- Glossary, page 41

Feature Overview

The DHCP Server—On-Demand Address Pool Manager is a feature in which pools of IP addresses can be dynamically increased or reduced in size depending on the address utilization level. On-demand address pools (ODAPs) support address assignment using the Dynamic Host Configuration Protocol (DHCP) for customers using private addresses. Each ODAP is configured and associated with a
particular Multiprotocol Label Switching (MPLS) Virtual Private Network (VPN). Cisco IOS Release 12.2(15)T introduces support for non-MPLS VPN address pools by adding pool name support to the peer default ip address dhcp-pool pool name command.

For MPLS VPNs, each VPN is associated with one or more VPN routing and forwarding instances (VRFs). The VRF is a key element in the VPN technology because it maintains the routing information that defines a customer VPN site. This customer site is attached to a provider edge (PE) router. A VRF consists of an IP routing table, a derived Cisco Express Forwarding (CEF) table, a set of interfaces that use the forwarding table, and a set of rules and routing protocol parameters that control the information that is included in the routing table.

Once configured, the ODAP is populated with one or more subnets leased from a source server and is ready to serve address requests from DHCP clients or from PPP sessions. The source server can be a remote DHCP server or a RADIUS server (via AAA). Currently, only the Cisco Access Registrar RADIUS server supports ODAPs. Subnets can be added to the pool when a certain utilization level (high utilization mark) is achieved. When the utilization level falls below a certain level (low utilization mark), a subnet can be returned to the server from which it was originally leased. Summarized routes for each leased subnet must be inserted or removed from the related VRF with each addition or removal of subnets into the ODAP.

A PPP session belonging to a specific VPN is only allocated an address from the ODAP associated with that VPN. These PPP sessions are terminated on a Virtual Home Gateway (VHG)/PE router where the ODAP is configured. The VHG/PE router maps the remote user to the corresponding MPLS VPNs.

For PPP sessions, individual address allocation from an ODAP follows a First Leased subnet First (FLF) policy. FLF searches for a free address beginning on the very first leased subnet, followed by a search on the second leased subnet if no free address is available in the first subnet, and so on. This policy provides the benefit of grouping the leased addresses over time to a set of subnets, which allows an efficient subnet release and route summarization.

However, the FLF policy differs from the normal DHCP address selection policy. Normal DHCP address selection takes into account the IP address of the receiving interface or the gateway address if it is nonzero. To support both policies, the DHCP server needs to be able to distinguish between a normal DHCP address request and an address request for a PPP client. The DHCP Server—On-Demand Address Pool Manager feature introduces a new IP address pooling mechanism for PPP that allows the DHCP server to distinguish between a normal DHCP address request and a request from a PPP client.

Subnet release from an ODAP follows a Last Leased subnet First (LLF) policy, which prefers the last leased subnet to be released first. This LLF policy searches for a releasable subnet (a subnet with no addresses currently being leased) starting with the last leased subnet. If a releasable subnet is found (candidate subnet), it is released, and the summarized route for that subnet is removed. If more than one releasable subnet exists at that time, only the most recently allocated is released. If there are no releasable subnets, no action is taken. If by releasing the candidate subnet, the high utilization mark is reached, the subnet is not released. The first leased subnet is never released (regardless of the instantaneous utilization level) until the ODAP is disabled.

**Benefits**

**Efficient Address Management**

The ODAP Manager allows customers to optimize their use of IP addresses, thus conserving address space.

**Efficient Route Summarization and Update**

The ODAP Manager inserts a summarized route when a subnet is added to the ODAP.
Restrictions

Currently, the `ip dhcp excluded-address` global configuration command cannot be used to exclude addresses from VRF associated pools.

The `vrf` DHCP pool configuration command is currently not supported for host pools.

Attribute inheritance is not supported on VRF pools.

Supported Platforms

Refer to feature navigator for the latest platform information as referenced below.

**Finding Support Information for Platforms and Cisco IOS Software Images**

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at [http://www.cisco.com/go/fn](http://www.cisco.com/go/fn). You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.
Supported Standards, MIBs, and RFCs

Standards
No new or modified standards are supported by this feature.

MIBs
No new or modified MIBs are supported by this feature.
To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:

RFCs
- RFC 3046, DHCP Relay Information Option
- RFC 2685, Virtual Private Networks Identifier

Prerequisites
Before configuring the DHCP Server—On-Demand Address Pool Manager feature, you must configure standard MPLS VPNs unless you intend to use non-MPLS VPNs.
In order for the IP address pooling mechanism to work correctly, the VRF of the PPP session must match that configured on the pool. Typically this matching is done either by configuring the `ip vrf forwarding vrf-name` command on the virtual template interface, or if AAA is used to authorize the PPP user, it can be part of the user’s profile configuration.
For more information on configuring MPLS VPNs, refer to the Cisco IOS Switching Services Configuration Guide, Release 12.2. For more information on configuring AAA, refer to the Cisco IOS Security Configuration Guide, Release 12.2.

Configuration Tasks
See the following sections for configuration tasks for this feature. Each task in the list is identified as either required or optional.
- Defining DHCP ODAPs as the Global Default Mechanism (required)
- Defining DHCP ODAPs on an Interface (optional)
- Configuring the DHCP Pool as an ODAP (required)
- Configuring ODAPs to Obtain Subnets Through IPCP Negotiation (optional)
- Configuring AAA (required)
- Configuring RADIUS (required)
- Disabling ODAPs (optional)
- Verifying ODAP Operation (optional)
Defining DHCP ODAPs as the Global Default Mechanism

IP addressing allows configuration of a global default address pooling mechanism. The DHCP server needs to be able to distinguish between a normal DHCP address request and an address request for a PPP client.

