

Network Admission Control

Last Updated: January 15, 2012

The Network Admission Control feature addresses the increased threat and impact of worms and viruses have on business networks. This feature is part of the Cisco Self-Defending Network Initiative that helps customers identify, prevent, and adapt to security threats.

In its initial phase, the Cisco Network Admission Control (NAC) functionality enables Cisco routers to enforce access privileges when an endpoint attempts to connect to a network. This access decision can be on the basis of information about the endpoint device, such as its current antivirus state. The antivirus state includes information such as version of antivirus software, virus definitions, and version of scan engine.

Network admission control systems allow noncompliant devices to be denied access, placed in a quarantined area, or given restricted access to computing resources, thus keeping insecure nodes from infecting the network.

The key component of the Cisco Network Admission Control program is the Cisco Trust Agent, which resides on an endpoint system and communicates with Cisco routers on the network. The Cisco Trust Agent collects security state information, such as what antivirus software is being used, and communicates this information to Cisco routers. The information is then relayed to a Cisco Secure Access Control Server (ACS) where access control decisions are made. The ACS directs the Cisco router to perform enforcement against the endpoint.

- [Prerequisites for Network Admission Control, page 1](#)
- [Restrictions for Network Admission Control, page 2](#)
- [Information About Network Admission Control, page 2](#)
- [How to Configure Network Admission Control, page 6](#)
- [Configuration Examples for Network Admission Control, page 23](#)
- [Additional References, page 25](#)
- [Feature Information for Network Admission Control, page 26](#)
- [Glossary, page 28](#)

Prerequisites for Network Admission Control

- The Cisco IOS router must be running Cisco IOS software Release 12.3(8)T or later.
- The Cisco Trust Agent must be installed on the endpoint devices (for example, on PCs and laptops).
- A Cisco Secure ACS is required for authentication, authorization, and accounting (AAA).

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

- A proficiency with configuring access control lists (ACLs) and AAA is necessary.

Restrictions for Network Admission Control

- This feature is available only on Cisco IOS firewall feature sets.

Information About Network Admission Control

Before configuring the Network Admission Control feature, the following concepts need to be understood:

- [Virus Infections and Their Effect on Networks, page 2](#)
- [How Network Admission Control Works, page 2](#)
- [Network Access Device, page 3](#)
- [Cisco Trust Agent, page 3](#)
- [Cisco Secure ACS, page 4](#)
- [Remediation, page 4](#)
- [Network Admission Control and Authentication Proxy, page 5](#)
- [NAC MIB, page 5](#)

Virus Infections and Their Effect on Networks

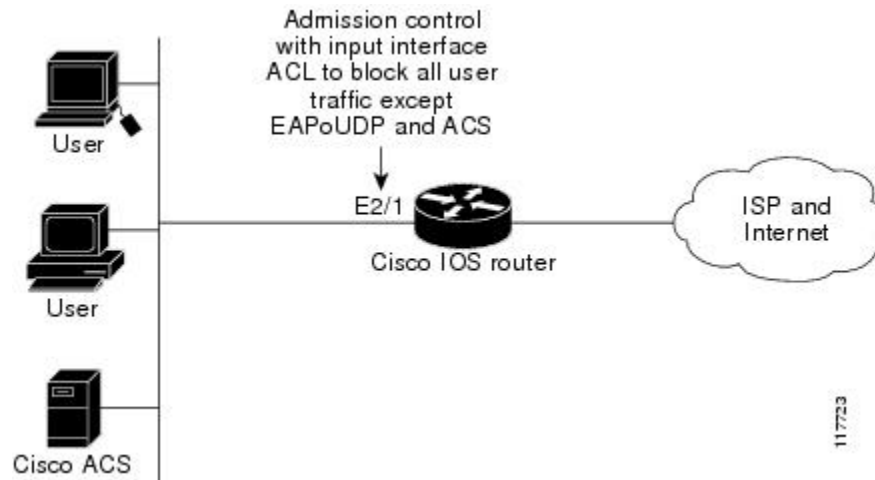

Virus infections are the single largest cause of serious security breaches for networks and often result in huge financial losses. Sources of virus infections are insecure endpoints (for example, PCs, laptops, and servers). Although the endpoints may have antivirus software installed, the software is often disabled. Even if the software is enabled, the endpoints may not have the latest virus definitions and scan engines. A larger security risk is from devices that do not have any antivirus software installed. Although antivirus vendors today are making it more difficult to disable the antivirus software, they are not addressing the risk of outdated virus definitions and scan engines.

How Network Admission Control Works

Endpoint systems, or clients, are normally hosts on the network, such as PCs, laptops, workstations, and servers. The endpoint systems are a potential source of virus infections, and their antivirus states have to be validated before they are granted network access. When an endpoint attempts an IP connection to a network through an upstream Cisco network access device (typically a Cisco IOS router), the router challenges the endpoint for its antivirus state. The endpoint systems run a client called Cisco Trust Agent, which collects antivirus state information from the end device and transports the information to the Cisco network access device. This information is then communicated to a Cisco Secure ACS where the antivirus state of the endpoint is validated and access control decisions are made and returned to Cisco network access devices. The network devices either permit, deny, or quarantine the end device. The Cisco Secure ACS may in turn use back-end antivirus vendor-specific servers for evaluating the antivirus state of the endpoint.

The figure below illustrates how Cisco Network Admission Control works.

Figure 1 Cisco IOS Network Admission Control System

The figure above shows that IP admission control is applied at the LAN interface. All network devices must be validated for their antivirus states upon their initial IP connections through the router. Until then, all traffic from endpoint systems (except for EAPoUDP and Cisco Secure ACS traffic) is blocked at the interface.

