About Cisco IOS and Cisco IOS XE Software Documentation

Last updated: December 10, 2008

This document describes the objectives, audience, conventions, and organization used in Cisco IOS and Cisco IOS XE software documentation, collectively referred to in this document as Cisco IOS documentation. Also included are resources for obtaining technical assistance, additional documentation, and other information from Cisco. This document is organized into the following sections:

- Documentation Objectives, page i
- Audience, page i
- Documentation Conventions, page ii
- Documentation Organization, page iii
- Additional Resources and Documentation Feedback, page xi

Documentation Objectives

Cisco IOS documentation describes the tasks and commands available to configure and maintain Cisco networking devices.

Audience

The Cisco IOS documentation set is intended for users who configure and maintain Cisco networking devices (such as routers and switches) but who may not be familiar with the configuration and maintenance tasks, the relationship among tasks, or the Cisco IOS commands necessary to perform particular tasks. The Cisco IOS documentation set is also intended for those users experienced with Cisco IOS who need to know about new features, new configuration options, and new software characteristics in the current Cisco IOS release.
Documentation Conventions

In Cisco IOS documentation, the term router may be used to refer to various Cisco products; for example, routers, access servers, and switches. These and other networking devices that support Cisco IOS software are shown interchangeably in examples and are used only for illustrative purposes. An example that shows one product does not necessarily mean that other products are not supported.

This section includes the following topics:

- Typographic Conventions, page ii
- Command Syntax Conventions, page ii
- Software Conventions, page iii
- Reader Alert Conventions, page iii

Typographic Conventions

Cisco IOS documentation uses the following typographic conventions:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>^ or Ctrl</td>
<td>Both the ^ symbol and Ctrl represent the Control (Ctrl) key on a keyboard. For example, the key combination ^D or Ctrl-D means that you hold down the Control key while you press the D key. (Keys are indicated in capital letters but are not case sensitive.)</td>
</tr>
<tr>
<td>string</td>
<td>A string is a nonquoted set of characters shown in italics. For example, when setting a Simple Network Management Protocol (SNMP) community string to public, do not use quotation marks around the string; otherwise, the string will include the quotation marks.</td>
</tr>
</tbody>
</table>

Command Syntax Conventions

Cisco IOS documentation uses the following command syntax conventions:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bold</td>
<td>Bold text indicates commands and keywords that you enter as shown.</td>
</tr>
<tr>
<td>italic</td>
<td>Italic text indicates arguments for which you supply values.</td>
</tr>
<tr>
<td>[x]</td>
<td>Square brackets enclose an optional keyword or argument.</td>
</tr>
<tr>
<td>...</td>
<td>An ellipsis (three consecutive nonbolded periods without spaces) after a syntax element indicates that the element can be repeated.</td>
</tr>
<tr>
<td>l</td>
<td>A vertical line, called a pipe, indicates a choice within a set of keywords or arguments.</td>
</tr>
<tr>
<td>[x</td>
<td>y]</td>
</tr>
<tr>
<td>{x</td>
<td>y}</td>
</tr>
<tr>
<td>[x {y</td>
<td>z}]</td>
</tr>
</tbody>
</table>
Software Conventions

Cisco IOS uses the following program code conventions:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Courier font</td>
<td>Courier font is used for information that is displayed on a PC or terminal screen.</td>
</tr>
<tr>
<td>Bold Courier font</td>
<td>Bold Courier font indicates text that the user must enter.</td>
</tr>
<tr>
<td>&lt; &gt;</td>
<td>Angle brackets enclose text that is not displayed, such as a password. Angle brackets also are used in contexts in which the italic font style is not supported; for example, ASCII text.</td>
</tr>
<tr>
<td>!</td>
<td>An exclamation point at the beginning of a line indicates that the text that follows is a comment, not a line of code. An exclamation point is also displayed by Cisco IOS software for certain processes.</td>
</tr>
<tr>
<td>[ ]</td>
<td>Square brackets enclose default responses to system prompts.</td>
</tr>
</tbody>
</table>

Reader Alert Conventions

The Cisco IOS documentation set uses the following conventions for reader alerts:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Caution</td>
<td>Means <em>reader be careful</em>. In this situation, you might do something that could result in equipment damage or loss of data.</td>
</tr>
<tr>
<td>Note</td>
<td>Means <em>reader take note</em>. Notes contain helpful suggestions or references to material not covered in the manual.</td>
</tr>
<tr>
<td>Timesaver</td>
<td>Means <em>the described action saves time</em>. You can save time by performing the action described in the paragraph.</td>
</tr>
</tbody>
</table>

Documentation Organization

This section describes the Cisco IOS documentation set, how it is organized, and how to access it on Cisco.com. Included are lists of configuration guides, command references, and supplementary references and resources that make up the documentation set. The following topics are included:

- [Cisco IOS Documentation Set](#)
- [Cisco IOS Documentation on Cisco.com](#)
- [Configuration Guides, Command References, and Supplementary Resources](#)
Cisco IOS Documentation Set

Cisco IOS documentation consists of the following:

- Release notes and caveats provide information about platform, technology, and feature support for a release and describe severity 1 (catastrophic), severity 2 (severe), and severity 3 (moderate) defects in released Cisco IOS code. Review release notes before other documents to learn whether or not updates have been made to a feature.

- Sets of configuration guides and command references organized by technology and published for each standard Cisco IOS release.
  - Configuration guides—Compilations of documents that provide informational and task-oriented descriptions of Cisco IOS features.
  - Command references—Compilations of command pages that provide detailed information about the commands used in the Cisco IOS features and processes that make up the related configuration guides. For each technology, there is a single command reference that covers all Cisco IOS releases and that is updated at each standard release.

- Lists of all the commands in a specific release and all commands that are new, modified, removed, or replaced in the release.

- Command reference book for `debug` commands. Command pages are listed in alphabetical order.

- Reference book for system messages for all Cisco IOS releases.

Cisco IOS Documentation on Cisco.com

The following sections describe the documentation organization and how to access various document types.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Cisco IOS XE, and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

New Features List
The New Features List for each release provides a list of all features in the release with hyperlinks to the feature guides in which they are documented.

Feature Guides
Cisco IOS features are documented in feature guides. Feature guides describe one feature or a group of related features that are supported on many different software releases and platforms. Your Cisco IOS software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release.

Configuration Guides
Configuration guides are provided by technology and release and comprise a set of individual feature guides relevant to the release and technology.
Command References

Command reference books describe Cisco IOS commands that are supported in many different software releases and on many different platforms. The books are provided by technology. For information about all Cisco IOS commands, use the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or the Cisco IOS Master Command List, All Releases, at http://www.cisco.com/en/US/docs/ios/mcl/allrelease.html.

Cisco IOS Supplementary Documents and Resources

Supplementary documents and resources are listed in Table 2 on page xi.

Configuration Guides, Command References, and Supplementary Resources

Table 1 lists, in alphabetical order, Cisco IOS and Cisco IOS XE software configuration guides and command references, including brief descriptions of the contents of the documents. The Cisco IOS command references are comprehensive, meaning that they include commands for both Cisco IOS software and Cisco IOS XE software, for all releases. The configuration guides and command references support many different software releases and platforms. Your Cisco IOS software release or platform may not support all these technologies.

For additional information about configuring and operating specific networking devices, go to the Product Support area of Cisco.com at http://www.cisco.com/web/psa/products/index.html.

Table 2 lists documents and resources that supplement the Cisco IOS software configuration guides and command references. These supplementary resources include release notes and caveats; master command lists; new, modified, removed, and replaced command lists; system messages; and the debug command reference.

| **Cisco IOS High Availability Configuration Guide**  
**Cisco IOS XE High Availability Configuration Guide**  
**Cisco IOS High Availability Command Reference** | A variety of High Availability (HA) features and technologies that are available for different network segments (from enterprise access to service provider core) to facilitate creation of end-to-end highly available networks. Cisco IOS HA features and technologies can be categorized in three key areas: system-level resiliency, network-level resiliency, and embedded management for resiliency. |
| **Cisco IOS Integrated Session Border Controller Command Reference** | A VoIP-enabled device that is deployed at the edge of networks. An SBC is a toolkit of functions, such as signaling interworking, network hiding, security, and quality of service (QoS). |
| **Cisco IOS Intelligent Services Gateway Configuration Guide**  
**Cisco IOS Intelligent Services Gateway Command Reference** | Subscriber identification, service and policy determination, session creation, session policy enforcement, session life-cycle management, accounting for access and service usage, session state monitoring. |
| **Cisco IOS Interface and Hardware Component Configuration Guide**  
**Cisco IOS XE Interface and Hardware Component Configuration Guide**  
**Cisco IOS Interface and Hardware Component Command Reference** | LAN interfaces, logical interfaces, serial interfaces, virtual interfaces, and interface configuration. |
| **Cisco IOS IP Addressing Services Configuration Guide**  
**Cisco IOS XE Addressing Services Configuration Guide**  
**Cisco IOS IP Addressing Services Command Reference** | Address Resolution Protocol (ARP), Network Address Translation (NAT), Domain Name System (DNS), Dynamic Host Configuration Protocol (DHCP), and Next Hop Address Resolution Protocol (NHRP). |
| **Cisco IOS IP Application Services Configuration Guide**  
**Cisco IOS XE IP Application Services Configuration Guide**  
| **Cisco IOS IP Mobility Configuration Guide**  
**Cisco IOS IP Mobility Command Reference** | Mobile ad hoc networks (MANet) and Cisco mobile networks. |
| **Cisco IOS IP Multicast Configuration Guide**  
**Cisco IOS XE IP Multicast Configuration Guide**  
**Cisco IOS IP Multicast Command Reference** | Protocol Independent Multicast (PIM) sparse mode (PIM-SM), bidirectional PIM (bidir-PIM), Source Specific Multicast (SSM), Multicast Source Discovery Protocol (MSDP), Internet Group Management Protocol (IGMP), and Multicast VPN (MVPN). |

Additional Resources and Documentation Feedback

What’s New in Cisco Product Documentation is published monthly and describes all new and revised Cisco technical documentation. The What's New in Cisco Product Documentation publication also provides information about obtaining the following resources:

- Technical documentation
- Cisco product security overview
- Product alerts and field notices
- Technical assistance

Cisco IOS technical documentation includes embedded feedback forms where you can rate documents and provide suggestions for improvement. Your feedback helps us improve our documentation.
Using the Command-Line Interface in Cisco IOS and Cisco IOS XE Software

Last updated: December 10, 2008

This document provides basic information about the command-line interface (CLI) in Cisco IOS and Cisco IOS XE software and how you can use some of the CLI features. This document contains the following sections:

- Initially Configuring a Device, page i
- Using the CLI, page ii
- Saving Changes to a Configuration, page xii
- Additional Information, page xii

For more information about using the CLI, see the “Using the Cisco IOS Command-Line Interface” section of the Cisco IOS Configuration Fundamentals Configuration Guide.

For information about the software documentation set, see the “About Cisco IOS and Cisco IOS XE Software Documentation” document.

Initially Configuring a Device

Initially configuring a device varies by platform. For information about performing an initial configuration, see the hardware installation documentation that is provided with the original packaging of the product or go to the Product Support area of Cisco.com at http://www.cisco.com/web/psa/products/index.html.

After you have performed the initial configuration and connected the device to your network, you can configure the device by using the console port or a remote access method, such as Telnet or Secure Shell (SSH), to access the CLI or by using the configuration method provided on the device, such as Security Device Manager.
Using the CLI

This section describes the following topics:
- Understanding Command Modes, page ii
- Using the Interactive Help Feature, page v
- Understanding Command Syntax, page vi
- Understanding Enable and Enable Secret Passwords, page viii
- Using the Command History Feature, page viii
- Abbreviating Commands, page ix
- Using Aliases for CLI Commands, page ix
- Using the no and default Forms of Commands, page x
- Using the debug Command, page x
- Filtering Output Using Output Modifiers, page x
- Understanding CLI Error Messages, page xi

Understanding Command Modes

The CLI command mode structure is hierarchical, and each mode supports a set of specific commands. This section describes the most common of the many modes that exist.

Table 1 lists common command modes with associated CLI prompts, access and exit methods, and a brief description of how each mode is used.
Table 1  CLI Command Modes

<table>
<thead>
<tr>
<th>Command Mode</th>
<th>Access Method</th>
<th>Prompt</th>

### Table 1 CLI Command Modes (continued)

<table>
<thead>
<tr>
<th>Command Mode</th>
<th>Access Method</th>
<th>Prompt</th>
<th>Exit Method</th>
<th>Mode Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROM monitor</td>
<td>From privileged EXEC mode, issue the <code>reload</code> command. Press the <strong>Break</strong> key during the first 60 seconds while the system is booting.</td>
<td><code>common # &gt;</code>&lt;br&gt;The # symbol represents the line number and increments at each prompt.</td>
<td>Issue the <code>continue</code> command.</td>
<td>• Run as the default operating mode when a valid image cannot be loaded.&lt;br&gt;• Access the fall-back procedure for loading an image when the device lacks a valid image and cannot be booted.&lt;br&gt;• Perform password recovery when a CTRL-Break sequence is issued within 60 seconds of a power-on or reload event.</td>
</tr>
</tbody>
</table>
| Diagnostic (available only on the Cisco ASR1000 series router) | The router boots or enters diagnostic mode in the following scenarios. When a Cisco IOS process or processes fail, in most scenarios the router will reload.  
- A user-configured access policy was configured using the `transport-map` command, which directed the user into diagnostic mode.  
- The router was accessed using an RP auxiliary port.  
- A break signal (Ctrl-C, Ctrl-Shift-6, or the `send break` command) was entered, and the router was configured to enter diagnostic mode when the break signal was received. | `Router(diag)#` | If a Cisco IOS process failure is the reason for entering diagnostic mode, the failure must be resolved and the router must be rebooted to exit diagnostic mode.  
If the router is in diagnostic mode because of a transport-map configuration, access the router through another port or using a method that is configured to connect to the Cisco IOS CLI.  
If the RP auxiliary port was used to access the router, use another port for access. Accessing the router through the auxiliary port is not useful for customer purposes. | • Inspect various states on the router, including the Cisco IOS state.<br>• Replace or roll back the configuration.<br>• Provide methods of restarting the Cisco IOS software or other processes.<br>• Reboot hardware, such as the entire router, an RP, an ESP, a SIP, a SPA, or possibly other hardware components.<br>• Transfer files into or off of the router using remote access methods such as FTP, TFTP, and SCP. |
EXEC commands are not saved when the software reboots. Commands that you issue in a configuration mode can be saved to the startup configuration. If you save the running configuration to the startup configuration, these commands will execute when the software is rebooted. Global configuration mode is the highest level of configuration mode. From global configuration mode, you can enter a variety of other configuration modes, including protocol-specific modes.

ROM monitor mode is a separate mode that is used when the software cannot load properly. If a valid software image is not found when the software boots or if the configuration file is corrupted at startup, the software might enter ROM monitor mode. Use the question symbol (?) to view the commands that you can use while the device is in ROM monitor mode.

```plaintext
rommon 1 > ?
alias set and display aliases command
boot boot up an external process
confreg configuration register utility
cont continue executing a downloaded image
context display the context of a loaded image
cookie display contents of cookie PROM in hex
```

The following example shows how the command prompt changes to indicate a different command mode:

```plaintext
Router> enable
Router# configure terminal
Router(config)# interface ethernet 1/1
Router(config-if)# ethernet
Router(config-line)# exit
Router(config)# end
Router#
```

A keyboard alternative to the `end` command is Ctrl-Z.

# Using the Interactive Help Feature

The CLI includes an interactive Help feature. Table 2 describes how to use the Help feature.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>help</code></td>
<td>Provides a brief description of the help feature in any command mode.</td>
</tr>
<tr>
<td><code>?</code></td>
<td>Lists all commands available for a particular command mode.</td>
</tr>
<tr>
<td><code>partial command?</code></td>
<td>Provides a list of commands that begin with the character string</td>
</tr>
<tr>
<td></td>
<td>(no space between the command and the question mark).</td>
</tr>
<tr>
<td><code>partial command&lt;Tab&gt;</code></td>
<td>Completes a partial command name (no space between the command</td>
</tr>
<tr>
<td></td>
<td>and &lt;Tab&gt;).</td>
</tr>
<tr>
<td><code>command ?</code></td>
<td>Lists the keywords, arguments, or both associated with the command</td>
</tr>
<tr>
<td></td>
<td>(space between the command and the question mark).</td>
</tr>
<tr>
<td><code>command keyword ?</code></td>
<td>Lists the arguments that are associated with the keyword (space</td>
</tr>
<tr>
<td></td>
<td>between the keyword and the question mark).</td>
</tr>
</tbody>
</table>
The following examples show how to use the help commands:

help
Router> help
Help may be requested at any point in a command by entering a question mark '?'. If nothing matches, the help list will be empty and you must backup until entering a '?' shows the available options.

Two styles of help are provided:
1. Full help is available when you are ready to enter a command argument (e.g. 'show ?') and describes each possible argument.
2. Partial help is provided when an abbreviated argument is entered and you want to know what arguments match the input (e.g. 'show pr?'.)

   enable        Enable pppoe
   max-sessions  Maximum PPPOE sessions

command keyword?
Router(config-if)# pppoe enable ?
   group  attach a BBA group
<cr>

Understanding Command Syntax

Command syntax is the format in which a command should be entered in the CLI. Commands include the name of the command, keywords, and arguments. Keywords are alphanumeric strings that are used literally. Arguments are placeholders for values that a user must supply. Keywords and arguments may be required or optional.

Specific conventions convey information about syntax and command elements. Table 3 describes these conventions.
The following examples show syntax conventions:

```
Router(config)# ethernet cfm domain ?
  WORD  domain name
Router(config)# ethernet cfm domain dname ?
  level
Router(config)# ethernet cfm domain dname level ?
  <0-7>  maintenance level number
Router(config)# ethernet cfm domain dname level 7 ?
  <cr>
Router(config)# snmp-server file-transfer access-group 10 ?
  protocol  protocol options
  <cr>
Router(config)# logging host ?
  Hostname or A.B.C.D  IP address of the syslog server
  ipv6
  Configure IPv6 syslog server
Router(config)# snmp-server file-transfer access-group 10 ?
  protocol  protocol options
  <cr>
```
Understanding Enable and Enable Secret Passwords

Some privileged EXEC commands are used for actions that impact the system, and it is recommended that you set a password for these commands to prevent unauthorized use. Two types of passwords, enable (not encrypted) and enable secret (encrypted), can be set. The following commands set these passwords and are issued in global configuration mode:

- `enable password`  
- `enable secret password`

Using an enable secret password is recommended because it is encrypted and more secure than the enable password. When you use an enable secret password, text is encrypted (unreadable) before it is written to the config.text file. When you use an enable password, the text is written as entered (readable) to the config.text file.

Each type of password is case sensitive, can contain from 1 to 25 uppercase and lowercase alphanumeric characters, and can start with a number. Spaces are also valid password characters; for example, “two words” is a valid password. Leading spaces are ignored, but trailing spaces are recognized.

Note: Both password commands have numeric keywords that are single integer values. If you choose a number for the first character of your password followed by a space, the system will read the number as if it were the numeric keyword and not as part of your password.

When both passwords are set, the enable secret password takes precedence over the enable password.

To remove a password, use the `no` form of the commands: `no enable password` or `no enable secret password`.

Using the Command History Feature

The CLI command history feature saves the commands you enter during a session in a command history buffer. The default number of commands saved is 10, but the number is configurable within the range of 0 to 256. This command history feature is particularly useful for recalling long or complex commands.

To change the number of commands saved in the history buffer for a terminal session, issue the `terminal history size` command:

```
Router# terminal history size num
```

A command history buffer is also available in line configuration mode with the same default and configuration options. To set the command history buffer size for a terminal session in line configuration mode, issue the `history` command:

```
Router(config-line)# history [size num]
```

To recall commands from the history buffer, use the following methods:

- Press Ctrl-P or the up arrow key—Recalls commands beginning with the most recent command. Repeat the key sequence to recall successively older commands.
• Press Ctrl-N or the down arrow key—Recalls the most recent commands in the history buffer after they have been recalled using Ctrl-P or the up arrow key. Repeat the key sequence to recall successively more recent commands.

Note The arrow keys function only on ANSI-compatible terminals such as the VT100.

• Issue the show history command in user EXEC or privileged EXEC mode—Lists the most recent commands that you entered. The number of commands that are displayed is determined by the setting of the terminal history size and history commands.

The CLI command history feature is enabled by default. To disable this feature for a terminal session, issue the terminal no history command in user EXEC or privileged EXEC mode or the no history command in line configuration mode.

### Abbreviating Commands

Typing a complete command name is not always required for the command to execute. The CLI recognizes an abbreviated command when the abbreviation contains enough characters to uniquely identify the command. For example, the show version command can be abbreviated as sh ver. It cannot be abbreviated as s ver because s could mean show, set, or systat. The sh v abbreviation also is not valid because the show command has vrrp as a keyword in addition to version. (Command and keyword examples from Cisco IOS Release 12.4(13)T.)

### Using Aliases for CLI Commands

To save time and the repetition of entering the same command multiple times, you can use a command alias. An alias can be configured to do anything that can be done at the command line, but an alias cannot move between modes, type in passwords, or perform any interactive functions.

Table 4 shows the default command aliases.

<table>
<thead>
<tr>
<th>Command Alias</th>
<th>Original Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>h</td>
<td>help</td>
</tr>
<tr>
<td>lo</td>
<td>logout</td>
</tr>
<tr>
<td>p</td>
<td>ping</td>
</tr>
<tr>
<td>s</td>
<td>show</td>
</tr>
<tr>
<td>u or un</td>
<td>undebug</td>
</tr>
<tr>
<td>w</td>
<td>where</td>
</tr>
</tbody>
</table>

To create a command alias, issue the alias command in global configuration mode. The syntax of the command is alias mode command-alias original-command. Following are some examples:

• Router(config)# alias exec prt partition—privileged EXEC mode
• Router(config)# alias configure sb source-bridge—global configuration mode
• Router(config)# alias interface rl rate-limit—interface configuration mode
To view both default and user-created aliases, issue the `show alias` command.

### Using the no and default Forms of Commands

Most configuration commands have a **no** form that is used to reset a command to its default value or disable a feature or function. For example, the `ip routing` command is enabled by default. To disable this command, you would issue the `no ip routing` command. To re-enable IP routing, you would issue the `ip routing` command.

Configuration commands may also have a **default** form, which returns the command settings to their default values. For commands that are disabled by default, using the `default` form has the same effect as using the `no` form of the command. For commands that are enabled by default and have default settings, the `default` form enables the command and returns the settings to their default values.

The **no** and **default** forms of commands are described in the command pages of command references.

### Using the debug Command

A `debug` command produces extensive output that helps you troubleshoot problems in your network. These commands are available for many features and functions within Cisco IOS and Cisco IOS XE software. Some `debug` commands are `debug all`, `debug aaa accounting`, and `debug mpls packets`. To use `debug` commands during a Telnet session with a device, you must first enter the `terminal monitor` command.

To turn off debugging completely, you must enter the `undebug all` command.

⚠️ **Caution**

Debugging is a high priority and high CPU utilization process that can render your device unusable. Use `debug` commands only to troubleshoot specific problems. The best times to run debugging are during periods of low network traffic and when few users are interacting with the network. Debugging during these periods decreases the likelihood that the `debug` command processing overhead will affect network performance or user access or response times.

### Filtering Output Using Output Modifiers

Many commands produce lengthy output that may use several screens to display. Using output modifiers, you can filter this output to show only the information that you want to see.

Three output modifiers are available and are described as follows:

- **begin regular expression**—Displays the first line in which a match of the regular expression is found and all lines that follow.
- **include regular expression**—Displays all lines in which a match of the regular expression is found.
- **exclude regular expression**—Displays all lines except those in which a match of the regular expression is found.
To use one of these output modifiers, type the command followed by the pipe symbol (|), the modifier, and the regular expression that you want to search for or filter. A regular expression is a case-sensitive alphanumeric pattern. It can be a single character or number, a phrase, or a more complex string.

The following example illustrates how to filter output of the `show interface` command to display only lines that include the expression “protocol.”

```
Router# show interface | include protocol
FastEthernet0/0 is up, line protocol is up
Serial4/0 is up, line protocol is up
Serial4/1 is up, line protocol is up
Serial4/2 is administratively down, line protocol is down
Serial4/3 is administratively down, line protocol is down
```

### Understanding CLI Error Messages

You may encounter some error messages while using the CLI. Table 5 shows the common CLI error messages.

<table>
<thead>
<tr>
<th>Error Message</th>
<th>Meaning</th>
<th>How to Get Help</th>
</tr>
</thead>
<tbody>
<tr>
<td>% Ambiguous command: “show con”</td>
<td>You did not enter enough characters for the command to be recognized.</td>
<td>Reenter the command followed by a space and a question mark (?). The keywords that you are allowed to enter for the command appear.</td>
</tr>
<tr>
<td>% Incomplete command.</td>
<td>You did not enter all the keywords or values required by the command.</td>
<td>Reenter the command followed by a space and a question mark (?). The keywords that you are allowed to enter for the command appear.</td>
</tr>
<tr>
<td>% Invalid input detected at “^” marker.</td>
<td>You entered the command incorrectly. The caret (^) marks the point of the error.</td>
<td>Enter a question mark (?) to display all the commands that are available in this command mode. The keywords that you are allowed to enter for the command appear.</td>
</tr>
</tbody>
</table>

For more system error messages, see the following documents:

- *Cisco IOS Release 12.2SR System Message Guide*
- *Cisco IOS System Messages, Volume 1 of 2* (Cisco IOS Release 12.4)
- *Cisco IOS System Messages, Volume 2 of 2* (Cisco IOS Release 12.4)
Saving Changes to a Configuration

To save changes that you made to the configuration of a device, you must issue the `copy running-config startup-config` command or the `copy system:running-config nvram:startup-config` command. When you issue these commands, the configuration changes that you made are saved to the startup configuration and saved when the software reloads or power to the device is turned off or interrupted. The following example shows the syntax of the `copy running-config startup-config` command:

Router# copy running-config startup-config
Destination filename [startup-config]?

You press Enter to accept the startup-config filename (the default), or type a new filename and then press Enter to accept that name. The following output is displayed indicating that the configuration was saved:

Building configuration...
[OK]
Router#

On most platforms, the configuration is saved to NVRAM. On platforms with a Class A flash file system, the configuration is saved to the location specified by the CONFIG_FILE environment variable. The CONFIG_FILE variable defaults to NVRAM.

AAA Overview

Access control is the way you control who is allowed access to the network server and what services they are allowed to use once they have access. Authentication, authorization, and accounting (AAA) network security services provide the primary framework through which you set up access control on your router or access server.

In This Chapter

This chapter includes the following sections:

- About AAA Security Services
- Where to Begin
- What to Do Next

About AAA Security Services

AAA is an architectural framework for configuring a set of three independent security functions in a consistent manner. AAA provides a modular way of performing the following services:

- Authentication—Provides the method of identifying users, including login and password dialog, challenge and response, messaging support, and, depending on the security protocol you select, encryption.

Authentication is the way a user is identified prior to being allowed access to the network and network services. You configure AAA authentication by defining a named list of authentication methods, and then applying that list to various interfaces. The method list defines the types of authentication to be performed and the sequence in which they will be performed; it must be applied to a specific interface before any of the defined authentication methods will be performed. The only exception is the default method list (which is named “default”). The default method list is automatically applied to all interfaces if no other method list is defined. A defined method list overrides the default method list.
All authentication methods, except for local, line password, and enable authentication, must be defined through AAA. For information about configuring all authentication methods, including those implemented outside of the AAA security services, refer to the chapter “Configuring Authentication.”

- **Authorization**—Provides the method for remote access control, including one-time authorization or authorization for each service, per-user account list and profile, user group support, and support of IP, IPX, ARA, and Telnet.

AAA authorization works by assembling a set of attributes that describe what the user is authorized to perform. These attributes are compared to the information contained in a database for a given user and the result is returned to AAA to determine the user’s actual capabilities and restrictions. The database can be located locally on the access server or router or it can be hosted remotely on a RADIUS or TACACS+ security server. Remote security servers, such as RADIUS and TACACS+, authorize users for specific rights by associating attribute-value (AV) pairs, which define those rights with the appropriate user. All authorization methods must be defined through AAA.

As with authentication, you configure AAA authorization by defining a named list of authorization methods, and then applying that list to various interfaces. For information about configuring authorization using AAA, refer to the chapter “Configuring Authorization.”

- **Accounting**—Provides the method for collecting and sending security server information used for billing, auditing, and reporting, such as user identities, start and stop times, executed commands (such as PPP), number of packets, and number of bytes.

Accounting enables you to track the services users are accessing as well as the amount of network resources they are consuming. When AAA accounting is activated, the network access server reports user activity to the RADIUS or TACACS+ security server (depending on which security method you have implemented) in the form of accounting records. Each accounting record is comprised of accounting AV pairs and is stored on the access control server. This data can then be analyzed for network management, client billing, and/or auditing. All accounting methods must be defined through AAA. As with authentication and authorization, you configure AAA accounting by defining a named list of accounting methods, and then applying that list to various interfaces. For information about configuring accounting using AAA, refer to the chapter “Configuring Accounting.”

In many circumstances, AAA uses protocols such as RADIUS, TACACS+, or Kerberos to administer its security functions. If your router or access server is acting as a network access server, AAA is the means through which you establish communication between your network access server and your RADIUS, TACACS+, or Kerberos security server.

Although AAA is the primary (and recommended) method for access control, Cisco IOS software provides additional features for simple access control that are outside the scope of AAA, such as local username authentication, line password authentication, and enable password authentication. However, these features do not provide the same degree of access control that is possible by using AAA.

This section includes the following sections:

- Benefits of Using AAA
- AAA Philosophy
- Method Lists

### Benefits of Using AAA

AAA provides the following benefits:

- Increased flexibility and control of access configuration
AAA Overview

About AAA Security Services

- Scalability
- Standardized authentication methods, such as RADIUS, TACACS+, and Kerberos
- Multiple backup systems

**Note**
The deprecated protocols, TACACS and extended TACACS, are not compatible with AAA; if you select these security protocols, you will not be able to take advantage of the AAA security services.

AAA Philosophy

AAA is designed to enable you to dynamically configure the type of authentication and authorization you want on a per-line (per-user) or per-service (for example, IP, IPX, or VPDN) basis. You define the type of authentication and authorization you want by creating method lists, then applying those method lists to specific services or interfaces.

For information about applications that use AAA, such as per-user configuration and virtual profiles, refer to the chapters “Configuring Per-User Configuration” and “Configuring Virtual Profiles” in the *Cisco IOS Dial Technologies Configuration Guide*, Release 12.2.

Method Lists

A method list is a sequential list that defines the authentication methods used to authenticate a user. Method lists enable you to designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. Cisco IOS software uses the first method listed to authenticate users; if that method does not respond, Cisco IOS software selects the next authentication method in the method list. This process continues until there is successful communication with a listed authentication method or the authentication method list is exhausted, in which case authentication fails.

**Note**
Cisco IOS software attempts authentication with the next listed authentication method only when there is no response from the previous method. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops and no other authentication methods are attempted.

*Figure* 1 shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers, and T1 and T2 are TACACS+ servers.
Suppose the system administrator has defined a method list where R1 will be contacted first for authentication information, then R2, T1, T2, and finally the local username database on the access server itself. When a remote user attempts to dial in to the network, the network access server first queries R1 for authentication information. If R1 authenticates the user, it issues a PASS response to the network access server and the user is allowed to access the network. If R1 returns a FAIL response, the user is denied access and the session is terminated. If R1 does not respond, then the network access server processes that as an ERROR and queries R2 for authentication information. This pattern continues through the remaining designated methods until the user is either authenticated or rejected, or until the session is terminated. If all of the authentication methods return errors, the network access server will process the session as a failure, and the session will be terminated.

Note

A FAIL response is significantly different from an ERROR. A FAIL means that the user has not met the criteria contained in the applicable authentication database to be successfully authenticated. Authentication ends with a FAIL response. An ERROR means that the security server has not responded to an authentication query. Because of this, no authentication has been attempted. Only when an ERROR is detected will AAA select the next authentication method defined in the authentication method list.

Where to Begin

You must first decide what kind of security solution you want to implement. You need to assess the security risks in your particular network and decide on the appropriate means to prevent unauthorized entry and attack. For more information about assessing your security risks and possible security solutions, refer to the chapter “Security Overview.” Cisco recommends that you use AAA, no matter how minor your security needs might be.

This section includes the following subsections:

- Overview of the AAA Configuration Process
- Enabling AAA
- Disabling AAA
Overview of the AAA Configuration Process

Configuring AAA is relatively simple after you understand the basic process involved. To configure security on a Cisco router or access server using AAA, follow this process:

1. Enable AAA by using the `aaa new-model` global configuration command.
2. If you decide to use a separate security server, configure security protocol parameters, such as RADIUS, TACACS+, or Kerberos.
3. Define the method lists for authentication by using an AAA authentication command.
4. Apply the method lists to a particular interface or line, if required.
5. (Optional) Configure authorization using the `aaa authorization` command.

For a complete description of the commands used in this chapter, refer to the chapter “Authentication Commands” of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

Enabling AAA

Before you can use any of the services AAA network security services provide, you must enable AAA.

**Note**

When you enable AAA, you can no longer access the commands to configure the older protocols, TACACS or extended TACACS. If you decided to use TACACS or extended TACACS in your security solution, do not enable AAA.

To enable AAA, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router (config)# aaa new-model</code></td>
<td>Enables AAA.</td>
</tr>
</tbody>
</table>

Disabling AAA

You can disable AAA functionality with a single command if you decide that your security needs cannot be met by AAA but can be met by using TACACS, extended TACACS, or a line security method that can be implemented without AAA. To disable AAA, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config)# no aaa new-model</code></td>
<td>Disables AAA.</td>
</tr>
</tbody>
</table>

What to Do Next

Once you have enabled AAA, you are ready to configure the other elements relating to your selected security solution. **Table 3** describes AAA configuration tasks and where to find more information.
If you have elected not to use the AAA security services, see the “Configuring Authentication” chapter for the non-AAA configuration task “Configuring Login Authentication.”

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

</tbody>
</table>

Authentication verifies users before they are allowed access to the network and network services. The Cisco IOS software implementation of authentication is divided into two main categories:

- AAA Authentication Methods Configuration Task List
- Non-AAA Authentication Methods

Authentication, for the most part, is implemented through the AAA security services. Cisco recommends that, whenever possible, AAA be used to implement authentication.

This chapter describes both AAA and non-AAA authentication methods. For authentication configuration examples, refer to the “Authentication Examples” section at the end of this chapter. For a complete description of the AAA commands used in this chapter, refer to the “Authentication, Authorization, and Accounting (AAA)” part of the Cisco IOS Security Command Reference. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature, or refer to the software release notes for a specific release. For more information, see the section “Identifying Supported Platforms” in the chapter “Using Cisco IOS Software.”

In This Chapter

This chapter contains the following sections:

- AAA Authentication Methods Configuration Task List
Configuring Authentication

Named Method Lists for Authentication

To configure AAA authentication, you must first define a named list of authentication methods, and then apply that list to various interfaces. The method list defines the types of authentication to be performed and the sequence in which they will be performed; it must be applied to a specific interface before any of the defined authentication methods will be performed. The only exception is the default method list (which is named “default”). The default method list is automatically applied to all interfaces except those that have a named method list explicitly defined. A defined method list overrides the default method list.

A method list is a sequential list describing the authentication methods to be queried in order to authenticate a user. Method lists enable you to designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. Cisco IOS software uses the first listed method to authenticate users. If that method fails to respond, the Cisco IOS software selects the next authentication method listed in the method list. This process continues until there is successful communication with a listed authentication method, or all methods defined in the method list are exhausted.

It is important to note that the Cisco IOS software attempts authentication with the next listed authentication method only when there is no response from the previous method. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops and no other authentication methods are attempted.

Note
Effective with Cisco IOS Release 12.3, the number of AAA method lists that can be configured is 250.

This section contains the following subsections:

- Method Lists and Server Groups
- Method List Examples
- AAA Authentication General Configuration Procedure

Method Lists and Server Groups

A server group is a way to group existing RADIUS or TACACS+ server hosts for use in method lists. Figure 2 shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers and T1 and T2 are TACACS+ servers. R1 and R2 make up the group of RADIUS servers. T1 and T2 make up the group of TACACS+ servers.
Using server groups, you can specify a subset of the configured server hosts and use them for a particular service. For example, server groups allow you to define R1 and R2 as a server group, and define T1 and T2 as a separate server group. For example, you can specify R1 and T1 in the method list for authentication login, while specifying R2 and T2 in the method list for PPP authentication.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, authentication—the second host entry configured acts as failover backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server will try the second host entry configured on the same device for accounting services. (The RADIUS host entries will be tried in the order in which they are configured.)

For more information about configuring server groups and about configuring server groups based on Dialed Number Identification Service (DNIS) numbers, refer to the “Configuring RADIUS” or “Configuring TACACS+” chapter.

**Method List Examples**

Suppose the system administrator has decided on a security solution where all interfaces will use the same authentication methods to authenticate PPP connections. In the RADIUS group, R1 is contacted first for authentication information, then if there is no response, R2 is contacted. If R2 does not respond, T1 in the TACACS+ group is contacted; if T1 does not respond, T2 is contacted. If all designated servers fail to respond, authentication falls to the local username database on the access server itself. To implement this solution, the system administrator would create a default method list by entering the following command:

```
aaa authentication ppp default group radius group tacacs+ local
```

In this example, “default” is the name of the method list. The protocols included in this method list are listed after the name, in the order they are to be queried. The default list is automatically applied to all interfaces.
When a remote user attempts to dial in to the network, the network access server first queries R1 for authentication information. If R1 authenticates the user, it issues a PASS response to the network access server and the user is allowed to access the network. If R1 returns a FAIL response, the user is denied access and the session is terminated. If R1 does not respond, then the network access server processes that as an ERROR and queries R2 for authentication information. This pattern would continue through the remaining designated methods until the user is either authenticated or rejected, or until the session is terminated.

It is important to remember that a FAIL response is significantly different from an ERROR. A FAIL means that the user has not met the criteria contained in the applicable authentication database to be successfully authenticated. Authentication ends with a FAIL response. An ERROR means that the security server has not responded to an authentication query. Because of this, no authentication has been attempted. Only when an ERROR is detected will AAA select the next authentication method defined in the authentication method list.

Suppose the system administrator wants to apply a method list only to a particular interface or set of interfaces. In this case, the system administrator creates a named method list and then applies this named list to the applicable interfaces. The following example shows how the system administrator can implement an authentication method that will be applied only to interface 3:

```plaintext
aaa authentication ppp default group radius group tacacs+ local
aaa authentication ppp apple group radius group tacacs+ local none
interface async 3
ppp authentication chap apple
```

In this example, “apple” is the name of the method list, and the protocols included in this method list are listed after the name in the order in which they are to be performed. After the method list has been created, it is applied to the appropriate interface. Note that the method list name (apple) in both the AAA and PPP authentication commands must match.

In the following example, the system administrator uses server groups to specify that only R2 and T2 are valid servers for PPP authentication. To do this, the administrator must define specific server groups whose members are R2 (172.16.2.7) and T2 (172.16.2.77), respectively. In this example, the RADIUS server group “rad2only” is defined as follows using the `aaa group server` command:

```plaintext
aaa group server radius rad2only
server 172.16.2.7
```

The TACACS+ server group “tac2only” is defined as follows using the `aaa group server` command:

```plaintext
aaa group server tacacs+ tac2only
server 172.16.2.77
```

The administrator then applies PPP authentication using the server groups. In this example, the default methods list for PPP authentication follows this order: `group rad2only, group tac2only, and local`:

```plaintext
aaa authentication ppp default group rad2only group tac2only local
```

## AAA Authentication General Configuration Procedure

To configure AAA authentication, perform the following tasks:

1. Enable AAA by using the `aaa new-model` global configuration command. For more information about configuring AAA, refer to the chapter “AAA Overview”.

2. Configure security protocol parameters, such as RADIUS, TACACS+, or Kerberos if you are using a security server. For more information about RADIUS, refer to the chapter “Configuring RADIUS”. For more information about TACACS+, refer to the chapter “Configuring TACACS+”. For more information about Kerberos, refer to the chapter “Configuring Kerberos”.

---

**Configuring Authentication**

**Named Method Lists for Authentication**

4
3. Define the method lists for authentication by using an AAA authentication command.
4. Apply the method lists to a particular interface or line, if required.

AAA Authentication Methods Configuration Task List

This section discusses the following AAA authentication methods:
- Configuring Login Authentication Using AAA
- Configuring PPP Authentication Using AAA
- Configuring AAA Scalability for PPP Requests
- Configuring ARAP Authentication Using AAA
- Configuring NASI Authentication Using AAA
- Specifying the Amount of Time for Login Input
- Enabling Password Protection at the Privileged Level
- Changing the Text Displayed at the Password Prompt
- Configuring Message Banners for AAA Authentication
- Configuring AAA Packet of Disconnect
- Enabling Double Authentication
- Enabling Automated Double Authentication

Note
AAA features are not available for use until you enable AAA globally by issuing the `aaa new-model` command. For more information about enabling AAA, refer to the “AAA Overview” chapter.

For authentication configuration examples using the commands in this chapter, refer to the section “Authentication Examples” at the end of the this chapter.

Configuring Login Authentication Using AAA

The AAA security services facilitate a variety of login authentication methods. Use the `aaa authentication login` command to enable AAA authentication no matter which of the supported login authentication methods you decide to use. With the `aaa authentication login` command, you create one or more lists of authentication methods that are tried at login. These lists are applied using the `login authentication` line configuration command.

To configure login authentication by using AAA, use the following commands beginning in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Router(config)# aaa new-model</td>
</tr>
<tr>
<td>Step 2</td>
<td>Router(config)# aaa authentication login {default</td>
</tr>
</tbody>
</table>
AAA Authentication Methods Configuration Task List

## Configuring Authentication

### AAA Authentication Methods Configuration Task List

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Router(config)# line [aux | console | tty | vty]
| line-number [ending-line-number] | Enters line configuration mode for the lines to which you want to apply the authentication list. |

<table>
<thead>
<tr>
<th>Step 4</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config-line)# login authentication (default</td>
<td>list-name)</td>
<td>Applies the authentication list to a line or set of lines.</td>
</tr>
</tbody>
</table>

The **list-name** is a character string used to name the list you are creating. The method argument refers to the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

For example, to specify that authentication should succeed even if (in this example) the TACACS+ server returns an error, enter the following command:

```
aaa authentication login default group tacacs+ none
```

**Note**

Because the **none** keyword enables any user logging in to successfully authenticate, it should be used only as a backup method of authentication.

To create a default list that is used when a named list is not specified in the **login authentication** command, use the **default** keyword followed by the methods that are to be used in default situations. The default method list is automatically applied to all interfaces.

For example, to specify RADIUS as the default method for user authentication during login, enter the following command:

```
aaa authentication login default group radius
```

Table 4 lists the supported login authentication methods.

### Table 4 AAA Authentication Login Methods

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Uses the enable password for authentication.</td>
</tr>
<tr>
<td>krb5</td>
<td>Uses Kerberos 5 for authentication.</td>
</tr>
<tr>
<td>krb5-telnet</td>
<td>Uses Kerberos 5 Telnet authentication protocol when using Telnet to connect to the router. If selected, this keyword must be listed as the first method in the method list.</td>
</tr>
<tr>
<td>line</td>
<td>Uses the line password for authentication.</td>
</tr>
<tr>
<td>local</td>
<td>Uses the local username database for authentication.</td>
</tr>
<tr>
<td>local-case</td>
<td>Uses case-sensitive local username authentication.</td>
</tr>
<tr>
<td>none</td>
<td>Uses no authentication.</td>
</tr>
<tr>
<td>group radius</td>
<td>Uses the list of all RADIUS servers for authentication.</td>
</tr>
<tr>
<td>group tacacs+</td>
<td>Uses the list of all TACACS+ servers for authentication.</td>
</tr>
<tr>
<td>group group-name</td>
<td>Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the aaa group server radius or aaa group server tacacs+ command.</td>
</tr>
</tbody>
</table>

---
The **login** command only changes username and privilege level but does not execute a shell; therefore autocommands will not be executed. To execute autocommands under this circumstance, you need to establish a Telnet session back into the router (loop-back). Make sure that the router has been configured for secure Telnet sessions if you choose to implement autocommands this way.

This section includes the following sections:

- Login Authentication Using Enable Password
- Login Authentication Using Kerberos
- Login Authentication Using Line Password
- Login Authentication Using Local Password
- Login Authentication Using Group RADIUS
- Login Authentication Using Group TACACS+
- Login Authentication Using group group-name

### Login Authentication Using Enable Password

Use the `aaa authentication login` command with the `enable` *method* keyword to specify the enable password as the login authentication method. For example, to specify the enable password as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default enable
```

Before you can use the enable password as the login authentication method, you need to define the enable password. For more information about defining enable passwords, refer to the chapter “Configuring Passwords and Privileges.”

### Login Authentication Using Kerberos

Authentication via Kerberos is different from most other authentication methods: the user’s password is never sent to the remote access server. Remote users logging in to the network are prompted for a username. If the key distribution center (KDC) has an entry for that user, it creates an encrypted ticket granting ticket (TGT) with the password for that user and sends it back to the router. The user is then prompted for a password, and the router attempts to decrypt the TGT with that password. If it succeeds, the user is authenticated and the TGT is stored in the user’s credential cache on the router.

While `krb5` does use the KINIT program, a user does not need to run the KINIT program to get a TGT to authenticate to the router. This is because KINIT has been integrated into the login procedure in the Cisco IOS implementation of Kerberos.

Use the `aaa authentication login` command with the `krb5` *method* keyword to specify Kerberos as the login authentication method. For example, to specify Kerberos as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default krb5
```

Before you can use Kerberos as the login authentication method, you need to enable communication with the Kerberos security server. For more information about establishing communication with a Kerberos server, refer to the chapter “Configuring Kerberos.”
Login Authentication Using Line Password

Use the `aaa authentication login` command with the `line` method keyword to specify the line password as the login authentication method. For example, to specify the line password as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default line
```

Before you can use a line password as the login authentication method, you need to define a line password. For more information about defining line passwords, refer to the section “Configuring Line Password Protection” in this chapter.

Login Authentication Using Local Password

Use the `aaa authentication login` command with the `local` method keyword to specify that the Cisco router or access server will use the local username database for authentication. For example, to specify the local username database as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default local
```

For information about adding users into the local username database, refer to the section “Establishing Username Authentication” in this chapter.

Login Authentication Using Group RADIUS

Use the `aaa authentication login` command with the `group radius` method to specify RADIUS as the login authentication method. For example, to specify RADIUS as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default group radius
```

Before you can use RADIUS as the login authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.”

Configuring RADIUS Attribute 8 in Access Requests

Once you have used the `aaa authentication login` command to specify RADIUS and your login host has been configured to request its IP address from the NAS, you can send attribute 8 (Framed-IP-Address) in access-request packets by using the `radius-server attribute 8 include-in-access-req` command in global configuration mode. This command makes it possible for a NAS to provide the RADIUS server with a hint of the user IP address in advance of user authentication. For more information about attribute 8, refer to the appendix “RADIUS Attributes” at the end of the book.

Login Authentication Using Group TACACS+

Use the `aaa authentication login` command with the `group tacacs+` method to specify TACACS+ as the login authentication method. For example, to specify TACACS+ as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default group tacacs+
```
Before you can use TACACS+ as the login authentication method, you need to enable communication
with the TACACS+ security server. For more information about establishing communication with a
TACACS+ server, refer to the chapter “Configuring TACACS+.”

### Login Authentication Using group group-name

Use the `aaa authentication login` command with the `group group-name` method to specify a subset of
RADIUS or TACACS+ servers to use as the login authentication method. To specify and define the group
name and the members of the group, use the `aaa group server` command. For example, use the `aaa
group server` command to first define the members of group `loginrad`:

```
aaa group server radius loginrad
  server 172.16.2.3
  server 172.16.2.17
  server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the
group `loginrad`.

To specify `group loginrad` as the method of user authentication at login when no other method list has
been defined, enter the following command:

```
aaa authentication login default group loginrad
```

Before you can use a group name as the login authentication method, you need to enable communication
with the RADIUS or TACACS+ security server. For more information about establishing communication
with a RADIUS server, refer to the chapter “Configuring RADIUS.” For more information about
establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

### Configuring PPP Authentication Using AAA

Many users access network access servers through dialup via async or ISDN. Dialup via async or ISDN
bypasses the CLI completely; instead, a network protocol (such as PPP or ARA) starts as soon as the
connection is established.

The AAA security services facilitate a variety of authentication methods for use on serial interfaces
running PPP. Use the `aaa authentication ppp` command to enable AAA authentication no matter which
of the supported PPP authentication methods you decide to use.

To configure AAA authentication methods for serial lines using PPP, use the following commands in
global configuration mode:

```
<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**

  Router(config)# aaa new-model

| **Step 2**

  Router(config)# aaa authentication ppp {default | list-name} method1 [method2...] |

  Enables AAA globally.                     |

  Creates a local authentication list.      |
```
Configuring Authentication

AAA Authentication Methods Configuration Task List

1. With the `aaa authentication ppp` command, you create one or more lists of authentication methods that are tried when a user tries to authenticate via PPP. These lists are applied using the `ppp authentication` line configuration command.

2. To create a default list that is used when a named list is not specified in the `ppp authentication` command, use the `default` keyword followed by the methods you want used in default situations.

   For example, to specify the local username database as the default method for user authentication, enter the following command:

   ```
   aaa authentication ppp default local
   ```

   The `list-name` is any character string used to name the list you are creating. The method argument refers to the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify `none` as the final method in the command line.

   For example, to specify that authentication should succeed even if (in this example) the TACACS+ server returns an error, enter the following command:

   ```
   aaa authentication ppp default group tacacs+ none
   ```

   Note: Because `none` allows all users logging in to authenticate successfully, it should be used as a backup method of authentication.

3. Table 5 lists the supported login authentication methods.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>if-needed</td>
<td>Does not authenticate if user has already been authenticated on a TTY line.</td>
</tr>
<tr>
<td>krb5</td>
<td>Uses Kerberos 5 for authentication (can only be used for PAP authentication).</td>
</tr>
<tr>
<td>local</td>
<td>Uses the local username database for authentication.</td>
</tr>
<tr>
<td>local-case</td>
<td>Uses case-sensitive local username authentication.</td>
</tr>
<tr>
<td>none</td>
<td>Uses no authentication.</td>
</tr>
<tr>
<td>group radius</td>
<td>Uses the list of all RADIUS servers for authentication.</td>
</tr>
</tbody>
</table>
This section includes the following sections:

- **PPP Authentication Using Kerberos**
- **PPP Authentication Using Local Password**
- **PPP Authentication Using Group RADIUS**
- **PPP Authentication Using Group TACACS+**
- **PPP Authentication Using group group-name**

### PPP Authentication Using Kerberos

Use the `aaa authentication ppp` command with the `krb5` method keyword to specify Kerberos as the authentication method for use on interfaces running PPP. For example, to specify Kerberos as the method of user authentication when no other method list has been defined, enter the following command:

```
aaa authentication ppp default krb5
```

Before you can use Kerberos as the PPP authentication method, you need to enable communication with the Kerberos security server. For more information about establishing communication with a Kerberos server, refer to the chapter “Configuring Kerberos”.

**Note**

Kerberos login authentication works only with PPP PAP authentication.

### PPP Authentication Using Local Password

Use the `aaa authentication ppp` command with the `method` keyword `local` to specify that the Cisco router or access server will use the local username database for authentication. For example, to specify the local username database as the method of authentication for use on lines running PPP when no other method list has been defined, enter the following command:

```
aaa authentication ppp default local
```

For information about adding users into the local username database, refer to the section “Establishing Username Authentication” in this chapter.

### PPP Authentication Using Group RADIUS

Use the `aaa authentication ppp` command with the `group radius` method to specify RADIUS as the login authentication method. For example, to specify RADIUS as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication ppp default group radius
```
Before you can use RADIUS as the PPP authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.”

Configuring RADIUS Attribute 44 in Access Requests

Once you have used the `aaa authentication ppp` command with the `group radius` method to specify RADIUS as the login authentication method, you can configure your router to send attribute 44 (Acct-Seccion-ID) in access-request packets by using the `radius-server attribute 44 include-in-access-req` command in global configuration mode. This command allows the RADIUS daemon to track a call from the beginning of the call to the end of the call. For more information on attribute 44, refer to the appendix “RADIUS Attributes” at the end of the book.

PPP Authentication Using Group TACACS+

Use the `aaa authentication ppp` command with the `group tacacs+` method to specify TACACS+ as the login authentication method. For example, to specify TACACS+ as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication ppp default group tacacs+
```

Before you can use TACACS+ as the PPP authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

PPP Authentication Using group group-name

Use the `aaa authentication ppp` command with the `group group-name` method to specify a subset of RADIUS or TACACS+ servers to use as the login authentication method. To specify and define the group name and the members of the group, use the `aaa group server` command. For example, use the `aaa group server` command to first define the members of `group ppprad`:

```
aaa group server radius ppprad
   server 172.16.2.3
   server 172.16.2.17
   server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group `ppprad`.

To specify `group ppprad` as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication ppp default group ppprad
```

Before you can use a group name as the PPP authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS”. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”
Configuring AAA Scalability for PPP Requests

You can configure and monitor the number of background processes allocated by the PPP manager in the network access server (NAS) to deal with AAA authentication and authorization requests. In previous Cisco IOS releases, only one background process was allocated to handle all AAA requests for PPP. This meant that parallelism in AAA servers could not be fully exploited. The AAA Scalability feature enables you to configure the number of processes used to handle AAA requests for PPP, thus increasing the number of users that can be simultaneously authenticated or authorized.

To allocate a specific number of background processes to handle AAA requests for PPP, use the following command in global configuration mode:

```
Router(config)# aaa processes number
```

The argument `number` defines the number of background processes earmarked to process AAA authentication and authorization requests for PPP and can be configured for any value from 1 to 2147483647. Because of the way the PPP manager handles requests for PPP, this argument also defines the number of new users that can be simultaneously authenticated. This argument can be increased or decreased at any time.

```
Note
Allocating additional background processes can be expensive. You should configure the minimum number of background processes capable of handling the AAA requests for PPP.
```

Configuring ARAP Authentication Using AAA

With the `aaa authentication arap` command, you create one or more lists of authentication methods that are tried when AppleTalk Remote Access Protocol (ARAP) users attempt to log in to the router. These lists are used with the `arap authentication` line configuration command.

Use the following commands starting in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Router(config)# aaa new-model</td>
</tr>
<tr>
<td>Step 2</td>
<td>Router(config)# aaa authentication arap {</td>
</tr>
<tr>
<td>Step 3</td>
<td>Router(config)# line number</td>
</tr>
<tr>
<td>Step 4</td>
<td>Router(config-line)# autoselect arap</td>
</tr>
<tr>
<td>Step 5</td>
<td>Router(config-line)# autoselect during-login</td>
</tr>
<tr>
<td>Step 6</td>
<td>Router(config-line)# arap authentication list-name</td>
</tr>
</tbody>
</table>
The list-name is any character string used to name the list you are creating. The method argument refers to the actual list of methods the authentication algorithm tries, in the sequence entered.

To create a default list that is used when a named list is not specified in the arap authentication command, use the default keyword followed by the methods you want to be used in default situations.

The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify none as the final method in the command line.

Because none allows all users logging in to authenticate successfully, it should be used as a backup method of authentication.

Table 6 lists the supported login authentication methods.

Table 6  AAA Authentication ARAP Methods

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auth-guest</td>
<td>Allows guest logins only if the user has already logged in to EXEC.</td>
</tr>
<tr>
<td>guest</td>
<td>Allows guest logins.</td>
</tr>
<tr>
<td>line</td>
<td>Uses the line password for authentication.</td>
</tr>
<tr>
<td>local</td>
<td>Uses the local username database for authentication.</td>
</tr>
<tr>
<td>local-case</td>
<td>Uses case-sensitive local username authentication.</td>
</tr>
<tr>
<td>group radius</td>
<td>Uses the list of all RADIUS servers for authentication.</td>
</tr>
<tr>
<td>group tacacs+</td>
<td>Uses the list of all TACACS+ servers for authentication.</td>
</tr>
<tr>
<td>group group-name</td>
<td>Uses a subset of RADIUS or TACACS+ servers for authentication as defined by</td>
</tr>
<tr>
<td></td>
<td>the aaa group server radius or aaa group server tacacs+ command.</td>
</tr>
</tbody>
</table>

For example, to create a default AAA authentication method list used with ARAP, enter the following command:

```plaintext
aaa authentication arap default if-needed none
```

To create the same authentication method list for ARAP but name the list MIS-access, enter the following command:

```plaintext
aaa authentication arap MIS-access if-needed none
```

This section includes the following sections:

- ARAP Authentication Allowing Authorized Guest Logins
- ARAP Authentication Allowing Guest Logins
- ARAP Authentication Using Line Password
- ARAP Authentication Using Local Password
- ARAP Authentication Using Group RADIUS
- ARAP Authentication Using Group TACACS+
- ARAP Authentication Using Group group-name
ARAP Authentication Allowing Authorized Guest Logins

Use the `aaa authentication arap` command with the `auth-guest` keyword to allow guest logins only if the user has already successfully logged in to the EXEC. This method must be the first listed in the ARAP authentication method list but it can be followed by other methods if it does not succeed. For example, to allow all authorized guest logins—meaning logins by users who have already successfully logged in to the EXEC—as the default method of authentication, using RADIUS only if that method fails, enter the following command:

```
aaa authentication arap default auth-guest group radius
```

For more information about ARAP authorized guest logins, refer to the chapter “Configuring AppleTalk” in the *Cisco IOS AppleTalk and Novell IPX Configuration Guide*.

**Note**

By default, guest logins through ARAP are disabled when you initialize AAA. To allow guest logins, you must use the `aaa authentication arap` command with either the `guest` or the `auth-guest` keyword.

ARAP Authentication Allowing Guest Logins

Use the `aaa authentication arap` command with the `guest` keyword to allow guest logins. This method must be the first listed in the ARAP authentication method list but it can be followed by other methods if it does not succeed. For example, to allow all guest logins as the default method of authentication, using RADIUS only if that method fails, enter the following command:

```
aaa authentication arap default guest group radius
```

For more information about ARAP guest logins, refer to the chapter “Configuring AppleTalk” in the *Cisco IOS AppleTalk and Novell IPX Configuration Guide*.

ARAP Authentication Using Line Password

Use the `aaa authentication arap` command with the `method` keyword `line` to specify the line password as the authentication method. For example, to specify the line password as the method of ARAP user authentication when no other method list has been defined, enter the following command:

```
aaa authentication arap default line
```

Before you can use a line password as the ARAP authentication method, you need to define a line password. For more information about defining line passwords, refer to the section “Configuring Line Password Protection” in this chapter.

ARAP Authentication Using Local Password

Use the `aaa authentication arap` command with the `method` keyword `local` to specify that the Cisco router or access server will use the local username database for authentication. For example, to specify the local username database as the method of ARAP user authentication when no other method list has been defined, enter the following command:

```
aaa authentication arap default local
```

For information about adding users to the local username database, refer to the section “Establishing Username Authentication” in this chapter.
**ARAP Authentication Using Group RADIUS**

Use the `aaa authentication arap` command with the `group radius` method to specify RADIUS as the ARAP authentication method. For example, to specify RADIUS as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication arap default group radius
```

Before you can use RADIUS as the ARAP authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.”

**ARAP Authentication Using Group TACACS+**

Use the `aaa authentication arap` command with the `group tacacs+` method to specify TACACS+ as the ARAP authentication method. For example, to specify TACACS+ as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication arap default group tacacs+
```

Before you can use TACACS+ as the ARAP authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

**ARAP Authentication Using Group group-name**

Use the `aaa authentication arap` command with the `group group-name` method to specify a subset of RADIUS or TACACS+ servers to use as the ARAP authentication method. To specify and define the group name and the members of the group, use the `aaa group server` command. For example, use the `aaa group server` command to first define the members of `group araprad`:

```
aaa group server radius araprad
  server 172.16.2.3
  server 172.16.2.17
  server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group `araprad`.

To specify `group araprad` as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication arap default group araprad
```

Before you can use a group name as the ARAP authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.” For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

**Configuring NASI Authentication Using AAA**

With the `aaa authentication nasi` command, you create one or more lists of authentication methods that are tried when NetWare Asynchronous Services Interface (NASI) users attempt to log in to the router. These lists are used with the `nasi authentication` line configuration command.
To configure NASI authentication using AAA, use the following commands starting in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Router(config)# aaa new-model Enables AAA globally.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Router(config)# aaa authentication nasi (default</td>
</tr>
<tr>
<td>Step 3</td>
<td>Router(config)# line number (Optional—not needed if default is used in the aaa authentication nasi command) Enters line configuration mode.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Router(config-line)# nasi authentication list-name (Optional—not needed if default is used in the aaa authentication nasi command) Enables authentication for NASI on a line.</td>
</tr>
</tbody>
</table>

The list-name is any character string used to name the list you are creating. The method argument refers to the actual list of methods the authentication algorithm tries, in the sequence entered.

To create a default list that is used when a named list is not specified in the aaa authentication nasi command, use the default keyword followed by the methods you want to be used in default situations.

The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify none as the final method in the command line.

**Note**

Because none allows all users logging in to authenticate successfully, it should be used as a backup method of authentication.

*Table 7* lists the supported NASI authentication methods.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Uses the enable password for authentication.</td>
</tr>
<tr>
<td>line</td>
<td>Uses the line password for authentication.</td>
</tr>
<tr>
<td>local</td>
<td>Uses the local username database for authentication.</td>
</tr>
<tr>
<td>local-case</td>
<td>Uses case-sensitive local username authentication.</td>
</tr>
<tr>
<td>none</td>
<td>Uses no authentication.</td>
</tr>
<tr>
<td>group radius</td>
<td>Uses the list of all RADIUS servers for authentication.</td>
</tr>
<tr>
<td>group tacacs+</td>
<td>Uses the list of all TACACS+ servers for authentication.</td>
</tr>
<tr>
<td>group group-name</td>
<td>Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the aaa group server radius or aaa group server tacacs+ command.</td>
</tr>
</tbody>
</table>

This section includes the following sections:

- NASI Authentication Using Enable Password
- NASI Authentication Using Line Password
- NASI Authentication Using Local Password
NASI Authentication Using Enable Password

Use the `aaa authentication nasi` command with the `method` keyword `enable` to specify the enable password as the authentication method. For example, to specify the enable password as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default enable
```

Before you can use the enable password as the authentication method, you need to define the enable password. For more information about defining enable passwords, refer to the chapter “Configuring Passwords and Privileges.”

NASI Authentication Using Line Password

Use the `aaa authentication nasi` command with the `method` keyword `line` to specify the line password as the authentication method. For example, to specify the line password as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default line
```

Before you can use a line password as the NASI authentication method, you need to define a line password. For more information about defining line passwords, refer to the section “Configuring Line Password Protection” in this chapter.

NASI Authentication Using Local Password

Use the `aaa authentication nasi` command with the `method` keyword `local` to specify that the Cisco router or access server will use the local username database for authentication information. For example, to specify the local username database as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default local
```

For information about adding users to the local username database, refer to the section “Establishing Username Authentication” in this chapter.

NASI Authentication Using Group RADIUS

Use the `aaa authentication nasi` command with the `group radius` `method` to specify RADIUS as the NASI authentication method. For example, to specify RADIUS as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default group radius
```

Before you can use RADIUS as the NASI authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.”
NASI Authentication Using Group TACACS+

Use the `aaa authentication nasi` command with the `group tacacs+` method keyword to specify TACACS+ as the NASI authentication method. For example, to specify TACACS+ as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default group tacacs+
```

Before you can use TACACS+ as the authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

NASI Authentication Using group group-name

Use the `aaa authentication nasi` command with the `group group-name` method to specify a subset of RADIUS or TACACS+ servers to use as the NASI authentication method. To specify and define the group name and the members of the group, use the `aaa group server` command. For example, use the `aaa group server` command to first define the members of `group nasirad`:

```
aaa group server radius nasirad
    server 172.16.2.3
    server 172.16.2.17
    server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group `nasirad`.

To specify `group nasirad` as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication nasi default group nasirad
```

Before you can use a group name as the NASI authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS”. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

Specifying the Amount of Time for Login Input

The `timeout login response` command allows you to specify how long the system will wait for login input (such as username and password) before timing out. The default login value is 30 seconds; with the `timeout login response` command, you can specify a timeout value from 1 to 300 seconds. To change the login timeout value from the default of 30 seconds, use the following command in line configuration mode:

```
Router(config-line)# timeout login response seconds
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>timeout login response seconds</code></td>
<td>Specifies how long the system will wait for login information before timing out.</td>
</tr>
</tbody>
</table>
Enabling Password Protection at the Privileged Level

Use the `aaa authentication enable default` command to create a series of authentication methods that are used to determine whether a user can access the privileged EXEC command level. You can specify up to four authentication methods. The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify `none` as the final method in the command line.

Use the following command in global configuration mode:

```
Router(config)# aaa authentication enable default method1 [method2...]
```

The method argument refers to the actual list of methods the authentication algorithm tries, in the sequence entered. Table 8 lists the supported enable authentication methods.

### Table 8 AAA Authentication Enable Default Methods

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Uses the enable password for authentication.</td>
</tr>
<tr>
<td>line</td>
<td>Uses the line password for authentication.</td>
</tr>
<tr>
<td>none</td>
<td>Uses no authentication.</td>
</tr>
<tr>
<td>group radius</td>
<td>Uses the list of all RADIUS hosts for authentication.</td>
</tr>
<tr>
<td>group tacacs+</td>
<td>Uses the list of all TACACS+ hosts for authentication.</td>
</tr>
<tr>
<td>group group-name</td>
<td>Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the <code>aaa group server radius</code> or <code>aaa group server tacacs+</code> command.</td>
</tr>
</tbody>
</table>

**Changing the Text Displayed at the Password Prompt**

Use the `aaa authentication password-prompt` command to change the default text that the Cisco IOS software displays when prompting a user to enter a password. This command changes the password prompt for the enable password as well as for login passwords that are not supplied by remote security servers. The `no` form of this command returns the password prompt to the following default value:

```
Password:
```

The `aaa authentication password-prompt` command does not change any dialog that is supplied by a remote TACACS+ or RADIUS server.

The `aaa authentication password-prompt` command works when RADIUS is used as the login method. You will be able to see the password prompt defined in the command shown even when the RADIUS server is unreachable. The `aaa authentication password-prompt` command does not work with
TACACS+. TACACS+ supplies the NAS with the password prompt to display to the users. If the TACACS+ server is reachable, the NAS gets the password prompt from the server and uses that prompt instead of the one defined in the `aaa authentication password-prompt` command. If the TACACS+ server is not reachable, the password prompt defined in the `aaa authentication password-prompt` command may be used.

Use the following command in global configuration mode:

Command Purpose
---
`Router(config)# aaa authentication password-prompt text-string` Changes the default text displayed when a user is prompted to enter a password.

---

### Configuring Message Banners for AAA Authentication

AAA supports the use of configurable, personalized login and failed-login banners. You can configure message banners that will be displayed when a user logs in to the system to be authenticated using AAA and when, for whatever reason, authentication fails.

This section includes the following sections:

- Configuring a Login Banner
- Configuring a Failed-Login Banner

### Configuring a Login Banner

To create a login banner, you need to configure a delimiting character, which notifies the system that the following text string is to be displayed as the banner, and then the text string itself. The delimiting character is repeated at the end of the text string to signify the end of the banner. The delimiting character can be any single character in the extended ASCII character set, but once defined as the delimiter, that character cannot be used in the text string making up the banner.

To configure a banner that will be displayed whenever a user logs in (replacing the default message for login), use the following commands in global configuration mode:

Command Purpose
---
Step 1 `Router(config)# aaa new-model` Enables AAA.
Step 2 `Router(config)# aaa authentication banner delimiter string delimiter` Creates a personalized login banner.

The maximum number of characters that can be displayed in the login banner is 2996 characters.

### Configuring a Failed-Login Banner

To create a failed-login banner, you need to configure a delimiting character, which notifies the system that the following text string is to be displayed as the banner, and then the text string itself. The delimiting character is repeated at the end of the text string to signify the end of the failed-login banner. The delimiting character can be any single character in the extended ASCII character set, but once defined as the delimiter, that character cannot be used in the text string making up the banner.
To configure a message that will be displayed whenever a user fails login (replacing the default message for failed login), use the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Router(config)# aaa new-model</td>
</tr>
<tr>
<td>Step 2</td>
<td>Router(config)# aaa authentication fail-message delimiter string delimiter</td>
</tr>
</tbody>
</table>

The maximum number of characters that can be displayed in the failed-login banner is 2996 characters.

### Configuring AAA Packet of Disconnect

Packet of disconnect (POD) terminates connections on the network access server (NAS) when particular session attributes are identified. By using session information obtained from AAA, the POD client residing on a UNIX workstation sends disconnect packets to the POD server running on the network access server. The NAS terminates any inbound user session with one or more matching key attributes. It rejects requests when required fields are missing or when an exact match is not found.

To configure POD, perform the following tasks in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Router(config)# aaa accounting network default start-stop radius</td>
</tr>
<tr>
<td>Step 2</td>
<td>Router(config)# aaa accounting delay-start</td>
</tr>
<tr>
<td>Step 3</td>
<td>Router(config)# aaa pod server server-key string</td>
</tr>
<tr>
<td>Step 4</td>
<td>Router(config)# radius-server host IP address non-standard</td>
</tr>
</tbody>
</table>

### Enabling Double Authentication

Previously, PPP sessions could only be authenticated by using a single authentication method: either PAP or CHAP. Double authentication requires remote users to pass a second stage of authentication—after CHAP or PAP authentication—before gaining network access.

This second (“double”) authentication requires a password that is known to the user but not stored on the user’s remote host. Therefore, the second authentication is specific to a user, not to a host. This provides an additional level of security that will be effective even if information from the remote host is stolen. In addition, this also provides greater flexibility by allowing customized network privileges for each user.

The second stage authentication can use one-time passwords such as token card passwords, which are not supported by CHAP. If one-time passwords are used, a stolen user password is of no use to the perpetrator.

This section includes the following subsections:

- How Double Authentication Works
- Configuring Double Authentication
- Accessing the User Profile After Double Authentication

**How Double Authentication Works**

With double authentication, there are two authentication/authorization stages. These two stages occur after a remote user dials in and a PPP session is initiated.

In the first stage, the user logs in using the remote host name; CHAP (or PAP) authenticates the remote host, and then PPP negotiates with AAA to authorize the remote host. In this process, the network access privileges associated with the remote host are assigned to the user.

**Note**

We suggest that the network administrator restrict authorization at this first stage to allow only Telnet connections to the local host.

In the second stage, the remote user must Telnet to the network access server to be authenticated. When the remote user logs in, the user must be authenticated with AAA login authentication. The user then must enter the `access-profile` command to be reauthorized using AAA. When this authorization is complete, the user has been double authenticated, and can access the network according to per-user network privileges.

The system administrator determines what network privileges remote users will have after each stage of authentication by configuring appropriate parameters on a security server. To use double authentication, the user must activate it by issuing the `access-profile` command.

**Caution**

Double authentication can cause certain undesirable events if multiple hosts share a PPP connection to a network access server, as shown in Figure 3.

First, if a user, Bob, initiates a PPP session and activates double authentication at the network access server (per Figure 3), any other user will automatically have the same network privileges as Bob until Bob’s PPP session expires. This happens because Bob’s authorization profile is applied to the network access server’s interface during the PPP session and any PPP traffic from other users will use the PPP session Bob established.

Second, if Bob initiates a PPP session and activates double authentication, and then—before Bob’s PPP session has expired—another user, Jane, executes the `access-profile` command (or, if Jane Telnets to the network access server and `autocommand access-profile` is executed), a reauthorization will occur and Jane’s authorization profile will be applied to the interface—replacing Bob’s profile. This can disrupt or halt Bob’s PPP traffic, or grant Bob additional authorization privileges Bob should not have.
Configuring Double Authentication

To configure double authentication, you must complete the following steps:

1. Enable AAA by using the `aaa-new-model` global configuration command. For more information about enabling AAA, refer to the chapter “AAA Overview.”

2. Use the `aaa authentication` command to configure your network access server to use login and PPP authentication method lists, then apply those method lists to the appropriate lines or interfaces.

3. Use the `aaa authorization` command to configure AAA network authorization at login. For more information about configuring network authorization, refer to the “Configuring Authorization” chapter.

4. Configure security protocol parameters (for example, RADIUS or TACACS+). For more information about RADIUS, refer to the chapter “Configuring RADIUS”. For more information about TACACS+, refer to the chapter “Configuring TACACS+.”

5. Use access control list AV pairs on the security server that the user can connect to the local host only by establishing a Telnet connection.

6. (Optional) Configure the `access-profile` command as an autocommand. If you configure the autocommand, remote users will not have to manually enter the `access-profile` command to access authorized rights associated with their personal user profile. To learn about configuring autocommands, refer to the `autocommand` command in the Cisco IOS Dial Technologies Command Reference: Network Services.

Note
If the `access-profile` command is configured as an autocommand, users will still have to Telnet to the local host and log in to complete double authentication.

Follow these rules when creating the user-specific authorization statements (These rules relate to the default behavior of the `access-profile` command):

- Use valid AV pairs when configuring access control list AV pairs on the security server. For a list of valid AV pairs, refer to the chapter “Authentication Commands” in the Cisco IOS Security Command Reference.

- If you want remote users to use the interface’s existing authorization (that which existed prior to the second stage authentication/authorization), but you want them to have different access control lists (ACLs), you should specify only ACL AV pairs in the user-specific authorization definition. This might be desirable if you set up a default authorization profile to apply to the remote host, but want to apply specific ACLs to specific users.
When these user-specific authorization statements are later applied to the interface, they can either be added to the existing interface configuration or they can replace the existing interface configuration—depending on which form of the `access-profile` command is used to authorize the user. You should understand how the `access-profile` command works before configuring the authorization statements.

If you will be using ISDN or Multilink PPP, you must also configure virtual templates at the local host.

To troubleshoot double authentication, use the `debug aaa per-user` debug command. For more information about this command, refer to the *Cisco IOS Debug Command Reference*.

### Accessing the User Profile After Double Authentication

In double authentication, when a remote user establishes a PPP link to the local host using the local host name, the remote host is CHAP (or PAP) authenticated. After CHAP (or PAP) authentication, PPP negotiates with AAA to assign network access privileges associated with the remote host to the user. (We suggest that privileges at this stage be restricted to allow the user to connect to the local host only by establishing a Telnet connection.)

When the user needs to initiate the second phase of double authentication, establishing a Telnet connection to the local host, the user enters a personal username and password (different from the CHAP or PAP username and password). This action causes AAA reauthentication to occur according to the personal username/password. The initial rights associated with the local host, though, are still in place. By using the `access-profile` command, the rights associated with the local host are replaced by or merged with those defined for the user in the user’s profile.

To access the user profile after double authentication, use the following command in EXEC configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`Router&gt; access-profile [merge</td>
<td>Accesses the rights associated for the user after double replace] [ignore-sanity-checks]` authentication.</td>
</tr>
</tbody>
</table>

If you configured the `access-profile` command to be executed as an autocommand, it will be executed automatically after the remote user logs in.

### Enabling Automated Double Authentication

You can make the double authentication process easier for users by implementing automated double authentication. Automated double authentication provides all of the security benefits of double authentication, but offers a simpler, more user-friendly interface for remote users. With double authentication, a second level of user authentication is achieved when the user Telnets to the network access server or router and enters a username and password. With automated double authentication, the user does not have to Telnet to the network access server; instead the user responds to a dialog box that requests a username and password or personal identification number (PIN). To use the automated double authentication feature, the remote user hosts must be running a companion client application. As of Cisco IOS Release 12.0, the only client application software available is the Glacier Bay application server software for PCs.
Automated double authentication, like the existing double authentication feature, is for Multilink PPP ISDN connections only. Automated double authentication cannot be used with other protocols such as X.25 or SLIP.

Automated double authentication is an enhancement to the existing double authentication feature. To configure automated double authentication, you must first configure double authentication by completing the following steps:

1. Enable AAA by using the `aaa-new model` global configuration command. For more information about enabling AAA, refer to the chapter “AAA Overview.”

2. Use the `aaa authentication` command to configure your network access server to use login and PPP authentication method lists, then apply those method lists to the appropriate lines or interfaces.

3. Use the `aaa authorization` command to configure AAA network authorization at login. For more information about configuring network authorization, refer to the chapter “Configuring Authorization.”

4. Configure security protocol parameters (for example, RADIUS or TACACS+). For more information about RADIUS, refer to the chapter “Configuring RADIUS”. For more information about TACACS+, refer to the chapter “Configuring TACACS+.”

5. Use access control list AV pairs on the security server that the user can connect to the local host only by establishing a Telnet connection.

6. Configure the `access-profile` command as an autocmd. If you configure the autocmd, remote users will not have to manually enter the `access-profile` command to access authorized rights associated with their personal user profile. To learn about configuring autocmds, refer to the `autocommand` command in the Cisco IOS Dial Technologies Command Reference, Release 12.2.

Follow these rules when creating the user-specific authorization statements (These rules relate to the default behavior of the `access-profile` command):

- Use valid AV pairs when configuring access control list AV pairs on the security server. For a list of valid AV pairs, refer to the chapter “Authentication Commands” in the Cisco IOS Security Command Reference.

- If you want remote users to use the interface’s existing authorization (that which existed prior to the second stage authentication/authorization), but you want them to have different access control lists (ACLs), you should specify only ACL AV pairs in the user-specific authorization definition. This might be desirable if you set up a default authorization profile to apply to the remote host, but want to apply specific ACLs to specific users.

- When these user-specific authorization statements are later applied to the interface, they can either be added to the existing interface configuration, or replace the existing interface configuration—depending on which form of the `access-profile` command is used to authorize the user. You should understand how the `access-profile` command works before configuring the authorization statements.

- If you will be using ISDN or Multilink PPP, you must also configure virtual templates at the local host.

To troubleshoot double authentication, use the `debug aaa per-user` debug command. For more information about this command, refer to the Cisco IOS Debug Command Reference.
After you have configured double authentication, you are ready to configure the automation enhancement.

To configure automated double authentication, use the following commands, starting in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Router(config)# ip trigger-authentication [timeout seconds] [port number] Enables automation of double authentication.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Router(config)# interface bri number or Router(config)# interface serial number:23 Selects an ISDN BRI or ISDN PRI interface and enter the interface configuration mode.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Router(config-if)# ip trigger-authentication Applies automated double authentication to the interface.</td>
</tr>
</tbody>
</table>

To troubleshoot automated double authentication, use the following commands in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Router# show ip trigger-authentication Displays the list of remote hosts for which automated double authentication has been attempted (successfully or unsuccessfully).</td>
</tr>
<tr>
<td>Step 2</td>
<td>Router# clear ip trigger-authentication Clears the list of remote hosts for which automated double authentication has been attempted. (This clears the table displayed by the show ip trigger-authentication command.)</td>
</tr>
<tr>
<td>Step 3</td>
<td>Router# debug ip trigger-authentication Displays debug output related to automated double authentication.</td>
</tr>
</tbody>
</table>

### Non-AAA Authentication Methods

This section discusses the following non-AAA authentication tasks:

- Configuring Line Password Protection
- Establishing Username Authentication
- Enabling CHAP or PAP Authentication
- Using MS-CHAP

### Configuring Line Password Protection

You can provide access control on a terminal line by entering the password and establishing password checking. To do so, use the following commands in line configuration mode:
Configuring Authentication

Non-AAA Authentication Methods

The password checker is case sensitive and can include spaces; for example, the password “Secret” is different from the password “secret,” and “two words” is an acceptable password.

You can disable line password verification by disabling password checking. To do so, use the following command in line configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config-line)# no login</code></td>
<td>Disables password checking or allow access to a line without password verification.</td>
</tr>
</tbody>
</table>

If you configure line password protection and then configure TACACS or extended TACACS, the TACACS username and password take precedence over line passwords. If you have not yet implemented a security policy, we recommend that you use AAA.

**Note**

The `login` command only changes username and privilege level but it does not execute a shell; therefore autocommands will not be executed. To execute autocommands under this circumstance, you need to establish a Telnet session back into the router (loop-back). Make sure that the router has been configured for secure Telnet sessions if you choose to implement autocommands this way.

**Establishing Username Authentication**

You can create a username-based authentication system, which is useful in the following situations:

- To provide a TACACS-like username and encrypted password-authentication system for networks that cannot support TACACS
- To provide special-case logins: for example, access list verification, no password verification, autocommand execution at login, and “no escape” situations

To establish username authentication, use the following commands in global configuration mode as needed for your system configuration:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>`Router(config)# username name [nopassword</td>
<td>password password</td>
</tr>
<tr>
<td>or</td>
<td></td>
</tr>
<tr>
<td><code>Router(config)# username name [access-class number]</code></td>
<td>(Optional) Establishes username authentication by access list.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>Router(config)# username name [privilege level]</code></td>
<td>(Optional) Sets the privilege level for the user.</td>
</tr>
</tbody>
</table>
The keyword `noescape` prevents users from using escape characters on the hosts to which they are connected. The `nohangup` feature does not disconnect after using the autocommand.

**Caution**

Passwords will be displayed in clear text in your configuration unless you enable the `service password-encryption` command. For more information about the `service password-encryption` command, refer to the chapter “Passwords and Privileges Commands” in the *Cisco IOS Security Command Reference*.

## Enabling CHAP or PAP Authentication

One of the most common transport protocols used in Internet service providers’ (ISPs’) dial solutions is the Point-to-Point Protocol (PPP). Traditionally, remote users dial in to an access server to initiate a PPP session. After PPP has been negotiated, remote users are connected to the ISP network and to the Internet.

Because ISPs want only customers to connect to their access servers, remote users are required to authenticate to the access server before they can start up a PPP session. Normally, a remote user authenticates by typing in a username and password when prompted by the access server. Although this is a workable solution, it is difficult to administer and awkward for the remote user.

A better solution is to use the authentication protocols built into PPP. In this case, the remote user dials in to the access server and starts up a minimal subset of PPP with the access server. This does not give the remote user access to the ISP’s network—it merely allows the access server to talk to the remote device.

PPP currently supports two authentication protocols: Password Authentication Protocol (PAP) and Challenge Handshake Authentication Protocol (CHAP). Both are specified in RFC 1334 and are supported on synchronous and asynchronous interfaces. Authentication via PAP or CHAP is equivalent to typing in a username and password when prompted by the server. CHAP is considered to be more secure because the remote user’s password is never sent across the connection.

PPP (with or without PAP or CHAP authentication) is also supported in dialout solutions. An access server utilizes a dialout feature when it initiates a call to a remote device and attempts to start up a transport protocol such as PPP.

See the chapter “Configuring Interfaces” in the *Cisco IOS Configuration Fundamentals Configuration Guide* for more information about CHAP and PAP.

**Note**

To use CHAP or PAP, you must be running PPP encapsulation.

When CHAP is enabled on an interface and a remote device attempts to connect to it, the access server sends a CHAP packet to the remote device. The CHAP packet requests or “challenges” the remote device to respond. The challenge packet consists of an ID, a random number, and the host name of the local router.
When the remote device receives the challenge packet, it concatenates the ID, the remote device’s password, and the random number, and then encrypts all of it using the remote device’s password. The remote device sends the results back to the access server, along with the name associated with the password used in the encryption process.

When the access server receives the response, it uses the name it received to retrieve a password stored in its user database. The retrieved password should be the same password the remote device used in its encryption process. The access server then encrypts the concatenated information with the newly retrieved password—if the result matches the result sent in the response packet, authentication succeeds.

The benefit of using CHAP authentication is that the remote device’s password is never transmitted in clear text. This prevents other devices from stealing it and gaining illegal access to the ISP’s network.

CHAP transactions occur only at the time a link is established. The access server does not request a password during the rest of the call. (The local device can, however, respond to such requests from other devices during a call.)

When PAP is enabled, the remote router attempting to connect to the access server is required to send an authentication request. If the username and password specified in the authentication request are accepted, the Cisco IOS software sends an authentication acknowledgment.

After you have enabled CHAP or PAP, the access server will require authentication from remote devices dialing in to the access server. If the remote device does not support the enabled protocol, the call will be dropped.

To use CHAP or PAP, you must perform the following tasks:

1. Enable PPP encapsulation.
2. Enable CHAP or PAP on the interface.
3. For CHAP, configure host name authentication and the secret or password for each remote system with which authentication is required.

This section includes the following sections:

- Enabling PPP Encapsulation
- Enabling PAP or CHAP
- Inbound and Outbound Authentication
- Enabling Outbound PAP Authentication
- Refusing PAP Authentication Requests
- Creating a Common CHAP Password
- Refusing CHAP Authentication Requests
- Delaying CHAP Authentication Until Peer Authenticates

### Enabling PPP Encapsulation

To enable PPP encapsulation, use the following command in interface configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config-if)# encapsulation ppp</code></td>
<td>Enables PPP on an interface.</td>
</tr>
</tbody>
</table>
Enabling PAP or CHAP

To enable CHAP or PAP authentication on an interface configured for PPP encapsulation, use the following command in interface configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`Router(config-if)# ppp authentication {protocol1 [protocol2...]} [if-needed] [default</td>
<td>Defines the authentication protocols supported and the order in which they are used. In this command, <code>protocol1</code>, <code>protocol2</code> represent the following protocols: CHAP, MS-CHAP, and PAP. PPP authentication is attempted first using the first authentication method, which is <code>protocol1</code>. If <code>protocol1</code> is unable to establish authentication, the next configured protocol is used to negotiate authentication.</td>
</tr>
<tr>
<td>[callin] [one-time]</td>
<td></td>
</tr>
</tbody>
</table>

If you configure `ppp authentication chap` on an interface, all incoming calls on that interface that initiate a PPP connection will have to be authenticated using CHAP; likewise, if you configure `ppp authentication pap`, all incoming calls that start a PPP connection will have to be authenticated via PAP.

If you configure `ppp authentication chap pap`, the access server will attempt to authenticate all incoming calls that start a PPP session with CHAP. If the remote device does not support CHAP, the access server will try to authenticate the call using PAP. If the remote device does not support either CHAP or PAP, authentication will fail and the call will be dropped. If you configure `ppp authentication pap chap`, the access server will attempt to authenticate all incoming calls that start a PPP session with PAP. If the remote device does not support PAP, the access server will try to authenticate the call using CHAP. If the remote device does not support either protocol, authentication will fail and the call will be dropped. If you configure the `ppp authentication` command with the `callin` keyword, the access server will only authenticate the remote device if the remote device initiated the call.

Authentication method lists and the `one-time` keyword are only available if you have enabled AAA—they will not be available if you are using TACACS or extended TACACS. If you specify the name of an authentication method list with the `ppp authentication` command, PPP will attempt to authenticate the connection using the methods defined in the specified method list. If AAA is enabled and no method list is defined by name, PPP will attempt to authenticate the connection using the methods defined as the default. The `ppp authentication` command with the `one-time` keyword enables support for one-time passwords during authentication.

The `if-needed` keyword is only available if you are using TACACS or extended TACACS. The `ppp authentication` command with the `if-needed` keyword means that PPP will only authenticate the remote device via PAP or CHAP if they have not yet authenticated during the life of the current call. If the remote device authenticated via a standard login procedure and initiated PPP from the EXEC prompt, PPP will not authenticate via CHAP if `ppp authentication chap if-needed` is configured on the interface.

⚠️ Caution ⚠️

If you use a `list-name` that has not been configured with the `aaa authentication ppp` command, you disable PPP on the line.

For information about adding a `username` entry for each remote system from which the local router or access server requires authentication, see the section “Establishing Username Authentication.”
Inbound and Outbound Authentication

PPP supports two-way authentication. Normally, when a remote device dials into an access server, the access server requests that the remote device prove that it is allowed access. This is known as inbound authentication. At the same time, the remote device can also request that the access server prove that it is who it says it is. This is known as outbound authentication. An access server also does outbound authentication when it initiates a call to a remote device.

Enabling Outbound PAP Authentication

To enable outbound PAP authentication, use the following command in interface configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config-if)# ppp pap sent-username username password password</td>
<td>Enables outbound PAP authentication.</td>
</tr>
</tbody>
</table>

The access server uses the username and password specified by the `ppp pap sent-username` command to authenticate itself whenever it initiates a call to a remote device or when it has to respond to a remote device's request for outbound authentication.

Refusing PAP Authentication Requests

To refuse PAP authentication from peers requesting it, meaning that PAP authentication is disabled for all calls, use the following command in interface configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config-if)# ppp pap refuse</td>
<td>Refuses PAP authentication from peers requesting PAP authentication.</td>
</tr>
</tbody>
</table>

If the `refuse` keyword is not used, the router will not refuse any PAP authentication challenges received from the peer.

Creating a Common CHAP Password

For remote CHAP authentication only, you can configure your router to create a common CHAP secret password to use in response to challenges from an unknown peer; for example, if your router calls a rotary of routers (either from another vendor, or running an older version of the Cisco IOS software) to which a new (that is, unknown) router has been added. The `ppp chap password` command allows you to replace several username and password configuration commands with a single copy of this command on any dialer interface or asynchronous group interface.

To enable a router calling a collection of routers to configure a common CHAP secret password, use the following command in interface configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config-if)# ppp chap password secret</td>
<td>Enables a router calling a collection of routers to configure a common CHAP secret password.</td>
</tr>
</tbody>
</table>
Configuring Authentication

Non-AAA Authentication Methods

Refusing CHAP Authentication Requests

To refuse CHAP authentication from peers requesting it, meaning that CHAP authentication is disabled for all calls, use the following command in interface configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config-if)# ppp chap refuse [callin]</code></td>
<td>Refuses CHAP authentication from peers requesting CHAP authentication.</td>
</tr>
</tbody>
</table>

If the `callin` keyword is used, the router will refuse to answer CHAP authentication challenges received from the peer, but will still require the peer to answer any CHAP challenges the router sends.

If outbound PAP has been enabled (using the `ppp pap sent-username` command), PAP will be suggested as the authentication method in the refusal packet.

Delaying CHAP Authentication Until Peer Authenticates

To specify that the router will not authenticate to a peer requesting CHAP authentication until after the peer has authenticated itself to the router, use the following command in interface configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config-if)# ppp chap wait secret</code></td>
<td>Configures the router to delay CHAP authentication until after the peer has authenticated itself to the router.</td>
</tr>
</tbody>
</table>

This command (which is the default) specifies that the router will not authenticate to a peer requesting CHAP authentication until the peer has authenticated itself to the router. The `no ppp chap wait` command specifies that the router will respond immediately to an authentication challenge.

Using MS-CHAP

Microsoft Challenge Handshake Authentication Protocol (MS-CHAP) is the Microsoft version of CHAP and is an extension of RFC 1994. Like the standard version of CHAP, MS-CHAP is used for PPP authentication; in this case, authentication occurs between a PC using Microsoft Windows NT or Microsoft Windows 95 and a Cisco router or access server acting as a network access server.

MS-CHAP differs from the standard CHAP as follows:

- MS-CHAP is enabled by negotiating CHAP Algorithm 0x80 in LCP option 3, Authentication Protocol.
- The MS-CHAP Response packet is in a format designed to be compatible with Microsoft Windows NT 3.5 and 3.51, Microsoft Windows 95, and Microsoft LAN Manager 2.x. This format does not require the authenticator to store a clear or reversibly encrypted password.
- MS-CHAP provides an authenticator-controlled authentication retry mechanism.
- MS-CHAP provides an authenticator-controlled change password mechanism.
- MS-CHAP defines a set of “reason-for-failure” codes returned in the Failure packet message field.
Depending on the security protocols you have implemented, PPP authentication using MS-CHAP can be used with or without AAA security services. If you have enabled AAA, PPP authentication using MS-CHAP can be used in conjunction with both TACACS+ and RADIUS. Table 9 lists the vendor-specific RADIUS attributes (IETF Attribute 26) that enable RADIUS to support MS-CHAP.

### Table 9: Vendor-Specific RADIUS Attributes for MS-CHAP

<table>
<thead>
<tr>
<th>Vendor-ID Number</th>
<th>Vendor-Type Number</th>
<th>Vendor-Proprietary Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>311</td>
<td>11</td>
<td>MSCHAP-Challenge</td>
<td>Contains the challenge sent by a network access server to an MS-CHAP user. It can be used in both Access-Request and Access-Challenge packets.</td>
</tr>
<tr>
<td>211</td>
<td>11</td>
<td>MSCHAP-Response</td>
<td>Contains the response value provided by a PPP MS-CHAP user in response to the challenge. It is only used in Access-Request packets. This attribute is identical to the PPP CHAP Identifier.</td>
</tr>
</tbody>
</table>

To define PPP authentication using MS-CHAP, use the following commands in interface configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>step 1</td>
<td>Router(config-if)# encapsulation ppp</td>
</tr>
<tr>
<td>step 2</td>
<td>Router(config-if)# ppp authentication ms-chap [if-needed] [list-name</td>
</tr>
</tbody>
</table>

If you configure `ppp authentication ms-chap` on an interface, all incoming calls on that interface that initiate a PPP connection will have to be authenticated using MS-CHAP. If you configure the `ppp authentication` command with the `callin` keyword, the access server will only authenticate the remote device if the remote device initiated the call.

Authentication method lists and the `one-time` keyword are only available if you have enabled AAA—they will not be available if you are using TACACS or extended TACACS. If you specify the name of an authentication method list with the `ppp authentication` command, PPP will attempt to authenticate the connection using the methods defined in the specified method list. If AAA is enabled and no method list is defined by name, PPP will attempt to authenticate the connection using the methods defined as the default. The `ppp authentication` command with the `one-time` keyword enables support for one-time passwords during authentication.

The `if-needed` keyword is only available if you are using TACACS or extended TACACS. The `ppp authentication` command with the `if-needed` keyword means that PPP will only authenticate the remote device via MS-CHAP if that device has not yet authenticated during the life of the current call. If the remote device authenticated through a standard login procedure and initiated PPP from the EXEC prompt, PPP will not authenticate through MS-CHAP if `ppp authentication chap if-needed` is configured.
Note

If PPP authentication using MS-CHAP is used with username authentication, you must include the MS-CHAP secret in the local username/password database. For more information about username authentication, refer to the “Establish Username Authentication” section.

Authentication Examples

The following sections provide authentication configuration examples:

- RADIUS Authentication Examples
- TACACS+ Authentication Examples
- Kerberos Authentication Examples
- AAA Scalability Example
- Login and Failed Banner Examples
- AAA Packet of Disconnect Server Key Example
- Double Authentication Examples
- Automated Double Authentication Example
- MS-CHAP Example

RADIUS Authentication Examples

This section provides two sample configurations using RADIUS.

The following example shows how to configure the router to authenticate and authorize using RADIUS:

```
aaa authentication login radius-login group radius local
aaa authentication ppp radius-ppp if-needed group radius
aaa authorization exec default group radius if-authenticated
aaa authorization network default group radius
line 3
  login authentication radius-login
interface serial 0
  ppp authentication radius-ppp
```

The lines in this sample RADIUS authentication and authorization configuration are defined as follows:

- The `aaa authentication login radius-login group radius local` command configures the router to use RADIUS for authentication at the login prompt. If RADIUS returns an error, the user is authenticated using the local database.

- The `aaa authentication ppp radius-ppp if-needed group radius` command configures the Cisco IOS software to use PPP authentication using CHAP or PAP if the user has not already logged in. If the EXEC facility has authenticated the user, PPP authentication is not performed.

- The `aaa authorization exec default group radius if-authenticated` command queries the RADIUS database for information that is used during EXEC authorization, such as autocommands and privilege levels, but only provides authorization if the user has successfully authenticated.

- The `aaa authorization network default group radius` command queries RADIUS for network authorization, address assignment, and other access lists.

- The `login authentication radius-login` command enables the radius-login method list for line 3.
The `ppp authentication radius-ppp` command enables the radius-ppp method list for serial interface 0.

The following example shows how to configure the router to prompt for and verify a username and password, authorize the user’s EXEC level, and specify it as the method of authorization for privilege level 2. In this example, if a local username is entered at the username prompt, that username is used for authentication.

If the user is authenticated using the local database, EXEC authorization using RADIUS will fail because no data is saved from the RADIUS authentication. The method list also uses the local database to find an autocommand. If there is no autocommand, the user becomes the EXEC user. If the user then attempts to issue commands that are set at privilege level 2, TACACS+ is used to attempt to authorize the command.

