Configuring SIP QoS Features

This chapter discusses the following features that affect quality of service (QoS) in SIP networks:

- Enhanced Codec Support for SIP Using Dynamic Payloads
- Measurement-Based Call Admission Control for SIP
- SIP Gateway Support of RSVP
- SIP Gateway Support of ‘tel’ URL
- SIP: Hold Timer Support
- SIP Media Inactivity Timer
- SIP Stack Portability

This feature is described in “Configuring SIP Message, Timer, and Response Features”.

### Finding Support Information for Platforms and Cisco Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to [http://www.cisco.com/go/cfn](http://www.cisco.com/go/cfn). An account on Cisco.com is not required.

- Prerequisites for SIP QoS, on page 3
- Restrictions for SIP QoS, on page 4
- Information About SIP QoS, on page 4
- How to Configure SIP QoS Features, on page 17
- Configuration Examples for SIP QoS Features, on page 49
- Additional References, on page 58
Prerequisites for SIP QoS

Measurement-Based Call Admission Control for SIP Feature

- By default, gateways support reliable provisional responses. That is, no additional configuration tasks are necessary to enable reliable provisional responses.

Note
For information on configuring reliable provisional responses including enabling the feature again if it was disabled, see SIP Gateway Support of RSVP and TEL URL.

- Configure a basic VoIP network.
- Enable Service Assurance Agent (SAA) Responder on the originating and terminating gateway.

Note
For information on configuring Service Assurance Agent, see Network Monitoring Using Cisco Service Assurance Agent.

Note
For information about configuring VoIP, see Cisco IOS Voice, Video, and Fax Configuration Guide, Release 12.2. For information about configuring reliable provisional responses including reenabling the feature if it was disabled, see SIP Gateway Support of RSVP and TEL URL. For information about configuring Service Assurance Agent, see "Network Monitoring Using Cisco Service Assurance Agent".

SIP Gateway Support of RSVP and SIP Gateway Support of ‘tel’ URL Features

- Enable RSVP on the appropriate gateway interfaces by using the `ip rsvp bandwidth` command.

Note
For details on the command, see the Cisco IOS Quality of Service Solutions Command Reference, Release 12.3.

- Enable weighted fair queuing (WFQ) on these interfaces by using the `fair-queue` command. This ensures that the voice packets get priority over the interface.

Note
For details on the command, see the Cisco IOS Quality of Service Solutions Command Reference, Release 12.3. For an example, see "SIP Gateway Support of RSVP and TEL URL Example".

- Set the desired and acceptable quality of service (QoS) levels in your dial peers by using the `req-qos` and `acc-qos` dial-peer configuration commands.
Bandwidth reservation is not attempted unless the desired QoS for the associated dial peer is set to controlled-load or guaranteed-delay. If the desired QoS level is set to the default of best-effort, bandwidth reservation is not attempted. With the req-qos command, synchronized RSVP is attempted for a SIP call as long as the desired (requested) QoS for the associated dial peer is set to controlled-load or guaranteed-delay.

Note

For details on the commands, see the Cisco IOS Voice Command Reference, Release 12.3. For an example, see "SIP Gateway Support of RSVP and TEL URL Example".

Restrictions for SIP QoS

Enhanced Codec Support for SIP Using Dynamic Payloads Feature

Measurement-Based Call Admission Control for SIP Feature

• When detecting network congestion, the PSTN fallback feature does not affect an existing call; it affects only subsequent calls.
• Only a single calculated planning impairment factor (ICPIF) delay or loss value is allowed per system.
• A small additional call setup delay can be expected for the first call to a new IP destination.
• The Service Assurance Agent Responder feature, a network congestion analysis mechanism, cannot be configured for non-Cisco devices.

SIP Gateway Support of RSVP and SIP Gateway Support of "tel" URL Features

• Bandwidth reservation (QoS) is not supported for Session Description Protocol (SDP) changes between 183 Session Progress/180 Alerting and 200 OK responses.
• Bandwidth reservation (QoS) is not attempted if the desired QoS level is set to the default of best-effort. The desired QoS for the associated dial peer must be set to controlled-load or guaranteed-delay.
• Distributed Call Signaling (DCS) headers and extensions are not supported.
• SIP gateways do not support codecs other than those listed in the SIP codec table listed in "Additional Codec Support". When an unsupported codec is selected during configuration of the dial peers, the action taken depends on the selected gateway:
  • If on the originating gateway, an appropriate SIP debug trace is presented, indicating the failure to originate the SIP call leg.
  • If on the terminating gateway, an appropriate SIP response (4xx) with a warning indicating incompatible media types is sent.

Information About SIP QoS

To configure SIP QoS features, you should understand the following concepts:
Enhanced Codec Support for SIP Using Dynamic Payloads

The Enhanced Codec Support for SIP Using Dynamic Payloads feature enhances codec selection and payload negotiation between originating and terminating SIP gateways.

This feature offers the following benefits:

- Expanded dynamic payload support on Cisco IOS gateways, resulting in enhanced bandwidth control
- Expanded ability to advertise and negotiate all codecs available on a given platform
- Expanded interoperability and interconnectivity between gateways, applications, and services in the network

The feature provides the SIP enhancements described in the following sections:

Additional Codec Support

Codecs are a digital signal processor (DSP) software algorithm used to compress or decompress speech or audio signals. Previous implementations of the SIP stack on Cisco IOS gateways supported only a subset of the available codecs for each platform.

Support for codecs varies on different platforms. See the table below for a listing of SIP codec support by platform. Use the codec ? command to determine the codecs available on a specific platform.

Payload Type Selection

Payload types define the content and format of Real-Time Transport Protocol (RTP) packets and the resulting stream of data generated by the RTP flow. The payload type defines the codec in use and is identified in the payload type field of the header of each RTP packet. There are two mechanisms for specifying payload type, static and dynamic.