The endpoint system is then challenged for its antivirus state over an EAPoUDP association. The endpoint system gains access to the network if it complies with the network admission control policy as evaluated by the Cisco Secure ACS. If the endpoint system does not comply, the device is either denied access or quarantined.

Network Access Device

A network access device (NAD) is typically a Cisco IOS router (a Layer 3 Extensible Authentication Protocol over User Datagram Protocol [EAPoUDP] access point) that provides connectivity to external networks, such as the Internet or remote enterprise networks. Cisco Network Admission Control functionality may have an Intercept ACL, which determines connections that are intercepted for network admission. Connections from endpoints that match the access list are intercepted by Network Admission Control and are challenged for their antivirus states over a Layer 3 association before they are granted network access.

Cisco Trust Agent

Cisco Trust Agent is a specialized software that runs on endpoint systems. Cisco Trust Agent responds to challenges from the router about the antivirus state of an endpoint system. If an endpoint system is not running the Cisco Trust Agent, the network access device (router) classifies the endpoint system as “clientless.” The network access device uses the EOU clientless username and EOU clientless password that are configured on the network access device as the credentials of the endpoint system for validation with Cisco Secure ACS. The policy attributes that are associated with this username are enforced against the endpoint system.

Cisco Secure ACS

Cisco Secure ACS provides authentication, authorization, and accounting services for network admission control using industry-standard RADIUS authentication protocol. Cisco Secure ACS returns access control decisions to the network access device on the basis of the antivirus credentials of the endpoint system.

Using RADIUS `cisco_av_pair` vendor-specific attributes (VSAs), the following attribute-value pairs (AV pairs) can be set on the Cisco Secure ACS. These AV pairs are sent to the network access device along with other access-control attributes.

- `url-redirect`--Enables the AAA client to intercept an HTTP request and redirect it to a new URL. This redirection is especially useful if the result of posture validation indicates that the network access control endpoint requires an update or patch to be made available on a remediation web server. For example, a user can be redirected to a remediation web server to download and apply a new virus Directory Administration Tool (DAT) file or an operating system patch. (See the following example.)

```
url-redirect=http://10.1.1.1
```

- `posture-token`--Enables Cisco Secure ACS to send a text version of a system posture token (SPT) that is derived by posture validation. The SPT is always sent in numeric format, and using the `posture-token` AV pair makes it easier to view the result of a posture validation request on the AAA client. (See the following example.)

```
posture-token=Healthy
```

Valid SPTs, in order of best to worst, are as follows:

- - Healthy
 - Checkup
 - Quarantine
 - Infected
 - Unknown
- `status-query-timeout`--Overrides the `status-query` default value of the AAA client with the user specified value, in seconds. (See the following example.)

```
status-query-timeout=150
```

For more information about AV pairs that are supported by Cisco IOS software, see the documentation for the releases of Cisco IOS software that are implemented on your AAA clients.

Remediation

Network Admission Control supports HTTP redirection that redirects any HTTP request from the endpoint device to a specified redirect address. This support mechanism redirects all HTTP requests from a source to a specified web page (URL) to which the latest antivirus files can be downloaded. For the HTTP redirection to work, the value must be set for the “`url-redirect`” VSA on the ACS and, correspondingly, associate an access control entry in the downloadable ACL that permits the access of the endpoint system to the redirect URL address. After the value of the `url-redirect` VSA has been set and the access control entry has been associated, any HTTP request that matches the IP admission Intercept ACL are redirected to the specified redirect URL address.

Network Admission Control and Authentication Proxy

It is possible that network admission control and authentication proxy can be configured for the same set of hosts on a given interface. In each case, the Intercept ACL should be the same for IP admission EAPoUDP and authentication proxy. IP admission proxy with proxy authentication should be configured first, followed by IP admission control.

NAC MIB

The NAC MIB feature adds Simple Network Management Protocol (SNMP) support for the NAC subsystem. Using SNMP commands (get and set operations), an administrator can monitor and control NAC sessions on the network access device (NAD).

For more information about SNMP get and set operations, see the subsection “[NAC MIB, page 5](#)” in the section “[Additional References, page 25](#).”

- [Correlation Between SNMP Get and Set Operations and the Cisco CLI, page 5](#)
- [Using show Commands to View MIB Object Information, page 6](#)

Correlation Between SNMP Get and Set Operations and the Cisco CLI

Most of the objects in the object tables in the NAC MIB (CISCO-NAC-NAD-MIB.my) describe various EAPoUDP and session parameters that are applicable to the setup of a NAD. These properties can be viewed and modified by performing various SNMP get and set operations. Many of the values of the table objects can also be viewed or modified by configuring corresponding command-line interface (CLI) commands on a router. For example, an SNMP get operation can be performed on the `cnnEOUGlobalObjectsGroup` table or the `show eou` command can be configured on a router. The parameter information obtained from the SNMP get operation is the same as the output from the `show eou` command. Similarly, performing an SNMP get operation on the table `cnnEouIfConfigTable` provides interface-specific parameters that can also be viewed in output from the `show eou` command.

SNMP set operations are allowed for table objects that have corresponding CLI commands, which can be used to modify table object values. For example, to change the value range for the `cnnEouHostValidateAction` object in the `cnnEouHostValidateAction` MIB table to 2, you can either perform the SNMP set operation or configure the `eou initialize all` command on a router.

For examples of NAC MIB output, see the subsection `NAC MIB Output Examples` in the section `Configuration Examples for Network Admission Control`.

