IP Access List Overview

Access control lists (ACLs) perform packet filtering to control which packets move through a network and to where. The packet filtering provides security by helping to limit the network traffic, restrict the access of users and devices to a network, and prevent the traffic from leaving a network. IP access lists reduce the chance of spoofing and denial-of-service attacks and allow dynamic, temporary user-access through a firewall.

IP access lists can also be used for purposes other than security, such as bandwidth control, restrict the content of routing updates, redistribute routes, trigger dial-on-demand (DDR) calls, limit debug output, and identify or classify traffic for quality of service (QoS) features. This module provides an overview of IP access lists.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About IP Access Lists

Benefits of IP Access Lists

Access control lists (ACLs) perform packet filtering to control the flow of packets through a network. Packet filtering can restrict the access of users and devices to a network, providing a measure of security. Access lists can save network resources by reducing traffic. The benefits of using access lists are as follows:

• Authenticate incoming rsh and rcp requests—Access lists can simplify the identification of local users, remote hosts, and remote users in an authentication database that is configured to control access to a device. The authentication database enables Cisco software to receive incoming remote shell (rsh) and remote copy (rcp) protocol requests.
Border Routers and Firewall Routers Should Use Access Lists

There are many reasons to configure access lists; for example, you can use access lists to restrict contents of routing updates or to provide traffic flow control. One of the most important reasons to configure access lists is to provide a basic level of security for your network by controlling access to it. If you do not configure access lists on your router, all packets passing through the router could be allowed onto all parts of your network.

An access list can allow one host to access a part of your network and prevent another host from accessing the same area. In the figure below, by applying an appropriate access list to the interfaces of the router, Host A is allowed to access the Human Resources network and Host B is prevented from accessing the Human Resources network.

Access lists should be used in firewall routers, which are often positioned between your internal network and an external network such as the Internet. You can also use access lists on a router positioned between two parts of your network, to control traffic entering or exiting a specific part of your internal network.

To provide some security benefits of access lists, you should at least configure access lists on border routers--routers located at the edges of your networks. Such an access list provides a basic buffer from the outside network or from a less controlled area of your own network into a more sensitive area of your network. On these border routers, you should configure access lists for each network protocol configured on the router interfaces. You can configure access lists so that inbound traffic or outbound traffic or both are filtered on an interface.
Access lists are defined on a per-protocol basis. In other words, you should define access lists for every protocol enabled on an interface if you want to control traffic flow for that protocol.

**Definition of an Access List**

Access control lists (ACLs) perform packet filtering to control the movement of packets through a network. Packet filtering provides security by limiting the access of traffic into a network, restricting user and device access to a network, and preventing traffic from leaving a network. IP access lists reduce the chance of spoofing and denial-of-service attacks, and allow dynamic, temporary user-access through a firewall.

IP access lists can also be used for purposes other than security, such as to control bandwidth, restrict the content of routing updates, redistribute routes, trigger dial-on-demand (DDR) calls, limit debug output, and identify or classify traffic for quality of service (QoS) features.

An access list is a sequential list that consists of at least one `permit` statement and possibly one or more `deny` statements. In the case of IP access lists, these statements can apply to IP addresses, upper-layer IP protocols, or other fields in IP packets.

Access lists are identified and referenced by a name or a number. Access lists act as packet filters, filtering packets based on the criteria defined in each access list.

After you configure an access list, for the access list to take effect, you must either apply the access list to an interface (by using the `ip access-group` command), a vty (by using the `access-class` command), or reference the access list by any command that accepts an access list. Multiple commands can reference the same access list.

In the following configuration, an IP access list named branchoffices is configured on Fast Ethernet interface 0/1/0 and applied to incoming packets. Networks other than the ones specified by the source address and mask pair cannot access Fast Ethernet interface 0/1/0. The destinations for packets coming from sources on network 172.16.7.0 are unrestricted. The destination for packets coming from sources on network 172.16.2.0 must be 172.31.5.4.

```
ip access-list extended branchoffices
10 permit 172.16.7.0 0.0.0.3 any
20 permit 172.16.2.0 0.0.0.255 host 172.31.5.4
!
interface fastethernet 0/1/0
   ip access-group branchoffices in
```

**Access List Rules**

The following rules apply to access lists:

- Only one access list per interface, per protocol, and per direction is allowed.

- An access list must contain at least one `permit` statement or all packets are denied entry into the network.

- The order in which access list conditions or match criteria are configured is important. While deciding whether to forward or block a packet, Cisco software tests the packet against each criteria statement in the order in which these statements are created. After a match is found, no more criteria statements are checked. The same `permit` or `deny` statements specified in a different order can result in a packet being passed under one circumstance and denied in another circumstance.

- If an access list is referenced by a name, but the access list does not exist, all packets pass. An interface or command with an empty access list applied to it permits all traffic into the network.
• Standard access lists and extended access lists cannot have the same name.

• Inbound access lists process packets before the packets are routed to an outbound interface. Inbound access lists that have filtering criteria that deny packet access to a network saves the overhead of routing lookup. Packets that are permitted access to a network based on the configured filtering criteria are processed for routing. For inbound access lists, when you configure a permit statement, packets are processed after they are received, and when you configure a deny statement, packets are discarded.

• Outbound access lists process packets before they leave the device. Incoming packets are routed to the outbound interface and then processed by the outbound access list. For outbound access lists, when you configure a permit statement, packets are sent to the output buffer, and when you configure a deny statement, packets are discarded.

Note
Outbound access list is not supported in Cisco ASR 900 RSP3 Module.

• An access list can control traffic arriving at a device or leaving a device, but not traffic originating at a device.

Helpful Hints for Creating IP Access Lists

The following tips will help you avoid unintended consequences and help you create more efficient, useful access lists.

• Create the access list before applying it to an interface (or elsewhere), because if you apply a nonexistent access list to an interface and then proceed to configure the access list, the first statement is put into effect, and the implicit deny statement that follows could cause you immediate access problems.

• Another reason to configure an access list before applying it is because an interface with an empty access list applied to it permits all traffic.

• All access lists need at least one permit statement; otherwise, all packets are denied and no traffic passes.

• Use the statement permit any any if you want to allow all other packets not already denied. Using the statement permit any any in effect avoids denying all other packets with the implicit deny statement at the end of an access list. Do not make your first access list entry permit any any because all traffic will get through; no packets will reach the subsequent testing. In fact, once you specify permit any any, all traffic not already denied will get through.

• Although all access lists end with an implicit deny statement, we recommend use of an explicit deny statement (for example, deny ip any any). On most platforms, you can display the count of packets denied by issuing the show access-list command, thus finding out more information about who your access list is disallowing. Only packets denied by explicit deny statements are counted, which is why the explicit deny statement will yield more complete data for you.

• While you are creating an access list or after it is created, you might want to delete an entry.

  • You cannot delete an entry from a numbered access list; trying to do so will delete the entire access list. If you need to delete an entry, you need to delete the entire access list and start over.

  • You can delete an entry from a named access list. Use the no permit or no deny command to delete the appropriate entry.
• In order to make the purpose of individual statements more scannable and easily understood at a glance, you can write a helpful remark before or after any statement by using the `remark` command.

• If you want to deny access to a particular host or network and find out if someone from that network or host is attempting to gain access, include the `log` keyword with the corresponding `deny` statement so that the packets denied from that source are logged for you.

• This hint applies to the placement of your access list. When trying to save resources, remember that an inbound access list applies the filter conditions before the routing table lookup. An outbound access list applies the filter conditions after the routing table lookup.

• Outbound access list is not supported in Cisco ASR 900 RSP3 Module.

### Named or Numbered AccessLists

All access lists must be identified by a name or a number. Named access lists are more convenient than numbered access lists because you can specify a meaningful name that is easier to remember and associate with a task. You can reorder statements in or add statements to a named access list.

Named access lists support the following features that are not supported by numbered access lists:

- IP options filtering
- Noncontiguous ports
- TCP flag filtering
- Deleting of entries with the `no permit` or `no deny` command

---

**Note**

Not all commands that accept a numbered access list will accept a named access list. For example, vty uses only numbered access lists.

### Standard or Extended Access Lists

All access lists are either standard or extended access lists. If you only intend to filter on a source address, the simpler standard access list is sufficient. For filtering on anything other than a source address, an extended access list is necessary.

- Named access lists are specified as standard or extended based on the keyword `standard` or `extended` in the `ip access-list` command syntax.

- Numbered access lists are specified as standard or extended based on their number in the `access-list` command syntax. Standard IP access lists are numbered 1 to 99 or 1300 to 1999; extended IP access lists are numbered 100 to 199 or 2000 to 2699. The range of standard IP access lists was initially only 1 to 99, and was subsequently expanded with the range 1300 to 1999 (the intervening numbers were assigned to other protocols). The extended access list range was similarly expanded.
### Standard Access Lists

Standard IP access lists test only source addresses of packets (except for two exceptions). Because standard access lists test source addresses, they are very efficient at blocking traffic close to a destination. There are two exceptions when the address in a standard access list is not a source address:

- On outbound VTY access lists, when someone is trying to telnet, the address in the access list entry is used as a destination address rather than a source address.
- When filtering routes, you are filtering the network being advertised to you rather than a source address.