```
aaa authentication login default group radius local
aaa authorization exec default group radius local
aaa authorization command 2 default group tacacs+ if-authenticated
radius-server host 172.16.71.146 auth-port 1645 acct-port 1646
radius-server attribute 44 include-in-access-req
radius-server attribute 8 include-in-access-req
```

The lines in this sample RADIUS authentication and authorization configuration are defined as follows:

- The `aaa authentication login default group radius local` command specifies that the username and password are verified by RADIUS or, if RADIUS is not responding, by the router’s local user database.

- The `aaa authorization exec default group radius local` command specifies that RADIUS authentication information be used to set the user’s EXEC level if the user authenticates with RADIUS. If no RADIUS information is used, this command specifies that the local user database be used for EXEC authorization.

- The `aaa authorization command 2 default group tacacs+ if-authenticated` command specifies TACACS+ authorization for commands set at privilege level 2, if the user has already successfully authenticated.

- The `radius-server host 172.16.71.146 auth-port 1645 acct-port 1646` command specifies the IP address of the RADIUS server host, the UDP destination port for authentication requests, and the UDP destination port for accounting requests.

- The `radius-server attribute 44 include-in-access-req` command sends RADIUS attribute 44 (Acct-Session-ID) in access-request packets.

- The `radius-server attribute 8 include-in-access-req` command sends RADIUS attribute 8 (Framed-IP-Address) in access-request packets.

**TACACS+ Authentication Examples**

The following example shows how to configure TACACS+ as the security protocol to be used for PPP authentication:

```
aaa new-model
aaa authentication ppp test group tacacs+ local
interface serial 0
ppp authentication chap pap test
tacacs-server host 10.1.2.3
tacacs-server key goaway
```

The lines in this sample TACACS+ authentication configuration are defined as follows:
• The **aaa new-model** command enables the AAA security services.

• The **aaa authentication** command defines a method list, “test,” to be used on serial interfaces running PPP. The keywords **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.

• The **interface** command selects the line.

• The **ppp authentication** command applies the test method list to this line.

• The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3.

• The **tacacs-server key** command defines the shared encryption key to be “goaway.”

The following example shows how to configure AAA authentication for PPP:

```
aaa authentication ppp default if-needed group tacacs+ local
```

In this example, the keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP is not necessary and can be skipped. If authentication is needed, the keywords **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.

The following example shows how to create the same authentication algorithm for PAP, but it calls the method list “MIS-access” instead of “default”:

```
aaa authentication ppp MIS-access if-needed group tacacs+ local
interface serial 0
ppp authentication pap MIS-access
```

In this example, because the list does not apply to any interfaces (unlike the default list, which applies automatically to all interfaces), the administrator must select interfaces to which this authentication scheme should apply by using the **interface** command. The administrator must then apply this method list to those interfaces by using the **ppp authentication** command.

### Kerberos Authentication Examples

To specify Kerberos as the login authentication method, use the following command:

```
aaa authentication login default krb5
```

To specify Kerberos authentication for PPP, use the following command:

```
aaa authentication ppp default krb5
```

### AAA Scalability Example

The following example shows a general security configuration using AAA with RADIUS as the security protocol. In this example, the network access server is configured to allocate 16 background processes to handle AAA requests for PPP.

```
aaa new-model
radius-server host alcatraz
radius-server key myRaDiUSpassWoRd
radius-server configure-nas
username root password ALongPassword
```
aaa authentication ppp dialins group radius local
aaa authentication login admins local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius
aaa processes 16
line 1 16
  autoselect ppp
  autoselect during-login
  login authentication admins
  modem dialin
interface group-async 1
group-range 1 16
encapsulation ppp
ppp authentication pap dialins

The lines in this sample RADIUS AAA configuration are defined as follows:

- The **aaa new-model** command enables AAA network security services.
- The **radius-server host** command defines the name of the RADIUS server host.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **radius-server configure-nas** command defines that the Cisco router or access server will query the RADIUS server for static routes and IP pool definitions when the device first starts up.
- The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins,” which specifies that RADIUS authentication, then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
- The **aaa authentication login admins local** command defines another method list, “admins,” for login authentication.
- The **aaa authorization network default group radius local** command is used to assign an address and other network parameters to the RADIUS user.
- The **aaa accounting network default start-stop group radius** command tracks PPP usage.
- The **aaa processes** command allocates 16 background processes to handle AAA requests for PPP.
- The **line** command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.
- The **autoselect ppp** command configures the Cisco IOS software to allow a PPP session to start up automatically on these selected lines.
- The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.
- The **login authentication admins** command applies the “admins” method list for login authentication.
- The **modem dialin** command configures modems attached to the selected lines to only accept incoming calls.
- The **interface group-async** command selects and defines an asynchronous interface group.
- The **group-range** command defines the member asynchronous interfaces in the interface group.
- The **encapsulation ppp** command sets PPP as the encapsulation method used on the specified interfaces.
• The **ppp authentication pap dialins** command applies the “dialins” method list to the specified interfaces.

**Login and Failed Banner Examples**

The following example shows how to configure a login banner (in this case, the phrase “Unauthorized Access Prohibited”) that will be displayed when a user logs in to the system. The asterisk (*) is used as the delimiting character. (RADIUS is specified as the default login authentication method.)

```
aaa new-model
aaa authentication banner *Unauthorized Access Prohibited*
aaa authentication login default group radius
```

This configuration produces the following login banner:

```
Unauthorized Access Prohibited
Username:
```

The following example shows how to additionally configure a failed login banner (in this case, the phrase “Failed login. Try again.”) that will be displayed when a user tries to log in to the system and fails. The asterisk (*) is used as the delimiting character. (RADIUS is specified as the default login authentication method.)

```
aaa new-model
aaa authentication banner *Unauthorized Access Prohibited*
aaa authentication fail-message *Failed login. Try again.*
aaa authentication login default group radius
```

This configuration produces the following login and failed login banner:

```
Unauthorized Access Prohibited
Username:
Password:
Failed login. Try again.
```

**AAA Packet of Disconnect Server Key Example**

The following example shows how to configure POD (packet of disconnect), which terminates connections on the network access server (NAS) when particular session attributes are identified.

```
aaa new-model
aaa authentication ppp default radius
aaa accounting network default start-stop radius
aaa accounting delay-start
aaa pod server server-key xyz123
radius-server host 172.16.0.0 non-standard
radius-server key rad123
```

**Double Authentication Examples**

The examples in this section illustrate possible configurations to be used with double authentication. Your configurations could differ significantly, depending on your network and security requirements. This section includes the following examples:

• **Configuration of the Local Host for AAA with Double Authentication Examples**

• **Configuration of the AAA Server for First-Stage (PPP) Authentication and Authorization Example**
Configuring Authentication

Authentication Examples

- Configuration of the AAA Server for Second-Stage (Per-User) Authentication and Authorization Examples
- Complete Configuration with TACACS+ Example

Note

These configuration examples include specific IP addresses and other specific information. This information is for illustration purposes only: your configuration will use different IP addresses, different usernames and passwords, and different authorization statements.

Configuration of the Local Host for AAA with Double Authentication Examples

These two examples show how to configure a local host to use AAA for PPP and login authentication, and for network and EXEC authorization. One example is shown for RADIUS and one example for TACACS+.

In both examples, the first three lines configure AAA, with a specific server as the AAA server. The next two lines configure AAA for PPP and login authentication, and the last two lines configure network and EXEC authorization. The last line is necessary only if the access-profile command will be executed as an autocmd.

The following example shows router configuration with a RADIUS AAA server:

```plaintext
aaa new-model
radius-server host secureserver
radius-server key myradiuskey
aaa authentication ppp default group radius
aaa authentication login default group radius
aaa authorization network default group radius
aaa authorization exec default group radius
```

The following example shows router configuration with a TACACS+ server:

```plaintext
aaa new-model
tacacs-server host security
tacacs-server key mytacacskey
aaa authentication ppp default group tacacs+
tacacs+ authentication login default group tacacs+
tacacs+ authorization network default group tacacs+
tacacs+ authorization exec default group tacacs+
```

Configuration of the AAA Server for First-Stage (PPP) Authentication and Authorization Example

This example shows a configuration on the AAA server. A partial sample AAA configuration is shown for RADIUS.

TACACS+ servers can be configured similarly. (See the section “Complete Configuration with TACACS+ Example” later in this chapter.)

This example defines authentication/authorization for a remote host named “hostx” that will be authenticated by CHAP in the first stage of double authentication. Note that the ACL AV pair limits the remote host to Telnet connections to the local host. The local host has the IP address 10.0.0.2.

The following example shows a partial AAA server configuration for RADIUS:

```plaintext
hostx   Password = "welcome"
User-Service-Type = Framed-User,
    Framed-Protocol = PPP,
cisco-avpair = "lcp:interface-config=ip unnumbered ethernet 0",
cisco-avpair = "ip:inacl#3=permit tcp any 172.21.114.0 0.0.0.255 eq telnet",
```
cisco-avpair = "ip:inacl#4=deny icmp any any",
cisco-avpair = "ip:route#5=55.0.0.0 255.0.0.0",
cisco-avpair = "ip:route#6=66.0.0.0 255.0.0.0",
cisco-avpair = "ipx:inacl#3=deny any"

Configuration of the AAA Server for Second-Stage (Per-User) Authentication and Authorization Examples

This section contains partial sample AAA configurations on a RADIUS server. These configurations define authentication and authorization for a user (Pat) with the username “patuser,” who will be user-authenticated in the second stage of double authentication.

TACACS+ servers can be configured similarly. (See the section “Complete Configuration with TACACS+ Example” later in this chapter.)

Three examples show sample RADIUS AAA configurations that could be used with each of the three forms of the access-profile command.

The first example shows a partial sample AAA configuration that works with the default form (no keywords) of the access-profile command. Note that only ACL AV pairs are defined. This example also sets up the access-profile command as an autocommand.

```
patuser  Password = "welcome"
User-Service-Type = Shell-User,
cisco-avpair = "shell:autocmd=access-profile"
User-Service-Type = Framed-User,
Framed-Protocol = PPP,
cisco-avpair = "ip:inacl#3=permit tcp any host 10.0.0.2 eq telnet",
cisco-avpair = "ip:inacl#4=deny icmp any any"
```

The second example shows a partial sample AAA configuration that works with the access-profile merge form of the access-profile command. This example also sets up the access-profile merge command as an autocommand.

```
patuser  Password = "welcome"
User-Service-Type = Shell-User,
cisco-avpair = "shell:autocmd=access-profile merge"
User-Service-Type = Framed-User,
Framed-Protocol = PPP,
cisco-avpair = "ip:inacl#3=permit tcp any any"
cisco-avpair = "ip:route=10.0.0.0 255.255.0.0",
cisco-avpair = "ip:route=10.1.0.0 255.255.0.0",
cisco-avpair = "ip:route=10.2.0.0 255.255.0.0"
```

The third example shows a partial sample AAA configuration that works with the access-profile replace form of the access-profile command. This example also sets up the access-profile replace command as an autocommand.

```
patuser  Password = "welcome"
User-Service-Type = Shell-User,
cisco-avpair = "shell:autocmd=access-profile replace"
User-Service-Type = Framed-User,
Framed-Protocol = PPP,
cisco-avpair = "ip:inacl#3=permit tcp any any",
cisco-avpair = "ip:inacl#4=permit icmp any any"
cisco-avpair = "ip:route=10.10.0.0 255.255.0.0",
cisco-avpair = "ip:route=10.11.0.0 255.255.0.0",
cisco-avpair = "ip:route=10.12.0.0 255.255.0.0"
```
Complete Configuration with TACACS+ Example

This example shows TACACS+ authorization profile configurations both for the remote host (used in the first stage of double authentication) and for specific users (used in the second stage of double authentication). This TACACS+ example contains approximately the same configuration information as shown in the previous RADIUS examples.

This sample configuration shows authentication/authorization profiles on the TACACS+ server for the remote host “hostx” and for three users, with the usernames “pat_default,” “pat_merge,” and “pat_replace.” The configurations for these three usernames illustrate different configurations that correspond to the three different forms of the access-profile command. The three user configurations also illustrate setting up the autocommand for each form of the access-profile command.

Figure 4 shows the topology. The example that follows the figure shows a TACACS+ configuration file.

Figure 4  Example Topology for Double Authentication

This sample configuration shows authentication/authorization profiles on the TACACS+ server for the remote host “hostx” and for three users, with the usernames “pat_default,” “pat_merge,” and “pat_replace.”

key = "mytacacskey"

default authorization = permit

#-----------------------------Remote Host (BRI)-------------------------
#
# This allows the remote host to be authenticated by the local host
# during first-stage authentication, and provides the remote host
# authorization profile.
#
#---------------------------------------------------------------

user = hostx
{
    login = cleartext "welcome"
    chap = cleartext "welcome"

    service = ppp protocol = lcp {
        interface-config="ip unnumbered ethernet 0"
    }

    service = ppp protocol = ip {
        # It is important to have the hash sign and some string after
        # it. This indicates to the NAS that you have a per-user
        # config.
        inacl#3="permit tcp any 172.21.114.0 0.0.0.255 eq telnet"
        inacl#4="deny icmp any any"
    }
}
route#5="55.0.0.0 255.0.0.0"
route#6="66.0.0.0 255.0.0.0"
)

service = ppp protocol = ipx {
    # see previous comment about the hash sign and string, in protocol = ip
    inacl#3="deny any"
}
)

#------------------- "access-profile" default user "only acls" ------------------
#
# Without arguments, access-profile removes any access-lists it can find
# in the old configuration (both per-user and per-interface), and makes sure
# that the new profile contains ONLY access-list definitions.
#
#--------------------------------------------------------------------------------

user = pat_default
{
    login = cleartext "welcome"
    chap = cleartext "welcome"

    service = exec
    {
        # This is the autocommand that executes when pat_default logs in.
        autocmd = "access-profile"
    }

    service = ppp protocol = ip {
        # Put whatever access-lists, static routes, whatever
        # here.
        # If you leave this blank, the user will have NO IP
        # access-lists (not even the ones installed prior to
        # this)!
        inacl#3="permit tcp any host 10.0.0.2 eq telnet"
        inacl#4="deny icmp any any"
    }

    service = ppp protocol = ipx {
        # Put whatever access-lists, static routes, whatever
        # here.
        # If you leave this blank, the user will have NO IPX
        # access-lists (not even the ones installed prior to
        # this)!
    }
}

#--------------------- "access-profile merge" user ---------------------------
#
# With the 'merge' option, first all old access-lists are removed (as before),
# but then (almost) all AV pairs are uploaded and installed. This will allow
# for uploading any custom static routes, sap-filters, and so on, that the user
# may need in his or her profile. This needs to be used with care, as it leaves
# open the possibility of conflicting configurations.
# -----------------------------------------------

user = pat_merge
{
    login = cleartext "welcome"
    chap = cleartext "welcome"

    service = exec
    {
        # This is the autocommand that executes when pat_merge logs in.
        autocmd = "access-profile merge"
    }

    service = ppp protocol = ip
    {
        # Put whatever access-lists, static routes, whatever
        # here.
        # If you leave this blank, the user will have NO IP
        # access-lists (not even the ones installed prior to
        # this)!
        inacl#3="permit tcp any any"
        route#2="10.0.0.0 255.255.0.0"
        route#3="10.1.0.0 255.255.0.0"
        route#4="10.2.0.0 255.255.0.0"
    }

    service = ppp protocol = ipx
    {
        # Put whatever access-lists, static routes, whatever
        # here.
        # If you leave this blank, the user will have NO IPX
        # access-lists (not even the ones installed prior to
        # this)!
    }
}

#--------------------- "access-profile replace" user ----------------------------

# With the 'replace' option, ALL old configuration is removed and ALL new
# configuration is installed.
#
# One caveat: access-profile checks the new configuration for address-pool and
# address AV pairs. As addresses cannot be renegotiated at this point, the
# command will fail (and complain) when it encounters such an AV pair.
# Such AV pairs are considered to be "invalid" for this context.
#-----------------------------------------------

user = pat_replace
{
    login = cleartext "welcome"
    chap = cleartext "welcome"

    service = exec
    {
        # This is the autocommand that executes when pat_replace logs in.
    }
Automated Double Authentication Example

This example shows a complete configuration file for a Cisco 2509 router with automated double authentication configured. The configuration commands that apply to automated double authentication are preceded by descriptions with a double asterisk (**).

Current configuration:

```
version 11.3
no service password-encryption
!
hostname myrouter
!
!
**The following AAA commands are used to configure double authentication:
!
**The following command enables AAA:
 aaa new-model
**The following command enables user authentication via the TACACS+ AAA server:
 aaa authentication login default group tacacs+
 aaa authentication login console none
**The following command enables device authentication via the TACACS+ AAA server:
 aaa authentication ppp default group tacacs+
**The following command causes the remote user’s authorization profile to be
 downloaded from the AAA server to the Cisco 2509 router when required:
 aaa authorization exec default group tacacs+
**The following command causes the remote device’s authorization profile to be
 downloaded from the AAA server to the Cisco 2509 router when required:
 aaa authorization network default group tacacs+
 enable password mypassword
```
Configuring Authentication

Authentication Examples

```
! ip host blue 172.21.127.226
ip host green 172.21.127.218
ip host red 172.21.127.114
ip domain-name example.com
ip name-server 171.69.2.75
! **The following command globally enables automated double authentication:
ip trigger-authentication timeout 60 port 7500
isdn switch-type basic-5ess
!
interface Ethernet0
ip address 172.21.127.186 255.255.255.248
no ip route-cache
no ip mroute-cache
no keepalive
ntp disable
no cdp enable
!
interface Virtual-Template1
ip unnumbered Ethernet0
no ip route-cache
no ip mroute-cache
!
interface Serial0
ip address 172.21.127.105 255.255.255.248
encapsulation ppp
no ip mroute-cache
no keepalive
shutdown
clockrate 2000000
no cdp enable
!
interface Serial1
no ip address
no ip route-cache
no ip mroute-cache
shutdown
no cdp enable
!
! **Automated double authentication occurs via the ISDN BRI interface BRI0:
interface BRI0
ip unnumbered Ethernet0
! **The following command turns on automated double authentication at this interface:
ip trigger-authentication
! **PPP encapsulation is required:
encapsulation ppp
no ip route-cache
no ip mroute-cache
dialer idle-timeout 500
dialer map ip 172.21.127.113 name myrouter 60074
dialer-group 1
no cdp enable```

**The following command specifies that device authentication occurs via PPP CHAP:**
```
ppp authentication chap
```

```
router eigrp 109
network 172.21.0.0
no auto-summary

ip default-gateway 172.21.127.185
no ip classless
ip route 172.21.127.114 255.255.255.255 172.21.127.113
```

**Virtual profiles are required for double authentication to work:**
```
virtual-profile virtual-template 1
dialer-list 1 protocol ip permit
no cdp run
```

**The following command defines where the TACACS+ AAA server is:**
```
tacacs-server host 171.69.57.35 port 1049
tacacs-server timeout 90
```

**The following command defines the key to use with TACACS+ traffic (required):**
```
tacacs-server key mytacacskey
snmp-server community public RO
```

```
line con 0
  exec-timeout 0 0
  login authentication console
line aux 0
  transport input all
line vty 0 4
  exec-timeout 0 0
  password lab
```

```
end
```

---

**MS-CHAP Example**

The following example shows how to configure a Cisco AS5200 Universal Access Server (enabled for AAA and communication with a RADIUS security server) for PPP authentication using MS-CHAP:

```
aaa new-model
aaa authentication login admins local
aaa authentication ppp dialins group radius local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius

username root password ALongPassword
radius-server host alcatraz
radius-server key myRaDiUSpassWoRd

interface group-async 1
  group-range 1 16
  encapsulation ppp
  ppp authentication ms-chap dialins

  line 1 16
    autoselect ppp
    autoselect during-login
    login authentication admins
    modem dialin
```
The lines in this sample RADIUS AAA configuration are defined as follows:

- The **aaa new-model** command enables AAA network security services.
- The **aaa authentication login admins local** command defines another method list, “admins”, for login authentication.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins,” which specifies that RADIUS authentication then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
- The **aaa authorization network default group radius local** command is used to assign an address and other network parameters to the RADIUS user.
- The **aaa accounting network default start-stop group radius** command tracks PPP usage.
- The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The **radius-server host** command defines the name of the RADIUS server host.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **interface group-async** command selects and defines an asynchronous interface group.
- The **group-range** command defines the member asynchronous interfaces in the interface group.
- The **encapsulation ppp** command sets PPP as the encapsulation method used on the specified interfaces.
- The **ppp authentication ms-chap dialins** command selects MS-CHAP as the method of PPP authentication and applies the “dialins” method list to the specified interfaces.
- The **line** command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.
- The **autoselect ppp** command configures the Cisco IOS software to allow a PPP session to start up automatically on these selected lines.
- The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.
- The **login authentication admins** command applies the “admins” method list for login authentication.
- The **modem dialin** command configures modems attached to the selected lines to only accept incoming calls.

The AAA Double Authentication Secured by Absolute Timeout feature allows you to secure the double authentication mechanism by protecting it with a per-user session timeout. This feature optimizes the connection to the network by service providers to only connections that are authorized, and it increases the security of the overall access to the network by ensuring that no unwanted sessions are connected.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “Feature Information for AAA Double Authentication Secured by Absolute Timeout” section on page 10.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for AAA Double Authentication Secured by Absolute Timeout

- You need access to a Cisco RADIUS or TACACS+ server and should be familiar with configuring RADIUS or TACACS+.
- You should be familiar with configuring authentication, authorization, and accounting (AAA).
- You should be familiar with enabling AAA automated double authentication.

Restrictions for AAA Double Authentication Secured by Absolute Timeout

- The AAA Double Authentication Secured by Absolute Timeout feature, like the existing double authentication feature, is for PPP connections only. Automated double authentication cannot be used with other protocols, such as X.25 or Serial Line Internet Protocol (SLIP).
- There may be a minimal impact on performance if a TACACS+ server is used. However, there is no performance impact if a RADIUS server is used.

Information About AAA Double Authentication Secured by Absolute Timeout

To configure the AAA Double Authentication Secured by Absolute Timeout feature, you should understand the following concept:

- AAA Double Authentication, page 2

AAA Double Authentication

With the current AAA double authentication mechanism, a user must pass the first authentication using a host username and password. The second authentication, after Challenge Handshake Authentication Protocol (CHAP) or Password Authentication Protocol (PAP), uses a login username and password. In the first authentication, a PPP session timeout will be applied to the virtual access interface if it is configured locally or remotely. The AAA Double Authentication Secured by Absolute Timeout feature allows you to secure the double authentication mechanism by protecting it with a per-user session timeout. The per-user timeout, which can be customized, supersedes the generic absolute timeout value. This method works on the same principle as per-user access control lists (ACLs) in double authentication.

How to Apply AAA Double Authentication Secured by Absolute Timeout

This section contains the following procedures:
Applying AAA Double Authentication Secured by Absolute Timeout

To apply the absolute timeout, you need to configure “Session-Timeout” in the login user profile as a link control protocol (LCP) per-user attribute. There is no new or modified command-line interface (CLI) for this feature, but before you use the `access-profile` command when enabling AAA double authentication, you must first reauthorize LCP per-user attributes (for example, Session-Timeout) and then reauthorize Network Control Protocols (NCPs) to apply other necessary criteria, such as ACLs and routes. See the “Examples for AAA Double Authentication Secured by Absolute Timeout” section on page 5.

Note: Timeout configuration in a TACACS+ user profile is a little different from the configuration in a RADIUS user profile. In a RADIUS profile, only one “Session-Timeout” is configured, along with the autocmd “access-profile.” The timeout will be applied to the EXEC session and to the PPP session. In TACACS+, however, the timeout must be configured under the service types “exec” and “ppp” (LCP) to apply a timeout to the EXEC session and to the PPP session. If the timeout is configured only under the service type “ppp,” the timeout value is not available while doing an EXEC authorization—and the timeout will not be applied to the EXEC session.

Verifying AAA Double Authentication Secured by Absolute Timeout

To verify that AAA double authentication has been secured by absolute timeout and to see information about various attributes associated with the authentication, perform the following steps. These `show` and `debug` commands can be used in any order.

SUMMARY STEPS

1. `enable`
2. `show users`
3. `show interfaces virtual-access number [configuration]`
4. `debug aaa authentication`
5. `debug aaa authorization`
6. `debug aaa per-user`
7. `debug ppp authentication`
8. `debug radius`
   or
   `debug tacacs`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  - Enter your password if prompted. |
| **Example:**  
  *Router* > enable | |
| **Step 2** show users enable | Displays information about the active lines on the router. |
| **Example:**  
  *Router*# show users enable | |
| **Step 3** show interfaces virtual-access number [configuration] | Displays status, traffic data, and configuration information about a specified virtual access interface. |
| **Example:**  
  *Router*# show interfaces virtual-access 2 configuration | |
| **Step 4** debug aaa authentication | Displays information about AAA TACACS+ authentication. |
| **Example:**  
  *Router*# debug aaa authentication | |
| **Step 5** debug aaa authorization | Displays information about AAA TACACS+ authorization. |
| **Example:**  
  *Router*# debug aaa authorization | |
| **Step 6** debug aaa per-user | Displays the attributes that are applied to each user as the user authenticates. |
| **Example:**  
  *Router*# debug aaa per-user | |
| **Step 7** debug ppp authentication | Displays whether a user is passing authentication. |
| **Example:**  
  *Router*# debug ppp authentication | |
| **Step 8** debug radius  
  or  
  debug tacacs | Displays information associated with the RADIUS server.  
  or  
  Displays information associated with the TACACS+ server. |
| **Example:**  
  *Router*# debug radius  
  or  
  *Router*# debug tacacs | |
Examples

The following sample output is from the `show users` command:

```
Router# show users

Line      User       Host(s)       Idle       Location
*  0 con 0  aaapbx2   idle     00:00:00     aaacon2 10
     8 vty 0  broker_def idle     00:00:08     192.168.1.8

Interface User            Mode       Idle       Peer Address
  V12  broker_default VDP   00:00:01     192.168.1.8 <========
  Se0:22 aaapbx2          Sync PPP  00:00:23
```

The following sample output is from the `show interfaces virtual-access` command:

```
Router# show interfaces virtual-access 2 configuration

Virtual-Access2 is a Virtual Profile (sub)interface

Derived configuration: 150 bytes
!
interface Virtual-Access2
  ip unnumbered Serial0:23
  no ip route-cache
  timeout absolute 3 0
  ! The above line shows that the per-user session timeout has been applied.
  ppp authentication chap
  ppp timeout idle 180000
  ! The above line shows that the absolute timeout has been applied.
```

Examples for AAA Double Authentication Secured by Absolute Timeout

This section includes the following examples:

- **RADIUS User Profile: Example**, page 5
- **TACACS+ User Profile: Example**, page 6

RADIUS User Profile: Example

The following sample output shows that a RADIUS user profile has been applied and that AAA double authentication has been secured by an absolute timeout:

```
aaapbx2 Password = "cisco",
Service-Type = Framed,
Framed-Protocol = PPP,
Session-Timeout = 180,
Idle-Timeout = 180000,
cisco-avpair = "ip:inacl#1=permit tcp any any eq telnet"
cisco-avpair = "ip:inacl#2=permit icmp any any"

broker_default Password = "cisco",
Service-Type = Administrative,
cisco-avpair = "shell:autocmd=access-profile",
Session-Timeout = 360,
```
Examples for AAA Double Authentication Secured by Absolute Timeout

AAA Double Authentication Secured by Absolute Timeout

cisco-avpair = "ip:inacl#1=permit tcp any any"
cisco-avpair = "ip:inacl#2=permit icmp any any"

broker_merge Password = "cisco",
Service-Type = Administrative,
cisco-avpair = "shell:autocmd=access-profile merge",
Session-Timeout = 360,
cisco-avpair = "ip:inacl#1=permit tcp any any"
cisco-avpair = "ip:inacl#2=permit icmp any any"
cisco-avpair = "ip:route#3=10.4.0.0 255.0.0.0"
cisco-avpair = "ip:route#4=10.5.0.0 255.0.0.0"
cisco-avpair = "ip:route#5=10.6.0.0 255.0.0.0"

broker_replace Password = "cisco",
Service-Type = Administrative,
cisco-avpair = "shell:autocmd=access-profile replace",
Session-Timeout = 360,
cisco-avpair = "ip:inacl#1=permit tcp any any"
cisco-avpair = "ip:inacl#2=permit icmp any any"
cisco-avpair = "ip:route#3=10.4.0.0 255.0.0.0"
cisco-avpair = "ip:route#4=10.5.0.0 255.0.0.0"
cisco-avpair = "ip:route#5=10.6.0.0 255.0.0.0"

TACACS+ User Profile: Example

The following sample output shows that a TACACS+ user profile has been applied and that AAA double authentication has been secured by an absolute timeout.

Remote Host

The following allows the remote host to be authenticated by the local host during first-stage authentication and provides the remote host authorization profile.

user = aaapbx2
chap = cleartext Cisco
pap = cleartext cisco
login = cleartext cisco

service = ppp protocol = lcp
    idletime = 3000
timeout = 3

service = ppp protocol = ip
    inacl#1="permit tcp any any eq telnet"

service = ppp protocol = ipx

access-profile Command Without Any Arguments

Using the access-profile command without any arguments causes the removal of any access lists that are found in the old configuration (both per-user and per-interface) and ensures that the new profile contains only access-list definitions.

user = broker_default
login = cleartext Cisco
chap = cleartext "cisco"

service = exec

autocmd = "access-profile"
AAA Double Authentication Secured by Absolute Timeout

Examples for AAA Double Authentication Secured by Absolute Timeout

! This is the autocommand that executes when broker_default logs in.
timeout = 6

service = ppp protocol = lcp
timeout = 6

service = ppp protocol = ip
! Put access lists, static routes, and other requirements that are
! needed here. Read the software specifications for details. If you leave
! this blank, the user will have no access lists (not even the ones that were
! installed prior to the creation of this user profile)!

inacl#1="permit tcp any any"
inacl#2="permit icmp host 10.0.0.0 any"

service = ppp protocol = ipx
! Put access lists, static routes, and other requirements that are
! needed here. Read the software specifications for details. If you leave
! this blank, the user will have no access lists (not even the ones that were
! installed prior to the creation of this user profile)!

route#1="10.4.0.0 255.0.0.0"
route#2="10.5.0.0 255.0.0.0"
route#3="10.6.0.0 255.0.0.0"
inac1#5="permit tcp any any"
inac1#6="permit icmp host 10.60.0.0 any"

access-profile Command with merge Keyword

With the “merge” option, all old access lists are removed (as before), but then almost any AV pair is
allowed to be uploaded and installed. This merge will allow for the uploading of any custom static routes,
Service Advertisement Protocol (SAP) filters, and other requirements that the user may need in his or
her profile. This merge must be used with care because it leaves everything open in terms of conflicting
configurations.

user = broker_merge
login = cleartext Cisco
chap = cleartext "cisco"

service = exec

autocmd = "access-profile merge"
! This is the autocommand that executes when broker_merge logs in.
timeout = 6

service = ppp protocol = lcp
timeout = 6

service = ppp protocol = ip
! Put access lists, static routes, and other requirements that are
! needed here. Read the software specifications for details. If you leave
! this blank, the user will have no access lists (not even the ones that were
! installed prior to the creation of this user profile)!

route#1="10.4.0.0 255.0.0.0"
route#2="10.5.0.0 255.0.0.0"
route#3="10.6.0.0 255.0.0.0"
inac1#5="permit tcp any any"
inac1#6="permit icmp host 10.60.0.0 any"

service = ppp protocol = ipx
! Put access lists, static routes, and other requirements that are
! needed here. Read the software specifications for details. If you leave
! this blank, the user will have no access lists (not even the ones that were
! installed prior to the creation of this user profile)!
access-profile Command with the replace Keyword

If you use the `access-profile` command with the `replace` keyword, the command works as it does currently; that is, any old configuration is removed and any new configuration is installed.

**Note**

When the `access-profile` command is configured, the new configuration is checked for address pools and address attribute-value (AV) pairs. Because addresses cannot be renegotiated at this point, the command will fail to work when it encounters such an address AV pair.

```plaintext
user = broker_replace
login = cleartext Cisco
chap = cleartext "cisco"

service = exec
  autocmd = "access-profile replace"
  ! This is the autocommand that executes when broker_replace logs in.
  timeout = 6

service = ppp protocol = lcp
  timeout = 6

service = ppp protocol = ip
  ! Put access lists, static routes, and other requirements that are
  ! needed here. Read the software specifications for details. If you leave
  ! this blank, the user will have no access lists (not even the ones that were
  ! installed prior to the creation of this user profile):
  route#1="10.7.0.0 255.0.0.0"
  route#2="10.8.0.0 255.0.0.0"
  route#3="10.9.0.0 255.0.0.0"
  inacl#4="permit tcp any any"

service = ppp protocol = ipx
  ! Put access lists, static routes, and other requirements that are
  ! needed here. Read the software specifications for details. If you leave
  ! this blank, the user will have no access lists (not even the ones that were
  ! installed prior to the creation of this user profile):
```

**Note**

Timeout configuration in a TACACS+ user profile is a little different from the configuration in a RADIUS user profile. In a RADIUS profile, only one “Session-Timeout” is configured, along with the autocommand `access-profile`. The timeout will be applied to the EXEC session and to the PPP session. In TACACS+, however, the timeout must be configured under the service types “exec” and “ppp” (LCP) to apply a timeout to the EXEC session and to the PPP session. If the timeout is configured only under the service type “ppp,” the timeout value is not available while doing an EXEC authorization—and the timeout will not be applied to the EXEC session.

Feature Information for AAA Double Authentication Secured by Absolute Timeout

Table 1 lists the release history for this feature. Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Login Password Retry Lockout

The Login Password Retry Lockout feature allows system administrators to lock out a local authentication, authorization, and accounting (AAA) user account after a configured number of unsuccessful attempts by the user to log in.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at http://www.cisco.com/go/fn. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.

Contents

- Prerequisites for Login Password Retry Lockout, page 1
- Restrictions for Login Password Retry Lockout, page 2
- Information About Login Password Retry Lockout, page 2
- How to Configure Login Password Retry Lockout, page 2
- Configuration Examples for Login Password Retry Lockout, page 6
- Additional References, page 7
- Command Reference, page 8
- Glossary, page 9

Prerequisites for Login Password Retry Lockout

- You must be running a Cisco IOS image that contains the AAA component.
Restrictions for Login Password Retry Lockout

- Authorized users can lock themselves out because there is no distinction between an attacker who is guessing passwords and an authorized user who is entering the password incorrectly multiple times.
- A denial of service (DoS) attack is possible, that is, an authorized user could be locked out by an attacker if the username of the authorized user is known to the attacker.

Information About Login Password Retry Lockout

To configure the Login Password Retry Lockout feature, you should understand the following concept:

- Locking Out a Local AAA User Account, page 2

Locking Out a Local AAA User Account

The Login Password Retry Lockout feature allows system administrators to lock out a local AAA user account after a configured number of unsuccessful attempts by the user to log in using the username that corresponds to the AAA user account. A locked-out user cannot successfully log in again until the user account is unlocked by the administrator.

A system message is generated when a user is either locked by the system or unlocked by the system administrator. The following is an example of such a system message:

%AAA-5-USER_LOCKED: User user1 locked out on authentication failure.

The system administrator cannot be locked out.

Note

The system administrator is a special user who has been configured using the maximum privilege level (root privilege—level 15). A user who has been configured using a lesser privilege level can change the privilege level using the `enable` command. If the user can change to the root privilege (level 15), that user is able to act as a system administrator.

This feature is applicable to any login authentication method, such as ASCII, Challenge Handshake Authentication Protocol (CHAP), and Password Authentication Protocol (PAP).

Note

No messages are displayed to users after authentication failures that are due to the locked status (that is, there is no distinction between a normal authentication failure and an authentication failure due to the locked status of the user.

How to Configure Login Password Retry Lockout

This section contains the following procedures:

- Configuring Login Password Retry Lockout, page 3
- Unlocking a Locked-Out User, page 4
- Clearing the Unsuccessful Attempts of a User, page 5
• Monitoring and Maintaining Login Password Retry Lockout, page 5

Configuring Login Password Retry Lockout

To configure Login Password Retry Lockout, perform the following steps.

SUMMARY STEPS

1. enable
2. configure terminal
3. username name [privilege level] password encryption-type password
4. aaa new-model
5. aaa local authentication attempts max-fail number-of-unsuccessful-attempts
6. aaa authentication login default method

Unlocking a Locked-Out User

To unlock the locked-out user, perform the following steps.

**Note** This task can be performed only by users having root privilege (level 15).

SUMMARY STEPS

1. enable
2. clear aaa local user lockout {username username | all}
DETAILED STEPS

### Clearing the Unsuccessful Attempts of a User

To clear the unsuccessful attempts of a user that have already been logged, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `clear aaa local user fail-attempts {username username | all}`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><code>Router&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td>Step 2 `clear aaa local user fail-attempts {username username</td>
<td>all}`</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Router# clear aaa local user fail-attempts username user1</code></td>
<td></td>
</tr>
</tbody>
</table>

### Monitoring and Maintaining Login Password Retry Lockout

To monitor and maintain the Login Password Retry Lockout configuration, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `show aaa local user locked`
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2 show aaa local user locked</td>
<td>Displays a list of the locked-out users.</td>
</tr>
<tr>

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information
about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

- aaa local authentication attempts max-fail
- clear aaa local user fail-attempts
- clear aaa local user lockout

### Glossary

- **Local AAA method**—Method by which it is possible to configure a local user database on a router and to have AAA provision authentication or authorization of users from this database.
- **Local AAA user**—User who is authenticated using the Local AAA method.

MSCHAP Version 2

First Published: January 23, 2003
Last Updated: April 17, 2006

The MSCHAP Version 2 feature (introduced in Cisco IOS Release 12.2(2)XB5) allows Cisco routers to utilize Microsoft Challenge Handshake Authentication Protocol Version 2 (MSCHAP V2) authentication for PPP connections between a computer using a Microsoft Windows operating system and a network access server (NAS).

For Cisco IOS Release 12.4(6)T, MSCHAP V2 now supports a new feature: AAA Support for MSCHAPv2 Password Aging. Prior to Cisco IOS Release 12.4(6)T, when Password Authentication Protocol (PAP)-based clients sent username and password values to the authentication, authorization, and accounting (AAA) subsystem, AAA generated an authentication request to the RADIUS server. If the password expired, the RADIUS server replied with an authentication failure message. The reason for the authentication failure was not passed back to AAA subsystem; thus, users were denied access because of authentication failure but were not informed why they were denied access.

The Password Aging feature, available in Cisco IOS Release 12.4(6)T, notifies crypto-based clients that the password has expired and provides a generic way for the user to change the password. The Password Aging feature supports only crypto-based clients.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “Feature Information for MSCHAP Version 2” section on page 11.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at http://www.cisco.com/go/fn. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.
Prerequisites for MSCHAP Version 2

- Configure an interface type and enter interface configuration mode by using the `interface` command.
- Configure the interface for PPP encapsulation by using the `encapsulation` command.
- Be sure that the client operating system supports all MSCHAP V2 capabilities.
- For Cisco IOS Release 12.4(6)T, the Password Aging feature only supports RADIUS authentication for crypto-based clients.
- To ensure that the MSCHAP Version 2 features correctly interpret the authentication failure attributes sent by the RADIUS server, you must configure the `ppp max-bad-auth` command and set the number of authentication retries at two or more.
- In order for the MSCHAP Version 2 feature to support the ability to change a password, the authentication failure attribute, which is sent by the RADIUS server, must be correctly interpreted as described in “Configuring MSCHAP V2 Authentication” section on page 3.

In addition, the `radius server vsa send authentication` command must be configured, allowing the RADIUS client to send a vendor-specific attribute to the RADIUS server. The Change Password feature is supported only for RADIUS authentication.

- The Microsoft Windows 2000, Microsoft Windows XP, and Microsoft Windows NT operating systems have a known caveat that prevents the Change Password feature from working. You must download a patch from Microsoft at the following URL:
  http://support.microsoft.com/default.aspx?scid=kb;en-us;Q326770

For more information on completing these tasks, see the section “PPP Configuration” in the Cisco IOS Dial Technologies Configuration Guide, Release 12.2. The RADIUS server must be configured for authentication. Refer to vendor-specific documentation for information on configuring RADIUS authentication on the RADIUS server.

Restrictions for MSCHAP Version 2

- MSCHAP V2 authentication is not compatible with MSCHAP V1 authentication.
- The change password option is supported only for RADIUS authentication and is not available for local authentication.
Information About MSCHAP Version 2

MSCHAP V2 authentication is the default authentication method used by the Microsoft Windows 2000 operating system. Cisco routers that support this authentication method enable Microsoft Windows 2000 operating system users to establish remote PPP sessions without configuring an authentication method on the client.

MSCHAP V2 authentication introduced an additional feature not available with MSCHAP V1 or standard CHAP authentication: the Change Password feature. This feature allows the client to change the account password if the RADIUS server reports that the password has expired.

Note

MSCHAP V2 authentication is an updated version of MSCHAP that is similar to but incompatible with MSCHAP Version 1 (V1). MSCHAP V2 introduces mutual authentication between peers and a Change Password feature.

How to Configure MSCHAP Version 2

See the following sections for configuration tasks for the MSCHAP Version 2 feature.

- “Configuring MSCHAP V2 Authentication” section on page 3 (required)
- “Verifying MSCHAP V2 Configuration” section on page 5 (optional)
- “Configuring Password Aging for Crypto-Based Clients” section on page 5 (optional)

Configuring MSCHAP V2 Authentication

To configure the NAS to accept MSCHAP V2 authentication for local or RADIUS authentication and to allow proper interpretation of authentication failure attributes and vendor-specific RADIUS attributes for RADIUS authentication, use the following commands beginning in global configuration mode.

SUMMARY STEPS

1. enable
2. configure terminal
3. radius-server vsa send authentication
4. interface type number
5. ppp max-bad-auth number
6. ppp authentication ms-chap-v2
7. end
<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> radius-server vsa send authentication</td>
<td>Configures the NAS to recognize and use vendor-specific attributes.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config)# radius-server vsa send authentication</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> interface type number</td>
<td>Configures an interface type and enters interface configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config)# interface FastEthernet 0/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> ppp max-bad-auth number</td>
<td>Configures a point-to-point interface to reset immediately after an authentication failure or within a specified number of authentication retries.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config-if)# ppp max-bad-auth 2</td>
<td>• The default value for the <em>number</em> argument is 0 seconds (immediately).</td>
</tr>
<tr>
<td></td>
<td>• The range is between 0 and 255.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>The <em>number</em> argument must be set to a value of at least 2 for authentication failure attributes to be interpreted by the NAS.</td>
</tr>
<tr>
<td><strong>Step 6</strong> ppp authentication ms-chap-v2</td>
<td>Enables MSCHAP V2 authentication on a NAS.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config-if)# ppp authentication ms-chap-v2</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>
Verifying MSCHAP V2 Configuration

To verify that the MSCHAP Version 2 feature is configured properly, perform the following steps.

**SUMMARY STEPS**

1. `show running-config interface type number`
2. `debug ppp negotiation`
3. `debug ppp authentication`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>show running-config interface type number</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Router# show running-config interface Asynch65</code></td>
</tr>
<tr>
<td>Verifies the configuration of MSCHAP V2 as the authentication method for the specified interface.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>debug ppp negotiation</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Router# debug ppp negotiation</code></td>
</tr>
<tr>
<td>Verifies successful MSCHAP V2 negotiation.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>debug ppp authentication</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Router# debug ppp authentication</code></td>
</tr>
<tr>
<td>Verifies successful MSCHAP V2 authentication.</td>
<td></td>
</tr>
</tbody>
</table>

**Configuring Password Aging for Crypto-Based Clients**

The AAA security services facilitate a variety of login authentication methods. Use the `aaa authentication login` command to enable AAA authentication no matter which of the supported login authentication methods you decide to use. With the `aaa authentication login` command, you create one or more lists of authentication methods that are tried at login. These lists are applied using the `login authentication` line configuration command.

After the RADIUS server requests a new password, AAA queries the crypto client, which in turn prompts the user to enter a new password.

To configure login authentication and password aging for crypto-based clients, use the following commands beginning in global configuration mode.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `aaa new-model`
4. `aaa authentication login [default | list-name] passwd-expiry method1 [method2...]`
5. `crypto map map-name client authentication list list-name`
### Configuration Examples

This section provides the following configuration examples:

- "Configuring Local Authentication: Example" section on page 6
- "Configuring RADIUS Authentication: Example" section on page 7
- "Configuring Password Aging with Crypto Authentication: Example" section on page 7

### Configuring Local Authentication: Example

The following example configures PPP on an asynchronous interface and enables MSCHAP V2 authentication locally:

```
interface Async65
  ip address 10.0.0.2 255.0.0.0
  encapsulation ppp
  async mode dedicated
  no peer default ip address
  ppp max-bad-auth 3
  ppp authentication ms-chap-v2
  username client password secret
```
Configuring RADIUS Authentication: Example

The following example configures PPP on an asynchronous interface and enables MSCHAP V2 authentication via RADIUS:

```
interface Async65
  ip address 10.0.0.2 255.0.0.0
  encapsulation ppp
  async mode dedicated
  no peer default ip address
  ppp max-bad-auth 3
  ppp authentication ms-chap-v2
  exit
aaa authentication ppp default group radius
radius-server host 10.0.0.2 255.0.0.0
radius-server key secret
radius-server vsa send authentication
```

Configuring Password Aging with Crypto Authentication: Example

The following example configures password aging by using AAA with a crypto-based client:

```
aaa authentication login userauthen passwd-expiry group radius
!
aaa session-id common
!
crypto isakmp policy 3
  encr 3des
  authentication pre-share
  group 2
!
crypto isakmp client configuration group 3000client
  key cisco123
  dns 10.1.1.10
  wins 10.1.1.20
  domain cisco.com
  pool ippool
  acl 153
!
crypto ipsec transform-set myset esp-3des esp-sha-hmac
!
crypto dynamic-map dynmap 10
  set transform-set myset
!
crypto map clientmap client authentication list userauthen
!
radius-server host 10.140.15.203 auth-port 1645 acct-port 1646
radius-server domain-stripping prefix-delimiter $
radius-server key cisco123
radius-server vsa send authentication
radius-server vsa send authentication 3gpp2
!
end
```

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

- aaa authentication login
- ppp authentication ms-chap-v2

Feature Information for MSCHAP Version 2

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at http://www.cisco.com/go/fn. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

In 12.2(2)XB5, this feature was introduced.
In 12.2(13)T, this feature was integrated into Cisco IOS Release 12.2(13)T.
In 12.4(6)T, this feature was updated to include the crypto-based Password Aging feature. |
RADIUS EAP Support

First Published: October 15, 2001
Last Updated: February 28, 2006

The RADIUS EAP Support feature allows users to apply to the client authentication methods that may not be supported by the network access server; this is done via the Extensible Authentication Protocol (EAP). Before this feature was introduced, support for various authentication methods for PPP connections required custom vendor-specific work and changes to the client and NAS.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at http://www.cisco.com/go/fn. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.
Feature Overview

EAP is an authentication protocol for PPP that supports multiple authentication mechanisms that are negotiated during the authentication phase (instead of the link control protocol [LCP] phase). EAP allows a third-party authentication server to interact with a PPP implementation through a generic interface.

How EAP Works

By default, EAP runs in proxy mode. This means that EAP allows the entire authentication process to be negotiated by the NAS to a back-end server that may reside on or be accessed via a RADIUS server. After EAP is negotiated between the client and the NAS during LCP exchange, all further authentication messages are transparently transmitted between the client and the back-end server. The NAS is no longer directly involved in the authentication process; that is, the NAS works as a proxy, sending EAP messages between the remote peers.

Note

EAP can also run in a local mode; the session is authenticated using the Message Digest 5 (MD5) algorithm and obeys the same authentication rules as Challenge Handshake Authentication Protocol (CHAP). To disable proxy mode and authenticate locally, you must use the `ppp eap local` command.

Newly Supported Attributes

The RADIUS EAP Support feature introduces support for the following RADIUS attributes:

<table>
<thead>
<tr>
<th>Number</th>
<th>IETF Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>79</td>
<td>EAP-Message</td>
<td>Encapsulates one fragment of an EAP message, which includes the PPP type, request-id, length, and EAP-type fields.</td>
</tr>
<tr>
<td>80</td>
<td>Message Authenticator</td>
<td>Ensures source integrity of the message; all messages that are received with invalid checksums are silently discarded by either end. This attribute contains an HMAC-MD5 checksum of the entire RADIUS request or response message and uses the RADIUS server secret as the key.</td>
</tr>
</tbody>
</table>

Benefits

The RADIUS EAP Support feature makes it possible to apply to the client various authentication methods within PPP (including proprietary authentication) that are not supported by the NAS. Thus, customers can use standard support mechanisms for authentication schemes, such as token cards and public key, to strengthen end-user and device authenticated access to their networks.
Restrictions

When EAP is running in proxy mode, there may be a significant increase in the authentication time because every packet from the peer must be sent to the RADIUS server and every EAP packet from the RADIUS server must be sent back to the client. Although this extra processing will cause delays, you can increase the default authentication timeout value by using the `ppp timeout authentication` command.

Prerequisites

Before enabling EAP RADIUS on the client, you must perform the following tasks:

- Configure an interface type and enter interface configuration mode by using the `interface` command.
- Configure the interface for PPP encapsulation by using the `encapsulation` command.

For more information on completing these tasks, refer to the chapter “Configuring Media-Independent PPP and Multilink PPP” in the *Cisco IOS Dial Technologies Configuration Guide*, Release 12.4.

Configuration Tasks

See the following sections for configuration tasks for the RADIUS EAP Support feature. Each task in the list is identified as either required or optional.

- Configuring EAP, page 3 (required)
- Verifying EAP, page 4 (optional)

Configuring EAP

To configure EAP on an interface configured for PPP encapsulation, use the following commands in interface configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config-if)# ppp authentication eap</code></td>
<td>Enables EAP as the authentication protocol.</td>
</tr>
<tr>
<td><code>Router(config-if)# ppp eap identity string</code></td>
<td>(Optional) Specifies the EAP identity when requested by the peer.</td>
</tr>
<tr>
<td><code>Router(config-if)# ppp eap password [number] string</code></td>
<td>(Optional) Sets the EAP password for peer authentication. <strong>Note</strong> This command should only be configured on the client.</td>
</tr>
<tr>
<td><code>Router(config-if)# ppp eap local</code></td>
<td>(Optional) Authenticates locally instead of using a RADIUS back-end server, which is the default. <strong>Note</strong> This command should only be configured on the NAS.</td>
</tr>
</tbody>
</table>
Verifying EAP

To verify EAP configurations on your client or NAS, use at least one of the following commands in privileged EXEC configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router# show users</td>
<td>Displays information about the active lines on the router.</td>
</tr>
<tr>
<td>Router# show interfaces</td>
<td>Displays statistics for all interfaces configured on the router or access server.</td>
</tr>
<tr>
<td>Router# show running-config</td>
<td>Ensures that your configurations appear as part of the running configuration.</td>
</tr>
</tbody>
</table>

Configuration Examples

This section provides the following configuration examples:

- EAP Local Configuration on Client Example, page 4
- EAP Proxy Configuration for NAS Example, page 5

EAP Local Configuration on Client Example

The following example is a sample configuration for a client configured for EAP:

```bash
interface Ethernet0/0
  ip address 10.1.1.202 255.255.255.0
  no ip mroute-cache
  half-duplex

interface BRI0/0
  ip address 192.168.101.100 255.255.255.0
  encapsulation ppp
  no ip mroute-cache
dialer map ip 192.168.101.101 56167
dialer-group 1
isdn switch-type basic-5ess
ppp eap identity user
ppp eap password 7 141B1309
```
EAP Proxy Configuration for NAS Example

The following example is a sample configuration for a NAS configured to use EAP proxy:

```
aaa authentication login default group radius
aaa authentication login NOAUTH none
aaa authentication ppp default if-needed group radius
aaa session-id common
enable secret 5 $1$x5D0$cfTL/D8Be.34PgTb3Edgl/

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

- ppp authentication
- ppp eap identity
- ppp eap local
- ppp eap password
- ppp eap refuse
- ppp eap wait
attribute—A RADIUS Internet Engineering Task Force (IETF) attribute is one of the original set of 255 standard attributes that are used to communicate authentication, authorization, and accounting (AAA) information between a client and a server. Because IETF attributes are standard, the attribute data is predefined and well known; thus all clients and servers that exchange AAA information via IETF attributes must agree on attribute data such as the exact meaning of the attributes and the general bounds of the values for each attribute.

CHAP—Challenge Handshake Authentication Protocol. Security feature that is supported on lines using PPP encapsulation and prevents unauthorized access. CHAP does not itself prevent unauthorized access; it merely identifies the remote end. The router or access server then determines whether that user is allowed access.

EAP—Extensible Authentication Protocol. A PPP authentication protocol that supports multiple authentication mechanisms that are negotiated during the authentication phase (instead of the Link Control Protocol [LCP] phase). EAP allows a third-party authentication server to interact with the PPP implementation through a generic interface.

LCP—link control protocol. Protocol that establishes, configures, and tests data-link connections for use by PPP.

MD5 (HMAC variant)—Message Digest 5. A hash algorithm used to authenticate packet data. HMAC is a key hashing for message authentication.

NAS—network access server. A device providing local network access to users across a remote access network such as the public switched telephone network (PSTN).

PAP—Password Authentication Protocol. Authentication protocol that allows PPP peers to authenticate one another. The remote router attempting to connect to the local router is required to send an authentication request. Unlike CHAP, PAP passes the password and host name or username in the clear (unencrypted). PAP does not itself prevent unauthorized access; it merely identifies the remote end. The router or access server then determines if that user is allowed access. PAP is supported only on PPP lines.

PPP—Point-to-Point Protocol. A protocol that encapsulates network layer protocol information over point-to-point links. PPP is defined in RFC 1661.

RADIUS—Remote Authentication Dial-In User Service. Database for authenticating modem and ISDN connections and for tracking connection time.

The RADIUS Packet of Disconnect feature is used to terminate a connected voice call.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the “Feature Information for RADIUS Packet of Disconnect” section on page 9.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Catalyst OS, and Cisco IOS XE software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Contents

- Prerequisites for RADIUS Packet of Disconnect, page 2
- Restrictions for RADIUS Packet of Disconnect, page 2
- Information About RADIUS Packet of Disconnect, page 2
- How to Configure the RADIUS Packet of Disconnect, page 3
- Additional References, page 7
- Command Reference, page 8
- Feature Information for RADIUS Packet of Disconnect, page 9
- Glossary, page 10
Prerequisites for RADIUS Packet of Disconnect

- Configure AAA as described in *Cisco IOS Security Configuration Guide*, Release 12.4T.
- Use Cisco IOS Release 12.2(11)T or later.

RADIUS Packet of Disconnect Platform Support

The following platforms are supported for the RADIUS Packet of Disconnect feature:

- Cisco 3600 series
- Cisco AS5300
- Cisco AS5350
- Cisco AS5400
- Cisco AS5800
- Cisco AS5850

Restrictions for RADIUS Packet of Disconnect

Proper matching identification information must be communicated by the following:

- Billing server and gateway configuration
- Gateway’s original accounting start request
- Server’s POD request

Information About RADIUS Packet of Disconnect

The Packet of Disconnect (POD) is a RADIUS access_request packet and is intended to be used in situations where the authenticating agent server wants to disconnect the user after the session has been accepted by the RADIUS access_accept packet.

When the POD is Needed

The POD may be needed in at least two situations:

- Detection of fraudulent use, which cannot be performed before accepting the call. A price structure so complex that the maximum session duration cannot be estimated before accepting the call. This may be the case when certain types of discounts are applied or when multiple users use the same subscription simultaneously.
- To prevent unauthorized servers from disconnecting users, the authorizing agent that issues the POD packet must include three parameters in its packet of disconnect request. For a call to be disconnected, all parameters must match their expected values at the gateway. If the parameters do not match, the gateway discards the packet of disconnect packet and sends a NACK (negative acknowledgement message) to the agent.
POD Parameters

The POD has the following parameters:

- An h323-conf-id vendor-specific attribute (VSA) with the same content as received from the gateway for this call.
- An h323-call-origin VSA with the same content as received from the gateway for the leg of interest.
- A 16-byte MD5 hash value that is carried in the authentication field of the POD request.
- Cisco allocated POD code 50 as the new code value for the Voice POD Request in Cisco IOS Release 12.2(27)SB and 12.4(15)T. This change was made because RFC 3576 Dynamic Authorization Extensions to RADIUS recently extended RADIUS standards to officially support both a Disconnect Message (DM) and Change-of-Authorization (CoA), which is supported through the POD.

RFC 3576 specifies the following POD codes:

- 40 - Disconnect-Request
- 41 - Disconnect-ACK
- 42 - Disconnect-NAK
- 43 - CoA-Request
- 44 - CoA-ACK
- 45 - CoA-NAK

How to Configure the RADIUS Packet of Disconnect

Use the following section to configure the RADIUS Packet of Disconnect feature.

- Configuring the RADIUS POD

Configuring the RADIUS POD

Use the following tasks to configure the RADIUS POD:

SUMMARY STEPS

1. enable
2. configure terminal
3. aaa pod server [port port-number] [auth-type {any | all | session-key}] server-key [encryption-type] string
## DETAILED STEPS

<td><strong>encryption-type</strong></td>
<td>(Optional) Single-digit number that defines whether the text immediately following is encrypted, and, if so, what type of encryption is used. Defined encryption types are 0, which means that the text immediately following is not encrypted, and 7, which means that the text is encrypted using an encryption algorithm defined by Cisco.</td>
</tr>
<tr>
<td><strong>string</strong></td>
<td>The shared-secret text string that is shared between the network access server and the client workstation. This shared-secret string must be the same on both systems.</td>
</tr>
</tbody>
</table>
How to Configure the RADIUS Packet of Disconnect

Troubleshooting Tips

Use the following tips to troubleshoot POD issues:

- Ensure that the POD port is configured correctly in both the gateway (using `aaa pod server` command) and the radius server. Both should be the same.
- Ensure that the shared-secret key configured in the gateway (using `aaa pod server` command) and in the AAA server are the same.
- Turn on `debug aaa pod` command to see what’s going on. This will let you know if the gateway receives the POD packet from the server and if so, it will display any errors encountered.

The following example shows output from a successful POD request, when using the `show debug` command.

```
Router# debug aaa pod
AAA POD packet processing debugging is on
Router# show debug
General OS:
    AAA POD packet processing debugging is on
Router#
Apr 25 17:15:59.318:POD:172.19.139.206 request queued
Apr 25 17:15:59.318:voice_pod_request:
Apr 25 17:15:59.318:voip_populate_pod_attr_list:
Apr 25 17:15:59.318:voip_pod_get_guid:

## Command Reference

- aaa pod server
- debug aaa pod
Feature Information for RADIUS Packet of Disconnect

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

<td>The RADIUS Packet of Disconnect feature is used to terminate a connected voice call. In Cisco IOS Release 12.2(2)XB, this feature was introduced on the Cisco 3600, Cisco 5350, and Cisco 5400. In Cisco IOS Release 12.1(2)XH and 12.1(3)T, this feature was introduced on the Cisco 5300 and Cisco 5800. In Cisco IOS Release 12.2(11)T, this feature was introduced on the Cisco 5400, Cisco 5850. In Cisco IOS XE Release 2.1, this feature was introduced on the on Cisco ASR 1000 Series Routers. In Cisco IOS Release 12.2(27)SB and 12.4(15)T, Cisco allocated POD code 50 as the new code value for the voice POD request. The following commands were introduced or modified: aaa pod server and debug aaa pod</td>
</tr>
</tbody>
</table>
Glossary

AAA — authentication, authorization, and accounting.

NACK — negative acknowledgement message.

POD — packet of disconnect. An access_reject packet sent from a RADIUS server to the gateway in order to disconnect a call which has been connected already. After validation of the packet, the gateway disconnects the user. The packet contains the information to disconnect the call.

POD server — a Cisco gateway configured to accept and process POD requests from a RADIUS authentication/authorization agent.

RADIUS — Remote Authentication Dial-In User Service. An authentication and accounting system used by many Internet service providers.

UDP — User Datagram Protocol. Connectionless transport layer protocol in the TCP/IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, requiring that error processing and retransmission be handled by other protocols. UDP is defined in RFC 768.

VoIP — voice over IP. The ability to carry normal telephony-style voice over an IP-based Internet with POTS-like functionality, reliability, and voice quality. VoIP is a blanket term that generally refers to the Cisco standards-based (for example, H.323) approach to IP voice traffic.

VSA — vendor-specific attribute.
Configuring Authorization

AAA authorization enables you to limit the services available to a user. When AAA authorization is enabled, the network access server uses information retrieved from the user’s profile, which is located either in the local user database or on the security server, to configure the user’s session. Once this is done, the user will be granted access to a requested service only if the information in the user profile allows it.

For a complete description of the authorization commands used in this chapter, refer to the chapter “Authorization Commands” in the Cisco IOS Security Command Reference. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter “Identifying Supported Platforms” section in the “Using Cisco IOS Software.”

In This Chapter

This chapter contains the following sections:

- Named Method Lists for Authorization
- AAA Authorization Methods
- Method Lists and Server Groups
- AAA Authorization Types
- AAA Authorization Prerequisites
- AAA Authorization Configuration Task List
Method lists for authorization define the ways that authorization will be performed and the sequence in which these methods will be performed. A method list is simply a named list describing the authorization methods to be queried (such as RADIUS or TACACS+), in sequence. Method lists enable you to designate one or more security protocols to be used for authorization, thus ensuring a backup system in case the initial method fails. Cisco IOS software uses the first method listed to authorize users for specific network services; if that method fails to respond, the Cisco IOS software selects the next method listed in the method list. This process continues until there is successful communication with a listed authorization method, or all methods defined are exhausted.

The Cisco IOS software attempts authorization with the next listed method only when there is no response from the previous method. If authorization fails at any point in this cycle—meaning that the security server or local username database responds by denying the user services—the authorization process stops and no other authorization methods are attempted.

Method lists are specific to the authorization type requested:

- **Auth-proxy**—Applies specific security policies on a per-user basis. For detailed information on the authentication proxy feature, refer to the chapter “Configuring Authentication Proxy” in the “Traffic Filtering and Firewalls” part of this book.
- **Commands**—Applies to the EXEC mode commands a user issues. Command authorization attempts authorization for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.
- **EXEC**—Applies to the attributes associated with a user EXEC terminal session.
- **Network**—Applies to network connections. This can include a PPP, SLIP, or ARAP connection.
- **Reverse Access**—Applies to reverse Telnet sessions.

When you create a named method list, you are defining a particular list of authorization methods for the indicated authorization type.

Once defined, method lists must be applied to specific lines or interfaces before any of the defined methods will be performed. The only exception is the default method list (which is named “default”). If the `aaa authorization` command for a particular authorization type is issued without a named method list specified, the default method list is automatically applied to all interfaces or lines except those that have a named method list explicitly defined. (A defined method list overrides the default method list.) If no default method list is defined, local authorization takes place by default.

**AAA Authorization Methods**

AAA supports five different methods of authorization:

- **TACACS+**—The network access server exchanges authorization information with the TACACS+ security daemon. TACACS+ authorization defines specific rights for users by associating attribute-value pairs, which are stored in a database on the TACACS+ security server, with the appropriate user.
• If-Authenticated—The user is allowed to access the requested function provided the user has been authenticated successfully.

• None—The network access server does not request authorization information; authorization is not performed over this line/interface.

• Local—The router or access server consults its local database, as defined by the **username** command, for example, to authorize specific rights for users. Only a limited set of functions can be controlled via the local database.

• RADIUS—The network access server requests authorization information from the RADIUS security server. RADIUS authorization defines specific rights for users by associating attributes, which are stored in a database on the RADIUS server, with the appropriate user.

**Method Lists and Server Groups**

A server group is a way to group existing RADIUS or TACACS+ server hosts for use in method lists. **Figure 5** shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers, and T1 and T2 are TACACS+ servers. R1 and R2 make up the group of RADIUS servers. T1 and T2 make up the group of TACACS+ servers.

**Figure 5 Typical AAA Network Configuration**

Using server groups, you can specify a subset of the configured server hosts and use them for a particular service. For example, server groups allow you to define R1 and R2 as separate server groups, and T1 and T2 as separate server groups. This means you can specify either R1 and T1 in the method list or R2 and T2 in the method list, which provides more flexibility in the way that you assign RADIUS and TACACS+ resources.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, authorization—the second host entry configured acts as fail-over.
AAA Authorization Types

Cisco IOS software supports five different types of authorization:

- **Auth-proxy**—Applies specific security policies on a per-user basis. For detailed information on the authentication proxy feature, refer to the “Configuring Authentication Proxy” chapter in the “Traffic Filtering and Firewalls” section of this book.

- **Commands**—Applies to the EXEC mode commands a user issues. Command authorization attempts authorization for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.

- **EXEC**—Applies to the attributes associated with a user EXEC terminal session.

- **Network**—Applies to network connections. This can include a PPP, SLIP, or ARAP connection.

- **Reverse Access**—Applies to reverse Telnet sessions.

- **Configuration**—Applies to downloading configurations from the AAA server.

- **IP Mobile**—Applies to authorization for IP mobile services.

AAA Authorization Prerequisites

Before configuring authorization using named method lists, you must first perform the following tasks:

- Enable AAA on your network access server. For more information about enabling AAA on your Cisco router or access server, refer to the “AAA Overview” chapter.

- Configure AAA authentication. Authorization generally takes place after authentication and relies on authentication to work properly. For more information about AAA authentication, refer to the “Configuring Authentication” chapter.

- Define the characteristics of your RADIUS or TACACS+ security server if you are issuing RADIUS or TACACS+ authorization. For more information about configuring your Cisco network access server to communicate with your RADIUS security server, refer to the chapter “Configuring RADIUS”. For more information about configuring your Cisco network access server to communicate with your TACACS+ security server, refer to the chapter “Configuring TACACS+”.

- Define the rights associated with specific users by using the `username` command if you are issuing local authorization. For more information about the `username` command, refer to the *Cisco IOS Security Command Reference*.

AAA Authorization Configuration Task List

This section describes the following configuration tasks:

- **Configuring AAA Authorization Using Named Method Lists**
Disabling Authorization for Global Configuration Commands

Configuring Authorization for Reverse Telnet

For authorization configuration examples using the commands in this chapter, refer to the section “Authorization Configuration Examples” at the end of the this chapter.

### Configuring AAA Authorization Using Named Method Lists

To configure AAA authorization using named method lists, use the following commands beginning in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong>&lt;br&gt;Router(config)# aaa authorization {auth-proxy</td>
<td>network</td>
</tr>
<tr>
<td><strong>Step 2</strong>&lt;br&gt;Router(config)# line [aux</td>
<td>console</td>
</tr>
<tr>
<td><strong>Step 3</strong>&lt;br&gt;Router(config-line)# authorization {arap</td>
<td>commands level</td>
</tr>
</tbody>
</table>

This section includes the following sections:
- Authorization Types
- Authorization Methods

### Authorization Types

Named authorization method lists are specific to the indicated type of authorization.

To create a method list to enable authorization that applies specific security policies on a per-user basis, use the auth-proxy keyword. For detailed information on the authentication proxy feature, refer to the chapter “Configuring Authentication Proxy” in the “Traffic Filtering and Firewalls” part of this book.

To create a method list to enable authorization for all network-related service requests (including SLIP, PPP, PPP NCPs, and ARAP), use the network keyword.

To create a method list to enable authorization to determine if a user is allowed to run an EXEC shell, use the exec keyword.

To create a method list to enable authorization for specific, individual EXEC commands associated with a specific privilege level, use the commands keyword. (This allows you to authorize all commands associated with a specified command level from 0 to 15.)
To create a method list to enable authorization for reverse Telnet functions, use the `reverse-access` keyword.

For information about the types of authorization supported by the Cisco IOS software, refer to the “AAA Authorization Types” section of this chapter.
Authorization Methods

To have the network access server request authorization information via a TACACS+ security server, use the `aaa authorization` command with the `group tacacs+` method keyword. For more specific information about configuring authorization using a TACACS+ security server, refer to the chapter “Configuring TACACS+.” For an example of how to enable a TACACS+ server to authorize the use of network services, including PPP and ARA, see the section “TACACS+ Authorization Examples” at the end of this chapter.

To allow users to have access to the functions they request as long as they have been authenticated, use the `aaa authorization` command with the `if-authenticated` method keyword. If you select this method, all requested functions are automatically granted to authenticated users.

There may be times when you do not want to run authorization from a particular interface or line. To stop authorization activities on designated lines or interfaces, use the `none` method keyword. If you select this method, authorization is disabled for all actions.

To select local authorization, which means that the router or access server consults its local user database to determine the functions a user is permitted to use, use the `aaa authorization` command with the `local` method keyword. The functions associated with local authorization are defined by using the `username` global configuration command. For a list of permitted functions, refer to the chapter “Configuring Authentication.”

To have the network access server request authorization via a RADIUS security server, use the `radius` method keyword. For more specific information about configuring authorization using a RADIUS security server, refer to the chapter “Configuring RADIUS.”

To have the network access server request authorization via a RADIUS security server, use the `aaa authorization` command with the `group radius` method keyword. For more specific information about configuring authorization using a RADIUS security server, refer to the chapter “Configuring RADIUS”. For an example of how to enable a RADIUS server to authorize services, see the “RADIUS Authorization Example” section at the end of this chapter.

Note

Authorization method lists for SLIP follow whatever is configured for PPP on the relevant interface. If no lists are defined and applied to a particular interface (or no PPP settings are configured), the default setting for authorization applies.

Disabling Authorization for Global Configuration Commands

The `aaa authorization` command with the keyword `commands` attempts authorization for all EXEC mode commands, including global configuration commands, associated with a specific privilege level. Because there are configuration commands that are identical to some EXEC-level commands, there can be some confusion in the authorization process. Using `no aaa authorization config-commands` stops the network access server from attempting configuration command authorization.

To disable AAA authorization for all global configuration commands, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config)# no aaa authorization config-commands</code></td>
<td>Disables authorization for all global configuration commands.</td>
</tr>
</tbody>
</table>
Configuring Authorization for Reverse Telnet

Telnet is a standard terminal emulation protocol used for remote terminal connection. Normally, you log in to a network access server (typically through a dialup connection) and then use Telnet to access other network devices from that network access server. There are times, however, when it is necessary to establish a reverse Telnet session. In reverse Telnet sessions, the Telnet connection is established in the opposite direction—from inside a network to a network access server on the network periphery to gain access to modems or other devices connected to that network access server. Reverse Telnet is used to provide users with dialout capability by allowing them to Telnet to modem ports attached to a network access server.

It is important to control access to ports accessible through reverse Telnet. Failure to do so could, for example, allow unauthorized users free access to modems where they can trap and divert incoming calls or make outgoing calls to unauthorized destinations.

Authentication during reverse Telnet is performed through the standard AAA login procedure for Telnet. Typically the user has to provide a username and password to establish either a Telnet or reverse Telnet session. Reverse Telnet authorization provides an additional (optional) level of security by requiring authorization in addition to authentication. When enabled, reverse Telnet authorization can use RADIUS or TACACS+ to authorize whether or not this user is allowed reverse Telnet access to specific asynchronous ports, after the user successfully authenticates through the standard Telnet login procedure.

Reverse Telnet authorization offers the following benefits:
- An additional level of protection by ensuring that users engaged in reverse Telnet activities are indeed authorized to access a specific asynchronous port using reverse Telnet.
- An alternative method (other than access lists) to manage reverse Telnet authorization.

To configure a network access server to request authorization information from a TACACS+ or RADIUS server before allowing a user to establish a reverse Telnet session, use the following command in global configuration mode:

```
Router(config)# aaa authorization reverse-access method1 [method2 ...]
```

This feature enables the network access server to request reverse Telnet authorization information from the security server, whether RADIUS or TACACS+. You must configure the specific reverse Telnet privileges for the user on the security server itself.

Authorization Attribute-Value Pairs

RADIUS and TACACS+ authorization both define specific rights for users by processing attributes, which are stored in a database on the security server. For both RADIUS and TACACS+, attributes are defined on the security server, associated with the user, and sent to the network access server where they are applied to the user’s connection.

For a list of supported RADIUS attributes, refer to the appendix “RADIUS Attributes”. For a list of supported TACACS+ AV pairs, refer to the appendix “TACACS+ Attribute-Value Pairs.”
Authorization Configuration Examples

The following sections provide authorization configuration examples:

- Named Method List Configuration Example
- TACACS+ Authorization Examples
- RADIUS Authorization Example
- Reverse Telnet Authorization Examples

Named Method List Configuration Example

The following example shows how to configure a Cisco AS5300 (enabled for AAA and communication with a RADIUS security server) for AAA services to be provided by the RADIUS server. If the RADIUS server fails to respond, then the local database will be queried for authentication and authorization information, and accounting services will be handled by a TACACS+ server.

```config
aaa new-model
aaa authentication login admins local
aaa authentication ppp dialins group radius local
aaa authorization network scoobee group radius local
aaa accounting network charley start-stop group radius

username root password ALongPassword
radius-server host alcatraz
radius-server key myRaDiUSpassWoRd
interface group-async 1
group-range 1 16
encapsulation ppp
ppp authentication chap dialins
ppp authorization scoobee
ppp accounting charley

line 1 16
  autoselect ppp
  autoselect during-login
  login authentication admins
  modem dialin
```

The lines in this sample RADIUS AAA configuration are defined as follows:

- The `aaa new-model` command enables AAA network security services.
- The `aaa authentication login admins local` command defines a method list, admins, for login authentication.
- The `aaa authentication ppp dialins group radius local` command defines the authentication method list “dialins,” which specifies that RADIUS authentication then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
- The `aaa authorization network scoobee group radius local` command defines the network authorization method list named scoobee, which specifies that RADIUS authorization will be used on serial lines using PPP. If the RADIUS server fails to respond, then local network authorization will be performed.
• The **aaa accounting network charley start-stop group radius** command defines the network accounting method list named charley, which specifies that RADIUS accounting services (in this case, start and stop records for specific events) will be used on serial lines using PPP.

• The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.

• The **radius-server host** command defines the name of the RADIUS server host.

• The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.

• The **interface group-async** command selects and defines an asynchronous interface group.

• The **group-range** command defines the member asynchronous interfaces in the interface group.

• The **encapsulation ppp** command sets PPP as the encapsulation method used on the specified interfaces.

• The **ppp authentication chap dialins** command selects Challenge Handshake Authentication Protocol (CHAP) as the method of PPP authentication and applies the “dialins” method list to the specified interfaces.

• The **ppp authorization scoobee** command applies the scoobee network authorization method list to the specified interfaces.

• The **ppp accounting charley** command applies the charley network accounting method list to the specified interfaces.

• The **line** command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.