To specify that the global default mechanism to use is on-demand address pooling, use the following command in global configuration mode:

```
Router(config)# ip address-pool dhcp-pool
```

Command Purpose
---
Enables on-demand address pooling as the global default IP address mechanism. For remote access (PPP) sessions into MPLS VPNs, IP addresses are obtained from locally configured VRF-associated DHCP pools.

Defining DHCP ODAPs on an Interface

You can also configure the on-demand address pooling mechanism on an interface-by-interface basis, which overrides the global default mechanism on that interface. To enable DHCP on-demand address pooling assignment on an interface, use the following commands beginning in global configuration mode:

```
Step 1
Router(config)# interface name
```

Specifies the interface and enters interface configuration mode.

```
Step 2
Router(config-if)# peer default ip address dhcp-pool [pool name]
```

Specifies an IP address from an on-demand address pool to be returned to a remote peer connecting to this interface. The `pool name` argument is mandatory if the session is not associated with any VRF. Multiple pool names can be accepted.

Configuring the DHCP Pool as an ODAP

To configure a DHCP pool as an on-demand address pool, use the following commands beginning in global configuration mode:

```
Step 1
Router(config)# ip dhcp pool name
```

Configures a DHCP address pool on a Cisco IOS DHCP server and enters DHCP pool configuration mode.

```
Step 2
Router(config-dhcp)# vrf name
```

(Optional) Associates the address pool with a VRF name. Only use this command for MPLS VPNs.

```
Step 3
Router(config-dhcp)# origin {dhcp | aaa | ipcp} [subnet size initial size [autogrow size]]
```

Configures an address pool as an on-demand address pool.
DHCP Server—On-Demand Address Pool Manager

Configuration Tasks

Cisco IOS Release: Multiple releases (see the Feature History table)

Configuring ODAPs to Obtain Subnets Through IPCP Negotiation

You can assign IP address pools to customer premises equipment (CPE) devices, which, in turn, assign IP addresses to the CPE and to a DHCP pool. This functionality has three requirements:

- The Cisco IOS CPE device must be able to request and use the subnet.
- The RADIUS server (via AAA) must be able to provide that subnet and insert the framed route into the proper VRF table.
- The PE router must be able to facilitate providing the subnet through IP Control Protocol (IPCP) negotiation.

To configure your router to use subnets obtained through IPCP negotiation, use the following commands beginning in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Router(config)# ip dhcp pool name</td>
</tr>
<tr>
<td>Step 2</td>
<td>Router(config-dhcp)# import all</td>
</tr>
<tr>
<td>Step 3</td>
<td>Router(config-dhcp)# origin ipcp</td>
</tr>
<tr>
<td>Step 4</td>
<td>Router(config-dhcp)# exit</td>
</tr>
<tr>
<td>Step 5</td>
<td>Router(config)# interface type</td>
</tr>
<tr>
<td>Step 6</td>
<td>Router(config-if)# ip address pool name</td>
</tr>
</tbody>
</table>

Configuring AAA

To allow ODAP to obtain subnets from the RADIUS server, the AAA client must be configured on the VHG/PE router. To configure AAA on the VHG/PE router, use the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 4</td>
<td>Router(config-dhcp)# utilization mark low percentage-number</td>
</tr>
<tr>
<td>Step 5</td>
<td>Router(config-dhcp)# utilization mark high percentage-number</td>
</tr>
</tbody>
</table>
To configure RADIUS, use the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1  | Router(config)# aaa new-model  
Enables AAA access control. |
| Step 2  | Router(config)# aaa authorization configuration  
default group radius  
Downloads static route configuration information from the AAA server using RADIUS. |
| Step 3  | Router(config)# aaa accounting network default  
start-stop radius  
Enables AAA accounting of requested services for billing or security purposes when you use RADIUS. Sends a "start" accounting notice at the beginning of a process. |
| or     | Router(config)# aaa accounting network default  
stop-only radius  
Enables AAA accounting of requested services for billing or security purposes when you use RADIUS. Sends a "stop" accounting notice at the end of the requested user process. |
| Step 4  | Router(config)# aaa session-id common  
Ensures that the same session ID will be used for each AAA accounting service type within a call. |

**Disabling ODAPs**

When an ODAP is disabled, all leased subnets are released. If active PPP sessions are using addresses from the released subnets, those sessions will be reset. DHCP clients leasing addresses from the released subnets will not be able to renew their leases. To disable an ODAP from a DHCP pool, use the following command in DHCP pool configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1  | Router(config)# ip radius source-interface  
subinterface-name  
Forces RADIUS to use the IP address of a specified interface for all outgoing RADIUS packets. |
| Step 2  | Router(config)# radius-server host ip-address  
auth-port port-number acct-port port-number  
Specifies a RADIUS server host. |
| Step 3  | Router(config)# radius server attribute 32  
include-in-access-req  
Sends RADIUS attribute 32 (NAS-Identifier) in an access request or accounting request. |
| Step 4  | Router(config)# radius server attribute 44  
include-in-access-req  
Sends RADIUS attribute 44 (Accounting Session ID) in an access request or accounting request. |
| Step 5  | Router(config)# radius-server vsa send accounting  
Configures the network access server (NAS) to recognize and use vendor-specific accounting attributes. |
| Step 6  | Router(config)# radius-server vsa send authentication  
Configures the NAS to recognize and use vendor-specific authentication attributes. |
Verifying ODAP Operation