### Extended Access Lists

Extended access lists are good for blocking traffic anywhere. Extended access lists test source and destination addresses and other IP packet data, such as protocols, TCP or UDP port numbers, type of service (ToS), precedence, TCP flags, and IP options. Extended access lists can also provide capabilities that standard access lists cannot, such as the following:

- Filtering IP Options
- Filtering TCP flags
- Filtering noninitial fragments of packets (see the module “Refrining an IP Access List”)

---

**Note**

Packets that are subject to an extended access list will not be autonomous switched.

---

### IP Packet Fields You Can Filter to Control Access

You can use an extended access list to filter on any of the following fields in an IP packet. Source address and destination address are the two most frequently specified fields on which to base an access list:

- **Source address**—Specifies a source address to control packets coming from certain networking devices or hosts.
- **Destination address**—Specifies a destination address to control packets being sent to certain networking devices or hosts.
- **Protocol**—Specifies an IP protocol indicated by the keyword `eigrp`, `gre`, `icmp`, `igmp`, `ip`, `ipinip`, `nos`, `ospf`, `tcp`, or `udp`, or indicated by an integer in the range from 0 to 255 (representing an Internet protocol). If you specify a transport layer protocol (`icmp`, `igmp`, `tcp`, or `udp`), the command has a specific syntax.
  - **Ports and non-contiguous ports**—Specifies TCP or UDP ports by a port name or port number. The port numbers can be noncontiguous port numbers. Port numbers can be useful to filter Telnet traffic or HTTP traffic, for example.
  - **TCP flags**—Specifies that packets match any flag or all flags set in TCP packets. Filtering on specific TCP flags can help prevent false synchronization packets.
  - **IP options**—Specifies IP options; one reason to filter on IP options is to prevent routers from being saturated with spurious packets containing them.
Wildcard Mask for Addresses in an Access List

Address filtering uses wildcard masking to indicate to the software whether to check or ignore corresponding IP address bits when comparing the address bits in an access list entry to a packet being submitted to the access list. By carefully setting wildcard masks, you can specify one or more IP addresses for permit or deny tests.

Wildcard masking for IP address bits uses the number 1 and the number 0 to specify how the software treats the corresponding IP address bits. A wildcard mask is sometimes referred to as an inverted mask because a 1 and 0 mean the opposite of what they mean in a subnet (network) mask.

- A wildcard mask bit 0 means check the corresponding bit value; they must match.
- A wildcard mask bit 1 means ignore that corresponding bit value; they need not match.

If you do not supply a wildcard mask with a source or destination address in an access list statement, the software assumes an implicit wildcard mask of 0.0.0.0, meaning all values must match.

Unlike subnet masks, which require contiguous bits indicating network and subnet to be ones, wildcard masks allow noncontiguous bits in the mask.

The table below shows examples of IP addresses and masks from an access list, along with the corresponding addresses that are considered a match.

<table>
<thead>
<tr>
<th>Address</th>
<th>Wildcard Mask</th>
<th>Match Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0.0.0</td>
<td>255.255.255</td>
<td>All addresses will match the access list conditions.</td>
</tr>
<tr>
<td>172.18.0.0/16</td>
<td>0.0.255.255</td>
<td>Network 172.18.0.0</td>
</tr>
<tr>

<td>0.0.0.0</td>
<td>Only host 172.18.5.2 matches</td>
</tr>
<tr>
<td>172.18.8.0</td>
<td>0.0.0.7</td>
<td>Only subnet 172.18.8.0/29 matches</td>
</tr>
<tr>
<td>172.18.8.8</td>
<td>0.0.0.7</td>
<td>Only subnet 172.18.8.8/29 matches</td>
</tr>
<tr>
<td>172.18.8.15</td>
<td>0.0.0.3</td>
<td>Only subnet 172.18.8.15/30 matches</td>
</tr>
<tr>
<td>10.1.2.0</td>
<td>0.0.252.255 (noncontiguous bits in mask)</td>
<td>Matches any even-numbered network in the range of 10.1.2.0 to 10.1.254.0</td>
</tr>
</tbody>
</table>

Access List Sequence Numbers

The ability to apply sequence numbers to IP access list entries simplifies access list changes. Prior to the IP Access List Entry Sequence Numbering feature, there was no way to specify the position of an entry within an access list. If you wanted to insert an entry in the middle of an existing list, all of the entries after the desired position had to be removed, then the new entry was added, and then all the removed entries had to be reentered. This method was cumbersome and error prone.

This feature allows users to add sequence numbers to access list entries and resequence them. When you add a new entry, you specify the sequence number so that it is in a desired position in the access list. If necessary, entries currently in the access list can be resequenced to create room to insert the new entry.
Access List Logging

The Cisco IOS software can provide logging messages about packets permitted or denied by a single standard or extended IP access list entry. That is, any packet that matches the entry will cause an informational logging message about the packet to be sent to the console. The level of messages logged to the console is controlled by the `logging console` global configuration command.

The first packet that triggers the access list entry causes an immediate logging message, and subsequent packets are collected over 5-minute intervals before they are displayed or logged. The logging message includes the access list number, whether the packet was permitted or denied, the source IP address of the packet, and the number of packets from that source permitted or denied in the prior 5-minute interval.

However, you can use the `ip access-list log-update` command to set the number of packets that, when match an access list (and are permitted or denied), cause the system to generate a log message. You might want to do this to receive log messages more frequently than at 5-minute intervals.

⚠️ Caution

If you set the `number-of-matches` argument to 1, a log message is sent right away, rather than caching it; every packet that matches an access list causes a log message. A setting of 1 is not recommended because the volume of log messages could overwhelm the system.

Even if you use the `ip access-list log-update` command, the 5-minute timer remains in effect, so each cache is emptied at the end of 5 minutes, regardless of the count of messages in each cache. Regardless of when the log message is sent, the cache is flushed and the count reset to 0 for that message the same way it is when a threshold is not specified.

族自治县

The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from crashing due to many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.

Alternative to Access List Logging

Packets matching an entry in an ACL with a log option are process switched. It is not recommended to use the log option on ACLs, but rather use NetFlow export and match on a destination interface of Null0. This is done in the CEF path. The destination interface of Null0 is set for any packet that is dropped by the ACL.

Additional IP Access List Features

Beyond the basic steps to create a standard or extended access list, you can enhance your access lists as mentioned below. Each of these methods is described completely in the module entitled “Refining an Access List.”

- You can impose dates and times when `permit` or `deny` statements in an extended access list are in effect, making your access list more granular and specific to an absolute or periodic time period.
- After you create a named access list, you might want to add entries or change the order of the entries, known as resequencing an access list.
- You can achieve finer granularity when filtering packets by filtering on noninitial fragments of packets.
Where to Apply an Access List

You can apply access lists to the inbound or outbound interfaces of a device. Applying an access list to an inbound interface controls the traffic that enters the interface and applying an access list to an outbound interface controls the traffic that exits the interface.

Outbound access list is not supported in Cisco ASR 900 RSP3 Module.

When software receives a packet at the inbound interface, the software checks the packet against the statements that are configured for the access list. If the access list permits packets, the software processes the packet. Applying access lists to filter incoming packets can save device resources because filtered packets are discarded before entering the device.

Access lists on outbound interfaces filter packets that are transmitted (sent) out of the interface. You can use the TCP Access Control List (ACL) Splitting feature of the Rate-Based Satellite Control Protocol (RBSCP) on the outbound interface to control the type of packets that are subject to TCP acknowledgment (ACK) splitting on an outbound interface.

You can reference an access list by using a debug command to limit the amount of debug logs. For example, based on the filtering or matching criteria of the access list, debug logs can be limited to source or destination addresses or protocols.

You can use access lists to control routing updates, dial-on-demand (DDR), and quality of service (QoS) features.

CHAPTER 2

Creating an IP Access List and Applying It to an Interface

IP access lists provide many benefits for securing a network and achieving nonsecurity goals, such as determining quality of service (QoS) factors or limiting debug command output. This module describes how to create standard, extended, named, and numbered IP access lists. An access list can be referenced by a name or a number. Standard access lists filter on only the source address in IP packets. Extended access lists can filter on source address, destination address, and other fields in an IP packet.

After you create an access list, you must apply it to something in order for it to have any effect. This module describes how to apply an access list to an interface. However, there are many other uses for access lists, which are mentioned in this module and described in other modules and in other configuration guides for various technologies.

- Finding Feature Information, on page 11
- Restrictions for Creating an IP Access List and Applying It to an Interface, on page 11
- Information About Creating an IP Access List and Applying It to an Interface, on page 12
- How to Create an IP Access List and Apply It to an Interface, on page 13
- Configuration Examples for Creating an IP Access List and Applying It to an Interface, on page 23
- Additional References Creating an IP Access List and Applying It to an Interface, on page 26

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Creating an IP Access List and Applying It to an Interface

The following restrictions apply when configuring IPv4 and IPv6 access control lists (ACLs)
• Application control engine (ACE)-specific counters are not supported.

