About Cisco IOS Software Documentation

This chapter discusses the objectives, audience, organization, and conventions of Cisco IOS software documentation. It also provides sources for obtaining documentation from Cisco Systems.

Documentation Objectives

Cisco IOS software documentation describes the tasks and commands necessary to configure and maintain Cisco networking devices.

Audience

The Cisco IOS software documentation set is intended primarily for users who configure and maintain Cisco networking devices (such as routers and switches) but who may not be familiar with the tasks, the relationship between tasks, or the Cisco IOS software commands necessary to perform particular tasks. The Cisco IOS software documentation set is also intended for those users experienced with Cisco IOS software who need to know about new features, new configuration options, and new software characteristics in the current Cisco IOS software release.

Documentation Organization

The Cisco IOS software documentation set consists of documentation modules and master indexes. In addition to the main documentation set, there are supporting documents and resources.

Documentation Modules

The Cisco IOS documentation modules consist of configuration guides and corresponding command reference publications. Chapters in a configuration guide describe protocols, configuration tasks, and Cisco IOS software functionality and contain comprehensive configuration examples. Chapters in a command reference publication provide complete Cisco IOS command syntax information. Use each configuration guide in conjunction with its corresponding command reference publication.
Figure 1 shows the Cisco IOS software documentation modules.

The abbreviations (for example, FC and FR) next to the book icons are page designators, which are defined in a key in the index of each document to help you with navigation. The bullets under each module list the major technology areas discussed in the corresponding books.
Module DC/DR:
- Preparing for Dial Access
- Modern and Dial Shelf Configuration and Management
- ISDN Configuration
- Signalling Configuration
- Dial-on-Demand Routing Configuration
- Dial-Backup Configuration
- Dial-Related Addressing Services
- Virtual Templates, Profiles, and Networks
- PPP Configuration
- Callback and Bandwidth Allocation Configuration
- Dial Access Specialized Features
- Dial Access Scenarios

Module TC/TR:
- ARA
- LAT
- NASI
- Telnet
- TN3270
- X.28 PAD
- Protocol Translation

Module BC/B1R:
- DSPU and SNA Service Point
- SNA Switching Services
- Cisco Transaction Connection
- Cisco Mainframe Channel Connection
- CLAW and TCP/IP Offload
- CSNA, CMPC, and CMPC+
- TN3270 Server

Module BC/B2R:
- Transparent Bridging
- SRB
- Token Ring Inter-Switch Link
- Token Ring Route Switch Module
- RSRB
- DLSw+
- Serial Tunnel and Block Serial Tunnel
- LLC2 and SDLC
- IBM Network Media Translation
- SNA Frame Relay Access
- NCIA Client/Server
- Airline Product Set

Module VC/VR:
- Voice over IP
- Call Control Signalling
- Voice over Frame Relay
- Voice over ATM
- Telephony Applications
- Trunk Management
- Fax, Video, and Modem Support

Module QC/QR:
- Packet Classification
- Congestion Management
- Congestion Avoidance
- Policing and Shaping
- Signalling
- Link Efficiency Mechanisms

Module XC/XR:
- Cisco IOS Switching Paths
- NetFlow Switching
- Multiprotocol Label Switching
- Multilayer Switching
- Multicast Distributed Switching
- Virtual LANs
- LAN Emulation
Master Indexes

Two master indexes provide indexing information for the Cisco IOS software documentation set: an index for the configuration guides and an index for the command references. Individual books also contain a book-specific index.

The master indexes provide a quick way for you to find a command when you know the command name but not which module contains the command. When you use the online master indexes, you can click the page number for an index entry and go to that page in the online document.

Supporting Documents and Resources

The following documents and resources support the Cisco IOS software documentation set:

- *Cisco IOS Command Summary* (two volumes)—This publication explains the function and syntax of the Cisco IOS software commands. For more information about defaults and usage guidelines, refer to the Cisco IOS command reference publications.

- *Cisco IOS System Error Messages*—This publication lists and describes Cisco IOS system error messages. Not all system error messages indicate problems with your system. Some are purely informational, and others may help diagnose problems with communications lines, internal hardware, or the system software.

- *Cisco IOS Debug Command Reference*—This publication contains an alphabetical listing of the debug commands and their descriptions. Documentation for each command includes a brief description of its use, command syntax, usage guidelines, and sample output.

- *Dictionary of Internetworking Terms and Acronyms*—This Cisco publication compiles and defines the terms and acronyms used in the internetworking industry.

- New feature documentation—The Cisco IOS software documentation set documents the mainline release of Cisco IOS software (for example, Cisco IOS Release 12.2). New software features are introduced in early deployment releases (for example, the Cisco IOS “T” release train for 12.2, 12.2(x)T). Documentation for these new features can be found in standalone documents called “feature modules.” Feature module documentation describes new Cisco IOS software and hardware networking functionality and is available on Cisco.com and the Documentation CD-ROM.

- Release notes—This documentation describes system requirements, provides information about new and changed features, and includes other useful information about specific software releases. See the section “Using Software Release Notes” in the chapter “Using Cisco IOS Software” for more information.

- Caveats documentation—This documentation provides information about Cisco IOS software defects in specific software releases.

- RFCs—RFCs are standards documents maintained by the Internet Engineering Task Force (IETF). Cisco IOS software documentation references supported RFCs when applicable. The full text of referenced RFCs may be obtained on the World Wide Web at http://www.rfc-editor.org/.

- MIBs—MIBs are used for network monitoring. For lists of supported MIBs by platform and release, and to download MIB files, see the Cisco MIB website on Cisco.com at http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml.
New and Changed Information

The following is new or changed information since the last release of the Cisco IOS IP and IP routing publications:

- The title of the *Cisco IOS IP and IP Routing Configuration Guide* has been changed to *Cisco IOS IP Configuration Guide*.

- The *Cisco IOS IP and IP Routing Command Reference* has been divided into three separate publications with the following titles:
  - *Cisco IOS IP Command Reference, Volume 1 of 3: Addressing and Services*
  - *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols*
  - *Cisco IOS IP Command Reference, Volume 3 of 3: Multicast*

- The following new chapters were added to the *Cisco IOS IP Configuration Guide*:
  - “Configuring Server Load Balancing”
  - “Configuring Source Specific Multicast”
  - “Configuring Bidirectional PIM”
  - “Configuring Router-Port Group Management Protocol”

- The following new chapter was added to the *Cisco IOS IP Command Reference, Volume 1 of 3: Addressing and Services*:
  - “Server Load Balancing Commands”

Document Conventions

Within Cisco IOS software documentation, the term *router* is generally used to refer to a variety of Cisco products (for example, routers, access servers, and switches). Routers, access servers, and other networking devices that support Cisco IOS software are shown interchangeably within examples. These products are used only for illustrative purposes; that is, an example that shows one product does not necessarily indicate that other products are not supported.

The Cisco IOS documentation set uses the following conventions:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>^ or Ctrl</td>
<td>The ^ and Ctrl symbols represent the Control key. For example, the key combination ^D or Ctrl-D means hold down the Control key while you press the D key. Keys are indicated in capital letters but are not case sensitive.</td>
</tr>
<tr>
<td>string</td>
<td>A string is a nonquoted set of characters shown in italics. For example, when setting an SNMP community string to public, do not use quotation marks around the string or the string will include the quotation marks.</td>
</tr>
</tbody>
</table>
Command syntax descriptions use the following conventions:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface</strong></td>
<td>Boldface text indicates commands and keywords that you enter literally as shown.</td>
</tr>
<tr>
<td><em>italics</em></td>
<td>Italic text indicates arguments for which you supply values.</td>
</tr>
<tr>
<td>[x]</td>
<td>Square brackets enclose an optional element (keyword or argument).</td>
</tr>
<tr>
<td>( )</td>
<td>A vertical line indicates a choice within an optional or required set of keywords or arguments.</td>
</tr>
<tr>
<td>([x \mid y])</td>
<td>Square brackets enclosing keywords or arguments separated by a vertical line indicate an optional choice.</td>
</tr>
<tr>
<td>({x \mid y})</td>
<td>Braces enclosing keywords or arguments separated by a vertical line indicate a required choice.</td>
</tr>
</tbody>
</table>

Nested sets of square brackets or braces indicate optional or required choices within optional or required elements. For example:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>([x {y \mid z})]</td>
<td>Braces and a vertical line within square brackets indicate a required choice within an optional element.</td>
</tr>
</tbody>
</table>

Examples use the following conventions:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>screen</strong></td>
<td>Examples of information displayed on the screen are set in Courier font.</td>
</tr>
<tr>
<td><strong>boldface screen</strong></td>
<td>Examples of text that you must enter are set in Courier bold font.</td>
</tr>
<tr>
<td>&lt; &gt;</td>
<td>Angle brackets enclose text that is not printed to the screen, such as passwords.</td>
</tr>
<tr>
<td>!</td>
<td>An exclamation point at the beginning of a line indicates a comment line. (Exclamation points are also displayed by the Cisco IOS software for certain processes.)</td>
</tr>
<tr>
<td>[ ]</td>
<td>Square brackets enclose default responses to system prompts.</td>
</tr>
</tbody>
</table>

The following conventions are used to attract the attention of the reader:

- **Caution**
  
  Means *reader be careful*. In this situation, you might do something that could result in equipment damage or loss of data.

- **Note**
  
  Means *reader take note*. Notes contain helpful suggestions or references to materials not contained in this manual.

- **Timesaver**
  
  Means the *described action saves time*. You can save time by performing the action described in the paragraph.
Obtaining Documentation

The following sections provide sources for obtaining documentation from Cisco Systems.

World Wide Web

The most current Cisco documentation is available on the World Wide Web at the following website:
http://www.cisco.com
Translated documentation is available at the following website:

Documentation CD-ROM

Cisco documentation and additional literature are available in a CD-ROM package, which ships with your product. The Documentation CD-ROM is updated monthly and may be more current than printed documentation. The CD-ROM package is available as a single unit or through an annual subscription.

Ordering Documentation

Cisco documentation can be ordered in the following ways:

- Registered Cisco Direct Customers can order Cisco product documentation from the Networking Products MarketPlace:
  http://www.cisco.com/cgi-bin/order/order_root.pl
- Registered Cisco.com users can order the Documentation CD-ROM through the online Subscription Store:
  http://www.cisco.com/go/subscription
- Nonregistered Cisco.com users can order documentation through a local account representative by calling Cisco corporate headquarters (California, USA) at 408 526-7208 or, in North America, by calling 800 553-NETS(6387).

Documentation Feedback

If you are reading Cisco product documentation on the World Wide Web, you can submit technical comments electronically. Click Feedback in the toolbar and select Documentation. After you complete the form, click Submit to send it to Cisco.

You can e-mail your comments to bug-doc@cisco.com.
Obtaining Technical Assistance

Cisco provides Cisco.com as a starting point for all technical assistance. Customers and partners can obtain documentation, troubleshooting tips, and sample configurations from online tools. For Cisco.com registered users, additional troubleshooting tools are available from the TAC website.

Cisco.com

Cisco.com is the foundation of a suite of interactive, networked services that provides immediate, open access to Cisco information and resources at anytime, from anywhere in the world. This highly integrated Internet application is a powerful, easy-to-use tool for doing business with Cisco.

Cisco.com provides a broad range of features and services to help customers and partners streamline business processes and improve productivity. Through Cisco.com, you can find information about Cisco and our networking solutions, services, and programs. In addition, you can resolve technical issues with online technical support, download and test software packages, and order Cisco learning materials and merchandise. Valuable online skill assessment, training, and certification programs are also available.

Customers and partners can self-register on Cisco.com to obtain additional personalized information and services. Registered users can order products, check on the status of an order, access technical support, and view benefits specific to their relationships with Cisco.

To access Cisco.com, go to the following website:

http://www.cisco.com

Technical Assistance Center

The Cisco TAC website is available to all customers who need technical assistance with a Cisco product or technology that is under warranty or covered by a maintenance contract.

Contacting TAC by Using the Cisco TAC Website

If you have a priority level 3 (P3) or priority level 4 (P4) problem, contact TAC by going to the TAC website:

http://www.cisco.com/tac
P3 and P4 level problems are defined as follows:

- **P3**—Your network performance is degraded. Network functionality is noticeably impaired, but most business operations continue.
- **P4**—You need information or assistance on Cisco product capabilities, product installation, or basic product configuration.

In each of the above cases, use the Cisco TAC website to quickly find answers to your questions.

To register for Cisco.com, go to the following website:

http://www.cisco.com/register/

If you cannot resolve your technical issue by using the TAC online resources, Cisco.com registered users can open a case online by using the TAC Case Open tool at the following website:

http://www.cisco.com/tac/caseopen

**Contacting TAC by Telephone**

If you have a priority level 1 (P1) or priority level 2 (P2) problem, contact TAC by telephone and immediately open a case. To obtain a directory of toll-free numbers for your country, go to the following website:

P1 and P2 level problems are defined as follows:

- **P1**—Your production network is down, causing a critical impact to business operations if service is not restored quickly. No workaround is available.
- **P2**—Your production network is severely degraded, affecting significant aspects of your business operations. No workaround is available.
This chapter provides helpful tips for understanding and configuring Cisco IOS software using the command-line interface (CLI). It contains the following sections:

- Understanding Command Modes
- Getting Help
- Using the no and default Forms of Commands
- Saving Configuration Changes
- Filtering Output from the show and more Commands
- Identifying Supported Platforms

For an overview of Cisco IOS software configuration, refer to the *Cisco IOS Configuration Fundamentals Configuration Guide*.

For information on the conventions used in the Cisco IOS software documentation set, see the chapter “About Cisco IOS Software Documentation” located at the beginning of this book.

**Understanding Command Modes**

You use the CLI to access Cisco IOS software. Because the CLI is divided into many different modes, the commands available to you at any given time depend on the mode you are currently in. Entering a question mark (?) at the CLI prompt allows you to obtain a list of commands available for each command mode.

When you log in to the CLI, you are in user EXEC mode. User EXEC mode contains only a limited subset of commands. To have access to all commands, you must enter privileged EXEC mode, normally by using a password. From privileged EXEC mode you can issue any EXEC command—user or privileged mode—or you can enter global configuration mode. Most EXEC commands are one-time commands. For example, `show` commands show important status information, and `clear` commands clear counters or interfaces. The EXEC commands are not saved when the software reboots.

Configuration modes allow you to make changes to the running configuration. If you later save the running configuration to the startup configuration, these changed commands are stored when the software is rebooted. To enter specific configuration modes, you must start at global configuration mode. From global configuration mode, you can enter interface configuration mode and a variety of other modes, such as protocol-specific modes.

ROM monitor mode is a separate mode used when the Cisco IOS software cannot load properly. If a valid software image is not found when the software boots or if the configuration file is corrupted at startup, the software might enter ROM monitor mode.
Table 1 describes how to access and exit various common command modes of the Cisco IOS software. It also shows examples of the prompts displayed for each mode.

**Table 1  Accessing and Exiting Command Modes**

<table>
<thead>
<tr>
<th>Command Mode</th>
<th>Access Method</th>
<th>Prompt</th>
<th>Exit Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>User EXEC</td>
<td>Log in.</td>
<td>Router&gt;</td>
<td>Use the logout command.</td>
</tr>
<tr>
<td>Privileged EXEC</td>
<td>From user EXEC mode, use the enable EXEC command.</td>
<td>Router#</td>
<td>To return to user EXEC mode, use the disable command.</td>
</tr>
<tr>
<td>Global configuration</td>
<td>From privileged EXEC mode, use the configure terminal privileged EXEC command.</td>
<td>Router(config)#</td>
<td>To return to privileged EXEC mode from global configuration mode, use the exit or end command, or press Ctrl-Z.</td>
</tr>
<tr>
<td>Interface configuration</td>
<td>From global configuration mode, specify an interface using an interface command.</td>
<td>Router(config-if)#</td>
<td>To return to global configuration mode, use the exit command. To return to privileged EXEC mode, use the end command, or press Ctrl-Z.</td>
</tr>
<tr>
<td>ROM monitor</td>
<td>From privileged EXEC mode, use the reload EXEC command. Press the Break key during the first 60 seconds while the system is booting.</td>
<td>&gt;</td>
<td>To exit ROM monitor mode, use the continue command.</td>
</tr>
</tbody>
</table>

For more information on command modes, refer to the “Using the Command-Line Interface” chapter in the *Cisco IOS Configuration Fundamentals Configuration Guide*.

**Getting Help**

Entering a question mark (?) at the CLI prompt displays a list of commands available for each command mode. You can also get a list of keywords and arguments associated with any command by using the context-sensitive help feature.

To get help specific to a command mode, a command, a keyword, or an argument, use one of the following commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>help</td>
<td>Provides a brief description of the help system in any command mode.</td>
</tr>
<tr>
<td>abbreviated-command-entry?</td>
<td>Provides a list of commands that begin with a particular character string. (No space between command and question mark.)</td>
</tr>
<tr>
<td>abbreviated-command-entry&lt;Tab&gt;</td>
<td>Completes a partial command name.</td>
</tr>
<tr>
<td>?</td>
<td>Lists all commands available for a particular command mode.</td>
</tr>
<tr>
<td>command ?</td>
<td>Lists the keywords or arguments that you must enter next on the command line. (Space between command and question mark.)</td>
</tr>
</tbody>
</table>
Example: How to Find Command Options

This section provides an example of how to display syntax for a command. The syntax can consist of optional or required keywords and arguments. To display keywords and arguments for a command, enter a question mark (?) at the configuration prompt or after entering part of a command followed by a space. The Cisco IOS software displays a list and brief description of available keywords and arguments. For example, if you were in global configuration mode and wanted to see all the keywords or arguments for the `arp` command, you would type `arp ?`.

The `<cr>` symbol in command help output stands for “carriage return.” On older keyboards, the carriage return key is the Return key. On most modern keyboards, the carriage return key is the Enter key. The `<cr>` symbol at the end of command help output indicates that you have the option to press Enter to complete the command and that the arguments and keywords in the list preceding the `<cr>` symbol are optional. The `<cr>` symbol by itself indicates that no more arguments or keywords are available and that you must press Enter to complete the command.

Table 2 shows examples of how you can use the question mark (?) to assist you in entering commands. The table steps you through configuring an IP address on a serial interface on a Cisco 7206 router that is running Cisco IOS Release 12.0(3).

<table>
<thead>
<tr>
<th>Command</th>
<th>Comment</th>
</tr>
</thead>
</table>
| **Router> enable**  
Password: <password>  
Router# | Enter the `enable` command and password to access privileged EXEC commands. You are in privileged EXEC mode when the prompt changes to `Router#`. |
| **Router# configure terminal**  
Enter configuration commands, one per line. End with CNTL/Z.  
Router(config)# | Enter the `configure terminal` privileged EXEC command to enter global configuration mode. You are in global configuration mode when the prompt changes to `Router(config)#`. |
| **Router(config)# interface serial ?**  
  <0-6> Serial interface number  
**Router(config)# interface serial 4 ?**  
  /  
**Router(config)# interface serial 4/ ?**  
  <0-3> Serial interface number  
**Router(config)# interface serial 4/0**  
**Router(config-if)#** | Enter interface configuration mode by specifying the serial interface that you want to configure using the `interface serial` global configuration command. Enter ? to display what you must enter next on the command line. In this example, you must enter the serial interface slot number and port number, separated by a forward slash. You are in interface configuration mode when the prompt changes to `Router(config-if)#`. |
**Table 2  How to Find Command Options (continued)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config-if)# ? Interface configuration commands:</td>
<td>Enter ? to display a list of all the interface configuration commands available for the serial interface. This example shows only some of the available interface configuration commands.</td>
</tr>

</tr>
</tbody>
</table>
### Table 2  How to Find Command Options (continued)

<table>
<thead>
<tr>
<th>Command</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config-if)# ip address ?</td>
<td>Enter the command that you want to configure for the interface. This example uses the <code>ip address</code> command. Enter ? to display what you must enter next on the command line. In this example, you must enter an IP address or the <code>negotiated</code> keyword. A carriage return (&lt;cr&gt;) is not displayed; therefore, you must enter additional keywords or arguments to complete the command.</td>
</tr>
<tr>
<td>A.B.C.D negotiated</td>
<td>IP Address negotiated over PPP</td>
</tr>
<tr>
<td>Router(config-if)# ip address</td>
<td></td>
</tr>
</tbody>
</table>

| Router(config-if)# ip address 172.16.0.1 ? | Enter the keyword or argument you want to use. This example uses the 172.16.0.1 IP address. Enter ? to display what you must enter next on the command line. In this example, you must enter an IP subnet mask. A <cr> is not displayed; therefore, you must enter additional keywords or arguments to complete the command. |
| A.B.C.D | IP subnet mask |
| Router(config-if)# ip address 172.16.0.1 | |

| Router(config-if)# ip address 172.16.0.1 255.255.255.0 ? | Enter the IP subnet mask. This example uses the 255.255.255.0 IP subnet mask. Enter ? to display what you must enter next on the command line. In this example, you can enter the `secondary` keyword, or you can press Enter. A <cr> is displayed; you can press Enter to complete the command, or you can enter another keyword. |
| secondary | Make this IP address a secondary address |
| Router(config-if)# ip address 172.16.0.1 255.255.255.0 | |

| Router(config-if)# ip address 172.16.0.1 255.255.255.0 | In this example, Enter is pressed to complete the command. |
| Router(config-if)# | |

### Using the no and default Forms of Commands

Almost every configuration command has a no form. In general, use the no form to disable a function. Use the command without the no keyword to reenable a disabled function or to enable a function that is disabled by default. For example, IP routing is enabled by default. To disable IP routing, use the no `ip routing` command; to reenable IP routing, use the `ip routing` command. The Cisco IOS software command reference publications provide the complete syntax for the configuration commands and describe what the no form of a command does.

Configuration commands also can have a default form, which returns the command settings to the default values. Most commands are disabled by default, so in such cases using the default form has the same result as using the no form of the command. However, some commands are enabled by default and...
have variables set to certain default values. In these cases, the **default** form of the command enables the command and sets the variables to their default values. The Cisco IOS software command reference publications describe the effect of the **default** form of a command if the command functions differently than the **no** form.

## Saving Configuration Changes

Use the `copy system:running-config nvram:startup-config` command to save your configuration changes to the startup configuration so that the changes will not be lost if the software reloads or a power outage occurs. For example:

```
Router# copy system:running-config nvram:startup-config
Building configuration...
```

It might take a minute or two to save the configuration. After the configuration has been saved, the following output appears:

```
[OK]
Router#
```

On most platforms, this task saves the configuration to NVRAM. On the Class A Flash file system platforms, this task saves the configuration to the location specified by the CONFIG_FILE environment variable. The CONFIG_FILE variable defaults to NVRAM.

## Filtering Output from the show and more Commands

In Cisco IOS Release 12.0(1)T and later releases, you can search and filter the output of `show` and `more` commands. This functionality is useful if you need to sort through large amounts of output or if you want to exclude output that you need not see.

To use this functionality, enter a `show` or `more` command followed by the “pipe” character (|); one of the keywords `begin`, `include`, or `exclude`; and a regular expression on which you want to search or filter (the expression is case-sensitive):

```
command | {begin | include | exclude} regular-expression
```

The output matches certain lines of information in the configuration file. The following example illustrates how to use output modifiers with the `show interface` command when you want the output to include only lines in which the expression “protocol” appears:

```
Router# show interface | include protocol
```

```
FastEthernet0/0 is up, line protocol is up
Serial4/0 is up, line protocol is up
Serial4/1 is up, line protocol is up
Serial4/2 is administratively down, line protocol is down
Serial4/3 is administratively down, line protocol is down
```

For more information on the search and filter functionality, refer to the “Using the Command-Line Interface” chapter in the *Cisco IOS Configuration Fundamentals Configuration Guide*. 

Identifying Supported Platforms

Cisco IOS software is packaged in feature sets consisting of software images that support specific platforms. The feature sets available for a specific platform depend on which Cisco IOS software images are included in a release. To identify the set of software images available in a specific release or to find out if a feature is available in a given Cisco IOS software image, see the following sections:

- Using Feature Navigator
- Using Software Release Notes

Using Feature Navigator

Feature Navigator is a web-based tool that enables you to quickly determine which Cisco IOS software images support a particular set of features and which features are supported in a particular Cisco IOS image.

Feature Navigator is available 24 hours a day, 7 days a week. To access Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, e-mail the Contact Database Administration group at cdbadmin@cisco.com. If you do not have an account on Cisco.com, go to http://www.cisco.com/register and follow the directions to establish an account.

To use Feature Navigator, you must have a JavaScript-enabled web browser such as Netscape 3.0 or later, or Internet Explorer 4.0 or later. Internet Explorer 4.0 always has JavaScript enabled. To enable JavaScript for Netscape 3.x or Netscape 4.x, follow the instructions provided with the web browser. For JavaScript support and enabling instructions for other browsers, check with the browser vendor.

Feature Navigator is updated when major Cisco IOS software releases and technology releases occur. You can access Feature Navigator at the following URL:

http://www.cisco.com/go/fn

Using Software Release Notes

Cisco IOS software releases include release notes that provide the following information:

- Platform support information
- Memory recommendations
- Microcode support information
- Feature set tables
- Feature descriptions
- Open and resolved severity 1 and 2 caveats for all platforms

Release notes are intended to be release-specific for the most current release, and the information provided in these documents may not be cumulative in providing information about features that first appeared in previous releases.
IP Addressing Commands

The Internet Protocol (IP) is a packet-based protocol used to exchange data over computer networks. IP handles addressing, fragmentation, reassembly, and protocol demultiplexing. It is the foundation on which all other Internet protocols, collectively referred to as the Internet Protocol suite, are built. IP is a network-layer protocol that contains addressing information and some control information that allows data packets to be routed.

The Transmission Control Protocol (TCP) is built upon the IP layer. TCP is a connection-oriented protocol that specifies the format of data and acknowledgments used in the transfer of data. TCP also specifies the procedures that the computers use to ensure that the data arrives correctly. TCP allows multiple applications on a system to communicate concurrently because it handles all demultiplexing of the incoming traffic among the application programs.

Use the commands in this chapter to configure and monitor the addressing of IP networks. For IP addressing configuration information and examples, refer to the “Configuring IP Addressing” chapter of the Cisco IOS IP Configuration Guide.
arp (global)

To add a permanent entry in the Address Resolution Protocol (ARP) cache, use the `arp global` configuration command. To remove an entry from the ARP cache, use the `no` form of this command.

```
arp ip-address hardware-address type [alias]
no arp ip-address hardware-address type [alias]
```

**Syntax Description**

- `ip-address`  
  IP address in four-part dotted decimal format corresponding to the local data-link address.

- `hardware-address`  
  Local data-link address (a 48-bit address).

- `type`  
  Encapsulation description. For Ethernet interfaces, this is typically the `arpa` keyword. For FDDI and Token Ring interfaces, this is always the `snap` keyword.

- `alias`  
  (Optional) Indicates that the Cisco IOS software should respond to ARP requests as if it were the owner of the specified address.

**Defaults**

No entries are permanently installed in the ARP cache.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The Cisco IOS software uses ARP cache entries to translate 32-bit IP addresses into 48-bit hardware addresses.

Because most hosts support dynamic resolution, you generally need not specify static ARP cache entries.

To remove all nonstatic entries from the ARP cache, use the `clear arp-cache` privileged EXEC command.

**Examples**

The following is an example of a static ARP entry for a typical Ethernet host:

```
arp 192.31.7.19 0800.0900.1834 arpa
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear arp-cache</td>
<td>Deletes all dynamic entries from the ARP cache.</td>
</tr>
</tbody>
</table>
**arp (interface)**

To control the interface-specific handling of IP address resolution into 48-bit Ethernet, FDDI, Frame Relay, and Token Ring hardware addresses, use the `arp` interface configuration command. To disable an encapsulation type, use the `no` form of this command.

```
arp { arpa | frame-relay | probe | snap }
```

```
no arp { arpa | frame-relay | probe | snap }
```

### Syntax Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arpa</td>
<td>Standard Ethernet-style Address Resolution Protocol (ARP) (RFC 826).</td>
</tr>
<tr>
<td>frame-relay</td>
<td>Enables ARP over a Frame Relay encapsulated interface.</td>
</tr>
<tr>
<td>probe</td>
<td>HP Probe protocol for IEEE-802.3 networks.</td>
</tr>
<tr>
<td>snap</td>
<td>ARP packets conforming to RFC 1042.</td>
</tr>
</tbody>
</table>

### Defaults

Standard Ethernet-style ARP

### Command Modes

Interface configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

Unlike most commands that have multiple arguments, the `arp` command has arguments that are not mutually exclusive. Each command enables or disables a specific type of ARP. For example, if you enter the `arp arpa` command followed by the `arp probe` command, the Cisco IOS software would send three packets (two for `probe` and one for `arpa`) each time it needed to discover a MAC address.

The `arp probe` command allows the software to use the Probe protocol (in addition to ARP) whenever it attempts to resolve an IEEE-802.3 or Ethernet local data-link address. The subset of Probe that performs address resolution is called Virtual Address Request and Reply. Using Probe, the Cisco IOS software can communicate transparently with Hewlett Packard IEEE-802.3 hosts that use this type of data encapsulation.

**Note**

Cisco support for HP Probe proxy support changed as of Release 8.3(2) and subsequent software releases. The `no arp probe` command is now the default. All interfaces that will use Probe must now be explicitly configured for the `arp probe` command.

Given a network protocol address (IP address), the `arp frame-relay` command determines the corresponding hardware address, which would be a data-link connection identifier (DLCI) for Frame Relay.

The `show interfaces` EXEC command displays the type of ARP being used on a particular interface. To remove all nonstatic entries from the ARP cache, use the `clear arp-cache` privileged EXEC command.
Examples

The following example enables probe services:

```
interface ethernet 0
arp probe
```

Related Commands

<tr>
<td>show interfaces</td>
<td>Displays statistics for all interfaces configured on the router or access server.</td>
</tr>
</tbody>
</table>
arp timeout

To configure how long an entry remains in the Address Resolution Protocol (ARP) cache, use the `arp timeout` interface configuration command. To restore the default value, use the `no` form of this command.

```
arp timeout seconds
no arp timeout seconds
```

**Syntax Description**

| seconds | Time (in seconds) that an entry remains in the ARP cache. A value of zero means that entries are never cleared from the cache. |

**Defaults**

14400 seconds (4 hours)

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command is ignored when issued on interfaces that do not use ARP. The `show interfaces` EXEC command displays the ARP timeout value. The value follows the “Entry Timeout:” heading, as seen in the following example from the `show interfaces` command:

```
ARP type: ARPA, PROBE, Entry Timeout: 14400 sec
```

**Examples**

The following example sets the ARP timeout to 12000 seconds to allow entries to time out more quickly than the default:

```
interface ethernet 0
arp timeout 12000
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td><code>show interfaces</code></td>
<td>Displays statistics for all interfaces configured on the router or access server.</td>
</tr>
</tbody>
</table>
clear arp-cache

To delete all dynamic entries from the Address Resolution Protocol ARP cache, to clear the fast-switching cache, and to clear the IP route cache, use the clear arp-cache EXEC command.

```
clear arp-cache
```

**Syntax Description**

This command has no arguments or keywords.

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Examples**

The following example removes all dynamic entries from the ARP cache and clears the fast-switching cache:

```
clear arp-cache
```

**Related Commands**

<td>Controls the interface-specific handling of IP address resolution into 48-bit Ethernet, FDDI, and Token Ring hardware addresses.</td>
</tr>
</tbody>
</table>
clear host

To delete entries from the host name-to-address cache, use the `clear host` EXEC command.

```
clear host {name | *}
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Particular host entry to remove.</td>
</tr>
<tr>
<td>*</td>
<td>Removes all entries.</td>
</tr>
</tbody>
</table>

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The host name entries will not be removed from NVRAM, but will be cleared in running memory.

**Examples**

The following example clears all entries from the host name-to-address cache:

```
clear host *
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip host</td>
<td>Defines a static host name-to-address mapping in the host cache.</td>
</tr>
<tr>
<td>show hosts</td>
<td>Displays the default domain name, the style of name lookup service, a list of name server hosts, and the cached list of host names and addresses.</td>
</tr>
</tbody>
</table>
clear ip nat translation

To clear dynamic Network Address Translation (NAT) translations from the translation table, use the `clear ip nat translation` EXEC command.

```
clear ip nat translation { * | [forced] | [inside global-ip local-ip] [outside local-ip global-ip] }
clear ip nat translation protocol inside global-ip global-port local-ip local-port [outside local-ip global-ip]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>*</code></td>
<td>Clears all dynamic translations.</td>
</tr>
<tr>
<td><code>forced</code></td>
<td>(Optional) Clears all dynamic translations and processes that are causing the router to hang.</td>
</tr>
<tr>
<td><code>inside</code></td>
<td>(Optional) Clears the inside translations containing the specified <code>global-ip</code> and <code>local-ip</code> addresses.</td>
</tr>
<tr>
<td><code>global-ip</code></td>
<td>(Optional) When used without the arguments <code>protocol</code>, <code>global-port</code>, and <code>local-port</code> arguments, clears a simple translation that also contains the specified <code>local-ip</code> address. When used with the <code>protocol</code>, <code>global-port</code>, and <code>local-port</code> arguments, clears an extended translation.</td>
</tr>
<tr>
<td><code>local-ip</code></td>
<td>(Optional) Clears an entry that contains this local IP address and the specified <code>global-ip</code> address.</td>
</tr>
<tr>
<td><code>outside</code></td>
<td>(Optional) Clears the outside translations containing the specified <code>global-ip</code> and <code>local-ip</code> addresses.</td>
</tr>
<tr>
<td><code>protocol</code></td>
<td>Clears an entry that contains this protocol and the specified <code>global-ip</code> address, <code>local-ip</code> address, <code>global-port</code> value, and <code>local-port</code> value.</td>
</tr>
<tr>
<td><code>global-port</code></td>
<td>Clears an entry that contains this <code>global-port</code> value and the specified <code>protocol value</code>, <code>global-ip</code> address, <code>local-ip</code> address, and <code>local-port</code> value.</td>
</tr>
<tr>
<td><code>local-port</code></td>
<td>Clears an entry that contains this <code>local-port</code> value and the specified <code>protocol value</code>, <code>global-ip</code> address, <code>local-ip</code> address, and <code>global-port</code> value.</td>
</tr>
</tbody>
</table>

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.2</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Use this command to clear entries from the translation table before they time out.

**Examples**

The following example shows the NAT entries before and after the User Datagram Protocol (UDP) entry is cleared:

```
Router# show ip nat translation
Pre Inside global       Inside local       Outside local       Outside global
udp 171.69.233.209:1220 192.168.1.95:1220 171.69.2.132:53 171.69.2.132:53
```
**clear ip nat translation**

```plaintext

Router# clear ip nat translation udp inside 171.69.233.209 1220 192.168.1.95 1220
171.69.2.132 53 171.69.2.132 53

Router# show ip nat translation

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Inside global</th>
<th>Inside local</th>
<th>Outside local</th>
<th>Outside global</th>
</tr>
</thead>
</table>

---

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip nat</td>
<td>Designates that traffic originating from or destined for the interface is subject to NAT.</td>
</tr>
<tr>

<td>Displays active NAT translations.</td>
</tr>
</tbody>
</table>
clear ip nhrp

To clear all dynamic entries from the Next Hop Resolution Protocol (NHRP) cache, use the clear ip nhrp EXEC command.

```
clear ip nhrp
```

**Syntax Description**
This command has no arguments or keywords.

**Command Modes**
EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
This command does not clear any static (configured) IP-to-nonbroadcast multiaccess (NBMA) address mappings from the NHRP cache.

**Examples**
The following example clears all dynamic entries from the NHRP cache for the interface:

```
clear ip nhrp
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip nhrp</td>
<td>Displays the NHRP cache.</td>
</tr>
</tbody>
</table>
clear ip route

To delete routes from the IP routing table, use the clear ip route EXEC command.

    clear ip route {network [mask] | *}

Syntax Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>network</td>
<td>Network or subnet address to remove.</td>
</tr>
<tr>
<td>mask</td>
<td>(Optional) Subnet address to remove.</td>
</tr>
<tr>
<td>*</td>
<td>Removes all routing table entries.</td>
</tr>
</tbody>
</table>

Defaults

All entries are removed.

Command Modes

EXEC

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

Examples

The following example removes a route to network 132.5.0.0 from the IP routing table:

    clear ip route 132.5.0.0
ip address

To set a primary or secondary IP address for an interface, use the `ip address` interface configuration command. To remove an IP address or disable IP processing, use the `no` form of this command.

```
ip address ip-address mask [secondary]
no ip address ip-address mask [secondary]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip-address</td>
<td>IP address.</td>
</tr>
<tr>
<td>mask</td>
<td>Mask for the associated IP subnet.</td>
</tr>
<tr>
<td>secondary</td>
<td>(Optional) Specifies that the configured address is a secondary IP address. If this keyword is omitted, the configured address is the primary IP address.</td>
</tr>
</tbody>
</table>

**Defaults**

No IP address is defined for the interface.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

An interface can have one primary IP address and multiple secondary IP addresses. Packets generated by the Cisco IOS software always use the primary IP address. Therefore, all routers and access servers on a segment should share the same primary network number.

Hosts can determine subnet masks using the Internet Control Message Protocol (ICMP) mask request message. Routers respond to this request with an ICMP mask reply message.

You can disable IP processing on a particular interface by removing its IP address with the `no ip address` command. If the software detects another host using one of its IP addresses, it will print an error message on the console.

The optional `secondary` keyword allows you to specify an unlimited number of secondary addresses. Secondary addresses are treated like primary addresses, except the system never generates datagrams other than routing updates with secondary source addresses. IP broadcasts and Address Resolution Protocol (ARP) requests are handled properly, as are interface routes in the IP routing table.

Secondary IP addresses can be used in a variety of situations. The following are the most common applications:

- There may not be enough host addresses for a particular network segment. For example, your subnetting allows up to 254 hosts per logical subnet, but on one physical subnet you need 300 host addresses. Using secondary IP addresses on the routers or access servers allows you to have two logical subnets using one physical subnet.
Many older networks were built using Level 2 bridges. The judicious use of secondary addresses can aid in the transition to a subnetted, router-based network. Routers on an older, bridged segment can be easily made aware that many subnets are on that segment.

Two subnets of a single network might otherwise be separated by another network. This situation is not permitted when subnets are in use. In these instances, the first network is extended, or layered on top of the second network using secondary addresses.

**Note**

If any router on a network segment uses a secondary address, all other devices on that same segment must also use a secondary address from the same network or subnet. Inconsistent use of secondary addresses on a network segment can very quickly cause routing loops.

**Note**

When you are routing using the Open Shortest Path First (OSPF) algorithm, ensure that all secondary addresses of an interface fall into the same OSPF area as the primary addresses.

To transparently bridge IP on an interface, you must perform the following two tasks:

- Disable IP routing (specify the `no ip routing` command).
- Add the interface to a bridge group, see the `bridge-group` command.

To concurrently route and transparently bridge IP on an interface, see the `bridge crb` command.

**Examples**

In the following example, 131.108.1.27 is the primary address and 192.31.7.17 and 192.31.8.17 are secondary addresses for Ethernet interface 0:

```
interface ethernet 0
  ip address 131.108.1.27 255.255.255.0
  ip address 192.31.7.17 255.255.255.0 secondary
  ip address 192.31.8.17 255.255.255.0 secondary
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bridge crb</code></td>
<td>Enables the Cisco IOS software to both route and bridge a given protocol on separate interfaces within a single router.</td>

<tr>
<td><code>bridge-group</code></td>
<td>Assigns each network interface to a bridge group.</td>
</tr>
</tbody>
</table>
ip broadcast-address

To define a broadcast address for an interface, use the **ip broadcast-address** interface configuration command. To restore the default IP broadcast address, use the **no** form of this command.

```
ip broadcast-address [ip-address]
no ip broadcast-address [ip-address]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ip-address</strong></td>
<td>(Optional) IP broadcast address for a network.</td>
</tr>
</tbody>
</table>

**Defaults**

Default address: 255.255.255.255 (all ones)

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Examples**

The following example specifies an IP broadcast address of 0.0.0.0:

```
ip broadcast-address 0.0.0.0
```
ip cef traffic-statistics

To change the time interval that controls when Next Hop Resolution Protocol (NHRP) will set up or tear down a switched virtual circuit (SVC), use the `ip cef traffic-statistics` global configuration command. To restore the default values, use the `no` form of this command.

```
ip cef traffic-statistics [load-interval seconds] [update-rate seconds]
```

**Syntax Description**

- `load-interval seconds` (Optional) Length of time (in 30-second increments) during which the average `trigger-threshold` and `teardown-threshold` intervals are calculated before an SVC setup or teardown action is taken. (These thresholds are configured in the `ip nhrp trigger-svc` command.) The `load-interval` range is from 30 seconds to 300 seconds, in 30-second increments. The default value is 30 seconds.

- `update-rate seconds` (Optional) Frequency that the port adapter sends the accounting statistics to the Route Processor (RP). When using NHRP in distributed CEF switching mode, this value must be set to 5 seconds. The default value is 10 seconds.

**Defaults**

- `load-interval`: 30 seconds
- `update-rate`: 10 seconds

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The thresholds in the `ip nhrp trigger-svc` command are measured during a sampling interval of 30 seconds, by default. To change that interval, use the `load-interval seconds` option of the `ip cef traffic-statistics` command.

When NHRP is configured on a CEF switching node with a Versatile Interface Processor (VIP2) adapter, you must make sure the `update-rate` keyword is set to 5 seconds.

Other Cisco IOS features could also use the `ip cef traffic-statistics` command; this NHRP feature relies on it.

**Examples**

In the following example, the triggering and teardown thresholds are calculated based on an average over 120 seconds:

```conf
ip cef traffic-statistics load-interval 120
```
### Related Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip nhrp trigger-svc</code></td>
<td>Configures when NHRP will set up and tear down an SVC based on aggregate traffic rates.</td>
</tr>
</tbody>
</table>
ip classless

At times the router might receive packets destined for a subnet of a network that has no network default route. To have the Cisco IOS software forward such packets to the best supernet route possible, use the ip classless global configuration command. To disable this feature, use the no form of this command.

```text
ip classless
no ip classless
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

Enabled

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>11.3</td>
<td>The default behavior changed from disabled to enabled.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command allows the software to forward packets that are destined for unrecognized subnets of directly connected networks. The packets are forwarded to the best supernet route.

When this feature is disabled, the Cisco IOS software discards the packets when a router receives packets for a subnet that numerically falls within its subnetwork addressing scheme, no such subnet number is in the routing table and there is no network default route.

**Note**

If the supernet, or default route, is learned via IS-IS or OSPF, the no ip classless configuration command is ignored.

**Examples**

The following example prevents the software from forwarding packets destined for an unrecognized subnet to the best supernet possible:

```text
no ip classless
```
**ip default-gateway**

To define a default gateway (router) when IP routing is disabled, use the `ip default-gateway` global configuration command. To disable this function, use the `no` form of this command.

```
ip default-gateway ip-address
no ip default-gateway ip-address
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip-address</td>
<td>IP address of the router.</td>
</tr>
</tbody>
</table>

**Defaults**

Disabled

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The Cisco IOS software sends any packets that need the assistance of a gateway to the address you specify. If another gateway has a better route to the requested host, the default gateway sends an Internet Control Message Protocol (ICMP) redirect message back. The ICMP redirect message indicates which local router the Cisco IOS software should use.

**Examples**

The following example defines the router on IP address 192.31.7.18 as the default router:

```
ip default-gateway 192.31.7.18
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip redirects</td>
<td>Enables the sending of ICMP redirect messages if the Cisco IOS software is forced to resend a packet through the same interface on which it was received.</td>
</tr>
<tr>
<td>show ip redirects</td>
<td>Displays the address of a default gateway (router) and the address of hosts for which an ICMP redirect message has been received.</td>
</tr>
</tbody>
</table>
ip directed-broadcast

To enable the translation of a directed broadcast to physical broadcasts, use the `ip directed-broadcast` interface configuration command. To disable this function, use the `no` form of this command.

```
ip directed-broadcast [access-list-number] | [extended access-list-number]
no ip directed-broadcast [access-list-number] | [extended access-list-number]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>access-list-number</code></td>
<td>(Optional) Standard access list number in the range from 1 to 199. If specified, a broadcast must pass the access list to be forwarded.</td>
</tr>
<tr>
<td><code>extended access-list-number</code></td>
<td>(Optional) Extended access list number in the range from 1300 to 2699.</td>
</tr>
</tbody>
</table>

**Defaults**

Disabled; all IP directed broadcasts are dropped.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.0</td>
<td>The default behavior changed to directed broadcasts being dropped.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

An IP directed broadcast is an IP packet whose destination address is a valid broadcast address for some IP subnet, but which originates from a node that is not itself part of that destination subnet.

A router that is not directly connected to its destination subnet forwards an IP directed broadcast in the same way it would forward unicast IP packets destined to a host on that subnet. When a directed broadcast packet reaches a router that is directly connected to its destination subnet, that packet is “exploded” as a broadcast on the destination subnet. The destination address in the IP header of the packet is rewritten to the configured IP broadcast address for the subnet, and the packet is sent as a link-layer broadcast.

The `ip directed-broadcast` interface command controls the explosion of directed broadcasts when they reach their target subnets. The command affects only the final transmission of the directed broadcast on its ultimate destination subnet. It does not affect the transit unicast routing of IP directed broadcasts.

If directed broadcast is enabled for an interface, incoming IP packets whose addresses identify them as directed broadcasts intended for the subnet to which that interface is attached will be exploded as broadcasts on that subnet. If an access list has been configured with the `ip directed-broadcast` command, only directed broadcasts that are permitted by the access list in question will be forwarded; all other directed broadcasts destined for the interface subnet will be dropped.

If the `no ip directed-broadcast` command has been configured for an interface, directed broadcasts destined for the subnet to which that interface is attached will be dropped, rather than being broadcast.
Because directed broadcasts, and particularly Internet Control Message Protocol (ICMP) directed broadcasts, have been abused by malicious persons, we recommend that security-conscious users disable the `ip directed-broadcast` command on any interface where directed broadcasts are not needed and that they use access lists to limit the number of exploded packets.

