QoS: Per-Session Shaping and Queuing on LNS

First Published: February 28, 2006

The QoS: Per-Session Shaping and Queuing on LNS feature provides the ability to shape (for example, transmit or drop) or queue (for transmission later) the traffic going from an Internet service provider (ISP) to an ISP subscriber over Layer 2 Tunneling Protocol (L2TP) Network Server (LNS). With this feature, the outgoing traffic is shaped or queued on a per-session basis.

Prerequisites for Per-Session Shaping and Queuing on LNS

- Verify that the PPPoE (or PPoA) sessions are enabled.
- Verify that L2TP resequencing is disabled.
- This feature uses policy maps in which queuing mechanisms (such as class-based weighted fair queuing [CBWFQ]) are configured.

A policy map can be configured for a session and for an outgoing interface. With this feature, a policy map (in which a queuing mechanism is configured) cannot be used for both the session and the outgoing interface simultaneously. If a queuing mechanism is in both policy maps, one of these policy maps must be disabled.

Restrictions for Per-Session Shaping and Queuing on LNS

- This feature does not support L2TP sequencing.

Information About Per-Session Shaping and Queuing on LNS

To use the QoS: Per-Session Shaping and Queuing on LNS feature, you should understand the following concepts:

- Benefits of Per-Session Shaping and Queuing, page 2
- Per-Session Shaping and Queuing Sample Topology, page 3
- Per-Session Traffic Shaping, page 3
- Per-Session CBWFQ, page 4
- Two Methods for Configuring Per-Session Shaping and Queuing on LNS, page 4

Benefits of Per-Session Shaping and Queuing

The ability to shape or queue traffic on a per-session basis helps to avoid traffic congestion and allows the ISP to adhere to the Service Level Agreement (SLA) established for handling traffic. Shaping or queuing traffic on a per-session basis provides a higher degree of granularity when managing traffic on the network.
Per-Session Shaping and Queuing Sample Topology

Figure 1 is a sample topology for per-session shaping and queuing on LNS.

**Figure 1**  *Per-Session Shaping and Queuing Topology (PPP Sessions Forwarded)*

In this simplified topology example, downstream traffic is forwarded from the ISP (the source) to an ISP subscriber (the destination) during a PPP session. From an LNS at the ISP, the traffic is transmitted over an L2TP tunnel to an L2TP Access Concentrator (LAC), and then to the subscriber.

Figure 2 illustrates per-session shaping and queuing using a PPP termination and aggregation (PTA) topology.

**Figure 2**  *Per-Session Shaping and Queuing Using a PTA Topology*

In this simplified topology example, the downstream traffic is forwarded from the ISP (the source) over a LAC to an ISP subscriber (the destination) during a PPP session.

Per-Session Traffic Shaping

Traffic shaping allows you to control the traffic going out an interface in order to match its flow to the speed of the remote target interface. Traffic shaping ensures that the traffic conforms to policies contracted for it. Thus, traffic adhering to a particular profile can be shaped to meet downstream requirements, eliminating bottlenecks in topologies with data-rate mismatches.

A traffic shaper typically delays excess traffic using a buffer, or a similar mechanism, to hold packets and shape the flow when the data rate of the source is higher than expected.

The QoS: Per-Session Shaping and Queuing on LNS feature supports traffic shaping. With this feature, traffic shaping is implemented on a per-session basis (that is, when traffic arrives at the interface).

For more information about traffic shaping, see the *Cisco IOS Quality of Service Solutions Configuration Guide*, Release 12.4.
Per-Session CBWFQ

WFQ offers dynamic, fair queuing that divides bandwidth across queues of traffic based on weights. WFQ ensures that all traffic is treated fairly, given its weight.

CBWFQ extends the standard WFQ functionality to provide support for user-defined traffic classes. For CBWFQ, you define traffic classes based on match criteria including protocols, access control lists (ACLs), and input interfaces. Packets satisfying the match criteria for a class constitute the traffic for that class. A FIFO queue is reserved for each class, and traffic belonging to a class is directed to the queue for that class.

The QoS: Per-Session Shaping and Queuing on LNS feature supports CBWFQ. With this feature, CBWFQ is implemented on a per-session basis (that is, when traffic arrives at the interface).

For more information on CBWFQ, see the Cisco IOS Quality of Service Solutions Configuration Guide, Release 12.4.