• Layer 3 IPv4 and IPv6 ACLs are not supported on the same interface.

• MAC ACLs are not supported on Ethernet flow points (EFPs) or trunk EFP interfaces to which Layer 3 IPv4 or IPv6 ACLs are applied.

• A maximum of 500 ACEs per ACL are supported.

• IPv4 and IPv6 ACLs are not currently supported on EFP interfaces. IPv4 and IPv6 ACLs are supported on physical interfaces, bridge-domain interfaces, and port-channel interfaces.

• Layer 4 port-range functionality expands into Ternary Content-Addressable Memory (TCAM). IPv4 ACL scale is limited to 1K TCAM, Layer 2 ACL scale is limited to 1K TCAM entries.

• ACL counters or statistics are not supported in Cisco ASR 900 RSP3 Module.

• Object-groups are not supported with IP ACLs.

• Outbound ACL is not supported in Cisco ASR 900 RSP3 Module.

• The command any options is not supported.

Information About Creating an IP Access List and Applying It to an Interface

Helpful Hints for Creating IP Access Lists

• Create the access list before applying it to an interface (or elsewhere), because if you apply a nonexistent access list to an interface and then proceed to configure the access list, the first statement is put into effect, and the implicit deny statement that follows could cause immediate access problems.

• Another reason to configure an access list before applying it is because an interface with an empty access list applied to it permits all traffic.

• All access lists need at least one permit statement; otherwise, all packets are denied and no traffic passes.

• Organize your access list so that more specific references in a network or subnet appear before more general ones.

• A packet will match the first ACE in the ACL. Thus, a permit ip any any will match all packets, ignoring all subsequent ACES.

• Although all access lists end with an implicit deny statement, we recommend use of an explicit deny statement (for example, deny ip any any). On most platforms, you can display the count of packets denied by issuing the show access-list command, thus finding out more information about who your access list is disallowing. Only packets denied by explicit deny statements are counted, which is why the explicit deny statement will yield more complete data for you.

• While you are creating an access list or after it is created, you might want to delete an entry. You can delete an entry from a named access list. Use the no permit or no deny command to delete the appropriate entry.
In order to make the purpose of individual statements more scannable and easily understood at a glance, you can write a helpful remark before or after any statement by using the `remark` command.

If you want to deny access to a particular host or network and find out if someone from that network or host is attempting to gain access, include the `log` keyword with the corresponding `deny` statement so that the packets denied from that source are logged for you.

This hint applies to the placement of your access list. When trying to save resources, remember that an inbound access list applies the filter conditions before the routing table lookup. An outbound access list applies the filter conditions after the routing table lookup.

**Access List Remarks**

You can include comments or remarks about entries in any IP access list. An access list remark is an optional remark before or after an access list entry that describes the entry so that you do not have to interpret the purpose of the entry. Each remark is limited to 100 characters in length.

The remark can go before or after a `permit` or `deny` statement. Be consistent about where you add remarks. Users may be confused if some remarks precede the associated `permit` or `deny` statements and some remarks follow the associated statements.

The following is an example of a remark that describes function of the subsequent `deny` statement:

```
ip access-list extended telnetting
remark Do not allow host1 subnet to telnet out
deny tcp host 172.16.2.88 any eq telnet
```

**Additional IP Access List Features**

Beyond the basic steps to create a standard or extended access list, you can enhance your access lists as mentioned below. Each of these methods is described completely in the *Refining an IP Access List* module.

- You can impose dates and times when `permit` or `deny` statements in an extended access list are in effect, making your access list more granular and specific to an absolute or periodic time period.

- After you create a named or numbered access list, you might want to add entries or change the order of the entries, known as resequencing an access list.

- You can achieve finer granularity when filtering packets by filtering on noninitial fragments of packets.

**How to Create an IP Access List and Apply It to an Interface**

This section describes the general ways to create a standard or extended access list using either a name or a number. Access lists are very flexible; the tasks simply illustrate one `permit` command and one `deny` command to provide you the command syntax of each. Only you can determine how many `permit` and `deny` commands you need and their order.

**Note**

The first two tasks in this module create an access list; you must apply the access list in order for it to function. If you want to apply the access list to an interface, perform the task “Applying the Access List to an Interface”.

---

Creating a Standard Access List to Filter on Source Address

If you want to filter on source address only, a standard access list is simple and sufficient. There are two alternative types of standard access list: named and numbered. Named access lists allow you to identify your access lists with a more intuitive name rather than a number, and they also support more features than numbered access lists.

Creating a Named Access List to Filter on Source Address

Use a standard, named access list if you need to filter on source address only. This task illustrates one permit statement and one deny statement, but the actual statements you use and their order depend on what you want to filter or allow. Define your permit and deny statements in the order that achieves your filtering goals.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip access-list standard name
4. remark remark
5. deny {source [source-wildcard] | any} [log]
6. remark remark
7. permit {source [source-wildcard] | any} [log]
8. Repeat some combination of Steps 4 through 7 until you have specified the sources on which you want to base your access list.
9. end
10. show ip access-list

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong> ip access-list standard name</td>
<td>Defines a standard IP access list using a name and enters standard named access list configuration mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong> remark remark</td>
<td>(Optional) Adds a user-friendly comment about an access list entry.</td>
</tr>
<tr>
<td><strong>Step 5</strong> remark remark</td>
<td>• A remark can precede or follow an access list entry.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Device(config-std-nacl)# remark deny Sales network</td>
<td>- In this example, the remark reminds the network administrator that the subsequent entry denies the Sales network access to the interface (assuming this access list is later applied to an interface).</td>
</tr>
<tr>
<td><strong>Step 5</strong> deny {source [source-wildcard]</td>
<td>any} [log]</td>
</tr>
<tr>
<td>Example: Device(config-std-nacl)# deny 172.16.0.0 0.0.255.255 log</td>
<td>- If the source-wildcard is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address.</td>
</tr>
<tr>
<td>- Optionally use the keyword any as a substitute for the source source-wildcard to specify the source and source wildcard of 0.0.0.0 255.255.255.255.</td>
<td></td>
</tr>
<tr>
<td>- In this example, all hosts on network 172.16.0.0 are denied passing the access list.</td>
<td></td>
</tr>
<tr>
<td>- Because this example explicitly denies a source address and the log keyword is specified, any packets from that source are logged when they are denied. This is a way to be notified that someone on a network or host is trying to gain access.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> remark remark</td>
<td>(Optional) Adds a user-friendly comment about an access list entry.</td>
</tr>
<tr>
<td>Example: Device(config-std-nacl)# remark Give access to Tester’s host</td>
<td>- A remark can precede or follow an access list entry.</td>
</tr>
<tr>
<td>- This remark reminds the network administrator that the subsequent entry allows the Tester’s host access to the interface.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> permit {source [source-wildcard]</td>
<td>any} [log]</td>
</tr>
<tr>
<td>Example: Device(config-std-nacl)# permit 172.18.5.22 0.0.0.0</td>
<td>- Every access list needs at least one permit statement; it need not be the first entry.</td>
</tr>
<tr>
<td>- If the source-wildcard is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address.</td>
<td></td>
</tr>
<tr>
<td>- Optionally use the keyword any as a substitute for the source source-wildcard to specify the source and source wildcard of 0.0.0.0 255.255.255.255.</td>
<td></td>
</tr>
<tr>
<td>- In this example, host 172.18.5.22 is allowed to pass the access list.</td>
<td></td>
</tr>
</tbody>
</table>
Creating a Numbered Access List to Filter on Source Address

Configure a standard, numbered access list if you need to filter on source address only and you prefer not to use a named access list.

IP standard access lists are numbered 1 to 99 or 1300 to 1999. This task illustrates one permit statement and one deny statement, but the actual statements you use and their order depend on what you want to filter or allow. Define your permit and deny statements in the order that achieves your filtering goals.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **access-list** `access-list-number permit {source [source-wildcard] | any} [log]`  
4. **access-list** `access-list-number deny {source [source-wildcard] | any} [log]`  
5. Repeat some combination of Steps 3 through 6 until you have specified the sources on which you want to base your access list.
6. **end**
7. **show ip access-list**

</tbody>
</table>
Creating an Extended Access List

If you want to filter on anything other than source address, you need to create an extended access list. There are two alternative types of extended access list: named and numbered. Named access lists allow you to identify your access lists with a more intuitive name rather than a number, and they also support more features.

For details on how to filter something other than source or destination address, see the syntax descriptions in the command reference documentation.

Creating a Named Extended Access List

Create a named extended access list if you want to filter the source and destination address or filter a combination of addresses and other IP fields.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip access-list extended name
4. deny protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log | log-input] [time-range time-range-name] [fragments]
5. permit protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log | log-input] [time-range time-range-name] [fragments]
6. Repeat some combination of Steps 4 through 7 until you have specified the fields and values on which you want to base your access list.
7. end
8. show ip access-list

DETAILED STEPS

<tr>
<td><code>time-range-name</code></td>
<td></td>
</tr>
<tr>
<td><code>fragments</code></td>
<td></td>
</tr>
</tbody>
</table>

**Purpose**

- If the `source-wildcard` or `destination-wildcard` is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively.