Static payload types are assigned to specific RTP formats by RFC 1890 and these mappings are registered with the Internet Assigned Numbers Authority (IANA). Although not required, static payload types can also be mapped to RTP encodings using the rtpmap attribute. The following SIP-supported codecs have static payload values defined by the IANA:

• G711ulaw
• G711alaw
• G723r63
• G726r32
• G728
• G729r8
• GSM-FR

Dynamic payload values are used for codecs that do not have static payload values defined. Dynamic payload types do not have fixed mappings, and must be mapped to RTP encodings within the Session Description Protocol (SDP) itself using the a=rtpmap: line. The feature allows dynamic payload values to be used for the following codecs with no static payload values defined:

• Clear-channel
• G726r16
• G726r24
• GSM-EFR

Of the four codecs listed that allow dynamic payload values to be assigned, only the payload type for the clear-channel codec can be configured using the command-line interface (CLI). The remaining G.726r16, G.726r24 and GSM-EFR codecs are selected on a per-call basis by the SIP subsystem. The dynamic payload range is assigned by the IANA, with values from 96 to 127. The SIP subsystem looks for and uses the first value in the range that is both available and not reserved for Cisco IOS applications. Once a dynamic payload value is picked for a particular payload type, it cannot be used for other payload types. Of the 32 available IANA values, those reserved for special Cisco IOS applications are listed in the table below. To configure dynamic payload values for the payload types listed in the table, use the rtp payload-type command; otherwise the default values for the payload types are used.
Table 2: Default Dynamic Payload Values

</tbody>
</table>

After a dynamic payload value has been assigned from the reserved range, it cannot be used for any other payload types.

Advertising Codec Capabilities

The dynamic payload value selected by the SIP subsystem is advertised in the outgoing SIP INVITE request. The Enhanced Codec Support for SIP Using Dynamic Payloads feature supports dynamic payloads by expanding the SIP subsystem ability to advertise and negotiate available codecs. SIP uses the connection, media, and attribute fields of the SDP message during connection negotiation.

The feature supports the following Internet Engineering Task Force (IETF) drafts:

- draft-ietf-avt-rtp-mime-06.txt, MIME Type Registration of RTP Payload Formats (further developed and later published as RFC 3555).
- draft-ietf-avt-profile-new-12.txt, RTP Profile for Audio and Video Conferences with Minimal Control (further developed and later published as RFC 3551).

The following sample SIP INVITE message shows the payload value and codec selection resulting from the payload negotiation process. The media m= field includes the added payload value. The attribute a= field includes the selected codec. In this outgoing INVITE message, the first available dynamic payload value of 115 is selected by the SIP subsystem for a GSM-EFR codec.

```
INVITE sip:36602@172.18.193.120:5060;user=phone SIP/2.0

```

Configuring SIP QoS Features
G723 Codec Versions

In addition to the previously supported G.723r63 version of the G.723 codec, the feature supports the following versions:

- G723r53, where the number 53 indicates the bit rate of 5.3 kbps
- G723ar53, where the letter a indicates support for Annex A, which specifies voice activity detection (VAD)
- G723ar63, where the number 63 indicates a bit rate of 6.3 kbps

A static payload value of 4 is used for all versions of the G.723 codec.

Expanded codec support allows the originating and terminating gateways to advertise and negotiate additional codec capabilities. Cisco implements support for multiple G.723 codec versions by using a=fmtp and a=rtpmap attributes in the SDP body of outgoing INVITE requests to define the G.723 codec version. For the G.723 codec, the value of a=fmtp is 4 (the IANA assigned static value), and the annexa value is either yes or no. The default for annexa is yes.

The table below lists the possible codec configurations, that, taken together with Annex A support at the remote end, result in selecting the negotiated codec.

**Table 3: G723 Codcs**

<table>
<thead>
<tr>
<th>Configured Codec(s)</th>

m=audio 62986 RTP/AVP 4
a=rtpmap:4 G723/8000
a=fmtp:4 annexa=yes

G729 Codec Versions

The feature supports the following versions of G.729 codecs:

- G729r8, where r8 indicates the bit rate of 8 kbps
- G729br8, where b indicates support for Annex B, which specifies VAD, Discontinuity Transmission (DTX), and Comfort Noise generation (CNG).

A static payload value of 18 is used for all versions of the G.729 codec.

Cisco implements support for multiple G.729 codec versions by using a=fmtp and a=rtpmap attributes in the SDP body of outgoing INVITE requests. For the G.729 codec, the value of a=fmtp is 18 (the IANA assigned static value), and the annexb value is either yes or no. The default for annexb is yes.

The table below lists the possible codec configuration that, taken together with Annex B support at the remote end, result in selecting the negotiated codec.

<table>
<thead>
<tr>
<th>Configured Codec(s)</th>

</table>

The following partial SDP body shows the media m= field and attribute a= field for a gateway with G.729 codecs and Annex B specified:

m=audio 17928 RTP/AVP 18
**Measurement-Based Call Admission Control for SIP**

The Measurement-Based Call Admission Control for SIP feature implements support within SIP to monitor IP network capacity and reject or redirect calls based on congestion detection.

Feature benefits include the following:

- **PSTN fallback**
  - Automatically routes a call to an alternate destination when the data network is congested at the time of call setup, thereby enabling higher call completion rates.
  - Enables the service provider to give a reasonable guarantee about the quality of the conversation to VoIP users at the time of call admission.
  - PSTN fallback provides network congestion measurement, including delay, jitter, and packet loss information for the configured IP addresses.
  - A new call need not wait for probe results before being admitted, thereby minimizing delays.

- **Call admission control**
  - Configurable call treatment allows the Internet service provider (ISP) the flexibility to configure how the call will be treated when local resources to process the call are not available.
  - Resource unavailable signaling allows you to automatically busy out channels when local resources are not available to handle the call.
  - User-selected thresholds allow you the flexibility to configure thresholds to determine resource availability.

The Measurement-Based Call Admission Control for SIP feature does the following:

- Verifies that adequate resources are available to carry a successful VoIP session.
- Implements a mechanism to prevent calls arriving from the IP network from entering the gateway when required resources are not available to process the call.
- Supports measurement-based call admission control (CAC) processes.

Before the CAC feature was developed, gateways did not have a mechanism to check for IP network congestion and resource unavailability. Although quality of service (QoS) mechanisms provide a level of low latency and guaranteed delivery that is required for voice traffic, CAC mechanisms are intended to extend the capabilities of QoS to protect voice traffic from being negatively affected by other voice traffic. CAC is used to gracefully deny network access under congestion conditions and provide alternative call rerouting to prevent dropped or delayed calls. There are a variety of CAC mechanisms, including the following:

- **Measurement-based CAC**, which uses probes to look ahead into the packet network to gauge the state of the network to determine whether to allow a new call.
- **Resource-based CAC**, which calculates resources needed for the call, determines their availability, and reserves those resources.

The Cisco IOS VoiceXML feature provides an alternative to Resource Reservation Protocol (RSVP) for VoIP service providers that do not deploy RSVP.
The new feature implements measurement-based CAC using the mechanisms described in the following sections:

**Service Assurance Agents**

Service Assurance Agents (SAA) is a generic network management feature that provides a mechanism for network congestion analysis. SAA determine latency, delay, and jitter and provides real-time ICPIF calculations before establishing a call across an IP infrastructure. The SAA Responder feature uses SAA probes to traverse the network to a given IP destination and measure the loss and delay characteristics of the network along the path traveled. These values are returned to the outgoing gateway to use in making a decision on the condition of the network and its ability to carry a call. Threshold values for rejecting a call are configured at the outgoing gateway (see "PSTN_Fallback").