Two Methods for Configuring Per-Session Shaping and Queuing on LNS

When you configure the QoS: Per-Session Shaping and Queuing on LNS feature, you can choose one of the following configuration methods:

- Configure the feature using a virtual template.
  This method is considered a “legacy” method. It is of earlier origin and still an available option for those familiar with using virtual templates.
- Configure the feature using a RADIUS server.
  This method takes advantage of more recent technology and is the recommended method.

How to Configure Per-Session Shaping and Queuing on LNS

The tasks for configuring the QoS: Per-Session Shaping and Queuing on LNS feature vary according to the configuration method you are using. You can choose to configure the feature using either a virtual template or a RADIUS server.

To configure the feature using a virtual template, see the “Configuring Per-Session Queuing and Shaping Using a Virtual Template” section on page 4.

To configure the feature using a RADIUS server, see the “Configuring Per-Session Shaping and Queuing using a RADIUS Server” section on page 9.

Configuring Per-Session Queuing and Shaping Using a Virtual Template

This section contains the following tasks:

- Configuring the Policy Map, page 5
- Associating the Policy Map with a Virtual Template, page 7
- Verifying the Configuration, page 8
Configuring the Policy Map

A policy map specifies the quality of service (QoS) feature to be applied to network traffic. Examples of features that can be specified in a policy map include class-based weighted fair queuing (CBWFQ) and traffic shaping.

To configure the policy map, complete the following steps.

Hierarchical Policy Maps

Policy maps can be configured in a hierarchical structure. That is, policy maps can be configured in levels subordinate to one another. The policy map at the highest level is referred to as the “parent” policy map. A subordinate policy map is referred to as the “child” policy map.

A typical hierarchical policy map structure consists of a parent policy map and one child policy map. Configure the child policy map first; then configure the parent policy map. Both types of policy maps are configured in the same manner.

The parent policy map typically contains one class—the class called class-default. The child policy map can contain multiple classes.

Prerequisites

Before configuring the policy map, create the traffic classes and specify the match criteria used to classify traffic. To create traffic classes and specify match criteria, use the Modular Quality of Service (QoS) Command-Line Interface (CLI) (MQC).

Restrictions

The following restrictions apply to hierarchical policy maps:

- Specify CBWFQ in the child policy map only. CBWFQ cannot be specified in the parent policy map.
- Traffic shaping can be specified in either the parent policy map or the child policy map.
  However, for this feature, you must specify traffic shaping in the parent policy map. Specifying traffic shaping in the child policy map is optional.

SUMMARY STEPS

1. enable
2. configure terminal
3. policy-map policy-map-name
4. class {class-name | class-default}
5. shape [average | peak] mean-rate [burst-size] [excess-burst-size]
6. bandwidth {bandwidth-kbps | remaining percent | percent percentage}
7. service-policy {input | output} policy-map-name
8. exit
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  - Enter your password if prompted. |
| **Example:** Router> enable |
| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:** Router# configure terminal |
| **Step 3** policy-map policy-map-name | Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy, and enters policy-map configuration mode.  
  - Enter the name of the policy map. |
| **Example:** Router(config)# policy-map child |
| **Note** In a hierarchical policy map structure, the policy map can be either the child or the parent policy map. |
| **Step 4** class [class-name | class-default] | Specifies the name of the class whose policy you want to modify, and enters policy-map class configuration mode.  
  - Enter the class name or enter the class-default keyword. |
| **Example:** Router(config-pmap)# class class-default |
| **Step 5** shape [average | peak] mean-rate [burst-size] [excess-burst-size] | (Optional) Shapes traffic to the indicated bit rate according to the algorithm specified.  
  - Enter the bit rate in bits per second and any optional values. |
| **Example:** Router(config-pmap-c)# shape average 128000 |
| **Note** In a hierarchical policy map structure, traffic shaping can be enabled in *either* the parent policy map or the child policy map.  
  However, for this feature, you *must* specify traffic shaping in the parent policy map. Specifying traffic shaping in the child policy map is optional. |
| **Step 6** bandwidth [bandwidth-kbps | remaining percent percentage | percent percentage] | (Optional) Specifies or modifies the bandwidth allocated for a class belonging to a policy map.  
  - Enter the bandwidth allocated for the class. |
| **Example:** Router(config-pmap-c)# bandwidth percent 30 |
| **Note** This command configures CBWFQ. In a hierarchical policy map structure, CBWFQ can be configured in the child policy map only. CBWFQ cannot be specified in the parent policy map. |
How to Configure Per-Session Shaping and Queuing on LNS

What to Do Next?