**Examples**

The following example enables forwarding of IP directed broadcasts on Ethernet interface 0:

```
interface ethernet 0
ip directed-broadcast
```

ip domain list

To define a list of default domain names to complete unqualified host names, use the `ip domain list` command in global configuration mode. To delete a name from a list, use the `no` form of this command.

```
ip domain list name
no ip domain list name
```

**Syntax Description**

<table>
<thead>
<tr>
<th>name</th>
<th>Domain name. Do not include the initial period that separates an unqualified name from the domain name.</th>
</tr>
</thead>
</table>

**Defaults**

No domain names are defined.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.2</td>
<td>The syntax of the command changed from <code>ip domain-list</code> to <code>ip domain list</code>.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

If there is no domain list, the domain name that you specified with the `ip domain name` global configuration command is used. If there is a domain list, the default domain name is not used. The `ip domain list` command is similar to the `ip domain name` command, except that with the `ip domain list` command you can define a list of domains, each to be tried in turn.

The Cisco IOS software will still accept the previous version of the command `ip domain-list`.

**Examples**

The following example adds several domain names to a list:

```
ip domain list company.com
ip domain list school.edu
```

The following example adds a name to and then deletes a name from the list:

```
ip domain list school.edu
no ip domain list school.edu
```

ip domain round-robin

To enable round-robin functionality on DNS servers, use the `ip domain round-robin` command in global configuration mode. To disable round-robin functionality, use the no form of the command.

```
ip domain round-robin
no ip domain round-robin
```

Syntax Description

This command has no arguments or keywords.

Defaults

Round robin is not enabled.

Command Modes

Global configuration

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.1(3)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

Usage Guidelines

In a multiple server configuration without the DNS round-robin functionality, the first host server/IP address is used for the whole time to live (TTL) of the cache, and uses the second and third only in the event of host failure. This behavior presents a problem when a high volume of users all arrive at the first host during the TTL time. The network access server (NAS) then sends out a DNS query; the DNS servers reply with a list of the configured IP addresses to the NAS. The NAS then caches these IP addresses for a given time (for example, five minutes). All users that dial in during the five minute TTL time will land on one host, the first IP address in the list.

In a multiple server configuration with the DNS round-robin functionality, the DNS server returns the IP address of all hosts to rotate between the cache of host names. During the TTL of the cache, users are distributed among the hosts. This functionality distributes calls across the configured hosts and reduces the amount of DNS queries.

Examples

The following example allows a Telnet to www.company.com to connect to each of the three IP addresses specified in the following order: the first time the Telnet command is given, it would connect to 10.0.0.1; the second time the command is given, it would connect to 20.0.0.1; and the third time the command is given, it would connect to 30.0.0.1. In each case, the other two addresses would also be tried if the first one failed; this is the normal operation of the Telnet command.

```
Router(config)# ip host www.company.com 10.0.0.1 20.0.0.1 30.0.0.1
Router(config)# ip domain round-robin
```
ip forward-protocol

To specify which protocols and ports the router forwards when forwarding broadcast packets, use the **ip forward-protocol** global configuration command. To remove a protocol or port, use the **no** form of this command.

```
ip forward-protocol {udp [port] | nd | sdns}
no ip forward-protocol {udp [port] | nd | sdns}
```

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Enabling a helper address or UDP flooding on an interface causes the Cisco IOS software to forward particular broadcast packets. You can use the **ip forward-protocol** command to specify exactly which types of broadcast packets you would like to have forwarded. A number of commonly forwarded applications are enabled by default. Enabling forwarding for some ports (for example, Routing Information Protocol (RIP)) may be hazardous to your network.

If you use the **ip forward-protocol** command, specifying only UDP without the port enables forwarding and flooding on the default ports.

One common application that requires helper addresses is Dynamic Host Configuration Protocol (DHCP). DHCP is defined in RFC 1531. DHCP protocol information is carried inside of BOOTP packets. To enable BOOTP broadcast forwarding for a set of clients, configure a helper address on the router interface closest to the client. The helper address should specify the address of the DHCP server. If you have multiple servers, you can configure one helper address for each server. Because BOOTP packets are forwarded by default, DHCP information can now be forwarded by the software. The DHCP server now receives broadcasts from the DHCP clients.

If an IP helper address is defined, UDP forwarding is enabled on default ports. If UDP flooding is configured, UDP flooding is enabled on the default ports.

If a helper address is specified and UDP forwarding is enabled, broadcast packets destined to the following port numbers are forwarded by default:
- Trivial File Transfer Protocol (TFTP) (port 69)
- Domain Naming System (port 53)
- Time service (port 37)
- NetBIOS Name Server (port 137)
- NetBIOS Datagram Server (port 138)
- Boot Protocol (BOOTP) client and server datagrams (ports 67 and 68)
- TACACS service (port 49)
- IEN-116 Name Service (port 42)
### ip forward-protocol spanning-tree

To permit IP broadcasts to be flooded throughout the internetwork in a controlled fashion, use the `ip forward-protocol spanning-tree` global configuration command. To disable the flooding of IP broadcasts, use the `no` form of this command.

```
ip forward-protocol spanning-tree [any-local-broadcast]
no ip forward-protocol spanning-tree [any-local-broadcast]
```

#### Syntax Description

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>any-local-broadcast</td>
<td>(Optional) Accept any local broadcast when flooding.</td>
</tr>
</tbody>
</table>

#### Defaults

#### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

#### Usage Guidelines

A packet must meet the following criteria to be considered for flooding:

- The MAC address of the received frame must be all-ones broadcast address (ffff.ffff.ffff).
- The IP destination address must be one of the following: all-ones broadcast (255.255.255.255), subnet broadcast for the receiving interface; major-net broadcast for the receiving interface if the `no ip classless` command is also configured; or any local IP broadcast address if the `ip forward-protocol spanning-tree any-local-broadcast` command is configured.
- The IP time-to-live (TTL) value must be at least 2.
- The IP protocol must be UDP (17).
- The UDP destination port must be for TFTP, Domain Name System (DNS), Time, NetBIOS, ND, or BOOTP packet, or a UDP port specified by the `ip forward-protocol udp` global configuration command.

A flooded UDP datagram is given the destination address specified by the `ip broadcast-address` interface configuration command on the output interface. The destination address can be set to any desired address. Thus, the destination address may change as the datagram propagates through the network. The source address is never changed. The TTL value is decremented.

After a decision has been made to send the datagram out on an interface (and the destination address possibly changed), the datagram is handed to the normal IP output routines and is therefore subject to access lists, if they are present on the output interface.

The `ip forward-protocol spanning-tree` command uses the database created by the bridging Spanning-Tree Protocol. Therefore, the transparent bridging option must be in the routing software, and bridging must be configured on each interface that is to participate in the flooding in order to support this capability.
If an interface does not have bridging configured, it still will be able to receive broadcasts, but it will never forward broadcasts received on that interface. Also, it will never use that interface to send broadcasts received on a different interface.

If no actual bridging is desired, you can configure a type-code bridging filter that will deny all packet types from being bridged. Refer to the “Configuring Transparent Bridging” chapter in the Cisco IOS Bridging and IBM Networking Configuration Guide for more information about using access lists to filter bridged traffic. The spanning-tree database is still available to the IP forwarding code to use for the flooding.

The spanning-tree-based flooding mechanism forwards packets whose contents are all ones (255.255.255.255), all zeros (0.0.0.0), and, if subnetting is enabled, all networks (131.108.255.255 as an example in the network number 131.108.0.0). This mechanism also forwards packets whose contents are the zeros version of the all-networks broadcast when subnetting is enabled (for example, 131.108.0.0).

This command is an extension of the `ip helper-address` interface configuration command, in that the same packets that may be subject to the helper address and forwarded to a single network can now be flooded. Only one copy of the packet will be put on each network segment. In some cases, where DHCP broadcasts are being forwarded to spanning-tree enabled interfaces, a duplicate copy of the packet will be put on a network segment. See the `ip directed-broadcast` global configuration command for information on how to ensure that duplicate packets are not copied onto a network segment.

### Examples

The following example permits IP broadcasts to be flooded through the internetwork in a controlled fashion:

```
ip forward-protocol spanning-tree
```

</table>
ip forward-protocol turbo-flood

To speed up flooding of User Datagram Protocol (UDP) datagrams using the spanning-tree algorithm, use the `ip forward-protocol turbo-flood` global configuration command. To disable this feature, use the `no` form of this command.

```
ip forward-protocol turbo-flood
no ip forward-protocol turbo-flood
```

**Syntax Description**
This command has no arguments or keywords.

**Defaults**
Disabled

**Command Modes**
Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
Used in conjunction with the `ip forward-protocol spanning-tree` global configuration command, this feature is supported over Advanced Research Projects Agency (ARPA)-encapsulated Ethernets, FDDI, and High-Level Data Link Control (HDLC) encapsulated serials, but is not supported on Token Rings. As long as the Token Rings and the non-HDLC serials are not part of the bridge group being used for UDP flooding, turbo flooding will behave normally.

**Examples**
The following is an example of a two-port router using this command:

```
! ip forward-protocol turbo-flood
! ip forward-protocol spanning-tree
!
! interface ethernet 0
!     ip address 128.9.1.1
!     bridge-group 1
!
! interface ethernet 1
!     ip address 128.9.1.2
!     bridge-group 1
!
! bridge 1 protocol dec
```

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

Combined with the **ip forward-protocol** global configuration command, the **ip helper-address** command allows you to control which broadcast packets and which protocols are forwarded.

One common application that requires helper addresses is Dynamic Host Configuration Protocol (DHCP), which is defined in RFC 1531. DHCP protocol information is carried inside of BOOTP packets. To enable BOOTP broadcast forwarding for a set of clients, configure a helper address on the router interface closest to the client. The helper address should specify the address of the DHCP server. If you have multiple servers, you can configure one helper address for each server. Because BOOTP packets are forwarded by default, DHCP information can now be forwarded by the router. The DHCP server now receives broadcasts from the DHCP clients.

All of the following conditions must be met in order for a UDP or IP packet to be helpered by the **ip helper-address** command:

- The MAC address of the received frame must be all-ones broadcast address (ffff.ffff.ffff).
- The IP destination address must be one of the following: all-ones broadcast (255.255.255.255), subnet broadcast for the receiving interface; or major-net broadcast for the receiving interface if the **no ip classless** command is also configured.
- The IP time-to-live (TTL) value must be at least 2.
- The IP protocol must be UDP (17).
- The UDP destination port must be for TFTP, Domain Name System (DNS), Time, NetBIOS, ND, BOOTP or DHCP packet, or a UDP port specified by the **ip forward-protocol udp** global configuration command.
The `ip helper-address` command does not work on an X.25 interface on a destination router because the router cannot determine if the packet was intended as a physical broadcast.

Examples

The following example defines an address that acts as a helper address:

```plaintext
interface ethernet 1
ip helper-address 121.24.43.2
```

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The first character can be either a letter or a number. If you use a number, the types of operations you can perform (such as ping) are limited.

**Examples**

The following example defines two static mappings:

```
ip host croff 192.31.7.18
ip host bisso-gw 10.2.0.2 192.31.7.33
```
ip hp-host

To enter into the host table the host name of a Hewlett-Packard (HP) host to be used for HP Probe Proxy service, use the **ip hp-host** global configuration command. To remove a host name, use the **no** form of this command.

```
ip hp-host host-name ip-address

no ip hp-host host-name ip-address
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host-name</td>
<td>Name of the host.</td>
</tr>
<tr>
<td>ip-address</td>
<td>IP address of the host.</td>
</tr>
</tbody>
</table>

**Defaults**

No host names are defined.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

To use the HP Probe Proxy service, you must first enter the host name of the HP host into the host table using this command.

**Examples**

The following example specifies the name and address of an HP host, and then enables HP Probe Proxy:

```
ip hp-host BCWjo 131.108.1.27
interface ethernet 0
ip probe proxy
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ip probe proxy</strong></td>
<td>Enables the HP Probe Proxy support, which allows the Cisco IOS software to respond to HP Probe Proxy name requests.</td>
</tr>
</tbody>
</table>
ip irdp

To enable ICMP Router Discovery Protocol (IRDP) processing on an interface, use the `ip irdp` interface configuration command. To disable IRDP routing, use the `no` form of this command.

```
ip irdp [multicast | holdtime seconds | maxadvertinterval seconds | minadvertinterval seconds | preference number | address address [number]]
no ip irdp
```

### Syntax Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>multicast</code></td>
<td>(Optional) Use the multicast address (224.0.0.1) instead of IP broadcasts.</td>
</tr>
<tr>
<td><code>holdtime seconds</code></td>
<td>(Optional) Length of time in seconds that advertisements are held valid. Default is three times the <code>maxadvertinterval</code> value. Must be greater than <code>maxadvertinterval</code> and cannot be greater than 9000 seconds.</td>
</tr>
<tr>
<td><code>maxadvertinterval seconds</code></td>
<td>(Optional) Maximum interval in seconds between advertisements. The range is from 1 to 1800. A value of 0 means only advertise when solicited. The default is 600 seconds.</td>
</tr>
<tr>
<td><code>minadvertinterval seconds</code></td>
<td>(Optional) Minimum interval in seconds between advertisements. The range is from 1 to 1800. The default is 450 seconds.</td>
</tr>
<tr>
<td><code>preference number</code></td>
<td>(Optional) Preference value. The allowed range is $-2^{31}$ to $2^{31}$. The default is 0. A higher value increases the preference level of the router. You can modify a particular router so that it will be the preferred router to which other routers will home.</td>
</tr>
<tr>
<td><code>address address [number]</code></td>
<td>(Optional) IP address (address) to proxy advertise, and optionally, its preference value (number).</td>
</tr>
</tbody>
</table>

### Defaults

Disabled

When enabled, IRDP uses these defaults:

- Broadcast IRDP advertisements
- Maximum interval between advertisements: 600 seconds
- Minimum interval between advertisements: 450 seconds
- Preference: 0

### Command Modes

Interface configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>
Usage Guidelines

If you change the `maxadvertinterval` value, the other two values also change, so it is important to change the `maxadvertinterval` value before changing either the `holdtime` or `minadvertinterval` values.

The `ip irdp multicast` command allows for compatibility with Sun Microsystems Solaris, which requires IRDP packets to be sent out as multicasts. Many implementations cannot receive these multicasts; ensure end-host ability before using this command.

Examples

The following example sets the various IRDP processes:

```
! enable irdp on interface Ethernet 0
interface ethernet 0
  ip irdp
! send IRDP advertisements to the multicast address
  ip irdp multicast
! increase router preference from 100 to 50
  ip irdp preference 50
! set maximum time between advertisements to 400 secs
  ip irdp maxadvertinterval 400
! set minimum time between advertisements to 100 secs
  ip irdp minadvertinterval 100
! advertisements are good for 6000 seconds
  ip irdp holdtime 6000
! proxy-advertise 131.108.14.5 with default router preference
  ip irdp address 131.108.14.5
! proxy-advertise 131.108.14.6 with preference of 50
  ip irdp address 131.108.14.6 50
```

**ip mobile arp**

To enable local-area mobility, use the **ip mobile arp** interface configuration command. To disable local-area mobility, use the **no** form of this command.

```
ip mobile arp [timers keepalive hold-time] [access-group access-list-number | name]
no ip mobile arp [timers keepalive hold-time] [access-group access-list-number | name]
```

### Syntax Description

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timers</td>
<td>(Optional) Indicates that you are setting local-area mobility timers.</td>
</tr>
<tr>
<td>keepalive</td>
<td>(Optional) Frequency, in minutes, at which the Cisco IOS software sends unicast Address Resolution Protocol (ARP) messages to a relocated host to verify that the host is present and has not moved. The default keepalive time is 5 minutes (300 seconds).</td>
</tr>
<tr>
<td>hold-time</td>
<td>(Optional) Hold time, in minutes. This is the length of time the software considers that a relocated host is present without receiving some type of ARP broadcast or unicast from the host. Normally, the hold time should be at least three times greater than the keepalive time. The default hold time is 15 minutes (900 seconds).</td>
</tr>
<tr>
<td>access-group</td>
<td>(Optional) Indicates that you are applying an access list. This access list applies only to local-area mobility.</td>
</tr>
<tr>
<td>access-list-number</td>
<td>(Optional) Number of a standard IP access list. It is a decimal number from 1 to 99. Only hosts with addresses permitted by this access list are accepted for local-area mobility.</td>
</tr>
<tr>
<td>name</td>
<td>(Optional) Name of an IP access list. The name cannot contain a space or quotation mark, and must begin with an alphabetic character to avoid ambiguity with numbered access lists.</td>
</tr>
</tbody>
</table>

### Defaults

Local-area mobility is disabled.

If you enable local-area mobility:

- **keepalive**: 5 minutes (300 seconds)
- **hold-time**: 15 minutes (900 seconds)

### Command Modes

Interface configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

Local-area mobility is supported on Ethernet, Token Ring, and FDDI interfaces only.
To create larger mobility areas, you must first redistribute the mobile routes into your Interior Gateway Protocol (IGP). The IGP must support host routes. You can use Enhanced IGRP, Open Shortest Path First (OSPF), or Intermediate System-to-Intermediate System (IS-IS); you can also use Routing Information Protocol (RIP), but RIP is not recommended. The mobile area must consist of a contiguous set of subnets.

Using an access list to control the list of possible mobile nodes is strongly encouraged. Without an access list, misconfigured hosts can be taken for mobile nodes and disrupt normal operations.

### Examples

The following example configures local-area mobility on Ethernet interface 0:

```plaintext
access-list 10 permit 198.92.37.114
interface ethernet 0
ip mobile arp access-group 10
```

</tr>
</tbody>
</table>

### Defaults

Traffic leaving or arriving at this interface is not subject to NAT.

### Command Modes

Interface configuration

### Command History

**Release** | **Modification**
------------|------------------
11.2        | This command was introduced.

### Usage Guidelines

Only packets moving between inside and outside interfaces can be translated. You must specify at least one inside interface and outside interface for each border router where you intend to use NAT.

NAT translations logging can be enabled or disabled with the `ip nat log translations syslog` command.

### Examples

The following example translates between inside hosts addressed from either the 192.168.1.0 or 192.168.2.0 network to the globally unique 171.69.233.208/28 network:

```
ip nat pool net-208 171.69.233.208 171.69.233.223 prefix-length 28
ip nat inside source list 1 pool net-208
!
interface ethernet 0
  ip address 171.69.232.182 255.255.255.240
  ip nat outside
!
interface ethernet 1
  ip address 192.168.1.94 255.255.255.0
  ip nat inside
!
access-list 1 permit 192.168.1.0 0.0.0.255
access-list 1 permit 192.168.2.0 0.0.0.255
```

ip nat inside destination

To enable Network Address Translation (NAT) of the inside destination address, use the **ip nat inside destination** global configuration command. To remove the dynamic association to a pool, use the **no** form of this command.

```
ip nat inside destination list {access-list-number \ name} pool name
no ip nat inside destination list {access-list-number \ name}
```

**Syntax Description**

- **list access-list-number**  
  Standard IP access list number. Packets with destination addresses that pass the access list are translated using global addresses from the named pool.

- **list name**  
  Name of a standard IP access list. Packets with destination addresses that pass the access list are translated using global addresses from the named pool.

- **pool name**  
  Name of the pool from which global IP addresses are allocated during dynamic translation.

**Defaults**

No inside destination addresses are translated.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.2</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command has two forms: dynamic and static address translation. The form with an access list establishes dynamic translation. Packets from addresses that match the standard access list are translated using global addresses allocated from the pool named with the **ip nat pool** command.
Examples

The following example translates between inside hosts addressed to either the 192.168.1.0 or 192.168.2.0 network to the globally unique 171.69.233.208/28 network:

```
  ip nat pool net-208 171.69.233.208 171.69.233.223 prefix-length 28
  ip nat inside destination list 1 pool net-208

  interface ethernet 0
  ip address 171.69.232.182 255.255.255.240
  ip nat outside

  interface ethernet 1
  ip address 192.168.1.94 255.255.255.0
  ip nat inside

  access-list 1 permit 192.168.1.0 0.0.0.255
  access-list 1 permit 192.168.2.0 0.0.0.255
```

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.2</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command has two forms: dynamic and static address translation. The form with an access list establishes dynamic translation. Packets from addresses that match the standard access list are translated using global addresses allocated from the pool named with the `ip nat pool` command.

Packets that enter the router through the inside interface and packets sourced from the router are checked against the access list for possible NAT candidates. The access list is used to specify which traffic is to be translated.

Alternatively, the syntax form with the `static` keyword establishes a single static translation.

**Examples**

The following example translates between inside hosts addressed from either the 192.168.1.0 or 192.168.2.0 network to the globally unique 171.69.233.208/28 network:

```plaintext
ip nat pool net-208 171.69.233.208 171.69.233.223 prefix-length 28
ip nat inside source list 1 pool net-208
!
interface ethernet 0
  ip address 171.69.232.182 255.255.255.240
  ip nat outside
!
interface ethernet 1
  ip address 192.168.1.94 255.255.255.0
  ip nat inside
!
access-list 1 permit 192.168.1.0 0.0.0.255
access-list 1 permit 192.168.2.0 0.0.0.255
```

</tr>
</tbody>
</table>

### Usage Guidelines

You might have IP addresses that are not legal, officially assigned IP addresses. Perhaps you chose IP addresses that officially belong to another network. The case of an address used illegally and legally is called overlapping. You can use NAT to translate inside addresses that overlap with outside addresses. Use this feature if your IP addresses in the stub network happen to be legitimate IP addresses belonging to another network, and you need to communicate with those hosts or routers.

This command has two forms: dynamic and static address translation. The form with an access list establishes dynamic translation. Packets from addresses that match the standard access list are translated using global addresses allocated from the pool named with the `ip nat pool` command.

Alternatively, the syntax form with the `static` keyword establishes a single static translation.

### Examples

The following example translates between inside hosts addressed from the 9.114.11.0 network to the globally unique 171.69.233.208/28 network. Further packets from outside hosts addressed from the 9.114.11.0 network (the true 9.114.11.0 network) are translated to appear to be from the 10.0.1.0/24 network.

```plaintext
ip nat pool net-208 171.69.233.208 171.69.233.223 prefix-length 28
ip nat pool net-10 10.0.1.0 10.0.1.255 prefix-length 24
ip nat inside source list 1 pool net-208
ip nat outside source list 1 pool net-10
!
interface ethernet 0
   ip address 171.69.232.182 255.255.255.240
   ip nat outside
!
interface ethernet 1
   ip address 9.114.11.39 255.255.255.0
   ip nat inside
!
access-list 1 permit 9.114.11.0 0.0.0.255
```

**Command History**

- **Release** 11.2
- **Modification** This command was introduced.

**Usage Guidelines**

This command defines a pool of addresses using start address, end address, and either netmask or prefix length. The pool could define either an inside global pool, an outside local pool, or a rotary pool.

**Examples**

The following example translates between inside hosts addressed from either the 192.168.1.0 or 192.168.2.0 network to the globally unique 171.69.233.208/28 network:

```
ip nat pool net-208 171.69.233.208 171.69.233.223 prefix-length 28
ip nat inside source list 1 pool net-208
interface ethernet 0
ip address 171.69.232.182 255.255.255.240
ip nat outside
interface ethernet 1
ip address 192.168.1.94 255.255.255.0
```
**Related Commands**

</tr>
</tbody>
</table>
**ip nat service**

To specify a port other than the default port, use the `ip nat service` command in global configuration mode. To disable the port, use the `no` form of this command.

```
ip nat service {H225 | list} (access-list-number | access-list-name) ftp tcp port port-number | skinny tcp port port-number
no ip nat service {H225 | list} (access-list-number | access-list-name) ftp tcp port port-number | skinny tcp port port-number
```

**Syntax Description**

- **H225**: H323-H225 protocol.
- **list access-list-number**: Standard access list number in the range from 1 to 199.
- **access-list-name**: Name of a standard IP access list.
- **ftp**: FTP protocol.
- **tcp**: TCP protocol.
- **port port-number**: Port other than the default port in the range from 1 to 65533.
- **skinny**: Skinny protocol.

**Defaults**

Disabled

**Command Modes**

Global configuration

<tbody>
<tr>
<td>11.3</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>The <code>skinny</code> keyword was added.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

A host with an FTP server using a port other than the default port can have an FTP client using the default FTP control port. When a port other than the default port is configured for an FTP server, Network Address Translation (NAT) prevents FTP control sessions that are using port 21 for that particular server. If an FTP server uses the default port and a port other than the default port, both ports need to be configured using the `ip nat service` command.

NAT listens on the default port of the Cisco CallManager to translate the skinny messages. If the CallManager uses a port other than the default port, that port needs to be configured using the `ip nat service` command.

Use the `no ip nat service H225` command to disable support of H.225 packets by NAT.

**Examples**

The following example configures the nonstandard port 2021:

```
ip nat service list 10 ftp tcp port 2021
access-list 10 permit 10.1.1.1
```
The following example configures the standard FTP port 21 and the nonstandard port 2021:

```
ip nat service list 10 ftp tcp port 21
ip nat service list 10 ftp tcp port 2021
access-list 10 permit 10.1.1.1
```

The following example configures the 20002 port of the CallManager:

```
ip nat service skinny tcp port 20002
```

<table>

</tbody>
</table>
To change the amount of time after which Network Address Translation (NAT) translations time out, use the **ip nat translation** global configuration command. To disable the timeout, use the **no** form of this command.

```
ip nat translation [max-entries number] [timeout | udp-timeout | dns-timeout | tcp-timeout | finrst-timeout | icmp-timeout | pptp-timeout | syn-timeout | port-timeout] seconds | never

no ip nat translation [max-entries number] [timeout | udp-timeout | dns-timeout | tcp-timeout | finrst-timeout | icmp-timeout | pptp-timeout | syn-timeout | port-timeout]
```

### Syntax Description

- **max-entries number** (Optional) Specifies the maximum number (1-2147483647) of NAT entries. Default is unlimited.
- **timeout** Specifies that the timeout value applies to dynamic translations except for overload translations. Default is 86400 seconds (24 hours).
- **udp-timeout** Specifies that the timeout value applies to the User Datagram Protocol (UDP) port. Default is 300 seconds (5 minutes).
- **dns-timeout** Specifies that the timeout value applies to connections to the Domain Naming System (DNS). Default is 60 seconds.
- **tcp-timeout** Specifies that the timeout value applies to the TCP port. Default is 86400 seconds (24 hours).
- **finrst-timeout** Specifies that the timeout value applies to Finish and Reset TCP packets, which terminate a connection. Default is 60 seconds.
- **icmp-timeout** Specifies the timeout value for Internet Control Message Protocol (ICMP) flows. Default is 60 seconds.
- **pptp-timeout** Specifies the timeout value for NAT Point-to-Point Tunneling Protocol (PPTP) flows. Default is 86400 seconds (24 hours).
- **syn-timeout** Specifies the timeout value for TCP flows immediately after a synchronous transmission (SYN) message. The default is 60 seconds.
- **port-timeout** Specifies that the timeout value applies to the TCP/UDP port.
- **seconds** Number of seconds after which the specified port translation times out. The default is 0.
- **never** Specifies no port translation time out.

### Defaults

- **timeout**: 86400 seconds (24 hours)
- **udp-timeout**: 300 seconds (5 minutes)
- **dns-timeout**: 60 seconds (1 minute)
- **tcp-timeout**: 86400 seconds (24 hours)
- **finrst-timeout**: 60 seconds (1 minute)
- **icmp-timeout**: 60 seconds (1 minute)
- **pptp-timeout**: 86400 seconds (24 hours)
**ip nat translation**

- **syn-timeout**: 60 seconds (1 minute)
- **port-timeout**: 0 (never)

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.2</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

When port translation is configured, there is finer control over translation entry timeouts because each entry contains more context about the traffic that is using it. Non-DNS UDP translations time out after 5 minutes, while DNS times out in 1 minute. TCP translations timeout in 24 hours, unless an RST or FIN is seen on the stream, in which case they will time out in 1 minute.

**Examples**

The following example causes UDP port translation entries to time out after 10 minutes:

```plaintext
ip nat translation udp-timeout 600
```

</table>
ip netmask-format

To specify the format in which netmasks are displayed in show command output, use the **ip netmask-format** line configuration command. To restore the default display format, use the no form of this command.

```
ip netmask-format {bit-count | decimal | hexadecimal}
```

```
no ip netmask-format {bit-count | decimal | hexadecimal}
```

**Syntax Description**

- **bit-count**
  - Addresses are followed by a slash and the total number of bits in the netmask. For example, 131.108.11.0/24 indicates that the netmask is 24 bits.

- **decimal**
  - Network masks are displayed in dotted-decimal notation (for example, 255.255.255.0).

- **hexadecimal**
  - Network masks are displayed in hexadecimal format, as indicated by the leading 0X (for example, 0XFFFFFF00).

**Defaults**

- Netmasks are displayed in dotted-decimal format.

**Command Modes**

- Line configuration

**Command History**

- Release | Modification
  - 10.3 | This command was introduced.

**Usage Guidelines**

IP uses a 32-bit mask that indicates which address bits belong to the network and subnetwork fields, and which bits belong to the host field. This is called a netmask. By default, **show** commands display an IP address and then its netmask in dotted decimal notation. For example, a subnet would be displayed as 131.108.11.0 255.255.255.0.

However, you can specify that the display of the network mask appear in hexadecimal format or bit count format instead. The hexadecimal format is commonly used on UNIX systems. The previous example would be displayed as 131.108.11.0 0XFFFFFF00.

The bitcount format for displaying network masks is to append a slash (/) and the total number of bits in the netmask to the address itself. The previous example would be displayed as 131.108.11.0/24.

**Examples**

The following example configures network masks for the specified line to be displayed in bitcount notation in the output of **show** commands:

```
line vty 0 4
  ip netmask-format bitcount
```
**ip nhrp authentication**

To configure the authentication string for an interface using the Next Hop Resolution Protocol (NHRP), use the `ip nhrp authentication` interface configuration command. To remove the authentication string, use the `no` form of this command.

```
ip nhrp authentication string

no ip nhrp authentication [string]
```

**Syntax Description**

| string | Authentication string configured for the source and destination stations that controls whether NHRP stations allow intercommunication. The string can be up to eight characters long. |

**Defaults**

No authentication string is configured; the Cisco IOS software adds no authentication option to NHRP packets it generates.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

All routers configured with NHRP within one logical NBMA network must share the same authentication string.

**Examples**

In the following example, the authentication string named specialxx must be configured in all devices using NHRP on the interface before NHRP communication occurs:

```
ip nhrp authentication specialxx
```
ip nhrp holdtime

To change the number of seconds that Next Hop Resolution Protocol (NHRP) nonbroadcast multiaccess (NBMA) addresses are advertised as valid in authoritative NHRP responses, use the ip nhrp holdtime interface configuration command. To restore the default value, use the no form of this command.

```
ip nhrp holdtime seconds
no ip nhrp holdtime [seconds]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seconds</td>
<td>Time in seconds that NBMA addresses are advertised as valid in positive authoritative NHRP responses.</td>
</tr>
</tbody>
</table>

**Defaults**

7200 seconds (2 hours)

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The ip nhrp holdtime command affects authoritative responses only. The advertised holding time is the length of time the Cisco IOS software tells other routers to keep information that it is providing in authoritative NHRP responses. The cached IP-to-NBMA address mapping entries are discarded after the holding time expires.

The NHRP cache can contain static and dynamic entries. The static entries never expire. Dynamic entries expire regardless of whether they are authoritative or nonauthoritative.

**Examples**

In the following example, NHRP NBMA addresses are advertised as valid in positive authoritative NHRP responses for 1 hour:

```
ip nhrp holdtime 3600
```
**ip nhrp interest**

To control which IP packets can trigger sending a Next Hop Resolution Protocol (NHRP) request packet, use the **ip nhrp interest** interface configuration command. To restore the default value, use the **no** form of this command.

```
ip nhrp interest access-list-number

no ip nhrp interest [access-list-number]
```

**Syntax Description**

```
access-list-number  Standard or extended IP access list number in the range from 1 to 199.
```

**Defaults**

All non-NHRP packets can trigger NHRP requests.

**Command Modes**

Interface configuration

**Command History**

```
Release  Modification
10.3     This command was introduced.
```

**Usage Guidelines**

Use this command with the **access-list** command to control which IP packets trigger NHRP requests.

The **ip nhrp interest** command controls *which* packets cause NHRP address resolution to take place; the **ip nhrp use** command controls *how readily* the system attempts such address resolution.

**Examples**

In the following example, any TCP traffic can cause NHRP requests to be sent, but no other IP packets will cause NHRP requests:

```
ip nhrp interest 101
access-list 101 permit tcp any any
```

**Related Commands**

```
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>access-list (IP extended)</td>
<td>Defines an extended IP access list.</td>
</tr>
<tr>
<td>access-list (IP standard)</td>
<td>Defines a standard IP access list.</td>
</tr>
<tr>
<td>ip nhrp use</td>
<td>Configures the software so that NHRP is deferred until the system has attempted to send data traffic to a particular destination multiple times.</td>
</tr>
</tbody>
</table>
```
**ip nhrp map**

To statically configure the IP-to-NonBroadcast MultiAccess (NBMA) address mapping of IP destinations connected to an MBMA network, use the `ip nhrp map` interface configuration command. To remove the static entry from Next Hop Resolution Protocol (NHRP) cache, use the `no` form of this command.

```
ip nhrp map ip-address nbma-address
no ip nhrp map ip-address nbma-address
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ip-address</strong></td>
<td>IP address of the destinations reachable through the NBMA network. This address is mapped to the NBMA address.</td>
</tr>
<tr>
<td><strong>nbma-address</strong></td>
<td>NBMA address that is directly reachable through the NBMA network. The address format varies depending on the medium you are using. For example, ATM has a Network Service Access Point (NSAP) address, Ethernet has a MAC address, and Switched Multimegabit Data Service (SMDS) has an E.164 address. This address is mapped to the IP address.</td>
</tr>
</tbody>
</table>

**Defaults**

No static IP-to-NBMA cache entries exist.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

You will probably need to configure at least one static mapping in order to reach the Next Hop Server. Repeat this command to statically configure multiple IP-to-NBMA address mappings.

**Examples**

In the following example, this station in a multipoint tunnel network is statically configured to be served by two Next Hop Servers 100.0.0.1 and 100.0.1.3. The NBMA address for 100.0.0.1 is statically configured to be 11.0.0.1 and the NBMA address for 100.0.1.3 is 12.2.7.8.

```
interface tunnel 0
ip nhrp nhs 100.0.0.1
ip nhrp nhs 100.0.1.3
ip nhrp map 100.0.0.1 11.0.0.1
ip nhrp map 100.0.1.3 12.2.7.8
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear ip nhrp</td>
<td>Clears all dynamic entries from the NHRP cache.</td>
</tr>
</tbody>
</table>
**ip nhrp map multicast**

To configure NonBroadcast MultiAccess (NBMA) addresses used as destinations for broadcast or multicast packets to be sent over a tunnel network, use the `ip nhrp map multicast` interface configuration command. To remove the destinations, use the `no` form of this command.

```
ip nhrp map multicast nbma-address
no ip nhrp map multicast nbma-address
```

**Syntax Description**

<table>
<thead>
<tr>
<th>nbma-address</th>
<th>NBMA address that is directly reachable through the NBMA network. The address format varies depending on the medium you are using.</th>
</tr>
</thead>
</table>

**Defaults**

No NBMA addresses are configured as destinations for broadcast or multicast packets.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command applies only to tunnel interfaces.

The command is useful for supporting broadcasts over a tunnel network when the underlying network does not support IP multicast. If the underlying network does support IP multicast, you should use the `tunnel destination` command to configure a multicast destination for transmission of tunnel broadcasts or multicasts.

When multiple NBMA addresses are configured, the system replicates the broadcast packet for each address.

**Examples**

In the following example, if a packet is sent to 10.255.255.255, it is replicated to destinations 11.0.0.1 and 11.0.0.2. Addresses 11.0.0.1 and 11.0.0.2 are the IP addresses of two other routers that are part of the tunnel network, but those addresses are their addresses in the underlying network, not the tunnel network. They would have tunnel addresses that are in network 10.0.0.0.

```
interface tunnel 0
ip address 10.0.0.3 255.0.0.0
ip nhrp map multicast 11.0.0.1
ip nhrp map multicast 11.0.0.2
```
ip nhrp max-send

To change the maximum frequency at which Next Hop Resolution Protocol (NHRP) packets can be sent, use the ip nhrp max-send interface configuration command. To restore this frequency to the default value, use the no form of this command.

    ip nhrp max-send pkt-count every interval
    
    no ip nhrp max-send

Syntax Description

<table>
<thead>
<tr>
<th>Syntax Description</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>pkt-count</strong></td>
<td>Number of packets that can be sent in the range from 1 to 65535. Default is 5 packets.</td>
</tr>
<tr>
<td><strong>every interval</strong></td>
<td>Time (in seconds) in the range from 10 to 65535. Default is 10 seconds.</td>
</tr>
</tbody>
</table>

Defaults

- **pkt-count**: 5 packets
- **interval**: 10 seconds

Command Modes

Interface configuration

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.1</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

Usage Guidelines

The software maintains a per-interface quota of NHRP packets that can be sent. NHRP traffic, whether locally generated or forwarded, cannot be sent at a rate that exceeds this quota. The quota is replenished at the rate specified by the interval value.

Examples

In the following example, only one NHRP packet can be sent from serial interface 0 each minute:

```plaintext
interface serial 0
ip nhrp max-send 1 every 60
```

Related Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip nhrp interest</td>
<td>Controls which IP packets can trigger sending an NHRP request.</td>
</tr>
<tr>
<td>ip nhrp use</td>

</tbody>
</table>
ip nhrp network-id

To enable the Next Hop Resolution Protocol (NHRP) on an interface, use the `ip nhrp network-id` interface configuration command. To disable NHRP on the interface, use the `no` form of this command.

```plaintext
ip nhrp network-id number
no ip nhrp network-id [number]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>number</th>
<th>Globally unique, 32-bit network identifier from a nonbroadcast multiaccess (NBMA) network. The range is from 1 to 4294967295.</th>
</tr>
</thead>
</table>

**Defaults**

NHRP is disabled on the interface.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

In general, all NHRP stations within one logical NBMA network must be configured with the same network identifier.

**Examples**

The following example enables NHRP on the interface:

```
ip nhrp network-id 1
```
**ip nhrp nhs**

To specify the address of one or more Next Hop Resolution Protocol (NHRP) servers, use the `ip nhrp nhs` interface configuration command. To remove the address, use the `no` form of this command.

```
ip nhrp nhs nhs-address [net-address [netmask]]
no ip nhrp nhs nhs-address [net-address [netmask]]
```

**Syntax Description**

- `nhs-address` : Address of the Next Hop Server being specified.
- `net-address` : (Optional) IP address of a network served by the Next Hop Server.
- `netmask` : (Optional) IP network mask to be associated with the `net` IP address. The `net` IP address is logically ANDed with the mask.

**Defaults**

No Next Hop Servers are explicitly configured, so normal network layer routing decisions are used to forward NHRP traffic.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Use this command to specify the address of a Next Hop Server and the networks it serves. Normally, NHRP consults the network layer forwarding table to determine how to forward NHRP packets. When Next Hop Servers are configured, these next hop addresses override the forwarding path that would otherwise be used for NHRP traffic.

For any Next Hop Server that is configured, you can specify multiple networks that it serves by repeating this command with the same `nhs-address` argument, but with different `net-address` IP network addresses.

**Examples**

In the following example, the Next Hop Server with address 131.108.10.11 serves IP network 10.0.0.0. The mask is 255.0.0.0.

```
ip nhrp nhs 131.108.10.11 10.0.0.0 255.0.0.0
```
ip nhrp record

To reenable the use of forward record and reverse record options in Next Hop Resolution Protocol (NHRP) request and reply packets, use the **ip nhrp record** interface configuration command. To suppress the use of such options, use the **no** form of this command.

```
ip nhrp record
no ip nhrp record
```

**Syntax Description**
This command has no arguments or keywords.

**Defaults**
Forward record and reverse record options are used in NHRP request and reply packets.

**Command Modes**
Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
Forward record and reverse record options provide loop detection and are enabled by default. Using the **no** form of this command disables this method of loop detection. For another method of loop detection, see the **ip nhrp responder** command.

**Examples**
The following example suppresses forward record and reverse record options:
```
no ip nhrp record
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip nhrp responder</td>
<td>Designates the primary IP address of which interface the Next Hop Server will use in NHRP reply packets when the NHRP requester uses the Responder Address option.</td>
</tr>
</tbody>
</table>
**ip nhrp responder**

To designate the primary IP address the Next Hop Server that an interface will use in Next Hop Resolution Protocol (NHRP) reply packets when the NHRP requestor uses the Responder Address option, use the `ip nhrp responder` interface configuration command. To remove the designation, use the `no` form of this command.

```
ip nhrp responder type number
no ip nhrp responder [type] [number]
```

**Syntax Description**

- `type` Interface type whose primary IP address is used when a Next Hop Server complies with a Responder Address option (for example, `serial` or `tunnel`).
- `number` Interface number whose primary IP address is used when a Next Hop Server complies with a Responder Address option.

**Defaults**
The Next Hop Server uses the IP address of the interface where the NHRP request was received.

**Command Modes**
Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

If an NHRP requestor wants to know which Next Hop Server generates an NHRP reply packet, it can request that information through the Responder Address option. The Next Hop Server that generates the NHRP reply packet then complies by inserting its own IP address in the Responder Address option of the NHRP reply. The Next Hop Server uses the primary IP address of the specified interface.

If an NHRP reply packet being forwarded by a Next Hop Server contains the IP address of that Next Hop Server, the Next Hop Server generates an Error Indication of type “NHRP Loop Detected” and discards the reply packet.

**Examples**

In the following example, any NHRP requests for the Responder Address will cause this router acting as a Next Hop Server to supply the primary IP address of serial interface 0 in the NHRP reply packet:

```
ip nhrp responder serial 0
```
**ip nhrp server-only**

To configure the interface to operate in Next Hop Resolution Protocol (NHRP) server-only mode, use the `ip nhrp server-only` interface configuration command. To disable this feature, use the `no` form of this command.

```
ip nhrp server-only [non-caching]
no ip nhrp server-only
```

**Syntax Description**

| Syntax Description | non-caching | (Optional) The router will not cache NHRP information received on this interface. |

| Defaults | Disabled |

**Command Modes**

</table>

**Usage Guidelines**

When the interface is operating in NHRP server-only mode, the interface does not originate NHRP requests or set up an NHRP shortcut Switched Virtual Circuit (SVC).

**Examples**

The following example configures the interface to operate in server-only mode:

```
ip nhrp server-only
```
ip nhrp trigger-svc

To configure when the Next Hop Resolution Protocol (NHRP) will set up and tear down a switched virtual circuit (SVC) based on aggregate traffic rates, use the **ip nhrp trigger-svc** interface configuration command. To restore the default thresholds, use the *no* form of this command.

```
ip nhrp trigger-svc trigger-threshold teardown-threshold

no ip nhrp trigger-svc
```

### Syntax Description

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>trigger-threshold</td>
<td>Average traffic rate calculated during the load interval, at or above which NHRP will set up an SVC for a destination. The default value is 1 kbps.</td>
</tr>
<tr>
<td>teardown-threshold</td>
<td>Average traffic rate calculated during the load interval, at or below which NHRP will tear down the SVC to the destination. The default value is 0 kbps.</td>
</tr>
</tbody>
</table>

### Defaults

- **trigger-threshold**: 1 kbps
- **teardown-threshold**: 0 kbps

### Command Modes

Interface configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

The two thresholds are measured during a sampling interval of 30 seconds, by default. To change that interval, use the **load-interval seconds** argument of the **ip cef traffic-statistics** command.

### Examples

In the following example, the triggering and teardown thresholds are set to 100 kbps and 5 kbps, respectively:

```
ip nhrp trigger-svc 100 5
```

</tbody>
</table>
**ip nhrp use**

To configure the software so that Next Hop Resolution Protocol (NHRP) is deferred until the system has attempted to send data traffic to a particular destination multiple times, use the `ip nhrp use` interface configuration command. To restore the default value, use the **no** form of this command.

```
   ip nhrp use usage-count

   no ip nhrp use usage-count
```

**Syntax Description**

usage-count: Packet count in the range from 1 to 65535. Default is 1.

**Defaults**

usage-count: 1. The first time a data packet is sent to a destination for which the system determines NHRP can be used, an NHRP request is sent.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.1</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

When the software attempts to send a data packet to a destination for which it has determined that NHRP address resolution can be used, an NHRP request for that destination is normally sent immediately. Configuring the `usage-count` argument causes the system to wait until that many data packets have been sent to a particular destination before it attempts NHRP. The `usage-count` argument for a particular destination is measured over 1-minute intervals (the NHRP cache expiration interval).

The usage count applies per destination. So if the `usage-count` argument is configured to be 3, and four data packets are sent toward 10.0.0.1 and one packet toward 10.0.0.2, then an NHRP request is generated for 10.0.0.1 only.

If the system continues to need to forward data packets to a particular destination, but no NHRP response has been received, retransmission of NHRP requests is performed. This retransmission occurs only if data traffic continues to be sent to a destination.

The `ip nhrp interest` command controls which packets cause NHRP address resolution to take place; the `ip nhrp use` command controls how readily the system attempts such address resolution.

**Examples**

In the following example, if in the first minute five packets are sent to the first destination and five packets are sent to a second destination, then a single NHRP request is generated for the second destination.

If in the second minute the same traffic is generated and no NHRP responses have been received, then the system resends its request for the second destination.

```
ip nhrp use 5
```

</tbody>
</table>
**ip probe proxy**

To enable the HP Probe Proxy support, which allows the Cisco IOS software to respond to HP Probe Proxy name requests, use the `ip probe proxy` interface configuration command. To disable HP Probe Proxy, use the `no` form of this command.

```
ip probe proxy
no ip probe proxy
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

Disabled

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

HP Probe Proxy Name requests are typically used at sites that have Hewlett-Packard (HP) equipment and are already using HP Probe.

To use the HP Probe Proxy service, you must first enter the host name of the HP host into the host table using the `ip hp-host` global configuration command.