Each probe consists of multiple packets, a configurable parameter of this feature. SAA packets emulate voice packets and receive the same priority as voice throughout the entire network. The delay, loss, and ICPIF values entered into the cache for the IP destination are averaged from all the responses. If the call uses G.729 and G.711 codecs, the probe packet sizes mimic those of a voice packet for that codec. Other codecs use G.711-like probes. In Cisco IOS software releases later than Release 12.1(3)T, other codec choices may also be supported with their own specific probes.

The IP precedence of the probe packets can also be configured to simulate the priority of a voice packet more closely. This parameter should be set equal to the IP precedence used for other voice media packets in the network.

SAA probes used for CAC go out randomly on ports selected from within the top end of the audio User Datagram Protocol (UDP) defined port range (16384 to 32767). Probes use a packet size based on the codec the call will use. IP precedence can be set if desired, and a full Realtime Transport Protocol (RTP), UDP, or IP header is used just as a real voice packet would carry. The SAA Responder feature was called Response Time Reporter (RTR) in earlier releases of Cisco IOS software.

The SAA Responder feature cannot be configured for non-Cisco devices. For a complete description of SAA configuration, see the Cisco IOS Configuration Fundamentals and Network Management Configuration Guide, Release 12.3.

**Calculated Planning Impairment Factor**

The Cisco IOS VoiceXML feature supports the determination of ICPIF, as specified by International Telecommunications Union (ITU) standard G.113. The SIP subsystem calculates an impairment factor for network conditions to a particular IP address. ICPIF checks for end-to-end resource availability by calculating a Total Impairment Value, which is a function of codecs used and loss or delay of packets. You can configure router resources to make call admission decisions, using either the ICPIF threshold, or by setting delay and loss thresholds.

Configurable ICPIF values that represent the ITU specification for quality of voice as described in G.113 are the following:

- 5--Very good
- 10--Good
- 20--Adequate
- 30--Limiting case
- 45--Exceptional limiting case
- 55--Customers likely to react strongly
The default value is 20. SAA probe delay and loss information is used in calculating an ICPIF value, which is then used as a threshold for CAC decisions. You can base such decisions on either the ITU interpretation described or on the requirements of an individual customer network.

**PSTN Fallback**

The Cisco IOS VoiceXML feature supports PSTN Fallback, which monitors congestion in the IP network and either redirects calls to the public switched telephone network (PSTN) or rejects calls based on network congestion. Calls can be rerouted to an alternate IP destination or to the PSTN if the IP network is found unsuitable for voice traffic at that time. You can define congestion thresholds based on the configured network. This functionality allows the service provider to give a reasonable guarantee about the quality of the conversation to VoIP users at the time of call admission.

Note

PSTN Fallback does not provide assurances that a VoIP call that proceeds over the IP network is protected from the effects of congestion. This is the function of the other QoS mechanisms, such as IP Real-Time Transport Protocol (RTP) priority or low latency queueing (LLQ).

PSTN Fallback includes the following capabilities:

- Provides the ability to define the congestion thresholds based on the network.
  - Defines a threshold based on ICPIF, which is derived as part of ITU G.113 (see "Service Assurance Agents").
  - Defines a threshold based solely on packet delay and loss measurements.
- Uses SAA probes to provide packet delay, jitter, and loss information for the relevant IP addresses. Based on the packet loss, delay, and jitter encountered by these probes, an ICPIF or delay or loss value is calculated.
- Supports calls of any codec. Only G.729 and G.711 have accurately simulated probes. Calls of all other codecs are emulated by a G.711 probe.

The call fallback subsystem has a network traffic cache that maintains the ICPIF or delay or loss values for various destinations. This capability helps performance, because each new call to a well-known destination need not wait for a probe to be admitted because the value is usually cached from a previous call.

Once the ICPIF or delay or loss value is calculated, they are stored in a fallback cache where they remain until the cache ages out or overflows. Until an entry ages out, probes are sent periodically for that particular destination. This time interval is configurable.

**Media Information for Fallback Services**

SIP reliable provisional responses ensure that media information is exchanged and that resource and network checks can take place prior to connecting the call. The following SIP methods have been implemented to support fallback services:

- INVITE with Session Description Protocol (SDP) body. The PSTN Fallback feature provides support for a new attribute line, a=rtr, in the SDP message body. The rtr attribute enables support for invoking fallback services. The INVITE message with SDP body provides media connection information, including IP address and negotiated codec.
- Provisional Acknowledgment (PRACK). PRACK allows reliable exchanges of SIP provisional responses between SIP endpoints. When the INVITE message has no SDP body, that is, no delayed media, the
terminating gateway sends media information in the 183 Session Progress message and expects the SDP from the originating gateway in the PRACK message.

- Conditions Met (COMET), which indicates if the preconditions for a given call have been met.

### Call Admission Thresholds

User-selected thresholds allow you to configure call admission thresholds for local resources and end-to-end memory and CPU resources. You can configure two thresholds, high and low, for each global or interface-related resource. The specified call treatment is triggered when the current value of a resource goes beyond the configured high, and remains in effect until the current resource value falls below the configured low.

### Call Treatment Options

You can select how the call should be treated when local resources are not available to handle the call. For example, when the current resource value for any one of the configured triggers for call threshold exceeds the configured threshold, you have the following call treatment choices:

- TDM hairpinning--Hairpins the calls through the POTS dial peer.
- Reject--Disconnects the call.
- Play message or tone--Plays a configured message or tone to the user.

### Resource Unavailable Signaling

The Resource Unavailable Signaling feature supports autobusyout capability, which busies out channels when local resources are not available to handle the call. Autobusyout is supported on both channel-associated signaling (CAS) and primary rate interface (PRI) channels:

- CAS--Uses busyout to signal local resources are unavailable.
- PRI--Uses either service messages or disconnect with correct cause-code to signal resources are unavailable.

### SIP Gateway Support of RSVP and TEL URL

The SIP Gateway Support of RSVP and TEL URL feature provides the following SIP enhancements:

This section describes the SIP Gateway Support of RSVP and the SIP Gateway Support of ‘tel’ URL features. SIP gateways can enable resource reservation using Resource Reservation Protocol (RSVP). Resource reservation on SIP gateways synchronizes RSVP procedures with SIP call establishment procedures, ensuring that the required quality of service (QoS) for a call is maintained across the IP network.

