from any other protocol.

Sources of Routing Information Filtering

Filtering sources of routing information prioritizes routing information from different sources because some pieces of routing information might be more accurate than others. An administrative distance is a rating of the trustworthiness of a routing information source, such as an individual device or a group of devices. In a large network, some routing protocols and some devices can be more reliable than others as sources of routing...
information. Also, when multiple routing processes are running in the same device for IP, the same route could be advertised by more than one routing process. By specifying administrative distance values, you enable the device to intelligently discriminate between sources of routing information. The device always picks the route whose routing protocol has the lowest administrative distance.

There are no general guidelines for assigning administrative distances because each network has its own requirements. You must determine a reasonable matrix of administrative distances for the network as a whole.

For example, consider a device using the Enhanced Interior Gateway Routing Protocol (EIGRP) and the Routing Information Protocol (RIP). Suppose you trust the EIGRP-derived routing information more than the RIP-derived routing information. In this example, because the default EIGRP administrative distance is lower than the default RIP administrative distance, the device uses the EIGRP-derived information and ignores the RIP-derived information. However, if you lose the source of the EIGRP-derived information (because of a power shutdown at the source network, for example), the device uses the RIP-derived information until the EIGRP-derived information reappears.

You can also use administrative distance to rate the routing information from devices that are running the same routing protocol. This application is generally discouraged if you are unfamiliar with this particular use of administrative distance because it can result in inconsistent routing information, including forwarding loops.

The weight of a route can no longer be set with the distance command. To set the weight for a route, use a route map.

### Authentication Key Management and Supported Protocols

Key management is a method of controlling the authentication keys used by routing protocols. Not all protocols support key management. Authentication keys are available for Director Response Protocol (DRP) Agent, Enhanced Interior Gateway Routing Protocol (EIGRP), and Routing Information Protocol (RIP) Version 2.

You can manage authentication keys by defining key chains, identifying the keys that belong to the key chain, and specifying how long each key is valid. Each key has its own key identifier (specified using the key chain configuration command), which is stored locally. The combination of the key identifier and the interface associated with the message uniquely identifies the authentication algorithm and the message digest algorithm (MD5) authentication key in use.

You can configure multiple keys with lifetimes. Only one authentication packet is sent, regardless of how many valid keys exist. The software examines the key numbers in ascending order and uses the first valid key it encounters. The lifetimes allow for overlap during key changes.
How to Configure Basic IP Routing

Redistributing Routing Information

You can redistribute routes from one routing domain into another, with or without controlling the redistribution with a route map. To control which routes are redistributed, configure a route map and reference the route map from the `redistribute` command.

The tasks in this section describe how to define the conditions for redistributing routes (a route map), how to redistribute routes, and how to remove options for redistributing routes, depending on the protocol being used.

Defining Conditions for Redistributing Routes

Route maps can be used to control route redistribution (or to implement policy-based routing). To define conditions for redistributing routes from one routing protocol into another, configure the `route-map` command. Then use at least one `match` command in route map configuration mode, as needed. At least one `match` command is used in this task because the purpose of the task is to illustrate how to define one or more conditions on which to base redistribution.

```
Note
A route map is not required to have `match` commands; it can have only `set` commands. If there are no `match` commands, everything matches the route map.
```

There are many more `match` commands not shown in this table. For additional `match` commands, see the `Cisco IOS Master Command List`.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>match as-path path-list-number</code></td>
<td>Matches a BGP autonomous system path access list.</td>
</tr>
<tr>
<td>`match community {standard-list-number</td>
<td>Matches a BGP community.</td>
</tr>
<tr>
<td></td>
<td>expanded-list-number</td>
</tr>
<tr>
<td>`match ip address {access-list-number</td>
<td>Matches routes that have a destination network address that is permitted</td>
</tr>
<tr>
<td></td>
<td>access-list-name...</td>
</tr>
<tr>
<td></td>
<td>access-list-name</td>
</tr>
<tr>
<td><code>match metric metric-value</code></td>
<td>Matches routes with the specified metric.</td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Purpose</th>
<th>Command or Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Matches a next-hop device address passed by one of the specified access lists.</td>
<td>`match ip next-hop {access-list-number</td>
</tr>
<tr>
<td>Matches the specified tag value.</td>
<td><code>match tag tag-value [tag-value]</code></td>
</tr>
<tr>
<td>Matches routes that use the specified interface as the next hop.</td>
<td><code>match interface type number [type number]</code></td>
</tr>
<tr>
<td>Matches the address specified by the advertised access lists.</td>
<td>`match ip route-source {access-list-number</td>
</tr>
<tr>
<td>Matches the specified route type.</td>
<td>`match route-type {local</td>
</tr>
</tbody>
</table>

To optionally specify the routing actions for the system to perform if the match criteria are met (for routes that are being redistributed by the route map), use one or more `set` commands in route map configuration mode, as needed.

---

**Note**

A route map is not required to have `set` commands; it can have only `match` commands.

---

**Note**

There are more `set` commands not shown in this table. For additional `set` commands, see the *Cisco IOS Master Command List*.

**Removing Options for Redistribution Routes**

⚠️ **Caution**

Removing options that you have configured for the `redistribute` command requires careful use of the `no redistribute` command to ensure that you obtain the result that you are expecting.

Different protocols implement the `no redistribute` command differently as follows:

- In BGP, OSPF, and RIP configurations, the `no redistribute` command removes only the specified keywords from the `redistribute` commands in the running configuration. They use the *subtractive keyword* method when redistributing from other protocols. For example, in the case of BGP, if you configure `no redistribute static route-map interior`, only the route map is removed from the redistribution, leaving `redistribute static` in place with no filter.

- The `no redistribute isis` command removes the IS-IS redistribution from the running configuration. IS-IS removes the entire command, regardless of whether IS-IS is the redistributed or redistributing protocol.
• EIGRP used the subtractive keyword method prior to EIGRP component version rel5. Starting with EIGRP component version rel5, the no redistribute command removes the entire redistribute command when redistributing from any other protocol.

• For the no redistribute connected command, the behavior is subtractive if the redistribute command is configured under the router bgp or the router ospf command. The behavior is complete removal of the command if it is configured under the router isis or the router eigrp command.

The following OSPF commands illustrate how various options are removed from the redistribution in router configuration mode.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>no redistribute connected metric 1000 subnets</td>
<td>Removes the configured metric value of 1000 and the configured subnets and retains the redistribute connected command in the configuration.</td>
</tr>
<tr>
<td>no redistribute connected metric 1000</td>
<td>Removes the configured metric value of 1000 and retains the redistribute connected subnets command in the configuration.</td>
</tr>
<tr>
<td>no redistribute connected subnets</td>
<td>Removes the configured subnets and retains the redistribute connected metric metric-value command in the configuration.</td>
</tr>
<tr>
<td>no redistribute connected</td>
<td>Removes the redistribute connected command and any of the options that were configured for the command.</td>
</tr>
</tbody>
</table>

Configuring Routing Information Filtering

Note: When routes are redistributed between Open Shortest Path First (OSPF) processes, no OSPF metrics are preserved.

Controlling the Advertising of Routes in Routing Updates

To prevent other devices from learning one or more routes, you can suppress routes from being advertised in routing updates. To suppress routes from being advertised in routing updates, use the distribute-list {access-list-number | access-list-name} out [interface-name | routing-process | as-number] command in router configuration mode.
You cannot specify an interface name in Open Shortest Path First (OSPF). When used for OSPF, this feature applies only to external routes.

**Controlling the Processing of Routing Updates**

You might want to avoid processing certain routes that are listed in incoming updates (this does not apply to Open Shortest Path First [OSPF] or Intermediate System to Intermediate System [IS-IS]). To suppress routes in incoming updates, use the `distribute-list {access-list-number | access-list-name} in [interface-type interface-number]` command in router configuration mode.

**Filtering Sources of Routing Information**

To filter sources of routing information, use the `distance ip-address wildcard-mask [ip-standard-acl | ip-extended-acl | access-list-name]` command in router configuration mode.

**Managing Authentication Keys**

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `key chain name-of-chain`
4. `key number`
5. `key-string text`
6. `accept-lifetime start-time {infinite | end-time | duration seconds}`
7. `send-lifetime start-time {infinite | end-time | duration seconds}`
8. `end`
9. `show key chain`

**DETAILED STEPS**

<table>
<thead>
<tr>

### Command or Action

**Step 3**

**key chain name-of-chain**

*Example:*

Device(config)# key chain chain1

**Purpose:** Defines a key chain and enters key-chain configuration mode.

**Step 4**

**key number**

*Example:*

Device(config-keychain)# key 1

**Purpose:** Identifies number of an authentication key on a key chain. The range of keys is from 0 to 2147483647. The key identification numbers need not be consecutive.

**Step 5**

**key-string text**

*Example:*

Device(config-keychain-key)# key-string string1

**Purpose:** Identifies the key string.

**Step 6**

**accept-lifetime start-time {infinite | end-time | duration seconds}**

*Example:*

Device(config-keychain-key)# accept-lifetime 13:30:00 Dec 22 2011 duration 7200

**Purpose:** Specifies the time period during which the key can be received.

**Step 7**

**send-lifetime start-time {infinite | end-time | duration seconds}**

*Example:*

Device(config-keychain-key)# send-lifetime 14:30:00 Dec 22 2011 duration 3600

**Purpose:** Specifies the time period during which the key can be sent.

**Step 8**

**end**

*Example:*

Device(config-keychain-key)# end

**Purpose:** Exits key-chain key configuration mode and returns to privileged EXEC mode.

**Step 9**

**show key chain**

*Example:*

Device# show key chain

**Purpose:** (Optional) Displays authentication key information.

---

### Monitoring and Maintaining the IP Network

**Clearing Routes from the IP Routing Table**

You can remove all contents of a particular table. Clearing a table may become necessary when the contents of the particular structure have become, or are suspected to be, invalid.

To clear one or more routes from the IP routing table, use the `clear ip route {network [mask] | *}` command in privileged EXEC mode.

**Displaying System and Network Statistics**

You can use the following `show` commands to display system and network statistics. You can display specific statistics such as contents of IP routing tables, caches, and databases. You can also display information about
node reachability and discover the routing path that packets leaving your device are taking through the network. This information can be used to determine resource utilization and solve network problems.

<table>

Configuration Examples for Basic IP Routing

Example: Variable-Length Subnet Mask

The following example uses two different subnet masks for the class B network address of 172.16.0.0. A subnet mask of /24 is used for LAN interfaces. The /24 mask allows 265 subnets with 254 host IP addresses on each subnet. The final subnet of the range of possible subnets using a /24 mask (172.16.255.0) is reserved for use on point-to-point interfaces and assigned a longer mask of /30. The use of a /30 mask on 172.16.255.0 creates 64 subnets (172.16.255.0 to 172.16.255.252) with 2 host addresses on each subnet.

Caution: To ensure unambiguous routing, you must not assign 172.16.255.0/24 to a LAN interface in your network.

Device(config)# interface GigabitEthernet 0/0/0
Device(config-if)# ip address 172.16.1.1 255.255.255.0
Device(config-if)# ! 8 bits of host address space reserved for GigabitEthernet interfaces
Device(config-if)# exit
Device(config)# interface Serial 0/0/0
Example: Overriding Static Routes with Dynamic Protocols

In the following example, packets for network 10.0.0.0 from Device B (where the static route is installed) will be routed through 172.18.3.4 if a route with an administrative distance less than 110 is not available. The figure below illustrates this example. The route learned by a protocol with an administrative distance of less than 110 might cause Device B to send traffic destined for network 10.0.0.0 via the alternate path through Device D.

```
Device(config-if)# ip route 10.0.0.0 255.0.0.0 172.18.3.4 110
```

Figure 7: Overriding Static Routes

Example: IP Default Gateway as a Static IP Next Hop When IP Routing Is Disabled

The following example shows how to configure IP address 172.16.5.4 as the default route when IP routing is disabled:

```
Device> enable
Device# configure terminal
Device(config)# no ip routing
Device(config)# ip default-gateway 172.16.15.4
```

Examples: Administrative Distances

In the following example, the `router eigrp` global configuration command configures Enhanced Interior Gateway Routing Protocol (EIGRP) routing in autonomous system 1. The `network` command configuration specifies EIGRP routing on networks 192.168.7.0 and 172.16.0.0. The first `distance` router configuration command sets the default administrative distance to 255, which instructs the device to ignore all routing
updates from devices for which an explicit distance has not been set. The second distance command sets the administrative distance to 80 for internal EIGRP routes and to 100 for external EIGRP routes. The third distance command sets the administrative distance to 120 for the device with the address 172.16.1.3.