- Additionally, you can use the `any` keyword as a substitute to indicate a source and source wildcard of 0.0.0.0 255.255.255.255.

- Use the `host` keyword to indicate a source or destination. The abbreviations `host source` or `host destination` can be used to indicate a source or destination wildcard of 0.0.0.0.

- Every access list needs at least one `permit` statement.

- If the `source-wildcard` or `destination-wildcard` is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively.

<table>
<thead>
<tr>
<th>Step 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>`permit protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log</td>
</tr>
</tbody>
</table>

**Example:**

```
Device(config-ext-nacl)# permit tcp any any
```

Permits any packet that matches all of the conditions specified in the statement.

- Every access list needs at least one `permit` statement.

- If the `source-wildcard` or `destination-wildcard` is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively.

- Optionally use the `any` keyword as a substitute for the `source-wildcard` or `destination-wildcard` to specify the address and wildcard of 0.0.0.0 255.255.255.255.

- In this example, TCP packets are allowed from any source to any destination.

- Use the `log-input` keyword to include input interface, source MAC address, or virtual circuit in the logging output.

<table>
<thead>
<tr>
<th>Step 6</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repeat some combination of Steps 4 through 7 until you have specified the fields and values on which you want to base your access list.</td>
</tr>
</tbody>
</table>

Remember that all sources not specifically permitted are denied by an implicit `deny` statement at the end of the access list.
### Creating a Numbered Extended Access List

Create a numbered extended access list if you want to filter on source and destination address, or a combination of addresses and other IP fields, and you prefer not to use a name. Extended IP access lists are numbered 100 to 199 or 2000 to 2699.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `access-list access-list-number remark remark`  
   `access-list access-list-number permit protocol {source [source-wildcard] | any} {destination [destination-wildcard] | any} [precedence precedence] [tos tos] [established] [log | log-input] [time-range time-range-name] [fragments]`
4. `access-list access-list-number remark remark`  
   `access-list access-list-number deny protocol {source [source-wildcard] | any} {destination [destination-wildcard] | any} [precedence precedence] [tos tos] [established] [log | log-input] [time-range time-range-name] [fragments]`
5. Repeat some combination of Steps 3 through 6 until you have specified the fields and values on which you want to base your access list.
6. `end`
7. `show ip access-list`

#### DETAILED STEPS

<td>Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.</td>
</tr>
</tbody>
</table>
### Applying an Access List to an Interface

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ip access-group {access-list-number | access-list-name} {in | out}`
5. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  Example:  
  Device> enable |
| **Step 2** configure terminal | Enters global configuration mode.  
  Example:  
  Device# configure terminal |
| **Step 3** interface type number | Specifies an interface and enters interface configuration mode.  
  Example:  
  Device# interface type number |
| **Step 4** ip access-group {access-list-number | access-list-name} {in | out} | Applies the specified access list to the inbound interface.  
  Example:  
  Device(config-if)# ip access-group acl1 in |
| **Step 5** end | Exits interface configuration mode and returns to privileged EXEC mode.  
  Example:  
  Device(config-if)# end |
Configuration Examples for Creating an IP Access List and Applying It to an Interface

Example: Filtering on Host Source Address

In the following example, the workstation belonging to user1 is allowed access to gigabitethernet 0/0/0, and the workstation belonging to user2 is not allowed access:

```
interface gigabitethernet 0/0/0
  ip access-group workstations in
!
  ip access-list standard workstations
    remark Permit only user1 workstation through
    permit 172.16.2.88
    remark Do not allow user2 workstation through
    deny 172.16.3.13
```

Example: Filtering on Subnet Source Address

In the following example, the user1 subnet is not allowed access to gigabitethernet interface 0/0/0, but the Main subnet is allowed access:

```
interface gigabitethernet 0/0/0
  ip access-group prevention in
!
  ip access-list standard prevention
    remark Do not allow user1 subnet through
    deny 172.22.0.0 0.0.255.255
    remark Allow Main subnet
    permit 172.25.0.0 0.0.255.255
```

Example: Filtering on Source and Destination Addresses and IP Protocols

The following configuration example shows an interface with two access lists, one applied to outgoing packets and one applied to incoming packets. The standard access list named Internet-filter filters outgoing packets on source address. The only packets allowed out the interface must be from source 172.16.3.4.

The extended access list named marketing-group filters incoming packets. The access list permits Telnet packets from any source to network 172.26.0.0 and denies all other TCP packets. It permits any ICMP packets. It denies UDP packets from any source to network 172.26.0 0 on port numbers less than 1024. Finally, the access list denies all other IP packets and performs logging of packets passed or denied by that entry.

```
interface gigabitethernet 0/0/0
  ip address 172.20.5.1 255.255.255.0
  ip access-group Internet-filter out
  ip access-group marketing-group in
!
  ip access-list standard Internet-filter
    permit 172.16.3.4
  ip access-list extended marketing-group
    permit tcp any 172.26.0.0 0.0.255.255 eq telnet
```
Example: Filtering on Source Addresses Using a Numbered Access List

In the following example, network 10.0.0.0 is a Class A network whose second octet specifies a subnet; that is, its subnet mask is 255.255.0.0. The third and fourth octets of a network 10.0.0.0 address specify a particular host. Using access list 2, the Cisco IOS XE software would accept one address on subnet 48 and reject all others on that subnet. The last line of the list shows that the software would accept addresses on all other network 10.0.0.0 subnets.

interface gigabitethernet 0/0/0
 ip access-group 2 in
access-list 2 permit 10.48.0.3
access-list 2 deny 10.48.0.0 0.0.255.255
access-list 2 permit 10.0.0.0 0.255.255.255

Example: Preventing Telnet Access to a Subnet

In the following example, the user1 subnet is not allowed to telnet out of gigabitethernet interface 0/0/0:

interface gigabitethernet 0/0/0
 ip access-group telnetting out
 ip access-list extended telnetting
 remark Do not allow user1 subnet to telnet out
deny tcp 172.20.0.0 0.0.255.255 any eq telnet
 remark Allow Top subnet to telnet out
 permit tcp 172.33.0.0 0.0.255.255 any eq telnet

Example: Filtering on TCP and ICMP Using Port Numbers

In the following example, the first line of the extended access list named acl1 permits any incoming TCP connections with destination ports greater than 1023. The second line permits incoming TCP connections to the Simple Mail Transfer Protocol (SMTP) port of host 172.28.1.2. The last line permits incoming ICMP messages for error feedback.

interface gigabitethernet 0/0/0
 ip access-group acl1 in
 ip access-list extended acl1
 remark Do not allow user1 subnet to telnet out
deny tcp 172.20.0.0 0.0.255.255 any eq telnet
 remark Allow Top subnet to telnet out
 permit tcp 172.33.0.0 0.0.255.255 any eq telnet
permit icmp any 172.28.0.0 255.255.255.255

Example: Allowing SMTP E-mail and Established TCP Connections

Suppose you have a network connected to the Internet, and you want any host on an Ethernet to be able to form TCP connections to any host on the Internet. However, you do not want IP hosts to be able to form TCP connections to hosts on the gigabitethernet except to the mail (SMTP) port of a dedicated mail host.
SMTP uses TCP port 25 on one end of the connection and a random port number on the other end. The same two port numbers are used throughout the life of the connection. Mail packets coming in from the Internet will have a destination port of 25. Outbound packets will have the port numbers reversed. The fact that the secure system behind the router always will accept mail connections on port 25 is what makes possible separate control of incoming and outgoing services. The access list can be configured on either the outbound or inbound interface.

In the following example, the gigabitethernet network is a Class B network with the address 172.18.0.0, and the address of the mail host is 172.18.1.2. The `established` keyword is used only for the TCP protocol to indicate an established connection. A match occurs if the TCP datagram has the ACK or RST bits set, which indicate that the packet belongs to an existing connection.

```snippets
interface gigabitethernet 0/0/0
 ip access-group 102 in
!
access-list 102 permit tcp any 172.18.0.0 0.0.255.255 established
access-list 102 permit tcp any host 172.18.1.2 eq 25
```

**Example: Preventing Access to the Web by Filtering on Port Name**

In the following example, the w1 and w2 workstations are not allowed web access; other hosts on network 172.20.0.0 are allowed web access:

```snippets
interface gigabitethernet0/0/0
 ip access-group no-web out
!
ip access-list extended no-web
 remark Do not allow w1 to browse the web
deny host 172.20.3.85 any eq http
 remark Do not allow w2 to browse the web
deny host 172.20.3.13 any eq http
 remark Allow others on our network to browse the web
permit 172.20.0.0 0.0.255.255 any eq http
```

**Example: Filtering on Source Address and Logging the Packets**

The following example defines access lists 1 and 2, both of which have logging enabled:

```snippets
interface gigabitethernet 0/0/0
 ip address 172.16.1.1 255.0.0.0
 ip access-group 1 in
 ip access-group 2 out
!
access-list 1 permit 172.25.0.0 0.0.255.255 log
access-list 1 deny 172.30.0.0 0.0.255.255 log
!
access-list 2 permit 172.27.3.4 log
access-list 2 deny 172.17.0.0 0.0.255.255 log
```

If the interface receives 10 packets from 172.25.7.7 and 14 packets from 172.17.23.21, the first log will look like the following:

```shell
list 1 permit 172.25.7.7 1 packet
list 2 deny 172.17.23.21 1 packet
```

Five minutes later, the console will receive the following log:
**list 1 permit 172.25.7.7 9 packets**
**list 2 deny 172.17.23.21 13 packets**

---

**Note**

*ip access-group 2 out* is not applicable for Cisco ASR 900 RSP3 Module.

