MPLS VPN: VRF Selection Based on Source IP Address

The VPN Routing and Forwarding (VRF) Selection feature allows a specified interface on a provider edge (PE) router to route packets to different Virtual Private Networks (VPNs) based on the source IP address of the packet. This feature is an improvement over using a policy-based router to route packets to different VPNs.

Prerequisites for MPLS VPN: VRF Selection Based on Source IP Address

- MPLS VPNs must be enabled in the provider network.
- For the Cisco 12000 Internet Router Series must contain one of the following line cards:
  
  **Engine 0:**
  - 1-port OC-12 POS
  - 4-port OC-3 POS
  - 6- and 12- port DS3
  
  **Engine 2:**
  - 1-port OC-48 POS
  - 4-port OC-12 POS
  - 8- and 16-port OC-3 POS
  - 3-port Gigabit Ethernet
  
  **Engine 3:**
  - 4-port OC-12c/STM-4c POS ISE
  - 4-port CHOC-12 ISE
  - 1-port OC-48c POS ISE
  - 1-port CHOC-48 ISE
  - 4-, 8-, and 16-port OC-3c POS ISE
  
  **Engine 4:**
  - 4-port OC-48 POS
Restrictions for MPLS VPN: VRF Selection Based on Source IP Address

- VRF Select is supported only in Service Provider (-p-) images.
- The Cisco IOS software must support MPLS VPNs, and the provider network must have MPLS Label Distribution Protocol (LDP) installed and running.
- The VRF Selection feature is a unidirectional feature and can only be used from a customer (IP-based) network for a connection to a provider (MPLS-based) network and cannot be used from a provider network to a customer network.
- Subnet masks should be kept as short as possible for the VRF Selection criteria for Engine 2 line cards. VRF Selection performance can degrade with longer subnet masks (/24 or /32, for example).
- Cisco Express Forwarding (CEF) must be enabled on any interfaces that have the VRF Selection feature enabled. Distributed CEF is enabled by default on Cisco 12000 Series Internet routers.
- An IP traceroute command from an MPLS VPN VRF Selection CE router to a typical MPLS VPN VRF CE router works as expected. However, an IP traceroute command from a typical MPLS VPN VRF CE router to an MPLS VPN VRF Selection CE router might fail to show all the relevant hop information across the core.

Information About MPLS VPN: VRF Selection Based on Source IP Address

The VRF Selection feature allows packets arriving on an interface to be switched into the appropriate VRF table based upon the source IP address of the packets. Once the packets have been “selected” into the correct VRF routing table, they are processed normally, based on the destination address and forwarded through the rest of the Multiprotocol Label Switching (MPLS) VPN.

In most cases, the VRF Selection feature is a “one way” feature; it works on packets coming from the end users to the PE router.

VRF Selection Process

The VRF Selection feature uses the process described in this section to route packets from the customer networks to the PE router and into the provider network.

A two-table lookup mechanism is used at the ingress interface of the PE router to determine the routing and forwarding of packets coming from the customer networks, which use IP protocols, to the MPLS VPN networks, which use MPLS protocols.
The first table, the VRF Selection table, is used to compare the source IP address of the packet with a list of IP addresses in the table. Each IP address in the table is associated with an MPLS VPN. If a match is found between the source IP address of the packet and an IP address in the VRF Selection table, the packet is routed to the second table (the VRF table) or the routing table for the appropriate VPN.

If no match is found in the table for the source IP address of the packet, the packet is either routed via the global routing table used by the PE router (this is the default behavior), or is dropped. See the “Configuring a VRF to Eliminate Unnecessary Packet Forwarding: Example” section on page 14 for more information.

The second table, the VRF table (also known as the VPN routing table), contains the virtual routing and forwarding information for the specified VPN and is used to forward the selected VPN traffic to the correct MPLS label switched path (LSP) based upon the destination IP address of the packet. The VRF Selection process removes the association between the VPN and the interface and allows more than one MPLS VPN to be associated with the interface.

**VRF Selection Examples**

Here is an example of the VRF Selection feature. It is based on a network carrier that allows subscribers to the carrier to choose from multiple Internet service providers (ISPs) for Internet access. Figure 1 provides an example of the VRF Selection feature with an IP-based host network, an MPLS VPN network, and three ISPs connected to the MPLS VPN network.
In Figure 1, Carrier X represents the network carrier; Host A, Host B and Host C represent the carrier subscribers; and ISP 1, ISP 2 and ISP 3 represent the ISPs.

