Reverse Route Injection

Reverse route injection (RRI) is the ability to automatically insert static routes in the routing process for those networks and hosts protected by a remote tunnel endpoint. These protected hosts and networks are known as remote proxy identities.

Each route is created on the basis of a remote proxy network and mask, with the next hop to this network being the remote tunnel endpoint. By using the remote VPN device as the next hop, the traffic is forced through the crypto process to be encrypted.

Enhancements to the default behavior of RRI, the addition of a route tag value, and enhancements to how RRI is configured were added to the Reverse Route Injection feature in Cisco IOS Release 12.3(14)T.

An enhancement was added in Cisco IOS Release 12.4(15)T that allows a distance metric to be set for routes that are created by a VPN process so that the dynamically learned route on a device can take precedence over a locally configured static route.

Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the Next Generation Encryption (NGE) white paper.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.
Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

**Prerequisites for Reverse Route Injection**

- IP routing should be enabled and static routes should be redistributed if dynamic routing protocols are to be used to propagate RRI-generated static routes.

**Restrictions for Reverse Route Injection**

- If RRI is applied to a crypto map, that map must be unique to one interface on the router. In other words, the same crypto map cannot be applied to multiple interfaces. If more than one crypto map is applied to multiple interfaces, routes may not be cleaned up correctly. If multiple interfaces require a crypto map, each route must use a uniquely defined map. This restriction applies only to RRI before Cisco IOS Release 12.3(14)T.

- For static crypto maps, routes are always present if RRI is configured on an applied crypto map. In Cisco IOS Release 12.3(14)T, the default behavior—of routes always being present for a static map—will not apply unless the `static` keyword is added to the `reverse-route` command.

**Information About Reverse Route Injection**

**Reverse Route Injection**

RRI is the ability for static routes to be automatically inserted into the routing process for those networks and hosts that are protected by a remote tunnel endpoint. These protected hosts and networks are known as remote proxy identities.

Each route is created on the basis of the remote proxy network and mask, with the next hop to this network being the remote tunnel endpoint. By using the remote VPN device as the next hop, the traffic is forced through the crypto process to be encrypted.

After the static route is created on the VPN device, this information is propagated to upstream devices, allowing them to determine the appropriate VPN device to which the returning traffic must be sent to maintain IPsec state flows. Being able to determine the appropriate VPN device is particularly useful if multiple VPN devices are used at a site to provide load balancing or failover or if the remote VPN devices are not accessible via a default route. Depending on the scenario, routes are created in the global routing table and/or the appropriate virtual route forwarding (VRF) table.

**Note**

The `remote-peer` keyword is required in the `reverse-route` command to “leak” the routes.

RRI is applied on a per-crypto map basis, whether this is via a static crypto map or a dynamic crypto map template. The default behavior for the two map types is as follows:
• In the case of a dynamic crypto map, routes are created upon the successful establishment of IPsec security associations (SAs) for those remote proxies. The next hop back to those remote proxies is via the remote VPN device whose address is learned and applied during the creation of the dynamic crypto map template. The routes are deleted after the SAs are deleted. In Cisco IOS Release 12.3(14)T, the creation of routes on the basis of IPsec source proxies on static crypto maps was added. This behavior became the default behavior on static maps and overrode the creation of routes on the basis of crypto access control lists (ACL) (see the next bullet).

• For static crypto maps, routes are created on the basis of the destination information defined in the crypto access list. The next hop is taken from the first set peer statement that is attached to the crypto map. If at any time, RRI, the peer, or the access list is removed from the crypto map, routes will be deleted. This behavior changes with the addition of RRI enhancements, as explained in the sections below.

Enhancements to Reverse Route Injection in Cisco IOS Release 12.4(15)T

RRI Distance Metric

In general, a static route is created with an administrative distance of 1, which means that static routes always have precedence in the routing table. In some scenarios, however, it is required that dynamically learned routes take precedence over static routes, with the static route being used in the absence of a dynamically learned route. The addition of the `set reverse-route distance` command under either a crypto map or IPsec profile allows you to specify a different distance metric for VPN-created routes so that those routes will be in effect only if a dynamic or more favored route becomes unavailable.

Gateway Option

The RRI gateway option is relevant to the crypto map only.

This option allows you to configure unique next hops or gateways for remote tunnel endpoints. The option is identical to the way the `reverse-route remote-peer ip-address` command worked prior to Cisco IOS Release 12.3(14)T in that two routes are created for each VPN tunnel. The first route is to the destination-protected subnet via the remote tunnel endpoint. The second route specifies the next hop to be taken to reach this tunnel endpoint. This RRI gateway option allows specific default paths to be specified for specific groups of VPN connections on platforms that support recursive route lookups.

In 12.4(15)T and later releases, the `gateway` keyword option replaces the `reverse-route remote-peer` command (with no `ip-address`). Due to changes to Cisco Express Forwarding (formerly known as CEF), an interface as a next hop cannot be used without also adding a next hop IP address.

Support for RRI on IPsec Profiles

Previously RRI was available for crypto map configurations only. Cisco IOS Release 12.4(15)T introduces support for relevant RRI options on IPsec profiles that are predominantly used for virtual tunnel interfaces. On tunnel interfaces, only the distance metric and tag options are useful with the generic RRI capability.

It is not necessary to specifically enable RRI on dynamic virtual interfaces for Easy VPN clients. Route support is enabled by default. It is necessary to specify tag or distance metric values if these are required.
Tag Option Configuration Changes

The tag option was introduced in Cisco IOS Release 12.3(14)T for crypto maps. This option is now supported with IPsec profiles under the set reverse-route tag command syntax. The set reverse-route tag command is also available under the crypto map for uniformity although the legacy reverse-route tag command is no longer supported.

show crypto route Command

The show crypto route command displays routes that are created through IPsec via RRI or Easy VPN virtual tunnel interfaces (VTIs). The routes are displayed in one table. To see sample output for the show crypto route command, see the section “Example: show crypto route Command Output.”

How to Configure Reverse Route Injection

Configuring RRI Under Static Crypto Maps

To configure RRI under a static crypto map for software prior to Cisco IOS Release 12.4(15)T, perform the following steps.

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto map map-name seq-name ipsec-isakmp
4. reverse-route [static | tag tag-id [static] | remote-peer [static] remote-peer ip-address [static]]
5. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> crypto map map-name seq-name ipsec-isakmp</td>
<td>Creates or modifies a crypto map entry and enters crypto map configuration mode.</td>
</tr>
<tr>

### Configuring RRI Under a Dynamic Map Template for Cisco

To configure RRI under a dynamic map template for software prior to Cisco IOS Release 12.4(15)T, perform the following steps.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto dynamic-map dynamic-map-name dynamic-seq-name`
4. `reverse-route [static | tag tag-id [static] | remote-peer [static] remote-peer ip-address [static]]`
5. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>

<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config-crypto-map)# reverse-route</code></td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>The <code>gateway</code> keyword can be added to enable the dual route functionality for default gateway support.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Specifies a distance metric to be used or a tag value to be associated with these routes.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config-crypto-map)# set reverse-route distance 20</code></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Exits crypto map configuration mode and returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device(config-crypto-map)# end</code></td>
</tr>
</tbody>
</table>
Configuring RRI with Enhancements Under a Dynamic Map Template

To configure RRI with enhancements under a dynamic map template (for Cisco IOS Release 12.4(15)T and later releases), perform the following steps.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. crypto dynamic-map dynamic-map-name dynamic-seq-name
4. reverse-route [static | remote-peer ip-address [gateway] [static]]
5. set reverse-route [distance number | tag tag-id]
6. end

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>

<td></td>
<td></td>
</tr>
<tr>
<td>Example: `set reverse-route [distance number</td>
<td>tag tag-id]`</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>exits IPsec profile configuration mode and returns to privileged</td>
</tr>
<tr>
<td></td>
<td>EXEC mode.</td>
</tr>
</tbody>
</table>

Displaying Routes Created Through IPsec Using RRI or Easy VPN VTIs

To display routes that are created through IPsec via RRI or Easy VPN VTIs, perform the following steps. To observe the behavior of RRI and its relationship to the creation and deletion of an IPsec security association (SA), you can use the `debug crypto ipsec` command.
SUMMARY STEPS

1. enable
2. show crypto router

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>

Configuration Examples for Reverse Route Injection

Example: Configuring RRI Prior to Cisco IOS Release 12.3(14)T

Example: Configuring RRI When Crypto ACLs Exist

The following example shows how to connect all remote VPN gateways to the device via 192.168.0.3. RRI is added on the static crypto map, which creates routes on the basis of the source network and source netmask that are defined in the crypto access control list (ACL):

```
crypto map mymap 1 ipsec-isakmp
   set peer 10.1.1.1
   reverse-route
   crypto ipsec transform-set Trans1 esp-aes esp-sha-hmac
   match address 102
Interface FastEthernet 0/0
   ip address 192.168.0.2 255.255.255.0
   standby name group1
   standby ip 192.168.0.3
   crypto map mymap redundancy group1
   access-list 102 permit ip 192.168.1.0 0.0.0.255 10.0.0.0 0.0.255.255
```

In Cisco IOS Release 12.3(14)T and later releases, for the static map to retain this same behavior of creating routes on the basis of the crypto ACL content, the `static` keyword is required, that is, `reverse-route static`.