**Examples**

The following example specifies an HP host name and address, and then enables Probe Proxy:

```
ip hp-host BCWjo 131.108.1.27
interface ethernet 0
ip probe proxy
```

**Related Commands**

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip hp-host</code></td>
<td>Enters into the host table the host name of an HP host to be used for HP Probe Proxy service.</td>
</tr>
</tbody>
</table>
ip proxy-arp

To enable proxy Address Resolution Protocol (ARP) on an interface, use the `ip proxy-arp` interface configuration command. To disable proxy ARP on the interface, use the `no` form of this command.

```
ip proxy-arp
no ip proxy-arp
```

**Syntax Description**
This command has no arguments or keywords.

**Defaults**
Enabled

**Command Modes**
Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Examples**
The following example enables proxy ARP on Ethernet interface 0:

```
interface ethernet 0
ip proxy-arp
```
**ip routing**

To enable IP routing, use the `ip routing` global configuration command. To disable IP routing, use the `no` form of this command.

```
  ip routing

  no ip routing
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

Enabled

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

To bridge IP, the `no ip routing` command must be configured to disable IP routing. However, you need not specify `no ip routing` in conjunction with concurrent routing and bridging to bridge IP.

The `ip routing` command is disabled on the Cisco VG200 voice over IP gateway.

**Examples**

The following example enables IP routing:

```
  ip routing
```
ip subnet-zero

To enable the use of subnet 0 for interface addresses and routing updates, use the ip subnet-zero global configuration command. To restore the default, use the no form of this command.

    ip subnet-zero
    no ip subnet-zero

**Syntax Description**
This command has no arguments or keywords.

**Defaults**
Enabled

**Command Modes**
Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
The ip subnet-zero command provides the ability to configure and route to subnet 0 subnets. Subnetting with a subnet address of 0 is discouraged because of the confusion inherent in having a network and a subnet with indistinguishable addresses.

**Examples**
The following example enables subnet zero:

    ip subnet-zero
ip unnumbered

To enable IP processing on a serial interface without assigning an explicit IP address to the interface, use the **ip unnumbered** interface configuration command. To disable the IP processing on the interface, use the **no** form of this command.

```
  ip unnumbered type number
```

```
  no ip unnumbered type number
```

**Syntax Description**

| **type number** | Type and number of another interface on which the router has an assigned IP address. It cannot be another unnumbered interface. |

**Defaults**

Disabled

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th><strong>Release</strong></th>
<th><strong>Modification</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Whenever the unnumbered interface generates a packet (for example, for a routing update), it uses the address of the specified interface as the source address of the IP packet. It also uses the address of the specified interface in determining which routing processes are sending updates over the unnumbered interface. Restrictions include the following:

- Serial interfaces using High Level Data Link Control (HDLC), PPP, Link Access Procedure, Balanced (LAPB), Frame Relay encapsulations, and Serial Line Internet Protocol (SLIP) and tunnel interfaces can be unnumbered. It is not possible to use this interface configuration command with X.25 or Switched Multimegabit Data Service (SMDS) interfaces.
- You cannot use the **ping** EXEC command to determine whether the interface is up, because the interface has no address. Simple Network Management Protocol (SNMP) can be used to remotely monitor interface status.
- You cannot netboot a runnable image over an unnumbered serial interface.
- You cannot support IP security options on an unnumbered interface.

The interface you specify by the **type** and **number** arguments must be enabled (listed as “up” in the **show interfaces** command display).

If you are configuring Intermediate System-to-Intermediate System (IS-IS) across a serial line, you should configure the serial interfaces as unnumbered, which allows you to conform with RFC 1195, which states that IP addresses are not required on each interface.
Note

Using an unnumbered serial line between different major networks (or *majornets*) requires special care. If at each end of the link there are different majornets assigned to the interfaces you specified as unnumbered, then any routing protocol running across the serial line must not advertise subnet information.

Examples

In the following example, the first serial interface is given the address of Ethernet 0:

```plaintext
interface ethernet 0
ip address 131.108.6.6 255.255.255.0
!
interface serial 0
ip unnumbered ethernet 0
```
no ip gratuitous-arps

To disable the transmission of gratuitous Address Resolution Protocol (ARP) messages for an address in a local pool, use the `no ip gratuitous-arps` command in global configuration mode.

Syntax Description
This command has no keywords or arguments.

Defaults
Disabled

Command Modes
Global configuration

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.3</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

Usage Guidelines
A Cisco router will send out a gratuitous ARP message when a client connects and negotiates an address over a PPP connection. This transmission occurs even when the client receives the address from a local address pool.

Examples
The following example disables gratuitous arp messages from being sent:

```
no ip gratuitous-arps
```
show arp

To display the entries in the Address Resolution Protocol (ARP) table, use the `show arp` privileged EXEC command.

```
show arp
```

**Syntax Description**

This command has no arguments or keywords.

**Command Modes**

Privileged EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>

</tr>
<tr>
<td></td>
<td>clear host</td>
</tr>
</tbody>
</table>
**show ip aliases**

To display the IP addresses mapped to TCP ports (aliases) and Serial Line Internet Protocol (SLIP) addresses, which are treated similarly to aliases, use the `show ip aliases` EXEC command.

```
show ip aliases
```

**Syntax Description**

This command has no arguments or keywords.

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

To distinguish a SLIP address from a normal alias address, the command output uses the form SLIP TTY1 for the “port” number, where 1 is the auxiliary port.

**Examples**

The following is sample output from the `show ip aliases` command:

```
Router# show ip aliases

<table>
<thead>
<tr>
<th>IP Address</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>131.108.29.245</td>
<td>SLIP TTY1</td>
</tr>
</tbody>
</table>
```

The display lists the IP address and corresponding port number.

**Related Commands**

<table>
<thead>

</tr>
<tr>
<td>mac-address</td>
<td>(Optional) 48-bit MAC address.</td>
</tr>
<tr>
<td>interface type number</td>
<td>(Optional) ARP entries learned via this interface type and number are displayed.</td>
</tr>
</tbody>
</table>

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>9.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

ARP establishes correspondences between network addresses (an IP address, for example) and LAN hardware addresses (Ethernet addresses). A record of each correspondence is kept in a cache for a predetermined amount of time and then discarded.

**Examples**

The following is sample output from the show ip arp command:

```
Router# show ip arp
Protocol  AddressAge(min)  Hardware Addr  Type   Interface
Internet  171.69.233.2290000.0c59.f892 ARPA   Ethernet0/0
Internet  171.69.233.2180000.0c07.ac00 ARPA   Ethernet0/0
Internet  171.69.233.19-0000.0c63.1300 ARPA   Ethernet0/0
Internet  171.69.233.3090000.0c36.6965 ARPA   Ethernet0/0
Internet  172.19.168.11-0000.0c63.1300 ARPA   Ethernet0/0
Internet  172.19.168.25490000.0c36.6965 ARPA   Ethernet0/0
```

Table 5 describes the significant fields shown in the display.

**Table 5  show ip arp Field Descriptions**

<table>
<thead>
<tr>
<th>Field</th>

  - ARPA  
  - SNAP  
  - SAP |
| Interface | Indicates the interface associated with this network address. |
**show ip interface**

To display the usability status of interfaces configured for IP, use the `show ip interface` EXEC command.

```
show ip interface [type number] [brief]
```

**Syntax Description**

- **type**: (Optional) Interface type.
- **number**: (Optional) Interface number.
- **brief**: (Optional) Displays a summary of the usability status information for each interface.

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.0(3)T</td>
<td>This command was expanded to include the status of <code>ip wccp redirect out</code> and <code>ip wccp redirect exclude add in</code> commands.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The Cisco IOS software automatically enters a directly connected route in the routing table if the interface is usable. A usable interface is one through which the software can send and receive packets. If the software determines that an interface is not usable, it removes the directly connected routing entry from the routing table. Removing the entry allows the software to use dynamic routing protocols to determine backup routes to the network, if any.

If the interface can provide two-way communication, the line protocol is marked “up.” If the interface hardware is usable, the interface is marked “up.”

If you specify an optional interface type, you will see only information on that specific interface.

If you specify no optional arguments, you will see information on all the interfaces.

When an asynchronous interface is encapsulated with PPP or Serial Line Internet Protocol (SLIP), IP fast switching is enabled. A `show ip interface` command on an asynchronous interface encapsulated with PPP or SLIP displays a message indicating that IP fast switching is enabled.

**Examples**

The following is sample output from the `show ip interface` command:

```
Router# show ip interface
Ethernet0 is up, line protocol is up
    Internet address is 192.195.78.24, subnet mask is 255.255.255.240
    Broadcast address is 255.255.255.255
    Address determined by non-volatile memory
    MTU is 1500 bytes
    Helper address is not set
    Secondary address 131.192.115.2, subnet mask 255.255.255.0
    Directed broadcast forwarding is enabled
    Multicast groups joined: 224.0.0.1 224.0.0.2
```
show ip interface

Outgoing access list is not set
Inbound access list is not set
Proxy ARP is enabled
Security level is default
Split horizon is enabled
ICMP redirects are always sent
ICMP unreachables are always sent
ICMP mask replies are never sent
IP fast switching is enabled
IP fast switching on the same interface is disabled
IP SSE switching is disabled
Router Discovery is disabled
IP output packet accounting is disabled
IP access violation accounting is disabled
TCP/IP header compression is disabled
Probe proxy name replies are disabled
WCCP Redirect outbound is enabled
WCCP Redirect exclude is disabled

</tbody>
</table>
**show ip irdp**

To display ICMP Router Discovery Protocol (HRDP) values, use the `show ip irdp` EXEC command.

```
show ip irdp
```

**Syntax Description**

This command has no arguments or keywords.

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Examples**

The following is sample output from the `show ip irdp` command:

```
Router# show ip irdp

Ethernet 0 has router discovery enabled
Advertisements will occur between every 450 and 600 seconds.
Advertisements are valid for 1800 seconds.
Default preference will be 100.
--More--
Serial 0 has router discovery disabled
--More--
Ethernet 1 has router discovery disabled

As the display shows, `show ip irdp` output indicates whether router discovery has been configured for each router interface, and it lists the values of router discovery configurables for those interfaces on which router discovery has been enabled. Explanations for the less obvious lines of output in the display are as follows:

Advertisements will occur between every 450 and 600 seconds.

This indicates the configured minimum and maximum advertising interval for the interface.

Advertisements are valid for 1800 seconds.

This indicates the configured holdtime values for the interface.

Default preference will be 100.

This indicates the configured (or in this case default) preference value for the interface.
```

</table>
show ip masks

To display the masks used for network addresses and the number of subnets using each mask, use the `show ip masks` EXEC command.

```
show ip masks address
```

**Syntax Description**

- `address` : Network address for which a mask is required.

**Command Modes**

- EXEC

**Command History**

- **Release** : 10.0
- **Modification** : This command was introduced.

**Usage Guidelines**

The `show ip masks` command is useful for debugging when a variable-length subnet mask (VLSM) is used. It shows the number of masks associated with the network and the number of routes for each mask.

**Examples**

The following is sample output from the `show ip masks` command:

```
Router# show ip masks 131.108.0.0

Mask          Reference count
255.255.255.255 2
255.255.255.0   3
255.255.0.0     1
```
show ip nat statistics

To display Network Address Translation (NAT) statistics, use the `show ip nat statistics` EXEC command.

```
show ip nat statistics
```

**Syntax Description**

This command has no arguments or keywords.

**Command Modes**

EXEC

**Command History**

Release  Command History
---  -------------------
11.2  This command was introduced.

**Examples**

The following is sample output from the `show ip nat statistics` command:

```
Router# show ip nat statistics
Total translations: 2 (0 static, 2 dynamic; 0 extended)
Outside interfaces: Serial0
Inside interfaces: Ethernet1
Hits: 135  Misses: 5
Expired translations: 2
Dynamic mappings:
-- Inside Source
access-list 1 pool net-208 refcount 2
 pool net-208: netmask 255.255.255.240
  start 171.69.233.208 end 171.69.233.221
type generic, total addresses 14, allocated 2 (14%), misses 0
```

Table 7 describes the significant fields shown in the display.

</table>
show ip nat translations

To display active Network Address Translation (NAT) translations, use the **show ip nat translations** EXEC command.

```
show ip nat translations [verbose]
```

**Syntax Description**

- **verbose** *(Optional)* Displays additional information for each translation table entry, including how long ago the entry was created and used.

**Command Modes**

- EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.2</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Examples**

The following is sample output from the **show ip nat translations** command. Without overloading, two inside hosts are exchanging packets with some number of outside hosts.

```
Router# show ip nat translations
Pro Inside global      Inside local       Outside local      Outside global
--- 171.69.233.209     192.168.1.95       ---                ---
--- 171.69.233.210     192.168.1.89       ---                --
```

With overloading, a translation for a Domain Name Server (DNS) transaction is still active, and translations for two Telnet sessions (from two different hosts) are also active. Note that two different inside hosts appear on the outside with a single IP address.

```
Router# show ip nat translations
Pro Inside global      Inside local       Outside local      Outside global
udp 171.69.233.209:1220 192.168.1.95:1220 171.69.2.132:53    171.69.2.132:53
```

The following is sample output that includes the **verbose** keyword:

```
Router# show ip nat translations verbose
Pro Inside global      Inside local       Outside local      Outside global
udp 171.69.233.209:1220 192.168.1.95:1220 171.69.2.132:53    171.69.2.132:53
    create 00:00:02, use 00:00:00, flags: extended
    create 00:01:13, use 00:00:50, flags: extended
    create 00:00:02, use 00:00:00, flags: extended
```
Table 8 describes the significant fields shown in the display.

show ip nhrp

To display the Next Hop Resolution Protocol (NHRP) cache, use the `show ip nhrp` EXEC command.

```
show ip nhrp [detail | purge] [type number [detail]] [dynamic | incomplete | nhs | static [type number] [detail]]
```

**Syntax Description**

- `detail` (Optional) Displays detailed information about NHRP cache.
- `purge` (Optional) Displays NHRP cache purge information.
- `type number` (Optional) Displays the interface type and number in the NHRP cache. See Table 9 for types, number ranges, and descriptions.
- `dynamic` (Optional) Displays only the dynamic (learned) IP-to-nonbroadcast multiaccess address (NBMA) cache entries. See Table 9 for types, number ranges, and descriptions.
- `incomplete` (Optional) Displays information about an incomplete cache. See Table 9 for types, number ranges, and descriptions.
- `nhs` (Optional) Displays information about the next-hop server (NHS). See Table 9 for types, number ranges, and descriptions.
- `static` (Optional) Displays only the static IP-to-NBMA address entries in the cache (configured using the `ip nhrp map` command). See Table 9 for types, number ranges, and descriptions.

term ip netmask-format

To specify the format in which netmasks are displayed in show command output, use the term ip netmask-format EXEC command. To restore the default display format, use the no form of this command.

```
term ip netmask-format {bitcount | decimal | hexadecimal}
no term ip netmask-format [bitcount | decimal | hexadecimal]
```

**Syntax Description**
- **bitcount**: Number of bits in the netmask.
- **decimal**: Netmask dotted decimal notation.
- **hexadecimal**: Netmask hexadecimal format.

**Defaults**
Netmasks are displayed in dotted decimal format.

**Command Modes**
EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
IP uses a 32-bit mask that indicates which address bits belong to the network and subnetwork fields, and which bits belong to the host field. This range of IP addresses is called a netmask. By default, show commands display an IP address and then its netmask in dotted decimal notation. For example, a subnet would be displayed as 131.108.11.55 255.255.255.0.

However, you can specify that the display of the network mask appear in hexadecimal format or bit count format instead. The hexadecimal format is commonly used on UNIX systems. The previous example would be displayed as 131.108.11.55 0xFFFFFF00.

The bitcount format for displaying network masks is to append a slash (/) and the total number of bits in the netmask to the address itself. The previous example would be displayed as 131.108.11.55/24.

**Examples**
The following example specifies that network masks for the session be displayed in bitcount notation in the output of show commands:

term ip netmask-format bitcount
DHCP Commands

Use the commands in this chapter to configure and monitor Dynamic Host Configuration Protocol (DHCP). For DHCP configuration information and examples, refer to the “Configuring DHCP” chapter of the Cisco IOS IP Configuration Guide.
**bootfile**

To specify the name of the default boot image for a Dynamic Host Configuration Protocol (DHCP) client, use the `bootfile` DHCP pool configuration command. To delete the boot image name, use the `no` form of this command.

```
bootfile filename

no bootfile
```

### Syntax Description

| filename | Specifies the name of the file that is used as a boot image. |

### Defaults

No default behavior or values.

### Command Modes

DHCP pool configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Examples

The following example specifies xllboot as the name of the boot file:

```
bootfile xllboot
```

### Related Commands

<tr>
<td><code>next-server</code></td>
<td>Configures the next server in the boot process of a DHCP client.</td>
</tr>
</tbody>
</table>
clear ip dhcp binding

To delete an automatic address binding from the Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server database, use the `clear ip dhcp binding` privileged EXEC command.

```
clear ip dhcp binding {address | *}
```

**Syntax Description**

- **address**: The address of the binding you want to clear.
- *****: Clears all automatic bindings.

**Command Modes**

Privileged EXEC

**Command History**

- **Release**: 12.0(1)T
  - **Modification**: This command was introduced.

**Usage Guidelines**

Typically, the address denotes the IP address of the client. If the asterisk (*) character is used as the address parameter, DHCP clears all automatic bindings.

Use the `no ip dhcp pool` global configuration command to delete a manual binding.

**Examples**

The following example deletes the address binding 10.12.1.99 from a DHCP server database:

```
Router# clear ip dhcp binding 10.12.1.99
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip dhcp binding</code></td>
<td>Displays address bindings on the Cisco IOS DHCP Server.</td>
</tr>
</tbody>
</table>
clear ip dhcp conflict

To clear an address conflict from the Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server database, use the `clear ip dhcp conflict` privileged EXEC command.

```
clear ip dhcp conflict {address | *}
```

<table>
<thead>
<tr>
<th>Syntax Description</th>
<th>address</th>
<th>The IP address of the host that contains the conflicting address you want to clear.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>*</td>
<td>Clears all address conflicts.</td>
</tr>
</tbody>
</table>

**Command Modes**

Privileged EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The server detects conflicts using a ping session. The client detects conflicts using gratuitous Address Resolution Protocol (ARP). If the asterisk (*) character is used as the address parameter, DHCP clears all conflicts.

**Examples**

The following example shows an address conflict of 10.12.1.99 being deleted from the DHCP server database:

```
Router# clear ip dhcp conflict 10.12.1.99
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip dhcp conflict</code></td>
<td>Displays address conflicts found by a Cisco IOS DHCP Server when addresses are offered to the client.</td>
</tr>
</tbody>
</table>
clear ip dhcp server statistics

To reset all Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server counters, use the `clear ip dhcp server statistics` privileged EXEC command.

```
clear ip dhcp server statistics
```

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

Usage Guidelines

The `show ip dhcp server statistics` command displays DHCP counters. All counters are cumulative. The counters will be initialized, or set to zero, with the `clear ip dhcp server statistics` command.

Examples

The following example resets all DHCP counters to zero:

```
Router# clear ip dhcp server statistics
```
clear ip route dhcp

To remove routes from the routing table added by the Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server and Relay Agent for the DHCP clients on unnumbered interfaces, use the `clear ip route dhcp` command in EXEC configuration mode.

```
clear ip route dhcp [vrf vrf-name] dhcp [ip-address]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vrf</td>
<td>(Optional) VPN routing and forwarding instance.</td>
</tr>
<tr>
<td>vrf-name</td>
<td>(Optional) Name of the VRF.</td>
</tr>
<tr>
<td>ip-address</td>
<td>(Optional) Address about which routing information should be removed.</td>
</tr>
</tbody>
</table>

**Defaults**

No default behavior or values.

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

To remove information about global routes in the routing table, use the `clear ip route dhcp` command. To remove routes in the VRF routing table, use the `clear ip route vrf vrf-name dhcp` command.

**Examples**

The following example removes a route to network 55.5.5.217 from the routing table:

```
Router# clear ip route dhcp 55.5.5.217
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip route dhcp</td>
<td>Displays the routes added to the routing table by the Cisco IOS DHCP Server and Relay Agent.</td>
</tr>
</tbody>
</table>
**client-identifier**

To specify the unique identifier (in dotted hexadecimal notation) for a Microsoft Dynamic Host Configuration Protocol (DHCP) client, use the `client-identifier` DHCP pool configuration command. It is valid for manual bindings only. To delete the client identifier, use the `no` form of this command.

```
client-identifier unique-identifier

no client-identifier
```

**Syntax Description**

- `unique-identifier`: The distinct identification of the client in dotted-hexadecimal notation, for example, `01b7.0813.8811.66`.

**Command Modes**

- DHCP pool configuration

**Command History**

- **Release** | **Modification**
  - 12.0(1)T | This command was introduced.

**Usage Guidelines**

Microsoft DHCP clients require client identifiers instead of hardware addresses. The client identifier is formed by concatenating the media type and the MAC address. For example, the Microsoft client identifier for Ethernet address `b708.1388.166` is `01b7.0813.8811.66`, where `01` represents the Ethernet media type. For a list of media type codes, refer to the “Address Resolution Protocol Parameters” section of RFC 1700, *Assigned Numbers*.

**Examples**

The following example specifies the client identifier for MAC address `b7.0813.8811.66` in dotted hexadecimal notation:

```
client-identifier 01b7.0813.8811.66
```

**Related Commands**

<table>

<td><code>ip dhcp pool</code></td>
<td>Configures a DHCP address pool on a Cisco IOS DHCP Server and enters DHCP pool configuration mode.</td>
</tr>
</tbody>
</table>
client-name

To specify the name of a DHCP client, use the `client-name` DHCP pool configuration command. The client name should not include the domain name. To remove the client name, use the `no` form of this command.

```
client-name name

no client-name
```

**Syntax Description**

- `name` Specifies the name of the client, using any standard ASCII character. The client name should not include the domain name. For example, the name `mars` should not be specified as `mars.cisco.com`.

**Command Modes**

DHCP pool configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Examples**

The following example specifies a string `client1` that will be the name of the client:

```
client-name client1
```

**Related Commands**

<table>
<thead>
<tr>

</tbody>
</table>
default-router

To specify the default router list for a Dynamic Host Configuration Protocol (DHCP) client, use the `default-router` DHCP pool configuration command. To remove the default router list, use the `no` form of this command.

```
default-router address [address2...address8]
no default-router
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>address</code></td>
<td>Specifies the IP address of a router. One IP address is required, although you can specify up to eight addresses in one command line.</td>
</tr>
<tr>
<td><code>address2...address8</code></td>
<td>(Optional) Specifies up to eight addresses in the command line.</td>

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The IP address of the router should be on the same subnet as the client subnet. You can specify up to eight routers in the list. Routers are listed in order of preference (address1 is the most preferred router, address2 is the next most preferred router, and so on).

**Examples**

The following example specifies 10.12.1.99 as the IP address of the default router:

```
default-router 10.12.1.99
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>

</table>
To specify the Domain Name System (DNS) IP servers available to a Dynamic Host Configuration Protocol (DHCP) client, use the **`dns-server`** DHCP pool configuration command. To remove the DNS server list, use the **`no`** form of this command.

```plaintext
dns-server address [address2...address8]
```

**Syntax Description**

- `address` Specifies the IP address of a DNS server. One IP address is required, although you can specify up to eight addresses in one command line.
- `address2...address8` (Optional) Specifies up to eight addresses in the command line.

**Defaults**

If DNS IP servers are not configured for a DHCP client, the client cannot correlate host names to IP addresses.

**Command Modes**

DHCP pool configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>

</tbody>
</table>
host

To specify the IP address and network mask for a manual binding to a Dynamic Host Configuration Protocol (DHCP) client, use the `host` DHCP pool configuration command. To remove the IP address of the client, use the `no` form of this command.

```
host address [mask | prefix-length]
```

```
no host
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>Specifies the IP address of the client.</td>
</tr>
<tr>
<td>mask</td>
<td>(Optional) Specifies the network mask of the client.</td>
</tr>
<tr>
<td>prefix-length</td>
<td>(Optional) Specifies the number of bits that comprise the address prefix.</td>
</tr>
<tr>
<td>prefix-length</td>
<td>The prefix is an alternative way of specifying the network mask of the client.</td>
</tr>
<tr>
<td>prefix-length</td>
<td>The prefix length must be preceded by a forward slash (/).</td>
</tr>
</tbody>
</table>

**Command Modes**

DHCP pool configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

If the mask and prefix length are unspecified, DHCP examines its address pools. If no mask is found in the pool database, the Class A, B, or C natural mask is used. This command is valid for manual bindings only.

There is no limit on the number of manual bindings but you can only configure one manual binding per host pool.

**Examples**

The following example specifies 10.12.1.99 as the IP address of the client and 255.255.248.0 as the subnet mask:

```
host 10.12.1.99 255.255.248.0
```

**Related Commands**

</tbody>
</table>
import all

To import Dynamic Host Configuration Protocol (DHCP) option parameters into the DHCP Server database, use the import all DHCP pool configuration command. To disable this feature, use the no form of this command.

import all

no import all

Syntax Description
This command has no arguments or keywords.

Defaults
Disabled

Command Modes
DHCP pool configuration

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.1(2)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

Usage Guidelines
When the no import all command is used, the Cisco IOS DHCP Server deletes all “imported” option parameters that were added to the specified pool in the server database. Manually configured DHCP option parameters override imported DHCP option parameters.

Imported option parameters are not part of the router configuration and are not saved in NVRAM.

Examples
The following example allows the importing of all DHCP options for a pool named pool1:

```
ip dhcp pool pool1
network 172.16.0.0 /16
import all
```

Related Commands

</tbody>
</table>
**ip address dhcp**

To acquire an IP address on an Ethernet interface from the Dynamic Host Configuration Protocol (DHCP), use the `ip address dhcp` interface configuration command. To deconfigure any address that was acquired, use the `no` form of this command.

```plaintext
ip address dhcp [client-id interface-name] [hostname host-name]
no ip address dhcp [client-id interface-name] [hostname host-name]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client-id</td>
<td>(Optional) Specifies the client identifier. By default, the client identifier is an ASCII value. The <code>client-id interface-name</code> option sets the client identifier to the hexadecimal MAC address of the named interface.</td>
</tr>
<tr>
<td>interface-name</td>
<td>(Optional) The interface name from which the MAC address is taken.</td>
</tr>
<tr>
<td>hostname</td>
<td>(Optional) Specifies the host name.</td>
</tr>
<tr>
<td>host-name</td>
<td>(Optional) Name of the host to be placed in the DHCP option 12 field. This name need not be the same as the host name entered in global configuration mode.</td>
</tr>
</tbody>
</table>

**Defaults**

The host name is the globally configured host name of the router.

The client identifier is an ASCII value.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>

<td></td>
<td>- <code>host-name</code></td>
</tr>
<tr>
<td></td>
<td>The behavior of the <code>client-id interface-name</code> option changed. See the “Usage Guidelines” section for details.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The `ip address dhcp` command allows any interface to dynamically learn its IP address by using the DHCP protocol. It is especially useful on Ethernet interfaces that dynamically connect to an Internet Service Provider (ISP). Once assigned a dynamic address, the interface can be used with the Port Address Translation (PAT) of Cisco IOS Network Address Translation (NAT) to provide Internet access to a privately addressed network attached to the router.
Some ISPs require that the DHCPDISCOVER message have a specific host name and client identifier that is the MAC address of the interface. The most typical usage of the **ip address dhcp client-id interface-name hostname host-name** command is when *interface-name* is the Ethernet interface where the command is configured and *host-name* is the host name provided by the ISP.

A client identifier (DHCP option 61) can be a hexadecimal or an ASCII value. By default, the client identifier is an ASCII value. The **client-id interface** option overrides the default and forces the use of the hexadecimal MAC address of the named interface.

**Note** Between 12.1(3)T and 12.2(3), the **client-id** optional keyword allowed the change of the fixed ASCII value for the client identifier. After 12.2(3), the optional **client-id** keyword forced the use of the hexadecimal MAC address of the named interface.

If a Cisco router is configured to obtain its IP address from a DHCP server, it sends a DHCPDISCOVER message to provide information about itself to the DHCP server on the network.

If you use the **ip address dhcp** command with or without any of the optional keywords, the DHCP option 12 field (host name option) is included in the DISCOVER message. By default, the host name specified in option 12 will be the globally configured host name of the router. However, you can use the **ip address dhcp hostname host-name** command to place a different name in the DHCP option 12 field than the globally configured host name of the router.

The **no ip address dhcp** command deconfigures any IP address that was acquired, thus sending a DHCPRELEASE message.

You might need to experiment with different configurations to determine the one required by your DHCP server. Table 12 shows the possible configuration methods and the information placed in the DISCOVER message for each method.

**Table 12 Configuration Method and Resulting Contents of the DISCOVER Message**

| Configuration Method          | Contents of DISCOVER Messages                                                                 |
|------------------------------|------------------------------------------------------------------------------------------------|---|
| **ip address dhcp**          | The DISCOVER message contains “cisco-mac-address -Eth1” in the client ID field. The *mac-address* is the media access control (MAC) address of the Ethernet 1 interface and contains the default host name of the router in the option 12 field. |
| **ip address dhcp hostname host-name** | The DISCOVER message contains “cisco-mac-address -Eth1” in the client ID field. The *mac-address* is the MAC address of the Ethernet 1 interface, and contains *host-name* in the option 12 field. |
| **ip address dhcp client-id ethernet 1** | The DISCOVER message contains the MAC address of the Ethernet 1 interface in the client ID field and contains the default host name of the router in the option 12 field. |
| **ip address dhcp client-id ethernet 1 hostname host-name** | The DISCOVER message contains the MAC address of the Ethernet 1 interface in the client ID field and contains *host-name* in the option 12 field. |
DHCP Commands

Examples

In the examples that follow, the command `ip address dhcp` is entered for the Ethernet 1 interface. The DISCOVER message sent by a router configured as shown in the following example would contain “cisco- mac-address -Eth1” in the client-ID field, and the value fresno in the option 12 field.

```
hostname fresno
!
interface Ethernet 1
  ip address dhcp
```

The DISCOVER message sent by a router configured as shown in the following example would contain “cisco- mac-address -Eth1” in the client-ID field, and the value sanfran in the option 12 field.

```
hostname fresno
!
interface Ethernet 1
  ip address dhcp hostname sanfran
```

The DISCOVER message sent by a router configured as shown in the following example would contain the MAC address of the Ethernet 1 interface in the client-id field, and the value fresno in the option 12 field.

```
hostname fresno
!
interface Ethernet 1
  ip address dhcp client-id Ethernet 1
```

The DISCOVER message sent by a router configured as shown in the following example would contain the MAC address of the Ethernet 1 interface in the client-id field, and the value sanfran in the option 12 field.

```
hostname fresno
!
interface Ethernet 1
  ip address dhcp client-id Ethernet 1 hostname sanfran
```

ip dhcp-client broadcast-flag

To configure the Cisco IOS Dynamic Host Configuration (DHCP) client to set the broadcast flag, use the `ip dhcp-client broadcast-flag` command in global configuration mode. To disable this feature, use the `no` form of this command.

```
ip dhcp-client broadcast-flag
no dhcp-client broadcast-flag
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

The broadcast flag is on.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Use this command to set the broadcast flag to 1 or 0 in the DHCP header when the DHCP client sends a discover requesting an IP address. The DHCP Server listens to this broadcast flag and broadcasts the reply packet if the flag is set to 1.

If you enter `no ip dhcp-client broadcast-flag`, the broadcast flag is set to 0 and the DHCP Server unicasts the reply packets to the client with the offered IP address.

The Cisco IOS DHCP client can receive both broadcast and unicast offers from the DHCP Server.

**Examples**

The following example sets the broadcast flag on:

```
Router(config)# ip dhcp-client broadcast-flag
```

</table>
ip dhcp conflict logging

To enable conflict logging on a Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server, use the `ip dhcp conflict logging` global configuration command. To disable conflict logging, use the `no` form of this command.

```
ipo dhcp conflict logging
no ip dhcp conflict logging
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

Conflict logging is enabled.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

We recommend using a DHCP server database agent to store automatic bindings. If you decide not to use a DHCP Server database agent to store automatic bindings, use the `no ip dhcp conflict logging` command to disable the recording of address conflicts. By default, the Cisco IOS DHCP Server records DHCP address conflicts in a log file.

**Examples**

The following example disables the recording of DHCP address conflicts:

```
no ip dhcp conflict logging
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>clear ip dhcp conflict</code></td>
<td>Clears an address conflict from the Cisco IOS DHCP Server database.</td>

<td>Configures a Cisco IOS DHCP Server to save automatic bindings on a remote host called a database agent.</td>
</tr>
<tr>
<td><code>show ip dhcp conflict</code></td>
<td>Displays address conflicts found by a Cisco IOS DHCP Server when addresses are offered to the client.</td>
</tr>
</tbody>
</table>
**ip dhcp database**

To configure a Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server and relay agent to save automatic bindings on a remote host called a database agent, use the **ip dhcp database** global configuration command. To remove the database agent, use the **no** form of this command.

```
  ip dhcp database url [timeout seconds | write-delay seconds]
  no ip dhcp database url
```

**Syntax Description**

- **url**
  - Specifies the remote file used to store the automatic bindings. Following are the acceptable URL file formats:
    - tftp://host/filename
    - ftp://user:password@host/filename
    - rcp://user@host/filename

- **timeout seconds**
  - (Optional) Specifies how long (in seconds) the DHCP Server should wait before aborting a database transfer. Transfers that exceed the timeout period are aborted. By default, DHCP waits 300 seconds (5 minutes) before aborting a database transfer. Infinity is defined as 0 seconds.

- **write-delay seconds**
  - (Optional) Specifies how soon the DHCP server should send database updates. By default, DHCP waits 300 seconds (5 minutes) before sending database changes. The minimum delay is 60 seconds.

**Defaults**

DHCP waits 300 seconds for both a write delay and a timeout.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The administrator may configure multiple database agents. Bindings are transferred by using FTP, Trivial File Transport Protocol (TFTP), or remote copy protocol (rcp).

The DHCP relay agent can save route information to the same database agents to ensure recovery after reloads.

**Examples**

The following example specifies the DHCP database transfer timeout value at 80 seconds:

```
  ip dhcp database ftp://user:password@172.16.1.1/router-dhcp timeout 80
```

The following example specifies the DHCP database update delay value at 100 seconds:

```
  ip dhcp database tftp://172.16.1.1/router-dhcp write-delay 100
```
**DHCP Commands**

**ip dhcp database**

<table>

ip dhcp excluded-address

To specify IP addresses that a Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server should not assign to DHCP clients, use the **ip dhcp excluded-address** global configuration command. To remove the excluded IP addresses, use the **no** form of this command.

```
ip dhcp excluded-address low-address [high-address]

no ip dhcp excluded-address low-address [high-address]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>low-address</th>
<th>The excluded IP address, or first IP address in an excluded address range.</th>
</tr>
</thead>
<tbody>
<tr>
<td>high-address</td>
<td>(Optional) The last IP address in the excluded address range.</td>
</tr>
</tbody>
</table>

**Defaults**

All IP pool addresses are assignable.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The DHCP Server assumes that all pool addresses may be assigned to clients. Use this command to exclude a single IP address or a range of IP addresses.

**Examples**

The following example configures an excluded IP address range from 172.16.1.100 through 172.16.1.199:

```
ip dhcp excluded-address 172.16.1.100 172.16.1.199
```

**Related Commands**

</table>
ip dhcp limited-broadcast-address

To override a configured network broadcast and have the DHCP server and relay agent send all
networks, all nodes broadcast to a DHCP client, use the **ip dhcp limited-broadcast-address** global
configuration command. To disable this functionality, use the **no** form of this command.

```
ip dhcp limited-broadcast-address

no ip dhcp limited-broadcast-address
```

**Syntax Description**
This command has no arguments or keywords.

**Defaults**
Default broadcast address: 255.255.255.255 (all ones)

**Command Modes**
Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.1</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
When a DHCP client sets the broadcast bit in the DHCP packet, the DHCP server and relay agent send
DHCP messages to clients using the all ones broadcast address (255.255.255.255). If the
**ip broadcast-address** interface configuration command has been configured to send a network
broadcast, the all ones broadcast set by DHCP is overridden. To remedy this situation, use the
**ip dhcp limited-broadcast-address** command to ensure that a configured network broadcast does not
override the default DHCP behavior.

Some DHCP clients can only accept an all ones broadcast and may not be able to acquire a DHCP
address unless this command is configured on the router interface connected to the client.

**Examples**
The following example configures DHCP to override any network broadcast:

```
ip dhcp limited-broadcast-address
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip broadcast-address</td>
<td>Defines a broadcast address for an interface.</td>
</tr>
</tbody>
</table>
**ip dhcp ping packets**

To specify the number of packets a Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server sends to a pool address as part of a ping operation, use the **ip dhcp ping packets** global configuration command. To prevent the server from pinging pool addresses, use the **no** form of this command.

```
ip dhcp ping packets number

no ip dhcp ping packets
```

**Syntax Description**

| number | Indicates the number of ping packets that are sent before assigning the address to a requesting client. The default value is two packets. |

**Defaults**

Two packets

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The DHCP Server pings a pool address before assigning the address to a requesting client. If the ping is unanswered, the DHCP Server assumes (with a high probability) that the address is not in use and assigns the address to the requesting client.

Setting the `number` argument to a value of 0 turns off DHCP Server ping operation completely.

**Examples**

The following example specifies five ping attempts by the DHCP Server before ceasing any further ping attempts:

```
ip dhcp ping packets 5
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear ip dhcp conflict</td>
<td>Clears an address conflict from the Cisco IOS DHCP Server database.</td>
</tr>
<tr>
<td>ip dhcp ping timeout</td>
<td>Specifies how long a Cisco IOS DHCP Server waits for a ping reply from an address pool.</td>
</tr>
<tr>
<td>show ip dhcp conflict</td>
<td>Displays address conflicts found by a Cisco IOS DHCP Server when addresses are offered to the client.</td>
</tr>
</tbody>
</table>
ip dhcp ping timeout

To specify how long a Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server waits for a ping reply from an address pool, use the `ip dhcp ping timeout` global configuration command. To restore the default number of milliseconds (500) of the timeout, use the `no` form of this command.

```
ip dhcp ping timeout milliseconds
no ip dhcp ping timeout
```

**Syntax Description**

`milliseconds`  
The amount of time (in milliseconds) that the DHCP server waits for a ping reply before it stops attempting to reach a pool address for client assignment. The maximum timeout is 10000 milliseconds (10 seconds). The default timeout is 500 milliseconds.

**Defaults**

500 milliseconds

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command specifies how long to wait for a ping reply (in milliseconds).

**Examples**

The following example specifies that the DHCP Server will wait 800 milliseconds for a ping reply before considering the ping a failure:

```
ip dhcp ping timeout 800
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>clear ip dhcp conflict</code></td>
<td>Clears an address conflict from the Cisco IOS DHCP Server database.</td>

</tbody>
</table>
ip dhcp pool

To configure a Dynamic Host Configuration Protocol (DHCP) address pool on a Cisco IOS DHCP Server and enter DHCP pool configuration mode, use the **ip dhcp pool** global configuration command. To remove the address pool, use the **no** form of this command.

```
    ip dhcp pool name

    no ip dhcp pool name
```

**Syntax Description**

- `name` Can either be a symbolic string (such as engineering) or an integer (such as 0).

**Defaults**

DHCP address pools are not configured.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

During execution of this command, the configuration mode changes to DHCP pool configuration mode, which is identified by the (config-dhcp)# prompt. In this mode, the administrator can configure pool parameters, like the IP subnet number and default router list.

**Examples**

The following example configures pool1 as the DHCP address pool:

```
ip dhcp pool pool1
```

**Related Commands**

- **host** Specifies the IP address and network mask for a manual binding to a DHCP client.
- **ip dhcp excluded-address** Specifies IP addresses that a Cisco IOS DHCP Server should not assign to DHCP clients.
- **network (DHCP)** Configures the subnet number and mask for a DHCP address pool on a Cisco IOS DHCP Server.
**ip dhcp relay information check**

To configure a Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server to validate the relay agent information option in forwarded BOOTREPLY messages, use the **ip dhcp relay information check** global configuration command. To disable an information check, use the **no** form of this command.

```
ip dhcp relay information check
no ip dhcp relay information check
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

The DHCP server checks relay information. Invalid messages are dropped.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command is used by cable access router termination systems. By default, DHCP checks relay information. Invalid messages are dropped.

**Examples**

The following example configures the DHCP Server to check that the relay agent information option in forwarded BOOTREPLY messages is valid:

```
ip dhcp relay information check
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ip dhcp relay information option</strong></td>
<td>Configures a Cisco IOS DHCP Server to insert the DHCP relay agent information option in forwarded BOOTREQUEST messages.</td>
</tr>
<tr>
<td><strong>ip dhcp relay information policy</strong></td>
<td>Configures the information reforwarding policy of a DHCP relay agent (what a DHCP relay agent should do if a message already contains relay information).</td>
</tr>
</tbody>
</table>
ip dhcp relay information option

To enable the system to insert the Dynamic Host Configuration Protocol (DHCP) relay information option in forwarded BOOTREQUEST messages to a Cisco IOS DHCP Server, use the `ip dhcp relay information option` global configuration command. To disable inserting relay information into forwarded BOOTREQUEST messages, use the `no` form of this command.

```
  ip dhcp relay information option
  no ip dhcp relay information option
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

The DHCP Server does not insert relay information.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command is used by cable access router termination systems. This functionality enables a DHCP server to identify the user (cable access router) sending the request and initiate appropriate action based on this information. By default, DHCP does not insert relay information.

**Examples**

The following example configures a DHCP Server to insert the DHCP relay agent information option in forwarded BOOTREQUEST messages:

```
  ip dhcp relay information option
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip dhcp relay information check</code></td>
<td>Configures a Cisco IOS DHCP Server to validate the relay agent information option in forwarded BOOTREPLY messages.</td>
</tr>
<tr>
<td><code>ip dhcp relay information policy</code></td>
<td>Configures the information reforwarding policy of a DHCP relay agent (what a DHCP relay agent should do if a message already contains relay information).</td>
</tr>
</tbody>
</table>
ip dhcp relay information policy

To configure the information reforwarding policy for a Dynamic Host Configuration Protocol (DHCP) relay agent (what a relay agent should do if a message already contains relay information), use the `ip dhcp relay information policy` global configuration command. To restore the default relay information policy, use the `no` form of this command.

```
  ip dhcp relay information policy { drop | keep | replace }

  no ip dhcp relay information policy
```

**Syntax Description**

- **drop**: Directs the DHCP relay agent to discard messages with existing relay information if the relay information option is already present.
- **keep**: Indicates that existing information is left unchanged on the DHCP relay agent.
- **replace**: Indicates that existing information is overwritten on the DHCP relay agent.

**Defaults**
The DHCP server replaces existing relay information.

**Command Modes**
Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
This command is used by cable access router termination systems. When a DHCP relay agent receives a message from another DHCP relay agent, relay information might already be present in the message. By default, the relay information from the previous relay agent is replaced.

**Examples**
The following examples configure a DHCP relay agent to drop messages with existing relay information, keep existing information, and replace existing information:

```
  ip dhcp relay information policy drop
  ip dhcp relay information policy keep
  ip dhcp relay information policy replace
```
DHCP Commands

ip dhcp relay information policy

ip dhcp relay information trusted

To configure an interface as a trusted source of the Dynamic Host Configuration Protocol (DHCP) relay agent information option, use the `ip dhcp relay information trusted` command in interface configuration mode. To restore the interface to the default behavior, use the `no` form of the command.

```
ip dhcp relay information trusted
no ip dhcp relay information trusted
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

All interfaces on the router are considered untrusted.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

By default, if the gateway address is set to all zeros in the DHCP packet and the relay information option is already present in the packet, the Cisco IOS DHCP relay agent will discard the packet. If the `ip dhcp relay information trusted` command is configured on an interface, the Cisco IOS DHCP relay agent will not discard the packet even if the gateway address is set to all zeros. Instead, the received DHCPDISCOVER or DHCPREQUEST messages will be forwarded to the addresses configured by the `ip helper-address` command as in normal DHCP relay operation.

**Examples**

In the following example, interface Ethernet 1 is configured as a trusted source for the relay agent information:

```
interface ethernet 1
ip dhcp relay information trusted
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip helper-address</code></td>
<td>Enables the forwarding of UDP broadcasts, including BOOTP, received on an interface.</td>
</tr>
</tbody>
</table>
| `show ip dhcp relay
information trusted-sources` | Displays all interfaces on the router that are configured as a trusted source for the DHCP relay agent information option. |
**ip dhcp relay information trust-all**

To configure all interfaces on a router as trusted sources of the Dynamic Host Configuration Protocol (DHCP) relay agent information option, use the `ip dhcp relay information trust-all` command in global configuration mode. To restore the interfaces to their default behavior, use the `no` form of the command.

```
  ip dhcp relay information trust-all

  no ip dhcp relay information trust-all
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

All interfaces on the router are considered untrusted.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
</table>
| 12.2    | This command was introduced.

**Usage Guidelines**

By default, if the gateway address is set to all zeros in the DHCP packet and the relay information option is already present in the packet, the Cisco IOS DHCP relay agent will discard the packet. If the `ip dhcp relay information trust-all` command is configured globally, the Cisco IOS DHCP relay agent will not discard the packet even if the gateway address is set to all zeros. Instead, the received DHCPDISCOVER or DHCPREQUEST messages will be forwarded to the addresses configured by the `ip helper-address` command as in normal DHCP relay operation.

**Examples**

In the following example, all interfaces on the router are configured as a trusted source for relay agent information:

```
  ip dhcp relay information trust-all
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip helper-address</code></td>
<td>Enables the forwarding of UDP broadcasts, including BOOTP, received on an interface.</td>
</tr>
<tr>
<td><code>show ip dhcp relay information trusted-sources</code></td>
<td>Displays all interfaces on the router that are configured as a trusted source for the DHCP relay agent information option.</td>
</tr>
</tbody>
</table>
**ip dhcp smart-relay**

To allow the Cisco IOS Dynamic Host Configuration Protocol (DHCP) relay agent to switch the gateway address (giaddr field of a DHCP packet) to secondary addresses when there is no DHCPOFFER message from a DHCP server, use the `ip dhcp smart-relay` global configuration command. To disable this smart-relay functionality and restore the default behavior, use the **no** form of this command.

```
ip dhcp smart-relay
no ip dhcp smart-relay
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

Disabled

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.1</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The DHCP relay agent attempts to forward the primary address as the gateway address three times. After three attempts and no response, the relay agent automatically switches to secondary addresses.

**Examples**

The following example enables the DHCP relay agent to automatically switch to secondary address pools:

```
ip dhcp smart-relay
```
lease

To configure the duration of the lease for an IP address that is assigned from a Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server to a DHCP client, use the **lease** DHCP pool configuration command. To restore the default value, use the **no** form of this command.