• The **autoselect ppp** command configures the Cisco IOS software to allow a PPP session to start up automatically on these selected lines.

• The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.

• The **login authentication admins** command applies the admins method list for login authentication.

• The **modem dialin** command configures modems attached to the selected lines to only accept incoming calls.

---

**TACACS+ Authorization Examples**

The following examples show how to use a TACACS+ server to authorize the use of network services, including PPP and ARA. If the TACACS+ server is not available or an error occurs during the authorization process, the fallback method (none) is to grant all authorization requests:

```
aaa authorization network default group tacacs+ none
```

The following example shows how to allow network authorization using TACACS+:

```
aaa authorization network default group tacacs+
```

The following example shows how to provide the same authorization, but it also creates address pools called “mci” and “att”:

```
aaa authorization network default group tacacs+
ip address-pool local
ip local-pool mci 172.16.0.1 172.16.0.255
ip local-pool att 172.17.0.1 172.17.0.255
```
These address pools can then be selected by the TACACS daemon. A sample configuration of the daemon follows:

```bash
user = mci_customer1 {
    login = cleartext "some password"
    service = ppp protocol = ip {
        addr-pool=mci
    }
}
user = att_customer1 {
    login = cleartext "some other password"
    service = ppp protocol = ip {
        addr-pool=att
    }
}
```

### RADIUS Authorization Example

The following example shows how to configure the router to authorize using RADIUS:

```bash
aaa new-model
aaa authorization exec default group radius if-authenticated
aaa authorization network default group radius
radius-server host ip
radius-server key
```

The lines in this sample RADIUS authorization configuration are defined as follows:

- The `aaa authorization exec default group radius if-authenticated` command configures the network access server to contact the RADIUS server to determine if users are permitted to start an EXEC shell when they log in. If an error occurs when the network access server contacts the RADIUS server, the fallback method is to permit the CLI to start, provided the user has been properly authenticated.

  The RADIUS information returned may be used to specify an autocommand or a connection access list be applied to this connection.

- The `aaa authorization network default group radius` command configures network authorization via RADIUS. This can be used to govern address assignment, the application of access lists, and various other per-user quantities.

**Note**

Because no fallback method is specified in this example, authorization will fail if, for any reason, there is no response from the RADIUS server.

### Reverse Telnet Authorization Examples

The following examples show how to cause the network access server to request authorization information from a TACACS+ security server before allowing a user to establish a reverse Telnet session:

```bash
aaa new-model
aaa authentication login default group tacacs+
aaa authorization reverse-access default group tacacs+

! tacacs-server host 172.31.255.0
tacacs-server timeout 90
tacacs-server key goaway
```
The lines in this sample TACACS+ reverse Telnet authorization configuration are defined as follows:

- The `aaa new-model` command enables AAA.
- The `aaa authentication login default group tacacs+` command specifies TACACS+ as the default method for user authentication during login.
- The `aaa authorization reverse-access default group tacacs+` command specifies TACACS+ as the method for user authorization when trying to establish a reverse Telnet session.
- The `tacacs-server host` command identifies the TACACS+ server.
- The `tacacs-server timeout` command sets the interval of time that the network access server waits for the TACACS+ server to reply.
- The `tacacs-server key` command defines the encryption key used for all TACACS+ communications between the network access server and the TACACS+ daemon.

The following example shows how to configure a general TACACS+ server to grant a user, pat, reverse Telnet access to port tty2 on the network access server named “maple” and to port tty5 on the network access server named “oak”:

```
user = pat
login = cleartext lab
service = raccess {
    port#1 = maple/tty2
    port#2 = oak/tty5

Note In this example, “maple” and “oak” are the configured host names of network access servers, not DNS names or alias.
```

The following example shows how to configure the TACACS+ server (CiscoSecure) to grant a user named pat reverse Telnet access:

```
user = pat
profile_id = 90
profile_cycle = 1
member = Tacacs_Users
service=shell {
    default cmd=permit
}
service=raccess {
    allow "c2511e0" "tty1" ".*"
    refuse ".*" ".*" ".*"
    password = clear "goaway"

Note CiscoSecure only supports reverse Telnet using the command line interface in versions 2.1(x) through version 2.2(1).
```

An empty “service=raccess {}” clause permits a user to have unconditional access to network access server ports for reverse Telnet. If no “service=raccess” clause exists, the user is denied access to any port for reverse Telnet.

For more information about configuring TACACS+, refer to the chapter “Configuring TACACS+.” For more information about configuring CiscoSecure, refer to the CiscoSecure Access Control Server User Guide, version 2.1(2) or greater.

The following example shows how to cause the network access server to request authorization from a RADIUS security server before allowing a user to establish a reverse Telnet session:

```
aaa new-model
```
aaa authentication login default group radius
aaa authorization reverse-access default group radius
!
radius-server host 172.31.255.0
radius-server key go away
auth-port 1645 acct-port 1646

The lines in this sample RADIUS reverse Telnet authorization configuration are defined as follows:

- The `aaa new-model` command enables AAA.
- The `aaa authentication login default group radius` command specifies RADIUS as the default method for user authentication during login.
- The `aaa authorization reverse-access default group radius` command specifies RADIUS as the method for user authorization when trying to establish a reverse Telnet session.
- The `radius-server host` command identifies the RADIUS server.
- The `radius-server key` command defines the encryption key used for all RADIUS communications between the network access server and the RADIUS daemon.

The following example shows how to send a request to the RADIUS server to grant a user named “pat” reverse Telnet access at port tty2 on the network access server named “maple”:

Username = “pat”
Password = “goaway”
User-Service-Type = Shell-User
cisco-avpair = “raccess:port#1=maple/tty2”

The syntax “raccess:port=any/any” permits a user to have unconditional access to network access server ports for reverse Telnet. If no “raccess:port=\{nasname\}/\{tty number\}” clause exists in the user profile, the user is denied access to reverse Telnet on all ports.

For more information about configuring RADIUS, refer to the chapter “Configuring RADIUS.”
Configuring Accounting

The AAA accounting feature allows the services that users are accessing and the amount of network resources that users are consuming to be tracked. When AAA accounting is enabled, the network access server reports user activity to the TACACS+ or RADIUS security server (depending on which security method is implemented) in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can then be analyzed for network management, client billing, and auditing.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the “Feature Information for Configuring Accounting” section on page 28.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Catalyst OS, and Cisco IOS XE software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Contents

- Information About Configuring Accounting, page 2
- How to Configure AAA Accounting, page 16
- Accounting Attribute-Value Pairs, page 23
- Configuration Examples for AAA Accounting, page 23
- Feature Information for Configuring Accounting, page 28
Prerequisites for Configuring Accounting

The following tasks must be performed before configuring accounting using named method lists:

- Enable AAA on the network access server. For more information about enabling AAA on a Cisco router or access server, see the chapter “AAA Overview” in the Cisco IOS Security Configuration Guide.

- Define the characteristics of the RADIUS or TACACS+ security server if RADIUS or TACACS+ authorization is issued. For more information about configuring the Cisco network access server to communicate with the RADIUS security server, see the chapter “Configuring RADIUS.” For more information about configuring the Cisco network access server to communicate with the TACACS+ security server, see the chapter “Configuring TACACS+.”

Restrictions for Configuring Accounting

The AAA Accounting feature has the following restrictions:

- Accounting information can be sent simultaneously to a maximum of four AAA servers.

- SSG Restriction—For SSG systems, the `aaa accounting network broadcast` command broadcasts only start-stop accounting records. If interim accounting records are configured using the `ssg accounting interval` command, the interim accounting records are sent only to the configured default RADIUS server.

Information About Configuring Accounting

The following sections discuss how Accounting feature:

- Named Method Lists for Accounting, page 2
- AAA Accounting Types, page 5
- AAA Accounting Enhancements, page 14

Named Method Lists for Accounting

Like authentication and authorization method lists, method lists for accounting define the way accounting is performed and the sequence in which these methods are performed.

Named accounting method lists allow particular security protocol to be designated and used on specific lines or interfaces for accounting services. The only exception is the default method list (which, by coincidence, is named “default”). The default method list is automatically applied to all interfaces except those that have a named method list explicitly defined. A defined method list overrides the default method list.

A method list is simply a named list describing the accounting methods to be queried (such as RADIUS or TACACS+), in sequence. Method lists allow one or more security protocols to be designated and used for accounting, thus ensuring a backup system for accounting in case the initial method fails. Cisco IOS software uses the first method listed to support accounting; if that method fails to respond, the Cisco IOS software selects the next accounting method listed in the method list. This process continues until there is successful communication with a listed accounting method, or all methods defined are exhausted.
The Cisco IOS software attempts accounting with the next listed accounting method only when there is no response from the previous method. If accounting fails at any point in this cycle—meaning that the security server responds by denying the user access—the accounting process stops and no other accounting methods are attempted.

Accounting method lists are specific to the type of accounting being requested. AAA supports six different types of accounting:

- **Network**—Provides information for all PPP, SLIP, or ARAP sessions, including packet and byte counts.
- **EXEC**—Provides information about user EXEC terminal sessions of the network access server.
- **Commands**—Provides information about the EXEC mode commands that a user issues. Command accounting generates accounting records for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.
- **Connection**—Provides information about all outbound connections made from the network access server, such as Telnet, local-area transport (LAT), TN3270, packet assembler/disassembler (PAD), and rlogin.
- **System**—Provides information about system-level events.
- **Resource**—Provides “start” and “stop” records for calls that have passed user authentication, and provides “stop” records for calls that fail to authenticate.

Note: System accounting does not use named accounting lists; only the default list for system accounting can be defined.

Once again, when a named method list is created, a particular list of accounting methods for the indicated accounting type are defined.

Accounting method lists must be applied to specific lines or interfaces before any of the defined methods are performed. The only exception is the default method list (which is named “default”). If the `aaa accounting` command for a particular accounting type is issued without a named method list specified, the default method list is automatically applied to all interfaces or lines except those that have a named method list explicitly defined. (A defined method list overrides the default method list.) If no default method list is defined, then no accounting takes place.

This section includes the following subsections:

- Method Lists and Server Groups, page 4
- AAA Accounting Methods, page 5
Method Lists and Server Groups

A server group is a way to group existing RADIUS or TACACS+ server hosts for use in method lists. Figure 1 shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers, and T1 and T2 are TACACS+ servers. R1 and R2 comprise the group of RADIUS servers. T1 and T2 comprise the group of TACACS+ servers.

Figure 1  Typical AAA Network Configuration

In Cisco IOS software, RADIUS and TACACS+ server configurations are global. A subset of the configured server hosts can be specified using server groups. These server groups can be used for a particular service. For example, server groups allow R1 and R2 to be defined as separate server groups (SG1 and SG2), and T1 and T2 as separate server groups (SG3 and SG4). This means either R1 and T1 (SG1 and SG3) can be specified in the method list or R2 and T2 (SG2 and SG4) in the method list, which provides more flexibility in the way that RADIUS and TACACS+ resources are assigned.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as failover backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order in which they are configured.)

For more information about configuring server groups and about configuring server groups based on DNIS numbers, see “Configuring RADIUS” or “Configuring TACACS+” in the Cisco IOS Security Configuration Guide.
AAA Accounting Methods

Cisco IOS supports the following two methods for accounting:

- **TACACS+**—The network access server reports user activity to the TACACS+ security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server.

- **RADIUS**—The network access server reports user activity to the RADIUS security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server.

AAA Accounting Types

AAA supports six different accounting types:

- **Network Accounting**
- **Connection Accounting**
- **EXEC Accounting**
- **System Accounting**
- **Command Accounting**
- **Resource Accounting**

Network Accounting

Network accounting provides information for all PPP, SLIP, or ARAP sessions, including packet and byte counts.

The following example shows the information contained in a RADIUS network accounting record for a PPP user who comes in through an EXEC session:

```
Wed Jun 27 04:44:45 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 5
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "0000000D"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"
```

```
Wed Jun 27 04:45:00 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 5
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Framed
Acct-Session-Id = "0000000E"
Framed-IP-Address = "10.1.1.2"
```
Configuring Accounting

Information About Configuring Accounting

The following example shows the information contained in a TACACS+ network accounting record for a PPP user who first started an EXEC session:

```
Wed Jun 27 04:00:35 2001 172.16.25.15    username1   tty4    562/4327528
starttask_id=28      service=shell
Wed Jun 27 04:00:46 2001 172.16.25.15    username1   tty4 562/4327528     starttask_id=30
addr=10.1.1.1   service=ppp
Wed Jun 27 04:00:49 2001 172.16.25.15    username1   tty4 408/4327528     update
task_id=30      addr=10.1.1.1   service=ppp protocol=ip addr=10.1.1.1
Wed Jun 27 04:01:31 2001 172.16.25.15    username1   tty4 562/4327528
stoptask_id=30      addr=10.1.1.1   service=ppp protocol=ip addr=10.1.1.1
bytes_in=2844        bytes_out=1682  paks_in=36      paks_out=24     elapsed_time=51
Wed Jun 27 04:01:32 2001 172.16.25.15    username1   tty4 562/4327528
stoptask_id=28      service=shell elapsed_time=57
```

The following example shows the information contained in a TACACS+ network accounting record for a PPP user who comes in through autoselect:

```
Wed Jun 27 04:30:52 2001
```

The precise format of accounting packets records may vary depending on the security server daemon.

The following example shows the information contained in a RADIUS network accounting record for a PPP user who comes in through autoselect:

```
Wed Jun 27 04:30:52 2001
```
NAS-IP-Address = "172.16.25.15"
NAS-Port = 3
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Framed
Acct-Session-Id = "0000000B"
Framed-Protocol = PPP
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:36:49 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 3
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Framed
Acct-Session-Id = "0000000B"
Framed-Protocol = PPP
Framed-IP-Address = "10.1.1.1"
Acct-Input-Octets = 8630
Acct-Output-Octets = 5722
Acct-Input-Packets = 94
Acct-Output-Packets = 64
Acct-Session-Time = 357
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

The following example shows the information contained in a TACACS+ network accounting record for a PPP user who comes in through autoselect:

Wed Jun 27 04:02:19 2001 172.16.25.15 username1 Async5 562/4327528
start

Wed Jun 27 04:02:25 2001 172.16.25.15 username1 Async5 562/4327528
update
task_id=35
protocol=ip
addr=10.1.1.2

Wed Jun 27 04:05:03 2001 172.16.25.15 username1 Async5 562/4327528
stop

bytes_out=2149

Connection Accounting

Connection accounting provides information about all outbound connections made from the network access server, such as Telnet, local-area transport (LAT), TN3270, packet assembler/disassembler (PAD), and rlogin.

The following example shows the information contained in a RADIUS connection accounting record for an outbound Telnet connection:

Wed Jun 27 04:28:00 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 2
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "00000008"
Login-Service = Telnet
Login-IP-Host = "10.68.202.158"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

NAS-IP-Address = "172.16.25.15"
NAS-Port = 2
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "00000008"
Login-Service = Telnet
Login-IP-Host = "10.68.202.158"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"
Acct-Input-Octets = 10774
Acct-Output-Octets = 112
Acct-Input-Packets = 91
Acct-Output-Packets = 99
Acct-Session-Time = 39
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

The following example shows the information contained in a TACACS+ connection accounting record for an outbound Telnet connection:

Wed Jun 27 03:47:43 2001
172.16.25.15 username1 tty3 5622329430/4327528
start task_id=10 service=connection protocol=telnet addr=10.68.202.158
cmd=telnet username1-sun
Wed Jun 27 03:48:38 2001
172.16.25.15 username1 tty3 5622329430/4327528
stop task_id=10 service=connection protocol=telnet addr=10.68.202.158
cmd=telnet username1-sun bytes_in=4467 bytes_out=96 paks_in=61 paks_out=72 elapsed_time=55

The following example shows the information contained in a RADIUS connection accounting record for an outbound rlogin connection:

NAS-IP-Address = "172.16.25.15"
NAS-Port = 2
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "0000000A"
Login-Service = Rlogin
Login-IP-Host = "10.68.202.158"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:30:09 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 2
User-Name = "username1"
Configuring Accounting

Information About Configuring Accounting

Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "0000000A"
Login-Service = Rlogin
Login-IP-Host = "10.68.202.158"
Acct-Input-Octets = 18686
Acct-Output-Octets = 86
Acct-Input-Packets = 90
Acct-Output-Packets = 68
Acct-Session-Time = 22
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

The following example shows the information contained in a TACACS+ connection accounting record for an outbound rlogin connection:

Wed Jun 27 03:48:46 2001       172.16.25.15    username1   tty3    5622329430/4327528
start    task_id=12      service=connection      protocol=rlogin addr=10.68.202.158
          cmd=rlogin username1-sun /user username1

Wed Jun 27 03:51:37 2001       172.16.25.15    username1   tty3    5622329430/4327528
stop     task_id=12      service=connection      protocol=rlogin addr=10.68.202.158
          cmd=rlogin username1-sun /user username1 bytes_in=659926 bytes_out=138 paks_in=2378
          paks_out=1251 elapsed_time=171

The following example shows the information contained in a TACACS+ connection accounting record for an outbound LAT connection:

Wed Jun 27 03:53:06 2001       172.16.25.15    username1   tty3    5622329430/4327528
start    task_id=18      service=connection      protocol=lat addr=VAX    cmd=lat
           VAX
Wed Jun 27 03:54:15 2001       172.16.25.15    username1   tty3    5622329430/4327528
stop     task_id=18      service=connection      protocol=lat addr=VAX    cmd=lat
           VAX bytes_in=0 bytes_out=0 paks_in=0 paks_out=0 elapsed_time=6

EXEC Accounting

EXEC accounting provides information about user EXEC terminal sessions (user shells) on the network access server, including username, date, start and stop times, the access server IP address, and (for dial-in users) the telephone number the call originated from.

The following example shows the information contained in a RADIUS EXEC accounting record for a dial-in user:

Wed Jun 27 04:26:23 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 1
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329483"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "00000006"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"
NAS-IP-Address = "172.16.25.15"
NAS-Port = 1
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329483"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "00000006"
Acct-Session-Time = 62
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

The following example shows the information contained in a TACACS+ EXEC accounting record for a dial-in user:
Wed Jun 27 03:46:21 2001 172.16.25.15 username1 tty3 5622329430/4327528
start task_id=2 service=shell
Wed Jun 27 04:08:55 2001 172.16.25.15 username1 tty3 5622329430/4327528
stop task_id=2 service=shell elapsed_time=1354

The following example shows the information contained in a RADIUS EXEC accounting record for a Telnet user:
NAS-IP-Address = "172.16.25.15"
NAS-Port = 26
User-Name = "username1"
Caller-ID = "10.68.202.158"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "00000010"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"
NAS-IP-Address = "172.16.25.15"
NAS-Port = 26
User-Name = "username1"
Caller-ID = "10.68.202.158"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "00000010"
Acct-Session-Time = 14
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

The following example shows the information contained in a TACACS+ EXEC accounting record for a Telnet user:
start task_id=41 service=shell
stop task_id=41 service=shell elapsed_time=9
System Accounting

System accounting provides information about all system-level events (for example, when the system reboots or when accounting is turned on or off).

The following accounting record shows a typical TACACS+ system accounting record server indicating that AAA accounting has been turned off:

```
service=system event=sys_acct reason=reconfigure
```

Note

The precise format of accounting packets records may vary depending on the TACACS+ daemon.

The following accounting record shows a TACACS+ system accounting record indicating that AAA accounting has been turned on:

```
Wed Jun 27 03:55:22 2001 172.16.25.15 unknown unknown unknown stop task_id=23
service=system event=sys_acct reason=reconfigure
```

Additional tasks for measuring system resources are covered in the Cisco IOS software configuration guides. For example, IP accounting tasks are described in the chapter “Configuring IP Services” in the Cisco IOS Application Services Configuration Guide.

Command Accounting

Command accounting provides information about the EXEC shell commands for a specified privilege level that are being executed on a network access server. Each command accounting record includes a list of the commands executed for that privilege level, as well as the date and time each command was executed, and the user who executed it.

The following example shows the information contained in a TACACS+ command accounting record for privilege level 1:

```
Wed Jun 27 03:46:47 2001 172.16.25.15 username1 tty3 5622329430/4327528
stop task_id=3 service=shell priv-lvl=1 cmd=show version <cr>
Wed Jun 27 03:46:58 2001 172.16.25.15 username1 tty3 5622329430/4327528
stop task_id=4 service=shell priv-lvl=1 cmd=show interfaces Ethernet 0 <cr>
Wed Jun 27 03:47:03 2001 172.16.25.15 username1 tty3 5622329430/4327528
stop task_id=5 service=shell priv-lvl=1 cmd=show ip route <cr>
```

The following example shows the information contained in a TACACS+ command accounting record for privilege level 15:

```
Wed Jun 27 03:47:17 2001 172.16.25.15 username1 tty3 5622329430/4327528
stop task_id=6 service=shell priv-lvl=15 cmd=configure terminal <cr>
Wed Jun 27 03:47:21 2001 172.16.25.15 username1 tty3 5622329430/4327528
stop task_id=7 service=shell priv-lvl=15 cmd=interface Serial 0 <cr>
Wed Jun 27 03:47:29 2001 172.16.25.15 username1 tty3 5622329430/4327528
stop task_id=8 service=shell priv-lvl=15 cmd=ip address 10.1.1.1 255.255.255.0 <cr>
```

Note

The Cisco Systems implementation of RADIUS does not support command accounting.
Resource Accounting

The Cisco implementation of AAA accounting provides “start” and “stop” record support for calls that have passed user authentication. The additional feature of generating “stop” records for calls that fail to authenticate as part of user authentication is also supported. Such records are necessary for users employing accounting records to manage and monitor their networks.

This section includes the following subsections:
- AAA Resource Failure Stop Accounting, page 12
- AAA Resource Accounting for Start-Stop Records, page 14

AAA Resource Failure Stop Accounting

Before AAA resource failure stop accounting, there was no method of providing accounting records for calls that failed to reach the user authentication stage of a call setup sequence. Such records are necessary for users employing accounting records to manage and monitor their networks and their wholesale customers.

This functionality generates a “stop” accounting record for any calls that do not reach user authentication; “stop” records are generated from the moment of call setup. All calls that pass user authentication behave as they did before; that is, no additional accounting records are seen.

Figure 2 illustrates a call setup sequence with normal call flow (no disconnect) and without AAA resource failure stop accounting enabled.

Figure 2  Modern Dial-In Call Setup Sequence With Normal Flow and Without Resource Failure Stop Accounting Enabled

Figure 3 illustrates a call setup sequence with normal call flow (no disconnect) and with AAA resource failure stop accounting enabled.
Figure 3  
**Modem Dial-In Call Setup Sequence With Normal Flow and With Resource Failure Stop Accounting Enabled**

Figure 4 illustrates a call setup sequence with call disconnect occurring before user authentication and with AAA resource failure stop accounting enabled.

Figure 4  
**Modem Dial-In Call Setup Sequence With Call Disconnect Occurring Before User Authentication and With Resource Failure Stop Accounting Enabled**

Figure 11 illustrates a call setup sequence with call disconnect occurring before user authentication and without AAA resource failure stop accounting enabled.

Figure 5  
**Modem Dial-In Call Setup Sequence With Call Disconnect Occurring Before User Authentication and Without Resource Failure Stop Accounting Enabled**
AAA Resource Accounting for Start-Stop Records

AAA resource accounting for start-stop records supports the ability to send a “start” record at each call setup, followed by a corresponding “stop” record at the call disconnect. This functionality can be used to manage and monitor wholesale customers from one source of data reporting, such as accounting records.

With this feature, a call setup and call disconnect “start-stop” accounting record tracks the progress of the resource connection to the device. A separate user authentication “start-stop” accounting record tracks the user management progress. These two sets of accounting records are interlinked by using a unique session ID for the call.

Figure 6 illustrates a call setup sequence with AAA resource start-stop accounting enabled.

AAA Accounting Enhancements

The section includes the following enhancements:

- AAA Broadcast Accounting, page 14
- AAA Session MIB, page 14

AAA Broadcast Accounting

AAA broadcast accounting allows accounting information to be sent to multiple AAA servers at the same time; that is, accounting information can be broadcast to one or more AAA servers simultaneously. This functionality allows service providers to send accounting information to their own private AAA servers and to the AAA servers of their end customers. It also provides redundant billing information for voice applications.

Broadcasting is allowed among groups of RADIUS or TACACS+ servers, and each server group can define its backup servers for failover independently of other groups.

Thus, service providers and their end customers can use different protocols (RADIUS or TACACS+) for the accounting server. Service providers and their end customers can also specify their backup servers independently. As for voice applications, redundant accounting information can be managed independently through a separate group with its own failover sequence.

AAA Session MIB

The AAA session MIB feature allows customers to monitor and terminate their authenticated client connections using Simple Network Management Protocol (SNMP). The data of the client is presented so that it correlates directly to the AAA accounting information reported by either the RADIUS or the TACACS+ server. AAA session MIB provides the following information:
• Statistics for each AAA function (when used in conjunction with the `show radius statistics` command)
• Status of servers providing AAA functions
• Identities of external AAA servers
• Real-time information (such as idle times), providing additional criteria for use by SNMP networks for assessing whether or not to terminate an active call

**Note**
This command is supported only on Cisco AS5300 and Cisco AS5800 universal access server platforms.

Table 1 shows the SNMP user-end data objects that can be used to monitor and terminate authenticated client connections with the AAA session MIB feature.

**Table 1**  
**SNMP End-User Data Objects**

<table>
<thead>
<tr>
<th>SessionId</th>
<th>The session identification used by the AAA accounting protocol (same value as reported by RADIUS attribute 44 (Acct-Session-ID)).</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserId</td>
<td>The user login ID or zero-length string if a login is unavailable.</td>
</tr>
<tr>
<td>IpAddr</td>
<td>The IP address of the session or 0.0.0.0 if an IP address is not applicable or unavailable.</td>
</tr>
<tr>
<td>IdleTime</td>
<td>The elapsed time in seconds that the session has been idle.</td>
</tr>
<tr>
<td>Disconnect</td>
<td>The session termination object used to disconnect the given client.</td>
</tr>
<tr>
<td>CallId</td>
<td>The entry index corresponding to this accounting session that the Call Tracker record stored.</td>
</tr>
</tbody>
</table>

Table 2 describes the AAA summary information provided by the AAA session MIB feature using SNMP on a per-system basis.

**Table 2**  
**SNMP AAA Session Summary**

<table>
<thead>
<tr>
<th>ActiveTableEntries</th>
<th>Number of sessions currently active.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActiveTableHighWaterMark</td>
<td>Maximum number of sessions present at once since last system reinstallation.</td>
</tr>
<tr>
<td>TotalSessions</td>
<td>Total number of sessions since last system reinstallation.</td>
</tr>
<tr>
<td>DisconnectedSessions</td>
<td>Total number of sessions that have been disconnected using since last system reinstallation.</td>
</tr>
</tbody>
</table>
How to Configure AAA Accounting

This section describes the following configuration tasks involved in configuring AAA Accounting:

- Configuring AAA Accounting Using Named Method Lists
- Suppressing Generation of Accounting Records for Null Username Sessions
- Generating Interim Accounting Records
- Generating Accounting Records for Failed Login or Session
- Specifying Accounting NETWORK-Stop Records Before EXEC-Stop Records
- Configuring AAA Resource Failure Stop Accounting
- Configuring AAA Resource Accounting for Start-Stop Records
- Configuring AAA Broadcast Accounting
- Configuring AAA Resource Failure Stop Accounting
- Configuring AAA Session MIB
- Establishing a Session with a Router if the AAA Server is Unreachable
- Monitoring Accounting
- Troubleshooting Accounting

Configuring AAA Accounting Using Named Method Lists

To configure AAA accounting using named method lists, use the following commands beginning in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
Router(config)# aaa accounting {system | network | exec | connection | commands level} (default | list-name) {start-stop | stop-only | none} [method1 [method2...]]  
in global configuration mode  
This command creates an accounting method list and enables accounting. The argument list-name is a character string used to name the created list. |
| **Step 2**  
Router(config)# line [aux | console | tty | vty] line-number [ending-line-number]  
or  
Router(config)# interface interface-type interface-number  
This command enters the line configuration mode for the lines to which the accounting method list is applied. |
| **Step 3**  
Router(config-line)# accounting {arap | commands level | connection | exec} {default | list-name}  
or  
Router(config-if)# ppp accounting {default | list-name}  
This command applies the accounting method list to a line or set of lines. |

**Note**  
System accounting does not use named method lists. For system accounting, define only the default method list.
This section includes the following sections:

- Accounting Types, page 17
- Accounting Record Types, page 17
- Accounting Methods, page 17

**Accounting Types**

Named accounting method lists are specific to the indicated type of accounting.

- **network**—To create a method list to enable authorization for all network-related service requests (including SLIP, PPP, PPP NCPs, and ARA protocols), use the `network` keyword. For example, to create a method list that provides accounting information for ARAP (network) sessions, use the `arap` keyword.

- **exec**—To create a method list that provides accounting records about user EXEC terminal sessions on the network access server, including username, date, start and stop times, use the `exec` keyword.

- **commands**—To create a method list that provides accounting information about specific, individual EXEC commands associated with a specific privilege level, use the `commands` keyword.

- **connection**—To create a method list that provides accounting information about all outbound connections made from the network access server, use the `connection` keyword.

- **resource**—Creates a method list to provide accounting records for calls that have passed user authentication or calls that failed to be authenticated.

**Note**

System accounting does not support named method lists.

**Accounting Record Types**

For minimal accounting, use the `stop-only` keyword, which instructs the specified method (RADIUS or TACACS+) to send a stop record accounting notice at the end of the requested user process. For more accounting information, use the `start-stop` keyword to send a start accounting notice at the beginning of the requested event and a stop accounting notice at the end of the event. To stop all accounting activities on this line or interface, use the `none` keyword.

**Accounting Methods**

Table 3 lists the supported accounting methods.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group radius</td>
<td>Uses the list of all RADIUS servers for accounting.</td>
</tr>
<tr>
<td>group tacacs+</td>
<td>Uses the list of all TACACS+ servers for accounting.</td>
</tr>
<tr>
<td>group group-name</td>
<td>Uses a subset of RADIUS or TACACS+ servers for accounting as defined by the server group group-name.</td>
</tr>
</tbody>
</table>
Configuring Accounting

The method argument refers to the actual method the authentication algorithm tries. Additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all other methods return an error, specify additional methods in the command. For example, to create a method list named acct_tac1 that specifies RADIUS as the backup method of authentication in the event that TACACS+ authentication returns an error, enter the following command:

```sh
aaa accounting network acct_tac1 stop-only group tacacs+ group radius
```

To create a default list that is used when a named list is *not* specified in the `aaa accounting` command, use the `default` keyword followed by the methods that are wanted to be used in default situations. The default method list is automatically applied to all interfaces.

For example, to specify RADIUS as the default method for user authentication during login, enter the following command:

```sh
aaa accounting network default stop-only group radius
```

AAA accounting supports the following methods:

- **group tacacs**—To have the network access server send accounting information to a TACACS+ security server, use the `group tacacs+` method keyword.

- **group radius**—To have the network access server send accounting information to a RADIUS security server, use the `group radius` method keyword.

*Note* Accounting method lists for SLIP follow whatever is configured for PPP on the relevant interface. If no lists are defined and applied to a particular interface (or no PPP settings are configured), the default setting for accounting applies.

- **group group-name**—To specify a subset of RADIUS or TACACS+ servers to use as the accounting method, use the `aaa accounting` command with the `group group-name` method. To specify and define the group name and the members of the group, use the `aaa group server` command. For example, use the `aaa group server` command to first define the members of `group loginrad`:

  ```sh
  aaa group server radius loginrad
  server 172.16.2.3
  server 172.16.2.17
  server 172.16.2.32
  ```

  This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group `loginrad`.

  To specify `group loginrad` as the method of network accounting when no other method list has been defined, enter the following command:

  ```sh
  aaa accounting network default start-stop group loginrad
  ```

Before a group name can be used as the accounting method, communication with the RADIUS or TACACS+ security server must be enabled.
Suppressing Generation of Accounting Records for Null Username Sessions

When AAA accounting is activated, the Cisco IOS software issues accounting records for all users on the system, including users whose username string, because of protocol translation, is NULL. An example of this is users who come in on lines where the `aaa authentication login method-list none` command is applied. To prevent accounting records from being generated for sessions that do not have usernames associated with them, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config)# aaa accounting suppress null-username</code></td>
<td>Prevents accounting records from being generated for users whose username string is NULL.</td>
</tr>
</tbody>
</table>

Generating Interim Accounting Records

To enable periodic interim accounting records to be sent to the accounting server, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config)# aaa accounting update {[newinfo] [periodic] number}</code></td>
<td>Enables periodic interim accounting records to be sent to the accounting server.</td>
</tr>
</tbody>
</table>

When the `aaa accounting update` command is activated, the Cisco IOS software issues interim accounting records for all users on the system. If the keyword `newinfo` is used, interim accounting records are sent to the accounting server every time there is new accounting information to report. An example of this would be when IPCP completes IP address negotiation with the remote peer. The interim accounting record includes the negotiated IP address used by the remote peer.

When used with the keyword `periodic`, interim accounting records are sent periodically as defined by the argument number. The interim accounting record contains all of the accounting information recorded for that user up to the time the interim accounting record is sent.

⚠️ **Caution**

Using the `aaa accounting update periodic` command can cause heavy congestion when many users are logged in to the network.

Generating Accounting Records for Failed Login or Session

When AAA accounting is activated, the Cisco IOS software does not generate accounting records for system users who fail login authentication, or who succeed in login authentication but fail PPP negotiation for some reason.

To specify that accounting stop records be generated for users who fail to authenticate at login or during session negotiation, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config)# aaa accounting send stop-record authentication failure</code></td>
<td>Generates “stop” records for users who fail to authenticate at login or during session negotiation using PPP.</td>
</tr>
</tbody>
</table>
Specifying Accounting NETWORK-Stop Records Before EXEC-Stop Records

For PPP users who start EXEC terminal sessions, it can be specified that NETWORK records be generated before EXEC-stop records. In some cases, such as billing customers for specific services, it can be desirable to keep network start and stop records together, essentially “nesting” them within the framework of the EXEC start and stop messages. For example, a user dialing in using PPP can create the following records: EXEC-start, NETWORK-start, EXEC-stop, NETWORK-stop. By nesting the accounting records, NETWORK-stop records follow NETWORK-start messages: EXEC-start, NETWORK-start, NETWORK-stop, EXEC-stop.

To nest accounting records for user sessions, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# aaa accounting nested</td>
<td>Nests network accounting records.</td>
</tr>
</tbody>
</table>

Configuring AAA Resource Failure Stop Accounting

To enable resource failure stop accounting, use the following command in global configuration:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# aaa accounting resource method-list stop-failure group server-group</td>
<td>Generates a “stop” record for any calls that do not reach user authentication.</td>
</tr>
</tbody>
</table>

Note Before configuring this feature, the tasks described in the section “Prerequisites for Configuring Accounting” must be performed, and SNMP must be enabled on the network access server. For more information about enabling SNMP on a Cisco router or access server, see the chapter “Configuring SNMP Support” in the Cisco IOS Network Management Configuration Guide.
### Configuring AAA Resource Accounting for Start-Stop Records

To enable full resource accounting for start-stop records, use the following command in global configuration mode:

**Command**

```
Router(config)# aaa accounting resource method-list start-stop group server-group
```

**Purpose**

Supports the ability to send a “start” record at each call setup, followed with a corresponding “stop” record at the call disconnect.

**Note**

Before configuring this feature, the tasks described in the section “Prerequisites for Configuring Accounting” must be performed, and SNMP must be enabled on the network access server. For more information about enabling SNMP on a Cisco router or access server, see the chapter “Configuring SNMP Support” in the *Cisco IOS Network Management Configuration Guide*.

### Configuring AAA Broadcast Accounting

To configure AAA broadcast accounting, use the `aaa accounting` command in global configuration mode. This command has been modified to allow the `broadcast` keyword.

**Command**

```
Router(config)# aaa accounting {system | network | exec | connection | commands level} {default | list-name} {start-stop | stop-only | none} [broadcast] method1 [method2...]
```

**Purpose**

Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that group.

### Configuring Per-DNIS AAA Broadcast Accounting

To configure AAA broadcast accounting per Dialed Number Identification Service (DNIS), use the `aaa dnis map accounting network` command in global configuration mode. This command has been modified to allow the `broadcast` keyword and multiple server groups.

**Command**

```
Router(config)# aaa dnis map dnis-number accounting network [start-stop | stop-only | none] [broadcast] method1 [method2...]
```

**Purpose**

Allows per-DNIS accounting configuration. This command has precedence over the global `aaa accounting` command.

Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that group.
Configuring AAA Session MIB

The following tasks must be performed before configuring the AAA session MIB feature:

- Configure SNMP. For information on SNMP, see the chapter “Configuring SNMP Support” in the Cisco IOS Network Management Configuration Guide.
- Configure AAA.
- Define the RADIUS or TACACS+ server characteristics.

Note: Overusing SNMP can affect the overall system performance; therefore, normal network management performance must be considered when this feature is used.

To configure AAA session MIB, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>aaa session-mib disconnect</code></td>
</tr>
</tbody>
</table>

Establishing a Session with a Router if the AAA Server is Unreachable

To establish a console or telnet session with a router if the AAA server is unreachable, use the following command in Global Configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# <code>no aaa accounting system guarantee-first</code></td>
<td>The <code>aaa accounting system guarantee-first</code> command guarantees system accounting as the first record, which is the default condition. In some situations, users may be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than three minutes. To resolve this problem, the <code>no aaa accounting system guarantee-first</code> command can be used.</td>
</tr>
</tbody>
</table>

Note: Entering the `no aaa accounting system guarantee-first` command is not the only condition by which the console or telnet session can be started. For example, if the Privileged EXEC session is being authenticated by TACACS and the TACACS server is not reachable, then the session cannot start.

## Monitoring Accounting

No specific `show` command exists for either RADIUS or TACACS+ accounting. To obtain accounting records displaying information about users currently logged in, use the following command in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router# <code>show accounting</code></td>
<td>Allows display of the active accountable events on the network and helps collect information in the event of a data loss on the accounting server.</td>
</tr>
</tbody>
</table>

## Troubleshooting Accounting

To troubleshoot accounting information, use the following command in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router# <code>debug aaa accounting</code></td>
<td>Displays information on accountable events as they occur.</td>
</tr>
</tbody>
</table>

## Accounting Attribute-Value Pairs

The network access server monitors the accounting functions defined in either TACACS+ attribute-value (AV) pairs or RADIUS attributes, depending on which security method is implemented.

## Configuration Examples for AAA Accounting

This section contains the following examples:

- Configuring Named Method List: Example
- Configuring AAA Resource Accounting: Example
- Configuring AAA Broadcast Accounting: Example
- Configuring Per-DNIS AAA Broadcast Accounting: Example
- AAA Session MIB: Example
Configuring Named Method List: Example

The following example shows how to configure a Cisco AS5200 (enabled for AAA and communication with a RADIUS security server) in order for AAA services to be provided by the RADIUS server. If the RADIUS server fails to respond, then the local database is queried for authentication and authorization information, and accounting services are handled by a TACACS+ server.

```
aaa new-model
aaa authentication login admins local
aaa authentication ppp dialins group radius local
aaa authorization network blue1 group radius local
aaa accounting network red1 start-stop group radius group tacacs+

username root password ALongPassword
tacacs-server host 172.31.255.0
tacacs-server key goaway
radius-server host 172.16.2.7
radius-server key myRaDiUSpassWoRd

interface group-async 1
group-range 1 16
encapsulation ppp
ppp authentication chap dialins
ppp authorization blue1
ppp accounting red1

line 1 16
autoselect ppp
autoselect during-login
login authentication admins
modem dialin
```

The lines in this sample RADIUS AAA configuration are defined as follows:

- The `aaa new-model` command enables AAA network security services.
- The `aaa authentication login admins local` command defines a method list, “admins”, for login authentication.
- The `aaa authentication ppp dialins group radius local` command defines the authentication method list “dialins”, which specifies that first RADIUS authentication and then (if the RADIUS server does not respond) local authentication is used on serial lines using PPP.
- The `aaa authorization network blue1 group radius local` command defines the network authorization method list named “blue1”, which specifies that RADIUS authorization is used on serial lines using PPP. If the RADIUS server fails to respond, then local network authorization is performed.
- The `aaa accounting network red1 start-stop group radius group tacacs+` command defines the network accounting method list named “red1”, which specifies that RADIUS accounting services (in this case, start and stop records for specific events) are used on serial lines using PPP. If the RADIUS server fails to respond, accounting services are handled by a TACACS+ server.
- The `username` command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The `tacacs-server host` command defines the name of the TACACS+ server host.
- The `tacacs-server key` command defines the shared secret text string between the network access server and the TACACS+ server host.
The `radius-server host` command defines the name of the RADIUS server host.

The `radius-server key` command defines the shared secret text string between the network access server and the RADIUS server host.

The `interface group-async` command selects and defines an asynchronous interface group.

The `group-range` command defines the member asynchronous interfaces in the interface group.

The `encapsulation ppp` command sets PPP as the encapsulation method used on the specified interfaces.

The `ppp authentication chap dialins` command selects Challenge Handshake Authentication Protocol (CHAP) as the method of PPP authentication and applies the “dialins” method list to the specified interfaces.

The `ppp authorization blue1` command applies the blue1 network authorization method list to the specified interfaces.

The `ppp accounting red1` command applies the red1 network accounting method list to the specified interfaces.

The `line` command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.

The `autoselect ppp` command configures the Cisco IOS software to allow a PPP session to start up automatically on these selected lines.

The `autoselect during-login` command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.

The `login authentication admins` command applies the admins method list for login authentication.

The `modem dialin` command configures modems attached to the selected lines to only accept incoming calls.

The `show accounting` command yields the following output for the preceding configuration:

```
Active Accounted actions on tty1, User username2 Priv 1
Task ID 5, Network Accounting record, 00:00:52 Elapsed
  task_id=5 service=ppp protocol=ip address=10.0.0.98
```

Table 4 describes the fields contained in the preceding output.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active Accounted actions on</td>
<td>Terminal line or interface name user with which the user logged in.</td>
</tr>
<tr>
<td>User</td>
<td>User’s ID.</td>
</tr>
<tr>
<td>Priv</td>
<td>User’s privilege level.</td>
</tr>
<tr>
<td>Task ID</td>
<td>Unique identifier for each accounting session.</td>
</tr>
<tr>
<td>Accounting Record</td>
<td>Type of accounting session.</td>
</tr>
<tr>
<td>Elapsed</td>
<td>Length of time (hh:mm:ss) for this session type.</td>
</tr>
<tr>
<td>attribute=value</td>
<td>AV pairs associated with this accounting session.</td>
</tr>
</tbody>
</table>
Configuring AAA Resource Accounting: Example

The following example shows how to configure the resource failure stop accounting and resource accounting for start-stop records functions:

!Enable AAA on your network access server.
aaa new-model
!Enable authentication at login and list the AOL string name to use for login authentication.
aaa authentication login AOL group radius local
!Enable authentication for ppp and list the default method to use for PPP authentication.
aaa authentication ppp default group radius local
!Enable authorization for all exec sessions and list the AOL string name to use for authorization.
aaa authorization exec AOL group radius if-authenticated
!Enable authorization for all network-related service requests and list the default method to use for all network-related authorizations.
aaa authorization network default group radius if-authenticated
!Enable accounting for all exec sessions and list the default method to use for all start-stop accounting services.
aaa accounting exec default start-stop group radius
!Enable accounting for all network-related service requests and list the default method to use for all start-stop accounting services.
aaa accounting network default start-stop group radius
!Enable failure stop accounting.
aaa accounting resource default stop-failure group radius
!Enable resource accounting for start-stop records.
aaa accounting resource default start-stop group radius

Configuring AAA Broadcast Accounting: Example

The following example shows how to turn on broadcast accounting using the global aaa accounting command:
aaa group server radius isp
  server 10.0.0.1
  server 10.0.0.2

aaa group server tacacs+ isp_customer
  server 172.0.0.1

aaa accounting network default start-stop broadcast group isp group isp_customer
radius-server host 10.0.0.1
radius-server host 10.0.0.2
radius-server key key1
tacacs-server host 172.0.0.1 key key2

The broadcast keyword causes “start” and “stop” accounting records for network connections to be sent simultaneously to server 10.0.0.1 in the group isp and to server 172.0.0.1 in the group isp_customer. If server 10.0.0.1 is unavailable, failover to server 10.0.0.2 occurs. If server 172.0.0.1 is unavailable, no failover occurs because backup servers are not configured for the group isp_customer.
Configuring Per-DNIS AAA Broadcast Accounting: Example

The following example shows how to turn on per DNIS broadcast accounting using the global `aaa dnis map accounting network` command:

```
 aaa group server radius isp
   server 10.0.0.1
   server 10.0.0.2

 aaa group server tacacs+ isp_customer
   server 172.0.0.1

 aaa dnis map enable
 aaa dnis map 7777 accounting network start-stop broadcast group isp group isp_customer

 radius-server host 10.0.0.1
 radius-server host 10.0.0.2
 radius-server key key_1
 tacacs-server host 172.0.0.1 key key_2
```

The `broadcast` keyword causes “start” and “stop” accounting records for network connection calls having DNIS number 7777 to be sent simultaneously to server 10.0.0.1 in the group isp and to server 172.0.0.1 in the group isp_customer. If server 10.0.0.1 is unavailable, failover to server 10.0.0.2 occurs. If server 172.0.0.1 is unavailable, no failover occurs because backup servers are not configured for the group isp_customer.

AAA Session MIB: Example

The following example shows how to set up the AAA session MIB feature to disconnect authenticated client connections for PPP users:

```
 aaa new-model
 aaa authentication ppp default group radius
 aaa authorization network default group radius
 aaa accounting network default start-stop group radius
 aaa session-mib disconnect
```
Feature Information for Configuring Accounting

Table 5 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Releases 12.2(1) or 12.0(3)S or a later release appear in the table.

Not all commands may be available in the Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 5 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 5: Feature Information for Configuring Accounting

This chapter describes the Remote Authentication Dial-In User Service (RADIUS) security system, defines its operation, and identifies appropriate and inappropriate network environments for using RADIUS technology. The “RADIUS Configuration Task List” section describes how to configure RADIUS with the authentication, authorization, and accounting (AAA) command set.

For a complete description of the RADIUS commands used in this chapter, refer to the chapter “RADIUS Commands” in the Cisco IOS Security Command Reference. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the “Identifying Supported Platforms” section in the “Using Cisco IOS Software” chapter.

In This Chapter

This chapter includes the following sections:

- About RADIUS
- RADIUS Operation
- RADIUS Configuration Task List
- Monitoring and Maintaining RADIUS
- RADIUS Attributes
- RADIUS Configuration Examples
About RADIUS

RADIUS is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

RADIUS is a fully open protocol, distributed in source code format, that can be modified to work with any security system currently available on the market.

Cisco supports RADIUS under its AAA security paradigm. RADIUS can be used with other AAA security protocols, such as TACACS+, Kerberos, and local username lookup. RADIUS is supported on all Cisco platforms, but some RADIUS-supported features run only on specified platforms.

RADIUS has been implemented in a variety of network environments that require high levels of security while maintaining network access for remote users.

Use RADIUS in the following network environments that require access security:

- Networks with multiple-vendor access servers, each supporting RADIUS. For example, access servers from several vendors use a single RADIUS server-based security database. In an IP-based network with multiple vendors’ access servers, dial-in users are authenticated through a RADIUS server that has been customized to work with the Kerberos security system.

- Turnkey network security environments in which applications support the RADIUS protocol, such as in an access environment that uses a “smart card” access control system. In one case, RADIUS has been used with Enigma’s security cards to validate users and grant access to network resources.

- Networks already using RADIUS. You can add a Cisco router with RADIUS to the network. This might be the first step when you make a transition to a Terminal Access Controller Access Control System Plus (TACACS+) server.

- Networks in which a user must only access a single service. Using RADIUS, you can control user access to a single host, to a single utility such as Telnet, or to a single protocol such as Point-to-Point Protocol (PPP). For example, when a user logs in, RADIUS identifies this user as having authorization to run PPP using IP address 10.2.3.4 and the defined access list is started.

- Networks that require resource accounting. You can use RADIUS accounting independent of RADIUS authentication or authorization. The RADIUS accounting functions allow data to be sent at the start and end of services, indicating the amount of resources (such as time, packets, bytes, and so on) used during the session. An Internet service provider (ISP) might use a freeware-based version of RADIUS access control and accounting software to meet special security and billing needs.

- Networks that wish to support preauthentication. Using the RADIUS server in your network, you can configure AAA preauthentication and set up the preauthentication profiles. Preauthentication enables service providers to better manage ports using their existing RADIUS solutions, and to efficiently manage the use of shared resources to offer differing service-level agreements.

RADIUS is not suitable in the following network security situations:

- Multiprotocol access environments. RADIUS does not support the following protocols:
  - AppleTalk Remote Access (ARA)
  - NetBIOS Frame Control Protocol (NBFCP)
  - NetWare Asynchronous Services Interface (NASI)
  - X.25 PAD connections
Router-to-router situations. RADIUS does not provide two-way authentication. RADIUS can be used to authenticate from one router to a non-Cisco router if the non-Cisco router requires RADIUS authentication.

Networks using a variety of services. RADIUS generally binds a user to one service model.

**RADIUS Operation**

When a user attempts to log in and authenticate to an access server using RADIUS, the following steps occur:

1. The user is prompted for and enters a username and password.
2. The username and encrypted password are sent over the network to the RADIUS server.
3. The user receives one of the following responses from the RADIUS server:
   a. ACCEPT—The user is authenticated.
   b. REJECT—The user is not authenticated and is prompted to reenter the username and password, or access is denied.
   c. CHALLENGE—A challenge is issued by the RADIUS server. The challenge collects additional data from the user.
   d. CHANGE PASSWORD—A request is issued by the RADIUS server, asking the user to select a new password.

The ACCEPT or REJECT response is bundled with additional data that is used for EXEC or network authorization. You must first complete RADIUS authentication before using RADIUS authorization. The additional data included with the ACCEPT or REJECT packets consists of the following:

- Services that the user can access, including Telnet, rlogin, or local-area transport (LAT) connections, and PPP, Serial Line Internet Protocol (SLIP), or EXEC services.
- Connection parameters, including the host or client IP address, access list, and user timeouts.

**RADIUS Configuration Task List**

To configure RADIUS on your Cisco router or access server, you must perform the following tasks:

- Use the *aaa new-model* global configuration command to enable AAA. AAA must be configured if you plan to use RADIUS. For more information about using the *aaa new-model* command, refer to the “AAA Overview” chapter.

- Use the *aaa authentication* global configuration command to define method lists for RADIUS authentication. For more information about using the *aaa authentication* command, refer to the “Configuring Authentication” chapter.

- Use *line* and *interface* commands to enable the defined method lists to be used. For more information, refer to the “Configuring Authentication” chapter.

The following configuration tasks are optional:

- You may use the *aaa group server* command to group selected RADIUS hosts for specific services. For more information about using the *aaa group server* command, refer to the “Configuring AAA Server Groups” section in this chapter.

- You may use the *aaa dnis map* command to select RADIUS server groups based on DNIS number. To use this command, you must define RADIUS server groups using the *aaa group server* command. For more information about using the *aaa dnis map* command, refer to the section “Configuring AAA Server Group Selection Based on DNIS” in this chapter.

- You may use the *aaa authorization* global command to authorize specific user functions. For more information about using the *aaa authorization* command, refer to the chapter “Configuring Authorization.”

- You may use the *aaa accounting* command to enable accounting for RADIUS connections. For more information about using the *aaa accounting* command, refer to the chapter “Configuring Accounting.”

- You may use the *dialer aaa* interface configuration command to create remote site profiles that contain outgoing call attributes on the AAA server. For more information about using the *dialer aaa* command, refer to the section “Configuring Suffix and Password in RADIUS Access Requests” in this chapter.
This section describes how to set up RADIUS for authentication, authorization, and accounting on your network, and includes the following sections:

- Configuring Router to RADIUS Server Communication (Required)
- Configuring Router to Use Vendor-Specific RADIUS Attributes (Optional)
- Configuring Router for Vendor-Proprietary RADIUS Server Communication (Optional)
- Configuring Router to Query RADIUS Server for Static Routes and IP Addresses (Optional)
- Configuring Router to Expand Network Access Server Port Information (Optional)
- Configuring AAA Server Groups (Optional)
- Configuring AAA Server Groups with Deadtime (Optional)
- Configuring AAA DNIS Authentication
- Configuring AAA Server Group Selection Based on DNIS (Optional)
- Configuring AAA Preauthentication
- Configuring a Guard Timer
- Specifying RADIUS Authentication
- Specifying RADIUS Authorization (Optional)
- Specifying RADIUS Accounting (Optional)
- Configuring RADIUS Login-IP-Host (Optional)
- Configuring RADIUS Prompt (Optional)
- Configuring Suffix and Password in RADIUS Access Requests (Optional)

For RADIUS configuration examples using the commands in this chapter, refer to the section “RADIUS Configuration Examples” at the end of this chapter.

**Configuring Router to RADIUS Server Communication**

The RADIUS host is normally a multiuser system running RADIUS server software from Cisco (CiscoSecure ACS), Livingston, Merit, Microsoft, or another software provider. Configuring router to RADIUS server communication can have several components:

- Host name or IP address
- Authentication destination port
- Accounting destination port
- Timeout period
- Retransmission value
- Key string

RADIUS security servers are identified on the basis of their host name or IP address, host name and specific UDP port numbers, or IP address and specific UDP port numbers. The combination of the IP address and UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as fail-over backup to the first one. Using this
example, if the first host entry fails to provide accounting services, the network access server will try the second host entry configured on the same device for accounting services. (The RADIUS host entries will be tried in the order they are configured.)

A RADIUS server and a Cisco router use a shared secret text string to encrypt passwords and exchange responses. To configure RADIUS to use the AAA security commands, you must specify the host running the RADIUS server daemon and a secret text (key) string that it shares with the router.

The timeout, retransmission, and encryption key values are configurable globally for all RADIUS servers, on a per-server basis, or in some combination of global and per-server settings. To apply these settings globally to all RADIUS servers communicating with the router, use the three unique global commands: `radius-server timeout`, `radius-server retransmit`, and `radius-server key`. To apply these values on a specific RADIUS server, use the `radius-server host` command.

| Note | You can configure both global and per-server timeout, retransmission, and key value commands simultaneously on the same Cisco network access server. If both global and per-server functions are configured on a router, the per-server timer, retransmission, and key value commands override global timer, retransmission, and key value commands. |

To configure per-server RADIUS server communication, use the following command in global configuration mode:

```
Router(config)# radius-server host {hostname | ip-address} [auth-port port-number] [acct-port port-number] [timeout seconds] [retransmit retries] [key string] [alias {hostname | ip address}]
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>radius-server host</code></td>
<td>Specifies the IP address or host name of the remote RADIUS server host and assign authentication and accounting destination port numbers. Use the <code>auth-port port-number</code> option to configure a specific UDP port on this RADIUS server to be used solely for authentication. Use the <code>acct-port port-number</code> option to configure a specific UDP port on this RADIUS server to be used solely for accounting. Use the <code>alias</code> keyword to configure up to eight multiple IP addresses for use when referring to RADIUS servers.</td>
</tr>
<tr>
<td><code>timeout</code></td>
<td>To configure the network access server to recognize more than one host entry associated with a single IP address, simply repeat this command as many times as necessary, making sure that each UDP port number is different. Set the timeout, retransmit, and encryption key values to use with the specific RADIUS host. If no timeout is set, the global value is used; otherwise, enter a value in the range 1 to 1000. If no retransmit value is set, the global value is used; otherwise enter a value in the range 1 to 1000. If no key string is specified, the global value is used.</td>
</tr>
<tr>
<td><code>key string</code></td>
<td>The key is a text string that must match the encryption key used on the RADIUS server. Always configure the key as the last item in the <code>radius-server host</code> command because the leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks themselves are part of the key.</td>
</tr>
</tbody>
</table>
To configure global communication settings between the router and a RADIUS server, use the following `radius-server` commands in global configuration mode:

### Configuring Router to Use Vendor-Specific RADIUS Attributes

The Internet Engineering Task Force (IETF) draft standard specifies a method for communicating vendor-specific information between the network access server and the RADIUS server by using the vendor-specific attribute (attribute 26). Vendor-specific attributes (VSAs) allow vendors to support their own extended attributes not suitable for general use. The Cisco RADIUS implementation supports one vendor-specific option using the format recommended in the specification. Cisco’s vendor-ID is 9, and the supported option has vendor-type 1, which is named “cisco-avpair.” The value is a string of the following format:

```
protocol : attribute sep value *
```

“Protocol” is a value of the Cisco “protocol” attribute for a particular type of authorization; protocols that can be used include IP, IPX, VPDN, VOIP, SHELL, RSVP, SIP, AIRNET, OUTBOUND. “Attribute” and “value” are an appropriate attribute-value (AV) pair defined in the Cisco TACACS+ specification, and “sep” is “=” for mandatory attributes and “*” for optional attributes. This allows the full set of features available for TACACS+ authorization to also be used for RADIUS.

For example, the following AV pair causes Cisco’s “multiple named ip address pools” feature to be activated during IP authorization (during PPP’s IPCP address assignment):

```
cisco-avpair= "ip:addr-pool=first"
```

If you insert an “*”, the AV pair “ip:addr-pool=first” becomes optional. Note that any AV pair can be made optional.

```
cisco-avpair= "ip:addr-pool*first"
```

The following example shows how to cause a user logging in from a network access server to have immediate access to EXEC commands:

```
cisco-avpair= "shell:priv-lvl=15"
```

Other vendors have their own unique vendor-IDs, options, and associated VSAs. For more information about vendor-IDs and VSAs, refer to RFC 2138, Remote Authentication Dial-In User Service (RADIUS).
To configure the network access server to recognize and use VSAs, use the following command in global configuration mode:

```
Router(config)# radius-server vsa send [accounting | authentication]
```

Enables the network access server to recognize and use VSAs as defined by RADIUS IETF attribute 26.

For a complete list of RADIUS attributes or more information about vendor-specific attribute 26, refer to the appendix “RADIUS Attributes.”

### Configuring Router for Vendor-Proprietary RADIUS Server Communication

Although an Internet Engineering Task Force (IETF) draft standard for RADIUS specifies a method for communicating vendor-proprietary information between the network access server and the RADIUS server, some vendors have extended the RADIUS attribute set in a unique way. Cisco IOS software supports a subset of vendor-proprietary RADIUS attributes.

As mentioned earlier, to configure RADIUS (whether vendor-proprietary or IETF draft-compliant), you must specify the host running the RADIUS server daemon and the secret text string it shares with the Cisco device. You specify the RADIUS host and secret text string by using the `radius-server` commands. To identify that the RADIUS server is using a vendor-proprietary implementation of RADIUS, use the `radius-server host non-standard` command. Vendor-proprietary attributes will not be supported unless you use the `radius-server host non-standard` command.

To specify a vendor-proprietary RADIUS server host and a shared secret text string, use the following commands in global configuration mode:

**Command**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Router(config)# radius-server host (hostname</td>
</tr>
<tr>
<td></td>
<td>Specifies the IP address or host name of the remote RADIUS server host and identifies that it is using a vendor-proprietary implementation of RADIUS.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Router(config)# radius-server key {0 string</td>
</tr>
<tr>
<td></td>
<td>Specifies the shared secret text string used between the router and the vendor-proprietary RADIUS server. The router and the RADIUS server use this text string to encrypt passwords and exchange responses.</td>
</tr>
</tbody>
</table>

### Configuring Router to Query RADIUS Server for Static Routes and IP Addresses

Some vendor-proprietary implementations of RADIUS let the user define static routes and IP pool definitions on the RADIUS server instead of on each individual network access server in the network. Each network access server then queries the RADIUS server for static route and IP pool information.

To have the Cisco router or access server query the RADIUS server for static routes and IP pool definitions when the device first starts up, use the following command in global configuration mode:
Configuring RADIUS

RADIUS Configuration Task List

### Note
Because the `radius-server configure-nas` command is performed when the Cisco router starts up, it will not take effect until you issue a `copy system:running-config nvram:startup-config` command.

Configuring Router to Expand Network Access Server Port Information

There are some situations when PPP or login authentication occurs on an interface different from the interface on which the call itself comes in. For example, in a V.120 ISDN call, login or PPP authentication occurs on a virtual asynchronous interface “ttt” but the call itself occurs on one of the channels of the ISDN interface.

The `radius-server attribute nas-port extended` command configures RADIUS to expand the size of the NAS-Port attribute (RADIUS IETF attribute 5) field to 32 bits. The upper 16 bits of the NAS-Port attribute display the type and number of the controlling interface; the lower 16 bits indicate the interface undergoing authentication.

To display expanded interface information in the NAS-Port attribute field, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config)# radius-server configure-nas</code></td>
<td>Tells the Cisco router or access server to query the RADIUS server for the static routes and IP pool definitions used throughout its domain.</td>
</tr>
<tr>
<td><code>radius-server attribute nas-port format</code></td>
<td>Expands the size of the NAS-Port attribute from 16 to 32 bits to display extended interface information.</td>
</tr>
</tbody>
</table>

This command replaces the `radius-server extended-portnames` command and the `radius-server attribute nas-port extended` command.

On platforms with multiple interfaces (ports) per slot, the Cisco RADIUS implementation will not provide a unique NAS-Port attribute that permits distinguishing between the interfaces. For example, if a dual PRI interface is in slot 1, calls on both Serial1/0:1 and Serial1/1:1 will appear as NAS-Port = 20101.

Once again, this is because of the 16-bit field size limitation associated with RADIUS IETF NAS-Port attribute. In this case, the solution is to replace the NAS-Port attribute with a vendor-specific attribute (RADIUS IETF attribute 26). Cisco’s vendor-ID is 9, and the Cisco-NAS-Port attribute is subtype 2. Vendor-specific attributes (VSAs) can be turned on by entering the `radius-server vsa send` command. The port information in this attribute is provided and configured using the `aaa nas port extended` command.

To replace the NAS-Port attribute with RADIUS IETF attribute 26 and to display extended field information, use the following commands in global configuration mode:
The standard NAS-Port attribute (RADIUS IETF attribute 5) will continue to be sent. If you do not want this information to be sent, you can suppress it by using the `no radius-server attribute nas-port` command. When this command is configured, the standard NAS-Port attribute will no longer be sent.

For a complete list of RADIUS attributes, refer to the appendix “RADIUS Attributes.”

For information about configuring RADIUS port identification for PPP, see the *Cisco IOS Wide-Area Networking Configuration Guide*.

### Configuring AAA Server Groups

Configuring the router to use AAA server groups provides a way to group existing server hosts. This allows you to select a subset of the configured server hosts and use them for a particular service. A server group is used in conjunction with a global server-host list. The server group lists the IP addresses of the selected server hosts.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as failover backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server will try the second host entry configured on the same device for accounting services. (The RADIUS host entries will be tried in the order in which they are configured.)

To define a server host with a server group name, enter the following commands in global configuration mode. The listed server must exist in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Router(config)# radius-server host (hostname</td>
</tr>
</tbody>
</table>
Configuring AAA Server Groups with Deadtime

After you have configured a server host with a server name, you can use the `deadtime` command to configure each server per server group. Configuring deadtime within a server group allows you to direct AAA traffic to separate groups of servers that have different operational characteristics.

Configuring deadtime is no longer limited to a global configuration. A separate timer has been attached to each server host in every server group. Therefore, when a server is found to be unresponsive after numerous retransmissions and timeout, the server is assumed to be dead. The timers attached to each server host in all server groups are triggered. In essence, the timers are checked and subsequent requests to a server (once it is assumed to be dead) are directed to alternate timers, if configured. When the network access server receives a reply from the server, it checks and stops all configured timers (if running) for that server in all server groups.

If the timer has expired, only the server to which the timer is attached is assumed to be alive. This becomes the only server that can be tried for later AAA requests using the server groups to which the timer belongs.

Note: Since one server has different timers and may have different deadtime values configured in the server groups, the same server may in the future have different states (dead and alive) at the same time.

Note: To change the state of a server, you must start and stop all configured timers in all server groups.

The size of the server group will be slightly increased because of the addition of new timers and the deadtime attribute. The overall impact of the structure depends on the number and size of the server groups and how the servers are shared among server groups in a specific configuration.

To configure deadtime within a server group, use the following commands beginning in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 2</td>
<td>Router(config-if)# aaa group server (radius</td>
</tr>
<tr>
<td></td>
<td>tacacs+) group-name</td>
</tr>
<tr>
<td>Step 3</td>
<td>Router(config-sg)# server ip-address</td>
</tr>
<tr>
<td></td>
<td>[auth-port port-number] [acct-port port-number]</td>
</tr>
<tr>
<td></td>
<td>Note Each server in the group must be defined previously using the <code>radius-server host</code> command.</td>
</tr>
</tbody>
</table>
RADIUS Configuration Task List

## Configuring RADIUS

### DNIS preauthentication enables preauthentication at call setup based on the number dialed. The DNIS number is sent directly to the security server when a call is received. If authenticated by AAA, the call is accepted.

To configure DNIS authentication, perform the following tasks in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config)# aaa group server radius group1</code></td>
<td>Defines a RADIUS type server group.</td>
</tr>
<tr>
<td><code>Router(config-sg)# deadtime 1</code></td>
<td>Configures and defines deadtime value in minutes. <strong>Note</strong> Local server group deadtime will override the global configuration. If omitted from the local server group configuration, the value will be inherited from the master list.</td>
</tr>
<tr>
<td><code>Router(config-sg)# exit</code></td>
<td>Exits server group configuration mode.</td>
</tr>
</tbody>
</table>

### Configuring AAA DNIS Authentication

DNIS preauthentication enables preauthentication at call setup based on the number dialed. The DNIS number is sent directly to the security server when a call is received. If authenticated by AAA, the call is accepted.

To configure DNIS authentication, perform the following tasks in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router# config term</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><code>Router(config)# aaa preauth</code></td>
<td>Enters AAA preauthentication mode.</td>
</tr>
<tr>
<td>`Router(config-preauth)# group (radius</td>
<td>tacacs+</td>
</tr>
<tr>
<td><code>Router(config-preauth)# dnis [password string]</code></td>
<td>Enables preauthentication using DNIS and optionally specifies a password to use in Access-Request packets.</td>
</tr>
</tbody>
</table>

### Configuring AAA Server Group Selection Based on DNIS

Cisco IOS software allows you to assign a Dialed Number Identification Service (DNIS) number to a particular AAA server group so that the server group can process authentication, authorization, and accounting requests for users dialing in to the network using that particular DNIS. Any phone line (a regular home phone or a commercial T1/PRI line) can be associated with several phone numbers. The DNIS number identifies the number that was called to reach you.

For example, suppose you want to share the same phone number with several customers, but you want to know which customer is calling before you pick up the phone. You can customize how you answer the phone because DNIS allows you to know which customer is calling when you answer.

Cisco routers with either ISDN or internal modems can receive the DNIS number. This functionality allows users to assign different RADIUS server groups for different customers (that is, different RADIUS servers for different DNIS numbers). Additionally, using server groups you can specify the same server group for AAA services or a separate server group for each AAA service.
Cisco IOS software provides the flexibility to implement authentication and accounting services in several ways:

- Globally—AAA services are defined using global configuration access list commands and applied in general to all interfaces on a specific network access server.
- Per Interface—AAA services are defined using interface configuration commands and applied specifically to the interface being configured on a specific network access server.
- DNIS mapping—You can use DNIS to specify an AAA server to supply AAA services.

Because each of these AAA configuration methods can be configured simultaneously, Cisco has established an order of precedence to determine which server or groups of servers provide AAA services. The order of precedence is as follows:

- Per DNIS—if you configure the network access server to use DNIS to identify/determine which server group provides AAA services, then this method takes precedence over any additional AAA selection method.
- Per interface—if you configure the network access server per interface to use access lists to determine how a server provides AAA services, this method takes precedence over any global configuration AAA access lists.
- Globally—if you configure the network access server by using global AAA access lists to determine how the security server provides AAA services, this method has the least precedence.

Prior to configuring AAA Server Group Selection Based on DNIS, you must configure the list of RADIUS server hosts and configure the AAA server groups. See the sections “Configuring Router to RADIUS Server Communication” and “Configuring AAA Server Groups” of this chapter.

To configure the router to select a particular AAA server group based on the DNIS of the server group, configure DNIS mapping. To map a server group with a group name with DNIS number, use the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong>&lt;br&gt;Router(config)# aaa dnis map enable</td>
<td>Enables DNIS mapping.</td>
</tr>
<tr>
<td><strong>Step 2</strong>&lt;br&gt;Router(config)# aaa dnis map dnis-number authentication ppp group server-group-name</td>
<td>Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for authentication.</td>
</tr>
<tr>
<td><strong>Step 3</strong>&lt;br&gt;Router(config)# aaa dnis map dnis-number authorization network group server-group-name</td>
<td>Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for authorization.</td>
</tr>
<tr>
<td><strong>Step 4</strong>&lt;br&gt;Router(config)# aaa dnis map dnis-number accounting network [none</td>
<td>start-stop</td>
</tr>
</tbody>
</table>
Configuring AAA Preauthentication

Configuring AAA preauthentication with ISDN PRI or channel-associated signalling (CAS) allows service providers to better manage ports using their existing RADIUS solutions and efficiently manage the use of shared resources to offer differing service-level agreements. With ISDN PRI or CAS, information about an incoming call is available to the network access server (NAS) before the call is connected. The available call information includes the following:

- The Dialed Number Identification Service (DNIS) number, also referred to as the called number
- The Calling Line Identification (CLID) number, also referred to as the calling number
- The call type, also referred to as the bearer capability

This feature allows a Cisco NAS to decide—on the basis of the DNIS number, the CLID number, or the call type—whether to connect an incoming call. (With ISDN PRI, it enables user authentication and authorization before a call is answered. With CAS, the call must be answered; however, the call can be dropped if preauthentication fails.)

When an incoming call arrives from the public network switch, but before it is connected, AAA preauthentication enables the NAS to send the DNIS number, CLID number, and call type to a RADIUS server for authorization. If the server authorizes the call, then the NAS accepts the call. If the server does not authorize the call, then the NAS sends a disconnect message to the public network switch to reject the call.

In the event that the RADIUS server application becomes unavailable or is slow to respond, a guard timer can be set in the NAS. When the timer expires, the NAS uses a configurable parameter to accept or reject the incoming call that has no authorization.

This feature supports the use of attribute 44 by the RADIUS server application and the use of RADIUS attributes that are configured in the RADIUS preauthentication profiles to specify preauthentication behavior. They may also be used, for instance, to specify whether subsequent authentication should occur and, if so, what authentication method should be used.

The following restrictions apply to AAA preauthentication with ISDN PRI and CAS:

- Attribute 44 is available for CAS calls only when preauthentication or resource pooling is enabled.
- MMP is not available with ISDN PRI.
- AAA preauthentication is available only on the Cisco AS5300, Cisco AS5400, and Cisco AS5800 platforms.

Note

Prior to configuring AAA preauthentication, you must enable the `aaa new-model` command and make sure the supporting preauthentication application is running on a RADIUS server in your network.

To configure AAA preauthentication, use the following commands beginning in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>aaa preauth</code> Enters AAA preauthentication configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td><code>group server-group</code> Specifies the AAA RADIUS server group to use for preauthentication.</td>
</tr>
<tr>
<td>Step 3</td>
<td>`clid [if-avail</td>
</tr>
</tbody>
</table>
Configuring RADIUS

RADIUS Configuration Task List

To configure DNIS preauthentication, use the following commands beginning in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 4</td>
<td>Router(config-preauth)# <strong>ctype</strong> [if-avail</td>
</tr>
<tr>
<td>Step 5</td>
<td>Router(config-preauth)# <strong>dnis</strong> [if-avail</td>
</tr>
<tr>
<td>Step 6</td>
<td>Router(config-preauth)# <strong>dnis bypass</strong> (dnis-group-name) Specifies a group of DNIS numbers that will be bypassed for preauthentication.</td>
</tr>
</tbody>
</table>

To set up the RADIUS preauthentication profile, use the DNIS or CLID number as the username, and use the password defined in the `dnis` or `clid` command as the password.
Configuring RADIUS

RADIUS Configuration Task List

1. Note
   The preauthentication profile must have “outbound” as the service type because the password is predefined on the NAS. Setting up the preauthentication profile in this manner prevents users from trying to log in to the NAS with the username of the DNIS number, CLID number, or call type and an obvious password. The “outbound” service type is also included in the access-request packet sent to the RADIUS server.

Setting Up the RADIUS Profile for Call Type Preauthentication

To set up the RADIUS preauthentication profile, use the call type string as the username, and use the password defined in the `ctype` command as the password. The following table shows the call type strings that may be used in the preauthentication profile:

<table>
<thead>
<tr>
<th>Call Type String</th>
<th>ISDN Bearer Capabilities</th>
</tr>
</thead>
<tbody>
<tr>
<td>digital</td>
<td>Unrestricted digital, restricted digital.</td>
</tr>
<tr>
<td>speech</td>
<td>Speech, 3.1 kHz audio, 7 kHz audio.</td>
</tr>
<tr>
<td>v.110</td>
<td>Anything with V.110 user information layer.</td>
</tr>
<tr>
<td>v.120</td>
<td>Anything with V.120 user information layer.</td>
</tr>
</tbody>
</table>

Note
   The destination IP address is not required to be returned from the RADIUS server.

Setting Up the RADIUS Profile for Preauthentication Enhancements for Callback

Callback allows remote network users such as telecommuters to dial in to the NAS without being charged. When callback is required, the NAS hangs up the current call and dials the caller back. When the NAS performs the callback, only information for the outgoing connection is applied. The rest of the attributes from the preauthentication access-accept message are discarded.

The following example shows a RADIUS profile configuration with a callback number of 555-1111 and the service type set to outbound. The `cisco-avpair = "preauth:send-name=<string>"` uses the string “andy” and the `cisco-avpair = "preauth:send-secret=<string>"` uses the password “cisco.”

```
5551111 password = "cisco", Service-Type = Outbound
  Service-Type = Callback-Framed
  Framed-Protocol = PPP,
  Dialback-No = "5551212"
  Class = "ISP12"
  cisco-avpair = "preauth:send-name=andy"
```
cisco-avpair = "preauth:send-secret=cisco"

**Setting Up the RADIUS Profile for a Remote Host Name Used for Large-Scale Dial-Out**

The following example adds to the previous example by protecting against accidentally calling a valid telephone number but accessing the wrong router by providing the name of the remote, for use in large-scale dial-out:

```
5551111 password = "cisco", Service-Type = Outbound
    Service-Type = Callback-Framed
    Framed-Protocol = PPP,
    Dialback-No = "5551212"
    Class = 'ISP12'
    cisco-avpair = "preauth:send-name=andy"
    cisco-avpair = "preauth:send-secret=cisco"
    cisco-avpair = "preauth:remote-name=Router2"
```

**Setting Up the RADIUS Profile for Modem Management**

When DNIS, CLID, or call type preauthentication is used, the affirmative response from the RADIUS server may include a modem string for modem management in the NAS through vendor-specific attribute (VSA) 26. The modem management VSA has the following syntax:

```
cisco-avpair = "preauth:modem-service=modem min-speed <x> max-speed <y>
    modulation <z> error-correction <a> compression <b>"
```

The modem management string within the VSA may contain the following:

<table>
<thead>
<tr>
<th>Command</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>min-speed</td>
<td>&lt;300 to 56000&gt;, any</td>
</tr>
<tr>
<td>max-speed</td>
<td>&lt;300 to 56000&gt;, any</td>
</tr>
<tr>
<td>modulation</td>
<td>K56Flex, v22bis, v32bis, v34, v90, any</td>
</tr>
<tr>
<td>error-correction</td>
<td>lapm, mnp4</td>
</tr>
<tr>
<td>compression</td>
<td>mnp5, v42bis</td>
</tr>
</tbody>
</table>

When the modem management string is received from the RADIUS server in the form of a VSA, the information is passed to the Cisco IOS software and applied on a per-call basis. Modem ISDN channel aggregation (MICA) modems provide a control channel through which messages can be sent during the call setup time. Hence, this modem management feature is supported only with MICA modems and newer technologies. This feature is not supported with Microcom modems.

For more information on modem management, refer to the “Modem Configuration and Management” chapter of the *Cisco IOS Dial Technologies Configuration Guide*, Release 12.2.

**Setting Up the RADIUS Profile for Subsequent Authentication**

If preauthentication passes, you may use vendor-proprietary RADIUS attribute 201 (Require-Auth) in the preauthentication profile to determine whether subsequent authentication is to be performed. If attribute 201, returned in the access-accept message, has a value of 0, then subsequent authentication will not be performed. If attribute 201 has a value of 1, then subsequent authentication will be performed as usual.
Attribute 201 has the following syntax:

cisco-avpair = "preauth:auth-require=<n>"

where <n> has the same value range as attribute 201 (that is, 0 or 1).

If attribute 201 is missing in the preauthentication profile, then a value of 1 is assumed, and subsequent authentication is performed.

---

**Note**

To perform subsequent authentication, you must set up a regular user profile in addition to a preauthentication profile.

---

### Setting Up the RADIUS Profile for Subsequent Authentication Type

If you have specified subsequent authentication in the preauthentication profile, you must also specify the authentication types to be used for subsequent authentication. To specify the authentication types allowed in subsequent authentication, use the following VSA:

cisco-avpair = "preauth:auth-type=<string>"

where <string> can be one of the following:

<table>
<thead>
<tr>
<th>String</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chap</td>
<td>Requires username and password of CHAP for PPP authentication.</td>
</tr>
<tr>
<td>ms-chap</td>
<td>Requires username and password of MS-CHAP for PPP authentication.</td>
</tr>
<tr>
<td>pap</td>
<td>Requires username and password of PAP for PPP authentication.</td>
</tr>
</tbody>
</table>

To specify that multiple authentication types are allowed, you can configure more than one instance of this VSA in the preauthentication profile. The sequence of the authentication type VSAs in the preauthentication profile is significant because it specifies the order of authentication types to be used in the PPP negotiation.

This VSA is a per-user attribute and replaces the authentication type list in the `ppp authentication` interface command.

---

**Note**

You should use this VSA only if subsequent authentication is required because it specifies the authentication type for subsequent authentication.

---

### Setting Up the RADIUS Profile to Include the Username

If only preauthentication is used to authenticate a call, the NAS could be missing a username when it brings up the call. RADIUS may provide a username for the NAS to use through RADIUS attribute 1 (User-Name) or through a VSA returned in the access-accept packet. The VSA for specifying the username has the following syntax:

cisco-avpair = "preauth:username=<string>"

If no username is specified, the DNIS number, CLID number, or call type is used, depending on the last preauthentication command that has been configured (for example, if `clid` was the last preauthentication command configured, the CLID number will be used as the username).
If subsequent authentication is used to authenticate a call, there might be two usernames: one provided by RADIUS and one provided by the user. In this case, the username provided by the user overrides the one contained in the RADIUS preauthentication profile; the username provided by the user is used for both authentication and accounting.

**Setting Up the RADIUS Profile for Two-Way Authentication**

In the case of two-way authentication, the calling networking device will need to authenticate the NAS. The Password Authentication Protocol (PAP) username and password or Challenge Handshake Authentication Protocol (CHAP) username and password need not be configured locally on the NAS. Instead, username and password can be included in the access-accept messages for preauthentication.

*Note*  
The `ppp authentication` command must be configured with the `radius` method.

To apply for PAP, do not configure the `ppp pap sent-name password` command on the interface. The vendor-specific attributes (VSAs) “preauth:send-name” and “preauth:send-secret” will be used as the PAP username and PAP password for outbound authentication.

For CHAP, “preauth:send-name” will be used not only for outbound authentication, but also for inbound authentication. For a CHAP inbound case, the NAS will use the name defined in “preauth:send-name” in the challenge packet to the caller networking device. For a CHAP outbound case, both “preauth:send-name” and “preauth:send-secret” will be used in the response packet.

The following example shows a configuration that specifies two-way authentication:

```
5551111 password = "cisco", Service-Type = Outbound
   Service-Type = Framed-User
   cisco-avpair = "preauth:auth-required=1"
   cisco-avpair = "preauth:auth-type=pap"
   cisco-avpair = "preauth:send-name=andy"
   cisco-avpair = "preauth:send-secret=cisco"
   class = "<some class>"
```

*Note*  
Two-way authentication does not work when resource pooling is enabled.

**Setting Up the RADIUS Profile to Support Authorization**

If only preauthentication is configured, then subsequent authentication will be bypassed. Note that because the username and password are not available, authorization will also be bypassed. However, you may include authorization attributes in the preauthentication profile to apply per-user attributes and avoid having to return subsequently to RADIUS for authorization. To initiate the authorization process, you must also configure the `aaa authorization network` command on the NAS.

You may configure authorization attributes in the preauthentication profile with one exception: the service-type attribute (attribute 6). The service-type attribute must be converted to a VSA in the preauthentication profile. This VSA has the following syntax:

```
cisco-avpair = "preauth:service-type=<n>"
```

where `<n>` is one of the standard RFC 2138 values for attribute 6. For a list of possible Service-Type values, refer to the appendix RADIUS Attributes.
Configuring RADIUS

Configuring a Guard Timer

Because response times for preauthentication and authentication requests can vary, the guard timer allows you to control the handling of calls. The guard timer starts when the DNIS is sent to the RADIUS server. If the NAS does not receive a response from AAA before the guard timer expires, it accepts or rejects the calls on the basis of the configuration of the timer.

To set a guard timer to accept or reject a call in the event that the RADIUS server fails to respond to an authentication or preauthentication request, use one of the following commands in interface configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config-if)# isdn guard-timer milliseconds [on-expiry {accept</td>
<td>reject}]</td>
</tr>
<tr>
<td>Router(control-config)# call guard-timer milliseconds [on-expiry {accept</td>
<td>reject}]</td>
</tr>
</tbody>
</table>

Specifying RADIUS Authentication

After you have identified the RADIUS server and defined the RADIUS authentication key, you must define method lists for RADIUS authentication. Because RADIUS authentication is facilitated through AAA, you must enter the `aaa authentication` command, specifying RADIUS as the authentication method. For more information, refer to the chapter “Configuring Authentication.”

Specifying RADIUS Authorization

AAA authorization lets you set parameters that restrict a user’s access to the network. Authorization using RADIUS provides one method for remote access control, including one-time authorization or authorization for each service, per-user account list and profile, user group support, and support of IP, IPX, ARA, and Telnet. Because RADIUS authorization is facilitated through AAA, you must issue the `aaa authorization` command, specifying RADIUS as the authorization method. For more information, refer to the chapter “Configuring Authorization.”

Specifying RADIUS Accounting

The AAA accounting feature enables you to track the services users are accessing as well as the amount of network resources they are consuming. Because RADIUS accounting is facilitated through AAA, you must issue the `aaa accounting` command, specifying RADIUS as the accounting method. For more information, refer to the chapter “Configuring Accounting.”
Configuring RADIUS Login-IP-Host

To enable the network access server to attempt more than one login host when trying to connect a dial-in user, you can enter as many as three Login-IP-Host entries in the user’s profile on the RADIUS server. The following example shows that three Login-IP-Host instances have been configured for the user *joeuser*, and that TCP-Clear will be used for the connection:

```
joeuser       Password = xyz
             Service-Type = Login,
             Login-Service = TCP-Clear,
             Login-IP-Host = 10.0.0.0,
             Login-IP-Host = 10.2.2.2,
             Login-IP-Host = 10.255.255.255,
             Login-TCP-Port = 23
```

The order in which the hosts are entered is the order in which they are attempted. Use the `ip tcp synwait-time` command to set the number of seconds that the network access server waits before trying to connect to the next host on the list; the default is 30 seconds.

Your RADIUS server might permit more than three Login-IP-Host entries; however, the network access server supports only three hosts in access-accept packets.

Configuring RADIUS Prompt

To control whether user responses to access-challenge packets are echoed to the screen, you can configure the Prompt attribute in the user profile on the RADIUS server. This attribute is included only in access-challenge packets. The following example shows the Prompt attribute set to No-Echo, which prevents the user’s responses from echoing:

```
joeuser Password = xyz
             Service-Type = Login,
             Login-Service = Telnet,
             Prompt = No-Echo,
             Login-IP-Host = 172.31.255.255
```

To allow user responses to echo, set the attribute to Echo. If the Prompt attribute is not included in the user profile, responses are echoed by default.

This attribute overrides the behavior of the `radius-server challenge-noecho` command configured on the access server. For example, if the access server is configured to suppress echoing, but the individual user profile allows echoing, then the user responses are echoed.

**Note**

To use the Prompt attribute, your RADIUS server must be configured to support access-challenge packets.

Configuring Suffix and Password in RADIUS Access Requests

Large-scale dial-out eliminates the need to configure dialer maps on every NAS for every destination. Instead, you can create remote site profiles that contain outgoing call attributes on the AAA server. The profile is downloaded by the NAS when packet traffic requires a call to be placed to a remote site.

You can configure the username in the access-request message to RADIUS. The default suffix of the username, “-out,” is appended to the username. The format for composing the username attribute is IP address plus configured suffix.
To provide username configuration capability for large-scale dial-out, the `dialer aaa` command is implemented with the new `suffix` and `password` keywords.

### Monitoring and Maintaining RADIUS

To monitor and maintain RADIUS, use the following commands in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router# debug radius</code></td>
<td>Displays information associated with RADIUS.</td>
</tr>
<tr>
<td><code>Router# show radius statistics</code></td>
<td>Displays the RADIUS statistics for accounting and authentication packets.</td>
</tr>
</tbody>
</table>

### RADIUS Attributes

The network access server monitors the RADIUS authorization and accounting functions defined by RADIUS attributes in each user-profile. For a list of supported RADIUS attributes, refer to the appendix “RADIUS Attributes.”

This section includes the following sections:
- [Vendor-Proprietary RADIUS Attributes](#)
- [RADIUS Tunnel Attributes](#)

### Vendor-Proprietary RADIUS Attributes

An Internet Engineering Task Force (IETF) draft standard for RADIUS specifies a method for communicating vendor-proprietary information between the network access server and the RADIUS server. Some vendors, nevertheless, have extended the RADIUS attribute set in a unique way. Cisco IOS software supports a subset of vendor-proprietary RADIUS attributes. For a list of supported vendor-proprietary RADIUS attributes, refer to the appendix “RADIUS Attributes.”
RADIUS Tunnel Attributes

RADIUS is a security server authentication, authorization, and accounting (AAA) protocol originally developed by Livingston, Inc. RADIUS uses attribute value (AV) pairs to communicate information between the security server and the network access server. RFC 2138 and RFC 2139 describe the basic functionality of RADIUS and the original set of Internet Engineering Task Force (IETF)-standard AV pairs used to send AAA information. Two draft IETF standards, "RADIUS Attributes for Tunnel Protocol Support" and "RADIUS Accounting Modifications for Tunnel Protocol Support," extend the IETF-defined set of AV pairs to include attributes specific to virtual private networks (VPNs); these attributes are used to carry the tunneling information between the RADIUS server and the tunnel initiator. RFC 2865 and RFC 2868 extend the IETF-defined set of AV pairs to include attributes specific to compulsory tunneling in VPNs by allowing the user to specify authentication names for the network access server and the RADIUS server.

Cisco routers and access servers now support new RADIUS IETF-standard VPDN tunnel attributes. These new RADIUS IETF-standard attributes are listed in the “RADIUS Attributes” appendix. Refer to the following three configuration examples later in this chapter:

- RADIUS User Profile with RADIUS Tunneling Attributes Example
- L2TP Access Concentrator Examples
- L2TP Network Server Examples

For more information about L2F, L2TP, VPN, or VPDN, refer to the Cisco IOS Dial Technologies Configuration Guide, Release 12.2.

RADIUS Configuration Examples

The following sections provide RADIUS configuration examples:

- RADIUS Authentication and Authorization Example
- RADIUS Authentication, Authorization, and Accounting Example
- Vendor-Proprietary RADIUS Configuration Example
- RADIUS Server with Server-Specific Values Example
- Multiple RADIUS Servers with Global and Server-Specific Values Example
- Multiple RADIUS Server Entries for the Same Server IP Address Example
- RADIUS Server Group Examples
- Multiple RADIUS Server Entries Using AAA Server Groups Example
- AAA Server Group Selection Based on DNIS Example
- AAA Preauthentication Examples
- RADIUS User Profile with RADIUS Tunneling Attributes Example
- Guard Timer Examples
- L2TP Access Concentrator Examples
- L2TP Network Server Examples
RADIUS Authentication and Authorization Example

The following example shows how to configure the router to authenticate and authorize using RADIUS:

```
aaa authentication login use-radius group radius local
aaa authentication ppp user-radius if-needed group radius
aaa authorization exec default group radius
aaa authorization network default group radius
```

The lines in this sample RADIUS authentication and authorization configuration are defined as follows:

- **The `aaa authentication login use-radius group radius local` command** configures the router to use RADIUS for authentication at the login prompt. If RADIUS returns an error, the user is authenticated using the local database. In this example, `use-radius` is the name of the method list, which specifies RADIUS and then local authentication.

- **The `aaa authentication ppp user-radius if-needed group radius` command** configures the Cisco IOS software to use RADIUS authentication for lines using PPP with CHAP or PAP if the user has not already been authorized. If the EXEC facility has authenticated the user, RADIUS authentication is not performed. In this example, `user-radius` is the name of the method list defining RADIUS as the if-needed authentication method.

- **The `aaa authorization exec default group radius` command** sets the RADIUS information that is used for EXEC authorization, autocommands, and access lists.

- **The `aaa authorization network default group radius` command** sets RADIUS for network authorization, address assignment, and access lists.

RADIUS Authentication, Authorization, and Accounting Example

The following example shows a general configuration using RADIUS with the AAA command set:

```
radius-server host 123.45.1.2
radius-server key myRaDiUSpassWoRd
username root password ALongPassword
aaa authentication ppp dialins group radius local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius
aaa authentication login admins local
aaa authorization exec default local
line 1 16
  autoselect ppp
  autoselect during-login
  login authentication admins
  modem ri-is-cd
interface group-async 1
  encaps ppp
  ppp authentication pap dialins
```

The lines in this example RADIUS authentication, authorization, and accounting configuration are defined as follows:

- **The `radius-server host` command** defines the IP address of the RADIUS server host.

- **The `radius-server key` command** defines the shared secret text string between the network access server and the RADIUS server host.

- **The `aaa authentication ppp dialins group radius local` command** defines the authentication method list “dialins,” which specifies that RADIUS authentication and then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
The **ppp authentication pap dialins** command applies the “dialins” method list to the lines specified.

- **The aaa authorization network default group radius local** command is used to assign an address and other network parameters to the RADIUS user.
- **The aaa accounting network default start-stop group radius** command tracks PPP usage.
- **The aaa authentication login admins local** command defines another method list, “admins,” for login authentication.
- **The login authentication admins** command applies the “admins” method list for login authentication.

### Vendor-Proprietary RADIUS Configuration Example

The following example shows a general configuration using vendor-proprietary RADIUS with the AAA command set:

```plaintext
radius-server host alcatraz non-standard
radius-server key myRaDiUSpassWoRd
radius-server configure-nas
username root password ALongPassword
aaa authentication ppp dialins group radius local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius
aaa authentication login admins local
aaa authorization exec default local
line 1 16
autoselect ppp
autoselect during-login
login authentication admins
modem ri-is-cd
interface group-async 1
encaps ppp
ppp authentication pap dialins
```

The lines in this example RADIUS authentication, authorization, and accounting configuration are defined as follows:

- **The radius-server host non-standard** command defines the name of the RADIUS server host and identifies that this RADIUS host uses a vendor-proprietary version of RADIUS.
- **The radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- **The radius-server configure-nas** command defines that the Cisco router or access server will query the RADIUS server for static routes and IP pool definitions when the device first starts up.
- **The aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins,” which specifies that RADIUS authentication, and then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
- **The ppp authentication pap dialins** command applies the “dialins” method list to the lines specified.
- **The aaa authorization network default group radius local** command is used to assign an address and other network parameters to the RADIUS user.
- **The aaa accounting network default start-stop group radius** command tracks PPP usage.
• The **aaa authentication login admins local** command defines another method list, “admins,” for login authentication.

• The **login authentication admins** command applies the “admins” method list for login authentication.

### RADIUS Server with Server-Specific Values Example

The following example shows how to configure server-specific timeout, retransmit, and key values for the RADIUS server with IP address 172.31.39.46:

```
radius-server host 172.31.39.46 timeout 6 retransmit 5 key rad123
```

### Multiple RADIUS Servers with Global and Server-Specific Values Example

The following example shows how to configure two RADIUS servers with specific timeout, retransmit, and key values. In this example, the **aaa new-model** command enables AAA services on the router, while specific AAA commands define the AAA services. The **radius-server retransmit** command changes the global retransmission value to 4 for all RADIUS servers. The **radius-server host** command configures specific timeout, retransmission, and key values for the RADIUS server hosts with IP addresses 172.16.1.1 and 172.29.39.46.

