CHAPTER 1

Configuring RADIUS

The RADIUS security system is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco devices and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

- Finding Feature Information, on page 1
- Prerequisites for RADIUS, on page 1
- Restrictions for RadSec (RADIUS Security), on page 2
- Information About RADIUS, on page 2
- How to Configure RADIUS, on page 11
- Configuration Examples for RADIUS, on page 17
- Additional References, on page 22
- Feature Information for Configuring RADIUS, on page 23

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for RADIUS

To configure RADIUS on your Cisco device or access server, you must perform these tasks:

- Use the `aaa new-model` global configuration command to enable Authentication, Authorization, and Accounting (AAA). AAA must be configured if you plan to use RADIUS.

- Use the `aaa authentication` global configuration command to define method lists for RADIUS authentication.

- Use `line` and `interface` commands to enable the defined method lists to be used.
Restrictions for RadSec (RADIUS Security)

RadSec is not supported on any of the Cisco enterprise routing platforms.

Information About RADIUS

RADIUS Network Environments

Cisco supports RADIUS under its authentication, authorization, and accounting (AAA) security paradigm. RADIUS can be used with other AAA security protocols such as TACACS+, Kerberos, and local username lookup. RADIUS is supported on all Cisco platforms, but some RADIUS-supported features run only on specified platforms.

RADIUS has been implemented in a variety of network environments that require high levels of security while maintaining network access for remote users.

Use RADIUS in the following network environments that require access security:

- Networks with multiple-vendor access servers, each supporting RADIUS. For example, access servers from several vendors use a single RADIUS server-based security database. In an IP-based network with multiple vendors’ access servers, dial-in users are authenticated through a RADIUS server that has been customized to work with the Kerberos security system.

- Turnkey network security environments in which applications support the RADIUS protocol, such as in an access environment that uses a smart card access control system. In one case, RADIUS has been used with Enigma’s security cards to validate users and grant access to network resources.

- Networks already using RADIUS. You can add a Cisco device with RADIUS to the network. This might be the first step when you make a transition to a TACACS+ server.

- Networks in which a user must only access a single service. Using RADIUS, you can control user access to a single host, to a single utility such as Telnet, or to a single protocol such as PPP. For example, when a user logs in, RADIUS identifies this user as having authorization to run PPP using the IP address 10.2.3.4 and the defined access list is started.

- Networks that require resource accounting. You can use RADIUS accounting independent of RADIUS authentication or authorization. The RADIUS accounting functions allow data to be sent at the start and end of services, indicating the amount of resources (such as time, packets, and bytes) used during the session. An ISP might use a freeware-based version of RADIUS access control and accounting software to meet special security and billing needs.

- Networks that support preauthentication. Using the RADIUS server in your network, you can configure AAA preauthentication and set up the preauthentication profiles. Preauthentication enables service providers to better manage ports using their existing RADIUS solutions, and to efficiently manage the use of shared resources to offer differing service-level agreements.

RADIUS is not suitable in these network security situations:

- Multiprotocol access environments. RADIUS does not support the following protocols:
  - AppleTalk Remote Access (ARA)
• NetBIOS Frame Control Protocol (NBFCP)
• NetWare Asynchronous Services Interface (NASI)
• X.25 Packet Assemblers/Disassemblers (PAD) connections

• Device-to-device situations. RADIUS does not provide two-way authentication. RADIUS can be used to authenticate from one device to a non-Cisco device if the non-Cisco device requires RADIUS authentication.

• Networks using a variety of services. RADIUS generally binds a user to one service model.

**RADIUS Operation**

When a user attempts to log in and authenticate to an access server using RADIUS, the following steps occur:

1. The user is prompted to enter the username and password.
2. The username and encrypted password are sent over the network to the RADIUS server.
3. The user receives one of the following responses from the RADIUS server:
   1. ACCEPT—The user is authenticated.
   2. CHALLENGE—A challenge is issued by the RADIUS server. The challenge collects additional data from the user.
   3. CHANGE PASSWORD—A request is issued by the RADIUS server, asking the user to select a new password.
   4. REJECT—The user is not authenticated and is prompted to reenter the username and password, or access is denied.

The ACCEPT or REJECT response is bundled with additional data that is used for EXEC or network authorization. You must first complete RADIUS authentication before using RADIUS authorization. The additional data included with the ACCEPT or REJECT packets consists of the following:

- Services that the user can access, including connections such as Telnet, rlogin, or local-area transport (LAT), and services such as PPP, Serial Line Protocol (SLIP), or EXEC services.
- Connection parameters, including the host or client IP address, access list, and user timeouts.

**RADIUS Attributes**

The network access server monitors the RADIUS authorization and accounting functions defined by RADIUS attributes in each user profile:

**Vendor-Proprietary RADIUS Attributes**

An Internet Engineering Task Force (IETF) standard for RADIUS specifies a method for communicating vendor-proprietary information between the network access server and the RADIUS server. Some vendors, nevertheless, have extended the RADIUS attribute set in a unique way. Cisco software supports a subset of vendor-proprietary RADIUS attributes.
RADIUS Tunnel Attributes

RADIUS is a security server AAA protocol originally developed by Livingston, Inc. RADIUS uses attribute value (AV) pairs to communicate information between the security server and the network access server.

RFC 2138 and RFC 2139 describe the basic functionality of RADIUS and the original set of IETF-standard AV pairs used to send AAA information. Two IETF standards, “RADIUS Attributes for Tunnel Protocol Support” and “RADIUS Accounting Modifications for Tunnel Protocol Support,” extend the IETF-defined set of AV pairs to include attributes specific to VPNs. These attributes are used to carry the tunnelling information between the RADIUS server and the tunnel initiator.

RFC 2865 and RFC 2868 extend the IETF-defined set of AV pairs to include attributes specific to compulsory tunnelling in VPNs by allowing the user to specify authentication names for the network access server and the RADIUS server.

Cisco devices and access servers support new RADIUS IETF-standard virtual private dialup network (VPDN) tunnel attributes.

Preauthentication on a RADIUS Server

RADIUS attributes are configured in the RADIUS preauthentication profiles to specify preauthentication behavior. In addition to configuring preauthentication on your Cisco device, you must set up the preauthentication profiles on the RADIUS server.

RADIUS Profile for DNIS or CLID Preauthentication

To configure the RADIUS preauthentication profile, use the Dialed Number Identification Service (DNIS) or Calling Line Identification (CLID) number as the username, and use the password defined in the `dnis` or `clid` command as the password.

Note

The preauthentication profile must have “outbound” as the service type because the password is predefined on the network access server (NAS). Setting up the preauthentication profile in this manner prevents users from trying to log in to the NAS with the username of the DNIS number, CLID number, or call type and an obvious password. The “outbound” service type is also included in the Access-Request packet sent to the RADIUS server.

RADIUS Profile for Call Type Preauthentication

To set up the RADIUS preauthentication profile, use the call type string as the username, and use the password defined in the `ctype` command as the password. The table below lists the call type strings that can be used in the preauthentication profile.

Table 1: Call Type Strings Used in Preauthentication

<table>
<thead>
<tr>
<th>Call Type String</th>
<th>ISDN Bearer Capabilities</th>
</tr>
</thead>
<tbody>
<tr>
<td>digital</td>
<td>Unrestricted digital, restricted digital.</td>
</tr>
</tbody>
</table>
**Call Type String** | **ISDN Bearer Capabilities**
---|---
speech | Speech, 3.1 kHz audio, 7 kHz audio.  
**Note** | This is the only call type available for channel-associated signaling (CAS).  
v.110 | Anything with the V.110 user information layer.  
v.120 | Anything with the V.120 user information layer.

---

**Note**  
The preauthentication profile must have “outbound” as the service type because the password is predefined on the NAS. Setting up the preauthentication profile in this manner prevents users from trying to log in to the NAS with the username of the DNIS number, CLID number, or call type and an obvious password. The “outbound” service type is also included in the Access-Request packet sent to the RADIUS server and should be a checkin item if the RADIUS server supports checkin items.

**RADIUS Profile for Preauthentication Enhancements for Callback**

Callback allows remote network users such as telecommuters to dial in to the NAS without being charged. When callback is required, the NAS hangs up the current call and dials the caller back. When the NAS performs the callback, only information for the outgoing connection is applied. The rest of the attributes from the preauthentication access-accept message are discarded.

**Note**  
The destination IP address is not required to be returned from the RADIUS server.

The following example shows a RADIUS profile configuration with a callback number of 555-0101 and the service type set to outbound. The cisco-avpair = “preauth:send-name=<string>” uses the string “user1” and the cisco-avpair = “preauth:send-secret=<string>” uses the password “cisco.”

```
5550101 password = "cisco", Service-Type = Outbound
Service-Type = Callback-Framed
Framed-Protocol = PPP,
Dialback-No = "5550119"
Class = "ISP12"
cisco-avpair = "preauth:send-name=user1"
cisco-avpair = "preauth:send-secret=cisco"
```

**RADIUS Profile for a Remote Hostname Used for Large-Scale Dial-Out**

The following example protects against accidentally calling a valid telephone number but accessing the wrong device by providing the name of the remote device, for use in large-scale dial-out:

```
5550101 password = "PASSWORD1", Service-Type = Outbound
Service-Type = Callback-Framed
Framed-Protocol = PPP,
Dialback-No = "5550190"
Class = "ISP12"
cisco-avpair = "preauth:send-name=user1"
```
**RADIUS Profile for Modem Management**

When DNIS, CLID, or call type preauthentication is used, the affirmative response from the RADIUS server might include a modem string for modem management in the NAS through vendor-specific attribute (VSA) 26. The modem management VSA has this syntax:

```cisco-avpair = "preauth:modem-service-modem min-speed < x > max-speed < y > modulation < z > error-correction < a > compression < b >"```

The table below lists the modem management string elements within the VSA.

**Table 2: Modem Management String**

<table>
<thead>
<tr>
<th>Command</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>min-speed</td>
<td>300 to 56000, any</td>
</tr>
<tr>
<td>max-speed</td>
<td>300 to 56000, any</td>
</tr>
<tr>
<td>modulation</td>
<td>K56Flex, v22bis, v32bis, v34, v90, any</td>
</tr>
<tr>
<td>error-correction</td>
<td>lapm, mnp4</td>
</tr>
<tr>
<td>compression</td>
<td>mnp5, v42bis</td>
</tr>
</tbody>
</table>

When the modem management string is received from the RADIUS server in the form of a VSA, the information is passed to the Cisco software and applied on a per-call basis. Modem ISDN channel aggregation (MICA) modems provide a control channel through which messages can be sent during the call setup time. Hence, this modem management feature is supported only with MICA modems. This feature is not supported with Microcom modems.

**RADIUS Profile for Subsequent Authentication**

If preauthentication passes, you can use vendor-proprietary RADIUS attribute 201 (Require-Auth) in the preauthentication profile to determine whether subsequent authentication is performed. If attribute 201, returned in the access-accept message, has a value of 0, subsequent authentication is not performed. If attribute 201 has a value of 1, subsequent authentication is performed as usual.

Attribute 201 has this syntax:

```cisco-avpair = "preauth:auth-required=< n >"```
where \(<n>\) has the same value range as attribute 201 (that is, 0 or 1).

If attribute 201 is missing in the preauthentication profile, a value of 1 is assumed, and subsequent authentication is performed.

---

**Note**

Before you can perform subsequent authentication, you must set up a regular user profile in addition to a preauthentication profile.

---

**RADIUS Profile for Subsequent Authentication Types**

If you specified subsequent authentication in the preauthentication profile, you must also specify the authentication types to be used for subsequent authentication. To specify the authentication types allowed in subsequent authentication, use this VSA:

```
cisco-avpair = "preauth:auth-type=<string>
```

The table below lists the allowed values for the `<string>` element.

**Table 3: `<string>` Element Values**

<table>
<thead>
<tr>
<th>String</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chap</td>
<td>Requires the username and password for the Challenge-Handshake Authentication Protocol (CHAP) for PPP authentication.</td>
</tr>
<tr>
<td>ms-chap</td>
<td>Requires the username and password for the MS-CHAP for PPP authentication.</td>
</tr>
<tr>
<td>pap</td>
<td>Requires the username and password for the Password Authentication Protocol (PAP) for PPP authentication.</td>
</tr>
</tbody>
</table>

To specify that multiple authentication types are allowed, you can configure more than one instance of this VSA in the preauthentication profile. The sequence of the authentication type VSAs in the preauthentication profile is significant because it specifies the order of authentication types to be used in the PPP negotiation.

This VSA is a per-user attribute and replaces the authentication type list in the `ppp authentication` interface configuration command.

---

**Note**

You should use this VSA only if subsequent authentication is required because it specifies the authentication type for subsequent authentication.

---

**RADIUS Profile to Include the Username**

If only preauthentication is used to authenticate a call, the NAS could be missing a username when it brings up the call. RADIUS can provide a username for the NAS to use through RADIUS attribute 1 (User-Name) or through a VSA returned in the Access-Accept packet. The VSA for specifying the username has this syntax:

```
cisco-avpair = "preauth:username=<
```
If no username is specified, the DNIS number, CLID number, or call type is used, depending on the last preauthentication command configured (for example, if clid was the last preauthentication command configured, the CLID number is used as the username).

If subsequent authentication is used to authenticate a call, there might be two usernames: one provided by RADIUS and one provided by the user. In this case, the username provided by the user overrides the one contained in the RADIUS preauthentication profile. The username provided by the user is used for both authentication and accounting.

**RADIUS Profile for Two-Way Authentication**

In the case of two-way authentication, the calling networking device must authenticate the NAS. The PAP username and password or CHAP username and password need not be configured locally on the NAS. Instead, the username and password can be included in the Access-Accept messages for preauthentication.

**Note**

Do not configure the `ppp authentication` command with the `radius` command.

To set up PAP, do not configure the `ppp pap sent-name password` command on the interface. The VSAs “preauth:send-name” and “preauth:send-secret” are used as the PAP username and PAP password for outbound authentication.

For CHAP, “preauth:send-name” is used not only for outbound authentication but also for inbound authentication. For a CHAP inbound case, the NAS uses the name defined in “preauth:send-name” in the challenge packet to the caller networking device. For a CHAP outbound case, both “preauth:send-name” and “preauth:send-secret” are used in the response packet.

The following example shows a configuration that specifies two-way authentication:

```
5550101 password = "PASSWORD2", Service-Type = Outbound
Service-Type = Framed-User
cisco-avpair = "preauth:auth-required=1"
cisco-avpair = "preauth:auth-type=pap"
cisco-avpair = "preauth:send-name=user1"
cisco-avpair = "preauth:send-secret=PASSWORD2"
class = "<some class>"
```

**Note**

Two-way authentication does not work when resource pooling is enabled.

**RADIUS Profile to Support Authorization**

If only preauthentication is configured, subsequent authentication is bypassed. Note that because the username and password are not available, authorization is also bypassed. However, you can include authorization attributes in the preauthentication profile to apply per-user attributes and avoid having to return subsequently to RADIUS for authorization. To initiate the authorization process, you must also configure the `aaa authorization network` command on the NAS.
You can configure authorization attributes in the preauthentication profile with one exception: the service-type attribute (attribute 6). The service-type attribute must be converted to a VSA in the preauthentication profile. This VSA has this syntax:

```
cisco-avpair = "preauth:service-type=<n>"
```

where \(<n>\) is one of the standard RFC 2865 values for attribute 6.

---

**Note**

If subsequent authentication is required, the authorization attributes in the preauthentication profile are not applied.

---

**RADIUS Authentication**

After you have identified the RADIUS server and defined the RADIUS authentication key, you must define method lists for RADIUS authentication. Because RADIUS authentication is facilitated through AAA, you must enter the `aaa authentication` command, specifying RADIUS as the authentication method.

**RADIUS Authorization**

AAA authorization lets you set parameters that restrict a user’s access to the network. Authorization using RADIUS provides one method for remote access control, including one-time authorization or authorization for each service, per-user account list and profile, user group support, and support of IP, IPX, AppleTalk Remote Access (ARA), and Telnet. Because RADIUS authorization is facilitated through AAA, you must enter the `aaa authorization` command, specifying RADIUS as the authorization method.

**RADIUS Accounting**

The AAA accounting feature enables you to track the services users are accessing and the amount of network resources they are consuming. Because RADIUS accounting is facilitated through AAA, you must enter the `aaa accounting` command, specifying RADIUS as the accounting method.

**RADIUS Login-IP-Host**

To enable the network access server (NAS) to attempt more than one login host when trying to connect a dial-in user, you can enter as many as three Login-IP-Host entries in the user’s profile on the RADIUS server. The following example shows that three Login-IP-Host instances are configured for the user `user1`, and that TCP-Clear is used for the connection:

```
user1 Password = xyz
  Service-Type = Login,
  Login-Service = TCP-Clear,
  Login-IP-Host = 10.0.0.0,
  Login-IP-Host = 10.2.2.2,
  Login-IP-Host = 10.255.255.255,
  Login-TCP-Port = 23
```
The order in which the hosts are entered is the order in which they are attempted. Use the `ip tcp synwait-time` command to set the number of seconds that the NAS waits before trying to connect to the next host on the list; the default is 30 seconds.

Your RADIUS server might permit more than three Login-IP-Host entries; however, the NAS supports only three hosts in Access-Accept packets.

### RADIUS Prompt

To control whether user responses to Access-Challenge packets are echoed to the screen, you can configure the Prompt attribute in the user profile on the RADIUS server. This attribute is included only in Access-Challenge packets. The following example shows the Prompt attribute set to No-Echo, which prevents the user’s responses from echoing:

```
user1 Password = xyz
Service-Type = Login,
Login-Service = Telnet,
Prompt = No-Echo,
Login-IP-Host = 172.31.255.255
```

To allow user responses to echo, set the attribute to Echo. If the Prompt attribute is not included in the user profile, responses are echoed by default.