Figure 1 illustrates a packet traveling from Host A to ISP 1. The dashed line represents the travel of the packet.

Host A chooses ISP 1 to use as its ISP. Carrier X will provide an IP address to Host A that falls within the range of the ISP 1 registered network addresses. Based upon this IP address allocation, the VRF Selection criteria are set.
The POOL network, by using default routes, forwards traffic from the Carrier X IP-based (POOL) network to the Carrier X MPLS-based VPN network. The MPLS VPN network forwards (shunts) the traffic from Host A into the correct VPN, which is VPN 1 (ISP 1), by using the VRF Selection-enabled router PE2.

To enable the VRF Selection feature on the routers PE1 and PE2, enter the following commands:

```
Router(config)# vrf selection source 10.1.0.0 255.255.0.0 vrf vpn1
Router(config)# vrf selection source 172.16.0.0 255.255.0.0 vrf vpn2
Router(config)# interface POS1/0
Router(config-if)# description Link to CE POS1/0
Router(config-if)# ip vrf select source
```

For more information on the commands used to configure the VRF Selection feature, see the “Command Reference” section on page 15.

The VRF Selection feature is a one-way (unidirectional) feature in most implementations; it only works on packets coming from the customer networks to a PE router. See the “VRF Selection is a Unidirectional Feature” section on page 6 for more information.

Traffic coming from the ISPs to the hosts (in the example, traffic traveling from the ISPs on the right to the hosts on the left) is not affected by the VRF Selection feature and does not have to be returned via an MPLS path. This traffic can return via the shortest available IP path.

Another example of VRF Selection in use might involve a cable modem termination system (CMTS). If the owner of the CMTS wants to allow cable modem subscribers to choose their ISP from a group of ISPs, the VRF Selection feature provides a fast and scalable solution.

### VRF Selection is a Unidirectional Feature

In Figure 1, the end users are typical Internet home users. If the VRF Selection feature were a two-way (bidirectional) feature, traffic coming from the ISPs to the hosts would be required to use only the PE routers that have VRF Selection enabled, which might cause performance issues.

When traffic from the POOL network goes through the carrier network to the ISP networks for Internet access, the traffic in the carrier network must be forwarded by means of MPLS VPN paths, because the VRF Selection-enabled router has “selected” the traffic into the correct MPLS VPN.

Traffic from the ISP networks to the POOL network does not have to use MPLS VPN paths in the carrier network and can use the path that seems most efficient to return to the POOL network. This traffic can use a path that uses either MPLS or IP for routing and forwarding and does not have to travel via an MPLS VPN.

Traffic from the ISP networks to the POOL networks can be forwarded by the global routing table used by every interface. One way to accomplish this is to enter VRF static routes on the PE router interfaces connected to the ISPs. The VRF static routes would route traffic from the ISPs to the carrier network. See “Establishing IP Static Routes for a VRF Instance” section on page 10 for information on placing a default VRF static route onto an interface.

Establishing static VRF routes allows traffic from the ISPs to enter the carrier network as traffic that can only be routed by using the global routing table toward the POOL network.

If the ISPs are not providing global host address space, or the VRF feature is not being used to route Internet traffic, the PE interfaces connected to the ISPs must be placed into a VRF. If the PE interfaces are using VRFs for routing traffic from the ISPs, all traffic from the ISPs to the hosts through the carrier network would be forwarded by MPLS VPN paths, and performance would not be as good as if IP forwarding were used.
Normal IP-based VPN operations, such as populating the routing information base (RIB) and forwarding information base (FIB) from a routing protocol such as Border Gateway Protocol (BGP), are used to route and forward packets within the various VPNs in the customer networks. The provider network uses MPLS-based routing protocols to perform VPN routing and forwarding inside the provider network. See the “Configuring VRF Selection” section on page 8 for a sample configuration of the VRF Selection feature.

**Conditions Under Which VRF Selection Becomes Bidirectional**

Forwarding of traffic from the carrier network to the POOL network by using the global routing table is possible only if the ISPs have provided registered IP address space for all of the subscribed users within the POOL network.