```
! Enable AAA services on the router and define those services.
aaa new-model
aaa authentication login default group radius
aaa authentication login console-login none
aaa authentication ppp default group radius
aaa authorization network default group radius
aaa accounting exec default start-stop group radius
aaa accounting network default start-stop group radius
enable password tryit1
!
! Change the global retransmission value for all RADIUS servers.
radius-server retransmit 4
!
! Configure per-server specific timeout, retransmission, and key values.
! Change the default auth-port and acct-port values.
radius-server host 172.16.1.1 auth-port 1612 acct-port 1616 timeout 3 retransmit 3 key radkey
!
! Configure per-server specific timeout and key values. This server uses the global ! retransmission value.
radius-server host 172.29.39.46 timeout 6 key rad123
```

### Multiple RADIUS Server Entries for the Same Server IP Address Example

The following example shows how to configure the network access server to recognize several RADIUS host entries with the same IP address. Two different host entries on the same RADIUS server are configured for the same services—authentication and accounting. The second host entry configured acts as fail-over backup to the first one. (The RADIUS host entries will be tried in the order they are configured.)

```
! This command enables AAA.
aaa new-model
! The next command configures default RADIUS parameters.
aaa authentication ppp default group radius
```
! The next set of commands configures multiple host entries for the same IP address.
radius-server host 172.20.0.1 auth-port 1000 acct-port 1001
radius-server host 172.20.0.1 auth-port 2000 acct-port 2000

RADIUS Server Group Examples

The following example shows how to create server group radgroup1 with three different RADIUS server members, each using the default authentication port (1645) and accounting port (1646):

aaa group server radius radgroup1
server 172.16.1.11
server 172.17.1.21
server 172.18.1.31

The following example shows how to create server group radgroup2 with three RADIUS server members, each with the same IP address but with unique authentication and accounting ports:

aaa group server radius radgroup2
server 172.16.1.1 auth-port 1000 acct-port 1001
server 172.16.1.1 auth-port 2000 acct-port 2001
server 172.16.1.1 auth-port 3000 acct-port 3001

Multiple RADIUS Server Entries Using AAA Server Groups Example

The following example shows how to configure the network access server to recognize two different RADIUS server groups. One of these groups, group1, has two different host entries on the same RADIUS server configured for the same services. The second host entry configured acts as failover backup to the first one. Each group is individually configured for deadtime; deadtime for group 1 is one minute, and deadtime for group 2 is two minutes.

Note

In cases where both global commands and server commands are used, the server command will take precedence over the global command.

! This command enables AAA.
aaa new-model
! The next command configures default RADIUS parameters.
aaa authentication ppp default group group1
! The following commands define the group1 RADIUS server group and associate servers
! with it and configures a deadtime of one minute.
aaa group server radius group1
server 1.1.1.1 auth-port 1645 acct-port 1646
server 2.2.2.2 auth-port 2000 acct-port 2001
deadtime 1
! The following commands define the group2 RADIUS server group and associate servers
! with it and configures a deadtime of two minutes.
aaa group server radius group2
server 2.2.2.2 auth-port 2000 acct-port 2001
server 3.3.3.3 auth-port 1645 acct-port 1646
deadtime 2
! The following set of commands configures the RADIUS attributes for each host entry
! associated with one of the defined server groups.
radius-server host 1.1.1.1 auth-port 1645 acct-port 1646
radius-server host 2.2.2.2 auth-port 2000 acct-port 2001
radius-server host 3.3.3.3 auth-port 1645 acct-port 1646
AAA Server Group Selection Based on DNIS Example

The following example shows how to select RADIUS server groups based on DNIS to provide specific AAA services:

```plaintext
! This command enables AAA.
aaa new-model
!
! The following set of commands configures the RADIUS attributes for each server
! that will be associated with one of the defined server groups.
radius-server host 172.16.0.1 auth-port 1645 acct-port 1646 key cisco1
radius-server host 172.17.0.1 auth-port 1645 acct-port 1646 key cisco2
radius-server host 172.18.0.1 auth-port 1645 acct-port 1646 key cisco3
radius-server host 172.19.0.1 auth-port 1645 acct-port 1646 key cisco4
radius-server host 172.20.0.1 auth-port 1645 acct-port 1646 key cisco5
!
! The following commands define the sg1 RADIUS server group and associate servers
! with it.
aaa group server radius sg1
  server 172.16.0.1
  server 172.17.0.1
!
! The following commands define the sg2 RADIUS server group and associate a server
! with it.
aaa group server radius sg2
  server 172.18.0.1
!
! The following commands define the sg3 RADIUS server group and associate a server
! with it.
aaa group server radius sg3
  server 172.19.0.1
!
! The following commands define the default-group RADIUS server group and associate
! a server with it.
aaa group server radius default-group
  server 172.20.0.1
!
! The next set of commands configures default-group RADIUS server group parameters.
aaa authentication ppp default group default-group
aaa accounting network default start-stop group default-group
!"
The next set of commands enables DNIS mapping and maps DNIS numbers to the defined RADIUS server groups. In this configuration, all PPP connection requests using DNIS 7777 are sent to the sg1 server group. The accounting records for these connections (specifically, start-stop records) are handled by the sg2 server group. Calls with a DNIS of 8888 use server group sg3 for authentication and server group default-group for accounting. Calls with a DNIS of 9999 use server group default-group for authentication and server group sg3 for accounting records. (stop records only). All other calls with DNIS other than the ones defined use the server group default-group for both authentication and stop-start accounting records.

```
aaa dnis map enable
aaa dnis map 7777 authentication ppp group sg1
aaa dnis map 7777 accounting network start-stop group sg2
aaa dnis map 8888 authentication ppp group sg3
aaa dnis map 9999 accounting network stop-only group sg3
```

### AAA Preauthentication Examples

The following example shows a simple configuration that specifies that the DNIS number be used for preauthentication:

```
aaa preauth
group radius
dnis required
```

The following example shows a configuration that specifies that both the DNIS number and the CLID number be used for preauthentication. DNIS preauthentication will be performed first, followed by CLID preauthentication.

```
aaa preauth
group radius
dnis required
clid required
```

The following example specifies that preauthentication be performed on all DNIS numbers except the two DNIS numbers specified in the DNIS group called “hawaii”:

```
aaa preauth
group radius
dnis required
dnis bypass hawaii

dialer dnis group hawaii
  number 12345
  number 12346
```

The following example shows a sample AAA configuration with DNIS preauthentication:

```
aaa new-model
aaa authentication login CONSOLE none
aaa authentication login RADIUS_LIST group radius
aaa authentication login TAC_PLUS group tacacs+ enable
aaa authentication login V.120 none
aaa authentication enable default enable group tacacs+
aaa authentication ppp RADIUS_LIST if-needed group radius
aaa authorization exec RADIUS_LIST group radius if-authenticated
aaa authorization exec V.120 none
aaa authorization network default group radius if-authenticated
aaa authorization network RADIUS_LIST if-authenticated group radius
aaa authorization network V.120 group radius if-authenticated
aaa accounting suppress null-username
aaa accounting exec default start-stop group radius
aaa accounting commands 0 default start-stop group radius
```
aaa accounting network default start-stop group radius
aaa accounting connection default start-stop group radius
aaa accounting system default start-stop group radius
aaa preauth
dnis password Cisco-DNIS
aaa nas port extended
!radius-server configure-nas
radius-server host 10.0.0.0 auth-port 1645 acct-port 1646 non-standard
radius-server host 10.255.255.255 auth-port 1645 acct-port 1646 non-standard
radius-server retransmit 2
radius-server deadtime 1
radius-server attribute nas-port format c
radius-server unique-ident 18
radius-server key MyKey

Note
To configure preauthentication, you must also set up preauthentication profiles on the RADIUS server.

RADIUS User Profile with RADIUS Tunneling Attributes Example

The following example shows a RADIUS user profile (Merit Daemon format) that includes RADIUS tunneling attributes. This entry supports two tunnels, one for L2F and the other for L2TP. The tag entries with :1 support L2F tunnels, and the tag entries with :2 support L2TP tunnels.
cisco.com Password = "cisco", Service-Type = Outbound,
Service-Type = Outbound,
Tunnel-Type = :1:L2F,
Tunnel-Medium-Type = :1:IP,
Tunnel-Client-Endpoint = :1:"10.0.0.2",
Tunnel-Server-Endpoint = :1:"10.0.0.3",
Tunnel-Client-Auth-Id = :1:"l2f-cli-auth-id",
Tunnel-Server-Auth-Id = :1:"l2f-svr-auth-id",
Tunnel-Assignment-Id = :1:"l2f-assignment-id",
Cisco-Avpair = "vpdn:nas-password=l2f-cli-pass",
Cisco-Avpair = "vpdn:gw-password=l2f-svr-pass",
Tunnel-Preference = :1:1,
Tunnel-Type = :2:L2TP,
Tunnel-Medium-Type = :2:IP,
Tunnel-Client-Endpoint = :2:"10.0.0.2",
Tunnel-Server-Endpoint = :2:"10.0.0.3",
Tunnel-Client-Auth-Id = :2:"l2tp-cli-auth-id",
Tunnel-Server-Auth-Id = :2:"l2tp-svr-auth-id",
Tunnel-Assignment-Id = :2:"l2tp-assignment-id",
Cisco-Avpair = "vpdn:l2tp-tunnel-password=l2tp-tnl-pass",
Tunnel-Preference = :2:2

Guard Timer Examples

The following example shows an ISDN guard timer that is set at 8000 milliseconds. A call will be rejected if the RADIUS server has not responded to a preauthentication request when the timer expires.
interface serial1/0/0:23
isdn guard-timer 8000 on-expiry reject
aaa preauth
group radius
dnis required
The following example shows a CAS guard timer that is set at 20,000 milliseconds. A call will be accepted if the RADIUS server has not responded to a preauthentication request when the timer expires.

```
controller T1 0
framing esf
clock source line primary
linecode b8zs
ds0-group 0 timeslots 1-24 type e&m-fgb dtmf dnis
cas-custom 0
call guard-timer 20000 on-expiry accept
```

**aaa preauth**

**group radius**

**dnis required**

---

### L2TP Access Concentrator Examples

The following example shows a basic L2TP configuration for the L2TP access concentrator (LAC) for the topology shown in Figure 12. The local name is not defined, so the host name used is the local name. Because the L2TP tunnel password is not defined, the username password is used. In this example, VPDN is configured locally on the LAC and does not take advantage of the new RADIUS tunnel attributes.

**Figure 12  Topology for Configuration Examples**

<table>
<thead>
<tr>
<th>Dial client</th>
<th>ISP or PSTN</th>
<th>LAC = DJ</th>
<th>Corporate network</th>
<th>LNS = partner</th>
</tr>
</thead>
</table>

! Enable AAA globally.

```
aaa new-model
! Enable AAA authentication for PPP and list the default method to use for PPP
! authentication.
aaa authentication ppp default local
! Define the username as "DJ."
username DJ password 7 030C5E070A00781B
! Enable VPDN.
vpdn enable
! Define VPDN group number 1.
vpdn-group 1
! Allow the LAC to respond to dialin requests using L2TP from IP address 172.21.9.13
! domain "cisco.com."
request dialin
protocol l2tp
domain cisco.com
initiate-ip to 172.21.9.13
local name nas-1
```

The following example shows how to configure the LAC if RADIUS tunnel attributes are supported. In this example, there is no local VPDN configuration on the LAC; the LAC, instead, is configured to query the remote RADIUS security server.

```
! Enable global AAA security services.
aaa new-model
```
### Configuring RADIUS

**RADIUS Configuration Examples**

- Enable AAA authentication for PPP and list RADIUS as the default method to use for PPP authentication.
  ```
  aaa authentication ppp default group radius local
  ```
- Enable AAA (network) authorization and list RADIUS as the default method to use for authorization.
  ```
  aaa authorization network default group radius
  ```
- Define the username as “DJ.”
  ```
  username DJ password 7 030C5E070A00781B
  ```
- Enable VPDN.
  ```
  vpdn enable
  ```
- Configure the LAC to interface with the remote RADIUS security server.
  ```
  radius host 171.69.1.1 auth-port 1645 acct-port 1646
  ```

### L2TP Network Server Examples

The following example shows a basic L2TP configuration with corresponding comments on the L2TP network server (LNS) for the topology shown in [Figure 12:]

- Enable AAA globally.
  ```
  aaa new-model
  ```
- Enable AAA authentication for PPP and list the default method to use for PPP authentication.
  ```
  aaa authentication ppp default local
  ```
- Define the username as “partner.”
  ```
  username partner password 7 030C5E070A00781B
  ```
- Create virtual-template 1 and assign all values for virtual access interfaces.
  ```
  interface Virtual-Template1
  ```
- Borrow the IP address from interface ethernet 1.
  ```
  ip unnumbered Ethernet0
  ```
- Disable multicast fast switching.
  ```
  no ip mroute-cache
  ```
- Use CHAP to authenticate PPP.
  ```
  ppp authentication chap
  ```
- Enable VPDN.
  ```
  vpdn enable
  ```
- Create vpdn-group number 1.
  ```
  vpdn-group 1
  ```
- Accept all dialin l2tp tunnels from virtual-template 1 from remote peer DJ.
  ```
  accept dialin l2tp virtual-template 1 remote DJ
  ```
- Protocol any
  ```
  virtual-template 1
  ```
- Terminate-from hostname nas1
  ```
  local name hgw1
  ```

The following example shows how to configure the LNS with a basic L2F and L2TP configuration using RADIUS tunneling attributes:

```
aaa new-model
aaa authentication login default none
aaa authentication login console none
aaa authentication ppp default local group radius
aaa authorization network default group radius if-authenticated

username l2f-cli-auth-id password 0 l2f-cli-pass
username l2f-svr-auth-id password 0 l2f-svr-pass
username l2tp-svr-auth-id password 0 l2tp-tnl-pass

vpdn enable
vpdn search-order domain

vpdn-group 1
```
accept-dialin
protocol 12f
virtual-template 1
terminate-from hostname 12f-cli-auth-id
local name 12f-svr-auth-id
!
vpdn-group 2
accept-dialin
protocol 12tp
virtual-template 2
terminate-from hostname 12tp-cli-auth-id
local name 12tp-svr-auth-id
!
interface Ethernet1/0
ip address 10.0.0.3 255.255.255.0
no ip route-cache
no ip mroute-cache
!
interface Virtual-Template1
ip unnumbered Ethernet1/0
ppp authentication pap
!
interface Virtual-Template2
ip unnumbered Ethernet1/0
ppp authentication pap
!
radius-server host 1.1.1.1 auth-port 1645 acct-port 1646
radius-server key <deleted>
!

AAA Dead-Server Detection

First Published: February 13, 2004
Last Updated: March 4, 2008

The AAA Dead-Server Detection feature allows you to configure the criteria that are to be used to mark a RADIUS server as dead. If no criteria are explicitly configured, the criteria will be computed dynamically on the basis of the number of outstanding transactions. Using this feature will result in less deadtime and quicker packet processing.

Finding Feature Information in This Module
Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “Feature Information for AAA Dead-Server Detection” section on page 9.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images
Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Contents

- Command Reference, page 8
Prerequisites for AAA Dead-Server Detection

- You must have access to a RADIUS server.
- You should be familiar with configuring a RADIUS server.
- You should be familiar with configuring authentication, authorization, and accounting (AAA).
- Before a server can be marked as dead, you must first configure the `radius-server deadtime` command. If this command is not configured, even if the criteria are met for the server to be marked as dead, the server state will be the “up” state.

Restrictions for AAA Dead-Server Detection

- Original transmissions are not counted in the number of consecutive timeouts that must occur on the router before the server is marked as dead—only the number of retransmissions are counted.

Information About AAA Dead-Server Detection

To configure the AAA Dead-Server Detection feature, you should understand the following concept:

- **Criteria for Marking a RADIUS Server As Dead, page 2**

Criteria for Marking a RADIUS Server As Dead

The AAA Dead-Server Detection feature allows you to determine the criteria that are used to mark a RADIUS server as dead. That is, you can configure the minimum amount of time, in seconds, that must elapse from the time that the router last received a valid packet from the RADIUS server to the time the server is marked as dead. If a packet has not been received since the router booted, and there is a timeout, the time criterion will be treated as though it has been met.

In addition, you can configure the number of consecutive timeouts that must occur on the router before the RADIUS server is marked as dead. If the server performs both authentication and accounting, both types of packets are included in the number. Improperly constructed packets are counted as though they are timeouts. Only retransmissions are counted, not the initial transmission. (Each timeout causes one retransmission to be sent.)

Both the time criterion and the tries criterion must be met for the server to be marked as dead.

The RADIUS dead-server detection configuration will result in the prompt detection of RADIUS servers that have stopped responding. This configuration will also result in the avoidance of servers being improperly marked as dead when they are “swamped” (responding slowly) and the avoidance of the state of servers being rapidly changed from dead to live to dead again. This prompt detection of nonresponding RADIUS servers and the avoidance of swamped and dead-to-live-to-dead-again servers will result in less deadtime and quicker packet processing.
How to Configure AAA Dead-Server Detection

This section contains the following procedures:

- Configuring AAA Dead-Server Detection, page 3 (required)
- Verifying AAA Dead-Server Detection, page 4 (optional)

Configuring AAA Dead-Server Detection

To configure AAA Dead-Server Detection, perform the following steps.

SUMMARY STEPS

1. enable
2. configure terminal
3. aaa new-model
4. radius-server deadtime minutes
5. radius-server dead-criteria [time seconds] [tries number-of-tries]
### Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> aaa new-model</td>
<td>Enables the AAA access control model.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Router (config)# aaa new-model</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> radius-server deadtime minutes</td>
<td>Improves RADIUS response times when some servers might be unavailable and causes the unavailable servers to be skipped immediately.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>

<tr>
<td>Router (config)# radius-server deadtime 5</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> radius-server dead-criteria [time seconds] [tries number-of-tries]</td>
<td>Forces one or both of the criteria—used to mark a RADIUS server as dead—to be the indicated constant.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Router (config)# radius-server dead-criteria time 5 tries 4</td>
<td></td>
</tr>
</tbody>
</table>

### Troubleshooting Tips

After you have configured AAA Dead-Server Detection, you should verify your configuration using the `show running-config` command. This verification is especially important if you have used the no form of the `radius-server dead-criteria` command. The output of the `show running-config` command must show the same values in the “Dead Criteria Details” field that you configured using the `radius-server dead-criteria` command.

### Verifying AAA Dead-Server Detection

To verify your AAA Dead-Server Detection configuration, perform the following steps. The `show` and `debug` commands may be used in any order.

### Summary Steps

1. enable
2. debug aaa dead-criteria transactions
3. show aaa dead-criteria
4. show aaa servers
**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  • Enter your password if prompted. |
| **Example:**  
  Router> enable | |
| **Step 2** debug aaa dead-criteria transactions | Displays AAA dead-criteria transaction values. |
| **Example:**  
  Router# debug aaa dead-criteria transactions | |
| **Step 3** show aaa dead-criteria | Displays dead-criteria information for a AAA server. |
| **Example:**  
  Router# show aaa dead-criteria | |
| **Step 4** show aaa servers [private | public] | Displays the status and number of packets that are sent to and received from all public and private authentication, authorization, and accounting (AAA) RADIUS servers.  
  • The **private** keyword optionally displays the AAA servers only.  
  • The **public** keyword optionally displays the AAA servers only. |
| **Example:**  
  Router# show aaa server private | |

**Configuration Examples for AAA Dead-Server Detection**

This section provides the following configuration examples:

- Configuring AAA Dead-Server Detection: Example, page 5
- debug aaa dead-criteria transactions Command: Example, page 6
- show aaa dead-criteria Command: Example, page 6

**Configuring AAA Dead-Server Detection: Example**

The following example shows that the router will be considered dead after 5 seconds and four tries:

```
Router (config)# aaa new-model
Router (config)# radius-server deadtime 5
Router (config)# radius-server dead-criteria time 5 tries 4
```
debug aaa dead-criteria transactions Command: Example

The following output example shows dead-criteria transaction information for a particular server group:

Router# debug aaa dead-criteria transactions
AAA Transaction debugs debugging is on

show aaa dead-criteria Command: Example

The following output example shows that dead-server-detection information has been requested for a RADIUS server at the IP address 172.19.192.80:

Router# show aaa dead-criteria radius 172.19.192.80 radius
RADIUS Server Dead Criteria:
=================================
Server Details:
   Address : 172.19.192.80
   Auth Port : 1645
   Acct Port : 1646
Server Group : radius
Dead Criteria Details:
   Configured Retransmits : 62
   Configured Timeout : 27
   Estimated Outstanding Transactions: 5
   Dead Detect Time : 25s
   Computed Retransmit Tries: 22
Statistics Gathered Since Last Successful Transaction
=================================
Max Computed Outstanding Transactions: 5
Max Computed Dead Detect Time: 25s
Max Computed Retransmits : 22

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

- `debug aaa dead-criteria transactions`
- `radius-server dead-criteria`
- `show aaa dead-criteria`
- `show aaa servers`
Feature Information for AAA Dead-Server Detection

Table 15 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Releases 12.2(1) or 12.0(3)S or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Note: Table 15 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Contents

- Prerequisites for ACL Default Direction, page 2
- Information About ACL Default Direction, page 2
- How to Configure ACL Default Direction, page 2
- Configuration Examples for ACL Default Direction, page 4
- Additional References, page 5
- Command Reference, page 7
Prerequisites for ACL Default Direction

Before you can change the default direction of filters from RADIUS, you must perform the following tasks:

- Configure your network access server (NAS) for authentication, authorization, and accounting (AAA) and to accept incoming calls.
  

- Create a filter on your NAS.
  
  For more information, refer to the section “Configuring IP Services” section of the chapter IP Addressing and Services of the *Cisco IOS IP Addressing Services Configuration Guide*, Release 12.4.

- Add a filter definition for a RADIUS user; for example, Filter-Id = “myfilter”.

Information About ACL Default Direction

Before changing the default direction of filters for your access control lists (ACLs) from RADIUS, you should understand the following concepts:

- The radius-server attribute 11 direction default Command, page 2
- Benefits of ACL Default Direction, page 2

The radius-server attribute 11 direction default Command

The *radius-server attribute 11 direction default* command allows you to change the default direction of filters for your ACLs via RADIUS. (RADIUS attribute 11 (Filter-Id) indicates the name of the filter list for the user.) Enabling this command allows you to change the filter direction to inbound—which stops traffic from entering a router, and reduces resource consumption—rather than keeping the outbound default direction, where filtering occurs only as the traffic is about to leave the network.

Benefits of ACL Default Direction

The ACL Default Direction feature allows you to change the default direction, which is outbound, of filters for your ACLs to inbound via the *radius-server attribute 11 direction default* command.

How to Configure ACL Default Direction

This section contains the following procedures:

- Configuring the ACL Default Direction from RADIUS via Attribute 11 (Filter-Id), page 3 (required)
- Verifying the ACL Default Direction from RADIUS via Attribute 11 (Filter-Id), page 3 (optional)
Configuring the ACL Default Direction from RADIUS via Attribute 11 (Filter-Id)

To configure the default direction of filters from RADIUS via attribute 11, perform the following steps.

SUMMARY STEPS

1. enable
2. configure terminal
3. radius-server attribute 11 direction default [inbound | outbound]

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router&gt; enable</td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router# configure terminal</td>
</tr>
<tr>
<td>Step 3 radius-server attribute 11 direction default [inbound</td>
<td>outbound]</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config)# radius-server attribute 11 direction default inbound</td>
</tr>
</tbody>
</table>

Verifying the ACL Default Direction from RADIUS via Attribute 11 (Filter-Id)

To verify the default direction of filters from RADIUS and to verify that RADIUS attribute 11 is being sent in access accept requests, perform the following steps.

SUMMARY STEPS

1. enable
2. more system:running-config
3. debug radius
**Configuration Examples for ACL Default Direction**

This section provides the following configuration examples:

- Default Direction of Filters via RADIUS Attribute 11 (Filter-Id): Example, page 4
- RADIUS User Profile with Filter-Id: Example, page 4

### Default Direction of Filters via RADIUS Attribute 11 (Filter-Id): Example

The following example shows how to configure RADIUS attribute 11 to change the default direction of filters. In this example, the filtering is applied to inbound packets only.

```
radius-server attribute 11 direction default inbound
```

### RADIUS User Profile with Filter-Id: Example

The following is an example of a RADIUS user profile (Merit Daemon format) that includes RADIUS attribute 11 (Filter-Id):

```
client Password = "password1"
Service-Type = Framed,
Framed-Protocol = PPP,
Filter-Id = "myfilter.out"
```

The RADIUS user profile shown in this example produces the following reply from the NAS:

```
RADIUS: Send to unknown id 79 10.51.13.4:1645, Access-Request, len 85
RADIUS: authenticator 84 D3 B5 7D C2 5B 70 AD - 1E 5C 56 E8 3A 91 D0 6E
RADIUS: User-Name           [1]   8  "client"
RADIUS: CHAP-Password       [3]   19  *
RADIUS: NAS-Port            [5]   6   20030
RADIUS: NAS-Port-Type       [61]  6   ISDN                      [2]
RADIUS: Called-Station-Id   [30]  6   "4321"
RADIUS: Calling-Station-Id  [31]  6   "1234"
RADIUS: Service-Type        [6]   6  Framed
```
The following sections provide references related to the ACL Default Direction feature.

Attribute Screening for Access Requests

First Published: November 19, 2003
Last Updated: December 17, 2007

The Attribute Screening for Access Requests feature allows you to configure your network access server (NAS) to filter attributes in outbound Access Requests to the RADIUS server for purposes of authentication or authorization.

Finding Feature Information in This Module
Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “Feature Information for Attribute Screening for Access Requests” section on page 9.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images
Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Contents

- Prerequisites for Attribute Screening for Access Requests, page 2

- Information About Attribute Screening for Access Requests, page 2
- How to Configure Attribute Screening for Access Requests, page 2
- Configuration Examples for Attribute Filtering for Access Requests, page 6
- Additional References, page 7
- Command Reference, page 8
- Feature Information for Attribute Screening for Access Requests, page 9
Prerequisites for Attribute Screening for Access Requests

- You must be familiar with configuring attribute lists.

Restrictions for Attribute Screening for Access Requests

- Attributes 1 (Username), 2 (User-Password), and 3 (Chap-Password) cannot be filtered.

Information About Attribute Screening for Access Requests

To configure the Attribute Screening for Access Requests feature, you should understand the following concept:

- Configuring an NAS to Filter Attributes in Outbound Access Requests, page 2

Configuring an NAS to Filter Attributes in Outbound Access Requests

The Attribute Screening for Access Requests feature allows you to configure your NAS to filter attributes in outbound Access Requests to the RADIUS server for purposes of authentication or authorization. The filters can be configured on the NAS, or they can be downloaded via downloadable vendor-specific attributes (VSAs) from the authentication, authorization, and accounting (AAA) server.

The following are some examples of the downloadable VSAs:

- Cisco:Cisco-Avpair="ppp-authen-type=chap"
- Cisco:Cisco-Avpair="ppp-authen-list=group 1"
- Cisco:Cisco-Avpair="ppp-author-list=group 1"
- Cisco:Cisco-Avpair="vpdn:tunnel-id=B53"
- Cisco:Cisco-Avpair="vpdn:ip-addresses=10.0.58.35"

Note

You must be aware of which attributes you want to filter. Filtering certain key attributes can result in authentication failure (for example, attribute 60 should not be filtered).

How to Configure Attribute Screening for Access Requests

This section contains the following procedures:

- Configuring Attribute Screening for Access Requests, page 3
- Configuring a Router to Support Downloadable Filters, page 4
- Monitoring and Maintaining Attribute Filtering for Access Requests, page 5
Configuring Attribute Screening for Access Requests

To configure the attribute screening for access requests, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `radius-server attribute list listname`
4. `attribute value1 [value2 [value3...]]`
5. `aaa group server radius group-name`
6. `authorization [request | reply] [accept | reject] listname`
   
   or
   
   `accounting [request | reply] [accept | reject] listname`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** `enable` | Enables privileged EXEC mode.  
  • Enter your password if prompted. |
| **Example:**  
  Router> enable | |
| **Step 2** `configure terminal` | Enters global configuration mode. |
| **Example:**  
  Router# configure terminal | |
| **Step 3** `radius-server attribute list listname` | Defines an attribute list. |
| **Example:**  
  Router (config)# radius-server attribute list attrlist | |
| **Step 4** `attribute value1 [value2 [value3...]]` | Adds attributes to an accept or reject list. |
| **Example:**  
  Router (config)# attribute 6-10, 12 | |
| **Step 5** `aaa group server radius group-name` | Applies the attribute list to the AAA server group and enters server-group configuration mode. |
| **Example:**  
  Router (config)# aaa group server radius rad1 | |
### Configuring a Router to Support Downloadable Filters

To configure your router to support downloadable filters, perform the following steps.

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa authorization template**
4. **aaa authorization network default group radius**
5. **radius-server attribute list list-name**
6. **attribute value1 [value2 [value3...]]**

Configuration Examples for Attribute Filtering for Access Requests

This section provides the following configuration examples:

- Attribute Filtering for Access Requests: Example, page 6
- Attribute Filtering User Profile: Example, page 6
- debug radius Command: Example, page 7

Attribute Filtering for Access Requests: Example

The following example shows that the attributes 30-31 that are defined in “all-attr” will be rejected in all outbound Access Request messages:

aaa group server radius ras
server 172.19.192.238 auth-port 1745 acct-port 1746
authorization request reject all-attr

radius-server attribute list all-attr
attribute 30-31
!

Attribute Filtering User Profile: Example

The following is a sample user profile after attribute filtering has been configured for Access Requests:

cisco.com Password = "cisco"
Service-Type = Framed,
Framed-Protocol = PPP,
Cisco:Cisco-Avpair = :1:"rad-serv=172.19.192.87 key rad123",
Cisco:Cisco-Avpair = :1:"rad-serv-filter=authorization request reject range1",
Cisco:Cisco-Avpair = :1:"rad-serv-filter=accounting request reject range1",
Cisco:Cisco-Avpair = "ppp-authen-type=chap"
Cisco:Cisco-Avpair = "ppp-authen-list=group 1",
Cisco:Cisco-Avpair = "ppp-author-list=group 1",
Cisco:Cisco-Avpair = "ppp-acct-list=start-stop group 1",
Cisco:Cisco-Avpair = "vpdn:tunnel-id=B53",
Cisco:Cisco-Avpair = "vpdn:tunnel-type=l2tp",
Cisco:Cisco-Avpair = "vpdn:ip-addresses=10.0.58.35",
Cisco:Cisco-Avpair = "vpdn:12tp-tunnel-password=cisco"

user2@cisco.com
Service-Type = Outbound,
Cisco:Cisco-Avpair = "vpdn:tunnel-id=B53",
Cisco:Cisco-Avpair = "vpdn:tunnel-type=l2tp",
Cisco:Cisco-Avpair = "vpdn:ip-addresses=10.0.58.35",
Cisco:Cisco-Avpair = "vpdn:12tp-tunnel-password=cisco"
When a session for user2@cisco.com “comes up” at the Layer 2 Tunneling Protocol (L2TP) Network Server (LNS)—as is shown above—because the **aaa authorization template** command has been configured, a RADIUS request is sent to the server for Cisco.com. The server then sends an Access Accept message if authentication is successful, along with the VSAs that are configured as part of the Cisco.com profile. If filters are configured as part of the Cisco.com profile, these filters will be parsed and applied to the RADIUS requests for user2@cisco.com.

In the above profile example, filter range1 has been applied to the authorization and accounting requests.

**debug radius Command: Example**

If the attribute you are trying to filter is rejected, you will see an **debug radius** output statement similar to the following:

```
RADIUS: attribute 31 rejected
```

If you try to filter an attribute that cannot be filtered, you will see an output statement similar to the following:

```
RADIUS: attribute 1 cannot be rejected
```

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

- authorization (server-group)
Feature Information for Attribute Screening for Access Requests

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at http://www.cisco.com/go/fn. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.

This feature module describes the Enable Multilink PPP via RADIUS for Preauthentication User feature in Cisco IOS Release 12.2(11)T. It includes the following sections:

- Feature Overview, page 1
- Supported Platforms, page 3
- Supported Standards, MIBs, and RFCs, page 4
- Prerequisites, page 4
- Configuration Tasks, page 4
- Configuration Examples, page 5
- Command Reference, page 6
- Glossary, page 7

Feature Overview

The Enable Multilink PPP via RADIUS for Preauthentication User feature allows you to selectively enable and disable Multilink PPP (MLP) negotiation for different users via RADIUS vendor-specific attribute (VSA) preauth:ppp-multilink=1.
You can enable MLP by configuring the `ppp multilink` command on an interface, but then this command enables MLP negotiation for all connections and users on that interface; that is, you cannot selectively enable or disable MLP negotiation for specific connections and users on an interface.

**Note**
To enable this feature, the `ppp multilink` command should not be configured on the interface; this command will disable MLP by default. If the `ppp multilink` command is already configured on the interface, the attribute “preauth:ppp-multilink=1” will not override this command.

**How MLP via RADIUS Works**

Because MLP parameters are negotiated at the time of link control protocol (LCP) negotiation, RADIUS VSA `preauth:ppp-multilink=1` should only be a part of preauthentication user authorization. You should add this VSA to the preauthentication profile of the user to enable MLP. Thus, MLP will be enabled only for preauthentication users whose profiles contain this VSA; MLP will be disabled for all other users. If the MLP VSA is received during PPP user authorization (as opposed to preauthentication user authorization), it will be too late to negotiate MLP, and MLP will not be enabled.

When this VSA is received during preauthentication user authorization, MLP negotiation for the user is enabled. MLP is enabled when the VSA value is 1. All attribute values other than 1 are ignored.

**Roles of the L2TP Access Server and L2TP Network Server**

With this feature, you do not need to configure MLP on the interface of the L2TP access server (LAC); during preauthentication user authorization, the LAC will selectively choose to enable MLP for preauthentication users who receive `preauth:ppp-multilink=1`. On the L2TP network server (LNS), you can control the maximum number of links allowed in the multilink bundle by sending RADIUS VSA `multilink:max-links=n` during PPP user authorization.

**New Vendor-Specific Attributes**

This feature introduces the following new VSAs:

- **Cisco-A Vpair = preauth:ppp-multilink=1**
  
  Turns on MLP on the interface and is applied to the preauthentication profile.

- **Cisco-A Vpair = multilink:max-links=n**
  
  Restricts the maximum number of links that a user can have in a multilink bundle and is used with the `service=ppp` attribute. The range of “n” is from 1 to 255.

- **Cisco-A Vpair = multilink:min-links=1**
  
  Sets the minimum number of links for MLP. The range of “n” is from 0 to 255.

- **Cisco-A Vpair = multilink:load-threshold=n**
  
  Sets the load threshold for the caller for which additional links are added or deleted from the multilink bundle. If the load exceeds the specified value, links are added; if the load drops below the specified value, links are deleted. This attribute is used with the `service=ppp` attribute. The range of “n” is from 1 to 255.
RADIUS VSAs multilink:max-links, multilink:min-links, and multilink:load-threshold serve the same purpose as TACACS+ per-user attributes, max-links, min-links, and load-threshold respectively.

Benefits

Selective Multilink PPP Configuration
MLP negotiation can be selectively enabled and disabled for different users by applying RADIUS VSA preauth:ppp-multilink=1 to the preauthentication profile.

Supported Platforms

- Cisco AS5300 series
- Cisco AS5350 series
- Cisco AS5400 series
- Cisco AS5800 series
- Cisco AS5850 series

Determining Platform Support Through Feature Navigator

Cisco IOS software is packaged in feature sets that support specific platforms. To get updated information regarding platform support for this feature, access Feature Navigator. Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Feature Navigator is a web-based tool that enables you to quickly determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image.

To access Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions at http://www.cisco.com/register.

Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Feature Navigator home page at the following URL:
http://www.cisco.com/go/fn
Supported Standards, MIBs, and RFCs

Standards
None

MIBs
None

To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:

RFCs
No new or modified RFCs are supported by this feature.

Prerequisites

Before enabling MLP via RADIUS VSA preauth:ppp-multilink=1, you should perform the following tasks:

- Enable the network access server (NAS) to recognize and use VSAs as defined by RADIUS IETF attribute 26 by using the `radius-server vsa send` command.
  
  For more information about using VSAs, refer to the section “Configuring Router to Use Vendor-Specific RADIUS Attributes” of the chapter “Configuring RADIUS” in the *Cisco IOS Security Configuration Guide*, Release 12.2.

- Enable preauthentication.
  

Configuration Tasks

None

Verifying MLP Negotiation via RADIUS in Preauthentication

To display bundle information for the MLP bundles, use the `show ppp multilink` EXEC command.

```
Router# show ppp multilink

Virtual-Access1, bundle name is mlpuser
Bundle up for 00:00:15
Dialer interface is Serial0:23
0 lost fragments, 0 reordered, 0 unassigned
0 discarded, 0 lost received, 1/255 load
0x0 received sequence, 0x0 sent sequence
Member links: 1 (max 7, min 1)
    Serial0:22, since 00:00:15, no frags rcvd
```
Table 15 describes the significant fields shown when MLP is enabled.

<table>
<thead>
<tr>

### Configuration Examples

This section provides dialin VPDN configurations using Cisco VSA ppp-multilink examples:

- **LAC for MLP Configuration Example**
- **LAC RADIUS Profile for Preauthentication Example**
- **LNS for MLP Configuration Example**
- **LNS RADIUS Profile Example**

### LAC for MLP Configuration Example

The following example is a sample configuration that can be used to configure a LAC for MLP via RADIUS:

```plaintext
! Enable preauthentication
aaa preauth
   group radius
dnis required

! Enable VPDN
vpdn enable
! vpdn-group 1
   request-dialin
   protocol 12tp
dnis 56118
   initiate-to ip 10.0.1.22
   local name lac-router

! Don't need to configure multilink on the interface
! Multilink will be enabled by "ppp-multilink" attribute
interface Serial0:23
   ip address 15.0.1.7 255.0.0.0
   encapsulation ppp
   dialer-group 1
   isdn switch-type primary-5ess
   isdn calling-number 56118
   peer default ip address pool pool1
   no cdp enable
   ppp authentication chap
```
LAC RADIUS Profile for Preauthentication Example

The following example shows a LAC RADIUS profile for a preauthentication user who has applied the preauth:ppp-multilink=1 VSA:

```
56118   Password = "cisco"
Service-Type = Outbound,
Framed-Protocol = PPP,
Framed-MTU = 1500,
Cisco-Avpair = "preauth:auth-required=1",
Cisco-Avpair = "preauth:auth-type=chap",
Cisco-Avpair = "preauth:username=dnis:56118",
Cisco-Avpair = "preauth:ppp-multilink=1"
```

LNS for MLP Configuration Example

The following example is a sample configuration that can be used to configure a LNS to limit the number of links in a MLP bundle:

```
! Enable VPDN
vpdn enable
!
vpdn-group 1
    accept-dialin
    protocol any
    virtual-template 1
terminate-from hostname lac-router
local name lns-router
!
! Configure multilink on interface
interface Virtual-Template 1
    ip unnumbered Ethernet 0/0
    ppp authentication chap
    ppp multilink
```

LNS RADIUS Profile Example

The following example shows a LNS RADIUS profile for specifying the maximum number of links in a multilink bundle. The following multilink VSAs should be specified during PPP user authorization.

```
mascot   password = "cisco"
Service-Type = Framed,
Framed-Protocol = PPP,
Cisco-Avpair = "multilink:max-links=7"
Cisco-Avpair = "multilink:min-links=1"
Cisco-Avpair = "multilink:load-threshold=128"
```

Command Reference

This feature uses no new or modified commands. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.
Glossary

AAA—authentication, authorization, and accounting. Suite of network security services that provide the primary framework through which access control can be set up on your Cisco router or access server.

attribute—RADIUS Internet Engineering Task Force (IETF) attributes are the original set of 255 standard attributes that are used to communicate AAA information between a client and a server. Because IETF attributes are standard, the attribute data is predefined and well known; thus all clients and servers that exchange AAA information via IETF attributes must agree on attribute data such as the exact meaning of the attributes and the general bounds of the values for each attribute.

L2F—Layer 2 Forwarding. Protocol that supports the creation of secure virtual private dial-up networks over the Internet.

L2TP—Layer 2 Tunnel Protocol. A Layer 2 tunneling protocol that enables an ISP or other access service to create a virtual tunnel to link customer remote sites or remote users with corporate home networks. In particular, a network access server (NAS) at the ISP point of presence (POP) exchanges PPP messages with the remote users and communicates by L2F or L2TP requests and responses with the customer tunnel server to set up tunnels.

LAC—L2TP access concentrator. A network access server (NAS) to which the client directly connects and through which PPP frames are tunneled to the L2TP network server (LNS). The LAC need only implement the media over which L2TP is to operate to pass traffic to one or more LNSs. The LAC may tunnel any protocol carried within PPP. The LAC initiates incoming calls and receives outgoing calls. A LAC is analogous to an L2F network access server.

LNS—L2TP network server. A termination point for L2TP tunnels, and an access point where PPP frames are processed and passed to higher-layer protocols. An LNS can operate on any platform that terminates PPP. The LNS handles the server side of the L2TP protocol. L2TP relies only on the single medium over which L2TP tunnels arrive. The LNS initiates outgoing calls and receives incoming calls. An LNS is analogous to a home gateway in L2F technology.

MLP—Multilink PPP. MLP allows packets to be fragmented and the fragments to be sent at the same time over multiple point-to-point links to the same remote address. The multiple links come up in response to a defined dialer load threshold. The load can be calculated on inbound traffic, outbound traffic, or on either, as needed for the traffic between the specific sites. MLP provides bandwidth on demand and reduces transmission latency across WAN links.

MLP is designed to work over synchronous and asynchronous serial and BRI and PRI types of single or multiple interfaces that have been configured to support both dial-on-demand rotary groups and PPP encapsulation.

RADIUS—Remote Authentication Dial-In User Service. RADIUS is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

VSA—Vendor-Specific Attribute. VSAs derived from one IETF attribute—vendor-specific (attribute 26). Attribute 26 allows a vendor to create and implement an additional 255 attributes. That is, a vendor can create an attribute that does not match the data of any IETF attribute and encapsulate it behind attribute 26: essentially, Vendor-Specific = "protocol:attribute=value."
Enhanced Test Command

First Published: August 9, 2001
Last Updated: December 17, 2007

The Enhanced Test Command feature allows a named user profile to be created with calling line ID (CLID) or dialed number identification service (DNIS) attribute values. The CLID or DNIS attribute values can be associated with the RADIUS record that is sent with the user profile so that the RADIUS server can access CLID or DNIS attribute information for all incoming calls.

Finding Feature Information in This Module
Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “Feature Information for Enhanced Test Command” section on page 6.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images
Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Contents

- Restrictions for the Enhanced Test Command, page 2
- How to Configure the Enhanced Test Command, page 2
- Configuration Example for Enhanced Test Command, page 3
- Additional References, page 4
- Command Reference, page 5
- Feature Information for Enhanced Test Command, page 6
- Glossary, page 7
Restrictions for the Enhanced Test Command

The `test aaa group` command does not work with TACACS+.

How to Configure the Enhanced Test Command

The following sections describe how to configure the Enhanced Test Command feature:

- Configuring a User Profile and Associating it with the RADIUS Record
- Verifying the Enhanced Test Command Configuration

Configuring a User Profile and Associating it with the RADIUS Record

This section describes how to create a named user profile with CLID or DNIS attribute values and associate it with the RADIUS record.

SUMMARY STEPS

1. enable
2. configure terminal
3. `aaa user profile profile-name`
4. `aaa attribute {dnis | clid} attribute-value`
5. exit
6. `test aaa group {group-name | radius} username password new-code [profile profile-name]`

Verifying the Enhanced Test Command Configuration

To verify the Enhanced Test Command configuration, use the following commands in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>exit</td>
<td>Exit Global Configuration mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Associates a DNIS or CLID named user profile with the record sent to the RADIUS server.</td>
</tr>
</tbody>
</table>

**Example:**

```text
Router# test aaa group (group-name | radius) username password new-code [profile profile-name]
```

**Note**  The *profile-name* must match the *profile-name* specified in the *aaa user profile* command.

---

**Command or Action**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 5</strong></td>
<td>Exit Global Configuration mode.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>Associates a DNIS or CLID named user profile with the record sent to the RADIUS server.</td>
</tr>
</tbody>
</table>

**Example:**

```text
Router# test aaa group radius secret new-code profile profile1
```

**Configuration Example for Enhanced Test Command**

This section provides the following configuration example:

- User Profile Associated With a test aaa group command Example

**User Profile Associated With a test aaa group command Example**

The following example shows how to configure the `dnis = dnisvalue` user profile “prfl1” and associate it with a `test aaa group` command. In this example, the `debug radius` command has been enabled and the output follows the configuration.

```text
aaa user profile prfl1
  aaa attribute dnis
  aaa attribute dnis dnisvalue
! Attribute not found.
  aaa attribute clid clidvalue
no aaa attribute clid
exit
!
! Associate the dnis user profile with the test aaa group command.
test aaa group radius user1 pass new-code profile prfl1
!
!
! debug radius output, which shows that the dnis value has been passed to the radius server.
```
Additional References

The following sections provide references related to Enhanced Test Command.

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, use the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

- aaa attribute
- aaa user profile
- test aaa group
Feature Information for Enhanced Test Command

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

</table>
attribute—RADIUS Internet Engineering Task Force (IETF) attributes are the original set of 255 standard attributes that are used to communicate AAA information between a client and a server. Because IETF attributes are standard, the attribute data is predefined and well known; thus all clients and servers who exchange AAA information via IETF attributes must agree on attribute data such as the exact meaning of the attributes and the general bounds of the values for each attribute.

CLID—calling line ID. CLID provides the number from which a call originates.

DNIS—dialed number identification service. DNIS provides the number that is dialed.
Framed-Route in RADIUS Accounting

First Published: November 3, 2003
Last Updated: December 17, 2007

The Framed-Route in RADIUS Accounting feature provides for the presence of Framed-Route (RADIUS attribute 22) information in RADIUS Accounting-Request accounting records. The Framed-Route information is returned to the RADIUS server in the Accounting-Request packets. The Framed-Route information can be used to verify that a per-user route or routes have been applied for a particular static IP customer on the network access server (NAS).

Finding Feature Information in This Module
Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “Feature Information for Framed-Route in RADIUS Accounting” section on page 7.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images
Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Contents

Prerequisites for Framed-Route in RADIUS Accounting

Be familiar with configuring authentication, authorization, and accounting (AAA), RADIUS servers, and RADIUS attribute screening.

Information About Framed-Route in RADIUS Accounting

This section includes the following concepts:

- Framed-Route, Attribute 22, page 2
- Framed-Route in RADIUS Accounting Packets, page 2

Framed-Route, Attribute 22

Framed-Route, attribute 22 as defined in Internet Engineering Task Force (IETF) standard RFC 2865, provides for routing information to be configured for the user on the NAS. The Framed-Route attribute information is usually sent from the RADIUS server to the NAS in Access-Accept packets. The attribute can appear multiple times.

Framed-Route in RADIUS Accounting Packets

The Framed-Route attribute information in RADIUS accounting packets shows per-user routes that have been applied for a particular static IP customer on the NAS. The Framed-Route attribute information is currently sent in Access-Accept packets. Effective with Cisco IOS Release 12.3(4)T, the Framed-Route attribute information is also sent in Accounting-Request packets if it was provided in the Access-Accept packets and was applied successfully. Zero or more instances of the Framed-Route attribute may be present in the Accounting-Request packets.

If there is more than one Framed-Route attribute in an Access-Accept packet, there can also be more than one Framed-Route attribute in the Accounting-Request packet.

The Framed-Route information is returned in Stop and Interim accounting records and in Start accounting records when accounting Delay-Start is configured.

No configuration is required to have the Frame-Route attribute information returned in the RADIUS accounting packets.
How to Monitor Framed-Route in RADIUS Accounting

Use the `debug radius` command to monitor whether Framed-Route (attribute 22) information is being sent in RADIUS Accounting-Request packets.

Examples

This section provides the following example:

- `debug radius Command Output: Example, page 3`

**debug radius Command Output: Example**

In the following example, the `debug radius` command is used to verify that Framed-Route (attribute 22) information is being sent in the Accounting-Request packets (see the line `00:06:23: RADIUS: Framed-Route [22] 26 "10.80.0.1 255.255.255.255 10.60.0.1 100"`).

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at http://www.cisco.com/go/fn. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.

For the latest feature information and caveats, see the release notes for your Cisco IOS software release.

Contents

- Feature Overview, page 2
- Prerequisites, page 2
- Configuration Tasks, page 3
- Configuration Examples, page 4
- Additional References, page 5
- Command Reference, page 6
- Glossary, page 6
Feature Overview

The Offload Server Accounting Enhancement feature allows users to configure their network access servers (NAS) to synchronize authentication and accounting information—NAS-IP-Address (attribute 4) and Class (attribute 25)—with the offload server.

An offload server interacts with a NAS via Virtual Private Network (VPN) to perform required Point-to-Point Protocol (PPP) negotiation for calls. The NAS performs call preauthentication, whereas the offload server performs user authentication. This feature allows the authentication and accounting data of the NAS to synchronize with the offload server as follows:

- During preauthentication, the NAS generates a unique session-id, adding the Acct-Session-Id (attribute 44) before the existing session-id (NAS-IP-Address), and retrieves a Class attribute. The new session-id is sent in preauthentication requests and resource accounting requests; the Class attribute is sent in resource accounting requests.

  Note

  Unique session-ids are needed when multiple NASs are being processed by one offload server.

- The NAS-IP-Address, the Acct-Session-Id, and the Class attribute are transmitted to the offload server via Layer 2 Forwarding (L2F) options.

- The offload server will include the new, unique session-id in user access requests and user session accounting requests. The Class attribute that was passed from the NAS will be included in the user access request, but a new Class attribute will be received in the user access reply; this new Class attribute should be included in user session accounting requests.

Benefits

The Offload Server Accounting Enhancement feature allows users to maintain authentication and accounting information between their NAS and offload server.

Although NASs can already synchronize information with an offload server, this feature extends the functionality to include a unique session-id, adding the Acct-Session-Id (attribute 44) before the existing session-id (NAS-IP-Address), and Class (attribute 25) information collected by the NASs.

Prerequisites

Before configuring the Offload Server Accounting Enhancement feature, you must perform the following tasks:

- Enable AAA. (For more information, refer to chapter “Configuring Authentication” of the Cisco IOS Security Configuration Guide)
- Enable VPN. (For more information, refer to the chapter “Configuring Virtual Private Networks” of the Cisco IOS Dial Technologies Configuration Guide)
Configuration Tasks

See the following sections for configuration tasks for the Offload Server Accounting Enhancement feature. Each task in the list is identified as either required or optional.

- Configuring Unique Session IDs, page 3 (required)
- Configuring Offload Server to Synchronize with NAS Clients, page 3 (required)
- Verifying Offload Server Accounting, page 4 (optional)

Configuring Unique Session IDs

To maintain unique session IDs among NASs, use the following global configuration command. When multiple NASs are being processed by one offload server, this feature must be enabled by all NASs and by the offload server to ensure a common and unique session-id.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# radius-server attribute 44 extend-with-addr</td>
<td>Adds the accounting IP address in front of the existing AAA session ID.</td>
</tr>
<tr>
<td>Note</td>
<td>The unique session-id is different from other NAS session-ids because it adds the Acct-Session-Id (attribute 44) before the existing session-id (NAS-IP-Address).</td>
</tr>
</tbody>
</table>

Configuring Offload Server to Synchronize with NAS Clients

To configure the offload server to synchronize accounting session information with the NAS clients, use the following global configuration command:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# radius-server attribute 44 sync-with-client</td>
<td>Configures the offload server to synchronize accounting session information with the NAS clients.</td>
</tr>
</tbody>
</table>
Verifying Offload Server Accounting

To verify whether the NAS has synchronized authentication and accounting data with the offload server, use the following commands in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router# more system:running-config</td>
<td>Displays the contents of the current running configuration file. (Note that the <code>more system:running-config</code> command has replaced the <code>show running-config</code> command.)</td>
</tr>
<tr>
<td>Router(config)# debug radius</td>
<td>Displays information associated with RADIUS. The output of this command shows whether attribute 44 is being sent in access requests. The output, however, does not show the entire value for attribute 44. To view the entire value for attribute 44, refer to your RADIUS server log.</td>
</tr>
</tbody>
</table>

Configuration Examples

This section provides the following configuration examples:

- Unique Session ID Configuration Example, page 4
- Offload Server Synchronization with NAS Clients Example, page 4

Unique Session ID Configuration Example

The following example shows how to configure unique session IDs among NASs:

```plaintext
aaa new-model
aaa authentication ppp default group radius
radius-server host 10.100.1.34
radius-server attribute 44 include-in-access-req
radius-server attribute 44 extend-with-addr
```

Offload Server Synchronization with NAS Clients Example

The following example shows how to configure the offload server to synchronize accounting session information with NAS clients:

```plaintext
radius-server attribute 44 sync-with-client
```

- radius-server attribute 44 sync-with-client

Glossary

AAA—authentication, authorization, and accounting. Suite of network security services that provide the primary framework through which access control can be set up on your Cisco router or access server.

Acct-Session-ID (attribute 44)—A unique accounting identifier that makes it easy to match start and stop records in a log file. Acct-Session ID numbers restart at 1 each time the router is power-cycled or the software is reloaded.

Class (attribute 25)—An accounting attribute. Arbitrary value that the network access server includes in all accounting packets for this user if the attribute is supplied by the RADIUS server.

L2F—Layer 2 Forwarding. A Layer 2 tunneling protocol that enables an ISP or other access service to create a virtual tunnel to link customer remote sites or remote users with corporate home networks. In particular, a network access server (NAS) at the ISP point of presence (POP) exchanges PPP messages with the remote users and communicates by L2F or L2TP requests and responses with the customer tunnel server to set up tunnels.

NAS—network access server. A Cisco platform (or collection of platforms, such as an AccessPath system) that interfaces between the packet world (for example, the Internet) and the circuit world (for example, the public switched telephone network).

NAS-IP Address (attribute 4)—Specifies the IP address of the network access server that is requesting authentication. The default value is 0.0.0.0/0.
PPP—Point-to-Point Protocol. Successor to SLIP that provides router-to-router and host-to-network connections over synchronous and asynchronous circuits. Whereas SLIP was designed to work with IP, PPP was designed to work with several network layer protocols, such as IP, IPX, and ARA. PPP also has built-in security mechanisms, such as CHAP and PAP. PPP relies on two protocols: LCP and NCP.

RADIUS—Remote Authentication Dial-In User Service. RADIUS is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

VPN—A system that permits dial-in networks to exist remotely to home networks, while giving the appearance of being directly connected. VPNs use L2TP and L2F to terminate the Layer 2 and higher parts of the network connection at the LNS instead of the LAC.

See Internetworking Terms and Acronyms for terms not included in this glossary.
Per VRF AAA

The Per VRF AAA feature allows authentication, authorization, and accounting (AAA) on the basis of Virtual Private Network (VPN) routing and forwarding (VRF) instances.

For Cisco IOS Release 12.2(15)T or later releases, a customer template can be used, which may be stored either locally or remotely, and AAA services can be performed on the information that is stored in the customer template. This feature has also been referred to as the Dynamic Per VRF AAA feature.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the “Feature Information for Per VRF AAA” section on page 30.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Catalyst OS, and Cisco IOS XE software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Per VRF AAA

Before configuring the Per VRF AAA feature, you must enable AAA. (For information on completing this task, refer to the AAA chapters of the Cisco IOS Security Configuration Guide.)

Restrictions for Per VRF AAA

- This feature is supported only for RADIUS servers.
- Operational parameters should be defined once per VRF rather than set per server group, because all functionality must be consistent between the network access server (NAS) and the AAA servers.
- The ability to configure a customer template either locally or remotely is available only for Cisco IOS Release 12.2(15)T and later releases.

Information About Per VRF AAA

When you use the Per VRF AAA feature, AAA services can be based on VRF instances. This feature permits the Provider Edge (PE) or Virtual Home Gateway (VHG) to communicate directly with the customer's RADIUS server, which is associated with the customer's Virtual Private Network (VPN), without having to go through a RADIUS proxy. Thus, ISPs can scale their VPN offerings more efficiently because they no longer have to use RADIUS proxies and ISPs can also provide their customers with additional flexibility.

How Per VRF AAA Works

To support AAA on a per customer basis, some AAA features must be made VRF aware. That is, ISPs must be able to define operational parameters—such as AAA server groups, method lists, system accounting, and protocol-specific parameters—and bind those parameters to a particular VRF instance. Defining and binding the operational parameters can be accomplished using one or more of the following methods:

- Virtual private dialup network (VPDN) virtual template or dialer interfaces that are configured for a specific customer
- Locally defined customer templates—Per VPN with customer definitions. The customer template is stored locally on the VHG. This method can be used to associate a remote user with a specific VPN based on the domain name or dialed number identification service (DNIS) and provide the VPN-specific configuration for virtual access interface and all operational parameters for the customer AAA server.
• Remotely defined customer templates—Per VPN with customer definitions that are stored on the service provider AAA server in a RADIUS profile. This method is used to associate a remote user with a specific VPN based on the domain name or DNIS and provide the VPN-specific configuration for the virtual access interface and all operational parameters for the AAA server of the customer.

Note
The ability to configure locally or remotely defined customer templates is available only with Cisco IOS Release 12.2(15)T and later releases.

Benefits

Configuration Support
ISPs can partition AAA services on a per VRF basis. Thus, ISPs can allow their customers to control some of their own AAA services.

Server Group List Extension
The list of servers in server groups is extended to include the definitions of private servers in addition to references to the hosts in the global configuration, allowing access to both customer servers and global service provider servers simultaneously.

AAA Accounting Records
The Cisco implementation of AAA accounting provides “start” and “stop” record support for calls that have passed user authentication. Start and stop records are necessary for users employing accounting records to manage and monitor their networks.

New Vendor-Specific Attributes
The Internet Engineering Task Force (IETF) draft standard specifies a method for communicating vendor-specific information between the network access server and the RADIUS server by using the vendor-specific attribute (VSA) attribute 26. Attribute 26 encapsulates VSAs, thereby, allowing vendors to support their own extended attributes otherwise not suitable for general use.

The Cisco RADIUS implementation supports one vendor-specific option using the format recommended in the specification. Cisco’s vendor-ID is 9, and the supported option has vendor-type 1, which is named “cisco-avpair.” The value is a string of the following format:

```
protocol : attribute Sep value *
```

“Protocol” is a value of the Cisco “protocol” attribute for a particular type of authorization. “Attribute” and “value” are an appropriate attribute-value (AV) pair defined in the Cisco TACACS+ specification, and “sep” is “=” for mandatory attributes and “*” for optional attributes. This format allows the full set of features available for TACACS+ authorization to be used also for RADIUS.

Table 1 summarizes the VSAs that are now supported with Per VRF AAA.
### Table 1  
**VSAs supported with Per VRF AAA**

<table>
<thead>
<tr>
<th>VSA Name</th>
<th>Value Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note</strong></td>
<td></td>
<td>Each VSA must have the prefix “template:” before the VSA name, unless a different prefix is explicitly stated.</td>
</tr>
<tr>
<td>account-delay</td>
<td>string</td>
<td>This VSA must be “on.” The functionality of this VSA is equal to the <code>aaa accounting delay-start</code> command for the customer template.</td>
</tr>
<tr>
<td>account-send-stop</td>
<td>string</td>
<td>This VSA must be “on.” The functionality of this VSA is equal to the <code>aaa accounting send stop-record authentication</code> command with the <code>failure</code> keyword.</td>
</tr>
<tr>
<td>account-send-success-remote</td>
<td>string</td>
<td>This VSA must be “on.” The functionality of this VSA is equal to the <code>aaa accounting send stop-record authentication</code> command with the <code>success</code> keyword.</td>
</tr>
<tr>
<td>attr-44</td>
<td>string</td>
<td>This VSA must be “access-req.” The functionality of this VSA is equal to the <code>radius-server attribute 44 include-in-access-req</code> command.</td>
</tr>
<tr>
<td>ip-addr</td>
<td>string</td>
<td>This VSA specifies the IP address, followed by the mask that the router uses to indicate its own IP address and mask in negotiation with the client; for example, <code>ip-addr=1.2.3.4 255.255.255.255</code></td>
</tr>
<tr>
<td>ip-unnumbered</td>
<td>string</td>
<td>This VSA specifies the name of an interface on the router. The functionality of this VSA is equal to the <code>ip unnumbered</code> command, which specifies an interface name such as “Loopback 0.”</td>
</tr>
<tr>
<td>ip-vrf</td>
<td>string</td>
<td>This VSA specifies which VRF will be used for the packets of the end user. This VRF name should match the name that is used on the router via the <code>ip vrf forwarding</code> command.</td>
</tr>
<tr>
<td>peer-ip-pool</td>
<td>string</td>
<td>This VSA specifies the name of an IP address pool from which an address will be allocated for the peer. This pool should be configured using the <code>ip local pool</code> command or should be automatically downloadable via RADIUS.</td>
</tr>
<tr>
<td>ppp-acct-list</td>
<td>string</td>
<td>This VSA defines the accounting method list that is to be used for PPP sessions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The VSA syntax is as follows: “ppp-acct-list=[start-stop</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The user must specify at least one of the following options: start-stop, stop-only, or none. If either start-stop or stop-only is specified, the user must specify at least one, but not more than four, group arguments. Each group name must consist of integers. The servers in the group should have already been identified in the access-accept via the VSA “rad-serv.” After each group has been specified, the user can specify the broadcast option</td>
</tr>
</tbody>
</table>
### VSA Name | Value Type | Description
--- | --- | ---
ppp-authen-list | string | This VSA defines which authentication method list is to be used for PPP sessions and, if more than one method is specified, in what order the methods should be used.

The VSA syntax is as follows: “ppp-authen-list=[groupX | local | local-case | none | if-needed],” which is equal to the **aaa authentication ppp mylist** command functionality.

The user must specify at least one, but no more than four, authentication methods. If a server group is specified, the group name must be an integer. The servers in the group should have already been identified in the access-accept via the VSA “rad-serv.”

ppp-authen-type | string | This VSA allows the end user to specify at least one of the following authentication types: pap, chap, eap, ms-chap, ms-chap-v2, any, or a combination of the available types that is separated by spaces.

The end user will be permitted to log in using only the methods that are specified in this VSA.

PPP will attempt these authentication methods in the order presented in the attribute.

ppp-author-list | string | This VSA defines the authorization method list that is to be used for PPP sessions. It indicates which methods will be used and in what order.

The VSA syntax is as follows:

“ppp-author-list=[groupX] [local] [if-authenticated] [none],” which is equal to the **aaa authorization network mylist** command functionality.

The user must specify at least one, but no more than four, authorization methods. If a server group is specified, the group name must be an integer. The servers in the group should have already been identified in the access-accept via the VSA “rad-serv.”

#### Note
The RADIUS VSAs—rad-serv, rad-server-filter, rad-serv-source-if, and rad-serv-vrf—must have the prefix “aaa:” before the VSA name.

rad-serv | string | This VSA indicates the IP address, key, timeout, and retransmit number of a server, as well as the group of the server.

The VSA syntax is as follows: “rad-serv=a.b.c.d [key SomeKey] [auth-port X] [acct-port Y] [retransmit V] [timeout W].” Other than the IP address, all parameters are optional and can be issued in any order. If the optional parameters are not specified, their default values will be used.

The key cannot contain any spaces; for “retransmit V,” “V” can range from 1-100; for “timeout W,” the “W” can range from 1-1000.
<table>
<thead>
<tr>
<th>VSA Name</th>
<th>Value Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rad-serv-filter</td>
<td>string</td>
<td>The VSA syntax is as follows: “rad-serv-filter=authorization</td>
</tr>
<tr>
<td>rad-serv-source-if</td>
<td>string</td>
<td>This VSA specifies the name of the interface that is used for transmitting RADIUS packets. The specified interface must match the interface configured on the router.</td>
</tr>
<tr>
<td>rad-serv-vrf</td>
<td>string</td>
<td>This VSA specifies the name of the VRF that is used for transmitting RADIUS packets. The VRF name should match the name that was specified via the <code>ip vrf forwarding</code> command.</td>
</tr>
</tbody>
</table>

## How to Configure Per VRF AAA

The following sections contain procedures for possible deployment scenarios for using the Per VRF AAA feature.

- Configuring Per VRF AAA, page 7 (required)
- Configuring Per VRF AAA Using Local Customer Templates, page 12 (optional)
- Configuring Per VRF AAA Using Remote Customer Templates, page 15 (optional)
- Verifying VRF Routing Configurations, page 17 (optional)
- Troubleshooting Per VRF AAA Configurations, page 18 (optional)
Configuring Per VRF AAA

This section contains the following procedures.
- Configuring AAA, page 7
- Configuring Server Groups, page 7
- Configuring Authentication, Authorization, and Accounting for Per VRF AAA, page 8
- Configuring RADIUS-Specific Commands for Per VRF AAA, page 10
- Configuring Interface-Specific Commands for Per VRF AAA, page 11

Configuring AAA

To enable AAA you need to complete the following steps.

SUMMARY STEPS

1. enable
2. configure terminal
3. aaa new-model

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router&gt; enable</td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>aaa new-model</td>
<td>Enables AAA globally.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config)# aaa new-model</td>
<td></td>
</tr>
</tbody>
</table>

Configuring Server Groups

To configure server groups you need to complete the following steps.

SUMMARY STEPS

1. enable
2. configure terminal
3. aaa new-model
4. aaa group server radius *groupName*
How to Configure Per VRF AAA

To configure authentication, authorization, and accounting for Per VRF AAA, you need to complete the following steps.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. aaa new-model

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>

| **Step 1** enable | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| Example:          |         |
| Router> enable    |         |
| **Step 2** configure terminal | Enters global configuration mode. |
| Example:          |         |
| Router# configure terminal |         |
| **Step 3** aaa authentication ppp {default | list-name} method1 [method2...] | Specifies one or more authentication, authorization, and accounting (AAA) authentication methods for use on serial interfaces that are running PPP. |
| Example:          |         |
| Router(config)# ppp authentication ppp default group radius |         |
| **Step 4** aaa authorization {network | exec | commands level | reverse-access | configuration} {default | list-name} [method1 [method2...]] | Sets parameters that restrict user access to a network. |
| Example:          |         |
| Router(config)# aaa authorization network default group sp |         |

### Configuring Authorization for Per VRF AAA with Remote Customer Profiles

To configuring authorization for Per VRF AAA with remote customer profiles, you need to perform the following step.

### SUMMARY STEPS

1. enable
2. configure terminal
3. aaa authorization template
4. aaa authorization {network | exec | commands level | reverse-access | configuration} {default | list-name} [method1 [method2...]]
**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| **Example:** Router> enable | |
| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:** Router# configure terminal | |
| **Step 3** aaa authorization template | Enables use of local or remote templates. |
| **Example:** Router(config)# aaa authorization template | |
| **Step 4** aaa authorization {network | exec | commands level | reverse-access | configuration} {default | list-name} [[method1 [method2...]] | Specifies the server group that is named as the default method for authorization. |
| **Example:** Router(config)# aaa authorization network default sp | |

**Configuring the RADIUS Profile on the SP RADIUS Server**

Configure the RADIUS profile on the Service Provider (SP) RADIUS server. See the “Per VRF AAA Using a Remote RADIUS Customer Template: Example” section on page 20 for an example of how to update the RADIUS profile.

**Verifying VRF Routing Configurations**

To verify VRF routing configurations, you need to complete the following steps:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. show ip route vrf vrf-name
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> show ip route vrf vrf-name</td>
<td>Displays the IP routing table associated with a VRF.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Router(config)# show ip route vrf northvrf</td>
<td></td>
</tr>
</tbody>
</table>

Troubleshooting Per VRF AAA Configurations

To troubleshoot the Per VRF AAA feature, use at least one of the following commands in EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router# debug aaa accounting</td>
<td>Displays information on accountable events as they occur.</td>
</tr>
<tr>
<td>Router# debug aaa authentication</td>
<td>Displays information on AAA authentication.</td>
</tr>
<tr>
<td>Router# debug aaa authorization</td>
<td>Displays information on AAA authorization.</td>
</tr>
<tr>
<td>Router# debug ppp negotiation</td>
<td>Displays information on traffic and exchanges in an internetwork implementing PPP.</td>
</tr>
<tr>
<td>Router# debug radius</td>
<td>Displays information associated with RADIUS.</td>
</tr>
<tr>
<td>Router# debug vpdn event</td>
<td>Displays Layer 2 Transport Protocol (L2TP) errors and events that are a part of normal tunnel establishment or shutdown for VPNs.</td>
</tr>
<tr>
<td>Router# debug vpdn error</td>
<td>Displays debug traces for VPN.</td>
</tr>
</tbody>
</table>

Configuration Examples for Per VRF AAA

This section provides the following configuration examples:

- Per VRF Configuration: Examples, page 19
- Customer Template: Examples, page 20
- AAA Accounting Stop Records: Examples, page 22
Per VRF Configuration: Examples

This section provides the following configuration examples:

- **Per VRF AAA: Example, page 19**
- **Per VRF AAA Using a Locally Defined Customer Template: Example, page 19**
- **Per VRF AAA Using a Remote RADIUS Customer Template: Example, page 20**

### Per VRF AAA: Example

The following example shows how to configure the Per VRF AAA feature using a AAA server group with associated private servers:

```plaintext
aaa new-model

aaa authentication ppp method_list_v1.55.com group v1.55.com
aaa authorization network method_list_v1.55.com group v1.55.com
aaa accounting network method_list_v1.55.com start-stop group v1.55.com
aaa accounting system default vrf v1.55.com start-stop group v1.55.com
aaa accounting delay-start vrf v1.55.com
aaa accounting send stop-record authentication failure vrf v1.55.com

aaa group server radius v1.55.com
    server-private 10.10.132.4 auth-port 1645 acct-port 1646 key ww
    ip vrf forwarding v1.55.com

ip radius source-interface loopback55
radius-server attribute 44 include-in-access-req vrf v1.55.com
```

### Per VRF AAA Using a Locally Defined Customer Template: Example

The following example shows how to configure the Per VRF AAA feature using a locally defined customer template with a AAA server group that has associated private servers:

```plaintext
aaa new-model

aaa authentication ppp method_list_v1.55.com group v1.55.com
aaa authorization network method_list_v1.55.com group v1.55.com
aaa authorization network default local
aaa authorization template
aaa accounting network method_list_v1.55.com start-stop group v1.55.com
aaa accounting system default vrf v1.55.com start-stop group v1.55.com

aaa group server radius V1_55_com
    server-private 10.10.132.4 auth-port 1645 acct-port 1646 key ww
    ip vrf forwarding V1.55.com

template V1.55.com
    peer default ip address pool V1_55_com_pool
    ppp authentication chap callin V1_55_com
    ppp authorization V1_55_com
    ppp accounting V1_55_com
    aaa accounting delay-start
    aaa accounting send stop-record authentication failure
radius-server attribute 44 include-in-access-req
ip vrf forwarding V1.55.com
ip radius source-interface Loopback55
```
Per VRF AAA Using a Remote RADIUS Customer Template: Example

The following examples show how to configure the Per VRF AAA feature using a remotely defined customer template on the SP RADIUS server with a AAA server group that has associated private servers:

```plaintext
aaa new-model
aaa authentication ppp default group radius
aaa authorization template
aaa authorization network default group sp

aaa group server radius sp
server 10.3.3.3
radius-server host 10.3.3.3 auth-port 1645 acct-port 1646 key sp_key
```

The following RADIUS server profile is configured on the SP RADIUS server:

```plaintext
cisco-avpair = "aaa:rad-serv#1=10.10.132.4 key ww"
cisco-avpair = "aaa:rad-serv-vrf#1=V1.55.com"
cisco-avpair = "aaa:rad-serv-source-if#1=Loopback 55"
cisco-avpair = "template:ppp-authen-list=group 1"
cisco-avpair = "template:ppp-author-list=group 1"
cisco-avpair = "template:ppp-acct-list= start-stop group 1"
cisco-avpair = "template:account-delay=on"
cisco-avpair = "template:account-send-stop=on"
cisco-avpair = "template:rad-attr4=access-req"
cisco-avpair = "template:peer-ip-pool=V1.55-pool"
cisco-avpair = "template:ip-vrf=V1.55.com"
cisco-avpair = "template:ip-unnumbered=Loopback 55"
framed-protocol = ppp
service-type = framed
```

Customer Template: Examples

This section provides the following configuration examples:

- Located Configured Customer Template with RADIUS Attribute Screening and Broadcast Accounting: Example, page 20
- Remotely Configured Customer Template with RADIUS Attribute Screening and Broadcast Accounting: Example, page 21

Locally Configured Customer Template with RADIUS Attribute Screening and Broadcast Accounting: Example

The following example shows how to create a locally configured template for a single customer, configuring additional features including RADIUS attribute screening and broadcast accounting:

```plaintext
aaa authentication ppp default local group radius
aaa authentication ppp V1_55_com group V1_55_com
aaa authorization template
aaa authorization network default local group radius
aaa authorization network V1_55_com group V1_55_com
aaa accounting network V1_55_com start-stop broadcast group V1_55_com group SP_AAA_server

aaa group server radius SP_AAA_server
server 10.10.100.7 auth-port 1645 acct-port 1646
```
aaa group server radius V1_55_com
server-private 10.10.132.4 auth-port 1645 acct-port 1646
authorization accept min-author
accounting accept usage-only
ip vrf forwarding V1.55.com

ip vrf V1.55.com
rd 1:55
route-target export 1:55
route-target import 1:55

template V1.55.com
peer default ip address pool V1.55-pool
ppp authentication chap callin V1_55_com
ppp authorization V1_55_com
ppp accounting V1_55_com
aaa accounting delay-start
aaa accounting send stop-record authentication failure
radius-server attribute 44 include-in-access-req

vpdn-group V1.55
accept-dialin
protocol l2tp
virtual-template 13
terminate-from hostname lac-lb-V1.55
source-ip 10.10.104.12
lcp renegotiation always
l2tp tunnel password 7 060506324F41

interface Virtual-Template13
ip vrf forwarding V1.55.com
ip unnumbered Loopback55
ppp authentication chap callin
ppp multilink

ip local pool V1.55-pool 10.1.55.10 10.1.55.19 group V1.55-group

ip radius source-interface Loopback0
ip radius source-interface Loopback55 vrf V1.55.com

radius-server attribute list min-author
attribute 6-7,22,27-28,242
radius-server attribute list usage-only
attribute 1,40,42-43,46

radius-server host 10.10.100.7 auth-port 1645 acct-port 1646 key ww
radius-server host 10.10.132.4 auth-port 1645 acct-port 1646 key ww

**Remotely Configured Customer Template with RADIUS Attribute Screening and Broadcast Accounting: Example**

The following example shows how to create a remotely configured template for a single customer, configuring additional features including RADIUS attribute screening and broadcast accounting:

aaa authentication ppp default local group radius
aaa authorization template
aaa authorization network default local group radius

ip vrf V1.55.com
rd 1:55
route-target export 1:55
route-target import 1:55

vpdn-group V1.55
accept-dialin
protocol l2tp
virtual-template 13
terminate-from hostname lac-lb-V1.55
source-ip 10.10.104.12
lcp renegotiation always
l2tp tunnel password 7 060506324F41

interface Virtual-Template13
no ip address
ppp authentication chap callin
ppp multilink
ip local pool V1.55-pool 10.1.55.10 10.1.55.19 group V1.55-group
radius-server attribute list min-author
attribute 6-7,22,27-28,242
radius-server attribute list usage-only
attribute 1,40,42-43,46

The customer template is stored as a RADIUS server profile for v1.55.com.

cisco-avpair = "aaa:rad-serv#1=10.10.132.4 key ww"
cisco-avpair = "aaa:rad-serv-vrf#1=V1.55.com"
cisco-avpair = "aaa:rad-serv-source-if#1=Loopback 55"
cisco-avpair = "aaa:rad-serv#2=10.10.100.7 key ww"
cisco-avpair = "aaa:rad-serv-source-if#2=Loopback 0"
cisco-avpair = "template:ppp-authen-list=group 1"
cisco-avpair = "template:ppp-author-list=group 1"
cisco-avpair = "template:ppp-acct-list=start-stop group 1 group 2 broadcast"
cisco-avpair = "template:account-delay=on"
cisco-avpair = "template:account-send-stop=on"
cisco-avpair = "template:rad-attr44=access-req"
cisco-avpair = "aaa:rad-serv-filter#1=authorization accept min-author"
cisco-avpair = "aaa:rad-serv-filter#1=accounting accept usage-only"
cisco-avpair = "template:peer-ip-pool=V1.55-pool"
cisco-avpair = "template:ip-vrf=V1.55.com"
cisco-avpair = "template:ip-unnumbered=Loopback 55"
framed-protocol = ppp
service-type = framed

AAA Accounting Stop Records: Examples

The following AAA accounting stop record examples show how to configure the `aaa accounting send stop-record authentication` command to control the generation of “stop” records when the `aaa accounting` command is issued with the `start-stop` or `stop-only` keyword.

Note: The `success` and `remote-server` keywords are available in Cisco IOS Release 12.4(2)T and later releases.
This section provides the following configuration examples:

- **AAA Accounting Stop Record and Successful Call: Example**, page 23
- **AAA Accounting Stop Record and Rejected Call: Example**, page 25

### AAA Accounting Stop Record and Successful Call: Example

The following example shows “start” and “stop” records being sent for a successful call when the `aaa accounting send stop-record authentication` command is issued with the `failure` keyword.