This attribute overrides the behavior of the `radius-server challenge-noecho` command configured on the access server. For example, if the access server is configured to suppress echoing, but the individual user profile allows echoing, the user responses are echoed.

---

**Note**
If you want to use the Prompt attribute, your RADIUS server must be configured to support Access-Challenge packets.

### Vendor-Specific RADIUS Attributes

The IETF standard specifies a method for communicating vendor-specific information between the network access server and the RADIUS server by using the vendor-specific attribute (attribute 26). Vendor-specific attributes (VSAs) allow vendors to support their own extended attributes not suitable for general use. The Cisco RADIUS implementation supports one vendor-specific option using the format recommended in the specification. Cisco’s vendor ID is 9, and the supported option has vendor type 1, which is named “cisco-avpair.” The value is a string with this format:

```
protocol : attribute sep value *
```

“Protocol” is a value of the Cisco “protocol” attribute for a particular type of authorization; protocols that can be used include IP, Internetwork Packet Exchange (IPX), VPDN, VoIP, Secure Shell (SSH), Resource Reservation Protocol (RSVP), Serial Interface Processor (SIP), AirNet, and Outbound. “Attribute” and “value” are an appropriate AV pair defined in the Cisco TACACS+ specification, and “sep” is “=” for mandatory attributes and “=*” for optional attributes, allowing the full set of features available for TACACS+ authorization to also be used for RADIUS.

For example, the following AV pair causes Cisco’s “multiple named ip address pools” feature to be activated during IP authorization (during PPP’s Internet Protocol Control Protocol (IPCP) address assignment):
cisco-avpair= "ip:addr-pool=first"

If you insert an "*", the AV pair “ip:addr-pool=first” becomes optional. Note that any AV pair can be made optional:

cisco-avpair= "ip:addr-pool*first"

The following example shows how to cause a user logging in from a network access server to have immediate access to EXEC commands:

cisco-avpair= "shell:priv-lvl=15"

Other vendors have their own unique vendor IDs, options, and associated VSAs.

Static Routes and IP Addresses on the RADIUS Server

Some vendor-proprietary implementations of RADIUS let the user define static routes and IP pool definitions on the RADIUS server instead of on each individual network access server in the network. Each network access server then queries the RADIUS server for static route and IP pool information.

To have the Cisco device or access server query the RADIUS server for static routes and IP pool definitions when the device starts up, use the radius-server configure-nas command.

Because the radius-server configure-nas command is performed when the Cisco device starts up, it does not take effect until you enter a copy system:running-config nvram:startup-config command.

How to Configure RADIUS

Configuring a Device for Vendor-Proprietary RADIUS Server Communication

Although an IETF standard for RADIUS specifies a method for communicating vendor-proprietary information between the network access server and the RADIUS server, some vendors have extended the RADIUS attribute set in a unique way. Cisco software supports a subset of vendor-proprietary RADIUS attributes.

To configure RADIUS (whether vendor-proprietary or IETF compliant), you must use the radius-server commands to specify the host running the RADIUS server daemon and the secret text string it shares with the Cisco device. To identify that the RADIUS server is using a vendor-proprietary implementation of RADIUS, use the radius-server host non-standard command. Vendor-proprietary attributes are not supported unless you use the radius-server host non-standard command.

The radius-server host command is deprecated from Cisco IOS Release 15.4(2)S. To configure an IPv4 or IPv6 RADIUS server, use the radius server name command. For more information about the radius server command, see Cisco IOS Security Command Reference: Commands M to R.

SUMMARY STEPS

1. enable
2. configure terminal

Configuring a Device to Expand Network Access Server Port Information

Sometimes PPP or login authentication occurs on an interface that is different from the interface on which the call itself comes in. For example, in a V.120 ISDN call, login or PPP authentication occurs on a virtual asynchronous interface “ttt”, but the call itself occurs on one of the channels of the ISDN interface.

The `radius-server attribute nas-port extended` command configures RADIUS to expand the size of the NAS-Port attribute (RADIUS IETF attribute 5) field to 32 bits. The upper 16 bits of the NAS-Port attribute display the type and number of the controlling interface; the lower 16 bits indicate the interface undergoing authentication.

The `radius-server attribute nas-port format` command replaces the `radius-server extended-portnames` command and the `radius-server attribute nas-port extended` command.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. radius-server configure-nas
4. radius-server attribute nas-port format
5. exit

**DETAILED STEPS**

### Replacing the NAS-Port Attribute with the RADIUS Attribute

On platforms with multiple interfaces (ports) per slot, the Cisco RADIUS implementation does not provide a unique NAS-Port attribute that permits distinguishing between the interfaces. For example, if a dual PRI is in slot 1, calls on both Serial1/0:1 and Serial1/1:1 appear as NAS-Port = 20101 because of the 16-bit field size limitation associated with the RADIUS IETF NAS-Port attribute. In this case, you can replace the NAS-Port attribute with a VSA (RADIUS IETF attribute 26). Cisco’s vendor ID is 9, and the Cisco-NAS-Port attribute is subtype 2. VSAs can be turned on by entering the `radius-server vsa send` command. The port information in this attribute is provided and configured using the `aaa nas port extended` command.

The standard NAS-Port attribute (RADIUS IETF attribute 5) is sent. If you do not want this information to be sent, you can suppress it by using the `no radius-server attribute nas-port` command. After this command is configured, the standard NAS-Port attribute is no longer sent.

### SUMMARY STEPS

1. enable
2. configure terminal
3. radius-server vsa send [accounting | authentication]
4. aaa nas port extended
5. exit

### DETAILED STEPS

#### Configuring the Suffix and Password in RADIUS Access Requests

Large-scale dial-out eliminates the need to configure dialer maps on every NAS for every destination. Instead, you can create remote site profiles that contain outgoing call attributes on the AAA server. The profile is downloaded by the NAS when packet traffic requires a call to be placed to a remote site.

You can configure the username in the Access-Request message to RADIUS. The default suffix of the username, “-out,” is appended to the username. The format for composing the username attribute is the IP address plus the configured suffix.

#### SUMMARY STEPS

1. enable
2. configure terminal
3. aaa new-model
4. aaa route download  time
5. aaa authorization configuration default
6. interface dialer  number
7. dialer aaa
8. dialer aaa suffix  suffix  password  password
9. exit

Configuration Examples for RADIUS

Example: RADIUS Authentication and Authorization

The following example shows how to configure the device to authenticate and authorize using RADIUS:

```
aaa authentication login use-radius group radius local
```
The lines in this sample RADIUS authentication and authorization configuration are defined as follows:

- The `aaa authentication login use-radius group radius local` command configures the device to use RADIUS for authentication at the login prompt. If RADIUS returns an error, the user is authenticated using the local database. In this example, `use-radius` is the name of the method list, which specifies RADIUS and then local authentication.

- The `aaa authentication ppp user-radius if-needed group radius` command configures the Cisco software to use RADIUS authentication for lines using PPP with CHAP or PAP if the user has not already been authorized. If the EXEC facility has authenticated the user, RADIUS authentication is not performed. In this example, `user-radius` is the name of the method list defining RADIUS as the if-needed authentication method.

- The `aaa authorization exec default group radius` command sets the RADIUS information that is used for EXEC authorization, autocommands, and access lists.

- The `aaa authorization network default group radius` command sets RADIUS for network authorization, address assignment, and access lists.

**Example: RADIUS Authentication, Authorization, and Accounting**

The following example shows a general configuration using RADIUS with the AAA command set:

```
radius-server host 10.45.1.2
radius-server key myRaDiUSpassWoRd
username root password ALongPassword
aaa authentication ppp dialins group radius local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius
aaa authentication login admins local
aaa authorization exec default local
line 1 16
    autoselect ppp
    autoselect during-login
    login authentication admins
    modem ri-is-cd
    interface group-async 1
    encaps ppp
    ppp authentication pap dialins
```

The lines in this example RADIUS authentication, authorization, and accounting configuration are defined as follows:

- The `radius-server host` command defines the IP address of the RADIUS server host.

- The `radius-server key` command defines the shared secret text string between the network access server and the RADIUS server host.

- The `aaa authentication ppp dialins group radius local` command defines the authentication method list “dialins,” which specifies that RADIUS authentication and then (if the RADIUS server does not respond) local authentication is used on serial lines using PPP.

- The `aaa authorization network default group radius local` command is used to assign an address and other network parameters to the RADIUS user.
• The `aaa accounting network default start-stop group radius` command tracks PPP usage.

• The `aaa authentication login admins local` command defines another method list, “admins,” for login authentication.

• The `login authentication admins` command applies the “admins” method list for login authentication.

• The `ppp authentication pap dialins` command applies the “dialins” method list to the lines specified.

**Example: Vendor-Proprietary RADIUS Configuration**

The following example shows a general configuration using vendor-proprietary RADIUS with the AAA command set:

```plaintext
radius server myserver
radius server address ipv4 192.0.2.2
non-standard
key 7 any key
radius-server configure-nas
username root password ALongPassword
aaa authentication ppp dialins group radius local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius
aaa authentication login admins local
aaa authorization exec default local
```

The lines in this RADIUS authentication, authorization, and accounting configuration example are defined as follows:

• The `non-standard` command defines the name of the RADIUS server host and identifies that this RADIUS host uses a vendor-proprietary version of RADIUS.

• The `key` command defines the shared secret text string between the network access server and the RADIUS server host.

• The `configure-nas` command defines that the Cisco device or access server queries the RADIUS server for static routes and IP pool definitions when the device first starts up.

• The `aaa authentication ppp dialins group radius local` command defines the authentication method list “dialins,” which specifies that RADIUS authentication and then (if the RADIUS server does not respond) local authentication is used on serial lines using PPP.

• The `aaa authorization network default group radius local` command assigns an address and other network parameters to the RADIUS user.

• The `aaa accounting network default start-stop group radius` command tracks PPP usage.

• The `aaa authentication login admins local` command defines another method list, “admins,” for login authentication.
Example: Multiple RADIUS Server Entries for the Same Server IP Address

The following example shows how to configure the network access server to recognize several RADIUS host entries with the same IP address. Two different host entries on the same RADIUS server are configured for the same services—authentication and accounting. The second host entry configured acts as failover backup to the first one. (The RADIUS host entries are tried in the order they are configured.)

```
! This command enables AAA.
aaa new-model
! The next command configures default RADIUS parameters.
aaa authentication ppp default group radius
! The next set of commands configures multiple host entries for the same IP address.
radius-server host 172.20.0.1 auth-port 1000 acct-port 1001
radius-server host 172.20.0.1 auth-port 2000 acct-port 2001
```

Example: RADIUS User Profile with RADIUS Tunneling Attributes

The following example shows a RADIUS user profile (Merit Daemon format) that includes RADIUS tunneling attributes:

```
cisco-avpair = vpdn:l2tp-cm-local-window-size=1024
cisco-avpair = vpdn:l2tp-nosession-timeout=30
cisco-avpair = vpdn:l2tp-cm-retransmit-retries=10
cisco-avpair = vpdn:l2tp-cm-min-timeout=2
cisco-avpair = vpdn:l2tp-hello-interval=60
Service-Type = outbound
Tunnel-Assignment-Id_tag1 = ISP1
Tunnel-Client-Auth-Id_tag1 = LAC1
Tunnel-Client-Endpoint_tag1 = 10.0.0.2
Tunnel-Medium-Type_tag1 = IPv4
Tunnel-Password_tag1 = tunnel1
Tunnel-Server-Auth-Id_tag1 = LNS1
Tunnel-Server-Endpoint_tag1 = 10.0.0.1
Tunnel-Type_tag1 = l2tp
```

Examples: L2TP Access Concentrator Configuration

The following example shows a basic L2TP configuration for the L2TP access concentrator (LAC) for the topology shown in the figure below. The local name is not defined, so the hostname used is the local name. Because the L2TP tunnel password is not defined, the username password is used. In this example, VPDN is configured locally on the LAC and does not take advantage of the new RADIUS tunnel attributes.

```
! Enable AAA globally.
aaa new-model
! Enable AAA authentication for PPP and list the default method to use for PPP
! authentication.
```
aaa authentication ppp default local
! Define the username as "DJ."
username DJ password 7 030C5E070A00781B
! Enable VPDN.
vpdn enable
! Define VPDN group number 1.
vpdn-group 1
! Allow the LAC to respond to dialin requests using L2TP from IP address 172.21.9.13
! domain “cisco.com.”
request dialin
  protocol l2tp
  domain cisco.com
initiate-ip to 172.21.9.13
local name nas=1

The following example shows the configuration for the LAC if RADIUS tunnel attributes are supported. In this example, there is no local VPDN configuration on the LAC; the LAC, instead, is configured to query the remote RADIUS security server.

! Enable global AAA securities services.
aaa new-model
! Enable AAA authentication for PPP and list RADIUS as the default method to use
! for PPP authentication.
aaa authentication ppp default group radius local
! Enable AAA (network) authorization and list RADIUS as the default method to use for
! authorization.
aaa authorization network default group radius
! Define the username as “DJ.”
username DJ password 7 030C5E070A00781B
! Enable VPDN.
vpdn enable
! Configure the LAC to interface with the remote RADIUS security server.
radius host 171.19.1.1 auth-port 1645 acct-port 1646
radius-server key cisco

Examples: L2TP Network Server Configuration

The following example shows a basic L2TP configuration with corresponding comments on the L2TP network server (LNS):

! Enable AAA globally.
aaa new-model
! Enable AAA authentication for PPP and list the default method to use for PPP
! authentication.
aaa authentication ppp default local
! Define the username as “partner.”
username partner password 7 030C5E070A00781B
! Create virtual-template 1 and assign all values for virtual access interfaces.
interface Virtual-Template1
! Borrow the IP address from loopback interface.
ip unnumbered loopback0
! Disable multicast fast switching.
no ip mroute-cache
! Use CHAP to authenticate PPP.
ppp authentication chap
! Enable VPDN.
vpdn enable
! Create vpdn-group number 1.
vpdn-group 1
! Accept all dialin l2tp tunnels from virtual-template 1 from remote peer DJ.
accept dialin l2tp virtual-template 1 remote DJ
The following example shows how to configure the LNS with a basic L2TP configuration using RADIUS tunneling attributes:

```
protocol any
virtual-template 1
terminate-from hostname nas1
local name hgw1

aaa new-model
aaa authentication login default none
aaa authentication login console none
aaa authentication ppp default local group radius
aaa authorization network default group radius if-authenticated
username l2tp-svr-auth-id password 0 l2tp-tnl-pass
vpdn enable
vpdn search-order domain
vpdn-group 1
accept-dialin
protocol l2tp
virtual-template 1
terminate-from hostname l2tp-cli-auth-id
local name l2tp-svr-auth-id
interface GigabitEthernet1/0/0
ip address 10.0.0.3 255.255.255.0
no ip route-cache
no ip mroute-cache
interface Virtual-Template1
ip unnumbered loopback0
ppp authentication pap
radius-server host 10.1.1.1 auth-port 1645 acct-port 1646
radius-server key <deleted>
```

RADIUS for Multiple UDP Ports

RADIUS security servers are identified on the basis of their hostname or IP address, hostname and specific UDP port numbers, or IP address and specific UDP port numbers. The combination of the IP address and UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific authentication, authorization, and accounting (AAA) service. This unique identifier enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as a failover backup to the first one. If the first host entry fails to provide accounting services, the network access server tries the second host entry configured on the same device for accounting services.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for RADIUS for Multiple UDP Ports

To configure RADIUS on your Cisco device or access server, you must perform these tasks:

• Use the aaa new-model global configuration command to enable AAA. AAA must be configured if you plan to use RADIUS.
• Use the `aaa authentication` global configuration command to define method lists for RADIUS authentication.
• Use `line` and `interface` commands to enable the defined method lists to be used.

## Information About RADIUS for Multiple UDP Ports

### Device-to-RADIUS Server Communication

The RADIUS host is normally a multiuser system running RADIUS server software from Cisco (CiscoSecure ACS), Livingston, Merit, Microsoft, or another software provider. Configuring device to RADIUS server communication can have several components:

- Hostname or IP address
- Authentication destination port
- Accounting destination port
- Timeout period
- Retransmission value
- Key string

RADIUS security servers are identified on the basis of their hostname or IP address, hostname and specific UDP port numbers, or IP address and specific UDP port numbers. The combination of the IP address and UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. This unique identifier enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as a failover backup to the first one. If the first host entry fails to provide accounting services, the network access server tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order they are configured.)

A RADIUS server and a Cisco device use a shared secret text string to encrypt passwords and exchange responses. To configure RADIUS to use the AAA security commands, you must specify the host running the RADIUS server daemon and a secret text (key) string that it shares with the device.

The timeout, retransmission, and encryption key values are configurable globally for all RADIUS servers, on a per-server basis or in some combination of global and per-server settings. To apply these settings globally to all RADIUS servers communicating with the device, use the three unique global commands: `radius-server timeout`, `radius-server retransmit`, and `radius-server key`. To apply these values on a specific RADIUS server, use the `radius-server host` command.