---

**Example: Limiting Debug Output**

The following sample configuration uses an access list to limit the `debug` command output. Limiting the `debug` output restricts the volume of data to what you are interested in, saving you time and resources.

```
Device(config)# ip access-list acl1
Device(config-std-nacl)# remark Displays only advertisements for LDP peer in acl1
Device(config-std-nacl)# permit host 10.0.0.44
Device(config)# debug mpls ldp advertisements peer-acl acl1
```

```
tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 172.17.0.33
tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 172.16.0.31
tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 172.22.0.33
tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 192.168.0.1
tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 192.168.0.3
tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 192.168.1.33
```

---

Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports

This module describes how to use an IP access list to filter IP packets that contain certain IP Options, TCP flags, noncontiguous ports.

- Finding Feature Information, on page 29
- Prerequisites for Creating an IP Access List to Filter IP Options TCP Flags Noncontiguous Ports, on page 29
- Information About Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, on page 30
- How to Create an IP Access List to Filter IP Options TCP Flags Noncontiguous Ports, on page 32
- Configuration Examples for Filtering IP Options, TCP Flags, Noncontiguous Ports, on page 40
- Additional References, on page 41

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Creating an IP Access List to Filter IP Options TCP Flags Noncontiguous Ports

Before you perform any of the tasks in this module, you should be familiar with the information in the following modules:

- “IP Access List Overview”
- “Creating an IP Access List and Applying It to an Interface”
Information About Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports

**IP Options**

IP uses four key mechanisms in providing its service: Type of Service, Time to Live, Options, and Header Checksum.

The Options, commonly referred to as IP Options, provide for control functions that are required in some situations but unnecessary for the most common communications. IP Options include provisions for time stamps, security, and special routing.

IP Options may or may not appear in datagrams. They must be implemented by all IP modules (host and gateways). What is optional is their transmission in any particular datagram, not their implementation. In some environments the security option may be required in all datagrams.

The option field is variable in length. There may be zero or more options. IP Options can have one of two formats:

- Format 1: A single octet of option-type.
- Format 2: An option-type octet, an option-length octet, and the actual option-data octets.

The option-length octet counts the option-type octet, the option-length octet, and the option-data octets.

The option-type octet is viewed as having three fields: a 1-bit copied flag, a 2-bit option class, and a 5-bit option number. These fields form an 8-bit value for the option type field. IP Options are commonly referred to by their 8-bit value.

For a complete list and description of IP Options, refer to RFC 791, *Internet Protocol* at the following URL: http://www.faqs.org/rfcs/rfc791.html

**Benefits of Filtering IP Options**

- Filtering of packets that contain IP Options from the network relieves downstream devices and hosts of the load from options packets.

- This feature also minimizes load to the Route Processor (RP) for packets with IP Options that require RP processing on distributed systems. Previously, the packets were always routed to or processed by the RP CPU. Filtering the packets prevents them from impacting the RP.

**Benefits of Filtering on TCP Flags**

The ACL TCP Flags Filtering feature provides a flexible mechanism for filtering on TCP flags. Previously, an incoming packet was matched as long as any TCP flag in the packet matched a flag specified in the access control entry (ACE). This behavior allows for a security loophole, because packets with all flags set could get past the access control list (ACL). The ACL TCP Flags Filtering feature allows you to select any combination of flags on which to filter. The ability to match on a flag set and on a flag not set gives you a greater degree of control for filtering on TCP flags, thus enhancing security.
Because TCP packets can be sent as false synchronization packets that can be accepted by a listening port, it is recommended that administrators of firewall devices set up some filtering rules to drop false TCP packets. The ACEs that make up an access list can be configured to detect and drop unauthorized TCP packets by allowing only the packets that have a very specific group of TCP flags set or not set. The ACL TCP Flags Filtering feature provides a greater degree of packet-filtering control in the following ways:

- You can select any desired combination of TCP flags on which to filter TCP packets.
- You can configure ACEs to allow matching on a flag that is set, as well as on a flag that is not set.

**TCP Flags**

The table below lists the TCP flags, which are further described in RFC 793, *Transmission Control Protocol*.

<table>
<thead>
<tr>
<th>TCP Flag</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACK</td>
<td>Acknowledge flag—Indicates that the acknowledgment field of a segment specifies the next sequence number the sender of this segment is expecting to receive.</td>
</tr>
<tr>
<td>FIN</td>
<td>Finish flag—Used to clear connections.</td>
</tr>
<tr>
<td>PSH</td>
<td>Push flag—Indicates the data in the call should be immediately pushed through to the receiving user.</td>
</tr>
<tr>
<td>RST</td>
<td>Reset flag—Indicates that the receiver should delete the connection without further interaction.</td>
</tr>
<tr>
<td>SYN</td>
<td>Synchronize flag—Used to establish connections.</td>
</tr>
<tr>
<td>URG</td>
<td>Urgent flag—Indicates that the urgent field is meaningful and must be added to the segment sequence number.</td>
</tr>
</tbody>
</table>

**Benefits of Using the Named ACL Support for Noncontiguous Ports on an Access Control Entry Feature**

This feature greatly reduces the number of access control entries (ACEs) required in an access control list to handle multiple entries for the same source address, destination address, and protocol. If you maintain large numbers of ACEs, use this feature to consolidate existing groups of access list entries wherever it is possible and when you create new access list entries. When you configure access list entries with noncontiguous ports, you will have fewer access list entries to maintain.
How to Create an IP Access List to Filter IP Options TCP Flags Noncontiguous Ports

Filtering Packets That Contain IP Options

Complete these steps to configure an access list to filter packets that contain IP options and to verify that the access list has been configured correctly.

Note

- The ACL Support for Filtering IP Options feature can be used only with named, extended ACLs.
- Resource Reservation Protocol (RSVP) Multiprotocol Label Switching Traffic Engineering (MPLS TE), Internet Group Management Protocol Version 2 (IGMPV2), and other protocols that use IP options packets may not function in drop or ignore mode if this feature is configured.
- On most Cisco devices, a packet with IP options is not switched in hardware, but requires control plane software processing (primarily because there is a need to process the options and rewrite the IP header), so all IP packets with IP options will be filtered and switched in software.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip access-list extended access-list-name
4. [sequence-number] deny protocol source source-wildcard destination destination-wildcard [option option-value] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
5. [sequence-number] permit protocol source source-wildcard destination destination-wildcard [option option-value] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
6. Repeat Step 4 or Step 5 as necessary.
7. end
8. show ip access-lists access-list-name

DETAILED STEPS

<table>

<tr>
<td><strong>Example:</strong></td>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td><code>Device# show ip access-lists mylist1</code></td>
<td><code>Device(config-ext-nacl)# end</code></td>
</tr>
</tbody>
</table>

**What to Do Next**

Apply the access list to an interface or reference it from a command that accepts an access list.

**Note**

To effectively eliminate all packets that contain IP Options, we recommend that you configure the global `ip options drop` command.

**Filtering Packets That Contain TCP Flags**

This task configures an access list to filter packets that contain TCP flags and verifies that the access list has been configured correctly.
TCP flag filtering can be used only with named, extended ACLs.

The ACL TCP Flags Filtering feature is supported only for Cisco ACLs.

Previously, the following command-line interface (CLI) format could be used to configure a TCP flag-checking mechanism:

```
permit tcp any any rst
```

The following format that represents the same ACE can now be used: `permit tcp any any match-any +rst`

Both the CLI formats are accepted; however, if the new keywords `match-all` or `match-any` are chosen, they must be followed by the new flags that are prefixed with “+” or “-”. It is advisable to use only the old format or the new format in a single ACL. You cannot mix and match the old and new CLI formats.

---

**Note**

If a device having ACEs with the new syntax format is reloaded with a previous version of the Cisco software that does not support the ACL TCP Flags Filtering feature, the ACEs will not be applied, leading to possible security loopholes.

---

**Caution**

If a device having ACEs with the new syntax format is reloaded with a previous version of the Cisco software that does not support the ACL TCP Flags Filtering feature, the ACEs will not be applied, leading to possible security loopholes.