**Router#** `show running config | include aaa`

```
...  aaa new-model
  aaa authentication ppp default group radius
  aaa authorization network default local
  aaa accounting send stop-record authentication failure
  aaa accounting network default start-stop group radius
...

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html.

- aaa accounting
- aaa accounting delay-start
- aaa accounting send stop-record authentication
- aaa authorization template
- ip radius source-interface
- ip vrf forwarding (server-group)
- radius-server attribute 44 include-in-access-req
- radius-server domain-stripping
- server-private (RADIUS)
Feature Information for Per VRF AAA

Table 2 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS, and Cisco IOS XE, software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Note
Table 2 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

<table>

<tr>
<td>Per VRF AAA</td>
<td>12.2(1)DX, 12.2(2)DD, 12.2(4)B, 12.2(13)T, 12.2(15)T, 12.4(2)T, 12.2(28)SB, 12.2(33)SR, 12.2(33)SXI, 12.2(33)SXH4, XE 2.1</td>
<td>The Per VRF AAA feature allows authentication, authorization, and accounting (AAA) on the basis of Virtual Private Network (VPN) routing and forwarding (VRF) instances. For Cisco IOS Release 12.2(15)T or later releases, you can use a customer template, which may be stored either locally or remotely, and AAA services can be performed on the information that is stored in the customer template. In 12.2(1)DX, this feature was introduced on the Cisco 7200 series and the Cisco 7401ASR. In 12.2(2)DD, the <code>ip vrf forwarding (server-group)</code> and <code>radius-server domain-stripping</code> commands were added. In 12.2(15)T, the <code>aaa authorization template</code> command was added. In 12.4(2)T, the <code>aaa accounting send stop-record authentication</code> command was updated with additional support for AAA accounting stop records. In 12.2(33)SRC, dynamic configuration of AAA was introduced. In Cisco IOS Release 12.2(33)SXI, this feature was introduced. In Cisco IOS Release 12.2(33)SXH4, this feature was introduced. The following commands were introduced or modified: <code>aaa accounting</code>, <code>aaa accounting delay-start</code>, <code>ip radius source-interface</code>, <code>radius-server attribute 44</code>, <code>include-in-access-req</code>, <code>server-private (RADIUS)</code>. In Cisco IOS XE Release 2.1, this feature was introduced on Cisco ASR 1000 Series Routers.</td>
</tr>
</tbody>
</table>
AAA—authentication, authorization, and accounting. A framework of security services that provide the method for identifying users (authentication), for remote access control (authorization), and for collecting and sending security server information used for billing, auditing, and reporting (accounting).

L2TP—Layer 2 Tunnel Protocol. A Layer 2 tunneling protocol that enables an ISP or other access service to create a virtual tunnel to link customer remote sites or remote users with corporate home networks. In particular, a network access server (NAS) at the ISP point of presence (POP) exchanges PPP messages with the remote users and communicates by L2F or L2TP requests and responses with the customer tunnel server to set up tunnels.

PE—Provider Edge. Networking devices that are located on the edge of a service provider network.

RADIUS—Remote Authentication Dial-In User Service. RADIUS is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

VPN—Virtual Private Network. A system that permits dial-in networks to exist remotely to home networks, while giving the appearance of being directly connected. VPNs use L2TP and L2F to terminate the Layer 2 and higher parts of the network connection at the LNS instead of the LAC.

VRF—Virtual Route Forwarding. Initially, a router has only one global default routing/forwarding table. VRFs can be viewed as multiple disjoined routing/forwarding tables, where the routes of a user have no correlation with the routes of another user.
RFC-2867 RADIUS Tunnel Accounting

The RFC-2867 RADIUS Tunnel Accounting introduces six new RADIUS accounting types that are used with the RADIUS accounting attribute Acct-Status-Type (attribute 40), which indicates whether an accounting request marks the beginning of user service (start) or the end (stop).

This feature also introduces two new virtual private virtual private dialup network (VPDN) commands that help users better troubleshoot VPDN session events.

History for RFC-2867 RADIUS Tunnel Accounting

Restrictions for RFC-2867 RADIUS Tunnel Accounting

RADIUS tunnel accounting works only with L2TP tunnel support.

Information About RFC-2867 RADIUS Tunnel Accounting

To use RADIUS tunnel attributes and commands, you should understand the following concepts:

- Benefits of RFC-2867 RADIUS Tunnel Accounting, page 2
- RADIUS Attributes Support for RADIUS Tunnel Accounting, page 2

Benefits of RFC-2867 RADIUS Tunnel Accounting

Without RADIUS tunnel accounting support, VPDN with network accounting, which allows users to determine tunnel-link status changes, did not report all possible attributes to the accounting record file. Now that all possible attributes can be displayed, users can better verify accounting records with their Internet Service Providers (ISPs).

RADIUS Attributes Support for RADIUS Tunnel Accounting

Table 1 outlines the new RADIUS accounting types that are designed to support the provision of compulsory tunneling in dialup networks; that is, these attribute types allow you to better track tunnel status changes.

Note

The accounting types are divided into two separate tunnel types so users can decide if they want tunnel type, tunnel-link type, or both types of accounting.

• Tunnel-Type (64)—from client  
• Tunnel-Medium-Type (65)—from client  
• Tunnel-Client-Endpoint (66)—from client  
• Tunnel-Server-Endpoint (67)—from client  
• Acct-Tunnel-Connection (68)—from client |

1. If the specified tunnel type is used, these attributes should also be included in the accounting request packet.
How to Configure RADIUS Tunnel Accounting

This section contains the following procedures

- Enabling Tunnel Type Accounting Records, page 6
- Verifying RADIUS Tunnel Accounting, page 8

Enabling Tunnel Type Accounting Records

Use this task to configure your LAC to send tunnel and tunnel-link accounting records to be sent to the RADIUS server.

VPDN Tunnel Events

Two new command line interfaces (CLIs)—vpdn session accounting network (tunnel-link-type records) and vpdn tunnel accounting network (tunnel-type records)—are supported to help identify the following events:

- A VPDN tunnel is brought up or destroyed
- A request to create a VPDN tunnel is rejected
- A user session within a VPDN tunnel is brought up or brought down
- A user session create request is rejected

Note: The first two events are tunnel-type accounting records: authentication, authorization, and accounting (AAA) sends Tunnel-Start, Tunnel-Stop, or Tunnel-Reject accounting records to the RADIUS server. The next two events are tunnel-link-type accounting records: AAA sends Tunnel-Link-Start, Tunnel-Link-Stop, or Tunnel-Link-Reject accounting records to the RADIUS server.

SUMMARY STEPS

1. enable
2. configure terminal
3. aaa accounting network {default | list-name} {start-stop | stop-only | wait-start | none} group groupname
4. vpdn enable
5. vpdn tunnel accounting network list-name
6. vpdn session accounting network list-name
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 1    | `enable`         | Enables privileged EXEC mode.  
|      |                  | • Enter your password if prompted. |
| 2    | `configure terminal` | Enters global configuration mode. |
| 3    | `Router(config)# aaa accounting network {default | list-name} {start-stop | stop-only | wait-start | none} group groupname` | Enables network accounting.  
|      |                  | • `default`—If the default network accounting method-list is configured and no additional accounting configurations are enabled on the interface, network accounting is enabled by default.  
|      |                  | • `list-name`—The `list-name` defined in the `aaa accounting` command must be the same as the `list-name` defined in the VPDN command; otherwise, accounting will not occur.  
|      |                  | If either the `vpdn session accounting network` command or the `vpdn tunnel accounting network` command is linked to the `default` method-list, all tunnel and tunnel-link accounting records are enabled for those sessions. |
| 4    | `Router(config)# vpdn enable` | Enables virtual private dialup networking on the router and informs the router to look for tunnel definitions in a local database and on a remote authorization server (if applicable). |
| 5    | `Router(config)# vpdn tunnel accounting network list-name` | Enables Tunnel-Start, Tunnel-Stop, and Tunnel-Reject accounting records.  
|      |                  | • `list-name`—The `list-name` must match the `list-name` defined in the `aaa accounting` command; otherwise, network accounting will not occur. |
| 6    | `Router(config)# vpdn session accounting network list-name` | Enables Tunnel-Link-Start, Tunnel-Link-Stop, and Tunnel-Link-Reject accounting records.  
|      |                  | • `list-name`—The `list-name` must match the `list-name` defined in the `aaa accounting` command; otherwise, network accounting will not occur. |

## What To Do Next

After you have enabled RADIUS tunnel accounting, you can verify your configuration via the following optional task “Verifying RADIUS Tunnel Accounting.”
Verifying RADIUS Tunnel Accounting

Use either one or both of the following optional steps to verify your RADIUS tunnel accounting configuration.

SUMMARY STEPS

1. `enable`
2. `show accounting`
3. `show vpdn [session | tunnel]

DETAILED STEPS

<table>

RADIUS Attribute Screening

First Published: May 18, 2001
Last Published: December 17, 2007

The RADIUS Attribute Screening feature allows users to configure a list of “accept” or “reject” RADIUS attributes on the network access server (NAS) for purposes such as authorization or accounting.

If a NAS accepts and processes all RADIUS attributes received in an Access-Accept packet, unwanted attributes may be processed, creating a problem for wholesale providers who do not control their customers’ authentication, authorization, and accounting (AAA) servers. For example, there may be attributes that specify services to which the customer has not subscribed, or there may be attributes that may degrade service for other wholesale dial users. The ability to configure the NAS to restrict the use of specific attributes has therefore become a requirement for many users.

The RADIUS Attribute Screening feature should be implemented in one of the following ways:

- To allow the NAS to accept and process all standard RADIUS attributes for a particular purpose, except for those on a configured reject list
- To allow the NAS to reject (filter out) all standard RADIUS attributes for a particular purpose, except for those on a configured accept list

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “Feature Information for RADIUS Attribute Screening” section on page 10.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.
Prerequisites for RADIUS Attribute Screening

Before configuring a RADIUS accept or reject list, you must enable AAA.

For more information, refer to the AAA chapters in the *Cisco IOS Security Configuration Guide*, Release 12.2.

Restrictions for RADIUS Attribute Screening

**NAS Requirements**

To enable this feature, your NAS should be configured for authorization with RADIUS groups.

**Accept or Reject Lists Limitations**

The two filters used to configure accept or reject lists are mutually exclusive; therefore, a user can configure only one access list or one reject list for each purpose, per server group.

**Vendor-Specific Attributes**

This feature does not support vendor-specific attribute (VSA) screening; however, a user can specify attribute 26 (Vendor-Specific) in an accept or reject list, which accepts or reject all VSAs.
Required Attributes Screening Recommendation

It is recommended that users do not reject the following required attributes:

- For authorization:
  - 6 (Service-Type)
  - 7 (Framed-Protocol)

- For accounting:
  - 4 (NAS-IP-Address)
  - 40 (Acct-Status-Type)
  - 41 (Acct-Delay-Time)
  - 44 (Acct-Session-ID)

If an attribute is required, the rejection is refused, and the attribute is allowed to pass through.

Note

The user does not receive an error at the point of configuring a reject list for required attributes because the list does not specify a purpose—authorization or accounting. The server determines whether an attribute is required when it is known what the attribute is to be used for.

Information About RADIUS Attribute Screening

The RADIUS Attribute Screening feature provides the following benefits:

- Users can configure an accept or reject list consisting of a selection of attributes on the NAS for a specific purpose so unwanted attributes are not accepted and processed.
- Users may wish to configure an accept list that includes only relevant accounting attributes, thereby reducing unnecessary traffic and allowing users to customize their accounting data.

How to Screen RADIUS Attributes

The following sections describe how RADIUS attributes are screened and verified:

- Configuring RADIUS Attribute Screening
- Verifying RADIUS Attribute Screening

Configuring RADIUS Attribute Screening

To configure a RADIUS attribute accept or reject list for authorization or accounting, use the following commands:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `aaa authentication ppp default group group-name`
4. `aaa authorization network default group group-name`
5. `aaa group server radius group-name`
6. `server ip-address`
7. `authorization [accept | reject] listname - or - accounting [accept | reject] listname`
8. `exit`
9. `radius-server host (hostname | ip-address) [key string]`
10. `radius-server attribute list listname`
11. `attribute value1 [value2 [value3...]]`
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>enable</strong>&lt;br&gt;Enable privileged EXEC mode.&lt;br&gt;Example: Router&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>configure terminal</strong>&lt;br&gt;Enters global configuration mode.&lt;br&gt;Example: Router# configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><strong>Router(config)# aaa authentication ppp default group group-name</strong>&lt;br&gt;Specifies one or more AAA authentication methods for use on serial interfaces running PPP.</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><strong>Router(config)# aaa authorization network default group group-name</strong>&lt;br&gt;Sets parameters that restrict network access to the user.</td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><strong>Router(config)# aaa group server radius group-name</strong>&lt;br&gt;Groups different RADIUS server hosts into distinct lists and distinct methods.</td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><strong>Router(config-sg-radius)# server ip-address</strong>&lt;br&gt;Configures the IP address of the RADIUS server for the group server.</td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>**Router(config-sg-radius)# authorization [accept</td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td><strong>Router(config-sg-radius)# exit</strong>&lt;br&gt;Exits server-group configuration mode.</td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>**Router(config)# radius-server host {hostname</td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td><strong>Router(config)# radius-server attribute list listname</strong>&lt;br&gt;Defines the list name given to the set of attributes defined in the attribute command.&lt;br&gt;Note: The listname must be the same as the listname defined in Step 5.</td>
</tr>
<tr>
<td><strong>Step 11</strong></td>
<td><strong>Router(config-sg-radius)# attribute value1 [value2 [value3...]]</strong>&lt;br&gt;Adds attributes to the configured accept or reject list.&lt;br&gt;Note: This command can be used multiple times to add attributes to an accept or reject list.</td>
</tr>
</tbody>
</table>

Verifying RADIUS Attribute Screening

To verify an accept or reject list, use one of the following commands in privileged EXEC mode:
Configuration Examples for RADIUS Attribute Screening

This section provides the following configuration examples:

- **Authorization Accept: Example**
- **Accounting Reject: Example**
- **Authorization Reject and Accounting Accept: Example**
- **Rejecting Required Attributes: Example**

### Authorization Accept: Example

The following example shows how to configure an accept list for attribute 6 (Service-Type) and attribute 7 (Framed-Protocol); all other attributes (including VSAs) are rejected for RADIUS authorization.

```
AAA new-model
AAA authentication ppp default group radius-sg
AAA authorization network default group radius-sg
AAA group server radius radius-sg
    server 10.1.1.1
    authorization accept min-author
radius-server host 10.1.1.1 key mykey1
radius-server attribute list min-author
    attribute 6-7
```

### Accounting Reject: Example

The following example shows how to configure a reject list for attribute 66 (Tunnel-Client-Endpoint) and attribute 67 (Tunnel-Server-Endpoint); all other attributes (including VSAs) are accepted for RADIUS accounting.

```
AAA new-model
AAA authentication ppp default group radius-sg
AAA authorization network default group radius-sg
AAA group server radius radius-sg
    server 10.1.1.1
    accounting reject tnl-x-endpoint
radius-server host 10.1.1.1 key mykey1
radius-server attribute list tnl-x-endpoint
    attribute 66-67
```
Authorization Reject and Accounting Accept: Example

The following example shows how to configure a reject list for RADIUS authorization and configure an accept list for RADIUS accounting. Although you cannot configure more than one accept or reject list per server group for authorization or accounting, you can configure one list for authorization and one list for accounting per server group.

```c
aaa new-model
aaa authentication ppp default group radius-sg
aaa authorization network default group radius-sg
aaa group server radius radius-sg
    server 10.1.1.1
        authorization reject bad-author
        accounting accept usage-only

radius-server host 10.1.1.1 key mykey1
radius-server attribute list usage-only
    attribute 1,40,42-43,46

radius-server attribute list bad-author
    attribute 22,27-28,56-59
```

Rejecting Required Attributes: Example

The following example shows debug output for the `debug aaa accounting` command. In this example, required attributes 44, 40, and 41 have been added to the reject list “standard.”

```c
Router# debug aaa authorization

AAA/ACCT(6): Accounting method=radius-sg (radius)
RADIUS: attribute 44 cannot be rejected
RADIUS: attribute 61 rejected
RADIUS: attribute 31 rejected
RADIUS: attribute 40 cannot be rejected
RADIUS: attribute 41 cannot be rejected
```

Command Reference

The following commands are introduced or modified in the feature or features documented in this module.

- accounting (server-group configuration)
- authorization (server-group configuration)
- attribute (server-group configuration)
- radius-server attribute list

For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the *Cisco IOS Master Commands List*. 
# Feature Information for RADIUS Attribute Screening

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to [http://www.cisco.com/go/cfn](http://www.cisco.com/go/cfn). An account on Cisco.com is not required.

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

</table>
AAA—authentication, authorization, and accounting. Suite of network security services that provide the primary framework through which access control can be set up on your Cisco router or access server.

attribute—RADIUS Internet Engineering Task Force (IETF) attributes are the original set of 255 standard attributes that are used to communicate AAA information between a client and a server. Because IETF attributes are standard, the attribute data is predefined and well known; thus all clients and servers who exchange AAA information via IETF attributes must agree on attribute data such as the exact meaning of the attributes and the general bounds of the values for each attribute.

NAS—network access server. A Cisco platform (or collection of platforms, such as an AccessPath system) that interfaces between the packet world (for example, the Internet) and the circuit world (for example, the Public Switched Telephone Network).

RADIUS—Remote Authentication Dial-In User Service. RADIUS is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

VSA—vendor-specific attribute. VSAs are derived from one IETF attribute—vendor-specific (attribute 26). Attribute 26 allows a vendor to create and implement an additional 255 attributes. That is, a vendor can create an attribute that does not match the data of any IETF attribute and encapsulate it behind attribute 26: essentially, Vendor-Specific ="protocol:attribute=value".
RADIUS Centralized Filter Management

First Published: November 25, 2002
Last Updated: December 17, 2007

The RADIUS Centralized Filter Management feature introduces a filter-server to simplify ACL configuration and management. This filter-server serves as a centralized RADIUS repository and administration point, which users can centrally manage and configure access control list (ACL) filters.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “Feature Information for RADIUS Centralized Filter Management” section on page 10.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for RADIUS Centralized Filter Management

- You may need to add a dictionary file to your server if it does not support the new RADIUS VSAs. For a sample dictionary and vendors file, see the section “RADIUS Dictionary and Vendors File: Example” later in this document.
- If you need to add a dictionary file, ensure that your RADIUS server is nonstandard and that it can send the newly introduced VSAs.
- You want to set up RADIUS network authentication so a remote user can dial in and get IP connectivity.

Restrictions for RADIUS Centralized Filter Management

Multiple method lists are not supported in this feature; only a single global filter method list can be configured.

Information About RADIUS Centralized Filter Management

Before the RADIUS Centralized Filter Management feature, wholesale providers (who provide premium charges for customer services such as access control lists [ACLs]) were unable to prevent customers from applying exhaustive ACLs, which could impact router performance and other customers. This feature introduces a centralized administration point—a filter server—for ACL management. The filter server acts as a centralized RADIUS repository for ACL configuration.

Whether or not the RADIUS server that is used as the filter server is the same server that is used for access authentication, the network access server (NAS) will initiate a second access request to the filter server. If configured, the NAS will use the filter-ID name as the authentication username and the filter server password for the second access request. The RADIUS server will attempt to authenticate the filter-ID name, returning any required filtering configuration in the access-accept response.

Because downloading ACLs is time consuming, a local cache is maintained on the NAS. If an ACL name exists on the local cache, that configuration will be used without consulting the filter server.

**Note**

An appropriately configured cache should minimize delays; however, the first dialin user to require a filter will always experience a longer delay because the ACL configuration is retrieved for the first time.

Cache Management

A global filter cache is maintained on the NAS of recently downloaded ACLs; thus, users no longer have to repeatedly request the same ACL configuration information from a potentially overloaded RADIUS server. Users are required to flush the cache when the following criteria have been met:

- After an entry becomes associated with a newly active call, the idle timer that is associated with that entry will be reset, if configured to do so.
- After the idle-time stamp of an entry expires, the entry will be removed.
• After the global cache of entries reaches a specified maximum number, the entry whose idle-timer is closest to the idle time limit will be removed.

A single timer is responsible for managing all cache entries. The timer is started after the first cache entry is created, and it runs periodically until reboot. The period of the timer will correspond to the minimum granularity offered when configuring cache idle timers, which is one expiration per minute. A single timer prevents users from having to manage individual timers per cache entry.

---

**Note**

The single timer introduces a lack of precision in timer expiration. There is an average error of approximately 50 percent of the timer granularity. Although decreasing the timer granularity will decrease the average error, the decreased timer granularity will negatively impact performance. Because precise timing is not required for cache management, the error delay should be acceptable.

---

### New Vendor-Specific Attribute Support

This feature introduces support for three new vendor-specific attributes (VSAs), which can be divided into the following two categories:

• User profile extensions
  - Filter-Required (50)—Specifies whether the call should be permitted if the specified filter is not found. If present, this attribute will be applied after any authentication, authorization, and accounting (AAA) filter method-list.

• Pseudo-user profile extensions
  - Cache-Refresh (56)—Specifies whether cache entries should be refreshed each time an entry is referenced by a new session. This attribute corresponds to the `cache refresh` command.
  - Cache-Time (57)—Specifies the idle timeout, in minutes, for cache entries. This attribute corresponds to the `cache clear` command.

---

**Note**

All RADIUS attributes will override any command-line interface (CLI) configurations.

---

### How to Configure Centralized Filter Management for RADIUS

Use the following sections to configure the Centralized Filter Management feature.

• Configuring the RADIUS ACL Filter Server
• Configuring the Filter Cache
• Verifying the Filter Cache
Configuring the RADIUS ACL Filter Server

To enable the RADIUS ACL filter server, use the following command in global configuration mode:

```
Router(config)# aaa authorization cache filterserver default methodlist[methodlist2...]
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# aaa authorization cache filterserver default methodlist[methodlist2...]</td>
<td>Enables AAA authorization caches and the downloading of an ACL configuration from a RADIUS filter server.</td>
</tr>
<tr>
<td>• default—The default authorization list.</td>
<td></td>
</tr>
<tr>
<td>• methodlist [methodlist2... ]—One of the keywords listed on the password command page.</td>
<td></td>
</tr>
</tbody>
</table>

Configuring the Filter Cache

Follow the steps in this section to configure the AAA filter cache.

SUMMARY STEPS

1. enable
2. configure terminal
3. aaa cache filter
4. password {0 | 7} password
5. cache disable
6. cache clear age minutes
7. cache refresh
8. cache max number

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>• Enter your password if prompted.</td>
<td></td>
</tr>
<tr>
<td>Example: Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3 Router(config)# aaa cache filter</td>
<td>Enables filter cache configuration and enters AAA filter configuration mode.</td>
</tr>
</tbody>
</table>
## Command Purpose

| Step 4 | Router(config-aaa-filter)# password (0 | 7) password | (Optional) Specifies the optional password that is to be used for filter server authentication requests.  
|       |             | 0—Specifies that an unencrypted password will follow.  
|       |             | 7—Specifies that a hidden password will follow.  
|       |             | *Note* If a password is not specified, the default password (“cisco”) is enabled.  |
| Step 5 | Router(config-aaa-filter)# cache disable | (Optional) Disables the cache.  |
| Step 6 | Router(config-aaa-filter)# cache clear age minutes | (Optional) Specifies, in minutes, when cache entries expire and the cache is cleared.  
|       |             | minutes—Any value between 0 to 4294967295.  
|       |             | *Note* If a time is not specified, the default (1400 minutes [1 day]) is enabled.  |
| Step 7 | Router(config-aaa-filter)# cache refresh | (Optional) Refreshes a cache entry when a new session begins.  
|       |             | This command is enabled by default. To disable this functionality, use the `no cache refresh` command.  |
| Step 8 | Router(config-aaa-filter)# cache max number | (Optional) Limits the absolute number of entries the cache can maintain for a particular server.  
|       |             | number—The maximum number of entries the cache can contain. Any value between 0 to 4294967295.  
|       |             | *Note* If a number is not specified, the default (100 entries) is enabled.  |

## Verifying the Filter Cache

To display the cache status, use the `show aaa cache filterserver` EXEC command. The following is sample output for the `show aaa cache filterserver` command:

```
Router# show aaa cache filterserver

<table>
<thead>
<tr>
<th>Filter</th>
<th>Server</th>
<th>Age</th>
<th>Expires</th>
<th>Refresh</th>
<th>Access-Control-Lists</th>
</tr>
</thead>
<tbody>
<tr>
<td>aol</td>
<td>10.2.3.4</td>
<td>0</td>
<td>1440</td>
<td>100 ip in icmp drop</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>ip out icmp drop</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>ip out forward tcp dstip 1.2.3...</td>
<td></td>
</tr>
<tr>
<td>msn</td>
<td>10.3.3.4</td>
<td>N/A</td>
<td>Never</td>
<td>2 ip in tcp drop</td>
<td></td>
</tr>
<tr>
<td>msn2</td>
<td>10.4.3.4</td>
<td>N/A</td>
<td>Never</td>
<td>2 ip in tcp drop</td>
<td></td>
</tr>
<tr>
<td>vone</td>
<td>10.5.3.4</td>
<td>N/A</td>
<td>Never</td>
<td>0 ip in tcp drop</td>
<td></td>
</tr>
</tbody>
</table>
```

*Note* The `show aaa cache filterserver` command shows how many times a particular filter has been referenced or refreshed. This function may be used in administration to determine which filters are actually being used.
Troubleshooting Tips

To help troubleshoot your filter cache configurations, use the privileged EXEC `debug aaa cache filterserver` command. To view sample output for the `debug aaa cache filterserver` command, refer to the section “Debug Output: Example” later in this document.

Monitoring and Maintaining the Filter Cache

To monitor and maintain filter caches, use at least one of the following EXEC commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>clear aaa cache filterserver acl [filter-name]</code></td>
<td>Clears the cache status for a particular filter or all filters.</td>
</tr>
<tr>
<td><code>show aaa cache filterserver</code></td>
<td>Displays the cache status.</td>
</tr>
</tbody>
</table>

Configuration Examples for RADIUS Centralized Filter Management

This section provides the following configuration examples:

- NAS Configuration: Example, page 6
- RADIUS Server Configuration: Example, page 7
- RADIUS Dictionary and Vendors File: Example, page 7
- Debug Output: Example, page 7

NAS Configuration: Example

The following example shows how to configure the NAS for cache filtering. In this example, the server group “mygroup” in contacted first. If there is no response, the default RADIUS server will then be contacted. If there still is no response, the local filters care contacted. Finally, the call is accepted if the filter cannot be resolved.

```bash
aaa authorization cache filterserver group mygroup group radius local none
!
aaa group server radius mygroup

    cache max 100
!```
RADIUS Server Configuration: Example

The following example is a sample RADIUS configuration that is for a remote user “user1” dialing into the NAS:

myfilter Password = "cisco"
Service-Type = Outbound,
Ascend:Ascend-Call-Filter = "ip in drop srcip 10.0.0.1/32 dstip 10.0.0.10/32 icmp",
Ascend:Ascend-Call-Filter = "ip in drop srcip 10.0.0.1/32 dstip 10.0.0.10/32 tcp dstport = telnet",
Ascend:Ascend-Cache-Refresh = Refresh-No,
Ascend:Ascend-Cache-Time = 15

user1 Password = "cisco"
Service-Type = Framed,
Filter-Id = "myfilter",
Ascend:Ascend-Filter-Required = Filter-Required-Yes,

RADIUS Dictionary and Vendors File: Example

The following example is a sample RADIUS dictionary file for the new VSAs. In this example, the dictionary file is for a Merit server.

dictionary file:
Ascend.attr Ascend-Filter-Required 50 integer (*, 0, NOENCAPS)
Ascend.attr Ascend-Cache-Refresh 56 integer (*, 0, NOENCAPS)
Ascend.attr Ascend-Cache-Time 57 integer (*, 0, NOENCAPS)

Ascend.value Ascend-Cache-Refresh Refresh-No 0
Ascend.value Ascend-Cache-Refresh Refresh-Yes 1
Ascend.value Ascend-Filter-Required Filter-Required-No 0
Ascend.value Ascend-Filter-Required Filter-Required-Yes 1

vendors file:
50 50
56 56
57 57

Debug Output: Example

The following is sample output from the debug aaa cache filterserver command:

Router# debug aaa cache filterserver
AAA/FLTSV: need "myfilter" (fetch), call 0x612DAC64
AAA/FLTSV: send req, call 0x612DAC50
AAA/FLTSV: method SERVER_GROUP myradius
AAA/FLTSV: recv reply, call 0x612DAC50 (PASS)
AAA/FLTSV: create cache
AAA/FLTSV: add attr "call-inacl"
AAA/FLTSV: add attr "call-inacl"
AAA/FLTSV: add attr "call-inacl"
AAA/FLTSV: skip attr "filter-cache-refresh"
AAA/FLTSV: skip attr "filter-cache-time"
AAA/CACHE: set "AAA filtserv cache" entry "myfilter" refresh? no

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

- aaa authorization cache filterserver
- aaa cache filter
- cache clear age
- cache disable
- cache refresh
- clear aaa cache filterserver acl
- debug aaa cache filterserver
- password
- show aaa cache filterserver
Feature Information for RADIUS Centralized Filter Management

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

This document describes the Remote Authentication Dial-In User Services (RADIUS) Debug Enhancements feature in Cisco IOS Release 12.2(11)T. It includes the following sections:

- Feature Overview, page 1
- Supported Platforms, page 2
- Supported Standards, MIBs, and RFCs, page 3
- Prerequisites, page 4
- Configuration Tasks, page 4
- Configuration Examples, page 7
- Command Reference, page 9
- Glossary, page 10

Feature Overview

This document details the RADIUS Debug Enhancements feature. RADIUS is a distributed client/server system that provides the following functionality:

- secures networks against unauthorized access
- enables authorization of specific service limits
- provides accounting information so that services can be billed

In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.
The `debug radius` command displays information associated with RADIUS. Prior to the RADIUS Debug Enhancements feature, `debug radius` output was available only in an expanded, hexadecimal string format, resulting in displays that were difficult to interpret and analyze. Moreover, attribute value displays were truncated, particularly for vendor-specific attributes (VSAs). The new feature provides enhanced RADIUS display including the following:

- Packet dump in a more readable, user-friendly ASCII format than before
- Complete display of attribute values without truncation
- Ability to select a brief RADIUS `debug` output display

### Benefits

- Provides RADIUS debug display in a user-friendly format
- Supports complete RADIUS debug information
- Provides the default display of packet dump in ASCII format
- Allows a compact debugging output option that is useful for high-traffic, operational environments

### Restrictions

Only Internet Engineering Task Force (IETF) attributes and Cisco VSAs used in voice applications are supported. For unsupported attributes, “undebuggable” is displayed.

### Related Features and Technologies

- Cisco IOS security
- RADIUS authentication, authorization, and accounting (AAA)
- Cisco Voice over IP (VoIP)

### Related Documents

- *RADIUS Vendor-Specific Attributes Voice Implementation Guide*, Release 12.1
- *Cisco IOS Debug Command Reference*, Release 12.2

### Supported Platforms

- Cisco 1400 series
- Cisco 1600 series
- Cisco 1700 series
- Cisco 2500 series
Supported Standards, MIBs, and RFCs

Standards
No new or modified standards are supported by this feature.

MIBs
To locate and download MIBs for selected platforms, Cisco IOS releases, and feature sets, use Cisco MIB Locator found at the following URL:

http://tools.cisco.com/ITDIT/MIBS/servlet/index

If Cisco MIB Locator does not support the MIB information that you need, you can also obtain a list of supported MIBs and download MIBs from the Cisco MIBs page at the following URL:

To access Cisco MIB Locator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

http://www.cisco.com/register

RFCs
No new or modified RFCs are supported by this feature.

Availability of Cisco IOS Software Images
Platform support for particular Cisco IOS software releases is dependent on the availability of the software images for those platforms. Software images for some platforms may be deferred, delayed, or changed without prior notice. For updated information about platform support and availability of software images for each Cisco IOS software release, refer to the online release notes or, if supported, Cisco Feature Navigator.
Prerequisites

- Configure the gateway as a RADIUS client. Refer to the chapter “Configuring the RADIUS Client Gateway” in the RADIUS Vendor-Specific Attributes Voice Implementation Guide, Release 12.1.
- Be familiar with IETF RFC 2138.

Configuration Tasks

See the following sections for configuration tasks for the RADIUS Debug Enhancements feature. Each task in the list is identified as either required or optional.

- Configuring Default Debug ASCII Display (optional)
- Configuring Debug Display in Brief Format (optional)
- Configuring Debug Display in Hex Format (optional)
- Verifying the debug radius Command (optional)

Configuring Default Debug ASCII Display

The complete ASCII format debug display with no truncation is enabled by default; no configuration tasks are required to enable this feature. To reenable the feature if it was disabled by using the no debug radius command, use the following command in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router# debug radius</td>
<td>Enables RADIUS debugging output.</td>
</tr>
</tbody>
</table>

Note

Prior to Cisco IOS Release 12.2(11)T, the debug radius command enabled truncated debugging output in hexadecimal notation, rather than ASCII. To enable debugging output in hex format, use the debug radius hex command.

Configuring Debug Display in Brief Format

Debugging output is available in a compact output that displays only basic information. To enable this display option, use the following command in privileged EXEC mode:
RADIUS Debug Enhancements

Configuration Tasks

Configuring Debug Display in Hex Format

Debugging output is available in hexadecimal notation. To enable this display option, use the following command in privileged EXEC mode:

```
Router# debug radius hex
```

Verifying the debug radius Command

Use the `show debug` command to verify RADIUS output options.

```
5300# show debug

Radius protocol debugging is on
Radius packet hex dump debugging is on
5300# show debug

Configuration Examples

This section provides the following configuration examples:

- Default debug radius Command Example
- Compact Debugging Output Example

Default debug radius Command Example

The following sample output shows the default RADIUS output in ASCII notation, generated by the debug radius command:

```
router# debug radius
Radius protocol debugging is on
Radius packet hex dump debugging is off

00:02:50: RADIUS: ustruct sharecount=3
```

Note: The following output displays the internal information that is found inside a RADIUS protocol message. For more information about RADIUS protocol messages, see IETF RFC 2138.
00:02:51: RADIUS: Received from id 0 10.0.0.0:1824, Accounting-response, len 20

Compact Debugging Output Example

A new EXEC command, `debug radius brief`, enables this abbreviated output option. The following sample output displays only the client/server interaction and minimum packet information (packet type, ID and so forth).

```
router# debug radius brief

Radius protocol debugging is on
Radius packet hex dump debugging is off
Radius protocol in brief format debugging is on
00:05:21: RADIUS: Initial Transmit ISDN 0:D:23 id 6 10.0.0.1:1824, Accounting-Request, len 358
00:05:21: %ISDN-6-CONNECT: Interface Serial0:22 is now connected to 4085554206
00:05:26: RADIUS: Retransmit id 6

```
AAA — authentication, authorization, and accounting. Pronounced “triple a.”

ASCII — American Standard Code for Information Interchange. 8-bit code for character representation (7 bits plus parity).

attribute — Form of information items provided by the X.500 Directory Service. The directory information base consists of entries, each containing one or more attributes. Each attribute consists of a type identifier together with one or more values.

IETF — Internet Engineering Task Force. Task force consisting of over 80 working groups responsible for developing Internet standards. The IETF operates under the auspices of ISOC.

RADIUS — Remote Authentication Dial-In User Service. Database for authenticating modem and ISDN connections and for tracking connection time.

VoIP — Voice over IP. The capability to carry normal telephony-style voice over an IP-based internet with POTS-like functionality, reliability, and voice quality. VoIP enables a router to carry voice traffic (for example, telephone calls and faxes) over an IP network. In VoIP, the DSP segments the voice signal into frames, which then are coupled in groups of two and stored in voice packets. These voice packets are transported using IP in compliance with ITU-T specification H.323.

VSA — vendor-specific attribute. An attribute that has been implemented by a particular vendor. It uses the attribute Vendor-Specific to encapsulate the resulting AV pair: essentially, Vendor-Specific = protocol:attribute = value.
RADIUS Logical Line ID

First Published: November 25, 2002
Last Updated: December 17, 2007

The RADIUS Logical Line ID feature, also known as the Logical Line Identification (LLID) Blocking feature enables administrators to track their customers on the basis of the physical lines on which customer calls originate. Administrators use a virtual port that does not change as customers move from one physical line to another. This virtual port facilitates the maintenance of the administrator’s customer profile database and allows the administrator to do additional security checks on customers.

Finding Feature Information in This Module
Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “Feature Information for RADIUS Logical Line ID” section on page 9.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images
Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

- Configuration Examples for RADIUS Logical Line ID, page 5
- Additional References, page 7
- Command Reference, page 8
- Feature Information for RADIUS Logical Line ID, page 9
Prerequisites for RADIUS Logical Line ID

Although this feature can be used with any RADIUS server, some RADIUS servers may require modifications to their dictionary files to allow the Calling-Station-ID attribute to be returned in Access-Accept messages. For example, the Merit RADIUS server does not support LLID downloading unless you modify its dictionary as follows: “ATTRIBUTE Calling-Station-Id 31 string (*, *)”

Restrictions for RADIUS Logical Line ID

The RADIUS Logical Line ID feature supports RADIUS only. TACACS+ is not supported.

This feature can be applied only toward PPP over Ethernet over ATM (PPPoEoATM) and PPP over Ethernet over VLAN (PPPoEoVLAN) (Dot1Q) calls; no other calls, such as ISDN, can be used.

Information About RADIUS Logical Line ID

LLID is an alphanumeric string (which must be a minimum of one character and a maximum of 253 characters) that is a logical identification of a subscriber line. LLID is maintained in a customer profile database on a RADIUS server. When the customer profile database receives a preauthorization request from the access router, the RADIUS server sends the LLID to the router as the Calling-Station-ID attribute (attribute 31).

The Layer 2 Tunneling Protocol (L2TP) access concentrator (LAC) sends a preauthorization request to the customer profile database when the LAC is configured for preauthorization. Configure the LAC for preauthorization using the subscriber access command.

Note

Downloading the LLID is referred to as “preauthorization” because it occurs before either service (domain) authorization or user authentication and authorization occur.

The customer profile database on the RADIUS server consists of user profiles for each physical network access server (NAS) port that is connected to the router. Each user profile contains a profile matched to a username (attribute 1) representing the physical port on the router. When the router is configured for preauthorization, it queries the customer profile database using a username representative of the physical NAS port making the connection to the router. When a match is found in the customer profile database, the customer profile database returns an Access-Accept message containing the LLID in the user profile. The LLID is defined in the Access-Accept record as the Calling-Station-ID attribute.

The preauthorization process can also provide the real username being used for authentication to the RADIUS server. Because the physical NAS port information is being used as the username (attribute 1), RADIUS attribute 77 (Connect-Info) can be configured to contain the authentication username. This configuration allows the RADIUS server to provide additional validation on the authorization request if it chooses, such as analyzing the username for privacy rules, before returning an LLID back to the router.
How to Configure RADIUS Logical Line ID

See the following sections for configuration tasks for the RADIUS Logical Line ID feature. Each task in the list is identified as either required or optional.

- Configuring Preauthorization, page 3 (required)
- Configuring the LLID in a RADIUS User Profile, page 4 (required)
- Verifying Logical Line ID, page 4 (optional)

Configuring Preauthorization

To download the LLID and configure the LAC for preauthorization, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip radius source-interface interface-name`
4. `subscriber access {pppoe | pppoa} pre-authorize nas-port-id [default | list-name][send username]`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router&gt; enable</td>
</tr>
<tr>
<td>Step 2 <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router# configure terminal</td>
</tr>
<tr>
<td>Step 3 <code>ip radius source-interface interface-name</code></td>
<td>Specifies the IP address portion of the username for the preauthorization request.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router (config)# ip radius source-interface Loopback1</td>
</tr>
<tr>
<td>Step 4 `subscriber access {pppoe</td>
<td>pppoa} pre-authorize nas-port-id [default</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router (config)# subscriber access pppoe pre-authorize nas-port-id mlist_llid send username</td>
</tr>
</tbody>
</table>

The `send username` option specifies that you include the authentication username of the session inside the Connect-Info (attribute 77) in the Access-Request message.
Configuring the LLID in a RADIUS User Profile

To configure the user profile for preauthorization, add a NAS port user to the customer profile database and add RADIUS Internet Engineering Task Force (IETF) attribute 31 (Calling-Station-ID) to the user profile.

**SUMMARY STEPS**

1. UserName=nas_port: ip-address:slot/module/port/vpi.vci
2. UserName=nas-port: ip-address:slot/module/port/vlan-id
3. Calling-Station-Id = “string (*,*)”

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 UserName=nas_port: ip-address:slot/module/port/vpi.vci</td>
<td>(Optional) Adds a PPPoE over ATM NAS port user.</td>
</tr>
<tr>
<td>Step 2 UserName=nas-port: ip-address:slot/module/port/vlan-id</td>
<td>(Optional) Adds a PPPoE over VLAN NAS port user.</td>
</tr>
<tr>
<td>Step 3 Calling-Station-Id = ”string (<em>,</em>)”</td>
<td>Adds attribute 31 to the user profile.</td>
</tr>
<tr>
<td></td>
<td>• String—One or more octets, containing the phone number from which the user placed the call.</td>
</tr>
</tbody>
</table>

Verifying Logical Line ID

To verify feature functionality, perform the following steps.

**SUMMARY STEPS**

1. enable
2. debug radius

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
</tbody>
</table>
| Example: 
Router> enable | Checks to see that RADIUS attribute 31 is the LLID in the Accounting-Request on LAC and in the Access-Request and Accounting-Request on the LNS. |
| Step 2 debug radius | Checks to see that RADIUS attribute 31 is the LLID in the Accounting-Request on LAC and in the Access-Request and Accounting-Request on the LNS. |
| Example: 
Router# debug radius | Checks to see that RADIUS attribute 31 is the LLID in the Accounting-Request on LAC and in the Access-Request and Accounting-Request on the LNS. |
Configuration Examples for RADIUS Logical Line ID

RADIUS NAS-IP-Address Attribute Configurability

First Published: November 19, 2003
Last Updated: December 3, 2007

The RADIUS NAS-IP-Address Attribute Configurability feature allows an arbitrary IP address to be configured and used as RADIUS attribute 4, NAS-IP-Address, without changing the source IP address in the IP header of the RADIUS packets. This feature may be used for situations in which service providers are using a cluster of small network access servers (NASs) to simulate a large NAS to improve scalability. This feature allows the NASs to behave as a single RADIUS client from the perspective of the RADIUS server.

Finding Feature Information in This Module
Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “Feature Information for RADIUS NAS-IP-Address Attribute Configurability” section on page 8.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images
Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Contents

- Prerequisites for RADIUS NAS-IP-Address Attribute Configurability, page 2
- Restrictions for RADIUS NAS-IP-Address Attribute Configurability, page 2
- Information About RADIUS NAS-IP-Address Attribute Configurability, page 2
- How to Configure RADIUS NAS-IP-Address Attribute Configurability, page 3
- Configuration Examples for RADIUS NAS-IP-Address Attribute Configurability, page 5
Prerequisites for RADIUS NAS-IP-Address Attribute Configurability

The following requirements are necessary before configuring this feature:

- Experience with IP Security (IPSec) and configuring both RADIUS servers and authentication, authorization, and accounting (AAA) is necessary.
- RADIUS server and AAA lists must be configured.

Restrictions for RADIUS NAS-IP-Address Attribute Configurability

The following restrictions apply if a cluster of RADIUS clients are being used to simulate a single RADIUS client for scalability. Solutions, or workarounds, to the restrictions are also provided.

- RADIUS attribute 44, Acct-Session-Id, may overlap among sessions from different NASs.
  There are two solutions. Either the `radius-server attribute 44 extend-with-addr` or `radius-server unique-ident` command can be used on NAS routers to specify different prepending numbers for different NAS routers.
- RADIUS server-based IP address pool for different NASs must be managed.
  The solution is to configure different IP address pool profiles for different NASs on the RADIUS server. Different NASs use different pool usernames to retrieve them.
- RADIUS request message for sessions from different NASs must be differentiated.
  One of the solutions is to configure different format strings for RADIUS attribute 32, NAS-Identifier, using the `radius-server attribute 32 include-in-access-req` command on different NASs.

Information About RADIUS NAS-IP-Address Attribute Configurability

To simulate a large NAS RADIUS client using a cluster of small NAS RADIUS clients, as shown in Figure 1, a Network Address Translation (NAT) or Port Address Translation (PAT) device is inserted in a network. The device is placed between a cluster of NASs and the IP cloud that is connected to a RADIUS server. When RADIUS traffic from different NASs goes through the NAT or PAT device, the source IP addresses of the RADIUS packets are translated to a single IP address, most likely an IP address on a loopback interface on the NAT or PAT device. Different User Datagram Protocol (UDP) source ports are assigned to RADIUS packets from different NASs. When the RADIUS reply comes
back from the server, the NAT or PAT device receives it, uses the destination UDP port to translate the destination IP address back to the IP address of the NAS, and forwards the reply to the corresponding NAS.

Figure 1 demonstrates how the source IP addresses of several NASs are translated to a single IP address as they pass through the NAT or PAT device on the way to the IP cloud.

Figure 1  NAS Addresses Translated to a Single IP Address

RADIUS servers normally check the source IP address in the IP header of the RADIUS packets to track the source of the RADIUS requests and to maintain security. The NAT or PAT solution satisfies these requirements because only a single source IP address is used even though RADIUS packets come from different NAS routers.

However, when retrieving accounting records from the RADIUS database, some billing systems use RADIUS attribute 4, NAS-IP-Address, in the accounting records. The value of this attribute is recorded on the NAS routers as their own IP addresses. The NAS routers are not aware of the NAT or PAT that runs between them and the RADIUS server; therefore, different RADIUS attribute 4 addresses will be recorded in the accounting records for users from the different NAS routers. These addresses eventually expose different NAS routers to the RADIUS server and to the corresponding billing systems.

Using the RADIUS NAS-IP-Address Attribute Configurability Feature

The RADIUS NAS-IP-Address Attribute Configurability feature allows you to freely configure an arbitrary IP address as RADIUS NAS-IP-Address, RADIUS attribute 4. By manually configuring the same IP address, most likely the IP address on the loopback interface of the NAT or PAT device, for all the routers, you can hide a cluster of NAS routers behind the NAT or PAT device from the RADIUS server.

How to Configure RADIUS NAS-IP-Address Attribute Configurability

This section contains the following procedures:

- Configuring RADIUS NAS-IP-Address Attribute Configurability, page 4
- Monitoring and Maintaining RADIUS NAS-IP-Address Attribute Configurability, page 4
Configuring RADIUS NAS-IP-Address Attribute Configurability

Before configuring the RADIUS NAS-IP-Address Attribute Configurability feature, you must have configured the RADIUS servers or server groups and AAA method lists.

To configure the RADIUS NAS-IP-Address Attribute Configurability feature, perform the following steps.

SUMMARY STEPS

1. enable
2. configure terminal
3. radius-server attribute 4 ip-address

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 3 radius-server attribute 4 ip-address</td>
<td>Configures an IP address to be used as the RADIUS NAS-IP-Address, attribute 4.</td>
</tr>
</tbody>
</table>

Example:

Router> enable

Example:

Router# configure terminal

Example:

Router (config)# radius-server attribute 4 10.2.1.1

Monitoring and Maintaining RADIUS NAS-IP-Address Attribute Configurability

To monitor the RADIUS attribute 4 address that is being used inside the RADIUS packets, use the debug radius command.

SUMMARY STEPS

1. enable
2. debug radius
DETAILED STEPS

Configuration Examples for RADIUS NAS-IP-Address Attribute Configurability

This section provides the following configuration example:

- Configuring a RADIUS NAS-IP-Address Attribute Configurability: Example, page 5

Configuring a RADIUS NAS-IP-Address Attribute Configurability: Example

The following example shows that IP address 10.0.0.21 has been configured as the RADIUS NAS-IP-Address attribute:

```
radius-server attribute 4 10.0.0.21
radius-server host 10.0.0.10 auth-port 1645 acct-port 1646 key cisco
```

Feature Information for RADIUS NAS-IP-Address Attribute Configurability

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

RADIUS Route Download

First Published: February 25, 2002
Last Updated: December 17, 2007

The RADIUS Route Download feature allows users to configure their network access server (NAS) to direct RADIUS authorization. Users configure a separate named method list (in addition to the default method list) for static route download requests sent by their NAS to authorization, authentication, and accounting (AAA) servers.

Before this feature, RADIUS authorization for static route download requests was sent only to AAA servers specified by the default method list.

This feature extends the functionality of the `aaa route download` command to allow users to specify the name of the method list that will be used to direct static route download requests to the AAA servers. The `aaa route download` command may be used to specify a separate method list for downloading static routes. This method list can be added by using the `aaa authorization configuration` command.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “Feature Information for RADIUS Route Download” section on page 6.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.
Contents

- Prerequisites, page 2
- Configuration Tasks, page 2
- Configuration Examples, page 3
- Additional References, page 4
- Command Reference, page 5
- Feature Information for RADIUS Route Download, page 6

Prerequisites

AAA network security must be enabled before you perform the tasks in this feature. For information about enabling AAA, refer to the AAA section in the Cisco IOS Security Configuration Guide, Release 12.4.

Configuration Tasks

Use the following sections to configure the RADIUS Route Download feature.

- Configuring RADIUS Route Download
- Verifying RADIUS Route Download

Configuring RADIUS Route Download

To configure the NAS to send static route download requests to the servers specified by a named method list, use the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
Router(config)# aaa authorization configuration method-name [radius | tacacs+ | group group-name] | Downloads static route configuration information from the AAA server using RADIUS. |
| **Step 2**  
Router(config)# aaa route download [time] [authorization method-list] | Enables the static route download feature. Use the authorization method-list attributes to specify a named method list to which RADIUS authorization requests for static route downloads are sent. |

Verifying RADIUS Route Download

To verify the routes that are installed, use the `show ip route` command in EXEC mode.

To display information that is associated with RADIUS, use the `debug radius` command in privileged EXEC mode.
Configuration Examples

This section provides the following configuration examples:

- RADIUS Route Download Configuration Example

RADIUS Route Download Configuration Example

The following example shows how to configure the NAS to send static route download requests to the servers specified by the method list named “list1”:

```
aaa new-model
aaa group server radius rad1
  server 10.2.2.2 auth-port 1645 acct-port 1646
!
aaa group server tacacs+ tac1
  server 172.17.3.3
!
aaa authorization configuration default group radius
aaa authorization configuration list1 group rad1 group tac1
aaa route download 1 authorization list1

tacacs-server host 172.17.3.3
tacacs-server key cisco
tacacs-server administration
!
radius-server host 10.2.2.2 auth-port 1645 acct-port 1646
radius-server key cisco
```
Additional References

The following sections provide references related to RADIUS Route Download.

RADIUS Support of 56-Bit Acct Session-Id

The RADIUS Support of 56-Bit Acct Session-Id feature introduces a new 32-bit authentication, authorization, and accounting (AAA) variable, acct-session-id-count. The first eight bits of the acct-session-id-count variable are reserved for the unique identifier variable, a unique number assigned to the accounting session which is preserved between reloads. The acct-session-id-count variable is used in addition to the existing 32-bit acct-session-id variable, RADIUS attribute 44, providing a total of 56 bits of to represent the actual Accounting Session Identifier (ID). Benefits of this feature include the following:

- The 8-bit unique identifier variable allows accounting sessionIDs to be identified if a reload occurs.
- The additional space provided by the acct-session-id-count variable can keep track of acct-session-id wrapping when there is a high volume of traffic, such as voice calls. By incrementing each time the acct-session-id variable wraps, the acct-session-id-count variable preserves accounting information.

Supported Platforms

- Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, Cisco AS5850

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at http://www.cisco.com/go/fn. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.
Prerequisites for RADIUS Support of 56-Bit Acct Session-Id

Information About RADIUS Support of 56-Bit Acct Session-Id

To configure the RADIUS Support of 56-bit Acct Session-Id feature, you must understand the following concepts:

- **Acct-Session-Id Attribute**, page 2
- **Acct-Session-Id-Count Attribute**, page 2
- **Benefits of RADIUS Support of 56-Bit Acct Session-Id**, page 3

**Acct-Session-Id Attribute**

RADIUS attribute 44, Accounting Session ID, is a unique accounting identifier that makes it easy to match start and stop records in a log file. Accounting session ID numbers restart at 1 each time the router is power-cycled or the software is reloaded. RADIUS attribute 44 is automatically enabled when AAA accounting is configured.

The acct-session-id variable is a 32-bit variable that can take on values from 00000000–FFFFFFFF.

**Acct-Session-Id-Count Attribute**

The new acct-session-id-count variable is a 32-bit variable. The first eight bits of the variable are reserved for the unique identifier variable, an identifier that allows the RADIUS server to identify an accounting session if a reload occurs. The remaining 24 bits of the acct-session-id-count variable acts as a counter variable. When the first acct-session-id variable is assigned, this counter variable is set to 1. The variable increments by 1 every time the acct-session-id variable wraps, preventing the loss of accounting information.

The acct-session-id-count variable can take on values from ##000000–##FFFFFF, where ## represents the eight bits that are reserved for the unique identifier variable.

The acct-session-id-count and acct-session-id variables are concatenated before being sent to the RADIUS server, resulting in the acct-session variable being represented as the following:

##000000 00000000–##FFFFFF FFFFFFFF

This allows a total of 56 bits to be used for acct-session-id space.
Benefits of RADIUS Support of 56-Bit Acct Session-Id

Allows RADIUS Servers to Identify Accounting Sessions After a Reload
The 8-bit unique identifier variable allows accounting session identities to be identified if a reload occurs.

Provides Accounting Information Space for High Volume Traffic
The additional space provided by the acct-session-id-count variable can keep track of acct-session-id wrapping when there is a high volume of traffic, such as voice calls. By incrementing each time the acct-session-id variable wraps, the acct-session-id-count variable preserves accounting information.

How to Configure RADIUS Support of 56-Bit Acct Session-Id

This section contains the following procedure:
- Configuring RADIUS Support of 56-Bit Acct Session-Id, page 3

Configuring RADIUS Support of 56-Bit Acct Session-Id

This task enables the acct-session-id-count variable containing the unique identifier variable.

SUMMARY STEPS

1. enable
2. radius-server unique-ident \textit{id}

DETAILED STEPS

<table>
<thead>
<tr>

RADIUS Tunnel Preference for Load Balancing and Fail-Over

Feature History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2(4)T</td>
<td>This feature was introduced.</td>
</tr>
</tbody>
</table>

This document describes the RADIUS Tunnel Preference for Load Balancing and Fail-Over feature in Cisco IOS Release 12.2(4)T. It includes the following sections:

- Feature Overview, page 1
- Supported Platforms, page 4
- Supported Standards, MIBs, and RFCs, page 5
- Prerequisites, page 5
- Configuration Tasks, page 5
- Configuration Example, page 6
- Command Reference, page 6
- Glossary, page 6

Feature Overview

The RADIUS Tunnel Preference for Load Balancing and Fail-Over feature provides load balancing and fail-over virtual private dialup network (VPDN) home gateway (HGW) groups in a standardized fashion. This feature introduces new software functionality; no new command is associated with this feature.

Industry-Standard Rather Than Proprietary Attributes

Until Cisco IOS Release 12.2(4)T, load balancing and fail-over functionality for a Layer 2 Tunnel Protocol network server (LNS) was provided by the Cisco proprietary Vendor Specific Attribute (VSA). In a multivendor network environment, using VSA on a RADIUS server can cause interoperability issues.
among network access servers (NASs) manufactured by different vendors. Even though some RADIUS server implementations can send VSAs that the requesting NAS can understand, the user still must maintain different VSAs for the same purpose in a single-service profile.

A consensus regarding the tunnel attributes that are to be used in a multivendor network environment is defined in RFC 2868. In RFC 2868, Tunnel-Server-Endpoint, in conjunction with the Tunnel-Medium-Type, specifies the address to which the NAS should initiate a new session. If multiple Tunnel-Server-Endpoint attributes are defined in one tagged attribute group, they are interpreted as equal-cost load-balancing HGWs.

The Tunnel-Preference attribute defined in RFC 2868 can be used as a measure to form load balancing and fail-over HGW groups. When the Tunnel-Preference values of different tagged attribute groups are the same, the Tunnel-Server-Endpoint of those attribute groups is considered to have the same priority unless otherwise specified. When the Tunnel-Preference values of some attribute groups are higher (they have a lower preference) than other attribute groups, their Tunnel-Server-Endpoint attributes will have higher priority values. When an attribute group has a higher priority value, that attribute group will be used for fail-over in case the attribute groups with lower priority values are unavailable for the connections.

Until Cisco IOS Release 12.2(4)T, a specially formatted string would be transported within a Cisco VSA “vpdn:ip-addresses” string to a NAS for the purpose of HGW load balancing and fail-over. For example, 10.0.0.1 10.0.0.2 10.0.0.3/2.0.0.1 2.0.0.2 would be interpreted as IP addresses 10.0.0.1, 10.0.0.2, and 10.0.0.3 for the first group for load balancing. New sessions are projected to these three addresses based on the least-load-first algorithm. This algorithm uses its local knowledge to select an HGW that has the least load to initiate the new session. In this example, the addresses 2.0.0.1 and 2.0.0.2 in the second group have a lower priority and are applicable only when all HGWs specified in the first group fail to respond to the new connection request, thereby making 2.0.0.1 and 2.0.0.2 the fail-over addresses. See the section “Configuration Example” for an example of how to configure these fail-over addresses in a RADIUS tunnel profile.

Load Balancing and Fail-Over in a Multivendor Network

The RADIUS Tunnel Preference for Load Balancing and Fail-Over feature was designed for large multivendor networks that use VPDN Layer 2 tunnels over WAN links such as ATM and Ethernet, such as the configuration shown in Figure 1.
In the configuration shown in Figure 1, the NAS uses tunnel profiles downloaded from the RADIUS server to establish VPDN Layer 2 tunnels for load balancing and fail-over. The Point-to-Point over Ethernet (PPPoE) protocol is used as the client to generate PPP sessions.

**Benefits**

The RADIUS Tunnel Preference for Load Balancing and Fail-Over feature provides industry-standard load balancing and fail-over functionality for an LNS, rather than requiring the use of a Cisco proprietary VSA. The feature conforms to the tunnel attributes that are to be used in a multivendor network environment as defined in RFC 2868, thereby eliminating interoperability issues among NASs manufactured by different vendors.

**Restrictions**

The following restrictions and limitations apply to the RADIUS Tunnel Preference for Load Balancing and Fail-Over feature:

- This feature does not support VPDN dial-out networks; it is designed only for dial-in applications.
- The maximum number of LNSs allowed in the network is 1550, which is 50 per tag attribute group and a limit of 31 tags.
- This feature requires a RADIUS server implementation to support RFC 2868.
Related Features and Technologies

The RADIUS Tunnel Preference for Load Balancing and Fail-Over feature is used in VPDNs. Additionally, familiarity with the following technologies and protocols is recommended:

- ATM
- Ethernet
- L2TP and L2F
- PPP and PPPoE
- RADIUS servers

See the next section for a list of documentation that describes these technologies and protocols.

Supported Platforms

This feature is platform independent and was either developed for or tested on the following Cisco routers:

- Cisco 800 series
- Cisco 1600 series
- Cisco 1700 series
- Cisco 2600 series
- Cisco 3600 series
- Cisco 7100 series
- Cisco 7200 series

See the next section for information about Feature Navigator and how to use this tool to determine the platforms and software images in which this feature is available.
Determining Platform Support Through Feature Navigator

Cisco IOS software is packaged in feature sets that support specific platforms. To get updated information regarding platform support for this feature, access Feature Navigator. Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Feature Navigator is a web-based tool that enables you to quickly determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image.

To access Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions at http://www.cisco.com/register.

Feature Navigator is updated when major Cisco IOS software releases and technology releases occur. As of May 2001, Feature Navigator supports M, T, E, S, and ST releases. You can access Feature Navigator at the following URL:

http://www.cisco.com/go/fn

Supported Standards, MIBs, and RFCs

Standards
None

MIBs
None

To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:

RFCs
RFC 2868, RADIUS Attributes for Tunnel Protocol Support

Prerequisites

Configuring VPDNs and HGW groups is beyond the scope of this document. Refer to the documentation listed in the section “Related Documents” for the tasks and commands to configure these types of networks.

Configuration Tasks

This feature has no new configuration commands; however, see the next section for an example of how to implement the RADIUS Tunnel Preference for Load Balancing and Fail-Over feature in a RADIUS tunnel profile.
**Configuration Example**

The following example shows how to create RADIUS tunnel profiles:

```
net3 Password = "cisco" Service-Type = Outbound
    Tunnel-Type = :0:L2TP,
    Tunnel-Medium-Type = :0:IP,
    Tunnel-Server-Endpoint = :0:"1.1.3.1",
    Tunnel-Assignment-Id = :0:"1",
    Tunnel-Preference = :0:1,
    Tunnel-Password = :0:"welcome"

Tunnel-Type = :1:L2TP,
    Tunnel-Medium-Type = :1:IP,
    Tunnel-Server-Endpoint = :1:"1.1.5.1",
    Tunnel-Assignment-Id = :1:"1",
    Tunnel-Preference = :1:1,
    Tunnel-Password = :1:"welcome"

Tunnel-Type = :2:L2TP,
    Tunnel-Medium-Type = :2:IP,
    Tunnel-Server-Endpoint = :2:"1.1.4.1",
    Tunnel-Assignment-Id = :2:"1",
    Tunnel-Preference = :2:1,
    Tunnel-Password = :2:"welcome"

Tunnel-Type = :3:L2TP,
    Tunnel-Medium-Type = :3:IP,
    Tunnel-Server-Endpoint = :3:"1.1.6.1",
    Tunnel-Assignment-Id = :3:"1",
    Tunnel-Preference = :3:1,
    Tunnel-Password = :3:"welcome"
```

The section “Feature Overview” describes how fail-over addresses are selected in these profiles. The section “Related Documents” lists documentation that describes how to create RADIUS tunnel profiles.

**Command Reference**

None

**Glossary**

**HGW**—home gateway. A gateway that terminates Layer 2 tunneling protocols such as L2TP.

**home gateway**—See HGW.

**L2TP**—Layer 2 Tunnel Protocol. An Internet Engineering Task Force (IETF) standards track protocol defined in RFC 2661 that provides tunneling of PPP. Based upon the best features of L2F and PPTP, L2TP provides an industry-wide interoperable method of implementing VPDN.

**L2TP network server**—See LNS.

**Layer 2 Tunnel Protocol**—See L2TP.
LNS—L2TP network server. A node that acts as one side of an L2TP tunnel endpoint and is a peer to the NAS or L2TP access concentrator (LAC). The LNS is the logical termination point of a PPP session that is being tunneled from the remote system by the access server. Analogous to the Layer 2 Forwarding (L2F) HGW.

NAS—network access server. Cisco platform or collection of platforms that interfaces between the packet world (the Internet, for example) and the circuit world (the public switched telephone network, for example).

network access server—See NAS.

Request for Comments—See RFCs.

RFCs—Request for Comments. A series of notes about the Internet collected by the Internet Engineering Task Force (IETF). Started in 1969, the IETF is a large open international community of network designers, operators, vendors, and researchers concerned with the evolution of the Internet architecture. RFCs define many aspects of computer communication, focusing on networking protocols, procedures, programs, and concepts.

virtual private dialup network—See VPDN.

VPDN—virtual private dialup network. Enables IP traffic to travel securely over a public TCP/IP network by encrypting all traffic from one network to another.
RADIUS Server Reorder on Failure

The RADIUS Server Reorder on Failure feature provides failover to another server in the server group during periods of high load or when server failure occurs. Subsequent to the failure, all RADIUS traffic is directed to the new server. Traffic is switched from the new server to another server in the server group only if the new server also fails. Traffic is not automatically switched back to the first server.

By spreading the RADIUS transactions across multiple servers, authentication and accounting requests are serviced more quickly.

Finding Feature Information in This Module
Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “Feature Information for RADIUS Server Reorder on Failure” section on page 12.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images
Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for RADIUS Server Reorder on Failure

Before you can configure your RADIUS server to perform reorder on failure, you must enable authentication, authorization, and accounting (AAA) by using the `aaa new-model` command. (Refer to the chapter “AAA Overview” in the *Cisco IOS Security Configuration Guide*, Release 12.3.)

You must also have RADIUS configured, for functions such as authentication, accounting, or static route download.

Restrictions for RADIUS Server Reorder on Failure

An additional 4 bytes of memory is required per server group. However, because most server configurations have only a small number of server groups configured, the additional 4 bytes should have a minimal impact on performance.

Some RADIUS features within the Cisco IOS software set may not be capable of using this feature. If a RADIUS feature cannot use the RADIUS Server Reorder on Failure feature, your server behaves as though the reorder feature is not configured.

Information About RADIUS Server Reorder on Failure

To configure the RADIUS Server Reorder on Failure feature, you must understand the following concepts:

- RADIUS Server Failure, page 2
- How the RADIUS Server Reorder on Failure Feature Works, page 3

RADIUS Server Failure

If the RADIUS Server Reorder on Failure feature is not configured and server failure occurs:

1. A new RADIUS transaction has to be performed.
2. A RADIUS packet for the transaction is sent to the first server in the group that is not marked dead (as per the configured deadtime) and is retransmitted for the configured number of retransmissions.
3. If all of those retransmits time out (as per the configured timeout), the router transmits the packet to the next nondead server in the list for the configured number of retransmissions.
4. Step 3 is repeated until the specified maximum number of transmissions per transaction have been made. If the end of the list is reached before the maximum number of transmissions has been reached, the router goes back to the beginning of the list and continue from there.

If at any time during this process, a server meets the dead-server detection criteria (not configurable; it varies depending on the version of Cisco IOS software being used), the server is marked as dead for the configured deadtime.
How the RADIUS Server Reorder on Failure Feature Works

If you have configured the RADIUS Server Reorder on Failure feature, the decision about which RADIUS server to use as the initial server is as follows:

- The network access server (NAS) maintains the status of “flagged” server, which is the first server to which a transmission is sent.
- After the transmission is sent to the flagged server, the transmission is sent to the flagged server again for the configured number of retransmissions.
- The NAS then sequentially sends the transmission through the list of nondead servers in the server group, starting with the one listed after the flagged server, until the configured transaction maximum tries is reached or until a response is received.
- At boot time, the flagged server is the first server in the server group list as was established using the `radius-server host` command.
- If the flagged server is marked as dead (even if the dead time is zero), the first nondead server listed after the flagged server becomes the flagged server.
- If the flagged server is the last server in the list, and it is marked as dead, the flagged server becomes the first server in the list that is not marked as dead.
- If all servers are marked as dead, the transaction fails, and no change is made to the flagged server.
- If the flagged server is marked as dead, and the dead timer expires, nothing happens.

Note

Some types of transmissions (for example, Challenge Handshake Authentication Protocol [CHAP], Microsoft CHAP [MS-CHAP], and Extensible Authentication Protocol [EAP]) require multiple roundtrips to a single server. For these special transactions, the entire sequence of roundtrips to the server are treated as though they were one transmission.

When RADIUS Servers Are Dead

A server can be marked as dead if the criteria in 1 and 2 are met:

1. The server has not responded to at least the configured number of retransmissions as specified by the `radius-server transaction max-tries` command.
2. The server has not responded to any request for at least the configured timeout. The server is marked dead only if both criteria (this and the one listed above) are met. The marking of a server as dead, even if the dead time is zero, is significant for the RADIUS server retry method reorder system.

How to Configure RADIUS Server Reorder on Failure

This section contains the following procedures.

- Configuring a RADIUS Server to Reorder on Failure, page 4 (required)
- Monitoring RADIUS Server Reorder on Failure, page 5 (optional)
## Configuring a RADIUS Server to Reorder on Failure

Perform this task to configure a server in a server group to direct traffic to another server in the server group when the first server fails.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `aaa new-model`
4. `radius-server retry method reorder`
5. `radius-server retransmit {retries}`
6. `radius-server transaction max-tries {number}`
7. `radius-server host {hostname | ip-address} [key string]`
8. `radius-server host {hostname | ip-address} [key string]`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router&gt; enable</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> aaa new-model</td>
<td>Enables the AAA access control model.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router (config)# aaa new-model</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> radius-server retry method reorder</td>
<td>Specifies the reordering of RADIUS traffic retries among a server group.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router (config)# radius-server retry method reorder</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> radius-server retransmit {retries}</td>
<td>Specifies the number of times the Cisco IOS software searches the list of RADIUS server hosts before giving up.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router (config)# radius-server retransmit 1</td>
<td>The <code>retries</code> argument is the maximum number of retransmission attempts. The default is 3 attempts.</td>
</tr>
</tbody>
</table>
### Command or Action

**Step 6**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>radius-server transaction max-tries {number}</code></td>
<td>Specifies the maximum number of transmissions per transaction that may be retried on a RADIUS server. The <em>number</em> argument is the total number of transmissions per transaction. If this command is not configured, the default is eight transmissions.</td>
</tr>
</tbody>
</table>

**Example:**

```
Router (config)# radius-server transaction max-tries 3
```

**Note**

This command is global across all RADIUS servers for a given transaction.

**Step 7**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`radius-server host {hostname</td>
<td>ip-address} [key string]`</td>
</tr>
</tbody>
</table>

**Example:**

```
Router (config)# radius-server host 10.2.3.4 key radi23
```

**Note**

You can also configure a global key for all RADIUS servers that do not have a per-server key configured by issuing the `radius-server key` command.

**Step 8**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`radius-server host {hostname</td>
<td>ip-address} [key string]`</td>
</tr>
</tbody>
</table>

**Example:**

```
Router (config)# radius-server host 10.5.6.7 key rad234
```

**Note**

At least two servers must be configured.

---

### Monitoring RADIUS Server Reorder on Failure

To monitor the server-reorder-on-failure process on your router, use the following commands:

**SUMMARY STEPS**

1. `enable`
2. `debug aaa sg-server selection`
3. `debug radius`
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 debug aaa sg-server selection</td>
<td>Displays information about why the RADIUS and TACAC+ server group system in the router is choosing a particular server.</td>
</tr>
<tr>
<td>Example: Router# debug aaa sg-server selection</td>
<td></td>
</tr>
<tr>
<td>Step 3 debug radius</td>
<td>Displays information about why the router is choosing a particular RADIUS server.</td>
</tr>
<tr>
<td>Example: Router# debug radius</td>
<td></td>
</tr>
</tbody>
</table>

Examples

The following two debug outputs display the behavior of the RADIUS Server Reorder on Failure feature:

**Debug 1**

In the following sample output, the RADIUS Server Reorder on Failure feature is configured. The server retransmits are set to 0 (so each server is tried just one time before failover to the next configured server), and the transmissions per transaction are set to 4 (the transmissions stop on the third failover). The third server in the server group (10.107.164.118) has accepted the transaction on the third transmission (second failover).

```

00:39:04: RADIUS: Fail-over to (10.107.164.118:1645,1646) for id 21645/11
00:39:04: RADIUS/ENCODE: Best Local IP-Address 10.0.1.130 for Radius-Server 128.107.164.118
```
Debug 2

In the following sample output, the RADIUS Server Reorder on Failure feature is configured. The server retransmits are set to 0, and the transmissions per transaction are set to 8. In this transaction, the transmission to server 10.10.10.0 has failed on the eighth transmission.

Configuration Examples for RADIUS Server Reorder on Failure

This section provides the following configuration examples:

- Configuring a RADIUS Server to Reorder on Failure Example, page 8
- Determining Transmission Order When RADIUS Servers Are Dead, page 8
Configuring a RADIUS Server to Reorder on Failure Example

The following configuration example shows that a RADIUS server is configured to reorder on failure. The maximum number of transmissions per transaction that may be retried on the RADIUS server is six.

```
aaa new-model
radius-server retry method reorder
radius-server retransmit 0
radius-server transaction max-tries 6
radius-server host 10.2.3.4 key rad123
radius-server host 10.5.6.7 key rad123
```

Determining Transmission Order When RADIUS Servers Are Dead

If at boot time you have configured the following:

```
aaa new-model
radius-server retry method reorder
radius-server retransmit 0
radius-server transaction max-tries 6
radius-server host 10.2.3.4
radius-server host 10.5.6.7
```

and both servers are down, but not yet marked dead, for the first transaction you would see the transmissions as follows:

```
10.2.3.4
10.5.6.7
10.2.3.4
10.5.6.7
10.2.3.4
10.5.6.7
```

If you configure the reorder as follows:

```
aaa new-model
radius-server retry method reorder
radius-server retransmit 1
radius-server transaction max-tries 3
radius-server host 10.2.3.4
radius-server host 10.4.5.6
```

and both RADIUS servers are not responding to RADIUS packets but are not yet marked dead (as after the NAS boots), the transmissions for the first transaction are as follows:

```
10.2.3.4
10.2.3.4
10.4.5.6
```

Subsequent transactions may be transmitted according to a different pattern. The transmissions depend on whether the criteria for marking one (or both) servers as dead have been met, and as per the server flagging pattern already described.
If you configure the reorder as follows:

```
aaa new-model
radius-server retry method reorder
radius-server retransmit 1
radius-server max-trries-per-transaction 8
radius-server host 10.1.1.1
radius-server host 10.2.2.2
radius-server host 10.3.3.3
radius-server timeout 3
```

And the RADIUS server 10.1.1.1 is not responding to RADIUS packets but is not yet marked as dead, and the remaining two RADIUS servers are live, you see the following:

For the first transaction:

```
10.1.1.1
10.1.1.1
10.2.2.2
```

For any additional transaction initiated for any transmissions before the server is marked as dead:

```
10.1.1.1
10.1.1.1
10.2.2.2
```

For transactions initiated thereafter:

```
10.2.2.2
```

If servers 10.2.2.2 and 10.3.3.3 then go down as well, you see the following transmissions until servers 10.2.2.2 and 10.3.3.3 meet the criteria for being marked as dead:

```
10.2.2.2
10.2.2.2
10.3.3.3
10.3.3.3
10.1.1.1
10.1.1.1
10.2.2.2
10.2.2.2
```

The above is followed by the failure of the transmission and by the next method in the method list being used (if any).

If servers 10.2.2.2 and 10.3.3.3 go down but server 10.1.1.1 comes up at the same time, you see the following:

```
10.2.2.2
10.2.2.2
10.3.3.3
10.3.3.3
10.1.1.1
```

When servers 10.2.2.2 and 10.3.3.3 are then marked as dead, you see the following:

```
10.1.1.1
```

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

- `debug aaa sg-server selection`
- `radius-server retry method reorder`
- `radius-server transaction max-tries`
Feature Information for RADIUS Server Reorder on Failure

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Feature Overview

The Tunnel Authentication via RADIUS on Tunnel Terminator feature allows the Layer 2 Tunneling Protocol (L2TP) network server (LNS) to perform remote authentication and authorization with RADIUS on incoming L2TP access concentrator (LAC) dialin connection requests. This feature also allows the L2TP LAC to perform remote authentication and authorization with RADIUS on incoming L2TP LNS dialout connection requests.

Before the introduction of this feature, the LNS could only perform L2TP tunnel authentication and authorization locally. These processes can be difficult to maintain across numerous LNSs, especially if the number of virtual private dialup network (VPDN) groups is large, because the LAC information must be configured under the VPDN group configurations of the LNS. Remote RADIUS authentication and authorization allows users to store the LAC configurations on the RADIUS server, thereby avoiding the
need to store information locally. Thus, the new LAC information can be added to the RADIUS server as necessary, and the group of LNSs can authenticate and authorize by using a common user database on RADIUS.

Figure 1 and the corresponding steps explain how this feature works.

Figure 1  LNS Remote RADIUS Tunnel Authentication and Authorization for L2TP Dialin Calls Topology

- After the LNS receives a start-control-connection request (SCCRQ), it starts tunnel authentication and submits a request to RADIUS with the LAC hostname and the dummy password “cisco.” (If the LNS determines that authorization should be performed locally, it will search the VPDN group configurations.)

Note To change the dummy password, use the `vpdn tunnel authorization password` command.

- If the password sent by the LNS matches the password that is configured in the RADIUS server, the server will return attribute 90 (Tunnel-Client-Auth-ID) and attribute 69 (Tunnel-Password) after the LAC information is located. Otherwise, the RADIUS server replies back with an access-reject, and the LNS drops the tunnel.

- The LNS will check for the following attribute information from the RADIUS reply:
  - Attribute 90 (Tunnel-Client-Auth-ID), which is used as the LAC hostname. If this attribute does not match the LAC hostname, the tunnel will be dropped.
  - Attribute 69 (Tunnel-Password), which is used for the L2TP CHAP-like authentication shared secret. This attribute is compared against the LAC challenge attribute-value pair (AVP) that was received in the SCCRQ. If this attribute does not match the AVP, the tunnel will be dropped.

- If both attributes match, the L2TP tunnel will be established. Thereafter, you can proceed with PPP negotiation and authentication with the remote client.

Note PPP remote authentication is done to a potential different customer RADIUS server by a separate access-request/access-accept sequence. The tunnel authorization may be done by a different tunnel RADIUS server.
New RADIUS Attributes

To help implement this feature, the following two new Cisco-specific RADIUS attributes have been introduced:

- Cisco:Cisco-Avpair = “vpdn:dout-dialer = <LAC dialer number>”—Specifies which LAC dialer to use on the LAC for a dialout configuration.
- Cisco:Cisco-Avpair = “vpdn:vpdn-vtemplate = <vtemplate number>”—Specifies the virtual template number that will be used for cloning on the LNS for a dialin configuration. (This attribute is the RADIUS counterpart for the virtual-template under the vpdn-group configuration.)

**Note**
The service-type in the RADIUS user’s profile for the tunnel initiator should always be set to “Outbound.”

Benefits

This feature allows tunnel authentication and authorization to occur via a remote RADIUS server instead of local configuration on the tunnel terminator. Thus, users no longer have to configure LAC or LNS data in a VPDN group when an LNS or LAC is configured for incoming dialin or dialout L2TP tunnel termination; this information can now be added to a remote RADIUS server, providing a more manageable and scalable solution for L2TP tunnel authentication and authorization on the tunnel terminator.

Restrictions

This is applicable only to L2TP; that is, protocols such as (Layer 2 Forwarding) L2F and Point-to-Point Tunneling Protocol (PPTP) are not supported.

Supported Platforms

- Cisco 6400 series
- Cisco 7200 series
- Cisco 7400 series
Availability of Cisco IOS Software Images

Platform support for particular Cisco IOS software releases is dependent on the availability of the software images for those platforms. Software images for some platforms may be deferred, delayed, or changed without prior notice. For updated information about platform support and availability of software images for each Cisco IOS software release, refer to the online release notes or, if supported, Cisco Feature Navigator.

Supported Standards, MIBs, and RFCs

Standards
None

MIBs
None

To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:

RFCs
RFC 2868, RADIUS Attributes for Tunnel Protocol Support

Prerequisites

Before configuring this feature, you should define a RADIUS server group. For information on completing this task, refer to the chapter “Configuring RADIUS” in the Cisco IOS Security Configuration Guide, Release 12.2.

Configuration Tasks

See the following sections for configuration tasks for the Tunnel Authentication via RADIUS on Tunnel Terminator feature. Each task in the list is identified as either required or optional.

- Configuring the LNS or LAC for Remote RADIUS Tunnel Authentication and Authorization (required)
- Verifying Remote RADIUS Tunnel Authentication and Authorization Configurations (optional)

Configuring the LNS or LAC for Remote RADIUS Tunnel Authentication and Authorization

To configure an LNS or LAC for incoming dialin or dialout L2TP tunnel termination, use the following commands in global configuration:
To verify that the L2TP tunnel is up, use the `show vpdn tunnel` command in EXEC mode. One tunnel and one session must be set up.

```
Router# show vpdn tunnel
L2TP Tunnel and Session Information Total tunnels 1 sessions 1
LocID RemID Remote Name   State  Remote Address  Port  Sessions VPDN Group
4571  61568 csidtw13 est    10.0.195.4      1701  1        ?
LocID RemID TunID Intf          Username               State  Last Chg
4     11    4571  Vi4.1         csidtw9@cisco.com       est    00:02:29
```

%No active L2F tunnels
%No active PPTP tunnels
%No active PPPoE tunnels

To verify that the AAA authorization RADIUS server is configured on the LNS and that the LNS can receive attributes 90 and 69 from the RADIUS server, perform the following steps:

### Step 1
Enable the `debug radius` command on the LNS.

### Step 2
Enable the `show logging` command on the LNS and ensure that “access-accept” is in the output and that attributes 90 and 69 can be seen in the RADIUS reply.

```
00:32:56: RADIUS: Received from id 21645/5 172.19.192.50:1645, Access-Accept, len 81
00:32:56: RADIUS:   username csidtw9@cisco.com
00:32:56: RADIUS:   service-type 6 [Service-Type]
00:32:56: RADIUS:   tunnel-type 64 [Tunnel-Type]
00:32:56: RADIUS:   tunnel-medium-type 65 [Tunnel-Medium-Type]
```
To verify that the L2TP tunnel has been established and that the LNS can perform PPP negotiation and authentication with the remote client, perform the following steps:

**Step 1** Enable the `debug ppp negotiation` and `debug ppp authentication` commands on LNS.

**Step 2** Enable the `show logging` command on LNS and observe that LNS receives a PPP CHAP challenge and then sends a PPP CHAP “SUCCESS” to the client.

**Step 3** After PPP authentication is successful, observe from the debug output that PPP negotiation has started, that the LNS has received LCP (IPCP) packets, and that negotiation is successful.

---

**Configuration Examples**

This section provides the following configuration examples:

- L2TP Network Server (LNS) Configuration Example
- RADIUS User Profile for Remote RADIUS Tunnel Authentication Example

### L2TP Network Server (LNS) Configuration Example

The following example shows how to configure the LNS to enable remote RADIUS tunnel authentication and authorization:

```plaintext
! Define a RADIUS server group
aaa group server radius VPDN-group
  server 64.102.48.91 auth-port 1645 acct-port 1646
!
! RADIUS configurations only
aaa authorization network mymethodlist group VPDN-Group
vpdn tunnel authorization network mymethodlist
vpdn tunnel authorization virtual-template 10
```
RADIUS User Profile for Remote RADIUS Tunnel Authentication Example

The following are examples of RADIUS user profiles for the LNS to terminate L2TP tunnels from a LAC. In the first user profile, the final line is optional if the `vpdn tunnel authorization virtual-template` command is used. Also, the first RADIUS user profile is for L2TP dialin, and the second RADIUS user profile is for L2TP dialout.

The service-type in the RADIUS user’s profile for the tunnel initiator should always be set to “Outbound.”

```plaintext
csidtw13  Password = “cisco”
    Service-Type = Outbound,
    Tunnel-Type = :0:L2TP,
    Tunnel-Medium-Type = :0:IP,
    Tunnel-Client-Auth-ID = :0:”csidtw13”,
    Tunnel-Password = :0:”cisco”
    Cisco:Cisco-Avpair = ”vpdn:vpdn-vtemplate=1”

csidtw1  Password = “cisco”
    Service-Type = Outbound,
    Tunnel-Type = :0:L2TP,
    Tunnel-Medium-Type = :0:IP,
    Tunnel-Client-Auth-ID = :0:”csidtw1”,
    Tunnel-Password = :0:”cisco”
    Cisco:Cisco-Avpair = ”vpdn:dout-dialer=2”
```

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

- `vpdn tunnel authorization network`
- `vpdn tunnel authorization password`
- `vpdn tunnel authorization virtual-template`
**Glossary**

**L2TP**—Layer 2 Tunnel Protocol. A Layer 2 tunneling protocol that enables an ISP or other access service to create a virtual tunnel to link customer remote sites or remote users with corporate home networks. In particular, a network access server (NAS) at the ISP point of presence (POP) exchanges PPP messages with the remote users and communicates by L2F or L2TP requests and responses with the customer tunnel server to set up tunnels.

**LAC**—L2TP access concentrator. A network access server (NAS) to which the client directly connects and through which PPP frames are tunneled to the L2TP network server (LNS). The LAC need only implement the media over which L2TP is to operate to pass traffic to one or more LNSs. The LAC may tunnel any protocol carried within PPP. The LAC initiates incoming calls and receives outgoing calls. A LAC is analogous to an L2F network access server.

**LNS**—L2TP network server. A termination point for L2TP tunnels and an access point where PPP frames are processed and passed to higher layer protocols. An LNS can operate on any platform that terminates PPP. The LNS handles the server side of the L2TP protocol. L2TP relies only on the single medium over which L2TP tunnels arrive. The LNS initiates outgoing calls and receives incoming calls. An LNS is analogous to a home gateway in L2F technology.

This chapter discusses how to enable and configure TACACS+, which provides detailed accounting information and flexible administrative control over authentication and authorization processes. TACACS+ is facilitated through AAA and can be enabled only through AAA commands.

For a complete description of the TACACS+ commands used in this chapter, refer to the chapter “TACACS+ Commands” in the Cisco IOS Security Command Reference. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature, or refer to the software release notes for a specific release. For more information, see the section “Identifying Supported Platforms” in the chapter “Using Cisco IOS Software.”

In This Chapter

This chapter includes the following sections:

- About TACACS+
- TACACS+ Operation
- TACACS+ Configuration Task List
- TACACS+ AV Pairs
- TACACS+ Configuration Examples
About TACACS+

TACACS+ is a security application that provides centralized validation of users attempting to gain access to a router or network access server. TACACS+ services are maintained in a database on a TACACS+ daemon running, typically, on a UNIX or Windows NT workstation. You must have access to and must configure a TACACS+ server before the configured TACACS+ features on your network access server are available.

TACACS+ provides for separate and modular authentication, authorization, and accounting facilities. TACACS+ allows for a single access control server (the TACACS+ daemon) to provide each service—authentication, authorization, and accounting—Independently. Each service can be tied into its own database to take advantage of other services available on that server or on the network, depending on the capabilities of the daemon.

The goal of TACACS+ is to provide a methodology for managing multiple network access points from a single management service. The Cisco family of access servers and routers and the Cisco IOS user interface (for both routers and access servers) can be network access servers.

Network access points enable traditional “dumb” terminals, terminal emulators, workstations, personal computers (PCs), and routers in conjunction with suitable adapters (for example, modems or ISDN adapters) to communicate using protocols such as Point-to-Point Protocol (PPP), Serial Line Internet Protocol (SLIP), Compressed SLIP (CSLIP), or AppleTalk Remote Access (ARA) protocol. In other words, a network access server provides connections to a single user, to a network or subnetwork, and to interconnected networks. The entities connected to the network through a network access server are called network access clients; for example, a PC running PPP over a voice-grade circuit is a network access client. TACACS+, administered through the AAA security services, can provide the following services:

- Authentication—Provides complete control of authentication through login and password dialog, challenge and response, messaging support.
  