Device(config)# router eigrp 1
Device(config-router)# network 192.168.7.0
Device(config-router)# network 172.16.0.0
Device(config-router)# distance 255
Device(config-router)# distance eigrp 80 100
Device(config-router)# distance 120 172.16.1.3 0.0.0.0

The distance eigrp command must be used to set the administrative distance for EIGRP-derived routes.

The following example assigns the device with the address 192.168.7.18 an administrative distance of 100 and all other devices on subnet 192.168.7.0 an administrative distance of 200:

Device(config-router)# distance 100 192.168.7.18 0.0.0.0
Device(config-router)# distance 200 192.168.7.0 0.0.0.255

However, if you reverse the order of these two commands, all devices on subnet 192.168.7.0 are assigned an administrative distance of 200, including the device at address 192.168.7.18:

Device(config-router)# distance 200 192.168.7.0 0.0.0.255
Device(config-router)# distance 100 192.168.7.18 0.0.0.0

Assigning administrative distances can be used to solve unique problems. However, administrative distances should be applied carefully and consistently to avoid the creation of routing loops or other network failures.

In the following example, the distance value for IP routes learned is 90. Preference is given to these IP routes rather than routes with the default administrative distance value of 110.

Device(config)# router isis
Device(config-router)# distance 90 ip

Example: Static Routing Redistribution

In the example that follows, three static routes are specified, two of which are to be advertised. The static routes are created by specifying the redistribute static router configuration command and then specifying an access list that allows only those two networks to be passed to the Enhanced Interior Gateway Routing Protocol (EIGRP) process. Any redistributed static routes should be sourced by a single device to minimize the likelihood of creating a routing loop.

Device(config)# ip route 192.168.2.0 255.255.255.0 192.168.7.65
Device(config)# ip route 192.168.5.0 255.255.255.0 192.168.7.65
Device(config)# ip route 10.10.10.0 255.255.255.0 10.20.1.2
Device(config)# !
Device(config)# access-list 3 permit 192.168.2.0 0.0.255.255
Device(config)# access-list 3 permit 192.168.5.0 0.0.255.255
Device(config)# access-list 3 permit 10.10.10.0 0.0.0.0
Examples: EIGRP Redistribution

Each Enhanced Interior Gateway Routing Protocol (EIGRP) routing process provides routing information to only one autonomous system. The Cisco software must run a separate EIGRP process and maintain a separate routing database for each autonomous system that it services. However, you can transfer routing information between these routing databases.

In the following configuration, network 10.0.0.0 is configured under EIGRP autonomous system 1 and network 192.168.7.0 is configured under EIGRP autonomous system 101:

Device(config)# router eigrp 1
Device(config-router)# network 10.0.0.0
Device(config-router)# exit
Device(config)# router eigrp 101
Device(config-router)# network 192.168.7.0

In the following example, routes from the 192.168.7.0 network are redistributed into autonomous system 1 (without passing any other routing information from autonomous system 101):

Device(config)# access-list 3 permit 192.168.7.0
Device(config)# !
Device(config)# route-map 101-to-1 permit 10
Device(config-route-map)# match ip address 3
Device(config-route-map)# set metric 10000 100 1 255 1500
Device(config-route-map)# exit
Device(config)# router eigrp 1
Device(config-router)# redistribute eigrp 101 route-map 101-to-1
Device(config-router)# !

The following example is an alternative way to redistribute routes from the 192.168.7.0 network into autonomous system 1. Unlike the previous configuration, this method does not allow you to set the metric for redistributed routes.

Device(config)# access-list 3 permit 192.168.7.0
Device(config)# !
Device(config)# router eigrp 1
Device(config-router)# redistribute eigrp 101
Device(config-router)# distribute-list 3 out eigrp 101
Device(config-router)# !

Example: Mutual Redistribution Between EIGRP and RIP

Consider a WAN at a university that uses the Routing Information Protocol (RIP) as an interior routing protocol. Assume that the university wants to connect its WAN to regional network 172.16.0.0, which uses the Enhanced Interior Gateway Routing Protocol (EIGRP) as the routing protocol. The goal in this case is to advertise the networks in the university network to devices in the regional network.

Mutual redistribution is configured between EIGRP and RIP in the following example:
Device(config)# access-list 10 permit 172.16.0.0
Device(config)#!
Device(config)# router eigrp 1
Device(config-router)# network 172.16.0.0
Device(config-router)# redistribute rip metric 10000 100 255 1 1500
Device(config-router)# default-metric 10
Device(config-router)# distribute-list 10 out rip
Device(config-router)# exit
Device(config)# router rip
Device(config-router)# redistribute eigrp 1
Device(config-router)#!

In this example, an EIGRP routing process is started. The network router configuration command specifies that network 172.16.0.0 (the regional network) is to send and receive EIGRP routing information. The redistribute router configuration command specifies that RIP-derived routing information be advertised in routing updates. The default-metric router configuration command assigns an EIGRP metric to all RIP-derived routes. The distribute-list router configuration command instructs the Cisco software to use access list 10 (not defined in this example) to limit the entries in each outgoing update. The access list prevents unauthorized advertising of university routes to the regional network.

Example: Mutual Redistribution Between EIGRP and BGP

In the following example, mutual redistribution is configured between the Enhanced Interior Gateway Routing Protocol (EIGRP) and the Border Gateway Protocol (BGP).

Routes from EIGRP routing process 101 are injected into BGP autonomous system 50000. A filter is configured to ensure that the correct routes are advertised, in this case, three networks. Routes from BGP autonomous system 50000 are injected into EIGRP routing process 101. The same filter is used.

Device(config)# ! All networks that should be advertised from R1 are controlled with ACLs:
Device(config)# access-list 1 permit 172.18.0.0 0.0.255.255
Device(config)# access-list 1 permit 172.16.0.0 0.0.255.255
Device(config)# access-list 1 permit 172.25.0.0 0.0.255.255
Device(config)#!
Device(config-router)# router bgp 50000
Device(config-router)# network 172.18.0.0
Device(config-router)# network 172.16.0.0
Device(config-router)# neighbor 192.168.10.1 remote-as 2
Device(config-router)# neighbor 192.168.10.15 remote-as 1
Device(config-router)# neighbor 192.168.10.24 remote-as 3
Device(config-router)# redistribute eigrp 101
Device(config-router)# distribute-list 1 out eigrp 101
Device(config-router)#!
Device(config-router)# router eigrp 101
Device(config-router)# network 172.25.0.0
Device(config-router)# redistribute bgp 50000
Device(config-router)# distribute-list 1 out bgp 50000
Device(config-router)#!

Caution

BGP should be redistributed into an Interior Gateway Protocol (IGP) when there are no other suitable options. Redistribution from BGP into any IGP should be applied with proper filtering by using distribute lists, IP prefix lists, and route map statements to limit the number of prefixes.
Examples: OSPF Routing and Route Redistribution

OSPF typically requires coordination among many internal devices, area border routers (ABRs), and Autonomous System Boundary Routers (ASBRs). At a minimum, OSPF-based devices can be configured with all default parameter values, with no authentication, and with interfaces assigned to areas.

This section provides the following configuration examples:

- The first example shows simple configurations illustrating basic OSPF commands.
- The second example shows configurations for an internal device, ABR, and ASBR within a single, arbitrarily assigned OSPF autonomous system.
- The third example illustrates a more complex configuration and the application of various tools available for controlling OSPF-based routing environments.

Examples: Basic OSPF Configuration

The following example illustrates a simple OSPF configuration that enables OSPF routing process 1, attaches Gigabit Ethernet interface 0/0/0 to area 0.0.0.0, and redistributes RIP into OSPF and OSPF into RIP:

```
Device(config)# interface GigabitEthernet 0/0/0
Device(config-if)# ip address 172.16.1.1 255.255.255.0
Device(config-if)# ip ospf cost 1
Device(config-if)# exit
Device(config)# interface GigabitEthernet 1/0/0
Device(config-if)# ip address 172.17.1.1 255.255.255.0
Device(config-if)# exit
Device(config)# router ospf 1
Device(config-router)# network 172.18.0.0 0.0.255.255 area 0.0.0.0
Device(config-router)# redistribute rip metric 1 subnets
Device(config-router)# exit
Device(config)# router rip
Device(config-router)# network 172.17.0.0
Device(config-router)# redistribute ospf 1
Device(config-router)# default-metric 1
Device(config-router)# !
```

The following example illustrates the assignment of four area IDs to four IP address ranges. In the example, OSPF routing process 1 is initialized, and four OSPF areas are defined: 10.9.50.0, 2, 3, and 0. Areas 10.9.50.0, 2, and 3 mask specific address ranges, whereas area 0 enables OSPF for all other networks.

```
Device(config)# router ospf 1
Device(config-router)# network 172.18.20.0 0.0.0.255 area 10.9.50.0
Device(config-router)# network 172.18.0.0 0.0.255.255 area 2
Device(config-router)# network 172.19.10.0 0.0.0.255 area 3
Device(config-router)# network 0.0.0.0 255.255.255.255 area 0
Device(config-router)# exit
Device(config)# ! GigabitEthernet interface 0/0/0 is in area 10.9.50.0:
Device(config)# interface GigabitEthernet 0/0/0
Device(config-if)# ip address 172.18.20.5 255.255.255.0
Device(config-if)# exit
Device(config)# ! GigabitEthernet interface 1/0/0 is in area 2:
Device(config)# interface GigabitEthernet 1/0/0
Device(config-if)# ip address 172.18.1.1 255.255.255.0
Device(config-if)# exit
Device(config)# ! GigabitEthernet interface 2/0/0 is in area 2:
Device(config)# interface GigabitEthernet 2/0/0
```
Device(config-if)# ip address 172.18.2.5 255.255.255.0
Device(config)# ! GigabitEthernet interface 3/0/0 is in area 3:
Device(config)# interface GigabitEthernet 3/0/0
Device(config-if)# ip address 172.19.10.5 255.255.255.0
Device(config-if)# exit
Device(config)# ! GigabitEthernet interface 4/0/0 is in area 0:
Device(config)# interface GigabitEthernet 4/0/0
Device(config-if)# ip address 172.19.1.1 255.255.255.0
Device(config-if)# exit
Device(config)# ! GigabitEthernet interface 5/0/0 is in area 0:
Device(config)# interface GigabitEthernet 5/0/0
Device(config-if)# ip address 10.1.0.1 255.255.0.0
Device(config-if)# !

Each network router configuration command is evaluated sequentially, so the specific order of these commands in the configuration is important. The Cisco software sequentially evaluates the address/wildcard-mask pair for each interface. See the IP Routing Protocols Command Reference for more information.

Consider the first network command. Area ID 10.9.50.0 is configured for the interface on which subnet 172.18.20.0 is located. Assume that a match is determined for Gigabit Ethernet interface 0/0/0. Gigabit Ethernet interface 0/0/0 is attached to Area 10.9.50.0 only.

The second network command is evaluated next. For Area 2, the same process is then applied to all interfaces (except Gigabit Ethernet interface 0/0/0). Assume that a match is determined for Gigabit Ethernet interface 1/0/0. OSPF is then enabled for that interface, and Gigabit Ethernet 1/0/0 is attached to Area 2.

This process of attaching interfaces to OSPF areas continues for all network commands. Note that the last network command in this example is a special case. With this command, all available interfaces (not explicitly attached to another area) are attached to Area 0.

Example: Internal Device ABR and ASBRs Configuration

The figure below provides a general network map that illustrates a sample configuration for several devices within a single OSPF autonomous system.
In this configuration, five devices are configured in OSPF autonomous system 1:

- Device A and Device B are both internal devices within area 1.
- Device C is an OSPF ABR. Note that for Device C, area 1 is assigned to E3 and Area 0 is assigned to S0.
- Device D is an internal device in area 0 (backbone area). In this case, both `network` router configuration commands specify the same area (area 0, or the backbone area).
- Device E is an OSPF ASBR. Note that the Border Gateway Protocol (BGP) routes are redistributed into OSPF and that these routes are advertised by OSPF.
Definitions of all areas in an OSPF autonomous system need not be included in the configuration of all devices in the autonomous system. You must define only the directly connected areas. In the example that follows, routes in Area 0 are learned by the devices in area 1 (Device A and Device B) when the ABR (Device C) injects summary link state advertisements (LSAs) into area 1.