**Note**

You can configure both global and per-server timeout, retransmission, and key value commands simultaneously on the same Cisco network access server. If both global and per-server functions are configured on a device, the per-server timer, retransmission, and key value commands override global timer, retransmission, and key value commands.
# How to Configure RADIUS for Multiple UDP Ports

## Configuring Device-to-RADIUS Server Communication

### SUMMARY STEPS

1. enable
2. configure terminal
3. radius server server-name
4. address ipv4 ip-address
5. key {0 string | 7 string | string}
6. retransmit retries
7. timeout seconds
8. radius-server deadtime minutes
9. exit

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>

**Configuration Examples for RADIUS for Multiple UDP Ports**

**Example: Device-to-RADIUS Server Communication**

The following example shows how to configure two RADIUS servers with specific timeout, retransmit, and key values. In this example, the `aaa new-model` command enables AAA services on the device, and specific AAA commands define the AAA services. The `retransmit` command changes the global retransmission value to 4 for all RADIUS servers. The `host` command configures specific timeout, retransmission, and key values for the RADIUS server hosts with IP addresses 172.16.1.1 and 172.29.39.46.

```
! Enable AAA services on the device and define those services.
aaa new-model
aaa authentication login default group radius
aaa authentication login console-login none
aaa authentication ppp default group radius
aaa authorization network default group radius
aaa accounting exec default start-stop group radius
aaa accounting network default start-stop group radius
enable password tryit1
!
Device(config)# radius server rad1
```
Example: RADIUS Server with Server-Specific Values

The following example shows how to configure server-specific timeout, retransmit, and key values for the RADIUS server with IP address 172.31.39.46:

```
radius-server host 172.31.39.46 timeout 6 retransmit 5 key rad123
```

AAA DNIS Map for Authorization

The AAA DNIS Map for Authorization feature allows you to assign a Dialed Number Identification Service (DNIS) number to a particular authentication, authorization, and accounting (AAA) server group so that the server group can process authentication, authorization, and accounting requests for users dialing in to the network using that particular DNIS. Any phone line (a regular home phone or a commercial T1/PRI line) can be associated with several phone numbers. The DNIS number identifies the number that was called to reach you.

• Finding Feature Information, on page 31
• Prerequisites for AAA DNIS Map for Authorization, on page 31
• Information About AAA DNIS Map for Authorization, on page 32
• How to Configure AAA DNIS Map for Authorization, on page 33
• Configuration Examples for AAA DNIS Map for Authorization, on page 38
• Additional References, on page 41
• Feature Information for AAA DNIS Map for Authorization, on page 41

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for AAA DNIS Map for Authorization

• Before configuring the device to select a particular AAA server group based on the DNIS of the server group, you must configure the list of RADIUS server hosts and AAA server groups.

• Before configuring AAA preauthentication, you must configure the **aaa new-model** command and make sure that the supporting preauthentication application is running on a RADIUS server in your network.
Information About AAA DNIS Map for Authorization

AAA Server Group Selection Based on DNIS

Cisco software allows you to assign a DNIS number to a particular AAA server group so that the server group can process authentication, authorization, and accounting requests for users dialing into the network using that particular DNIS. Any phone line (a regular home phone or a commercial T1/PRI line) can be associated with several phone numbers. The DNIS number identifies the number that was called to reach you.

For example, suppose you want to share the same phone number with several customers, but you want to know which customer is calling before you pick up the phone. You can customize how you answer the phone because DNIS allows you to know which customer is calling when you answer.

Cisco devices with either ISDN or internal modems can receive the DNIS number. This functionality allows users to assign different RADIUS server groups for different customers (that is, different RADIUS servers for different DNIS numbers). Additionally, using server groups, you can specify the same server group for AAA services or a separate server group for each AAA service.

Cisco software provides the flexibility to implement authentication and accounting services in several ways:

• Globally—AAA services are defined using global configuration access list commands and applied in general to all interfaces on a specific network access server.

• Per interface—AAA services are defined using interface configuration commands and applied specifically to the interface being configured on a specific network access server.

• DNIS mapping—You can use DNIS to specify an AAA server to supply AAA services.

Because each of these AAA configuration methods can be configured simultaneously, Cisco has established an order of precedence to determine which server or groups of servers provide AAA services. The order of precedence is as follows:

• Per DNIS—If you configure the network access server to use DNIS to identify or determine which server group provides AAA services, this method takes precedence over any additional AAA selection method.

• Per interface—If you configure the network access server per interface to use access lists to determine how a server provides AAA services, this method takes precedence over any global configuration AAA access lists.

• Globally—If you configure the network access server by using global AAA access lists to determine how the security server provides AAA services, this method has the least precedence.

AAA Preauthentication

Configuring AAA preauthentication with ISDN PRI or channel-associated signaling (CAS) allows service providers to better manage ports using their existing RADIUS solutions and efficiently manage the use of shared resources to offer differing service-level agreements. With ISDN PRI or CAS, information about an incoming call is available to the network access server (NAS) before the call is connected. The available call information includes the following:

• The DNIS number, also referred to as the called number
• The Calling Line Identification (CLID) number, also referred to as the calling number

• The call type, also referred to as the bearer capability

The AAA preauthentication feature allows a Cisco NAS to decide—on the basis of the DNIS number, the CLID number, or the call type—whether to connect an incoming call. (With ISDN PRI, it enables user authentication and authorization before a call is answered. With CAS, the call must be answered; however, the call can be dropped if preauthentication fails.)

When an incoming call arrives from the public network switch, but before it is connected, AAA preauthentication enables the NAS to send the DNIS number, CLID number, and call type to a RADIUS server for authorization. If the server authorizes the call, the NAS accepts the call. If the server does not authorize the call, the NAS sends a disconnect message to the public network switch to reject the call.

In the event that the RADIUS server application becomes unavailable or is slow to respond, a guard timer can be set in the NAS. When the timer expires, the NAS uses a configurable parameter to accept or reject the incoming call that has no authorization.

The AAA preauthentication feature supports the use of attribute 44 by the RADIUS server application and the use of RADIUS attributes that are configured in the RADIUS preauthentication profiles to specify preauthentication behavior. They can also be used, for instance, to specify whether subsequent authentication should occur and, if so, what authentication method should be used.

The following restrictions apply to AAA preauthentication with ISDN PRI and CAS:

• Attribute 44 is available for CAS calls only when preauthentication or resource pooling is enabled.

• Multichassis Multilink PPP (MMP) is not available with ISDN PRI.

• AAA preauthentication is available only on some hardware platforms.

• ISDN PRI is supported only on some hardware platforms.

Guard Timer for Call Handling

Because response times for preauthentication and authentication requests can vary, the guard timer allows you to control the handling of calls. The guard timer starts when the DNIS is sent to the RADIUS server. If the NAS does not receive a response from AAA before the guard timer expires, it accepts or rejects the calls on the basis of the configuration of the timer.

How to Configure AAA DNIS Map for Authorization

Configuring AAA DNIS Preauthentication

DNIS preauthentication enables preauthentication at call setup based on the number dialed. The DNIS number is sent directly to the security server when a call is received. If the call authenticated by AAA, it is accepted.

SUMMARY STEPS

1. enable
2. configure terminal
3. aaa preauthorization

### Configuring AAA Server Group Selection Based on DNIS

To configure the device to select a particular AAA server group based on the DNIS of the server group, configure DNIS mapping. To map a server group with a group name with a DNIS number, perform the following task.

### SUMMARY STEPS

1. enable
2. configure terminal
3. aaa dnis map enable
AAA DNIS Map for Authorization

4. `aaa dnis map dnis-number authentication ppp group server-group-name`
5. `aaa dnis map dnis-number authorization network group server-group-name`
6. `aaa dnis map dnis-number accounting network [none | start-stop | stop-only] group server-group-name`
7. `exit`

### DETAILED STEPS

### Configuring a Guard Timer

To set a guard timer to accept or reject a call in the event that the RADIUS server fails to respond to an authentication or preauthentication request, perform the following task.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `isdn guard-timer milliseconds [on-expiry {accept | reject}]`
5. `call guard-timer milliseconds [on-expiry {accept | reject}]`
6. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>

<tr>
<td></td>
<td><em>Device</em>&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td><em>Device</em># configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong> interface type number</td>
<td>Enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

Device(config)# interface serial 1/0/0:23

### Purpose

Sets an ISDN guard timer to accept or reject a call in the event that the RADIUS server fails to respond to a preauthentication request.

#### Step 4

**Command**

```plaintext
isdn guard-timer milliseconds [on-expiry {accept | reject}]
```

**Example:**

Device(config-if)# isdn guard-timer 8000 on-expiry reject

Sets a CAS guard timer to accept or reject a call in the event that the RADIUS server fails to respond to a preauthentication request.

#### Step 5

**Command**

```plaintext
call guard-timer milliseconds [on-expiry {accept | reject}]
```

**Example:**

Device(config-if)# call guard-timer 2000 on-expiry accept

Exits interface configuration mode and returns to privileged EXEC mode.

#### Step 6

**Command**

```plaintext
end
```

**Example:**

Device(config-if)# end

---

### Configuration Examples for AAA DNIS Map for Authorization

#### Example: AAA Server Group Selection Based on DNIS

The following example shows how to select RADIUS server groups based on DNIS to provide specific AAA services:

```plaintext
! This command enables AAA.
aaa new-model
! The following set of commands configures the RADIUS attributes for each server that will be associated with one of the defined server groups.
radius-server host 172.16.0.1 auth-port 1645 acct-port 1646 key cisco1
radius-server host 172.17.0.1 auth-port 1645 acct-port 1646 key cisco2
radius-server host 172.18.0.1 auth-port 1645 acct-port 1646 key cisco3
radius-server host 172.19.0.1 auth-port 1645 acct-port 1646 key cisco4
radius-server host 172.20.0.1 auth-port 1645 acct-port 1646 key cisco5
! The following commands define the sg1 RADIUS server group and associate servers with it.
aaa group server radius sg1
   server 172.16.0.1
   server 172.17.0.1
! The following commands define the sg2 RADIUS server group and associate a server with it.
aaa group server radius sg2
   server 172.18.0.1
! The following commands define the sg3 RADIUS server group and associate a server with it.
aaa group server radius sg3
```
Examples: AAA Preauthentication

The following is a simple configuration that specifies that the DNIS number be used for preauthentication:

aaa preauthentication
  group radius
  dnis required

The following example shows a configuration that specifies that both the DNIS number and the CLID number be used for preauthentication. DNIS preauthentication is performed first, followed by CLID preauthentication.

aaa preauthentication
  group radius
  dnis required
  clid required

The following example specifies that preauthentication be performed on all DNIS numbers except the two DNIS numbers specified in the DNIS group called “dnis-group1”:

aaa preauthentication
  group radius
  dnis required
  dnis bypass dnis-group1
dialer dnis group dnis-group1
  number 12345
  number 12346

The following is a sample AAA configuration with DNIS preauthentication:

aaa new-model
aaa authentication login CONSOLE none
aaa authentication login RADIUS_LIST group radius
aaa authentication login TAC_PLUS group tacacs+ enable
aaa authentication login V.120 none
aaa authentication enable default enable group tacacs+
aaa authentication ppp RADIUS_LIST if-needed group radius
aaa authorization exec RADIUS_LIST group radius if-authenticated
aaa authorization exec V.120 none
aaa authorization network default group radius if-authenticated
aaa authorization network RADIUS_LIST if-authenticated group radius
aaa authorization network V.120 group radius if-authenticated
aaa accounting suppress null-username
aaa accounting exec default start-stop group radius
aaa accounting commands 0 default start-stop group radius
aaa accounting network default start-stop group radius
aaa accounting connection default start-stop group radius
aaa accounting system default start-stop group radius
aaa preauthentication
dnis password Cisco-DNIS
aaa nas port extended
radius-server configure-nas
radius-server host 10.0.0.0 auth-port 1645 acct-port 1646 non-standard
radius-server host 10.255.255.255 auth-port 1645 acct-port 1646 non-standard
radius-server retransmit 2
radius-server deadtime 1
radius-server attribute nas-port format c
radius-server unique-ident 18
radius-server key MyKey

To configure preauthentication, you must also set up preauthentication profiles on the RADIUS server.

Examples: Guard Timer for ISDN and CAS

The following example shows an ISDN guard timer that is set at 8000 milliseconds. A call is rejected if the RADIUS server does not respond to a preauthentication request when the timer expires.

interface serial 1/0/0:23
isdn guard-timer 8000 on-expiry reject
aaa preauthentication
group radius
dnis required

The following example shows a CAS guard timer that is set at 20,000 milliseconds. A call is accepted if the RADIUS server does not respond to a preauthentication request when the timer expires.

controller T1 0
framing esf
clock source line primary
linenode b8zs
ds0-group 0 timeslots 1-24 type e&m-fgb dtmf dnis
cas-custom 0
call guard-timer 20000 on-expiry accept
aaa preauthentication
group radius
dnis required

AAA Server Groups

Configuring a device to use authentication, authorization, and accounting (AAA) server groups provides a way to group existing server hosts. Grouping existing server hosts allows you to select a subset of the configured server hosts and use them for a particular service. Configuring deadtime within a server group allows you to direct AAA traffic to separate groups of servers that have different operational characteristics. This feature module describes how to configure AAA server groups and the deadtimer.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About AAA Server Groups

AAA Server Groups

Configuring the device to use AAA server groups provides a way to group existing server hosts. Grouping existing server hosts allows you to select a subset of the configured server hosts and use them for a particular service. A server group is used with a global server-host list. The server group lists the IP addresses of the selected server hosts.

Server groups can also include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. This unique
identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry that is configured acts as a failover backup to the first one. If the first host entry fails to provide accounting services, the network access server tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order in which they are configured.)

AAA Server Groups with a Deadtimer

After you configure a server host with a server name, you can use the `deadtime` command to configure each server per server group. Configuring deadtime within a server group allows you to direct AAA traffic to separate groups of servers that have different operational characteristics.

Configuring deadtime is not limited to a global configuration. A separate timer is attached to each server host in every server group. Therefore, when a server is found to be unresponsive after numerous retransmissions and timeouts, the server is assumed to be dead. The timers attached to each server host in all server groups are triggered. In essence, the timers are checked and subsequent requests to a server (once it is assumed to be dead) are directed to alternate timers, if configured. When the network access server receives a reply from the server, it checks and stops all configured timers (if running) for that server in all server groups.

If the timer has expired, the server to which the timer is attached is assumed to be alive. This becomes the only server that can be tried for later AAA requests using the server groups to which the timer belongs.

---

**Note**

Because one server has different timers and might have different deadtime values configured in the server groups, the same server might, in the future, have different states (dead and alive) at the same time.

**Note**

To change the state of a server, you must start and stop all configured timers in all server groups.

The size of the server group will be slightly increased because of the addition of new timers and the deadtime attribute. The overall impact of the structure depends on the number and size of the server groups and how the servers are shared among server groups in a specific configuration.

How to Configure AAA Server Groups

Configuring AAA Server Groups

To define a server host with a server group name, enter the following commands in global configuration mode. The listed server must exist in global configuration mode.

**Before you begin**

Each server in the group must be defined previously using the `radius-server host` command.
SUMMARY STEPS

1. enable
2. configure terminal
3. radius server server-name
4. aaa group server {radius | tacacs+} group-name
5. server ip-address [auth-port port-number] [acct-port port-number]
6. end

DETAILED STEPS

<table>

</tbody>
</table>

| **Step 2**        | Enters global configuration mode. |
| configure terminal| Example: |
| Example:          | |
| Device# configure terminal | |

| **Step 3**        | Defines a RADIUS type server group and enters server group RADIUS configuration mode. |
| aaa group server radius group | Example: |
| Device(config)# aaa group server radius group1 | |

| **Step 4**        | Configures and defines a deadtime value in minutes. |
| deadtime minutes  | Note | Local server group deadtime overrides the global configuration. If the deadtime value is omitted from the local server group configuration, it is inherited from the master list. |
| Example:          | |
| Device(config-sg-radius)# deadtime 1 | |

| **Step 5**        | Exits server group RADIUS configuration mode and returns to privileged EXEC mode. |
| end               | Example: |
| Example:          | |
| Device(config-sg-radius)# end | |

Configuration Examples for AAA Server Groups

Examples: AAA Server Groups

The following example shows how to create server group radgroup1 with three different RADIUS server members, each using the default authentication port (1645) and accounting port (1646):
aaa group server radius radgroup1
  server 172.16.1.11
  server 172.17.1.21
  server 172.18.1.31

The following example shows how to create server group radgroup2 with three RADIUS server members, each with the same IP address but with unique authentication and accounting ports:

aaa group server radius radgroup2
  server 172.16.1.1 auth-port 1000 acct-port 1001
  server 172.16.1.1 auth-port 2000 acct-port 2001
  server 172.16.1.1 auth-port 3000 acct-port 3001

Example: Multiple RADIUS Server Entries Using AAA Server Groups

The following example shows how to configure the network access server to recognize two different RADIUS server groups. One of these groups, group1, has two different host entries on the same RADIUS server configured for the same services. The second host entry configured acts as failover backup to the first one. Each group is individually configured for the deadtime; the deadtime for group 1 is one minute, and the deadtime for group 2 is two minutes.

Note
In cases where both global commands and server commands are used, the server command takes precedence over the global command.

! This command enables AAA.
! The next command defines default RADIUS parameters.
! The following commands define the group1 RADIUS server group and associate servers
! with it and configures a deadtime of one minute.
aaa group server radius group1
  server 10.1.1.1 auth-port 1645 acct-port 1646
deadtime 1

aaa group server radius group2
  server 10.2.2.2 auth-port 2000 acct-port 2001
deadtime 2

! The following set of commands configures the RADIUS attributes for each host entry
! associated with one of the defined server groups.
radius-server host 10.1.1.1 auth-port 1645 acct-port 1646
radius-server host 10.2.2.2 auth-port 2000 acct-port 2001
radius-server host 10.3.3.3 auth-port 1645 acct-port 1646

CHAPTER 5

Framed-Route in RADIUS Accounting

Framed-Routing indicates the routing method to a user on a network and is used only in Access-Accept packets. The Framed-Route in RADIUS Accounting feature provides for the presence of Framed-Route (RADIUS attribute 22) information in RADIUS Accounting-Request accounting records. The Framed-Route information is returned to the RADIUS server in the Accounting-Request packets. The Framed-Route information can be used to verify that a per-user route or routes have been applied for a particular static IP customer on the network access server (NAS).