Step 1 Enter the `show ip dhcp pool [name]` command:

The following output is for two DHCP pools: Green and Global. Pool Green is configured with a high utilization mark of 50 and a low utilization mark of 30. The pool is also configured to obtain more subnets when the high utilization mark is reached (autogrow). The Subnet size field indicates the values configured in the `origin` command as the initial and incremental subnet sizes that would be requested by the pool named Green. The Total addresses field is a count of all the usable addresses in the pool. The Leased addresses field is a total count of how many bindings were created from the pool. The Pending event field shows subnet request, which means that a subnet request is pending for the pool. The subnet request was scheduled because the Leased addresses count has exceeded the high utilization level of the pool. Subnets currently added to pool Green are shown in sequence. The Current index columns shows the address that would be allocated next from this subnet. The IP address range column shows the range of usable addresses from the subnet. The Leased addresses column shows individual count of bindings created from each subnet. Three subnets are currently added to pool Green. The first two subnets have used all their addresses and thus the Current index is showing 0.0.0.0.

Notice that pool Green and pool Global can have the same subnet (172.16.0.1-172.16.0.6) because pool Green is configured to be in VRF Green, while pool Global is configured to be in the global address space.

Step 2 Enter the `show ip dhcp binding` command:

The output following shows the bindings from pool Green. The Type field shows On-demand, which
indicates that the address binding was created for a PPP session. The Lease expiration field shows Infinite, which means that the binding is valid as long as the session is up. If a subnet must be released back to the leasing server while the session is still up, the session is reset so that it will be forced to obtain a new IP address. The Hardware address column for an On-demand entry shows the identifier for the session as detected by PPP. There are no bindings shown under the Bindings from all pools not associated with VRF field because the Global pool has not allocated any addresses.

Troubleshooting Tips

By default, the Cisco IOS DHCP server on which the ODAP Manager is based attempts to verify an address availability by performing a ping operation to the address before allocation. The default DHCP ping configuration will wait for 2 seconds for an ICMP echo reply. This default configuration results in the DHCP server servicing one address request every 2 seconds. The number of ping packets being sent and the ping timeout are configurable. Thus, to reduce the address allocation time, you can reduce either the timeout or the number of ping packets sent. Reducing the timeout or the ping packets being sent will improve the address allocation time, at the cost of less ability to detect duplicate addresses.
Each ODAP will make a finite number of attempts (up to four retries) to obtain a subnet from DHCP or AAA. If these attempts are not successful, the subnet request from the pool automatically starts when there is another individual address request to the pool (for example, from a newly brought up PPP session). If a pool has not been allocated any subnets, you can force restarting the subnet request process by using the clear ip dhcp pool name subnet * EXEC command.

## Monitoring and Maintaining the ODAP

To monitor and maintain the ODAP, use the following EXEC commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router# clear ip dhcp [pool name] binding { *</td>
<td>address}</td>
</tr>
<tr>
<td>Router# clear ip dhcp [pool name] conflict { *</td>
<td>address}</td>
</tr>
<tr>
<td>Router# clear ip dhcp [pool name] subnet { *</td>
<td>address}</td>
</tr>
<tr>
<td>Router# debug dhcp details</td>
<td>Monitors the subnet allocation/releasing in the on-demand address pools.</td>
</tr>
<tr>
<td>Router# debug ip dhcp server events</td>
<td>Reports DHCP server events, like address assignments and database updates.</td>
</tr>
<tr>
<td>Router# show ip dhcp import</td>
<td>Displays the option parameters that were imported into the DHCP server database.</td>
</tr>
<tr>
<td>Router# show ip interface [type number]</td>
<td>Displays the usability status of interfaces configured for IP.</td>
</tr>
<tr>
<td>Router# show ip dhcp pool name</td>
<td>Displays DHCP address pool information.</td>
</tr>
</tbody>
</table>

Note the following behavior for the clear ip dhcp binding, clear ip dhcp conflict, and clear ip dhcp subnet commands:

- If you do not specify the pool name option and an IP address is specified, it is assumed that the IP address is an address in the global address space and will look among all the non-VRF DHCP pools for the specified binding/conflict/subnet.
- If you do not specify the pool name option and the * option is specified, it is assumed that all automatic/ or on-demand bindings/conflicts/subnets in all VRF and non-VRF pools are to be deleted.
- If you specify both the pool name option and the * option, all automatic or on-demand bindings/conflicts/subnets in the specified pool only will be cleared.
- If you specify the pool name option and an IP address, the specified binding/conflict or the subnet containing the specified IP address will be deleted from the specified pool.
Configuration Examples

This section provides the following configuration examples:

- Defining DHCP ODAPs as the Global Default Mechanism Example
- Defining DHCP ODAPs on an Interface Example
- Configuring the DHCP Pool as an ODAP Example
- Configuring the DHCP Pool as an ODAP for Non-MPLS VPNs Example
- IPCP Subnet Mask Delivery Example
- Configuring AAA and RADIUS Example

Defining DHCP ODAPs as the Global Default Mechanism Example

The following example shows that the on-demand address pooling mechanism will be used to serve an address request from a PPP client.

```-config
! ip address-pool dhcp-pool
! ip dhcp pool Green-pool
!```

Defining DHCP ODAPs on an Interface Example

The following example shows how to configure an interface to retrieve an IP address from an on-demand address pool:

```-template
! interface Virtual-Template1
  ip vrf forwarding green
  ip unnumbered loopback1
  ppp authentication chap
  peer default ip address dhcp-pool
!```

Configuring the DHCP Pool as an ODAP Example

The following example shows two ODAPs configured to obtain their subnets from an external DHCP server:

```-template
Router# show running-config
Building configuration...

Current configuration : 3943 bytes
!

**Configuring the DHCP Pool as an ODAP for Non-MPLS VPNs Example**

The following example shows how to configure an interface to retrieve an IP address from an on-demand address pool. In this example, two non-VRF ODAPs are configured. There are two virtual-templates and two DHCP address pools, usergroup1 and usergroup2. Each virtual-template interface is configured to obtain IP addresses for the peer from the associated address pool.