Autonomous system 60000 is connected to the outside world via the BGP link to the external peer at IP address 172.16.1.6.

Following is the sample configuration for the general network map shown in the figure above.

**Device A Configuration—Internal Device**

Device(config)# interface GigabitEthernet 1/0/0
Device(config-if)# ip address 192.168.1.1 255.255.255.0
Device(config-if)# exit
Device(config)# router ospf 1
Device(config-router)# network 192.168.1.0 0.0.0.255 area 1
Device(config-router)# exit

**Device B Configuration—Internal Device**

Device(config)# interface GigabitEthernet 2/0/0
Device(config-if)# ip address 192.168.1.2 255.255.255.0
Device(config-if)# exit
Device(config)# router ospf 1
Device(config-router)# network 192.168.1.0 0.0.0.255 area 1
Device(config-router)# exit

**Device C Configuration—ABR**

Device(config)# interface GigabitEthernet 3/0/0
Device(config-if)# ip address 192.168.1.3 255.255.255.0
Device(config-if)# exit
Device(config)# interface Serial 0/0/0
Device(config-if)# ip address 192.168.2.3 255.255.255.0
Device(config-if)# exit
Device(config)# router ospf 1
Device(config-router)# network 192.168.1.0 0.0.0.255 area 1
Device(config-router)# network 192.168.2.0 0.0.0.255 area 0
Device(config-router)# exit

**Device D Configuration—Internal Device**

Device(config)# interface GigabitEthernet 4/0/0
Device(config-if)# ip address 10.0.0.4 255.0.0.0
Device(config-if)# exit
Device(config)# interface Serial 1/0/0
Device(config-if)# ip address 192.168.2.4 255.255.255.0
Device(config-if)# exit
Device(config)# router ospf 1
Device(config-router)# network 192.168.2.0 0.0.0.255 area 0
Device(config-router)# network 10.0.0.0 0.255.255.255 area 0
Device(config-router)# exit
Example: Complex OSPF Configuration

The following sample configuration accomplishes several tasks in setting up an ABR. These tasks can be split into two general categories:

- Basic OSPF configuration
- Route redistribution

The specific tasks outlined in this configuration are detailed briefly in the following descriptions. The figure below illustrates the network address ranges and area assignments for the interfaces.

**Figure 9: Interface and Area Specifications for OSPF Configuration Example**

The basic configuration tasks in this example are as follows:

- Configure address ranges for Gigabit Ethernet interface 0/0/0 through Gigabit Ethernet interface 3/0/0.
- Enable OSPF on each interface.
- Set up an OSPF authentication password for each area and network.
- Assign link-state metrics and other OSPF interface configuration options.
• Create a stub area with area ID 10.0.0.0. (Note that the **authentication** and **stub** options of the **area** router configuration command are specified with separate **area** command entries, but they can be merged into a single **area** command.)

• Specify the backbone area (area 0).

Configuration tasks associated with redistribution are as follows:

• Redistribute the Enhanced Interior Gateway Routing Protocol (EIGRP) and the Routing Information Protocol (RIP) into OSPF with various options set (including metric-type, metric, tag, and subnet).

• Redistribute EIGRP and OSPF into RIP.

The following is an example OSPF configuration:

```plaintext
Device(config)# interface GigabitEthernet 0/0/0
Device(config-if)# ip address 192.168.110.201 255.255.255.0
Device(config-if)# ip ospf authentication-key abcdefgh
Device(config-if)# ip ospf cost 10
Device(config-if)# exit
Device(config)# interface GigabitEthernet 1/0/0
Device(config-if)# ip address 172.19.251.201 255.255.255.0
Device(config-if)# ip ospf authentication-key ijklmnop
Device(config-if)# ip ospf cost 20
Device(config-if)# ip ospf retransmit-interval 10
Device(config-if)# ip ospf transmit-delay 2
Device(config-if)# ip ospf priority 4
Device(config-if)# exit
Device(config)# interface GigabitEthernet 2/0/0
Device(config-if)# ip address 172.19.254.201 255.255.255.0
Device(config-if)# ip ospf authentication-key abcdefgh
Device(config-if)# ip ospf cost 10
Device(config-if)# exit
Device(config)# interface GigabitEthernet 3/0/0
Device(config-if)# ip address 10.56.0.201 255.255.0.0
Device(config-if)# ip ospf authentication-key ijklmnop
Device(config-if)# ip ospf cost 20
Device(config-if)# ip ospf dead-interval 80
Device(config-if)# exit

In the following configuration, OSPF is on network 172.19.0.0:

```plaintext
Device(config)# router ospf 1
Device(config-router)# network 10.0.0.0 0.255.255.255 area 10.0.0.0
Device(config-router)# network 192.168.110.0 0.0.0.255 area 192.168.110.0
Device(config-router)# network 172.19.0.0 0.0.255.255 area 0
Device(config-router)# area 0 authentication
Device(config-router)# area 10.0.0.0 stub
Device(config-router)# area 10.0.0.0 authentication
Device(config-router)# area 10.0.0.0 default-cost 20
Device(config-router)# area 192.168.110.0 authentication
Device(config-router)# area 10.0.0.0 range 10.0.0.0 255.0.0.0
Device(config-router)# area 192.168.110.0 range 192.168.110.0 255.255.255.0
Device(config-router)# area 0 range 172.19.251.0 255.255.255.0
Device(config-router)# area 0 range 172.19.254.0 255.255.255.0
Device(config-router)# redistribute eigrp 200 metric-type 2 metric 1 tag 200 subnets
Device(config-router)# redistribute rip metric-type 2 metric 1 tag 200
Device(config-router)# exit

In the following configuration, EIGRP autonomous system 1 is on 172.19.0.0:

```plaintext
Device(config-router)# redistribute eigrp 200 metric-type 2 metric 1 tag 200 subnets
Device(config-router)# redistribute rip metric-type 2 metric 1 tag 200
Device(config-router)# exit
```
Example: Default Metric Values Redistribution

The following example shows a device in autonomous system 1 that is configured to run both the Routing Information Protocol (RIP) and the Enhanced Interior Gateway Routing Protocol (EIGRP). The example advertises EIGRP-derived routes using RIP and assigns the EIGRP-derived routes a RIP metric of 10.

Example: Redistribution With and Without Route Maps

The examples in this section illustrate the use of redistribution, with and without route maps. Examples from both the IP and Connectionless Network Service (CLNS) routing protocols are given. The following example redistributes all Open Shortest Path First (OSPF) routes into the Enhanced Interior Gateway Routing Protocol (EIGRP):

The following example redistributes Routing Information Protocol (RIP) routes with a hop count equal to 1 into OSPF. These routes will be redistributed into OSPF as external link state advertisements (LSAs) with a metric of 5, metric a type of type 1, and a tag equal to 1.

The following example redistributes OSPF learned routes with tag 7 as a RIP metric of 15:
The following example redistributes OSPF intra-area and interarea routes with next hop devices on serial interface 0/0/0 into the Border Gateway Protocol (BGP) with an INTER_AS metric of 5:

Device(config)# router bgp 50000
Device(config-router)# redistribute ospf 1 route-map 10
Device(config-router)# exit
Device(config)# route-map 10 permit
Device(config-router)# match route-type internal
Device(config-router)# match interface serial 0/0/0
Device(config-router)# set metric 5

The following example redistributes two types of routes into the integrated IS-IS routing table (supporting both IP and CLNS). The first type is OSPF external IP routes with tag 5; these routes are inserted into Level 2 IS-IS link-state packets (LSPs) with a metric of 5. The second type is ISO-IGRP derived CLNS prefix routes that match CLNS access list 2000; these routes will be redistributed into IS-IS as Level 2 LSPs with a metric of 30.

Device(config)# router isis
Device(config-router)# redistribute ospf 1 route-map 2
Device(config-router)# redistribute is-o-igrp nsfnet route-map 3
Device(config-router)# exit
Device(config)# route-map 2 permit
Device(config-router)# match route-type external
Device(config-router)# match tag 5
Device(config-router)# set metric 5
Device(config-router)# set level level-2
Device(config-router)# exit
Device(config)# route-map 3 permit
Device(config-router)# match address 2000
Device(config-router)# set metric 30
Device(config-router)# exit

With the following configuration, OSPF external routes with tags 1, 2, 3, and 5 are redistributed into RIP with metrics of 1, 1, 5, and 5, respectively. The OSPF routes with a tag of 4 are not redistributed.

Device(config)# router rip
Device(config-router)# redistribute ospf 101 route-map 1
Device(config-router)# exit
Device(config)# route-map 1 permit
Device(config-router)# match tag 1 2
Device(config-router)# set metric 1
Device(config-router)# exit
Device(config)# route-map 1 permit
Device(config-router)# match tag 3
Device(config-router)# set metric 5
Device(config-router)# exit
Device(config)# route-map 1 deny
Device(config-router)# match tag 4
Device(config-router)# exit

Given the following configuration, a RIP learned route for network 172.18.0.0 and an ISO-IGRP learned route with prefix 49.0001.0002 will be redistributed into an IS-IS Level 2 LSP with a metric of 5:

Device(config)# router isis
Device(config-router)# redistribute rip route-map 1
Device(config-router)# redistribute iso-igrp remote route-map 1
Device(config-router)# exit
Device(config)# route-map 1 permit
Device(config-route-map)# match ip address 1
Device(config-route-map)# match clns address 2
Device(config-route-map)# set metric 5
Device(config-route-map)# set level level-2
Device(config-route-map)# exit
Device(config)# access-list 1 permit 172.18.0.0 0.0.255.255
Device(config)# clns filter-set 2 permit 49.0001.0002...

The following configuration example illustrates how a route map is referenced by the `default-information` router configuration command. This type of reference is called conditional default origination. OSPF will originate the default route (network 0.0.0.0) with a type 2 metric of 5 if 172.20.0.0 is in the routing table.

Device(config)# route-map ospf-default permit
Device(config-route-map)# match ip address 1
Device(config-route-map)# set metric 5
Device(config-route-map)# set metric-type type-2
Device(config-route-map)# exit
Device(config)# access-list 1 172.20.0.0 0.0.255.255
Device(config)# router ospf 101
Device(config-router)# default-information originate route-map ospf-default

Examples: Key Management

The following example configures a key chain named chain1. In this example, the software always accepts and sends key1 as a valid key. The key key2 is accepted from 1:30 p.m. to 3:30 p.m. and is sent from 2:00 p.m. to 3:00 p.m. The overlap allows for migration of keys or discrepancy in the set time of the device. Likewise, the key key3 immediately follows key2, and there is 30-minutes on each side to handle time-of-day differences.