Feature benefits include the following:

- SIP Gateway Support of RSVP and TEL URL enables Quality of Service (QoS), ensuring certain bandwidth reservations for specific calls. The bandwidth reservation can be best-effort, in which case the call is completed even if the reservation is not supported by both sides or cannot be established. Or the bandwidth reservation can be required, and the call is not set up if the bandwidth reservation is not performed successfully.
RSVP

Before this feature was implemented, SIP applications over IP networks functioned as best-effort services--their media packets were delivered with no performance guarantees. However, SIP gateway support of RSVP and TEL URL ensures quality of service (QoS) by coordinating SIP call signaling and RSVP resource management. This feature reserves sufficient network-layer resources to guarantee bandwidth and bounds on packet loss, delay, and jitter; thus ensuring that the called party’s phone rings only after bandwidth required for the call has been successfully reserved.

Additionally, appropriate changes to the resources reserved for the SIP call are made when mid-call INVITE messages, requiring media change (such as a change of codec) are requested.

Synchronization with Cisco IOS QoS

A QoS module is provided that acts as a broker between the VoIP service-provider interfaces (SPIs) and the Cisco IOS RSVP subsystem. The QoS module enables the VoIP SPIs to initiate resource reservation, modify parameters of an existing reservation, and clean up the reserved resources. The QoS module then communicates the results of the operation to the RSVP subsystem.

The conditions for SIP calls using QoS are as shown in the table below.

<table>
<thead>
<tr>
<th>SIP Call Setup</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bandwidth reservation (QoS) is attempted when:</td>
<td>The desired (requested) QoS for the associated dial peer is set</td>

<tr>
<td></td>
<td>to <strong>controlled-load</strong> or <strong>guaranteed-delay</strong>.</td>
</tr>
<tr>
<td>Bandwidth reservation (QoS) is not attempted when:</td>
<td>The desired QoS level is set to the default of <strong>best-effort</strong>.</td>
</tr>
<tr>
<td>If bandwidth reservation (QoS) is attempted but fails, the acceptable QoS for the dial peer determines the outcome of the call:</td>
<td>The call proceeds without any bandwidth reservation in place</td>
</tr>
<tr>
<td></td>
<td>if the acceptable QoS is configured with <strong>best-effort</strong>.</td>
</tr>
<tr>
<td></td>
<td>The call is released if the acceptable QoS on either gateway is</td>
</tr>
<tr>
<td></td>
<td>configured with <strong>controlled-load</strong> or <strong>guaranteed-delay</strong>.</td>
</tr>
</tbody>
</table>

The desired QoS and acceptable QoS are configured through Cisco IOS software by using the **req-qos** and **acc-qos** dial-peer configuration commands, respectively.

TEL URL Format in SIP Messages

The SIP Gateway Support of RSVP and TEL URL feature also supports Telephone Uniform Resource Locators or TEL URL. Currently SIP gateways support URLs in the SIP format. SIP URLs are used in SIP messages to indicate the originator, recipient, and destination of the SIP request. However, SIP gateways may also encounter URLs in other formats, such as TEL URLs. TEL URLs describe voice call connections. They also
enable the gateway to accept TEL calls sent through the Internet, and to generate TEL URLs in the request line of outgoing INVITEs requests.

**SIP and TEL URL Examples**

**SIP URL**
A SIP URL identifies a user’s address and appears similar to an email address: user@host where *user* is the telephone number and *host* is either a domain name or a numeric network address. For example, the request line of an outgoing INVITE request might appear as:

```
INVITE sip:5550100@example.com; user=phone.
```

The *user=phone* parameter distinguishes that the user address is a telephone number rather than a username.

**TEL URL**
A TEL URL takes the basic form of `tel:telephone subscriber number`, where *tel* requests the local entity to place a voice call, and *telephone subscriber number* is the number to receive the call. For example:

```
tel:+555-0100
```

For more detailed information on the structure of TEL URL, see RFC 2806, *URLs for Telephone Calls*.

**Reliability of SIP Provisional Responses**
SIP reliable provisional responses ensure that media information is exchanged and resource reservation can take place prior to connecting the call. Provisional acknowledgement (PRACK) and conditions met (COMET) are two methods that have been implemented.

PRACK allows reliable exchanges of SIP provisional responses between SIP endpoints. COMET indicates if the preconditions for a given call or session have been met.

**SIP Hold Timer Support**
The SIP: Hold Timer Support feature provides the ability to terminate a call that has been placed on hold in excess of a configurable time period, and to thereby free up trunk resources.

Feature benefits include the following:

- Improved trunk resource utilization
- Improved network monitoring and management capability

The SIP: Hold Timer Support feature provides a new configurable hold timer that allows you to specify a maximum hold time of up to 2880 minutes. Prior to this feature, there was no mechanism to automatically disconnect a call that had been on hold for a set period of time. When the SIP call hold process occurs in response to ISDN Suspend and Resume messages, a media inactivity timer allows a gateway to monitor and disconnect a VoIP call if no Real-Time Control Protocol (RTCP) packets are received within a configurable time period. This timer is deactivated when a call is placed on hold and no media packets are sent. As a result, a call is potentially allowed to stay on hold indefinitely.
For information on the media inactivity timer, see SIP Media Inactivity Timer and SIP: ISDN Suspend/Resume Support.

The SIP: Hold Timer Support feature resolves this problem by allowing you to configure a gateway to disconnect a held call when the hold timer is exceeded. The hold timer is activated when a gateway receives a call hold request from the other endpoint, for example, a SIP phone. SIP gateways receive notice of a call hold when the originating gateway sends a re-INVITE to the terminating gateway containing one of the following Session Description Protocol (SDP) lines: a connection IP address set to 0.0.0.0 (c=0.0.0.0), or the attribute field set to send only (a=sendonly) or to inactive (a=inactive). When the SIP phone or user-agent client cancels the hold, the originating gateway takes the call off hold by sending a re-INVITE with the attribute field (a=) set to sendrecv or with the connection field (c=) set back to the actual IP address of the remote SIP entity, in place of 0.0.0.0.

The following call flows show gateway behavior upon receiving a call hold request from a SIP endpoint. In the figure below, the originating gateway sends an INVITE with an indication to place a call on hold (c=INIP4.0.0.0.0, a=sendonly, or a=inactive in the SDP), which starts the hold timer. When the gateway on hold receives a re-INVITE with the indication to resume the call (c=IN IP4 User A or a=sendrecv), it stops the hold timer, sends a 200 OK, and resumes the call.