```
lease {days [hours][minutes] | infinite}

no lease
```

**Syntax Description**

- **days** Specifies the duration of the lease in numbers of days.
- **hours** (Optional) Specifies the number of hours in the lease. A **days** value must be supplied before you can configure an **hours** value.
- **minutes** (Optional) Specifies the number of minutes in the lease. A **days** value and an **hours** value must be supplied before you can configure a **minutes** value.
- **infinite** Specifies that the duration of the lease is unlimited.

**Defaults**

One day

**Command Modes**

DHCP pool configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Examples**

The following example shows a one-day lease:

```
lease 1
```

The following example shows a one-hour lease:

```
lease 0 1
```

The following example shows a one-minute lease:

```
lease 0 0 1
```

The following example shows an infinite (unlimited) lease:

```
lease infinite
```

<td><code>address2...address8</code></td>
<td>(Optional) Specifies up to eight addresses in the command line.</td>
</tr>
</tbody>
</table>

**Command Modes**

DHCP pool configuration

**Command History**

- **Release**: 12.0(1)T
  - **Modification**: This command was introduced.

**Usage Guidelines**

One IP address is required, although you can specify up to eight addresses in one command line. Servers are listed in order of preference (address1 is the most preferred server, address2 is the next most preferred server, and so on).

**Examples**

The following example specifies the IP address of a NetBIOS name server available to the client:

```
netbios-name-server 10.12.1.90
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>

<tr>
<td><code>netbios-node-type</code></td>
<td>Configures the NetBIOS node type for Microsoft DHCP clients.</td>
</tr>
</tbody>
</table>
**netbios-node-type**

To configure the NetBIOS node type for Microsoft Dynamic Host Configuration Protocol (DHCP) clients, use the `netbios-node-type` DHCP pool configuration command. To remove the NetBIOS node type, use the `no` form of this command.

```
netbios-node-type type
no netbios-node-type
```

**Syntax Description**

- `type` Specifies the NetBIOS node type. Valid types are:
  - `b-node`—Broadcast
  - `p-node`—Peer-to-peer
  - `m-node`—Mixed
  - `h-node`—Hybrid (recommended)

**Command Modes**

DHCP pool configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The recommended type is `h-node` (hybrid).

**Examples**

The following example specifies the client’s NetBIOS type as hybrid:

```
netbios node-type h-node
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>

</table>
network (DHCP)

To configure the subnet number and mask for a Dynamic Host Configuration Protocol (DHCP) address pool on a Cisco IOS DHCP Server, use the `network` DHCP pool configuration command. To remove the subnet number and mask, use the `no` form of this command.

```
network network-number [mask | prefix-length]

no network
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>network-number</code></td>
<td>The IP address of the DHCP address pool.</td>
</tr>
<tr>
<td><code>mask</code></td>
<td>(Optional) The bit combination that renders which portion of the address of the DHCP address pool refers to the network or subnet and which part refers to the host.</td>
</tr>
<tr>
<td><code>prefix-length</code></td>
<td>(Optional) Specifies the number of bits that comprise the address prefix. The prefix is an alternative way of specifying the network mask of the client. The prefix length must be preceded by a forward slash (/).</td>
</tr>
</tbody>
</table>

**Command Modes**

DHCP pool configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command is valid for DHCP subnetwork address pools only. If the mask or prefix length is not specified, the class A, B, or C natural mask is used. The DHCP Server assumes that all host addresses are available. The system administrator can exclude subsets of the address space by using the `ip dhcp excluded-address` command.

You can not configure manual bindings within the same pool that is configured with the `network` command.

**Examples**

The following example configures 172.16.0.0/16 as the subnetwork number and mask of the DHCP pool:

```
network 172.16.0.0/16
```

**Related Commands**

<table>
<thead>
<tr>

<td>Specifies IP addresses that a Cisco IOS DHCP Server should not assign to DHCP clients.</td>
</tr>
<tr>
<td><code>ip dhcp pool</code></td>
<td>Configures a DHCP address pool on a Cisco IOS DHCP Server and enters DHCP pool configuration mode.</td>
</tr>
</tbody>
</table>
next-server

To configure the next server in the boot process of a Dynamic Host Configuration Protocol (DHCP) client, use the `next-server` DHCP pool configuration command. To remove the boot server list, use the `no` form of this command.

```
next-server address [address2...address8]
no next-server address
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>address</code></td>
<td>Specifies the IP address of the next server in the boot process, which is typically a Trivial File Transfer Protocol (TFTP) server. One IP address is required, although you can specify up to eight addresses in one command line.</td>
</tr>
<tr>
<td><code>address2...address8</code></td>
<td>(Optional) Specifies up to eight addresses in the command line.</td>
</tr>
</tbody>
</table>

**Defaults**

If the `next-server` command is not used to configure a boot server list, the DHCP Server uses inbound interface helper addresses as boot servers.

**Command Modes**

DHCP pool configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

You can specify up to eight servers in the list. Servers are listed in order of preference (address1 is the most preferred server, address2 is the next most preferred server, and so on).

**Examples**

The following example specifies 10.12.1.99 as the IP address of the next server in the boot process:

```
next-server 10.12.1.99
```

**Related Commands**

<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

DHCP provides a framework for passing configuration information to hosts on a TCP/IP network. Configuration parameters and other control information are carried in tagged data items that are stored in the options field of the DHCP message. The data items themselves are also called options. The current set of DHCP options are documented in RFC 2131, *Dynamic Host Configuration Protocol*.

### Examples

The following example configures DHCP option 19, which specifies whether the client should configure its IP layer for packet forwarding. A value of 0 means disable IP forwarding; a value of 1 means enable IP forwarding. IP forwarding is enabled in the following example:

```
option 19 hex 01
```

The following example configures DHCP option 72, which specifies the World Wide Web servers for DHCP clients. World Wide Web servers 172.16.3.252 and 172.16.3.253 are configured in the following example:

```
option 72 ip 172.16.3.252 172.16.3.253
```

</table>
service dhcp

To enable the Cisco IOS Dynamic Host Configuration Protocol (DHCP) server and relay agent features on your router, use the service dhcp global configuration command. To disable the Cisco IOS DHCP server and relay agent features, use the no form of this command.

```
service dhcp
no service dhcp
```

### Syntax Description
This command has no arguments or keywords.

### Defaults
Enabled

### Command Modes
Global configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines
The BOOTP and DHCP servers in Cisco IOS software both use the ICMP port (port 67) by default. ICMP “port unreachable messages” will only be returned to the sender if both the BOOTP server and DHCP server are disabled. Disabling only one of the servers will not result in ICMP port unreachable messages.

### Examples
The following example enables DHCP services on the DHCP Server:

```
service dhcp
```
show ip dhcp binding

To display address bindings on the Cisco IOS Dynamic Host Configuration Protocol (DHCP) server, use the `show ip dhcp binding` EXEC command.

```
show ip dhcp binding [ip-address]
```

### Syntax Description

- **ip-address** (Optional) Specifies the IP address of the DHCP client for which bindings will be displayed.

### Command Modes

EXEC

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

If the address is not specified, all address bindings are shown. Otherwise, only the binding for the specified client is displayed.

### Examples

The following examples show the DHCP binding address parameters, including an IP address, an associated MAC address, a lease expiration date, and the type of address assignment that have occurred. Table 13 lists descriptions of the fields in each example.

**Router> show ip dhcp binding 172.16.1.11**

<table>
<thead>
<tr>
<th>IP address</th>
<th>Hardware address</th>
<th>Lease expiration</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>172.16.1.11</td>

show ip dhcp conflict

To display address conflicts found by a Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server when addresses are offered to the client, use the show ip dhcp conflict EXEC command.

    show ip dhcp conflict [ip-address]

Syntax Description

    ip-address  (Optional) Specifies the IP address of the conflict found.

Command Modes

    EXEC

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

Usage Guidelines

The server detects conflicts using ping. The client detects conflicts using gratuitous Address Resolution Protocol (ARP). If an address conflict is detected, the address is removed from the pool and the address will not be assigned until an administrator resolves the conflict.

Examples

The following example displays the detection method and detection time for all IP addresses the DHCP Server has offered that have conflicts with other devices. Table 14 lists descriptions of the fields in the example.

    Router> show ip dhcp conflict
    IP address  Detection Method  Detection time
    172.16.1.32  Ping            Feb 16 1998 12:28 PM
    172.16.1.64  Gratuitous ARP  Feb 23 1998 08:12 AM

show ip dhcp database

To display Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server database agent information, use the show ip dhcp database privileged EXEC command.

    show ip dhcp database [url]

Syntax Description

url  (Optional) Specifies the remote file used to store automatic DHCP bindings. Following are the acceptable URL file formats:

- tftp://host/filename
- ftp://user:password@host/filename
- rcp://user@host/filename

Defaults

If a URL is not specified, all database agent records are shown. Otherwise, only information about the specified agent is displayed.

Command Modes

Privileged EXEC

Command History

Release       Modification
12.0(1)T       This command was introduced.

Examples

The following example shows all DHCP Server database agent information. Table 15 lists descriptions for each field in the example.

Router# show ip dhcp database

    URL :  ftp://user:password@172.16.4.253/router-dhcp
    Read :  Dec 01 1997 12:01 AM
    Written:  Never
    Status :  Last read succeeded. Bindings have been loaded in RAM.
    Delay :  300 seconds
    Timeout :  300 seconds
    Failures :  0
    Successes :  1
**DHCP Commands**

**show ip dhcp database**

**Table 15 show ip dhcp database Field Descriptions**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| URL    | Specifies the remote file used to store automatic DHCP bindings. Following are the acceptable URL file formats:  
  - tftp://host/filename  
  - ftp://user:password@host/filename  
  - rcp://user@host/filename |
| Read   | The last time bindings were read from the file server. |
| Written| The last time bindings were written to the file server. |
| Status | Indication of whether the last read or write of host bindings was successful. |
| Delay  | The amount of time to wait before updating the database. |
| Timeout| The amount of time before the file transfer is aborted. |
| Failures| The number of failed file transfers. |
| Successes| The number of successful file transfers. |

**Related Commands**

**show ip dhcp import**

To display the option parameters that were imported into the Dynamic Host Configuration Protocol (DHCP) Server database, use the `show ip dhcp import` EXEC command.

```
show ip dhcp import
```

**Syntax Description**

This command has no arguments or keywords.

**Command Modes**

EXEC

**Command History**

```
<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.1(2)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>
```

**Usage Guidelines**

Imported option parameters are not part of the router configuration and are not saved in NVRAM. Thus, the `show ip dhcp import` command is necessary to display the imported option parameters.

**Examples**

The following is sample output from the `show ip dhcp import` command:

```
Router# show ip dhcp import
Address Pool Name:2
Domain Name Server(s): 1.1.1.1
NetBIOS Name Server(s): 3.3.3.3
```

The following example indicates the address pool name:

```
Address Pool Name:2
```

The following example indicates the imported values, which are domain name and NetBIOS name information:

```
Domain Name Server(s): 1.1.1.1
NetBIOS Name Server(s): 3.3.3.3
```

show ip dhcp relay information trusted-sources

To display all interfaces configured to be a trusted source for the Dynamic Host Configuration Protocol (DHCP) relay information option, use the `show ip dhcp relay information trusted-sources` command in EXEC mode.

```
show ip dhcp relay information trusted-sources
```

**Syntax Description**
This command has no arguments or keywords.

**Command Modes**
EXEC

**Command History**
```
Release    Modification
12.2        This command was introduced.
```

**Examples**
The following is sample output when the `ip dhcp relay information trusted` interface configuration command is configured. Note that the display output lists the interfaces that are configured to be trusted sources.

```
Router# show ip dhcp relay information trusted-sources

List of trusted sources of relay agent information option:
Ethernet1/1     Ethernet1/2     Ethernet1/3     Serial4/1.1
Serial4/1.2     Serial4/1.3
```

The following is sample output when the `ip dhcp relay information trust-all` global configuration command is configured. Note that the display output does not list the individual interfaces.

```
Router# show ip dhcp relay information trusted-sources

All interfaces are trusted source of relay agent information option
```

**Related Commands**
```

show ip route dhcp

To display the routes added to the routing table by the Cisco IOS Dynamic Host Configuration Protocol (DHCP) Server and Relay Agent, use the `show ip route dhcp` command in EXEC configuration mode.

```
show ip route [vrf vrf-name] dhcp [ip-address]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vrf</td>
<td>(Optional) VPN routing and forwarding instance.</td>
</tr>
<tr>
<td>vrf-name</td>
<td>(Optional) Name of the VRF.</td>
</tr>
<tr>
<td>ip-address</td>
<td>(Optional) Address about which routing information should be displayed.</td>
</tr>
</tbody>
</table>

**Defaults**

No default behavior or values.

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

To display information about global routes, use the `show ip route dhcp` command. To display routes in the VRF routing table, use the `show ip route vrf vrf-name dhcp` command.

**Examples**

The following is sample output from the `show ip route dhcp` command when entered without an address. This command gives the list of all routes added by the Cisco IOS DHCP Server and Relay Agent.

```
Router# show ip route dhcp
55.5.5.56/32 is directly connected, ATM0.2
55.5.5.217/32 is directly connected, ATM0.2
```

The following is sample output from the `show ip route dhcp` command when an address is specified. This command gives the details of the address with the server address (who assigned it) and the lease expiration time.

```
Router# show ip route dhcp 55.5.5.217
55.5.5.217 is directly connected, ATM0.2
DHCP Server: 49.9.9.10 Lease expires at Nov 08 2001 01:19 PM
```

The following is sample output from the `show ip route vrf vrf-name dhcp` command when entered without an address:

```
Router# show ip route vrf red dhcp
55.5.5.218/32 is directly connected, ATM0.2
```
The following is sample output from the `show ip route vrf vrf-name dhcp` command when an address is specified. This command gives the details of the address with the server address (who assigned it) and the lease expiration time.

```
Router# show ip route vrf red dhcp 55.5.5.218
55.5.5.218/32 is directly connected, ATM0.2
   DHCP Server: 49.9.9.10   Lease expires at Nov 08 2001 03:15PM
```

show ip route dhcp
IP Services Commands

Use the commands in this chapter to configure various IP services. For configuration information and examples on IP services, refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Configuration Guide*. 
access-class

To restrict incoming and outgoing connections between a particular vty (into a Cisco device) and the addresses in an access list, use the access-class command in line configuration mode. To remove access restrictions, use the no form of this command.

```
access-class access-list-number [in [vrf-also] | out]
no access-class access-list-number {in | out}
```

**Syntax Description**

- `access-list-number` Number of an IP access list. This is a decimal number from 1 to 199 or from 1300 to 2699.
- `in` Restricts incoming connections between a particular Cisco device and the addresses in the access list.
- `vrf-also` Accepts incoming connections from interfaces that belong to a VRF.
- `out` Restricts outgoing connections between a particular Cisco device and the addresses in the access list.

**Defaults**
No access lists are defined.

**Command Modes**
Line configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.2</td>
<td>The <strong>vrf-also</strong> keyword was added.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
Remember to set *identical restrictions* on all the virtual terminal lines because a user can connect to any of them.

To display the access lists for a particular terminal line, use the `show line` EXEC command and specify the line number.

If you do not specify the **vrf-also** keyword, incoming Telnet connections from interfaces that are part of a VRF are rejected.

**Examples**
The following example defines an access list that permits only hosts on network 192.89.55.0 to connect to the virtual terminal ports on the router:

```
access-list 12 permit 192.89.55.0 0.0.0.255
line 1 5
access-class 12 in
```
The following example defines an access list that denies connections to networks other than network 36.0.0.0 on terminal lines 1 through 5:

```plaintext
access-list 10 permit 36.0.0.0 0.255.255.255
line 1 5
access-class 10 out
```

### Related Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show line</td>
<td>Displays the parameters of a terminal line.</td>
</tr>
</tbody>
</table>
access-list (IP extended)

To define an extended IP access list, use the extended version of the access-list command in global configuration mode. To remove the access list, use the no form of this command.

```
access-list access-list-number [dynamic dynamic-name [timeout minutes]] [deny | permit]
  [protocol source source-wildcard destination destination-wildcard [timeout timeout]
   [tos tos] [log | log-input] [time-range time-range-name] [fragments]

no access-list access-list-number
```

Internet Control Message Protocol (ICMP)

For ICMP, you can also use the following syntax:

```
access-list access-list-number [dynamic dynamic-name [timeout minutes]] [deny | permit]
  icmp source source-wildcard destination destination-wildcard [icmp-type [icmp-code]
   [icmp-message] [precedence precedence] [tos tos] [log | log-input] [time-range
   time-range-name] [fragments]
```

Internet Group Management Protocol (IGMP)

For IGMP, you can also use the following syntax:

```
access-list access-list-number [dynamic dynamic-name [timeout minutes]] [deny | permit]
  igmp source source-wildcard destination destination-wildcard [igmp-type]
   [precedence precedence] [tos tos] [log | log-input] [time-range time-range-name]
   [fragments]
```

Transmission Control Protocol (TCP)

For TCP, you can also use the following syntax:

```
access-list access-list-number [dynamic dynamic-name [timeout minutes]] [deny | permit]
  tcp source source-wildcard [operator [port]] destination destination-wildcard
   [operator [port]] [established] [precedence precedence] [tos tos] [log | log-input]
   [time-range time-range-name] [fragments]
```

User Datagram Protocol (UDP)

For UDP, you can also use the following syntax:

```
access-list access-list-number [dynamic dynamic-name [timeout minutes]] [deny | permit]
  udp source source-wildcard [operator [port]] destination destination-wildcard
   [operator [port]] [precedence precedence] [tos tos] [log | log-input] [time-range
   time-range-name] [fragments]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>access-list-number</td>
<td>Number of an access list. This is a decimal number from 100 to 199 or from 2000 to 2699.</td>
</tr>
<tr>
<td>dynamic dynamic-name</td>
<td>(Optional) Identifies this access list as a dynamic access list. Refer to lock-and-key access documented in the “Configuring Lock-and-Key Security (Dynamic Access Lists)” chapter in the Cisco IOS Security Configuration Guide.</td>
</tr>
</tbody>
</table>
timeout minutes (Optional) Specifies the absolute length of time, in minutes, that a temporary access list entry can remain in a dynamic access list. The default is an infinite length of time and allows an entry to remain permanently. Refer to lock-and-key access documented in the “Configuring Lock-and-Key Security (Dynamic Access Lists)” chapter in the Cisco IOS Security Configuration Guide.

deny Denies access if the conditions are matched.
permit Permits access if the conditions are matched.

protocol Name or number of an Internet protocol. It can be one of the keywords eigrp, gre, icmp, igmp, igrp, ip, ipinip, nos, ospf, pim, tcp, or udp, or an integer in the range from 0 to 255 representing an Internet protocol number. To match any Internet protocol (including ICMP, TCP, and UDP) use the ip keyword. Some protocols allow further qualifiers described below.

source Number of the network or host from which the packet is being sent. There are three alternative ways to specify the source:
- Use a 32-bit quantity in four-part, dotted-decimal format.
- Use the any keyword as an abbreviation for a source and source-wildcard of 0.0.0.0 255.255.255.255.
- Use host source as an abbreviation for a source and source-wildcard of source 0.0.0.0.

source-wildcard Wildcard bits to be applied to source. Each wildcard bit 0 indicates the corresponding bit position in the source. Each wildcard bit set to 1 indicates that both a 0 bit and a 1 bit in the corresponding position of the IP address of the packet will be considered a match to this access list entry.

There are three alternative ways to specify the source wildcard:
- Use a 32-bit quantity in four-part, dotted-decimal format. Place 1s in the bit positions you want to ignore.
- Use the any keyword as an abbreviation for a source and source-wildcard of 0.0.0.0 255.255.255.255.
- Use host source as an abbreviation for a source and source-wildcard of source 0.0.0.0.

Wildcard bits set to 1 need not be contiguous in the source wildcard. For example, a source wildcard of 0.255.0.64 would be valid.

destination Number of the network or host to which the packet is being sent. There are three alternative ways to specify the destination:
- Use a 32-bit quantity in four-part, dotted-decimal format.
- Use the any keyword as an abbreviation for the destination and destination-wildcard of 0.0.0.0 255.255.255.255.
- Use host destination as an abbreviation for a destination and destination-wildcard of destination 0.0.0.0.
**destination-wildcard**

Wildcard bits to be applied to the destination. There are three alternative ways to specify the destination wildcard:

- Use a 32-bit quantity in four-part, dotted-decimal format. Place 1s in the bit positions you want to ignore.
- Use the `any` keyword as an abbreviation for a destination and `destination-wildcard` of `0.0.0.0 255.255.255.255`.
- Use `host destination` as an abbreviation for a destination and `destination-wildcard` of `destination 0.0.0.0`.

**precedence precedence**

(Optional) Packets can be filtered by precedence level, as specified by a number from 0 to 7, or by name as listed in the section “Usage Guidelines.”

**tos tos**

(Optional) Packets can be filtered by type of service level, as specified by a number from 0 to 15, or by name as listed in the section “Usage Guidelines.”

**log**

(Optional) Causes an informational logging message about the packet that matches the entry to be sent to the console. (The level of messages logged to the console is controlled by the `logging console` command.)

The message includes the access list number, whether the packet was permitted or denied; the protocol, whether it was TCP, UDP, ICMP, or a number; and, if appropriate, the source and destination addresses and source and destination port numbers. By default, the message is generated for the first packet that matches, and then at 5-minute intervals, including the number of packets permitted or denied in the prior 5-minute interval.

Use the `ip access-list log-update` command to generate logging messages when the number of matches reaches a configurable threshold (rather than waiting for a 5-minute interval). See the `ip access-list log-update` command for more information.

The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from crashing due to too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.

If you enable CEF and then create an access list that uses the `log` keyword, the packets that match the access list are not CEF switched. They are fast switched. Logging disables CEF.

**log-input**

(Optional) Includes the input interface and source MAC address or VC in the logging output.

**time-range time-range-name**

(Optional) Name of the time range that applies to this statement. The name of the time range and its restrictions are specified by the `time-range` command.

**icmp-type**

(Optional) ICMP packets can be filtered by ICMP message type. The type is a number from 0 to 255.

**icmp-code**

(Optional) ICMP packets that are filtered by ICMP message type can also be filtered by the ICMP message code. The code is a number from 0 to 255.

access-list (IP extended)

Defaults
An extended access list defaults to a list that denies everything. An extended access list is terminated by an implicit deny statement.

Command Modes
Global configuration
**access-list (IP extended)**

</table>

**Usage Guidelines**

You can use access lists to control the transmission of packets on an interface, control vty access, and restrict the contents of routing updates. The Cisco IOS software stops checking the extended access list after a match occurs.

Fragmented IP packets, other than the initial fragment, are immediately accepted by any extended IP access list. Extended access lists used to control vty access or restrict the contents of routing updates must not match against the TCP source port, the type of service (ToS) value, or the precedence of the packet.

After a numbered access list is created, any subsequent additions (possibly entered from the terminal) are placed at the end of the list. In other words, you cannot selectively add or remove access list command lines from a specific numbered access list.

The following is a list of precedence names:

- critical
- flash
- flash-override
- immediate
- internet
- network
- priority
- routine

The following is a list of ToS names:
- max-reliability
- max-throughput
- min-delay
- min-monetary-cost
- normal

The following is a list of ICMP message type names and ICMP message type and code names:
- administratively-prohibited
- alternate-address
- conversion-error
- dod-host-prohibited
- dod-net-prohibited
- echo
- echo-reply

### Access List Processing of Fragments

The behavior of access-list entries regarding the use or lack of the `fragments` keyword can be summarized as follows:

<table>
<thead>
<tr>
<th>If the Access-List Entry has...</th>
<th>Then...</th>
</tr>
</thead>
<tbody>
<tr>
<td>...no <code>fragments</code> keyword (the default behavior), and assuming all of the access-list entry information matches,</td>
<td>For an access-list entry containing only Layer 3 information:</td>
</tr>
<tr>
<td></td>
<td>• The entry is applied to nonfragmented packets, initial fragments and noninitial fragments.</td>
</tr>
<tr>
<td></td>
<td>For an access list entry containing Layer 3 and Layer 4 information:</td>
</tr>
<tr>
<td></td>
<td>• The entry is applied to nonfragmented packets and initial fragments.</td>
</tr>
<tr>
<td></td>
<td>– If the entry is a <code>permit</code> statement, the packet or fragment is permitted.</td>
</tr>
<tr>
<td></td>
<td>– If the entry is a <code>deny</code> statement, the packet or fragment is denied.</td>
</tr>
<tr>
<td></td>
<td>• The entry is also applied to noninitial fragments in the following manner. Because noninitial fragments contain only Layer 3 information, only the Layer 3 portion of an access-list entry can be applied. If the Layer 3 portion of the access-list entry matches, and</td>
</tr>
<tr>
<td></td>
<td>– If the entry is a <code>permit</code> statement, the noninitial fragment is permitted.</td>
</tr>
<tr>
<td></td>
<td>– If the entry is a <code>deny</code> statement, the next access-list entry is processed.</td>
</tr>
</tbody>
</table>

### Note

The `deny` statements are handled differently for noninitial fragments versus nonfragmented or initial fragments.

<table>
<thead>
<tr>
<th>...the <code>fragments</code> keyword, and assuming all of the access-list entry information matches,</th>
<th>The access-list entry is applied only to noninitial fragments.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Note</strong> The <code>fragments</code> keyword cannot be configured for an access-list entry that contains any Layer 4 information.</td>
</tr>
</tbody>
</table>

Be aware that you should not simply add the `fragments` keyword to every access list entry because the first fragment of the IP packet is considered a nonfragment and is treated independently of the subsequent fragments. An initial fragment will not match an access list `permit` or `deny` entry that contains the `fragments` keyword, the packet is compared to the next access list entry, and so on, until it is either permitted or denied by an access list entry that does not contain the `fragments` keyword. Therefore, you may need two access list entries for every `deny` entry. The first `deny` entry of the pair...
will not include the **fragments** keyword, and applies to the initial fragment. The second **deny** entry of the pair will include the **fragments** keyword and applies to the subsequent fragments. In the cases where there are multiple **deny** access list entries for the same host but with different Layer 4 ports, a single **deny** access-list entry with the **fragments** keyword for that host is all that needs to be added. Thus all the fragments of a packet are handled in the same manner by the access list.

Packet fragments of IP datagrams are considered individual packets and each counts individually as a packet in access list accounting and access list violation counts.

**Note**

The **fragments** keyword cannot solve all cases involving access lists and IP fragments.

**Fragments and Policy Routing**

Fragmentation and the fragment control feature affect policy routing if the policy routing is based on the **match ip address** command and the access list had entries that match on Layer 4 through 7 information. It is possible that noninitial fragments pass the access list and are policy routed, even if the first fragment was not policy routed or the reverse.

By using the **fragments** keyword in access list entries as described earlier, a better match between the action taken for initial and noninitial fragments can be made and it is more likely policy routing will occur as intended.

**Examples**

In the following example, serial interface 0 is part of a Class B network with the address 128.88.0.0, and the address of the mail host is 128.88.1.2. The **established** keyword is used only for the TCP protocol to indicate an established connection. A match occurs if the TCP datagram has the ACK or RST bits set, which indicates that the packet belongs to an existing connection.

```plaintext
access-list 102 permit tcp 0.0.0.0 255.255.255.255 128.88.0.0 0.0.255.255 established
access-list 102 permit tcp 0.0.0.0 255.255.255.255 128.88.1.2 0.0.0.0 eq 25
interface serial 0
  ip access-group 102 in
```

The following example permits Domain Naming System (DNS) packets and ICMP echo and echo reply packets:

```plaintext
access-list 102 permit tcp any 128.88.0.0 0.0.255.255 established
access-list 102 permit tcp any host 128.88.1.2 eq smtp
access-list 102 permit tcp any any eq domain
access-list 102 permit udp any any eq domain
access-list 102 permit icmp any any echo
access-list 102 permit icmp any any echo-reply
```

The following examples show how wildcard bits are used to indicate the bits of the prefix or mask that are relevant. Wildcard bits are similar to the bitmasks that are used with normal access lists. Prefix or mask bits corresponding to wildcard bits set to 1 are ignored during comparisons and prefix or mask bits corresponding to wildcard bits set to 0 are used in comparison.

The following example permits 192.108.0.0 255.255.0.0 but denies any more specific routes of 192.108.0.0 (including 192.108.0.0 255.255.255.0):

```plaintext
access-list 101 permit ip 192.108.0.0 0.0.0.0 255.255.0.0 0.0.0.0
access-list 101 deny ip 192.108.0.0 0.0.0.0 255.255.255.0 0.0.0.0
```

The following example permits 131.108.0/24 but denies 131.108/16 and all other subnets of 131.108.0.0:

```plaintext
access-list 101 permit ip 131.108.0.0 0.0.0.0 255.255.255.0 0.0.0.0
access-list 101 deny ip 131.108.0.0 0.0.0.0 255.255.255.0 0.0.0.0
```
The following example uses a time range to deny HTTP traffic on Monday through Friday from 8:00 a.m. to 6:00 p.m.:

```plaintext
time-range no-http
    periodic weekdays 8:00 to 18:00
!
access-list 101 deny tcp any any eq http time-range no-http
!
interface ethernet 0
    ip access-group 101 in
```

</tbody>
</table>
access-list (IP standard)

To define a standard IP access list, use the standard version of the `access-list` command in global configuration mode. To remove a standard access list, use the `no` form of this command.

```
access-list access-list-number {deny | permit} source [source-wildcard] [log]
no access-list access-list-number
```

**Caution**
Enhancements to this command are backward compatible; migrating from releases prior to Cisco IOS Release 10.3 will convert your access lists automatically. However, releases prior to Release 10.3 are not upwardly compatible with these enhancements. Therefore, if you save an access list with these images and then use software prior to Release 10.3, the resulting access list will not be interpreted correctly. **This condition could cause you severe security problems.** Save your old configuration file before booting these images.

### Syntax Description

<table>
<thead>
<tr>
<th><code>access-list-number</code></th>
<th>Number of an access list. This is a decimal number from 1 to 99 or from 1300 to 1999.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>deny</code></td>
<td>Denies access if the conditions are matched.</td>
</tr>
<tr>
<td><code>permit</code></td>
<td>Permits access if the conditions are matched.</td>
</tr>
<tr>
<td><code>source</code></td>
<td>Number of the network or host from which the packet is being sent. There are two alternative ways to specify the source:</td>
</tr>
<tr>
<td></td>
<td>- Use a 32-bit quantity in four-part, dotted-decimal format.</td>
</tr>
<tr>
<td></td>
<td>- Use the <code>any</code> keyword as an abbreviation for a <code>source</code> and <code>source-wildcard</code> of 0.0.0.0 255.255.255.255.</td>
</tr>
</tbody>
</table>
source-wildcard  (Optional) Wildcard bits to be applied to the source. There are two alternative ways to specify the source wildcard:

- Use a 32-bit quantity in four-part, dotted-decimal format. Place 1s in the bit positions you want to ignore.
- Use the any keyword as an abbreviation for a source and source-wildcard of 0.0.0.0 255.255.255.255.

log  (Optional) Causes an informational logging message about the packet that matches the entry to be sent to the console. (The level of messages logged to the console is controlled by the logging console command.)

The message includes the access list number, whether the packet was permitted or denied, the source address, and the number of packets. The message is generated for the first packet that matches, and then at 5-minute intervals, including the number of packets permitted or denied in the prior 5-minute interval.

Use the ip access-list log-update command to generate the logging messages to appear when the number of matches reaches a configurable threshold (rather than waiting for a 5-minute interval). See the ip access-list log-update command for more information.

The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from crashing due to too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.

If you enable CEF and then create an access list that uses the log keyword, the packets that match the access list are not CEF switched. They are fast switched. Logging disables CEF.

Defaults
The access list defaults to an implicit deny statement for everything. The access list is always terminated by an implicit deny statement for everything.

Command Modes
Global configuration

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>11.3(3)T</td>
<td>The log keyword was added.</td>
</tr>
</tbody>
</table>

Usage Guidelines
Plan your access conditions carefully and be aware of the implicit deny statement at the end of the access list.

You can use access lists to control the transmission of packets on an interface, control vty access, and restrict the contents of routing updates.

Use the show access-lists EXEC command to display the contents of all access lists.
Use the `show ip access-list` EXEC command to display the contents of one access list.

**Examples**

The following example of a standard access list allows access for only those hosts on the three specified networks. The wildcard bits apply to the host portions of the network addresses. Any host with a source address that does not match the access list statements will be rejected.

```
access-list 1 permit 192.5.34.0  0.0.0.255
access-list 1 permit 128.88.0.0  0.0.255.255
access-list 1 permit 36.0.0.0  0.255.255.255
! (Note: all other access implicitly denied)
```

The following example of a standard access list allows access for devices with IP addresses in the range from 10.29.2.64 to 10.29.2.127. All packets with a source address not in this range will be rejected.

```
access-list 1 permit 10.29.2.64 0.0.0.63
! (Note: all other access implicitly denied)
```

To specify a large number of individual addresses more easily, you can omit the wildcard if it is all zeros. Thus, the following two configuration commands are identical in effect:

```
access-list 2 permit 36.48.0.3
access-list 2 permit 36.48.0.3  0.0.0.0
```

**Related Commands**

<table>

</table>
access-list compiled

To enable the Turbo Access Control Lists (Turbo ACL) feature, use the `access-list compiled` command in global configuration mode. To disable the Turbo ACL feature, use the `no` form of this command.

```plaintext
access-list compiled
no access-list compiled
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

Disabled

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(6)S</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(1)E</td>
<td>This command was introduced for Cisco 7200 series routers on Release 12.1 E.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

By default, the Turbo ACL feature is disabled. When Turbo ACL is disabled, normal ACL processing is enabled, and no ACL acceleration occurs.

When the Turbo ACL feature is enabled using the `access-list compiled` command, the ACLs in the configuration are scanned and, if suitable, compiled for Turbo ACL acceleration. This scanning and compilation may take a few seconds when the system is processing large and complex ACLs, or when the system is processing a configuration that contains a large number of ACLs.

Any configuration change to an ACL that is being accelerated, such as the addition of new ACL entries or the deletion of the ACL, triggers a recompilation of that ACL.

When Turbo ACL tables are being built (or rebuilt) for a particular ACL, the normal sequential ACL search is used until the new tables are ready for installation.

**Examples**

The following example enables the Turbo ACL feature:

```plaintext
access-list compiled
```
access-list remark

To write a helpful comment (remark) for an entry in a numbered IP access list, use the `access-list remark` command in global configuration mode. To remove the remark, use the `no` form of this command.

```
access-list access-list-number remark remark
```

```
no access-list access-list-number remark remark
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>access-list-number</code></td>
<td>Number of an IP access list.</td>
</tr>
<tr>
<td><code>remark</code></td>
<td>Comment that describes the access list entry, up to 100 characters long.</td>
</tr>
</tbody>
</table>

**Defaults**

The access list entries have no remarks.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(2)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The remark can be up to 100 characters long; anything longer is truncated.

If you want to write a comment about an entry in a named access list, use the `remark` command.

**Examples**

In the following example, the workstation belonging to Jones is allowed access, and the workstation belonging to Smith is not allowed access:

```
access-list 1 remark Permit only Jones workstation through
access-list 1 permit 171.69.2.88
access-list 1 remark Do not allow Smith workstation through
access-list 1 deny 171.69.3.13
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>access-list (IP extended)</code></td>
<td>Defines an extended IP access list.</td>
</tr>
<tr>
<td><code>access-list (IP standard)</code></td>
<td>Defines a standard IP access list.</td>
</tr>
<tr>
<td><code>ip access-list</code></td>
<td>Defines an IP access list by name.</td>
</tr>
<tr>
<td><code>remark</code></td>
<td>Writes a helpful comment (remark) for an entry in a named IP access list.</td>
</tr>
</tbody>
</table>
clear access-list counters

To clear the counters of an access list, use the `clear access-list counters` command in EXEC mode.

```
clear access-list counters {access-list-number | access-list-name}
```

**Syntax Description**

- `access-list-number` Access list number of the access list for which to clear the counters.
- `access-list-name` Name of an IP access list. The name cannot contain a space or quotation mark, and must begin with an alphabetic character to avoid ambiguity with numbered access lists.

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Some access lists keep counters that count the number of packets that pass each line of an access list. The `show access-lists` command displays the counters as a number of matches. Use the `clear access-list counters` command to restart the counters for a particular access list to 0.

**Examples**

The following example clears the counters for access list 101:

```
Router> clear access-list counters 101
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show access-lists</td>
<td>Displays the contents of current IP and rate-limit access lists.</td>
</tr>
</tbody>
</table>
clear ip accounting

To clear the active or checkpointed database when IP accounting is enabled, use the `clear ip accounting` command in EXEC mode.

```
clear ip accounting [checkpoint]
```

**Syntax Description**
- `checkpoint` (Optional) Clears the checkpointed database.

**Command Modes**
- EXEC

**Command History**
- Release 10.0: This command was introduced.

**Usage Guidelines**
You can also clear the checkpointed database by issuing the `clear ip accounting` command twice in succession.

**Examples**
The following example clears the active database when IP accounting is enabled:

```
Router> clear ip accounting
```

**Related Commands**
- `ip accounting-list`: Defines filters to control the hosts for which IP accounting information is kept.
- `ip accounting-threshold`: Sets the maximum number of accounting entries to be created.
- `ip accounting-transits`: Controls the number of transit records that are stored in the IP accounting database.
- `show ip accounting`: Displays the active accounting or checkpointed database or displays access list violations.
**clear ip drp**

To clear all statistics being collected on Director Response Protocol (DRP) requests and replies, use the `clear ip drp` command in EXEC mode.

```
clear ip drp
```

**Syntax Description**
This command has no arguments or keywords.

**Command Modes**
EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.2 F</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Examples**
The following example clears all DRP statistics:

```
Router> clear ip drp
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip drp access-group</code></td>
<td>Controls the sources of DRP queries to the DRP Server Agent.</td>
</tr>
<tr>
<td><code>ip drp authentication key-chain</code></td>
<td>Configures authentication on the DRP Server Agent for DistributedDirector.</td>
</tr>
</tbody>
</table>
clear tcp statistics

To clear TCP statistics, use the clear tcp statistics command in privileged EXEC mode.

    clear tcp statistics

Syntax Description
This command has no arguments or keywords.

Command Modes
Privileged EXEC

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.3</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

Examples

The following example clears all TCP statistics:

```
Router# clear tcp statistics
```
deny (IP)

To set conditions for a named IP access list, use the `deny` command in access-list configuration mode. To remove a deny condition from an access list, use the `no` form of this command.

```
deny source [source-wildcard]
no deny source [source-wildcard]

deny protocol source source-wildcard destination destination-wildcard [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
no deny protocol source source-wildcard destination destination-wildcard
```

**Internet Control Message Protocol (ICMP)**

For ICMP, you can also use the following syntax:

```
deny icmp source source-wildcard destination destination-wildcard [icmp-type [icmp-code] [icmp-message]] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
```

**Internet Group Management Protocol (IGMP)**

For IGMP, you can also use the following syntax:

```
deny igmp source source-wildcard destination destination-wildcard [igmp-type] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
```

**Transmission Control Protocol (TCP)**

For TCP, you can also use the following syntax:

```
deny tcp source source-wildcard [operator port [port]] destination destination-wildcard [operator [port]] [established] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
```

**User Datagram Protocol (UDP)**

For UDP, you can also use the following syntax:

```
deny udp source source-wildcard [operator port [port]] destination destination-wildcard [operator [port]] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
```
### Syntax Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>source</strong></td>
<td>Number of the network or host from which the packet is being sent. There are three alternative ways to specify the source:</td>
</tr>
<tr>
<td></td>
<td>- Use a 32-bit quantity in four-part, dotted-decimal format.</td>
</tr>
<tr>
<td></td>
<td>- Use the <code>any</code> keyword as an abbreviation for a source and source-wildcard of 0.0.0.0 255.255.255.255.</td>
</tr>
<tr>
<td></td>
<td>- Use <code>host source</code> as an abbreviation for a source and source-wildcard of source 0.0.0.0.</td>
</tr>
<tr>
<td><strong>source-wildcard</strong></td>
<td>Wildcard bits to be applied to the source. There are three alternative ways to specify the source wildcard:</td>
</tr>
<tr>
<td></td>
<td>- Use a 32-bit quantity in four-part, dotted decimal format. Place 1s in the bit positions you want to ignore.</td>
</tr>
<tr>
<td></td>
<td>- Use the <code>any</code> keyword as an abbreviation for a source and source-wildcard of 0.0.0.0 255.255.255.255.</td>
</tr>
<tr>
<td></td>
<td>- Use <code>host source</code> as an abbreviation for a source and source-wildcard of source 0.0.0.0.</td>
</tr>
<tr>
<td><strong>protocol</strong></td>
<td>Name or number of an Internet protocol. It can be one of the keywords <code>eigrp</code>, <code>gre</code>, <code>icmp</code>, <code>igmp</code>, <code>igrp</code>, <code>ip</code>, <code>ipinip</code>, <code>nos</code>, <code>ospf</code>, <code>tcp</code>, or <code>udp</code>, or an integer in the range from 0 to 255 representing an Internet protocol number. To match any Internet protocol (including ICMP, TCP, and UDP), use the <code>ip</code> keyword. Some protocols allow further qualifiers described later.</td>
</tr>
<tr>
<td><strong>destination</strong></td>
<td>Number of the network or host to which the packet is being sent. There are three alternative ways to specify the destination:</td>
</tr>
<tr>
<td></td>
<td>- Use a 32-bit quantity in four-part, dotted-decimal format.</td>
</tr>
<tr>
<td></td>
<td>- Use the <code>any</code> keyword as an abbreviation for the destination and destination-wildcard of 0.0.0.0 255.255.255.255.</td>
</tr>
<tr>
<td></td>
<td>- Use <code>host destination</code> as an abbreviation for a destination and destination-wildcard of destination 0.0.0.0.</td>
</tr>
<tr>
<td><strong>destination-wildcard</strong></td>
<td>Wildcard bits to be applied to the destination. There are three alternative ways to specify the destination wildcard:</td>
</tr>
<tr>
<td></td>
<td>- Use a 32-bit quantity in four-part, dotted decimal format. Place 1s in the bit positions you want to ignore.</td>
</tr>
<tr>
<td></td>
<td>- Use the <code>any</code> keyword as an abbreviation for a destination and destination-wildcard of 0.0.0.0 255.255.255.255.</td>
</tr>
<tr>
<td></td>
<td>- Use <code>host destination</code> as an abbreviation for a destination and destination-wildcard of destination 0.0.0.0.</td>
</tr>
<tr>
<td><strong>precedence</strong></td>
<td>(Optional) Packets can be filtered by precedence level, as specified by a number from 0 to 7 or by name as listed in the section “Usage Guidelines.”</td>
</tr>
<tr>
<td><strong>tos</strong></td>
<td>(Optional) Packets can be filtered by type of service (ToS) level, as specified by a number from 0 to 15, or by name as listed in the section “Usage Guidelines” of the <code>access-list</code> (IP extended) command.</td>
</tr>
</tbody>
</table>
### log

(Optional) Causes an informational logging message about the packet that matches the entry to be sent to the console. (The level of messages logged to the console is controlled by the `logging console` command.)

The message includes the access list number, whether the packet was permitted or denied; the protocol, whether it was TCP, UDP, ICMP, or a number; and, if appropriate, the source and destination addresses and source and destination port numbers. The message is generated for the first packet that matches, and then at 5-minute intervals, including the number of packets permitted or denied in the prior 5-minute interval.

Use the `ip access-list log-update` command to generate logging messages when the number of matches reaches a configurable threshold (rather than waiting for a 5-minute interval). See the `ip access-list log-update` command for more information.

The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from crashing due to too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.

If you enable CEF and then create an access list that uses the `log` keyword, the packets that match the access list are not CEF switched. They are fast switched. Logging disables CEF.

<table>
<thead>
<tr>
<th>time-range</th>
<th>time-range-name</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Optional) Name of the time range that applies to this <code>deny</code> statement. The name of the time range and its restrictions are specified by the <code>time-range</code> and <code>absolute</code> or <code>periodic</code> commands, respectively.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>icmp-type</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Optional) ICMP packets can be filtered by ICMP message type. The type is a number from 0 to 255.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>icmp-code</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Optional) ICMP packets that are filtered by ICMP message type can also be filtered by the ICMP message code. The code is a number from 0 to 255.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>icmp-message</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Optional) ICMP packets can be filtered by an ICMP message type name or ICMP message type and code name. The possible names are listed in the section “Usage Guidelines” of the <code>access-list</code> (IP extended) command.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>igmp-type</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Optional) IGMP packets can be filtered by IGMP message type or message name. A message type is a number from 0 to 15. IGMP message names are listed in the section “Usage Guidelines” of the <code>access-list</code> (IP extended) command.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>operator</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Optional) Compares source or destination ports. Possible operands include <code>lt</code> (less than), <code>gt</code> (greater than), <code>eq</code> (equal), <code>neq</code> (not equal), and <code>range</code> (inclusive range).</td>
</tr>
</tbody>
</table>

If the operator is positioned after the `source` and `source-wildcard`, it must match the source port.

If the operator is positioned after the `destination` and `destination-wildcard`, it must match the destination port.

The `range` operator requires two port numbers. All other operators require one port number.
deny (IP)

port (Optional) The decimal number or name of a TCP or UDP port. A port number is a number from 0 to 65535. TCP and UDP port names are listed in the section “Usage Guidelines” of the access-list (IP extended) command.

TCP port names can only be used when filtering TCP. UDP port names can only be used when filtering UDP.

established (Optional) For the TCP protocol only: Indicates an established connection. A match occurs if the TCP datagram has the ACK or RST bits set. The nonmatching case is that of the initial TCP datagram to form a connection.

fragments (Optional) The access list entry applies to noninitial fragments of packets; the fragment is either permitted or denied accordingly. For more details about the fragments keyword, see the “Access List Processing of Fragments” and “Fragments and Policy Routing” sections in the “Usage Guidelines” section.

Defaults

There is no specific condition under which a packet is denied passing the named access list.

Command Modes

Access-list configuration

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.2</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.0(1)T</td>
<td>The time-range time-range-name keyword and argument were added.</td>
</tr>
<tr>
<td>12.0(11) and 12.1(2)</td>
<td>The fragments keyword was added.</td>
</tr>
</tbody>
</table>

Usage Guidelines

Use this command following the ip access-list command to specify conditions under which a packet cannot pass the named access list.

The time-range option allows you to identify a time range by name. The time-range, absolute, and periodic commands specify when this deny statement is in effect.
Access List Processing of Fragments

The behavior of access-list entries regarding the use or lack of the `fragments` keyword can be summarized as follows:

<table>
<thead>
<tr>
<th>If the Access-List Entry has...</th>
<th>Then..</th>
</tr>
</thead>
<tbody>
<tr>
<td>...no <code>fragments</code> keyword (the default behavior), and assuming all of the access-list entry information matches,</td>
<td>For an access-list entry containing only Layer 3 information:</td>
</tr>
<tr>
<td></td>
<td>• The entry is applied to nonfragmented packets, initial fragments and noninitial fragments.</td>
</tr>
<tr>
<td></td>
<td>For an access list entry containing Layer 3 and Layer 4 information:</td>
</tr>
<tr>
<td></td>
<td>• The entry is applied to nonfragmented packets and initial fragments.</td>
</tr>
<tr>
<td></td>
<td>– If the entry is a <code>permit</code> statement, the packet or fragment is permitted.</td>
</tr>
<tr>
<td></td>
<td>– If the entry is a <code>deny</code> statement, the packet or fragment is denied.</td>
</tr>
<tr>
<td></td>
<td>• The entry is also applied to noninitial fragments in the following manner. Because noninitial fragments contain only Layer 3 information, only the Layer 3 portion of an access-list entry can be applied. If the Layer 3 portion of the access-list entry matches, and</td>
</tr>
<tr>
<td></td>
<td>– If the entry is a <code>permit</code> statement, the noninitial fragment is permitted.</td>
</tr>
<tr>
<td></td>
<td>– If the entry is a <code>deny</code> statement, the next access-list entry is processed.</td>
</tr>
</tbody>
</table>

Note

The `deny` statements are handled differently for noninitial fragments versus nonfragmented or initial fragments.

<table>
<thead>
<tr>
<th>...the <code>fragments</code> keyword, and assuming all of the access-list entry information matches,</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The access-list entry is applied only to noninitial fragments. The <code>fragments</code> keyword cannot be configured for an access-list entry that contains any Layer 4 information.</td>
</tr>
</tbody>
</table>

Be aware that you should not simply add the `fragments` keyword to every access list entry because the first fragment of the IP packet is considered a nonfragment and is treated independently of the subsequent fragments. An initial fragment will not match an access list `permit` or `deny` entry that contains the `fragments` keyword, the packet is compared to the next access list entry, and so on, until it is either permitted or denied by an access list entry that does not contain the `fragments` keyword. Therefore, you may need two access list entries for every `deny` entry. The first `deny` entry of the pair will not include the `fragments` keyword, and applies to the initial fragment. The second `deny` entry of the pair will include the `fragments` keyword and applies to the subsequent fragments. In the cases where
there are multiple `deny` access list entries for the same host but with different Layer 4 ports, a single `deny` access-list entry with the `fragments` keyword for that host is all that needs to be added. Thus all the fragments of a packet are handled in the same manner by the access list.

Packet fragments of IP datagrams are considered individual packets and each counts individually as a packet in access list accounting and access list violation counts.

**Note**
The `fragments` keyword cannot solve all cases involving access lists and IP fragments.

**Fragments and Policy Routing**
Fragmentation and the fragment control feature affect policy routing if the policy routing is based on the `match ip address` command and the access list had entries that match on Layer 4 through 7 information. It is possible that noninitial fragments pass the access list and are policy routed, even if the first fragment was not policy routed or the reverse.

By using the `fragments` keyword in access list entries as described earlier, a better match between the action taken for initial and noninitial fragments can be made and it is more likely policy routing will occur as intended.

**Examples**
The following example sets a deny condition for a standard access list named Internetfilter:

```
ip access-list standard Internetfilter
deny 192.5.34.0 0.0.0.255
permit 128.88.0.0 0.0.255.255
permit 36.0.0.0 0.255.255.255
! (Note: all other access implicitly denied)
```

The following example denies HTTP traffic on Monday through Friday from 8:00 a.m. to 6:00 p.m.:

```
time-range no-http
  periodic weekdays 8:00 to 18:00
!
ip access-list extended strict
deny tcp any any eq http time-range no-http
!
interface ethernet 0
ip access-group strict in
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>access-list (IP extended)</code></td>
<td>Defines an extended IP access list.</td>
</tr>
<tr>
<td><code>access-list (IP standard)</code></td>
<td>Defines a standard IP access list.</td>
</tr>
<tr>
<td><code>ip access-group</code></td>
<td>Controls access to an interface.</td>
</tr>
<tr>
<td><code>ip access-list</code></td>
<td>Defines an IP access list by name.</td>
</tr>
<tr>
<td><code>ip access-list log-update</code></td>
<td>Sets the threshold number of packets that cause a logging message.</td>
</tr>
<tr>
<td><code>permit (IP)</code></td>
<td>Sets conditions under which a packet passes a named IP access list.</td>
</tr>
<tr>
<td><code>remark</code></td>

</tr>
<tr>
<td><code>show ip access-list</code></td>
<td>Displays the contents of all current IP access lists.</td>
</tr>
<tr>
<td><code>time-range</code></td>
<td>Specifies when an access list or other feature is in effect.</td>
</tr>
</tbody>
</table>
To define a named dynamic IP access list, use the `dynamic` access-list configuration command. To remove the access lists, use the `no` form of this command.

```
dynamic dynamic-name [timeout minutes] {deny | permit} protocol source source-wildcard destination destination-wildcard [precedence precedence] [tos tos] [log] [fragments]
```

```
no dynamic dynamic-name
```

**Internet Control Message Protocol (ICMP)**

For ICMP, you can also use the following syntax:

```
dynamic dynamic-name [timeout minutes] {deny | permit} icmp source source-wildcard destination destination-wildcard [icmp-type [icmp-code] | icmp-message] [precedence precedence] [tos tos] [log] [fragments]
```

**Internet Group Management Protocol (IGMP)**

For IGMP, you can also use the following syntax:

```
dynamic dynamic-name [timeout minutes] {deny | permit} igmp source source-wildcard destination destination-wildcard [igmp-type] [precedence precedence] [tos tos] [log] [fragments]
```

**Transmission Control Protocol (TCP)**

For TCP, you can also use the following syntax:

```
dynamic dynamic-name [timeout minutes] {deny | permit} tcp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established] [precedence precedence] [tos tos] [log] [fragments]
```

**User Datagram Protocol (UDP)**

For UDP, you can also use the following syntax:

```
dynamic dynamic-name [timeout minutes] {deny | permit} udp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [precedence precedence] [tos tos] [log] [fragments]
```

**Caution**

Named IP access lists will not be recognized by any software release prior to Cisco IOS Release 11.2.