So far, you have created and configured a policy map. If you want to configure additional policy maps (for example, a parent policy map for use in a hierarchical policy map structure), repeat the steps in “Configuring the Policy Map” section on page 5 to configure any additional policy maps.

Otherwise, advance to the “Associating the Policy Map with a Virtual Template” section on page 7.

Note

If you are using a RADIUS server, after configuring a policy map, advance to the “Adding the Cisco QoS AV Pairs to the User Profile on the RADIUS Server” section on page 9.

Associating the Policy Map with a Virtual Template

To associate the policy map (where the QoS features are specified) with the virtual template, complete the following steps.

Virtual Templates and Policy Maps

A virtual template is a logical interface configured with generic configuration information for a specific purpose or with configuration information common to specific users, plus router-dependent information. The template takes the form of a list of Cisco IOS interface commands that are applied to virtual access interfaces, as needed.

A virtual template is configured (defined) on an interface. When a session is enabled (that is, when a packet arrives at the interface), the virtual template inherits the QoS features specified in the policy map for use during the session.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface virtual-template number
4. service-policy [input | output] policy-map-name
5. exit

---

### Command or Action | Purpose
--- | ---
**Step 7** service-policy {input | output} policy-map-name
| (Optional) Attaches the policy map to an input or output interface to be used as the service policy for that interface. 
| • Enter the name of the child policy map.

**Example:**
Router(config-pmap-c)# service-policy output child

**Step 8** exit
| (Optional) Returns from policy-map class configuration mode.

**Example:**
Router(config-pmap-c)# exit

---
DETAILED STEPS

<table>

<td></td>
</tr>
<tr>
<td><strong>Note</strong> If you are using a hierarchical policy map structure, this policy map can be either the parent or the child policy map.</td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong> This feature does not support the input keyword. Enter the output keyword only.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> exit</td>
<td>(Optional) Returns from interface configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config-if)# exit</td>
<td></td>
</tr>
</tbody>
</table>

Verifying the Configuration

After configuring the policy maps (as many as needed) and associating the policy map(s) with the virtual template on the interface, you may want to verify the configuration. The verification tasks allow you to see whether the policy maps are configured the way you intended.

To verify the configuration, complete the following steps.

SUMMARY STEPS

1. enable
2. show policy-map session [uid uid-number] [input | output [class class-name]]
3. exit

What to Do Next?

After verifying the configuration, advance to the “Configuration Examples for Per-Session Shaping and Queuing on LNS” section on page 12.

Configuring Per-Session Shaping and Queuing using a RADIUS Server

This section contains the following tasks:
- Configuring the Policy Map, page 9
- Adding the Cisco QoS AV Pairs to the User Profile on the RADIUS Server, page 9
- Verifying the Configuration, page 11

Configuring the Policy Map

A policy map specifies the quality of service (QoS) feature to be applied to network traffic. Examples of features that can be specified in a policy map include class-based weighted fair queuing (CBWFQ) and traffic shaping.

To configure the policy map, complete the procedure in the “Configuring the Policy Map” section on page 5.

After configuring the policy map, return here and complete the steps in “Adding the Cisco QoS AV Pairs to the User Profile on the RADIUS Server” section on page 9.

Adding the Cisco QoS AV Pairs to the User Profile on the RADIUS Server

To configure QoS on the RADIUS server, you must add two Cisco QoS AV pairs to the subscriber’s user profile on the RADIUS server. To add the Cisco QoS AV pairs to the subscriber’s user profile, complete the following steps on the RADIUS server.
Cisco AV Pairs and VSAs

Cisco AV pairs are part of vendor-specific attributes (VSAs) that allow a policy map to be applied to the LNS. Cisco AV pairs are a combination of an attribute and a value. The purpose of Cisco VSA (attribute 26) is to communicate vendor-specific information between the LNS and the RADIUS server. The Cisco VSA encapsulates vendor-specific attributes that allow vendors such as Cisco to support their own extended attributes.

For this configuration, one of two Cisco AV pairs can be used (formatted as shown below):

- lcp:interface-config=service-policy output/input <policy name>
  
  This Cisco AV pair is considered a “legacy” AV pair. It is of earlier origin but is still an available choice.