- [Initializing and Revalidating Sessions, page 5](#)
- [Session-Specific Information, page 6](#)

Initializing and Revalidating Sessions

NAC allows administrators to initialize and revalidate sessions using the following CLI commands:

- `eou initialize all`
- `eou initialize authentication clientless`
- `eou initialize authentication eap`
- `eou initialize authentication static`
- `eou initialize ip {ip-address }`
- `eou initialize mac {mac-address }`

- **eou initialize posturetoken** {string}
- **eou revalidate all**
- **eou revalidate authentication clientless**
- **eou revalidate authentication eap**
- **eou revalidate authentication static**
- **eou revalidate ip** {ip-address}
- **eou revalidate mac** {mac-address }
- **eou revalidate posturetoken** {string}

The initialization and revalidation actions can also be accomplished by performing SNMP set operations on the objects of the `cnnEouHostValidateAction` table. For more information about initializing and revalidating sessions, see the section `Commands That Correlate to cnnEouHostValidateAction Table Objects`.

For examples of CLI commands that correlate to changes that can be made to `cnnEouHostValidateAction` table objects, see the subsection `NAC MIB Output Examples` in the section `Configuration Examples for Network Admission Control`.

Session-Specific Information

The NAC MIB provides a way to view session-specific details using the `cnnEouHostQueryTable` and `cnnEouHostResultTable`. The `cnnEouHostQueryTable` is used to build the query. The query is the same format as the **show eou ip** {ip-address} command (that is, the IP address would be shown as in the **show eou ip** command--for example, 10.1.1.1). Administrators must use the SNMP set operation on the objects of the `cnnEouHostQueryTable` to create the query. The results of the query are stored as a row in the `cnnEouHostResultTable`. For more information about viewing session-specific details, see the section `Viewing MIB Query Results`.

Using show Commands to View MIB Object Information

The CLI commands **show eou**, **show eou all**, **show eou authentication**, **show eou initialize**, **show eou ip**, **show eou mac**, **show eou posturetoken**, **show eou revalidate**, and **show ip device tracking all** provide the same output information as that in the `CISCO-NAC-NAD-MIB` tables using SNMP get operations.

For examples of **show** command output information that can also be viewed in MIB object tables, see the subsection `NAC MIB Output Examples` in the section `Configuration Examples for Network Admission Control`.

How to Configure Network Admission Control

- [Configuring the ACL and Admission Control, page 7](#)
- [Configuring Global EAPoUDP Values, page 9](#)
- [Configuring an Interface-Specific EAPoUDP Association, page 10](#)
- [Configuring AAA for EAPoUDP, page 11](#)
- [Configuring the Identity Profile and Policy, page 13](#)
- [Clearing EAPoUDP Sessions That Are Associated with an Interface, page 15](#)
- [Verifying Network Admission Control, page 15](#)
- [Troubleshooting Network Admission Control, page 16](#)
- [Monitoring and Controlling NAC with the CISCO-NAC-NAD-MIB, page 17](#)

Configuring the ACL and Admission Control

Network admission control is applied in the inbound direction at any interface. Applying network admission control inbound at an interface causes network admission control to intercept the initial IP connections of the intercept end system through the router.

Use the steps in this section to configure an intercept ACL.

Note

In this configuration, an intercept ACL is defined as “101,” and the Intercept ACL is associated with the IP admission control rule “greentree.” Any IP traffic that is destined to the 192.50.0.0 network are subjected to validation. In addition, beginning with Step 5, an intercept ACL is applied inbound to the interface that is associated with network admission control. This ACL typically blocks access to endpoint systems until they are validated. This ACL is referred to as the default access list.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **access-list** *access-list-number* { **permit** | **deny** } *protocol source destination*
4. **ip admission name** *admission-name* [**eapoudp** | **proxy** { **ftp** | **http** | **telnet** }] [**list** { *acl* | *acl-name* }]
5. **interface** *type slot / port*
6. **ip address** *ip-address mask*
7. **ip admission** *admission-name*
8. **exit**
9. Do one of the following:
 - **access-list** *access-list-number* { **permit** | **deny** } *protocol source destination*
10. **ip access-group** { *access-list-number* | *access-list-name* } **in**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

Command or Action	Purpose
<p>Step 3 <code>access-list access-list-number { permit deny } protocol source destination</code></p> <p>Example:</p> <pre>Router (config)# access-list 101 permit ip any 192.50.0.0 0.0.0.255</pre>	<p>Defines a numbered access list.</p>
<p>Step 4 <code>ip admission name admission-name [eapoudp proxy { ftp http telnet }] [list { acl acl-name }]</code></p> <p>Example:</p> <pre>Router (config)# ip admission name greentree eapoudp list 101</pre>	<p>Creates IP network admission control rules. The rules define how you apply admission control. The rules are as follows:</p> <ul style="list-style-type: none"> • eapoudp --Specifies IP network admission control using EAPoUDP. • proxy ftp --Specifies FTP to trigger authentication proxy. • proxy http --Specifies HTTP to trigger authentication proxy. • proxy telnet --Specifies Telnet to trigger authentication proxy. <p>You can associate the named rule with an ACL, providing control over which hosts use the admission control feature. If no standard access list is defined, the named admission rule intercepts IP traffic from all hosts whose connection-initiating packets are received at the configured interface.</p> <p>The list option allows you to apply a standard, extended (1 through 199) or named access list to a named admission control rule. IP connections that are initiated by hosts in the access list are intercepted by the admission control feature.</p>
<p>Step 5 <code>interface type slot / port</code></p> <p>Example:</p> <pre>Router (config)# interface ethernet 2/1</pre>	<p>Defines an interface and enters interface configuration mode.</p>
<p>Step 6 <code>ip address ip-address mask</code></p> <p>Example:</p> <pre>Router (config-if)# ip address 192.0.0.1 255.255.255.0</pre>	<p>Sets a primary or secondary IP address for an interface.</p>
<p>Step 7 <code>ip admission admission-name</code></p> <p>Example:</p> <pre>Router (config-if)# ip admission greentree</pre>	<p>Applies the named admission control rule at the interface.</p>