Device(config)# interface GigabitEthernet 0/0/0
Device(config-if)# ip rip authentication key-chain chain1
Device(config-if)# ip rip authentication mode md5
Device(config-if)# exit
Device(config)# router rip
Device(config-router)# network 172.19.0.0
Device(config-router)# version 2
Device(config-router)# exit
Device(config)# key chain chain1
Device(config-keychain)# key 1
Device(config-keychain-key)# key-string key1
Device(config-keychain-key)# exit
Device(config-keychain)# key 2
Device(config-keychain-key)# key-string key2
Device(config-keychain-key)# accept-lifetime 13:30:00 Jan 25 2005 duration 7200
Device(config-keychain-key)# send-lifetime 14:00:00 Jan 25 2005 duration 3600
Device(config-keychain-key)# exit
Device(config-keychain)# key 3
Device(config-keychain-key)# key-string key3
Device(config-keychain-key)# accept-lifetime 14:30:00 Jan 25 2005 duration 7200
Device(config-keychain-key)# send-lifetime 15:00:00 Jan 25 2005 duration 3600
Device(config-keychain-key)# end

The following example configures a key chain named chain1:
Device(config)# key chain chain1
Device(config-keychain)# key 1
Device(config-keychain-key)# key-string key1
Device(config-keychain-key)# exit
Device(config-keychain)# key 2
Device(config-keychain-key)# key-string key2
Device(config-keychain-key)# accept-lifetime 00:00:00 Dec 5 2004 23:59:59 Dec 5 2005
Device(config-keychain-key)# send-lifetime 06:00:00 Dec 5 2004 18:00:00 Dec 5 2005
Device(config-keychain-key)# exit
Device(config-keychain)# exit
Device(config)# interface GigabitEthernet 0/0/0
Device(config-if)# ip address 172.19.104.75 255.255.255.0 secondary 172.19.232.147 255.255.255.240
Device(config-if)# ip rip authentication key-chain chain1
Device(config-if)# media-type 10BaseT
Device(config-if)# exit
Device(config)# interface GigabitEthernet 1/0/0
Device(config-if)# no ip address
Device(config-if)# shutdown
Device(config-if)# media-type 10BaseT
Device(config-if)# exit
Device(config)# interface Fddi 0
Device(config-if)# ip address 10.1.1.1 255.255.255.0
Device(config-if)# no keepalive
Device(config-if)# exit
Device(config)# interface Fddi 1/0/0
Device(config-if)# ip address 172.16.1.1 255.255.255.0
Device(config-if)# ip rip send version 1
Device(config-if)# ip rip receive version 1
Device(config-if)# no keepalive
Device(config-if)# exit
Device(config)# router rip
Device(config-router)# version 2
Device(config-router)# network 172.19.0.0
Device(config-router)# network 10.0.0.0
Device(config-router)# network 172.16.0.0

Feature Information for Basic IP Routing

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Multi-VRF Support

The Multi-VRF Support feature allows you to configure and maintain more than one instance of a routing and forwarding table within the same customer edge (CE) device.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Multi-VRF Support

The network’s core and provider edge (PE) devices must be configured for Virtual Private Network (VPN) operation.

Restrictions for Multi-VRF Support

- You can configure the Multi-VRF Support feature only on Layer 3 interfaces.
- The Multi-VRF Support feature is not supported by Interior Gateway Routing Protocol (IGRP) nor Intermediate System to Intermediate System (IS-IS).
Label distribution for a given VPN routing and forwarding (VRF) instance on a given device can be handled by either Border Gateway Protocol (BGP) or Label Distribution Protocol (LDP), but not by both protocols at the same time.

Multicast cannot operate on a Layer 3 interface that is configured with the Multi-VRF Support feature.

Information About Multi-VRF Support

How the Multi-VRF Support Feature Works

The Multi-VRF Support feature enables a service provider to support two or more Virtual Private Networks (VPNs), where the IP addresses can overlap several VPNs. The Multi-VRF Support feature uses input interfaces to distinguish routes for different VPNs and forms virtual packet-forwarding tables by associating one or more Layer 3 interfaces with each virtual routing and forwarding (VRF) instance. Interfaces in a VRF can be either physical, such as FastEthernet ports, or logical, such as VLAN, but a Layer 3 interface cannot belong to more than one VRF at any one time. The Multi-VRF Support feature allows an operator to support two or more routing domains on a customer edge (CE) device, with each routing domain having its own set of interfaces and its own set of routing and forwarding tables. The Multi-VRF Support feature makes it possible to extend the label switched paths (LSPs) to the CE and into each routing domain that the CE supports.

The Multi-VRF Support feature works as follows:

• Each CE device advertises its site’s local routes to a provider edge (PE) device and learns the remote VPN routes from that provider edge (PE) device.

• PE devices exchange routing information with CE devices by using static routing or a routing protocol such as the Border Gateway Protocol (BGP), Routing Information Protocol version 1 (RIPv1), or RIPv2.

• PE devices exchange MPLS label information with CE devices through Label Distribution Protocol (LDP) or BGP.

• The PE device needs to maintain VPN routes only for those VPNs to which it is directly attached, eliminating the requirement that the PE maintain all of the service provider’s VPN routes. Each PE device maintains a VRF for each of its directly connected sites. Two or more interfaces on a PE device can be associated with a single VRF if all the sites participate in the same VPN. Each VPN is mapped to a specified VRF. After learning local VPN routes from CE devices, the PE device exchanges VPN routing information with other PE devices through internal BGP (iBGP).

With the Multi-VRF Support feature, two or more customers can share one CE device, and only one physical link is used between the CE and the PE devices. The shared CE device maintains separate VRF tables for each customer and routes packets for each customer based on that customer’s own routing table. The Multi-VRF Support feature extends limited PE device functionality to a CE device, giving it the ability, through the maintenance of separate VRF tables, to extend the privacy and security of a VPN to the branch office.

The figure below shows a configuration where each CE device acts as if it were two CE devices. Because the Multi-VRF Support feature is a Layer 3 feature, each interface associated with a VRF must be a Layer 3 interface.
How Packets Are Forwarded in a Network Using the Multi-VRF Support Feature

Following is the packet-forwarding process in an Multi-VRF customer edge (CE)-enabled network, as illustrated in the figure above:

• When the CE receives a packet from a Virtual Private Network (VPN), it looks up the routing table based on the input interface. When a route is found, the CE imposes the Multiprotocol Label Switching (MPLS) label that it received from the provider edge (PE) for that route and forwards the packet to the PE.

• When the ingress PE receives a packet from the CE, it swaps the incoming label with the corresponding label stack and sends the packet to the MPLS network.

• When an egress PE receives a packet from the network, it swaps the VPN label with the label that it had earlier received for the route from the CE, and it forwards the packet to the CE.

• When a CE receives a packet from an egress PE, it uses the incoming label on the packet to forward the packet to the correct VPN.

To configure Multi-VRF, you create a VRF table and then specify the Layer 3 interface associated with that VRF. Next, you configure the routing protocols within the VPN, and between the CE and the PE. The Border Gateway Protocol (BGP) is the preferred routing protocol for distributing VPN routing information across the provider’s backbone.

The Multi-VRF network has three major components:

• VPN route target communities: These are lists of all other members of a VPN community. You must configure VPN route targets for each VPN community member.

• Multiprotocol BGP peering of VPN community PE devices: This propagates VRF reachability information to all members of a VPN community. You must configure BGP peering in all PE devices within a VPN community.

• VPN forwarding: This transports all traffic between VPN community members across a VPN service-provider network.
Considerations When Configuring the Multi-VRF Support Feature

- A device with the Multi-VRF Support feature is shared by several customers, and each customer has its own routing table.
- Because each customer uses a different virtual routing and forwarding (VRF) table, the same IP addresses can be reused. Overlapping IP addresses are allowed in different Virtual Private Networks (VPNs).
- The Multi-VRF Support feature lets several customers share the same physical link between the provider edge (PE) and the customer edge (CE) devices. Trunk ports with several VLANs separate packets among the customers. Each customer has its own VLAN.
- For the PE device, there is no difference between using the Multi-VRF Support feature or using several CE devices.
- The Multi-VRF Support feature does not affect the packet-switching rate.

How to Configure Multi-VRF Support

Configuring VRFs

To configure virtual routing and forwarding (VRF) instances, complete the following procedure. Be sure to configure VRFs on both the provider edge (PE) and customer edge (CE) devices.

If a VRF has not been configured, the device has the following default configuration:
- No VRFs have been defined.
- No import maps, export maps, or route maps have been defined.
- No VRF maximum routes exist.
- Only the global routing table exists on the interface.

The following are the supported flavors of multicast over VRF on Cisco ASR 920 RSP2 module:
- Multicast with multi-VRF (MPLS VPN/MLDP)
- Multicast with GRE tunnel (MVPN GRE)
- Multicast with VRF-lite

Note

Multi-VRF/MVPN GRE configured layer-3 interface cannot participate in more than one VRF at the same time.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip routing
4. `ip vrf vrf-name`
5. `rd route-distinguisher`
6. `route-target {export | import | both} route-target-ext-community`
7. `import map route-map`
8. `exit`
9. `interface type slot/subslot/port[/subinterface]`
10. `ip vrf forwarding vrf-name`
11. `end`
12. `show ip vrf`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**
  `enable`
  **Example:**
  `Device> enable`
| Enables privileged EXEC mode.
  • Enter your password if prompted. |
| **Step 2**
  `configure terminal`
  **Example:**
  `Device# configure terminal`
| Enters global configuration mode. |
| **Step 3**
  `ip routing`
  **Example:**
  `Device(config)# ip routing`
| Enables IP routing. |
| **Step 4**
  `ip vrf vrf-name`
  **Example:**
  `Device(config)# ip vrf v1`
| Names the VRF, and enters VRF configuration mode. |
| **Step 5**
  `rd route-distinguisher`
  **Example:**
  `Device(config-vrf)# rd 100:1`
| Creates a VRF table by specifying a route distinguisher.
  Enter either an autonomous system number and an arbitrary number (xxx:y), or an IP address and an arbitrary number (A.B.C.D:y). |
| **Step 6**
  `route-target {export | import | both} route-target-ext-community`
  **Example:**
  `Device(config-vrf)# route-target export 100:1`
| Creates a list of import, export, or import and export route target communities for the specified VRF.
  Enter either an autonomous system number and an arbitrary number (xxx:y), or an IP address and an arbitrary number (A.B.C.D:y). |

**Note** This command works only if BGP is running.
### Configuring BGP as the Routing Protocol

Most routing protocols can be used between the customer edge (CE) and the provider edge (PE) devices. However, external BGP (eBGP) is recommended, because:

- BGP does not require more than one algorithm to communicate with many CE devices.
- BGP is designed to pass routing information between systems run by different administrations.
- BGP makes it easy to pass route attributes to the CE device.

When BGP is used as the routing protocol, it can also be used to handle the Multiprotocol Label Switching (MPLS) label exchange between the PE and CE devices. By contrast, if Open Shortest Path First (OSPF), Enhanced Interior Gateway Routing Protocol (EIGRP), Routing Information Protocol (RIP), or static routing is used, the Label Distribution Protocol (LDP) must be used to signal labels.

To configure a BGP PE-to-CE routing session, perform the following steps on the CE and on the PE devices.

<table>
<thead>
<tr>
<th>Step</th>

</tbody>
</table>
### Command or Action

**Step 7**

- `address-family ipv4 vrf vrf-name`

  **Example:**
  
  Device(config-router)# address-family ipv4 vrf v12

  **Purpose:**
  Identifies the name of the virtual routing and forwarding (VRF) instance that will be associated with the next two commands, and enters VRF address-family mode.

**Step 8**

- `neighbor {ip-address | peer-group-name} remote-as as-number`

  **Example:**
  
  Device(config-router-af)# neighbor 10.0.0.3 remote-as 100

  **Purpose:**
  Informs this device’s BGP neighbor table of the neighbor’s address (or peer group name) and the neighbor’s autonomous system number.

**Step 9**

- `neighbor address activate`

  **Example:**
  
  Device(config-router-af)# neighbor 10.0.0.3 activate

  **Purpose:**
  Activates the advertisement of the IPv4 address-family neighbors.

---

### Configuring PE-to-CE MPLS Forwarding and Signaling with BGP

If the Border Gateway Protocol (BGP) is used for routing between the provider edge (PE) and the customer edge (CE) devices, configure BGP to signal the labels on the virtual routing and forwarding (VRF) interfaces of both the CE and the PE devices. You must enable signalling globally at the router-configuration level and for each interface:

- At the router-configuration level, to enable Multiprotocol Label Switching (MPLS) label signalling via BGP, use the `neighbor send-label` command.

- At the interface level, to enable MPLS forwarding on the interface used for the PE-to-CE external BGP (eBGP) session, use the `mpls bgp forwarding` command.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `router bgp autonomous-system-number`
4. `address-family ipv4 vrf vrf-name`
5. `neighbor address send-label`
6. `neighbor address activate`
7. `end`
8. `configure terminal`
9. `interface type slot/subslot/port[,subinterface]`
10. `mpls bgp forwarding`

</table>
Configuring a Routing Protocol Other than BGP

You can use the Routing Information Protocol (RIP), Enhanced Interior Gateway Routing Protocol (EIGRP), Open Shortest Path First (OSPF), or static routing. This configuration uses OSPF, but the process is the same for other protocols.

If you use OSPF as the routing protocol between the provider edge (PE) and the customer edge (CE) devices, issue the `capability vrf-lite` command in router configuration mode.

