Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at http://www.cisco.com/go/fn. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.

This document describes the DHCP Client on WAN Interfaces feature in Cisco IOS Release 12.2(8)T and includes the following sections:

- Feature Overview, page 1
- Supported Platforms, page 2
- Supported Standards, MIBs, and RFCs, page 3
- Configuration Tasks, page 4
- Configuration Examples, page 4
- Command Reference, page 6
- Glossary, page 10

Feature Overview

The DHCP Client on WAN Interfaces feature extends the Dynamic Host Configuration Protocol (DHCP) to allow a DHCP client to acquire an IP address over PPP over ATM (PPPoA) and certain ATM interfaces. By using DHCP rather than the IP Control Protocol (IPCP), a DHCP client can acquire other useful information such as DNS addresses, the DNS default domain name, and the default route.
The configuration of PPPoA and Classical IP and ARP over ATM already allows for a broadcast capability over the interface (using the `broadcast` keyword on the ATM interface). Most changes in this feature are directed at removing already existing restrictions on what types of interfaces are allowed to send out DHCP packets (previously, dialer interfaces have not been allowed). This feature also ensures that DHCP RELEASE messages are sent out the interface before a connection is allowed to be broken.

**Benefits**

DHCP is beneficial on WAN interfaces because it can be used to acquire information such as DNS server addresses, the DNS default domain name, and the default route.

**Restrictions**

This feature works with ATM point-to-point interfaces and will accept any encapsulation type. For ATM multipoint interfaces, this feature is only supported using the aal5snap encapsulation type combined with Inverse ARP. Inverse ARP, which builds an ATM map entry, is necessary to send unicast packets to the server (or relay agent) on the other end of the connection. Inverse ARP is only supported for the aal5snap encapsulation type.

For multipoint interfaces, an IP address can be acquired using other encapsulation types because broadcast packets are used. However, unicast packets to the other end will fail because there is no ATM map entry and thus DHCP renewals and releases also fail.

See the “Troubleshooting Tips” section of this document for more information.

Determining Platform Support Through Cisco Feature Navigator

Cisco IOS software is packaged in feature sets that support specific platforms. To get updated information regarding platform support for this feature, access Cisco Feature Navigator. Cisco Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Cisco Feature Navigator is a web-based tool that enables you to quickly determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image. You can search by feature or release. Under the release section, you can compare releases side by side to display both the features unique to each software release and the features in common.

To access Cisco Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions at http://www.cisco.com/register.

Cisco Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Cisco Feature Navigator home page at the following URL:

http://www.cisco.com/go/fn

Supported Standards, MIBs, and RFCs

Standards
None
MIBs
None
To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:

RFCs
No new or modified RFCs are supported by this feature.

Configuration Tasks
This feature has no new configuration commands; however, the ip address dhcp interface configuration command can now be configured on PPPoA and certain ATM interfaces.

Troubleshooting Tips
- An ATM primary interface is always multipoint.
- An ATM subinterface can be multipoint or point-to-point.
- If you are using a point-to-point interface, the routing table determines when to send a packet to the interface and ATM map entries are not needed. Consequently, Inverse ARP, which builds ATM map entries, is not needed.
- If you are using a multipoint interface you must use Inverse ARP to discover the IP address of the other side of the connection.
- You can specify Inverse ARP through the protocol ip inarp interface configuration command. You must use the aal5snap encapsulation type when using Inverse ARP because it is the only encapsulation type that supports Inverse ARP.

Configuration Examples
This section provides the following configuration examples:
- ATM Primary Interface (Multipoint) Using aal5snap Encapsulation and Inverse ARP Example
- ATM Point-to-Point Subinterface Using aa15snap Encapsulation Example
- ATM Point-to-Point Subinterface Using aa15nlpid Encapsulation Example
- ATM Point-to-Point Subinterface Using aa15mux PPP Encapsulation Example
ATM Primary Interface (Multipoint) Using aal5snap Encapsulation and Inverse ARP Example

In the following example, the `protocol ip 255.255.255.255 broadcast` configuration is needed because there must be an ATM map entry to recognize the broadcast flag on the permanent virtual circuit (PVC). You can use any ATM map entry. The `protocol ip inarp` configuration is needed so the ATM Inverse ARP can operate on the interface such that the system on the other side can be pinged once an address is assigned by DHCP.

```
interface atm0
 ip address dhcp
 pvc 1/100
   encapsulation aal5snap
   broadcast
   protocol ip 255.255.255.255 broadcast
 protocol ip inarp
```

ATM Point-to-Point Subinterface Using aa15snap Encapsulation Example

The following example shows an ATM point-to-point subinterface configuration using aa15snap encapsulation:

```
interface atm0.1 point-to-point
 ip address dhcp
 pvc 1/100
   encapsulation aal5snap
   broadcast
```

ATM Point-to-Point Subinterface Using aa15nlpid Encapsulation Example

The following example shows an ATM point-to-point subinterface configuration using aa15nlpid encapsulation:

```
interface atm0.1 point-to-point
 ip address dhcp
 pvc 1/100
   encapsulation aa15nlpid
   broadcast
```

ATM Point-to-Point Subinterface Using aa15mux PPP Encapsulation Example

The following example shows an ATM point-to-point subinterface configuration using aa15mux PPP encapsulation:

```
interface atm0.1 point-to-point
 pvc 1/100
   encapsulation aa15mux ppp virtual-template1
   broadcast
 !
interface virtual-template1
 ip address dhcp
```
Command Reference

This section documents the modified **ip address dhcp** command. All other commands used with this feature are documented in the Cisco IOS Release 12.2 command reference publications.