- Finding Feature Information, on page 51
- Prerequisites for Framed-Route in RADIUS Accounting, on page 51
- Information About Framed-Route in RADIUS Accounting, on page 52
- How to Monitor Framed-Route in RADIUS Accounting, on page 52
- Additional References, on page 53
- Feature Information for Framed-Route in RADIUS Accounting, on page 54

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Framed-Route in RADIUS Accounting

Be familiar with configuring authentication, authorization, and accounting (AAA), RADIUS servers, and RADIUS attribute screening.
Information About Framed-Route in RADIUS Accounting

Framed-Route Attribute 22

Framed-Route, attribute 22 as defined in Internet Engineering Task Force (IETF) standard RFC 2865, provides for routing information to be configured for the user on the NAS. The Framed-Route attribute information is usually sent from the RADIUS server to the NAS in Access-Accept packets. The attribute can appear multiple times.

Framed-Route in RADIUS Accounting Packets

The Framed-Route attribute information in RADIUS accounting packets shows per-user routes that have been applied for a particular static IP customer on the NAS. The Framed-Route attribute information is currently sent in Access-Accept packets. Effective with Cisco IOS Release 12.3(4)T, the Framed-Route attribute information is also sent in Accounting-Request packets if it was provided in the Access-Accept packets and was applied successfully. Zero or more instances of the Framed-Route attribute may be present in the Accounting-Request packets.

**Note**

If there is more than one Framed-Route attribute in an Access-Accept packet, there can also be more than one Framed-Route attribute in the Accounting-Request packet.

The Framed-Route information is returned in Stop and Interim accounting records and in Start accounting records when accounting Delay-Start is configured.

No configuration is required to have the Framed-Route attribute information returned in the RADIUS accounting packets.

How to Monitor Framed-Route in RADIUS Accounting

Use the `debug radius` command to monitor whether Framed-Route (attribute 22) information is being sent in RADIUS Accounting-Request packets.

In the following example, the `debug radius` command is used to verify that Framed-Route (attribute 22) information is being sent in the Accounting-Request packets (see the line 00:06:23: RADIUS: Framed-Route [22] 26 "10.80.0.1 255.255.255.255 10.60.0.1 100").

**Note**

With CSCtz66183, the Service-Type AV pair (Attribute 6) is not displayed in the Accounting-Request records.

```
Device# debug radius
00:06:23: RADIUS: Send to unknown id 0 10.1.0.2:1645, Access-Request, len 126
00:06:23: RADIUS: authenticator 40 28 A8 BC 76 D4 AA 88 - 5A E9 C5 55 0E 50 84 37
00:06:23: RADIUS: User-Name [1] 14 "nari@trw1001"
```
Additional References

The following sections provide references related to the Framed-Route in RADIUS Accounting feature.
Feature Information for Framed-Route in RADIUS Accounting

</tr>
</tbody>
</table>
RFC-2867 RADIUS Tunnel Accounting

The RFC-2867 RADIUS Tunnel Accounting introduces six new RADIUS accounting types that are used with the RADIUS accounting attribute Acct-Status-Type (attribute 40), which indicates whether an accounting request marks the beginning of user service (start) or the end (stop).

This feature also introduces two virtual private virtual private dialup network (VPDN) commands that help users better troubleshoot VPDN session events.

Without RADIUS tunnel accounting support, VPDN with network accounting, which allows users to determine tunnel-link status changes, did not report all possible attributes to the accounting record file. Now that all possible attributes can be displayed, users can better verify accounting records with their Internet Service Providers (ISPs).

How to Configure RADIUS Tunnel Accounting

Enabling Tunnel Type Accounting Records

Use this task to configure your LAC to send tunnel and tunnel-link accounting records to be sent to the RADIUS server.

Two new command line interfaces (CLIs)--vpdn session accounting network(tunnel-link-type records) and vpdn tunnel accounting network(tunnel-type records)--are supported to help identify the following events:

- A VPDN tunnel is brought up or destroyed
- A request to create a VPDN tunnel is rejected
- A user session within a VPDN tunnel is brought up or brought down
- A user session create request is rejected

Note

The first two events are tunnel-type accounting records: authentication, authorization, and accounting (AAA) sends Tunnel-Start, Tunnel-Stop, or Tunnel-Reject accounting records to the RADIUS server. The next two events are tunnel-link-type accounting records: AAA sends Tunnel-Link-Start, Tunnel-Link-Stop, or Tunnel-Link-Reject accounting records to the RADIUS server.

1 If the specified tunnel type is used, these attributes should also be included in the accounting request packet.
SUMMARY STEPS

1. enable
2. configure terminal
3. Router(config)# aaa accounting network default list-name {start-stop | stop-only | wait-start | none group groupname
4. Router(config)# vpdn enable
5. Router(config)# vpdn tunnel accounting network list-name
6. Router(config)# vpdn session accounting network list-name

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 1    | enable           | Enables privileged EXEC mode.  
Example: 
Router> enable |
| 2    | configure terminal | Enters global configuration mode.  
Example: 
Router# configure terminal |
| 3    | Router(config)# aaa accounting network default list-name {start-stop | stop-only | wait-start | none group groupname | Enables network accounting.  
• default --If the default network accounting method-list is configured and no additional accounting configurations are enabled on the interface, network accounting is enabled by default.  
If either the vpdn session accounting network command or the vpdn tunnel accounting network command is linked to the default method-list, all tunnel and tunnel-link accounting records are enabled for those sessions.  
• list-name --The list-name defined in the aaa accounting command must be the same as the list-name defined in the VPDN command; otherwise, accounting will not occur. |
| 4    | Router(config)# vpdn enable | Enables virtual private dialup networking on the router and informs the router to look for tunnel definitions in a local database and on a remote authorization server (if applicable). |
| 5    | Router(config)# vpdn tunnel accounting network list-name | Enables Tunnel-Start, Tunnel-Stop, and Tunnel-Reject accounting records.  
• list-name --The list-name must match the list-name defined in the aaa accounting command; otherwise, network accounting will not occur. |
What To Do Next

After you have enabled RADIUS tunnel accounting, you can verify your configuration via the following optional task “Verifying RADIUS Tunnel Accounting.”

Verifying RADIUS Tunnel Accounting

Use either one or both of the following optional steps to verify your RADIUS tunnel accounting configuration.

SUMMARY STEPS

1. enable
2. Router# show accounting
3. Router# show vpdn [session] [tunnel]

DETAILED STEPS

Feature Information for RFC-2867 RADIUS Tunnel Accounting

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

</thead>
<tbody>
<tr>
<td>RFC-2867 RADIUS Tunnel Accounting</td>
<td>12.2(15)B, 12.3(4)T</td>
<td>The RFC-2867 RADIUS Tunnel Accounting introduces six new RADIUS accounting types that are used with the RADIUS accounting attribute Acct-Status-Type (attribute 40), which indicates whether an accounting request marks the beginning of user service (start) or the end (stop). This feature also introduces two virtual private virtual private dialup network (VPDN) commands that help users better troubleshoot VPDN session events. In 12.2(15)B, this feature was introduced on the Cisco 6400 series, Cisco 7200 series, and the Cisco 7400 series routers. This feature was integrated into Cisco IOS Release 12.3(4)T. The following commands were introduced or modified: aaa accounting, vpdn session accounting network, vpdn tunnel accounting network.</td>

CHAPTER 7

RADIUS Centralized Filter Management

The RADIUS Centralized Filter Management feature introduces a filter-server to simplify ACL configuration and management. This filter-server serves as a centralized RADIUS repository and administration point, which users can centrally manage and configure access control list (ACL) filters.

• Finding Feature Information, on page 71
• Prerequisites for RADIUS Centralized Filter Management, on page 71
• Restrictions for RADIUS Centralized Filter Management, on page 72
• Information About RADIUS Centralized Filter Management, on page 72
• How to Configure Centralized Filter Management for RADIUS, on page 73
• Configuration Examples for RADIUS Centralized Filter Management, on page 76
• Additional References, on page 77
• Feature Information for RADIUS Centralized Filter Management, on page 78

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for RADIUS Centralized Filter Management

• You may need to add a dictionary file to your server if it does not support the new RADIUS VSAs. For a sample dictionary and vendors file, see the section “RADIUS Dictionary and Vendors File Example” later in this document.

If you need to add a dictionary file, ensure that your RADIUS server is nonstandard and that it can send the newly introduced VSAs.

• You want to set up RADIUS network authentication so a remote user can dial in and get IP connectivity.
Restrictions for RADIUS Centralized Filter Management

Multiple method lists are not supported in this feature; only a single global filter method list can be configured.

Information About RADIUS Centralized Filter Management

Before the RADIUS Centralized Filter Management feature, wholesale providers (who provide premium charges for customer services such as access control lists [ACLs]) were unable to prevent customers from applying exhaustive ACLs, which could impact router performance and other customers. This feature introduces a centralized administration point—a filter server—for ACL management. The filter server acts as a centralized RADIUS repository for ACL configuration.

Whether or not the RADIUS server that is used as the filter server is the same server that is used for access authentication, the network access server (NAS) will initiate a second access request to the filter server. If configured, the NAS will use the filter-ID name as the authentication username and the filter server password for the second access request. The RADIUS server will attempt to authenticate the filter-ID name, returning any required filtering configuration in the access-accept response.

Because downloading ACLs is time consuming, a local cache is maintained on the NAS. If an ACL name exists on the local cache, that configuration will be used without consulting the filter server.

Note

An appropriately configured cache should minimize delays; however, the first dialin user to require a filter will always experience a longer delay because the ACL configuration is retrieved for the first time.

Cache Management

A global filter cache is maintained on the NAS of recently downloaded ACLs; thus, users no longer have to repeatedly request the same ACL configuration information from a potentially overloaded RADIUS server. Users are required to flush the cache when the following criteria have been met:

- After an entry becomes associated with a newly active call, the idle timer that is associated with that entry will be reset, if configured to do so.
- After the idle-time stamp of an entry expires, the entry will be removed.
- After the global cache of entries reaches a specified maximum number, the entry whose idle-timer is closest to the idle time limit will be removed.

A single timer is responsible for managing all cache entries. The timer is started after the first cache entry is created, and it runs periodically until reboot. The period of the timer will correspond to the minimum granularity offered when configuring cache idle timers, which is one expiration per minute. A single timer prevents users from having to manage individual timers per cache entry.
The single timer introduces a lack of precision in timer expiration. There is an average error of approximately 50 percent of the timer granularity. Although decreasing the timer granularity will decrease the average error, the decreased timer granularity will negatively impact performance. Because precise timing is not required for cache management, the error delay should be acceptable.

**New Vendor-Specific Attribute Support**

This feature introduces support for three new vendor-specific attributes (VSAs), which can be divided into the following two categories:

- **User profile extensions**
  - Filter-Required (50)-- Specifies whether the call should be permitted if the specified filter is not found. If present, this attribute will be applied after any authentication, authorization, and accounting (AAA) filter method-list.

- **Pseudo-user profile extensions**
  - Cache-Refresh (56)-- Specifies whether cache entries should be refreshed each time an entry is referenced by a new session. This attribute corresponds to the `cache refresh` command.
  - Cache-Time (57)-- Specifies the idle time out, in minutes, for cache entries. This attribute corresponds to the `cache clear age` command.

**Note**

All RADIUS attributes will override any command-line interface (CLI) configurations.

**How to Configure Centralized Filter Management for RADIUS**

**Configuring the RADIUS ACL Filter Server**

To enable the RADIUS ACL filter server, use the following command in global configuration mode:

```
Router(config)# aaa authorization cache filterserver default methodlist[methodlist2...]
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable AAA authorization caches and the downloading of an ACL configuration from a RADIUS filter server.</td>
<td></td>
</tr>
</tbody>
</table>

- **default** -- The default authorization list.
- **methodlist [methodlist2...]** -- One of the keywords listed on the `password` command page.

**Configuring the Filter Cache**

Follow the steps in this section to configure the AAA filter cache.
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `Router(config)# aaa cache filter`
4. `Router(config-aaa-filter)# password 0 7} password`
5. `Router(config-aaa-filter)# cache disable`
6. `Router(config-aaa-filter)# cache clear age minutes`
7. `Router(config-aaa-filter)# cache refresh`
8. `Router(config-aaa-filter)# cache max number`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><code>Router&gt; enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enables global configuration mode.</td>
</tr>
<tr>
<td><code>Router# configure terminal</code></td>
<td>Enables global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Enables filter cache configuration and enters AAA filter configuration mode.</td>
</tr>
<tr>
<td><code>Router(config)# aaa cache filter</code></td>
<td>Enables filter cache configuration and enters AAA filter configuration mode.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>(Optional) Specifies the optional password that is to be used for filter server authentication requests.</td>
</tr>
<tr>
<td>Example:</td>
<td>(Optional) Specifies the optional password that is to be used for filter server authentication requests.</td>
</tr>
<tr>
<td><code>Router(config-aaa-filter)# password 0 7} password</code></td>
<td>(Optional) Specifies the optional password that is to be used for filter server authentication requests.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>(Optional) Disables the cache.</td>
</tr>
<tr>
<td><code>Router(config-aaa-filter)# cache disable</code></td>
<td>(Optional) Disables the cache.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>(Optional) Specifies, in minutes, when cache entries expire and the cache is cleared.</td>
</tr>
<tr>
<td>Example:</td>
<td>(Optional) Specifies, in minutes, when cache entries expire and the cache is cleared.</td>
</tr>
<tr>
<td><code>Router(config-aaa-filter)# cache clear age minutes</code></td>
<td>(Optional) Specifies, in minutes, when cache entries expire and the cache is cleared.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>(Optional) Refreshes a cache entry when a new session begins. This command is enabled by default. To disable this functionality, use the no cache refresh command.</td>
</tr>
<tr>
<td><code>Router(config-aaa-filter)# cache refresh</code></td>
<td>(Optional) Refreshes a cache entry when a new session begins. This command is enabled by default. To disable this functionality, use the no cache refresh command.</td>
</tr>
</tbody>
</table>
### Verifying the Filter Cache

To display the cache status, use the `show aaa cache filterserver` EXEC command. The following is sample output for the `show aaa cache filterserver` command:

```plaintext
Router# show aaa cache filterserver
Filter Server Age Expires Refresh Access-Control-Lists
-----------------------------------
aol 10.2.3.4 0 1440 100 ip in icmp drop  ip out icmp drop  ip out forward tcp dstip 1.2.3...
man 10.3.3.4 N/A Never 2 ip in tcp drop
man2 10.4.3.4 N/A Never 2 ip in tcp drop
vone 10.5.3.4 N/A Never 0 ip in tcp drop
```

**Note**
The `show aaa cache filterserver` command shows how many times a particular filter has been referenced or refreshed. This function may be used in administration to determine which filters are actually being used.

### Troubleshooting Tips

To help troubleshoot your filter cache configurations, use the privileged EXEC `debug aaa cache filterserver` command. To view sample output for the `debug aaa cache filterserver` command, refer to the section “Debug Output Example” later in this document.

### Monitoring and Maintaining the Filter Cache

To monitor and maintain filter caches, use at least one of the following EXEC commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router# clear aaa cache filterserver acl [filter-name]</code></td>
<td>Clears the cache status for a particular filter or all filters.</td>
</tr>
<tr>
<td><code>Router# show aaa cache filterserver</code></td>
<td>Displays the cache status.</td>
</tr>
</tbody>
</table>
Configuration Examples for RADIUS Centralized Filter Management

NAS Configuration Example

The following example shows how to configure the NAS for cache filtering. In this example, the server group “mygroup” is contacted first. If there is no response, the default RADIUS server will then be contacted. If there still is no response, the local filters are contacted. Finally, the call is accepted if the filter cannot be resolved.

```
aaa authorization cache filterserver group mygroup group radius local none
!  aaa group server radius mygroup
    server 10.2.3.4
    server 10.2.3.5
!  radius-server host 10.1.3.4
!  aaa cache filter
    password mycisco
    no cache refresh
    cache max 100
!
```

RADIUS Server Configuration Example

The following example is a sample RADIUS configuration that is for a remote user “user1” dialing into the NAS:

```
myfilter Password = "cisco"
Service-Type = Outbound,
Ascend:Ascend-Call-Filter = "ip in drop srcip 10.0.0.1/32 dstip 10.0.0.10/32 icmp",
Ascend:Ascend-Call-Filter = "ip in drop srcip 10.0.0.1/32 dstip 10.0.0.10/32 tcp dstport = telnet",
Ascend:Ascend-Cache-Refresh = Refresh-No,
Ascend:Ascend-Cache-Time = 15
user1 Password = "cisco"
Service-Type = Framed,
Filter-Id = "myfilter",
Ascend:Ascend-Filter-Required = Filter-Required-Yes,
```

RADIUS Dictionary and Vendors File Example

The following example is a sample RADIUS dictionary file for the new VSAs. In this example, the dictionary file is for a Merit server.