**Note**

If RIP EIGRP, OSPF or static routing is used, the Label Distribution Protocol (LDP) must be used to signal labels.

The Multi-VRF Support feature is not supported by Interior Gateway Routing Protocol (IGRP) or Intermediate System-to-Intermediate System (IS-IS).

Multicast cannot be configured on the same Layer 3 interface as the Multi-VRF Support feature is configured.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `router ospf process-id [vrf vpn-name]`
4. `log-adjacency-changes`
5. `redistribute bgp autonomous-system-number subnets`
6. `network ip-address subnet-mask area area-id`
7. `end`
8. `show ip ospf`

### Purpose

**Command or Action**

Device# configure terminal

#### Step 3

**Command or Action**

router ospf process-id [vrf vpn-name]

**Example:**

Device(config)# router ospf 100 vrf v1

---

#### Step 4

**Command or Action**

log-adjacency-changes

**Example:**

Device(config-router)# log-adjacency-changes

---

#### Step 5

**Command or Action**

redistribute bgp autonomous-system-number subnets

**Example:**

Device(config-router)# redistribute bgp 800 subnets

---

#### Step 6

**Command or Action**

network ip-address subnet-mask area area-id

**Example:**

Device(config-router)# network 10.0.0.0 255.255.255.0 area 0

---

#### Step 7

**Command or Action**

end

**Example:**

Device(config-router)# end

---

#### Step 8

**Command or Action**

show ip ospf

**Example:**

Device# show ip ospf

---

### Configuring PE-to-CE MPLS Forwarding and Signaling with LDP

#### SUMMARY STEPS

1. enable
2. configure terminal
3. interface type slot/subslot/port/subinterface
4. mpls ip

#### DETAILED STEPS

**Command or Action**

enable

**Purpose**

Enables privileged EXEC mode.
<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

**Step 2**

**Example:**

Device# configure terminal

Enters global configuration mode.

**Step 3**

**Example:**

Device(config)# interface type slot/subslot/port [subinterface]

Enters interface configuration mode for the interface associated with the VRF. The interface can be a routed port or an .

**Step 4**

**Example:**

Device(config-if)# mpls ip

Enables MPLS forwarding of IPv4 packets along normally routed paths for this interface.

---

**Configuration Examples for Multi-VRF Support**

The figure below is an example of a Multi-VRF topology.

**Example: Configuring Multi-VRF Support on the PE Device**

The following example shows how to configure a VRF:

```
configure terminal
ip vrf v1
  rd 100:1
  route-target export 100:1
  route-target import 100:1
  exit
ip vrf v2
  rd 100:2
  route-target export 100:2
  route-target import 100:2
  exit
```

The following example shows how to configure on PE device, PE-to-CE connections using BGP for both routing and label exchange:

The following example shows how to configure on PE device, PE-to-CE connections using OSPF for routing and LDP for label exchange:

**Example: Configuring Multi-VRF Support on the CE Device**

The following example shows how to configure VRFs:
configure terminal
ip routing
ip vrf v11
rd 800:1
route-target export 800:1
route-target import 800:1
exit
ip vrf v12
rd 800:2
route-target export 800:2
route-target import 800:2
exit

The following example shows how to configure CE device VPN connections:

interface
ip vrf forwarding v11
ip address 10.0.0.8 255.255.255.0
exit
interface
ip vrf forwarding v12
ip address 10.0.0.8 255.255.255.0
exit
router ospf 1 vrf v11
network 10.0.0.0 255.255.255.0 area 0
network 10.0.0.0 255.255.255.0 area 0
exit
router ospf 2 vrf v12
network 10.0.0.0 255.255.255.0 area 0
network 10.0.0.0 255.255.255.0 area 0
exit

If BGP is used for routing between the PE and CE devices, the BGP-learned routes from the PE device can be redistributed into OSPF using the commands in the following example.

router ospf 1 vrf v11
redistribute bgp 800 subnets
exit
router ospf 2 vrf v12
redistribute bgp 800 subnets
exit

The following example shows how to configure on CE devices, PE-to-CE connections using BGP for both routing and label exchange:

The following example shows how to configure on CE devices, PE-to-CE connections using OSPF for both routing and LDP for label exchange:

CHAPTER 12

Default Passive Interfaces

The Default Passive Interfaces feature simplifies the configuration of distribution devices by allowing all interfaces to be set as passive by default. In ISPs and large enterprise networks, many distribution devices have more than 200 interfaces. Obtaining routing information from these interfaces requires configuration of the routing protocol on all interfaces and manual configuration of the `passive-interface` command on interfaces where adjacencies were not desired.

- Finding Feature Information, on page 179
- Information About Default Passive Interfaces, on page 179
- How to Configure Default Passive Interfaces, on page 180

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Default Passive Interfaces

Default Passive Interfaces

In large enterprise networks, many distribution devices have more than 200 interfaces. Before the introduction of the Default Passive Interfaces feature, routing information could be obtained from these interfaces in these ways:

- Configure a routing protocol such as Open Shortest Path First (OSPF) on the backbone interfaces and redistribute connected interfaces.
- Configure a routing protocol on all interfaces and manually set most of them as passive.
Network operators might not always be able to summarize type 5 link-state advertisements (LSAs) at the device level where redistribution occurs, as in the first possibility. Thus, a large number of type 5 LSAs can be flooded over the domain.

In the second possibility, large type 1 LSAs might be flooded over the domain. The Area Border Router (ABR) creates type 3 LSAs, one for each type 1 LSA, and floods them to the backbone. You can, however, have unique summarization at the ABR level, which injects only one summary route into the backbone, thereby reducing the processing overhead.

Before the introduction of the Default Passive Interfaces feature, you could configure the routing protocol on all interfaces and manually set the `passive-interface` router configuration command on interfaces where adjacencies were not desired. But in some networks, this solution meant configuring 200 or more passive interfaces. The Default Passive Interfaces feature solved this problem by allowing all interfaces to be set as passive by default. You can set all interfaces as passive by default by using the `passive-interface default` command and then configure individual interfaces where adjacencies are desired using the `no passive-interface` command.

The Default Passive Interfaces feature simplifies the configuration of distribution devices and allows the network administrator to obtain routing information from interfaces in ISPs and large enterprise networks.

### Preventing Routing Updates Through an Interface

To prevent other devices on a local network from learning about routes dynamically, you can keep routing update messages from being sent through a device interface. This feature applies to all IP-based routing protocols except the Border Gateway Protocol (BGP).

Open Shortest Path First (OSPF) and Intermediate System to Intermediate System (IS-IS) behave somewhat differently. In OSPF, the interface address that you specify as passive appears as a stub network in the OSPF domain. OSPF routing information is neither sent nor received through the specified device interface. In IS-IS, the specified IP addresses are advertised without actually running IS-IS on those interfaces.

To prevent routing updates through a specified interface, use the `passive-interface type number` command in router configuration mode.

### How to Configure Default Passive Interfaces

#### Configuring Default Passive Interfaces

Perform this task to set all interfaces on a device, in an Enhanced Interior Gateway Routing Protocol (EIGRP) environment, as passive by default, and then activate only those interfaces where adjacencies are desired.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `router eigrp {autonomous-system-number | virtual-instance-number}`
4. `passive-interface [default] [type number]`
5. `no passive-interface [default] [type number]`
6. `network network-address [options]`
7. `end`
8. show ip eigrp interfaces
9. show ip interface

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  Example:  
  Device> enable  
  - Enter your password if prompted. |
| **Step 2** configure terminal | Enters global configuration mode.  
  Example:  
  Device# configure terminal |
| **Step 3** router eigrp {autonomous-system-number | virtual-instance-number} | Configures an EIGRP process and enters router configuration mode.  
  Example:  
  Device(config)# router eigrp 1  
  - autonomous-system-number—Autonomous system number that identifies the services to the other EIGRP address-family devices. It is also used to tag routing information. The range is 1 to 65535.  
  - virtual-instance-number—EIGRP virtual instance name. This name must be unique among all address-family router processes on a single device, but need not be unique among devices |
| **Step 4** passive-interface [default] [type number] | Sets all interfaces as passive by default.  
  Example:  
  Device(config-router)# passive-interface default |
| **Step 5** no passive-interface [default] [type number] | Activates only those interfaces that need adjacencies.  
  Example:  
  Device(config-router)# no passive-interface gigabitethernet 0/0/0 |
| **Step 6** network network-address [options] | Specifies the list of networks to be advertised by routing protocols.  
  Example:  
  Device(config-router)# network 192.0.2.0 |
| **Step 7** end | Exits router configuration mode and returns to privileged EXEC mode.  
  Example:  
  Device(config-router)# end |

## Configuration Examples for Default Passive Interfaces

### Examples: Passive Interfaces Configuration for OSPF

In Open Shortest Path First (OSPF), hello packets are not sent on an interface that is specified as passive. Hence, the device is not able to discover any neighbors, and none of the OSPF neighbors are able to see the device on that network. In effect, this interface appears as a stub network to the OSPF domain. This configuration is useful if you want to import routes associated with a connected network into the OSPF domain without any OSPF activity on that interface.

The `passive-interface` router configuration command is typically used when the wildcard specification on the `network` router configuration command configures more interfaces than is desirable. The following configuration causes OSPF to run on all subnets of 172.18.0.0:

```
Device(config)# interface GigabitEthernet 0/0/0
Device(config-if)# ip address 172.18.1.1 255.255.255.0
Device(config-if)# exit
Device(config)# interface GigabitEthernet 1/0/0
Device(config-if)# ip address 172.18.2.1 255.255.255.0
Device(config-if)# exit
Device(config)# interface GigabitEthernet 2/0/0
Device(config-if)# ip address 172.18.3.1 255.255.255.0
Device(config-if)# exit
Device(config-router)# router ospf 1
Device(config-router)# network 172.18.0.0 0.0.255.255 area 0
Device(config-router)# exit
```

If you do not want OSPF to run on 172.18.3.0, enter the following commands:

```
Device(config)# router ospf 1
Device(config-router)# network 172.18.0.0 0.0.255.255 area 0
Device(config-router)# no passive-interface GigabitEthernet 2/0/0
Device(config-router)# exit
```

### Example: Default Passive Interfaces Configuration for OSPF

The following example configures the network interfaces, sets all interfaces that are running Open Shortest Path First (OSPF) as passive, and then enables serial interface 0/0/0:

```
```
Device(config)# interface GigabitEthernet 0/0/0
Device(config-if)# ip address 172.19.64.38 255.255.255.0 secondary
Device(config-if)# ip address 172.19.232.70 255.255.255.240
Device(config-if)# no ip directed-broadcast
Device(config-if)# exit
Device(config)# interface Serial 0/0/0
Device(config-if)# ip address 172.24.101.14 255.255.255.252
Device(config-if)# no ip directed-broadcast
Device(config-if)# no ip mroutecache
Device(config-if)# exit
Device(config)# interface TokenRing 0/0/0
Device(config-if)# ip address 172.20.10.4 255.255.255.0
Device(config-if)# no ip directed-broadcast
Device(config-if)# no ip mroutecache
Device(config-if)# ring-speed 16
Device(config-if)# exit
Device(config)# router ospf 1
Device(config-router)# passive-interface default
Device(config-router)# no passive-interface Serial 0/0/0
Device(config-router)# network 172.16.10.0 0.0.0.255 area 0
Device(config-router)# network 172.19.232.0 0.0.0.255 area 4
Device(config-router)# network 172.24.101.0 0.0.0.255 area 4
Device(config-router)# end

Fast-Switched Policy Routing

Currently policy-based routing is process-switched within the software, which means that on most platforms the switching rate was approximately 1000 to 10,000 packets per second. Such rates are not fast enough for many applications. The Fast-Switched Policy Routing feature allows customers to direct certain traffic profiles to take specified paths through the network, enabling source-based routing and leveraging security.

Prerequisites for Fast-Switched Policy Routing

Policy routing must be configured before you configure fast-switched policy routing.

Information About Fast-Switched Policy Routing

Fast-Switched Policy Routing

IP policy routing can be fast-switched. Prior to fast-switched policy routing, policy routing could only be process-switched, which meant that on most platforms, the switching rate was approximately 1000 to 10,000 packets per second. Such rates were not fast enough for many applications. With fast-switched policy routing,
users who need policy routing to occur at faster speeds can implement policy routing without slowing down
the device.