If the POOL network uses IP addresses that are not globally routeable and are designed for a nonconnected enterprise (defined by RFC1918), the VRF Selection feature becomes bidirectional. All traffic being sent and received by the host would have to travel via a router that has the VRF Selection feature enabled. The POOL network cannot be addressed with overlapping address space, regardless of the type of address space being used.

**Advantages of VRF Selection over Per-Interface IP VPN Configuration**

The VRF Selection feature removes the association between a VPN and an interface. Before the VRF Selection feature was introduced, the following implementation was used to route outgoing MPLS VPN packets to different destinations:

- A policy-based router (PBR) is attached to the customer edge (CE) router.
- The egress side of the PBR router side has VLANs connected to a PE.
- The PBR router uses a policy-based route map to select the correct output (VLAN) interface, and each VLAN is under a specific VRF. Figure 2 illustrates a sample configuration in which a PBR router is used for routing MPLS packets to different destinations.

![Figure 2 Implementation of Multiple VPNs Before VRF Selection](image-url)

The following limitations apply to PBR-based solutions that use this implementation:
Policy routing and MPLS VPN functions cannot be performed on the same platform. Integration into a single platform is critical for manageability and support.

Each VRF is limited to one VPN per interface, which limits scalability.

There is no network redundancy.

The PBR is the only point of connection for all the networks attached to the PBR. The capacity and the performance capabilities of the PBR router are critical.

There is no diversity in the connectivity to the networks.

Every network is required to connect to every PBR. If every network is not connected to every PBR, packets from the end user to the PBR are dropped because the PBR has no way of switching the IP traffic properly.

Adding multiple PBRs that are interconnected introduces more network policy-routed hops.

The VRF Selection feature addresses the limitations of and problems with using a PBR for packet routing and forwarding.

Benefits of VRF Selection Based on Source IP Address

The following are benefits to using the VRF Selection method of VPN routing and forwarding.

- **Association of VPN to interface is removed**—The VRF Selection feature removes the association between a VPN and an interface, thus allowing packets from the host network to the provider network to have more than one VPN available per interface.

- **Access to every customer network is possible from every PE router in the provider network**—Access points to each network can be established at any MPLS PE router and can be made redundant by connections to multiple PE routers (for example, the CE2 router in Figure 1 on page 5).

- **Multiple points in the provider network can be used for VPN routing and forwarding**—MPLS VPNs, like IP, are connectionless. Any PE router, whether VRF Selection-enabled or not, is capable of carrying VRF Selection traffic from the MPLS network out to the CE routers.

How to Configure VRF Selection Based on Source IP Address

This section contains the following procedures:

- **Configuring VRF Selection** (required)
- **Establishing IP Static Routes for a VRF Instance** (optional)
- **Verifying VRF Selection** (optional)

Configuring VRF Selection

To add a source IP address to a VRF Selection table, use the following commands, beginning in global configuration mode.

**SUMMARY STEPS**

1. enable
2. configure terminal  
3. vrf selection source source-IP-address source-IP-mask vrf vrf_name  
4. ip vrf select source  
5. ip vrf receive vrf_name

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Router&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3 vrf selection source source-IP-address source-IP-mask vrf vrf_name</td>
<td>Populates a single source IP address, or range of source IP addresses, to a VRF Selection table.</td>
</tr>
<tr>
<td>Example: Router(config)# vrf selection source 172.16.0.0 255.255.0.0 vrf test</td>
<td></td>
</tr>
<tr>
<td>Step 4 ip vrf select source</td>
<td>Enables the VRF Selection feature on an interface.</td>
</tr>
<tr>
<td>Example: Router(config-if)# ip vrf select source</td>
<td></td>
</tr>
<tr>
<td>Step 5 ip vrf receive vrf_name</td>
<td>Adds all the IP addresses that are associated with an interface into a VRF table.</td>
</tr>
<tr>
<td>Example: Router(config-if)# ip vrf receive red</td>
<td></td>
</tr>
</tbody>
</table>
Establishing IP Static Routes for a VRF Instance

Traffic coming from the ISPs to the hosts does not require the use of the MPLS VPN paths; this traffic can use the shortest IP route back to the host.

VPN static routes for traffic returning to the customer networks are only necessary if VPN traffic returning to the customer networks is being forwarded from the VRF Selection interface. The remote PE router could also be configured to route return traffic to the customer networks directly by using the global routing table.