The `reverse-route` command in this situation creates routes that are analogous to the following static route CLI (ip route):

```
Remote Tunnel Endpoint

ip route 10.1.1.1 255.255.255.255 192.168.1.1
```
VPNSM

ip route 10.1.1.1 255.255.255.255 vlan0.1

**Example: Configuring RRI for a Remote Endpoint and a Route Recursion Route**

In the following example, two routes are created, one for the remote endpoint and one for route recursion to the remote endpoint via the interface on which the crypto map is configured:

```
reverse-route remote-peer
```

**Example: Configuring RRI with Enhancements Added in Cisco IOS Release 12.3(14)T**

**Example: Configuring RRI When Crypto ACLs Exist**

The following example shows how to configure RRI for a situation in which there are existing ACLs:

```
crypto map mymap 1 ipsec-isakmp
  set peer 172.17.11.1
  reverse-route static
  crypto ipsec transform-set Trans1 esp-aes esp-sha-hmac
  match address 101
access-list 101 permit ip 192.168.1.0 0.0.0.255 172.17.11.0 0.0.0.255
```

**Example: Configuring RRI with Route Tags**

The following example shows how RRI-created routes can be tagged with a tag number and then used by a routing process to redistribute those tagged routes via a route map:

```
crypto dynamic-map ospf-clients 1
  reverse-route tag 5
router ospf 109
  redistribute rip route-map rip-to-ospf
route-map rip-to-ospf permit
  match tag 5
  set metric 5
  set metric-type type1
Device# show ip eigrp topology
  P 10.81.7.48/29, 1 successors, FD is 2588160, tag is 5
    via 192.168.82.25 (2588160/2585600), FastEthernet0/1
```

**Example: Configuring RRI for One Route to the Remote Proxy via a User-Defined Next Hop**

---

**Note**

This option is applicable only to crypto maps.

The preceding example shows that one route has been created to the remote proxy via a user-defined next hop. This next hop should not require a recursive route lookup unless it will recurse to a default route.
reverse-route remote-peer 10.4.4.4

The preceding example yields the following prior to Cisco IOS Release 12.3(14)T:

10.0.0.0/24 via 10.1.1.1 (in the VRF table if VRFs are configured)
10.1.1.1/32 via 10.4.4.4 (in the global route table)

And this result occurs with RRI enhancements:

10.0.0.0/24 via 10.4.4.4 (in the VRF table if VRFs are configured, otherwise in the global table)

Example: Configuring RRI with Enhancements Added in Cisco IOS Release 12.4(15)T

Example: Configuring an RRI Distance Metric Under a Crypto Map

The following configuration shows a server and client configuration for which an RRI distance metric has been set under a crypto map:

Server

crypto dynamic-map mymap
  set security-association lifetime seconds 300
  Crypto ipsec transform-set Trans1 esp-aes esp-sha-hmac
  set isakmp-profile profile1
  set reverse-route distance 20
  reverse-route

Client

crypto ipsec client ezvpn ez
  connect auto
  group cisco key cisco
  mode client
  peer 10.0.0.119
  username XXX password XXX
  xauth userid mode local

Example: Configuring RRI with Route Tags

The following example shows how RRI-created routes can be tagged with a tag number and then used by a routing process to redistribute those tagged routes via a route map:

crypto dynamic-map ospf-clients 1
  set reverse-route tag 5
  router ospf 109
  redistribute rip route-map rip-to-ospf
  route-map rip-to-ospf permit
  match tag 5
  set metric 5
  set metric-type type1
Device# show ip eigrp topology
Example: debug and show Command Output for an RRI Distance Metric Configuration Under a Crypto Map

The following are the debug and show command outputs for an RRI distance metric configuration under a crypto map on a server:

Device# debug crypto ipsec

00:23:37: IPSEC(validate_proposal_request): proposal part #1, (key eng. msg.) Example: Configuring an RRI Distance Metric for a VTI

The following configuration shows a server and client configuration in which an RRI distance metric has been set for a VTI:

Server Configuration

crypto isakmp profile profile1
  keyring mykeyring
match identity group cisco
client authentication list authenlist
isakmp authorization list autholist
client configuration address respond
virtual-template 1

crypto ipsec profile vi
set transform-set aes-sha
set reverse-route distance 20
set isakmp-profile profile1

interface Virtual-Templates1 type tunnel
ip unnumbered
tunnel mode ipsec ipv4
tunnel protection ipsec profile vi

Client Configuration

crypto ipsec client ezvpn ez
connect auto
group cisco key cisco
mode client
peer 10.0.0.119
username XXX password XXX
virtual-interface 1

Example: debug and show Command Output for an RRI Metric Configuration Having a VTI

The following are the debug and show command outputs for an RRI metric configuration for a VTI on a server:

Device# debug crypto ipsec

<td>Reverse Route Remote Peer Options</td>
<td>12.2(13)T 12.2(14)S</td>
<td>An enhancement was added to RRI to allow you to specify an interface or address as the explicit next hop to the remote VPN device. This functionality allows the overriding of a default route to properly direct outgoing encrypted packets.</td>
</tr>
</tbody>
</table>
| Reverse Route Injection Enhancements | 12.2(33)SRA 12.2(33)SXH 12.3(14)T | The following enhancements were added to the Reverse Route Injection feature:  
  - The default behavior of static crypto maps will be the same as that of dynamic crypto maps unless the `reverse-route` command and `static` keyword are used.  
  - A route tag value was added for any routes that are created using RRI.  
  - RRI can be configured on the same crypto map that is applied to multiple router interfaces.  
  - RRI configured with the `reverse-route remote-peer ip-address` command, keyword, and argument will create one route instead of two.  
  The following command was modified by these feature enhancements: `reverse-route`. |
| Gateway Option                      |          | This option allows you to configure unique next hops or gateways for remote tunnel endpoints. |
| RRI Distance Metric                 | 12.4(15)T 15.1(3)S | This enhancement allows you to define a metric distance for each static route. The following commands were introduced or modified: `reverse-route`, `set reverse-route`. |
| show crypto route Command           |          | This command displays routes that are created through IPsec via RRI or Easy VPN VTIs. |

CHAPTER 2

IPsec VPN High Availability Enhancements

The IPsec VPN High Availability Enhancements feature: Reverse Route Injection (RRI) and Hot Standby Router Protocol (HSRP) with IPsec. When used together, these two features provide you with a simplified network design for VPNs and reduced configuration complexity on remote peers when defining gateway lists.

Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the Next Generation Encryption (NGE) white paper.

- Finding Feature Information, on page 21
- Information About IPsec VPN High Availability Enhancements, on page 21
- How to Configure IPsec VPN High Availability Enhancements, on page 24
- Configuration Examples for IPsec VPN High Availability Enhancements, on page 28
- Additional References, on page 30
- Feature Information for IPsec VPN High Availability Enhancements, on page 31

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About IPsec VPN High Availability Enhancements

Reverse Route Injection

Reverse Route Injection (RRI) simplifies network design for Virtual Private Networks (VPNs) in which there is a requirement for redundancy or load balancing. RRI works with both dynamic and static crypto maps.
RRI provides the following benefits:

- Enables routing of IPsec traffic to a specific VPN headend device in environments that have multiple (redundant) VPN headend devices.
- Ensures predictable failover time of remote sessions between headend devices when using IKE keepalives, especially in environments in which remote device route flapping is common (not taking into consideration the effects of route convergence, which may vary depending on the routing protocol used and the size of the network).
- Eliminates the need for the administration of static routes on upstream devices, as routes are dynamically learned by these devices.

In the dynamic case, as remote peers establish IPsec security associations (SAs) with an RRI-enabled router, a static route is created for each subnet or host protected by that remote peer. For static crypto maps, a static route is created for each destination of an extended access list rule. When RRI is used on a static crypto map with an access control list (ACL), routes will always exist, even without the negotiation of IPsec SAs.

Note
The use of any keyword in ACLs with RRI is not supported.

When routes are created, they are injected into any dynamic routing protocol and distributed to surrounding devices. This traffic flows, requiring IPsec to be directed to the appropriate RRI router for transport across the correct SAs to avoid IPsec policy mismatches and possible packet loss.

The figure below shows an RRI configuration functionality topology. Remote A is being serviced by Router A and Remote B connected to Router B, providing load balancing across VPN gateways at the central site. RRI on the central site devices ensures that the other router on the inside of the network can automatically make the correct forwarding decision. RRI also eliminates the need to administer static routes on the inside router.

Figure 2: Topology Showing Reverse Route Injection Configuration Functionality
Hot Standby Router Protocol and IPsec

Hot Standby Router Protocol (HSRP) provides high network availability by routing IP traffic from hosts on Ethernet networks without relying on the availability of any single router. HSRP is particularly useful for hosts that do not support a router discovery protocol, such as ICMP Router Discovery Protocol (IRDP) and do not have the functionality to switch to a new router when their selected router reloads or loses power. Without this functionality, a router that loses its default gateway because of a router failure cannot communicate with the network.

HSRP is configurable on LAN interfaces using standby command-line interface (CLI) commands. You can use the standby IP address from an interface as the local IPsec identity or local tunnel endpoint. By using the standby IP address as the tunnel endpoint, failover can be applied to VPN routers by using HSRP. Remote VPN gateways connect to the local VPN router via the standby address that belongs to the active device in the HSRP group. In the event of failover, the standby device takes over ownership of the standby IP address and begins to service remote VPN gateways.