- sub-qos-policy-in/out=<policy name>
  
  This Cisco AV pair takes advantage of more recent technology and is the recommended choice. This Cisco AV pair is the one shown in the configuration tasks and examples.

The Cisco AV pair is added to the subscriber’s user file on the RADIUS server. A subscriber’s user file contains an entry for each user that the RADIUS server will authenticate. Each entry establishes an attribute the user can access.

When looking at a user file, the data to the left of the equal sign (=) is an attribute defined in the dictionary file, and the data to the right of the equal sign is the configuration data.

The Cisco AV pair identifies the policy map that was used to configure the specific QoS features. When the LNS requests the policy map name (specified in the Cisco AV pair), the policy map is pulled to the LNS from the RADIUS server when the session is established. The Cisco AV pair applies the appropriate policy map (and, therefore, the QoS feature) directly to the LNS from the RADIUS server.

Prerequisites

- Authentication, authorization, and accounting (AAA) must be enabled.
- The RADIUS server must be configured.
- The subscriber’s user profile on the RADIUS server must be created.
- The PPP session is established.
- A policy map is configured.

SUMMARY STEPS

1. sub-qos-policy-in/out=<policy name>
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 `sub-qos-policy-in/out=<policy name>` | Enters the Cisco QoS AV pairs for policy maps on the RADIUS server in the subscriber’s user file. When the LNS requests the policy name, the information in the subscriber’s user file is used.  
- Add the Cisco QoS AV pair to the subscriber’s user file.  
**Note** The first three lines of the subscriber’s user profile contain the user password, the service type, and the protocol type. This information is entered into the subscriber’s user profile when the profile is first created. |

Example:
```
userid  Password ="cisco"
Service-Type = Framed,
Framed-Protocol = PPP,
cisco-avpair = "sub-qos-policy-in/out=parent"
```

Verifying the Configuration

After adding the Cisco QoS AV pair to the subscriber’s user profile, you may want to verify the configuration. The verification tasks allow you to see whether the policy maps are configured the way you intended.

To verify the configuration, complete the follows steps.

SUMMARY STEPS

1. enable
2. `show policy-map session [uid uid-number] [input | output [class class-name]]`
3. exit

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Router&gt; enable</code></td>
</tr>
</tbody>
</table>

Step 2 `show policy-map session [uid uid-number] [input | output [class class-name]]`  
Displays the information about the session identified by the unique ID.

Example:
```
Router# show policy-map session uid 401 output
```

Step 3 `exit`  
(Optional) Returns from privileged EXEC mode.

Example:
```
Router# exit
```
Configuration Examples for Per-Session Shaping and Queuing on LNS

This section contains the following examples:

- Configuring the Policy Map: Example, page 12
- Associating the Policy Map with a Virtual Template: Example, page 12
- Adding the Cisco QoS AV Pairs to the User Profile on the RADIUS Server: Example, page 13
- Verifying the Configuration: Example, page 13

Configuring the Policy Map: Example

This section contains an example of a hierarchical policy map configuration. In this example, two policy maps, one called “parent” (the primary or parent policy map) and one called “child” (the secondary or child policy map) have been configured.

In this example, traffic shaping has been enabled in the parent policy map, and CBWFQ has been enabled in the child policy map. The service-policy command has been used to attach the policy map called child to the virtual template interface in the outgoing direction of the interface.

Router> enable
Router# configure terminal
Router(config)# policy-map child
Router(config-pmap)# class class1
Router(config-pmap-c)# bandwidth percent 30
Router(config-pmap-c)# exit

Router> enable
Router# configure terminal
Router(config)# policy-map parent
Router(config-pmap)# class class-default
Router(config-pmap-c)# shape average 128000
Router(config-pmap-c)# service-policy child
Router(config-pmap-c)# exit

Associating the Policy Map with a Virtual Template: Example

This section contains an example of associating a policy map with a virtual template. In this example, the policy map called “parent” is associated with virtual template 1. For a hierarchical policy map structure, the policy map can be either the parent or child policy map.

Router> enable
Router# configure terminal
Router(config)# interface virtual-template 1
Router(config-if)# service-policy output parent
Router(config-if)# exit
Adding the Cisco QoS AV Pairs to the User Profile on the RADIUS Server: Example

The following is an example of a subscriber’s user profile in which the Cisco QoS AV pairs have been added.