SUMMARY STEPS

1. enable
2. configure terminal
3. `ip route vrf vrf_name prefix mask [next-hop-address] [interface (interface-number)] [global] [distance] [permanent] [tag tag]`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
</tr>
<tr>
<td>Example:</td>
<td>Router&gt; enable</td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
</tr>
<tr>
<td>Example:</td>
<td>Router# configure terminal</td>
</tr>
<tr>
<td>Step 3</td>
<td><code>ip route vrf vrf_name prefix mask [next-hop-address] [interface (interface-number)] [global] [distance] [permanent] [tag tag]</code></td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config-if)# ip route vrf vpn1 172.16.0.0 255.255.0.0 POS1/0</td>
</tr>
</tbody>
</table>
Verifying VRF Selection

Enter the `show ip route vrf` command in EXEC mode to display the IP routing table associated with a VRF instance. This example shows the IP routing table associated with the VRF `vrf1`:

```
Router# show ip route vrf vpn1
Routing Table: vpn1
Codes: C - connected, S - static, I - IGRP, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default, U - per-user static route, o - ODR
Gateway of last resort is not set
B    10.0.0.0/8  [200/0] via 10.10.10.10, 00:00:37
172.16.0.0/16 is subnetted, 1 subnets
B       10.19.0.0  [200/0] via 10.10.10.10, 00:00:37
10.0.0.0/32 is subnetted, 1 subnets
B       10.14.14.14  [200/0] via 10.10.10.10, 00:00:37
10.0.0.0/32 is subnetted, 1 subnets
S       10.15.15.15  [1/0] via 10.0.0.1, POS1/1
```

Troubleshooting Tips

- Enter the `debug vrf select` command to enable debugging for the VRF Selection feature.

**Note**
The `debug vrf select` command can cause many messages to be logged when you change the configuration and when switching occurs.

- The following error messages appear if problems occur while configuring the VRF Selection feature:
  - If you attempt to configure a nonexisting VRF Selection table:
    ```
    Router(config)#vrf selection source 172.16.0.0 255.255.0.0 vrf VRF_NOEXIST
    VRF Selection: VRF table VRF_NOEXIST does not exist.
    ```
  - If you attempt to remove a VRF Selection entry that does not exist:
    ```
    Router(config)#no vrf selection source 172.16.0.0 255.255.0.0 vrf VRF1
    VRF Selection: Can't find the node to remove.
    ```
  - If you attempt to configure a duplicate IP address and subnet mask for a VRF Selection entry:
    ```
    Router(config)#vrf selection source 172.16.0.0 255.0.0.0 vrf VRF_AOL
    Router(config)#vrf selection source 172.16.0.0 255.0.0.0 vrf VRF_AOL
    VRF Selection: duplicate address and mask configured.
    ```
  - If an inconsistent IP address and mask are used for a VRF Selection entry:
    ```
    Router(config)#vrf selection source 172.16.2.1 255.255.255.0 vrf red
    % Inconsistent address and mask
    Router(config)#vrf selection source 172.16.2.1 255.255.255.0 vrf red
    % Inconsistent address and mask
    ```
  - If you attempt to configure a VRF instance on an interface that has VRF Selection already configured:
    ```
    Router(config-if)#ip vrf select source
    ```
    ```
    Router(config-if)#ip vrf forward red
    % Can not configure VRF if VRF Select is already configured
    ```
To enable VRF, first remove VRF Select from the interface

- If you attempt to configure a VRF Selection entry on an interface that has VRF already configured:

  Router(config-if)#ip vrf forward red
  Router(config-if)#ip vrf select source

  % Can not configure VRF Select if interface is under a non-global VRF

To enable VRF Select, first remove VRF from the interface

Configuration Examples for VRF Selection Based on Source IP Address

- Enabling MPLS VPNs: Example
- Creating a VRF Routing Table: Example
- Defining VRF Selection Entries: Example
- Defining IP Static Routes for a VRF: Example
- Configuring an Interface for VRF Selection: Example
- Configuring a BGP Router for VRF Selection: Example
- Configuring a VRF to Eliminate Unnecessary Packet Forwarding: Example
- Command Reference