Failover can be applied to VPN routers through the use of HSRP. Remote VPN gateways connect to the local VPN router through the standby address that belongs to the active device in the HSRP group. This functionality reduces configuration complexity on remote peers with respect to defining gateway lists, because only the HSRP standby address needs to be defined.

The figure below shows the enhanced HSRP functionality topology. Traffic is serviced by the active Router P, which is the active device in the standby group. In the event of failover, traffic is diverted to Router S, which is the original standby device. Router S assumes the role of the new active router and takes ownership of the standby IP address.

Figure 3: Topology Showing Hot Standby Router Protocol Functionality

In case of a failover, HSRP does not facilitate IPsec state information transference between VPN routers. This means that without this state transference, SAs to remotes will be deleted, requiring Internet Key Exchange (IKE) and IPsec SAs to be reestablished. To make IPsec failover more efficient, it is recommended that IKE keepalives be enabled on all routers.
How to Configure IPsec VPN High Availability Enhancements

Configuring Reverse Route Injection on a Dynamic Crypto Map

Dynamic crypto map entries, like regular static crypto map entries, are grouped into sets. A set is a group of dynamic crypto map entries all with the same dynamic map name, but each with a different dynamic sequence number. Each member of the set may be configured for RRI.

To create a dynamic crypto map entry and enable RRI, perform the steps in this section.

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto dynamic-map map-name seq-num
4. set transform-set
5. reverse-route

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>enable</td>

</tr>
<tr>
<td>set transform-set</td>
<td>Router(config-crypto-m)# set transform-set</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>This entry is the only configuration statement required in dynamic crypto map entries.</td>
</tr>
<tr>
<td>reverse-route</td>
<td>Example:</td>
</tr>
<tr>
<td>reverse-route</td>
<td>Router(config-crypto-m)# reverse-route</td>
</tr>
<tr>
<td></td>
<td>Creates source proxy information.</td>
</tr>
</tbody>
</table>
Configuring Reverse Route Injection on a Static Crypto Map

Before configuring RRI on a static crypto map, note that:

- Routes are not created based on access list 102, as reverse-route is not enabled on mymap 2. RRI is not enabled by default and is not displayed in the router configuration.

- Enable a routing protocol to distribute the VPN routes to upstream devices.

- If Cisco Express Forwarding (CEF) is run on a VPN router configured for RRI, adjacencies need to be formed for each RRI injected network through the next hop device. As the next hop is not explicitly defined in the routing table for these routes, proxy-ARP should be enabled on the next hop router, which allows the CEF adjacency to be formed using the Layer 2 addresses of that device. In cases where there are many RRI injected routes, adjacency tables may become quite large, as an entry is created for each device from each of the subnets represented by the RRI route.

To add RRI to a static crypto map set, perform the steps in this section.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. crypto map map-name seq-num ipsec-isakmp
4. set peer ip-address
5. reverse-route
6. match address
7. set transform-set transform-set-name

<td></td>
</tr>
</tbody>
</table>

**Configuring HSRP with IPsec**

When configuring HSRP with IPsec, the following conditions may apply:

- When HSRP is applied to a crypto map on an interface, the crypto map must be reapplied if the standby IP address or the standby name is changed on that interface.

- If HSRP is applied to a crypto map on an interface, and you delete the standby IP address or the standby name from that interface, the crypto tunnel endpoint is reinitialized to the actual IP address of that interface.

- If you add the standby IP address and the standby name to an interface with the requirement IPsec failover, the crypto map must be reapplied with the appropriate redundancy information.

- Standby priorities should be equal on active and standby routers. If they are not, the higher priority router takes over as the active router. If the old active router comes back up and immediately assumes the active role before having time to report itself, standby and sync connections will be dropped.

- The IP addresses on the HSRP-tracked interfaces on the standby and active routers should both be either lower or higher on one router than the other. In the case of equal priorities (an HA requirement), HSRP will assign the active state-based IP address. If an addressing scheme exists so that the public IP address of router A is lower than the public IP address of router B, but the opposite is true for their private interfaces, an active/standby-standby/active split condition could exist, which will break connectivity.

**Note** To configure HSRP without IPsec, refer to the “Configuring IP Services“ module in the IP Application Services Configuration Guide.

To apply a crypto map set to an interface, perform the steps in this section.

**SUMMARY STEPS**

1. `enable`

**Configuration Examples for IPsec VPN High Availability Enhancements**

**Example: Configuring Reverse Route Injection on a Dynamic Crypto Map**

In the following example, using the `reverse-route` command in the definition of the dynamic crypto map template ensures that routes are created for any remote proxies (subnets or hosts), protected by the connecting remote IPsec peers.

```
crypto dynamic mydynmap 1
    set transform-set my-transform-set
    reverse-route
```

This template is then associated with a “parent” crypto map statement and then applied to an interface.
crypto map mymap 3 ipsec-isakmp dynamic mydynmap
interface FastEthernet 0/0
crypto map mymap

Example: Configuring Reverse Route Injection on a Static Crypto Map

RRI is a good solution for topologies that require encrypted traffic to be diverted to a VPN router and all other traffic to a different router. In these scenarios, RRI eliminates the need to manually define static routes on devices.

RRI is not required if a single VPN router is used, and all traffic passes through the VPN router during its path in to and out of the network.

If you choose to manually define static routes on the VPN router for remote proxies and have these routes permanently installed in the routing table, RRI should not be enabled on the crypto map instance that covers the same remote proxies. In this case, there is no possibility of user-defined static routes being removed by RRI.

Routing convergence can affect the success of a failover based on the routing protocol used to advertise routes (link state versus periodic update). We recommend that a link state routing protocol such as OSPF be used to help speed convergence time by ensuring that routing updates are sent as soon as a change in routing state is detected.

In the following example, RRI is enabled for mymap 1, but not for mymap 2. Upon the application of the crypto map to the interface, a route is created based on access-list 101 analogous to the following:

```plaintext
IP route 172.17.11.0 255.255.255.0 FastEthernet 0/0
crypto map mymap 1 ipsec-isakmp
set peer 172.17.11.1
reverse-route
set transform-set my-transform-set
match address 101
crypto map mymap 2 ipsec-isakmp
set peer 10.1.1.1
set transform-set my-transform-set
match address 102
access-list 101 permit ip 192.168.1.0 0.0.0.255 172.17.11.0 0.0.0.255
access-list 102 permit ip 192.168.1.0 0.0.0.255 10.0.0.0 0.0.255.255
interface FastEthernet 0/0
crypto map mymap
```

Example: Configuring HSRP with IPsec

The following example shows how all remote VPN gateways connect to the router via 192.168.0.3. The crypto map on the interface binds this standby address as the local tunnel endpoint for all instances of the crypto map named mymap and at the same time ensures that HSRP failover is facilitated between an active and standby device belonging to the same standby group named group1.

Note that RRI also provides the ability for only the active device in the HSRP group to be advertising itself to inside devices as the next hop VPN gateway to the remote proxies. If there is a failover, routes are deleted on the formerly active device and created on the newly active device.

```plaintext
crypto map mymap 1 ipsec-isakmp
set peer 10.1.1.1
reverse-route
```
set transform-set esp-aes-sha
match address 102
Interface FastEthernet 0/0
  ip address 192.168.0.2 255.255.255.0
  standby name group1
  standby ip 192.168.0.3
  crypto map mymap redundancy group1
access-list 102 permit ip 192.168.1.0 0.0.0.255 10.0.0.0 0.0.255.255

The standby name needs to be configured on all devices in the standby group, and the standby address needs to be configured on at least one member of the group. If the standby name is removed from the router, the IPsec SAs will be deleted. If the standby name is added again, regardless of whether the same name or a different name is used, the crypto map (using the redundancy option) will have to be reapplied to the interface.

</tbody>
</table>
Stateful Failover for IPsec

Stateful failover for IP Security (IPsec) enables a router to continue processing and forwarding IPsec packets after a planned or unplanned outage occurs. Customers employ a backup (secondary) router that automatically takes over the tasks of the active (primary) router if the active router loses connectivity for any reason. This failover process is transparent to users and does not require adjustment or reconfiguration of any remote peer.

Stateful failover for IPsec is designed to work in conjunction with stateful switchover (SSO) and Hot Standby Routing Protocol (HSRP). HSRP provides network redundancy for IP networks, ensuring that user traffic immediately and transparently recovers from failures in network edge devices or access circuits. That is, HSRP monitors both the inside and outside interfaces so that if either interface goes down, the whole router is deemed to be down and the ownership of Internet Key Exchange (IKE) and IPsec security associations (SAs) is passed to the standby router (which transitions to the HSRP active state). SSO allows the active and standby routers to share IKE and IPsec state information so both routers have enough information to become the active router at any time. To configure stateful failover for IPsec, a network administrator must enable HSRP, assign a virtual IP address (VIP), and enable SSO.

Note

Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the Next Generation Encryption (NGE) white paper.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.
Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Stateful Failover for IPsec

Complete, Duplicate IPsec and IKE Configuration on the Active and Standby Devices

This document assumes that you have a complete IKE and IPsec configuration. The IKE and IPsec configuration that is set up on the active device must be duplicated on the standby device. That is, the crypto configuration must be identical with respect to Internet Security Association and Key Management Protocol (ISAKMP) policy, ISAKMP keys (preshared), IPsec profiles, IPsec transform sets, all crypto map sets that are used for stateful failover, all access control lists (ACLs) that are used in match address statements on crypto map sets, all AAA configurations used for crypto, client configuration groups, IP local pools used for crypto, and ISAKMP profiles.