**Figure 1: Start and Stop Hold Time**

In the figure below, the hold timer expires, the gateway on hold tears down the call and sends a BYE request to the other end.
The SIP Media Inactivity Timer feature enables Cisco gateways to monitor and disconnect VoIP calls if no Real-Time Control Protocol (RTCP) packets are received within a configurable time period.

When RTCP reports are not received by a Cisco gateway, the SIP Media Inactivity Timer feature releases the hung session and its network resources in an orderly manner. These network resources include the gateway digital signal processor (DSP) and time-division multiplexing (TDM) channel resources that are utilized by the hung sessions. Because call signaling is sent to tear down the call, any stateful SIP proxies involved in the call are also notified to clear the state that they have associated with the hung session. The call is also cleared back through the TDM port so that any attached TDM switching equipment also clears its resources.

Feature benefits include the following:

- Provides a mechanism for detecting and freeing hung network resources when no RTCP packets are received by the gateway.

**How to Configure SIP QoS Features**

For help with a procedure, see the verification and troubleshooting sections listed above. Before you perform a procedure, familiarize yourself with the following information:

**Configuring Enhanced Codec Support for SIP Using Dynamic Payloads**

This procedure is optional and selects a dynamic payload value from the IANA defined range of 96 to 127.
SUMMARY STEPS

1. enable
2. configure terminal
3. dial-peer voip number
4. rtp payload-type type number
5. exit

Configure PSTN Fallback

PSTN fallback configuration applies to both inbound and outbound gateways. In most networks, gateways generate calls to each other, so that every gateway is both an outgoing gateway and a terminating gateway.

- Configure the destination node, which is often but not necessarily the terminating gateway, with the SAA Responder feature.
- PSTN fallback configuration is done at the global level and therefore applies to all calls attempted by the gateway. You cannot selectively apply PSTN fallback only to calls initiated by specific PSTN or PBX interfaces.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. call fallback active
4. call fallback cache size *number*
5. call fallback instantaneous-value-weight *weight*
6. call fallback jitter-probe num-packets *number-of-packets*
7. call fallback jitter-probe precedence *precedence-value*
8. call fallback jitter-probe priority-queue
9. call fallback threshold delay *delay-value* loss *loss-value*
10. exit

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: Router&gt; Enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> call fallback active</td>
<td>Enables a call request to fall back to alternate dial peers in case of network congestion.</td>
</tr>
<tr>
<td>Example: Router(config)# call fallback active</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> call fallback cache size <em>number</em></td>
<td>Specifies the call-fallback cache size for network traffic probe entries. The argument is as follows:</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Router(config)# call fallback cache size 128</td>
<td>• <strong>number</strong> -- Cache size, in number of entries. Range: 1 to 256. Default: 128.</td>
</tr>
</tbody>
</table>

**Step 5**
**call fallback instantaneous-value-weight**  
*Example:*
Router(config)# call fallback instantaneous-value-weight 50

Configures the call-fallback subsystem to determine an average value based on the last two probes registered in the cache for call requests. This command allows the call-fallback subsystem to recover gradually from network congestion conditions. The argument is as follows:

• **weight** -- By percent, when a new probe is received, how much to rely upon the new probe as opposed to the previous cache entry. The configured weight applies to the new probe first. Range: 0 to 100. Default: 66.

**Step 6**
**call fallback jitter-probe num-packets**  
*Example:*
Router(config)# call fallback jitter-probe num-packets 15

Specifies the number of packets in a jitter probe used to determine network conditions. The argument is as follows:

• **num-packets** -- Number of packets. Range: 2 to 50. Default: 15.

**Step 7**
**call fallback jitter-probe precedence**  
*Example:*
Router(config)# call fallback jitter-probe precedence 2

Specifies the priority of the jitter-probe transmission by setting the IP precedence of IP packets. The argument is as follows:

**Step 8**
**call fallback jitter-probe priority-queue**  
*Example:*
Router(config)# call fallback jitter-probe priority-queue

Assigns a priority queue for jitter-probe transmissions. You must set IP priority queueing for UDP voice ports 16384 to 32767.

**Step 9**
**call fallback threshold delay**  
*Example:*
Router(config)# call fallback threshold delay 36000 loss 50

Configures the call-fallback threshold to use only specified packet delay and loss values. Arguments are as follows:

• **delay** -- Delay value, in ms. Range: 1 to 2147483647. No default.

• **loss** -- Loss value, as a percentage. Range: 0 to 100. No default.

**Step 10**
**exit**  
*Example:*
Router(config)# exit

Exits the current mode.
Configure Resource-Availability Check

To enable resource-availability checking, perform one of the following tasks:

Configuring Global Resources

To configure resource availability checking for global resources, perform the following steps.

SUMMARY STEPS

1. enable
2. configure terminal
3. call threshold global  trigger-name  low value high value [busyout | treatment]
4. call treatment  {on | action action [value] | cause-code cause-code | isdn-reject value}
5. exit

| Router(config)# exit |         |

### Configure SIP Reliable Provisional Response

**Note**  
By default, gateways support reliable provisional responses. That is, no additional configuration tasks are necessary to enable reliable provisional responses. This task enables reliable provisional response if it was disabled using the **no rel1xx** command.
### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **voice service voip**
4. **sip**
5. **rel1xx** \{**supported** value | **require** value | **disable**\}
6. **exit**

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
</tbody>
</table>
| **Example:**
  Router> Enable | |
| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:**
  Router# configure terminal | |
| **Step 3** voice service voip | Enters voice-service configuration mode. |
| **Example:**
  Router(config)# voice service voip | |
| **Step 4** sip | Enters SIP configuration mode. |
| **Example:**
  Router (config-voi-serv)# sip | |
| **Step 5** rel1xx \{**supported** value | **require** value | **disable**\} | Enables all SIP provisional responses (other than 100 Trying) to be sent reliably to the remote SIP endpoint. |
| **Example:**
  Router(config-srv-sip)# rel1xx supported 100rel | • **supported** value --Use provisional responses and you set the value; for instance, 100rel. The value argument may have any value, as long as both the user-agent client (UAC) and user-agent server (UAS) configure it the same. Default value is supported with the 100rel value. |
| **Example:**
  Router(config-srv-sip)# rel1xx require 100rel | • **require** value --Use provisional responses and you set the value; for instance, 100rel. The value argument may have any value, as long as both the UAC and UAS configure it the same. |
| **Example:**
  Router(config-srv-sip)# rel1xx disable | • **disable**--Disables the use of reliable provisional responses. |
PurposeCommand or Action | Purpose
--- | ---
Step 6 | exit | Exits the current mode.
   | Example: Router(config-srv-sip)# exit |

Configuring SIP Gateway Support of RSVP and TEL URL

This section contains the following procedures (you must perform them in the order listed):

Configure SIP Gateway Support of RSVP

Configuring Fair Queuing and RSVP

To configure fair queuing and RSVP, perform the following steps.