**Syntax Description**

- `dynamic-name` Identifies this access list as a dynamic access list. Refer to lock-and-key access documented in the “Configuring Lock-and-Key Security (Dynamic Access Lists)” chapter in the *Cisco IOS Security Configuration Guide*.

- `timeout minutes` (Optional) Specifies the absolute length of time (in minutes) that a temporary access list entry can remain in a dynamic access list. The default is an infinite length of time and allows an entry to remain permanently. Refer to lock-and-key access documented in the “Configuring Lock-and-Key Security (Dynamic Access Lists)” chapter in the *Cisco IOS Security Configuration Guide*.

<td>(Optional) Packets can be filtered by type of service (ToS) level, as specified by a number from 0 to 15, or by name as listed in the section “Usage Guidelines.”</td>
</tr>
</tbody>
</table>
**log**

(Optional) Causes an informational logging message about the packet that matches the entry to be sent to the console. (The level of messages logged to the console is controlled by the `logging console` command.)

The message includes the access list number, whether the packet was permitted or denied; the protocol, whether it was TCP, UDP, ICMP, or a number; and, if appropriate, the source and destination addresses and source and destination port numbers. The message is generated for the first packet that matches, and then at 5-minute intervals, including the number of packets permitted or denied in the prior 5-minute interval.

Use the `ip access-list log-update` command to generate logging messages when the number of matches reaches a configurable threshold (rather than waiting for a 5-minute interval). See the `ip access-list log-update` command for more information.

The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from crashing due to too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.

**icmp-type**

(Optional) ICMP packets can be filtered by ICMP message type. The type is a number from 0 to 255.

**icmp-code**

(Optional) ICMP packets that are filtered by ICMP message type can also be filtered by the ICMP message code. The code is a number from 0 to 255.

**icmp-message**

(Optional) ICMP packets can be filtered by an ICMP message type name or ICMP message type and code name. The possible names are found in the section “Usage Guidelines.”

**igmp-type**

(Optional) IGMP packets can be filtered by IGMP message type or message name. A message type is a number from 0 to 15. IGMP message names are listed in the section “Usage Guidelines.”

**operator**

(Optional) Compares source or destination ports. Possible operands include `lt` (less than), `gt` (greater than), `eq` (equal), `neq` (not equal), and `range` (inclusive range).

If the operator is positioned after the `source` and `source-wildcard`, it must match the source port.

If the operator is positioned after the `destination` and `destination-wildcard`, it must match the destination port.

The `range` operator requires two port numbers. All other operators require one port number.

**port**

(Optional) The decimal number or name of a TCP or UDP port. A port number is a number from 0 to 65535. TCP and UDP port names are listed in the section “Usage Guidelines” of the `access-list` (IP extended) command. TCP port names can only be used when filtering TCP. UDP port names can only be used when filtering UDP.
An extended access list defaults to a list that denies everything. An extended access list is terminated by an implicit deny statement.

Usage Guidelines

You can use named access lists to control the transmission of packets on an interface and restrict contents of routing updates. The Cisco IOS software stops checking the extended access list after a match occurs. Fragmented IP packets, other than the initial fragment, are immediately accepted by any extended IP access list. Extended access lists used to control vty access or restrict the contents of routing updates must not match against the TCP source port, the ToS value, or the precedence of the packet.

Note
After an access list is created initially, any subsequent additions (possibly entered from the terminal) are placed at the end of the list. In other words, you cannot selectively add or remove access list command lines from a specific access list.

Access List Processing of Fragments

The behavior of access-list entries regarding the use or lack of the `fragments` keyword can be summarized as follows:

<table>
<thead>
<tr>
<th>If the Access-List Entry has...</th>
<th>Then..</th>
</tr>
</thead>
<tbody>
<tr>
<td>...no <code>fragments</code> keyword (the default behavior), and assuming all of the access-list entry information matches,</td>
<td>For an access-list entry containing only Layer 3 information:</td>
</tr>
<tr>
<td></td>
<td>• The entry is applied to nonfragmented packets, initial fragments and noninitial fragments.</td>
</tr>
<tr>
<td></td>
<td>For an access list entry containing Layer 3 and Layer 4 information:</td>
</tr>
<tr>
<td></td>
<td>• The entry is applied to nonfragmented packets and initial fragments.</td>
</tr>
<tr>
<td></td>
<td>– If the entry is a <code>permit</code> statement, the packet or fragment is permitted.</td>
</tr>
<tr>
<td></td>
<td>– If the entry is a <code>deny</code> statement, the packet or fragment is denied.</td>
</tr>
<tr>
<td></td>
<td>• The entry is also applied to noninitial fragments in the following manner. Because noninitial fragments contain only Layer 3 information, only the Layer 3 portion of an access-list entry can be applied. If the Layer 3 portion of the access-list entry matches, and</td>
</tr>
<tr>
<td></td>
<td>– If the entry is a <code>permit</code> statement, the noninitial fragment is permitted.</td>
</tr>
<tr>
<td></td>
<td>– If the entry is a <code>deny</code> statement, the next access-list entry is processed.</td>
</tr>
</tbody>
</table>

**Note**

The `deny` statements are handled differently for noninitial fragments versus nonfragmented or initial fragments.

| ...the `fragments` keyword, and assuming all of the access-list entry information matches, | The access-list entry is applied only to noninitial fragments. The `fragments` keyword cannot be configured for an access-list entry that contains any Layer 4 information. |

Be aware that you should not simply add the `fragments` keyword to every access list entry because the first fragment of the IP packet is considered a nonfragment and is treated independently of the subsequent fragments. An initial fragment will not match an access list `permit` or `deny` entry that contains the `fragments` keyword, the packet is compared to the next access list entry, and so on, until it is either permitted or denied by an access list entry that does not contain the `fragments` keyword. Therefore, you may need two access list entries for every `deny` entry. The first `deny` entry of the pair will not include the `fragments` keyword, and applies to the initial fragment. The second `deny` entry of the pair will include the `fragments` keyword and applies to the subsequent fragments. In the cases where
there are multiple **deny** access list entries for the same host but with different Layer 4 ports, a single **deny** access-list entry with the **fragments** keyword for that host is all that needs to be added. Thus all the fragments of a packet are handled in the same manner by the access list.

Packet fragments of IP datagrams are considered individual packets and each counts individually as a packet in access list accounting and access list violation counts.

---

**Note**

The **fragments** keyword cannot solve all cases involving access lists and IP fragments.

**Fragments and Policy Routing**

Fragmentation and the fragment control feature affect policy routing if the policy routing is based on the **match ip address** command and the access list had entries that match on Layer 4 through 7 information. It is possible that noninitial fragments pass the access list and are policy routed, even if the first fragment was not policy routed or the reverse.

By using the **fragments** keyword in access list entries as described earlier, a better match between the action taken for initial and noninitial fragments can be made and it is more likely policy routing will occur as intended.

---

**Examples**

The following example defines a dynamic access list named washington:

```
  ip access-group washington in
  !
  ip access-list extended washington
dynamic testlist timeout 5
  permit ip any any
  permit tcp any host 185.302.21.2 eq 23
```
forwarding-agent

To specify the port on which the Forwarding Agent will listen for wildcard and fixed affinities, use the `forwarding-agent` command in CASA-port configuration mode. To disable listening on that port, use the `no` form of the command.

```
forwarding-agent port-number [password [timeout]]

no forwarding-agent
```

Syntax Description

- `port-number`: Port numbers on which the Forwarding Agent will listen for wildcards broadcast from the services manager. This must match the port number defined on the services manager.
- `password`: (Optional) Text password used for generating the MD5 digest.
- `timeout`: (Optional) Duration (in seconds) during which the Forwarding Agent will accept the new and old password. Valid range is from 0 to 3600 seconds. The default is 180 seconds.

Defaults

The default password timeout is 180 seconds.
The default port for the services manager is 1637.

Command Modes

CASA-port configuration

</thead>
<tbody>
<tr>
<td></td>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td></td>
<td>11.2</td>
<td>The access-list-name argument was added.</td>
</tr>
</tbody>
</table>

Usage Guidelines

Access lists are applied on either outbound or inbound interfaces. For standard inbound access lists, after receiving a packet, the Cisco IOS software checks the source address of the packet against the access list. For extended access lists, the router also checks the destination access list. If the access list permits the address, the software continues to process the packet. If the access list rejects the address, the software discards the packet and returns an ICMP host unreachable message.

For standard outbound access lists, after receiving and routing a packet to a controlled interface, the software checks the source address of the packet against the access list. For extended access lists, the router also checks the destination access list. If the access list permits the address, the software sends the packet. If the access list rejects the address, the software discards the packet and returns an ICMP host unreachable message.

If the specified access list does not exist, all packets are passed.

When you enable outbound access lists, you automatically disable autonomous switching for that interface. When you enable input access lists on any CBus or CxBus interface, you automatically disable autonomous switching for all interfaces (with one exception—an SSE configured with simple access lists can still switch packets, on output only).
Examples

The following example applies list 101 on packets outbound from Ethernet interface 0:

```
interface ethernet 0
ip access-group 101 out
```

Related Commands

</tbody>
</table>
ip access-list

To define an IP access list by name, use the `ip access-list` command in global configuration mode. To remove a named IP access list, use the `no` form of this command.

```
ip access-list {standard | extended} access-list-name
no ip access-list {standard | extended} access-list-name
```

**Caution**

Named access lists will not be recognized by any software release prior to Cisco IOS Release 11.2.

### Syntax Description

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>standard</code></td>
<td>Specifies a standard IP access list.</td>
</tr>
<tr>
<td><code>extended</code></td>
<td>Specifies an extended IP access list.</td>
</tr>
<tr>
<td><code>access-list-name</code></td>
<td>Name of the access list. Names cannot contain a space or quotation mark, and must begin with an alphabetic character to prevent ambiguity with numbered access lists.</td>
</tr>
</tbody>
</table>

### Defaults

No named IP access list is defined.

### Command Modes

Global configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.2</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

Use this command to configure a named IP access list as opposed to a numbered IP access list. This command will take you into access-list configuration mode, where you must define the denied or permitted access conditions with the `deny` and `permit` commands.

Specifying the `standard` or `extended` keyword with the `ip access-list` command determines the prompt you get when you enter access-list configuration mode.

Use the `ip access-group` command to apply the access list to an interface.

Named access lists are not compatible with Cisco IOS releases prior to Release 11.2.

### Examples

The following example defines a standard access list named Internetfilter:

```
ip access-list standard Internetfilter
  permit 192.5.34.0 0.0.0.255
  permit 128.88.0.0 0.0.255.255
  permit 36.0.0.0 0.255.255.255
! (Note: all other access implicitly denied)
```
**Related Commands**

</tr>
<tr>
<td>show ip access-list</td>
<td>Displays the contents of all current IP access lists.</td>
</tr>
</tbody>
</table>
ip access-list log-update

To set the threshold number of packets that generate a log message if they match an access list, use the **ip access-list log-update** command in global configuration mode. To remove the threshold, use the **no** form of this command.

```
ip access-list log-update threshold number-of-matches
no ip access-list log-update
```

### Syntax Description

- **number-of-matches**  
  Threshold number of packets necessary to match an access list before a log message is generated. The range is 0 to 2147483647. There is no default number of matches.

### Defaults

Log messages are sent at the first matching packet and at 5-minute intervals after that.

### Command Modes

Global configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(2)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

Log messages are generated if you have specified the **log** keyword in the **access-list (IP standard)**, **access-list (IP extended)**, **deny (IP)**, **dynamic**, or **permit** command.

Log messages provide information about the packets that are permitted or denied by an access list. By default, log messages appear at the console. (The level of messages logged to the console is controlled by the **logging console** command.) The log message includes the access list number, whether the packet was permitted or denied, and other information.

By default, the log messages are sent at the first matching packet and after that, identical messages are accumulated for 5-minute intervals, with a single message being sent with the number of packets permitted and denied during that interval. However, you can use the **ip access-list log-update** command to set the number of packets that, when match an access list (and are permitted or denied), cause the system to generate a log message. You might want to do this to receive log messages more frequently than at 5-minute intervals.

**Caution**

If you set the **number-of-matches** argument to 1, a log message is sent right away, rather than caching it; every packet that matches an access list causes a log message. A setting of 1 is not recommended because the volume of log messages could overwhelm the system.

Even if you use the **ip access-list log-update** command, the 5-minute timer remains in effect, so the cache is emptied at the end of 5 minutes, regardless of the count of messages in the cache. Regardless of when the log message is sent, the cache is flushed and the count reset to 0 for that message the same way it is when a threshold is not specified.
If the syslog server is not directly connected to a LAN that the router shares, any intermediate router might drop the log messages because they are UDP (unreliable) messages.

**Examples**

The following example enables logging whenever the 1000th packet matches an access list entry:

```
ip access-list log-update threshold 1000
```

**Related Commands**

</tbody>
</table>
ip accounting

To enable IP accounting on an interface, use the **ip accounting** command in interface configuration mode. To disable IP accounting, use the **no** form of this command.

```
ip accounting [access-violations] [output-packets]
no ip accounting [access-violations] [output-packets]
```

| Syntax Description | access-violations | (Optional) Enables IP accounting with the ability to identify IP traffic that fails IP access lists.
| output-packets | (Optional) Enables IP accounting based on the IP packets output on the interface.

**Defaults**

Disabled

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>10.3</td>
<td>The <strong>access-violations</strong> keyword was added.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The **ip accounting** command records the number of bytes (IP header and data) and packets switched through the system on a source and destination IP address basis. Only transit IP traffic is measured and only on an outbound basis; traffic generated by the router access server or terminating in this device is not included in the accounting statistics. Traffic coming from a remote site and transiting through a router is also recorded.

If you specify the **access-violations** keyword, the **ip accounting** command provides information identifying IP traffic that fails IP access lists. Identifying IP source addresses that violate IP access lists alerts you to possible attempts to breach security. The data might also indicate that you should verify IP access list configurations.

To receive a logging message on the console when an extended access list entry denies a packet access (to log violations), you must include the **log** keyword in the **access-list** (IP extended) or **access-list** (IP standard) command.

Statistics are accurate even if IP fast switching or IP access lists are being used on the interface.

IP accounting disables autonomous switching, SSE switching, and distributed switching (dCEF) on the interface. IP accounting will cause packets to be switched on the Route Switch Processor (RSP) instead of the Versatile Interface Processor (VIP), which can cause performance degradation.
Examples

The following example enables IP accounting on Ethernet interface 0:

```
interface ethernet 0
ip accounting
```

Related Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>

ip accounting-list

To define filters to control the hosts for which IP accounting information is kept, use the **ip accounting-list** command in global configuration mode. To remove a filter definition, use the **no** form of this command.

```
ip accounting-list ip-address wildcard

no ip accounting-list ip-address wildcard
```

**Syntax Description**

- `ip-address`  
  IP address in dotted decimal format.

- `wildcard`  
  Wildcard bits to be applied to the `ip-address` argument.

**Defaults**

No filters are defined.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The `wildcard` argument is a 32-bit quantity written in dotted-decimal format. Address bits corresponding to wildcard bits set to 1 are ignored in comparisons; address bits corresponding to wildcard bits set to zero are used in comparisons.

**Examples**

The following example adds all hosts with IP addresses beginning with 192.31 to the list of hosts for which accounting information will be kept:

```
ip accounting-list 192.31.0.0 0.0.255.255
```

**Related Commands**

<table>
<thead>
<tr>

<td><code>show ip accounting</code></td>
<td>Displays the active accounting or checkpointed database or displays access list violations.</td>
</tr>
</tbody>
</table>
ip accounting-threshold

To set the maximum number of accounting entries to be created, use the `ip accounting-threshold` command in global configuration mode. To restore the default number of entries, use the `no` form of this command.

```
ip accounting-threshold threshold
no ip accounting-threshold threshold
```

**Syntax Description**

```
threshold
```

Maximum number of entries (source and destination address pairs) that the Cisco IOS software accumulates.

**Defaults**

The default maximum number of accounting entries is 512 entries.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The accounting threshold defines the maximum number of entries (source and destination address pairs) that the software accumulates, preventing IP accounting from possibly consuming all available free memory. This level of memory consumption could occur in a router that is switching traffic for many hosts. Overflows will be recorded; see the monitoring commands for display formats.

The default accounting threshold of 512 entries results in a maximum table size of 12,928 bytes. Active and checkpointed tables can reach this size independently.

**Examples**

The following example sets the IP accounting threshold to only 500 entries:

```
ip accounting-threshold 500
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear ip accounting</td>
<td>Clears the active or checkpointed database when IP accounting is enabled.</td>

</tbody>
</table>
ip accounting-transits

To control the number of transit records that are stored in the IP accounting database, use the `ip accounting-transits` command in global configuration mode. To return to the default number of records, use the `no` form of this command.

```
ip accounting-transits count
no ip accounting-transits
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>count</code></td>
<td>Number of transit records to store in the IP accounting database.</td>
</tr>
</tbody>
</table>

**Defaults**

The default number of transit records that are stored in the IP accounting database is 0.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Transit entries are those that do not match any of the filters specified by `ip accounting-list` global configuration commands. If no filters are defined, no transit entries are possible.

To maintain accurate accounting totals, the Cisco IOS software maintains two accounting databases: an active and a checkpointed database.

**Examples**

The following example specifies that no more than 100 transit records are stored:

```
ip accounting-transits 100
```

**Related Commands**

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.1CC</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This feature is supported on Ethernet, FastEthernet, and FDDI interfaces.

To display the MAC accounting information, use the `show interface mac` EXEC command.

MAC address accounting provides accounting information for IP traffic based on the source and destination MAC address on LAN interfaces. This calculates the total packet and byte counts for a LAN interface that receives or sends IP packets to or from a unique MAC address. It also records a timestamp for the last packet received or sent. With MAC address accounting, you can determine how much traffic is being sent to and/or received from various peers at NAPS/peering points.

**Examples**

The following example enables IP accounting based on the source and destination MAC address for received and transmitted packets:

```
interface ethernet 4/0/0
  ip accounting mac-address input
  ip accounting mac-address output
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>

Disabled

Command Modes

Interface configuration

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.1CC</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

Usage Guidelines

To display IP precedence accounting information, use the `show interface precedence` EXEC command. The precedence accounting feature provides accounting information for IP traffic, summarized by IP precedence value(s). This feature calculates the total packet and byte counts for an interface that receives or sends IP packets and sorts the results based on IP precedence. This feature is supported on all interfaces and subinterfaces and supports CEF, dCEF, flow, and optimum switching.

Examples

The following example enables IP accounting based on IP precedence for received and transmitted packets:

```
interface ethernet 4/0/0
  ip accounting precedence input
  ip accounting precedence output
```

Related Commands

<table>
<thead>
<tr>
<th>Command</th>

</tbody>
</table>
ip drp access-group

To control the sources of Director Response Protocol (DRP) queries to the DRP Server Agent, use the `ip drp access-group` command in global configuration mode. To remove the access list, use the `no` form of this command.

```
ip drp access-group access-list-number
no ip drp access-group access-list-number
```

**Syntax Description**

- `access-list-number` Number of a standard IP access list in the range from 1 to 99 or from 1300 to 1999.

**Defaults**

The DRP Server Agent will answer all queries.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.2 F</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command applies an access list to the interface, thereby controlling which devices can send queries to the DRP Server Agent.

If both an authentication key chain and an access group have been specified, both security measures must permit access before a request is processed.

**Examples**

The following example configures access list 1, which permits only queries from the host at 33.45.12.4:

```
access-list 1 permit 33.45.12.4
ip drp access-group 1
```

**Related Commands**

<td>show ip drp</td>
<td>Displays information about the DRP Server Agent for DistributedDirector.</td>
</tr>
</tbody>
</table>
ip drp authentication key-chain

To configure authentication on the Director Response Protocol (DRP) Server Agent for DistributedDirector, use the `ip drp authentication key-chain` command in global configuration mode. To remove the key chain, use the `no` form of this command.

```
ip drp authentication key-chain name-of-chain
no ip drp authentication key-chain name-of-chain
```

**Syntax Description**

```
name-of-chain       Name of the key chain containing one or more authentication keys.
```

**Defaults**

No authentication is configured for the DRP Server Agent.

**Command Modes**

Global configuration

**Command History**

```
Release          Modification
11.2 F           This command was introduced.
```

**Usage Guidelines**

When a key chain and key are configured, the key is used to authenticate all DRP requests and responses. The active key on the DRP Server Agent must match the active key on the primary agent. Use the `key` and `key-string` commands to configure the key.

**Examples**

The following example configures a key chain named ddchain:

```
ip drp authentication key-chain ddchain
```

**Related Commands**

</tbody>
</table>
The following example sets the rate of the ICMP destination unreachable message to one message every 10 milliseconds:

```
ip icmp rate-limit unreachable 10
```

The following example turns off the previously configured rate limit:

```
o ip icmp rate-limit unreachable
```

The following example sets the rate limit back to the default:

```
default ip icmp rate-limit unreachable
```
**ip icmp redirect**

To control the type of Internet Control Message Protocol (ICMP) redirect message that is sent by the Cisco IOS software, use the **ip icmp redirect** command in global configuration mode. To set the value back to the default, use the **no** form of this command.

```
ip icmp redirect [host | subnet]
no ip icmp redirect [host | subnet]
```

**Syntax Description**

- **host** (Optional) Sends ICMP host redirects.
- **subnet** (Optional) Sends ICMP subnet redirects.

**Defaults**

The router will send ICMP subnet redirect messages.

Because the **ip icmp redirect subnet** command is the default, the command will not be displayed in the configuration.

**Command Modes**

Global configuration

**Command History**

Release | Modification
--- | ---
12.0 | This command was introduced.

**Usage Guidelines**

An ICMP redirect message can be generated by a router when a packet is received and transmitted on the same interface. In this situation, the router will forward the original packet and send an ICMP redirect message back to the sender of the original packet. This behavior allows the sender to bypass the router and forward future packets directly to the destination (or a router closer to the destination).

There are two types of ICMP redirect messages: redirect for a host address or redirect for an entire subnet.

The **ip icmp redirect** command determines the type of ICMP redirects sent by the system and is configured on a per system basis. Some hosts do not understand ICMP subnet redirects and need the router to send out ICMP host redirects. Use the **ip icmp redirect host** command to have the router send out ICMP host redirects. Use the **ip icmp redirect subnet** command to set the value back to the default, which is to send subnet redirects.

To prevent the router from sending ICMP redirects, use the **no ip redirects** interface configuration command.

**Examples**

The following example enables the router to send out ICMP host redirects:

```
ip icmp redirect hosts
```

The following example sets the value back to the default, which is subnet redirects:

```
ip icmp redirect subnet
```
### Related Commands

ip mask-reply

To have the Cisco IOS software respond to Internet Control Message Protocol (ICMP) mask requests by sending ICMP mask reply messages, use the ip mask-reply command in interface configuration mode. To disable this function, use the no form of this command.

    ip mask-reply
    no ip mask-reply

Syntax Description

This command has no arguments or keywords.

Defaults

Disabled

Command Modes

Interface configuration

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

Examples

The following example enables the sending of ICMP mask reply messages on Ethernet interface 0:

```bash
interface ethernet 0
ip address 131.108.1.0 255.255.255.0
ip mask-reply
```
**ip mtu**

To set the maximum transmission unit (MTU) size of IP packets sent on an interface, use the `ip mtu` interface configuration command. To restore the default MTU size, use the `no` form of this command.

```
   ip mtu bytes
   no ip mtu
```

**Syntax Description**
- `bytes` MTU in bytes.

**Defaults**
Minimum is 128 bytes; maximum depends on the interface medium.

**Command Modes**
Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
If an IP packet exceeds the MTU set for the interface, the Cisco IOS software will fragment it.

All devices on a physical medium must have the same protocol MTU in order to operate.

**Note**
Changing the MTU value (with the `mtu` interface configuration command) can affect the IP MTU value. If the current IP MTU value is the same as the MTU value, and you change the MTU value, the IP MTU value will be modified automatically to match the new MTU. However, the reverse is not true; changing the IP MTU value has no effect on the value for the `mtu` command.

**Examples**
The following example sets the maximum IP packet size for the first serial interface to 300 bytes:

```
   interface serial 0
   ip mtu 300
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>

ip redirects

To enable the sending of Internet Control Message Protocol (ICMP) redirect messages if the Cisco IOS software is forced to resend a packet through the same interface on which it was received, use the ip redirects interface configuration command. To disable the sending of redirect messages, use the no form of this command.

    ip redirects
    no ip redirects

Syntax Description

This command has no arguments or keywords.

Defaults

Enabled

Command Modes

Interface configuration

Command History

Release Modification
10.0 This command was introduced.

Usage Guidelines

Previously, if the Hot Standby Router Protocol (HSRP) was configured on an interface, ICMP redirect messages were disabled by default for the interface. With Cisco IOS Release 12.1(3)T, ICMP redirect messages are enabled by default if HSRP is configured.

Examples

The following example enables the sending of ICMP redirect messages on Ethernet interface 0:

    interface ethernet 0
    ip redirects

**ip tcp chunk-size**

To alter the TCP maximum read size for Telnet or rlogin, use the `ip tcp chunk-size` global configuration command. To restore the default value, use the `no` form of this command.

```
ip tcp chunk-size characters
no ip tcp chunk-size
```

**Syntax Description**

<table>
<thead>
<tr>
<th>characters</th>
<th>Maximum number of characters that Telnet or rlogin can read in one read instruction. The default value is 0, which Telnet and rlogin interpret as the largest possible 32-bit positive number.</th>
</tr>
</thead>
</table>

**Defaults**

0, which Telnet and rlogin interpret as the largest possible 32-bit positive number.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>9.1</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

It is unlikely you will need to change the default value.

**Examples**

The following example sets the maximum TCP read size to 64,000 bytes:

```
ip tcp chunk-size 64000
```
ip tcp compression-connections

To specify the total number of TCP header compression connections that can exist on an interface, use the `ip tcp compression-connections` interface configuration command. To restore the default, use the `no` form of this command.

```
ip tcp compression-connections number
no ip tcp compression-connections number
```

**Syntax Description**

| `number` | Number of TCP header compression connections the cache supports, in the range from 3 to 1000. The default is 32 connections (16 calls). |

**Defaults**
The default number is 32 connections.

**Command Modes**
Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.0(7)T</td>
<td>For Frame Relay, PPP, and High-Level Data Link Control (HDLC) encapsulation, the maximum number of compression connections increased to 256. For Frame Relay, the maximum value is fixed, not configurable.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
You should configure one connection for each TCP connection through the specified interface. Each connection sets up a compression cache entry, so you are in effect specifying the maximum number of cache entries and the size of the cache. Too few cache entries for the specified interface can lead to degraded performance, and too many cache entries can lead to wasted memory.

**Note**
Both ends of the serial connection must use the same number of cache entries.

**Examples**
The following example sets the first serial interface for header compression with a maximum of ten cache entries:

```
interface serial 0
ip tcp header-compression
ip tcp compression-connections 10
```
<table>
<thead>
<tr>

</tbody>
</table>
ip tcp header-compression

To enable TCP header compression, use the ip tcp header-compression interface configuration command. To disable compression, use the no form of this command.

```
ip tcp header-compression [passive]
no ip tcp header-compression [passive]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>passive</td>
<td>(Optional) Compresses outgoing TCP packets only if incoming TCP packets on the same interface are compressed. If you do not specify the passive keyword, the Cisco IOS software compresses all traffic.</td>
</tr>
</tbody>
</table>

**Defaults**

Disabled

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

You can compress the headers of your TCP/IP packets in order to reduce the size of your packets. TCP header compression is supported on serial lines using Frame Relay, HDLC, or PPP encapsulation. You must enable compression on both ends of a serial connection. RFC 1144 specifies the compression process. Compressing the TCP header can speed up Telnet connections dramatically. In general, TCP header compression is advantageous when your traffic consists of many small packets, not for traffic that consists of large packets. Transaction processing (usually using terminals) tends to use small packets and file transfers use large packets. This feature only compresses the TCP header, so it has no effect on UDP packets or other protocol headers.

When compression is enabled, fast switching is disabled. This condition means that fast interfaces like T1 can overload the router. Consider the traffic characteristics of your network before using this command.

**Examples**

The following example sets the first serial interface for header compression with a maximum of ten cache entries:

```
interface serial 0
ip tcp header-compression
ip tcp compression-connections 10
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>

ip tcp mss

To enable a maximum segment size (MSS) for TCP connections originating or terminating on a router, use the `ip tcp mss` command in global configuration mode. To disable the configuration of the MSS, use the `no` form of this command.

```
ip tcp mss mss-value
no ip tcp mss mss-value
```

**Syntax Description**

| mss-value | Maximum segment size for TCP connections in bytes. The range is from 68 to 10000. |

**Defaults**

This command is disabled.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(05)S</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1</td>
<td>This command was integrated into Cisco IOS Release 12.1.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

If this command is not enabled, the MSS value of 536 bytes is used if the destination is not on a LAN, otherwise the MSS value is 1460 for a local destination.

For connections originating from a router, the specified value is used directly as an MSS option in the synchronize (SYN) segment. For connections terminating on a router, the value is used only if the incoming SYN segment has an MSS option value higher than the configured value. Otherwise the incoming value is used as the MSS option in the SYN/acknowledge (ACK) segment.

**Note**

The `ip tcp mss` command interacts with the `ip tcp path-mtu-discovery` command and not the `ip tcp header-compression` command. The `ip tcp path-mtu-discovery` command changes the default MSS to 1460 even for non-local nodes.

**Examples**

The following example sets the MSS value at 250:

```
ip tcp mss 250
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip tcp header-compression</code></td>
<td>Specifies the total number of header compression connections that can exist on an interface.</td>
</tr>
</tbody>
</table>
**ip tcp path-mtu-discovery**

To enable the Path MTU Discovery feature for all new TCP connections from the router, use the `ip tcp path-mtu-discovery` global configuration command. To disable the function, use the `no` form of this command.

```
ip tcp path-mtu-discovery [age-timer {minutes | infinite}]
no ip tcp path-mtu-discovery [age-timer {minutes | infinite}]
```

### Syntax Description

- **age-timer minutes** *(Optional)* Time interval (in minutes) after which TCP re-estimates the path MTU with a larger maximum segment size (MSS). The maximum is 30 minutes; the default is 10 minutes.
- **age-timer infinite** *(Optional)* Turns off the age timer.

### Defaults

Disabled. If enabled, the default `minutes` value is 10 minutes.

### Command Modes

Global configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>11.2</td>
<td>The <code>age-timer</code> and <code>infinite</code> keywords were added.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

Path MTU Discovery is a method for maximizing the use of available bandwidth in the network between the endpoints of a TCP connection. It is described in RFC 1191. Existing connections are not affected when this feature is turned on or off.

Customers using TCP connections to move bulk data between systems on distinct subnets would benefit most by enabling this feature.

The age timer is a time interval for how often TCP re-estimates the path MTU with a larger MSS. When the age timer is used, TCP path MTU becomes a dynamic process. If the MSS used for the connection is smaller than what the peer connection can handle, a larger MSS is tried every time the age timer expires. The discovery process is stopped when either the send MSS is as large as the peer negotiated, or the user has disabled the timer on the router. You can turn off the age timer by setting it to infinite.

### Examples

The following example enables Path MTU Discovery:

```
ip tcp path-mtu-discovery
```
**ip tcp queuemax**

To alter the maximum TCP outgoing queue per connection, use the `ip tcp queuemax` global configuration command. To restore the default value, use the `no` form of this command.

```
ip tcp queuemax packets
no ip tcp queuemax
```

**Syntax Description**

| packets | Outgoing queue size of TCP packets. The default value is 5 segments if the connection has a TTY associated with it. If no TTY is associated with it, the default value is 20 segments. |

**Defaults**

The default value is 5 segments if the connection has a TTY associated with it. If no TTY is associated with it, the default value is 20 segments.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Changing the default value changes the 5 segments, not the 20 segments.

**Examples**

The following example sets the maximum TCP outgoing queue to 10 packets:

```
ip tcp queuemax 10
```
ip tcp selective-ack

To enable TCP selective acknowledgment, use the `ip tcp selective-ack` global configuration command. To disable TCP selective acknowledgment, use the `no` form of this command.

```
ip tcp selective-ack
   no ip tcp selective-ack
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

Disabled

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.2 F</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

TCP might not experience optimal performance if multiple packets are lost from one window of data. With the limited information available from cumulative acknowledgments, a TCP sender can learn about only one lost packet per round-trip time. An aggressive sender could resend packets early, but such re-sent segments might have already been received.

The TCP selective acknowledgment mechanism helps overcome these limitations. The receiving TCP returns selective acknowledgment packets to the sender, informing the sender about data that has been received. The sender can then resend only the missing data segments.

TCP selective acknowledgment improves overall performance. The feature is used only when a multiple number of packets drop from a TCP window. There is no performance impact when the feature is enabled but not used.

This command becomes effective only on new TCP connections opened after the feature is enabled.

This feature must be disabled if you want TCP header compression. You might disable this feature if you have severe TCP problems.

Refer to RFC 2018 for more detailed information on TCP selective acknowledgment.

**Examples**

The following example enables the router to send and receive TCP selective acknowledgments:

```
ip tcp selective-ack
```

**Related Commands**

</table>
ip tcp synwait-time

To set a period of time the Cisco IOS software waits while attempting to establish a TCP connection before it times out, use the `ip tcp synwait-time` global configuration command. To restore the default time, use the `no` form of this command.

```
ip tcp synwait-time seconds

no ip tcp synwait-time seconds
```

**Syntax Description**

| seconds         | Time (in seconds) the software waits while attempting to establish a TCP connection. It can be an integer from 5 to 300 seconds. The default is 30 seconds. |

**Defaults**

The default time is 30 seconds.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

In versions previous to Cisco IOS software Release 10.0, the system would wait a fixed 30 seconds when attempting to establish a TCP connection. If your network contains Public Switched Telephone Network (PSTN) dial-on-demand routing (DDR), the call setup time may exceed 30 seconds. This amount of time is not sufficient in networks that have dialup asynchronous connections because it will affect your ability to Telnet over the link (from the router) if the link must be brought up. If you have this type of network, you might want to set this value to the UNIX value of 75.

Because this is a host parameter, it does not pertain to traffic going *through* the router, just for traffic originated *at* this device. Because UNIX has a fixed 75-second timeout, hosts are unlikely to experience this problem.

**Examples**

The following example configures the Cisco IOS software to continue attempting to establish a TCP connection for 180 seconds:

```
ip tcp synwait-time 180
```
**ip tcp timestamp**

To enable TCP time stamp, use the `ip tcp timestamp` global configuration command. To disable TCP time stamp, use the `no` form of this command.

```plaintext
ip tcp timestamp
no ip tcp timestamp
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

Disabled

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.2 F</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

TCP time stamp improves round-trip time estimates. Refer to RFC 1323 for more detailed information on TCP time stamp.

This feature must be disabled if you want to use TCP header compression.

**Examples**

The following example enables the router to send TCP time stamps:

```plaintext
ip tcp timestamp
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ip tcp header-compression</code></td>
<td>Enables TCP header compression.</td>
</tr>
</tbody>
</table>
**ip tcp window-size**

To alter the TCP window size, use the `ip tcp window-size` global configuration command. To restore the default value, use the `no` form of this command.

```
ip tcp window-size bytes
no ip tcp window-size
```

**Syntax Description**

| bytes | Window size (in bytes). The maximum is 65,535 bytes. The default value is 2144 bytes. |

**Defaults**

The default size is 2144 bytes.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>9.1</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Do not use this command unless you clearly understand why you want to change the default value.

If your TCP window size is set to 1000 bytes, for example, you could have 1 packet of 1000 bytes or 2 packets of 500 bytes, and so on. However, there is also a limit on the number of packets allowed in the window. There can be a maximum of 5 packets if the connection has TTY; otherwise there can be 20 packets.

**Examples**

The following example sets the TCP window size to 1000 bytes:

```
ip tcp window-size 1000
```
ip unreachables

To enable the generation of Internet Control Message Protocol (ICMP) unreachable messages, use the `ip unreachables` interface configuration command. To disable this function, use the `no` form of this command.

```
   ip unreachables
   no ip unreachables
```

**Syntax Description**
This command has no arguments or keywords.

**Defaults**
Enabled

**Command Modes**
Interface configuration

**Command History**

<table>
<thead>

</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
If the Cisco IOS software receives a nonbroadcast packet destined for itself that uses a protocol it does not recognize, it sends an ICMP unreachable message to the source.

If the software receives a datagram that it cannot deliver to its ultimate destination because it knows of no route to the destination address, it replies to the originator of that datagram with an ICMP host unreachable message.

This command affects all types of ICMP unreachable messages.

**Examples**
The following example enables the generation of ICMP unreachable messages, as appropriate, on an interface:

```
interface ethernet 0
ip unreachables
```
permit (IP)

To set conditions for a named IP access list, use the **permit** access-list configuration command. To remove a condition from an access list, use the **no** form of this command.

```
permit source [source-wildcard]
no permit source [source-wildcard]

permit protocol source source-wildcard destination destination-wildcard [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
no permit protocol source source-wildcard destination destination-wildcard [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
```

**Internet Control Message Protocol (ICMP)**

For ICMP, you can also use the following syntax:

```
permit icmp source source-wildcard destination destination-wildcard [icmp-type [icmp-code] | icmp-message] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
```

**Internet Group Management Protocol (IGMP)**

For IGMP, you can also use the following syntax:

```
permit igmp source source-wildcard destination destination-wildcard [igmp-type] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
```

**Transmission Control Protocol (TCP)**

For TCP, you can also use the following syntax:

```
permit tcp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
```

**User Datagram Protocol UDP**

For UDP, you can also use the following syntax:

```
permit udp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]
```
## Syntax Description

<tr>
<td></td>
<td>- Use a 32-bit quantity in four-part, dotted decimal format. Place 1s in the bit positions you want to ignore.</td>
</tr>
<tr>
<td></td>
<td>- Use the <code>any</code> keyword as an abbreviation for a <code>source</code> and <code>source-wildcard</code> of <code>0.0.0.0 255.255.255.255</code>.</td>
</tr>
<tr>
<td></td>
<td>- Use <code>host source</code> as an abbreviation for a <code>source</code> and <code>source-wildcard</code> of <code>source 0.0.0.0</code>.</td>
</tr>
<tr>
<td><strong>protocol</strong></td>
<td>Name or number of an Internet protocol. It can be one of the keywords <code>eigrp</code>, <code>gre</code>, <code>icmp</code>, <code>igmp</code>, <code>igrp</code>, <code>ip</code>, <code>ipinip</code>, <code>nos</code>, <code>ospf</code>, <code>tcp</code>, or <code>udp</code>, or an integer in the range from 0 to 255 representing an Internet protocol number. To match any Internet protocol (including ICMP, TCP, and UDP), use the <code>ip</code> keyword. Some protocols allow further qualifiers described later.</td>
</tr>
<tr>
<td><strong>destination</strong></td>
<td>Number of the network or host to which the packet is being sent. There are three alternative ways to specify the destination:</td>
</tr>
<tr>
<td></td>
<td>- Use a 32-bit quantity in four-part, dotted-decimal format.</td>
</tr>
<tr>
<td></td>
<td>- Use the <code>any</code> keyword as an abbreviation for the <code>destination</code> and <code>destination-wildcard</code> of <code>0.0.0.0 255.255.255.255</code>.</td>
</tr>
<tr>
<td></td>
<td>- Use <code>host destination</code> as an abbreviation for a <code>destination</code> and <code>destination-wildcard</code> of <code>destination 0.0.0.0</code>.</td>
</tr>
<tr>
<td><strong>destination-wildcard</strong></td>
<td>Wildcard bits to be applied to the destination. There are three alternative ways to specify the destination wildcard:</td>
</tr>
<tr>
<td></td>
<td>- Use a 32-bit quantity in four-part, dotted decimal format. Place 1s in the bit positions you want to ignore.</td>
</tr>
<tr>
<td></td>
<td>- Use the <code>any</code> keyword as an abbreviation for a <code>destination</code> and <code>destination-wildcard</code> of <code>0.0.0.0 255.255.255.255</code>.</td>
</tr>
<tr>
<td></td>
<td>- Use <code>host destination</code> as an abbreviation for a <code>destination</code> and <code>destination-wildcard</code> of <code>destination 0.0.0.0</code>.</td>
</tr>
<tr>
<td><strong>precedence</strong></td>
<td>(Optional) Packets can be filtered by precedence level, as specified by a number from 0 to 7 or by name as listed in the section “Usage Guidelines.”</td>
</tr>
<tr>
<td><strong>tos</strong></td>
<td>(Optional) Packets can be filtered by type of service (ToS) level, as specified by a number from 0 to 15, or by name as listed in the section “Usage Guidelines” of the <code>access-list</code> (IP extended) command.</td>
</tr>
</tbody>
</table>
log  (Optional) Causes an informational logging message about the packet that matches the entry to be sent to the console. (The level of messages logged to the console is controlled by the `logging console` command.)