  The authentication facility provides the ability to conduct an arbitrary dialog with the user (for example, after a login and password are provided, to challenge a user with a number of questions, like home address, mother’s maiden name, service type, and social security number). In addition, the TACACS+ authentication service supports sending messages to user screens. For example, a message could notify users that their passwords must be changed because of the company’s password aging policy.

- Authorization—Provides fine-grained control over user capabilities for the duration of the user’s session, including but not limited to setting auto commands, access control, session duration, or protocol support. You can also enforce restrictions on what commands a user may execute with the TACACS+ authorization feature.

- Accounting—Collects and sends information used for billing, auditing, and reporting to the TACACS+ daemon. Network managers can use the accounting facility to track user activity for a security audit or to provide information for user billing. Accounting records include user identities, start and stop times, executed commands (such as PPP), number of packets, and number of bytes.

The TACACS+ protocol provides authentication between the network access server and the TACACS+ daemon, and it ensures confidentiality because all protocol exchanges between a network access server and a TACACS+ daemon are encrypted.

You need a system running TACACS+ daemon software to use the TACACS+ functionality on your network access server.

Cisco makes the TACACS+ protocol specification available as a draft RFC for those customers interested in developing their own TACACS+ software.
TACACS+ Operation

When a user attempts a simple ASCII login by authenticating to a network access server using TACACS+, the following process typically occurs:

1. When the connection is established, the network access server will contact the TACACS+ daemon to obtain a username prompt, which is then displayed to the user. The user enters a username, and the network access server then contacts the TACACS+ daemon to obtain a password prompt. The network access server displays the password prompt to the user, the user enters a password, and the password is then sent to the TACACS+ daemon.

Note

TACACS+ allows an arbitrary conversation to be held between the daemon and the user until the daemon receives enough information to authenticate the user. This is usually done by prompting for a username and password combination, but may include other items, such as mother’s maiden name, all under the control of the TACACS+ daemon.

2. The network access server will eventually receive one of the following responses from the TACACS+ daemon:
   a. ACCEPT—The user is authenticated and service may begin. If the network access server is configured to require authorization, authorization will begin at this time.
   b. REJECT—The user has failed to authenticate. The user may be denied further access, or will be prompted to retry the login sequence depending on the TACACS+ daemon.
   c. ERROR—An error occurred at some time during authentication. This can be either at the daemon or in the network connection between the daemon and the network access server. If an ERROR response is received, the network access server will typically try to use an alternative method for authenticating the user.
   d. CONTINUE—The user is prompted for additional authentication information.

3. A PAP login is similar to an ASCII login, except that the username and password arrive at the network access server in a PAP protocol packet instead of being typed in by the user, so the user is not prompted. PPP CHAP logins are also similar in principle.

Following authentication, the user will also be required to undergo an additional authorization phase, if authorization has been enabled on the network access server. Users must first successfully complete TACACS+ authentication before proceeding to TACACS+ authorization.

4. If TACACS+ authorization is required, the TACACS+ daemon is again contacted and it returns an ACCEPT or REJECT authorization response. If an ACCEPT response is returned, the response will contain data in the form of attributes that are used to direct the EXEC or NETWORK session for that user, determining services that the user can access.

Services include the following:
   a. Telnet, rlogin, Point-to-Point Protocol (PPP), Serial Line Internet Protocol (SLIP), or EXEC services
   b. Connection parameters, including the host or client IP address, access list, and user timeouts

TACACS+ Configuration Task List

To configure your router to support TACACS+, you must perform the following tasks:
• Use the `aaa new-model` global configuration command to enable AAA. AAA must be configured if you plan to use TACACS+. For more information about using the `aaa new-model` command, refer to the chapter “AAA Overview”.

• Use the `tacacs-server host` command to specify the IP address of one or more TACACS+ daemons. Use the `tacacs-server key` command to specify an encryption key that will be used to encrypt all exchanges between the network access server and the TACACS+ daemon. This same key must also be configured on the TACACS+ daemon.

• Use the `aaa authentication` global configuration command to define method lists that use TACACS+ for authentication. For more information about using the `aaa authentication` command, refer to the chapter “Configuring Authentication”.

• Use `line` and `interface` commands to apply the defined method lists to various interfaces. For more information, refer to the chapter “Configuring Authentication”.

• If needed, use the `aaa authorization` global command to configure authorization for the network access server. Unlike authentication, which can be configured per line or per interface, authorization is configured globally for the entire network access server. For more information about using the `aaa authorization` command, refer to the “Configuring Authorization” chapter.

• If needed, use the `aaa accounting` command to enable accounting for TACACS+ connections. For more information about using the `aaa accounting` command, refer to the “Configuring Accounting” chapter.

To configure TACACS+, perform the tasks in the following sections:

- **Identifying the TACACS+ Server Host** (Required)
- **Setting the TACACS+ Authentication Key** (Optional)
- **Configuring AAA Server Groups** (Optional)
- **Configuring AAA Server Group Selection Based on DNIS** (Optional)
- **Specifying TACACS+ Authentication** (Required)
- **Specifying TACACS+ Authorization** (Optional)
- **Specifying TACACS+ Accounting** (Optional)

For TACACS+ configuration examples using the commands in this chapter, refer to the “TACACS+ Configuration Examples” section at the end of this chapter.

### Identifying the TACACS+ Server Host

The `tacacs-server host` command enables you to specify the names of the IP host or hosts maintaining a TACACS+ server. Because the TACACS+ software searches for the hosts in the order specified, this feature can be useful for setting up a list of preferred daemons.

To specify a TACACS+ host, use the following command in global configuration mode:

```
Router(config)# tacacs-server host hostname
[ single-connection] [port integer] [timeout integer] [key string]
```

Using the `tacacs-server host` command, you can also configure the following options:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# tacacs-server host hostname [ single-connection] [port integer] [timeout integer] [key string]</td>
<td>Specifies a TACACS+ host.</td>
</tr>
</tbody>
</table>
• Use the **single-connection** keyword to specify single-connection (only valid with CiscoSecure Release 1.0.1 or later). Rather than have the router open and close a TCP connection to the daemon each time it must communicate, the single-connection option maintains a single open connection between the router and the daemon. This is more efficient because it allows the daemon to handle a higher number of TACACS operations.

  **Note**  
  The daemon must support single-connection mode for this to be effective, otherwise the connection between the network access server and the daemon will lock up or you will receive spurious errors.

• Use the **port integer** argument to specify the TCP port number to be used when making connections to the TACACS+ daemon. The default port number is 49.

• Use the **timeout integer** argument to specify the period of time (in seconds) the router will wait for a response from the daemon before it times out and declares an error.

  **Note**  
  Specifying the timeout value with the `tacacs-server host` command overrides the default timeout value set with the `tacacs-server timeout` command for this server only.

• Use the **key string** argument to specify an encryption key for encrypting and decrypting all traffic between the network access server and the TACACS+ daemon.

  **Note**  
  Specifying the encryption key with the `tacacs-server host` command overrides the default key set by the global configuration `tacacs-server key` command for this server only.

Because some of the parameters of the `tacacs-server host` command override global settings made by the `tacacs-server timeout` and `tacacs-server key` commands, you can use this command to enhance security on your network by uniquely configuring individual TACACS+ connections.

### Setting the TACACS+ Authentication Key

To set the global TACACS+ authentication key and encryption key, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config)# tacacs-server key key</code></td>
<td>Sets the encryption key to match that used on the TACACS+ daemon.</td>
</tr>
</tbody>
</table>

  **Note**  
  You must configure the same key on the TACACS+ daemon for encryption to be successful.
Configuring AAA Server Groups

Configuring the router to use AAA server groups provides a way to group existing server hosts. This allows you to select a subset of the configured server hosts and use them for a particular service. A server group is used in conjunction with a global server-host list. The server group lists the IP addresses of the selected server hosts.

Server groups can include multiple host entries as long as each entry has a unique IP address. If two different host entries in the server group are configured for the same service—for example, accounting—the second host entry configured acts as fail-over backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server will try the second host entry for accounting services. (The TACACS+ host entries will be tried in the order in which they are configured.)

To define a server host with a server group name, enter the following commands starting in global configuration mode. The listed server must exist in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
  `Router(config)# tacacs-server host name [single-connection] [port integer] [timeout integer] [key string]` | Specifies and defines the IP address of the server host before configuring the AAA server-group. Refer to the “Identifying the TACACS+ Server Host” section of this chapter for more information on the `tacacs-server host` command. |
| **Step 2**  
  `Router(config-if)# aaa group server {radius | tacacs+} group-name` | Defines the AAA server-group with a group name. All members of a group must be the same type; that is, RADIUS or TACACS+. This command puts the router in server group subconfiguration mode. |
| **Step 3**  
  `Router(config-sg)# server ip-address [auth-port port-number] [acct-port port-number]` | Associates a particular TACACS+ server with the defined server group. Use the `auth-port port-number` option to configure a specific UDP port solely for authentication. Use the `acct-port port-number` option to configure a specific UDP port solely for accounting.  
  Repeat this step for each TACACS+ server in the AAA server group.  
  **Note** Each server in the group must be defined previously using the `tacacs-server host` command. |

Configuring AAA Server Group Selection Based on DNIS

Cisco IOS software allows you to authenticate users to a particular AAA server group based on the Dialed Number Identification Service (DNIS) number of the session. Any phone line (a regular home phone or a commercial T1/PRI line) can be associated with several phone numbers. The DNIS number identifies the number that was called to reach you.

For example, suppose you want to share the same phone number with several customers, but you want to know which customer is calling before you pick up the phone. You can customize how you answer the phone because DNIS allows you to know which customer is calling when you answer.
Cisco routers with either ISDN or internal modems can receive the DNIS number. This functionality allows users to assign different TACACS+ server groups for different customers (that is, different TACACS+ servers for different DNIS numbers). Additionally, using server groups you can specify the same server group for AAA services or a separate server group for each AAA service.

Cisco IOS software provides the flexibility to implement authentication and accounting services in several ways:

- **Globally**—AAA services are defined using global configuration access list commands and applied in general to all interfaces on a specific network access server.
- **Per interface**—AAA services are defined using interface configuration commands and applied specifically to the interface being configured on a specific network access server.
- **DNIS mapping**—You can use DNIS to specify an AAA server to supply AAA services.

Because AAA configuration methods can be configured simultaneously, Cisco has established an order of precedence to determine which server or groups of servers provide AAA services. The order of precedence is as follows:

- **Per DNIS**—If you configure the network access server to use DNIS to identify which server group provides AAA services, then this method takes precedence over any additional AAA selection method.
- **Per interface**—If you configure the network access server per interface to use access lists to determine how a server provides AAA services, this method takes precedence over any global configuration AAA access lists.
- **Globally**—If you configure the network access server by using global AAA access lists to determine how the security server provides AAA services, this method has the lowest precedence.

**Note** Prior to configuring AAA Server Group Selection Based on DNIS, you must configure the remote security servers associated with each AAA server group. See the sections “Identifying the TACACS+ Server Host” and “Configuring AAA Server Groups” in this chapter.

To configure the router to select a particular AAA server group based on the DNIS of the server group, configure DNIS mapping. To map a server group with a group name with DNIS number, use the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>aaa dnis map enable</strong>&lt;br&gt;Router(config)#</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><strong>aaa dnis map dnis-number authentication ppp group server-group-name</strong>&lt;br&gt;Router(config)#</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>**aaa dnis map dnis-number accounting network {none</td>
</tr>
</tbody>
</table>
Specifying TACACS+ Authentication

After you have identified the TACACS+ daemon and defined an associated TACACS+ encryption key, you must define method lists for TACACS+ authentication. Because TACACS+ authentication is operated via AAA, you need to issue the `aaa authentication` command, specifying TACACS+ as the authentication method. For more information, refer to the chapter “Configuring Authentication.”

Specifying TACACS+ Authorization

AAA authorization enables you to set parameters that restrict a user’s access to the network. Authorization via TACACS+ may be applied to commands, network connections, and EXEC sessions. Because TACACS+ authorization is facilitated through AAA, you must issue the `aaa authorization` command, specifying TACACS+ as the authorization method. For more information, refer to the chapter “Configuring Authorization.”

Specifying TACACS+ Accounting

AAA accounting enables you to track the services users are accessing as well as the amount of network resources they are consuming. Because TACACS+ accounting is facilitated through AAA, you must issue the `aaa accounting` command, specifying TACACS+ as the accounting method. For more information, refer to the chapter “Configuring Accounting.”

TACACS+ AV Pairs

The network access server implements TACACS+ authorization and accounting functions by transmitting and receiving TACACS+ attribute-value (AV) pairs for each user session. For a list of supported TACACS+ AV pairs, refer to the appendix “TACACS+ Attribute-Value Pairs.”

TACACS+ Configuration Examples

The following sections provide TACACS+ configuration examples:

- TACACS+ Authentication Examples
- TACACS+ Authorization Example
- TACACS+ Accounting Example
- TACACS+ Server Group Example
- AAA Server Group Selection Based on DNIS Example
- TACACS+ Daemon Configuration Example

TACACS+ Authentication Examples

The following example shows how to configure TACACS+ as the security protocol for PPP authentication:

```
aaa new-model
```
aaa authentication ppp test group tacacs+ local
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
ppp authentication chap pap test

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “test,” to be used on serial interfaces running PPP. The keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the test method list to this line.

The following example shows how to configure TACACS+ as the security protocol for PPP authentication, but instead of the “test” method list, the “default” method list is used.

aaa new-model
aaa authentication ppp default if-needed group tacacs+ local
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
ppp authentication chap default

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “default,” to be used on serial interfaces running PPP. The keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the default method list to this line.

The following example shows how to create the same authentication algorithm for PAP, but it calls the method list “MIS-access” instead of “default”:

aaa new-model
aaa authentication pap MIS-access if-needed group tacacs+ local
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
ppp authentication pap MIS-access

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
The \texttt{aaa authentication} command defines a method list, “MIS-access,” to be used on serial interfaces running PPP. The method list, “MIS-access,” means that PPP authentication is applied to all interfaces. The \texttt{if-needed} keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword \texttt{group tacacs+} means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword \texttt{local} indicates that authentication will be attempted using the local database on the network access server.

The \texttt{tacacs-server host} command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The \texttt{tacacs-server key} command defines the shared encryption key to be “goaway.”

The \texttt{interface} command selects the line, and the \texttt{ppp authentication} command applies the default method list to this line.

The following example shows the configuration for a TACACS+ daemon with an IP address of 10.2.3.4 and an encryption key of “apple”:

\begin{verbatim}
aaa new-model
aaa authentication login default group tacacs+ local
tacacs-server host 10.2.3.4
tacacs-server key apple
\end{verbatim}

The lines in the preceding sample configuration are defined as follows:

- The \texttt{aaa new-model} command enables the AAA security services.
- The \texttt{aaa authentication} command defines the default method list. Incoming ASCII logins on all interfaces (by default) will use TACACS+ for authentication. If no TACACS+ server responds, then the network access server will use the information contained in the local username database for authentication.
- The \texttt{tacacs-server host} command identifies the TACACS+ daemon as having an IP address of 10.2.3.4. The \texttt{tacacs-server key} command defines the shared encryption key to be “apple.”

**TACACS+ Authorization Example**

The following example shows how to configure TACACS+ as the security protocol for PPP authentication using the default method list; it also shows how to configure network authorization via TACACS+:

\begin{verbatim}
aaa new-model
aaa authentication ppp default if-needed group tacacs+ local
aaa authorization network default group tacacs+
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
  ppp authentication chap default
\end{verbatim}

The lines in the preceding sample configuration are defined as follows:

- The \texttt{aaa new-model} command enables the AAA security services.
- The \texttt{aaa authentication} command defines a method list, “default,” to be used on serial interfaces running PPP. The keyword \texttt{default} means that PPP authentication is applied by default to all interfaces. The \texttt{if-needed} keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword \texttt{group tacacs+} means that authentication will be done
through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword `local` indicates that authentication will be attempted using the local database on the network access server.

- The `aaa authorization` command configures network authorization via TACACS+. Unlike authentication lists, this authorization list always applies to all incoming network connections made to the network access server.

- The `tacacs-server host` command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The `tacacs-server key` command defines the shared encryption key to be “goaway.”

- The `interface` command selects the line, and the `ppp authentication` command applies the default method list to this line.

**TACACS+ Accounting Example**

The following example shows how to configure TACACS+ as the security protocol for PPP authentication using the default method list; it also shows how to configure accounting via TACACS+:

```
aaa new-model
aaa authentication ppp default if-needed group tacacs+ local
aaa accounting network default stop-only group tacacs+
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
ppp authentication chap default
```

The lines in the preceding sample configuration are defined as follows:

- The `aaa new-model` command enables the AAA security services.

- The `aaa authentication` command defines a method list, “default,” to be used on serial interfaces running PPP. The keyword `default` means that PPP authentication is applied by default to all interfaces. The `if-needed` keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword `group tacacs+` means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword `local` indicates that authentication will be attempted using the local database on the network access server.

- The `aaa accounting` command configures network accounting via TACACS+. In this example, accounting records describing the session that just terminated will be sent to the TACACS+ daemon whenever a network connection terminates.

- The `tacacs-server host` command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The `tacacs-server key` command defines the shared encryption key to be “goaway.”

- The `interface` command selects the line, and the `ppp authentication` command applies the default method list to this line.

**TACACS+ Server Group Example**

The following example shows how to create a server group with three different TACACS+ servers members:

```
aaa group server tacacs tacgroup1
    server 172.16.1.1
    server 172.16.1.21
```
AAA Server Group Selection Based on DNIS Example

The following example shows how to select TACAC+ server groups based on DNIS to provide specific AAA services:

! This command enables AAA.
aaa new-model

! The following set of commands configures the TACACS+ servers that will be associated with one of the defined server groups.
tacacs-server host 172.16.0.1
tacacs-server host 172.17.0.1
tacacs-server host 172.18.0.1
tacacs-server host 172.19.0.1
tacacs-server host 172.20.0.1
tacacs-server key abcdefg

! The following commands define the sg1 TACACS+ server group and associate servers with it.
aaa group server tacacs sg1
    server 172.16.0.1
    server 172.17.0.1

! The following commands define the sg2 TACACS+ server group and associate a server with it.
aaa group server tacacs sg2
    server 172.18.0.1

! The following commands define the sg3 TACACS+ server group and associate a server with it.
aaa group server tacacs sg3
    server 172.19.0.1

! The following commands define the default-group TACACS+ server group and associate a server with it.
aaa group server tacacs default-group
    server 172.20.0.1

! The next set of commands configures default-group tacacs server group parameters.
aaa authentication ppp default group default-group
aaa accounting network default start-stop group default-group

! The next set of commands enables DNIS mapping and maps DNIS numbers to the defined RADIUS server groups. In this configuration, all PPP connection requests using DNIS 7777 are sent to the sg1 server group. The accounting records for these connections (specifically, start-stop records) are handled by the sg2 server group. Calls with a DNIS of 8888 use server group sg3 for authentication and server group default-group for accounting. Calls with a DNIS of 9999 use server group default-group for authentication and server group sg3 for accounting records (stop records only). All other calls with DNIS other than the ones defined use the server group default-group for both authentication and stop-start accounting records.
aaa dnis map enable
aaa dnis map 7777 authentication ppp group sg1
aaa dnis map 7777 accounting network start-stop group sg2
aaa dnis map 8888 authentication ppp group sg3
aaa dnis map 9999 accounting network stop-only group sg3
TACACS+ Daemon Configuration Example

The following example shows a sample configuration of the TACACS+ daemon. The precise syntax used by your TACACS+ daemon may be different from what is included in this example.

```
user = mci_customer1 {
  chap = cleartext "some chap password"
  service = ppp protocol = ip {
   inacl#1="permit ip any any precedence immediate"
   inacl#2="deny igrp 0.0.1.2 255.255.0.0 any"
  }
}
```

Per VRF for TACACS+ Servers

First Published: March 1, 2004
Last Updated: November 17, 2008

The Per VRF for TACACS+ Servers feature allows per virtual route forwarding (per VRF) to be configured for authentication, authorization, and accounting (AAA) on TACACS+ servers.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the “Feature Information for Per VRF for TACACS+ Servers” section on page 8.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Catalyst OS, and Cisco IOS XE software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Contents

- Prerequisites for Per VRF for TACACS+ Servers, page 2
- Restrictions for Per VRF for TACACS+ Servers, page 2
- Information About Per VRF for TACACS+ Servers, page 2
- How to Configure Per VRF for TACACS+ Servers, page 2
- Configuration Examples for Per VRF for TACACS+ Servers, page 5

Prerequisites for Per VRF for TACACS+ Servers

- TACACS+ server access is required.
- Experience configuring TACACS+, AAA and per VRF AAA, and group servers is necessary.

Restrictions for Per VRF for TACACS+ Servers

- The VRF instance must be specified before per VRF for a TACACS+ server is configured.

Information About Per VRF for TACACS+ Servers

To configure the Per VRF for TACACS+ Servers feature, the following concept should be understood:

- Per VRF for TACACS+ Servers Overview, page 2

Per VRF for TACACS+ Servers Overview

The Per VRF for TACACS+ Servers feature allows per VRF AAA to be configured on TACACS+ servers. Prior to Cisco IOS Release 12.3(7)T, this functionality was available only on RADIUS servers.

How to Configure Per VRF for TACACS+ Servers

This section contains the following procedures:

- Configuring Per VRF on a TACACS+ Server, page 2 (required)
- Verifying Per VRF for TACACS+ Servers, page 4 (optional)

Configuring Per VRF on a TACACS+ Server

The initial steps in this procedure are used to configure AAA and a server group, create a VRF routing table, and configure an interface. Steps 10 through 13 are used to configure the per VRF on a TACACS+ server feature:

SUMMARY STEPS

1. enable
2. configure terminal
3. ip vrf vrf-name
4. rd route-distinguisher
5. exit
6. interface interface-name
7. ip vrf forwarding vrf-name
8. `ip address ip-address mask [secondary]`
9. `exit`
10. `aaa group server tacacs+ group-name`
11. `server-private [ip-address | name] [nat] [single-connection] [port port-number] [timeout seconds] [key [0 | 7] string]`
12. `ip vrf forwarding vrf-name`
13. `ip tacacs source-interface subinterface-name`
14. `exit`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
`enable` | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| **Example:**  
`Router> enable` | |
| **Step 2**  
`configure terminal` | Enters global configuration mode. |
| **Example:**  
`Router# configure terminal` | |
| **Step 3**  
`ip vrf vrf-name` | Configures a VRF table and enters VRF configuration mode. |
| **Example:**  
`Router (config)# ip vrf cisco` | |
| **Step 4**  
`rd route-distinguisher` | Creates routing and forwarding tables for a VRF instance. |
| **Example:**  
`Router (config-vrf)# rd 100:1` | |
| **Step 5**  
`exit` | Exits VRF configuration mode. |
| **Example:**  
`Router (config-vrf)# exit` | |
| **Step 6**  
`interface interface-name` | Configures an interface and enters interface configuration mode. |
| **Example:**  
`Router (config)# interface Loopback0` | |
| **Step 7**  
`ip vrf forwarding vrf-name` | Configures a VRF for the interface. |
| **Example:**  
`Router (config-if)# ip vrf forwarding cisco` | |
| **Step 8**  
`ip address ip-address mask [secondary]` | Sets a primary or secondary IP address for an interface. |
| **Example:**  
`Router (config-if)# ip address 10.0.0.2 255.0.0.0` | |
How to Configure Per VRF for TACACS+ Servers

Verifying Per VRF for TACACS+ Servers

To verify the per VRF TACACS+ configuration, perform the following steps:

Note

The debug commands may be used in any order.

SUMMARY STEPS

1. enable
2. debug tacacs authentication
3. debug tacacs authorization
4. debug tacacs accounting
5. debug tacacs packets
Configuration Examples for Per VRF for TACACS+ Servers

This section includes the following configuration example:

- Configuring Per VRF for TACACS+ Servers: Example, page 5

### Configuring Per VRF for TACACS+ Servers: Example

The following output example shows that the group server `tacacs1` is configured for per VRF AAA services:

```
aaa group server tacacs+ tacacs1
    server-private 10.1.1.1 port 19 key cisco
    ip vrf forwarding cisco
    ip tacacs source-interface Loopback0

    ip vrf cisco
    rd 100:1

interface Loopback0
    ip address 10.0.0.2 255.0.0.0
    ip vrf forwarding cisco
```

This chapter describes the Kerberos security system. For a complete description of the Kerberos commands used in this chapter, refer to the “Kerberos Commands” chapter in the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature, or refer to the software release notes for a specific release. For more information, see the section “Identifying Supported Platforms” in the chapter “Using Cisco IOS Software.”

**In This Chapter**

This chapter includes the following topics and tasks:

- About Kerberos
- Kerberos Client Support Operation
- Kerberos Configuration Task List
- Kerberos Configuration Examples

**About Kerberos**

Kerberos is a secret-key network authentication protocol, developed at the Massachusetts Institute of Technology (MIT), that uses the Data Encryption Standard (DES) cryptographic algorithm for encryption and authentication. Kerberos was designed to authenticate requests for network resources.
Kerberos, like other secret-key systems, is based on the concept of a trusted third party that performs secure verification of users and services. In the Kerberos protocol, this trusted third party is called the key distribution center (KDC).

The primary use of Kerberos is to verify that users and the network services they use are really who and what they claim to be. To accomplish this, a trusted Kerberos server issues tickets to users. These tickets, which have a limited lifespan, are stored in a user’s credential cache and can be used in place of the standard username-and-password authentication mechanism.

The Kerberos credential scheme embodies a concept called “single logon.” This process requires authenticating a user once, and then allows secure authentication (without encrypting another password) wherever that user’s credential is accepted.

Starting with Cisco IOS Release 11.2, Cisco IOS software includes Kerberos 5 support, which allows organizations already deploying Kerberos 5 to use the same Kerberos authentication database on their routers that they are already using on their other network hosts (such as UNIX servers and PCs).

The following network services are supported by the Kerberos authentication capabilities in Cisco IOS software:

- Telnet
- rlogin
- rsh
- rcp

Note

Cisco Systems’ implementation of Kerberos client support is based on code developed by CyberSafe, which was derived from the MIT code. As a result, the Cisco Kerberos implementation has successfully undergone full compatibility testing with the CyberSafe Challenger commercial Kerberos server and MIT’s server code, which is freely distributed.

Table 20 lists common Kerberos-related terms and their definitions.

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>A process by which a user or service identifies itself to another service. For example, a client can authenticate to a router or a router can authenticate to another router.</td>
</tr>
<tr>
<td>authorization</td>
<td>A means by which the router determines what privileges you have in a network or on the router and what actions you can perform.</td>
</tr>
<tr>
<td>credential</td>
<td>A general term that refers to authentication tickets, such as ticket granting tickets (TGTs) and service credentials. Kerberos credentials verify the identity of a user or service. If a network service decides to trust the Kerberos server that issued a ticket, it can be used in place of reotyping in a username and password. Credentials have a default lifespan of eight hours.</td>
</tr>
</tbody>
</table>
This section describes how the Kerberos security system works with a Cisco router functioning as the security server. Although (for convenience or technical reasons) you can customize Kerberos in a number of ways, remote users attempting to access network services must pass through three layers of security before they can access network services.

This section includes the following sections:

- Authenticating to the Boundary Router
- Obtaining a TGT from a KDC
- Authenticating to Network Services
Authenticating to the Boundary Router

This section describes the first layer of security that remote users must pass through when they attempt to access a network. The first step in the Kerberos authentication process is for users to authenticate themselves to the boundary router. The following process describes how users authenticate to a boundary router:

1. The remote user opens a PPP connection to the corporate site router.
2. The router prompts the user for a username and password.
3. The router requests a TGT from the KDC for this particular user.
4. The KDC sends an encrypted TGT to the router that includes (among other things) the user’s identity.
5. The router attempts to decrypt the TGT using the password the user entered. If the decryption is successful, the remote user is authenticated to the router.

A remote user who successfully initiates a PPP session and authenticates to the boundary router is inside the firewall but still must authenticate to the KDC directly before being allowed to access network services. This is because the TGT issued by the KDC is stored on the router and is not useful for additional authentication unless the user physically logs on to the router.

Obtaining a TGT from a KDC

This section describes how remote users who are authenticated to the boundary router authenticate themselves to a KDC.

When a remote user authenticates to a boundary router, that user technically becomes part of the network; that is, the network is extended to include the remote user and the user’s machine or network. To gain access to network services, however, the remote user must obtain a TGT from the KDC. The following process describes how remote users authenticate to the KDC:

1. The remote user, at a workstation on a remote site, launches the KINIT program (part of the client software provided with the Kerberos protocol).
2. The KINIT program finds the user’s identity and requests a TGT from the KDC.
3. The KDC creates a TGT, which contains the identity of the user, the identity of the KDC, and the expiration time of the TGT.
4. Using the user’s password as a key, the KDC encrypts the TGT and sends the TGT to the workstation.
5. When the KINIT program receives the encrypted TGT, it prompts the user for a password (this is the password that is defined for the user in the KDC).
6. If the KINIT program can decrypt the TGT with the password the user enters, the user is authenticated to the KDC, and the KINIT program stores the TGT in the user’s credential cache.

At this point, the user has a TGT and can communicate securely with the KDC. In turn, the TGT allows the user to authenticate to other network services.
Authenticating to Network Services

The following process describes how a remote user with a TGT authenticates to network services within a given Kerberos realm. Assume the user is on a remote workstation (Host A) and wants to log in to Host B.

1. The user on Host A initiates a Kerberized application (such as Telnet) to Host B.
2. The Kerberized application builds a service credential request and sends it to the KDC. The service credential request includes (among other things) the user’s identity and the identity of the desired network service. The TGT is used to encrypt the service credential request.
3. The KDC tries to decrypt the service credential request with the TGT it issued to the user on Host A. If the KDC can decrypt the packet, it is assured that the authenticated user on Host A sent the request.
4. The KDC notes the network service identity in the service credential request.
5. The KDC builds a service credential for the appropriate network service on Host B on behalf of the user on Host A. The service credential contains the client’s identity and the desired network service’s identity.
6. The KDC then encrypts the service credential twice. It first encrypts the credential with the SRVTAB that it shares with the network service identified in the credential. It then encrypts the resulting packet with the TGT of the user (who, in this case, is on Host A).
7. The KDC sends the twice-encrypted credential to Host A.
8. Host A attempts to decrypt the service credential with the user’s TGT. If Host A can decrypt the service credential, it is assured the credential came from the real KDC.
9. Host A sends the service credential to the desired network service. Note that the credential is still encrypted with the SRVTAB shared by the KDC and the network service.
10. The network service attempts to decrypt the service credential using its SRVTAB.
11. If the network service can decrypt the credential, it is assured the credential was in fact issued from the KDC. Note that the network service trusts anything it can decrypt from the KDC, even if it receives it indirectly from a user. This is because the user first authenticated with the KDC.

At this point, the user is authenticated to the network service on Host B. This process is repeated each time a user wants to access a network service in the Kerberos realm.

Kerberos Configuration Task List

For hosts and the KDC in your Kerberos realm to communicate and mutually authenticate, you must identify them to each other. To do this, you add entries for the hosts to the Kerberos database on the KDC and add SRVTAB files generated by the KDC to all hosts in the Kerberos realm. You also make entries for users in the KDC database.

This section describes how to set up a Kerberos-authenticated server-client system and contains the following topics:

- Configuring the KDC Using Kerberos Commands
- Configuring the Router to Use the Kerberos Protocol
This section assumes that you have installed the Kerberos administrative programs on a UNIX host, known as the KDC, initialized the database, and selected a Kerberos realm name and password. For instructions about completing these tasks, refer to documentation that came with your Kerberos software.

### Note
Write down the host name or IP address of the KDC, the port number you want the KDC to monitor for queries, and the name of the Kerberos realm it will serve. You need this information to configure the router.

## Configuring the KDC Using Kerberos Commands

After you set up a host to function as the KDC in your Kerberos realm, you must make entries to the KDC database for all principals in the realm. Principals can be network services on Cisco routers and hosts or they can be users.

To use Kerberos commands to add services to the KDC database (and to modify existing database information), complete the tasks in the following sections:

- Adding Users to the KDC Database
- Creating SRVTABs on the KDC
- Extracting SRVTABs

### Note
All Kerberos command examples are based on Kerberos 5 Beta 5 of the original MIT implementation. Later versions use a slightly different interface.

## Adding Users to the KDC Database

To add users to the KDC and create privileged instances of those users, use the `su` command to become root on the host running the KDC and use the kdb5_edit program to use the following commands in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td><code>Router# ank username@REALM</code></td>
<td>Use the <code>ank</code> (add new key) command to add a user to the KDC. This command prompts for a password, which the user must enter to authenticate to the router.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>Router# ank username/instance@REALM</code></td>
<td>Use the <code>ank</code> command to add a privileged instance of a user.</td>
</tr>
</tbody>
</table>

For example, to add user *loki* of Kerberos realm CISCO.COM, enter the following Kerberos command:

```
ank loki@CISCO.COM
```

### Note
The Kerberos realm name must be in uppercase characters.
You might want to create privileged instances to allow network administrators to connect to the router at the enable level, for example, so that they need not enter a clear text password (and compromise security) to enter enable mode.

To add an instance of loki with additional privileges (in this case, enable, although it could be anything) enter the following Kerberos command:

```
ank loki/enable@CISCO.COM
```

In each of these examples, you are prompted to enter a password, which you must give to user loki to use at login.

The “Enabling Kerberos Instance Mapping” section describes how to map Kerberos instances to various Cisco IOS privilege levels.

### Creating SRVTABs on the KDC

All routers that you want to authenticate to use the Kerberos protocol must have an SRVTAB. This section and the “Extracting SRVTABs” section describe how to create and extract SRVTABs for a router called router1. The section “Copying SRVTAB Files” describes how to copy SRVTAB files to the router.

To make SRVTAB entries on the KDC, use the following command in privileged EXEC mode:

```
Router# ark SERVICE/HOSTNAME@REALM
```

For example, to add a Kerberized authentication service for a Cisco router called router1 to the Kerberos realm CISCO.COM, enter the following Kerberos command:

```
ark host/router1.cisco.com@CISCO.COM
```

Make entries for all network services on all Kerberized hosts that use this KDC for authentication.

### Extracting SRVTABs

SRVTABs contain (among other things) the passwords or randomly generated keys for the service principals you entered into the KDC database. Service principal keys must be shared with the host running that service. To do this, you must save the SRVTAB entries to a file, then copy the file to the router and all hosts in the Kerberos realm. Saving SRVTAB entries to a file is called extracting SRVTABs. To extract SRVTABs, use the following command in privileged EXEC mode:

```
Router# xst router-name host
```

For example, to write the host/router1.cisco.com@CISCO.COM SRVTAB to a file, enter the following Kerberos command:

```
xst router1.cisco.com@CISCO.COM host
```

Use the quit command to exit the kdb5_edit program.
Configuring the Router to Use the Kerberos Protocol

To configure a Cisco router to function as a network security server and authenticate users using the Kerberos protocol, complete the tasks in the following sections:

- Defining a Kerberos Realm
- Copying SRVTAB Files
- Specifying Kerberos Authentication
- Enabling Credentials Forwarding
- Opening a Telnet Session to the Router
- Establishing an Encrypted Kerberized Telnet Session
- Enabling Mandatory Kerberos Authentication
- Enabling Kerberos Instance Mapping
- Monitoring and Maintaining Kerberos

Defining a Kerberos Realm

For a router to authenticate a user defined in the Kerberos database, it must know the host name or IP address of the host running the KDC, the name of the Kerberos realm and, optionally, be able to map the host name or Domain Name System (DNS) domain to the Kerberos realm.

To configure the router to authenticate to a specified KDC in a specified Kerberos realm, use the following commands in global configuration mode. Note that DNS domain names must begin with a leading dot (.):

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Router(config)# kerberos local-realm kerberos-realm</td>
<td>Defines the default realm for the router.</td>
</tr>
<tr>
<td>Step 2 Router(config)# kerberos server kerberos-realm</td>
<td>Specifies to the router which KDC to use in a given Kerberos realm and, optionally, the port number that the KDC is monitoring. (The default is 88.)</td>
</tr>
<tr>
<td>Step 3 Router(config)# kerberos realm (dns-domain</td>
<td>host) kerberos-realm</td>
</tr>
</tbody>
</table>

**Note**

Because the machine running the KDC and all Kerberized hosts must interact within a 5-minute window or authentication fails, all Kerberized machines, and especially the KDC, should be running the Network Time Protocol (NTP).

The `kerberos local-realm`, `kerberos realm`, and `kerberos server` commands are equivalent to the UNIX `krb.conf` file. Table 21 identifies mappings from the Cisco IOS configuration commands to a Kerberos 5 configuration file (krb5.conf).
Configuring Kerberos

Kerberos Configuration Task List

For an example of defining a Kerberos realm, see the section “Defining a Kerberos Realm” later in this chapter.

Copying SRVTAB Files

To make it possible for remote users to authenticate to the router using Kerberos credentials, the router must share a secret key with the KDC. To do this, you must give the router a copy of the SRVTAB you extracted on the KDC.

The most secure method to copy SRVTAB files to the hosts in your Kerberos realm is to copy them onto physical media and go to each host in turn and manually copy the files onto the system. To copy SRVTAB files to the router, which does not have a physical media drive, you must transfer them via the network using TFTP.

To remotely copy SRVTAB files to the router from the KDC, use the following command in global configuration mode:

```
Router(config)# kerberos srvtab remote {hostname | ip-address} {filename}
```

For an example of copying SRVTAB files, see the section “SRVTAB File Copying Example” later in this chapter.

Specifying Kerberos Authentication

You have now configured Kerberos on your router. This makes it possible for the router to authenticate using Kerberos. The next step is to tell it to do so. Because Kerberos authentication is facilitated through AAA, you need to enter the `aaa authentication` command, specifying Kerberos as the authentication method. For more information, refer to the chapter “Configuring Authentication”.

### Table 21  Kerberos 5 Configuration File and Commands

<table>
<thead>
<tr>
<th>krb5.conf File</th>
<th>Cisco IOS Configuration Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>[libdefaults]</td>
<td></td>
</tr>
<tr>
<td>default_realm  = DOMAIN.COM</td>
<td>kerberos local-realm DOMAIN.COM</td>
</tr>
<tr>
<td>[domain_realm]</td>
<td></td>
</tr>
<tr>
<td>.domain.com  = DOMAIN.COM</td>
<td>kerberos realm domain.com DOMAIN.COM</td>
</tr>
<tr>
<td>domain.com  = DOMAIN.COM</td>
<td>kerberos realm domain.com DOMAIN.COM</td>
</tr>
<tr>
<td>[realms]</td>
<td></td>
</tr>
<tr>
<td>kdc = DOMAIN.PIL.COM:750</td>
<td>kerberos server DOMAIN.COM 172.65.44.2</td>
</tr>
<tr>
<td>admin_server  = DOMAIN.PIL.COM</td>
<td>(172.65.44.2 is the example IP address for DOMAIN.PIL.COM)</td>
</tr>
<tr>
<td>default_domain = DOMAIN.COM</td>
<td></td>
</tr>
</tbody>
</table>

When you copy the SRVTAB file from the router to the KDC, the `kerberos srvtab remote` command parses the information in this file and stores it in the router’s running configuration in the `kerberos srvtab entry` format. To ensure that the SRVTAB is available (does not need to be acquired from the KDC) when you reboot the router, use the `write memory` configuration command to write your running configuration (which contains the parsed SRVTAB file) to NVRAM.

For an example of copying SRVTAB files, see the section “SRVTAB File Copying Example” later in this chapter.
Enabling Credentials Forwarding

With Kerberos configured thus far, a user authenticated to a Kerberized router has a TGT and can use it to authenticate to a host on the network. However, if the user tries to list credentials after authenticating to a host, the output will show no Kerberos credentials present.

You can optionally configure the router to forward users’ TGTs with them as they authenticate from the router to Kerberized remote hosts on the network when using Kerberized Telnet, rcp, rsh, and rlogin (with the appropriate flags).

To force all clients to forward users’ credentials as they connect to other hosts in the Kerberos realm, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# kerberos credentials forward</td>
<td>Forces all clients to forward user credentials upon successful Kerberos authentication.</td>
</tr>
</tbody>
</table>

With credentials forwarding enabled, users’ TGTs are automatically forwarded to the next host they authenticate to. In this way, users can connect to multiple hosts in the Kerberos realm without running the KINIT program each time to get a new TGT.

Opening a Telnet Session to the Router

To use Kerberos to authenticate users opening a Telnet session to the router from within the network, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# aaa authentication login (default</td>
<td>list-name) krb5_telnet</td>
</tr>
</tbody>
</table>

Although Telnet sessions to the router are authenticated, users must still enter a clear text password if they want to enter enable mode. The `kerberos instance map` command, discussed in a later section, allows them to authenticate to the router at a predefined privilege level.

Establishing an Encrypted Kerberized Telnet Session

Another way for users to open a secure Telnet session is to use Encrypted Kerberized Telnet. With Encrypted Kerberized Telnet, users are authenticated by their Kerberos credentials before a Telnet session is established. The Telnet session is encrypted using 56-bit Data Encryption Standard (DES) encryption with 64-bit Cipher Feedback (CFB). Because data sent or received is encrypted, not clear text, the integrity of the dialed router or access server can be more easily controlled.

This feature is available only if you have the 56-bit encryption image. 56-bit DES encryption is subject to U.S. Government export control regulations.

To establish an encrypted Kerberized Telnet session from a router to a remote host, use either of the following commands in EXEC command mode:
When a user opens a Telnet session from a Cisco router to a remote host, the router and remote host negotiate to authenticate the user using Kerberos credentials. If this authentication is successful, the router and remote host then negotiate whether or not to use encryption. If this negotiation is successful, both inbound and outbound traffic is encrypted using 56-bit DES encryption with 64-bit CFB.

When a user dials in from a remote host to a Cisco router configured for Kerberos authentication, the host and router will attempt to negotiate whether or not to use encryption for the Telnet session. If this negotiation is successful, the router will encrypt all outbound data during the Telnet session.

If encryption is not successfully negotiated, the session will be terminated and the user will receive a message stating that the encrypted Telnet session was not successfully established.

For information about enabling bidirectional encryption from a remote host, refer to the documentation specific to the remote host device.

For an example of using encrypted Kerberized Telnet to open a secure Telnet session, see the section “Encrypted Telnet Session Example” later in this chapter.

Enabling Mandatory Kerberos Authentication

As an added layer of security, you can optionally configure the router so that, after remote users authenticate to it, these users can authenticate to other services on the network only with Kerberized Telnet, rlogin, rsh, and rcp. If you do not make Kerberos authentication mandatory and Kerberos authentication fails, the application attempts to authenticate users using the default method of authentication for that network service; for example, Telnet and rlogin prompt for a password, and rsh attempts to authenticate using the local rhost file.

To make Kerberos authentication mandatory, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config)# kerberos clients mandatory</code></td>
<td>Sets Telnet, rlogin, rsh, and rcp to fail if they cannot negotiate the Kerberos protocol with the remote server.</td>
</tr>
</tbody>
</table>

Enabling Kerberos Instance Mapping

As mentioned in the section “Creating SRVTABs on the KDC,” you can create administrative instances of users in the KDC database. The `kerberos instance map` command allows you to map those instances to Cisco IOS privilege levels so that users can open secure Telnet sessions to the router at a predefined privilege level, obviating the need to enter a clear text password to enter enable mode.

To map a Kerberos instance to a Cisco IOS privilege level, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config)# kerberos instance map instance_name</code></td>
<td>Maps the Kerberos instance to the specified Cisco IOS privilege level.</td>
</tr>
</tbody>
</table>
Configuring Kerberos

If there is a Kerberos instance for user loki in the KDC database (for example, loki/admin), user loki can now open a Telnet session to the router as loki/admin and authenticate automatically at privilege level 15, assuming instance “admin” is mapped to privilege level 15. (See the section “Adding Users to the KDC Database” earlier in this chapter.)

Cisco IOS commands can be set to various privilege levels using the `privilege level` command.

After you map a Kerberos instance to a Cisco IOS privilege level, you must configure the router to check for Kerberos instances each time a user logs in. To run authorization to determine if a user is allowed to run an EXEC shell based on a mapped Kerberos instance, use the `aaa authorization` command with the `krb5-instance` keyword. For more information, refer to the chapter “Configuring Authorization.”

**Monitoring and Maintaining Kerberos**

To display or remove a current user’s credentials, use the following commands in EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# kerberos instance map instance privilege-level</td>
<td>Maps a Kerberos instance to a Cisco IOS privilege level.</td>
</tr>
</tbody>
</table>

For an example of Kerberos configuration, see the section “Kerberos Configuration Examples”.

**Kerberos Configuration Examples**

The following sections provide Kerberos configuration examples:

- Kerberos Realm Definition Examples
- SRVtab File Copying Example
- Kerberos Configuration Examples
- Encrypted Telnet Session Example

**Kerberos Realm Definition Examples**

To define CISCO.COM as the default Kerberos realm, use the following command:

```
kerberos local-realm CISCO.COM
```

To tell the router that the CISCO.COM KDC is running on host 10.2.3.4 at port number 170, use the following Kerberos command:

```
kerberos server CISCO.COM 10.2.3.4 170
```

To map the DNS domain cisco.com to the Kerberos realm CISCO.COM, use the following command:
SRVTAB File Copying Example

To copy over the SRVTAB file on a host named host123.cisco.com for a router named router1.cisco.com, the command would look like this:

```
kerberos srvtab remote host123.cisco.com router1.cisco.com-new-srvtab
```

Kerberos Configuration Examples

This section provides a typical non-Kerberos router configuration and shows output for this configuration from the `write term` command, then builds on this configuration by adding optional Kerberos functionality. Output for each configuration is presented for comparison against the previous configuration.

This example shows how to use the `kdb5_edit` program to perform the following configuration tasks:

- Adding user chet to the Kerberos database
- Adding a privileged Kerberos instance of user chet (chet/admin) to the Kerberos database
- Adding a restricted instance of chet (chet/restricted) to the Kerberos database
- Adding workstation chet-ss20.cisco.com
- Adding router chet-2500.cisco.com to the Kerberos database
- Adding workstation chet-ss20.cisco.com to the Kerberos database
- Extracting SRVTABs for the router and workstations
- Listing the contents of the KDC database (with the `ldb` command)

Note that, in this sample configuration, host chet-ss20 is also the KDC:

```
chet-ss20# sbin/kdb5_edit
kdb5_edit: ank chet
Enter password:
Re-enter password for verification:
kdb5_edit: ank chet/admin
Enter password:
Re-enter password for verification:
kdb5_edit: ank chet/restricted
Enter password:
Re-enter password for verification:
kdb5_edit: ark host/chet-ss20.cisco.com
kdb5_edit: ark host/chet-2500.cisco.com
kdb5_edit: xst chet-ss20.cisco.com host
'host/chet-ss20.cisco.com@CISCO.COM' added to keytab
'WRFILE:chet-ss20.cisco.com-new-srvtab'
kdb5_edit: xst chet-2500.cisco.com host
'host/chet-2500.cisco.com@CISCO.COM' added to keytab
'WRFILE:chet-2500.cisco.com-new-srvtab'
kdb5_edit: ldb
entry: host/chet-2500.cisco.com@CISCO.COM
entry: chet/restricted@CISCO.COM
entry: chet@CISCO.COM
entry: K/M@CISCO.COM
entry: host/chet-ss20.cisco.com@CISCO.COM
entry: krbtgt/CISCO.COM@CISCO.COM
entry: chet/admin@CISCO.COM
```
The following example shows output from a **write term** command, which displays the configuration of router `chet-2500`. This is a typical configuration with no Kerberos authentication.

```
chet-2500# write term

The following example shows how to enable user authentication on the router via the Kerberos database. To enable user authentication via the Kerberos database, you would perform the following tasks:

- Entering configuration mode
- Defining the Kerberos local realm
- Identifying the machine hosting the KDC
- Enabling credentials forwarding
- Specifying Kerberos as the method of authentication for login
- Exiting configuration mode (CTL-Z)
- Writing the new configuration to the terminal

```
chet-2500# configure term
Enter configuration commands, one per line. End with CNTL/Z.
chet-2500(config)# kerberos local-realm CISCO.COM
chet-2500(config)# kerberos server CISCO.COM chet-ss20
Translating "chet-ss20"...domain server (192.168.0.0) [OK]
chet-2500(config)# kerberos credentials forward
chet-2500(config)# aaa authentication login default krb5
chet-2500(config)#
chet-2500%SYS-5-CONFIG_I: Configured from console by console
chet-2500# write term
```

Compare the following configuration with the previous one. In particular, look at the lines beginning with the words “aaa,” “username,” and “kerberos” (lines 10 through 20) in this new configuration.

Cisco provides basic traffic filtering capabilities with access control lists (also referred to as access lists). Access lists can be configured for all routed network protocols (IP, AppleTalk, and so on) to filter the packets of those protocols as the packets pass through a router.

You can configure access lists at your router to control access to a network: access lists can prevent certain traffic from entering or exiting a network.

In This Chapter

This chapter describes access lists as part of a security solution. This chapter includes tips, cautions, considerations, recommendations, and general guidelines for how to use access lists.

This chapter has these sections:

- About Access Control Lists
- Overview of Access List Configuration
- Finding Complete Configuration and Command Information for Access Lists

About Access Control Lists

This section briefly describes what access lists do; why and when you should configure access lists; and basic versus advanced access lists.

This section has the following sections:

- What Access Lists Do
- Why You Should Configure Access Lists
- When to Configure Access Lists
- Basic Versus Advanced Access Lists
What Access Lists Do

Access lists filter network traffic by controlling whether routed packets are forwarded or blocked at the router’s interfaces. Your router examines each packet to determine whether to forward or drop the packet, on the basis of the criteria you specified within the access lists.

Access list criteria could be the source address of the traffic, the destination address of the traffic, the upper-layer protocol, or other information. Note that sophisticated users can sometimes successfully evade or fool basic access lists because no authentication is required.

Why You Should Configure Access Lists

There are many reasons to configure access lists; for example, you can use access lists to restrict contents of routing updates or to provide traffic flow control. One of the most important reasons to configure access lists is to provide security for your network, which is the focus of this chapter.

You should use access lists to provide a basic level of security for accessing your network. If you do not configure access lists on your router, all packets passing through the router could be allowed onto all parts of your network.

Access lists can allow one host to access a part of your network and prevent another host from accessing the same area. In Figure 17, host A is allowed to access the Human Resources network, and host B is prevented from accessing the Human Resources network.

Figure 17  Using Traffic Filters to Prevent Traffic from Being Routed to a Network

You can also use access lists to decide which types of traffic are forwarded or blocked at the router interfaces. For example, you can permit e-mail traffic to be routed, but at the same time block all Telnet traffic.
When to Configure Access Lists

Access lists should be used in “firewall” routers, which are often positioned between your internal network and an external network such as the Internet. You can also use access lists on a router positioned between two parts of your network, to control traffic entering or exiting a specific part of your internal network.

To provide the security benefits of access lists, you should at a minimum configure access lists on border routers—routers situated at the edges of your networks. This provides a basic buffer from the outside network, or from a less controlled area of your own network into a more sensitive area of your network.

On these routers, you should configure access lists for each network protocol configured on the router interfaces. You can configure access lists so that inbound traffic or outbound traffic or both are filtered on an interface.

Access lists must be defined on a per-protocol basis. In other words, you should define access lists for every protocol enabled on an interface if you want to control traffic flow for that protocol.

Note
Some protocols refer to access lists as filters.

Basic Versus Advanced Access Lists

This chapter describes how to use standard and static extended access lists, which are the basic types of access lists. Some type of basic access list should be used with each routed protocol that you have configured for router interfaces.

Besides the basic types of access lists described in this chapter, there are also more advanced access lists available, which provide additional security features and give you greater control over packet transmission. These advanced access lists and features are described in the other chapters within the part “Traffic Filtering and Firewalls.”

Overview of Access List Configuration

Each protocol has its own set of specific tasks and rules that are required in order for you to provide traffic filtering. In general, most protocols require at least two basic steps to be accomplished. The first step is to create an access list definition, and the second step is to apply the access list to an interface.

The following sections describe these two steps:

- Creating Access Lists
- Applying Access Lists to Interfaces

Note that some protocols refer to access lists as filters and refer to the act of applying the access lists to interfaces as filtering.

Creating Access Lists

Create access lists for each protocol you wish to filter, per router interface. For some protocols, you create one access list to filter inbound traffic, and one access list to filter outbound traffic.
To create an access list, you specify the protocol to filter, you assign a unique name or number to the access list, and you define packet filtering criteria. A single access list can have multiple filtering criteria statements.

Cisco recommends that you create your access lists on a TFTP server and then download the access lists to your router. This approach can considerably simplify maintenance of your access lists. For details, see the “Creating and Editing Access List Statements on a TFTP Server” section later in this chapter.

The protocols for which you can configure access lists are identified in Table 22.

This section has the following sections:

- Assigning a Unique Name or Number to Each Access List
- Defining Criteria for Forwarding or Blocking Packets
- Creating and Editing Access List Statements on a TFTP Server

### Assigning a Unique Name or Number to Each Access List

When configuring access lists on a router, you must identify each access list uniquely within a protocol by assigning either a name or a number to the protocol’s access list.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access lists of some protocols must be identified by a name, and access lists of other protocols must be identified by a number. Some protocols can be identified by either a name or a number. When a number is used to identify an access list, the number must be within the specific range of numbers that is valid for the protocol.</td>
</tr>
</tbody>
</table>

You can specify access lists by names for the following protocols:

- Apollo Domain
- IP
- IPX
- ISO CLNS
- NetBIOS IPX
- Source-route bridging NetBIOS

You can specify access lists by numbers for the protocols listed in Table 22. Table 22 also lists the range of access list numbers that is valid for each protocol.

Defining Criteria for Forwarding or Blocking Packets

When creating an access list, you define criteria that are applied to each packet that is processed by the router; the router decides whether to forward or block each packet on the basis of whether or not the packet matches the criteria.

Typical criteria you define in access lists are packet source addresses, packet destination addresses, and upper-layer protocol of the packet. However, each protocol has its own specific set of criteria that can be defined.

For a single access list, you can define multiple criteria in multiple, separate access list statements. Each of these statements should reference the same identifying name or number, to tie the statements to the same access list. You can have as many criteria statements as you want, limited only by the available memory. Of course, the more statements you have, the more difficult it will be to comprehend and manage your access lists.

The Implied “Deny All Traffic” Criteria Statement

At the end of every access list is an implied “deny all traffic” criteria statement. Therefore, if a packet does not match any of your criteria statements, the packet will be blocked.

Note

For most protocols, if you define an inbound access list for traffic filtering, you should include explicit access list criteria statements to permit routing updates. If you do not, you might effectively lose communication from the interface when routing updates are blocked by the implicit “deny all traffic” statement at the end of the access list.

The Order in Which You Enter Criteria Statements

Note that each additional criteria statement that you enter is appended to the end of the access list statements. Also note that you cannot delete individual statements after they have been created. You can only delete an entire access list.
The order of access list statements is important! When the router is deciding whether to forward or block a packet, the Cisco IOS software tests the packet against each criteria statement in the order in which the statements were created. After a match is found, no more criteria statements are checked.

If you create a criteria statement that explicitly permits all traffic, no statements added later will ever be checked. If you need additional statements, you must delete the access list and retype it with the new entries.

Creating and Editing Access List Statements on a TFTP Server

Because the order of access list criteria statements is important, and because you cannot reorder or delete criteria statements on your router, Cisco recommends that you create all access list statements on a TFTP server, and then download the entire access list to your router.

To use a TFTP server, create the access list statements using any text editor, and save the access list in ASCII format to a TFTP server that is accessible by your router. Then, from your router, use the `copy tftp:file_id system:running-config` command to copy the access list to your router. Finally, perform the `copy system:running-config nvram:startup-config` command to save the access list to your router’s NVRAM.

Then, if you ever want to make changes to an access list, you can make them to the text file on the TFTP server, and copy the edited file to your router as before.

Note

The first command of an edited access list file should delete the previous access list (for example, type a `no access-list` command at the beginning of the file). If you do not first delete the previous version of the access list, when you copy the edited file to your router you will merely be appending additional criteria statements to the end of the existing access list.

Applying Access Lists to Interfaces

For some protocols, you can apply up to two access lists to an interface: one inbound access list and one outbound access list. With other protocols, you apply only one access list which checks both inbound and outbound packets.

If the access list is inbound, when the router receives a packet, the Cisco IOS software checks the access list’s criteria statements for a match. If the packet is permitted, the software continues to process the packet. If the packet is denied, the software discards the packet.

If the access list is outbound, after receiving and routing a packet to the outbound interface, the software checks the access list’s criteria statements for a match. If the packet is permitted, the software transmits the packet. If the packet is denied, the software discards the packet.

Note

Access lists that are applied to interfaces do not filter traffic that originates from that router.
Finding Complete Configuration and Command Information for Access Lists

The guidelines discussed in this chapter apply in general to all protocols. The specific instructions for creating access lists and applying them to interfaces vary from protocol to protocol, and this specific information is not included in this chapter.

To find complete configuration and command information to configure access lists for a specific protocol, see the corresponding chapters in the Cisco IOS configuration guides and command references. For example, to configure access lists for the IP protocol, refer to the “Configuring IP Services” chapter in the Cisco IOS IP Configuration Guide.

For information on dynamic access lists, see the chapter “Configuring Lock-and-Key Security (Dynamic Access Lists)” later in this book.

For information on reflexive access lists, see the chapter “Configuring IP Session Filtering (Reflexive Access Lists)” later in this book.

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

Cisco IOS Firewall Overview

This chapter describes how you can configure your Cisco networking device to function as a firewall, using Cisco IOS Firewall security features.

This chapter has the following sections:

- About Firewalls
- The Cisco IOS Firewall Solution
- Creating a Customized Firewall
- Other Guidelines for Configuring Your Firewall

About Firewalls

Firewalls are networking devices that control access to your organization’s network assets. Firewalls are positioned at the entrance points into your network. If your network has multiple entrance points, you must position a firewall at each point to provide effective network access control.

Firewalls are often placed in between the internal network and an external network such as the Internet. With a firewall between your network and the Internet, all traffic coming from the Internet must pass through the firewall before entering your network.

Firewalls can also be used to control access to a specific part of your network. For example, you can position firewalls at all the entry points into a research and development network to prevent unauthorized access to proprietary information.

The most basic function of a firewall is to monitor and filter traffic. Firewalls can be simple or elaborate, depending on your network requirements. Simple firewalls are usually easier to configure and manage. However, you might require the flexibility of a more elaborate firewall.

The Cisco IOS Firewall Solution

Cisco IOS software provides an extensive set of security features, allowing you to configure a simple or elaborate firewall, according to your particular requirements. You can configure a Cisco device as a firewall if the device is positioned appropriately at a network entry point. Security features that provide firewall functionality are listed in the “Creating a Customized Firewall” section.
In addition to the security features available in standard Cisco IOS feature sets, Cisco IOS Firewall gives your router additional firewall capabilities.

The Cisco IOS Firewall Feature Set

The Cisco IOS Firewall feature set combines existing Cisco IOS firewall technology and Context-based Access Control (CBAC). When you configure the Cisco IOS Firewall on your Cisco router, you turn your router into an effective, robust firewall.

The Cisco IOS Firewall features are designed to prevent unauthorized external individuals from gaining access to your internal network and to block attacks on your network, while at the same time allowing authorized users to access network resources.

You can use the Cisco IOS Firewall features to configure your Cisco IOS router as one of the following:

- An Internet firewall or part of an Internet firewall
- A firewall between groups in your internal network
- A firewall providing secure connections to or from branch offices
- A firewall between your company’s network and your company’s partners’ networks

The Cisco IOS Firewall features provide the following benefits:

- Protection of internal networks from intrusion
- Monitoring of traffic through network perimeters
- Enabling of network commerce via the World Wide Web

Creating a Customized Firewall

To create a firewall customized to fit your organization’s security policy, you should determine which Cisco IOS Firewall features are appropriate, and configure those features. At a minimum, you must configure basic traffic filtering to provide a basic firewall. You can configure your Cisco networking device to function as a firewall by using the following Cisco IOS Firewall features:

- Standard Access Lists and Static Extended Access Lists
- Reflexive Access Lists
- Lock-and-Key (Dynamic Access Lists)
- TCP Intercept
- Context-based Access Control
- Intrusion Prevention System (IPS) (formerly known as Cisco IOS Firewall Intrusion Detection System)
- Authentication Proxy
- Port to Application Mapping
- Security Server Support
- Network Address Translation
- IPSec Network Security
- Neighbor Router Authentication
In addition to configuring these features, you should follow the guidelines listed in the “Other Guidelines for Configuring Your Firewall” section. This section outlines important security practices to protect your firewall and network. Table 23 describes Cisco IOS security features.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Chapter</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard Access Lists and Static Extended Access Lists</td>
<td>“Access Control Lists: Overview and Guidelines”</td>
<td>Standard and static extended access lists provide basic traffic filtering capabilities. You configure criteria that describe which packets should be forwarded, and which packets should be dropped at an interface, based on each packet’s network layer information. For example, you can block all UDP packets from a specific source IP address or address range. Some extended access lists can also examine transport layer information to determine whether to block or forward packets. To configure a basic firewall, you should at a minimum configure basic traffic filtering. You should configure basic access lists for all network protocols that will be routed through your firewall, such as IP, IPX, AppleTalk, and so forth.</td>
</tr>
<tr>
<td>Lock-and-Key (Dynamic Access Lists)</td>
<td>“Configuring Lock-and-Key Security (Dynamic Access Lists)”</td>
<td>Lock-and-Key provides traffic filtering with the ability to allow temporary access through the firewall for certain individuals. These individuals must first be authenticated (by a username/password mechanism) before the firewall allows their traffic through the firewall. Afterwards, the firewall closes the temporary opening. This provides tighter control over traffic at the firewall than with standard or static extended access lists.</td>
</tr>
<tr>
<td>Reflexive Access Lists</td>
<td>“Configuring IP Session Filtering (Reflexive Access Lists)”</td>
<td>Reflexive access lists filter IP traffic so that TCP or UDP “session” traffic is only permitted through the firewall if the session originated from within the internal network. You would only configure Reflexive Access Lists when not using Context-based Access Control.</td>
</tr>
<tr>
<td>TCP Intercept</td>
<td>“Configuring TCP Intercept (Preventing Denial-of-Service Attacks)”</td>
<td>TCP Intercept protects TCP servers within your network from TCP SYN-flooding attacks, a type of denial-of-service attack. You would only configure TCP Intercept when not using Context-based Access Control.</td>
</tr>
</tbody>
</table>
Table 23  Cisco IOS Features for a Robust Firewall (continued)

<table>
<thead>
<tr>
<th>Feature</th>
<th>Chapter</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Context-based Access Control</td>
<td>“Configuring Context-Based Access Control”</td>
<td>CBAC examines not only network layer and transport layer information, but also examines the application-layer protocol information (such as FTP information) to learn about the state of TCP and UDP connections. CBAC maintains connection state information for individual connections. This state information is used to make intelligent decisions about whether packets should be permitted or denied, and dynamically creates and deletes temporary openings in the firewall. CBAC also generates real-time alerts and audit trails. Enhanced audit trail features use SYSLOG to track all network transactions. Real-time alerts send SYSLOG error messages to central management consoles upon detecting suspicious activity. Using CBAC inspection rules, you can configure alerts and audit trail information on a per-application protocol basis. CBAC is only available in the Cisco IOS Firewall feature set.</td>
</tr>
</tbody>
</table>
| Cisco IOS Intrusion Prevention System (IPS)  | “Configuring Cisco IOS Intrusion Prevention System (IPS)” | The Cisco IOS IPS acts as an in-line intrusion detection sensor, “watching” packets and sessions as they flow through the router and scanning each packet to match any of the Cisco IOS IPS signatures. When Cisco IOS IPS detects suspicious activity, it responds before network security can be compromised and logs the event through Cisco IOS syslog messages or Security Device Event Exchange (SDEE). The network administrator can configure Cisco IOS IPS to choose the appropriate response to various threats. When packets in a session match a signature, Cisco IOS IPS can take any of the following actions, as appropriate:  
  - Send an alarm to a syslog server or a centralized management interface  
  - Drop the packet  
  - Reset the connection  
  - Deny traffic from the source IP address of the attacker for a specified amount of time  
  - Deny traffic on the connection for which the signature was seen for a specified amount of time |
| Authentication Proxy                         | “Configuring Authentication Proxy”                    | The Cisco IOS Firewall authentication proxy feature allows network administrators to apply specific security policies on a per-user basis. Previously, user identity and related authorized access was associated with a user’s IP address, or a single security policy had to be applied to an entire user group or sub network. Now, users can be identified and authorized on the basis of their per-user policy, and access privileges tailored on an individual basis are possible, as opposed to general policy applied across multiple users. |
### Table 23  Cisco IOS Features for a Robust Firewall (continued)

<table>
<thead>
<tr>
<th>Feature</th>
<th>Chapter</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port to Application Mapping</td>
<td>“Configuring Port to Application Mapping”</td>
<td>Port to Application Mapping (PAM) is a feature of Cisco IOS Firewall. PAM allows you to customize TCP or UDP port numbers for network services or applications. PAM uses this information to support network environments that run services using ports that are different from the registered or well-known ports associated with an application. The information in the PAM table enables CBAC supported services to run on nonstandard ports.</td>
</tr>
</tbody>
</table>
| Security Server Support         | “Configuring TACACS+,” “Configuring RADIUS,” and “Configuring Kerberos” | The Cisco IOS Firewall feature set can be configured as a client of the following supported security servers:  
  - TACACS+ (including CiscoSecure)  
  - RADIUS  
  - Kerberos  
  You can use any of these security servers to store a database of user profiles. To gain access into your firewall or to gain access through the firewall into another network, users must enter authentication information (such as a username and password), which is matched against the information on the security server. When users pass authentication, they are granted access according to their specified privileges. |
| Network Address Translation     | “Configuring NAT for IP Address Conservation” | You can use Network Address Translation (NAT) to hide internal IP network addresses from the world outside the firewall.  
  NAT was designed to provide IP address conservation and for internal IP networks that have unregistered (not globally unique) IP addresses: NAT translates these unregistered IP addresses into legal addresses at the firewall. NAT can also be configured to advertise only one address for the entire internal network to the outside world. This provides security by effectively hiding the entire internal network from the world.  
  NAT gives you limited spoof protection because internal addresses are hidden. Additionally, NAT removes all your internal services from the external name space.  
  NAT does not work with the application-layer protocols RPC, VDOLive, or SQL*Net “Redirected.” (NAT does work with SQL*Net “Bequeathed.”) Do not configure NAT with networks that will carry traffic for these incompatible protocols. |
Other Guidelines for Configuring Your Firewall

As with all networking devices, you should always protect access into the firewall by configuring passwords as described in the module “Configuring Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices.” You should also consider configuring user authentication, authorization, and accounting as described in the chapters in the “Authentication, Authorization, and Accounting (AAA)” part of this guide.

You should also consider the following recommendations:

- When setting passwords for privileged access to the firewall, use the **enable secret** command rather than the **enable password** command, which does not have as strong an encryption algorithm.
- Put a password on the console port. In authentication, authorization, and accounting (AAA) environments, use the same authentication for the console as for elsewhere. In a non-AAA environment, at a minimum configure the **login** and **password** commands.
- Think about access control before you connect a console port to the network in any way, including attaching a modem to the port. Be aware that a **break** on the console port might give total control of the firewall, even with access control configured.
- Apply access lists and password protection to all virtual terminal ports. Use access lists to limit who can Telnet into your router.

### Table 23  Cisco IOS Features for a Robust Firewall (continued)

<table>
<thead>
<tr>
<th>Feature</th>
<th>Chapter</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPSec Network Security</td>
<td>“Configuring Security for VPNs with IPSec”</td>
<td>IPSec is a framework of open standards developed by the Internet Engineering Task Force (IETF) that provides security for transmission of sensitive information over unprotected networks such as the Internet. IPSec acts at the network layer, protecting and authenticating IP packets between participating IPSec devices (“peers”) such as Cisco routers.</td>
</tr>
<tr>
<td>Neighbor Router</td>
<td>“Neighbor Router Authentication: Overview and Guidelines”</td>
<td>Neighbor router authentication requires the firewall to authenticate all neighbor routers before accepting any route updates from that neighbor. This ensures that the firewall receives legitimate route updates from a trusted source.</td>
</tr>
<tr>
<td>Authentication</td>
<td>“System Monitoring and Logging” chapter in the Cisco IOS Network Management Configuration Guide</td>
<td>Event logging automatically logs output from system error messages and other events to the console terminal. You can also redirect these messages to other destinations such as virtual terminals, internal buffers, or syslog servers. You can also specify the severity of the event to be logged, and you can configure the logged output to be timestamped. The logged output can be used to assist real-time debugging and management, and to track potential security breaches or other nonstandard activities throughout a network.</td>
</tr>
<tr>
<td>User Authentication and Authorization</td>
<td>“Configuring Authentication” and “Configuring Authorization”</td>
<td>Authentication and authorization help protect your network from access by unauthorized users.</td>
</tr>
</tbody>
</table>
- Do not enable any local service (such as SNMP or NTP) that you do not use. Cisco Discovery Protocol (CDP) and Network Time Protocol (NTP) are on by default, and you should turn these off if you do not need them.

  To turn off CDP, enter the `no cdp run` global configuration command. To turn off NTP, enter the `ntp disable` interface configuration command on each interface not using NTP.

  If you must run NTP, configure NTP only on required interfaces, and configure NTP to listen only to certain peers.

  Any enabled service could present a potential security risk. A determined, hostile party might be able to find creative ways to misuse the enabled services to access the firewall or the network.

  For local services that are enabled, protect against misuse. Protect by configuring the services to communicate only with specific peers, and protect by configuring access lists to deny packets for the services at specific interfaces.

- Protect against spoofing: protect the networks on both sides of the firewall from being spoofed from the other side. You could protect against spoofing by configuring input access lists at all interfaces to pass only traffic from expected source addresses, and to deny all other traffic.

  You should also disable source routing. For IP, enter the `no ip source-route` global configuration command. Disabling source routing at all routers can also help prevent spoofing.

  You should also disable minor services. For IP, enter the `no service tcp-small-servers` and `no service udp-small-servers` global configuration commands.

- Prevent the firewall from being used as a relay by configuring access lists on any asynchronous Telnet ports.

- Normally, you should disable directed broadcasts for all applicable protocols on your firewall and on all your other routers. For IP, use the `no ip directed-broadcast` command. Rarely, some IP networks do require directed broadcasts; if this is the case, do not disable directed broadcasts.

  Directed broadcasts can be misused to multiply the power of denial-of-service attacks, because every denial-of-service packet sent is broadcast to every host on a subnet. Furthermore, some hosts have other intrinsic security risks present when handling broadcasts.

- Configure the `no ip proxy-arp` command to prevent internal addresses from being revealed. (This is important to do if you do not already have NAT configured to prevent internal addresses from being revealed.)

- Keep the firewall in a secured (locked) room.

This chapter describes how to configure lock-and-key security at your router. Lock-and-key is a traffic filtering security feature available for the IP protocol.

For a complete description of lock-and-key commands, refer to the “Lock-and-Key Commands” chapter of the Cisco IOS Security Command Reference. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter “Identifying Supported Platforms” section in the “Using Cisco IOS Software.”

In This Chapter

This chapter has the following sections:

- About Lock-and-Key
- Compatibility with Releases Before Cisco IOS Release 11.1
- Risk of Spoofing with Lock-and-Key
- Router Performance Impacts with Lock-and-Key
- Prerequisites to Configuring Lock-and-Key
- Configuring Lock-and-Key
About Lock-and-Key

Lock-and-key is a traffic filtering security feature that dynamically filters IP protocol traffic. Lock-and-key is configured using IP dynamic extended access lists. Lock-and-key can be used in conjunction with other standard access lists and static extended access lists.

When lock-and-key is configured, designated users whose IP traffic is normally blocked at a router can gain temporary access through the router. When triggered, lock-and-key reconfigures the interface’s existing IP access list to permit designated users to reach their designated host(s). Afterwards, lock-and-key reconfigures the interface back to its original state.

For a user to gain access to a host through a router with lock-and-key configured, the user must first open a Telnet session to the router. When a user initiates a standard Telnet session to the router, lock-and-key automatically attempts to authenticate the user. If the user is authenticated, they will then gain temporary access through the router and be able to reach their destination host.

This section has the following sections:

- Benefits of Lock-and-Key
- When to Use Lock-and-Key
- How Lock-and-Key Works

Benefits of Lock-and-Key

Lock-and-key provides the same benefits as standard and static extended access lists (these benefits are discussed in the chapter “Access Control Lists: Overview and Guidelines”). However, lock-and-key also has the following security benefits over standard and static extended access lists:

- Lock-and-key uses a challenge mechanism to authenticate individual users.
- Lock-and-key provides simpler management in large internetworks.
- In many cases, lock-and-key reduces the amount of router processing required for access lists.
- Lock-and-key reduces the opportunity for network break-ins by network hackers.

With lock-and-key, you can specify which users are permitted access to which source and destination hosts. These users must pass a user authentication process before they are permitted access to their designated hosts. Lock-and-key creates dynamic user access through a firewall, without compromising other configured security restrictions.

When to Use Lock-and-Key

Two examples of when you might use lock-and-key follow:

- When you want a specific remote user (or group of remote users) to be able to access a host within your network, connecting from their remote hosts via the Internet. Lock-and-key authenticates the user, then permits limited access through your firewall router for the individual’s host or subnet, for a finite period of time.
When you want a subset of hosts on a local network to access a host on a remote network protected by a firewall. With lock-and-key, you can enable access to the remote host only for the desired set of local user’s hosts. Lock-and-key require the users to authenticate through a TACACS+ server, or other security server, before allowing their hosts to access the remote hosts.

**How Lock-and-Key Works**

The following process describes the lock-and-key access operation:

1. A user opens a Telnet session to a border (firewall) router configured for lock-and-key. The user connects via the virtual terminal port on the router.

2. The Cisco IOS software receives the Telnet packet, opens a Telnet session, prompts for a password, and performs a user authentication process. The user must pass authentication before access through the router is allowed. The authentication process can be done by the router or by a central access security server such as a TACACS+ or RADIUS server.

3. When the user passes authentication, they are logged out of the Telnet session, and the software creates a temporary entry in the dynamic access list. (Per your configuration, this temporary entry can limit the range of networks to which the user is given temporary access.)

4. The user exchanges data through the firewall.

5. The software deletes the temporary access list entry when a configured timeout is reached, or when the system administrator manually clears it. The configured timeout can either be an idle timeout or an absolute timeout.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>The temporary access list entry is not automatically deleted when the user terminates a session. The temporary access list entry remains until a configured timeout is reached or until it is cleared by the system administrator.</td>
</tr>
</tbody>
</table>

**Compatibility with Releases Before Cisco IOS Release 11.1**

Enhancements to the `access-list` command are used for lock-and-key. These enhancements are backward compatible—if you migrate from a release before Cisco IOS Release 11.1 to a newer release, your access lists will be automatically converted to reflect the enhancements. However, if you try to use lock-and-key with a release before Cisco IOS Release 11.1, you might encounter problems as described in the following caution paragraph:

<table>
<thead>
<tr>
<th>Caution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cisco IOS releases before Release 11.1 are not upwardly compatible with the lock-and-key access list enhancements. Therefore, if you save an access list with software older than Release 11.1, and then use this software, the resulting access list will not be interpreted correctly. This could cause you severe security problems. You must save your old configuration files with Cisco IOS Release 11.1 or later software before booting an image with these files.</td>
</tr>
</tbody>
</table>
Risk of Spoofing with Lock-and-Key

Caution

Lock-and-key access allows an external event (a Telnet session) to place an opening in the firewall. While this opening exists, the router is susceptible to source address spoofing.

When lock-and-key is triggered, it creates a dynamic opening in the firewall by temporarily reconfiguring an interface to allow user access. While this opening exists, another host might spoof the authenticated user’s address to gain access behind the firewall. Lock-and-key does not cause the address spoofing problem; the problem is only identified here as a concern to the user. Spoofing is a problem inherent to all access lists, and lock-and-key does not specifically address this problem.

To prevent spoofing, configure encryption so that traffic from the remote host is encrypted at a secured remote router, and decrypted locally at the router interface providing lock-and-key. You want to ensure that all traffic using lock-and-key will be encrypted when entering the router; this way no hackers can spoof the source address, because they will be unable to duplicate the encryption or to be authenticated as is a required part of the encryption setup process.

Router Performance Impacts with Lock-and-Key

When lock-and-key is configured, router performance can be affected in the following ways:

- When lock-and-key is triggered, the dynamic access list forces an access list rebuild on the silicon switching engine (SSE). This causes the SSE switching path to slow down momentarily.
- Dynamic access lists require the idle timeout facility (even if the timeout is left to default) and therefore cannot be SSE switched. These entries must be handled in the protocol fast-switching path.
- When remote users trigger lock-and-key at a border router, additional access list entries are created on the border router interface. The interface’s access list will grow and shrink dynamically. Entries are dynamically removed from the list after either the idle-timeout or max-timeout period expires. Large access lists can degrade packet switching performance, so if you notice performance problems, you should look at the border router configuration to see if you should remove temporary access list entries generated by lock-and-key.

Prerequisites to Configuring Lock-and-Key

Lock-and-key uses IP extended access lists. You must have a solid understanding of how access lists are used to filter traffic, before you attempt to configure lock-and-key. Access lists are described in the chapter “Access Control Lists: Overview and Guidelines.”

Lock-and-key employs user authentication and authorization as implemented in Cisco’s authentication, authorization, and accounting (AAA) paradigm. You must understand how to configure AAA user authentication and authorization before you configure lock-and-key. User authentication and authorization is explained in the “Authentication, Authorization, and Accounting (AAA)” part of this document.

Lock-and-key uses the autocommand command, which you should understand. This command is described in the “Modem Support and Asynchronous Device Commands” chapter of the Cisco IOS Dial Technologies Command Reference.
## Configuring Lock-and-Key

To configure lock-and-key, use the following commands beginning in global configuration mode. While completing these steps, be sure to follow the guidelines listed in the “Lock-and-Key Configuration Guidelines” section of this chapter.

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>`Router(config)# access-list access-list-number [dynamic dynamic-name [timeout minutes]] {deny</td>
<td>permit} telnet source source-wildcard destination destination-wildcard [precedence precedence] [tos tos] [established] [log]`</td>
</tr>
<tr>
<td>2</td>
<td><code>Router(config)# access-list dynamic-extend</code></td>
<td>(Optional) Extends the absolute timer of the dynamic ACL by six minutes when you open another Telnet session into the router to re-authenticate yourself using lock-and-key. Use this command if your job will run past the ACL’s absolute timer.</td>
</tr>
<tr>
<td>3</td>
<td><code>Router(config)# interface type number</code></td>
<td>Configures an interface and enters interface configuration mode.</td>
</tr>
<tr>
<td>4</td>
<td><code>Router(config-if)# ip access-group access-list-number</code></td>
<td>Applies the access list to the interface.</td>
</tr>
<tr>
<td>5</td>
<td><code>Router(config-if)# exit</code></td>
<td>Exits interface configuration mode and enters global configuration mode.</td>
</tr>
<tr>
<td>6</td>
<td><code>Router(config)# line vty line-number [ending-line-number]</code></td>
<td>Defines one or more virtual terminal (VTY) ports and enters line configuration mode. If you specify multiple VTY ports, they must all be configured identically because the software hunts for available VTY ports on a round-robin basis. If you do not want to configure all your VTY ports for lock-and-key access, you can specify a group of VTY ports for lock-and-key support only.</td>
</tr>
<tr>
<td>7</td>
<td><code>Router(config-line)# login tacacs</code> or <code>Router(config-line)# password password</code> or <code>Router(config-line)# login local</code> or <code>Router(config-line)# exit then</code> <code>Router(config)# username name password secret</code></td>
<td>Configures user authentication in line or global configuration mode.</td>
</tr>
<tr>
<td>8</td>
<td><code>Router(config-line)# autocommand access-enable [host] [timeout minutes]</code> or <code>Router(config)# autocommand access-enable [host] [timeout minutes]</code></td>
<td>Enables the creation of temporary access list entries in line or global configuration mode. If the optional <code>host</code> keyword is not specified, all hosts on the entire network are allowed to set up a temporary access list entry. The dynamic access list contains the network mask to enable the new network connection.</td>
</tr>
</tbody>
</table>

For an example of a lock-and-key configuration, see the section “Lock-and-Key Configuration Examples” later in this chapter.
Lock-and-Key Configuration Guidelines

Before you configure lock-and-key, you should understand the guidelines discussed in the following sections:

- **Dynamic Access Lists**
- **Lock-and-Key Authentication**
- **The autocommand Command**

### Dynamic Access Lists

Use the following guidelines for configuring dynamic access lists:

- **Do not** create more than one dynamic access list for any one access list. The software only refers to the first dynamic access list defined.
- **Do not** assign the same `dynamic-name` to another access list. Doing so instructs the software to reuse the existing list. All named entries must be globally unique within the configuration.
- Assign attributes to the dynamic access list in the same way you assign attributes for a static access list. The temporary access list entries inherit the attributes assigned to this list.
- Configure Telnet as the protocol so that users must open a Telnet session into the router to be authenticated before they can gain access through the router.
- Either define an idle timeout now with the `timeout` keyword in the `access-enable` command in the `autocommand` command, or define an absolute timeout value later with the `access-list` command. You must define either an idle timeout or an absolute timeout—otherwise, the temporary access list entry will remain configured indefinitely on the interface (even after the user has terminated their session) until the entry is removed manually by an administrator. (You could configure both idle and absolute timeouts if you wish.)
- If you configure an idle timeout, the idle timeout value should be equal to the WAN idle timeout value.
- If you configure both idle and absolute timeouts, the idle timeout value must be less than the absolute timeout value.
- If you realize that a job will run past the ACL’s absolute timer, use the `access-list dynamic-extend` command to extend the absolute timer of the dynamic ACL by six minutes. This command allows you to open a new Telnet session into the router to re-authentication yourself using lock-and-key.
- The only values replaced in the temporary entry are the source or destination address, depending whether the access list was in the input access list or output access list. All other attributes, such as port, are inherited from the main dynamic access list.
- Each addition to the dynamic list is always put at the beginning of the dynamic list. You cannot specify the order of temporary access list entries.
- Temporary access list entries are never written to NVRAM.
- To manually clear or to display dynamic access lists, refer to the section “Maintaining Lock-and-Key” later in this chapter.

### Lock-and-Key Authentication

There are three possible methods to configure an authentication query process. These three methods are described in this section.
Cisco recommends that you use the TACACS+ server for your authentication query process. TACACS+ provides authentication, authorization, and accounting services. It also provides protocol support, protocol specification, and a centralized security database. Using a TACACS+ server is described in the next section, “Method 1—Configuring a Security Server.”

**Method 1—Configuring a Security Server**

Use a network access security server such as TACACS+ server. This method requires additional configuration steps on the TACACS+ server but allows for stricter authentication queries and more sophisticated tracking capabilities.

Router(config-line)# login tacacs

**Method 2—Configuring the username Command**

Use the **username** command. This method is more effective because authentication is determined on a user basis.

Router(config)# username name {nopassword | password {mutual-password | encryption-type encryption-password}}

**Method 3—Configuring the password and login Commands**

Use the **password** and **login** commands. This method is less effective because the password is configured for the port, not for the user. Therefore, any user who knows the password can authenticate successfully.

Router(config-line)# password password
Router(config-line)# login local

**The autocommand Command**

Use the following guidelines for configuring the **autocommand** command:

- If you use a TACACS+ server to authenticate the user, you should configure the **autocommand** command on the TACACS+ server as a per-user autocommand. If you use local authentication, use the **autocommand** command on the line.

- Configure all virtual terminal (VTY) ports with the same **autocommand** command. Omitting an **autocommand** command on a VTY port allows a random host to gain EXEC mode access to the router and does not create a temporary access list entry in the dynamic access list.

- If you did not previously define an idle timeout with the **autocommand access-enable** command, you must define an absolute timeout now with the **access-list** command. You must define either an idle timeout or an absolute timeout—otherwise, the temporary access list entry will remain configured indefinitely on the interface (even after the user has terminated their session) until the entry is removed manually by an administrator. (You could configure both idle and absolute timeouts if you wish.)

- If you configure both idle and absolute timeouts, the absolute timeout value must be greater than the idle timeout value.
Verifying Lock-and-Key Configuration

You can verify that lock-and-key is successfully configured on the router by asking a user to test the connection. The user should be at a host that is permitted in the dynamic access list, and the user should have AAA authentication and authorization configured.

To test the connection, the user should Telnet to the router, allow the Telnet session to close, and then attempt to access a host on the other side of the router. This host must be one that is permitted by the dynamic access list. The user should access the host with an application that uses the IP protocol.

The following sample display illustrates what end-users might see if they are successfully authenticated. Notice that the Telnet connection is closed immediately after the password is entered and authenticated. The temporary access list entry is then created, and the host that initiated the Telnet session now has access inside the firewall.

Router% telnet corporate
Trying 172.21.52.1 ...
Connected to corporate.example.com.
Escape character is '^]'.
User Access Verification
Password: Connection closed by foreign host.

You can then use the `show access-lists` command at the router to view the dynamic access lists, which should include an additional entry permitting the user access through the router.

Maintaining Lock-and-Key

When lock-and-key is in use, dynamic access lists will dynamically grow and shrink as entries are added and deleted. You need to make sure that entries are being deleted in a timely way, because while entries exist, the risk of a spoofing attack is present. Also, the more entries there are, the bigger the router performance impact will be.

If you do not have an idle or absolute timeout configured, entries will remain in the dynamic access list until you manually remove them. If this is the case, make sure that you are extremely vigilant about removing entries.

Displaying Dynamic Access List Entries

You can display temporary access list entries when they are in use. After a temporary access list entry is cleared by you or by the absolute or idle timeout parameter, it can no longer be displayed. The number of matches displayed indicates the number of times the access list entry was hit.

To view dynamic access lists and any temporary access list entries that are currently established, use the following command in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router# show access-lists</code></td>
<td>Displays dynamic access lists and temporary access list entries.</td>
</tr>
</tbody>
</table>

Manually Deleting Dynamic Access List Entries

To manually delete a temporary access list entry, use the following command in privileged EXEC mode:
Lock-and-Key Configuration Examples

The following sections provide lock-and-key configuration examples:

- Lock-and-Key with Local Authentication Example
- Lock-and-Key with TACACS+ Authentication Example

Cisco recommends that you use a TACACS+ server for authentication, as shown in the second example.

Lock-and-Key with Local Authentication Example

This example shows how to configure lock-and-key access, with authentication occurring locally at the router. Lock-and-key is configured on the Ethernet 0 interface.