For details on these commands, see the Cisco IOS Quality of Service Solutions Command Reference, Release 12.3. For an example, see the "SIP Gateway Support of RSVP and TEL URL Example".

### SUMMARY STEPS

1. enable
2. configure terminal
3. interface fastethernet number
4. ip rsvp bandwidth [interface-kbps[single-flow-kbps]]
5. fair-queue [congestive-discard-threshold [dynamic-queues [reservable-queues]]]
6. exit

### DETAILED STEPS

#### SUMMARIZED STEPS

1. **enable**
2. **configure terminal**
3. **dial-peer voice tag voip**
4. **voice-class sip url {sip | sips | system | tel}**
5. **exit**

#### DEPENDENT STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td><em>Example:</em></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Router&gt; Enable</code></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td><code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td><em>Example:</em></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Router# configure terminal</code></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td><code>dial-peer voice tag voip</code></td>
<td>Enters dial-peer configuration mode for the specified VoIP dial peer.</td>
</tr>
<tr>
<td></td>
<td><em>Example:</em></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Router(config)# dial-peer voice 29 voip</code></td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>`voice-class sip url {sip</td>
<td>sips</td>
</tr>
<tr>
<td></td>
<td><em>Example:</em></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>Router(config-dial-peer)# voice-class sip url sip</code></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** The `voice-class sip url` command in dial-peer configuration mode takes precedence over the `url` command in global configuration. However, if the `voice-class sip url` command contains the configuration of `system`, the gateway uses what was globally configured under the `url` command.
### Configure Reliability of SIP Provisional Responses

The following are tasks for configuring reliability of SIP provisional responses:

By default, gateways support reliable provisional responses. That is, no additional configuration tasks are necessary to enable reliable provisional responses.

However, there are instances when you may want control over the use of reliable provisional responses. For example, you may want to:

- Always require the use of reliable provisional responses (use the Required header)
- Never use reliable provisional responses

In these cases, there are two ways to configure reliable provisional responses:

- Dial-peer mode. In this mode you can configure reliable provisional responses for the specific dial peer only. Configure with the `voice-class sip rel1xx` command.
- SIP mode. In this mode you can configure reliable provisional responses globally. Configure with the `rel1xx` command.

When the `voice-class sip rel1xx` command under dial-peer configuration is configured, it takes precedence over the **global configuration of the rel1xx command**. However, if the `voice-class sip rel1xx` command contains the configuration of `system`, the gateway uses what was globally configured under the `rel1xx` command.

The table below shows the possible configurations achieved with the `voice-class sip rel1xx` and the `rel1xx` commands. It outlines the possible configurations on both the originating gateway and the terminating gateway, and the results of the various configurations.

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sips</code></td>
<td>--Generate URLs in the SIPS-format for calls on a dial-peer basis.</td>
</tr>
<tr>
<td><code>system</code></td>
<td>--Use the system value. This is the default.</td>
</tr>
<tr>
<td><code>tel</code></td>
<td>--Generate URLs in the TEL format for calls on a dial-peer basis.</td>
</tr>
</tbody>
</table>

---

**Step 5**

**exit**

**Example:**

```
Router(config-dial-peer)# exit
```

---

**Note**

When configured with the **supported** option, the SIP gateway uses the Supported header in outgoing INVITE messages. When configured with the **require** option, the SIP gateway uses the Required header in outgoing INVITE messages.

### Reenabling SIP Hold Timer Support

To configure SIP hold timer support, perform the following steps.

**Note**

The SIP: Hold Timer Support feature is enabled by default; no configuration tasks are required to enable this feature. This task enables the feature again if it was disabled by using the **no timers hold** command.

### Summary Steps

1. enable
2. configure terminal
3. timers hold  \textit{time}
4. exit

\textbf{DETAILED STEPS}

<table>
<thead>
<tr>
<th>Step</th>

\textbf{Configuring the SIP Media Inactivity Timer}

The SIP Media Inactivity Timer feature requires configuration of the \texttt{ip rtcp report interval} command and the \texttt{timer receive-rtcp} command to enable detection of RTCP packets by the gateway. When these commands are configured, the gateway uses RTCP report detection, rather than Real-Time Protocol (RTP) packet detection, to determine whether calls on the gateway are still active or should be disconnected. This method is more reliable because there are periods during voice calls when one or both parties are not sending RTP packets.

One common example of a voice session in which no RTP is sent is when a caller dials into a conference call and mutes his endpoint. If voice activity detection (VAD, also known as silence suppression) is enabled, no RTP packets are sent while the endpoint is muted. However, the muted endpoint continues to send RTCP reports at the interval specified by the \texttt{ip rtcp report interval} command.

The \texttt{timer receive-rtcp value} argument (or Mfactor) is multiplied with the interval that is set using the \texttt{ip rtcp report interval} command. If no RTCP packets are received in the resulting time period, the call is disconnected. The gateway signals the disconnect to the SIP network and the TDM network so that upstream and downstream devices can clear their resources. The gateway sends a SIP BYE to disconnect the call and sends a Q.931 DISCONNECT back to the TDM network to clear the call upon the expiration of the timer. The Q.931 DISCONNECT is sent with a Cause code value of 3 (no route). There is no Q.931 Progress Indicator (PI) value included in the DISCONNECT.
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `gateway`
4. `timer receive-rtcp` *timer*
5. `exit`
6. `ip rtcp report interval` *value*
7. `exit`

<td>* value --Average interval (in ms) for RTCP report transmissions. Range: 1 to 65535. Default: 5000.</td>
</tr>
</tbody>
</table>
Verifying SIP QoS Features

To verify configuration of SIP QoS features, perform the following steps as appropriate (commands are listed in alphabetical order).

**SUMMARY STEPS**

1. `show call fallback cache`
2. `show call fallback config`
3. `show call fallback stats`
4. `show call rsvp-sync conf`
5. `show call rsvp-sync stats`
6. `show dial-peer voice`
7. `show ip rsvp reservation`
8. `show running-conf`
9. `show sip-ua retry`
10. `show sip-ua statistics`
11. `show sip-ua status`
12. `show sip-ua timers`
13. `test call fallback probe` *ip-address codec*

**DETAILED STEPS**

**Step 1**

`show call fallback cache`

Use this command to display the current ICPIF estimates for all IP addresses in the cache.

**Step 2**

`show call fallback config`

Use this command to display the call fallback configuration.
Step 3  
**show call fallback stats**

Use this command to display call fallback statistics.