	Command or Action	Purpose
Step 8	<p>exit</p> <p>Example:</p> <pre>Router (config-if)# exit</pre>	Exits interface configuration mode.
Step 9	<p>Do one of the following:</p> <ul style="list-style-type: none"> access-list <i>access-list-number</i> { permit deny } <i>protocol source destination</i> <p>Example:</p> <pre>Router (config)# access-list 105 permit udp any any</pre> <p>Example:</p> <pre>Router (config)# access-list 105 permit ip host 192.168.0.2 any</pre> <p>Example:</p> <pre>Router (config)# access-list 105 deny ip any any</pre> <p>Example:</p> <pre>Router (config)# access-list 105 deny ip any any</pre>	<p>Defines a numbered access list.</p> <p>Note In the first two examples (under “Command or Action”), ACL “105” denies all IP traffic except UDP and access to 192.168.0.2 (Cisco Secure ACS).</p> <p>Note In the third example (under “Command or Action,” ACL “105” is applied on the interface that is configured for network admission control, and access to endpoint systems (except for EAPoUDP traffic and access to Cisco Secure ACS [192.168.0.2 in the example] is blocked until their antivirus states are validated. This ACL (“105”) is referred to as “Interface ACL.”</p>
Step 10	<p>ip access-group { <i>access-list-number</i> <i>access-list-name</i> } in</p> <p>Example:</p> <pre>Router (config)# ip access-group 105 in</pre>	Controls access to an interface.

Configuring Global EAPoUDP Values

To configure global EAPoUDP values, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **eou** { **allow** | **clientless** | **default** | **initialize** | **logging** | **max-retry** | **port** | **rate-limit** | **revalidate** | **timeout** }

DETAILED STEPS

Command or Action	Purpose
<p>Step 1 <code>enable</code></p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
<p>Step 2 <code>configure terminal</code></p> <p>Example:</p> <pre>Router# configure terminal</pre>	<p>Enters global configuration mode.</p>
<p>Step 3 <code>eou { allow clientless default initialize logging max-retry port rate-limit revalidate timeout }</code></p> <p>Example:</p> <pre>Router (config)# eou initialize</pre>	<p>Specifies EAPoUDP values.</p> <ul style="list-style-type: none"> • For a breakout of available keywords and arguments for the <code>eou</code> command, see the following commands: <ul style="list-style-type: none"> ◦ <code>eou allow</code> ◦ <code>eou clientless</code> ◦ <code>eou default</code> ◦ <code>eou initialize</code> ◦ <code>eou logging</code> ◦ <code>eou max-retry</code> ◦ <code>eou port</code> ◦ <code>eou rate-limit</code> ◦ <code>eou revalidate</code> ◦ <code>eou timeout</code>

Configuring an Interface-Specific EAPoUDP Association

To configure an EAPoUDP association that can be changed or customized for a specific interface that is associated with network admission control, perform the following steps.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface type slot / port`
4. `eou [default | max-retry | revalidate | timeout]`

DETAILED STEPS

Command or Action	Purpose
Step 1 <code>enable</code> Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2 <code>configure terminal</code> Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3 <code>interface type slot / port</code> Example: <pre>Router (config)# interface ethernet 2/1</pre>	Defines an interface and enters interface configuration mode.
Step 4 <code>eou [default max-retry revalidate timeout]</code> Example: <pre>Router (config-if)# eou revalidate</pre>	Enables an EAPoUDP association for a specific interface. <ul style="list-style-type: none"> • For a breakout of available keywords and arguments for the eou command, see the following commands: <ul style="list-style-type: none"> ◦ eou default ◦ eou max-retry ◦ eou revalidate ◦ eou timeout

Configuring AAA for EAPoUDP

To set up AAA for EAPoUDP, perform the following steps.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `aaa new-model`
4. `aaa authentication eou default enable group radius`
5. `aaa authorization network default group radius`
6. `radius-server host {hostname | ip-address}`
7. `radius-server key {0 string | 7 string | string}`

DETAILED STEPS

Command or Action	Purpose
<p>Step 1 <code>enable</code></p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
<p>Step 2 <code>configure terminal</code></p> <p>Example:</p> <pre>Router# configure terminal</pre>	<p>Enters global configuration mode.</p>
<p>Step 3 <code>aaa new-model</code></p> <p>Example:</p> <pre>Router (config)# aaa new-model</pre>	<p>Enables the AAA access control model.</p>
<p>Step 4 <code>aaa authentication eou default enable group radius</code></p> <p>Example:</p> <pre>Router (config)# aaa authentication eou default enable group radius</pre>	<p>Sets authentication lists for an EAPoUDP association.</p>
<p>Step 5 <code>aaa authorization network default group radius</code></p> <p>Example:</p> <pre>Router (config)# aaa authorization network default group radius</pre>	<p>Uses the list of all RADIUS servers for authentication.</p>
<p>Step 6 <code>radius-server host {hostname ip-address}</code></p> <p>Example:</p> <pre>Router (config)# radius-server host 192.0.0.40</pre>	<p>Specifies a RADIUS server host.</p>
<p>Step 7 <code>radius-server key {0 string 7 string string}</code></p> <p>Example:</p> <pre>Router (config)# radius-server key cisco</pre>	<p>Sets the authentication and encryption key for all RADIUS communications between the router and the RADIUS daemon.</p>

Configuring the Identity Profile and Policy

Identity is a common infrastructure that is used to specify local profile and policy configurations. The identity profile allows you to statically authorize or validate individual devices on the basis of IP address, MAC address, or device type. Each statically authenticated device can be associated with a local policy that specifies the network access control attributes. Hosts are added to this “exception list” using the **identity profile** command, and corresponding policies are associated with these hosts using the **identity policy** command.