```
! ip dhcp pool usergroup1
    origin dhcp subnet size initial /24 autogrow /24
    lease 0 1
!
ip dhcp pool usergroup2
    origin dhcp subnet size initial /24 autogrow /24
    lease 0 1
!
interface virtual-template1
    ip unnumbered loopback1
    peer default ip address dhcp-pool usergroup1
!
interface virtual-template2
    ip unnumbered loopback1
    peer default ip address dhcp-pool usergroup2
```

**IPCP Subnet Mask Delivery Example**

The following example shows a Cisco 827 router configured to use IPCP subnet masks:

```
Router# show running-config

Configuring AAA and RADIUS Example

The following example shows one pool "Green" configured to obtain its subnets from the AAA (RADIUS) server located at IP address 172.16.1.1:

! aaa new-model
! aaa authorization configuration default group radius
aaa accounting network default start-stop group radius
aaa session-id common
!
ip subnet-zero
!
ip dhcp ping packets 0
!
ip dhcp pool Green
  vrf Green
  utilization mark high 50
  utilization mark low 30
  origin aaa subnet size initial /28 autogrow /28
!
ip vrf Green
  rd 300:1
  route-target export 300:1
  route-target import 300:1
!
interface Ethernet1/1
  ip address 172.16.1.12 255.255.255.0
duplex half
!
interface Virtual-Template1
  ip vrf forwarding Green
  no ip address
!
ip radius source-interface Ethernet1/1
!
!IP address of the RADIUS server host
radius-server host 172.16.1.1 auth-port 1645 acct-port 1646
radius-server retransmit 3
radius-server attribute 32 include-in-access-req
radius-server attribute 44 include-in-access-req
radius-server key cisco
radius-server vsa send accounting
radius-server vsa send authentication

Command Reference

This section documents new and modified commands. All other commands used with this feature are documented in the Cisco IOS Release 12.2 command reference publications.
New Commands

- aaa session-id
- clear ip dhcp subnet
- ip address pool (DHCP)
- ip dhcp aaa default username
- origin
- show ip dhcp pool
- utilization mark high
- utilization mark low
- vrf

Modified Commands

- clear ip dhcp binding
- clear ip dhcp conflict
- ip address-pool
- peer default ip address
aaa session-id

To specify whether the same session ID will be used for each authentication, authorization, and accounting (AAA) accounting service type within a call or whether a different session ID will be assigned to each accounting service type, use the `aaa session-id` command in global configuration mode. To restore the default behavior after the `unique` keyword is enabled, use the `no` form of this command.

```
aaa session-id [common | unique]
no aaa session-id [unique]
```

**Syntax Description**

- `common` (Optional) Ensures that all session identification (ID) information that is sent out for a given call will be made identical. The default behavior is common.
- `unique` (Optional) Ensures that only the corresponding service access-requests and accounting-requests will maintain a common session ID.

Accounting-requests for each service will have a different session ID.

**Defaults**
The `common` keyword is enabled.

**Command Modes**
Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2(4)B</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.2(8)T</td>
<td>This command was integrated into Cisco IOS Release 12.2(8)T.</td>
</tr>
<tr>
<td>12.2(27)SBA</td>
<td>This command was integrated into Cisco IOS Release 12.2(27)SBA.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**
The `common` keyword behavior allows the first session ID request of the call to be stored in a common database; all proceeding session ID requests will retrieve the value of the first session ID. Because a common session ID is the default behavior, this functionality is written to the system configuration after the `aaa new-model` command is configured.

The router configuration will always have either the `aaa session-id common` or the `aaa session-id unique` command enabled; it is not possible to have neither of the two enabled. Thus, the `no aaa session-id unique` command will revert to the default functionality, but the `no aaa session-id common` command will not have any effect because it is the default functionality.

The `unique` keyword behavior assigns a different session ID for each accounting type (Auth-Proxy, Exec, Network, Command, System, Connection, and Resource) during a call. To specify this behavior, the unique keyword *must* be specified. The session ID may be included in RADIUS access requests by
configuring the **radius-server attribute 44 include-in-access-req** command. The session ID in the access-request will be the same as the session ID in the accounting request for the same service; all other services will provide unique session IDs for the same call.

### Examples

The following example shows how to configure unique session IDs:

```config
aaa new-model
aaa authentication ppp default group radius
radius-server host 10.100.1.34
radius-server attribute 44 include-in-access-req
aaa session-id unique
```

clear ip dhcp binding

To delete an automatic address binding from the Cisco IOS Dynamic Host Configuration Protocol (DHCP) server database, use the clear ip dhcp binding command in privileged EXEC mode.

    clear ip dhcp [pool name] binding {* | address}

**Syntax Description**

- **pool name** (Optional) Name of the DHCP pool.
- 
- * Clears all automatic bindings.
- **address** The address of the binding you want to clear.