```
interface ethernet0
  ip address 172.18.23.9 255.255.255.0
  ip access-group 101 in

access-list 101 permit tcp any host 172.18.21.2 eq telnet
access-list 101 dynamic mytestlist timeout 120 permit ip any any

line vty 0
  login local
  autocommand access-enable timeout 5
```

The first access-list entry allows only Telnet into the router. The second access-list entry is always ignored until lock-and-key is triggered.

In the `access-list` command, the timeout is the absolute timeout. In this example, the lifetime of the mytestlist ACL is 120 minutes; that is, when a user logs in and enable the `access-enable` command, a dynamic ACL is created for 120 minutes (the maximum absolute time). The session is closed after 120 minutes, whether or not anyone is using it.

In the `autocommand` command, the timeout is the idle timeout. In this example, each time the user logs in or authenticates there is a 5-minute session. If there is no activity, the session closes in 5 minutes and the user has to reauthenticate. If the user uses the connection, the absolute time takes affect and the session closes in 120 minutes.

After a user opens a Telnet session into the router, the router will attempt to authenticate the user. If authentication is successful, the `autocommand` executes and the Telnet session terminates. The `autocommand` creates a temporary inbound access list entry at the Ethernet 0 interface, based on the second access-list entry (mytestlist). This temporary entry will expire after 5 minutes, as specified by the timeout.
Lock-and-Key with TACACS+ Authentication Example

The following example shows how to configure lock-and-key access, with authentication on a TACACS+ server. Lock-and-key access is configured on the BRI0 interface. Four VTY ports are defined with the password “cisco”.

Configuring IP Session Filtering (Reflexive Access Lists)

This chapter describes how to configure reflexive access lists on your router. Reflexive access lists provide the ability to filter network traffic at a router, based on IP upper-layer protocol “session” information.

For a complete description of reflexive access list commands, refer to the “Reflexive Access List Commands” chapter of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter “Identifying Supported Platforms” section in the “Using Cisco IOS Software.”

**In This Chapter**

This chapter has the following sections:

- About Reflexive Access Lists
- Prework: Before You Configure Reflexive Access Lists
- Reflexive Access Lists Configuration Task List
- Reflexive Access List Configuration Examples

**About Reflexive Access Lists**

Reflexive access lists allow IP packets to be filtered based on upper-layer session information. You can use reflexive access lists to permit IP traffic for sessions originating from within your network but to deny IP traffic for sessions originating from outside your network. This is accomplished by reflexive filtering, a kind of session filtering.

Reflexive access lists can be defined with extended named IP access lists only. You cannot define reflexive access lists with numbered or standard named IP access lists or with other protocol access lists.
You can use reflexive access lists in conjunction with other standard access lists and static extended access lists.

This section has the following sections:

- Benefits of Reflexive Access Lists
- What Is a Reflexive Access List?
- How Reflexive Access Lists Implement Session Filtering
- Where to Configure Reflexive Access Lists
- How Reflexive Access Lists Work
- Restrictions on Using Reflexive Access Lists

**Benefits of Reflexive Access Lists**

Reflexive access lists are an important part of securing your network against network hackers, and can be included in a firewall defense. Reflexive access lists provide a level of security against spoofing and certain denial-of-service attacks. Reflexive access lists are simple to use, and, compared to basic access lists, provide greater control over which packets enter your network.

**What Is a Reflexive Access List?**

Reflexive access lists are similar in many ways to other access lists. Reflexive access lists contain condition statements (entries) that define criteria for permitting IP packets. These entries are evaluated in order, and when a match occurs, no more entries are evaluated.

However, reflexive access lists have significant differences from other types of access lists. Reflexive access lists contain only temporary entries; these entries are automatically created when a new IP session begins (for example, with an outbound packet), and the entries are removed when the session ends. Reflexive access lists are not themselves applied directly to an interface, but are “nested” within an extended named IP access list that is applied to the interface. (For more information about this, see the section “Reflexive Access Lists Configuration Task List” later in this chapter.) Also, reflexive access lists do not have the usual implicit “deny all traffic” statement at the end of the list, because of the nesting.

**How Reflexive Access Lists Implement Session Filtering**

This section compares session filtering with basic access lists to session filtering with reflexive access lists. This section contains the following sections:

- With Basic Access Lists
- With Reflexive Access Lists
With Basic Access Lists

With basic standard and static extended access lists, you can approximate session filtering by using the `established` keyword with the `permit` command. The `established` keyword filters TCP packets based on whether the ACK or RST bits are set. (Set ACK or RST bits indicate that the packet is not the first in the session, and therefore, that the packet belongs to an established session.) This filter criterion would be part of an access list applied permanently to an interface.

With Reflexive Access Lists

Reflexive access lists, however, provide a truer form of session filtering, which is much harder to spoof because more filter criteria must be matched before a packet is permitted through. (For example, source and destination addresses and port numbers are checked, not just ACK and RST bits.) Also, session filtering uses temporary filters which are removed when a session is over. This limits the hacker’s attack opportunity to a smaller time window.

Moreover, the previous method of using the `established` keyword was available only for the TCP upper-layer protocol. So, for the other upper-layer protocols (such as UDP, ICMP, and so forth), you would have to either permit all incoming traffic or define all possible permissible source/destination host/port address pairs for each protocol. (Besides being an unmanageable task, this could exhaust NVRAM space.)

Where to Configure Reflexive Access Lists

Configure reflexive access lists on border routers—routers that pass traffic between an internal and external network. Often, these are firewall routers.

In this chapter, the words “within your network” and “internal network” refer to a network that is controlled (secured), such as your organization’s intranet, or to a part of your organization’s internal network that has higher security requirements than another part. “Outside your network” and “external network” refer to a network that is uncontrolled (unsecured) such as the Internet or to a part of your organization’s network that is not as highly secured.

How Reflexive Access Lists Work

A reflexive access list is triggered when a new IP upper-layer session (such as TCP or UDP) is initiated from inside your network, with a packet traveling to the external network. When triggered, the reflexive access list generates a new, temporary entry. This entry will permit traffic to enter your network if the traffic is part of the session, but will not permit traffic to enter your network if the traffic is not part of the session.

For example, if an outbound TCP packet is forwarded to outside of your network, and this packet is the first packet of a TCP session, then a new, temporary reflexive access list entry will be created. This entry is added to the reflexive access list, which applies to inbound traffic. The temporary entry has characteristics as described next.

This section contains the following sections:

- Temporary Access List Entry Characteristics
- When the Session Ends
Temporary Access List Entry Characteristics

- The entry is always a *permit* entry.
- The entry specifies the same protocol (TCP) as the original outbound TCP packet.
- The entry specifies the same source and destination addresses as the original outbound TCP packet, except the addresses are swapped.
- The entry specifies the same source and destination port numbers as the original outbound TCP packet, except the port numbers are swapped.
  
  (This entry characteristic applies only for TCP and UDP packets. Other protocols, such as ICMP and IGMP, do not have port numbers, and other criteria are specified. For example, for ICMP, type numbers are used instead.)
- Inbound TCP traffic will be evaluated against the entry, until the entry expires. If an inbound TCP packet matches the entry, the inbound packet will be forwarded into your network.
- The entry will expire (be removed) after the last packet of the session passes through the interface.
- If no packets belonging to the session are detected for a configurable length of time (the timeout period), the entry will expire.

When the Session Ends

Temporary reflexive access list entries are removed at the end of the session. For TCP sessions, the entry is removed 5 seconds after two set FIN bits are detected, or immediately after matching a TCP packet with the RST bit set. (Two set FIN bits in a session indicate that the session is about to end; the 5-second window allows the session to close gracefully. A set RST bit indicates an abrupt session close.) Or, the temporary entry is removed after no packets of the session have been detected for a configurable length of time (the timeout period).

For UDP and other protocols, the end of the session is determined differently than for TCP. Because other protocols are considered to be connectionless (sessionless) services, there is no session tracking information embedded in packets. Therefore, the end of a session is considered to be when no packets of the session have been detected for a configurable length of time (the timeout period).

Restrictions on Using Reflexive Access Lists

Reflexive access lists do not work with some applications that use port numbers that change during a session. For example, if the port numbers for a return packet are different from the originating packet, the return packet will be denied, even if the packet is actually part of the same session.

The TCP application of FTP is an example of an application with changing port numbers. With reflexive access lists, if you start an FTP request from within your network, the request will not complete. Instead, you must use Passive FTP when originating requests from within your network.

Prework: Before You Configure Reflexive Access Lists

Before you configure reflexive access lists, you must decide whether to configure reflexive access lists on an internal or external interface, as described in the next section, “Choosing an Interface: Internal or External.”
You should also be sure that you have a basic understanding of the IP protocol and of access lists; specifically, you should know how to configure extended named IP access lists. To learn about configuring IP extended access lists, refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Configuration Guide*.

### Choosing an Interface: Internal or External

Reflexive access lists are most commonly used with one of two basic network topologies. Determining which of these topologies is most like your own can help you decide whether to use reflexive access lists with an internal interface or with an external interface (the interface connecting to an internal network, or the interface connecting to an external network).

The first topology is shown in Figure 18. In this simple topology, reflexive access lists are configured for the *external* interface Serial 1. This prevents IP traffic from entering the router and the internal network, unless the traffic is part of a session already established from within the internal network.

The second topology is shown in Figure 19. In this topology, reflexive access lists are configured for the *internal* interface Ethernet 0. This allows external traffic to access the services in the Demilitarized Zone (DMZ), such as DNS services, but prevents IP traffic from entering your internal network—unless the traffic is part of a session already established from within the internal network.

Use these two example topologies to help you decide whether to configure reflexive access lists for an internal or external interface.
Reflexive Access Lists Configuration Task List

In the previous section, “Prework: Before You Configure Reflexive Access Lists,” you decided whether to configure reflexive access lists for an internal or external interface.

Now, complete the tasks in one of the following configuration task lists:

- External Interface Configuration Task List
- Internal Interface Configuration Task List

For configuration examples, refer to the “Reflexive Access List Configuration Examples” section at the end of this chapter.

External Interface Configuration Task List

To configure reflexive access lists for an external interface, perform the following tasks:

1. Defining the reflexive access list(s) in an **outbound** IP extended named access list
2. Nesting the reflexive access list(s) in an **inbound** IP extended named access list
3. Setting a global timeout value

These tasks are described in the sections following the “Internal Interface Configuration Task List” section.

**Note**

The defined (outbound) reflexive access list evaluates traffic traveling out of your network: if the defined reflexive access list is matched, temporary entries are created in the nested (inbound) reflexive access list. These temporary entries will then be applied to traffic traveling into your network.

Internal Interface Configuration Task List

To configure reflexive access lists for an internal interface, perform the following tasks:

1. Defining the reflexive access list(s) in an **inbound** IP extended named access list
2. Nesting the reflexive access list(s) in an **outbound** IP extended named access list
3. Setting a global timeout value

These tasks are described in the next sections.

**Note**

The defined (inbound) reflexive access list is used to evaluate traffic traveling out of your network: if the defined reflexive access list is matched, temporary entries are created in the nested (outbound) reflexive access list. These temporary entries will then be applied to traffic traveling into your network.

Defining the Reflexive Access List(s)

To define a reflexive access list, you use an entry in an extended named IP access list. This entry must use the `reflect` keyword.

- If you are configuring reflexive access lists for an external interface, the extended named IP access list should be one that is applied to outbound traffic.
If you are configuring reflexive access lists for an internal interface, the extended named IP access list should be one that is applied to inbound traffic.

To define reflexive access lists, use the following commands, beginning in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Router(config)# ip access-list extended name</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Router(config-ext-nacl)# permit protocol any any reflect name [timeout seconds]</td>
</tr>
</tbody>
</table>

If the extended named IP access list you just specified has never been applied to the interface, you must also apply the extended named IP access list to the interface.

To apply the extended named IP access list to the interface, use the following command in interface configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config-if)# ip access-group name out</td>
<td>External interface: Applies the extended access list to the interface’s outbound traffic.</td>
</tr>
<tr>
<td>or</td>
<td>Internal interface: Applies the extended access list to the interface’s inbound traffic.</td>
</tr>
<tr>
<td>Router(config-if)# ip access-group name in</td>
<td></td>
</tr>
</tbody>
</table>

**Mixing Reflexive Access List Statements with Other Permit and Deny Entries**

The extended IP access list that contains the reflexive access list permit statement can also contain other normal permit and deny statements (entries). However, as with all access lists, the order of entries is important, as explained in the next few paragraphs.

If you configure reflexive access lists for an external interface, when an outbound IP packet reaches the interface, the packet will be evaluated sequentially by each entry in the outbound access list until a match occurs.

If the packet matches an entry prior to the reflexive permit entry, the packet will not be evaluated by the reflexive permit entry, and no temporary entry will be created for the reflexive access list (reflexive filtering will not be triggered).
The outbound packet will be evaluated by the reflexive permit entry only if no other match occurs first. Then, if the packet matches the protocol specified in the reflexive permit entry, the packet is forwarded out of the interface and a corresponding temporary entry is created in the inbound reflexive access list (unless the corresponding entry already exists, indicating the outbound packet belongs to a session in progress). The temporary entry specifies criteria that permits inbound traffic only for the same session.

### Nesting the Reflexive Access List(s)

After you define a reflexive access list in one IP extended access list, you must “nest” the reflexive access list within a different extended named IP access list.

- If you are configuring reflexive access lists for an external interface, nest the reflexive access list within an extended named IP access list applied to inbound traffic.
- If you are configuring reflexive access lists for an internal interface, nest the reflexive access list within an extended named IP access list applied to outbound traffic.

After you nest a reflexive access list, packets heading into your internal network can be evaluated against any reflexive access list temporary entries, along with the other entries in the extended named IP access list.

To nest reflexive access lists, use the following commands, beginning in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td></td>
</tr>
<tr>
<td>Router(config)# ip access-list extended name</td>
<td>External interface: Specifies the inbound access list. or Internal interface: Specifies the outbound access list. (This command enters access-list configuration mode.)</td>
</tr>
<tr>
<td>Step 2</td>
<td></td>
</tr>
<tr>
<td>Router(config-ext-nacl)# evaluate name</td>
<td>Adds an entry that “points” to the reflexive access list. Adds an entry for each reflexive access list name previously defined.</td>
</tr>
</tbody>
</table>

Again, the order of entries is important. Normally, when a packet is evaluated against entries in an access list, the entries are evaluated in sequential order, and when a match occurs, no more entries are evaluated. With a reflexive access list nested in an extended access list, the extended access list entries are evaluated sequentially up to the nested entry, then the reflexive access list entries are evaluated sequentially, and then the remaining entries in the extended access list are evaluated sequentially. As usual, after a packet matches any of these entries, no more entries will be evaluated.

If the extended named IP access list you just specified has never been applied to the interface, you must also apply the extended named IP access list to the interface.

To apply the extended named IP access list to the interface, use one of the following commands in interface configuration mode:
Setting a Global Timeout Value

Reflexive access list entries expire after no packets in the session have been detected for a certain length of time (the “timeout” period). You can specify the timeout for a particular reflexive access list when you define the reflexive access list. But if you do not specify the timeout for a given reflexive access list, the list will use the global timeout value instead.

The global timeout value is 300 seconds by default. But, you can change the global timeout to a different value at any time.

To change the global timeout value, use the following command in global configuration mode:

```
Router(config)# ip reflexive-list timeout seconds
```

Reflexive Access List Configuration Examples

The following sections provide reflexive access list configuration examples:

- External Interface Configuration Example
- Internal Interface Configuration Example

External Interface Configuration Example

This example shows reflexive access lists configured for an external interface, for a topology similar to the one in Figure 18 (shown earlier in this chapter).

This configuration example permits both inbound and outbound TCP traffic at interface Serial 1, but only if the first packet (in a given session) originated from inside your network. The interface Serial 1 connects to the Internet.

Define the interface where the session-filtering configuration is to be applied:

```
interface serial 1
  description Access to the Internet via this interface
```

Apply access lists to the interface, for inbound traffic and for outbound traffic:

```
ip access-group inboundfilters in
ip access-group outboundfilters out
```

Define the outbound access list. This is the access list that evaluates all outbound traffic on interface Serial 1.
Reflexive Access List Configuration Examples

Configuring IP Session Filtering (Reflexive Access Lists)

Reflexive Access List Configuration Examples

10

ip access-list extended outboundfilters

Define the reflexive access list tcptraffic. This entry permits all outbound TCP traffic and creates a new access list named tcptraffic. Also, when an outbound TCP packet is the first in a new session, a corresponding temporary entry will be automatically created in the reflexive access list tcptraffic.

permit tcp any any reflect tcptraffic

Define the inbound access list. This is the access list that evaluates all inbound traffic on interface Serial 1.

ip access-list extended inboundfilters

Define the inbound access list entries. This example shows Enhanced IGRP permitted on the interface. Also, no ICMP traffic is permitted. The last entry points to the reflexive access list. If a packet does not match the first two entries, the packet will be evaluated against all the entries in the reflexive access list tcptraffic.

permit eigrp any any
deny icmp any any
evaluate tcptraffic

Define the global idle timeout value for all reflexive access lists. In this example, when the reflexive access list tcptraffic was defined, no timeout was specified, so tcptraffic uses the global timeout. Therefore, if for 120 seconds there is no TCP traffic that is part of an established session, the corresponding reflexive access list entry will be removed.

ip reflexive-list timeout 120

The example configuration looks as follows:

interface Serial 1
description Access to the Internet via this interface
ip access-list inboundfilters in
ip access-list outboundfilters out
!
ip reflexive-list timeout 120
!
ip access-list extended outboundfilters
permit tcp any any reflect tcptraffic
!
ip access-list extended inboundfilters
permit eigrp any any
deny icmp any any
evaluate tcptraffic

With this configuration, before any TCP sessions have been initiated the show access-list EXEC command displays the following:

Extended IP access list inboundfilters
permit eigrp any any
deny icmp any any
evaluate tcptraffic
Extended IP access list outboundfilters
permit tcp any any reflect tcptraffic

Notice that the reflexive access list does not appear in this output. This is because before any TCP sessions have been initiated, no traffic has triggered the reflexive access list, and the list is empty (has no entries). When empty, reflexive access lists do not show up in show access-list output.

After a Telnet connection is initiated from within your network to a destination outside of your network, the show access-list EXEC command displays the following:
Extended IP access list inboundfilters
   permit eigrp any any
deny icmp any any
evaluate tcptraffic
Extended IP access list outboundfilters
   permit tcp any any reflect tcptraffic
Reflexive IP access list tcptraffic
   permit tcp host 172.19.99.67 eq telnet host 192.168.60.185 eq 11005 (5 matches) (time left 115 seconds)

Notice that the reflexive access list tcptraffic now appears and displays the temporary entry generated when the Telnet session initiated with an outbound packet.

**Internal Interface Configuration Example**

This is an example configuration for reflexive access lists configured for an internal interface. This example has a topology similar to the one in Figure 19 (shown earlier in this chapter).

This example is similar to the previous example; the only difference between this example and the previous example is that the entries for the outbound and inbound access lists are swapped. Please refer to the previous example for more details and descriptions.

interface Ethernet 0
description Access from the I-net to our Internal Network via this interface
ip access-group inboundfilters in
ip access-group outboundfilters out
ip reflexive-list timeout 120
ip access-list extended outboundfilters
   permit eigrp any any
deny icmp any any
evaluate tcptraffic
ip access-list extended inboundfilters
   permit tcp any any reflect tcptraffic

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

</tbody>
</table>

This chapter describes how to configure your router to protect TCP servers from TCP SYN-flooding attacks, a type of denial-of-service attack. This task is accomplished by configuring the Cisco IOS feature known as TCP Intercept. You cannot use TCP Intercept on a device that also has network address translation (NAT) configured.

For a complete description of TCP Intercept commands, see the Cisco IOS Security Command Reference. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release.

In This Chapter

This chapter has the following sections:

- About TCP Intercept
- TCP Intercept Configuration Task List
- TCP Intercept Configuration Example
About TCP Intercept

The TCP intercept feature implements software to protect TCP servers from TCP SYN-flooding attacks, which are a type of denial-of-service attack.

A SYN-flooding attack occurs when a hacker floods a server with a barrage of requests for connection. Because these messages have unreachable return addresses, the connections cannot be established. The resulting volume of unresolved open connections eventually overwhelms the server and can cause it to deny service to valid requests, thereby preventing legitimate users from connecting to a web site, accessing e-mail, using FTP service, and so on.

The TCP intercept feature helps prevent SYN-flooding attacks by intercepting and validating TCP connection requests. In intercept mode, the TCP intercept software intercepts TCP synchronization (SYN) packets from clients to servers that match an extended access list. The software establishes a connection with the client on behalf of the destination server, and if successful, establishes the connection with the server on behalf of the client and knits the two half-connections together transparently. Thus, connection attempts from unreachable hosts will never reach the server. The software continues to intercept and forward packets throughout the duration of the connection. The number of SYNs per second and the number of concurrent connections proxied depends on the platform, memory, processor, and other factors.

In the case of illegitimate requests, the software’s aggressive timeouts on half-open connections and its thresholds on TCP connection requests protect destination servers while still allowing valid requests.

When establishing your security policy using TCP intercept, you can choose to intercept all requests or only those coming from specific networks or destined for specific servers. You can also configure the connection rate and threshold of outstanding connections.

You can choose to operate TCP intercept in watch mode, as opposed to intercept mode. In watch mode, the software passively watches the connection requests flowing through the router. If a connection fails to get established in a configurable interval, the software intervenes and terminates the connection attempt.

TCP options that are negotiated on handshake (such as RFC 1323 on window scaling) will not be negotiated because the TCP intercept software does not know what the server can do or will negotiate.

TCP Intercept Configuration Task List

To configure TCP intercept, perform the tasks in the following sections. The first task is required; the rest are optional.

Note

You cannot use TCP Intercept on a device that also has NAT configured.

- Enabling TCP Intercept (Required)
- Setting the TCP Intercept Mode (Optional)
- Setting the TCP Intercept Drop Mode (Optional)
- Changing the TCP Intercept Timers (Optional)
- Changing the TCP Intercept Aggressive Thresholds (Optional)
- Monitoring and Maintaining TCP Intercept (Optional)

For TCP intercept configuration examples using the commands in this chapter, refer to the “TCP Intercept Configuration Example” section at the end of this chapter.
Enabling TCP Intercept

To enable TCP intercept, use the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Defines an IP extended access list.</td>
</tr>
<tr>
<td>Router(config)# access-list access-list-number (deny</td>
<td>permit) tcp any destination destination-wildcard</td>
</tr>
<tr>
<td>Step 2</td>
<td>Enables TCP intercept.</td>
</tr>
<tr>
<td>Router(config)# ip tcp intercept list access-list-number</td>
<td></td>
</tr>
</tbody>
</table>

You can define an access list to intercept all requests or only those coming from specific networks or destined for specific servers. Typically the access list will define the source as any and define specific destination networks or servers. That is, you do not attempt to filter on the source addresses because you do not necessarily know who to intercept packets from. You identify the destination in order to protect destination servers.

If no access list match is found, the router allows the request to pass with no further action.

Setting the TCP Intercept Mode

The TCP intercept can operate in either active intercept mode or passive watch mode. The default is intercept mode.

In intercept mode, the software actively intercepts each incoming connection request (SYN) and responds on behalf of the server with an SYN-ACK, then waits for an ACK from the client. When that ACK is received, the original SYN is sent to the server and the software performs a three-way handshake with the server. When this is complete, the two half-connections are joined.

In watch mode, connection requests are allowed to pass through the router to the server but are watched until they become established. If they fail to become established within 30 seconds (configurable with the ip tcp intercept watch-timeout command), the software sends a Reset to the server to clear up its state.

To set the TCP intercept mode, use the following command in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# ip tcp intercept mode {intercept</td>
<td>watch}</td>
</tr>
</tbody>
</table>

Setting the TCP Intercept Drop Mode

When under attack, the TCP intercept feature becomes more aggressive in its protective behavior. If the number of incomplete connections exceeds 1100 or the number of connections arriving in the last one minute exceeds 1100, each new arriving connection causes the oldest partial connection to be deleted. Also, the initial retransmission timeout is reduced by half to 0.5 seconds (so the total time trying to establish a connection is cut in half).
By default, the software drops the oldest partial connection. Alternatively, you can configure the software to drop a random connection. To set the drop mode, use the following command in global configuration mode:

```
Command Purpose
Router(config)# ip tcp intercept drop-mode {oldest | random} Sets the drop mode.
```

### Changing the TCP Intercept Timers

By default, the software waits for 30 seconds for a watched connection to reach established state before sending a Reset to the server. To change this value, use the following command in global configuration mode:

```
Command Purpose
Router(config)# ip tcp intercept watch-timeout seconds Changes the time allowed to reach established state.
```

By default, the software waits for 5 seconds from receipt of a reset or FIN-exchange before it ceases to manage the connection. To change this value, use the following command in global configuration mode:

```
Command Purpose
Router(config)# ip tcp intercept finrst-timeout seconds Changes the time between receipt of a reset or FIN-exchange and dropping the connection.
```

By default, the software still manages a connection for 24 hours after no activity. To change this value, use the following command in global configuration mode:

```
Command Purpose
Router(config)# ip tcp intercept connection-timeout seconds Changes the time the software will manage a connection after no activity.
```

### Changing the TCP Intercept Aggressive Thresholds

Two factors determine when aggressive behavior begins and ends: total incomplete connections and connection requests during the last one-minute sample period. Both thresholds have default values that can be redefined.

When a threshold is exceeded, the TCP intercept assumes the server is under attack and goes into aggressive mode. When in aggressive mode, the following occurs:

- Each new arriving connection causes the oldest partial connection to be deleted. (You can change to a random drop mode.)
The initial retransmission timeout is reduced by half to 0.5 seconds, and so the total time trying to establish the connection is cut in half. (When not in aggressive mode, the code does exponential back-off on its retransmissions of SYN segments. The initial retransmission timeout is 1 second. The subsequent timeouts are 2 seconds, 4 seconds, 8 seconds, and 16 seconds. The code retransmits 4 times before giving up, so it gives up after 31 seconds of no acknowledgment.)

If in watch mode, the watch timeout is reduced by half. (If the default is in place, the watch timeout becomes 15 seconds.)

The drop strategy can be changed from the oldest connection to a random connection with the `ip tcp intercept drop-mode` command.

Note: The two factors that determine aggressive behavior are related and work together. When *either* of the *high* values is exceeded, aggressive behavior begins. When *both* quantities fall below the *low* value, aggressive behavior ends.

You can change the threshold for triggering aggressive mode based on the total number of incomplete connections. The default values for *low* and *high* are 900 and 1100 incomplete connections, respectively. To change these values, use the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1: <code>Router(config)# ip tcp intercept max-incomplete low number</code></td>
<td>Sets the threshold for stopping aggressive mode.</td>
</tr>
<tr>
<td>Step 2: <code>Router(config)# ip tcp intercept max-incomplete high number</code></td>
<td>Sets the threshold for triggering aggressive mode.</td>
</tr>
</tbody>
</table>

You can also change the threshold for triggering aggressive mode based on the number of connection requests received in the last 1-minute sample period. The default values for *low* and *high* are 900 and 1100 connection requests, respectively. To change these values, use the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1: <code>Router(config)# ip tcp intercept one-minute low number</code></td>
<td>Sets the threshold for stopping aggressive mode.</td>
</tr>
<tr>
<td>Step 2: <code>Router(config)# ip tcp intercept one-minute high number</code></td>
<td>Sets the threshold for triggering aggressive mode.</td>
</tr>
</tbody>
</table>

### Monitoring and Maintaining TCP Intercept

To display TCP intercept information, use either of the following commands in EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router# show tcp intercept connections</code></td>
<td>Displays incomplete connections and established connections.</td>
</tr>
<tr>
<td><code>Router# show tcp intercept statistics</code></td>
<td>Displays TCP intercept statistics.</td>
</tr>
</tbody>
</table>
TCP Intercept Configuration Example

The following configuration defines extended IP access list 101, causing the software to intercept packets for all TCP servers on the 192.168.1.0/24 subnet:

```
ip tcp intercept list 101
!
access-list 101 permit tcp any 192.168.1.0 0.0.0.255
```

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

Configuring Context-Based Access Control

This chapter describes how to configure Context-based Access Control (CBAC). CBAC provides advanced traffic filtering functionality and can be used as an integral part of your network’s firewall. For more information regarding firewalls, refer to the chapter “Cisco IOS Firewall Overview.”

For a complete description of the CBAC commands used in this chapter, refer to the “Context-Based Access Control Commands” chapter in the Cisco IOS Security Command Reference. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter “Identifying Supported Platforms” section in the “Using Cisco IOS Software.”

In This Chapter

This chapter has the following sections:

- About Context-Based Access Control
- CBAC Configuration Task List
- Monitoring and Maintaining CBAC
- CBAC Configuration Examples

About Context-Based Access Control

This section describes CBAC features and functions:

- What CBAC Does
- What CBAC Does Not Do
- How CBAC Works
- When and Where to Configure CBAC
- The CBAC Process
What CBAC Does

CBAC works to provide network protection on multiple levels using the following functions:

- Traffic Filtering
- Traffic Inspection
- Alerts and Audit Trails
- Intrusion Prevention

Traffic Filtering

CBAC intelligently filters TCP and UDP packets based on application-layer protocol session information. You can configure CBAC to permit specified TCP and UDP traffic through a firewall only when the connection is initiated from within the network you want to protect. CBAC can inspect traffic for sessions that originate from either side of the firewall, and CBAC can be used for intranet, extranet, and Internet perimeters of your network.

Without CBAC, traffic filtering is limited to access list implementations that examine packets at the network layer, or at most, the transport layer. However, CBAC examines not only network layer and transport layer information but also examines the application-layer protocol information (such as FTP connection information) to learn about the state of the session. This allows support of protocols that involve multiple channels created as a result of negotiations in the control channel. Most of the multimedia protocols as well as some other protocols (such as FTP, RPC, and SQL*Net) involve multiple channels.

Using CBAC, Java blocking can be configured to filter HTTP traffic based on the server address or to completely deny access to Java applets that are not embedded in an archived or compressed file. With Java, you must protect against the risk of users inadvertently downloading destructive applets into your network. To protect against this risk, you could require all users to disable Java in their browser. If this is not an acceptable solution, you can create a CBAC inspection rule to filter Java applets at the firewall, which allows users to download only applets residing within the firewall and trusted applets from outside the firewall. For extensive content filtering of Java, Active-X, or virus scanning, you might want to consider purchasing a dedicated content filtering product.

Traffic Inspection

CBAC inspects traffic that travels through the firewall to discover and manage state information for TCP and UDP sessions. This state information is used to create temporary openings in the firewall’s access lists to allow return traffic and additional data connections for permissible sessions.

Inspecting packets at the application layer, and maintaining TCP and UDP session information, provides CBAC with the ability to detect and prevent certain types of network attacks such as SYN-flooding. A SYN-flood attack occurs when a network attacker floods a server with a barrage of requests for connection and does not complete the connection. The resulting volume of half-open connections can overwhelm the server, causing it to deny service to valid requests. Network attacks that deny access to a network device are called denial-of-service (DoS) attacks.
CBAC helps to protect against DoS attacks in other ways. CBAC inspects packet sequence numbers in TCP connections to see if they are within expected ranges—CBAC drops any suspicious packets. You can also configure CBAC to drop half-open connections, which require firewall processing and memory resources to maintain. Additionally, CBAC can detect unusually high rates of new connections and issue alert messages.

CBAC can help by protecting against certain DoS attacks involving fragmented IP packets. Even though the firewall prevents an attacker from making actual connections to a given host, the attacker can disrupt services provided by that host. This is done by sending many non-initial IP fragments or by sending complete fragmented packets through a router with an ACL that filters the first fragment of a fragmented packet. These fragments can tie up resources on the target host as it tries to reassemble the incomplete packets.

**Alerts and Audit Trails**

CBAC also generates real-time alerts and audit trails. Enhanced audit trail features use SYSLOG to track all network transactions; recording time stamps, source host, destination host, ports used, and the total number of transmitted bytes, for advanced, session-based reporting. Real-time alerts send SYSLOG error messages to central management consoles upon detecting suspicious activity. Using CBAC inspection rules, you can configure alerts and audit trail information on a per-application protocol basis. For example, if you want to generate audit trail information for HTTP traffic, you can specify that in the CBAC rule covering HTTP inspection.

**Intrusion Prevention**

CBAC provides a limited amount of intrusion detection to protect against specific SMTP attacks. With intrusion detection, SYSLOG messages are reviewed and monitored for specific “attack signatures.” Certain types of network attacks have specific characteristics, or signatures. When CBAC detects an attacks, it resets the offending connections and sends SYSLOG information to the SYSLOG server. Refer to the section “Interpreting Syslog and Console Messages Generated by CBAC” later in this chapter for a list of supported signatures.

In addition to the limited intrusion detection offered by CBAC, the Cisco IOS Firewall feature set offers intrusion detection technology for mid-range and high-end router platforms using the Cisco IOS Intrusion Prevention System (IPS). Cisco IOS IPS restructures and replaces the existing Cisco IOS Intrusion Detection System (IDS). It is ideal for any network perimeter, and especially for locations in which a router is being deployed and additional security between network segments is required. It also can protect intranet and extranet connections where additional security is mandated, and branch-office sites connecting to the corporate office or Internet.

The Cisco IOS IPS acts as an in-line intrusion detection sensor, watching packets and sessions as they flow through the router and scanning each packet to match any of the Cisco IOS IPS signatures. When Cisco IOS IPS detects suspicious activity, it responds before network security can be compromised and logs the event through Cisco IOS syslog messages or Security Device Event Exchange (SDEE).

For more information about Cisco IOS IPS, refer to the module “Configuring Cisco IOS Intrusion Prevention System (IPS).”
What CBAC Does Not Do

CBAC does not provide intelligent filtering for all protocols; it only works for the protocols that you specify. If you do not specify a certain protocol for CBAC, the existing access lists will determine how that protocol is filtered. No temporary openings will be created for protocols not specified for CBAC inspection.

CBAC does not protect against attacks originating from within the protected network unless that traffic travels through a router that has the Cisco IOS Firewall feature set deployed on it. CBAC only detects and protects against attacks that travel through the firewall. This is a scenario in which you might want to deploy CBAC on an intranet-based router.

CBAC protects against certain types of attacks, but not every type of attack. CBAC should not be considered a perfect, impenetrable defense. Determined, skilled attackers might be able to launch effective attacks. While there is no such thing as a perfect defense, CBAC detects and prevents most of the popular attacks on your network.

How CBAC Works

You should understand the material in this section before you configure CBAC. If you do not understand how CBAC works, you might inadvertently introduce security risks by configuring CBAC inappropriately. This section contains the following sections:

- How CBAC Works—Overview
- How CBAC Works—Details

How CBAC Works—Overview

CBAC creates temporary openings in access lists at firewall interfaces. These openings are created when specified traffic exits your internal network through the firewall. The openings allow returning traffic (that would normally be blocked) and additional data channels to enter your internal network back through the firewall. The traffic is allowed back through the firewall only if it is part of the same session as the original traffic that triggered CBAC when exiting through the firewall.

Throughout this chapter, the terms “inbound” and “outbound” are used to describe the direction of traffic relative to the router interface on which CBAC is applied. For example, if a CBAC rule is applied inbound on interface E0, then packets entering interface E0 from the network will be inspected. If a CBAC rule is applied outbound on interface E0, then packets leaving interface E0 to the network will be inspected. This is similar to the way ACLs work.

For example, consider a CBAC inspection rule named *hqusers*, and suppose that rule is applied inbound at interface E0:

```
routing (config-if)# ip inspect hqusers in
```

This command causes CBAC to inspect the packets coming into this interface from the network. If a packet is attempting to initiate a session, CBAC will then determine if this protocol is allowed, create a CBAC session, add the appropriate ACLs to allow return traffic and do any needed content inspection on any future packets for this session.

The terms “input” and “output” are used to describe the interfaces at which network traffic enters or exits the firewall router. A packet enters the firewall router via the input interface, is inspected by the firewall software and then exits the router via the output interface.
In Figure 20, the inbound access lists at S0 and S1 are configured to block Telnet traffic, and there is no outbound access list configured at E0. When the connection request for User1’s Telnet session passes through the firewall, CBAC creates a temporary opening in the inbound access list at S0 to permit returning Telnet traffic for User1’s Telnet session. (If the same access list is applied to both S0 and S1, the same opening would appear at both interfaces.) If necessary, CBAC would also have created a similar opening in an outbound access list at E0 to permit return traffic.

**Figure 20 CBAC Opens Temporary Holes in Firewall Access Lists**

---

**How CBAC Works—Details**

This section describes how CBAC inspects packets and maintains state information about sessions to provide intelligent filtering.

**Packets Are Inspected**

With CBAC, you specify which protocols you want to be inspected, and you specify an interface and interface direction (in or out) where inspection originates. Only specified protocols will be inspected by CBAC.

Packets entering the firewall are inspected by CBAC only if they first pass the inbound access list at the input interface and outbound access list at the output interface. If a packet is denied by the access list, the packet is simply dropped and not inspected by CBAC.

CBAC inspection tracks sequence numbers in all TCP packets, and drops those packets with sequence numbers that are not within expected ranges.

CBAC inspection recognizes application-specific commands (such as illegal SMTP commands) in the control channel, and detects and prevents certain application-level attacks.

When CBAC suspects an attack, the DoS feature can take several actions:

- Generate alert messages
- Protect system resources that could impede performance
- Block packets from suspected attackers

CBAC uses timeout and threshold values to manage session state information, helping to determine when to drop sessions that do not become fully established. Setting timeout values for network sessions helps prevent DoS attacks by freeing up system resources, dropping sessions after a specified amount of time. Setting threshold values for network sessions helps prevent DoS attacks by controlling the number of half-open sessions, which limits the amount of system resources applied to half-open sessions. When a
session is dropped, CBAC sends a reset message to the devices at both end points (source and destination) of the session. When the system under DoS attack receives a reset command, it releases, or frees up, processes and resources related to that incomplete session.

CBAC provides three thresholds against DoS attacks:
- The total number of half-open TCP or UDP sessions
- The number of half-open sessions based upon time
- The number of half-open TCP-only sessions per host

If a threshold is exceeded, CBAC has two options:
- Send a reset message to the end points of the oldest half-open session, making resources available to service newly arriving SYN packets.
- In the case of half open TCP only sessions, CBAC blocks all SYN packets temporarily for the duration configured by the threshold value. When the router blocks a SYN packet, the TCP three-way handshake is never initiated, which prevents the router from using memory and processing resources needed for valid connections.

DoS detection and prevention requires that you create a CBAC inspection rule and apply that rule on an interface. The inspection rule must include the protocols that you want to monitor against DoS attacks. For example, if you have TCP inspection enabled on the inspection rule, then CBAC can track all TCP connections to watch for DoS attacks. If the inspection rule includes FTP protocol inspection but not TCP inspection, CBAC tracks only FTP connections for DoS attacks.

For detailed information about setting timeout and threshold values in CBAC to detect and prevent DoS attacks, refer in the “Configuring Global Timeouts and Thresholds” section.

**A State Table Maintains Session State Information**

Whenever a packet is inspected, a state table is updated to include information about the state of the session.

Return traffic will only be permitted back through the firewall if the state table contains information indicating that the packet belongs to a permissible session. CBAC controls the traffic that belongs to a valid session. When return traffic is inspected, the state table information is updated as necessary.

**UDP “Sessions” Are Approximated**

With UDP—a connectionless service—there are no actual sessions, so the software approximates sessions by examining the information in the packet and determining if the packet is similar to other UDP packets (for example, same source/destination addresses and port numbers) and if the packet was detected soon after another similar UDP packet. “Soon” means within the configurable UDP idle timeout period.

**Access List Entries Are Dynamically Created and Deleted to Permit Return Traffic and Additional Data Connections**

CBAC dynamically creates and deletes access list entries at the firewall interfaces, according to the information maintained in the state tables. These access list entries are applied to the interfaces to examine traffic flowing back into the internal network. These entries create temporary openings in the firewall to permit only traffic that is part of a permissible session.

The temporary access list entries are never saved to NVRAM.
When and Where to Configure CBAC

Configure CBAC at firewalls protecting internal networks. Such firewalls should be Cisco routers with the Cisco IOS Firewall feature set configured as described previously in the section “Cisco IOS Firewall.”

Use CBAC when the firewall will be passing traffic such as the following:

- Standard TCP and UDP Internet applications
- Multimedia applications
- Oracle support

Use CBAC for these applications if you want the application’s traffic to be permitted through the firewall only when the traffic session is initiated from a particular side of the firewall (usually from the protected internal network).

In many cases, you will configure CBAC in one direction only at a single interface, which causes traffic to be permitted back into the internal network only if the traffic is part of a permissible (valid, existing) session. This is a typical configuration for protecting your internal networks from traffic that originates on the Internet.

You can also configure CBAC in two directions at one or more interfaces. CBAC is configured in two directions when the networks on both sides of the firewall should be protected, such as with extranet or intranet configurations, and to protect against DoS attacks. For example, if the firewall is situated between two partner companies’ networks, you might wish to restrict traffic in one direction for certain applications, and restrict traffic in the opposite direction for other applications.

The CBAC Process

This section describes a sample sequence of events that occurs when CBAC is configured at an external interface that connects to an external network such as the Internet.

In this example, a TCP packet exits the internal network through the firewall’s external interface. The TCP packet is the first packet of a Telnet session, and TCP is configured for CBAC inspection.

1. The packet reaches the firewall’s external interface.
2. The packet is evaluated against the interface’s existing outbound access list, and the packet is permitted. (A denied packet would simply be dropped at this point.)
3. The packet is inspected by CBAC to determine and record information about the state of the packet’s connection. This information is recorded in a new state table entry created for the new connection.
   (If the packet’s application—Telnet—was not configured for CBAC inspection, the packet would simply be forwarded out the interface at this point without being inspected by CBAC. See the section “Defining an Inspection Rule” later in this chapter for information about configuring CBAC inspection.)
4. Based on the obtained state information, CBAC creates a temporary access list entry which is inserted at the beginning of the external interface’s inbound extended access list. This temporary access list entry is designed to permit inbound packets that are part of the same connection as the outbound packet just inspected.
5. The outbound packet is forwarded out the interface.
6. Later, an inbound packet reaches the interface. This packet is part of the same Telnet connection previously established with the outbound packet. The inbound packet is evaluated against the inbound access list, and it is permitted because of the temporary access list entry previously created.
7. The permitted inbound packet is inspected by CBAC, and the connection’s state table entry is updated as necessary. Based on the updated state information, the inbound extended access list temporary entries might be modified in order to permit only packets that are valid for the current state of the connection.

8. Any additional inbound or outbound packets that belong to the connection are inspected to update the state table entry and to modify the temporary inbound access list entries as required, and they are forwarded through the interface.

9. When the connection terminates or times out, the connection’s state table entry is deleted, and the connection’s temporary inbound access list entries are deleted.

In the sample process just described, the firewall access lists are configured as follows:

- An outbound IP access list (standard or extended) is applied to the external interface. This access list permits all packets that you want to allow to exit the network, including packets you want to be inspected by CBAC. In this case, Telnet packets are permitted.
- An inbound extended IP access list is applied to the external interface. This access list denies any traffic to be inspected by CBAC—including Telnet packets. When CBAC is triggered with an outbound packet, CBAC creates a temporary opening in the inbound access list to permit only traffic that is part of a valid, existing session.

If the inbound access list had been configured to permit all traffic, CBAC would be creating pointless openings in the firewall for packets that would be permitted anyway.

**Supported Protocols**

This section provides a list of CBAC supported protocols and includes a more detailed look at support for multimedia applications, specifically RTSP and H.323.

**CBAC Supported Protocols**

You can configure CBAC to inspect the following types of sessions:

- All TCP sessions, regardless of the application-layer protocol (sometimes called “single-channel” or “generic” TCP inspection)
- All UDP sessions, regardless of the application-layer protocol (sometimes called “single-channel” or “generic” UDP inspection)

You can also configure CBAC to specifically inspect certain application-layer protocols. The following application-layer protocols can all be configured for CBAC:

- CU-SeeMe (only the White Pine version)
- FTP
- H.323 (such as NetMeeting, ProShare)
- HTTP (Java blocking)
- Microsoft NetShow
- UNIX R-commands (such as rlogin, rexec, and rsh)
- RealAudio
- RTSP (Real Time Streaming Protocol)
- RPC (Sun RPC, not DCE RPC)
SMTP (Simple Mail Transport Protocol)

Note

CBAC can be configured to inspect SMTP but not ESMTP (Extended Simple Mail Transport Protocol). SMTP is described in RFC 821. CBAC SMTP inspect does not inspect the ESMTP session or command sequence. Configuring SMTP inspection is not useful for ESMTP, and it can cause problems.

To determine whether a mail-server is doing SMTP or ESMTP, contact your mail-server software vendor, or telnet to the mail-server port 25 and observe the banner to see if it reports SMTP or ESMTP.

- SQL*Net
- StreamWorks
- TFTP
- VDOLive

When a protocol is configured for CBAC, that protocol traffic is inspected, state information is maintained, and in general, packets are allowed back through the firewall only if they belong to a permissible session.

RTSP and H.323 Protocol Support for Multimedia Applications

CBAC supports a number of protocols for multimedia applications that require delivery of data with real-time properties such as audio and video conferencing. This support includes the following multimedia application protocols:

- Real Time Streaming Protocol (RTSP)
- H.323 Version 2 (H.323 V2)

RTSP and H.323 V2 inspection allows clients on a protected network to receive data associated with a multimedia session from a server on an unprotected network.

RTSP Support

RTSP is the IETF standards-based protocol (RFC 2326) for control over the delivery of data with real-time properties such as audio and video streams. It is useful for large-scale broadcasts and audio or video on demand streaming, and is supported by a variety of vendor products of streaming audio and video multimedia, including Cisco IP/TV, RealNetworks RealAudio G2 Player, and Apple QuickTime 4 software.

RFC 2326 allows RTSP to run over either UDP or TCP, though CBAC currently supports only TCP-based RTSP. RTSP establishes a TCP-based control connection, or channel, between the multimedia client and server. RTSP uses this channel to control commands such as “play” and “pause” between the client and server. These control commands and responses are text-based and are similar to HTTP.

RTSP typically relies on a UDP-based data transport protocol such as standard Real-Time Transport Protocol (RTP) to open separate channels for data and for RTP Control Protocol (RTCP) messages. RTP and RTCP channels occur in pairs, with RTP being an even numbered port and RTCP being the next consecutive port. Understanding the relationship of RTP and RTCP is important for verifying session information using CBAC show commands.
The RTSP client uses TCP port 554 or 8554 to open a multimedia connection with a server. The data channel or data control channel (using RTCP) between the client and the server is dynamically negotiated between the client and the server using any of the high UDP ports (1024 to 65536).

CBAC uses this port information along with connection information from the client to create dynamic access control list (ACL) entries in the firewall. As TCP or UDP connections are terminated, CBAC removes these dynamic entries from the appropriate ACLs.

CBAC support for RTSP includes the following data transport modes:

- **Standard Real-Time Transport Protocol (RTP)**
  RTP is an IETF standard (RFC 1889) supporting delivery of real-time data such as audio and video. RTP uses the RTP Control Protocol (RTCP) for managing the delivery of the multimedia data stream. This is the normal mode of operation for Cisco IP/TV and Apple QuickTime 4 software.

- **RealNetworks Real Data Transport (RDT)**
  RDT is a proprietary protocol developed by RealNetworks for data transport. This mode uses RTSP for communication control and uses RDT for the data connection and retransmission of lost packets. This is the normal mode of operation for the RealServer G2 from RealNetworks.

- **Interleaved (Tunnel Mode)**
  In this mode, RTSP uses the control channel to tunnel RTP or RDT traffic.

- **Synchronized Multimedia Integration Language (SMIL)**
  SMIL is a layout language that enables the creation of multimedia presentations consisting of multiple elements of music, voice, images, text, video and graphics. This involves multiple RTSP control and data streams between the player and the servers. This mode is available only using RTSP and RDT. SMIL is a proposed specification of the World Wide Web Consortium (W3C). The RealNetworks RealServer and RealServer G2 provide support for SMIL—Cisco IP/TV and Apple QuickTime 4 do not.

**H.323 Support**

CBAC support for H.323 inspection includes H.323 Version 2 and H.323 Version 1. H.323 V2 provides additional options over H.323 V1, including a “fast start” option. The fast start option minimizes the delay between the time that a user initiates a connection and the time that the user gets the data (voice, video). H.323 V2 inspection is backward compatible with H.323 V1.

With H.323 V1, after a TCP connection is established between the client and server (H.225 Channel), a separate channel for media control (H.245 Channel) is opened through which multimedia channels for audit and video are further negotiated.

The H.323 V2 client opens a connection to server which is listening on port 1720. The data channel between the client and the server is dynamically negotiated using any of the high UDP ports (1024 to 65536).

CBAC uses this port information along with connection information from the client to create dynamic access control list (ACL) entries in the firewall. As TCP or UDP connections are terminated, CBAC removes these dynamic entries from the appropriate ACLs.

**Restrictions**

CBAC has the following restrictions:
CBAC is available only for IP protocol traffic. Only TCP and UDP packets are inspected. (Other IP traffic, such as ICMP, cannot be inspected with CBAC and should be filtered with basic access lists instead.)

If you reconfigure your access lists when you configure CBAC, be aware that if your access lists block TFTP traffic into an interface, you will not be able to netboot over that interface. (This is not a CBAC-specific limitation, but is part of existing access list functionality.)

Packets with the firewall as the source or destination address are not inspected by CBAC.

CBAC ignores ICMP Unreachable messages.

H.323 V2 and RTSP protocol inspection supports only the following multimedia client-server applications: Cisco IP-TV, RealNetworks RealAudio G2 Player, Apple QuickTime 4.

You can use CBAC together with all the other firewall features mentioned previously in the “Cisco IOS Firewall Overview” chapter.

CBAC works with fast switching and process switching.

This section also discusses restrictions concerning:

- FTP Traffic and CBAC
- IPSec and CBAC Compatibility

**FTP Traffic and CBAC**

- With FTP, CBAC does not allow third-party connections (three-way FTP transfer).
- When CBAC inspects FTP traffic, it only allows data channels with the destination port in the range of 1024 to 65535.
- CBAC will not open a data channel if the FTP client-server authentication fails.

**IPSec and CBAC Compatibility**

When CBAC and IPSec are enabled on the same router, and the firewall router is an endpoint for IPSec for the particular flow, then IPSec is compatible with CBAC (that is, CBAC can do its normal inspection processing on the flow).

If the router is not an IPSec endpoint, but the packet is an IPSec packet, then CBAC will not inspect the packets because the protocol number in the IP header of the IPSec packet is not TCP or UDP. CBAC only inspects UDP and TCP packets.

**Memory and Performance Impact**

CBAC uses less than approximately 600 bytes of memory per connection. Because of the memory usage, you should use CBAC only when you need to. There is also a slight amount of additional processing that occurs whenever packets are inspected.

Sometimes CBAC must evaluate long access lists, which might have presented a negative impact to performance. However, this impact is avoided, because CBAC evaluates access lists using an accelerated method (CBAC hashes access lists and evaluates the hash).
CBAC Configuration Task List

To configure CBAC, perform the tasks described in the following sections. The tasks in the first seven sections are required; the task of verifying the CBAC configuration is optional.

- **Picking an Interface: Internal or External** (Required)
- **Configuring IP Access Lists at the Interface** (Required)
- **Configuring Global Timeouts and Thresholds** (Required)
- **Defining an Inspection Rule** (Required)
- **Applying the Inspection Rule to an Interface** (Required)
- **Configuring Logging and Audit Trail** (Required)
- **Other Guidelines for Configuring a Firewall** (Required)
- **Verifying CBAC** (Optional)

Following CBAC configuration, you can monitor and maintain CBAC using the information in this section.

---

**Note**

If you try to configure Context-based Access Control (CBAC) but do not have a good understanding of how CBAC works, you might inadvertently introduce security risks to the firewall and to the protected network. You should be sure you understand what CBAC does before you configure CBAC.

---

**Note**

As with all networking devices, protect access into the firewall by configuring passwords as described in the “Configuring Passwords and Privileges” chapter. You should also consider configuring user authentication, authorization, and accounting as described in the “Authentication, Authorization, and Accounting (AAA)” part of this guide. Additional guidelines to help you establish a good security policy can be found in the “Cisco IOS Firewall Overview” chapter.

For CBAC configuration examples, refer to the “CBAC Configuration Examples” section at the end of this chapter.

---

**Picking an Interface: Internal or External**

You must decide whether to configure CBAC on an internal or external interface of your firewall.

“Internal” refers to the side where sessions must originate for their traffic to be permitted through the firewall. “External” refers to the side where sessions cannot originate (sessions originating from the external side will be blocked).

If you will be configuring CBAC in two directions, you should configure CBAC in one direction first, using the appropriate “internal” and “external” interface designations. When you configure CBAC in the other direction, the interface designations will be swapped. (CBAC can be configured in two directions at one or more interfaces. Configure CBAC in two directions when the networks on both sides of the firewall require protection, such as with extranet or intranet configurations, and for protection against DoS attacks.)

The firewall is most commonly used with one of two basic network topologies. Determining which of these topologies is most like your own can help you decide whether to configure CBAC on an internal interface or on an external interface.
The first topology is shown in Figure 21. In this simple topology, CBAC is configured for the *external* interface Serial 1. This prevents specified protocol traffic from entering the firewall and the internal network, unless the traffic is part of a session initiated from within the internal network.

**Figure 21  Simple Topology—CBAC Configured at the External Interface**

The second topology is shown in Figure 22. In this topology, CBAC is configured for the *internal* interface Ethernet 0. This allows external traffic to access the services in the Demilitarized Zone (DMZ), such as DNS services, but prevents specified protocol traffic from entering your internal network—unless the traffic is part of a session initiated from within the internal network.

**Figure 22  DMZ Topology—CBAC Configured at the Internal Interface**

Using these two sample topologies, decide whether to configure CBAC on an internal or external interface.

To view various firewall configuration scenarios, see the “CBAC Configuration Examples” section at the end of this chapter.

### Configuring IP Access Lists at the Interface

For CBAC to work properly, you need to make sure that you have IP access lists configured appropriately at the interface.

Follow these three general rules when evaluating your IP access lists at the firewall:

- Start with a basic configuration.
If you try to configure access lists without a good understanding of how access lists work, you might inadvertently introduce security risks to the firewall and to the protected network. You should be sure you understand what access lists do before you configure your firewall. For more information about access control lists, refer to the “Access Control Lists: Overview and Guidelines” chapter. A basic initial configuration allows all network traffic to flow from the protected networks to the unprotected networks, while blocking network traffic from any unprotected networks.

- Permit CBAC traffic to leave the network through the firewall.
  All access lists that evaluate traffic leaving the protected network should permit traffic that will be inspected by CBAC. For example, if Telnet will be inspected by CBAC, then Telnet traffic should be permitted on all access lists that apply to traffic leaving the network.

- Use extended access lists to deny CBAC return traffic entering the network through the firewall.
  For temporary openings to be created in an access list, the access list must be an extended access list. So wherever you have access lists that will be applied to returning traffic, you must use extended access lists. The access lists should deny CBAC return traffic because CBAC will open up temporary holes in the access lists. (You want traffic to be normally blocked when it enters your network.)

Note: If your firewall only has two connections, one to the internal network and one to the external network, using all inbound access lists works well because packets are stopped before they get a chance to affect the router itself.

This section contains the following sections:

- Basic Configuration
- External Interface
- Internal Interface

Basic Configuration

The first time you configure the Cisco IOS Firewall, it is helpful to start with a basic access list configuration that makes the operation of the firewall easy to understand without compromising security. The basic configuration allows all network traffic from the protected networks access to the unprotected networks, while blocking all network traffic (with some exceptions) from the unprotected networks to the protected networks.

Any firewall configuration depends on your site security policy. If the basic configuration does not meet your initial site security requirements, configure the firewall to meet your policy. If you are unfamiliar with that policy or need help with the configuration, contact your network administration group for assistance. For additional guidelines on configuring a firewall, refer to the “Other Guidelines for Configuring a Firewall” section in this chapter.

Use the following guidelines for configuring the initial firewall access lists:

- Do not configure an access list for traffic from the protected networks to the unprotected networks, meaning that all traffic from the protected networks can flow through the interface.
  This helps to simplify firewall management by reducing the number of access lists applied at the interfaces. Of course this assumes a high level of trust for the users on the protected networks, and it assumes there are no malicious users on the protected networks who might launch attacks from the “inside.” You can fine tune network access for users on the protected networks as you gain experience with access list configuration and the operation of the firewall.
• Configure an access list that includes entries permitting certain ICMP traffic from unprotected networks.

While an access list that denies all IP traffic not part of a connection inspected by CBAC seems most secure, it is not practical for normal operation of the router. The router expects to see ICMP traffic from other routers in the network. Additionally, ICMP traffic is not inspected by CBAC, meaning specific entries are needed in the access list to permit return traffic for ICMP commands. For example, a user on a protected network uses the ping command to get the status of a host on an unprotected network; without entries in the access list that permit echo reply messages, the user on the protected network gets no response to the ping command.

Include access list entries to permit the following ICMP messages:

<table>
<thead>
<tr>
<th>Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>echo reply</td>
<td>Outgoing ping commands require echo-reply messages to come back.</td>
</tr>
<tr>
<td>time-exceeded</td>
<td>Outgoing traceroute commands require time-exceeded messages to come back.</td>
</tr>
<tr>
<td>packet-too-big</td>
<td>Path MTU discovery requires “too-big” messages to come back.</td>
</tr>
<tr>
<td>traceroute</td>
<td>Allow an incoming traceroute.</td>
</tr>
<tr>
<td>unreachable</td>
<td>Permit all “unreachable” messages to come back. If a router cannot forward or deliver a datagram, it sends an ICMP unreachable message back to the source and drops the datagram.</td>
</tr>
</tbody>
</table>

• Add an access list entry denying any network traffic from a source address matching an address on the protected network.

This is known as anti-spoofing protection because it prevents traffic from an unprotected network from assuming the identity of a device on the protected network.

• Add an entry denying broadcast messages with a source address of 255.255.255.255.

This entry helps to prevent broadcast attacks.

• By default, the last entry in an extended access list is an implicit denial of all IP traffic not specifically allowed by other entries in the access list.

Although this is the default setting, this final deny statement is not shown by default in an access list. Optionally, you can add an entry to the access list denying IP traffic with any source or destination address with no undesired effects.

For complete information about how to configure IP access lists, refer to the “Configuring IP Services” chapter of the Cisco IOS IP Addressing Services Configuration Guide.

For tips on applying access lists at an external or internal interface, review the sections “External Interface” and “Internal Interface” in this chapter.

**External Interface**

Here are some guidelines for your access lists when you will be configuring CBAC on an external interface:

• If you have an outbound IP access list at the external interface, the access list can be a standard or extended access list. This outbound access list should permit traffic that you want to be inspected by CBAC. If traffic is not permitted, it will not be inspected by CBAC, but will be simply dropped.
• The inbound IP access list at the external interface must be an extended access list. This inbound access list should deny traffic that you want to be inspected by CBAC. (CBAC will create temporary openings in this inbound access list as appropriate to permit only return traffic that is part of a valid, existing session.)

• For complete information about how to configure IP access lists, refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Addressing Services Configuration Guide*.

**Internal Interface**

Here are some tips for your access lists when you will be configuring CBAC on an internal interface:

• If you have an inbound IP access list at the internal interface or an outbound IP access list at external interface(s), these access lists can be either a standard or extended access list. These access lists should permit traffic that you want to be inspected by CBAC. If traffic is not permitted, it will not be inspected by CBAC, but will be simply dropped.

• The outbound IP access list at the internal interface and the inbound IP access list at the external interface must be extended access lists. These outbound access lists should deny traffic that you want to be inspected by CBAC. (CBAC will create temporary openings in these outbound access lists as appropriate to permit only return traffic that is part of a valid, existing session.) You do not necessarily need to configure an extended access list at both the outbound internal interface and the inbound external interface, but at least one is necessary to restrict traffic flowing through the firewall into the internal protected network.

• For complete information about how to configure IP access lists, refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Addressing Services Configuration Guide*.

**Configuring Global Timeouts and Thresholds**

CBAC uses timeouts and thresholds to determine how long to manage state information for a session, and to determine when to drop sessions that do not become fully established. These timeouts and thresholds apply globally to all sessions.

You can use the default timeout and threshold values, or you can change to values more suitable to your security requirements. You should make any changes to the timeout and threshold values before you continue configuring CBAC.

*Note*

If you want to enable the more aggressive TCP host-specific denial-of-service prevention that includes the blocking of connection initiation to a host, you must set the `block-time` specified in the `ip inspect tcp max-incomplete host` command (see the last row in Table 24).

All the available CBAC timeouts and thresholds are listed in Table 24, along with the corresponding command and default value. To change a global timeout or threshold listed in the “Timeout of Threshold Value to Change” column, use the global configuration command in the “Command” column:
To reset any threshold or timeout to the default value, use the no form of the command in Table 24.

**Half-Open Sessions**

An unusually high number of half-open sessions (either absolute or measured as the arrival rate) could indicate that a denial-of-service attack is occurring. For TCP, “half-open” means that the session has not reached the established state—the TCP three-way handshake has not yet been completed. For UDP, “half-open” means that the firewall has detected no return traffic.
CBAC measures both the total number of existing half-open sessions and the rate of session establishment attempts. Both TCP and UDP half-open sessions are counted in the total number and rate measurements. Rate measurements are made several times per minute.

When the number of existing half-open sessions rises above a threshold (the max-incomplete high number), the software will delete half-open sessions as required to accommodate new connection requests. The software will continue to delete half-open requests as necessary, until the number of existing half-open sessions drops below another threshold (the max-incomplete low number).

When the rate of new connection attempts rises above a threshold (the one-minute high number), the software will delete half-open sessions as required to accommodate new connection attempts. The software will continue to delete half-open sessions as necessary, until the rate of new connection attempts drops below another threshold (the one-minute low number). The rate thresholds are measured as the number of new session connection attempts detected in the last one-minute sample period.

**Defining an Inspection Rule**

After you configure global timeouts and thresholds, you must define an inspection rule. This rule specifies what IP traffic (which application-layer protocols) will be inspected by CBAC at an interface. Normally, you define only one inspection rule. The only exception might occur if you want to enable CBAC in two directions as described earlier in the section “When and Where to Configure CBAC.” For CBAC configured in both directions at a single firewall interface, you should configure two rules, one for each direction.

An inspection rule should specify each desired application-layer protocol as well as generic TCP or generic UDP if desired. The inspection rule consists of a series of statements each listing a protocol and specifying the same inspection rule name.

Inspection rules include options for controlling alert and audit trail messages and for checking IP packet fragmentation.

To define an inspection rule, follow the instructions in the following sections:

- Configuring Application-Layer Protocol Inspection
- Configuring Generic TCP and UDP Inspection

**Configuring Application-Layer Protocol Inspection**

This section provides instructions for configuring CBAC with the following inspection information:

- Configuring Application-Layer Protocols
- Configuring Java Blocking
- Configuring IP Packet Fragmentation Inspection

**Note**

For CBAC inspection to work with NetMeeting 2.0 traffic (an H.323 application-layer protocol), you must also configure inspection for TCP, as described later in the “Configuring Generic TCP and UDP Inspection” section. This requirement exists because NetMeeting 2.0 uses an additional TCP channel not defined in the H.323 specification.
Configuring Application-Layer Protocols

To configure CBAC inspection for an application-layer protocol, use one or both of the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# `ip inspect name inspection-name protocol [alert {on</td>
<td>off}] [audit-trail {on</td>
</tr>
<tr>
<td>Router(config)# `ip inspect name inspection-name rpc program-number number [wait-time minutes] [alert {on</td>
<td>off}] [audit-trail {on</td>
</tr>
</tbody>
</table>

Refer to the description of the `ip inspect name` global configuration command in the “Context-Based Access Control Commands” chapter of the Cisco IOS Security Command Reference for more information about how the command works with each application-layer protocol.

To enable CBAC inspection for Java blocking, see the following section, “Configuring Java Blocking.” Table 25 identifies application protocol keywords for the `ip inspect name` command.

**Table 25 Application Protocol Keywords for the `ip inspect name` Command**

<table>
<thead>
<tr>
<th>Application Protocol</th>
<th>Protocol Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>CU-SeeMe</td>
<td><code>cuseeme</code></td>
</tr>
<tr>
<td>FTP</td>
<td><code>ftp</code></td>
</tr>
<tr>
<td>H.323</td>
<td><code>h323</code></td>
</tr>
<tr>
<td>Microsoft NetShow</td>
<td><code>netshow</code></td>
</tr>
<tr>
<td>UNIX R commands (rlogin, rexec, rsh)</td>
<td><code>rcmd</code></td>
</tr>
<tr>
<td>RealAudio</td>
<td><code>realaudio</code></td>
</tr>
<tr>

<td><code>smtp</code></td>
</tr>
<tr>
<td>SQL*Net</td>
<td><code>sqlnet</code></td>
</tr>
<tr>
<td>StreamWorks</td>
<td><code>streamworks</code></td>
</tr>
<tr>
<td>TFTP</td>
<td><code>tftp</code></td>
</tr>
<tr>
<td>VDOLive</td>
<td><code>vdolive</code></td>
</tr>
</tbody>
</table>

**Configuring Java Blocking**

Java applet filtering distinguishes between trusted and untrusted applets by relying on a list of external sites that you designate as “friendly.” If an applet is from a friendly site, the firewall allows the applet through. If the applet is not from a friendly site, the applet will be blocked. (Alternately, you could permit applets from all external sites except for those you specifically designate as hostile.)
Java blocking forces a strict order on TCP packets. To properly verify that Java applets are not in the response, a firewall will drop any TCP packet that is out of order. Because the network—not the firewall—determines how packets are routed, the firewall cannot control the order of the packets; the firewall can only drop and retransmit all TCP packets that are not in order.

To block all Java applets except for applets from friendly locations, use the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><strong>Step 2</strong></td>
</tr>
<tr>
<td>Router(config)# ip access-list standard name permit ... deny ... (Use permit and deny statements as appropriate.)</td>
<td>Router(config)# ip inspect name inspection-name http [java-list access-list] [alert (on</td>
</tr>
<tr>
<td>or</td>
<td>Blocks all Java applets except for applets from the friendly sites defined previously in the access list. Java blocking only works with numbered standard access lists. To create a single inspection rule, use the same inspection-name value as when you specified other protocols.</td>
</tr>
<tr>
<td>Router(config)# access-list access-list-number {deny</td>
<td>permit} protocol source [source-wildcard]eq www destination [destination-wildcard]</td>
</tr>
<tr>
<td>Creates a standard access list that permits traffic only from friendly sites, and denies traffic from hostile sites. Use the any keyword for the destination as appropriate—but be careful to not misuse the any keyword to inadvertently allow all applets through.</td>
<td></td>
</tr>
</tbody>
</table>

**Caution**
CBAC does not detect or block encapsulated Java applets. Therefore, Java applets that are wrapped or encapsulated, such as applets in .zip or .jar format, are not blocked at the firewall. CBAC also does not detect or block applets loaded from FTP, gopher, HTTP on a nonstandard port, and so forth.

**Configuring IP Packet Fragmentation Inspection**

CBAC inspection rules can help protect hosts against certain DoS attacks involving fragmented IP packets.

Using fragmentation inspection, the firewall maintains an interfragment state (structure) for IP traffic. Non-initial fragments are discarded unless the corresponding initial fragment was permitted to pass through the firewall. Non-initial fragments received before the corresponding initial fragments are discarded.

**Note**
Fragmentation inspection can have undesirable effects in certain cases, because it can result in the firewall discarding any packet whose fragments arrive out of order. There are many circumstances that can cause out-of-order delivery of legitimate fragments. Applying fragmentation inspection in situations where legitimate fragments, which are likely to arrive out of order, might have a severe performance impact.
Because routers running Cisco IOS software are used in a large variety of networks, and because the CBAC feature is often used to isolate parts of internal networks from one another, the fragmentation inspection feature is disabled by default. Fragmentation detection must be explicitly enabled for an inspection rule using the `ip inspect name` command. Unfragmented traffic is never discarded because it lacks a fragment state. Even when the system is under heavy attack with fragmented packets, legitimate fragmented traffic, if any, gets some fraction of the firewall's fragment state resources, and legitimate, unfragmented traffic can flow through the firewall unimpeded.

### Configuring Generic TCP and UDP Inspection

You can configure TCP and UDP inspection to permit TCP and UDP packets to enter the internal network through the firewall, even if the application-layer protocol is not configured to be inspected. However, TCP and UDP inspection do not recognize application-specific commands, and therefore might not permit all return packets for an application, particularly if the return packets have a different port number than the previous exiting packet.

Any application-layer protocol that is inspected will take precedence over the TCP or UDP packet inspection. For example, if inspection is configured for FTP, all control channel information will be recorded in the state table, and all FTP traffic will be permitted back through the firewall if the control channel information is valid for the state of the FTP session. The fact that TCP inspection is configured is irrelevant to the FTP state information.

With TCP and UDP inspection, packets entering the network must exactly match the corresponding packet that previously exited the network. The entering packets must have the same source/destination addresses and source/destination port numbers as the exiting packet (but reversed); otherwise, the entering packets will be blocked at the interface. Also, all TCP packets with a sequence number outside the window are dropped.

With UDP inspection configured, replies will only be permitted back in through the firewall if they are received within a configurable time after the last request was sent out. (This time is configured with the `ip inspect udp idle-time` command.)

To configure CBAC inspection for TCP or UDP packets, use one or both of the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`Router(config)# ip inspect name inspection-name tcp [alert {on</td>
<td>off}] [audit-trail {on</td>
</tr>
<tr>
<td>`Router(config)# ip inspect name inspection-name udp [alert {on</td>
<td>off}] [audit-trail {on</td>
</tr>
</tbody>
</table>

### Applying the Inspection Rule to an Interface

After you define an inspection rule, you apply this rule to an interface.

Normally, you apply only one inspection rule to one interface. The only exception might occur if you want to enable CBAC in two directions as described earlier in the section “When and Where to Configure CBAC.” For CBAC configured in both directions at a single firewall interface, you should apply two rules, one for each direction.
If you are configuring CBAC on an external interface, apply the rule to outbound traffic.
If you are configuring CBAC on an internal interface, apply the rule to inbound traffic.

To apply an inspection rule to an interface, use the following command in interface configuration mode:

Command: `Router(config-if)# ip inspect inspection-name (in | out)`
Purpose: Applies an inspection rule to an interface.

---

### Configuring Logging and Audit Trail

Turn on logging and audit trail to provide a record of network access through the firewall, including illegitimate access attempts, and inbound and outbound services. To configure logging and audit trail functions, enter the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>Router(config)# service timestamps log datetime</code> Adds the date and time to syslog and audit trail messages.</td>
</tr>
<tr>
<td>Step 2</td>
<td><code>Router(config)# logging host</code> Specifies the host name or IP address of the host where you want to send syslog messages.</td>
</tr>
<tr>
<td>Step 3</td>
<td><code>Router(config)# logging facility facility-type</code> Configures the syslog facility in which error messages are sent.</td>
</tr>
<tr>
<td>Step 4</td>
<td><code>Router(config)# logging trap level</code> (Optional) Uses this command to limit messages logged to the syslog servers based on severity. The default is level 7 (informational).</td>
</tr>
<tr>
<td>Step 5</td>
<td><code>Router(config)# ip inspect audit-trail</code> Turns on CBAC audit trail messages.</td>
</tr>
</tbody>
</table>

For information on how to interpret the syslog and audit trail messages, refer to the “Interpreting Syslog and Console Messages Generated by CBAC” section.

To configure audit trail functions on a per-application basis, refer to the “Defining an Inspection Rule” section for more information.

For complete information about how to configure logging, refer to the “Troubleshooting the Router” chapter of the *Cisco IOS Network Management Configuration Guide*.

---

### Other Guidelines for Configuring a Firewall

As with all networking devices, you should always protect access into the firewall by configuring passwords as described in the module “Configuring Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices.” You should also consider configuring user authentication, authorization, and accounting as described in the “Authentication, Authorization, and Accounting (AAA)” part of this guide.

You should also consider the following recommendations:

- When setting passwords for privileged access to the firewall, use the `enable secret` command rather than the `enable password` command, which does not have as strong an encryption algorithm.
• Put a password on the console port. In authentication, authorization, and accounting (AAA) environments, use the same authentication for the console as for elsewhere. In a non-AAA environment, at a minimum configure the `login` and `password` commands.

• Think about access control before you connect a console port to the network in any way, including attaching a modem to the port. Be aware that a break on the console port might give total control of the firewall, even with access control configured.

• Apply access lists and password protection to all virtual terminal ports. Use access lists to limit who can Telnet into your router.

• Do not enable any local service (such as SNMP or NTP) that you do not use. Cisco Discovery Protocol (CDP) and Network Time Protocol (NTP) are on by default, and you should turn these off if you do not need them.

To turn off CDP, enter the `no cdp run` global configuration command. To turn off NTP, enter the `ntp disable` interface configuration command on each interface not using NTP.

If you must run NTP, configure NTP only on required interfaces, and configure NTP to listen only to certain peers.

Any enabled service could present a potential security risk. A determined, hostile party might be able to find creative ways to misuse the enabled services to access the firewall or the network.

For local services that are enabled, protect against misuse. Protect by configuring the services to communicate only with specific peers, and protect by configuring access lists to deny packets for the services at specific interfaces.

• Protect against spoofing: protect the networks on both sides of the firewall from being spoofed from the other side. You could protect against spoofing by configuring input access lists at all interfaces to pass only traffic from expected source addresses, and to deny all other traffic.

You should also disable source routing. For IP, enter the `no ip source-route` global configuration command. Disabling source routing at all routers can also help prevent spoofing.

You should also disable minor services. For IP, enter the `no service tcp-small-servers` and `no service udp-small-servers` global configuration commands. In Cisco IOS Release 12.0 and later, these services are disabled by default.

• Prevent the firewall from being used as a relay by configuring access lists on any asynchronous Telnet ports.

• Normally, you should disable directed broadcasts for all applicable protocols on your firewall and on all your other routers. For IP, use the `no ip directed-broadcast` command. Rarely, some IP networks do require directed broadcasts; if this is the case, do not disable directed broadcasts.

Directed broadcasts can be misused to multiply the power of denial-of-service attacks, because every denial-of-service packet sent is broadcast to every host on a subnet. Furthermore, some hosts have other intrinsic security risks present when handling broadcasts.

• Configure the `no proxy-arp` command to prevent internal addresses from being revealed. (This is important to do if you do not already have NAT configured to prevent internal addresses from being revealed.)

• Keep the firewall in a secured (locked) room.

**Verifying CBAC**

You can view and verify CBAC configuration, status, statistics, and session information by using one or more of the following commands in EXEC mode:
In most cases, you can tell whether CBAC is inspecting network traffic properly because network applications are working as expected. In some cases, however, you might want to verify CBAC operation. For example, to verify RTSP or H.323 inspection, initiate an RTSP- or H.323-based application through the firewall. Use the `show ip inspect session` and `show ip access lists` commands to verify CBAC operation. These commands display the dynamic ACL entries and the established connections for a multimedia session.

In the case of RTSP inspection, session output can vary based on the multimedia protocol and the transport mode. This section uses examples of RTSP and H.323 V2 sessions to illustrate verification procedures and to illustrate how session information, and the interpretation of that session information, varies based on the protocol being inspected. This section provides the following sample session output:

- RTSP with RDT
- RTSP with TCP Only (Interleaved Mode)
- RTSP with SMIL
- RTSP with RTP (IP/TV)
- H.323 V2

### RTSP with RDT

The following example illustrates the result of the `show ip inspect session` command. It shows that a control channel (rtsp) and data channel (rtsp-data) are open between hosts 192.168.155.2 and 192.168.35.1.

```
router# show ip inspect session
Established Sessions
  Session 616B4F1C (192.168.155.2:7548)=>(192.168.35.1:6970) rtsp-data SIS_OPEN
  Session 611E2904 (192.168.35.1:1221)=>(192.168.155.2:554) rtsp SIS_OPEN
```

The following example illustrates the result of the `show ip access-list` command. It shows that two dynamic entries (permit statements) were added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 554 (RTSP protocol port) on the client and port 1221 on the server. The UDP entry creates a dynamic opening between data port 7548 on the client and data port 6970 on the server.

```
router# show ip access-list
Extended IP access list 100
  permit udp host 192.168.155.2 eq 7548 host 192.168.35.1 eq 6970 (31 matches)
  permit tcp host 192.168.155.2 eq 554 host 192.168.35.1 eq 1221 (27 matches)
```
After closing the multimedia session, review the session output using the `show` commands to verify the firewall software has removed the dynamic entries from the configuration.

### RTSP with TCP Only (Interleaved Mode)

The following example illustrates the result of the `show ip inspect session` command. It shows that only a single control channel (rtsp) is open between hosts 192.168.155.2 and 192.168.35.1. In this mode, data is tunneled through the firewall using the TCP connection to interleave RDT or RTP data.

```plaintext
router# show ip inspect session
Established Sessions
Session 611E2B04 (192.168.35.1:1228) => (192.168.155.2:554) rtsp SIS_OPEN
```

The following example illustrates the result of the `show ip access-list` command. It shows that a single dynamic entry (permit statement) was added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 554 (RTSP protocol port) on the client and port 1228 on the server.

```plaintext
router# show ip access-lists
Extended IP access list 100
permit tcp host 192.168.155.2 eq 554 host 192.168.35.1 eq 1228 (391 matches)
```

After closing the multimedia session, review the session output using the `show` commands to verify the firewall software has removed the dynamic entries from the configuration.

### RTSP with SMIL

The following example illustrates the result of the `show ip inspect session` command for RTSP using Synchronized Multimedia Integration Language (SMIL). It shows that a single control channel (rtsp) and multiple data channels (rtsp-data) are open between hosts 192.168.155.2 and 192.168.35.1. The data channels appear as half open sessions because the UDP data flows in one direction only, which is from the server to the client.

```plaintext
router# show ip inspect session
Established Sessions
Session 616CA914 (192.168.155.2:30616) => (192.168.35.1:6974) rtsp-data SIS_OPEN
Session 616B4E78 (192.168.35.1:1230) => (192.168.155.2:554) rtsp SIS_OPEN
Session 614AB61C (192.168.155.2:29704) => (192.168.35.1:6976) rtsp-data SIS_OPEN
Session 615C6A88 (192.168.155.2:26764) => (192.168.35.1:6972) rtsp-data SIS_OPEN
Half-open Sessions
Session 614A6E80 (192.168.155.2:15520) => (192.168.35.1:6970) rtsp-data SIS_OPENING
```

The following example illustrates the result of the `show ip access-lists` command. It shows that multiple dynamic entries (permit statements) were added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 554 (RTSP protocol port) on the client and port 1230 on the server. The UDP entries create dynamic openings between negotiated data ports on the client (192.168.155.2) and the server (192.168.35.1).

```plaintext
router# show ip access-list
Extended IP access list 100
permit udp host 192.168.155.2 eq 29704 host 192.168.35.1 eq 6976 (182 matches)
permit udp host 192.168.155.2 eq 30616 host 192.168.35.1 eq 6974 (268 matches)
permit udp host 192.168.155.2 eq 26764 host 192.168.35.1 eq 6972 (4 matches)
permit udp host 192.168.155.2 eq 15520 host 192.168.35.1 eq 6970 (12 matches)
permit tcp host 192.168.155.2 eq 554 host 192.168.35.1 eq 1230 (41 matches)
```

After closing the multimedia session, review the session output using the `show` commands to verify the firewall software has removed the dynamic entries from the configuration.
RTSP with RTP (IP/TV)

The following example illustrates the result of the `show ip inspect session` command for RTSP with the Cisco IP/TV application. The output shows that a single control channel (rtsp) and multiple data channels (rtsp-data) are open between hosts 192.168.2.15 and 192.168.102.23. The data channels appear as half-open sessions because the UDP data flows in one direction only, which is from the server to the client.

```
router# show ip inspect session
Established Sessions
Session 611493C0 (192.168.2.15:2571)=>(192.168.102.23:8554) rtsp SIS_OPEN
Half-open Sessions
Session 6114A22C (192.168.102.23:2428)=>(192.168.2.15:20112) rtsp-data SIS_OPENING
Session 6114F44 (192.168.102.23:2428)=>(192.168.2.15:20113) rtsp-data SIS_OPENING
Session 6114A0B8 (192.168.102.23:2429)=>(192.168.2.15:20115) rtsp-data SIS_OPENING
Session 6114A3A0 (192.168.102.23:2429)=>(192.168.2.15:20114) rtsp-data SIS_OPENING
```

The following example illustrates the result of the `show ip access-lists` command. It shows that multiple dynamic entries (permit statements) were added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 554 (RTSP protocol port) on the client and port 1230 on the server. The UDP entries create dynamic openings between negotiated data ports on the client (192.168.2.15) and the server (192.168.102.23).

```
router# show ip access-lists
Extended IP access list 100
permit udp host 192.168.102.23 eq 2428 host 192.168.2.15 eq 20113 (11 matches)
permit udp host 192.168.102.23 eq 2428 host 192.168.2.15 eq 20112 (256 matches)
permit udp host 192.168.102.23 eq 2429 host 192.168.2.15 eq 20115 (11 matches)
permit udp host 192.168.102.23 eq 2429 host 192.168.2.15 eq 20114 (4598 matches)
permit tcp host 192.168.102.23 eq 8554 host 192.168.2.15 eq 2571 (22 matches)
```

After closing the multimedia session, review the session output using the `show` commands to verify that the firewall software has removed the dynamic entries from the configuration.

H.323 V2

The following example illustrates the result of the `show ip inspect session` command for H.323 V2. It shows a single H.323 control channel, an RTP Control Protocol channel for both audio and video data, and an RTP data channel between hosts 192.168.155.2 and 192.168.35.1.

```
Session 615E2688 (192.168.35.1:49609)=>(192.168.155.1:49609) H323-RTCP-audio SIS_OPEN
Session 615E2688 (192.168.35.1:49508)=>(192.168.155.1:49508) H323-RTP-audio SIS_OPEN
Session 615E2688 (192.168.35.1:49611)=>(192.168.155.1:49611) H323-RTCP-video SIS_OPEN
Session 615E1640 (192.168.35.1:4414) => (192.168.155.1:1720) H323 SIS_OPEN
```

The following example illustrates the result of the `show ip access-lists` command. It shows that multiple dynamic entries (permit statements) were added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 1720 (H.323 V2 protocol port) on the client and port 4414 on the server. The UDP entries create dynamic openings between negotiated data ports on the client (192.168.155.1) and the server (192.168.35.1).