Note

The configuration information between the active and standby devices is not automatically transferred; you are responsible for ensuring that the crypto configurations match on both devices. If the crypto configurations on both devices do not match, failover from the active device to the standby device will not be successful.

Device Requirements

Stateful failover for IPsec requires that your network contains two identical routers that are available to be either the primary or secondary device. Both routers should be the same type of device, have the same CPU and memory, and have either no encryption accelerator or identical encryption accelerators.

Restrictions for Stateful Failover for IPsec

When configuring redundancy for a VPN, the following restrictions apply:

- Both the active and standby devices must run the identical version of the Cisco IOS software, and both the active and standby devices must be connected via a hub or switch.
- The Cisco Integrated Services Routers (ISRs) and the VPN modules that support stateful failover for IPsec are as follows:
  - The AIM-VPN/BPII-PLUS and AIM-VPN/SSL-1 hardware encryption modules are supported on the Cisco 1841 router.
  - The AIM-VPN/EPII-Plus and AIM-VPN/SSL-2 hardware encryption modules are supported on Cisco 2801, 2811, 2821, and 2851 routers.
  - The AIM-VPN/EPII+ and AIM-VPN/SSL-3 hardware encryption modules are supported on the Cisco 3825 router.
  - The AIM-VPN/HPII+ and AIM-VPN/SSL-3 hardware encryption modules are supported on the Cisco 3845 router.
Information About Stateful Failover for IPsec

Supported Deployment Scenarios for Stateful Failover for IPsec

You can implement stateful failover for IPsec in one of the following recommended deployment scenarios: a single interface scenario or a dual interface scenario.

In a single interface scenario, VPN gateways use one LAN connection for both encrypted traffic arriving from remote peers and decrypted traffic flowing to inside hosts (see the figure below). The single interface design
allows customers to save money on router ports and subnets. This design is typically used if all traffic flowing in and out of the organization does not traverse the VPN routers.

*Figure 4: Single Interface Network Topology*

In a dual interface scenario, a VPN gateway has more than one interface, enabling traffic to flow in and out of the router via separate interfaces (see the figure below). This scenario is typically used if traffic flowing in and out of a site must traverse the routers, so the VPN routers will provide the default route out of the network.

*Figure 5: Dual Interface Network Topology*

The table below lists the functionality available in single-interface and dual-interface scenarios.
### Table 3: Single- and Dual-Interface Functionality Overview

<table>
<thead>
<tr>
<th>Functionality</th>
<th>Single Interface</th>
<th>Dual Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>Route Injection</td>
<td>Routes must be injected to provide the devices that are behind the VPN gateways with a next hop for traffic that requires encryption. Stateful failover for IPsec typically requires routes to be injected for this network topology.</td>
<td>If the VPN gateways are not the logical next hop for devices inside the network, the routes must be created and injected into the routing process. Thus, traffic that is returning from inside the network can be sent back to the VPN routers for IPsec services before it is sent out. A virtual IP (VIP) address cannot be used as the advertiser of routing updates, so flows must be synchronized via the injected routes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If the VPN gateways are the next hop (default route) for all devices inside the network, the VIP address that is used on the inside interfaces can be used as the next hop. Thus, injection of the VPN routes is not required. However, static routes on inside hosts must be used to direct the routes to the next hop VIP address.</td>
</tr>
<tr>
<td>HSRP Configuration</td>
<td>The role of HSRP is simplified in a single interface design because if the only interface is disabled, the entire device is deemed unavailable. This functionality helps to avoid some of the routing considerations to be discussed in the next scenario.</td>
<td>Because each interface pair functions independently, you should configure HSRP so that multiple pairs of interfaces can be tracked. (That is, HSRP should not be configured on only one pair of interfaces or on both pairs of interfaces without each pair mutually tracking each other.) Mutual tracking means that if the outside interface does fail, the inside interface on the same router will also be deemed down, allowing for complete router failover to the secondary router.</td>
</tr>
<tr>
<td>Secure State Information</td>
<td>If secure state information is passed between routers, the information is passed over the same interface as all other traffic.</td>
<td>The router has a separate inside and outside interface; thus, the inside interface can be used as a more secure channel for the exchange of state information.</td>
</tr>
</tbody>
</table>
### IPsec Stateful Failover for Remote Access Connections

The main difference between a remote access and a LAN-to-LAN connection is the use of Xauth and mode-config. IKE Xauth is often used to authenticate a user. IKE mode-config is often used to push security policy from a hub (concentrator) router to a user’s IPsec implementation. Mode-config is also typically used to assign an internal company network IP address to a user.

In addition to the differences between a remote access configuration and a LAN-to-LAN configuration, you should note the following remote-access-server-specific functions:

- **Assigned IP address**—An IP address can be assigned to the client via one of the following options:
  - **Local IP pools**
    
    For local IP pools, the administrator must first configure identical local IP address pools on each router in the high availability (HA) pair (via the `ip local pool client-address-pool` command). This pool name can be applied in one of two places—in a group policy via the `crypto isakmp client configuration group group-name` (and the submode command `pool pool-name`) or in a client configuration via the `crypto isakmp client configuration address-pool local local-pool` command.
  - **RADIUS-assigned address**
    
    If you are using RADIUS authentication and the RADIUS server returns the Framed-IP-Address attribute, the concentrator will always assign the address to the client. It is recommended that you refer to your RADIUS server vendor’s documentation, especially for vendors that allow you to configure address pools on the RADIUS server. Typically, those servers require crypto accounting to work properly.

To enable accounting on the HA pair, you should execute the following command on both active and standby devices: `aaa accounting network` and apply `radius-accounting` either to the `crypto ISAKMP profile` or the `crypto map set`.

- **RADIUS Network Access Server (NAS)-IP address**

  The HA pair should appear as a single device to the RADIUS server. Thus, both HA routers must communicate with the RADIUS server using the same IP address. However, when communicating with the RADIUS server, the router must use a physical IP address, not a virtual IP (VIP) address as the NAS-IP address of the router. To configure the RADIUS NAS-IP address for the HA pair, you must configure the same loopback address in the HA pair via `interface loopback` command; thereafter, you must execute the `ip radius source-interface` command in the HA pair. Finally, add the new loopback IP address to the RADIUS servers configuration so the RADIUS server can process requests from the HA pair.

For additional information on how to configure IPsec stateful failover for a remote access connection, see the section “Example: Configuring Stateful Failover for IPsec for an Easy VPN Server.”
Dead Peer Detection with IPsec High Availability

To configure Dead Peer Detection (DPD) with IPsec High Availability (HA), it is recommended that you use a value other than the default (2 seconds). A keepalive time of 10 seconds with 5 retries seems to work well with HA because of the time it takes for the router to get into active mode.

To configure DPD with IPsec HA, use the `crypto isakmp keepalive` command.

How to Enable Stateful Failover for IPsec

Enabling HSRP IP Redundancy and a Virtual IP Address

HSRP provides two services, IP redundancy and a virtual IP (VIP) address. Each HSRP group may provide either or both of these services. IPsec stateful failover uses the IP redundancy services from only one HSRP standby group. It can use the VIP address from one or more HSRP groups. Use this task to configure HSRP on the outside and inside interfaces of the device.

When configuring HSRP, you must ensure the following:

- Both the inside (private) interface and the outside (public) interface must belong to separate HSRP groups, but the HSRP group number can be the same.
- The state of the inside interface and the outside interface must be the same—both interfaces must be in the active state or standby state; otherwise, the packets will not have a route out of the private network.
- Standby priorities should be equal on both active and standby routers. If the priorities are not equal, the higher priority router will unnecessarily take over as the active router, negatively affecting uptime.
- The IP addresses on the HSRP-tracked interfaces of the standby and active routers should both be either lower or higher on one router than the other. In the case of equal priorities (an HA requirement), HSRP will assign the active state on the basis of the IP address. If an addressing scheme exists so that the public IP address of Router A is lower than the public IP address of Router B, but the opposite is true for their private interfaces, an active/standby-standby/active split condition could exist which will break connectivity.

Note

Each time an active device relinquishes control to become the standby device, the active device will reload. This functionality ensures that the state of the new standby device synchronizes correctly with the new active device.

Before you begin

Before you perform this task, you must perform one of the following steps to ensure that the correct HSRP settings are configured on the switch that connects the active and standby routers:

- Enable the `spanning-tree portfast` command on every switch port that connects to an HSRP-enabled router interface.
- Disable the Spanning Tree Protocol (STP) on the switch only if your switch does not connect to other switches. Disabling spanning tree in a multiswitch environment may cause network instability.
• Enable the **standby delay minimum** `[min-delay] reload [reload-delay]` command even if the **spanning-tree portfast** command is configured. This command must be applied to all HSRP interfaces on both routers. During HSRP stateful failover, configure **standby delay minimum 30 reload 60**.

For more information on HSRP instability, see the document *Avoiding HSRP Instability in a Switching Environment with Various Router Platforms*.

### SUMMARY STEPS

1. enable
2. configure terminal
3. interface type number
4. standby standby-group-number name standby-group-name
5. standby standby-group-number ip ip-address
6. standby standby-group-number track interface-type interface-number
7. standby [group-number] preempt
8. standby [group-number] timers [msec] hellotime [msec] holdtime
9. standby delay minimum [min-delay] reload [reload-delay]
10. Repeat this task on both routers (active and standby) and on both interfaces of each router.