---

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip access-list extended access-list-name`
4. `[sequence-number] permit tcp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established] [match-any] [match-all] [+ | -] flag-name [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]`
5. `[sequence-number] deny tcp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established] [match-any] [match-all] [+ | -] flag-name [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]`
6. Repeat Step 4 or Step 5 as necessary, adding statements by sequence number where you planned. Use the `no sequence-number` command to delete an entry.
7. `end`
8. `show ip access-lists access-list-name`

---

### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 3**  
`ip access-list extended access-list-name`  
**Example:**  
Device(config)# ip access-list extended kmd1 | Specifies the IP access list by name and enters named access list configuration mode. |
| **Step 4**  
`[sequence-number] permit tcp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established] [match-any | match-all] {+ | -} flag-name [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]`  
**Example:**  
Device(config-ext-nacl)# permit tcp any any match-any +rst | Specifies a `permit` statement in named IP access list mode.  
- This access list happens to use a `permit` statement first, but a `deny` statement could appear first, depending on the order of statements you need.  
- Use the TCP command syntax of the `permit` command.  
- Any packet with the RST TCP header flag set will be matched and allowed to pass the named access list kmd1 in Step 3. |
| **Step 5**  
`[sequence-number] deny tcp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established] [match-any | match-all] {+ | -} flag-name [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]`  
**Example:**  
Device(config-ext-nacl)# deny tcp any any match-all -ack -fin | (Optional) Specifies a `deny` statement in named IP access list mode.  
- This access list happens to use a `permit` statement first, but a `deny` statement could appear first, depending on the order of statements you need.  
- Use the TCP command syntax of the `deny` command.  
- Any packet that does not have the ACK flag set, and also does not have the FIN flag set, will not be allowed to pass the named access list kmd1 in Step 3.  
- See the `deny` command for additional command syntax to permit upper-layer protocols (ICMP, IGMP, TCP, and UDP). |
| **Step 6**  
Repeat Step 4 or Step 5 as necessary, adding statements by sequence number where you planned. Use the `no sequence-number` command to delete an entry. | Allows you to revise the access list. |
| **Step 7**  
`end`  
**Example:**  
Device(config-ext-nacl)# end | (Optional) Exits the configuration mode and returns to privileged EXEC mode. |
| **Step 8**  
`show ip access-lists access-list-name`  
**Example:**  
Device# show ip access-lists kmd1 | (Optional) Displays the contents of the IP access list.  
- Review the output to confirm that the access list includes the new entry. |
Configuring an Access Control Entry with Noncontiguous Ports

Perform this task to create access list entries that use noncontiguous TCP or UDP port numbers. Although this task uses TCP ports, you could use the UDP syntax of the `permit` and `deny` commands to filter noncontiguous UDP ports.

Although this task uses a `permit` command first, use the `permit` and `deny` commands in the order that achieves your filtering goals.

**Summary Steps**

1. `enable`
2. `configure terminal`
3. `ip access-list extended access-list-name`
4. `[sequence-number] permit tcp source source-wildcard [operator port [port]] destination destination-wildcard [operator [port]] [established {match-any | match-all} {+ | -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]`
5. `[sequence-number] deny tcp source source-wildcard [operator port [port]] destination destination-wildcard [operator [port]] [established {match-any | match-all} {+ | -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]`
6. Repeat Step 4 or Step 5 as necessary, adding statements by sequence number where you planned. Use the `no sequence-number` command to delete an entry.
7. `end`
8. `show ip access-lists access-list-name`

<tr>
<td><strong>Example:</strong> Device(config-ext-nacl)# permit tcp any eq telnet ftp any eq 450 679</td>
<td>• If the operator is positioned after the source and source-wildcard arguments, it must match the source port. If the operator is positioned after the destination and destination-wildcard arguments, it must match the destination port.</td>
</tr>
<tr>
<td>Step 5 [sequence-number] deny tcp source source-wildcard [operator port [port]] destination destination-wildcard [operator [port]] [established] {match-any</td>
<td>match-all} `{+</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-ext-nacl)# deny tcp any neq 45 565 632</td>
<td>• Operators include \textit{lt} (less than), \textit{gt} (greater than), \textit{eq} (equal), \textit{neq} (not equal), and \textit{range} (inclusive range).</td>
</tr>
<tr>
<td><strong>Step 6</strong> Repeat Step 4 or Step 5 as necessary, adding statements by sequence number where you planned. Use the \textbf{no sequence-number} command to delete an entry.</td>
<td>Allows you to revise the access list.</td>
</tr>
<tr>
<td><strong>Step 7</strong> end</td>
<td>(Optional) Exits named access list configuration mode and returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device(config-ext-nacl)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> show ip access-lists access-list-name</td>
<td>(Optional) Displays the contents of the access list.</td>
</tr>
<tr>
<td><strong>Example:</strong> Device# show ip access-lists kmd1</td>
<td></td>
</tr>
</tbody>
</table>
Consolidating Access List Entries with Noncontiguous Ports into One Access List Entry

Perform this task to consolidate a group of access list entries with noncontiguous ports into one access list entry.

Although this task uses TCP ports, you could use the UDP syntax of the permit and deny commands to filter noncontiguous UDP ports.

Although this task uses a permit command first, use the permit and deny commands in the order that achieves your filtering goals.

**SUMMARY STEPS**

1. enable
2. show ip access-lists access-list-name
3. configure terminal
4. ip access-list extended access-list-name
5. no [sequence-number] permit protocol source source-wildcard destination destination-wildcard [option option-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
6. [sequence-number] permit protocol source source-wildcard [operator port] [port] destination destination-wildcard [operator port] [port] [option option-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
7. Repeat Steps 5 and 6 as necessary, adding permit or deny statements to consolidate access list entries where possible. Use the no sequence-number command to delete an entry.
8. end
9. show ip access-lists access-list-name

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> show ip access-lists access-list-name</td>
<td>(Optional) Displays the contents of the IP access list.</td>
</tr>
<tr>
<td>Example: Device# show ip access-lists mylist1</td>
<td>• Review the output to see if you can consolidate any access list entries.</td>
</tr>
<tr>
<td><strong>Step 3</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ip access-list extended access-list-name</td>
<td>Specifies the IP access list by name and enters named access list configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# ip access-list extended mylist1</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

**Step 5**

```plaintext
no [sequence-number] permit protocol source source-wildcard destination destination-wildcard [option option-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
```  

**Example:**

Device(config-ext-nacl)# no 10

**Purpose:**

Removes the redundant access list entry that can be consolidated.

- Repeat this step to remove entries to be consolidated because only the port numbers differ.
- After this step is repeated to remove the access list entries 20, 30, and 40, for example, those entries are removed because they will be consolidated into one `permit` statement.
- If a `sequence-number` is specified, the rest of the command syntax is optional.

**Step 6**

```plaintext
[sequence-number] permit protocol source source-wildcard [operator port [port]] destination destination-wildcard [operator port [port]] [option option-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
```  

**Example:**

Device(config-ext-nacl)# permit tcp any neq 45 565 632 any eq 23 45 34 43

**Purpose:**

Specifies a `permit` statement in named access list configuration mode.

- In this instance, a group of access list entries with noncontiguous ports was consolidated into one `permit` statement.
- You can configure up to 10 ports after the `eq` and `neq` operators.

**Step 7**

Repeat Steps 5 and 6 as necessary, adding `permit` or `deny` statements to consolidate access list entries where possible. Use the `no sequence-number` command to delete an entry.

**Step 8**

```plaintext
end
```  

**Example:**

Device(config-std-nacl)# end

**Purpose:**

(Optional) Exits named access list configuration mode and returns to privileged EXEC mode.

**Step 9**

```plaintext
show ip access-lists access-list-name
```  

**Example:**

Device# show ip access-lists mylist1

**Purpose:**

(Optional) Displays the contents of the access list.

### What To Do Next

Apply the access list to an interface or reference it from a command that accepts an access list.
Configuration Examples for Filtering IP Options, TCP Flags, Noncontiguous Ports

Example: Filtering Packets That Contain IP Options

The following example shows an extended access list named mylist2 that contains access list entries (ACEs) that are configured to permit TCP packets only if they contain the IP Options that are specified in the ACEs:

```plaintext
ip access-list extended mylist2
10 permit ip any any option eool
20 permit ip any any option record-route
30 permit ip any any option zsu
40 permit ip any any option mtup
```

The `show access-list` command has been entered to show how many packets were matched and therefore permitted:

```plaintext
Device# show ip access-list mylist2
Extended IP access list test
10 permit ip any any option eool (1 match)
20 permit ip any any option record-route (1 match)
30 permit ip any any option zsu (1 match)
40 permit ip any any option mtup (1 match)
```

Example: Filtering Packets That Contain TCP Flags

The following access list allows TCP packets only if the TCP flags ACK and SYN are set and the FIN flag is not set:

```plaintext
ip access-list extended aaa
permit tcp any any match-all +ack +syn -fin
end
```

The `show access-list` command has been entered to display the ACL:

```plaintext
Device# show access-list aaa
Extended IP access list aaa
10 permit tcp any any match-all +ack +syn -fin
```

Example: Creating an Access List Entry with Noncontiguous Ports

The following access list entry can be created because up to ten ports can be entered after the `eq` and `neq` operators:

```plaintext
ip access-list extended aaa
permit tcp any eq telnet ftp any eq 23 45 34
end
```