```
dictionary file:
Ascend.attr Ascend-Filter-Required 50 integer (*, 0, NOENCAPS)
Ascend.attr Ascend-Cache-Refresh 56 integer (*, 0, NOENCAPS)
Ascend.attr Ascend-Cache-Time 57 integer (*, 0, NOENCAPS)
Ascend.value Ascend-Cache-Refresh Refresh-No 0
```
Debug Output Example

The following is sample output from the `debug aaa cache filterserver` command:

```
Router# debug aaa cache filterserver
AAA/FLTSV: need "myfilter" (fetch), call 0x612DAC64
AAA/FLTSV: send req, call 0x612DAC50
AAA/FLTSV: method SERVER_GROUP myradius
AAA/FLTSV: recv reply, call 0x612DAC50 (PASS)
AAA/FLTSV: create cache
AAA/FLTSV: add attr "call-inacl"
AAA/FLTSV: add attr "call-inacl"
AAA/FLTSV: add attr "call-inacl"
AAA/FLTSV: skip attr "filter-cache-refresh"
AAA/FLTSV: skip attr "filter-cache-time"
AAA/CACHE: set "AAA filtserv cache" entry "myfilter" refresh? no
AAA/CACHE: set "AAA filtserv cache" entry "myfilter" cachetime 15
AAA/FLTSV: add attr to list "call-inacl" call 0x612DAC64
AAA/FLTSV: add attr to list "call-inacl" call 0x612DAC64
AAA/FLTSV: add attr to list "call-inacl" call 0x612DAC64
AAA/FLTSV: PASS call 0x612DAC64
AAA/CACHE: timer "AAA filtserv cache", next in 10 secs (0 entries)
AAA/CACHE: timer "AAA filtserv cache", next in 10 secs (1 entry)
AAA/CACHE: destroy "AAA filtserv cache" entry "myfilter"
AAA/CACHE: timer "AAA filtserv cache", next in 10 secs (0 entries)
```

Feature Information for RADIUS Centralized Filter Management

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

RADIUS Debug Enhancements

This document describes the Remote Authentication Dial-In User Services (RADIUS) Debug Enhancements feature.

• Finding Feature Information, on page 81
• Prerequisites for RADIUS Debug Enhancements, on page 81
• Restrictions for RADIUS Debug Enhancements, on page 82
• Information About RADIUS Debug Enhancements, on page 82
• How to Enable RADIUS Debug Parameters, on page 82
• Configuration Examples for RADIUS Debug Enhancements, on page 84
• Additional References, on page 86
• Feature Information for RADIUS Debug Enhancements, on page 87
• Glossary, on page 87

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for RADIUS Debug Enhancements

• Establish a working IP network. For more information about configuring IP refer to the Configuring IPv4 Addresses module.

• Configure the gateway as a RADIUS client. Refer to the section “Configuring the Voice Gateway as a RADIUS Client” section in the CDR Accounting for Cisco IOS Voice Gateways document.

• Be familiar with IETF RFC 2138.
Restrictions for RADIUS Debug Enhancements

Only Internet Engineering Task Force (IETF) attributes and Cisco vendor-specific attributes (VSAs) used in voice applications are supported. For unsupported attributes, “undebuggable” is displayed.

Information About RADIUS Debug Enhancements

RADIUS Overview

RADIUS is a distributed client/server system that provides the following functionality:

• Secures networks against unauthorized access.
• Enables authorization of specific service limits.
• Provides accounting information so that services can be billed.

In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

Benefits of RADIUS Debug Enhancements

The debug radius command displays information associated with RADIUS. Prior to the RADIUS Debug Enhancements feature, debug radius output was available only in an expanded, hexadecimal string format, resulting in displays that were difficult to interpret and analyze. Moreover, attribute value displays were truncated, particularly for VSAs.

This feature provides enhanced RADIUS display including the following:

• Packet dump in a more readable, user-friendly ASCII format than before.
• Complete display of attribute values without truncation.
• Ability to select a brief RADIUS debug output display.
• Allows a compact debugging output option that is useful for high-traffic, operational environments.

How to Enable RADIUS Debug Parameters

Enabling RADIUS Debug Parameters

Perform this task to enable RADIUS debug parameters. By default, event logging is enabled.

Note

Prior to Cisco IOS Release 12.2(11)T, the debug radius command enabled truncated debugging output in hexadecimal notation, rather than ASCII.
SUMMARY STEPS

1. enable
2. debug radius [accounting | authentication | brief | elog | failover | retransmit | verbose]

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        | Enables debugging for the specified parameters associated with RADIUS configuration. |
| debug radius [accounting | authentication | brief | elog | failover | retransmit | verbose] |         |
| Example:          |         |
| Router# debug radius accounting |         |

Verifying RADIUS Debug Parameters

Perform this task to verify RADIUS debug parameters.

SUMMARY STEPS

1. enable
2. show debug

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
</tbody>
</table>

| **Step 2**        | Displays debug information. |
| show debug        |         |
| Example:          |         |
| Router# show debug |         |
Configuration Examples for RADIUS Debug Enhancements

Enabling RADIUS Debug Parameters Example

The following example shows how to enable debugging of RADIUS accounting collection.

```
Router> enable
Router# debug radius accounting
Radius protocol debugging is on
Radius protocol brief debugging is off
Radius protocol verbose debugging is off
Radius packet hex dump debugging is off
Radius packet protocol (authentication) debugging is on
Radius packet protocol (accounting) debugging is off
Radius server fail-over debugging is off
Radius elog debugging is off
```

**Note**
The sample output above displays information that is found inside a RADIUS protocol message. For more information about RADIUS protocol messages, see IETF RFC 2138.

Verifying RADIUS Debug Parameters Example

The following example shows how to verify RADIUS debug parameters.

```
Router> enable
Router# show debug
00:02:50: RADIUS: ustruct sharecount=3
00:02:50: Radius: radius_port_info() success=0 radius_nas_port=1

### Feature Information for RADIUS Debug Enhancements

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to [www.cisco.com/go/cfn](http://www.cisco.com/go/cfn). An account on Cisco.com is not required.

### Glossary

**AAA**—authentication, authorization, and accounting. Pronounced “triple A.”

**ASCII**—American Standard Code for Information Interchange. 8-bit code for character representation (7 bits plus parity).

**attribute**—Form of information items provided by the X.500 Directory Service. The directory information base consists of entries, each containing one or more attributes. Each attribute consists of a type identifier together with one or more values.

**IETF**—Internet Engineering Task Force. Task force consisting of over 80 working groups responsible for developing Internet standards. The IETF operates under the auspices of ISOC.

**RADIUS**—Remote Authentication Dial-In User Service. Database for authenticating modem and ISDN connections and for tracking connection time.
**VoIP** --Voice over IP. The capability to carry normal telephony-style voice over an IP-based internet with POTS-like functionality, reliability, and voice quality. VoIP enables a router to carry voice traffic (for example, telephone calls and faxes) over an IP network. In VoIP, the DSP segments the voice signal into frames, which then are coupled in groups of two and stored in voice packets. These voice packets are transported using IP in compliance with ITU-T specification H.323.

**VSA** --vendor-specific attribute. An attribute that has been implemented by a particular vendor. It uses the attribute Vendor-Specific to encapsulate the resulting AV pair: essentially, Vendor-Specific = protocol:attribute = value.
CHAPTER 9

RADIUS Logical Line ID

The RADIUS Logical Line ID feature, also known as the Logical Line Identification (LLID) Blocking feature enables administrators to track their customers on the basis of the physical lines on which customer calls originate. Administrators use a virtual port that does not change as customers move from one physical line to another. This virtual port facilitates the maintenance of the administrator’s customer profile database and allows the administrator to do additional security checks on customers.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for RADIUS Logical Line ID

Although this feature can be used with any RADIUS server, some RADIUS servers may require modifications to their dictionary files to allow the Calling-Station-ID attribute to be returned in Access-Accept messages. For example, the Merit RADIUS server does not support LLID downloading unless you modify its dictionary as follows: “ATTRIBUTE Calling-Station-Id 31 string (*, *)”
Restrictions for RADIUS Logical Line ID

The RADIUS Logical Line ID feature supports RADIUS only. TACACS+ is not supported. This feature can be applied only toward PPP over Ethernet over ATM (PPPoEoATM) and PPP over Ethernet over VLAN (PPPoEoVLAN) (Dot1Q) calls; no other calls, such as ISDN, can be used.

Information About RADIUS Logical Line ID

LLID is an alphanumeric string (which must be a minimum of one character and a maximum of 253 characters) that is a logical identification of a subscriber line. LLID is maintained in a customer profile database on a RADIUS server. When the customer profile database receives a preauthorization request from the access router, the RADIUS server sends the LLID to the router as the Calling-Station-ID attribute (attribute 31).

The Layer 2 Tunneling Protocol (L2TP) access concentrator (LAC) sends a preauthorization request to the customer profile database when the LAC is configured for preauthorization. Configure the LAC for preauthorization using the `subscriber access` command.

Note

Downloading the LLID is referred to as “preauthorization” because it occurs before either service (domain) authorization or user authentication and authorization occur.

The customer profile database on the RADIUS server consists of user profiles for each physical network access server (NAS) port that is connected to the router. Each user profile contains a profile matched to a username (attribute 1) representing the physical port on the router. When the router is configured for preauthorization, it queries the customer profile database using a username representative of the physical NAS port making the connection to the router. When a match is found in the customer profile database, the customer profile database returns an Access-Accept message containing the LLID in the user profile. The LLID is defined in the Access-Accept record as the Calling-Station-ID attribute.

The preauthorization process can also provide the real username being used for authentication to the RADIUS server. Because the physical NAS port information is being used as the username (attribute 1), RADIUS attribute 77 (Connect-Info) can be configured to contain the authentication username. This configuration allows the RADIUS server to provide additional validation on the authorization request if it chooses, such as analyzing the username for privacy rules, before returning an LLID back to the router.

How to Configure RADIUS Logical Line ID

Configuring Preauthorization

To download the LLID and configure the LAC for preauthorization, perform the following steps.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
RADIUS Logical Line ID

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router# configure terminal</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>ip radius source-interface <em>interface-name</em></td>
<td>Specifies the IP address portion of the username for the preauthorization request.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router (config)# ip radius source-interface Loopback1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>subscriber access {pppoe</td>
<td>pppoa} pre-authorize nas-port-id [default</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td>The <em>send username</em> option specifies that you include the authentication username of the session inside the Connect-Info (attribute 77) in the Access-Request message.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router (config)# subscriber access pppoe pre-authorize nas-port-id mlist_llid send username</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Configuring the LLID in a RADIUS User Profile

To configure the user profile for preauthorization, add a NAS port user to the customer profile database and add RADIUS Internet Engineering Task Force (IETF) attribute 31 (Calling-Station-ID) to the user profile.

### SUMMARY STEPS

1. UserName=nas_port:ip-address:slot/module/port/vpi.vci
2. User-Name=nas-port:ip-address:slot/module/port/vlan-id
3. Calling-Station-Id = “string (*,*)”

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><em>(Optional)</em> Adds a PPPoE over ATM NAS port user.</td>
</tr>
<tr>
<td>UserName=nas_port: ip-address:slot/module/port/vpi.vci</td>
<td><em>(Optional)</em> Adds a PPPoE over VLAN NAS port user.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Adds attribute 31 to the user profile.</td>
</tr>
<tr>
<td>User-Name=nas-port: ip-address:slot/module/port/vlan-id</td>
<td>• String—One or more octets, containing the phone number from which the user placed the call.</td>
</tr>
</tbody>
</table>

### Verifying Logical Line ID

To verify feature functionality, perform the following steps.

**SUMMARY STEPS**

1. **enable**
2. **debug radius**

**DETAILED STEPS**

<table>

RADIUS User Profile for LLID Example

The following example shows how to configure the user profile for LLID querying for PPPoEoVLAN and PPPoEoATM and how to add attribute 31:

```
pppoeovlan
--------
nas-port:10.1.0.3:6/0/0/0  Password = "cisco",
    Service-Type = Outbound,
    Calling-Station-ID = "cat-example"

pppoeoa
--------
nas-port:10.1.0.3:6/0/0/1.100  Password = "cisco",
    Service-Type = Outbound,
    Calling-Station-ID = "cat-example"
```

The RADIUS Route Download feature allows users to configure their network access server (NAS) to direct RADIUS authorization. Users configure a separate named method list (in addition to the default method list) for static route download requests sent by their NAS to authorization, authentication, and accounting (AAA) servers.

Before this feature, RADIUS authorization for static route download requests was sent only to AAA servers specified by the default method list.

This feature extends the functionality of the `aaa route download` command to allow users to specify the name of the method list that will be used to direct static route download requests to the AAA servers. The `aaa route download` command may be used to specify a separate method list for downloading static routes. This method list can be added by using the `aaa authorization configuration` command.

### Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

### Prerequisites for RADIUS Route Download

AAA network security must be enabled before you perform the tasks in this feature.
How to Configure RADIUS Route Download

Configuring RADIUS Route Download

To configure the NAS to send static route download requests to the servers specified by a named method list, use the following commands in global configuration mode:

**SUMMARY STEPS**

1. Router(config)# aaa authorization configuration method-name \[
   \text{radius | tacacs+ | group group-name}\]
2. Router(config)# aaa route download [time] [authorization method-list]

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | Router(config)# aaa authorization configuration method-name \[
   \text{radius | tacacs+ | group group-name}\] |
| Enables the static route download feature. Use the authorization method-list attributes to specify a named method list to which RADIUS authorization requests for static route downloads are sent. |
| **Step 2** | Router(config)# aaa route download [time] [authorization method-list] |
| Downloads static route configuration information from the AAA server using RADIUS. |

Verifying RADIUS Route Download

To verify the routes that are installed, use the `show ip route` command in EXEC mode.

To display information that is associated with RADIUS, use the `debug radius` command in privileged EXEC mode.

Configuration Examples for RADIUS Route Download

**RADIUS Route Download Configuration Example**

The following example shows how to configure the NAS to send static route download requests to the servers specified by the method list named “list1”:

```
aaa new-model
aaa group server radius rad1
   server 10.2.2.2 auth-port 1645 acct-port 1646
   
   aaa group server tacacs+ tac1
   server 172.17.3.3
   
   aaa authorization configuration default group radius
```
aaa authorization configuration list1 group radi group tac1
tacacs-server host 172.17.3.3
tacacs-server key cisco
tacacs-server administration
!
radius-server host 10.2.2.2 auth-port 1645 acct-port 1646
radius-server key cisco

RADIUS Server Load Balancing

The RADIUS Server Load Balancing feature distributes authentication, authorization, and accounting (AAA) authentication and accounting transactions across RADIUS servers in a server group. These servers can share the AAA transaction load and thereby respond faster to incoming requests.

This module describes the RADIUS Server Load Balancing feature.

- Finding Feature Information, on page 101
- Prerequisites for RADIUS Server Load Balancing, on page 101
- Restrictions for RADIUS Server Load Balancing, on page 102
- Information About RADIUS Server Load Balancing, on page 102
- How to Configure RADIUS Server Load Balancing, on page 104
- Configuration Examples for RADIUS Server Load Balancing, on page 108

- Feature Information for RADIUS Server Load Balancing, on page 115

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for RADIUS Server Load Balancing

- Authentication, authorization, and accounting (AAA) must be configured on the RADIUS server.
- AAA RADIUS server groups must be configured.
- RADIUS must be configured for functions such as authentication, accounting, or static route download.
Restrictions for RADIUS Server Load Balancing

- Incoming RADIUS requests, such as Packet of Disconnect (POD) requests, are not supported.

Information About RADIUS Server Load Balancing

RADIUS Server Load Balancing Overview

Load balancing distributes batches of transactions to RADIUS servers within a server group. Load balancing assigns each batch of transactions to the server with the lowest number of outstanding transactions in its queue. The process of assigning a batch of transactions is as follows:

1. The first transaction is received for a new batch.
2. All server transaction queues are checked.
3. The server with the lowest number of outstanding transactions is identified.
4. The identified server is assigned the next batch of transactions.

The batch size is a user-configured parameter. Changes in the batch size may impact CPU load and network throughput. As batch size increases, CPU load decreases and network throughput increases. However, if a large batch size is used, all available server resources may not be fully utilized. As batch size decreases, CPU load increases and network throughput decreases.

Note

There is no set number for large or small batch sizes. A batch with more than 50 transactions is considered large and a batch with fewer than 25 transactions is considered small.

Note

If a server group contains ten or more servers, we recommend that you set a high batch size to reduce CPU load.

Transaction Load Balancing Across RADIUS Server Groups

You can configure load balancing either per-named RADIUS server group or for the global RADIUS server group. The load balancing server group must be referred to as “radius” in the authentication, authorization, and accounting (AAA) method lists. All public servers that are part of the RADIUS server group are then load balanced.

You can configure authentication and accounting to use the same RADIUS server or different servers. In some cases, the same server can be used for preauthentication, authentication, or accounting transactions for a session. The preferred server, which is an internal setting and is set as the default, informs AAA to use the same server for the start and stop record for a session regardless of the server cost. When using the preferred server setting, ensure that the server that is used for the initial transaction (for example, authentication), the
preferred server, is part of any other server group that is used for a subsequent transaction (for example, accounting).

The preferred server is not used if one of the following criteria is true:

- The `load-balance method least-outstanding ignore-preferred-server` command is used.
- The preferred server is dead.
- The preferred server is in quarantine.
- The want server flag has been set, overriding the preferred server setting.

The want server flag, an internal setting, is used when the same server must be used for all stages of a multistage transaction regardless of the server cost. If the want server is not available, the transaction fails.

You can use the `load-balance method least-outstanding ignore-preferred-server` command if you have either of the following configurations:

- Dedicated authentication server and a separate dedicated accounting server
- Network where you can track all call record statistics and call record details, including start and stop records and records that are stored on separate servers

If you have a configuration where authentication servers are a superset of accounting servers, the preferred server is not used.