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>interface type number</td>
<td>Configures an interface type for the router and enters interface configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: Router(config)# interface Ethernet 0/0</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>standby standby-group-number name standby-group-name</td>
<td>Assigns a user-defined group name to the HSRP redundancy group.</td>
</tr>
<tr>
<td></td>
<td>Example: Router(config-if)# standby 1 name HA-out</td>
<td>Note: The <code>standby-group-number</code> argument should be the same for both routers that are on directly connected interfaces. However, the <code>standby-group-name</code> argument should be different between two (or more) groups on the same router. The <code>standby-group-number</code> argument can be the same on the other pair of interfaces as well.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Assigns an IP address that is to be “shared” among the members of the HSRP group and owned by the primary IP address.</td>
<td></td>
</tr>
</tbody>
</table>
| `standby standby-group-number ip ip-address` | **Example:**  
Router(config-if)# standby 1 ip 209.165.201.1 |
| **Note** | The virtual IP address must be configured identically on both routers (active and standby) that are on directly connected interfaces. |
| **Step 6**        | (Optional) Configures HSRP to monitor the second interface so that if either of the two interfaces goes down, HSRP causes failover to the standby device. |
| `standby standby-group-number track interface-type interface-number` | **Example:**  
Router(config-if)# standby 1 track Ethernet1/0 |
| **Note** | Although this command is not required, it is recommended for dual interface configurations. |
| **Step 7**        | Enables HSRP preemption and preemption delay. |
| `standby [group-number] preempt` | **Example:**  
Router(config-if)# standby 1 preempt |
| **Step 8**        | (Optional) Configures the time between hello packets and the time before other routers declare the active Hot Standby or standby router to be down. |
| `standby [group-number] timers [msec] hello-time [msec] hold-time` | **Example:**  
Router(config-if)# standby 1 timers 1 hellotime 5 holdtime 1 |
| **Note** | For the best stability, it is recommended that you set the hold time between 5 and 10 times the hello interval time; otherwise, a failover could falsely occur when no actual failure has happened. |
| **Step 9**        | Configures the delay period before the initialization of HSRP groups. |
| `standby delay minimum [min-delay] reload [reload-delay]` | **Example:**  
Router(config-if)# standby delay minimum reload 120 |
| **Note** | It is suggested that you enter 120 as the value for the `reload-delay` argument and leave the `min-delay` argument at the preconfigured default value. |
| **Step 10**       | Repeat this task on both routers (active and standby) and on both interfaces of each router. |

**Troubleshooting Tips**

To help troubleshoot possible HSRP-related configuration problems, issue any of the following HSRP-related debug commands—`debug standby errors`, `debug standby events`, and `debug standby packets [terse]`. 
Examples

The following example shows how to configure HSRP on a router:

interface Ethernet0/0
ip address 209.165.201.1 255.255.255.224
standby 1 ip 209.165.201.3
standby 1 preempt
standby 1 name HA-out
standby 1 track Ethernet1/0
standby delay reload 120

What to Do Next

After you have successfully configured HSRP on the inside and outside interfaces, you should enable SSO as described in the section “Enabling SSO.”

Enabling SSO

Enabling SSO Interaction with IPsec and IKE

SSO is a method of providing redundancy and synchronization for many Cisco IOS applications and features. SSO is necessary for IPsec and IKE to learn about the redundancy state of the network and to synchronize their internal application state with their redundant peers.

Before you begin

Before you perform this task, you must:

• Configure HSRP before enabling SSO.

• Include the following commands in the local address section of the Stream Control Transmission Protocol (SCTP) section when configuring Inter-Process Communication (IPC):

  • `retransmit-timeout retran-min [msec] retran-max [msec]`
  • `path-retransmit max-path-retries`
  • `assoc-retransmit retries`

Note

The above commands are included to avoid losing SCTP communication between peers.

SUMMARY STEPS

1. enable
2. configure terminal
3. redundancy inter-device
4. scheme standby `standby-group-name`
5. exit
6. ipc zone default
7. association `association-ID`

<td>Router&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>redundancy inter-device</td>
<td>Configures redundancy and enters inter-device configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router(config)# redundancy inter-device</td>
<td>• To exit inter-device configuration mode, use the exit command. To remove all inter-device configuration, use the no form of the command.</td>
</tr>
<tr>
<td>Step 4</td>
<td>scheme standby <strong>standby-group-name</strong></td>
<td>Defines the redundancy scheme. Currently, “standby” is the only supported scheme.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router(config-red-interdevice)# scheme standby <strong>HA-out</strong></td>
<td>• <strong>standby-group-name</strong>—Must match the standby name specified in the <strong>standby name</strong> interface configuration command. Also, the standby name should be the same on both routers.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>Only the active or standby state of the standby group is used for SSO. The VIP address of the standby group is not required or used by SSO. Also, the standby group does not have to be part of any crypto map configuration.</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>exit</td>
<td>Exits inter-device configuration mode and returns to global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router(config-red-interdevice)# exit</td>
<td></td>
</tr>
<tr>
<td>Step</td>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>------</td>
<td>------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| 6    | ipc zone default | Configures the inter-device communication protocol, Inter-Process Communication (IPC), and enters IPC zone configuration mode.  
- Use this command to initiate the communication link between the active router and standby router. |
| 7    | association association-ID | Configures an association between the two devices and enters IPC association configuration mode.  
- association-ID—Association ID assignment. The value range is from 1 through 255. The association ID must be unique within a specific zone. |
| 8    | protocol sctp    | Configures Stream Control Transmission Protocol (SCTP) as the transport protocol and enters SCTP protocol configuration mode. |
| 9    | local-port local-port-number | Defines the local SCTP port number that is used to communicate with the redundant peer and enters IPC transport-SCTP local configuration mode.  
- local-port-number—There is no default value. This argument must be configured for the local port to enable inter-device redundancy. Valid port values: 1 to 65535. The local port number should be the same as the remote port number on the peer router. |
| 10   | local-ip device-real-ip-address [device-real-ip-address2] | Defines at least one local IP address that is used to communicate with the redundant peer.  
- The local IP addresses must match the remote IP addresses on the peer router. There can be either one or two IP addresses, which must be in the global VRF. A virtual IP address cannot be used. |
| 11   | retransmit-timeout retrans-min [msec] retra-max [msec] | Configures the maximum amount of time, in milliseconds, that SCTP will wait before retransmitting data.  
- retrans-min—Range is 300 to 60000. Default value is 300.  
- retrans-max—Range is 300 to 60000. Default value is 600. |
| 12   | path-retransmit max-path-retries | Configures the number of consecutive retransmissions SCTP will perform before failing a path within an association.  
- max-path-retries—Range is 2 to 10. Default value is 4 retries. |
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 13   | `assoc-retransmit max-association-retries` | Configures the number of consecutive retransmissions SCTP will perform before failing an association.  
- `max-association-retries`—Range is 2 to 10. Default value is 4 retries. |
| 14   | `exit` | Exits IPC transport-SCTP local configuration mode and enters SCTP protocol configuration mode. |
| 15   | `remote-port remote-port-number` | Defines the remote SCTP port number that is used to communicate with the redundant peer and enters IPC transport-SCTP remote configuration mode.  
- `remote-port-number`—There is no default value. This argument must be configured for the remote port to enable inter-device redundancy. Valid port values: 1 to 65535. The remote port number should be the same as the local port number on the peer router. |
| 16   | `remote-ip peer-real-ip-address [peer-real-ip-address2]` | Defines at least one remote IP address of the redundant peer that is used to communicate with the local device.  
- All remote IP addresses must refer to the same device.  
- A virtual IP address cannot be used. |
| 17   | `end` | Exits IPC transport-SCTP remote configuration mode and returns to privileged EXEC mode. |

**Troubleshooting Tips**

To help troubleshoot possible SSO-related configuration problems, use the `debug redundancy` command.

**Examples**

The following example shows how to enable SSO:

```bash
!  redundancy inter-device  
  scheme standby HA-out  
!  !  
  ipc zone default  
  association 1  
  no shutdown  
  protocol sctp  
  local-port 5000  
  local-ip 10.0.0.1  
  retransmit-timeout 300 10000
```
What to Do Next

After you have enabled SSO, you should configure reverse route injection (RRI) on a crypto map as described in the section “Configuring Reverse Route Injection on a Crypto Map.”

Configuring Reverse Route Injection on a Crypto Map

You should configure Reverse Route Injection (RRI) on all existing crypto maps that you want to use with stateful failover. RRI is used with stateful failover so that the routers on the inside network can learn about the correct path to the current active device. When failover occurs, the new active device injects the RRI routes into its IP routing table and sends out routing updates to its routing peers.

Configuring Reverse Route Injection on Dynamic Crypto Map

Dynamic crypto map entries, like regular static crypto map entries, are grouped into sets. A set is a group of dynamic crypto map entries all with the same dynamic map name, but each with a different dynamic sequence number. Each member of the set may be configured for RRI.