If the client is part of the identity (that is, the client is on the exception list), the status of the client is set on the basis of the identity configuration. The client does not have to go through the posture validation process, and the associated identity policy is applied for the client.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **identity profile eapoudp**
4. **device** {**authorize** {**ip address** *ip-address* {**policy** *policy-name*} | **mac-address***mac-address* | **type** {**cisco** / **ip** / **phone**}} | **not-authorize**}
5. **exit**
6. **identity policy** *policy-name* [**access-group** *group-name* | **description** *line-of-description* | **redirect** *url* | **template** [**virtual-template** *interface-name*]]
7. **access-group** *group-name*
8. **exit**
9. **exit**
10. **ip access-list extended** *access-list-name*
11. {**permit** | **deny**} *source source-wildcard* *destination destination-wildcard*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

Command or Action	Purpose
<p>Step 3 <code>identity profile eapoudp</code></p> <p>Example:</p> <pre>Router (config)# identity profile eapoudp</pre>	Creates an identity profile and enters identity profile configuration mode.
<p>Step 4 <code>device {authorize {ip address <i>ip-address</i> {policy <i>policy-name</i>} mac-address <i>mac-address</i> type {cisco ip phone}} not-authorize}</code></p> <p>Example:</p> <pre>Router (config-identity-prof)# device authorize ip address 10.10.142.25 policy policynamel</pre>	Statically authorizes an IP device and applies an associated policy to the device.
<p>Step 5 <code>exit</code></p> <p>Example:</p> <pre>Router (config-identity-prof)# exit</pre>	Exits identity profile configuration mode.
<p>Step 6 <code>identity policy <i>policy-name</i> [access-group <i>group-name</i> description <i>line-of-description</i> redirect <i>url</i> template [virtual-template <i>interface-name</i>]]</code></p> <p>Example:</p> <pre>Router (config-identity-prof)# identity policy policynamel</pre>	Creates an identity policy and enters identity policy configuration mode.
<p>Step 7 <code>access-group <i>group-name</i></code></p> <p>Example:</p> <pre>Router (config-identity-policy)# access-group exempt-acl</pre>	Defines network access attributes for the identity policy.
<p>Step 8 <code>exit</code></p> <p>Example:</p> <pre>Router (config-identity-policy)# exit</pre>	Exits identity policy configuration mode.
<p>Step 9 <code>exit</code></p> <p>Example:</p> <pre>Router (config-identity-prof)# exit</pre>	Exits identity profile configuration mode.

Command or Action	Purpose
Step 10 <code>ip access-list extended <i>access-list-name</i></code> Example: <pre>Router (config)# ip access-list extended exempt-acl</pre>	Defines access control for statically authenticated devices (and enters network access control configuration mode).
Step 11 <code>{permit deny} <i>source source-wildcard</i> <i>destination destination-wildcard</i></code> Example: <pre>Router (config-ext-nacl)# permit ip any 192.50.0.0. 0.0.0.255</pre>	Set conditions to allow a packet to pass a named IP access list.

Clearing EAPoUDP Sessions That Are Associated with an Interface

To clear EAPoUDP sessions that are associated with a particular interface or that are on the NAD, perform the following steps.

SUMMARY STEPS

1. `enable`
2. `clear eou all`

DETAILED STEPS

Command or Action	Purpose
Step 1 <code>enable</code> Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2 <code>clear eou all</code> Example: <pre>Router# clear eou all</pre>	Clears all EAPoUDP sessions on the NAD.

Verifying Network Admission Control

To verify EAP and EAPoUDP messages or sessions, perform the following steps. The **show** commands may be used in any order or independent of the other **show** command.

SUMMARY STEPS

1. **enable**
2. **show eou all**
3. **show ip admission eapoudp**

DETAILED STEPS

Command or Action	Purpose
<p>Step 1 enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
<p>Step 2 show eou all</p> <p>Example:</p> <pre>Router# show eou all</pre>	<p>Displays information about EAPoUDP sessions on the network access device.</p>
<p>Step 3 show ip admission eapoudp</p> <p>Example:</p> <pre>Router# show ip admission eapoudp</pre>	<p>Displays the network admission control configuration or network admission cache entries.</p>

Troubleshooting Network Admission Control

The following commands may be used to display information about EAP and EAPoUDP messages or sessions. The **debug** commands may be used in any order or independent of the other **debug** commands.

SUMMARY STEPS

1. **enable**
2. **debug eap {all | errors | packets | sm}**
3. **debug eou {all | eap | errors | packets | sm}**
4. **debug ip admission eapoudp**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	<p>debug eap {all errors packets sm}</p> <p>Example:</p> <pre>Router# debug eap all</pre>	<p>Displays information about EAP messages.</p>
Step 3	<p>debug eou {all eap errors packets sm}</p> <p>Example:</p> <pre>Router# debug eou all</pre>	<p>Displays information about EAPoUDP messages.</p>
Step 4	<p>debug ip admission eapoudp</p> <p>Example:</p> <pre>Router# debug ip admission eapoudp</pre>	<p>Displays information about IP admission events.</p>

CLI Commands That Correlate to cnnEouGlobalObjectsGroup Table Objects

An SNMP get or set operation can be performed to obtain or change information about value ranges for objects in the cnnEouGlobalObjectsGroup table. The same information can be viewed in output from the **show eou** command. The table below displays examples of some global configuration objects and the SNMP get and set operations required to obtain or change their values.

For an example of `show eou` command output, see the `show eou` section of the NAC MIB Output Examples section.