## RADIUS Server Status and Automated Testing

The RADIUS Server Load Balancing feature considers the server status when assigning batches. Transaction batches are sent only to live servers. We recommend that you test the status of all RADIUS load-balanced servers, including low usage servers (for example, backup servers).

Transactions are not sent to a server that is marked dead. A server is marked dead until its timer expires, at which time it moves to quarantine state. A server is in quarantine until it is verified alive by the RADIUS automated tester functionality.

To determine if a server is alive and available to process transactions, the RADIUS automated tester sends a request periodically to the server for a test user ID. If the server returns an Access-Reject message, the server is alive; otherwise the server is either dead or quarantined.

A transaction sent to an unresponsive server is failed over to the next available server before the unresponsive server is marked dead. We recommend that you use the retry reorder mode for failed transactions.

When using the RADIUS automated tester, verify that the authentication, authorization, and accounting (AAA) servers are responding to the test packets that are sent by the network access server (NAS). If the servers are not configured correctly, packets may be dropped and the server erroneously marked dead.

---

### Caution

We recommend that you use a test user that is not defined on the RADIUS server for the RADIUS server automated testing to protect against security issues that may arise if the test user is not correctly configured.

### Note

Use the `test aaa group` command to check load-balancing transactions.
How to Configure RADIUS Server Load Balancing

Enabling Load Balancing for a Named RADIUS Server Group

**SUMMARY STEPS**

1. enable
2. configure terminal
3. radius-server host {hostname | ip-address} [test username name] [auth-port number] [ignore-auth-port] [acct-port number] [ignore-acct-port] [idle-time seconds]

### Enabling Load Balancing for a Global RADIUS Server Group

The global RADIUS server group is referred to as “radius” in the authentication, authorization, and accounting (AAA) method lists.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `radius-server host {hostname | ip-address} [test username name] [auth-port number] [ignore-auth-port] [acct-port number] [ignore-acct-port] [idle-time seconds]`
4. `radius-server load-balance method least-outstanding [batch-size number] [ignore-preferred-server]`
5. `load-balance method least-outstanding [batch-size number] [ignore-preferred-server]`
6. `end`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>

### Command or Action

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 4** | radius-server load-balance method least-outstanding [batch-size number] [ignore-preferred-server] | Enables the least-outstanding load balancing for the global RADIUS server group and enters server group configuration mode.  
• The default batch size is 25. The batch size range is from 1 to 2147483647. |
| **Example:** | Device(config)# radius-server load-balance method least-outstanding | |
| **Step 5** | load-balance method least-outstanding [batch-size number] [ignore-preferred-server] | Enables least-outstanding load balancing for a global named server group. |
| **Example:** | Device(config-sg)# load-balance method least-outstanding batch-size 5 | |
| **Step 6** | end                                             | Exits server group configuration mode and enters privileged EXEC mode. |
| **Example:** | Device(config-sg)# end | |

### Troubleshooting RADIUS Server Load Balancing

After configuring the RADIUS Server Load Balancing feature, you can monitor the idle timer, dead timer, and load balancing server selection or verify the server status by using a manual test command.

**SUMMARY STEPS**

1. Use the `debug aaa test` command to determine when an idle timer or dead timer has expired, when test packets are sent, the status of the server, or to verify the server state.
2. Use the `debug aaa sg-server selection` command to determine the server that is selected for load balancing.
3. Use the `test aaa group` command to manually verify the RADIUS load-balanced server status.

**DETAILED STEPS**

**Step 1**

Use the `debug aaa test` command to determine when an idle timer or dead timer has expired, when test packets are sent, the status of the server, or to verify the server state.

The idle timer is used to check the server status and is updated with or without any incoming requests. Monitoring the idle timer helps to determine if there are nonresponsive servers and to keep the RADIUS server status updated to efficiently utilize available resources. For instance, an updated idle timer would help ensure that incoming requests are sent to servers that are alive.

The dead timer is used either to determine that a server is dead or to update a dead server’s status appropriately.

Monitoring server selection helps to determine how often the server selection changes. Server selection is effective in analyzing if there are any bottlenecks, a large number of queued requests, or if only specific servers are processing incoming requests.

The following sample output from the `debug aaa test` command shows when the idle timer expired:

**Example:**

<table>
<thead>
<tr>
<th>Command</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug aaa test</td>
<td>...</td>
</tr>
</tbody>
</table>

---

106
Device# debug aaa test

Jul 16 00:07:01: AAA/SG/TEST: Server (192.0.2.245:1700,1701) quarantined.
Jul 16 00:07:01: AAA/SG/TEST: Sending test request(s) to server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Sending 1 Access-Requests, 1 Accounting-Requests in current batch.
Jul 16 00:07:01: AAA/SG/TEST(Req#: 1): Sending test AAA Accounting-Request.
Jul 16 00:07:01: AAA/SG/TEST: Obtained Test response from server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Obtained Test response from server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Necessary responses received from server (192.0.2.245:1700,1701) marked ALIVE. Idle timer set for 60 sec(s).
Jul 16 00:07:01: AAA/SG/TEST: Server (192.0.2.245:1700,1701) removed from quarantine.

Step 2

Use the debug aaa sg-server selection command to determine the server that is selected for load balancing.

The following sample output from the debug aaa sg-server selection command shows five access requests being sent to a server group with a batch size of three:

Example:

Device# debug aaa sg-server selection

Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining a new least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Server[0] load: 3
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Selected Server[1] with load 0
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.

Step 3

Use the test aaa group command to manually verify the RADIUS load-balanced server status.

The following sample output shows the response from a load-balanced RADIUS server that is alive when the username "test" does not match a user profile. The server is verified alive when it issues an Access-Reject response to an authentication, authorization, and accounting (AAA) packet generated using the test aaa group command.

Example:

Device# test aaa group SG1 test lab new-code

00:06:07: RADIUS/ENCODE(00000000):Orig. component type = INVALID
00:06:07: RADIUS/ENCODE(00000000): dropping service type, "radius-server attribute 6 on-for-login-auth" is off

Configuration Examples for RADIUS Server Load Balancing

Example: Enabling Load Balancing for a Named RADIUS Server Group

The following examples show load balancing enabled for a named RADIUS server group. These examples are shown in three parts: the current configuration of the RADIUS command output, debug output, and authentication, authorization, and accounting (AAA) server status information.

The following sample output shows the relevant RADIUS configuration:

```
Device# show running-config
aaa group server radius server-group1
server 192.0.2.238 auth-port 2095 acct-port 2096
server 192.0.2.238 auth-port 2015 acct-port 2016
load-balance method least-outstanding batch-size 5
!
Device(config-sg-radius)# load-balance method least-outstanding batch-size 30
```

The lines in the current configuration of the preceding RADIUS command output are defined as follows:

- The `aaa group server radius` command shows the configuration of a server group with two member servers.
- The `load-balance` command enables load balancing for global RADIUS server groups with the batch size specified.
- The `aaa authentication ppp default group server-group1` command authenticates all PPP users using RADIUS.
- The `aaa accounting network default start-stop group server-group1` command enables sending of all accounting requests to the AAA server when the client is authenticated and then disconnected using the `start-stop` keyword.

The show debug sample output below shows the selection of the preferred server and the processing of requests for the preceding configuration:

```
Device# show debug
```
The following sample output from the `show aaa servers` command shows the AAA server status for the named RADIUS server group configuration:

The sample output shows the status of two RADIUS servers. Both servers are alive, and no requests have been processed since the counters were cleared 0 minutes ago.

```
Device# show aaa servers

RADIUS: id 8, priority 1, host 192.0.2.238, auth-port 2095, acct-port 2096
    State: current UP, duration 3781s, previous duration 0s
    Dead: total time 0s, count 0
    Quarantined: No
    Authen: request 0, timeouts 0
      Response: unexpected 0, server error 0, incorrect 0, time 0ms
      Transaction: success 0, failure 0
    Author: request 0, timeouts 0
      Response: unexpected 0, server error 0, incorrect 0, time 0ms
      Transaction: success 0, failure 0
```
Example: Enabling Load Balancing for a Global RADIUS Server Group

The following examples show how to enable load balancing for global RADIUS server groups. These examples are shown in three parts: the current configuration of the RADIUS command output, debug output, and authentication, authorization, and accounting (AAA) server status information. You can use delimiting characters to display relevant parts of the configuration.

The following example shows the relevant RADIUS configuration:

```
Device# show running-config | include radius

aaa authentication ppp default group radius
aaa accounting network default start-stop group radius
radius-server host 192.0.2.238 auth-port 2095 acct-port 2096 key cisco
radius-server host 192.0.2.238 auth-port 2015 acct-port 2016 key cisco
radius-server load-balance method least-outstanding batch-size 5
```

Lines in the current configuration of the preceding RADIUS command output are defined as follows:

- The `aaa authentication ppp` command authenticates all PPP users using RADIUS.
- The `aaa accounting` command enables the sending of all accounting requests to an AAA server when the client is authenticated and then disconnected through use of the `start-stop` keyword.
- The `radius-server host` command defines the IP address of the RADIUS server host with the authorization and accounting ports specified and the authentication and encryption keys identified.
- The `radius-server load-balance` command enables load balancing for global RADIUS server groups with the batch size specified.

The `show debug` sample output below shows the selection of the preferred server and the processing of requests for the configuration:

```
Device# show debug

General OS:
  AAA server group server selection debugging is on
#<sending 10 pppoe requests>
```
The following sample output from the `show aaa servers` command shows the AAA server status for the global RADIUS server group configuration:

The sample output shows the status of two RADIUS servers. Both servers are up and successfully processed in the last 2 minutes:

- Five out of six authentication requests
- Five out of five accounting requests

```
Device# show aaa servers
RADIUSsId 4, priority 1, host 192.0.2.238, auth-port 2095, acct-port 2096
    State: current UP, duration 3175s, previous duration 0s
    Dead: total time 0s, count 0
    Quarantined: No
    Authen:request 6, timeouts 1
      Response: unexpected 1, server error 0, incorrect 0, time 1841ms
    Transaction: success 5, failure 0
```
Example: Monitoring Idle Timer

The following example shows idle timer and related server state for load balancing enabled for a named RADIUS server group. The current configuration of the RADIUS command output and debug command output are also displayed.

The following sample output shows the relevant RADIUS configuration:

```
Device# show running-config | include radius

aaa group server radius server-group1
radius-server host 192.0.2.238 auth-port 2095 acct-port 2096 test username junk1 idle-time 1 key cisco
radius-server host 192.0.2.238 auth-port 2015 acct-port 2016 test username junk1 idle-time 1 key cisco
radius-server load-balance method least-outstanding batch-size 5
```

The lines in the current configuration of the preceding RADIUS command output are defined as follows:

- The `aaa group server radius` command shows the configuration of a server group.
- The `radius-server host` command defines the IP address of the RADIUS server host with authorization and accounting ports specified and the authentication and encryption key identified.
- The `radius-server load-balance` command enables load balancing for the RADIUS server with the batch size specified.

The `show debug` sample output below shows test requests being sent to servers. The response to the test request sent to the server is received, the server is removed from quarantine as appropriate, the server is marked alive, and then the idle timer is reset.

```
Device# show debug

*Feb 28 13:52:20.835:AAA/SG/TEST:Sending test request(s) to server (192.0.2.238:2015,2016)
```
Example: Configuring the Preferred Server with the Same Authentication and Authorization Server

The following example shows an authentication server group and an authorization server group that use the same servers 209.165.200.225 and 209.165.200.226. Both server groups have the preferred server flag enabled.

```plaintext
aaa group server radius authentication-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2

aaa group server radius accounting-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2
```

When a preferred server is selected for a session, all transactions for that session will continue to use the original preferred server. The servers 209.165.200.225 and 209.165.200.226 are load balanced based on sessions rather than transactions.

Example: Configuring the Preferred Server with Different Authentication and Authorization Servers

The following example shows an authentication server group that uses servers 209.165.200.225 and 209.165.200.226 and an authorization server group that uses servers 209.165.201.1 and 209.165.201.2. Both server groups have the preferred server flag enabled.

```plaintext
aaa group server radius authentication-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2

aaa group server radius accounting-group
  server 209.165.201.1 key radkey3
  server 209.165.201.2 key radkey4
```

The authentication server group and the accounting server group do not share any common servers. A preferred server is never found for accounting transactions; therefore, authentication and accounting servers are load-balanced based on transactions. Start and stop records are sent to the same server for a session.

Example: Configuring the Preferred Server with Overlapping Authentication and Authorization Servers

The following example shows an authentication server group that uses servers 209.165.200.225, 209.165.200.226, and 209.165.201.1 and an accounting server group that uses servers 209.165.201.1 and 209.165.201.2. Both server groups have the preferred server flag enabled.

```plaintext
aaa group server radius authentication-group
  server 209.165.200.225 key radkey1
```
server 209.165.200.226 key radkey2
server 209.165.201.1 key radkey3
aaa group server radius accounting-group
  server 209.165.201.1 key radkey3
  server 209.165.201.2 key radkey4

If all servers have equal transaction processing capability, one-third of all authentication transactions are directed toward the server 209.165.201.1. Therefore, one-third of all accounting transactions are also directed toward the server 209.165.201.1. The remaining two-third of accounting transactions are load balanced equally between servers 209.165.201.1 and 209.165.201.2. The server 209.165.201.1 receives fewer authentication transactions because the server 209.165.201.1 has outstanding accounting transactions.

Example: Configuring the Preferred Server with Authentication Servers As a Subset of Authorization Servers

The following example shows an authentication server group that uses servers 209.165.200.225 and 209.165.200.226 and an authorization server group that uses servers 209.165.200.225, 209.165.200.226, and 209.165.201.1. Both server groups have the preferred server flag enabled.

aaa group server radius authentication-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2
aaa group server radius accounting-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2
  server 209.165.201.1 key radkey3

One-half of all authentication transactions are sent to the server 209.165.200.225 and the other half to the server 209.165.200.226. Servers 209.165.200.225 and 209.165.200.226 are preferred servers for authentication and accounting transaction. Therefore, there is an equal distribution of authentication and accounting transactions across servers 209.165.200.225 and 209.165.200.226. The server 209.165.201.1 is relatively unused.

Example: Configuring the Preferred Server with Authentication Servers As a Superset of Authorization Servers

The following example shows an authentication server group that uses servers 209.165.200.225, 209.165.200.226, and 209.165.201.1 and an authorization server group that uses servers 209.165.200.225 and 209.165.200.226. Both server groups have the preferred server flag enabled.

aaa group server radius authentication-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2
  server 209.165.201.1 key radkey3
aaa group server radius accounting-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2

Initially, one-third of authentication transactions are assigned to each server in the authorization server group. As accounting transactions are generated for more sessions, accounting transactions are sent to servers 209.165.200.225 and 209.165.200.226 because the preferred server flag is on. As servers 209.165.200.225 and 209.165.200.226 begin to process more transactions, authentication transactions will start to be sent to server 209.165.201.1. Transaction requests authenticated by server 209.165.201.1 do not have any preferred server setting and are split between servers 209.165.200.225 and 209.165.200.226, which negates the use of the preferred server flag. This configuration should be used cautiously.

CHAPTER 12

RADIUS Support of 56-Bit Acct Session-Id

The RADIUS Support of 56-Bit Acct Session-Id feature introduces a new 32-bit authentication, authorization, and accounting (AAA) variable, acct-session-id-count. The first eight bits of the acct-session-id-count variable are reserved for the unique identifier variable, a unique number assigned to the accounting session which is preserved between relogs. The acct-session-id-count variable is used in addition to the existing 32-bit acct-session-id variable, RADIUS attribute 44, providing a total of 56 bits of to represent the actual Accounting Session Identifier (ID). Benefits of this feature include the following:

• The 8-bit unique identifier variable allows accounting session IDs to be identified if a reload occurs.

• The additional space provided by the acct-session-id-count variable can keep track of acct-session-id wrapping when there is a high volume of traffic, such as voice calls. By incrementing each time the acct-session-id variable wraps, the acct-session-id-count variable preserves accounting information.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for RADIUS Support of 56-Bit Acct Session-Id

AAA accounting must be configured. For more information about configuring AAA accounting, refer to the “Configuring Accounting” chapter in the Cisco IOS Security Configuration Guide.
Information About RADIUS Support of 56-Bit Acct Session-Id

Acct-Session-Id Attribute

RADIUS attribute 44, Accounting Session ID, is a unique accounting identifier that makes it easy to match start and stop records in a log file. Accounting session ID numbers restart at 1 each time the router is power-cycled or the software is reloaded. RADIUS attribute 44 is automatically enabled when AAA accounting is configured.

The acct-session-id variable is a 32-bit variable that can take on values from 00000000-FFFFFFFF.

Acct-Session-Id-Count Attribute

The new acct-session-id-count variable is a 32-bit variable. The first eight bits of the variable are reserved for the unique identifier variable, an identifier that allows the RADIUS server to identify an accounting session if a reload occurs. The remaining 24 bits of the acct-session-id-count variable acts as a counter variable. When the first acct-session-id variable is assigned, this counter variable is set to 1. The variable increments by 1 every time the acct-session-id variable wraps, preventing the loss of accounting information.

The acct-session-id-count variable can take on values from ##000000-##FFFFFF, where ## represents the eight bits that are reserved for the unique identifier variable.

The acct-session-id-count and acct-session-id variables are concatenated before being sent to the RADIUS server, resulting in the acct-session variable being represented as the following:

##000000 00000000-##FFFFFF FFFFFFFF

This allows a total of 56 bits to be used for acct-session-id space.