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto dynamic-map map-name seq-num
4. reverse-route
5. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router&gt; enable</td>
</tr>
<tr>
<td></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router# configure terminal</td>
</tr>
<tr>
<td></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>crypto dynamic-map map-name seq-num</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router(config)# crypto dynamic-map mymap 10</td>
</tr>
<tr>
<td></td>
<td>Creates a dynamic crypto map entry and enters crypto map configuration mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>reverse-route</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Enables RRI for a dynamic crypto map.</td>
</tr>
</tbody>
</table>
## Configuring Reverse Route Injection on a Static Crypto Map

Static crypto map entries are grouped into sets. A set is a group of static crypto map entries all with the same static map name, but each with a different sequence number. Each static crypto map in the map set can be configured for RRI. Use this task to configure RRI on a static crypto map.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto map map-name seq-num ipsec-isakmp`
4. `reverse-route`
5. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Router&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Router# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>crypto map map-name seq-num ipsec-isakmp</code></td>
<td>Creates or modifies a crypto map entry and enters crypto map configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Router(config)# crypto map to-peer-outside 10 ipsec-isakmp</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>reverse-route</code></td>
<td>Dynamically creates static routes based on crypto ACLs.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Router(config-crypto-map)# reverse-route</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>end</code></td>
<td>Exits crypto map configuration mode and returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example: <code>Router(config-crypto-map)# end</code></td>
<td></td>
</tr>
</tbody>
</table>
Examples

The following example shows how to configure RRI on the static crypto map “to-peer-outside”:

```
crypto map to-peer-outside redundancy replay-interval inbound 1000 outbound 10000
crypto map to-peer-outside 10 ipsec-isakmp
set peer 209.165.200.225
set transform-set trans1
match address peer-outside
reverse-route
```

What to Do Next

After you have configured RRI, you can enable stateful failover for IPsec and IKE.

Enabling Stateful Failover for IKE and IPsec

Enabling Stateful Failover for IKE

There is no specific CLI necessary to enable stateful failover for IKE. It is enabled for a particular virtual IP address when a stateful failover crypto map is applied to an interface.

Enabling Stateful Failover for IPsec

Use this task to enable stateful failover for IPsec. All IPsec state information is transferred from the active router to the standby router via the SSO redundancy channel that was specified in the task “Enabling SSO.”

SUMMARY STEPS

1. enable
2. configure terminal
3. interface type number
4. crypto map map-name [redundancy standby-group-name [stateful]]
5. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>interface type number</td>
<td>Defines an interface that has already been configured for redundancy and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

Router(config)# interface Ethernet 0/0

**Step 4**

<table>
<thead>
<tr>
<th>crypto map map-name [redundancy standby-group-name [stateful]]</th>
</tr>
</thead>
</table>

**Example:**

Router(config-if)# crypto map to-peer-outside redundancy HA-out stateful

**Purpose**

Binds the crypto map on the specified interface to the redundancy group.

**Note**

Although the standby group does not have to be the same group that was used when enabling SSO, it must be the same group that was used with the **standby ip** command on this interface.

This crypto map will use the same virtual IP address for both IKE and IPsec to communicate with peers.

**Step 5**

<table>
<thead>
<tr>
<th>end</th>
</tr>
</thead>
</table>

**Example:**

Router(config-if)# end

**Purpose**

Exits interface configuration mode and returns to privileged EXEC mode.

### Troubleshooting Tips

To help troubleshoot possible IPsec-HA-related problems, use the **debug crypto ipsec ha [detail] [update]** command.

### Examples

The following example shows how to configure IPsec stateful failover on the crypto map “to-peer-outside”:

```bash
interface Ethernet0/0
ip address 209.165.201.1 255.255.255.224
standby 1 ip 209.165.201.3
standby 1 preempt
standby 1 name HA-out
standby 1 track Ethernet1/0
crypto map to-peer-outside redundancy HA-out stateful
```

### Enabling Stateful Failover for Tunnel Protection

Use an existing IPsec profile to configure stateful failover for tunnels using IPsec. (You do not configure the tunnel interface as you would with a crypto map configuration.)

**Note**

The tunnel source address must be a virtual IP address, and it must not be an interface name.

### SUMMARY STEPS

1. enable
2. configure terminal
3. crypto ipsec profile name
4. redundancy standby-group-name stateful
5. exit
6. interface tunnel number
7. `tunnel protection ipsec profile name`
8. `tunnel source virtual-ip-address`
9. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>enable</strong>&lt;br&gt;Example:&lt;br&gt;Router&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>configure terminal</strong>&lt;br&gt;Example:&lt;br&gt;Router# configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>crypto ipsec profile name</code>&lt;br&gt;Example:&lt;br&gt;Router(config)# crypto ipsec profile peer-profile</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>redundancy standby-group-name stateful</code>&lt;br&gt;Example:&lt;br&gt;Router(config-crypto-map)# redundancy HA-out stateful</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>exit</code>&lt;br&gt;Example:&lt;br&gt;Router(config-crypto-map)# exit</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><code>interface tunnel number</code>&lt;br&gt;Example:&lt;br&gt;Router(config)# interface tunnel 5</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td><code>tunnel protection ipsec profile name</code>&lt;br&gt;Example:&lt;br&gt;Router(config-if)# tunnel protection ipsec profile catprofile</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td><code>tunnel source virtual-ip-address</code>&lt;br&gt;Example:&lt;br&gt;Router(config-if)# tunnel source 10.1.1.1</td>
</tr>
</tbody>
</table>
Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 9 end</td>
<td>Exits interface configuration mode and returns to privileged EXEC mode.</td>
</tr>
</tbody>
</table>

Example:

```
Step 9
Router(config-if)# end
```

Examples

The following example shows how to configure stateful failover for tunnel protection:

```
crypto ipsec profile peer-profile
redundancy HA-out stateful

interface Tunnel1
  ip unnumbered Loopback 0
  tunnel source 209.165.201.3
  tunnel destination 10.0.0.5
  tunnel protection ipsec profile peer-profile

interface Ethernet0/0
  ip address 209.165.201.1 255.255.255.224
  standby 1 ip 209.165.201.3
  standby 1 name HA-out
```

What to Do Next

After you have configured stateful failover, you can use the CLI to protect, verify, and manage your configurations. For more information on completing these tasks, see the sections “Protecting SSO Traffic” and “Managing and Verifying HA Information.”

Protecting SSO Traffic

Use this task to secure a redundancy group via an IPsec profile. To configure SSO traffic protection, the active and standby devices must be directly connected to each other via Ethernet networks.

The crypto maps that are automatically generated when protecting SSO traffic are applied to each interface, which corresponds to an IP address that was specified via the `local-ip` command. Traffic destined for an IP address that was specified via the `remote-ip` command is forced out of the crypto-map-configured interface via an automatically created static host route.

Note

If you are certain that the SSO traffic between the redundancy group runs on a physically secure interface, you do not have to configure SSO traffic protection.

Note

Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the Next Generation Encryption (NGE) white paper.
SUMMARY STEPS

1. enable
2. configure terminal
3. crypto isakmp key keystore string address peer-address
4. crypto ipsec transform-set transform-set-name transform-set-list
5. crypto ipsec profile profile-name
6. set transform-set transform-set-name
7. exit
8. redundancy inter-device
9. security ipsec profile-name

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router&gt; enable</td>
<td></td>
</tr>
<tr>

<td><strong>Step 3</strong> crypto isakmp key keystring address peer-address</td>
<td>Configures a preshared authentication key.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config)# crypto isakmp key abc123 address 0.0.0.0 0.0.0.0</td>
<td>• peer-address—Specified the SCTP remote IP address.</td>
</tr>
<tr>
<td><strong>Step 4</strong> crypto ipsec transform-set transform-set-name transform-set-list</td>
<td>Configures a transform set that defines the packet format and cryptographic algorithms used for IPsec.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config)# crypto ipsec transform-set trans2 ah-sha-hmac esp-aes</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> crypto ipsec profile profile-name</td>
<td>Defines an IPsec profile that describes how the traffic will be protected and enters crypto map configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config)# crypto ipsec profile sso-secure</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> set transform-set transform-set-name</td>
<td>Specifies which transform sets can be used with the IPsec profile.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config-crypto-map)# set transform-set trans2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> exit</td>
<td>Exits crypto map configuration mode and returns to global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config-crypto-map)# exit</td>
<td></td>
</tr>
<tr>
<td>Step</td>
<td>Command or Action</td>
</tr>
<tr>
<td>------</td>
<td>------------------</td>

<tr>
<td>9</td>
<td>security ipsec profile-name</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td></td>
<td>Router(config-red-interdevice)# security ipsec sso-secure</td>
</tr>
</tbody>
</table>

Examples

The following example shows how to configure SSO traffic protection:

```plaintext
crypto isakmp key abc123 address 0.0.0.0 0.0.0.0 no-xauth !
crypto ipsec transform-set trans2 ah-sha-hmac esp-aes !
crypto ipsec profile sso-secure
  set transform-set trans2 !
  redundancy inter-device
  scheme standby HA-out
  security ipsec sso-secure
```

Managing and Verifying HA Information

Managing Anti-Replay Intervals

Use this optional task to modify the interval in which an IP redundancy-enabled crypto map forwards anti-replay updates from the active router to the standby router.