Table 1 *Obtaining and Changing Global Configuration Values Using SNMP Get and Set Operations*

Global Configuration Objects	SNMP Operation
EAPoUDP version	Performs a get operation on the <code>cnnEouVersion</code> object. (The object value is "1.")
EAPoUDP port	Performs a get operation on the <code>cnnEouPort</code> object.
Enabling logging (enable EOU logging)	Sets the <code>cnnEouLoggingEnable</code> object. (The object value is "true.")

CLI Commands That Correlate to `cnnEouIfConfigTable` Objects

An SNMP get operation is performed to obtain information about value ranges for objects in the `cnnEouIfConfigTable`. The same information can be viewed in output from the `show eou` command. The table below displays examples of some interface-specific configuration objects and the SNMP get operations required to obtain their values.

Table 2 *Obtaining Interface-Specific Configuration Values Using SNMP Get Operations*

Interface-Specific Object	SNMP Operation
AAA timeout	Performs a get operation on the <code>cnnEouIfTimeoutAAA</code> object. <ul style="list-style-type: none"> Format: GET <code>cnnEouIfTimeoutAAA.IfIndex</code> You must specify the corresponding index number of the specific interface.
Maximum retries	Performs a get operation on the <code>cnnEouIfMaxRetry</code> object. <ul style="list-style-type: none"> Format: GET <code>cnnEouIfMaxRetry.IfIndex</code>

CLI Commands That Correlate to `cnnEouHostValidateAction` Table Objects

EOU sessions can be initialized or revalidated by the CLI or by using the SNMP set operation on the table `cnnEouHostValidateAction`.

Following are some examples (listed by CLI command) that correlate to MIB objects.

`eou initialize all`

EOU initialization can be accomplished for all sessions by using the `eou initialize all` command or by using an SNMP set operation on the object `cnnEouHostValidateAction`. This object must be set to the numeric value 2.

eou initialize authentication clientless

EOU initialization can be accomplished for sessions having an authentication type “clientless” using the **eou initialize authentication clientless** command or an SNMP set operation on the object `cnnEouHostValidateAction`. This object must be set to the numeric value 3.

eou initialize ip

EOU initialization can be accomplished for a particular session using the **eou initialize ip** *{ip-address}* command.

To achieve the same result using an SNMP operation, three objects have to be set in the `cnnEouHostValidateAction` MIB table:

- `cnnEouHostValidateAction`--The value range must be set.
- `cnnEouHostValidateIpAddrType`--The IP address type must be set. This value must be set to IPv4 because IPv4 is currently the only address type supported by NAC. (This value is the type of address being set for the `cnnEouHostValidateIPAddr` object.)
- `cnnEouHostValidateIPAddr`--The IP address must be set.

**Note**

The three MIB objects should be set in a single SNMP set operation.

eou initialize posturetoken

All sessions having a particular posturetoken can be initialized using the **eou initialize posturetoken** *{string}* command. The default value range for this command is 8.

To achieve the same result using an SNMP set operation, you must set the following objects:

- `cnnEouHostValidateAction`--Set this value to 8.
- `cnnEouHostValidatePostureTokenStr`--Set the string value.

**Note**

The two MIB objects should be set in a single SNMP set operation.

Creating MIB Query Tables

The MIB table `cnnEouHostQueryTable` is used to create, or build, MIB queries.

MIB Query Correlating to the CLI `show eou all` Command

To build a query that provides the same results as using the **show eou all** command, perform the following SNMP get operation.

The object `cnnEouHostQueryMask` in the table `cnnEouHostQueryTable` indicates the kind of query. The corresponding value of the `cnnEouHostQueryMask` object in output from the **show eou all** command is 8 (the integer value).

SUMMARY STEPS

1. Set the `cnnEouHostQueryStatus` object to `createandgo`.
2. Set the `cnnEouHostQueryMask` object to 8.
3. Set the `cnnEouHostQueryStatus` object to `active`.

DETAILED STEPS

	Command or Action	Purpose
Step 1	Set the <code>cnnEouHostQueryStatus</code> object to <code>createandgo</code> .	Creates a query row.
Step 2	Set the <code>cnnEouHostQueryMask</code> object to 8.	Corresponds in value to the show eou all command.
Step 3	Set the <code>cnnEouHostQueryStatus</code> object to <code>active</code> .	Indicates that you have finished building the query.

**Note**

Examples are not shown in the previous table because the format differs depending on the software you are using.

- [What to Do Next, page 20](#)

What to Do Next

View the results. See the section *Viewing MIB Query Results Correlating to the show eou all Command*.

Viewing MIB Query Results Correlating to the show eou all Command

After the MIB query has been built and you have indicated that you are finished (with the “active” status), the results can be viewed. A query in the `cnnEouHostQueryTable` is represented by a row. The row number is the Query Index. Similarly, the `cnnEouHostResultTable` is composed of result rows. Each row in the `cnnEouHostResultTable` is uniquely identified by a combination of Query Index and Result Index. The results of the `cnnEouHostQueryTable` index and the `cnnEouHostResultTable` have to be matched. Match one row in the Query table to one of the rows in the Result table. For example, if a query that corresponds to a **show** command results in ten sessions, the Result table has ten rows, each row corresponding to a particular session. The first row in the Result table is R1.1. The second row is R1.2, and so on to R1.10. If another query is created in the Query table, and it results in five sessions, five rows are created in the Result table (R2.1, R2.2, R2.3, R2.4, and R2.5).

The table below illustrates how the Query table sessions are mapped to Result table rows.

Table 3 *Query Table-to-Result Table Mapping*

Query Table	Result Table Rows
Q1 (10 sessions)	R1.1, R1.2, R1.3, R1.4, R1.5, R1.6, R1.7, R1.8, R1.9, R1.10
Q2 (5 sessions)	R2.1, R2.2, R2.3, R2.4, R2.5

To create an SNMP query that provides the same information as output from the **show eou ip** {*ip-address*} **command**, perform the following steps.