The first three lines contain the user password, the service type, and the protocol type. This information is entered into the subscriber’s user profile when the user profile is first created.

The last line is an example of the Cisco QoS AV pair added to the user profile.

userid   Password =’cisco’
Service-Type = Framed,
Framed-Protocol = PPP,
cisco-avpair = ’sub-qos-policy-in/out=parent’

Verifying the Configuration: Example

The following is sample output of the show policy-map session command used to verify the configuration. The sample output allows you to verify the content of the policy maps to ensure that the policy maps are configured the way you intended (that is, that traffic shaping and traffic queuing are enabled and reporting statistics as expected).

Router# show policy-map session

SSS session identifier 1 -

Service-policy output: parent

Class-map: class-default (match-any)
  0 packets, 0 bytes
  30 second offered rate 0 bps, drop rate 0 bps
  Match: any
    0 packets, 0 bytes
    30 second rate 0 bps
  Queueing
  queue limit 128 packets
  (queue depth/total drops/no-buffer drops) 0/0/0
  (pkts output/bytes output) 0/0
  shape (average) cir 512000, bc 12800, be 12800
  target shape rate 512000

Service-policy : child

Class-map: prec0 (match-all)
  0 packets, 0 bytes
  30 second offered rate 0 bps, drop rate 0 bps
  Match: ip precedence 0
  Queueing
  queue limit 38 packets
  (queue depth/total drops/no-buffer drops) 0/0/0
  (pkts output/bytes output) 0/0
  bandwidth 30% (153 kbps)

Class-map: prec2 (match-all)
  0 packets, 0 bytes
  30 second offered rate 0 bps, drop rate 0 bps
  Match: ip precedence 2
  Queueing
queue limit 44 packets
(queue depth/total drops/no-buffer drops) 0/0/0
(pkts output/bytes output) 0/0
shape (average) cir 212000, bc 7632, be 7632
target shape rate 212000

Class-map: class-default (match-any)
0 packets, 0 bytes
30 second offered rate 0 bps, drop rate 0 bps
Match: any
0 packets, 0 bytes
30 second rate 0 bps

queue limit 44 packets
(queue depth/total drops/no-buffer drops) 0/0/0
(pkts output/bytes output) 0/0

Command Reference

This section documents one modified command only.

- `show policy-map session`
show policy-map session

To display the quality of service (QoS) policy map in effect for the Subscriber Service Switch (SSS) session, use the **show policy-map session** command in user EXEC or privileged EXEC mode.

```
show policy-map session [uid uid-number] [input | output [class class-name]]
```

### Syntax Description

- **uid** *(Optional)* Defines a unique session ID.
- **uid-number** *(Optional)* Unique session ID. Ranges from 1 to 65535.
- **input** *(Optional)* Displays the upstream traffic of the unique session.
- **output** *(Optional)* Displays the downstream traffic of the unique session.
- **class** *(Optional)* Identifies the class that is part of the QoS policy-map definition.
- **class-name** *(Optional)* Provides a class name that is part of the QoS policy-map definition.

### Command Modes

- User EXEC
- Privileged EXEC

### Command History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.3(8)T</td>
<td>This command was introduced.</td>
</tr>
<tr>
<td>12.2(28)SB</td>
<td>This command was integrated into Cisco IOS Release 12.2(28)SB.</td>
</tr>
</tbody>
</table>

### Usage Guidelines

Use the **show policy-map session** command with the **uid** keyword to verify the QoS policy map of a unique session ID in the input and output streams in the SSS session.

Use the **show policy-map session** command with the optional **class class-name** keyword argument combination to display statistics for a particular class. If you use the **show policy-map session** command without the **class class-name** keyword argument combination, statistics for all the classes defined in the QoS policy map display.