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto map map-name redundancy replay-interval inbound in-value outbound out-value
4. exit

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>Entrances global configuration mode.</strong></td>
<td></td>
</tr>
<tr>
<td>configure terminal</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router# configure terminal</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>Modifies the interval at which inbound and outbound replay counters are passed from an active device to a standby device.</strong></td>
<td></td>
</tr>
<tr>
<td>crypto map map-name redundancy replay-interval inbound in-value outbound out-value</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router(config)# crypto map to-peer-outside redundancy replay-interval inbound 1000 outbound 10000</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>Exits global configuration mode and returns to privileged EXEC mode.</strong></td>
<td></td>
</tr>
<tr>
<td>exit</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router(config)# exit</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Examples**

The following example shows how to modify replay counter intervals between the active and standby devices on the crypto map “to-peer-outside”:

```
crypto map to-peer-outside redundancy replay-interval inbound 1000 outbound 10000
crypto map to-peer-outside 10 ipsec-isakmp
set peer 209.165.200.225
set transform-set trans1
match address peer-outside
```

**Managing and Verifying HA Configurations**

Use any of the steps within this optional task to display and verify the high availability configurations.

**SUMMARY STEPS**

1. enable
2. show redundancy [states | inter-device]
3. show crypto isakmp sa [active | standby]
4. show crypto ipsec sa [active | standby]
5. show crypto session [active | standby]
6. show crypto ha
7. clear crypto isakmp [active | standby]
8. clear crypto sa [active | standby]
9. clear crypto session [active | standby]

## Detailed Steps

#### Examples

**Verifying the Active Device**

```plaintext
Router# show redundancy states
    my state = 13 -ACTIVE
    peer state = 8 -STANDBY HOT
    Mode = Duplex
    Unit ID = 0
    Split Mode = Disabled
    Manual Swact = Enabled
    Communications = Up
    client count = 7
    client_notification_TMR = 30000 milliseconds
    keep_alive TMR = 4000 milliseconds
    keep_alive count = 0
    keep_alive threshold = 7
    RF debug mask = 0x0
```

```plaintext
Router# show crypto isakmp sa active
    dst | src | state | conn-id | slot | status
    209.165.201.3 | 209.165.200.225 | QM_IDLE | 5 | 0 ACTIVE
```

```plaintext
Router# show crypto ipsec sa active
    interface:Ethernet0/0
    Crypto map tag:to-peer-outside, local addr 209.165.201.3
    protected vrf:(none)
    local ident (addr/mask/prot/port):(192.168.0.1/255.255.255.255/0/0)
    remote ident (addr/mask/prot/port):(172.16.0.1/255.255.255.255/0/0)
    current_peer 209.165.200.225 port 500
    PERMIT, flags=(origin_is_acl,)
    #pkts encaps:3, #pkts encrypt:3, #pkts digest:3
```
# pkts decaps:4, #pkts decrypt:4, #pkts verify:4
# pkts compressed:0, #pkts decompressed:0

Feature Information for Stateful Failover for IPsec

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

<tr>
<td>Stateful Failover for IPsec</td>
<td>12.3(11)T</td>
<td>The Stateful Failover for IP Sec feature enables a router to continue processing and forwarding IPsec packets after a planned or unplanned outage occurs. Customers employ a backup (secondary) router that automatically takes over the tasks of the active (primary) router if the active router loses connectivity for any reason. The following commands were introduced or modified: <code>clear crypto isakmp</code>, <code>clear crypto sa</code>, <code>clear crypto session</code>, <code>crypto map (interface IPsec)</code>, <code>crypto map redundancy replay-interval</code>, <code>debug crypto ha</code>, <code>debug crypto ipsec ha</code>, <code>debug crypto isakmp ha</code>, <code>local-ip (IPC transport-SCTP local)</code>, <code>local-port</code>, <code>redundancy inter-device</code>, <code>redundancy stateful</code>, <code>remote-ip (IPC transport-SCTP remote)</code>, <code>remote-port</code>, <code>scheme</code>, <code>security ipsec</code>, <code>show crypto ha</code>, <code>show crypto ipsec sa</code>, <code>show crypto isakmp sa</code>, <code>show crypto session</code>, <code>show redundancy</code>.</td>

IPsec Preferred Peer

The IP Security (IPsec) Preferred Peer feature allows you to control the circumstances by which multiple peers on a crypto map are tried in a failover scenario.

This feature includes the following capabilities:

• Default peer configuration
• IPsec idle-timer usage with default peer

Finding Feature Information, on page 71

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for IPsec Preferred Peer

• You must have a properly defined, complete crypto map.
Restrictions for IPsec Preferred Peer

Default Peer
- This feature must be used in conjunction with Dead Peer Detection (DPD). It is most effective on a remote site running DPD in periodic mode. DPD detects the failure of a device quickly and resets the peer list so that the default peer is tried for the next attempted connection.
- Only one peer can be designated as the default peer in a crypto map.
- The default peer must be the first peer in the peer list.

IPsec Idle Timer Usage with Default Peer
- This feature works only on the crypto map for which it is configured. You cannot configure the capability globally for all crypto maps.
- If there is a global idle timer, the crypto map idle-timer value must be different from the global value; otherwise, the idle timer is not added to the crypto map.

IPsec Failover
IPsec on the Cisco ASR 1000 Series Router supports only stateless failover. IPsec failover is a feature that increases the total uptime (or availability) of an IPsec network. This is accomplished traditionally by employing a redundant (standby) router in addition to the original (active) router. If the active router becomes unavailable for any reason, the standby router takes over the processing of IKE and IPsec.
IPsec failover falls into two categories: stateless failover and stateful failover. Stateless failover uses protocols such as the Hot Standby Router Protocol (HSRP) to provide primary-to-secondary cutover and also allows the active and standby VPN gateways to share a common virtual IP address.

Information About IPsec Preferred Peer

IPsec
IPsec is a framework of open standards developed by the Internet Engineering Task Force (IETF). IPsec provides security for transmission of sensitive information over unprotected networks such as the Internet. IPsec acts at the network layer, protecting and authenticating Internet Protocol (IP) packets between participating IPsec devices (peers), such as Cisco routers.
IPsec provides the following network security services. These services are optional. In general, local security policy dictates the use of one or more of these services:
- Data Confidentiality--The IPsec sender can encrypt packets before transmitting them across a network.
- Data Integrity--The IPsec receiver can authenticate packets sent by the IPsec sender to ensure that the data has not been altered during transmission.
- Data Origin Authentication--The IPsec receiver can authenticate the source of the IPsec packets sent.
• Anti-Replay--The IPsec receiver can detect and reject replayed packets.

With IPsec, data can be transmitted across a public network without fear of observation, modification, or spoofing. This enables applications such as Virtual Private Networks (VPNs), including intranets, extranets, and remote user access.

IPsec provides secure tunnels between two peers, such as two routers. You define which packets are considered sensitive and should be sent through these secure tunnels, and you define the parameters that should be used to protect these sensitive packets, by specifying characteristics of these tunnels. When the IPsec peer sees such a sensitive packet, it sets up the appropriate secure tunnel and sends the packet through the tunnel to the remote peer.

Dead Peer Detection

The VPN Client uses a keepalive mechanism called Dead Peer Detection (DPD) to check the availability of the VPN device on the other side of an IPsec tunnel. If the network is unusually busy or unreliable, you can increase the number of seconds that the VPN Client will wait before deciding whether the peer is no longer active.

Keepalive packets are not sent if traffic is received. This lowers the overhead associated with DPD, because on a heavily loaded network very few keepalive packets will be sent because traffic is being received on the tunnels. In addition, DPD sends keepalive packets only if there is user traffic to send (and no user traffic is received).

You can configure Internet Key Exchange (IKE) DPD so that DPD sends the keepalive packets whether or not there is outbound user data. That is, as long as there is no inbound user data, the keepalive packets are sent at the configured keepalive interval.

Default Peer Configuration

If a connection timeout occurs, the connection to the current peer is closed. The set peer command allows you to configure the first peer as the default peer. If there is a default peer, the next time a connection is initiated, the connection is directed to the default peer instead of to the next peer in the peer list. If the default peer is unresponsive, the next peer in the peer list becomes the current peer and future connections through the crypto map try that peer.

This capability is useful when traffic on a physical link stops due to the failure of a remote peer. DPD indicates that the remote peer is unavailable, but that peer remains the current peer.

A default peer facilitates the failover to a preferred peer that was previously unavailable, but has returned to service. Users can give preference to certain peers in the event of a failover. This is useful if the original failure was due to a network connectivity problem rather than failure of the remote peer.

Idle Timers

When a router creates an IPsec security association (SA) for a peer, resources must be allocated to maintain the SA. The SA requires both memory and several managed timers. For idle peers, these resources are wasted. If enough resources are wasted by idle peers, the router could be prevented from creating new SAs with other peers.
IPsec SA idle timers increase the availability of resources by deleting SAs associated with idle peers. Because IPsec SA idle timers prevent the wasting of resources by idle peers, more resources are available to create new SAs when required.

If IPsec SA idle timers are not configured, only the global lifetimes for IPsec SAs are applied. SAs are maintained until the global timers expire, regardless of peer activity.

**IPsec Idle-Timer Usage with Default Peer**

If all connections to the current peer time out, the next time a connection is initiated it is directed to the default peer configured in the `set peer` command. If a default peer is not configured and there is a connection timeout, the current peer remains the one that timed out.

This enhancement helps facilitate a failover to a preferred peer that was previously unavailable but is in service now.

**Peers on Crypto Maps**

A crypto map set can contain multiple entries, each with a different access list. The router searches the crypto map entries in order, and attempts to match the packet to the access list specified in that entry.