Fast-switched policy routing supports all **match** commands and most **set** commands, except for the following:

- **set ip default**
- **set interface**

The **set interface** command is supported only over point-to-point links, unless there is a route cache entry
that uses the same interface that is specified in the command in the route map.

To configure fast-switched policy routing, use the **ip route-cache policy** interface configuration command.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for NetFlow Policy Routing

For NetFlow policy routing to work, the following features must already be configured:

- Cisco Express Forwarding, distributed Cisco Express Forwarding, or NetFlow
- Policy routing

Restrictions for NetFlow Policy Routing

- NetFlow Policy Routing (NPR) is available only on Cisco platforms that support Cisco Express Forwarding.
• Distributed Forwarding Information Base (FIB)-based policy routing is available only on platforms that support distributed Cisco Express Forwarding.

• The `set ip next-hop verify-availability` command is not supported in distributed Cisco Express Forwarding because distributed Cisco Express Forwarding does not support the Cisco Discovery Protocol (formerly known as CDP) database.

### Information About NetFlow Policy Routing

#### NetFlow Policy Routing

NetFlow policy routing (NPR) integrates policy routing, which enables traffic engineering and traffic classification, with NetFlow services, which provide billing, capacity planning, and information monitoring on real-time traffic flows. IP policy routing works with Cisco Express Forwarding (formerly known as CEF), distributed Cisco Express Forwarding (formerly known as dCEF), and NetFlow.

NetFlow policy routing leverages the following technologies:

• Cisco Express Forwarding, which looks at a Forwarding Information Base (FIB) instead of a routing table when switching packets, to address maintenance problems of a demand caching scheme.

• Distributed Cisco Express Forwarding, which addresses the scalability and maintenance problems of a demand caching scheme.

• NetFlow, which provides accounting, capacity planning, and traffic monitoring capabilities.

The following are the benefits of NPR:

• NPR takes advantage of new switching services. Cisco Express Forwarding, distributed Cisco Express Forwarding, and NetFlow can now use policy routing.

• Policy routing can be deployed on a wide scale and on high-speed interfaces.

NPR is the default policy routing mode. No additional configuration tasks are required to enable policy routing with Cisco Express Forwarding, distributed Cisco Express Forwarding, or NetFlow. As soon as one of these features is turned on, packets are automatically subjected to policy routing in the appropriate switching path.

The following example shows how to configure policy routing with Cisco Express Forwarding. The route is configured to verify that the next hop 10.0.0.8 of the route map named test is a Cisco Discovery Protocol neighbor before the device tries to policy-route to it.

```bash
Device(config)# ip cef
Device(config)# interface GigabitEthernet 0/0/1
Device(config-if)# ip route-cache flow
Device(config-if)# ip policy route-map test
Device(config-if)# exit
Device(config)# route-map test permit 10
Device(config-route-map)# match ip address 1
Device(config-route-map)# set ip precedence priority
Device(config-route-map)# set ip next-hop 10.0.0.8
Device(config-route-map)# set ip next-hop verify-availability
Device(config-route-map)# exit
Device(config)# route-map test permit 20
Device(config-route-map)# match ip address 101
```
Next-Hop Reachability

You can use the `set ip next-hop verify-availability` command to configure policy routing to verify the reachability of the next hop of a route map before the device performs policy routing to that next hop. This command has the following restrictions:

- It can cause performance degradation.
- Cisco Discovery Protocol must be enabled on the interface.
- The directly connected next hop must be a Cisco Discovery Protocol-enabled Cisco device.
- It does not work with distributed Cisco Express Forwarding configurations.

If a device is policy routing packets to the next hop and the next hop happens to be down, the device tries unsuccessfully to use the Address Resolution Protocol (ARP). This behavior can continue indefinitely. You can prevent this behavior by configuring the `set ip next-hop verify availability` command on the device. This command first verifies (using a route map) whether the next hop is a Cisco Discovery Protocol neighbor of the device before routing packets to that next hop. However, if you configure this command on a device whose next hop is not a Cisco Discovery Protocol neighbor, the device looks at the subsequent next hop, if there is one. If there is no available next hop, packets are not policy-routed. This configuration is optional because some media or encapsulations do not support Cisco Discovery Protocol.

If the `set ip next-hop verify availability` command is not configured, packets are either policy-routed or remain forever unrouted.

If you want to verify the availability of only some next hops, you can configure different route-map entries (under the same route-map name) with different criteria (using access-list matching or packet-size matching), and use the `set ip next-hop verify availability` configuration command selectively.

CHAPTER 15

Policy-Based Routing

The Policy-Based Routing feature is a process whereby a device puts packets through a route map before routing the packets. The route map determines which packets are routed next to which device. Policy-based routing is a more flexible mechanism for routing packets than destination routing.

• Finding Feature Information, on page 193
• Prerequisites for Policy-Based Routing, on page 193
• Information About Policy-Based Routing, on page 193
• How to Configure Policy-Based Routing, on page 195

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Policy-Based Routing

For Policy-Based Routing, IPBase is a minimum licensing requirement.

Information About Policy-Based Routing

Policy-Based Routing

Policy-based routing (PBR) is a process whereby the device puts packets through a route map before routing them. The route map determines which packets are routed to which device next. You might enable policy-based
routing if you want certain packets to be routed some way other than the obvious shortest path. Possible applications for policy-based routing are to provide equal access, protocol-sensitive routing, source-sensitive routing, routing based on interactive versus batch traffic, and routing based on dedicated links. Policy-based routing is a more flexible mechanism for routing packets than destination routing.

To enable policy-based routing, you must identify which route map to use for policy-based routing and create the route map. The route map itself specifies the match criteria and the resulting action if all of the match clauses are met.

To enable policy-based routing on an interface, indicate which route map the device should use by using the `ip policy route-map map-tag` command in interface configuration mode. A packet arriving on the specified interface is subject to policy-based routing except when its destination IP address is the same as the IP address of the device’s interface. This `ip policy route-map` command disables fast switching of all packets arriving on this interface.

To define the route map to be used for policy-based routing, use the `route-map map-tag [permit | deny] [sequence-number] [ordering-seq] [sequence-name] global configuration command.

To define the criteria by which packets are examined to learn if they will be policy-based routed, use either the `match length minimum-length maximum-length` command or the `match ip address {access-list-number | access-list-name} [access-list-number | access-list-name]` command or both in route map configuration mode. No match clause in the route map indicates all packets.

To display the cache entries in the policy route cache, use the `show ip cache policy` command.

---

**Note**

Mediatrace will show statistics of incorrect interfaces with policy-based routing (PBR) if the PBR does not interact with CEF or Resource Reservation Protocol (RSVP). Hence configure PBR to interact with CEF or RSVP directly so that mediatrace collects statistics only on tunnel interfaces and not physical interfaces.

---

**Precedence Setting in the IP Header**

The precedence setting in the IP header determines whether, during times of high traffic, the packets are treated with more or less precedence than other packets. By default, the Cisco software leaves this value untouched; the header remains with the precedence value that it had.

The precedence bits in the IP header can be set in the device when policy-based routing is enabled. When the packets containing those headers arrive at another device, the packets are ordered for transmission according to the precedence set, if the queueing feature is enabled. The device does not honor the precedence bits if queueing is not enabled; the packets are sent in FIFO order.

You can change the precedence setting, using either a number or name (the names came from RFC 791). You can enable other features that use the values in the `set ip precedence` route map configuration command to determine precedence. The table below lists the possible numbers and their corresponding name, from lowest to highest precedence.

**Table 16: IP Precedence Values**

<table>
<thead>
<tr>
<th>Number</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>routine</td>
</tr>
<tr>
<td>1</td>
<td>priority</td>
</tr>
</tbody>
</table>
The set commands can be used with each other. They are evaluated in the order shown in the previous table. A usable next hop implies an interface. Once the local device finds a next hop and a usable interface, it routes the packet.

### Local Policy Routing

Packets that are generated by the device are not normally policy-routed. To enable local policy routing for such packets, indicate which route map the device should use by using the `ip local policy route-map map-tag` global configuration command. All packets originating on the device will then be subject to local policy routing.

**Note**

Unlike UDP or other IP traffic, TCP traffic between a Cisco IOS or Cisco IOS-XE device and a remote host cannot be controlled using a local IP policy, if the Cisco device does not have an entry for the remote host IP in the Routing Information Base (RIB) (routing table) and Forwarding Information Base (FIB) (for Cisco Express Forwarding). It is not necessary that the RIB or FIB entry should be the same path as the one being set by PBR. In the absence of this entry, TCP does not detect a valid path to the destination and TCP traffic fails. However, UDP or ICMP traffic continues to be routed as per the local policy.

Use the `show ip local policy` command to display the route map used for local policy routing, if one exists.

### How to Configure Policy-Based Routing

#### Configuring Policy-Based Routing

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ip policy route-map map-tag`
5. `exit`
6. `route-map map-tag [permit | deny] [sequence-number] [`
7. Enter one or both of the following commands:
   - match length
   - match ip address

8. set ip next-hop {ip-address |... | ip-address | dynamic dhcp | encapsulate l3vpn profile-name | peer-address | recursive [global | vrf vrf-name] ip-address | verify-availability [ip-address sequence track track-object-number]}

9. end

- Additional References for SGT Based PBR, on page 206
- Feature Information for SGT Based PBR, on page 206

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for SGT Based PBR

- SGT Based PBR feature supports policy configuration using number based tagging and does not support name based tagging.
- SGT Based PBR feature is not supported for IPV6 traffic on IOS XE.
- Dynamic route-map overrides static route-map when both are associated with the same interface. A warning message is issued during an override. The static route-map is enabled when the dynamic route-map is deleted.
- We recommend disassociating the route-map before it is deleted. You cannot configure static PBR if the route-map is deleted before disassociating it from the interface.
Information About SGT Based PBR

Cisco TrustSec

Cisco TrustSec assigns a Security Group Tag, (SGT) to the user’s or device’s traffic at ingress and applies the access policy based on the assigned tag. SGT Based PBR feature allows you to configure PBR based on Security Group classification enabling you to group users or devices into a role to match the defined policies.

SGT Based PBR

Security Group classification includes both Source and Destination Group, which is specified by source SGT and DGT. SGT Based PBR feature provides the PBR route-map match clause for SGT/DGT based packet classification. SGT Based PBR feature supports configuration of unlimited number of tags, but it is recommended to configure the tags based on memory available in the platform. SGT Based PBR supports VPN routing and forwarding (VRF) selection match criteria which can be used for policy based classification and forwarding of Virtual Private Network (VPN) traffic.

How to Configure SGT Based PBR

Configuring Match Security Group Tag

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `route-map map-tag`
4. `match security-group source tag sgt-number`
5. `set ip next-hop ip-address`
6. `match security-group destination tag sgt-number`
7. `set ip next-hop ip-address`
8. `end`

## Displaying and Verifying SGT Based PBR Configuration

### SUMMARY STEPS

1. `enable`
2. `show ip policy`
3. `show route-map map-tag`
4. `show route-map dynamic`

### DETAILED STEPS

**Step 1**

**enable**

**Example:**

Device> enable

Enables privileged EXEC mode.

- Enter your password if prompted.

**Step 2**

**show ip policy**

**Example:**

Device# show ip policy

<table>
<thead>
<tr>
<th>Interface</th>
<th>Route map</th>
</tr>
</thead>
<tbody>
<tr>
<td>G10/0/1.77</td>
<td>test</td>
</tr>
</tbody>
</table>

Displays IP policy information.

**Step 3**

**show route-map map-tag**

**Example:**

Device# show route-map test

route-map test, permit, sequence 10
Match clauses:
  security-group source tag 100 111
Set clauses:
  ip next-hop 71.71.71.6
Policy routing matches: 0 packets, 0 bytes
route-map test, permit, sequence 20
Match clauses:
  security-group destination tag 200 222
Set clauses:
  ip next-hop 72.72.72.6
Policy routing matches: 0 packets, 0 bytes

Displays route-map configuration.