How to Configure RADIUS Support of 56-Bit Acct Session-Id

Configuring RADIUS Support of 56-Bit Acct Session-Id

This task enables the acct-session-id-count variable containing the unique identifier variable.

SUMMARY STEPS

1. enable
2. radius-server unique-ident  id

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

<table>
<thead>
<tr>
<th>Step 2</th>
<th>radius-server unique-ident  id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td>Router(config)# radius-server unique-ident 5</td>
</tr>
</tbody>
</table>

**Purpose**

Enables the acct-session-id-count variable containing the unique identifier variable.

- The *id* argument specifies the unique identifier represented by the first eight bits of the acct-session-id-count variable. Valid values range from 0 to 255.

---

### Configuration Examples for RADIUS Support of 56-Bit Acct Session-Id

#### Configuring RADIUS Support of 56-Bit Acct Session-Id Example

The following example configures AAA authentication, enables RADIUS attribute 44 in access request packets, and enables the acct-session-id-count variable and sets the unique identifier variable to 5:

```plaintext
aaa new-model
aaa authentication ppp default group radius
radius-server host 10.100.1.34
radius-server unique-ident 5
```

---

Feature Information for RADIUS Support of 56-Bit Acct Session-Id
CHAPTER 13

RADIUS Tunnel Preference for Load Balancing and Fail-Over

The RADIUS Tunnel Preference for Load Balancing and Fail-Over feature provides industry-standard load balancing and fail-over functionality for an Layer 2 Tunnel Protocol network server (LNS), rather than requiring the use of a Cisco proprietary Vendor Specific Attribute (VSA). The feature conforms to the tunnel attributes that are to be used in a multivendor network environment as defined in RFC 2868, thereby eliminating interoperability issues among network access servers (NASs) manufactured by different vendors.

Finding Feature Information, on page 123
Prerequisites, on page 123
Restrictions, on page 124
Information About RADIUS Tunnel Preference for Load Balancing and Fail-Over, on page 124
How RADIUS Tunnel Preference for Load Balancing and Fail-Over is Configured, on page 126
Configuration Example for RADIUS Tunnel Preference for Load Balancing and Fail-Over, on page 126
Additional References, on page 126
Feature Information for RADIUS Tunnel Preference for Load Balancing and Fail-Over, on page 127
Glossary, on page 128

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites

Configuring VPDNs and HGW groups is beyond the scope of this document. See the Related Document section for more information.
Restrictions

The following restrictions and limitations apply to the RADIUS Tunnel Preference for Load Balancing and Fail-Over feature:

- This feature does not support VPDN dial-out networks; it is designed only for dial-in applications.
- The maximum number of LNSs allowed in the network is 1550, which is 50 per tag attribute group and a limit of 31 tags.
- This feature requires a RADIUS server implementation to support RFC 2868.

Information About RADIUS Tunnel Preference for Load Balancing and Fail-Over

The RADIUS Tunnel Preference for Load Balancing and Fail-Over feature provides load balancing and fail-over virtual private dialup network (VPDN) home gateway (HGW) groups in a standardized fashion. This feature introduces new software functionality; no new command is associated with this feature.

Industry-Standard Rather Than Proprietary Attributes

Until Cisco IOS Release 12.2(4)T, load balancing and fail-over functionality for a LNS was provided by the Cisco proprietary VSA. In a multivendor network environment, using VSA on a RADIUS server can cause interoperability issues among NASs manufactured by different vendors. Even though some RADIUS server implementations can send VSAs that the requesting NAS can understand, the user still must maintain different VSAs for the same purpose in a single-service profile.

A consensus regarding the tunnel attributes that are to be used in a multivendor network environment is defined in RFC 2868. In RFC 2868, Tunnel-Server-Endpoint, in conjunction with the Tunnel-Medium-Type, specifies the address to which the NAS should initiate a new session. If multiple Tunnel-Server-Endpoint attributes are defined in one tagged attribute group, they are interpreted as equal-cost load-balancing HGWs.

The Tunnel-Preference attribute defined in RFC 2868 can be used as a measure to form load balancing and fail-over HGW groups. When the Tunnel-Preference values of different tagged attribute groups are the same, the Tunnel-Server-Endpoint of those attribute groups is considered to have the same priority unless otherwise specified. When the Tunnel-Preference values of some attribute groups are higher (they have a lower preference) than other attribute groups, their Tunnel-Server-Endpoint attributes will have higher priority values. When an attribute group has a higher priority value, that attribute group will be used for fail-over in case the attribute groups with lower priority values are unavailable for the connections.

Until Cisco IOS Release 12.2(4)T, a specially formatted string would be transported within a Cisco VSA “vpdn:ip-addresses” string to a NAS for the purpose of HGW load balancing and fail-over. For example, 10.0.0.1 10.0.0.2 10.0.0.3/2.0.0.1 2.0.0.2 would be interpreted as IP addresses 10.0.0.1, 10.0.0.2, and 10.0.0.3 for the first group for load balancing. New sessions are projected to these three addresses based on the least-load-first algorithm. This algorithm uses its local knowledge to select an HGW that has the least load to initiate the new session. In this example, the addresses 2.0.0.1 and 2.0.0.2 in the second group have a lower priority and are applicable only when all HGWs specified in the first group fail to respond to the new connection request, thereby making 2.0.0.1 and 2.0.0.2 the fail-over addresses. See the section Configuration Example
for RADIUS Tunnel Preference for Load Balancing and Fail-Over, on page 126 for an example of how to configure these fail-over addresses in a RADIUS tunnel profile.

### Load Balancing and Fail-Over in a Multivendor Network

The RADIUS Tunnel Preference for Load Balancing and Fail-Over feature was designed for large multivendor networks that use VPDN Layer 2 tunnels over WAN links such as ATM and Ethernet, such as the configuration shown in the figure below.

*Figure 2: Typical Load Balancing and Fail-Over in a Multivendor Network*

In the configuration shown in the figure above, the NAS uses tunnel profiles downloaded from the RADIUS server to establish VPDN Layer 2 tunnels for load balancing and fail-over. The Point-to-Point over Ethernet (PPPoE) protocol is used as the client to generate PPP sessions.

### Related Features and Technologies

The RADIUS Tunnel Preference for Load Balancing and Fail-Over feature is used in VPDNs. Additionally, familiarity with the following technologies and protocols is recommended:

- ATM
- Ethernet
- L2TP and L2F
- PPP and PPPoE
- RADIUS servers
How RADIUS Tunnel Preference for Load Balancing and Fail-Over is Configured

This feature has no new configuration commands; however, see the next section for an example of how to implement the RADIUS Tunnel Preference for Load Balancing and Fail-Over feature in a RADIUS tunnel profile.

Configuration Example for RADIUS Tunnel Preference for Load Balancing and Fail-Over

The following example shows how to create RADIUS tunnel profiles:

```
net3 Password = "cisco" Service-Type = Outbound
    Tunnel-Type = :0:L2TP,
    Tunnel-Medium-Type = :0:IP,
    Tunnel-Server-Endpoint = :0:"1.1.3.1",
    Tunnel-Assignment-Id = :0:"1",
    Tunnel-Preference = :0:1,
    Tunnel-Password = :0:"welcome"
    Tunnel-Type = :1:L2TP,
    Tunnel-Medium-Type = :1:IP,
    Tunnel-Server-Endpoint = :1:"1.1.5.1",
    Tunnel-Assignment-Id = :1:"1",
    Tunnel-Preference = :1:1,
    Tunnel-Password = :1:"welcome"
    Tunnel-Type = :2:L2TP,
    Tunnel-Medium-Type = :2:IP,
    Tunnel-Server-Endpoint = :2:"1.1.4.1",
    Tunnel-Assignment-Id = :2:"1",
    Tunnel-Preference = :2:1,
    Tunnel-Password = :2:"welcome"
    Tunnel-Type = :3:L2TP,
    Tunnel-Medium-Type = :3:IP,
    Tunnel-Server-Endpoint = :3:"1.1.6.1",
    Tunnel-Assignment-Id = :3:"1",
    Tunnel-Preference = :3:1,
    Tunnel-Password = :3:"welcome"
```

See Information About RADIUS Tunnel Preference for Load Balancing and Fail-Over, on page 124 for more information on how fail-over addresses are selected in these profiles.

Feature Information for RADIUS Tunnel Preference for Load Balancing and Fail-Over

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Glossary

HGW --home gateway. A gateway that terminates Layer 2 tunneling protocols such as L2TP.

home gateway --See HGW.

L2TP --Layer 2 Tunnel Protocol. An Internet Engineering Task Force (IETF) standards track protocol defined in RFC 2661 that provides tunneling of PPP. Based upon the best features of L2F and PPTP, L2TP provides an industry-wide interoperable method of implementing VPDN.

L2TP network server--See LNS.

Layer 2 Tunnel Protocol --See L2TP.

LNS --L2TP network server. A node that acts as one side of an L2TP tunnel endpoint and is a peer to the NAS or L2TP access concentrator (LAC). The LNS is the logical termination point of a PPP session that is being tunneled from the remote system by the access server. Analogous to the Layer 2 Forwarding (L2F) HGW.

NAS --network access server. Cisco platform or collection of platforms that interfaces between the packet world (the Internet, for example) and the circuit world (the public switched telephone network, for example).

network access server --See NAS.

Request for Comments --See RFCs.

RFCs --Request for Comments. A series of notes about the Internet collected by the Internet Engineering Task Force (IETF). Started in 1969, the IETF is a large open international community of network designers, operators, vendors, and researchers concerned with the evolution of the Internet architecture. RFCs define many aspects of computer communication, focusing on networking protocols, procedures, programs, and concepts.

virtual private dialup network --See VPDN.

VPDN --virtual private dialup network. Enables IP traffic to travel securely over a public TCP/IP network by encrypting all traffic from one network to another.

Any Internet Protocol (IP) addresses and phone numbers used in this document are not intended to be actual addresses and phone numbers. Any examples, command display output, network topology diagrams, and other figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses
or phone numbers in illustrative content is unintentional and coincidental. © 2001-2009 Cisco Systems, Inc. All rights reserved.
CHAPTER 14

RADIUS Server Reorder on Failure

The RADIUS Server Reorder on Failure feature provides for failover to another server in the server group during periods of high load or when server failure occurs. Subsequent to the failure, all RADIUS traffic is directed to the new server. Traffic is switched from the new server to another server in the server group only if the new server also fails. Traffic is not automatically switched back to the first server.

By spreading the RADIUS transactions across multiple servers, authentication and accounting requests are serviced more quickly.

- Finding Feature Information, on page 131
- Prerequisites for RADIUS Server Reorder on Failure, on page 131
- Restrictions for RADIUS Server Reorder on Failure, on page 132
- Information About RADIUS Server Reorder on Failure, on page 132
- How to Configure RADIUS Server Reorder on Failure, on page 133

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for RADIUS Server Reorder on Failure

- Before you can configure your RADIUS server to perform reorder on failure, you must enable authentication, authorization, and accounting (AAA) by using the aaa new-model command.
- You must also have RADIUS configured, for functions such as authentication, accounting, or static route download.
Restrictions for RADIUS Server Reorder on Failure

- An additional 4 bytes of memory is required per server group. However, because most server configurations have only a small number of server groups configured, the additional 4 bytes should have a minimal impact on performance.

- Some RADIUS features within the software set may not be capable of using this feature. If a RADIUS feature cannot use the RADIUS Server Reorder on Failure feature, your server behaves as though the reorder feature is not configured.

Information About RADIUS Server Reorder on Failure

RADIUS Server Failure

If the RADIUS Server Reorder on Failure feature is not configured and server failure occurs:

1. A new RADIUS transaction has to be performed.

2. A RADIUS packet for the transaction is sent to the first server in the group that is not marked dead (as per the configured deadtime) and is retransmitted for the configured number of retransmissions.

3. If all of those retransmits time out (as per the configured timeout), the router transmits the packet to the next nondead server in the list for the configured number of retransmissions.

4. Step 3 is repeated until the specified maximum number of transmissions per transaction have been made. If the end of the list is reached before the maximum number of transmissions has been reached, the router goes back to the beginning of the list and continue from there.

If at any time during this process, a server meets the dead-server detection criteria (not configurable; it varies depending on the version of software being used), the server is marked as dead for the configured deadtime.

How the RADIUS Server Reorder on Failure Feature Works

If you have configured the RADIUS Server Reorder on Failure feature, the decision about which RADIUS server to use as the initial server is as follows:

- The network access server (NAS) maintains the status of “flagged” server, which is the first server to which a transmission is sent.

- After the transmission is sent to the flagged server, the transmission is sent to the flagged server again for the configured number of retransmissions.

- The NAS then sequentially sends the transmission through the list of nondead servers in the server group, starting with the one listed after the flagged server, until the configured transaction maximum tries is reached or until a response is received.

- At boot time, the flagged server is the first server in the server group list as was established using the `radius-server host` command.
• If the flagged server is marked as dead (even if the dead time is zero), the first nondead server listed after
the flagged server becomes the flagged server.

• If the flagged server is the last server in the list, and it is marked as dead, the flagged server becomes the
first server in the list that is not marked as dead.

• If all servers are marked as dead, the transaction fails, and no change is made to the flagged server.

• If the flagged server is marked as dead, and the dead timer expires, nothing happens.

Note
Some types of transmissions (for example, Challenge Handshake Authentication Protocol [CHAP], Microsoft
CHAP [MS-CHAP], and Extensible Authentication Protocol [EAP]) require multiple roundtrips to a single
server. For these special transactions, the entire sequence of roundtrips to the server are treated as though they
were one transmission.

When RADIUS Servers Are Dead

A server can be marked as dead if the criteria in 1 and 2 are met:

1. The server has not responded to at least the configured number of retransmissions as specified by the
radius-server transaction max-tries command.

2. The server has not responded to any request for at least the configured timeout. The server is marked dead
only if both criteria (this and the one listed above) are met. The marking of a server as dead, even if the
dead time is zero, is significant for the RADIUS server retry method reorder system.

How to Configure RADIUS Server Reorder on Failure

Configuring a RADIUS Server to Reorder on Failure

Perform this task to configure a server in a server group to direct traffic to another server in the server group
when the first server fails.

SUMMARY STEPS

1. enable
2. configure terminal
3. aaa new-model
4. radius-server retry method reorder
5. radius-server retransmit {retries}
6. radius-server transaction max-tries { number }
7. radius-server host {hostname | ip-address} [key string]
8. radius-server host {hostname | ip-address} [key string]
### DETAILED STEPS

## Monitoring RADIUS Server Reorder on Failure

To monitor the server-reorder-on-failure process on your router, use the following commands:

### SUMMARY STEPS

1. `enable`
2. `debug aaa sg-server selection`
3. `debug radius`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**

   **enable**

   **Example:**

   `Router> enable`

   Enables privileged EXEC mode.

   - Enter your password if prompted.

| **Step 2**

   **debug aaa sg-server selection**

   **Example:**

   `Router# debug aaa sg-server selection`

   Displays information about why the RADIUS and TACAC+ server group system in the router is choosing a particular server.

| **Step 3**

   **debug radius**

   **Example:**

   `Router# debug radius`

   Displays information about why the router is choosing a particular RADIUS server.

---

### Example

#### Debug 1

#### Debug 2

The following two debug outputs display the behavior of the RADIUS Server Reorder on Failure feature:

In the following sample output, the RADIUS Server Reorder on Failure feature is configured. The server retransmits are set to 0 (so each server is tried just one time before failover to the next configured server), and the transmissions per transaction are set to 4 (the transmissions stop on the third failover). The third server in the server group (10.107.164.118) has accepted the transaction on the third transmission (second failover).
In the following sample output, the RADIUS Server Reorder on Failure feature is configured. The server retransmits are set to 0, and the transmissions per transaction are set to 8. In this transaction, the transmission to server 10.10.10.0 has failed on the eighth transmission.
Configuration Examples for RADIUS Server Reorder on Failure

Configuring a RADIUS Server to Reorder on Failure Example

The following configuration example shows that a RADIUS server is configured to reorder on failure. The maximum number of transmissions per transaction that may be retried on the RADIUS server is six.

```conf
aaa new-model
radius-server retry method reorder
radius-server retransmit 0
radius-server transaction max-tries 6
radius-server host 10.2.3.4 key rad123
radius-server host 10.5.6.7 key rad123
```

Determining Transmission Order When RADIUS Servers Are Dead

If at boot time you have configured the following:

```conf
aaa new-model
radius-server retry method reorder
radius-server retransmit 0
radius-server transaction max-tries 6
radius-server host 10.2.3.4
radius-server host 10.5.6.7
```

and both servers are down, but not yet marked dead, for the first transaction you would see the transmissions as follows:

```
10.2.3.4
10.5.6.7
10.2.3.4
10.5.6.7
10.2.3.4
10.5.6.7
```

If you configure the reorder as follows:
aaa new-model
radius-server retry method reorder
radius-server retransmit 1
radius-server transaction max-tries 3
radius-server host 10.2.3.4
radius-server host 10.4.5.6

and both RADIUS servers are not responding to RADIUS packets but are not yet marked dead (as after the NAS boots), the transmissions for the first transaction are as follows:

10.2.3.4
10.2.3.4
10.4.5.6

Subsequent transactions may be transmitted according to a different pattern. The transmissions depend on whether the criteria for marking one (or both) servers as dead have been met, and as per the server flagging pattern already described.