Enabling MPLS VPNs: Example

The following example shows how to enable the router to accept MPLS VPNs:

```
Router(config)# mpls label protocol ldp
Router(config)# interface loopback0
Router(config-if)# ip address 10.13.13.13 255.255.255.255
Router(config-if)# no ip directed-broadcast
```

Creating a VRF Routing Table: Example

The following example shows how to create two VRF Selection tables (vpn1 and vpn2):

```
Router(config)# ip vrf vpn1
Router(config-vrf)# rd 1000:1
Router(config-vrf)# route-target export 1000:1
Router(config-vrf)# route-target import 1000:1
Router(config-vrf)# exit
Router(config)# ip vrf vpn2
Router(config-vrf)# rd 1000:2
Router(config-vrf)# route-target export 1000:2
Router(config-vrf)# route-target export 1000:2
```
Defining VRF Selection Entries: Example

The following example shows two entries (vpn1 and vpn2) being defined in the VRF Selection table. In this example, packets with the source address of 10.16.0.0 will be routed to the VRF vpn1, and packets with the source address of 10.17.0.0 will be routed to the VRF vpn2:

```
Router(config)# vrf selection source 10.16.0.0 255.255.0.0 vrf vpn1
Router(config)# vrf selection source 10.17.0.0 255.255.0.0 vrf vpn2
```

Defining IP Static Routes for a VRF: Example

The following example shows IP static routes being created for two VRFs (vpn1 and vpn2) for the POS1/0 interface:

```
Router(config)# ip route vrf vpn1 10.16.0.0 255.255.0.0 POS1/0
Router(config)# ip route vrf vpn2 10.17.0.0 255.255.0.0 POS1/0
```

Configuring an Interface for VRF Selection: Example

The following example shows the POS1/0 interface being configured for the VRF Selection feature and the configured IP address (31.0.0.1) being added to the VRFs vpn1 and vpn2 as connected routes:

```
Router(config)# interface POS1/0
Router(config-if)# description Link to CE1 POS1/0 (eng2)
Router(config-if)# ip vrf select source
Router(config-if)# ip vrf receive vpn1
Router(config-if)# ip vrf receive vpn2
Router(config-if)# ip address 10.0.0.1 255.0.0.0
Router(config-if)# no ip directed-broadcast
Router(config-if)# load-interval 30
Router(config-if)# crc 32
Router(config-if)# end
```

Configuring a BGP Router for VRF Selection: Example

A router that is VRF Selection-enabled requires an MPLS VPN BGP configuration. The following example configures a router that is using BGP for the VRF Selection feature:

```
Router(config)# router bgp 1000
Router(config-router)# no bgp default ipv4-unicast
Router(config-router)# bgp log-neighbor-changes
Router(config-router)# timers bgp 10 30
Router(config-router)# neighbor 10.11.11.11 remote-as 1000
Router(config-router)# neighbor 10.11.11.11 update-source Loopback0
Router(config-router)# no auto-summary

Router(config-router)# address-family vpnv4
Router(config-router-af)# neighbor 10.11.11.11 activate
Router(config-router-af)# neighbor 10.11.11.11 send-community extended
Router(config-router-af)# exit-address-family

Router(config-router)# address-family ipv4 vrf vpn2
Router(config-router-af)# redistribute static
Router(config-router-af)# no auto-summary
Router(config-router-af)# no synchronization
```
Configuring a VRF to Eliminate Unnecessary Packet Forwarding: Example

If a packet arrives at an interface that has VRF Selection enabled, and the packet source IP address does not match any VRF Selection definition, that packet will be forwarded by means of the global routing table. This default behavior could cause problems if IP address spoofing is being implemented. Unnecessary traffic could be forwarded by the global routing table. To eliminate this unnecessary routing of packets, create a VRF Selection definition that will forward all unknown incoming traffic to a null interface.

The following configuration causes all traffic not matching a more specific VRF Selection definition to be routed to the Null0 interface, thus causing the packets to be dropped.

```
Router(config)# ip vrf VRF_DROP
Router(config-vrf)# rd 999:99
Router(config-vrf)# route-target export 999:99
Router(config-vrf)# route-target import 999:99
Router(config-vrf)# exit

Router(config)# vrf selection source 0.0.0.0 0.0.0.0 vrf VRF_DROP

Router(config)# ip route vrf VRF_DROP 0.0.0.0 0.0.0.0 Null0
```