Step 4  show route-map dynamic
Example:

Device# show route-map dynamic

route-map AAA-02/11/15-12:32:52.955-1-test, permit, sequence 0, identifier 2818572289
Match clauses:
  Security-group source tag 100 300
Set clauses:
  ip next-hop 3.3.3.2
Nexthop tracking current: 3.3.3.2
3.3.3.2, fib_nh:7FDE41661370,oce:7FDE4C540AD0,status:1

Policy routing matches: 1012 packets, 83458 bytes
Current active dynamic routemaps = 1

Displays information about dynamic PBR route-map.

Configuration Examples for SGT Based PBR

Example: SGT Based PBR

The following example shows how to configure SGT Based PBR:

Example: SGT Based PBR

enable
configure terminal
route-map policy_security
match security-group source tag 100
match security-group source tag 111
set ip next-hop 71.71.71.6
match security-group destination tag 200
match security-group destination tag 222
set ip next-hop 72.72.72.6
end
interface gigabitEthernet0/0/0
ip policy route-map policy_security

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for SGT Based QoS

- The user groups and devices used for SGT Based QoS configuration must be assigned to the appropriate SGT groups. SGT definition and mapping can be done through Cisco ISE or through static SGT classification on the network device.

Restrictions for SGT Based QoS

- The SGT Based QoS feature does not support application prioritization within a user group.
The SGT Based QoS feature does not support combining match application or match protocol criteria with the match sgt criteria within a policy.

Information About SGT Based QoS

SGT Based QoS

Security Group classification includes both Source and Destination Group, which is specified by source SGT and DGT. The SGT Based QoS feature enables prioritized allocation of bandwidth and QoS policies for a defined user group or device. The SGT Based QoS feature provides you the capability to assign multiple QoS policies to an application or traffic type initiated by different user groups. Each user group is defined by a unique SGT value and supports hierarchical and non-hierarchical QoS configuration. The SGT Based QoS feature supports both user group and device based QoS service levels for SGT/DGT based packet classification. The SGT Based QoS feature supports defining of user groups based on contextual information for QoS policy prioritization.

How to Configure SGT Based QoS

Configuring User Group, Device, or Role Based QoS Policies

SUMMARY STEPS

1. enable
2. configure terminal
3. class-map class-map-name
4. match security-group source tag sgt-number
5. match security-group destination tag dgt-number
6. end

</tbody>
</table>

### Displaying and Verifying SGT Based QoS Configuration

**SUMMARY STEPS**

1. enable
2. show class-map
3. debug cpl provisioning {api | db | errors | ttc}

**DETAILED STEPS**

**Step 1** enable

**Example:**

Device> enable
Enables privileged EXEC mode.

- Enter your password if prompted.

**Step 2**

```
show class-map
```

**Example:**

```
Device# show class-map

Class Map match-any class-default (id 0)
   Match any

Class Map match-all c1 (id 1)
   Match security-group source tag 1000
   Match security-group destination tag 2000
```

Displays class-map information.

**Step 3**

```
debug cpl provisioning {api | db | errors | ttc}
```

**Example:**

```
Device# debug cpl provisioning api

CPL Policy Provisioning Manager API calls debugging is on
```

Enables debugging for Call Processing Language (CPL) provisioning.

---

**Configuration Examples for SGT Based QoS**

**Example: Configuring User Group, Device, or Role Based QoS Policies**

The following example shows how to configure User Group, Device, or Role Based QoS Policies:

```
enable
configure terminal
class-map c4
   match security-group source tag 7000
   match security-group destination tag 8000
end
policy-map p5
   class c4
      bandwidth percent 50
      set dscp ef
end
interface gigabitEthernet0/0/0.1
   service-policy input p5
```

Feature Information for SGT Based QoS

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.
The SGT Based QoS feature supports classification of packets based on Security Group Tag (SGT) for grouping the traffic into user groups and devices to match the defined QoS policies.

The following commands were introduced or modified: `debug cpl provisioning`, `class-map match security-group destination tag`, `match security-group source tag`, `show class-map`.

CHAPTER 18

Policy-Based Routing Default Next-Hop Routes

The Policy-Based Routing Default Next-Hop Route feature introduces the ability for packets that are forwarded as a result of the `set ip default next-hop` command to be switched at the hardware level. In prior software releases, the packets to be forwarded that are generated from the route map for policy-based routing are switched at the software level.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Policy-Based Routing Default Next-Hop Routes

Policy-Based Routing

Policy-based routing (PBR) is a process whereby the device puts packets through a route map before routing them. The route map determines which packets are routed to which device next. You might enable policy-based routing if you want certain packets to be routed some way other than the obvious shortest path. Possible applications for policy-based routing are to provide equal access, protocol-sensitive routing, source-sensitive routing, routing based on interactive versus batch traffic, and routing based on dedicated links. Policy-based routing is a more flexible mechanism for routing packets than destination routing.
To enable policy-based routing, you must identify which route map to use for policy-based routing and create the route map. The route map itself specifies the match criteria and the resulting action if all of the match clauses are met.

To enable policy-based routing on an interface, indicate which route map the device should use by using the `ip policy route-map map-tag` command in interface configuration mode. A packet arriving on the specified interface is subject to policy-based routing except when its destination IP address is the same as the IP address of the device’s interface. This `ip policy route-map` command disables fast switching of all packets arriving on this interface.

To define the route map to be used for policy-based routing, use the `route-map map-tag [permit | deny] [sequence-number] [ordering-seq] [sequence-name]` global configuration command.

To define the criteria by which packets are examined to learn if they will be policy-based routed, use either the `match length minimum-length maximum-length` command or the `match ip address {access-list-number | access-list-name} [access-list-number | access-list-name]` command or both in route map configuration mode. No match clause in the route map indicates all packets.

To display the cache entries in the policy route cache, use the `show ip cache policy` command.

---

**Note**

Mediatrace will show statistics of incorrect interfaces with policy-based routing (PBR) if the PBR does not interact with CEF or Resource Reservation Protocol (RSVP). Hence configure PBR to interact with CEF or RSVP directly so that mediatrace collects statistics only on tunnel interfaces and not physical interfaces.

---

**Precedence Setting in the IP Header**

The precedence setting in the IP header determines whether, during times of high traffic, the packets are treated with more or less precedence than other packets. By default, the Cisco software leaves this value untouched; the header remains with the precedence value that it had.

The precedence bits in the IP header can be set in the device when policy-based routing is enabled. When the packets containing those headers arrive at another device, the packets are ordered for transmission according to the precedence set, if the queueing feature is enabled. The device does not honor the precedence bits if queueing is not enabled; the packets are sent in FIFO order.

You can change the precedence setting, using either a number or name (the names came from RFC 791). You can enable other features that use the values in the `set ip precedence` route map configuration command to determine precedence. The table below lists the possible numbers and their corresponding name, from lowest to highest precedence.

<table>
<thead>
<tr>
<th>Number</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>routine</td>
</tr>
<tr>
<td>1</td>
<td>priority</td>
</tr>
<tr>
<td>2</td>
<td>immediate</td>
</tr>
<tr>
<td>3</td>
<td>flash</td>
</tr>
<tr>
<td>4</td>
<td>flash-override</td>
</tr>
</tbody>
</table>
The set commands can be used with each other. They are evaluated in the order shown in the previous table. A usable next hop implies an interface. Once the local device finds a next hop and a usable interface, it routes the packet.

## How to Configure Policy-Based Routing Default Next-Hop Routes

### Configuring Precedence for Policy-Based Routing Default Next-Hop Routes

Perform this task to configure the precedence of packets and specify where packets that pass the match criteria are output.

### Note

The set ip next-hop and set ip default next-hop commands are similar but have a different order of operation. Configuring the set ip next-hop command causes the system to first use policy routing and then use the routing table. Configuring the set ip default next-hop command causes the system to first use the routing table and then the policy-route-specified next hop.

### SUMMARY STEPS

1. enable
2. configure terminal
3. route-map map-tag [permit | deny] [sequence-number]
4. set ip precedence {number | name}
5. set ip next-hop ip-address [ip-address]
6. set interface type number [...type number]
7. set ip default next-hop ip-address [ip-address]
8. set default interface type number [...type number]
9. end

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

<table>
<thead>
<tr>
<th>Step 2</th>
<th>configure terminal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device# configure terminal</td>
</tr>
</tbody>
</table>

**Purpose**

Enters global configuration mode.

| Step 3 | route-map  map-tag [permit | deny] [sequence-number] |
|--------|--------------------------|
| Example: | Device(config)# route-map alpha permit ordering-seq |

**Purpose**

Configures a route map and specifies how the packets are to be distributed.

| Step 4 | set ip precedence {number | name} |
|--------|-----------------------------------|
| Example: | Device(config-route-map)# set ip precedence 5 |

**Purpose**

Sets the precedence value in the IP header.

**Note**

You can specify either a precedence number or a precedence name.

<table>
<thead>
<tr>
<th>Step 5</th>
<th>set ip next-hop ip-address [ip-address]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device(config-route-map)# set ip next-hop 192.0.2.1</td>
</tr>
</tbody>
</table>

**Purpose**

Specifies the next hop for routing packets.

**Note**

The next hop must be an adjacent device.

<table>
<thead>
<tr>
<th>Step 6</th>
<th>set interface type number [...type number]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device(config-route-map)# set interface gigabitethernet 0/0/0</td>
</tr>
</tbody>
</table>

**Purpose**

Specifies the output interface for the packet.

<table>
<thead>
<tr>
<th>Step 7</th>
<th>set ip default next-hop ip-address [ip-address]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device(config-route-map)# set ip default next-hop 172.16.6.6</td>
</tr>
</tbody>
</table>

**Purpose**

Specifies the next hop for routing packets if there is no explicit route for this destination.

**Note**

Like the set ip next-hop command, the set ip default next-hop command must specify an adjacent device.

<table>
<thead>
<tr>
<th>Step 8</th>
<th>set default interface type number [...type number]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device(config-route-map)# set default interface serial 0/0/0</td>
</tr>
</tbody>
</table>

**Purpose**

Specifies the output interface for the packet if there is no explicit route for the destination.

<table>
<thead>
<tr>
<th>Step 9</th>
<th>end</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Device(config-route-map)# end</td>
</tr>
</tbody>
</table>

**Purpose**

Exits route-map configuration mode and returns to privileged EXEC mode.
Configuration Examples for Policy-Based Routing Default Next-Hop Routes

Example: Policy-Based Routing

The following example provides two sources with equal access to two different service providers. Packets that arrive on asynchronous interface 1/0/0 from the source 10.1.1.1 are sent to the device at 172.16.6.6 if the device has no explicit route for the destination of the packet. Packets that arrive from the source 172.17.2.2 are sent to the device at 192.168.7.7 if the device has no explicit route for the destination of the packet. All other packets for which the device has no explicit route to the destination are discarded.

```
Device(config)# access-list 1 permit ip 10.1.1.1
Device(config)# access-list 2 permit ip 172.17.2.2
Device(config)# interface async 1/0/0
Device(config-if)# ip policy route-map equal-access
Device(config-if)# exit
Device(config-route-map)# route-map equal-access permit 10
Device(config-route-map)# match ip address 1
Device(config-route-map)# set ip default next-hop 172.16.6.6
Device(config-route-map)# exit
Device(config)# route-map equal-access permit 20
Device(config-route-map)# match ip address 2
Device(config-route-map)# set ip default next-hop 192.168.7.7
Device(config-route-map)# exit
Device(config)# route-map equal-access permit 30
Device(config-route-map)# set default interface null 0
Device(config-route-map)# exit
```

CHAPTER 19

QoS Policy Propagation via BGP

The QoS Policy Propagation via BGP feature allows you to classify packets by IP precedence based on the Border Gateway Protocol (BGP) community lists, BGP autonomous system paths, and access lists. After packets have been classified, you can use other quality of service (QoS) features such as committed access rate (CAR) and Weighted Random Early Detection (WRED) to specify and enforce policies to fit your business model.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for QoS Policy Propagation via BGP

- Enable the Border Gateway Protocol (BGP) and Cisco Express Forwarding (CEF) or distributed CEF (dCEF) on the device. Subinterfaces on an ATM interface that have the bgp-policy command enabled must use CEF mode because dCEF is not supported. dCEF uses the Versatile Interface Processor (VIP) rather than the Route Switch Processor (RSP) to perform forwarding functions.

- Define the policy.

- Apply the policy through BGP.
• Configure the BGP community list, BGP autonomous system path, or access list and enable the policy on an interface.