If you configure the reorder as follows:

aaa new-model
radius-server retry method reorder
radius-server retransmit 1
radius-server max-tries-per-transaction 8
radius-server host 10.1.1.1
radius-server host 10.2.2.2
radius-server host 10.3.3.3
radius-server timeout 3

And the RADIUS server 10.1.1.1 is not responding to RADIUS packets but is not yet marked as dead, and the remaining two RADIUS servers are live, you see the following:

For the first transaction:

10.1.1.1
10.1.1.1
10.2.2.2

For any additional transaction initiated for any transmissions before the server is marked as dead:

10.1.1.1
10.1.1.1
10.2.2.2

For transactions initiated thereafter:

10.2.2.2

If servers 10.2.2.2 and 10.3.3.3 then go down as well, you see the following transmissions until servers 10.2.2.2 and 10.3.3.3 meet the criteria for being marked as dead:

10.2.2.2
10.2.2.2
10.3.3.3
10.3.3.3
10.1.1.1
10.1.1.1
10.2.2.2
10.2.2.2
The above is followed by the failure of the transmission and by the next method in the method list being used (if any).

If servers 10.2.2.2 and 10.3.3.3 go down but server 10.1.1.1 comes up at the same time, you see the following:

10.2.2.2
10.2.2.2
10.3.3.3
10.3.3.3
10.1.1.1

When servers 10.2.2.2 and 10.3.3.3 are then marked as dead, you see the following:

10.1.1.1

CHAPTER 15

RADIUS Interim Update at Call Connect

The RADIUS Interim Update at Call Connect feature generates an additional accounting record that provides the call connection timestamp for the billing server.

- Finding Feature Information, on page 141
- Information About RADIUS Interim Update at Call Connect, on page 141
- How to Enable RADIUS Interim Update at Call Connect Feature, on page 141
- Additional References, on page 142
- Feature Information for RADIUS Interim Update at Call Connect, on page 143

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About RADIUS Interim Update at Call Connect

When the RADIUS Interim Update at Call Connect feature enabled, Cisco IOS software generates and sends an additional updated interim accounting record to the accounting server when a call leg is connected. A call leg is a distinct segment of a call connection in a voice over IP (VOIP) network that is a logical connection between the router and either a telephony endpoint over a bearer channel, or another endpoint using a session protocol. All attributes (for example, h323-connect-time and backward-call-indicators) available at the time of call connection are sent through this interim updated accounting record.

How to Enable RADIUS Interim Update at Call Connect Feature

Perform the following task to enable the Cisco IOS to generate and send an additional updated interim accounting record to the accounting server when a call leg is connected.
SUMMARY STEPS

1. enable
2. configure terminal
3. aaa new-model
4. gw-accounting aaa
5. aaa accounting update newinfo

### Feature Information for RADIUS Interim Update at Call Connect

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.
Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

CHAPTER 16

RADIUS EAP Support

The RADIUS EAP Support feature makes it possible for users to apply the client authentication methods within PPP (including proprietary authentication), which may not be supported by the network access server (NAS); to be accomplished through the Extensible Authentication Protocol (EAP). Before this feature was introduced, support for various authentication methods for PPP connections required custom vendor-specific configuration and changes to the client and NAS. RADIUS EAP support allows authentication schemes, such as token cards and public key, to strengthen end-user and device authenticated access to their networks.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for RADIUS EAP Support

Before enabling EAP RADIUS on the client, you must perform the following tasks:

• Configure an interface type and enter interface configuration mode by using the interface command.
• Configure the interface for PPP encapsulation by using the encapsulation command.
For more information on completing these tasks, refer to the “Configuring Asynchronous SLIP and PPP” module.

Restrictions for RADIUS EAP Support

When EAP is running in proxy mode, there may be a significant increase in the authentication time because every packet from the peer must be sent to the RADIUS server and every EAP packet from the RADIUS server must be sent back to the client. Although this extra processing causes delays, you can increase the default authentication timeout value by using the `ppp timeout authentication` command.

Information About RADIUS EAP Support

EAP is an authentication protocol for PPP that supports multiple authentication mechanisms that are negotiated during the authentication phase (instead of the link control protocol [LCP] phase). EAP allows a third-party authentication server to interact with a PPP implementation through a generic interface.

How EAP Works

By default, EAP runs in proxy mode. This means that EAP allows the entire authentication process to be negotiated by the NAS to a back-end server that may reside on or be accessed through a RADIUS server. After EAP is negotiated between the client and the NAS during LCP exchange, all further authentication messages are transparently transmitted between the client and the back-end server. The NAS is no longer directly involved in the authentication process; that is, the NAS works as a proxy, sending EAP messages between the remote peers.

Note

EAP can also run in a local mode; the session is authenticated using the Message Digest 5 (MD5) algorithm and obeys the same authentication rules as Challenge Handshake Authentication Protocol (CHAP). To disable proxy mode and authenticate locally, you must use the `ppp eap local` command.

Newly Supported Attributes

The RADIUS EAP Support feature introduces support for the following RADIUS attributes:

<table>
<thead>
<tr>
<th>Number</th>
<th>IETF Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>79</td>
<td>EAP-Message</td>
<td>Encapsulates one fragment of an EAP message, which includes the PPP type, request-id, length, and EAP-type fields.</td>
</tr>
<tr>
<td>80</td>
<td>Message Authenticator</td>
<td>Ensures source integrity of the message; all messages that are received with invalid checksums are silently discarded by either end. This attribute contains an HMAC-MD5 checksum of the entire RADIUS request or response message and uses the RADIUS server secret as the key.</td>
</tr>
</tbody>
</table>
How to Configure RADIUS EAP Support

Configuring EAP

Perform this task to configure EAP on an interface configured for PPP encapsulation.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ppp authentication eap
4. ppp eap identity *string*
5. ppp eap password *number* *string*
6. ppp eap local
7. ppp eap wait
8. ppp eap refuse *callin*

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>

<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>ppp authentication eap</td>
<td>Enables EAP as the authentication protocol.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config-if)# ppp authentication eap</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>ppp eap identity <em>string</em></td>
<td>(Optional) Specifies the EAP identity when requested by the peer.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config-if)# ppp eap identity user</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>ppp eap password <em>number</em> <em>string</em></td>
<td>(Optional) Sets the EAP password for peer authentication. This command should only be configured on the client.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config-if)# ppp eap password 7 141B1309</td>
<td></td>
</tr>
</tbody>
</table>
### Verifying EAP

To verify EAP configurations on your client or NAS, use at least one of the following commands in privileged EXEC configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router# show users</td>
<td>Displays information about the active lines on the router.</td>
</tr>
<tr>
<td>Router# show interfaces</td>
<td>Displays statistics for all interfaces configured on the router or access server.</td>
</tr>
<tr>
<td>Router# show running-config</td>
<td>Ensures that your configurations appear as part of the running configuration.</td>
</tr>
</tbody>
</table>

### Configuration Examples

#### EAP Local Configuration on Client Example

The following example is a sample configuration for a client configured for EAP:

```plaintext
interface Ethernet0/0
  ip address 10.1.1.202 255.255.255.0
  no ip mroute-cache
  half-duplex
!
interface BRI0/0
```
ip address 192.168.101.100 255.255.255.0
encapsulation ppp
no ip mroute-cache
dialer map ip 192.168.101.101 56167
dialer-group 1
isdn switch-type basic-5ess
ppp eap identity user
ppp eap password 7 141B1309
!
ip default-gateway 10.1.1.1
ip classless
ip route 192.168.101.101 255.255.255.255 BRI0/0

### Glossary

**attribute** -- A RADIUS Internet Engineering Task Force (IETF) attribute is one of the original set of 255 standard attributes that are used to communicate authentication, authorization, and accounting (AAA) information between a client and a server. Because IETF attributes are standard, the attribute data is predefined and well known; thus all clients and servers that exchange AAA information through IETF attributes must agree on attribute data such as the exact meaning of the attributes and the general bounds of the values for each attribute.

**CHAP** -- Challenge Handshake Authentication Protocol. Security feature that is supported on lines using PPP encapsulation and prevents unauthorized access. CHAP does not itself prevent unauthorized access; it merely identifies the remote end. The router or access server then determines whether that user is allowed access.

**EAP** -- Extensible Authentication Protocol. A PPP authentication protocol that supports multiple authentication mechanisms that are negotiated during the authentication phase (instead of the Link Control Protocol [LCP] phase). EAP allows a third-party authentication server to interact with the PPP implementation through a generic interface.

**LCP** -- link control protocol. Protocol that establishes, configures, and tests data-link connections for use by PPP.

**MD5 (HMAC variant)** -- Message Digest 5. A hash algorithm used to authenticate packet data. HMAC is a key hashing for message authentication.

**NAS** -- network access server. A device providing local network access to users across a remote access network such as the public switched telephone network (PSTN).

**PAP** -- Password Authentication Protocol. Authentication protocol that allows PPP peers to authenticate one another. The remote router attempting to connect to the local router is required to send an authentication request. Unlike CHAP, PAP passes the password and host name or username in the clear (unencrypted). PAP
does not itself prevent unauthorized access; it merely identifies the remote end. The router or access server then determines if that user is allowed access. PAP is supported only on PPP lines.

**PPP** --Point-to-Point Protocol. A protocol that encapsulates network layer protocol information over point-to-point links. PPP is defined in RFC 1661.

**RADIUS** --Remote Authentication Dial-In User Service. Database for authenticating modem and ISDN connections and for tracking connection time.

Any Internet Protocol (IP) addresses and phone numbers used in this document are not intended to be actual addresses and phone numbers. RADIUS Separate Retransmit Counter for Accounting

The RADIUS: Separate Retransmit Counter for Accounting feature allows users to configure an exponential backoff retransmit. That is, after the normally configured retransmission retries have been used, the router continues trying with an interval that doubles on each retransmission failure until a configured maximum interval is reached. This functionality allows users to retransmit accounting requests for many hours without overloading the RADIUS server when it does come back up.

- Finding Feature Information, on page 155
- Restrictions for RADIUS Separate Retransmit Counter for Accounting, on page 155
- Information About RADIUS Separate Retransmit Counter for Accounting, on page 156
- How to Configure RADIUS Separate Retransmit Counter for Accounting, on page 156
- Configuration Examples for RADIUS Separate Retransmit Counter for Accounting, on page 159
- Additional References, on page 160
- Feature Information for RADIUS Separate Retransmit Counter for Accounting, on page 161

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for RADIUS Separate Retransmit Counter for Accounting

The following tasks result in excessive memory consumption on the router:

- Configuring this feature on a router with a high call rate.
Information About RADIUS Separate Retransmit Counter for Accounting

In many environments, a single RADIUS server is used for authentication and accounting. Whenever this server is down for approximately 24 hours, the accounting records of users already on the router are lost after authentication, authorization, and accounting (AAA) does all the retransmissions. Before the introduction of this feature, the retransmissions could be configured for a maximum of 100 retries and the timeout could be configured for 1,000 seconds. Although these configurations keep the accounting records on the router for 24 hours, a timeout of 1,000 seconds is unreasonable, causing problems when the RADIUS server cannot be reached due to network congestion.

The RADIUS: Separate Retransmit Counter for Accounting feature allows users to configure an exponential backoff retransmit. That is, after the normally configured retransmission retries have been used, the router continues trying with an interval that doubles on each retransmission failure until a configured maximum interval is reached. This functionality allows users to retransmit accounting requests for many hours without overloading the RADIUS server when it does come back up.

This feature can be configured globally (through the `radius-server backoff exponential` command), per server (through the `radius-server host` command), or per group (through the `backoff exponential` command).

Benefits

With this feature, users can extend the time in which the RADIUS client (the router) sends accounting requests to the RADIUS server in the event that the RADIUS server or the connection to the server is down and there is no accounting response confirmation. This functionality enables accounting records to remain on the router for up to 24 hours.

How to Configure RADIUS Separate Retransmit Counter for Accounting

Configuring a Retransmit Counter for Accounting Globally or per RADIUS Host

To configure exponential backoffs of RADIUS retransmits over an extended period of time on a global basis and per RADIUS host, perform the following steps:

**SUMMARY STEPS**

1. enable
2. configure terminal
DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable&lt;br&gt;Example: Router&gt; enable</td>
<td>Enters privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal&lt;br&gt;Example: Router# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Router(config)# radius-server backoff exponential [max-delay minutes] [backoff-retry retransmits]&lt;br&gt;Example: Router (config)# radius-server backoff exponential max-delay 60 backoff-retry 32</td>
<td>Configures the router for exponential backoff retransmit of accounting requests.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Router(config)# radius-server host {hostname</td>
<td>ip-address} [test username user-name] [auth-port port-number] [ignore-auth-port] [acct-port port-number] [ignore-acct-port] [timeout seconds] [retransmit retries] [key string] [alias {hostname</td>
</tr>
</tbody>
</table>

Configuring a Retransmit Counter for Accounting per RADIUS Server Group

To configure exponential backoffs of RADIUS retransmits over an extended period of time per RADIUS server group, perform the following steps:

SUMMARY STEPS

1. enable
2. configure terminal
3. Router(config)# aaa group server radius group-name
4. Router(config -sg-radius)# backoff exponential max-delay minutes] [backoff-retry retransmits

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**        | Enters privileged EXEC mode.  
| enable            | • Enter your password if prompted. |
| Example:          |  
| Router> enable    | |
| **Step 2**        | Enters global configuration mode. |
| configure terminal|  
| Example:          |  
| Router (config)# configure terminal | |
| **Step 3**        | Groups different RADIUS server hosts into distinct lists and distinct methods and enters server-group RADIUS configuration mode. |
| Router(config)# aaa group server radius group-name | |
| **Step 4**        | Configures the router for exponential backoff retransmit of accounting requests per RADIUS server group. |
| Router(config -sg-radius)# backoff exponential max-delay minutes] [backoff-retry retransmits | |

Verifying Retransmit Configurations

To verify feature functionality, use any of the following EXEC commands:

**SUMMARY STEPS**

1. enable
2. debug radius
3. show accounting
4. show radius statistics

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**        | Enters privileged EXEC mode.  
| enable            | • Enter your password if prompted. |
| Example:          |  
| Router> enable    | |
| **Step 2**        | Displays information associated with RADIUS. |
| debug radius      |  
| Example:          |  
| Router# debug radius | |
### Command or Action

| Step 3 | show accounting
| Example: |
| Router# show accounting |

| Purpose |
| Displays all active sessions and prints all the accounting records for actively accounted functions. |

| Step 4 | show radius statistics
| Example: |
| Router# show radius statistics |

| Purpose |
| Displays the RADIUS statistics for accounting packets. |

## Configuration Examples for RADIUS Separate Retransmit Counter for Accounting

### Retransmit Counter for Accounting Comprehensive Configuration Example

The following example shows how to configure your router for exponential backoff retransmit of accounting requests. In this example, an exponential backoff is configured globally (through the `radius-server backoff exponential` command) and for the RADIUS server host “172.107.164.206” (through the `radius-server host` command).

```plaintext
aaa new-model
aaa authentication login default group radius
aaa authentication ppp default group radius
aaa authorization exec default group radius
aaa authorization network default group radius
aaa accounting send stop-record authentication failure
aaa accounting update periodic 1
aaa accounting network default start-stop group radius
!
interface BRI1/0
 ip address 10.0.0.2 255.0.0.0
 encapsulation ppp
 no ip mroute-cache
dialer idle-timeout 0
dialer-group 1
 isdn switch-type basic-5ess
!
radius-server host 172.107.164.206 auth-port 1645 acct-port 1646 backoff exponential max-delay 60 backoff-retry 32
radius-server backoff exponential max-delay 60 backoff-retry 32
radius-server retransmit 3
radius-server key rad123
end
```

### Per-Server Configuration Example

The following example shows how to enable exponential backoff retransmits on a per-server basis. In this example, assume that the retransmit is configured for 3 retries and the timeout is configured for 5 seconds;
that is, the RADIUS request is transmitted 3 times with a delay of 5 seconds. Thereafter, the router continues
to retransmit RADIUS requests with a delayed interval that doubles each time until 32 retries have been
achieved. The router stops doubling the retransmit intervals after the interval surpasses the configured 60
minutes; it transmits every 60 minutes.

radius-server host foo.xyz.com backoff exponential max-delay 60 backoff-retry 32

After enabling this command, the retransmits are sent as follows (“t” equals seconds):

<table>
<thead>
<tr>
<th>t</th>
<th>req sent</th>
<th>retrans 1</th>
<th>retrans 2</th>
<th>retrans 3</th>
<th>retrans 4</th>
<th>retrans 5</th>
<th>retrans 6</th>
<th>retrans 7</th>
<th>retrans 8</th>
<th>retrans 9</th>
<th>retrans 10</th>
<th>retrans 11</th>
<th>retrans 12</th>
<th>retrans 13</th>
<th>retrans 14 till retransmit 35</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>req sent</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>8725 retrans 13 (The interval has stabilized to 60 minutes here).</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>retrans 1</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>12325 retrans 14 till retransmit 35</td>
<td></td>
</tr>
</tbody>
</table>

After all the retransmits are sent, the RADIUS request follows the same path that it would when all the normal retransmits are done.

Feature Information for RADIUS Separate Retransmit Counter for Accounting

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.
Table 21: Feature Information for RADIUS: Separate Retransmit Counter for Accounting

<tr>
<td>RADIUS: Separate Retransmit Counter</td>
<td>12.2(15)B</td>
<td>The RADIUS: Separate Retransmit Counter for Accounting feature allows users to configure an exponential backoff retransmit. That is, after the normally configured retransmission retries have been used, the router continues trying with an interval that doubles on each retransmission failure until a configured maximum interval is reached. This functionality allows users to retransmit accounting requests for many hours without overloading the RADIUS server when it does come back up.</td>