**Command Modes**

Privileged EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.2(8)T</td>
<td>The pool name keyword and argument combination was added.</td>
</tr>
<tr>
<td>12.2(27)SBA</td>
<td>This command was integrated into Cisco IOS Release 12.2(27)SBA.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Typically, the address denotes the IP address of the client. If the asterisk (*) character is used as the address parameter, DHCP clears all automatic bindings.

Use the `no ip dhcp pool` global configuration command to delete a manual binding.

Note the following behavior for the clear ip dhcp binding command:

- If you do not specify the pool name option and an IP address is specified, it is assumed that the IP address is an address in the global address space and will look among all the non-VRF DHCP pools for the specified binding.
- If you do not specify the pool name option and the * option is specified, it is assumed that all automatic or on-demand bindings in all VRF and non-VRF pools are to be deleted.
- If you specify both the pool name option and the * option, all automatic or on-demand bindings in the specified pool only will be cleared.
- If you specify the pool name option and an IP address, the specified binding will be deleted from the specified pool.

**Examples**

The following example deletes the address binding 10.12.1.99 from a DHCP server database:

    Router# clear ip dhcp binding 10.12.1.99

The following example deletes all bindings from all pools:

    Router# clear ip dhcp binding *

The following example deletes all bindings from the address pool named pool1:

    Router# clear ip dhcp pool pool1 binding *
The following example deletes address binding 10.13.2.99 from the address pool named pool2:

Router# clear ip dhcp pool red binding pool2

clear ip dhcp conflict

To clear an address conflict from the Cisco IOS Dynamic Host Configuration Protocol (DHCP) server database, use the `clear ip dhcp conflict` command in privileged EXEC mode.

```
clear ip dhcp [pool name] conflict {* | address}
```

**Syntax Description**

- **pool name** (Optional) Name of the DHCP pool.
- **{***: Clears all address conflicts.
- **address**: The IP address of the host that contains the conflicting address you want to clear.

**Command Modes**

Privileged EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0(1)T</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.2(8)T</td>
<td>The <code>pool name</code> keyword and argument combination were added.</td>
</tr>
<tr>
<td>12.2(27)SBA</td>
<td>This command was integrated into Cisco IOS Release 12.2(27)SBA.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The server detects conflicts using a ping session. The client detects conflicts using gratuitous Address Resolution Protocol (ARP). If the asterisk (*) character is used as the address parameter, DHCP clears all conflicts.

Note the following behavior for the `clear ip dhcp conflict` command:

- If you do not specify the `pool name` option and an IP address is specified, it is assumed that the IP address is an address in the global address space and will look among all the non-VRF DHCP pools for the specified conflict.
- If you do not specify the `pool name` option and the * option is specified, it is assumed that all automatic/ or on-demand conflicts in all VRF and non-VRF pools are to be deleted.
- If you specify both the `pool name` option and the * option, all automatic or on-demand conflicts in the specified pool only will be cleared.
- If you specify the `pool name` option and an IP address, the specified conflict will be deleted from the specified pool.

**Examples**

The following example shows an address conflict of 10.12.1.99 being deleted from the DHCP server database:

```
Router# clear ip dhcp conflict 10.12.1.99
```

The following example deletes all address conflicts from all pools:

```
Router# clear ip dhcp conflict *
```

The following example deletes all address conflicts from the address pool named pool1:
Router# clear ip dhcp pool pool1 conflict *

The following example deletes address conflict 10.13.2.99 from the address pool named pool2:
Router# clear ip dhcp pool pool2 conflict 10.13.2.99

### Related Commands

clear ip dhcp subnet

To clear all currently leased subnets in the Cisco IOS Dynamic Host Configuration Protocol (DHCP) pool, use the `clear ip dhcp subnet` command in privileged EXEC configuration mode.

```
clear ip dhcp [pool name] subnet [ * | address]
```

**Syntax Description**

- **pool name**: (Optional) Name of the DHCP pool.
- **address**: Clears a subnet containing the specified IP address.
- *****: Clears all leased subnets.

**Command Modes**

Privileged EXEC

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2(8)T</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.2(27)SBA</td>
<td>This command was integrated into Cisco IOS Release 12.2(27)SBA.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

A PPP session that is allocated an IP address from the released subnet will be reset.

Note the following behavior for the `clear ip dhcp subnet` command:

- If you do not specify the `pool name` option and an IP address is specified, it is assumed that the IP address is an address in the global address space and will look among all the non-VRF DHCP pools for the specified subnet.
- If you do not specify the `pool name` option and the * option is specified, it is assumed that all automatic or on-demand subnets in all VRF and non-VRF pools are to be deleted.
- If you specify both the `pool name` option and the * option, all automatic or on-demand subnets in the specified pool only will be cleared.
- If you specify the `pool name` option and an IP address, the subnet containing the specified IP address will be deleted from the specified pool.

**Caution**

Use this command with caution to prevent undesired termination of active PPP sessions.