Enter the `show access-lists` command to display the newly created access list entry.
Device# show access-lists aaa

Extended IP access list aaa
  10 permit tcp any eq telnet ftp any eq 23 45 34

Example: Consolidating Some Existing Access List Entries into One Access List Entry with Noncontiguous Ports

The `show access-lists` command is used to display a group of access list entries for the access list named abc:

Device# show access-lists abc
Extended IP access list abc
  10 permit tcp any eq telnet any eq 450
  20 permit tcp any eq telnet any eq 679
  30 permit tcp any eq ftp any eq 450
  40 permit tcp any eq ftp any eq 679

Because the entries are all for the same `permit` statement and simply show different ports, they can be consolidated into one new access list entry. The following example shows the removal of the redundant access list entries and the creation of a new access list entry that consolidates the previously displayed group of access list entries:

```
ip access-list extended abc
  no 10
  no 20
  no 30
  no 40
  permit tcp any eq telnet ftp any eq 450 679
end
```

When the `show access-lists` command is reentered, the consolidated access list entry is displayed:

Device# show access-lists abc
Extended IP access list abc
  10 permit tcp any eq telnet ftp any eq 450 679

IPv6 Access Control Lists

Access lists determine what traffic is blocked and what traffic is forwarded at device interfaces and allow filtering of traffic based on source and destination addresses, and inbound and outbound traffic to a specific interface. Standard IPv6 ACL functionality was extended to support traffic filtering based on IPv6 option headers and optional, upper-layer protocol type information for finer granularity of control. Standard IPv6 ACL functionality was extended to support traffic filtering based on IPv6 option headers and optional, upper-layer protocol type information for finer granularity of control.

This module describes how to configure IPv6 traffic filtering and to control access to virtual terminal lines.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for IPv6 Access Control Lists

- IPv4 / IPv6 ACL is supported only at the access Layer 3 or bridge domain interfaces. It is not supported on the MPLS enabled core interfaces.
- IPv6 ACL is not supported on port-channel member link.
- IPv4 or IPv6 is not supported on label interface.
- MAC ACL supports only non-IP packets.
- MAC ACL counters are not supported.
- MAC ACL is not supported on trunk EFP or port channel EFP.
- TCAMS are programmed for ACL configured on both physical interface and BDI.
- A total of 512 unique and combination of IPv4 and IPv6 ACLs can be configured.
- Filtering based on extension header types is not supported except for filtering based on fragmentation.
- Filtering based on IPv6 Protocols and L4 ports will not work for IPv6 traffic carrying extension headers.
- Filtering based on TCP Control Flags is not supported.
- Egress IPv6 ACL is not supported.
- All NDP packets (ICMPv6 type 133-137) are allowed by default.
- IPv6 ACL is not supported on Link Local Addresses (LL).

**Note**
IPv6 packets with LL address as SA is permitted by default.

- Per ACE counters are not supported.
- Re-sequencing of ACE’s for an IPv6 ACL is not supported.
- Starting Cisco IOS XE Release 3.18SP, IPv6 ACLs are supported on the RSP3 module.
- Although the hardware is not programmed for TCAM exhaustion, ACL stats get incremented for control packets on the interface.

**Restrictions - Dual Stack (IPv4 + IPv6 ACL on an Interface)**

- When a unique combination of IPv4 ACL and IPv6 ACL are configured on the same interface for the first time, there is a delay in filtering when the first ACL applied (in the sequence) is reattached.
- If an interface has both IPv4 ACL and IPv6 ACL configured, there is a delay in filtering when one unique ACL is removed and the other unique ACL is attached. For example, IPv4 ACL is x and IPv4 ACL is y on an interface. When x is removed and y is reattached there is a delay in filtering.
- A single IPv6 ACL attached to an interface or multiple interfaces works as a unique ACL when compared to a combination of IPv6 ACL and IPv4 ACL applied to one or more interfaces.
- The ACL attachment is rejected and may result in TCAM overflow, when you attach an IPv6 ACL where an IPv4 ACL was attached and the reverser.
- The IPv6 ACL attachment, for the first time, to an interface is rejected and may result in TCAM overflow when there is no IPv4 ACL attached.
- If a IPv6 ACL is detached from an interface, which also has IPv4 ACL attached to it may result in TCAM overflow of the IPv4 ACL and detach of both ACLs from that interface.
Information About IPv6 Access Control Lists

Access Control Lists for IPv6 Traffic Filtering

The standard ACL functionality in IPv6 is similar to standard ACLs in IPv4. Access lists determine what traffic is blocked and what traffic is forwarded at device interfaces and allow filtering based on source and destination addresses, inbound and outbound to a specific interface. Each access list has an implicit deny statement at the end. IPv6 ACLs are defined and their deny and permit conditions are set using the `ipv6 access-list` command with the `deny` and `permit` keywords in global configuration mode.

IPv6 extended ACLs augments standard IPv6 ACL functionality to support traffic filtering based on IPv6 option headers and optional, upper-layer protocol type information for finer granularity of control (functionality similar to extended ACLs in IPv4).

IPv6 Packet Inspection

The following header fields are used for IPv6 inspection: traffic class, flow label, payload length, next header, hop limit, and source or destination IP address. For further information on and descriptions of the IPv6 header fields, see RFC 2474.

Access Class Filtering in IPv6

Filtering incoming and outgoing connections to and from the device based on an IPv6 ACL is performed using the `ipv6 access-class` command in line configuration mode. The `ipv6 access-class` command is similar to the `access-class` command, except the IPv6 ACLs are defined by a name. If the IPv6 ACL is applied to inbound traffic, the source address in the ACL is matched against the incoming connection source address and the destination address in the ACL is matched against the local device address on the interface. If the IPv6 ACL is applied to outbound traffic, the source address in the ACL is matched against the local device address on the interface and the destination address in the ACL is matched against the outgoing connection source address. We recommend that identical restrictions are set on all the virtual terminal lines because a user can attempt to connect to any of them.

How to Configure IPv6 Access Control Lists

Configuring IPv6 Traffic Filtering

Creating and Configuring an IPv6 ACL for Traffic Filtering

**Note**

IPv6 ACLs on the Cisco ASR 1000 platform do not contain implicit permit rules. The IPv6 neighbor discovery process uses the IPv6 network-layer service; therefore, to enable IPv6 neighbor discovery, you must add IPv6 ACLs to allow IPv6 neighbor discovery packets to be sent and received on an interface. In IPv4, the Address Resolution Protocol (ARP), which is equivalent to the IPv6 neighbor discovery process, uses a separate data-link-layer protocol; therefore, by default IPv4 ACLs implicitly allow ARP packets to be sent and received on an interface.
### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ipv6 access-list access-list-name**
4. Do one of the following:
   - **permit protocol** `{source-ipv6-prefix/prefix-length | any | host source-ipv6-address} [operator [port-number]] {destination-ipv6-prefix / prefix-length | any | host destination-ipv6-address} [operator [port-number]] [dest-option-type [doh-number | doh-type]] [dscp value] [flow-label value] [fragments] [log] [log-input] [mobility] [mobility-type [mh-number | mh-type]] [routing] [routing-type routing-number] [sequence value] [time-range name]
   - **deny protocol** `{source-ipv6-prefix/prefix-length | any | host source-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/prefix-length | any | host destination-ipv6-address} [operator [port-number]] [dest-option-type [doh-number | doh-type]] [dscp value] [flow-label value] [fragments] [log] [log-input] [mobility] [mobility-type [mh-number | mh-type]] [routing] [routing-type routing-number] [sequence value] [time-range name] [undetermined-transport]

<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Device# configure terminal</code></td>
<td></td>
</tr>
</tbody>
</table>

---

Example:

```
Device(config-ipv6-acl)# permit ipv6 host 2001:DB8:0:4::32 any

Example:

Device(config-ipv6-acl)# deny ipv6 host 2001:DB8:0:6::6 any
```
### Configuration Examples for IPv6 Access Control Lists

#### Example: Verifying IPv6 ACL Configuration

In this example, the `show ipv6 access-list` command is used to verify that IPv6 ACLs are configured correctly:

```
Device> show ipv6 access-list

IPv6 access list inbound
perm tcp any any eq bgp (8 matches) sequence 10
perm tcp any any eq telnet (15 matches) sequence 20
perm udp any any sequence 30

IPv6 access list Virtual-Access2.1#427819008151 (per-user)
perm tcp host 2001:DB8:1::32 eq bgp host 2001:DB8:2::32 eq 11000 sequence 1
perm tcp host 2001:DB8:1::32 eq telnet host 2001:DB8:2::32 eq 11001 sequence 2
```