Step 4  
**show call rsvp-sync conf**

Use this command to display the configuration settings for RSVP synchronization.

Step 5  
**show call rsvp-sync stats**

Use this command to display statistics for calls that attempted RSVP reservation.

**Example:**

```
Router# show call rsvp-sync
conf  Show RSVP/Voice Synchronization Config. information
state Show RSVP/Voice Statistics

The following sample output also shows configuration settings for RSVP synchronization. Of particular note in the example are the following:

- Overture Synchronization is ON--Indicates that RSVP synchronization is enabled.
- Reservation Timer is set to 10 seconds--Number of seconds for which the RSVP reservation timer is configured.

**Example:**

```
Router# show call rsvp-sync conf
VoIP QoS:RSVP/Voice Signaling Synchronization config:
Overture Synchronization is ON
Reservation Timer is set to 10 seconds
```

The following sample output shows configuration settings for RSVP synchronization. Of particular note in the example are the following:

- Number of calls for which QoS was initiated--Number of calls for which RSVP setup was attempted.
- Number of calls for which QoS was torn down--Number of calls for which an established RSVP reservation was released.
- Number of calls for which Reservation Success was notified--Number of calls for which an RSVP reservation was successfully established.
- Total Number of PATH Errors encountered--Number of path errors that occurred.
- Total Number of RESV Errors encountered--Number of reservation errors that occurred.
- Total Number of Reservation Timeouts encountered--Number of calls in which the reservation setup was not complete before the reservation timer expires.

**Example:**

```
Router# show call rsvp-sync stats
VoIP QoS:Statistics Information:
Number of calls for which QoS was initiated : 0
Number of calls for which QoS was torn down : 0
Number of calls for which Reservation Success was notified : 0
Total Number of PATH Errors encountered : 0
Total Number of RESV Errors encountered : 0
Total Number of Reservation Timeouts encountered : 0
```
Step 6  
**show dial-peer voice**

Use this command to display detailed information for a specific voice dial peer.

**Example:**

```
Router# show dial-peer voice 5
VoiceOverIPPeer5
   information type = voice,
   tag = 5, destination-pattern = '5550100',
   answer-address = '', preference=0,
   numbering Type = 'unknown'
   group = 5, Admin state is up, Operation state is up,
   incoming called-number = '', connections/maximum = 0/unlimited,
   DTMF Relay = disabled,
   modem passthrough = system,
   huntstop = disabled,
   in bound application associated:session
   out bound application associated
   dnis-map =
   permission :both
   incoming COR list:maximum capability
   outgoing COR list:minimum requirement
   type = voip, session-target = 'ipv4:172.18.192.218',
   technology prefix:
   settle-call = disabled
   ip media DSCP = default, ip signaling DSCP = default, UDP checksum = disabled,
   session-protocol = sipv2, session-transport = system, req-qos = best-effort,
   acc-qos = best-effort,
   fax rate = voice, payload size = 20 bytes
   fax protocol = system
   fax NSF = 0xAD0051 (default)
   codec = g711ulaw, payload size = 160 bytes,
   Expect factor = 0, Icpif = 20,
   Playout Mode is set to default,
   Initial 60 ms, Max 300 ms
   Playout-delay Minimum mode is set to default, value 40 ms
   Expect factor = 0,
   Max Redirects = 1, Icpif = 20, signaling-type = cas,
   CLID Restrict = disabled
   VAD = enabled, Poor QOV Trap = disabled,
   voice class sip url = system,
   voice class sip rel1xx = system,
   voice class perm tag = ''
   Connect Time = 0, Charged Units = 0,
   Successful Calls = 0, Failed Calls = 0, Incomplete Calls = 0
   Accepted Calls = 0, Refused Calls = 0,
   Last Disconnect Cause is '',
   Last Disconnect Text is '',
   Last Setup Time = 0.
```
**Step 8**

`show running-conf`

Use this command to display the contents of the currently running configuration file, the configuration for a specific interface, or map class information. Use it to display SIP user-agent statistics, including reliable provisional response information. Use it also to display configuration for the Cisco IOS VoiceXML feature.

The following sample output shows SIP user-agent statistics, including reliable provisional response information. In the following partial output, a dynamic payload value of 115 is configured, freeing up the reserved value of 101.

**Example:**

```
Router# show running-config
Building configuration...
Current configuration: 2024 bytes
version 12.3
service timestamps debug uptime
service timestamps log uptime
no service password-encryption
hostname r4
ip subnet-zero
ip tcp synwait-time 5
no ip domain-lookup

privilege level 15
password password1
logging synchronous
line aux 0
line vty 0 4
extimeout 0 0
privilege level 15
password password1
logging synchronous
no login
end

The following sample output shows configuration for the Cisco IOS VoiceXML feature. If the SIP hold timer is enabled, which is the default setting, and the timer is set to the default value of 2880 minutes, command output does not display the timers hold 2880 command. In the following partial output, the hold timer is set to a nondefault value of 18 minutes.

Example:

Router# show running-config
Building configuration...
Current configuration :2791 bytes
.
.
.
sip-ua
max-forwards 10
retry invite 1
retry response 4
retry bye 1
retry cancel 1
timers expires 300000
timers hold 18
.
.
.
end!

Step 9 show sip-ua retry
Use this command to display SIP retry statistics.

Example:

Router# show sip-ua retry
SIP UA Retry Values
invite retry count = 10  response retry count = 1
bye retry count = 1  cancel retry count = 8
prack retry count = 10  comet retry count = 10
reliable 1xx count = 6

Step 10 show sip-ua statistics
Use this command to display response, traffic, and retry SIP statistics.

Note When 0/0 is included in a field, the first number is an inbound count and the last number is an outbound count.