### Examples

The following example from the **show policy-map session** command displays QoS policy-map statistics for traffic in the downstream direction for the QoS policy maps configured:

```
Router# show policy-map session uid 401 output

SSS session identifier 401 -
Service-policy output: downstream-policy

Class-map: customer1234 (match-any)  
4464 packets, 249984 bytes  
5 minute offered rate 17000 bps, drop rate 0 bps  
Match: ip dscp cs1 cs2 cs3 cs4  
4464 packets, 249984 bytes  
5 minute rate 17000 bps  
QoS Set
```
dscp af11
   Packets marked 4464

Class-map: customer56 (match-any)
   2232 packets, 124992 bytes
   5 minute offered rate 8000 bps, drop rate 0 bps
   Match: ip dscp cs5  cs6
   2232 packets, 124992 bytes
   5 minute rate 8000 bps
   police:
      cir 20000 bps, bc 10000 bytes
      pir 40000 bps, be 10000 bytes
      conformed 2232 packets, 124992 bytes; actions:
      set-dscp-transmit af21
      exceeded 0 packets, 0 bytes; actions:
      set-dscp-transmit af22
      violated 0 packets, 0 bytes; actions:
      set-dscp-transmit af23
      conformed 8000 bps, exceed 0 bps, violate 0 bps

Class-map: customer7 (match-any)
   1116 packets, 62496 bytes
   5 minute offered rate 4000 bps, drop rate 4000 bps
   Match: ip dscp cs7
   1116 packets, 62496 bytes
   5 minute rate 4000 bps
   drop

Class-map: class-default (match-any)
   1236 packets, 68272 bytes
   5 minute offered rate 4000 bps, drop rate 0 bps
   Match: any

Table 1 describes the significant fields shown in the display.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSS session identifier</td>
<td>Name of the session identifier.</td>
</tr>
<tr>
<td>Service-policy output</td>
<td>Name of the output service policy applied to the specified interface or virtual circuit (VC).</td>
</tr>
<tr>
<td>Class-map</td>
<td>Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.</td>
</tr>
<tr>
<td>packets and bytes</td>
<td>Number of packets (also shown in bytes) identified as belonging to the class of traffic being displayed.</td>
</tr>
</tbody>
</table>
If the packets are compressed over an outgoing interface, the improved packet rate achieved by packet compression is not reflected in the offered rate. Also, if the packets are classified before they enter a combination of tunnels (for example, a generic routing encapsulation (GRE) tunnel and an IP Security (IPSec) tunnel), the offered rate does not include all the extra overhead associated with tunnel encapsulation in general. Depending on the configuration, the offered rate may include no overhead, may include the overhead for only one tunnel encapsulation, or may include the overhead for all tunnel encapsulations. In most of the GRE and IPSec tunnel configurations, the offered rate includes the overhead for GRE tunnel encapsulation only.

The drop rate is calculated by subtracting the number of successfully transmitted packets from the offered rate.

Match criteria specified for the class of traffic. Choices include criteria such as IP precedence, IP differentiated services code point (DSCP) value, Multiprotocol Label Switching (MPLS) experimental (EXP) value, access groups, and QoS groups. For more information about the variety of match criteria options available, refer to the chapter “Configuring the Modular Quality of Service Command-Line Interface” in the Cisco IOS Quality of Service Solutions Configuration Guide.

Indicates that packet marking is in place.

Value used in packet marking.

The number of packets marked.

Indicates that the police command has been configured to enable traffic policing. Also, displays the specified committed information rate (CIR), conform burst (bc) size, peak information rate (PIR), and peak burst (be) size used for marking packets.

Displays the action to be taken on packets conforming to a specified rate. Displays the number of packets and bytes on which the action was taken.

Displays the action to be taken on packets exceeding a specified rate. Displays the number of packets and bytes on which the action was taken.

Displays the action to be taken on packets violating a specified rate. Displays the number of packets and bytes on which the action was taken.
The following example from the `show policy-map session` command displays QoS policy-map statistics for traffic in the upstream direction for all the QoS policy maps configured:

```
Router# show policy-map session uid 401 input

SSS session identifier 401 -

Service-policy input: upstream-policy

Class-map: class-default (match-any)
  1920 packets, 111264 bytes
  5 minute offered rate 7000 bps, drop rate 5000 bps
  Match: any
  police:
    cir 8000 bps, bc 1500 bytes
    conformed 488 packets, 29452 bytes; actions: transmit
    exceeded 1432 packets, 81812 bytes; actions: drop
    conformed 7000 bps, exceed 5000 bps
```

Table 2 describes the significant fields shown in the display.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSS session identifier</td>
<td>Name of the session identifier.</td>
</tr>
<tr>
<td>Service-policy input</td>
<td>Name of the input service policy applied to the specified interface or VC.</td>
</tr>
<tr>
<td>Class-map</td>
<td>Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.</td>
</tr>
<tr>
<td>packets and bytes</td>
<td>Number of packets (also shown in bytes) identified as belonging to the class of traffic being displayed.</td>
</tr>
<tr>
<td>offered rate</td>
<td>Rate, in bps, of packets coming in to the class.</td>
</tr>
</tbody>
</table>