**Examples**

The following example releases the subnet containing 10.0.0.2 from any non-VRF on-demand address pools:

```
Router# clear ip dhcp subnet 10.0.0.2
```

The following example clears all leased subnets from all pools:

```
Router# clear ip dhcp subnet *
```

The following example clears all leased subnets from the address pool named pool3:

```
Router# clear ip dhcp pool pool3 subnet *
```
The following example clears the address 10.0.0.2 from the address pool named pool2:

Router# clear ip dhcp pool pool2 subnet 10.0.0.2

ip address-pool

To enable an address pooling mechanism used to supply IP addresses to dial-in asynchronous, synchronous, or ISDN point-to-point interfaces, use the `ip address-pool` command in global configuration mode. To disable IP address pooling globally on all interfaces with the default configuration, use the `no` form of this command.

```
ip address-pool [dhcp-pool | dhcp-proxy-client | local]

no ip address-pool
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dhcp-pool</td>
<td>(Optional) Uses on-demand address pooling as the global default address mechanism. This option supports only remote access (PPP) sessions into MPLS VPNs. IP addresses are obtained from locally configured VRF-associated Dynamic Host Configuration Protocol (DHCP) pools.</td>
</tr>
<tr>
<td>dhcp-proxy-client</td>
<td>(Optional) Uses the router as the proxy-client between a third-party (DHCP) server and peers connecting to the router.</td>
</tr>
<tr>
<td>local</td>
<td>(Optional) Uses the local address pool named <code>default</code>.</td>
</tr>
</tbody>
</table>

**Defaults**

IP address pooling is disabled.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.0</td>
<td>This command was introduced.</td>

<tr>
<td>12.2(8)T</td>
<td>The <code>dhcp-pool</code> keyword was added.</td>
</tr>
<tr>
<td>12.2(27)SBA</td>
<td>This command was integrated into Cisco IOS Release 12.2(27)SBA.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The global default mechanism applies to all interfaces that have been left in the default setting of the `peer default ip address pool` command.

If any `peer default ip address` command other than `peer default ip address pool` (the default) is configured, the interface uses that mechanism and not the global default mechanism. Thus all interfaces can be independently configured or left unconfigured so that the global default mechanism setting applies. This flexibility minimizes the configuration effort on the part of the administrator.

The `ip address-pool dhcp-pool` command supports only remote access (PPP) sessions into Multiprotocol Label Switching Virtual Private Networks (MPLS VPNs). IP addresses are obtained from locally configured virtual routing and forwarding (VRF)-associated DHCP pools. A VRF VPN instance is a per-VPN routing information repository that defines the VPN membership of a customer site.

**Examples**

The following example specifies the DHCP on-demand address pooling mechanism as the global default mechanism for assigning peer IP addresses:
ip address-pool dhcp-pool

The following example specifies the DHCP proxy client mechanism as the global default mechanism for assigning peer IP addresses:

ip address-pool dhcp-proxy-client

The following example specifies a local IP address pool named “default” as the global default mechanism for all interfaces that have been left in their default setting:

ip address-pool local

ip address pool (DHCP)

To enable the IP address of an interface to be automatically configured when a DHCP pool is populated with a subnet from IP Control Protocol (IPCP) negotiation, use the `ip address pool` command in interface configuration mode. To disable autoconfiguring of the IP address of the interface, use the `no` form of this command.

```
ip address pool name

no ip address pool
```

**Syntax Description**

| name | Name of the DHCP pool. The IP address of the interface will be automatically configured from the DHCP pool specified in `name`. |

**Defaults**

IP address pooling is disabled.

**Command Modes**

Interface configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2(8)T</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.2(27)SBA</td>
<td>This command was integrated into Cisco IOS Release 12.2(27)SBA.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Use this command to automatically configure the IP address of a LAN interface when there are DHCP clients on the attached LAN that should be serviced by the DHCP pool on the router. The DHCP pool obtains its subnet dynamically through IPCP subnet negotiation.

**Examples**

The following example specifies that the IP address of Ethernet interface 2 will be automatically configured from the address pool named abc:

```
ip dhcp pool abc
    import all
    origin ipcp
    interface Ethernet 2
    ip address pool abc
```

ip dhcp aaa default username

To specify the default user name for non-VRF address pools that have been configured to obtain subnets through AAA, use the `ip dhcp aaa default username` command in global configuration mode. To disable this functionality, use the `no` form of this command.

```
ip dhcp aaa default username name
no ip dhcp aaa default username name
```

**Syntax Description**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>name</code></td>
<td>Name of the address pool.</td>
</tr>
</tbody>
</table>

**Defaults**

No default behavior or values.

**Command Modes**

Global configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2(8)T</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.2(15)T</td>
<td>The behavior for when the USERNAME attribute is sent in the AAA request was changed.</td>
</tr>
<tr>
<td>12.2(27)SBA</td>
<td>This command was integrated into Cisco IOS Release 12.2(27)SBA.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Address pools that are configured with the `vrf` and `origin aaa` DHCP pool configuration commands will set the USERNAME attribute in the AAA request to the specified VRF name. If the VPN ID as specified in RFC 2685 is configured for the VRF, the VPN ID will be sent instead.

Address pools that are not configured with the `vrf` command but are configured with the `origin aaa` command, will set the USERNAME attribute in the AAA request to the specified `name` in the `ip dhcp aaa default username` command.

Use the `debug aaa attribute` command to verify the value of the USERNAME attribute in the subnet request to the AAA server.

In Cisco IOS Release 12.2(8)T, if this command is not configured, no AAA subnet request from non-VRF ODAPs will be sent.

In Cisco IOS Release 12.2(15)T, if the DHCP pool is not configured with VRF and the `ip dhcp aaa default username` command is not configured, the AAA request will still be sent with the USERNAME attribute set to the DHCP pool name.

This command is not needed if all ODAPs on the VHG/PE are VRF-associated.

**Examples**

The following example sets the USERNAME attribute in the AAA request to green:

```
ip dhcp aaa default username green
```

</tbody>
</table>
origin

To configure an address pool as an on-demand address pool (ODAP) or static mapping pool, use the \texttt{origin} command in DHCP pool configuration mode. To disable the ODAP, use the \texttt{no} form of this command.

\begin{verbatim}
origin \{ dhcp | aaa | ipcp | file url \} [subnet size initial size [autogrow size]]
\end{verbatim}

\begin{verbatim}
no origin \{ dhcp | aaa | ipcp | file url \} [subnet size initial size [autogrow size]]
\end{verbatim}

\textbf{Syntax Description}

- **dhcp**: Specifies the Dynamic Host Configuration Protocol (DHCP) as the subnet allocation protocol.
- **aaa**: Specifies authentication, authorization, and accounting (AAA) as the subnet allocation protocol.
- **ipcp**: Specifies the IP Control Protocol (IPCP) as the subnet allocation protocol.
- **file url**: Specifies the external database file that contains the static bindings assigned by the DHCP server. The \texttt{url} argument specifies the location of the external database file.
- **subnet size initial size**: (Optional) Specifies the initial size of the first requested subnet. You can enter \texttt{size} as either the subnet mask (nnnn.nnnn.nnnn.nnnn) or prefix size (/nn). The valid values are /0 and /4 to /30.
- **autogrow size**: (Optional) Specifies that the pool can grow incrementally. The \texttt{size} argument is the size of the requested subnets when the pool requests additional subnets (upon detection of high utilization). You can enter \texttt{size} as either the subnet mask (nnnn.nnnn.nnnn.nnnn) or prefix size (/nn). The valid values are /0 and /4 to /30.

\textbf{Defaults}

The default size value is /0.

\textbf{Command Modes}

DHCP pool configuration

\textbf{Command History}

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2(8)T</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.3(11)T</td>
<td>The \texttt{file} keyword was added.</td>
</tr>
<tr>
<td>12.2(27)SBA</td>
<td>This command was integrated into Cisco IOS Release 12.2(27)SBA.</td>
</tr>
</tbody>
</table>

\textbf{Usage Guidelines}

If you do not configure the pool as an autogrow pool, the pool will not request additional subnets if one subnet is already in the pool.

Use the \texttt{dhcp} keyword to obtain subnets from DHCP, the \texttt{aaa} keyword to obtain subnets from the AAA server, and the \texttt{ipcp} keyword to obtain subnets from IPCP negotiation. If you expect that the utilization of the pool may grow over time, use the \texttt{autogrow size} option. If a pool has been configured with the
**autogrow size** option, ensure that the source server is capable of providing more than one subnet to the same pool. Even though the Cisco IOS software specifies the requested subnet size, it can accept any offered subnet size from the source server.

**Examples**

The following example shows how to configure an address pool named green to use DHCP as the subnet allocation protocol with an initial subnet size of 24 and an autogrow subnet size of 24:

```plaintext
ip dhcp pool green
  vrf green
  origin dhcp subnet size initial /24 autogrow /24
  utilization mark high 80
  utilization mark low 20
```

The following example shows how to configure the location of the external text file:

```plaintext
ip dhcp pool abcpool
  origin file tftp://10.1.0.1/staticbindingfile
```

</tr>
<tr>
<td>12.2(27)SBA</td>
<td>This command was integrated into Cisco IOS Release 12.2(27)SBA.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

This command applies to point-to-point interfaces that support the PPP or Serial Line Internet Protocol (SLIP) encapsulation. This command sets the address used on the remote (PC) side.

**Note**
This command replaces the `async default ip address` command.

This command allows an administrator to configure all possible address pooling mechanisms on an interface-by-interface basis.
The `peer default ip address` command can override the global default mechanism defined by the `ip address-pool` command on an interface-by-interface basis, as follows:

- For all interfaces not configured with a peer default IP address mechanism (equivalent to selecting the `peer default ip address pool` command), the router uses the global default mechanism that is defined by the `ip address-pool` command.
- If you select the `peer default ip address pool pool-name` form of this command, then the router uses the locally configured pool on this interface and does not follow the global default mechanism.
- If you select the `peer default ip address ip-address` form of this command, the specified IP address is assigned to any peer connecting to this interface and any global default mechanism is overridden for this interface.
- If you select the `peer default ip address dhcp` form of this command, the DHCP proxy-client mechanism is used by default on this interface and any global default mechanism is overridden for this interface.
- If you select the `peer default ip address dhcp-pool` form of this command, the DHCP on-demand address pooling mechanism is used by default on this interface and any global default mechanism is overridden for this interface.

**Examples**

The following command specifies that this interface will use a local IP address pool named pool3:
```
peer default ip address pool pool3
```

The following command specifies that this interface will use the IP address 172.19.34.21:
```
peer default ip address 172.19.34.21
```

The following command reenables the global default mechanism to be used on this interface:
```
peer default ip address pool
```

The following example specifies address 192.168.7.51 for asynchronous interface 6:
```
line 20
  speed 115200
interface async 6
  peer default ip address 192.168.7.51
```

</tbody>
</table>

**Usage Guidelines**

Use this command to determine the subnets allocated and to examine the current utilization level for the pool or all the pools if the `name` argument is not used.

**Examples**

The following example shows DHCP address pool information for pool 1. Table 1 lists descriptions for each field in the example.

```
Router# show ip dhcp pool 1
Pool 1:
  Utilization mark (high/low) : 85 / 15
  Subnet size (first/next)    : 24 / 24 (autogrow)
  VRF name                   : RED
  Total addresses            : 28
  Leased addresses           : 11
  Pending event              : none

2 subnets are currently in the pool:
  Current index        IP address range      Leased addresses
  10.1.1.12            10.1.1.1 - 10.1.1.14   11
  10.1.1.17            10.1.1.17 - 10.1.1.30   0
```

</table>
utilization mark high

To configure the high utilization mark of the current address pool size, use the `utilization mark high` command in DHCP pool configuration mode. To remove the high utilization mark, use the `no` form of this command.