#### Example: Creating and Applying an IPv6 ACL

The following example shows how to restrict HTTP access to certain hours during the day and log any activity outside of the permitted hours:

```
Device# configure terminal
Device(config)# time-range lunchtime
Device(config-time-range)# periodic weekdays 12:00 to 13:00
Device(config-time-range)# exit
Device(config)# ipv6 access-list INBOUND
Device(config-ipv6-acl)# permit tcp any any eq www time-range lunchtime
Device(config-ipv6-acl)# deny tcp any any eq www log-input
Device(config-ipv6-acl)# permit tcp 2001:DB8::/32 any
Device(config-ipv6-acl)# permit udp 2001:DB8::/32 any
Device(config-ipv6-acl)# end
```
**Example: Controlling Access to a vty**

In the following example, incoming connections to the virtual terminal lines 0 to 4 are filtered based on the IPv6 access list named acl1:

```
ipv6 access-list acl1
   permit ipv6 host 2001:DB8:0:4::2/32 any
!
line vty 0 4
   ipv6 access-class acl1 in
```

**Use Case or Deployment Scenarios**

**Creating and Applying a IPv6 Access List**

```
Device(config)#ipv6 access-list test
Device(config-ipv6-acl)#deny ipv6 10:10:10:10::/64 20:20:20:20::/64 log-input
Device(config-ipv6-acl)#permit ipv6 any any log
Device(config)#int gig 0/0/5
Device(config-if)#ipv6 traffic-filter test in
Device(config-if)#end

Device# show ipv6 access-list
IPv6 access list test
   deny ipv6 10:10:10:10::/64 20:20:20:20::/64 log-input (100 matches) sequence 10
   permit ipv6 any any log sequence 20

Device# show ipv6 access-list
deny ipv6 10:10:10:10::/64 20:20:20:20::/64 log-input (100 matches) sequence 10
permit ipv6 any any log sequence 20

CHAPTER 5

MAC Access Control Lists

This chapter describes how to configure MAC access control lists (ACLs) on a Cisco router. It contains the following sections:

- Finding Feature Information, on page 53
- Prerequisites for MAC Access Control Lists, on page 53
- Restrictions for MAC Access Control Lists, on page 53
- Information About MAC Access Control Lists, on page 54
- How to Configure MAC Access Control Lists, on page 54
- Configuration Examples for MAC Access Control Lists, on page 58
- Additional References for MAC Access Control Lists, on page 58

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for MAC Access Control Lists

- You must be familiar with MAC addressing and non-IP protocols to configure MAC ACLs.

Restrictions for MAC Access Control Lists

- MAC ACL is not supported on:
  - Trunk EFP or trunk port
  - Egress
  - Interface
• MAC ACL is not supported for IP packets.
• MAC ACL counters are not supported.
• MAC ACLs are not supported on port, routed interface, and BDI.
• ACL and QoS cannot be applied on the same interface, EFP and bridge domain interface (BDI).
• Outbound MAC ACL is not supported on the Cisco RSP3 Module.
• MAC ACL does not deny broadcast packets on the EFP on the RSP3 module. To deny broadcast packets do any of the following:
  • Use storm control feature to restrict the broadcast packets.
  • Create a policy with the ACL (permit broadcast), and apply it to the interface with the 64K policer, to rate limit and allow only minimal amount of broadcast packets.

Information About MAC Access Control Lists

MAC Access Control Lists

MAC ACLs are ACLs that filter traffic using information in the Layer 2 header of each packet. You can use ACLs to control which hosts can access different parts of a network or to decide which types of traffic are forwarded or blocked at the router interfaces. MAC ACL is supported on EFP and Cross-Connect.

How to Configure MAC Access Control Lists

Configuring ACL

To configure ACL, perform the steps below.

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>enable</td>
</tr>
</tbody>
</table>
|      |         | Router> enable
|      |         | Enables privileged EXEC mode.
|      |         | • Enter your password if prompted. |
| 2    | configure terminal | configure terminal |
|      |         | Router# configure terminal
|      |         | Enters global configuration mode. |
| 3    | mac access-list extended name | mac access-list extended name |
Example:
Router(config)# mac access-list ext macext2
Creates an extended MAC access control list (ACL) and define its access control entries (ACEs).

- name—Name of the ACL to which the entry belongs.

Step 4
\{permit | deny\} \{any | host \textit{src-MAC-addr}\} \{any | host \textit{dst-MAC-addr}\}
Example:
Router(config-ext-macl)# deny any any
Permits or denies Layer 2 traffic to be forwarded if the conditions are matched.

- permit—Permits Layer 2 traffic to be forwarded if the conditions are matched.
- deny—Denies Layer 2 traffic to be forwarded if the conditions are matched.
- any—Keyword to deny any source or destination MAC address.
- host \textit{src-MAC-addr}—Defines a host MAC address. MAC address-based subnets are not allowed.
- host \textit{dst-MAC-addr}—Defines a destination MAC address. MAC address-based subnets are not allowed.

Step 5
end
Example:
Router(config-ext-macl)# end
Returns to privileged EXEC mode.

---

Applying ACL on Cross-Connect

To apply ACL on Cross-Connect, perform the steps below.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface gigabitethernet \textit{slot/subslot/port}
4. service instance \textit{id} ethernet
5. description \textit{string}
6. encapsulation dot1q \textit{sp-vlan-id} second-dot1q \{\textit{ce-vlan-id} | any\}
7. rewrite ingress tag \{pop \{1 | 2\}\} [symmetric]
8. mac access-group \textit{access-list-name} in
9. xconnect \textit{peer-router-id} \textit{vcid} encapsulation mpls
10. mtu \textit{mtu-value}
11. exit
12. service instance \textit{id} ethernet
13. encapsulation dot1q \textit{vlan-id}
14. mac access-group \textit{access-list-name} in
15. bridge-domain \textit{bridge-id}
16. end

</table>
| **Step 8** | **mac access-group** access-list-name **in**<br>**Example:**<br>Router(config-if-srv)# mac access-group macext2 in | To use a MAC access control list (ACL) to control inbound traffic on an Ethernet service instance.  
- **access-list-name**—Name of a MAC ACL to apply to an interface or subinterface (as specified by the `mac access-list extended` command).  
- **in**—Filters on inbound packets. |
| **Step 9** | **xconnect** peer-router-id vcid encapsulation mpls<br>**Example:**<br>Router(config-if-srv)# xconnect 77.77.77.77 1120 encapsulation mpls | Binds the attachment circuit to a pseudowire VC. The syntax for this command is the same as for all other Layer 2 transports. Enters cross-connect configuration mode.  
- **peer-router-id**—IP address of the remote provider edge (PE) peer router.  
- **vcid**—32-bit identifier to assign to the pseudowire. |
| **Step 10** | **mtu** mtu-value<br>**Example:**<br>Router(config-if-xconn)# mtu 1500 | Specifies the MTU for the VC.  
- **mtu-value**—Specifies the value of the MTU. |
| **Step 11** | **exit**<br>**Example:**<br>Router(config-if-xconn)# exit | Exits cross-connect configuration mode. |
| **Step 12** | **service instance** id ethernet<br>**Example:**<br>Router(config-if)# service instance 1000 ethernet | Configures an Ethernet service instance on an interface and enters service instance configuration mode.  
- **id**—Specifies the EFP identifier, an integer from 1 to 4000. |
| **Step 13** | **encapsulation dot1q** vlan-id<br>**Example:**<br>Router(config-if-srv)# encapsulation dot1q 141 second-dot1q 120 | To define the matching criteria to map 802.1Q frames ingress on an interface to the appropriate service instance.  
- **vlan-id**—VLAN ID, integer in the range 1 to 4094. |
| **Step 14** | **mac access-group** access-list-name **in**<br>**Example:**<br>Router(config-if-srv)# mac access-group macext2 in | To use a MAC access control list (ACL) to control inbound traffic on an Ethernet service instance.  
- **access-list-name**—Name of a MAC ACL to apply to an interface or subinterface (as specified by the `mac access-list extended` command).  
- **in**—Filters on inbound packets. |
| **Step 15** | **bridge-domain** bridge-id<br>**Example:**<br>Router(config-if-srv)# bridge-domain 1000 | Binds a service instance or a MAC tunnel to a bridge domain instance.  
- **bridge-id**—Numerical identifier for the bridge domain instance. The range is an integer from 1 to 4000. |
Purpose
Command or Action | Purpose
---|---
Step 16 | end
Example: Router(config-if-srv)# end | Exits service instance mode and returns to privileged EXEC mode.

Verifying MAC Access Control Lists

To verify the MAC ACL configuration, use the following `show` command.

- `show access-lists name`—Displays information about the named access list.

Router# `show access-list macext4`

Extended MAC access list macext4  
permit any host 0000.0000.0009  
permit any host 0000.0000.0010  
permit any host 0000.0000.0011  
permit any host 0000.0000.0012

Configuration Examples for MAC Access Control Lists

MAC ACL Configuration

Example: Allowing Specified Source or Destination MAC Addresses

(config)#mac access-list extended macext5  
(config-ext-macl)#permit any host 0000.0000.0009  
(config-ext-macl)#permit any host 0000.0000.0010  
(config-ext-macl)#permit any host 0000.0000.0011  
(config-ext-macl)#permit any host 0000.0000.0012

Example: Allowing any Source or Destination MAC Address

(config)#mac access-list extended macext9  
(config-ext-macl)#permit any any