The message includes the access list number, whether the packet was permitted or denied; the protocol, whether it was TCP, UDP, ICMP or a number; and, if appropriate, the source and destination addresses and source and destination port numbers. The message is generated for the first packet that matches, and then at 5-minute intervals, including the number of packets permitted or denied in the prior 5-minute interval.

Use the `ip access-list log-update` command to generate logging messages when the number of matches reaches a configurable threshold (rather than waiting for a 5-minute interval). See the `ip access-list log-update` command for more information.

The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from crashing due to too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.

If you enable CEF and then create an access list that uses the `log` keyword, the packets that match the access list are not CEF switched. They are fast switched. Logging disables CEF.

<table>
<thead>
<tr>
<th>time-range</th>
<th>(Optional) Name of the time range that applies to this <code>permit</code> statement. The name of the time range and its restrictions are specified by the <code>time-range</code> and <code>absolute</code> or <code>periodic</code> commands, respectively.</th>
</tr>
</thead>
<tbody>
<tr>
<td>icmp-type</td>
<td>(Optional) ICMP packets can be filtered by ICMP message type. The type is a number from 0 to 255.</td>
</tr>
<tr>
<td>icmp-code</td>
<td>(Optional) ICMP packets that are filtered by ICMP message type can also be filtered by the ICMP message code. The code is a number from 0 to 255.</td>
</tr>
<tr>
<td>icmp-message</td>
<td>(Optional) ICMP packets can be filtered by an ICMP message type name or ICMP message type and code name. The possible names are found in the section “Usage Guidelines” of the <code>access-list</code> (IP extended) command.</td>
</tr>
<tr>
<td>igmp-type</td>
<td>(Optional) IGMP packets can be filtered by IGMP message type or message name. A message type is a number from 0 to 15. IGMP message names are listed in the section “Usage Guidelines” of the <code>access-list</code> (IP extended) command.</td>
</tr>
<tr>
<td>operator</td>
<td>(Optional) Compares source or destination ports. Possible operands include <code>lt</code> (less than), <code>gt</code> (greater than), <code>eq</code> (equal), <code>neq</code> (not equal), and <code>range</code> (inclusive range).</td>
</tr>
</tbody>
</table>

If the operator is positioned after the `source` and `source-wildcard`, it must match the source port.

If the operator is positioned after the `destination` and `destination-wildcard`, it must match the destination port.

The `range` operator requires two port numbers. All other operators require one port number.
permit (IP)

port  (Optional) The decimal number or name of a TCP or UDP port. A port number is a number from 0 to 65535. TCP and UDP port names are listed in the section “Usage Guidelines” of the access-list (IP extended) command.

TCP port names can only be used when filtering TCP. UDP port names can only be used when filtering UDP.

established  (Optional) For the TCP protocol only: Indicates an established connection. A match occurs if the TCP datagram has the ACK or RST bits set. The nonmatching case is that of the initial TCP datagram to form a connection.

fragments  (Optional) The access list entry applies to noninitial fragments of packets; the fragment is either permitted or denied accordingly. For more details about the fragments keyword, see the “Access List Processing of Fragments” and “Fragments and Policy Routing” sections in the “Usage Guidelines” section.

Defaults

There are no specific conditions under which a packet passes the named access list.

Command Modes

Access-list configuration

Command History

</tr>
<tr>
<td>12.0(11) and 12.1(2)</td>
<td>The fragments keyword was added.</td>
</tr>
</tbody>
</table>

Usage Guidelines

Use this command following the ip access-list command to define the conditions under which a packet passes the access list.

The time-range option allows you to identify a time range by name. The time-range, absolute, and periodic commands specify when this permit statement is in effect.
Access List Processing of Fragments

The behavior of access-list entries regarding the use or lack of the `fragments` keyword can be summarized as follows:

If the Access-List Entry has... | Then..
---|---
...no `fragments` keyword (the default behavior), and assuming all of the access-list entry information matches, | For an access-list entry containing only Layer 3 information:
  - The entry is applied to nonfragmented packets, initial fragments and noninitial fragments.

For an access list entry containing Layer 3 and Layer 4 information:
  - The entry is applied to nonfragmented packets and initial fragments.
    - If the entry is a `permit` statement, the packet or fragment is permitted.
    - If the entry is a `deny` statement, the packet or fragment is denied.
  - The entry is also applied to noninitial fragments in the following manner. Because noninitial fragments contain only Layer 3 information, only the Layer 3 portion of an access-list entry can be applied. If the Layer 3 portion of the access-list entry matches, and
    - If the entry is a `permit` statement, the noninitial fragment is permitted.
    - If the entry is a `deny` statement, the next access-list entry is processed.

| Note | The `deny` statements are handled differently for noninitial fragments versus nonfragmented or initial fragments.

...the `fragments` keyword, and assuming all of the access-list entry information matches, | The access-list entry is applied only to noninitial fragments.

| Note | The `fragments` keyword cannot be configured for an access-list entry that contains any Layer 4 information.

Be aware that you should not simply add the `fragments` keyword to every access list entry because the first fragment of the IP packet is considered a nonfragment and is treated independently of the subsequent fragments. An initial fragment will not match an access list `permit` or `deny` entry that contains the `fragments` keyword, the packet is compared to the next access list entry, and so on, until it is either permitted or denied by an access list entry that does not contain the `fragments` keyword. Therefore, you may need two access list entries for every `deny` entry. The first `deny` entry of the pair will not include the `fragments` keyword, and applies to the initial fragment. The second `deny` entry of the pair will include the `fragments` keyword and applies to the subsequent fragments. In the cases where
there are multiple deny access list entries for the same host but with different Layer 4 ports, a single deny access-list entry with the fragments keyword for that host is all that needs to be added. Thus all the fragments of a packet are handled in the same manner by the access list.

Packet fragments of IP datagrams are considered individual packets and each counts individually as a packet in access list accounting and access list violation counts.

Note

The fragments keyword cannot solve all cases involving access lists and IP fragments.

Fragments and Policy Routing

Fragmentation and the fragment control feature affect policy routing if the policy routing is based on the match ip address command and the access list had entries that match on Layer 4 through 7 information. It is possible that noninitial fragments pass the access list and are policy routed, even if the first fragment was not policy routed or the reverse.

By using the fragments keyword in access list entries as described earlier, a better match between the action taken for initial and noninitial fragments can be made and it is more likely policy routing will occur as intended.

Examples

The following example sets conditions for a standard access list named Internetfilter:

```
ip access-list standard Internetfilter
deny 192.5.34.0 0.0.0.255
permit 128.88.0.0 0.0.255.255
permit 36.0.0.0 0.255.255.255
! (Note: all other access implicitly denied)
```

The following example permits Telnet traffic on Mondays, Tuesdays, and Fridays from 9:00 a.m. to 5:00 p.m.:

```
time-range testing
   periodic Monday Tuesday Friday 9:00 to 17:00
! ip access-list extended legal
   permit tcp any any eq telnet time-range testing
! interface ethernet 0
   ip access-group legal in
```

Related Commands

<td>Specifies when an access list or other feature is in effect.</td>
</tr>
</tbody>
</table>
**remark**

To write a helpful comment (remark) for an entry in a named IP access list, use the `remark` access-list configuration command. To remove the remark, use the `no` form of this command.

```
remark remark
no remark remark
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>remark</td>
<td>Comment that describes the access list entry, up to 100 characters long.</td>
</tr>
</tbody>
</table>

**Defaults**

The access list entries have no remarks.

**Command Modes**

Standard named or extended named access-list configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(2)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The remark can be up to 100 characters long; anything longer is truncated.

If you want to write a comment about an entry in a numbered IP access list, use the `access-list remark` command.

**Examples**

In the following example, the Jones subnet is not allowed to use outbound Telnet:

```
ip access-list extended telnetting
remark Do not allow Jones subnet to telnet out
deny tcp host 171.69.2.88 any eq telnet
```

show access-lists

To display the contents of current access lists, use the `show access-lists` privileged EXEC command.

```
show access-lists [access-list-number | access-list-name]
```

### Syntax Description

- **access-list-number** (Optional) Number of the access list to display. The system displays all access lists by default.
- **access-list-name** (Optional) Name of the IP access list to display.

### Defaults

The system displays all access lists.

### Command Modes

Privileged EXEC

<tr>
<td>12.1(5)T</td>
<td>The command output was modified to identify compiled access lists.</td>
</tr>
</tbody>
</table>

### Examples

The following is sample output from the `show access-lists` command when access list 101 is specified:

```
Router# show access-lists 101

Extended IP access list 101
    permit tcp host 198.92.32.130 any established (4304 matches) check=5
    permit udp host 198.92.32.130 any eq domain (129 matches)
    permit icmp host 198.92.32.130 any
    permit tcp host 198.92.32.130 host 171.69.2.141 gt 1023
    permit tcp host 198.92.32.130 host 171.69.2.135 eq smtp (2 matches)
    permit tcp host 198.92.32.130 host 198.92.30.32 eq smtp
    permit tcp host 198.92.32.130 host 171.69.108.33 eq smtp
    permit udp host 198.92.32.130 host 171.68.225.190 eq syslog
    permit udp host 198.92.32.130 host 171.68.225.126 eq syslog
    deny ip 150.136.0.0 0.0.255.255 224.0.0.0 15.255.255.255
    deny ip 171.68.0.0 0.1.255.255 224.0.0.0 15.255.255.255 (2 matches) check=1
    deny ip 172.24.24.0 0.0.1.255 224.0.0.0 15.255.255.255
    deny ip 192.82.152.0 0.0.0.255 224.0.0.0 15.255.255.255
    deny ip 192.122.173.0 0.0.0.255 224.0.0.0 15.255.255.255
    deny ip 192.122.174.0 0.0.0.255 224.0.0.0 15.255.255.255
    deny ip 192.135.239.0 0.0.0.255 224.0.0.0 15.255.255.255
    deny ip 192.135.240.0 0.0.7.255 224.0.0.0 15.255.255.255
    deny ip 192.135.248.0 0.0.3.255 224.0.0.0 15.255.255.255
```

An access list counter counts how many packets are allowed by each line of the access list. This number is displayed as the number of matches. Check denotes how many times a packet was compared to the access list but did not match.

The following is sample output from the `show access-lists` command when the Turbo Access Control List (ACL) feature is configured on all of the following access lists.
The permit and deny information displayed by the `show access-lists` command may not be in the same order as that entered using the `access-list` command.

```
Router# show access-lists
Standard IP access list 1 (Compiled)
   deny any
Standard IP access list 2 (Compiled)
   deny 192.168.0.0, wildcard bits 0.0.0.255
   permit any
Standard IP access list 3 (Compiled)
   deny 0.0.0.0
   deny 192.168.0.1, wildcard bits 0.0.0.255
   permit any
Standard IP access list 4 (Compiled)
   permit 0.0.0.0
   permit 192.168.0.2, wildcard bits 0.0.0.255
```

For information on how to configure access lists, refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Configuration Guide*.

For information on how to configure dynamic access lists, refer to the “Traffic Filtering and Firewalls” chapter of the *Cisco IOS Security Configuration Guide*.

show access-list compiled

To display a table showing Turbo Access Control Lists (ACLs), use the `show access-list compiled` EXEC command.

```
show access-list compiled
```

**Syntax Description**

This command has no arguments or keywords.

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(6)S</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(1)E</td>

</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command is used to display the status and condition of the Turbo ACL tables associated with each access list. The memory usage is displayed for each table; large and complex access lists may require substantial amounts of memory. If the memory usage is greater than the memory available, you can disable the Turbo ACL feature so that memory exhaustion does not occur, but the acceleration of the access lists is not then enabled.

**Examples**

The following is a partial sample output of the `show access-list compiled` command:

```
Router# show access-list compiled

Compiled ACL statistics:
12 ACLs loaded, 12 compiled tables
ACL     State    Tables Entries Config Fragment Redundant Memory
1      Operational 1   2        1   0       0       0    1Kb
2      Operational 1   3        2   0       0       0    1Kb
3      Operational 1   4        3   0       0       0    1Kb
4      Operational 1   3        2   0       0       0    1Kb
5      Operational 1   5        4   0       0       0    1Kb
9      Operational 1   3        2   0       0       0    1Kb
20     Operational 1   9        8   0       0       0    1Kb

<td>11.1 CC</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The `show interface mac` command displays information for all interfaces configured for MAC accounting. To display information for a single interface, use the `show interface type number mac` command.

For incoming packets on the interface, the accounting statistics are gathered before the CAR/DCAR feature is performed on the packet. For outgoing packets on the interface, the accounting statistics are gathered after output CAR, before output DCAR or DWRED or DWFQ feature is performed on the packet. Therefore, if a you are using DCAR or DWRED on the interface and packets are dropped, the dropped packets are still counted in the `show interface mac` command because the calculations are done prior to the features.

The maximum number of MAC addresses that can be stored for the input address is 512 and the maximum number of MAC address that can be stored for the output address is 512. After the maximum is reached, subsequent MAC addresses are ignored.

To clear the accounting statistics, use the `clear counter` EXEC command. To configure an interface for IP accounting based on the MAC address, use the `ip accounting mac-address` interface configuration command.
Examples

The following is sample output from the `show interface mac` command. This feature calculates the total packet and byte counts for the interface that receives (input) or sends (output) IP packets to or from a unique MAC address. It also records a timestamp for the last packet received or sent.

```
Router# show interface ethernet 0/1/1 mac
Ethernet0/1/1
   Input (511 free)
    0007.f618.4449(228):  4 packets, 456 bytes, last: 2684ms ago
    Total: 4 packets, 456 bytes
   Output (511 free)
    0007.f618.4449(228):  4 packets, 456 bytes, last: 2692ms ago
    Total: 4 packets, 456 bytes
```

show interface precedence

To display precedence accounting information for interfaces configured for precedence accounting, use the `show interface precedence` EXEC command.

```
show interface [type number] precedence
```

### Syntax Description

- **type** (Optional) Interface type supported on your router.
- **number** (Optional) Port number of the interface. The syntax varies depending on the type router. For example, on a Cisco 7500 series router the syntax is 0/0/0, where 0 represents the slot, port adapter, and port number (the slash is required). Refer to the appropriate hardware manual for numbering information.

### Command Modes

EXEC

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.1 CC</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

The `show interface precedence` command displays information for all interfaces configured for IP precedence accounting. To display information for a single interface, use the `show interface type number precedence` command.

For incoming packets on the interface, the accounting statistics are gathered before input CAR/DCAR is performed on the packet. Therefore, if CAR/DCAR changes the precedence on the packet, it is counted based on the old precedence setting with the `show interface precedence` command.

For outgoing packets on the interface, the accounting statistics are gathered after output DCAR or DWRED or DWFQ feature is performed on the packet.

To clear the accounting statistics, use the `clear counter` EXEC command.

To configure an interface for IP accounting based on IP precedence, use the `ip accounting precedence` interface configuration command.

### Examples

The following is sample output from the `show interface precedence` command. This feature calculates the total packet and byte counts for the interface that receives (input) or sends (output) IP packets and sorts the results based on IP precedence.

```
Router# show interface ethernet 0/1/1 precedence
Ethernet0/1/1
  Input
    Precedence 0: 4 packets, 456 bytes
  Output
    Precedence 0: 4 packets, 456 bytes
```

show ip accounting

To display the active accounting or checkpointed database or to display access list violations, use the show ip accounting EXEC command.

```
show ip accounting [checkpoint] [output-packets | access-violations]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checkpoint</td>
<td>(Optional) Indicates that the checkpointed database should be displayed.</td>
</tr>
<tr>
<td>output-packets</td>
<td>(Optional) Indicates that information pertaining to packets that passed access control and were routed should be displayed. If neither the output-packets nor access-violations keyword is specified, output-packets is the default.</td>
</tr>
<tr>
<td>access-violations</td>
<td>(Optional) Indicates that information pertaining to packets that failed access lists and were not routed should be displayed. If neither the output-packets nor access-violations keyword is specified, output-packets is the default.</td>
</tr>
</tbody>
</table>

**Defaults**

If neither the output-packets nor access-violations keyword is specified, the show ip accounting command displays information pertaining to packets that passed access control and were routed.

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>10.3</td>
<td>The access-violations and output-packet keywords were added.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

If you do not specify any keywords, the show ip accounting command displays information about the active accounting database, and traffic coming from a remote site and transiting through a router.

To display IP access violations, you must use the access-violations keyword. If you do not specify the keyword, the command defaults to displaying the number of packets that have passed access lists and were routed.

To use this command, you must first enable IP accounting on a per-interface basis.

**Examples**

The following is sample output from the show ip accounting command:

```
Router# show ip accounting
Source           Destination              Packets   Bytes
131.108.19.40    192.67.67.20                     7         306
131.108.13.55    192.67.67.20                    67        2749
131.108.2.50     192.12.33.51                    17        1111
131.108.2.50     130.93.2.1                       5         319
131.108.2.50     130.93.1.2                     463       30991
131.108.19.40    130.93.2.1                       4         262
```
The following is sample output from the `show ip accounting access-violations` command. The output pertains to packets that failed access lists and were not routed:

```
Router# show ip accounting access-violations
Source           Destination      Packets        Bytes        ACL
131.108.19.40    192.67.67.20              7          306         77
131.108.13.55    192.67.67.20             67         2749        185
131.108.2.50     192.12.33.51             17         1111        140
131.108.2.50     130.93.2.1                5          319        140
131.108.19.40    130.93.2.1                4          262         77
```

Accounting data age is 41

The following is sample output from the `show ip accounting` command. The output shows the original source and destination addresses that are separated by three routers:

```
Router3# show ip accounting
Source Destination Packets Bytes
10.225.231.154 172.16.10.2 44 28160
10.76.97.34 172.16.10.2 44 28160
10.10.10.1 172.16.10.2 507 324480
10.10.10.1 172.16.10.2 507 318396
10.100.45.1 172.16.10.2 508 325120
10.98.32.5 172.16.10.2 44 28160
```

Accounting data age is 2

</tr>
</thead>
<tbody>
<tr>
<td>11.2 F</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Examples**

The following is sample output from the `show ip drp` command:

```
Router# show ip drp

Director Responder Protocol Agent is enabled
717 director requests, 712 successful lookups, 5 failures, 0 no route
Authentication is enabled, using "test" key-chain
```

Table 22 describes the significant fields shown in the display.

**Table 22 show ip drp Field Descriptions**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>director requests</td>
<td>Number of DRP requests that have been received (including any using authentication key-chain encryption that failed).</td>
</tr>

show ip redirects

To display the address of a default gateway (router) and the address of hosts for which an Internet Control Message Protocol (ICMP) redirect message has been received, use the `show ip redirects` EXEC command.

`show ip redirects`

**Syntax Description**
This command has no arguments or keywords.

**Command Modes**
EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
This command displays the default router (gateway) as configured by the `ip default-gateway` command. The `ip mtu` command enables the router to send ICMP redirect messages.

**Examples**
The following is sample output from the `show ip redirects` command:

```
Router# show ip redirects
Default gateway is 160.89.80.29

  Host               Gateway           Last Use    Total Uses  Interface
  131.108.1.111      160.89.80.240         0:00             9  Ethernet0
  128.95.1.4         160.89.80.240         0:00             4  Ethernet0
Router#
```

</tbody>
</table>
show ip sockets

To display IP socket information, use the **show ip sockets** command in privileged EXEC mode or user EXEC mode.

```
show ip sockets
```

**Syntax Description**

This command has no keywords or arguments.

**Defaults**

No default behavior or values.

**Command Modes**

Privileged EXEC

User EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0 T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Use this command to verify that the socket being used is opening correctly. If there is a local and remote endpoint, a connection is established with the ports indicated.

**Examples**

The following is sample output from the **show ip sockets** command:

```
Router# show ip sockets

Proto Remote     Port Local         Port In Out Stat TTY Output IF
17 0.0.0.0 0 171.68.186.193 67 0 0 1 0
17 171.68.191.135 514 171.68.191.129 1811 0 0 0 0
17 172.16.135.20 514 171.68.191.1 4125 0 0 0 0

show ip tcp header-compression

To display statistics about TCP header compression, use the `show ip tcp header-compression` EXEC command.

```
show ip tcp header-compression
```

**Syntax Description**

This command has no arguments or keywords.

**Command Modes**

EXEC

**Command History**

Release Modification
10.0 This command was introduced.

**Examples**

The following is sample output from the `show ip tcp header-compression` command:

```
Router# show ip tcp header-compression
TCP/IP header compression statistics:
    Interface Serial1: (passive, compressing)
Rcvd:  4060 total, 2891 compressed, 0 errors
    0 dropped, 1 buffer copies, 0 buffer failures
Sent:  4284 total, 3224 compressed,
     105295 bytes saved, 661973 bytes sent
     1.15 efficiency improvement factor
    Connect:  16 slots, 1543 long searches, 2 misses, 99% hit ratio
        Five minute miss rate 0 misses/sec, 0 max misses/sec
```

show standby

To display Hot Standby Router Protocol (HSRP) information, use the show standby command in user EXEC or privileged EXEC mode.

`show standby [type number [group]] [all | brief]`

**Syntax Description**

- `type number` (Optional) Interface type and number for which output is displayed.
- `group` (Optional) Group number on the interface for which output is displayed.
- `all` (Optional) Displays information for groups that are learned or who do not have the standby ip command configured.
- `brief` (Optional) A single line of output summarizes each standby group.

**Command Modes**

User EXEC
Privileged EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>T2.2(8)T</td>
<td>The output for the command was made clearer and easier to understand.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

To specify a group, you must specify an interface type and number.

**Examples**

The following is sample output from the show standby command:

```
Router# show standby

Ethernet0/1 - Group 1
  State is Active
    2 state changes, last state change 00:30:59
  Virtual IP address is 10.1.0.20
  Secondary virtual IP address 10.1.0.21
  Active virtual MAC address is 0004.4d82.7981
  Local virtual MAC address is 0004.4d82.7981 (bia)
  Hello time 4 sec, hold time 12 sec
  Next hello sent in 1.412 secs
  Preemption enabled, min delay 50 sec, sync delay 40 sec
  Active router is local
  Standby router is 10.1.0.6, priority 75 (expires in 9.184 sec)
  Priority 95 (configured 120)
  Tracking 2 objects, 0 up
    Down Interface Ethernet0/2, pri 15
    Down Interface Ethernet0/3
  IP redundancy name is "HSRP1", advertisement interval is 34 sec
```

The following is sample output from the show standby command with the brief keyword specified:
Router# show standby brief

<table>
<thead>
<tr>
<th>Interface</th>
<th>Grp</th>
<th>Prio</th>
<th>State</th>
<th>Active addr</th>
<th>Standby addr</th>
<th>Group addr</th>
</tr>
</thead>
<tbody>
<tr>
<td>Et0</td>
<td>0</td>
<td>120</td>
<td>Init</td>
<td>10.0.0.1</td>
<td>unknown</td>
<td>10.0.0.12</td>
</tr>
</tbody>
</table>

Table 26 describes the significant fields shown in the displays.

**Table 26  show standby Field Descriptions**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ethernet - Group</td>
<td>Interface type and number and Hot Standby group number for the interface.</td>
</tr>
<tr>
<td>State is</td>
<td>State of local router; can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Active—Indicates the current Hot Standby router.</td>
</tr>
<tr>
<td></td>
<td>• Standby—Indicates the router next in line to be the Hot Standby router.</td>
</tr>
<tr>
<td></td>
<td>• Speak—Router is sending packets to claim the active or standby role.</td>
</tr>
<tr>
<td></td>
<td>• Listen—Router is neither in the active nor standby state, but if no messages are received from the active or standby router, it will start to speak.</td>
</tr>
<tr>
<td></td>
<td>• Init or Disabled—Router is not yet ready or able to participate in HSRP, possibly because the associated interface is not up. HSRP groups configured on other routers on the network that are learned via snooping are displayed as being in the Init state. Locally configured groups with an interface that is down or groups without a specified interface IP address appear in the Init state. For these cases, the Active addr and Standby addr fields will show “unknown.” The state is listed as disabled in the fields when the standby ip command has not been specified.</td>
</tr>
<tr>
<td>Virtual IP address, secondary virtual IP addresses</td>
<td>All secondary virtual IP addresses are listed on separate lines. If one of the virtual IP addresses is a duplicate of an address configured for another device, it will be marked as “duplicate.” A duplicate address indicates that the router has failed to defend its ARP (Address Resolution Protocol) cache entry.</td>
</tr>
<tr>
<td>Active virtual MAC address</td>
<td>Virtual MAC address being used by the current active router.</td>
</tr>
<tr>
<td>Local virtual MAC address</td>
<td>Virtual MAC address that would be used if this router became the active router. The origin of this address (displayed in parentheses) can be “default,” “bia,” (burned-in address) or “confgd” (configured).</td>
</tr>
<tr>
<td>Hello time, hold time</td>
<td>The hello time is the time between hello packets (in seconds) based on the command. The holdtime is the time (in seconds) before other routers declare the active or standby router to be down, based on the standby timers command. All routers in an HSRP group use the hello and hold-time values of the current active router. If the locally configured values are different, the variance appears in parentheses after the hello time and hold-time values.</td>
</tr>
<tr>
<td>Next hello sent in ...</td>
<td>Time in which the Cisco IOS software will send the next hello packet (in hours:minutes:seconds).</td>
</tr>
<tr>
<td>Preemption enabled, sync delay</td>
<td>Indicates whether preemption is enabled. If enabled, the minimum delay is the time a higher-priority nonactive router will wait before preempting the lower-priority active router. The sync delay is the maximum time a group will wait to synchronize with the IP redundancy clients.</td>
</tr>
</tbody>
</table>

show standby capability

To display the limitation on how many virtual MAC addresses that some interfaces can listen to, use the `show standby capability` command in user EXEC or privileged EXEC mode.

```
show standby capability [type number]
```

**Syntax Description**

```
Syntax Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type number</td>
<td>(Optional) Interface type and number for which output is displayed.</td>
</tr>
</tbody>
</table>
```

**Command Modes**

```
User EXEC
Privileged EXEC
```

**Command History**

```
Release   | Modification                      |
-----------|-----------------------------------|
12.2       | This command was introduced.      |
```

**Usage Guidelines**

HSRP allows up to 256 groups to be configured on each interface, but it is possible that the MAC address filter of the interface does not support that many entries. For example, Versatile Interface Processor (VIP) interfaces only support 32 MAC addresses in their MAC address filter. If more HSRP groups are created than there are address filter entries, then it is likely that the router will stop listening to packets sent to the MAC address of an active HSRP group.

**Examples**

The following is sample output from the `show standby capability` command:

```
Router# show standby capability
7206VXR * indicates hardware may support HSRP

show standby internal

To display internal flags and conditions, use the \texttt{show standby internal} command in user EXEC or privileged EXEC mode.

\texttt{show standby internal [type number]}

\textbf{Syntax Description}

\begin{itemize}
  \item \texttt{type number} (Optional) Interface type and number for which output is displayed.
\end{itemize}

\textbf{Command Modes}

User EXEC  
Privileged EXEC

\textbf{Command History}

\begin{tabular}{ll}
\textbf{Release} & \textbf{Modification} \\
12.2 & This command was introduced. \\
\end{tabular}

\textbf{Examples}

This example shows a configuration example and the output from the \texttt{show standby internal} command for the configuration:

```
interface Ethernet2/0
  ip address 10.0.0.254 255.255.0.0
  standby use-bia
  standby version 2
  standby 1 ip 10.0.0.1
  standby 1 timers 2 6
  standby 1 priority 110
  standby 1 preempt

Router# show standby internal
```

```
Global           Confg: 0000
Et2/0 If hw      AmdP2, State 0x210040
Et2/0 If hw      Confg: 0001, USEBIA
Et2/0 If sw      Confg: 0040, VERSION
Et2/0 If sw      Flags: 0000
Et2/0 Grp 1      Confg: 0072, IP_PRI, PRIORITY, PREEMPT, TIMERS
Et2/0 Grp 1      Flags: 0000
```

The above output shows internal flags and hardware and software information for Ethernet interface 2/0. The output shows that HSRP group 1 is configured for priority, preemption, and the \texttt{standby timers} and \texttt{standby-use bia} commands have been configured.

standby authentication

To configure an authentication string for the Hot Standby Router Protocol (HSRP), use the `standby authentication` interface configuration command. To delete an authentication string, use the `no` form of this command.

```
standby [group-number] authentication [mode text] string
no standby [group-number] authentication [mode text] string
```

**Syntax Description**

- `group-number` (Optional) Group number on the interface to which this authentication string applies.
- `mode text` (Optional) Indicates use of a plain text authentication mode.
- `string` Authentication string. It can be up to eight characters long. The default string is `cisco`.

**Defaults**

The default group number is 0. The default string is `cisco`.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1</td>
<td>The <code>mode</code> and <code>text</code> keywords were added.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

HSRP ignores unauthenticated HSRP messages.

The authentication string is sent unencrypted in all HSRP messages. The same authentication string must be configured on all routers and access servers on a cable to ensure interoperability. Authentication mismatch prevents a device from learning the designated Hot Standby IP address and the Hot Standby timer values from other routers configured with HSRP.

When group number 0 is used, no group number is written to NVRAM, providing backward compatibility.

**Examples**

The following example configures “company1” as the authentication string required to allow Hot Standby routers in group 1 to interoperate:

```
interface ethernet 0
standby 1 authentication mode text company1
```
standby delay minimum reload

To configure the delay period before the initialization of Hot Standby Router Protocol (HSRP) groups, use the `standby delay minimum reload` interface configuration command. To disable the delay period, use the `no` form of this command.

```
standby delay minimum min-delay reload reload-delay

no standby delay minimum min-delay reload reload-delay
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>min-delay</td>
<td>Minimum time (in seconds) to delay HSRP group initialization after an interface comes up. This minimum delay period applies to all subsequent interface events.</td>
</tr>
<tr>
<td>reload-delay</td>
<td>Time (in seconds) to delay after the router has reloaded. This delay period only applies to the first interface-up event after the router has reloaded.</td>
</tr>
</tbody>
</table>

**Defaults**

The default minimum delay is 1 second.

The default reload delay is 5 seconds.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

If the active router fails or is removed from the network, then the standby router will automatically become the new active router. If the former active router comes back online, you can control whether it takes over as the active router by using the `standby preempt` command.

However, in some cases, even if the `standby preempt` command is not configured, the former active router will resume the active role after it reloads and comes back online. Use the `standby delay minimum reload` command to set a delay period for HSRP group initialization. This command allows time for the packets to get through before the router resumes the active role.

We recommend that you use the `standby delay minimum reload` command if the `standby timers` command is configured in milliseconds or if HSRP is configured on a VLAN interface of a switch.

In most configurations, the default values provide sufficient time for the packets to get through and it is not necessary to configure longer delay values.

The delay will be cancelled if an HSRP packet is received on an interface.

You can view the delays with the `show standby delay` command.

**Examples**

The following example sets the minimum delay period to 30 seconds and the delay period after the first reload to 120 seconds:

```
interface ethernet 0
```

```
ip address 10.20.0.7 255.255.0.0
standby delay minimum 30 reload 120
standby 3 ip 10.20.0.21
standby 3 timers msec 300 msec 700
standby 3 priority 100

**Related Commands**

</table>
**standby ip**

To activate the Hot Standby Router Protocol (HSRP), use the **standby ip** interface configuration command. To disable HSRP, use the **no** form of this command.

```
standby [group-number] ip [ip-address [secondary]]
no standby [group-number] ip [ip-address]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group-number</td>
<td>(Optional) Group number on the interface for which HSRP is being activated. The default is 0.</td>
</tr>
<tr>
<td>ip-address</td>
<td>(Optional) IP address of the Hot Standby router interface.</td>
</tr>
<tr>
<td>secondary</td>
<td>(Optional) Indicates the IP address is a secondary Hot Standby router interface. Useful on interfaces with primary and secondary addresses; you can configure primary and secondary HSRP addresses.</td>
</tr>
</tbody>
</table>

**Defaults**

The default group number is 0.

HSRP is disabled by default.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>10.3</td>
<td>The group-number argument was added.</td>
</tr>
<tr>
<td>11.1</td>
<td>The secondary keyword was added.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The **standby ip** command activates HSRP on the configured interface. If an IP address is specified, that address is used as the designated address for the Hot Standby group. If no IP address is specified, the designated address is learned through the standby function. For HSRP to elect a designated router, at least one router on the cable must have been configured with, or have learned, the designated address. Configuring the designated address on the active router always overrides a designated address that is currently in use.

When the **standby ip** command is enabled on an interface, the handling of proxy ARP requests is changed (unless proxy ARP was disabled). If the Hot Standby state of the interface is active, proxy ARP requests are answered using the MAC address of the Hot Standby group. If the interface is in a different state, proxy ARP responses are suppressed.

When group number 0 is used, no group number is written to NVRAM, providing backward compatibility.

**Examples**

The following example activates HSRP for group 1 on Ethernet interface 0. The IP address used by the Hot Standby group will be learned using HSRP.
interface ethernet 0
    standby 1 ip

In the following example, all three virtual IP addresses appear in the ARP table using the same (single) virtual MAC address. All three virtual IP addresses are using the same HSRP group (group 0).

    ip address 1.1.1.1. 255.255.255.0
    ip address 1.2.2.2. 255.255.255.0 secondary
    ip address 1.3.3.3. 255.255.255.0 secondary
    ip address 1.4.4.4. 255.255.255.0 secondary
    standby ip 1.1.1.254
    standby ip 1.2.2.254 secondary
    standby ip 1.3.3.254 secondary
standby mac-address

To specify a virtual MAC address for the Hot Standby Router Protocol (HSRP), use the `standby mac-address` interface configuration command. To revert to the standard virtual MAC address (0000.0C07.ACxy), use the `no` form of this command.

```
standby [group-number] mac-address mac-address

no standby [group-number] mac-address
```

**Syntax Description**

<table>

<tr>
<td><code>mac-address</code></td>
<td>MAC address.</td>
</tr>
</tbody>
</table>

**Defaults**

If this command is not configured, and the `standby use-bia` command is not configured, the standard virtual MAC address is used: 0000.0C07.ACxy, where xy is the group number in hexadecimal. This address is specified in RFC 2281, *Cisco Hot Standby Router Protocol (HSRP)*.

**Command Modes**

Interface configuration

**Command History**

- **Release** 11.2: This command was introduced.

**Usage Guidelines**

This command cannot be used on a Token Ring interface.

HSRP is used to help end stations locate the first hop gateway for IP routing. The end stations are configured with a default gateway. However, HSRP can provide first-hop redundancy for other protocols. Some protocols, such as Advanced Peer-to-Peer Networking (APPN), use the MAC address to identify the first hop for routing purposes. In this case, it is often necessary to be able to specify the virtual MAC address; the virtual IP address is unimportant for these protocols. Use the `standby mac-address` command to specify the virtual MAC address.

The MAC address specified is used as the virtual MAC address when the router is active.

This command is intended for certain APPN configurations. The parallel terms are shown in Table 30.

**Table 30 Parallel Terms Between APPN and IP**

<table>
<thead>
<tr>
<th>APPN</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>End node</td>
<td>Host</td>
</tr>
<tr>
<td>Network node</td>
<td>Router or gateway</td>
</tr>
</tbody>
</table>
In an APPN network, an end node is typically configured with the MAC address of the adjacent network node. Use the **standby mac-address** command in the routers to set the virtual MAC address to the value used in the end nodes.

**Examples**

If the end nodes are configured to use 4000.1000.1060 as the MAC address of the network node, the following example shows the command used to configure HSRP group 1 with the virtual MAC address:

```plaintext
standby 1 mac-address 4000.1000.1060
```

standby mac-refresh

To change the interval at which packets are sent to refresh the MAC cache when the Hot Standby Router Protocol (HSRP) is running over FDDI, use the `standby mac-refresh` interface configuration command. To restore the default value, use the `no` form of this command.

```
standby mac-refresh seconds
no standby mac-refresh
```

**Syntax Description**

```
seconds
```

Number of seconds in the interval at which a packet is sent to refresh the MAC cache. The maximum value is 255 seconds. The default is 10 seconds.

**Defaults**

The default interval is 10 seconds.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command applies to HSRP running over FDDI only. Packets are sent every 10 seconds to refresh the MAC cache on learning bridges or switches. By default, the MAC cache entries age out in 300 seconds (5 minutes).

All other routers participating in HSRP on the FDDI ring receive the refresh packets, although the packets are intended only for the learning bridge or switch. Use this command to change the interval. Set the interval to 0 if you want to prevent refresh packets (if you have FDDI but do not have a learning bridge or switch).

**Examples**

The following example changes the MAC refresh interval to 100 seconds. Therefore, a learning bridge would need to miss three packets before the entry ages out.

```
standby mac-refresh 100
```
standby name

To configure the name of the standby group, use the **standby name** interface configuration command. To disable the name, use the **no** form of this command.

```
standby name group-name

no standby name group-name
```

**Syntax Description**

- `group-name` Specifies the name of the standby group.

**Defaults**

The Hot Standby Router Protocol (HSRP) is disabled.

**Command Modes**

Interface configuration

**Command History**

```
<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(2)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>
```

**Usage Guidelines**

The name specifies the HSRP group used.

**Examples**

The following example specifies the standby name as SanJoseHA:

```
interface ethernet0
  ip address 1.0.0.1 255.0.0.0
  standby ip 1.0.0.10
  standby name SanJoseHA
  standby preempt delay sync 100
  standby priority 110
```

</tr>
</tbody>
</table>
**standby preempt**

To configure Hot Standby Router Protocol (HSRP) preemption and preemption delay, use the `standby preempt` command in interface configuration mode. To restore the default values, use the `no` form of this command.

```plaintext
standby [group-number] preempt [delay{minimum delay | reload delay | sync delay}]

no standby [group-number] preempt [delay{minimum delay | reload delay | sync delay}]
```

<table>
<thead>
<tr>
<th>Syntax Description</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group-number</td>
<td>(Optional) Group number on the interface to which the other arguments in this command apply.</td>
</tr>
<tr>
<td>delay</td>
<td>(Optional) Required if either the <code>minimum</code>, <code>reload</code>, or <code>sync</code> keywords are specified.</td>
</tr>
<tr>
<td>minimum delay</td>
<td>(Optional) Specifies the minimum delay period in delay seconds. The delay argument causes the local router to postpone taking over the active role for delay (minimum) seconds since that router was last restarted. The range is from 0 to 3600 seconds (1 hour). The default is 0 seconds (no delay).</td>
</tr>
<tr>
<td>reload delay</td>
<td>(Optional) Specifies the preemption delay period after a reload only. This delay period applies only to the first interface-up event after the router has reloaded.</td>
</tr>
<tr>
<td>sync delay</td>
<td>(Optional) Specifies the maximum synchronization period for IP redundancy clients in delay seconds.</td>
</tr>
</tbody>
</table>

**Defaults**

The default group number is 0.
The default delay is 0 seconds; if the router wants to preempt, it will do so immediately.
By default, the router that comes up later becomes the standby.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.3</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.0(2)T</td>
<td>The <code>minimum</code> and <code>sync</code> keywords were added.</td>

<td>The behavior of the command changed such that <code>standby preempt</code> and <code>standby priority</code> must be entered as separate commands.</td>
</tr>
<tr>
<td>12.2</td>
<td>The <code>reload</code> keyword was added.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

When this command is configured, the router is configured to preempt, which means that when the local router has a Hot Standby priority higher than the current active router, the local router should attempt to assume control as the active router. If preemption is not configured, the local router assumes control as the active router only if it receives information indicating no router is in the active state (acting as the designated router).
When a router first comes up, it does not have a complete routing table. If it is configured to preempt, it will become the active router, yet it is unable to provide adequate routing services. Solve this problem by configuring a delay before the preemtong router actually preempts the currently active router.

When group number 0 is used, no group number is written to NVRAM, providing backward compatibility.

IP redundancy clients can prevent preemption from taking place. The **standby preempt delay sync delay** command specifies a maximum number of seconds to allow IP redundancy clients to prevent preemption. When this expires, then preemption takes place regardless of the state of the IP redundancy clients.

The **standby preempt delay reload delay** command allows preemption to occur only after a router reloads. This provides stabilization of the router at startup. After this initial delay at startup, the operation returns to the default behavior.

The **no standby preempt delay** command will disable the preemption delay but preemption will remain enabled. The **no standby preempt delay minimum delay** command will disable the minimum delay but leave any synchronization delay if it was configured.

### Examples

In the following example, the router will wait for 300 seconds (5 minutes) before attempting to become the active router:

```
interface ethernet 0
  standby ip 172.19.108.254
  standby preempt delay minimum 300
```
standby priority

To configure Hot Standby Router Protocol (HSRP) priority, use the `standby priority` command in interface configuration mode. To restore the default values, use the `no` form of this command.

```
standby [group-number] priority priority

no standby [group-number] priority priority
```

**Syntax Description**

<table>
<thead>
<tr>
<th><strong>Syntax</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>group-number</code></td>
<td>(Optional) Group number on the interface to which the other arguments in this command apply.</td>
</tr>
<tr>
<td><code>priority</code></td>
<td>Priority value that prioritizes a potential Hot Standby router. The range is from 1 to 255, where 1 denotes the lowest priority and 255 denotes the highest priority. The default priority value is 100. The router in the HSRP group with the highest priority value becomes the active router.</td>
</tr>
</tbody>
</table>

**Defaults**

The default group number is 0.
The default priority is 100.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th><strong>Release</strong></th>
<th><strong>Modification</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>11.3</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.0(2)T</td>
<td>The <code>minimum</code> and <code>sync</code> keywords were added.</td>
</tr>
<tr>
<td>12.2</td>
<td>The behavior of the command changed such that <code>standby preempt</code> and <code>standby priority</code> must be entered as separate commands.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

When group number 0 is used, no group number is written to NVRAM, providing backward compatibility.

The assigned priority is used to help select the active and standby routers. Assuming preemption is enabled, the router with the highest priority becomes the designated active router. In case of ties, the primary IP addresses are compared, and the higher IP address has priority.

Note that the priority of the device can change dynamically if an interface is configured with the `standby track` command and another interface on the router goes down.

**Examples**

In the following example, the router has a priority of 120 (higher than the default value):

```
interface ethernet 0
standby ip 172.19.108.254
standby priority 120
standby preempt delay 300
```
<table>

<td>(Optional) HSRP Router advertisement interval in seconds. This is an integer from 10 to 180. The default is 60 seconds.</td>
</tr>
<tr>
<td>holddown</td>
<td>(Optional) HSRP router holddown interval in seconds. This is an integer from 61 to 3600. The default is 180 seconds.</td>
</tr>
<tr>
<td>unknown</td>
<td>(Optional) Allows sending of ICMP packets when the next hop IP address contained in the packet is unknown in the HSRP table of real IP addresses and active virtual IP addresses. The <code>no standby redirect unknown</code> command stops the redirects from being sent.</td>
</tr>
</tbody>
</table>

**Defaults**

HSRP filtering of ICMP redirect messages is enabled if HSRP is configured on an interface.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.1(3)T</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.2</td>
<td>The following keywords and arguments were added to the command:</td>
</tr>
<tr>
<td></td>
<td>- <code>timers advertisement holddown</code></td>
</tr>
<tr>
<td></td>
<td>- <code>unknown</code></td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The `standby redirect` command can be configured globally or on a per-interface basis. When HSRP is first configured on an interface, the setting for that interface will inherit the global value. If the filtering of ICMP redirects is explicitly disabled on an interface, then the global command cannot reenable this functionality.

The `no standby redirect` command is the same as the `standby redirect disable` command. However, it is not desirable to save the `no` form of this command to NVRAM. Because the command is enabled by default, it is preferable to use the `standby redirect disable` command to disable the functionality.
With the `standby redirect` command enabled, the real IP address of a router can be replaced with a virtual IP address in the next hop address or gateway field of the redirect packet. HSRP looks up the next hop IP address in its table of real IP addresses versus virtual IP addresses. If HSRP does not find a match, the HSRP router allows the redirect packet to go out unchanged. The host HSRP router is redirected to a router that is unknown, that is, a router with no active HSRP groups. You can specify the `no standby redirect unknown` command to stop these redirects from being sent.

**Examples**

The following example allows HSRP to filter ICMP redirect messages on interface Ethernet 0:

```plaintext
Router(config)# interface ethernet 0
Router(config-if)# ip address 10.0.0.1 255.0.0.0
Router(config-if)# standby redirect
Router(config-if)# standby 1 ip 10.0.0.11
```

The following example shows how to change the HSRP router advertisement interval to 90 seconds and the holddown timer to 270 seconds on interface Ethernet 0:

```plaintext
Router(config)# interface ethernet 0
Router(config-if)# ip address 10.0.0.1 255.0.0.0
Router(config-if)# standby redirect timers 90 270
Router(config-if)# standby 1 ip 10.0.0.11
```

<tr>
<td><code>msec</code></td>
<td>(Optional) Interval in milliseconds. Millisecond timers allow for faster failover.</td>
</tr>
<tr>
<td><code>hellotime</code></td>
<td>Hello interval (in seconds). This is an integer from 1 to 254. The default is 3 seconds. If the <code>msec</code> option is specified, hello interval is in milliseconds. This is an integer from 15 to 999.</td>
</tr>
<tr>
<td><code>holdtime</code></td>
<td>Time (in seconds) before the active or standby router is declared to be down. This is an integer from y to 255. The default is 10 seconds. If the <code>msec</code> option is specified, holdtime is in milliseconds. This is an integer from x to 3000. Where:</td>
</tr>
<tr>
<td></td>
<td>• y is the hellotime + 50 milliseconds, then rounded up to the nearest 1 second</td>
</tr>
<tr>
<td></td>
<td>• x is greater than or equal to 3 times the hellotime and is not less than 50 milliseconds.</td>
</tr>
</tbody>
</table>

**Defaults**

The default group number is 0.