Example:

Router# show sip-ua statistics
SIP Response Statistics (Inbound/Outbound)

Informational:
- Trying 15/9, Ringing 9/0,
- Forwarded 0/0, Queued 0/0,
- SessionProgress 36/9

Success:
- OkInvite 6/4, OkBye 5/5,
- OkCancel 5/5, OkOptions 0/0,
- OkPrack 29/8, OkPreconditionMet 11/0

Redirection (Inbound only):
- MultipleChoice 0, MovedPermanently 0,
- MovedTemporarily 0, SeeOther 0,
- UseProxy 0, AlternateService 0

Client Error:
- BadRequest 0/0, Unauthorized 0/0,
- PaymentRequired 0/0, Forbidden 0/0,
- NotFound 0/0, MethodNotAllowed 0/0,
- NotAcceptable 0/0, ProxyAuthReqd 0/0,
- ReqTimeout 0/0, Conflict 0/0, Gone 0/0,
- LengthRequired 0/0, ReqEntityTooLarge 0/0,
- ReqURITooLarge 0/0, UnsupportedMediaType 0/0,
- BadExtension 0/0, TempNotAvailable 0/0,
- CallLegNonExistent 0/0, LoopDetected 0/0,
- TooManyHops 0/0, AddrIncomplete 0/0,
- Ambiguous 0/0, BusyHere 0/0,
- RequestCancel 0/0, NotAcceptableMedia 0/0

Server Error:
- InternalError 0/0, NotImplemented 0/0,
- BadGateway 0/0, ServiceUnavail 0/0,
- GatewayTimeout 0/0, BadSipVer 0/0,
- PreCondFailure 0/0

Global Failure:
- BusyEverywhere 0/0, Decline 0/0,
- NotExistAnywhere 0/0, NotAcceptable 0/0

SIP Total Traffic Statistics (Inbound/Outbound)
- Invite 9/16, Ack 4/6, Bye 5/5,
- Cancel 5/9, Options 0/0,
- Prack 8/43, Comet 0/11

Retry Statistics
- Invite 5, Bye 0, Cancel 4, Response 0,
- Prack 13, Comet 0, Reliable1xx 0

Step 11  show sip-ua status

Use this command to display SIP user-agent status.

Example:

Router# show sip-ua status
SIP User Agent Status
SIP User Agent for UDP : ENABLED
SIP User Agent for TCP : ENABLED
SIP User Agent bind status(signaling): DISABLED
SIP User Agent bind status(media): DISABLED
SIP max-forwards : 6
SIP DNS SRV version: 1 (rfc 2052)

Step 12  show sip-ua timers

Use this command to display SIP user-agent timer settings.

Example:
Router# show sip-ua timers
SIP UA Timer Values (milliseconds unless noted)
trying 500, expires 150000, connect 500, disconnect 500
comet 500, prack 500, re1xx 500, notify 500, hold 2880 minutes

Step 13  test call fallback probe  ip-address codec
Use this command to test a probe to a specific IP address and display ICPIF RTR values. Keywords and arguments are as follows:

• ip-address -- Target IP address.
• codec -- Codec type to test. Valid values are 711 (G.711 codec) and 729 (G.729 codec).

Troubleshooting Tips

Note  For general troubleshooting tips and a list of important debug commands, see the “General Troubleshooting Tips” section.

• Make sure that you can make a voice call.
• Make sure VoIP is working before call fallback is configured.
• Use the debug ccsip events command, which includes output specific to the SIP Media Inactivity Timer feature.
• Use the debug ccsip events command to show all SIP SPI events tracing.
• Use the debug call fallback detail command to display details of the VoIP call fallback.
• Use the debug ccsip messages command to enable CCSIP SPI messages debugging trace.
• Use the debug ccsip error command to enable SIP error debugging trace.
• Use the debug ccsip all command to enable all SIP debugging traces.
• Use the debug rtr trace command to trace the execution of an SAA operation.
• Use the debug call fallback probe command to verify that probes are being sent correctly.

• Use the debug ccsip all command to enable all SIP debugging capabilities or use one of the following SIP debug commands:
  • debug ccsip calls
  • debug ccsip error
  • debug ccsip events
  • debug ccsip messages
  • debug ccsip states
When terminating long distance or international calls over ISDN, the terminating switch receives information from the gateway. Generally, the information received consists of the numbering plan and the ISDN number type. As a default, the gateway tags both the numbering plan and number type as Unknown. However, this Unknown tag may cause interworking issues with some switches.

You can override the default ISDN numbering plan and number type with custom values, using the isdn map command. This command sets values on a per-number basis or on numbers that match set patterns. The following example shows an override of any plan or type with a called or calling number that begins with the numeral 1. Thus, the ISDN setup sent to the switch is used only for long distance numbers, the numbering plan is ISDN, and the type of number is National:

```
isdn map address 1.* plan isdn type* national
```

For more details on the isdn map command, see the Cisco IOS Dial Technologies Command Reference, Release 12.3.

Following is sample output for some of these commands:

**Sample Output for the debug ccsip events Command**

The following example trace shows a timer being set:

```
Router# debug ccsip events
00:04:29: sipSPICreateAndStartRtpTimer: Valid RTP/RTCP session found and CLI enabled to create and start the inactivity timer
00:04:29: sipSPICreateAndStartRtpTimer: Media Inactivity timer created for call.
Mfactor(from CLI): 5 RTCP bandwidth: 500
RTCP Interval(in ms): 5000
Normalized RTCP interval (in ms): 25000
```

The following example trace shows a timer expiring:

```
Router# debug ccsip events
02:41:03: %LINEPROTO-5-UPDOWN: Line protocol on Interface Ethernet0, changed state to down
*Jan 1 02:41:34.107: sipSPIRtpDiscTimerExpired: RTP/RTCP receive timer expired. Disconnect the call.
*Jan 1 02:41:34.107: Queued event From SIP SPI to CCAPI/DNS : SIPSPI_EV_CC_CALL_DISCONNECT
*Jan 1 02:41:34.107: CCSIP-SPI-CONTROL: act_active_disconnect
```

The timer receive-rtcp command configures a media activity timer that is common to both H.323 and SIP. If set, it affects both H.323 and SIP calls.

**Sample Output for the debug rtr trace Command**

```
Router# debug rtr trace
```

```
Router#
*Mar 1 00:11:42.439: RTR 1: Starting An Echo Operation - IP RTR Probe 1
*Mar 1 00:11:42.439: rtt hash insert : 10.1.1.63 32117
*Mar 1 00:11:42.439: source=10.1.1.63(32117) dest-ip=10.1.1.67(32057) vrf tableid = 0
*Mar 1 00:11:42.439: sending control enable:
*Mar 1 00:11:42.439: cmd: command: , ip: 10.1.1.67, port: 32057, duration: 1200
*Mar 1 00:11:42.439: sending control msg:
*Mar 1 00:11:42.439: Ver: 1 ID: 20 Len: 52
*Mar 1 00:11:42.443: receiving reply
```
Sample Output for the debug call fallback probe Command

Router# debug call fallback probe
Router#
Configuration Examples for SIP QoS Features

SIP Gateway Support of RSVP and TEL URL Example

This configuration example shows RSVP for SIP calls on gateways being enabled. Gateway A is the originating gateway and Gateway B is the terminating gateway:

Use the debug ccsip all command to troubleshoot the SIP: Hold Timer Support feature. To minimize the possibility of performance impact, use this command during periods of minimal traffic. Make sure VoIP is working before hold timer support is configured.

Router# debug ccsip all