```
utilization mark high percentage-number

no utilization mark high percentage-number
```

**Syntax Description**

`percentage-number` Percentage of the current pool size.

**Defaults**

The default high utilization mark is 100 percent of the current pool size.

**Command Modes**

DHCP pool configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2(8)T</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.2(27)SBA</td>
<td>This command was integrated into Cisco IOS Release 12.2(27)SBA.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

The current pool size is the sum of all addresses in all the subnets in the pool. If the utilization level exceeds the configured high utilization mark, the pool will schedule a subnet request.

This command cannot be used unless the `autogrow size` option of the `origin` command is configured.

**Examples**

The following example sets the high utilization mark to 80 percent of the current pool size:

```
utilization mark high 80
```

<td>origin</td>
<td>Configures an address pool as an on-demand address pool.</td>
</tr>
<tr>
<td>utilization mark low</td>
<td>Configures the low utilization mark of the current address pool size.</td>
</tr>
</tbody>
</table>
utilization mark low

To configure the low utilization mark of the current address pool size, use the `utilization mark low` command in DHCP pool configuration mode. To remove the low utilization mark, use the `no` form of this command.

```
utilization mark low percentage-number

no utilization mark low percentage-number
```

Syntax Description

| percentage-number | Percentage of the current pool size. |

Defaults

The default low utilization mark is 0 percent of the current pool size.

Command Modes

DHCP pool configuration

Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2(8)T</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.2(27)SBA</td>
<td>This command was integrated into Cisco IOS Release 12.2(27)SBA.</td>
</tr>
</tbody>
</table>

Usage Guidelines

The current pool size is the sum of all addresses in all the subnets in the pool. If the utilization level drops below the configured low utilization mark, a subnet release is scheduled from the address pool. This command cannot be used unless the `autogrow size` option of the `origin` command is configured.

Examples

The following example sets the low utilization mark to 20 percent of the current pool size:

```
utilization mark low 20
```

Related Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>origin</code></td>
<td>Configures an address pool as an on-demand address pool.</td>
</tr>
<tr>
<td><code>utilization mark high</code></td>
<td>Configures the high utilization mark of the current address pool size.</td>
</tr>
</tbody>
</table>
vrf

To associate the on-demand address pool with a VPN routing and forwarding instance (VRF) name, use the vrf command in DHCP pool configuration mode. To remove the VRF name, use the no form of this command.

```
vrf name
no vrf name
```

**Syntax Description**

| name | Name of the VRF to which the address pool is associated. |

**Defaults**

No default behavior or values

**Command Modes**

DHCP pool configuration

**Command History**

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2(8)T</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.2(27)SBA</td>
<td>This command was integrated into Cisco IOS Release 12.2(27)SBA.</td>
</tr>
</tbody>
</table>

**Usage Guidelines**

Associating a pool with a VRF allows overlapping addresses with other pools that are not on the same VRF. Only one pool can be associated with each VRF. If the pool is configured with the origin dhcp command or origin aaa command, the VRF information is sent in the subnet request. If the VRF is configured with an RFC 2685 VPN ID, the VPN ID will be sent instead of the VRF name.

**Examples**

The following example associates the on-demand address pool with a VRF named red:

```
ip dhcp pool red_pool
  origin dhcp subnet size initial 24 autogrow 24
  utilization mark high 85
  utilization mark low 15
  vrf red
```

AAA—authentication, authorization, and accounting. Suite of network security services that provide the primary framework through which access control can be set up on your Cisco router or access server.

Cisco Access Registrar—A RADIUS server that supports service provider deployment of access services by centralizing AAA information and simplifying provisioning and management.

client—A host trying to configure its interface (obtain an IP address) using DHCP or BOOTP protocols.

DHCP—Dynamic Host Configuration Protocol.

incremental subnet size—The desired size of the second and subsequent subnets requested for an on-demand pool.

initial subnet size—The desired size of the first subnet requested for an on-demand pool.

IPCP—IP Control Protocol. Protocol that establishes and configures IP over PPP.

MPLS—Multiprotocol Label Switching. Emerging industry standard upon which tag switching is based.

ODAP—on-demand address pool.

PE router—provider edge router.

PPP—Point-to-Point Protocol.

RADIUS—Remote Authentication Dial-In User Service. Database for authenticating modem and ISDN connections and for tracking connection time.

relay agent—A router that forwards DHCP and BOOTP messages between a server and a client on different subnets.

releasable subnet—A leased subnet that has no address leased from it.

server—DHCP or BOOTP server.

VHG—Virtual Home Gateway. A Cisco IOS software component that terminates PPP sessions. It is owned and managed by the service provider on behalf of its customer to provide access to remote users of that customers network. A single service provider device (router) can host multiple VHGs of different customers. A VHG can be dynamically brought up and down based on the access pattern of the remote users. Note that there is no single IOS feature called the VHG; it is a collection of function and features.

VHG/PE router—A device that terminates PPP sessions and maps the remote users to the corresponding MPLS VPNs.

VPN—Virtual Private Network. Enables IP traffic to use tunneling to travel securely over a public TCP/IP network.

VPN information—In this document, VPN information refers to VRF name or VPN ID.

VRF—VPN routing and forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a PE router. Each VPN instantiated on the PE router has its own VRF.