- **ip address dhcp**
ip address dhcp

To acquire an IP address on an interface from the Dynamic Host Configuration Protocol (DHCP), use the `ip address dhcp` command in interface configuration mode. To remove any address that was acquired, use the `no` form of this command.

```
ip address dhcp [client-id interface-name] [hostname host-name]
no ip address dhcp [client-id interface-name] [hostname host-name]
```

**Syntax Description**

- `client-id` (Optional) Specifies the client identifier. By default, the client identifier is an ASCII value. The `client-id interface-name` option sets the client identifier to the hexadecimal MAC address of the named interface.

- `interface-name` (Optional) The interface name from which the MAC address is taken.

- `hostname` (Optional) Specifies the host name.

- `host-name` (Optional) Name of the host to be placed in the DHCP option 12 field. This name need not be the same as the host name entered in global configuration mode.

**Defaults**

The host name is the globally configured host name of the router. The client identifier is an ASCII value.

</tbody>
</table>

**Usage Guidelines**

Prior to Release 12.2(8)T, the `ip address dhcp` command could be used only on Ethernet interfaces.

The `ip address dhcp` command allows any interface to dynamically learn its IP address by using the DHCP protocol. It is especially useful on Ethernet interfaces that dynamically connect to an internet service provider (ISP). Once assigned a dynamic address, the interface can be used with the Port Address Translation (PAT) of Cisco IOS Network Address Translation (NAT) to provide Internet access to a privately addressed network attached to the router.
The `ip address dhcp` command also works with ATM point-to-point interfaces and will accept any encapsulation type. However, for ATM multipoint interfaces you must specify Inverse ARP via the `protocol ip inarp` interface configuration command and use only the aa15snap encapsulation type.

Some ISPs require that the DHCPDISCOVER message have a specific host name and client identifier that is the MAC address of the interface. The most typical usage of the `ip address dhcp client-id interface-name hostname host-name` command is when `interface-name` is the Ethernet interface where the command is configured and `host-name` is the host name provided by the ISP.

A client identifier (DHCP option 61) can be a hexadecimal or an ASCII value. By default, the client identifier is an ASCII value. The `client-id interface-name` command is when `interface-name` is the Ethernet interface where the command is configured and `host-name` is the host name provided by the ISP.

If a Cisco router is configured to obtain its IP address from a DHCP server, it sends a DHCPDISCOVER message to provide information about itself to the DHCP server on the network.

If you use the `ip address dhcp` command with or without any of the optional keywords, the DHCP option 12 field (host name option) is included in the DISCOVER message. By default, the host name specified in option 12 will be the globally configured host name of the router. However, you can use the `ip address dhcp hostname host-name` command to place a different name in the DHCP option 12 field than the globally configured host name of the router.

The `no ip address dhcp` command removes any IP address that was acquired, thus sending a DHCPRELEASE message.

You might need to experiment with different configurations to determine the one required by your DHCP server. Table 1 shows the possible configuration methods and the information placed in the DISCOVER message for each method.

<table>
<thead>
<tr>
<th>Configuration Method</th>

</tr>
</thead>
<tbody>
<tr>
<td><code>ip address dhcp</code></td>
<td>The DISCOVER message contains “cisco-mac-address -Eth1” in the client ID field. The <code>mac-address</code> is the MAC address of the Ethernet 1 interface and contains the default host name of the router in the option 12 field.</td>
</tr>
<tr>
<td><code>ip address dhcp hostname host-name</code></td>
<td>The DISCOVER message contains “cisco-mac-address -Eth1” in the client ID field. The <code>mac-address</code> is the MAC address of the Ethernet 1 interface, and contains <code>host-name</code> in the option 12 field.</td>
</tr>
</tbody>
</table>
DHCP Client on WAN Interfaces

Examples

In the examples that follow, the command `ip address dhcp` is entered for the Ethernet interface 1. The DISCOVER message sent by a router configured as shown in the following example would contain “cisco- mac-address -Eth1” in the client-ID field, and the value host1 in the option 12 field.

```
hostname host1
!
interface Ethernet 1
   ip address dhcp
```

The DISCOVER message sent by a router configured as shown in the following example would contain “cisco- mac-address -Eth1” in the client-ID field, and the value host2 in the option 12 field.

```
hostname host1
!
interface Ethernet 1
   ip address dhcp hostname host2
```

The DISCOVER message sent by a router configured as shown in the following example would contain the MAC address of the Ethernet 1 interface in the client-ID field, and the value host1 in the option 12 field.

```
hostname host1
!
interface Ethernet 1
   ip address dhcp client-id Ethernet 1
```

The DISCOVER message sent by a router configured as shown in the following example would contain the MAC address of the Ethernet 1 interface in the client-ID field, and the value host2 in the option 12 field.

```
hostname host1
!
interface Ethernet 1
   ip address dhcp client-id Ethernet 1 hostname host2
```