**Note**
If the packets are compressed over an outgoing interface, the improved packet rate achieved by packet compression is not reflected in the offered rate. Also, if the packets are classified *before* they enter a combination of tunnels (for example, a generic routing encapsulation (GRE) tunnel and an IP Security (IPSec) tunnel), the offered rate does not include all the extra overhead associated with tunnel encapsulation in general. Depending on the configuration, the offered rate may include no overhead, may include the overhead for only one tunnel encapsulation, or may include the overhead for all tunnel encapsulations. In most of the GRE and IPSec tunnel configurations, the offered rate includes the overhead for GRE tunnel encapsulation only.
### Table 2  show policy-map session uid input Field Descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>drop rate</td>
<td>Rate, in bps, at which packets are dropped from the class. The drop rate is calculated by subtracting the number of successfully transmitted packets from the offered rate.</td>
</tr>
</tbody>
</table>

**Match**

Match criteria specified for the class of traffic. Choices include criteria such as IP precedence, IP differentiated services code point (DSCP) value, Multiprotocol Label Switching (MPLS) experimental (EXP) value, access groups, and QoS groups. For more information about the variety of match criteria options available, refer to the chapter “Configuring the Modular Quality of Service Command-Line Interface” in the *Cisco IOS Quality of Service Solutions Configuration Guide*.

| police    | Indicates that the police command has been configured to enable traffic policing. Also, displays the specified committed information rate (CIR), conform burst (bc) size, peak information rate (PIR), and peak burst (be) size used for marking packets.                                      |
| conformed | Displays the action to be taken on packets conforming to a specified rate. Displays the number of packets and bytes on which the action was taken.                                                                                                                                         |
| exceeded  | Displays the action to be taken on packets exceeding a specified rate. Displays the number of packets and bytes on which the action was taken.                                                                                                                                                                                                           |
| violated  | Displays the action to be taken on packets violating a specified rate. Displays the number of packets and bytes on which the action was taken.                                                                                                                                                                                                           |

**Glossary**

**L2TP**—Layer 2 Tunneling Protocol. An Internet Engineering Task Force (IETF) standards track protocol defined in RFC 2661 that provides tunneling of PPP. Based upon the best features of L2F and PPTP, L2TP provides an industry-wide interoperable method of implementing virtual private dialup network (VPDN).

**LAC**—Layer 2 Tunneling Protocol (L2TP) access concentrator. A node that acts as one side of an L2TP tunnel endpoint and is a peer to the L2TP network server (LNS). The LAC sits between an LNS and a remote system and forwards packets to and from each. Packets sent from the LAC to the LNS require tunneling with the L2TP protocol. The connection from the LAC to the remote system is either local or a PPP link.

**LNS**—L2TP Network Server. A node that acts as one side of an L2TP tunnel endpoint and is a peer to the L2TP access concentrator (LAC). The LNS is the logical termination point of a PPP session that is being tunneled from the remote system by the LAC.

**PPP**—Point-to-Point Protocol. A protocol that provides router-to-router and host-to-network connections over synchronous and asynchronous circuits. PPP is designed to work with several network layer protocols, such as IP, Internetwork Packet Exchange (IPX), and AppleTalk Remote Access (ARA).

**PPPoA**—Point-to-Point Protocol over ATM. A feature that allows a PPP session to be initiated on a simple bridging ATM connected client. PPPoA provides the ability to connect a network of hosts over a simple bridging access device to a remote access concentrator or aggregation concentrator.

**PPPoE**—Point-to-Point Protocol over Ethernet. A feature that allows a PPP session to be initiated on a simple bridging Ethernet connected client. PPPoE provides the ability to connect a network of hosts over a simple bridging access device to a remote access concentrator or aggregation concentrator.

**QoS**—Quality of Service. A measure of performance for a transmission system that reflects its transmission quality and service availability.

**SSS**—Subscriber Service Switch. A switch that provides flexibility on where and how many subscribers are connected to available services and how those services are defined. The primary focus of SSS is to direct PPP from one point to another using a Layer 2 subscriber policy. The policy will manage tunneling of PPP in a policy-based bridging fashion.