The default hello interval is 3 seconds.

The default hold time is 10 seconds.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>11.2</td>
<td>The <code>msec</code> keyword was added.</td>
</tr>
<tr>
<td>12.2</td>
<td>The minimum values of hellotime and holdtime in milliseconds changed.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The `standby timers` command configures the time between standby hello packets and the time before other routers declare the active or standby router to be down. Routers or access servers on which timer values are not configured can learn timer values from the active or standby router. The timers configured on the active router always override any other timer settings. All routers in a Hot Standby group should
use the same timer values. Normally, holdtime is greater than or equal to three times the value of 
hellotime. The range of values for holdtime force the holdtime to be greater than the hellotime. If the 
timer values are specified in milliseconds, the holdtime is required to be at least three times the hellotime 
value and not less than 50 milliseconds.

Some HSRP state flapping can occasionally occur if the holdtime is set to less than 250 milliseconds, 
and the processor is busy. It is recommended that a holdtime value less than 250 millisecond only be 
used on 7200 platforms or better, and on fast-ethernet or FDDI interfaces or better. Setting the 
process-max-time command to a suitable value may also help with flapping.

The value of the standby timer will not be learned through HSRP hellos if it is less than 1 second. 
When group number 0 is used, no group number is written to NVRAM, providing backward 
compatibility.

Examples

The following example sets, for group number 1 on Ethernet interface 0, the time between hello packets 
to 5 seconds, and the time after which a router is considered to be down to 15 seconds:

```
interface ethernet 0
  standby 1 ip
  standby 1 timers 5 15
```

The following example sets, for the Hot Router interface located at 172.19.10.1 on Ethernet interface 0, 
the time between hello packets to 300 milliseconds, and the time after which a router is considered to be 
down to 900 milliseconds.

```
interface ethernet 0
  standby ip 172.19.10.1
  standby timers msec 300 msec 900
```

The following example sets, for the Hot Router interface located at 172.18.10.1 on Ethernet interface 0, 
the time between hello packets to 15 milliseconds, and the time after which a router is considered to be 
down to 50 milliseconds. Note that the holdtime is larger than three times the hellotime because the 
minimum holdtime value in milliseconds is 50.

```
interface ethernet 0
  standby ip 172.18.10.1
  standby timers msec 15 msec 50
```
standby track

To configure an interface so that the Hot Standby priority changes based on the availability of other interfaces, use the `standby track` interface configuration command. To remove the tracking, use the `no` form of this command.

```
standby [group-number] track interface-type interface-number [interface-priority]
```

```
no standby [group-number] track interface-type interface-number [interface-priority]
```

### Syntax Description

- **group-number** (Optional) Group number on the interface to which the tracking applies.
- **interface-type** Interface type (combined with interface number) that will be tracked.
- **interface-number** Interface number (combined with interface type) that will be tracked.
- **interface-priority** (Optional) Amount by which the Hot Standby priority for the router is decremented (or incremented) when the interface goes down (or comes back up). The default value is 10.

### Defaults

The default group number is 0.

The default interface priority is 10.

### Command Modes

Interface configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

This command ties the Hot Standby priority of the router to the availability of its interfaces. It is useful for tracking interfaces that are not configured for the Hot Standby Router Protocol (HSRP).

When a tracked interface goes down, the Hot Standby priority decreases by 10. If an interface is not tracked, its state changes do not affect the Hot Standby priority. For each interface configured for Hot Standby, you can configure a separate list of interfaces to be tracked.

The optional `interface-priority` argument specifies by how much to decrement the Hot Standby priority when a tracked interface goes down. When the tracked interface comes back up, the priority is incremented by the same amount.

When multiple tracked interfaces are down, the decrements are cumulative whether configured with `interface-priority` values or not.

A tracked interface is considered down if the IP address is disabled on that interface.

If HSRP is configured to track an interface, and that interface is physically removed as in the case of an online insertion and removal (OIR) operation, then HSRP will regard the interface as always down. Further, it will not be possible to remove the HSRP interface tracking configuration. To prevent this problem, use the `no standby track interface-type interface-number` command before you physically remove the interface.
Use the **no standby group-number track** command to delete all tracking configuration for a group. When group number 0 is used, no group number is written to NVRAM, providing backward compatibility.

### Examples

In the following example, Ethernet interface 1 tracks Ethernet interface 0 and serial interface 0. If one or both of these two interfaces go down, the Hot Standby priority of the router decreases by 10. Because the default Hot Standby priority is 100, the priority becomes 90 when one or both of the tracked interfaces go down.

```
interface ethernet 1
  ip address 198.92.72.37 255.255.255.240
  no ip redirects
  standby track ethernet 0
  standby track serial 0
  standby preempt
  standby ip 198.92.72.46
```

standby use-bia

To configure the Hot Standby Router Protocol (HSRP) to use the burned-in address of the interface as its virtual MAC address, instead of the preassigned MAC address (on Ethernet and FDDI) or the functional address (on Token Ring), use the `standby use-bia` interface configuration command. To restore the default virtual MAC address, use the `no` form of this command.

```
standby use-bia [scope interface]
```

```
no standby use-bia
```

<table>
<thead>
<tr>
<th>Syntax Description</th>
<th>scope interface</th>
<th>(Optional) Specifies that this command is configured just for the subinterface on which it was entered, instead of the major interface.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Defaults</th>
<th>HSRP uses the preassigned MAC address on Ethernet and FDDI, or the functional address on Token Ring.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Command Modes</th>
<th>Interface configuration</th>
</tr>
</thead>
</table>

<table>
<thead>

<tbody>
<tr>
<td></td>
<td>11.2</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td></td>
<td>12.1</td>
<td>The behavior was modified to allow multiple standby groups to be configured for an interface configured with this command</td>
</tr>
</tbody>
</table>

| Usage Guidelines  | For an interface with this command configured, multiple standby group can be configured. Hosts on the interface must have a default gateway configured. We recommend that you set the `no ip proxy-arp` command on the interface. It is desirable to configure the `standby use-bia` command on a Token Ring interface if there are devices that reject ARP replies with source hardware addresses set to a functional address.

When HSRP runs on a multiple-ring, source-routed bridging environment and the HRSP routers reside on different rings, configuring the `standby use-bia` command can prevent confusion about the routing information field (RFI).

Without the `scope interface` keywords, the `standby use-bia` command applies to all subinterfaces on the major interface. The `standby use-bia` command may not be configured both with and without the `scope interface` keywords at the same time. |

<table>
<thead>
<tr>
<th>Examples</th>
<th>In the following example, the burned-in address of Token Ring interface 4/0 will be the virtual MAC address mapped to the virtual IP address:</th>

start-forwarding-agent

To start the Forwarding Agent, use the `start-forwarding-agent` CASA-port configuration command.

```
start-forwarding-agent port-number [password [timeout]]
```

<table>
<thead>
<tr>
<th>Syntax Description</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>port-number</td>
<td>Port numbers on which the Forwarding Agent will listen for wildcards broadcast from the services manager. This must match the port number defined on the services manager.</td>
</tr>
<tr>
<td>password</td>
<td>(Optional) Text password used for generating the MD5 digest.</td>
</tr>
<tr>
<td>timeout</td>
<td>(Optional) Duration (in seconds) during which the Forwarding Agent will accept the new and old password. Valid range is from 0 to 3600 seconds. The default is 180 seconds.</td>
</tr>
</tbody>
</table>

**Defaults**

- The default initial number of affinities is 5000.
- The default maximum number of affinities is 30,000.

**Command Modes**

CASA-port configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(5)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The Forwarding Agent must be started before you can configure any port information for the forwarding agent.

**Examples**

The following example specifies that the forwarding agent will listen for wildcard and fixed affinities on port 1637:

```
start-forwarding-agent 1637
```

**Related Commands**

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.0</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Receive-only interfaces are used commonly with microwave Ethernet links.

**Examples**

The following example specifies Ethernet interface 0 as a simplex Ethernet interface:

```
interface ethernet 1
ip address 128.9.1.2
transmit-interface ethernet 0
```
Server Load Balancing Commands

Use the commands in this chapter to configure the IOS Server Load Balancing (SLB) feature. For configuration information and examples, refer to the “Configuring Server Load Balancing” chapter of the Cisco IOS IP Configuration Guide.
advertise

To control the installation of a static route to the Null0 interface for a virtual server address, use the advertise SLB virtual server configuration command. To prevent the installation of a static route for the virtual server IP address, use the no form of this command.

advertise

no advertise

Syntax Description

This command has no arguments or keywords.

Defaults

The SLB virtual server IP address is added to the routing table.

Command Modes

SLB virtual server configuration

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

Usage Guidelines

By default, virtual server addresses are advertised. That is, static routes to the Null0 interface are installed for the virtual server addresses.
Advertisement of this static route using the routing protocol requires that you configure redistribution of static routes for the routing protocol.

Examples

The following example prevents advertisement of the IP address of the virtual server in routing protocol updates:

```
ip slb vserver PUBLIC_HTTP
no advertise
```

Related Commands

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip slb vservers</td>
<td>Displays information about the virtual servers.</td>
</tr>
</tbody>
</table>
agent

To configure a Dynamic Feedback Protocol (DFP) agent, use the **agent SLB DFP configuration command**. To remove an agent definition from the DFP configuration, use the **no** form of this command.

```
agent ip-address port [timeout [retry-count [retry-interval]]]
```

```
oagent ip-address port
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ip-address</strong></td>
<td>Agent IP address.</td>
</tr>
<tr>
<td><strong>port</strong></td>
<td>Agent port number.</td>
</tr>
<tr>
<td><strong>timeout</strong></td>
<td>(Optional) Time period (in seconds) during which the DFP manager must receive an update from the DFP agent. The default is 0 seconds, which means there is no timeout.</td>
</tr>
<tr>
<td><strong>retry-count</strong></td>
<td>(Optional) Number of times the DFP manager attempts to establish the TCP connection to the DFP agent. The default is 0 retries, which means there are infinite retries.</td>
</tr>
<tr>
<td><strong>retry-interval</strong></td>
<td>(Optional) Interval (in seconds) between retries. The default is 180 seconds.</td>
</tr>
</tbody>
</table>

**Defaults**

- The default timeout is 0 seconds (no timeout).
- The default retry count is 0 (infinite retries).
- The default retry interval is 180 seconds.

**Command Modes**

SLB DFP configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

You can configure up to 1024 agents.

A DFP agent collects status information about the load capability of a server and reports that information to a load manager. The DFP agent may reside on the server, or it may be a separate device that collects and consolidates the information from several servers before reporting to the load manager.

**Examples**

The following example configures a DFP agent on the DFP manager, sets the DFP password to Cookies and the timeout to 360 seconds, changes the configuration mode to DFP configuration mode, sets the IP address of the DFP agent to 10.1.1.1, and sets the port number of the DFP agent to 2221 (FTP):

```
ip slb dfp password Cookies 360
agent 10.1.1.1 2221
```
<table>
<thead>
<tr>
<th>Related Commands</th>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>ip slb dfp</code></td>
<td>Configures the IOS SLB DFP.</td>
</tr>
</tbody>
</table>
**bindid**

To configure a bind ID, use the **bindid** SLB server farm configuration command. To remove a bind ID from the server farm configuration, use the **no** form of this command.

```
bindid [bind-id]
no bindid [bind-id]
```

**Syntax Description**

- `bind-id`  
  (Optional) Bind ID number. The default bind ID is 0.

**Defaults**

The default bind ID is 0.

**Command Modes**

SLB server farm configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

You can configure one bind ID on each **bindid** command.

The bind ID allows a single physical server to be bound to multiple virtual servers and report a different weight for each one. Thus, the single real server is represented as multiple instances of itself, each having a different bind ID. DFP uses the bind ID to identify for which instance of the real server a given weight is specified.

**Examples**

The following example configures bind ID 309:

```
ip slb serverfarm PUBLIC
bindid 309
```

**Related Commands**

<table>
<thead>
<tr>

</tbody>
</table>
clear ip slb

To clear IP IOS SLB connections or counters, use the `clear ip slb` privileged EXEC command.

```
clear ip slb {connections [serverfarm farm-name | vserver server-name] | counters}
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax Description</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connections</td>
<td>Clears the IP IOS SLB connection database.</td>
</tr>
<tr>
<td>serverfarm</td>
<td>(Optional) Clears the connection database for the server farm named.</td>
</tr>
<tr>
<td>farm-name</td>
<td>(Optional) Character string used to identify the server farm.</td>
</tr>
<tr>
<td>vserver</td>
<td>(Optional) Clears the connection database for the virtual server named.</td>
</tr>
<tr>
<td>server-name</td>
<td>(Optional) Character string used to identify the virtual server.</td>
</tr>
<tr>
<td>counters</td>
<td>Clears the IP IOS SLB counters.</td>
</tr>
</tbody>
</table>

**Defaults**

No default behavior or values.

**Command Modes**

Privileged EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.1(1)E</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

**Examples**

The following example clears the connection database of the server farm named FARM1:

```
Router# clear ip slb connections serverfarm FARM1
```

The following example clears the connection database of the virtual server named VSERVER1:

```
Router# clear ip slb connections vserver VSERVER1
```

The following example clears the IOS SLB counters:

```
Router# clear ip slb counters
```

<td>show ip slb vservers</td>
<td>Displays information about the IOS SLB virtual servers.</td>
</tr>
</tbody>
</table>
client

To define which clients are allowed to use the virtual server, use the `client` SLB virtual server configuration command. You can use more than one client command to define more than one client. To remove a client definition from the IOS SLB configuration, use the `no` form of this command.

```
client ip-address network-mask

no client ip-address network-mask
```

**Syntax Description**

- `ip-address`  
  Client IP address. The default is 0.0.0.0 (all clients).
- `network-mask`  
  Client IP network mask. The default is 0.0.0.0 (all subnetworks).

**Defaults**

The default IP address is 0.0.0.0 (all clients).

The default network mask is 0.0.0.0 (all subnetworks).

Taken together, the default is `client 0.0.0.0 0.0.0.0` (allows all clients on all subnetworks to use the virtual server).

**Command Modes**

SLB virtual server configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The `network-mask` value is applied to the source IP address of incoming connections. The result must match the `ip-address` value for the client to be allowed to use the virtual server.

**Examples**

The following example allows only clients from 10.4.4.x access to the virtual server:

```
ip slb vserver PUBLIC_HTTP
client 10.4.4.0 255.255.255.0
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show ip slb vservers</code></td>
<td>Displays information about the virtual servers.</td>
</tr>
<tr>
<td><code>virtual</code></td>
<td>Configures the virtual server attributes.</td>
</tr>
</tbody>
</table>
**delay (virtual server)**

To change the amount of time the IOS SLB feature maintains TCP connection context after a connection has terminated, use the `delay` SLB virtual server configuration command. To restore the default delay timer, use the `no` form of this command.

```
delay duration
no delay
```

### Syntax Description

```
duration
```

Delay timer duration in seconds. The valid range is from 1 to 600 seconds. The default value is 10 seconds.

### Defaults

The default duration is 10 seconds.

### Command Modes

SLB virtual server configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

The delay timer allows out-of-sequence packets and final acknowledgments (ACKs) to be delivered after a TCP connection ends.

Do not set this value to zero (0).

If you are configuring a delay timer for HTTP flows, choose a low number such as 5 seconds as a starting point.

### Examples

The following example specifies that the IOS SLB feature maintains TCP connection context for 30 seconds after a connection has terminated:

```
ip slb vserver PUBLIC_HTTP
delay 30
```

### Related Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>show ip slb vservers</td>
<td>Displays information about the virtual servers.</td>
</tr>
<tr>
<td>virtual</td>
<td>Configures the virtual server attributes.</td>
</tr>
</tbody>
</table>
faildetect

To specify the conditions that indicate a server failure, use the `faildetect` SLB real server configuration command. To restore the default values that indicate a server failure, use the `no` form of this command.

```
faildetect numconns number-conns [numclients number-clients]
no faildetect
```

Syntax Description

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>numconns</td>
<td>Number of consecutive TCP connection reassignments allowed before a real server is considered to have failed.</td>
</tr>
<tr>
<td>number-conns</td>
<td>Connection reassignment threshold value in the range from 1 to 255. The default is 8 connection failures.</td>
</tr>
<tr>
<td>numclients</td>
<td>(Optional) Number of unique client connection failures allowed before a real server is considered to have failed.</td>
</tr>
<tr>
<td>number-clients</td>
<td>(Optional) Client connection reassignment threshold value in the range from 1 to 8. The default is 2 client connection failures.</td>
</tr>
</tbody>
</table>

Defaults

If you do not specify the `faildetect` command, the default value of the connection reassignment threshold is 8.

If you do not specify the `numclients` keyword, the default value of the unique client failure threshold is 2.

Command Modes

SLB real server configuration

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

Examples

In the following example the connection reassignment threshold is set to 16 and, because the `numclients` keyword is not configured, the threshold for unique client connection failure is set to the default value 8. The real server is considered to have failed when 8 unique clients have had connection failures and there have been 16 connection reassignments.

```
ip slb serverfarm PUBLIC
real 10.10.1.1
faildetect numconns 16
```

Related Commands

</tr>
</tbody>
</table>
idle

To specify the minimum amount of time for which IOS SLB maintains connection information in the absence of packet activity, use the `idle` virtual server configuration command. To restore the default idle duration value, use the `no` form of this command.

```
idle duration

no idle
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>duration</code></td>
<td>Idle connection timer duration (in seconds). Valid values range from 10 to 65535. The default is 3600 seconds (1 hour).</td>
</tr>
</tbody>
</table>

**Defaults**

The default duration is 3600 seconds.

**Command Modes**

SLB virtual server configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

TCP connections that do not send flows or keepalives before the idle timer expires are assumed to be inactive and are reset (RST).

If you are configuring an idle timer for HTTP flows, choose a low number such as 120 seconds as a starting point. A low number ensures that the IOS SLB connection database maintains a manageable size if problems at the server, client, or network result in a large number of connections. However, do not choose a value under 60 seconds; such a low value can reduce the efficiency of the IOS SLB feature.

**Examples**

The following example instructs the IOS SLB feature to maintain connection information for an idle connection for 120 seconds:

```
ip slb vs server PUBLIC_HTTP
idle 120
```

**Related Commands**

<table>
<thead>
<tr>

<td><strong>show ip slb serverfarms</strong></td>
<td>Displays information about the server farm configuration.</td>
</tr>
</tbody>
</table>
inservice (virtual server)

To enable the virtual server for use by the IOS SLB feature, use the `inservice` SLB virtual server configuration command. To remove the virtual server from service, use the `no` form of this command.

```
inservice [standby group-name]

no inservice [standby group-name]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>standby</code></td>
<td>(Optional) Configures the Hot Standby Router Protocol (HSRP) standby virtual server.</td>
</tr>
<tr>
<td><code>group-name</code></td>
<td>(Optional) Specifies the HSRP group name with which the IOS SLB virtual server is associated.</td>
</tr>
</tbody>
</table>

**Defaults**

If you do not specify the `inservice` command, the virtual server is defined to IOS SLB but is not used.

**Command Modes**

SLB virtual server configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(1)E</td>
<td>The <code>standby</code> keyword and <code>group-name</code> argument were added.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>

</table>
ip slb dfp

To configure the Dynamic Feedback Protocol (DFP) and supply an optional password, use the `ip slb dfp` global configuration command. To remove the DFP configuration, use the `no` form of this command.

```
        ip slb dfp [password password [timeout]]
```

```
        no ip slb dfp
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>password</td>
<td>(Optional) Specifies a password for MD5 authentication.</td>
</tr>
<tr>
<td>password</td>
<td>(Optional) Password value for MD5 authentication. This password must match the password configured on the host agent.</td>
</tr>
<tr>
<td>timeout</td>
<td>(Optional) Delay period (in seconds) during which both the old password and the new password are accepted. The default value is 180 seconds.</td>
</tr>
</tbody>
</table>

**Defaults**

The password timeout default is 180 seconds.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The optional password, if configured, must match the password configured on the host agent.

The `timeout` option allows you to change the password without stopping messages between the DFP agent and its manager. The default value is 180 seconds.

During the timeout, the agent sends packets with the old password (or null, if there is no old password), and receives packets with either the old or new password. After the timeout expires, the agent sends and receives packets only with the new password; received packets that use the old password are discarded.

If you are changing the password for an entire load-balanced environment, set a longer timeout. This setting allows enough time for you to update the password on all agents and servers before the timeout expires. It also prevents mismatches between agents and servers that have begun running the new password and agents, and servers on which you have not yet changed the old password.

**Examples**

The following example configures DFP, sets the password to flounder, configures a timeout period of 60 seconds, and changes to DFP configuration mode:

```
ip slb dfp flounder 60
```

</tbody>
</table>
nat

To configure IOS SLB Network Address Translation (NAT) and specify a NAT mode, use the `nat` SLB server farm configuration command. To remove a NAT configuration, use the `no` form of this command.

```
nat server

no nat server
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>server</td>
<td>Specifies that the destination address in load-balanced packets sent to the real server is the address of the real server chosen by the server farm load-balancing algorithm.</td>
</tr>
</tbody>
</table>

**Defaults**

No default behavior or values.

**Command Modes**

SLB server farm configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.1(1)E</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The `no nat` command is allowed only if the virtual server was removed from service with the `no inservice` command.

**Examples**

The following example changes to IOS SLB server farm configuration mode and configures NAT mode as server address translation on the server farm named FARM2:

```
ip slb serverfarm FARM2
  nat server
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>

<td>Identifies a real server as a member of a server farm.</td>
</tr>
<tr>
<td>show ip slb serverfarms</td>
<td>Displays information about the server farm configuration.</td>
</tr>
</tbody>
</table>
predictor

To specify the load-balancing algorithm for selecting a real server in the server farm, use the predictor SLB server farm configuration command. To restore the default load-balancing algorithm of weighted round robin, use the no form of this command.

```
predictor [roundrobin | leastconns]
no predictor
```

### Syntax Description

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roundrobin</td>
<td>(Optional) Use the weighted round robin algorithm for selecting the real server to handle the next new connection for the server farm.</td>
</tr>
<tr>
<td>leastconns</td>
<td>(Optional) Use the weighted least connections algorithm for selecting the real server to handle the next new connection for this server farm.</td>
</tr>
</tbody>
</table>

### Defaults

The default predictor is weighted round robin.

### Command Modes

SLB server farm configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>

real

To identify a real server as a member of a server farm, use the `real` SLB server farm configuration command. To remove the real server from the IOS SLB configuration, use the `no` form of this command.

```
real ip-address

no real ip-address
```

**Syntax Description**

| `ip-address` | Real server IP address. |

**Defaults**

No default behavior or values.

**Command Modes**

SLB server farm configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>

<tr>
<td><code>show ip slb reals</code></td>
<td>Displays information about the real servers.</td>
</tr>
</tbody>
</table>
To specify the threshold of consecutive unanswered synchronizations that, if exceeded, results in an attempted connection to a different real server, use the `reassign` SLB real server configuration command. To restore the default reassignment threshold, use the `no` form of this command.

```
reassign threshold

no reassign
```

### Syntax Description

| `threshold` | Number of unanswered TCP SYNs that are directed to a real server before the connection is reassigned to a different real server. An unanswered SYN is one for which no SYN or ACK is detected before the next SYN arrives from the client. IOS SLB allows 30 seconds for the connection to be established or for a new SYN to be received. If neither of these events occurs within that time, the connection is removed from the IOS SLB database.

The 30-second timer is restarted for each SYN as long as the number of connection reassignments specified on the `faildetect` command’s `numconns` keyword is not exceeded. See the `faildetect` command for more information.

Valid threshold values range from 1 to 4 SYNs. The default value is 3.

### Defaults

The default threshold is three SYNs.

### Command Modes

SLB real server configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

### Examples

The following example sets the threshold of unanswered SYNs to 2:

```
ip slb serverfarm PUBLIC
real 10.10.1.1
reassign 2
```

</tr>
</tbody>
</table>
retry (real server)

To specify how long to wait before a new connection is attempted to a failed server, use the `retry` SLB real server configuration command. To restore the default retry value, use the `no` form of this command.

```
retry retry-value

no retry
```

### Syntax Description

<table>
<thead>
<tr>
<th>retry-value</th>
<th>Time, in seconds, to wait after the detection of a server failure before a new connection to the server is attempted.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>If the new connection attempt succeeds, the real server is placed in OPERATIONAL state. If the connection attempt fails, the timer is reset, the connection is reassigned, and the process repeats until it is successful or until the server is placed OUTOFSERVICE by the network administrator.</td>
</tr>
<tr>
<td></td>
<td>Valid values range from 1 to 3600. The default value is 60 seconds.</td>
</tr>
<tr>
<td></td>
<td>A value of 0 means do not attempt a new connection to the server when it fails.</td>
</tr>
</tbody>
</table>

### Defaults

The `retry-value` default is 60 seconds.

### Command Modes

SLB real server configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

### Examples

The following example specifies that 120 seconds must elapse after the detection of a server failure before a new connection is attempted:

```
ip slb serverfarm PUBLIC
real 10.10.1.1
retry 120
```

### Related Commands

serverfarm

To associate a real server farm with a virtual server, use the `serverfarm` SLB virtual server configuration command. To remove the server farm association from the virtual server configuration, use the `no` form of this command.

```
serverfarm serverfarm-name

no serverfarm
```

**Syntax Description**

```
serverfarm-name
```

Name of a server farm that has already been defined using the `ip slb serverfarm` command.

**Defaults**

No default behavior or values.

**Command Modes**

SLB virtual server configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>

<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

**Examples**

The following example shows how the `ip slb vserver`, `virtual`, and `serverfarm` commands are used to associate the real server farm named PUBLIC with the virtual server named PUBLIC_HTTP:

```
ip slb vserver PUBLIC_HTTP
virtual 10.0.0.1 tcp www
serverfarm PUBLIC
```

**Related Commands**

<tr>
<td>ftp-cntrl</td>
<td>Number of FTP control connections currently using this sticky assignment.</td>
</tr>
</tbody>
</table>
show ip slb vservers

To display information about the virtual servers, use the `show ip slb vservers` privileged EXEC command.

```
show ip slb vservers [name virtserver-name] [detail]
```

**Syntax Description**

- **name** (Optional) Displays information about only this virtual server.
- **virtserver-name** (Optional) Name of the virtual server.
- **detail** (Optional) Displays detailed virtual server information.

**Defaults**

If no options are specified, the command displays information about all virtual servers.

**Command Modes**

Privileged EXEC

**Command History**

<tr>
<td>state</td>
<td>Current state of the virtual server detailed on a given line.</td>
</tr>
<tr>
<td>conns</td>
<td>Number of connections associated with the virtual server detailed on a given line.</td>
</tr>
</tbody>
</table>
**sticky**

To assign all connections from a client to the same real server, use the `sticky` virtual server configuration command. To remove the client/server coupling, use the `no` form of this command.

```
sticky duration [group group-id]
no sticky
```

### Syntax Description

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>duration</td>
<td>Sticky timer duration (in seconds). Valid values range from 0 to 65535.</td>
</tr>
<tr>
<td>group</td>
<td>(Optional) Places the virtual server in a sticky group, for coupling of services.</td>
</tr>
<tr>
<td>group-id</td>
<td>(Optional) Number identifying the sticky group to which the virtual server belongs. Valid values range from 0 to 255.</td>
</tr>
</tbody>
</table>

### Defaults

Sticky connections are not tracked.

Virtual servers are not associated with any groups.

### Command Modes

SLB virtual server configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

The last real server that was used for a connection from a client is stored for the set `duration` seconds. If a new connection from the client to the virtual server is initiated during that time, the same real server that was used for the previous connection is chosen for the new connection. If two virtual servers are placed in the same group, coincident connection requests for those services from the same IP address are handled by the same real server.

### Examples

The following example specifies that if a subsequent request from a client for a virtual server is made within 60 seconds of the previous request, then the same real server is used for the connection. This example also places the virtual server in group 10.

```
ip slb vserver VS1
sticky 60 group 10
```
### Related Commands

</tr>
</tbody>
</table>
**synguard**

To limit the rate of TCP SYNs handled by a virtual server to prevent an SYN flood Denial-of-Service attack, use the `synguard` virtual server configuration command. To remove the threshold, use the `no` form of this command.

```
synguard syncount [interval]
```

```
no synguard
```

### Syntax Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>syncount</code></td>
<td>Number of unanswered SYNs that are allowed to be outstanding to a virtual server. Valid values range from 0 (off) to 4294967295. The default is 0.</td>
</tr>
<tr>
<td><code>interval</code></td>
<td>(Optional) Interval (in milliseconds) for SYN threshold monitoring. Valid values range from 50 to 5000. The default is 100 ms.</td>
</tr>
</tbody>
</table>

### Defaults

The default SYN count is 0 (off).
The default interval is 100 ms.

### Command Modes

SLB virtual server configuration

### Command History

<table>

virtual

To configure virtual server attributes, use the `virtual` virtual server configuration command. To remove the attributes, use the `no` form of this command.

```
virtual ip-address {tcp | udp} port-number [service service-name]
```

```
no virtual
```

**Syntax Description**

- **ip-address**: IP address for this virtual server instance, used by clients to connect to the server farm.
- **tcp**: Performs load balancing for only TCP connections.
- **udp**: Performs load balancing for only UDP connections.

**port-number**: (Optional) IOS SLB virtual port (the TCP or UDP port number or port name). If specified, only the connections for the specified port on the server are load balanced. The ports and the valid name or number for the `port-number` argument are as follows:

- Domain Name System: `dns 53`
- File Transfer Protocol: `ftp 21`
- HTTP over Secure Socket Layer: `https 443`
- Mapping of Airline Traffic over IP, Type A: `matip-a 350`
- Network News Transport Protocol: `nntp 119`
- Post Office Protocol v2: `pop2 109`
- Post Office Protocol v3: `pop3 110`
- Simple Mail Transport Protocol: `smtp 25`
- Telnet: `telnet 23`
- World Wide Web (HTTP): `www 80`

Specify a port number of `0` to configure an all-port virtual server (that is, a virtual server that accepts flows destined for all ports).

- **service**: (Optional) Couple connections associated with a given service, such as HTTP or Telnet, so all related connections from the same client use the same real server.

- **service-name**: (Optional) Type of connection coupling. Currently, the only choice is `ftp`. Couple FTP data connections with the control session that created them.

**Defaults**

- No default behavior or values.

**Command Modes**

- SLB virtual server configuration
**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(7)XE</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.1(5)T</td>
<td>This command was integrated into Cisco IOS Release 12.1(5)T.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The **no virtual** command is allowed only if the virtual server was removed from service by the **no inservice** command.

For some applications, it is not feasible to configure all the virtual server TCP or UDP port numbers for the IOS SLB feature. To support such applications, you can configure IOS SLB virtual servers to accept flows destined for all ports. To configure an all-port virtual server, specify a port number of 0.

**Note**

In general, you should use port-bound virtual servers instead of all-port virtual servers. When you use all-port virtual servers, flows can be passed to servers for which no application port exists. When servers reject these flows, IOS SLB might fail the server and remove it from load balancing.

**Examples**

The following example specifies that the virtual server with the IP address 10.0.0.1 performs load balancing for TCP connections for the port named www. The virtual server processes HTTP requests.

```
ip slb vserver PUBLIC_HTTP
virtual 10.0.0.1 tcp www
```

</table>
weight

To specify the capacity of a real server relative to other real servers in the server farm, use the **weight** real server configuration command. To restore the default weight value, use the **no** form of this command.

```
weight weighting-value

no weight
```

**Syntax Description**

| weighting-value | Weighting value to use for real server predictor algorithm. Valid values range from 1 to 155. The default weighting value is 8. |

**Defaults**

The default weighting value is 8.

**Command Modes**

SLB real server configuration

**Command History**

<table>

Mobile IP Commands

Use the commands in this chapter to configure and monitor Mobile IP. For Mobile IP configuration information and examples, refer to the “Configuring Mobile IP” chapter of the *Cisco IOS IP Configuration Guide*. 
aaa authorization ipmobile

To authorize Mobile IP to retrieve security associations from the AAA server using TACACS+ or RADIUS, use the `aaa authorization ipmobile` global configuration command. To remove authorization, use the `no` form of this command.

```
aaa authorization ipmobile { [radius | tacacs+] | default } [group server-groupname]
no aaa authorization ipmobile { [radius | tacacs+] | default } [group server-groupname]
```

### Syntax Description

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>radius</td>
<td>Authorization list named radius.</td>
</tr>
<tr>
<td>tacacs+</td>
<td>Authorization list named tacacs+.</td>

<td>Default authorization list.</td>
</tr>
<tr>
<td>group</td>
<td>Name of the server group to use.</td>
</tr>
<tr>
<td>server-groupname</td>
<td>Name of the server group to use.</td>
</tr>
</tbody>
</table>

### Defaults

AAA is not used to retrieve security associations for authentication.

### Command Modes

Global configuration

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

Mobile IP requires security associations for registration authentication. The security associations are configured on the router or on a AAA server. This command is not needed for the former; but in the latter case, this command authorizes Mobile IP to retrieve the security associations from the AAA server.

Once the authorization list is named, it can be used in other areas such as login. You can only use one named authorization list; multiple named authorization lists are not supported.

The `aaa authorization ipmobile default group server-groupname` command is the most commonly used method to retrieve security associations from the AAA server.

*Note*

The AAA server does not authenticate the user. It stores the security association that is retrieved by the router to authenticate registration.

### Examples

The following example uses TACACS+ to retrieve security associations from the AAA server:

```
aaa new-model
aaa authorization ipmobile tacacs+
tacacs-server host 1.2.3.4
tacacs-server key mykey
ip mobile host 10.0.0.1 10.0.0.5 virtual-network 10.0.0.0 255.0.0.0 aaa
```
The following example uses RADIUS as the default group to retrieve security associations from the AAA server:

```
aaa new-model
aaa authentication login default enable
aaa authorization ipmobile default group radius
aaa session-id common
radius-server host 128.107.162.173 auth-port 1645 acct-port 1646
radius-server retransmit 3
radius-server key cisco
ip mobile host 10.0.0.1 10.0.0.5 virtual-network 10.0.0.0 255.0.0.0
```

**Related Commands**

</tr>
<tr>
<td></td>
<td>• all</td>
</tr>
<tr>
<td></td>
<td>• load</td>
</tr>
<tr>
<td></td>
<td>• standby-group-name</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The home agent creates a mobility binding for each roaming mobile node. The mobility binding allows the mobile node to exchange packets with the correspondent node. Associated with the mobility binding is the tunnel to the visited network and a host route to forward packets destined for the mobile node. There should be no need to clear the binding because it expires after lifetime is reached or when the mobile node deregisters.

When the mobility binding is removed, the number of users on the tunnel is decremented and the host route is removed from the routing table. The mobile node is not notified.

Use this command with care, because it may terminate any sessions used by the mobile node. After using this command, the visitor will need to reregister to continue roaming.

**Examples**

The following example administratively stops mobile node 10.0.0.1 from roaming:

```
Router# clear ip mobile binding 10.0.0.1
Router# show ip mobile binding
```

**Mobility Binding List:**

```
Total 1
10.0.0.1:
    Care-of Addr 68.0.0.31, Src Addr 68.0.0.31,
    Lifetime granted 02:46:40 (10000), remaining 02:46:32
    Flags SbdmGvt, Identification B750FAC4.C28F56A8,
    Tunnel100 src 66.0.0.5 dest 68.0.0.31 reverse-allowed
    Routing Options - (G)GRE
```
## Mobile IP Commands

**clear ip mobile binding**

<td>(Optional) Upper end of range of IP addresses.</td>
</tr>
<tr>
<td>empty</td>
<td>Load in only mobile nodes without security associations. Must be used with the load keyword.</td>
</tr>
<tr>
<td>all</td>
<td>Clears all mobile nodes.</td>
</tr>
<tr>
<td>load</td>
<td>(Optional) Reload the security association from the AAA server after security association has been cleared.</td>
</tr>
</tbody>
</table>

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Security associations are required for registration authentication. They can be stored on an AAA server. During registration, they may be stored locally after retrieval from the AAA server. The security association on the router may become stale or out of date when the security association on the AAA server changes.

This command clears security associations that have been downloaded from the AAA server.

**Note**

Security associations that are manually configured on the router or not stored on the router after retrieval from the AAA server are not applicable.

**Examples**

In the following example, the AAA server has the security association for user 10.0.0.1 after registration:

Router# show ip mobile secure host 10.0.0.1

Security Associations (algorithm,mode,replay protection,key):
10.0.0.1:
SPI 300, MD5, Prefix-suffix, Timestamp +/- 7,
Key 'oldkey' 1230552d39b7c1751f86bae5209ec0c8

The security association of the AAA server changes as follows:

Router# clear ip mobile secure host 10.0.0.1 load

Router# show ip mobile secure host 10.0.0.1
10.0.0.1:
   SPI 300, MD5, Prefix-suffix, Timestamp +/- 7,
   Key ‘newkey’ 1230552d39b7c1751f86bae5205ec0c8

<table>

</tbody>
</table>
clear ip mobile traffic

To clear counters, use the `clear ip mobile traffic` EXEC command.

```
clear ip mobile traffic [undo]
```

Syntax Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>undo</code></td>
<td>Restores the previously cleared counters.</td>
</tr>
</tbody>
</table>

Command Modes

`EXEC`

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

Usage Guidelines

Mobile IP counters are accumulated during operation. They are useful for debugging and monitoring. This command clears all Mobile IP counters. The `undo` keyword restores the counters (this is useful for debugging). See the `show ip mobile traffic` command for a description of all counters.

Examples

The following example shows how the counters can be used for debugging:

```
Router# show ip mobile traffic
IP Mobility traffic:
Advertisements:
    Solicitations received 0
    Advertisements sent 0, response to solicitation 0
Home Agent Registrations:
    Register 8, Deregister 0 requests
    Register 7, Deregister 0 replied
    Accepted 6, No simultaneous bindings 0
    Denied 1, Ignored 1
    Unspecified 0, Unknown HA 0
    Administrative prohibited 0, No resource 0
    Authentication failed MN 0, FA 0
    Bad identification 1, Bad request form 0
.
Router# clear ip mobile traffic
Router# show ip mobile traffic
IP Mobility traffic:
Advertisements:
    Solicitations received 0
    Advertisements sent 0, response to solicitation 0
Home Agent Registrations:
    Register 0, Deregister 0 requests
    Register 0, Deregister 0 replied
    Accepted 0, No simultaneous bindings 0
    Denied 0, Ignored 0
    Unspecified 0, Unknown HA 0
    Administrative prohibited 0, No resource 0
    Authentication failed MN 0, FA 0
    Bad identification 0, Bad request form 0
```

</table>
clear ip mobile visitor

To remove visitor information, use the clear ip mobile visitor EXEC command.

```
clear ip mobile visitor [ip-address]
```

**Syntax Description**

- `ip-address` (Optional) IP address. If not specified, visitor information will be removed for all addresses.

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The foreign agent creates a visitor entry for each accepted visitor. The visitor entry allows the mobile node to receive packets while in a visited network. Associated with the visitor entry is the ARP entry for the visitor. There should be no need to clear the entry because it expires after lifetime is reached or when the mobile node deregisters.

When a visitor entry is removed, the number of users on the tunnel is decremented and the ARP entry is removed from the ARP cache. The visitor is not notified.

Use this command with care because it may terminate any sessions used by the mobile node. After using this command, the visitor will need to reregister to continue roaming.

**Examples**

The following example administratively stops visitor 10.0.0.1 from visiting:

```
Router# clear ip mobile visitor 10.0.0.1
```

**Related Commands**

<table>

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

This command enables foreign agent service when at least one care-of address is configured. When no care-of address exists, foreign agent service is disabled.

The foreign agent is responsible for relaying the registration request to the home agent, setting up tunnel to the home agent, and forwarding packets to the mobile node. The `show` commands used to display relevant information are shown in parentheses in the following paragraph.

When a registration request comes in, the foreign agent will ignore requests when foreign agent service is not enabled on interface or no care-of address is advertised. If a security association exists for a visiting mobile node, the visitor is authenticated (`show ip mobile secure visitor` command). The registration bitflag is handled as described in Table 38 (`show ip mobile interface` command). The foreign agent checks the validity of the request. If successful, the foreign agent relays the request to the home agent, appending an FH authentication extension if a security association for the home agent exists. The pending registration timer of 15 seconds is started (`show ip mobile visitor pending` command). At most, five outstanding pending requests per mobile node are allowed. If a validity check fails, the foreign agent sends a reply with error code to the mobile node (reply codes are listed in Table 39). A security violation is logged when visiting mobile node authentication fails (`show ip mobile violation` command). (Violation reasons are listed in Table 43.)

When a registration reply comes in, the home agent is authenticated (`show ip mobile secure home-agent` command) if a security association exists for the home agent (IP source address or home agent address in reply). The reply is relayed to the mobile node.
When registration is accepted, the foreign agent creates or updates the visitor table, which contains the expiration timer. If no binding existed before this registration, a virtual tunnel is created, a host route to the mobile node via the interface (of the incoming request) is added to the routing table (show ip route mobile command), and an ARP entry is added to avoid sending ARP requests for the visiting mobile node. Visitor binding is removed (along with its associated host route, tunnel, and ARP entry) when the registration lifetime expires or deregistration is accepted.

When registration is denied, the foreign agent will remove the request from the pending registration table. The table and timers of the visitor will be unaffected.

When a packet destined for the mobile node arrives on the foreign agent, the foreign agent will deencapsulates the packet and forwards it out its interface to the visiting mobile node, without sending ARP requests.

The care-of address must be advertised by the foreign agent. This is used by the mobile node to register with the home agent. The foreign agent and home agent use this address as the source and destination point of tunnel, respectively. The foreign agent is not enabled until at least one care-of address is available. The foreign agent will advertise on interfaces configured with the ip mobile foreign-service command.

Only care-of addresses with interfaces that are up are considered available.

Table 38 lists foreign agent registration bitflags.

# ip mobile foreign-service

To enable foreign agent service on an interface if care-of addresses are configured, use the `ip mobile foreign-service` interface configuration command. To disable this service, use the `no` form of this command.

```
ip mobile foreign-service [home-access acl] [limit number] [registration-required]
```

```
no ip mobile foreign-service [home-access acl] [limit number] [registration-required]
```

## Syntax Description

**Syntax**

- `home-access acl` *(Optional)* Controls which home agent addresses mobile nodes can be used to register. The access list can be a string or number from 1 to 99. You cannot use this keyword when you enable foreign agent service on a subinterface.

- `limit number` *(Optional)* Number of visitors allowed on interface. The Busy (B) bit will be advertised when the number of registered visitors reach this limit. Range is from 1 to 1000. Default is no limit. You cannot use this keyword when you enable foreign agent service on a subinterface.

- `registration-required` *(Optional)* Solicits registration from the mobile node even if it uses colocated care-of addresses. The Registration-required (R) bit will be advertised. You cannot use this keyword when you enable foreign agent service on a subinterface.

## Defaults

Disabled. Default is no limit to the number of visitors allowed on an interface.

## Command Modes

Interface configuration

## Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

## Usage Guidelines

This command enables foreign agent service on the interface. The foreign agent (F) bit will be set in the agent advertisement, which is appended to the IRDP router advertisement whenever the foreign agent or home agent service is enabled on the interface.

**Note**

The Registration-required bit only tells the visiting mobile node to register even if the visiting mobile node is using a colocated care-of address. You must set up packet filters to enforce this. For example, you could deny packets destined for port 434 from the interface of this foreign agent.

Table 40 lists the advertised bitflags.
Table 40  Foreign Agent Advertisement Bitflags

<table>
<thead>
<tr>

### ip mobile home-agent

To enable and control home agent services on the router, use the `ip mobile home-agent` global configuration command. To disable these services, use the `no` form of this command.

```
ip mobile home-agent [address ip-address][broadcast] [care-of-access acl] [lifetime number] [replay seconds] [reverse-tunnel-off] [roam-access acl] [suppress-unreachable]

no ip mobile home-agent [broadcast] [care-of-access acl] [lifetime number] [replay seconds] [reverse-tunnel-off] [roam-access acl] [suppress-unreachable]
```

#### Syntax Description

- **address ip-address** *(Optional)* Specifies the IP address of the home agent. This option is only applicable when home agent redundancy is used for virtual networks.
- **broadcast** *(Optional)* Enables broadcast datagram routing. By default, broadcasting is disabled.
- **care-of-access acl** *(Optional)* Controls which care-of addresses (in registration request) are permitted by the home agent. By default, all care-of addresses are permitted. The access control list can be a string or number from 1 to 99.
- **lifetime number** *(Optional)* Specifies the global registration lifetime for a mobile node. Note that this can be overridden by the individual mobile node configuration. Range is from 3 to 65535 (infinity). Default is 36000 seconds (10 hours). Registrations requesting a lifetime greater than this value will still be accepted, but will use this lifetime value.
- **replay seconds** *(Optional)* Sets the replay protection time-stamp value. Registration received within this time is valid.
- **reverse-tunnel-off** *(Optional)* Disables support of reverse tunnel by the home agent. By default, reverse tunnel support is enabled.
- **roam-access acl** *(Optional)* Controls which mobile nodes are permitted or denied to roam. By default, all specified mobile nodes can roam.
- **suppress-unreachable** *(Optional)* Disables sending ICMP unreachable messages to the source when a mobile node on the virtual network is not registered, or when a packet came in from a tunnel interface created by the home agent (in the case of a reverse tunnel). By default, ICMP unreachable messages are sent.

#### Defaults

Disabled. Broadcasting is disabled by default. Reverse tunnel support is enabled by default. ICMP Unreachable messages are sent by default.

#### Command Modes

Global configuration

#### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>
This command enables and controls home agent services on the router. Changes to service take effect immediately; however, broadcast and lifetime settings for previously registered mobile nodes are unaffected. Tunnels are shared by mobile nodes registered with the same endpoints, so the reverse-tunnel-off keyword also affects registered mobile nodes.