When a packet matches a `permit` entry in a particular access list, and the corresponding crypto map entry is tagged as Cisco, connections are established with the remote peer as specified in the `set peer` statements within the crypto map.

**How to Configure IPsec Preferred Peer**

**Configuring a Default Peer**

To configure a default peer, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto map map-name seq-num [ipsec-isakmp] [dynamic dynamic-map-name] [discover] [profile profile-name]`
4. `set peer {host-name [dynamic] [default] | ip-address [default]}`
5. `exit`

**DETAILED STEPS**

<table>
<thead>
<tr>

### Configuring the Idle Timer

To configure the idle timer, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto map map-name seq-num [ipsec-isakmp] [dynamic dynamic-map-name] [discover] [profile profile-name]`
4. `set security-association idle-time seconds [default]`
5. `exit`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Router&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action | Purpose
--- | ---
**Step 2**
configure terminal  
Example:  
Router# configure terminal  
| Enters global configuration mode.

**Step 3**
crypto map map-name seq-num [ipsec-isakmp]  
[dynamic dynamic-map-name] [discover] [profile profile-name]  
Example:  
Router(config)# crypto map mymap 10 ipsec-isakmp  
| Enters crypto map configuration mode. Creates or modifies a crypto map entry, creates a crypto profile that provides a template for configuration of dynamically created crypto maps, or configures a client accounting list.

**Step 4**
set security-association idletime seconds [default]  
Example:  
Router(config-crypto-map)# set security-association idletime 120 default  
| Specifies the maximum amount of time for which the current peer can be idle before the default peer is used.

**Step 5**
exit  
Example:  
Router(config-crypto-map)# exit  
| Exits crypto map configuration mode and returns to global configuration mode.

## Configuration Examples for IPsec Preferred Peer

### Configuring a Default Peer Example

The following example shows that the first peer, at IP address 10.1.1.1, is the default peer:

crypto map tohub 1 ipsec-isakmp  
set peer 10.1.1.1 default  
set peer 10.2.2.2

### Configuring the IPsec Idle Timer Example

In the following example, if the current peer is idle for 120 seconds, the default peer 10.1.1.1 (which was specified in the `set peer` command) is used for the next attempted connection:

crypto map tohub 1 ipsec-isakmp  
set peer 10.1.1.1 default  
set peer 10.2.2.2  
set security-association idletime 120 default

Glossary

crypto access list --A list that defines which IP traffic will be protected by crypto and which traffic will not be protected by crypto.

crypto map --A map that specifies which traffic should be protected by IPsec, where IPsec-protected traffic should be sent, and what IPsec transform sets should be applied to this traffic.

dead peer detection --A feature that allows the router to detect an unresponsive peer.

keepalive message --A message sent by one network device to inform another network device that the virtual circuit between the two is still active.

peer --Router or other device that participates in IPsec and IKE. In IPsec, peers are devices or entities that communicate securely either through the exchange of keys or the exchange of digital certificates.

SA --security association. An instance of security policy and keying material applied to a data flow. Both IKE and IPsec use SAs, although SAs are independent of one another. IPsec SAs are unidirectional and are unique in each security protocol. An IKE SA is used by IKE only, and unlike the IPsec SA, it is bidirectional. IKE negotiates and establishes SAs on behalf of IPsec. A user also can establish IPsec SAs manually. A set of SAs are needed for a protected data pipe, one per direction per protocol. For example, if you have a pipe that supports Encapsulating Security Payload (ESP) between peers, one ESP SA is required for each direction. SAs are identified uniquely by destination (IPsec endpoint) address, security protocol (AH or ESP), and security parameter index (SPI).

transform set --An acceptable combination of security protocols, algorithms, and other settings to apply to IPsec-protected traffic. During the IPsec security association negotiation, the peers agree to use a particular transform set when protecting a particular data flow.
Real-Time Resolution for IPsec Tunnel Peer

After a user specifies a host name (instead of an IP address) for remote IP Security (IPsec) peer, the Real-Time Resolution for IPsec Tunnel Peer feature allows the host name to be domain name server (DNS) resolved before the router establishes the IPsec tunnel. Thus, the router can immediately discover whether the IP address of the peer has changed.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Real-Time Resolution for IPsec Tunnel Peer

Secure DNS Requirement

It is recommended that you use this feature only with secure DNS and when the DNS responses can be authenticated. Otherwise, an attacker can spoof or forge DNS responses and have access to Internet Key Exchange (IKE) authentication data, such as a certificate. If an attacker has a certificate that is trusted by the initiating host, the attacker can successfully establish Phase 1 IKE security association (SA), or the attacker can try to guess the preshared key that is shared between the initiator and the actual responder.
DNS Initiator

DNS names resolution for remote IPsec peers will work only if they are used as an initiator. The first packet that is to be encrypted will trigger a DNS lookup; after the DNS lookup is complete, subsequent packets will trigger IKE.

Information About Real-Time Resolution for IPsec Tunnel Peer

Real-Time Resolution Via Secure DNS

When specifying the host name of a remote IPsec peer via the `set peer` command, you can also issue the `dynamic` keyword, which defers DNS resolution of the host name until right before the IPsec tunnel has been established. Deferring resolution enables the Cisco IOS software to detect whether the IP address of the remote IPsec peer has changed. Thus, the software can contact the peer at the new IP address.

If the `dynamic` keyword is not issued, the host name is resolved immediately after it is specified. So, the software cannot detect an IP address change and, therefore, attempts to connect to the IP address that it previously resolved.

DNS resolution assures users that their established IPsec tunnel is secure and authenticated.

How to Configure Real-Time Resolution

Configuring Real-Time Resolution for IPsec Peers

Use this task to configure a router to perform real-time DNS resolution with a remote IPsec peer; that is, the host name of peer is resolved through a DNS lookup right before the router establishes a connection (an IPsec tunnel) with the peer.

Before you begin

Before creating a crypto map, you should perform the following tasks:

- Define Internet Security Association Key Management Protocol (ISAKMP) policies.
- Define IPsec transform sets.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto map map-name seq-num ipsec-isakmp`
4. `match address access-list-id`
5. `set peer {host-name [dynamic] [default] | ip-address [default]}`
6. `set transform-set transform-set-name1 [transform-set-name2...transform-set-name6]`
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | enable | Enables privileged EXEC mode.  
* Enter your password if prompted.  
**Example:**  
Router> enable |
| **Step 2** | configure terminal | Enters global configuration mode.  
**Example:**  
Router# configure terminal |
| **Step 3** | crypto map map-name seq-num ipsec-isakmp | Specifies the crypto map entry to create (or modify) and enters crypto map configuration mode.  
**Example:**  
Router(config)# crypto map secure_b 10 ipsec-isakmp |
| **Step 4** | match address access-list-id | Names an extended access list.  
This access list determines which traffic should be protected by IPsec and which traffic should not be protected by IPsec in the context of this crypto map entry.  
**Example:**  
Router(config-crypto-m)# match address 140 |
| **Step 5** | set peer {host-name [dynamic] [default] | ip-address [default] } | Specifies a remote IPsec peer.  
This is the peer to which IPsec-protected traffic can be forwarded.  
* The *host-name* argument specifies the IPsec peer by its hostname. This is the peer's hostname concatenated with its domain name (for example, myhost.example.com).  
* The optional *dynamic* keyword allows the hostname of the IPsec peer to be resolved through a domain name server (DNS) lookup immediately before the router establishes the IPsec tunnel.  
* The optional *default* keyword designates that the first peer is the default peer if there are multiple IPsec peers.  
* The *ip-address* argument specifies the IPsec peer by its IP address.  
**Example:**  
Router(config-crypto-m)# set peer b.cisco.com dynamic |
| **Step 6** | set transform-set transform-set-name1  
[transform-set-name2...transform-set-name6] | Specifies which transform sets are allowed for this crypto map entry. List multiple transform sets in order of priority (highest priority first).  
**Example:**  
Router(config-crypto-m)# set transform-set myset |
Troubleshooting Tips

To display crypto map configuration information, use the `show crypto map` command.

What to Do Next

You need to apply a crypto map set to each interface through which IPsec traffic will flow. Applying the crypto map set to an interface instructs the router to evaluate all the interface’s traffic against the crypto map set and to use the specified policy during connection or security association (SA) negotiation on behalf of traffic to be protected by crypto.

Configuration Examples for Real-Time Resolution

Configuring Real-Time Resolution for an IPsec Peer Example

The figure below and the following example illustrate how to create a crypto map that configures the host name of a remote IPsec peer to DNS resolved through a DNS lookup right before the Cisco IOS software attempts to establish a connection with that peer.

**Figure 7: Real-Time Resolution Sample Topology**

```
! Configure the initiating router.
hostname a.cisco.com
ip domain name cisco.com
ip name server 10.0.0.1
!
crypto map secure_b 10 ipsec-isakmp
   match address 140
   set peer b.cisco.com dynamic
   set transform-set xset
interface serial1
   ip address 30.0.0.1
   crypto map secure_b
access-list 140 permit ...
!
! Configure the responding router (the remote IPsec peer).
hostname b.cisco.com
!
crypto map secure_a 10 ipsec-isakmp
   match address 150
   set peer 30.0.0.1
```
set transform-set
interface serial0/1
ip address 40.0.0.1
crypto map secure_a
access-list 150 ...
! DNS server configuration
b.cisco.com 40.0.0.1  # the address of serial0/1 of b.cisco.com