SUMMARY STEPS

1. Set `cnnEouHostQueryStatus` to `createandgo`.
2. Set `cnnEouHostQueryIpAddrType` to `IPv4` and the IP address (for example, 10.2.3.4).
3. Set `cnnEouHostQueryStatus` to `active`.

DETAILED STEPS

	Command or Action	Purpose
Step 1	Set <code>cnnEouHostQueryStatus</code> to <code>createandgo</code> .	Creates a query row.
Step 2	Set <code>cnnEouHostQueryIpAddrType</code> to <code>IPv4</code> and the IP address (for example, 10.2.3.4).	Sets the address type. <ul style="list-style-type: none"> • The only address type currently supported by NAC is IPv4.
Step 3	Set <code>cnnEouHostQueryStatus</code> to <code>active</code> .	Indicates you have finished building the query.

Note

Examples are not shown in the previous table because the format differs depending on the software you are using.

Viewing the Results in the cnnEouHostResultTable

To view the results in the `cnnEouHostResultTable`, perform the following steps.

SUMMARY STEPS

1. Perform a get operation on `cnnEouHostQueryRows`.
2. Perform a get operation on the `cnnEouHostResultTable` objects in the format `resultTableObjectName.QueryIndex.ResultIndex`.

DETAILED STEPS

	Command or Action	Purpose
Step 1	Perform a get operation on <code>cnnEouHostQueryRows</code> .	Finds how many rows are created in a Result table for a particular query. <ul style="list-style-type: none"> • If a query row is a negative number, the query is still being processed.
Step 2	Perform a get operation on the <code>cnnEouHostResultTable</code> objects in the format <code>resultTableObjectName.QueryIndex.ResultIndex</code> .	Finds the value of a particular object in a Result table that matches a particular query. <ul style="list-style-type: none"> • For multiple rows in the Result table for a single query, the <code>ResultIndex</code> ranges from 1 to the value of <code>cnnEouHostQueryRows</code>.

**Note**

Examples are not shown in the above table because the format differs depending on the software you are using.

MIB Query Correlating to the show eou ip Command

To build a MIB query that provides the same results as the **show eou ip** {*ip-address*} command, perform the following SNMP get operation.

SUMMARY STEPS

1. Set the `cnnEouHostQueryStatus` object to `createandgo`.
2. Set the `cnnEouHostQueryIpAddrType` object to “IPv4”.
3. Set the `cnnEouHostQueryIpAddr` object to IP address (for example, 10.2.3.4).
4. Set the `cnnEouHostQueryStatus` object to `active`.

DETAILED STEPS

Command or Action	Purpose
Step 1 Set the <code>cnnEouHostQueryStatus</code> object to <code>createandgo</code> .	Sets the query status.
Step 2 Set the <code>cnnEouHostQueryIpAddrType</code> object to “IPv4”.	Sets the address type. Note The only address type currently supported by NAC is IPv4.
Step 3 Set the <code>cnnEouHostQueryIpAddr</code> object to IP address (for example, 10.2.3.4).	Sets the IP address.
Step 4 Set the <code>cnnEouHostQueryStatus</code> object to <code>active</code> .	Indicates that you have finished building the query.

**Note**

Examples are not shown in the previous table because the format differs depending on the software you are using.

Viewing MIB Query Results

After the MIB query has been built, the results can be viewed in `cnnEouHostResultTable`. For information about how to review the results, see the subsection *Viewing MIB Query Results Correlating to the show eou all Command* for more information.

If you are doing a MIB query that correlates to the **show eou all** command, there could possibly be as many as 2,000 rows of output. To ensure that you can view all the information in a MIB query, you can split the query into subqueries. For example, for a query having 2,000 rows of output, you could split the query into four subqueries to view the results in a page-by-page format. The first subquery would include rows 1 through 500 (the first 500 sessions); the second subquery would include rows 501 through 1,000; the third subquery would include rows 1,001 through 1,500; and the fourth subquery would include rows 1,501 through 2,000.

**Note**

The `cnnEouHostQueryTotalHosts` object provides the total number of hosts (number of rows) that match a query criterion. By looking at this number, you can determine how many subqueries are necessary. However, you cannot get the `cnnEouHostQueryTotalHosts` object number until you have built your first query.

Build your query by performing the following steps.

SUMMARY STEPS

1. Set the `cnnEouHostQueryStatus` object to `createandgo`.
2. Set the `cnnEouHostQueryMask` object to 8.
3. Set `cnnEouHostQueryRows` to 500.
4. Set `cnnEouHostQuerySkipNHosts` to 0.
5. Set the `cnnEouHostQueryStatus` object to `active`.

DETAILED STEPS

	Command or Action	Purpose
Step 1	Set the <code>cnnEouHostQueryStatus</code> object to <code>createandgo</code> .	Sets the query status.
Step 2	Set the <code>cnnEouHostQueryMask</code> object to 8.	Correlates to the default of the show eou all command.
Step 3	Set <code>cnnEouHostQueryRows</code> to 500.	Identifies the maximum number of rows to be built in the result table for this query.
Step 4	Set <code>cnnEouHostQuerySkipNHosts</code> to 0.	Corresponds to the result rows to be created.
Step 5	Set the <code>cnnEouHostQueryStatus</code> object to <code>active</code> .	Indicates that you have finished building the query.

**Note**

Examples are not shown in the previous table because the format differs depending on the software you are using. The table is on the basis of a query having 2,000 sessions (rows).