The home agent is responsible for processing registration requests from the mobile node and setting up tunnels and routes to the care-of address. Packets to the mobile node are forwarded to the visited network.

The home agent will forward broadcast packets to mobile nodes if they registered with the service. However, heavy broadcast traffic utilizes the CPU of the router. The home agent can control where the mobile nodes roam by the care-of-access parameter, and which mobile node is allowed to roam by the roam-access parameter.

When a registration request comes in, the home agent will ignore requests when home agent service is not enabled or the security association of the mobile node is not configured. The latter condition occurs because the security association must be available for the MH authentication extension in the reply. If a security association exists for the foreign agent (IP source address or care-of address in request), the foreign agent is authenticated, and then the mobile node is authenticated. The Identification field is verified to protect against replay attack. The home agent checks the validity of the request (see Table 41) and sends a reply. (Replay codes are listed in Table 42.) A security violation is logged when foreign agent authentication, MH authentication, or Identification verification fails. (The violation reasons are listed in Table 43.)

After registration is accepted, the home agent creates or updates the mobility binding of the mobile node, which contains the expiration timer. If no binding existed before this registration, a virtual tunnel is created, a host route to the mobile node via the care-of address is added to the routing table, and gratuitous ARPs are sent out. For deregistration, the host route is removed from the routing table, the virtual tunnel interface is removed (if no mobile nodes are using it), and gratuitous ARPs are sent out if the mobile node is back home. Mobility binding is removed (along with its associated host route and tunnel) when registration lifetime expires or deregistration is accepted.

When the packet destined for the mobile node arrives on the home agent, the home agent encapsulates the packet and tunnels it to the care-of address. If the Don’t fragment bit is set in the packet, the outer bit of the IP header is also set. This allows the Path MTU Discovery to set the MTU of the tunnel. Subsequent packets greater than the MTU of the tunnel will be dropped and an ICMP datagram too big message sent to the source. If the home agent loses the route to the tunnel endpoint, the host route to the mobile node will be removed from the routing table until tunnel route is available. Packets destined for the mobile node without a host route will be sent out the interface (home link) or to the virtual network (see the description of suppress-unreachable keyword). For subnet-directed broadcasts to the home link, the home agent will send a copy to all mobile nodes registered with the broadcast routing option.

Table 41 describes how the home agent treats registrations with various bits set when authentication and identification are passed.

ip mobile home-agent resync-sa

To configure the home agent to clear out the old cached security associations and query the AAA server for a new security association when the mobile node fails authentication, use the `ip mobile home-agent resync-sa` command in global configuration mode. To disable this functionality, use the `no` form of this command.

```
ip mobile home-agent resync-sa sec

no ip mobile home-agent resync-sa sec
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sec</code></td>
<td>Specifies the time in which the home agent will wait to initiate a resynchronization.</td>
</tr>
</tbody>
</table>

**Defaults**

This command is off by default. The normal behavior of the home agent is to never query the AAA server for a new security association.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

You must enable security association caching for the `ip mobile home-agent resync-sa` command to work. Use the `ip mobile host aaa load-sa` global configuration command to enable caching of security associations retrieved from a AAA server.

When a security association is downloaded for a mobile node from a AAA server, the security association is time stamped. If the mobile node fails reregistration and the time interval since the security association was cached is greater than `sec` seconds, the home agent will clear out the old security association and query the AAA server. If the time period is less than the `sec` value, the home agent will not query the AAA server for the security association of the mobile node.

The `sec` value represents the number of seconds the home agent will consider the downloaded security association synchronized with the AAA server. After that time period, it is considered old and can be replaced by a new security association from the AAA server.

This time-based resynchronization process helps prevent denial-of-service attacks on the AAA server and provides a way to synchronize the home agent’s cached security association entry when a change to the security association for the mobile node is made at the AAA server and on the mobile node. By using this process, once the mobile node fails reregistration with the old cached security association, the home agent will clear the cache for that mobile node, and resynchronize with the AAA server.
Examples

In the following example, if a registration fails authentication, the home agent retrieves a new security association from the AAA server if the existing security association was downloaded more than 10 seconds ago:

```
ip mobile home-agent resync-sa 10
```
**ip mobile home-agent standby**

To configure the home agent (HA) for redundancy by using the Hot Standby Router Protocol (HSRP) group name, use the `ip mobile home-agent standby` global configuration command. To remove the address, use the `no` form of this command.

```
ip mobile home-agent standby hsrp-group-name [virtual-network] address address
no ip mobile home-agent standby hsrp-group-name [virtual-network] address address
```

<table>
<thead>
<tr>
<th>Syntax Description</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>hsrp-group-name</code></td>
<td>Specifies the HSRP group name.</td>
</tr>
<tr>
<td><code>virtual-network</code></td>
<td>(Optional) Specifies that the HSRP group is used to support virtual networks.</td>
</tr>
<tr>
<td><code>address address</code></td>
<td>(Optional) Home agent address.</td>
</tr>
</tbody>
</table>

**Defaults**

No global home agent addresses are specified.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(2)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The `virtual-network` keyword specifies that the HSRP group supports virtual networks.

```
Note
```

Redundant home agents must have identical Mobile IP configurations. You can use a standby group to provide HA redundancy for either physical or virtual networks, but not both at the same time.

When Mobile IP standby is configured, the home agent can request mobility bindings from the peer home agent. When Mobile IP standby is deconfigured, the home agent can remove mobility bindings. Operation of home agent redundancy on physical and virtual networks is described as follows:

- **Physical Network**—Only the active home agent will receive registrations on a physical network. It updates the standby home agent. The standby home agent requests the mobility binding table from the active home agent. When Mobile IP standby is deconfigured, the standby home agent removes all bindings, but the active home agent keeps all bindings.

- **Virtual Network**—Both active and standby home agents receive registrations if the loopback interface is used; each will update the peer after accepting a registration. Otherwise, the active home agent receives registrations. Both active and standby home agents request mobility binding tables from each other. When Mobile IP standby is deconfigured, the standby or active home agent removes all bindings.
Mobile IP Commands

Examples

The following example specifies an HSRP group named SanJoseHA:

```
ip mobile home-agent standby SanJoseHA
```

Related Commands

ip mobile host

To configure the mobile host or mobile node group, use the `ip mobile host` global configuration command.

```
ip mobile host lower [upper] {interface name | virtual-network net mask} [aaa [load-sa]]
    [care-of-access acl] [lifetime number]

no ip mobile host lower [upper] {interface name | virtual-network net mask} [aaa [load-sa]]
    [care-of-access acl] [lifetime number]
```

### Syntax Description

- **lower [upper]**  
  Range of mobile host or mobile node group IP addresses.

- **interface name**  
  Mobile node that belongs to the specified interface.

- **virtual-network net mask**  
  The wireless mobile node resides in the virtual network created using the `ip mobile virtual-network` command.

- **aaa**  
  (Optional) Retrieves security associations from AAA (TACACS+ or RADIUS) server.

- **load-sa**  
  (Optional) Stores security associations in memory after retrieval.

- **care-of-access acl**  
  (Optional) Access list. This can be a string or number from 1 to 99. Controls where mobile nodes roam—the acceptable care-of addresses.

- **lifetime number**  
  (Optional) Lifetime (in seconds). The lifetime for each mobile node (group) can be set to override the global value. Range is from 3 to 65535.

### Defaults

No host is configured.

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

This command configures the mobile host or mobile node group (ranging from `lower` address to `upper` address) to be supported by the home agent. These mobile nodes belong to the network on an interface or a virtual network (via the `ip mobile virtual-network` command). The security association for each mobile host must be configured using the `ip mobile secure` command or downloaded from an AAA server. When using an AAA server, the router will attempt to download all security associations when the command is entered. If no security associations are retrieved, retrieval will be attempted when a registration request arrives or the `clear ip mobile secure` command is entered.

All hosts must have security associations for registration authentication. Mobile nodes can have more than one security association. The memory consumption calculations shown in Table 44 are based on the assumption of one security association per mobile node.
Security associations can be stored using one of three methods:

- On the router
- On the AAA server, retrieve security association each time registration comes in
- On the AAA server, retrieve and store security association

Each method has advantages and disadvantages, which are described in Table 44.

**Table 44 Methods for Storing Security Associations**

<table>
<thead>
<tr>
<th>Storage Method</th>

<td>(for example, using RADIUS or unencrypted TACACS+ mode).</td>
</tr>
</tbody>
</table>
Mobile IP Commands

Table 44  Methods for Storing Security Associations (continued)

<table>
<thead>
<tr>
<th>Storage Method</th>
<th>Advantage</th>
<th>Disadvantage</th>
</tr>
</thead>
<tbody>
<tr>
<td>On the AAA server, retrieve and store security association</td>
<td>• AAA acts as an offload configuration server, security associations are loaded into router DRAM, which is more abundant (for example, 16 MB, 32 MB, 64 MB) when the first registration comes in. Each security association takes only about 50 bytes of DRAM, so 10,000 mobile nodes will use up 0.5 MB. • If keys remain fairly constant, once security associations are loaded, home agent authenticates as fast as when stored on the router. • Only security associations that are needed are loaded into router memory. Mobile nodes that never register will not waste memory.</td>
<td>• If keys change on the AAA server after the mobile node registered, then you need to use <code>clear ip mobile secure</code> command to clear and load in new security association from AAA, otherwise the security association of the router is stale.</td>
</tr>
</tbody>
</table>

Examples

The following example configures a mobile node group to reside on virtual network 20.0.0.0 and store its security associations on the AAA server:

```
ip mobile host 20.0.0.1 20.0.0.3 virtual-network 20.0.0.0 aaa
```

</table>
**ip mobile prefix-length**

To append the prefix-length extension to the advertisement, use the **ip mobile prefix-length** interface configuration command. To restore the default, use the **no** form of this command.

```
ip mobile prefix-length
no ip mobile prefix-length
```

**Syntax Description**

This command has no arguments or keywords.

**Defaults**

The prefix-length extension is not appended.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The prefix-length extension is used for movement detection. When a mobile node registered with one foreign agent receives an agent advertisement from another foreign agent, the mobile node uses the prefix-length extension to determine whether the advertisements arrived on the same network. The mobile node needs to register with the second foreign agent if it is on a different network. If the second foreign agent is on the same network, reregistration is not necessary.

**Examples**

The following example appends the prefix-length extension to agent advertisements sent by a foreign agent:

```
ip mobile prefix-length
```

**Related Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>

<td></td>
</tr>
</tbody>
</table>
**ip mobile registration-lifetime**

To set the registration lifetime value advertised, use the `ip mobile registration-lifetime` interface configuration command.

```
ip mobile registration-lifetime seconds
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>seconds</code></td>
<td>Lifetime in seconds. Range is from 3 to 65535 (infinity).</td>
</tr>
</tbody>
</table>

**Defaults**

36000 seconds

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command allows an administrator to control the advertised lifetime on the interface. The foreign agent uses this command to control duration of registration. Visitors requesting longer lifetimes will be denied.

**Examples**

The following example sets the registration lifetime to 10 minutes on interface Ethernet 1 and 1 hour on interface Ethernet 2:

```
interface e1
 ip mobile registration-lifetime 600
interface e2
 ip mobile registration-lifetime 3600
```

ip mobile secure aaa-download

To specify that authentication, authorization, and accounting (AAA) mobility security associations (SAs) are downloaded from the AAA server and at what rate the information is downloaded, use the **ip mobile secure aaa-download** command in global configuration mode. To delete the AAA download rate, use the **no** form of this command.

```
ip mobile secure aaa-download rate seconds

no ip mobile secure aaa-download rate seconds
```

**Syntax Description**

<table>
<thead>
<tr>

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

SAs are downloaded from a AAA server on the first use. This command allows the home agent (HA) to prepopulate an SA table.

**Examples**

The following example shows a download rate of 35 seconds:

```
ip mobile secure aaa-download rate 35
```

ip mobile secure foreign-agent

To specify the mobility security associations (SAs) for a foreign agent (FA), use the `ip mobile secure foreign-agent` command in global configuration mode. To remove the mobility SAs, use the `no` form of this command.

```
ip mobile secure foreign-agent lower-address [upper-address] {inbound-spi spi-in outbound-spi spi-out | spi {hex-value | decimal decimal-value}} key {ascii string | hex string} [replay timestamp seconds] [algorithm {md5 mode prefix-suffix | hmac-md5}]
no ip mobile secure foreign-agent lower-address [upper-address] {inbound-spi spi-in outbound-spi spi-out | spi {hex-value | decimal decimal-value}} key {ascii string | hex string} [replay timestamp seconds] [algorithm {md5 mode prefix-suffix | hmac-md5}]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Parameter</th>

</tr>
</tbody>
</table>
**replay timestamp**  
(Optional) Specifies the number of seconds that the router uses for replay protection.  
- *seconds*—Time, in seconds, that a router uses for replay protection. The range is from plus or minus 255. The default is plus or minus 7.  

**Note** The registration packet is considered “not replayed” if the time stamp in the packet is within plus or minus the configured number of seconds of the router clock.  

**algorithm**  
(Optional) Algorithm used to authenticate messages during registration. The keywords are as follows:  
- **md5 mode**—Message Digest 5 (MD5) mode used to authenticate packets during registration.  
- **prefix-suffix**—Wrapped registration information for authentication (for example, key registration information key) that calculates the message digest.  

**Note** Cisco no longer recommends this method of authentication, but it is retained for backward compatibility.  

- **hmac-md5**—Hash-based Message Authentication Code (HMAC) MD5.  

**Note** The HMAC-MD5 authentication algorithm or MD5 (prefix-suffix) authentication algorithm is mandatory for mobile-home authentication (MHAE), mobile-foreign authentication (MFAE), or foreign-home authentication (FHAE).  

**Defaults**  
No SA is specified for FAs.  

**Command Modes**  
Global configuration  

**Command History**

<tr>
<td>12.2(13)T</td>
<td>The <em>hmac-md5</em> keyword was added.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**  
The SA consists of an entity address, SPI, key, replay protection method, authentication algorithm, and authentication algorithm mode (prefix-suffix).  

On a FA, the SA of the visiting mobile host and the SA of the home agent (HA) are optional. Multiple SAs for each entity can be configured.  

The SA of a visiting mobile host on the MFAE and the SA of the HA on the FHAE are optional on the FA as long as they are not specified on the other entity. Multiple SAs for each entity can be configured.  

**Note**  
NTP is not required for operation, but NTP can be used to synchronize time for all parties.
Examples

The following example shows the configuration of SAs for an FA with an IP address of 209.165.200/254:

```
ip mobile secure foreign-agent 209.165.200/254 inbound-spi 203 outbound-spi 150 key hex ffffffff
```

ip mobile secure home-agent

To specify the mobility security associations (SAs) for a home agent (HA), use the ip mobile secure home-agent command in global configuration mode. To remove the mobility SAs, use the no form of this command.

**ip mobile secure home-agent lower-address [upper-address] { inbound-spi spi-in outbound-spi spi-out | spi {hex-value | decimal decimal-value} } key { ascii string | hex string } [ replay timestamp seconds ] [ algorithm { md5 mode prefix-suffix | hmac-md5 } ]

**no ip mobile secure home-agent lower-address [upper-address] { inbound-spi spi-in outbound-spi spi-out | spi {hex-value | decimal decimal-value} } key { ascii string | hex string } [ replay timestamp seconds ] [ algorithm { md5 mode prefix-suffix | hmac-md5 } ]

**Syntax Description**

- **lower-address**
  - IP address of an HA or lower range of IP address pool.
  - **upper-address**—(Optional) Upper range of IP address pool. If specified, SAs for multiple HAs are configured.
  - **Note** The upper-address value must be greater than the lower-address value.

- **inbound-spi**
  - Bidirectional 4-byte security parameter index (SPI) used for authenticating inbound registration packets.
  - **spi-in**—Index for inbound registration packets. The range is from 100 to ffffffff.

- **outbound-spi**
  - SPI used for calculating the authenticator in outbound registration packets.
  - **spi-out**—Index for outbound registration packets. The range is from 100 to ffffffff.

- **spi**
  - SPI authenticates a peer. The argument and keyword are as follows:
    - **hex-value**—SPI expressed as a hexadecimal. The range is from 100 to ffffffff.
    - **Note** Cisco recommends that you use hexadecimal values instead of decimal values for interoperability.
  - **decimal**—Decimal SPI. The argument is as follows:
    - **decimal-value**—SPI expressed as a decimal number. The range is from 256 to 4294967295.

- **key**
  - Security key. The arguments and keywords are as follows:
    - **ascii string**—Security key expressed as an ASCII string. A maximum of 32 characters is allowed. No spaces are allowed.
    - **hex string**—Security key expressed in hexadecimal digits. A maximum of 32 hex digits is allowed. The range is from 100 to ffffffff. No spaces are allowed.
**replay timestamp** (Optional) Specifies the number of seconds that the router uses for replay protection.

- **seconds**—Time, in seconds, that a router uses for replay protection. The range is from plus or minus 255. The default is plus or minus 7.

**Note** The registration packet is considered “not replayed” if the time stamp in the packet is within plus or minus the configured number of seconds of the router clock.

**algorithm** (Optional) Algorithm used to authenticate messages during registration. The keywords are as follows:

- **md5 mode**—Message Digest 5 (MD5) mode used to authenticate packets during registration.
- **prefix-suffix**—Wrapped registration information for authentication (for example, key registration information key) that calculates the message digest.

**Note** Cisco no longer recommends this method of authentication, but it is retained for backward compatibility.

- **hmac-md5**—Hash-based Message Authentication Code (HMAC) MD5.

**Note** The HMAC-MD5 authentication algorithm or MD5 (prefix-suffix) authentication algorithm is mandatory for mobile-home authentication (MHAE), mobile-foreign authentication (MFAE), or foreign-home authentication (FHAE).

**Defaults**

No SA is specified for HAs.

**Command Modes**

Global configuration

</tr>
</tbody>
</table>

**Usage Guidelines**

The SA consists of an entity address, SPI, key, replay protection method, authentication algorithm, and authentication algorithm mode (prefix-suffix).

The HA may have multiple SAs for each peer. The SPI specifies which SA to use for the peer and selects the specific security parameters to be used to authenticate the peer.

On an HA, the SA of the mobile host is mandatory for mobile host authentication and allows the HA to compute the MHAE for mobile host authentication. If desired, configure a foreign agent (FA) SA on your HA.
The mobile IP protocol automatically synchronizes the time stamp used by the mobile node (MN) in its registration requests. If the MN registration request time stamp is outside the HA permitted replay protection time interval, the HA will respond with the number of seconds by which the MN time stamp is off relative to the HA clock. This allows the MN to adjust its time stamp and use synchronized time stamps in subsequent registration attempts.

If you prefer that the MN first registration attempt always falls within the HA replay protection time interval, use Network Time Protocol (NTP) to synchronize the MN and HA.

Note

NTP is not required for operation, but NTP can be used to synchronize time for all parties.

Examples

The following example shows the configuration of an SA for an HA with an IP address of 10.0.0.4:

```
ip mobile secure home-agent 10.0.0.4 spi 100 key hex ffffffff
```

### Usage Guidelines
The SA consists of an entity address, SPI, key, replay protection method, authentication algorithm, and authentication algorithm mode (prefix-suffix).

The SA of a visiting mobile host on the MFAE and the SA of the home agent (HA) on the FHAEE are optional as long as they are not specified on the other entity. Multiple SAs for each entity can be configured.

The HMAC-MD5 authentication algorithm is mandatory for MHAE, MFAE, and FHAEE.

**Note** NTP is not required for operation, but NTP can be used to synchronize time for all parties.
The following example shows the configuration of an SA for a host:

`ip mobile secure host 10.0.0.4 spi 100 key hex 12345678123456781234567812345678`

ip mobile secure mn-aaa

To specify non-standard security parameter index (SPI) values in the MN-AAA authentication extension that need to be accepted by the home agent or the foreign agent, use the `ip mobile secure mn-aaa` command in global configuration mode. To disable this functionality, use the `no` form of this command.

```
ip mobile secure mn-aaa spi {hex-value \| decimal decimal-value} algorithm md5 mode ppp-chap-style
no ip mobile secure mn-aaa spi {hex-value \| decimal decimal-value} algorithm md5 mode ppp-chap-style
```

**Syntax Description**
- **spi**
  - Bidirectional security parameter index (SPI). The index can be a hexadecimal or decimal value. The arguments and keyword are as follows:
  - **hex-value**—SPI expressed in hexadecimal digits. The range is from 100 to ffffffff. No spaces are allowed. The maximum is 32 characters.
  - **decimal decimal-value**—SPI expressed as a decimal number. The range is from 256 to 4294967295. No spaces are allowed. The maximum is 32 characters.

- **algorithm md5 mode**
  - Message Digest 5 (MD5) authentication algorithm used during authentication by the Challenge-Handshake Authentication Protocol (CHAP).

- **ppp-chap-style**

**Defaults**
The home agent or foreign agent only accept the standard SPI value in the MN-AAA authentication extension that specifies CHAP-style authentication using MD5. The standard value for the SPI is 2.

**Command Modes**
Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
The SPI is the 4-byte index that selects the specific security parameters to be used to authenticate the peer. The security parameters consist of the authentication algorithm and mode.

A mobile node configured to be authenticated via an MN-AAA authentication extension is required to use an SPI value of 2 to indicate CHAP-style authentication using MD5 as specified by RFC 3012, *Mobile IPv4 Challenge/Response Extensions*.

Some network implementations need the flexibility to allow an SPI value other than 2 even though the mobile node is authenticated using CHAP. The `ip mobile secure mn-aaa` command maps new SPI values in the MN-AAA extension of the registration message to the SPI value pre-defined by RFC 3012. When a registration request arrives at the foreign agent or home agent with the MN-AAA extension containing an SPI value specified by the `ip mobile secure mn-aaa` command, the foreign agent or home agent will process it as if the value was 2 instead of rejecting the request.
Use this command with caution because it is non-standard behavior. For example, different vendors might use the same non-standard SPI to denote different authentication methods and this could affect interoperability. In general, Cisco recommends the use of standard SPI values to be used in the MN-AAA authentication extension by the mobile node.

**Examples**

In the following example, the foreign agent or home agent will process the registration request even though the CHAP SPI value is not 2:

```
ip mobile secure mn-aaa spi 1234 algorithm md5 mode ppp-chap-style
```
ip mobile secure proxy-host

To specify the mobility security associations (SAs) for a proxy host, use the `ip mobile secure proxy-host` command in global configuration mode. To remove the mobility SAs, use the `no` form of this command.

```
no ip mobile secure proxy-host {lower-address [upper-address] | nai nai-string} {inbound-spi spi-in outbound-spi spi-out | spi {hex-value | decimal decimal-value}} [replay timestamp seconds] [algorithm {md5 mode prefix-suffix | hmac-md5}]
```

**Syntax Description**

- `lower-address` IP address of a proxy host or lower range of IP address pool.
  - `upper-address` (Optional) Upper range of IP address pool. If specified, SAs for multiple proxy hosts are configured.
  - **Note** The `upper-address` value must be greater than the `lower-address` value.

- `nai` Network access identifier (NAI) of the mobile node (MN).
  - `nai-string` NAI username or username@realm.

- `inbound-spi` Bidirectional 4-byte security parameter index (SPI) used for authenticating inbound registration packets.
  - `spi-in` Index for inbound registration packets. The range is from 100 to ffffffff.

- `outbound-spi` SPI used for calculating the authenticator in outbound registration packets.
  - `spi-out` Index for outbound registration packets. The range is from 100 to ffffffff.

- `spi` SPI authenticates a peer. The argument and keyword are as follows:
  - `hex-value` SPI expressed as a hexadecimal. The range is from 100 to ffffffff.
  - **Note** Cisco recommends that you use hexadecimal values instead of decimal values for interoperability.
  - `decimal` Decimal SPI. The argument is as follows:
    - `decimal-value` SPI expressed as a decimal number. The range is from 256 to 4294967295.

- `key` Security key. The arguments and keywords are as follows:
  - `ascii string` Security key expressed as an ASCII string. A maximum of 32 characters is allowed. No spaces are allowed.
  - `hex string` Security key expressed in hexadecimal digits. A maximum of 32 hex digits is allowed. The range is from 100 to ffffffff. No spaces are allowed.
Mobile IP Commands

```
ip mobile secure proxy-host
```

**Defaults**

No SA is specified for proxy hosts.

**Command Modes**

Global configuration

**Command History**

<table>

<tr>
<td>12.3(4)T</td>
<td>The <code>proxy-host</code> keyword was added for Packet Data Serving Node (PDSN) platforms only.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The SA consists of an entity address, SPI, key, replay protection method, authentication algorithm, and authentication algorithm mode (prefix-suffix).

The HMAC-MD5 authentication algorithm is mandatory for MHAE, MFAE, and FHAE.

**Note**

The `proxy-host` keyword is available only on PDSN platforms that are running specific PDSN code images; consult Cisco Feature Navigator for your Cisco IOS software release.
Mobile IP Commands

Note

NTP is not required for operation, but NTP can be used to synchronize time for all parties.

Examples

The following example shows the configuration of an SA for a proxy host:

```
ip mobile secure proxy-host 10.0.0.4 spi 100 key hex 12345678123456781234567812345678
```

ip mobile secure visitor

To specify the mobility security associations (SAs) for a visitor, use the `ip mobile secure visitor` command in global configuration mode. To remove the mobility security associations, use the `no` form of this command.

```
ip mobile secure visitor [lower-address [upper-address] | nai nai-string] [inbound-spi spi-in outbound-spi spi-out | spi {hex-value | decimal decimal-value}] {key {ascii string | hex string} [replay timestamp seconds] [algorithm {md5 mode prefix-suffix | hmac-md5}]]
```

```
o ip mobile secure visitor [lower-address [upper-address] | nai nai-string] [inbound-spi spi-in outbound-spi spi-out | spi {hex-value | decimal decimal-value}] {key {ascii string | hex string} [replay timestamp seconds] [algorithm {md5 mode prefix-suffix | hmac-md5}]]
```

### Syntax Description

**lower-address**

- **IP address of a visitor or lower range of IP address pool.**
  - **upper-address**—(Optional) Upper range of IP address pool. If specified, SAs for multiple visitors are configured.
  
  **Note** The `upper-address` value must be greater than the `lower-address` value.

**nai**

- **Network access identifier (NAI) of the mobile node (MN).**
  - **nai-string**—NAI username or username@realm.

**inbound-spi**

- **Bidirectional 4-byte security parameter index (SPI) used for authenticating inbound registration packets.**
  - **spi-in**—Index for inbound registration packets. The range is from 100 to ffffff.

**outbound-spi**

- **SPI used for calculating the authenticator in outbound registration packets.**
  - **spi-out**—Index for outbound registration packets. The range is from 100 to ffffff.

**spi**

- **SPI authenticates a peer.** The argument and keyword are as follows:
  - **hex-value**—SPI expressed as a hexadecimal. The range is from 100 to ffffff.
  
  **Note** Cisco recommends that you use hexadecimal values instead of decimal values for interoperability.
  - **decimal**—Decimal SPI. The argument is as follows:
    - **decimal-value**—SPI expressed as a decimal number. The range is from 256 to 4294967295.

**key**

- **Security key.** The arguments and keywords are as follows:
  - **ascii string**—Security key expressed as an ASCII string. A maximum of 32 characters is allowed. No spaces are allowed.
  - **hex string**—Security key expressed in hexadecimal digits. A maximum of 32 hex digits is allowed. The range is from 100 to ffffffff. No spaces are allowed.
**ip mobile secure visitor**

**Defaults**
No SA is specified for visitors.

</tr>
</tbody>
</table>

**Usage Guidelines**

The SA consists of an entity address, SPI, key, replay protection method, authentication algorithm, and authentication algorithm mode (prefix-suffix).

The SA of a visiting mobile host on the MFAE and the SA of the home agent (HA) on the FFAE are optional as long as they are not specified on the other entity. Multiple SAs for each entity can be configured.

**replay timestamp**
(Optional) Specifies the number of seconds that the router uses for replay protection.

- *seconds*—Time, in seconds, that a router uses for replay protection. The range is from plus or minus 255. The default is plus or minus 7.

**algorithm**
(Optional) Algorithm used to authenticate messages during registration. The keywords are as follows:

- *md5 mode*—Message Digest 5 (MD5) mode used to authenticate packets during registration.
- *prefix-suffix*—Wrapped registration information for authentication (for example, key registration information key) that calculates the message digest.

**Note** Cisco no longer recommends this method of authentication, but it is retained for backward compatibility.

**Note** The HMAC-MD5 authentication algorithm or MD5 (prefix-suffix) authentication algorithm is mandatory for mobile-home authentication (MHAE), mobile-foreign authentication (MFAE), or foreign-home authentication (FHAE).
The Mobile IP protocol automatically synchronizes the time stamp used by the MN in its registration requests. If the MN registration request time stamp is outside the visitor permitted replay protection time interval, the visitor will respond with the number of seconds the MN time stamp is off relative to the visitor clock. This allows the MN to adjust its time stamp and use synchronized time stamps in subsequent registration attempts.

If you prefer that the MN first registration attempt always fall within the visitor replay protection time interval, use Network Time Protocol (NTP) to synchronize the MN and visitor.

The HMAC-MD5 authentication algorithm is mandatory for MHAE, MFAE, and FFAE.

Note

NTP is not required for operation, but NTP can be used to synchronize time for all parties.

Examples

The following example shows the configuration of an SA for a visitor:

```
ip mobile secure visitor 10.0.0.4 spi 100 key hex 12345678123456781234567812345678
```

</table>
ip mobile tunnel

To specify the settings of tunnels created by Mobile IP, use the ip mobile tunnel global configuration command.

```
ip mobile tunnel { route-cache | path-mtu-discovery [age-timer {minutes | infinite}] | nat {inside | outside} }
```

### Syntax Description

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>route-cache</td>
<td>Sets tunnels to default or process switching mode.</td>
</tr>
<tr>
<td>path-mtu-discovery</td>
<td>Specifies when the tunnel MTU should expire if set by Path MTU Discovery.</td>
</tr>
<tr>
<td>age-timer minutes</td>
<td>(Optional) Time interval in minutes after which the tunnel reestimates the path MTU.</td>

</tr>
<tr>
<td></td>
<td>• nat</td>
</tr>
<tr>
<td></td>
<td>• inside</td>
</tr>
<tr>
<td></td>
<td>• outside</td>
</tr>
</tbody>
</table>

### Usage Guidelines

Path MTU Discovery is used by end stations to find a packet size that does not need fragmentation between them. Tunnels must adjust their MTU to the smallest MTU interior to achieve this condition, as described in RFC 2003.

The discovered tunnel MTU should be aged out periodically to possibly recover from a case where suboptimum MTU existed at time of discovery. It is reset to the outgoing MTU of the interface.

### Examples

The following example sets the discovered tunnel MTU to expire in 10 minutes (600 seconds):

```
ip mobile tunnel path-mtu-discovery age-timer 600
```

ip mobile virtual-network

To define a virtual network, use the **ip mobile virtual-network** global configuration command. To remove the virtual network, use the **no** form of this command.

```
ip mobile virtual-network net mask [address address]
no ip mobile virtual-network net mask
```

**Syntax Description**

- **net**: Network associated with the IP address of the virtual network.
- **mask**: Mask associated with the IP address of the virtual network.
- **address address**: (Optional) IP address of a home agent on a virtual network.

**Defaults**

No home agent addresses are specified.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.0(2)T</td>
<td>The following keyword and argument were added:</td>
</tr>
</tbody>
</table>

  * address
  * address

**Usage Guidelines**

This command inserts the virtual network into the routing table to allow mobile nodes to use the virtual network as their home network. The network is propagated when redistributed to other routing protocols.

**Note**

You may need to include virtual networks when configuring the routing protocols. If this is the case, use the **redistribute mobile** router configuration command to redistribute routes from one routing domain to another.

**Examples**

The following example adds the virtual network 20.0.0.0 to the routing table and specifies that the home agent IP address is configured on the loopback interface for that virtual network:

```plaintext
interface ethernet 0
ip addr 1.0.0.1 255.0.0.0
standby ip 1.0.0.10
standby name SanJoseHA

interface loopback 0
ip address 20.0.0.1 255.255.255.255
```
Mobile IP Commands

**ip mobile virtual-network**

```
ip mobile home-agent
ip mobile virtual-network 20.0.0.0 255.255.0.0 20.0.0.1
ip mobile home-agent standby SanJoseHA virtual-network
ip mobile secure home-agent 1.0.0.2 spi 100 hex 00112233445566778899001122334455
```

**Related Commands**

<tr>
<td><strong>ip mobile host</strong></td>
<td>Configures the mobile host or mobile node group.</td>
</tr>
<tr>
<td><strong>redistribute mobile</strong></td>
<td>Redistributes routes from one routing domain into another routing domain.</td>
</tr>
</tbody>
</table>
router mobile

To enable Mobile IP on the router, use the `router mobile` global configuration command. To disable Mobile IP, use the `no` form of this command.

```
router mobile
no router mobile
```

**Syntax Description**
This command has no arguments or keywords.

**Defaults**
Disabled

**Command Modes**
Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
This command must be used in order to run Mobile IP on the router, as either a home agent or a foreign agent. The process is started, and counters begin. Disabling Mobile IP removes all related configuration commands, both global and interface.

**Examples**
The following example enables Mobile IP:

```
router mobile
```

**Related Commands**

<table>
<thead>
<tr>

</table>
show ip mobile binding

To display the mobility binding table, use the **show ip mobile binding** EXEC command.

```
show ip mobile binding [home-agent address | summary]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>home-agent address</td>
<td>(Optional) IP address of mobile node.</td>
</tr>
<tr>
<td>summary</td>
<td>(Optional) Total number of bindings in the table.</td>
</tr>
</tbody>
</table>

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.0(2)T</td>
<td>The following keyword and argument were added:</td>
</tr>
<tr>
<td></td>
<td>• home-agent</td>
</tr>
<tr>
<td></td>
<td>• address</td>
</tr>
<tr>
<td>12.1(2)T</td>
<td>The <strong>summary</strong> keyword was added.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The home agent updates the mobility binding table in response to registration events from mobile nodes. If the **address** argument is specified, bindings are shown for only that mobile node.

**Examples**

The following is sample output from the **show ip mobile binding** command:

```
Router# show ip mobile binding

Mobility Binding List:
Total 1
20.0.0.1:
   Care-of Addr 68.0.0.31, Src Addr 68.0.0.31,
   Lifetime granted 02:46:40 (10000), remaining 02:46:32
   Flags SbdmQvt, Identification B750FAC4.C28F56A8,
   Tunnel100 src 66.0.0.5 dest 68.0.0.31 reverse-allowed
   Routing Options - (G)GRE
```

Table 45 describes the significant fields shown in the display.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total</td>
<td>Total number of mobility bindings.</td>
</tr>
<tr>
<td>&lt;IP address&gt;</td>
<td>Home IP address of the mobile node.</td>
</tr>
<tr>
<td>Care-of Addr</td>
<td>Care-of address of the mobile node.</td>
</tr>
</tbody>
</table>
### Field Descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Src Addr</strong></td>
<td>IP source address of the Registration Request as received by the home agent. Will be either the colocated care-of address of a mobile node or an address of the foreign agent.</td>
</tr>
<tr>
<td><strong>Lifetime granted</strong></td>
<td>The lifetime granted to the mobile node for this registration. Number of seconds in parentheses.</td>
</tr>
<tr>
<td><strong>Lifetime remaining</strong></td>
<td>The time remaining until the registration is expired. It has the same initial value as lifetime granted, and is counted down by the home agent.</td>
</tr>
<tr>
<td><strong>Flags</strong></td>
<td>Registration flags sent by mobile node. Uppercase characters denote bit set. See Table 41 for a description of each bit.</td>
</tr>
<tr>
<td><strong>Identification</strong></td>
<td>Identification used in that binding by the mobile node. This field has two purposes: unique identifier for each request, and replay protection.</td>
</tr>
<tr>
<td><strong>Tunnel</strong></td>
<td>The tunnel used by the mobile node is characterized by the source and destination addresses, and reverse-allowed or reverse-off for reverse tunnel. The default is IPIP encapsulation, otherwise GRE will be displayed in the Routing Options field.</td>
</tr>
<tr>
<td><strong>Routing Options</strong></td>
<td>Routing options list all home agent-accepted services. For example, the V bit may have been requested by the mobile node (shown in the Flags field), but the home agent will not provide such service. Possible options are B (broadcast), D (direct-to-mobile node), G (GRE), and T (reverse-tunnel).</td>
</tr>
</tbody>
</table>
show ip mobile globals

To display global information for mobile agents, use the `show ip mobile globals` EXEC command.

```
show ip mobile globals
```

**Syntax Description**

This command has no arguments or keywords.

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command shows the services provided by the home agent or foreign agent. Note the deviation from RFC 2006: the foreign agent will not display busy or registration required information. Both are handled on a per-interface basis (see the `show ip mobile interface` command in this chapter), not at the global foreign agent level.

**Examples**

The following is sample output from the `show ip mobile globals` command:

```
Router# show ip mobile globals
IP Mobility global information:

Home Agent

  Registration lifetime: 10:00:00 (36000 secs)
  Broadcast enabled
  Replay protection time: 7 secs
  Reverse tunnel enabled
  ICMP Unreachable enabled
  Virtual networks
    20.0.0.0/8

Foreign Agent is not enabled, no care-of address

0 interfaces providing service
Encapsulations supported: IPIP and GRE
Tunnel fast switching enabled
Discovered tunnel MTU aged out after 1:00:00
```
Table 46 describes the significant fields shown in the display.

show ip mobile secure

To display the mobility security associations for the mobile host, mobile visitor, foreign agent, or home agent, use the show ip mobile secure EXEC command.

```
show ip mobile secure { host | visitor | foreign-agent | home-agent | summary } address
```

### Syntax Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Security association of the mobile host on the home agent.</td>
</tr>
<tr>
<td>visitor</td>
<td>Security association of the mobile visitor on the foreign agent.</td>
</tr>
<tr>
<td>foreign-agent</td>
<td>Security association of the remote foreign agents on the home agent.</td>
</tr>
<tr>
<td>home-agent</td>
<td>Security association of the remote home agent on the foreign agent.</td>
</tr>
<tr>
<td>summary</td>
<td>All values in the table.</td>
</tr>
<tr>
<td>address</td>
<td>IP address.</td>
</tr>
</tbody>
</table>

### Command Modes
EXEC

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

Multiple security associations can exist for each entity.

### Examples

The following is sample output from the show ip mobile secure command:

```
Router# show ip mobile secure

Security Associations {algorithm,mode,replay protection,key}:
  20.0.0.6
    SPI 300, MD5, Prefix-suffix, Timestamp +/- 7,
    Key 00112233445566778899001122334455
```

Table 50 describes the significant fields shown in the display.

### Table 50 show ip mobile secure Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>20.0.0.6</td>
<td>IP address.</td>
</tr>
<tr>
<td>In/Out SPI</td>
<td>The SPI is the 4-byte opaque index within the Mobility Security Association that selects the specific security parameters to be used to authenticate the peer. Allows either “SPI” or “In/Out SPI.” The latter specifies an inbound and outbound SPI pair. If an inbound SPI is received, then outbound SPI will be used when a response is sent.</td>
</tr>
<tr>
<td>MD5</td>
<td>Message Digest 5 authentication algorithm.</td>
</tr>
</tbody>
</table>

<td>The shared secret key for the security associations, in hexadecimal format.</td>
</tr>
</tbody>
</table>
show ip mobile traffic

To display protocol counters, use the show ip mobile traffic EXEC command.

show ip mobile traffic

Syntax Description

This command has no arguments or keywords.

Command Modes

EXEC

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

Usage Guidelines

Counters can be reset to zero using the clear ip mobile traffic command, which also allows you to undo the reset.

Examples

The following is sample output from the show ip mobile traffic command:

Router# show ip mobile traffic

IP Mobility traffic:
Advertisements:
Solicitations received 0
Advertisements sent 0, response to solicitation 0
Home Agent Registrations:
Register 0, Deregister 0 requests
Register 0, Deregister 0 replied
Accepted 0, No simultaneous bindings 0
Denied 0, Ignored 0
Unspecified 0, Unknown HA 0
Administrative prohibited 0, No resource 0
Authentication failed MN 0, FA 0
Bad identification 0, Bad request form 0
Unavailable encaps 0, reverse tunnel 0
Binding updates received 0, sent 0 total 0 fail 0
Binding update acks received 0, sent 0
Binding info request received 0, sent 0 total 0 fail 0
Binding info reply received 0 drop 0, sent 0 total 0 fail 0

**show ip mobile tunnel**

To display active tunnels, use the `show ip mobile tunnel` EXEC command.

```
show ip mobile tunnel [interface]
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>interface</td>
<td>(Optional) Displays a particular tunnel interface. The <em>interface</em> argument is tunnel x.</td>
</tr>
</tbody>
</table>

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command displays active tunnels created by Mobile IP. When no more users are on the tunnel, the tunnel is released.

**Examples**

The following is sample output from the `show ip mobile tunnel` command:

```
Router# show ip mobile tunnel
Mobile Tunnels:
Tunnel0:
  src 68.0.0.32, dest 68.0.0.48
  encap IP/IP, mode reverse-allowed, tunnel-users 1
  IP MTU 1480 bytes
  HA created, fast switching enabled, ICMP unreachable enabled
  0 packets input, 0 bytes, 0 drops
  1591241 packets output, 1209738478 bytes
```

Table 52 describes the significant fields shown in the display.

**Table 52  show ip mobile tunnel Field Descriptions**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>src</td>
<td>Tunnel source IP address.</td>
</tr>
<tr>
<td>dest</td>
<td>Tunnel destination IP address.</td>
</tr>
<tr>
<td>encap</td>
<td>Tunnel encapsulation type.</td>
</tr>
<tr>
<td>mode</td>
<td>Either reverse-allowed or reverse-off for reverse tunnel mode.</td>
</tr>
<tr>
<td>tunnel-users</td>
<td>Number of users on tunnel.</td>
</tr>
<tr>
<td>HA created</td>
<td>Home agent created.</td>
</tr>
<tr>
<td>fast switching</td>
<td>Enabled or disabled.</td>
</tr>
</tbody>
</table>
### Table 52  show ip mobile tunnel Field Descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP unreachable</td>
<td>Enabled or disabled.</td>
</tr>
<tr>
<td>packets input</td>
<td>Number of packets in.</td>
</tr>
<tr>
<td>bytes</td>
<td>Number of bytes in.</td>
</tr>
<tr>
<td>0 drops</td>
<td>Number of packets dropped. Packets are dropped when there are no visitors to send to after the foreign agent deencapsulates incoming packets. This prevents loops because the foreign agent will otherwise route the deencapsulated packets back to the home agent.</td>
</tr>
<tr>
<td>packets output</td>
<td>Number of packets output.</td>
</tr>
<tr>
<td>bytes</td>
<td>Number of bytes output.</td>
</tr>
</tbody>
</table>

</table>
show ip mobile violation

To display information about security violations, use the show ip mobile violation EXEC command.

```
show ip mobile violation [address]
```

**Syntax Description**

- `address` (Optional) Displays violations from a specific IP address.

**Command Modes**

- EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The most recent violation is saved for all the mobile nodes. A circular log holds up to 50 unknown requesters, violators without security association. The oldest violations will be purged to make room for new unknown requesters when the log limit is reached.

Security violation messages are logged at the informational level (see the logging global configuration command). When logging is enabled to include this severity level, violation history can be displayed using the show logging command.

**Examples**

The following is sample output from the show ip mobile violation command:

```
Router# show ip mobile violation
Security Violation Log:

Mobile Hosts:
20.0.0.1:
  Violations: 1, Last time: 06/18/97 01:16:47
  SPI: 300, Identification: B751B581.77FD0E40
  Error Code: MN failed authentication (131), Reason: Bad authenticator (2)
```

Table 53 describes significant fields shown in the display.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>20.0.0.1</td>
<td>IP address of the violator.</td>
</tr>
<tr>
<td>Violations</td>
<td>Total number of security violations for this peer.</td>
</tr>
<tr>
<td>Last time</td>
<td>Time of the most recent security violation for this peer.</td>
</tr>
<tr>
<td>SPI</td>
<td>SPI of the most recent security violation for this peer. If the security violation is due to an identification mismatch, then this is the SPI from the Mobile-Home Authentication Extension. If the security violation is due to an invalid authenticator, then this is the SPI from the offending authentication extension. In all other cases, it should be set to zero.</td>
</tr>
</tbody>
</table>

<td>Error code in request or reply. See Table 51 for list of error codes.</td>
</tr>
<tr>
<td>Reason</td>
<td>Reason for the most recent security violation for this peer. Possible reasons are:</td>
</tr>
<tr>
<td></td>
<td>• No mobility security association</td>
</tr>
<tr>
<td></td>
<td>• Bad authenticator</td>
</tr>
<tr>
<td></td>
<td>• Bad identifier</td>
</tr>
<tr>
<td></td>
<td>• Bad SPI</td>
</tr>
<tr>
<td></td>
<td>• Missing security extension</td>
</tr>
<tr>
<td></td>
<td>• Other</td>
</tr>
</tbody>
</table>
show ip mobile visitor

To display the table containing the visitor list of the foreign agent, use the show ip mobile visitor EXEC command.

`show ip mobile visitor [pending] [address | summary]`

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax Description</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pending</td>
<td>(Optional) Pending registration table.</td>
</tr>
<tr>
<td>address</td>
<td>(Optional) IP address.</td>
</tr>
<tr>
<td>summary</td>
<td>(Optional) All values in the table.</td>
</tr>
</tbody>
</table>

**Command Modes**

EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The foreign agent updates the table containing the visitor list of the foreign agent in response to registration events from mobile nodes.

**Examples**

The following is sample output from the show ip mobile visitor command:

```
Router# show ip mobile visitor
Mobile Visitor List:
Total 1
20.0.0.1:
    Interface Ethernet1/2, MAC addr 0060.837b.95ec
    IP src 20.0.0.1, dest 67.0.0.31, UDP src port 434
    HA addr 66.0.0.5, Identification B7510E60.64436B38
    Lifetime 08:20:00 (30000) Remaining 08:19:16
    Tunnel100 src 68.0.0.31, dest 66.0.0.5, reverse-allowed
    Routing Options - (T)Reverse-tunnel
```

Table 54 describes the significant fields shown in the display.