• Enable committed access rate (CAR) or Weighted Random Early Detection (WRED) to use the policy.

Information About QoS Policy Propagation via BGP

Benefits of QoS Policy Propagation via BGP

The QoS Policy Propagation via BGP feature allows you to classify packets by IP precedence based on Border Gateway Protocol (BGP) community lists, BGP autonomous system paths, and access lists. ### Step 11

**Interface type number**

**Example:**

Device(config)# interface gigabitethernet 0/0/0

Classifies packets using IP precedence.

### Step 12

bgp-policy {source | destination} ip-prec-map

**Example:**

Device(config-if)# bgp-policy source ip-prec-map

Exits interface configuration mode and returns to global configuration mode.

### Step 13

exit

**Example:**

Device(config-if)# exit

(Optional) Displays the BGP community number in AA:NN (autonomous system:community number/4-byte number) format.

### Step 14

ip bgp-community new-format

**Example:**

Device(config)# ip bgp-community new-format

Exits global configuration mode and returns to privileged EXEC mode.

### Step 15

diend

**Example:**

Device(config)# end

---

### Purpose

**Command or Action**

Device(config-router)# table-map rm1

**Purpose**

Exits router configuration mode and returns to global configuration mode.

---

**Step 10**

**exit**

**Example:**

Device(config-router)# exit

**Purpose**

Defines an autonomous system path access list.

---

**Step 11**

**ip as-path access-list** **access-list-number**

**permit**

**deny**

*as-regular-expression*

**as-regular-expression**

**Example:**

Device(config)# ip as-path access-list 500 permit 45000

**Step 12**

**interface** **type** **number**

**Example:**

Device(config)# interface gigabitethernet 0/0/0

**Purpose**

Specifies the interface (or subinterface) and enters interface configuration mode.

---

**Step 13**

**bgp-policy** **source**

**destination**

**ip-prec-map**

**Example:**

Device(config-if)# bgp-policy source ip-prec-map

**Purpose**

Classifies packets using IP precedence.

---

**Step 14**

**end**

**Example:**

Device(config-if)# end

**Purpose**

Exits interface configuration mode and returns to privileged EXEC mode.

---

### Configuring QoS Policy Propagation via BGP Based on an Access List

## Monitoring QoS Policy Propagation via BGP

To monitor the QoS Policy Propagation via the BGP feature configuration, use the following optional commands.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip bgp</td>
<td>Displays entries in the Border Gateway Protocol (BGP) routing table to verify whether the correct community is set on the prefixes.</td>
</tr>
<tr>
<td>show ip bgp community-list community-list-number</td>
<td>Displays routes permitted by the BGP community to verify whether correct prefixes are selected.</td>
</tr>
<tr>
<td>show ip cef network</td>
<td>Displays entries in the forwarding information base (FIB) table based on the specified IP address to verify whether Cisco Express Forwarding has the correct precedence value for the prefix.</td>
</tr>
<tr>
<td>show ip interface</td>
<td>Displays information about the interface.</td>
</tr>
</tbody>
</table>
### Configuration Examples for QoS Policy Propagation via BGP

#### Example: Configuring QoS Policy Propagation via BGP

The following example shows how to create route maps to match access lists, Border Gateway Protocol (BGP) community lists, and BGP autonomous system paths, and apply IP precedence to routes learned from neighbors.

In the figure below, Device A learns routes from autonomous system 10 and autonomous system 60. The quality of service (QoS) policy is applied to all packets that match defined route maps. Any packets from Device A to autonomous system 10 or autonomous system 60 are sent the appropriate QoS policy, as the numbered steps in the figure indicate.

**Figure 11: Device Learning Routes and Applying QoS Policy**

</table>
CHAPTER 20

Recursive Static Route

The Recursive Static Route feature enables you to install a recursive static route into the Routing Information Base (RIB) even if the next-hop address of the static route or the destination network itself is already available in the RIB as part of a previously learned route. This module explains recursive static routes and how to configure the Recursive Static Route feature.

• Finding Feature Information, on page 237
• Restrictions for Recursive Static Route, on page 237
• Information About Recursive Static Route, on page 238
• How to Install Recursive Static Route, on page 239
• Configuration Examples for Recursive Static Route, on page 243
• Additional References for Recursive Static Route, on page 244
• Feature Information for Recursive Static Route, on page 244

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Recursive Static Route

When recursive static routes are enabled using route maps, only one route map can be entered per virtual routing and forwarding (VRF) instance or topology. If a second route map is entered, the new map will overwrite the previous one.
Information About Recursive Static Route

Recursive Static Routes

A recursive static route is a route whose next hop and the destination network are covered by another learned route in the Routing Information Base (RIB). Such static routes cannot be installed in the RIB because they are considered redundant routes. The Recursive Static Route feature allows you to install recursive static routes in the RIB, thereby allowing the redistribution of such specific routes within the network. When the learned route covering the next hop or the destination network is withdrawn from the RIB, the recursive static route also gets withdrawn from the RIB.

Given below is a detailed explanation of how recursive static routes work.

*Figure 12: How Recursive Static Routes Work*

The figure above shows three customers connected to three private virtual routing and forwarding (VRF) instances on a provider edge (PE) device. All three of them have private addressing in their networks.

Let us assume that the network on these VRFs is 10.0.0.0/8. The PE communicates these routes as is to the customer edge (CE) device, along with the VRF information of each customer. For security purposes and to avoid overlapping routes, the CE advertises only /32 routes to the service delivery network (SDN) edge device (which has only a service VRF) rather than advertising the whole 10.0.0.0/8 network for each customer. Static routes can be used to configure /32 routes for specific hosts. However, static routes that are recursive in nature cannot be configured for specific hosts. By default, recursive static routes are eliminated from the Routing Information Base (RIB) because these routes or the next hops to these routes may already be covered by another learned route in the RIB. The Recursive Static Route feature enables a recursive static route to be part of the RIB even if the next-hop address of the static route or the destination network of the static route is
already available in the RIB as part of a previously learned route. Additionally, if the learned route that covers the next-hop gateway is withdrawn from the RIB, the recursive static route is also deleted from the RIB.

### How to Install Recursive Static Route

#### Installing Recursive Static Routes in a VRF

Perform these steps to install recursive static routes in a specific virtual routing and forwarding (VRF) instance. You can configure the recursive-static-route functionality on any number of VRFs. Installing recursive static routes in specific VRFs allows you to retain the default RIB behavior (of removing recursive static routes) for the rest of the network.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. vrf definition vrf-name
4. rd route-distinguisher
5. address-family {ipv4 | ipv6}
6. exit
7. exit
8. ip route [vrf vrf-name] prefix mask ip-address
9. ip route static install-routes-recurse-via-nexthop [vrf vrf-name]
10. end
11. show running-config | include install
12. show ip route vrf vrf-name

</table>

**Installing Recursive Static Routes Using a Route Map**

Perform this task to install recursive static routes in a virtual routing and forwarding (VRF) instance defined by a route map. You can perform this task if you want to install recursive static routes for only a certain range of networks. If the **route-map** keyword is used without the **vrf** keyword, recursive static routes defined by the route map will be applicable for the global VRF or topology.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. vrf definition vrf-name
4. rd route-distinguisher
5. address-family {ipv4 | ipv6}
6. exit
7. exit
8. ip route [vrf vrf-name] prefix mask ip-address
9. access-list access-list-number permit source [source-wildcard]
10. route-map map-tag
11. match ip address access-list-number
12. exit
13. ip route static install-routes-recurse-via-nexthop [vrf vrf-name] [route-map map-name]
14. end
15. show running-config | include install
16. show ip route vrf vrf-name

| **Step 2**        | Enters global configuration mode. |
| configure terminal|         |
| Example:          |         |
| Device# configure terminal |         |

| **Step 3**        | Creates a virtual routing and forwarding (VRF) routing table instance and enters VRF configuration mode. |
| vrf definition vrf-name |         |
| Example:          |         |
| Device(config)# vrf definition vrf1 |         |

| **Step 4**        | Specifies a route distinguisher for a VRF instance. |
| rd route-distinguisher |         |
| Example:          |         |
| Device(config-vrf)# rd 100:1 |         |

| **Step 5**        | Enters VRF address family configuration mode to specify an IPv4 or an IPv6 address-family type for a VRF. |
| address-family {ipv4 | ipv6} |         |
| Example:          |         |
| Device(config-vrf)# address-family ipv4 |         |

| **Step 6**        | Exits VRF address family configuration mode. |
| exit              |         |
| Example:          |         |
| Device(config-vrf-af)# exit |         |

<p>| <strong>Step 7</strong>        | Exits VRF configuration mode. |
| exit              |         |
| Example:          |         |
|                    |         |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device(config-vrf)# exit</td>
<td>Configures a static route for a specific VRF instance.</td>
</tr>
</tbody>
</table>

**Step 8**  
*ip route [vrf vrf-name] prefix mask ip-address*  
**Example:**  
Device(config)# ip route vrf vrf1 10.0.2.0 255.255.255.0 10.0.1.1

**Step 9**  
*access-list access-list-number permit source*  
*[source-wildcard]*  
**Example:**  
Device(config)# access-list 10 permit 10.0.2.0 255.255.255.0

**Step 10**  
*route-map map-tag*  
**Example:**  
Device(config)# route-map map1

**Step 11**  
*match ip address access-list-number*  
**Example:**  
Device(config-route-map)# match ip address 10

**Step 12**  
*exit*  
**Example:**  
Device(config-route-map)# exit

**Step 13**  
*ip route static install-routes-recurse-via-nexthop [vrf vrf-name] [route-map map-name]*  
**Example:**  
Device(config)# ip route static install-routes-recurse-via-nexthop vrf vrf1 route-map map1

**Step 14**  
*end*  
**Example:**  
Device(config)# end

**Step 15**  
*show running-config | include install*  
**Example:**  
Device# show running-config | inc install

**Step 16**  
*show ip route vrf vrf-name*  
**Example:**  
Device# show ip route vrf vrf1
Configuration Examples for Recursive Static Route

Example: Installing Recursive Static Routes in a VRF

The following example shows how to install recursive static routes into a specific virtual routing and forwarding instance. By using the vrf keyword, you can ensure that recursive static routes are installed in the Routing Information Base (RIB) of only the specified VRF. The rest of the network retains the default behavior of not installing recursive static routes in the RIB. This example is based on the assumption that a 10.0.0.0/8 route is already installed dynamically or statically in the RIB of vrf1.

```
Device> enable
Device# configure terminal
Device(config)# vrf definition vrf1
Device(config-vrf)# rd 1:100
Device(config-vrf)# address-family ipv4
Device(config-vrf-af)# exit
Device(config-vrf)# exit
Device(config)# ip route vrf vrf1 10.0.2.0 255.255.255.0 10.0.1.1
Device(config)# ip route static install-routes-recurse-via-nexthop vrf vrf1
Device(config)# end
```

Example: Installing Recursive Static Routes using a Route Map

You can use the route-map keyword to install recursive static routes defined by the route map into the Routing Information Base (RIB). You can also specify a route map for a specific virtual routing and forwarding (VRF) instance to ensure that the route map is applied to only the specified VRF. In the example given below, a route map is specified for a specific VRF. This example is based on the assumption that a 10.0.0.0/8 route is already installed statically or dynamically in the RIB of vrf1.

```
Device> enable
Device# configure terminal
Device(config)# vrf definition vrf1
Device(config-vrf)# rd 100:2
Device(config-vrf)# address-family ipv4
Device(config-vrf-af)# exit
Device(config-vrf)# exit
Device(config)# access-list 10 permit 10.0.2.0 255.255.255.0
Device(config)# route-map map1
Device(config-route-map)# match ip address 10
Device(config-route-map)# exit
Device(config)# ip route static install-routes-recurse-via-nexthop vrf vrf1 route-map map1
Device(config)# ip route vrf vrf1 10.0.2.0 255.255.255.0 10.0.1.1
Device(config)# ip route vrf vrf1 10.0.3.0 255.255.255.0 10.0.1.1
Device(config)# end
```

In the example above, route 10.0.2.0 255.255.255.0 10.0.1.1 will be installed in the RIB, but the route 10.0.3.0 255.255.255.0 10.0.1.1 will not be installed in the RIB because this route does not match the network defined in the route map.

Feature Information for Recursive Static Route

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.