- [What to Do Next, page 23](#)

What to Do Next

After the above task is performed, information for the first 500 hosts (rows) is queried. To view query information for the next 500 hosts (rows), perform the same five steps, with the exception of changing the `cnnEouHostQuerySkipNHosts` object value to 500 in Step 4. This task results in query information for rows 501 through 1000. In the same way, to obtain query information for the remaining hosts (through 2000), perform the same five steps again, with the exception of changing the `cnnEouHostQuerySkipNHosts` object values in Step 4 to 1000 and 1500, respectively.

Configuration Examples for Network Admission Control

- [Network Admission Control Example, page 24](#)

- [NAC MIB Output Examples, page 25](#)

Network Admission Control Example

The following output example shows that IP admission control has been configured on a Cisco IOS router:

```
Router# show running-config
Building configuration...

Current configuration: 1240 bytes
!
version 12.3
service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption
!
hostname Router
!
boot-start-marker
boot-end-marker
!
aaa new-model
!
!
aaa authentication eou default group radius
aaa session-id common
ip subnet-zero
ip cef
!
! The following line creates a network admission rule. A list is not specified; therefore,
! the rule intercepts all traffic on the applied interface.
ip admission name avrule eapoudp
!
eou logging
!
!
interface FastEthernet0/0
 ip address 10.13.11.106 255.255.255.0
 duplex auto
 speed auto
!
interface FastEthernet0/1
 ip address 10.0.0.1 255.255.255.0
 ip access-group 102 in
! The following line configures an IP admission control interface.
 ip admission avrule
 duplex auto
 speed auto
!
 ip http server
 no ip http secure-server

!
control-plane
!
!
!
line con 0
 exec-timeout 0 0
line aux 0
```

```

line vty 0 4
!
!
end

```

NAC MIB Output Examples

The following are examples of **show** command output displaying MIB object information.

- [show eou, page 25](#)
- [show ip device tracking all, page 25](#)

show eou

The **show eou** command provides output for information that can also be viewed in various CISCO-NAC-NAD-MIB tables. The information that follows the **show eou** command can also be found in the `cnnEouGlobalObjectsGroup` table and the information that follows the **show eou all** command can be found in the `cnnEouIfConfigTable`.

```

Router# show eou
Global EAPoUDP Configuration
-----
EAPoUDP Version      = 1
EAPoUDP Port         = 0x5566
Clientless Hosts     = Enabled
IP Station ID        = Disabled
Revalidation         = Enabled
Revalidation Period  = 36000 Seconds
ReTransmit Period    = 3 Seconds
StatusQuery Period   = 300 Seconds
Hold Period          = 30 Seconds
AAA Timeout          = 60 Seconds
Max Retries          = 3
EAP Rate Limit       = 20
EAPoUDP Logging      = Enabled
Clientless Host Username = clientless
Clientless Host Password = clientless
Router# show eou all
Interface Specific EAPoUDP Configurations
-----
Interface Vlan333
AAA Timeout          = 60 Seconds
Max Retries          = 3
eou initialize interface {interface-name}
eou revalidate interface {interface-name}

```

show ip device tracking all

The **show ip device tracking all** command provides output for information that can also be found in the `cnnIpDeviceTrackingObjectsGroup` MIB table. The following is an example of such **show** command output:

```

Router# show ip device tracking all
IP Device Tracking = Enabled
Probe Count: 2
Probe Interval: 10

```

Technical Assistance

Description	Link
The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for Network Admission Control

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 4 Feature Information for Network Admission Control

Feature Name	Releases	Feature Information
Network Admission Control	12.3(8)T	<p>The Network Admission Control feature addresses the increased threat and impact of worms and viruses to networked businesses. This feature is part of the Cisco Self-Defending Network Initiative that helps customers identify, prevent, and adapt to security threats.</p> <p>In its initial phase, the Cisco Network Admission Control functionality enables Cisco routers to enforce access privileges when an endpoint attempts to connect to a network.</p> <p>The following commands were introduced or modified by this feature: aaa authentication eou default enable group radius, access-group (identity policy), auth-type, clear eou, clear ip admission cache, debug eap, debug eou, debug ip admission eapoudp, description (identity policy), description (identity profile), device (identity profile), eou allow, eou clientless, eou default, eou initialize, eou logging, eou max-retry, eou port, eou rate-limit, eou revalidate, eou timeout, identity policy, identity profile eapoudp, ip admission, ip admission name, redirect (identity policy), show eou, show ip admission, template (identity policy).</p>
NAC MIB	12.4(15)T	<p>Support was added for the CISCO-NAC-NAD-MIB. This MIB module is used to monitor and configure the NAD on the Cisco NAC system.</p> <p>The following commands were introduced or modified by this feature: show ip device tracking.</p>

Feature Name	Releases	Feature Information
	12.2(33)SXI	This feature was integrated into Cisco IOS Release 12.2(33)SXI.

Glossary

default access policy-- Set of ACLs that are applied to a client device until its credentials are validated by the AAA server.

EAPoUDP-- Extensible Authentication Protocol over User Datagram Protocol. EAP is a framework that supports multiple, optional authentication mechanisms for PPP, including clear-text passwords, challenge-response, and arbitrary dialogue sequences. UDP is a connectionless transport layer protocol in the TCP/IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, and it requires that error processing and retransmission be handled by other protocols. UDP is defined in RFC 768.

ip admission rule --Named rule that defines how IP admission control is applied. The IP admission rule is associated with an Intercept ACL and provides control over which hosts can use the IP admission feature. To create an IP admission control rule, use the ip admission name command.

posture token --Status that is used to convey the result of the evaluation of posture credentials. The AAA server maps the posture token (its status can be Healthy, Checkup, Quarantine, Infected, or Unknown) to a network access policy (ACL, URL, redirect, or status query timer) for the peer that the client wants to reach.