```
router# show ip access-lists
Extended IP access list 100
permit udp host 192.168.155.1 eq 49609 host 192.168.155.1 eq 49609 (11 matches)
permit udp host 192.168.155.1 eq 49508 host 192.168.155.1 eq 49508 (256 matches)
permit udp host 192.168.155.1 eq 49411 host 192.168.155.1 eq 49411 (11 matches)
permit udp host 192.168.155.1 eq 49610 host 192.168.155.1 eq 49610 (4598 matches)
permit tcp host 192.168.155.1 eq 4414 host 192.168.35.1 eq 4414 (22 matches)
```
Monitoring and Maintaining CBAC

You can watch for network attacks and investigate network problems using debug commands and system messages. This section has the following sections:

- Debugging Context-Based Access Control
- Interpreting Syslog and Console Messages Generated by CBAC
- Turning Off CBAC

Debugging Context-Based Access Control

To assist CBAC debugging, you can turn on audit trail messages that will be displayed on the console after each CBAC session closes. Audit trail information is also configurable on a per-application basis using the CBAC inspection rules.

To turn on audit trail messages, use the following command in global configuration mode:

```
Router(config)# ip inspect audit-trail
```

If required, you can also use the CBAC `debug` commands listed in this section. (Debugging can be turned off for each of the commands in this section by using the `no` form of the command. To disable all debugging, use the privileged EXEC commands `no debug all` or `undebug all`.)

The following `debug` commands are available:

- Generic Debug Commands
- Transport Level Debug Commands
- Application Protocol Debug Commands

For a complete description of the debug commands, refer to the Cisco IOS Debug Command Reference.

Note: Effective with Cisco IOS Release 12.4(20)T, the `debug ip inspect` command is replaced by the `debug policy-firewall` command. See the Cisco IOS Debug Command Reference for more information.

Generic Debug Commands

You can use the following generic `debug` commands, entered in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>debug ip inspect function-trace</code></td>
<td>Displays messages about software functions called by CBAC.</td>
</tr>
<tr>
<td><code>debug ip inspect object-creation</code></td>
<td>Displays messages about software objects being created by CBAC. Object creation corresponds to the beginning of CBAC-inspected sessions.</td>
</tr>
<tr>
<td><code>debug ip inspect object-deletion</code></td>
<td>Displays messages about software objects being deleted by CBAC. Object deletion corresponds to the closing of CBAC-inspected sessions.</td>
</tr>
</tbody>
</table>
Configuring Context-Based Access Control

Monitoring and Maintaining CBAC

Transport Level Debug Commands

You can use the following transport-level `debug` commands, entered in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router# <code>debug ip inspect events</code></td>
<td>Displays messages about CBAC software events, including information about CBAC packet processing.</td>
</tr>
<tr>
<td>Router# <code>debug ip inspect timers</code></td>
<td>Displays messages about CBAC timer events such as when a CBAC idle timeout is reached.</td>
</tr>
<tr>
<td>Router# <code>debug ip inspect detail</code></td>
<td>Enables the detailed option, which can be used in combination with other options to get additional information.</td>
</tr>
</tbody>
</table>

Application Protocol Debug Commands

You can use the following application protocol `debug` command, entered in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router# <code>debug ip inspect protocol</code></td>
<td>Displays messages about CBAC-inspected protocol events, including details about the protocol’s packets. Refer to Table 26 to determine the protocol keyword.</td>
</tr>
</tbody>
</table>

Table 26 identifies application protocol keywords for the `debug ip inspect` command.

Table 26 Application Protocol Keywords for the `debug ip inspect` Command

<table>
<thead>
<tr>
<th>Application Protocol</th>
<th>Protocol Keyword</th>
</tr>
</thead>
<tbody>
<tr>

Interpreting Syslog and Console Messages Generated by CBAC

CBAC provides syslog messages, console alert messages, and audit trail messages. These messages are useful because they can alert you to network attacks and because they provide an audit trail that provides details about sessions inspected by CBAC. While they are generally referred to as error messages, not all error messages indicate problems with your system.

Audit trail and alert information is configurable on a per-application basis using the CBAC inspection rules.

The following types of messages can be generated by CBAC:

- Denial-of-Service Attack Detection Error Messages
- SMTP Attack Detection Error Messages
- Java Blocking Error Messages
- FTP Error Messages
- Audit Trail Messages

For explanations and recommended actions related to the error messages mentioned in this section, refer to the *Cisco IOS System Error Messages*.

### Denial-of-Service Attack Detection Error Messages

CBAC detects and blocks denial-of-service attacks and notifies you when denial-of-service attacks occur. Error messages such as the following may indicate that denial-of-service attacks have occurred:

%FW-4-ALERT_ON: getting aggressive, count (550/500) current 1-min rate: 250
%FW-4-ALERT_OFF: calming down, count (0/400) current 1-min rate: 0

When %FW-4-ALERT_ON and %FW-4-ALERT_OFF error messages appear together, each “aggressive/calming” pair of messages indicates a separate attack. The preceding example shows one separate attack.

Error messages such as the following may indicate that a denial-of-service attack has occurred on a specific TCP host:

%FW-4-HOST_TCP_ALERT_ON: Max tcp half-open connections (50) exceeded for host 172.21.127.242.
%FW-4-BLOCK_HOST: Blocking new TCP connections to host 172.21.127.242 for 2 minutes (half-open count 50 exceeded)
%FW-4-UNBLOCK_HOST: New TCP connections to host 172.21.127.242 no longer blocked
SMTP Attack Detection Error Messages

CBAC detects and blocks SMTP attacks (illegal SMTP commands) and notifies you when SMTP attacks occur. Error messages such as the following may indicate that an SMTP attack has occurred:

%FW-4-SMTP_INVALID_COMMAND: Invalid SMTP command from initiator (192.168.12.3:52419)

CBAC also detects a limited number of SMTP attack signatures. A signature in a SYSLOG message indicates a possible attack against the protected network, such as the detection of illegal SMTP commands in a packet. Whenever a signature is detected, the connection will be reset.

The Cisco IOS Firewall supports the following SMTP attack signatures:

<table>
<thead>
<tr>
<th>Signature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mail: bad rcpt</td>
<td>Triggers on any mail message with a “pipe” (</td>
</tr>
<tr>
<td>Mail: bad from</td>
<td>Triggers on any mail message with a “pipe” (</td>
</tr>
<tr>
<td>Mail: old attack</td>
<td>Triggers when “wiz” or “debug” commands are sent to the SMTP port.</td>
</tr>
<tr>
<td>Mail: decode</td>
<td>Triggers on any mail message with a “:decode@” in the header.</td>
</tr>
<tr>
<td>Majordomo</td>
<td>A bug in the Majordomo program will allow remote users to execute arbitrary commands at the privilege level of the server.</td>
</tr>
</tbody>
</table>

The following is a sample SMTP attack signature message:

02:04:55: %FW-4-TCP_MAJORDOMO_EXEC_BUG: Sig:3107:Majordomo Execute Attack - from 192.168.25.1 to 192.168.205.1:

Java Blocking Error Messages

CBAC detects and selectively blocks Java applets and notifies you when a Java applet has been blocked. Error messages such as the following may indicate that a Java applet has been blocked:

%FW-4-HTTP_JAVA_BLOCK: JAVA applet is blocked from (172.21.127.218:80) to (172.16.57.30:44673).

FTP Error Messages

CBAC detects and prevents certain FTP attacks and notifies you when this occurs. Error messages such as the following may appear when CBAC detects these FTP attacks:

%FW-3-FTP_PRIV_PORT: Privileged port 1000 used in PORT command -- FTP client 10.0.0.1  FTP server 10.1.0.1
%FW-3-FTP_SESSION_NOT_AUTHENTICATED: Command issued before the session is authenticated -- FTP client 10.0.0.1
%FW-3-FTP_NON_MATCHING_IP_ADDR: Non-matching address 172.19.148.154 used in PORT command -- FTP client 172.19.54.143  FTP server 172.16.127.242
Audit Trail Messages

CBAC provides audit trail messages to record details about inspected sessions. Audit trail information is configurable on a per-application basis using the CBAC inspection rules. To determine which protocol was inspected, use the responder’s port number. The port number follows the responder’s address. The following are sample audit trail messages:

%FW-6-SESS_AUDIT_TRAIL: tcp session initiator (192.168.1.13:33192) sent 22 bytes -- responder (192.168.129.11:25) sent 208 bytes
%FW-6-SESS_AUDIT_TRAIL: http session initiator (172.16.57.30:44673) sent 1599 bytes -- responder (172.21.127.218:80) sent 93124 bytes

Turning Off CBAC

You can turn off CBAC using the no ip inspect global configuration command.

Note

The no ip inspect command removes all CBAC configuration entries and resets all CBAC global timeouts and thresholds to the defaults. All existing sessions are deleted and their associated access lists removed.

In most situations, turning off CBAC has no negative security impact because CBAC creates “permit” access lists. Without CBAC configured, no “permit” access lists are maintained. Therefore, no derived traffic (returning traffic or traffic from the data channels) can go through the firewall. The exception is SMTP and Java blocking. With CBAC turned off, unacceptable SMTP commands or Java applets may go through the firewall.

CBAC Configuration Examples

The following sections provide CBAC configuration examples:

- Ethernet Interface Configuration Example
- ATM Interface Configuration Example
- Remote Office to ISP Configuration Example
- Remote Office to Branch Office Configuration Example
- Two-Interface Branch Office Configuration Example
- Multiple-Interface Branch Office Configuration Example

The first example develops a CBAC inspection rule for specific protocols and a supporting access control list (ACL). This example focuses how to configure CBAC; it does not provide a complete router configuration and does not describe other elements of the configuration.

The next example develops a CBAC inspection rule for sites that might have remote traffic through an ATM interface. This example further illustrates on how to configure CBAC and emphasizes the application of the configuration rule at the interface, whatever that interface might be. This example does not provide a complete router configuration and does not describe other elements of the configuration.

The remote-office examples also focus on the firewall configuration but do not provide detailed descriptions of other configuration elements, such as the Basic Rate Interface (BRI) and dialer interface configurations.
Other examples provide more complete firewall configurations, further illustrating ways in which to apply CBAC.

In each example, configuring protocol inspection using CBAC has four components:

- Defining an access list with the appropriate permissions.
- Applying the ACL at an interface where you want to control access.
- Defining an inspection rule that includes the protocol that you want to inspect.
- Applying the inspection rule at an interface where you want to inspect traffic.

**Ethernet Interface Configuration Example**

This example looks at each of these four components. For this example, CBAC is being configured to inspect RTSP and H.323 protocol traffic inbound from the protected network on a router with two Ethernet interfaces. Interface Ethernet1/0 is the protected network and interface Ethernet1/1 is the unprotected network. The security policy for the protected site uses access control lists (ACLs) to restrict inbound traffic on the unprotected interface to specific ICMP protocol traffic, denying inbound access for TCP and UDP protocol traffic. Inbound access for specific protocol traffic is provided through dynamic access lists, which are generated according to CBAC inspection rules.

ACL 100 denies TCP and UDP traffic from any source or destination while permitting specific ICMP protocol traffic. The final deny statement is not required, but is included for explicitness—the final entry in any ACL is an implicit denial of all IP protocol traffic.

```plaintext
Router(config)# access-list 100 deny tcp any any
Router(config)# access-list 100 deny udp any any
Router(config)# access-list 100 permit icmp any any echo-reply
Router(config)# access-list 100 permit icmp any any time-exceeded
Router(config)# access-list 100 permit icmp any any packet-too-big
Router(config)# access-list 100 permit icmp any any traceroute
Router(config)# access-list 100 permit icmp any any unreachable
Router(config)# access-list 100 deny ip any any
```

ACL 100 is applied inbound at interface Ethernet1/1 to block all access from the unprotected network to the protected network.

```plaintext
Router(config)# interface Ethernet1/1
Router(config-if)# ip access-group 100 in
```

An inspection rule is created for “hqusers” that covers two protocols: RTSP and H.323.

```plaintext
Router(config)# ip inspect name hqusers rtsp
Router(config)# ip inspect name hqusers h323
```

The inspection rule is applied inbound at interface Ethernet1/0 to inspect traffic from users on the protected network. When CBAC detects multimedia traffic from the protected network, CBAC creates dynamic entries in access list 100 to allow return traffic for multimedia sessions.

```plaintext
Router(config)# interface Ethernet1/0
Router(config-if)# ip inspect hqusers in
```

**ATM Interface Configuration Example**

In this example, CBAC inspection (firewall protection) is required against inbound traffic on an ATM interface. This example might apply to sites where local hosts require access to hosts or services on a remote network. The security policy for this site uses access control lists (ACLs) to restrict inbound
traffic on the ATM interface to specific ICMP protocol traffic, denying inbound access for TCP and UDP protocol traffic. Inbound access for specific TCP and UDP protocol traffic is provided through dynamic access lists, which are generated according to CBAC inspection rules.

For information on how to select the interface on which to apply CBAC, refer to the “Picking an Interface: Internal or External” section.

For Frame Relay or ATM interfaces, you can apply CBAC inspection rules separately on each sub-interface, even though the subinterfaces are physically connected through one interface.

```plaintext
! -------------------------
! Create the Inspection Rule
! -------------------------
! Create the CBAC inspection rule "test", allowing inspection of the protocol traffic
! specified by the rule. This inspection rule sets the timeout value to 30 seconds for
! each protocol (except for RPC). The timeout value defines the maximum time that a
! connection for a given protocol can remain active without any traffic passing through
! the router. When these timeouts are reached, the dynamic ACLs that are inserted to
! permit the returning traffic are removed, and subsequent packets (possibly even valid
! ones) are not permitted.
! Create the CBAC inspection rule "test", allowing inspection of the protocol traffic
ip inspect name test cuseeme timeout 30
ip inspect name test ftp timeout 30
ip inspect name test h323 timeout 30
ip inspect name test realaudio timeout 30
ip inspect name test rpc program-number 100000
ip inspect name test streamworks timeout 30
ip inspect name test vdolive timeout 30
!
! ------------------------------
! Create the Access Control List
! ------------------------------
! In this example, ACL 105 denies all TCP and UDP protocol traffic. ICMP traffic from
! subnet 192.168.1.0 is permitted to allow access for routing and control traffic.
! ACL 105 specifies that only the return traffic for protocols defined in the
! inspection rule is allow access through the interface where this rule is applied. The
! final deny statement is added for explicitness.
access-list 105 deny TCP any any
access-list 105 deny UDP any any
access-list 105 permit icmp any any echo-reply
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 time-exceeded
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 packet-too-big
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 traceroute
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 unreachable
access-list 105 deny ip any any
!
! ---------------------------------
! Apply the Inspection Rule and ACL
! ---------------------------------
! In this example, the inspection rule "test" is applied to traffic at interface ATM3/0
! for connections initiated in the outbound direction; that is, from hosts that are
! located on a local network. CBAC creates dynamic access list entries for traffic
! initiated by local hosts. These dynamic entries allow inbound (returning) traffic for
! that connection. ACL 105 is applied at interface ATM3/0 in the inbound direction to
! block traffic initiated from hosts on a remote network that is not part of an
! existing connection.
interface ATM3/0
    ip address 10.1.10.1 255.0.0.0
    ip access-group 105 in
```
Remote Office to ISP Configuration Example

This example describes one possible Cisco IOS Firewall configuration for a remote office router connected to an Internet service provider (ISP). In this configuration, the site security policy allows hosts on the local network to initiate traffic to the ISP while traffic inbound to the router from the ISP is blocked at the ISDN interface. Specific ICMP control message traffic is permitted through the firewall. No mail or Web services are available from the local network. Figure 23 illustrates this example.

![Figure 23 Remote Office to ISP Sample Configuration]

The firewall has two interfaces:

- An Ethernet interface connects to the internal protected network.
  - Interface Ethernet0 has no ACL applied to it, meaning that all traffic initiated on the LAN is allowed access to the ISP. In this configuration example, Network Address Translation (NAT) is not turned on, and the addresses on interface Ethernet0 are reserved IP addresses. In a production environment, addresses on Ethernet0 either must be registered network addresses, or you must turn on NAT to hide these inside addresses from being visible on the Internet.

- An ISDN Basic Rate Interface (BRI) connects the router to the ISP. In this example, a dialer profile is used to control the BRI interface. This means that the ACL and CBAC inspection rules are applied at the dialer interface, not directly at the physical ISDN (BRI) interface using a dialer map.
ip inspect name STOP h323
ip inspect name STOP rcmd

! ---------------------------------
! Create Access Control List 105
! ---------------------------------
! ACL 105 denies all IP protocol traffic except for specific ICMP control traffic.
! This means that only the return traffic for protocols defined in the
! inspection rule and the specified ICMP traffic is allowed access through the
! interface where this rule is applied.
!
! Deny broadcast messages with a source address of 255.255.255.255; this helps to
! prevent broadcast attacks.
access-list 105 deny ip host 255.255.255.255 any
!
! Add anti-spoofing protection by denying traffic with a source address matching a host
! on the Ethernet interface.
acl 105 deny ip 192.168.1.0 0.0.0.255 any
!
! ICMP traffic is not inspected by CBAC. To control the type of ICMP traffic at the
! interface, add static access list entries. This example has the following ICMP
! requirements: outgoing ping commands require echo-reply messages to come back,
! outgoing traceroute commands require time-exceeded messages to come back, path MTU
! discovery requires "too-big" messages to come back, and incoming traceroute
! messages must be allowed. Additionally, permit all "unreachable" messages to come
! back; that is, if a router cannot forward or deliver a datagram, it sends an ICMP
! unreachable message back to the source and drops the datagram.
access-list 105 permit icmp any any echo-reply
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 time-exceeded
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 packet-too-big
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 traceroute
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 unreachable
!
! Final deny for explicitness. This entry is not required but helps complete the access
! list picture. By default, the final entry in any access list is an implicit deny of
! IP protocol traffic. This ensures that the firewall blocks any traffic not explicitly
! permitted by the access list.
access-list 105 deny ip any any
!
! ----------------------------------------------------------
! Configure the interface
! ----------------------------------------------------------
! In this example, no ACLs or inspection rules are applied at interface Ethernet0,
! meaning that all traffic on the local network is allowed to go out. This assumes a
! high-level of trust for the users on the local network.
interface Ethernet0
   ip address 192.168.1.104 255.255.255.0
!
no ip directed-broadcast
!
! This example uses a dialer profile, so the ACL and CBAC inspection rules are applied
! at the dialer interface, not the physical BRI interface. The dialer pool-member
! command is used to associate the physical interface with a dialer profile.
interface BRI0
   no ip address
   no ip directed-broadcast
   encapsulation ppp
dialer pool-member 1
   isdn switch-type basic-5ess
!
! Create the dialer profile.
! Through the dialer profile, the ACL and CBAC inspection rules are
! applied to every pool member. In this example, the ACL is applied in, meaning that it
! applies to traffic inbound from the ISP. The CBAC inspection rule STOP is applied
! out, meaning that CBAC monitors the traffic through the interface and controls return
! traffic to the router for an existing connection.
interface Dialer0
  ip address negotiated
  ip access-group 105 in
  no ip directed-broadcast
  ip inspect STOP out

| ! protocol that triggers dialing.                        |
| dialer-list 1 protocol ip permit                         |
| ! Add a user name (name of the router you are configuring) |
| ! and password for caller identification and password    |
| ! authentication with the ISP router.                     |
| username <router host name> password 5 <elided>          |

Remote Office to Branch Office Configuration Example

This example describes one possible Cisco IOS Firewall configuration for a remote office router
connected to a branch office. In this configuration, the site security policy allows hosts on the local
network to initiate traffic to the branch office. Mail or Web services are available from a server on the local network, and access to these services is available from the branch office. Traffic from the branch office, except for mail and Web traffic, is blocked at the outside interface. Specific ICMP control message traffic is permitted through the firewall. Figure 24 illustrates this example.

Figure 24 Remote Office to Branch Office Sample Configuration

The firewall has two interfaces:
- An Ethernet interface connects to the internal protected network.
Interface Ethernet0 has no ACL applied to it, meaning that all traffic initiated from the LAN is allowed access through the firewall.

- An ISDN Basic Rate Interface (BRI) connects the router to the branch office. In this example, a dialer profile is used to control the BRI interface. This means that the ACL and CBAC inspection rules are applied at dialer interface, not directly at the physical ISDN (BRI) interface.

```plaintext
! -------------------------------------------
! General firewall configuration guidelines
! -------------------------------------------
! The following global configuration entries illustrate good security practices.
enable secret 5 <elided>
no ip source-route
do cdp run

! Create the Inspection Rule
! ---------------------------
! Create the CBAC inspection rule STOP to allow inspection of the specified protocol traffic. Create the inspection rule GO to allow inspection of SMTP traffic.
ip inspect name STOP tcp
ip inspect name STOP ftp
ip inspect name STOP smtp
ip inspect name STOP h323
ip inspect name GO smtp

! Create Access Control Lists 106 and 51
! ---------------------------------------------
! ACL 106 permits mail and Web traffic from any host to the specified server. ACL 106 denies all other ip protocol traffic except for specific ICMP control traffic. This means that only the return traffic for protocols defined in the inspection rule and the specified ICMP traffic is allowed access through the interface where this rule is applied.
!
! Deny broadcast messages with a source address of 255.255.255.255; this helps to prevent broadcast attacks.
access-list 106 deny ip host 255.255.255.255 any

! Add anti-spoofing protection by denying traffic with a source address matching a host on the Ethernet interface.
access-list 106 deny ip 192.168.1.0 0.0.0.255 any

! ICMP traffic is not inspected by CBAC. To control the type of ICMP traffic at the interface, add static access list entries. This example has the following ICMP requirements: outgoing ping commands require echo-reply messages to come back. outgoing traceroute commands require time-exceeded messages to come back, path MTU discovery requires "too-big" messages to come back, and incoming traceroute must be allowed. Additionally, permit all "unreachable" messages to come back; that is, if a router cannot forward or deliver a datagram, it sends an ICMP unreachable message back to the source and drops the datagram.
access-list 106 permit icmp any any echo-reply
access-list 106 permit icmp any 192.168.1.0 0.0.0.255 time-exceeded
access-list 106 permit icmp any 192.168.1.0 0.0.0.255 packet-too-big
access-list 106 permit icmp any 192.168.1.0 0.0.0.255 traceroute
access-list 106 permit icmp any 192.168.1.0 0.0.0.255 unreachable

! Permit mail and Web access to a specific server.
access-list 106 permit tcp any host 192.168.1.20 eq smtp
access-list 106 permit tcp any host 192.168.1.20 eq www

! Final deny for explicitness. This entry is not required but helps complete the access list picture. By default, the final entry in any access list is an implicit deny of IP protocol traffic. This ensures that the firewall blocks any traffic not explicitly
permitted by the access list.
access-list 106 deny ip any any
!
! Configuring the interface.
! ----------------------------------------------------------
! In this example, no ACLs or inspection rules are applied at interface Ethernet0, meaning that all traffic on the local network is allowed to go out. This assumes a high-level of trust for the users on the local network.
interface Ethernet0
  ip address 192.168.1.104 255.255.255.0
  no ip directed-broadcast
!
! This example uses a dialer profile, so the ACL and CBAC inspection rules are applied at the dialer interface, not the physical BRI interface. The dialer pool-member command is used to associate the physical interface with a dialer profile.
interface BRI0
  no ip address
  no ip directed-broadcast
  encapsulation ppp
  dialer pool-member 1
  isdn switch-type basic-5ess
!
! Apply the ACL and CBAC inspection rules at the dialer interface.
! ----------------------------------------------------------
! Through the dialer profile, the ACL and CBAC inspection rules are applied to every pool member. In this example, the ACL is applied in, meaning that it applies to traffic inbound from the branch office. The CBAC inspection rule STOP is applied out, meaning that CBAC monitors the traffic and controls return traffic to the router for an existing connection. The CBAC inspection rule GO is applied in, protecting against certain types of DoS attacks as described in this document. Note that the GO inspection rule does not control return traffic because there is no ACL blocking traffic in that direction; however, it does monitor the connections.
interface Dialer0
  ip address <ISDN interface address>
  ip access-group 106 in
  no ip directed-broadcast
  ip inspect STOP out
  ip inspect GO in

username <router host name> password 5 <elided>
Two-Interface Branch Office Configuration Example

This sample configuration file describes a firewall configured with CBAC. The firewall is positioned between a protected field office’s internal network and a WAN connection to the corporate headquarters. CBAC is configured on the firewall in order to protect the internal network from potential network threats coming from the WAN side.

The firewall has two interfaces configured:

- Interface Ethernet0 connects to the internal protected network
- Interface Serial0 connects to the WAN with Frame Relay

! ----------------------------------------------------------------------
! This first section contains some configuration that is not required for CBAC,
! but illustrates good security practices. Note that there are no
! services on the Ethernet side. Email is picked up via POP from a server on the
! corporate side.
! ----------------------------------------------------------------------
!
hostname user1-examplecorp-fr
!
boot system flash c1600-fw1600-l
enable secret 5 <elided>
!
username user1 password <elided>
ip subnet-zero
no ip source-route
ip domain-name example.com
ip name-server 172.19.2.132
ip name-server 198.92.30.32
!
!
! -----------------------------------------------------------------------
! The next section includes configuration required specifically for CBAC.
! -----------------------------------------------------------------------
!
! The following commands define the inspection rule "myfw", allowing
! the specified protocols to be inspected. Note that Java applets will be permitted
! according to access list 51, defined later in this configuration.
ip inspect name myfw cuseeme timeout 3600
ip inspect name myfw ftp timeout 3600
ip inspect name myfw http java-list 51 timeout 30
ip inspect name myfw rcmd timeout 3600
ip inspect name myfw realaudio timeout 3600
ip inspect name myfw smtp timeout 3600
ip inspect name myfw tftp timeout 30
ip inspect name myfw udp timeout 15
ip inspect name myfw tcp timeout 3600
!
! The following interface configuration applies the "myfw" inspection rule to
! inbound traffic at Ethernet 0. Since this interface is on the internal network
! side of the firewall, traffic entering Ethernet 0 is actually
! exiting the internal network. Applying the inspection rule to this interface causes
! inbound traffic (which is exiting the network) to be inspected; return traffic will
! only be permitted back through the firewall if part of a session which began from
! within the network.
! Also note that access list 101 is applied to inbound traffic at Ethernet 0.
! (Traffic blocked by the access list will not be inspected.)
interface Ethernet0
description ExampleCorp Ethernet chez user1
ip address 172.19.139.1 255.255.255.248
ip broadcast-address 172.19.131.7

!
! The following access list defines "friendly" and "hostile" sites for Java
! applet blocking. Because Java applet blocking is defined in the inspection
! rule "myfw" and references access list 51, applets will be actively denied
! if they are from any of the "deny" addresses and allowed only if they are from
! either of the two "permit" networks.
!
access-list 51 deny 172.19.1.203
access-list 51 deny 172.19.2.147
access-list 51 permit 172.18.0.0 0.1.255.255
access-list 51 permit 192.168.1.0 0.0.0.255
access-list 51 deny any
!
! The following access list 101 is applied to interface Ethernet 0 above.
! This access list permits all traffic that should be CBAC inspected, and also
! provides anti-spoofing. The access list is deliberately set up to deny unknown
! IP protocols, because no such unknown protocols will be in legitimate use.
!
access-list 101 permit tcp 172.19.139.0 0.0.0.7 any
access-list 101 permit udp 172.19.139.0 0.0.0.7 any
access-list 101 permit icmp 172.19.139.0 0.0.0.7 any
access-list 101 deny ip any any
!
! The following access list 111 is applied to interface Serial 0.1 above.
! This access list filters traffic coming in from the external side. When
! CBAC inspection occurs, temporary openings will be added to the beginning of
! this access list to allow return traffic back into the internal network.
! This access list should restrict traffic that will be inspected by
! CBAC. (Remember that CBAC will open holes as necessary to permit returning traffic.)
! Comments precede each access list entry. These entries are not all specifically
! related to CBAC, but are created to provide general good security.
! Anti-spoofing.
access-list 111 deny ip 172.19.139.0 0.0.0.7 any
! Sometimes EIGRP is run on the Frame Relay link. When you use an
! input access list, you have to explicitly allow even control traffic.
! This could be more restrictive, but there would have to be entries
! for the EIGRP multicast as well as for the office’s own unicast address.
access-list 111 permit igmp any any
!
! These are the ICMP types actually used...
! administratively-prohibited is useful when you are trying to figure out why
! you cannot reach something you think you should be able to reach.
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 administratively-prohibited
!
! This allows network admins at headquarters to ping hosts at the field office:
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 echo
!
! This allows the field office to do outgoing pings
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 echo-reply
!
! Path MTU discovery requires too-big messages
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 packet-too-big
!

Multiple-Interface Branch Office Configuration Example

In this configuration example, a single Cisco 3600 series firewall router is positioned at a branch office. It has four internal networks and two WAN connections to the corporate headquarters. CBAC is configured on the firewall to protect two of the internal networks from potential network threats coming from the WAN side and from less secure internal networks. Anti-spoofing protection is added at each interface with client systems. Figure 25 illustrates this configuration.

Note

This example shows a moderately high level of trust by the administrators toward the expected users. Additional protection could be added to this configuration for a situation in a lower level of trust. That configuration would include ICMP filtering statements, significantly more protocol and address control through the use of more restrictive access control lists, and anti-spoofing applied everywhere. This configuration does not contain those additional restrictions because that would detract from the CBAC example.
The branch office has this sample network configuration:

- Ethernet interface 0/0 supports the Human Resources department servers. This network includes an email (SMTP and POP3) host and a Windows NT server. The Windows NT server is the Primary Domain Controller (PDC) for the Human Resources domain and has a trust relationship with the rest of the company; however, it contains applications and databases that must not be accessed by the rest of the company or the other groups in the branch office. The devices on this LAN are accessible only by users in the Human Resources department on Ethernet interface 0/1. The Mail server must be able to send and receive email (through SMTP sessions) with all other devices. The Windows 95 machines can use this machine as their email server (for sending email through SMTP sessions) and as a repository for accumulating email that they can then download through POP3 sessions. No one else in the company is allowed to form POP3 sessions to any machine on this LAN.

- Ethernet interface 0/1 supports the Human Resources department PCs. These users must have access to the Human Resources mail servers located on Ethernet interface 0/0 as well as access to the rest of the company. Access to the Windows NT server resources are controlled through the Windows NT permissions assigned to each user in the Windows NT domain.

- Ethernet interface 1/0 supports the branch office web servers, which can be accessed by everyone in the company. These servers use TCP ports 80 (HTTP) and 443 (SHTTP) for inbound Web access. This network also includes a backup domain controller (BDC) for the overall domain that is also used as file, print, and service server.
Ethernet interface 1/1 supports all users who are not in the Human Resources department. These users have no access to the Human Resources department servers, but they can access the other network interfaces and the serial interfaces for WAN connectivity. Serial interface 0/0 and 0/1 connect to the WAN with T1 links (links to corporate headquarters). In this sample configuration, the Domain Name System (DNS) servers are located somewhere within the rest of the company.

Additionally, network management (SNMP) and Telnet sessions are limited to the management network (192.168.55.0), which is located somewhere within the rest of the company across the serial interface.

```
! This first section contains some configuration that is not required for CBAC, but illustrates good security practices.
! Add this line to get timestamps on the syslog messages.
service timestamps log datetime localtime show-timezone

enable secret 5 <elided>
ip subnet-zero
!
! Disable source routing to help prevent spoofing.
no ip source-route
!
! Set up the domain name and server IP addresses.
ip domain-name example.com
ip name-server 192.168.55.132
ip name-server 192.168.27.32
!
! The audit-trail command enables the delivery of specific CBAC messages through the syslog notification process.
ip inspect audit-trail
!
! Establish the time-out values for DNS queries. When this idle-timer expires, the dynamic ACL entries that were created to permit the reply to a DNS request will be removed and any subsequent packets will be denied.
ip inspect dns-timeout 10
!
! The next section includes configuration statements required specifically for CBAC.
!
! Define the CBAC inspection rule “inspect1”, allowing the specified protocols to be inspected. The first rule enables SMTP specific inspection. SMTP inspection causes the exchange of the SMTP session to be inspected for illegal commands. Any packets with illegal commands are dropped, and the SMTP session will hang and eventually time out.
ip inspect name inspect1 smtp timeout 30
!
! In the next two lines of inspect1, define the maximum time that each of the UDP and TCP sessions are allowed to continue without any traffic passing through the router. When these timeouts are reached, the dynamic ACLs that are inserted to permit the returning traffic are removed and subsequent packets (possibly even valid ones) will not be permitted.
ip inspect name inspect1 udp timeout 30
ip inspect name inspect1 tcp timeout 30
```
Define the CBAC inspection rule "inspect2", allowing the specified protocols to be inspected. These rules are similar to those used in the inspection rule "inspect1," except that on the interfaces where this rule is applied, SMTP sessions are not expected to go through; therefore, the SMTP rule element is not applied here.

ip inspect name inspect2 udp timeout 30
ip inspect name inspect2 tcp timeout 30

The next section shows the Ethernet interface configuration statements for each interface, including access lists and inspections rules.

Apply the "inspect1" inspection rule to sessions that are initiated in the outbound direction (toward the LAN) at Ethernet interface 0/0. All packets in these sessions will be inspected by CBAC. Provided that network traffic passes the Access Control List (ACL) restrictions, traffic is then inspected by CBAC for access through the Cisco Secure Integrated Software. Traffic blocked by the access list is not inspected by CBAC. Access list 110 is applied to outbound traffic on this interface.

The next section shows the Ethernet interface configuration statements for each interface, including access lists and inspections rules.

Apply access list 120 to inbound traffic on Ethernet interface 0/1. Applying access list 120 to inbound traffic provides anti-spoofing on this interface by dropping traffic with a source address matching the IP address on a network other than Ethernet 0/1. The IP helper address lists the IP address of the DHCP server on Ethernet interface 1/0.

Apply the "inspect2" inspection rule to sessions that are initiated in the outbound direction (toward the LAN) at Ethernet interface 1/0. Provided that network traffic passes the Access Control List (ACL) restrictions, traffic is then inspected by CBAC through the Cisco Secure Integrated Software. Traffic blocked by the access list is not inspected by CBAC. Access list 130 is applied to outbound traffic on this interface.

Apply access list 140 to inbound traffic at Ethernet interface 1/1. This provides anti-spoofing on the interface by dropping traffic with a source address matching the IP address of a network other than Ethernet 1/1. The IP helper address lists the IP address of the DHCP server on Ethernet interface 1/0.
no ip directed-broadcast

Cisco IOS Firewall Performance Improvements

Feature History

<table>
<thead>
<tr>
<th>Release</th>
<th>Modification</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.2(8)T</td>
<td>This feature was introduced.</td>
</tr>
</tbody>
</table>

This document describes the Cisco IOS Firewall Performance Improvements feature in Cisco IOS Release 12.2(8)T. It includes the following sections:

- Feature Overview, page 1
- Supported Platforms, page 3
- Supported Standards, MIBs, and RFCs, page 3
- Configuration Tasks, page 4
- Configuration Examples, page 4
- Command Reference, page 5

Feature Overview

The Cisco IOS Firewall Performance Improvements feature introduces three performance metrics for Context-Based Access Control (CBAC)—Throughput Improvement, Connections Per Second Improvement, and CPU Utilization Improvement.

CBAC is a context-based firewall that performs the following:

- Inspects traffic in one direction for network, transport, and application layer information
- Extracts relevant port information
- Dynamically creates access list entries for return traffic
- Closes ports at the end of a connection

CBAC also forces protocol conformance for some protocols, has a limited vulnerability signature detection mechanism, and extensive denial-of-service (DOS) prevention mechanisms. However, many of these features are CPU intensive, thereby, adversely affecting the performance of the router. The router is also affected during times of heavy traffic due to the processing of the base engine itself. With this feature, the performance of the router running CBAC is no longer subdued.
Throughput Improvement

Throughput is a metric defined by the number of packets transferred from the input interface to the output interface within 1 second by a router running CBAC. When the CBAC base engine inspects packets that belong to an existing session, it must find out which session the packet belongs to; thus, the base engine implements a hash table to search for the session of the packet.

Collisions in a hash table result in poor hash function distribution because many entries are hashed into the same bucket for certain patterns of addresses. Even if a hash function distribution evenly dispenses the input across all of the buckets, a small hashtable size will not scale well if there are a large number of sessions. As the number of sessions increase, the collisions increase, which increases the length of the linked lists, thereby, deteriorating the throughput performance.

The Cisco IOS Firewall Performance Improvements feature allows users to dynamically change the size of the session hash table without reloading the router by using the `ip inspect hashtable` command. By increasing the size of the hash table, the number of sessions per hash bucket can be reduced, which improves the throughput performance of the base engine.

Connections Per Second Improvement

Connections per second is a metric defined by the number of short-lived connections that can be created and deleted within 1 second by a router running CBAC. (These connections apply only to TCP connections because UDP is a connectionless protocol.)

Initially, CBAC had several restrictions that limited the connections per second metric. While a packet was being processed for connection setup and connection teardown of TCP connections, the base engine (which allocates and de-allocates memory while processing packets) would “bump up” several packets to the process switching path. Bumping up these packets drastically slowed down their processing. Also, the base engine had to process each packet again when it was bumped up into the process switching path, which also contributed to the degrading performance.

The Cisco IOS Firewall Performance Improvements feature prevents these restrictions by allowing only the first packet of any connection to be bumped up to the process switching path while the remaining packets are processed by the base engine in the fast path. Thus, the base engine is no longer slowed down by bumping up several packets or by processing packets twice.

---

Note

In this document, a connection is defined as creating a session, sending a data packet, and immediately deleting a session.

CPU Utilization Improvement

The CPU utilization of the router running CBAC can be measured while a specific throughput or connections per second metric is maintained. This improvement is used in conjunction with the throughput and connections per second metrics.
Benefits

Layer 4 Processing Performance Improvement
This enhancement improves the connections per second metric and the CPU utilization. The code path for connection initiation and teardown was rewritten, thereby, enabling quicker creation of the connections per second metric, which reduces CPU utilization per connection.

Hash Table Function Performance Improvement
With this enhancement, the hash function has been rewritten to ensure better distribution. This newly improved feature allows users to dynamically configure the size of the session hash table from 1K to 8K. When a packet belonging to an existing session comes into the router, a hash table is used to map the packet to an existing firewall session. As the number of sessions increases, the number of sessions hashing into the same bucket increases if the size of the hash table is fixed. By allowing the user to change the size of the hash table when the number of concurrent sessions increases or to reduce the search time for the session, the throughput performance of the base engine is greatly improved.

Application Module Tuning Performance Improvement
This enhancement makes changes to application modules, ensuring that only the connection-initiating packet from all the packets belonging to the connection initiation and teardown is bumped up to the process switching path. Thus, the connections per second metric is significantly improved.

Restrictions

To benefit from the performance enhancements, your router must be running CBAC.

Supported Platforms

Cisco IOS Firewall is not supported on all hardware platforms. Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Catalyst OS, and Cisco IOS XE software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Supported Standards, MIBs, and RFCs

Standards
None

MIBs
None
To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:

RFCs
None

Configuration Tasks

See the following sections for configuration tasks for the Cisco IOS Firewall Performance Improvements feature. Each task in the list is identified as either required or optional.

- Changing the Size of the Hash Table (required)
- Verifying CBAC Configurations (optional)

Changing the Size of the Hash Table

You can increase the hash table to improve packet distribution. To change the size of the session hash table, use the following command in global configuration mode:

```
Router# ip inspect hashtable number
```

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router# ip inspect hashtable number</td>
<td>Changes the size of the hash table. number specifies the size of the hash table in terms of buckets. Possible values for the hash table are 1024, 2048, 4096, and 8192; the default value is 1024.</td>
</tr>
</tbody>
</table>

Note You should increase the hash table size when the total number of sessions running through the CBAC router is approximately twice the current hash size; decrease the hash table size when the total number of sessions is reduced to approximately half the current hash size. Essentially, try to maintain a 1:1 ratio between the number of sessions and the size of the hash table.

Verifying CBAC Configurations

To verify all CBAC configurations and all existing sessions that are currently being tracked and inspected by CBAC, use the `show ip inspect all` command in EXEC mode.

Configuration Examples

This section provides the following configuration example:

- Changing the Size of the Hash Table Example
Changing the Size of the Hash Table Example

The following example shows how to change the size of the hash table to 2048 buckets:

ip inspect hashtable 2048

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

- ip inspect hashtable
E-mail Inspection Engine

The E-mail Inspection Engine feature allows the Cisco IOS Firewall to inspect Post Office Protocol 3 (POP3) and Internet Message Access Protocol (IMAP) e-mail, in addition to Simple Mail Transfer Protocol (SMTP) and Extended Simple Mail Transfer Protocol (ESMTP) e-mail which were previously supported.

The `secure-login` enhancement allows people to download external POP3 e-mail only if authentication methods are secure.

Prerequisites for E-mail Inspection Engine

- Configure CBAC.
- Enable SSL VPN tunnels.

Restrictions for E-mail Inspection Engine

None.

Information About E-mail Inspection Engine

To configure E-mail Inspection Engine, you need to understand the following concepts:

- E-mail Inspection Engine Operation, page 2
- Inspection, page 3
- POP3, page 3
- IMAP Protocol, page 3
- Client Command Validation, page 4
- SMTP, page 4
- SSL, page 4

E-mail Inspection Engine Operation

The client/server communication is validated from the time the TCP connection is initialized until the client is authenticated. The Cisco IOS Firewall uses a state router to track each stage of authentication. After the client is authenticated, the Cisco IOS Firewall allows all the client/server commands without further L7 inspection. TCP L4 inspection continues until the connection is closed. At the end of the e-mail session when the client host quits and before the TCP connection is closed, no further client/server interaction is allowed unless the client is reauthenticated.

During the authentication, any unrecognized command causes the Cisco IOS Firewall to drop the packet and close the connection.

If encryption is negotiated between the client and server control channel, no further validation occurs. An e-mail client logging in from a nonsecure location may need to use encryption for authentication. For information about secure logins, see the description of the secure-login keyword of the ip inspect name command.
Inspection

Context Based Access Control (CBAC) inspects traffic that travels through the firewall to discover and manage state information for TCP and User Datagram Protocol (UDP) sessions. This state information is used to create temporary openings in the firewall’s access lists to allow return traffic and additional data connections for permissible sessions.

Inspecting packets at the application layer and maintaining TCP and UDP session information provides CBAC with the ability to detect and prevent certain types of network attacks such as SYN-flooding. A SYN-flood attack occurs when a network attacker floods a server with a barrage of requests for connection and does not complete the connection. The resulting volume of half-open connections can overwhelm the server, causing it to deny service to valid requests. Network attacks that deny access to a network device are called denial-of-service (DoS) attacks.

POP3

The Post Office Protocol, Version 3 (POP3) is used to receive e-mail that is stored on a mail server. Unlike IMAP, POP only retrieves mail from a remote host.

POP3 works best when there is only one computer because it supports “offline” message access where messages are downloaded and then deleted from the mail server. This mode of access is not compatible with access from multiple computers because it tends to sprinkle messages across all the computers used for mail access.

With POP3-based e-mail clients, messages are downloaded to the user’s local message store and can also be deleted from the mail server. Deletion is optional in most clients. When a new voice message arrives, the subscriber’s only immediate notification is the activation of the MWI on the phone. New messages are displayed in the Inbox only after the client’s local message store is updated with the Exchange message store. After the subscriber downloads new messages, the message state automatically changes from “new” to “read” on the server, even though the subscriber has not actually listened to the voice messages. MWIs on the subscriber’s phone are extinguished, and the message state between the TUI and the subscriber’s Inbox are not synchronized.

IMAP Protocol

The Internet Message Access Protocol (IMAP) is a method of accessing electronic mail or bulletin board messages that are kept on a mail server that may be shared. It permits a “client” e-mail program to access remote messages as though they were local. For example, e-mail stored on an IMAP server can be retrieved, sent, and managed from a desktop computer at home, from a workstation at the office, or from a laptop without transferring messages or files back and forth between the computers.

Only the message header and sender information are displayed in the Inbox until the user downloads the entire message, including attachments, from the server. When a new voice message arrives, the subscriber’s only immediate notification is the activation of the Message Waiting Indication (MWI) on the phone. New messages are displayed in the Inbox only after the client’s local message store is updated with the Exchange message store. When the subscriber listens to a new message by using the telephone user interface (TUI), the MWI is extinguished. In this case again, the message state is not updated in the Inbox until the client’s message store is refreshed. However, if the subscriber uses an installed multimedia player to listen to the WaveForm Audio (WAV) attachment from the e-mail client’s Inbox, message state changes are automatically synchronized with the TUI.
How message state changes are conveyed to the Cisco Unity subscriber, and how these changes are synchronized with the TUI, depend on whether the subscriber's e-mail client is configured to use POP3 or IMAP4 to access Exchange.

Client Command Validation

The Cisco IOS Firewall authenticates an e-mail client accessing an IMAP or POP3 server before allowing complete access into the server. The firewall searches the IMAP/POP3 TCP stream for valid protocol commands. If the client’s commands are outside the protocol’s definition, the Cisco IOS Firewall drops the packets and resets the connection.

Client command validation is typically needed in a DeMilitarized Zone (DMZ). Client access is allowed into the DMZ only if the e-mail server validates the user authentication. After the client is authenticated, the client becomes a trusted user and access is permitted.

SMTP

The Simple Mail Transfer Protocol (SMTP) is used to transfer e-mail between servers and clients on the Internet. E-mail clients and mail servers that use protocols other than Message Application Programming Interface (MAPI) can use the SMTP protocol to transfer a message from a client to the server, and then forward it to a message recipient’s server. To retrieve, send, and manage these messages from the e-mail client use POP3 or IMAP4.

Cisco Unity uses SMTP to route voice messages via the Internet Voice Connector (IVC) gateway between other Exchange servers that are not connected by using a Site Message Connector. There is an IVC gateway on either end of the SMTP connection between Exchange servers. This ensures that MAPI message attributes survive the outbound transit between SMTP connections. It also ensures that the MIME-encoded attributes survive the inbound transit, and are included with the message stored in the Exchange message store.

SSL

The Secure Socket Layer (SSL) protocol is the standard protocol that delivers secure content over the Internet. It is a point-to-point security protocol that secures communication between a client and a server. SSL usually does not require a special client (that is, a Web browser often will suffice) and it does not require any additional operating system software.

SSL includes client and server authentication and data encryption for a limited set of applications (for example, the Web, e-mail, news, and file transfer). SSL is useful for securing e-commerce transactions over the Internet, and the protocol is well suited for extranets and remote access because it is relatively simple to deploy.

How to Configure E-mail Inspection Engine

This section contains the following procedures:

- Configuring Firewall Inspection of POP3 or IMAP E-mail, page 5 (required)
- Verifying the E-mail Inspection Engine Configuration, page 6 (optional)
Configuring Firewall Inspection of POP3 or IMAP E-mail

To allow the Cisco IOS Firewall to inspect POP3 or IMAP e-mail, perform the following steps.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip inspect name inspection-name protocol [alert {on | off}] [audit-trail {on | off}] [reset] [secure-login] [timeout seconds]
4. interface type slot/port
5. ip inspect name inspection-name {in | out}
6. exit
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 enable     | Enables privileged EXEC mode.  
  - Enter your password if prompted. |
| Example:          |         |
| Router> enable    |         |
| Step 2 configure terminal | Enters global configuration mode. |
| Example:          |         |
| Router# configure terminal |         |
| Step 3 ip inspect name inspection-name protocol [alert (on | off)] [audit-trail (on | off)][reset] [secure-login] [timeout seconds] | Defines a set of inspection rules. |
| Example:          |         |
| Router(config)# ip inspect name mail-guard pop3 |         |
| Step 4 interface type slot/port | Configures an interface type. |
| Example:          |         |
| Router(config-if)# interface 1/0 |         |
| Step 5 ip inspect name inspection-name (in | out) | Enables the Cisco IOS Firewall on an interface. |
| Example:          |         |
| Router(config-if)# ip inspect name mail-guard in |         |
| Step 6 exit       | Exits interface configuration mode and returns to global configuration mode. |
| Example:          |         |
| Router(config-if)# exit |         |

Verifying the E-mail Inspection Engine Configuration

To verify the E-mail Inspection Engine configuration, perform the following steps.

Note: Effective with Cisco IOS Release 12.4(20)T, the debug ip inspect command is replaced by the debug policy-firewall command. See the Cisco IOS Debug Command Reference for more information.

SUMMARY STEPS

1. `debug ip inspect imap`
2. `debug ip inspect pop3`
3. `show ip inspect {name inspection-name | config | interfaces | session [detail] | all}`
### DETAILED STEPS

**Step 1**
**debug ip inspect imap**

Use this command to display messages about Cisco IOS Firewall events related to IMAP protocol e-mail messages.

```
Router# debug ip inspect imap
```

**Step 2**
**debug ip inspect pop3**

Use this command to display messages about Cisco IOS Firewall events related to POP3 protocol e-mail messages.

```
Router# debug ip inspect pop3
```

**Step 3**
**show ip inspect {name inspection-name | config | interfaces | session [detail] | all}**

Use this command to view CBAC configuration and session information.

```
Router# show ip inspect
```

- Session audit trail is disabled
- one-minute (sampling period) thresholds are [400:500] connections
- max-incomplete sessions thresholds are [400:500]
- max-incomplete tcp connections per host is 50. Block-time 0 minute.
- tcp synwait-time is 30 sec -- tcp finwait-time is 5 sec
- tcp idle-time is 3600 sec -- udp idle-time is 30 sec
- dns-timeout is 5 sec

**Inspection Rule Configuration**

Inspection name mail-guard
- tcp timeout 3600
- tdp timeout 30
- ftp timeout 3600

---

### Configuration Examples for E-mail Inspection Engine

- **Configuring IMAP and POP3 Protocol E-mail: Example, page 7**

### Configuring IMAP and POP3 Protocol E-mail: Example

The following example configures the Cisco IOS Firewall inspection of IMAP and POP3 protocol e-mail:

```
configure terminal
ip inspect name mail-guard pop3
ip inspect name mail-guard imap
exit
```

The following commands enable this functionality on an interface:

```
configure terminal
interface 1/0
ip inspect name mail-guard in
exit
```
Additional References

The following sections provide references related to E-Mail Inspection Engine.

- debug ip inspect
- ip inspect name
- show ip inspect
**Glossary**

**authentication**—Process during which any unrecognized command causes the Cisco IOS Firewall to drop the packet and close the connection.

**CBAC**—Context-Based Access Control. A Cisco IOS Firewall set feature that scrutinizes source and destination addresses to enhance security for TCP and UDP applications that use well-known ports, such as FTP and e-mail traffic.

**ESMTP**—Extended Simple Mail Transfer Protocol. An extended version of the Simple Mail Transfer Protocol (SMTP), which includes additional functionality, such as delivery notification and session delivery.

**IMAP**—Internet Message Access Protocol. A method of accessing e-mail or bulletin board messages kept on a mail server that can be shared. IMAP permits client e-mail applications to access remote message stores as if they were local without actually transferring the message.

**POP**—Post Office Protocol. A protocol that client e-mail applications use to retrieve mail from a mail server.

**SMTP**—Simple Mail Transfer Protocol. An Internet protocol providing e-mail services.

**SSL**—Secure Socket Layer Protocol. This protocol is used to deliver secure information over the Internet.

**state router**—A router that tracks the client/server commands until the client is authenticated.

**TCP**—Transmission Control Protocol. A connection-oriented transport layer protocol that provides reliable full-duplex data transmission. TCP is part of the TCP/IP protocol stack.

**UDP**—User Datagram Protocol. A connectionless transport-layer protocol for exchanging datagrams without acknowledgments or guaranteed delivery.

**VPN**—Virtual Private Network. A network that enables IP traffic to travel securely over a public TCP/IP network by encrypting all traffic from one network to another. A VPN network uses “tunneling” to encrypt all information at the IP level.

Note

Refer to *Internetworking Terms and Acronyms* for terms not included in this glossary.

ESMTP Support for Cisco IOS Firewall

The ESMTP Support for Cisco IOS Firewall feature enhances the Cisco IOS Firewall to support Extended Simple Mail Transport Protocol (ESMTP), allowing customers who install mail servers behind Cisco IOS firewalls to install their servers on the basis of ESMTP (instead of Simple Mail Transport Protocol [SMTP]).

Feature History for ESMTP Support for Cisco IOS Firewall

Prerequisites for ESMTP Support for Cisco IOS Firewall

To enable this feature, your Cisco IOS image must contain the Cisco IOS firewall.
Information About ESMTP Support for Cisco IOS Firewall

To configure a Cisco IOS firewall to inspect an ESMTP session and command sequence, you should understand the following concepts:

- SMTP Functionality Overview, page 2
- ESMTP Overview, page 3
- SMTP Firewall and ESMTP Firewall Comparison, page 3

SMTP Functionality Overview

SMTP inspection provides a basic method for exchanging e-mail messages. Figure 26 and the following steps outline a basic SMTP session.

4. The client establishes a TCP connection with the server.
5. The client sends a HELO command with its domain name. If the server can accept mail from that domain name, it responds with a 250 reply code, which allows the client to continue with the mail transaction. (If the server does not respond with a 250 reply code, the client will send a QUIT command and terminate the TCP session.)
6. The client sends the MAIL command, indicating who initiated the mail. If the server accepts the mail, it responds with an OK reply. Then, the client sends the RCPT command, identifying the recipient of the mail. If the server accepts mail for the specified recipient, it responds with an OK reply; if the server cannot accept mail for the specified recipient, it rejects the recipient but not the entire transaction. (Several recipients can be negotiated.)
7. After the list of recipients has been negotiated between the client and the server, the client sends a DATA command. If the server is ready to receive data, it responds with a 354 reply code. If the server is not ready to receive data, it responds with an error reply, and the client terminates the transaction.
8. The client sends mail data ending with a special sequence. When the server sees the end of the message, it sends a 250 code reply.
9. The client sends a QUIT command, waits for the server to respond, then terminates the session.
ESMTP Overview

Like SMTP, ESMTP inspection provides a basic method for exchanging e-mail messages. Although an ESMTP session is similar to SMTP, there is one difference—the EHLO command.

After the TCP connection has been established between the client (the ESMTP sender) and the server (the ESMTP receiver), the client sends the EHLO command (instead of the HELO command that is used for SMTP). If the server does not support ESMTP, it sends a failure reply to the client because it did not recognize the EHLO command. If it supports ESMTP, the server responds with the code 250 and a list of extensions that the server supports. (Refer to RFC 1869 for an explanation of the extensions that your server may support.)

The server may send any of the following error codes if it supports ESMTP but is unable to function as normal:

- Error code 501—The server recognizes the EHLO command but is unable to accept it.
- Error code 502—The server recognizes the EHLO command but does not implement it.
- Error code 554—The server is unable to list the service extensions it supports.

If the client receives any of these error codes, it should issue the HELO command to revert to SMTP mode or issue the QUIT command to end the session.

After the client receives a successful response to the EHLO command, it will work the same way as SMTP, except that the client may issue new extended commands, and it may add a few parameters to the MAIL FROM and REPT TO commands.

SMTP Firewall and ESMTP Firewall Comparison

Although a SMTP firewall and an ESMTP firewall support the same functionality—command inspection, session conversion, and Intrusion Detection System (IDS) detection—slight variations exist between the protocols. Table 27 explains the firewall functionality and protocol-specific differences.
**Table 27  SMTP and ESMTP Firewalls Functionality Comparison**

<table>
<thead>
<tr>
<th>Functionality</th>
<th>SMTP Firewall Description</th>
<th>ESMTP Firewall Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command Inspection</td>
<td>The SMTP firewall inspects commands for illegal commands. Illegal commands found in a packet are modified to an “xxxx” pattern and forwarded to the server. This process causes the server to send a negative reply, forcing the client to issue a valid command. An illegal SMTP command is any command except the following: DATA, HELO, HELP, MAIL, NOOP, QUIT, RCPT, RSET, SAML, SEND, SOML, and VRFY.</td>
<td>ESMTP command inspection is the same as SMTP command inspection, except that ESMTP supports three additional commands—AUTH, EHLO, and ETRN. An illegal ESMTP command is any command except the following: AUTH, DATA, EHLO, ETRN, HELO, HELP, MAIL, NOOP, QUIT, RCPT, RSET, SAML, SEND, SOML, and VRFY.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> Prior to Cisco IOS Release 12.3(7)T, an SMTP firewall will reset the TCP connection upon detection of an illegal command. That is, an SMTP firewall no longer resets the TCP connection upon detecting an illegal command.</td>
<td></td>
</tr>
<tr>
<td>Parameter Inspection</td>
<td>Not applicable.</td>
<td>The ESMTP firewall inspects the following extensions by performing deeper command inspection:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Message Size Declaration (SIZE)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Remote Queue Processing Declaration (ETRN)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Binary MIME (BINARYMIME)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Command Pipelining</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Authentication</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Delivery Status Notification (DSN)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Enhanced Status Code (ENHANCEDSTATUSCODE)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 8bit-MIMEtransport (8BITMIME)</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note</strong> All other extensions, including private extensions, are not supported.</td>
</tr>
</tbody>
</table>
### Table 27  
**SMTP and ESMTP Firewalls Functionality Comparison (continued)**

<table>
<thead>
<tr>
<th>Functionality</th>
<th>SMTP Firewall Description</th>
<th>ESMTP Firewall Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EHLO Inspection</td>
<td>Not applicable.</td>
<td>The ESMTP firewall inspects the EHLO reply, which contains a list of SMTP extensions that the server supports. Any unsupported extension that is found in the server’s reply will be replaced with the “XXXX” pattern, which labels that extension “private.” Thus, the client will no longer use the unsupported extension.</td>
</tr>
<tr>
<td>ESMTP to SMTP Session Conversion</td>
<td>The SMTP firewall forces a client that initiates an ESMTP session to use SMTP. When a client attempts to initiate an ESMTP session by sending the ELHO command, the firewall treats the EHLO command as an illegal command and modified it to the “xxxx” pattern. This response causes the server to send a 5xx code reply, forcing the client to revert to SMTP mode.</td>
<td>Not applicable (because EHLO is supported in ESMTP).</td>
</tr>
<tr>
<td>IDS Signature Detection</td>
<td>The SMTP and ESMTP firewalls scan for a set of hard-coded IDS signatures. There are 11 signatures—6 are hard coded in the firewall and are enabled by default. The other 5 signatures remain in the IDS code and are disabled by default.</td>
<td></td>
</tr>
</tbody>
</table>

**Note**  
Prior to Cisco IOS Release 12.3(7)T, the firewall intercepts the EHLO command and changes it to the NOOP command. The server responds with a 250 code reply. The firewall intercepts the response and modifies it to 502 code reply, which tells the client that the EHLO command is not supported.
How to Configure a Firewall to Support ESMTP

This section contains the following procedures:

- Configuring a Firewall for ESMTP Inspection, page 6

Configuring a Firewall for ESMTP Inspection

Use this task to configure a Cisco IOS Firewall to inspect an ESMTP session and command sequence.

Restrictions

SMTP and ESMTP cannot exist simultaneously. If SMTP is already configured, an attempt to configure ESMTP will result in the error message, “%ESMTP cannot coexist with SMTP, please unconfigure SMTP and try again...”. If ESMTP is already configured, an attempt to configure SMTP will result in the error message, “%SMTP cannot coexist with ESMTP, please unconfigure ESMTP and try again...”

The following example illustrates how the router will react if you attempt to configure both protocols:

```
Router(config)# ip inspect name mail-guard smtp
Router(config)# ip inspect name mail-guard esmtp
ESMTP cannot coexist with SMTP, please unconfigure SMTP and try again...
Router(config)# end
Router# show running-config
```

Table 27 SMTP and ESMTP Firewalls Functionality Comparison (continued)

<table>
<thead>
<tr>
<th>Functionality</th>
<th>SMTP Firewall Description</th>
<th>ESMTP Firewall Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command Pipelining</td>
<td>Not available. (The client sends a command to the server and must wait for a reply before sending another command.)</td>
<td>An ESMTP firewall can inspect commands that are in the pipeline. That is, commands that are sent before a response is received are inspected.</td>
</tr>
<tr>
<td>Resetting a Connection</td>
<td>Both SMTP and ESMTP firewalls will always send a “5xx” error code and close the connection upon detection of an unsupported parameter or an IDS signature in a command. That is, the firewall sends an appropriate reply code and closes the connection with proper TCP closing sequence packets (such as FIN or FIN+ACK) so the client does not continually attempt to send the same message.</td>
<td>Note Prior to Cisco IOS Release 12.3(7)T, an SMTP firewall will reset the TCP connection upon detection of an illegal command or IDS signature. This behavior causes the client to keep trying to send the same message for up to 4 days (which is when the original message is bounced back to the user).</td>
</tr>
</tbody>
</table>
ESMTP Support for Cisco IOS Firewall

How to Configure a Firewall to Support ESMTP

SUMMARY STEPS

1. enable
2. configure terminal
3. ip inspect name inspection-name {smtp | esmtp} [alert {on | off}] [audit-trail {on | off}] [max-data number] [timeout seconds]
4. interface type number
5. ip inspect inspection-name {in | out}

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router&gt; enable</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip inspect name inspection-name {smtp</td>
<td>esmtp} [alert {on</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config)# ip inspect name test esmtp</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> interface type number</td>
<td>Configures an interface type and enters interface configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config)# interface ethernet0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> ip inspect inspection-name {in</td>
<td>out}</td>
</tr>
<tr>
<td><strong>Example:</strong> Router(config-if)# ip inspect test in</td>
<td></td>
</tr>
</tbody>
</table>

Troubleshooting Tips

To view and verify the inspection configuration, status, or session information, you can use any of the following EXEC commands:

- **show ip inspect name inspection-name**—Shows a particular configured inspection rule.
- **show ip inspect session**—Shows existing sessions that are currently being tracked and inspected by the firewall.
- **show ip inspect all**—Shows all inspection configuration and all existing sessions that are currently being tracked and inspected by the firewall.
Alert Messages
The existing SMTP-related alert message will not change. This message is logged every time the firewall detects an illegal or unsupported command. The message format is as follows:
FW-3-SMTP_INVALID_COMMAND: Invalid SMTP command (%s) (total %d chars) from initiator (%i:%d)

A new alert message is added. This message is logged whenever the firewall detects an illegal parameter in an SMTP command. The message includes the address and port of the sender as well as the illegal parameter. The message format is as follows:
FW-3-SMTP_INVALID_PARAMETER: Invalid SMTP parameter (%s) from initiator (%i:%d)

What to Do Next
To provide a record of network access through the firewall, including illegitimate access attempts, and inbound and outbound services, you should turn on logging and audit trail. For information on completing this task, refer to the section “Configuring Logging and Audit Trail” in the chapter “Configuring Context-Based Access Control” in the Cisco IOS Security Configuration Guide.

Configuration Examples for Firewall ESMTP Support
This section contains the following configuration example:
- ESMTP Inspection Configuration: Example, page 8

ESMTP Inspection Configuration: Example
The following example shows how to configure inspection of ESMTP traffic:
Router# configure terminal
Router(config)# ip inspect name mail-guard esmtp timeout 30

Firewall ACL Bypass

The Firewall ACL Bypass feature allows a packet to avoid redundant access control list (ACL) checks by allowing the firewall to permit the packet on the basis of existing inspection sessions instead of dynamic ACLs. Thus, input and output dynamic ACLs searches are eliminated, improving the overall throughput performance of the base engine.

Feature History for Firewall ACL Bypass

Information About Firewall ACL Bypass

To better understand how dynamic ACL bypass works, you should understand the following concepts:

- Benefits of Firewall ACL Bypass, page 2
Benefits of Firewall ACL Bypass

Because input and output dynamic ACLs are no longer necessary, the need for context-based access control (CBAC) to create dynamic ACLs on the interface is eliminated. Thus, the following benefits are now available:

- Improved connections per second performance of the firewall
- Reduced run-time memory consumption of the firewall

Firewall ACL Bypass Functionality Overview

Before ACL bypassing was implemented, a packet could be subjected to as many as three redundant searches—an input ACL search, an output ACL search, and an inspection session search. Each dynamic ACL that CBAC creates corresponds to a single inspection session. Thus, a matching dynamic ACL entry for a given packet implies that a matching inspection session exists and that the packet should be permitted through the ACL. Because a matching inspection session is often found in the beginning of IP processing, the input and output dynamic ACL searches are no longer necessary and can be eliminated.

ACL bypassing subjects the packet to one search—the inspection session search—during its processing path through the router. When a packet is subjected to a single inspection session search before the ACL checks, the packet is matched against the list of session identifiers that already exist on the interface. (Session identifiers keep track of the source and destination IP addresses and ports of the packets and on which interface the packet arrived.)

Note: Session identifiers are not created on interfaces for inspection sessions that are only Intrusion Detection Sessions (IDS).

How to Use Firewall ACL Bypass

After your firewall is configured for inspection, ACL bypassing is performed by default. That is, you should configure inspection as normal.

To configure CBAC for your firewall, see the following chapter “Configuring Context-Based Access Control” in the *Cisco IOS Security Configuration Guide*.

Configuration Examples for Verifying Firewall Session Information

After you have configured your firewall for inspection, you can use the `show ip inspect sessions detail` command to view session inspection information. The following examples show how eliminating dynamic ACLs changes the sample output:

- Old show ip inspect CLI Output: Example, page 3
- New show ip inspect CLI Output: Example, page 3
Old show ip inspect CLI Output: Example

The following is sample output from the `show ip inspect session detail` command, which shows that an outgoing ACL and an inbound ACL (dynamic ACLs) have been created to allow return traffic:

Router# `show ip inspect session detail`

Established Sessions
  Created 00:00:08, Last heard 00:00:04
  Bytes sent (initiator:responder) [140:298] acl created 2
  Outgoing access-list 102 applied to interface FastEthernet0/0
  Inbound access-list 101 applied to interface FastEthernet0/1

Router# `show access-list`

Extended IP access list 101
  permit tcp host 192.168.101.115 eq telnet host 192.168.1.116 eq 32956 (27 matches)
  deny udp any any
  deny tcp any any
  permit ip any any

Extended IP access list 102
  permit tcp host 192.168.101.115 eq telnet host 192.168.1.116 eq 32956 (27 matches)
  deny udp any any
  deny tcp any any
  permit ip any any

New show ip inspect CLI Output: Example

The following is sample output from the `show ip inspect session detail` command, which shows related ACL information (such as session identifiers [SID]), but does not show dynamic ACLs, which are no longer created:

Router# `show ip inspect session detail`

Established Sessions
  Created 00:00:10, Last heard 00:00:06
  Bytes sent (initiator:responder) [140:298]

Router# `show access-list`

Extended IP access list 101
  deny udp any any (20229 matches)
  deny tcp any any
  permit ip any any (6 matches)

Extended IP access list 102
  deny udp any any
  deny tcp any any
  permit ip any any (1 match)

Firewall N2H2 Support

The Firewall N2H2 Support feature provides users with an additional option when choosing the URL filter vendor. Just like the Websense URL filtering server, N2H2 interacts with your Cisco IOS firewall (also known as Cisco Secure Integrated Software [CSIS]) to allow you to prevent users from accessing specified websites on the basis of some policy. The Cisco IOS firewall works with the N2H2 Internet Filtering Protocol (IFP) server to know whether a particular URL should be allowed or denied (blocked).

Feature Specifications for the Firewall N2H2 Support feature

Restrictions for Firewall N2H2 Support

N2H2 IFP (Server) Requirement
To enable this feature, you must have at least one N2H2 server; however, two or more N2H2 servers are preferred. Although there is no limit to the number of N2H2 servers you may have, and you can configure as many servers as you wish, only one server will be active at any given time—the primary server. URL lookup requests will be sent only to the primary server.

URL Filtering Support Restriction
This feature supports only one active URL filtering scheme at a time. (Before enabling N2H2 URL filtering, you should always ensure that there is not another URL filtering scheme configured, such as Websense.)

Username Restriction
N2H2 requires the username to be supplied with the URL lookup request. Thus, the user-based policy will not work with N2H2 because the current Cisco IOS software does not retrieve the username.

Protocol Used to Communicate Between Firewall and N2H2 Server Restriction
TCP is currently the only protocol used to communicate between the Cisco IOS firewall (UNIX FileSystem [UFS]) and the N2H2 server.

Information About Cisco N2H2 Support
To configure Firewall N2H2 support, you must understand the following concepts:

- Benefits of Firewall N2H2 Support, page 2
- Feature Design of Firewall N2H2 Support, page 4
- Supported N2H2 Filtering Methods, page 5

Benefits of Firewall N2H2 Support
The Cisco IOS Firewall N2H2 Support feature provides an Internet management application that allows you to control web traffic for a given host or user on the basis of a specified security policy. In addition, the following functions are available in this feature:

Primary and Secondary Servers
When users configure multiple N2H2 servers, the firewall will use only one server at a time—the primary server; all other servers are called secondary servers. When the primary server becomes unavailable for any reason, it becomes a secondary server and one of the secondary servers becomes the primary server.

A firewall marks a primary server as down when sending a request to or receiving a response from the server fails. When a primary server goes down, the system will go to the beginning of the configured servers list and try to activate the first server on the list. If the first server on the list is unavailable, it will
try the second server on the list; the system will keep trying to activate a server until it is successful or until it reaches the end of the server list. If the system reaches the end of the server list, it will set a flag indicating that all of the servers are down, and it will enter allowmode.

When all the servers are down and the system is in allow mode, a periodic event that occurs for each minute will trace through the server list, trying to bring up a server by opening a TCP connection. If the TCP connection is successfully opened, the server is considered to be up, and the system will return to operational mode.

**IP Cache Table**

This function provides an IP cache table that contains the IP addresses of web servers whose underlying URLs can be accessed by all users and hosts.

The caching algorithm involves three parameters—the maximum number of IP addresses that can be cached, an idle time, and an absolute time. The algorithm also involves two timers—idle timer and absolute timer. The idle timer is a small periodic timer (1 minute) that checks to see whether the number of cached IP addresses in the cache table exceeds 80 percent of the maximum limit. If the cached IP addresses have exceeded 80 percent, it will start removing idle entries; if it has not exceeded 80 percent, it will quit and wait for the next cycle. The absolute timer is a large periodic timer (1 hour) that is used to remove all of the elapsed entries. (The age of an elapsed entry is greater than the absolute time.) An elapsed entry will also be removed during cache lookup.

The idle time value is fixed at 10 minutes. The absolute time value is taken from the N2H2 lookup response, which is often greater than 15 hours. The absolute value for cache entries made out of exclusive-domains is 12 hours. The maximum number of cache entries is configurable.

To configure cache table parameters, use the `ip urlfilter cache` command.

**Packet Buffering**

This function allows you to increase the maximum number of HTTP responses that a Cisco IOS firewall can hold. If the HTTP responses arrive prior to an N2H2 server reply, this buffering scheme allows your firewall to store a maximum of 200 HTTP responses. (After 200 responses have been reached, the firewall will drop further responses.) The responses will remain in the buffer until an allow or deny message is received from N2H2: if the status indicates that the URL is allowed, the firewall will release the HTTP responses in the buffer to the browser of the end user; if the status indicates that the URL is blocked, the firewall will discard the HTTP responses in the buffer and close the connection to both ends. This function prevents numerous HTTP responses from overwhelming your system.

To configure the maximum number of HTTP responses for your firewall, use the `ip urlfilter max-resp-pak` command.

**Exclusive Domains**

This function provides a configurable list of domain names so that the Cisco IOS firewall does not have to send a lookup request to the N2H2 server for the HTTP traffic that is destined for one of the domains in the exclusive list. Thus, the N2H2 server does not have to deal with look-up requests for HTTP traffic that is destined for a host that has already been marked as “allowed.”

Flexibility when entering domain names is also provided; that is, the user can enter the complete domain name or a partial domain name. If the user adds a complete domain name such as “www.cisco.com” to the exclusive domain list, all HTTP traffic whose URLs are destined for this domain (such as www.cisco.com/news and www.cisco.com/index) will be excluded from the N2H2 URL filtering policies and, on the basis of the configuration, the URLs will be permitted or blocked (denied).
If the user adds only a partial domain name to the exclusive domain list, such as “.cisco.com,” all URLs whose domain names end with this partial domain name (such as www.cisco.com/products and www.cisco.com/eng) will be excluded from the N2H2 URL filtering policies and, based upon the configuration, the URLs will be permitted or blocked (denied).

To configure an exclusive domain list, use the `ip urlfilter exclusive-domain` command.

**Allow Mode**
The system will go into allow mode when connections to all the N2H2 servers are down. The system will return to normal mode when a connection to at least one web N2H2 server is up. Allow mode directs your system to forward or drop all packets on the basis of the configurable allow mode setting. By default, allow mode is off, so all HTTP requests are forbidden if all N2H2 servers are down.

To configure allow mode for your system, use the `ip urlfilter allowmode` command.

---

**Feature Design of Firewall N2H2 Support**

This feature assumes that the N2H2 server will be part of a protected network and that requests from the Cisco IOS firewall will not travel over any unprotected network to reach the N2H2 server.

Figure 27 and the corresponding steps explain a sample URL filtering network topology.

**Figure 27**  
Cisco IOS Firewall N2H2 URL Filtering Sample Topology

1. The end user browses a page on the web server, and the browser sends an HTTP request.
2. After the Cisco IOS firewall receives this request, it forwards the request to the web server, while simultaneously extracting the URL and sending a look-up request to the N2H2 server.
3. After the N2H2 server receives the look-up request, it checks its database to see whether it should permit or deny the URL; it returns a permit or deny status via a look-up response to the Cisco IOS firewall.
4. After the Cisco IOS Firewall receives this look-up response, it performs one of the following functions:
   - If the look-up response permits the URL, it sends the HTTP response to the end user.
If the look-up response denies the URL, the N2H2 server redirects the user to its own internal web server, which displays a message that describes the category under which the URL is blocked; thereafter, the connection is reset to both ends.

Supported N2H2 Filtering Methods

The Cisco IOS firewall supports most of the filtering methods that are supported by the N2H2 server. Table 28 lists N2H2 filtering methods and identifies which methods are supported by Cisco.

<table>
<thead>
<tr>
<th>N2H2 Filtering Method</th>
<th>Description</th>
<th>Supported by Cisco IOS Firewall?</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>Global filtering</td>
<td>Filtering is applied to all users, groups, and IP addresses</td>
<td>Yes</td>
</tr>
<tr>
<td>User-based filtering</td>
<td>Filtering is applied to a specified user</td>
<td>No</td>
</tr>
</tbody>
</table>

How to Configure N2H2 URL Support

To configure your Cisco IOS firewall to interact with at least one N2H2 server to provide URL filtering, configure the following procedures:

- Configuring Cisco IOS Firewall N2H2 URL Filtering, page 5 (required)
- Verifying Firewall and N2H2 URL Filtering, page 10 (optional)
- Maintaining the Cache Table, page 10 (optional)
- Monitoring the URL Filter Subsystems, page 11 (optional)

Configuring Cisco IOS Firewall N2H2 URL Filtering

N2H2 is based on a pass-through filtering technology, which is the most accurate, reliable, and scalable method of Internet filtering. Pass-through filtering requires all requests for web pages to pass through an Internet control point, such as a firewall, proxy server, or caching device. N2H2 is integrated with these control points and checks each request to determine whether it should be allowed or denied. All responses are logged for reporting purposes.

Prerequisites

- Before enabling N2H2 URL filtering, you should always ensure that there is not another URL filtering scheme configured, such as Websense. If you try to enter a new filtering scheme when one already exists, the new scheme will be ignored, and the system will display an error message that says, “different URL filtering scheme cannot co-exist.”
• URL filtering does not have an interface-specific command. It relies on Cisco IOS firewall HTTP inspection to classify the traffic that needs filtering. This makes the configuration of Cisco IOS firewall inspection mandatory for the URL filtering feature to work. For more details on Cisco IOS firewall configuration, refer to the chapter “Cisco IOS Firewall Overview” in the IOS IOS Security Configuration Guide, Release 12.2.

Restrictions

Enabling HTTP inspection (via the `ip inspect name` command) triggers the Java applet scanner, which is very CPU intensive. The only way to stop the Java applet scanner is to specify the `java-list access-list` option and configure a standard access-list to allow any traffic. Configuring URL filtering without enabling the `java-list access-list` option will severely impact performance.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip inspect name inspection-name http [urlfilter] [java-list access-list] [alert {on | off}] [timeout seconds] [audit-trail {on | off}]`
4. `ip urlfilter server vendor {websense | n2h2} ip-address [port port-number] [timeout seconds] [retransmit number]`
5. `ip urlfilter alert`
6. `ip urlfilter audit-trail`
7. `ip urlfilter urlf-server-log`
8. `ip urlfilter exclusive-domain {permit | deny} domain-name`
9. `ip urlfilter cache number`
10. `ip urlfilter allowmode {on | off}`
11. `ip urlfilter max-resp-pak number`
12. `ip urlfilter max-request number`
13. `interface type slot/port`
14. `ip inspect inspection-name {in | out}`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

#### Step 3
```
ip inspect name inspection-name http
     [urlfilter] [java-list access-list] [alert {on | off}] [timeout seconds] [audit-trail {on | off}]```

**Example:**
```
Router(config)# ip inspect name fw_urlf http urlfilter java-list 51 timeout 30```

**Purpose:**
Turns on HTTP inspection. The `urlfilter` keyword associates URL filtering with HTTP inspection.

**Note**
You may configure two or more inspections in a router, but URL filtering will work only with the inspections in which the `urlfilter` keyword is enabled.

**Note**
Enabling HTTP inspection with or without any options triggers the Java applet scanner, which is CPU intensive. The only way to stop the Java applet scanner is to specify the `java-list access-list` option. Configuring URL filtering without enabling the `java-list access-list` option will severely impact performance.

#### Step 4
```
ip urlfilter server vendor {websense | n2h2} ip-address [port port-number] [timeout seconds] [retransmit number]```

**Example:**
```
Router(config)# ip urlfilter server vendor websense 10.201.6.202```

**Purpose:**
Configures an N2H2 server to interact with the firewall to filter HTTP requests based on a specified policy.

- **ip-address**—IP address of the vendor server.
- **port port-number**—Port number that the vendor server listens on. The default port number is 4005.
- **timeout seconds**—Length of time that the firewall will wait for a response from the vendor server. The default timeout is 5 minutes.
- **retransmit number**—Number of times the firewall will retransmit the request when a response does not arrive. The default value is 2 times.

#### Step 5
```
ip urlfilter alert```

**Example:**
```
Router(config)# ip urlfilter alert```

(Optional) Enables the system alert, which displays system messages such as a server entering allow mode or going down.

- The system alert is enabled by default.

#### Step 6
```
ip urlfilter audit-trail```

**Example:**
```
Router(config)# ip urlfilter audit-trail```

(Optional) Enables the logging of messages into the syslog server of router.

- This function is disabled by default.

#### Step 7
```
ip urlfilter urlf-server-log```

**Example:**
```
Router(config)# ip urlfilter urlf-server-log```

(Optional) Enables the logging of system messages on the URL filtering server (the N2H2 server). This function is disabled by default.
## Command or Action

### Step 8

```
ip urlfilter exclusive-domain (permit | deny) domain-name
```

**Example:**
```
Router(config)# ip urlfilter exclusive-domain permit www.cisco.com
```

(Optional) Adds a domain name to or from the exclusive domain list so the firewall does not have to send look-up requests to the N2H2 server.
- **permit**—Permits all traffic destined for the specified domain name.
- **deny**—Denies all traffic destined for the specified domain name.
- **domain-name**—Domain name that is added or removed from the exclusive domain list.

### Step 9

```
ip urlfilter cache number
```

**Example:**
```
Router(config)# ip urlfilter cache 4500
```

(Optional) Configures cache table parameters.
- **number**—Specifies the maximum number of destination IP addresses that can be cached into the cache table; the default is 5000.

### Step 10

```
ip urlfilter allowmode [on | off]
```

**Example:**
```
Router(config)# ip urlfilter allowmode on
```

(Optional) Turns on the default mode of the filtering systems.
- **on**—Allows HTTP requests to pass to the end user if all N2H2 servers are down.
- **off**—Blocks all HTTP requests if all N2H2 servers are down; **off** is the default setting.

### Step 11

```
ip urlfilter max-resp-pak number
```

**Example:**
```
Router(config)# ip urlfilter max-resp-pak 150
```

(Optional) Configures the maximum number of HTTP responses that the firewall can keep in its packet buffer.
- The default value is 200. The maximum value is 20000, so you may set the `max-resp-pak number` to a value up to 20000.

### Step 12

```
ip urlfilter max-request number
```

**Example:**
```
Router(config)# ip urlfilter max-request 500
```

(Optional) Sets the maximum number of outstanding requests that can exist at any given time.
- The default value is 1000.

### Step 13

```
interface type slot/port
```

**Example:**
```
Router(config)# interface FastEthernet 0/0
```

Configures an interface type and enters interface configuration mode

### Step 14

```
ip inspect inspection-name {in | out}
```

**Example:**
```
Router(config-if)# ip inspect inspection-name out
```

Applies a set of inspection rules to an interface.
- URL filtering is associated with inspection, and inspection is an interface-specific command. Hence, the `ip inspect` command needs to be configured on an interface.

## Troubleshooting Tips

This feature introduces the following alert messages:
- “%URLF-3-SERVER_DOWN: Connection to the URL filter server 10.92.0.9 is down”
This level three LOG_ERR-type message is displayed when a configured UFS goes down. When this happens, the firewall will mark the configured server as secondary, try to bring up one of the other secondary servers, and mark that server as the primary server. If there is no other server configured, the firewall will enter allow mode and display the “URLF-3-ALLOW_MODE” message.

- `%URLF-3-ALLOW_MODE`: Connection to all URL filter servers are down and ALLOW MODE is OFF
  
  This LOG_ERR type message is displayed when all UFSs are down and the system enters allow mode.

**Note** Whenever the system goes into allow mode (all filter servers are down), a periodic keepalive timer will be triggered which will try to bring up a server by opening a TCP connection.

- “%URLF-5-SERVER_UP: Connection to an URL filter server 10.92.0.9 is made, the system is returning from ALLOW MODE”
  
  This LOG_NOTICE-type message is displayed when the UFSs are detected as being up and the system is returning from allow-mode.

- “%URLF-4-URL_TOO_LONG: URL too long (more than 3072 bytes), possibly a fake packet?”
  
  This LOG_WARNING-type message is displayed when the URL in a look-up request is too long; any URL longer than 3K will be dropped.

- “%URLF-4-MAX_REQ: The number of pending request exceeds the maximum limit <1000>”
  
  This LOG_WARNING-type message is displayed when the number of pending requests in the system exceeds the maximum limit and all further requests are dropped.

To display these alert messages, use the `ip urlfilter alert` command.

This feature introduces the following syslog messages:

- “%URLF-6-SITE_ALLOWED: Client 10.0.0.2:12543 accessed server 10.76.82.21:8080”
  
  This message is logged for each request whose destination IP address is found in the cache. It includes the source IP address, source port number, destination IP address, and destination port number. The URL is not logged because the IP address of the request is found in the cache, so parsing the request and extracting the URL is a waste of time.

  
  This message is logged when a request finds a match against one of the blocked domains in the exclusive-domain list or the corresponding entry in the IP cache.

- “%URLF-6-URL_ALLOWED: Access allowed for URL http://www.n2h2.com/; client 10.54.192.6:54123 server 192.168.0.1:80”
  
  This message is logged for each URL request that is allowed by a UFS. It includes the allowed URL, source IP address, source port number, destination IP address, and destination port number. Longer URLs will be truncated to 300 bytes and logged.

  
  This message is logged for each URL request that is blocked by a UFS. It includes the blocked URL, source IP address, source port number, destination IP address, and destination port number. Longer URLs will be truncated to 300 bytes and then logged.
To display these syslog messages, use the `ip urlfilter audit-trail` command.

### Verifying Firewall and N2H2 URL Filtering

To verify that the Firewall N2H2 Support feature is working, perform any of the following optional steps:

**SUMMARY STEPS**

1. `enable`
2. `show ip urlfilter cache`
3. `show ip urlfilter config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Router&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><code>show ip urlfilter cache</code></td>
<td>Displays the destination IP addresses that are cached into the cache table.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Router# show ip urlfilter cache</code></td>
<td></td>
</tr>
<tr>
<td><code>show ip urlfilter config</code></td>
<td>Displays the size of the cache, the maximum number of outstanding requests, the allow mode state, and the list of configured N2H2 servers.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Router# show ip urlfilter config</code></td>
<td></td>
</tr>
<tr>
<td><code>show ip urlfilter statistics</code></td>
<td>Displays information such as the number of requests that are sent to the N2H2 server, the number of responses received from the N2H2 server, the number pending requests in the system, the number of failed requests, the number of blocked URLs.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Router# show ip urlfilter statistics</code></td>
<td></td>
</tr>
</tbody>
</table>

### Maintaining the Cache Table

To clear the cache table of a specified or all IP addresses, perform the following optional steps:

**SUMMARY STEPS**

1. `enable`
2. `clear ip urlfilter cache`
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>clear ip urlfilter cache {ip-address</td>
<td>all}</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>clear ip urlfilter cache all</td>
<td></td>
</tr>
</tbody>
</table>

**Monitoring the URL Filter Subsystems**

To monitor the URL filter subsystems, perform the following optional steps:

**SUMMARY STEPS**

1. enable
2. debug ip urlfilter {function-trace | detailed | events}

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>debug ip urlfilter {function-trace</td>
<td>detailed</td>
</tr>
<tr>
<td></td>
<td>• function-trace—Prints a sequence of important functions that are called when configuring URL filtering.</td>
</tr>
<tr>
<td></td>
<td>• detailed—Prints detailed information about various activities that occur during URL filtering.</td>
</tr>
<tr>
<td></td>
<td>• events—Prints various events such as queue event, timer event, and socket event.</td>
</tr>
<tr>
<td>Example: debug ip urlfilter detailed</td>
<td></td>
</tr>
</tbody>
</table>

**Configuration Examples for Firewall and Webserver**

This section provides the following comprehensive configuration example:

- URL Filter Client (Firewall) Configuration Example, page 12
URL Filter Client (Firewall) Configuration Example

The following example shows how to configure the Cisco IOS firewall (also known as the URL filter client [UFC]) for N2H2 URL filtering:

Topology:

End User------LAN-----Fa0/0 -- Firewall -- S2/0----- Internet ---- Web Server

|                Router
|                 
N2H2           
|    
Server -------+

Router Configuration:

Example 1:

hostname fw9-7200b

!-------------------------------------------------------------------
! The following commands define the inspection rule "myfw," allowing
! the specified protocols to be inspected. Note that the "urlfilter"
! keyword entered for HTTP protocol enables URL filtering on HTTP
! traffic that are bound to this inspection.
!-------------------------------------------------------------------
!
ip inspect name myfw http urlfilter
ip inspect name myfw ftp
ip inspect name myfw smtp
ip inspect name myfw h323
!
!----------------------------------------------------------------------
! The following command sets the URL filtering cache table size to 12000.
!----------------------------------------------------------------------
ip urlfilter cache 12000
!
!--------------------------------------------------------------------
! The following commands configure three exclusive domains--
! two partial domains and one complete domain.
!--------------------------------------------------------------------
ip urlfilter exclusive-domain permit .weapons.com
ip urlfilter exclusive-domain deny .nbc.com
ip urlfilter exclusive-domain permit www.cisco.com
!
!-----------------------------------------------------------------
! The following two commands enable URL filtering Audit Trail and
! Alert messages.
!-----------------------------------------------------------------
ip urlfilter audit-trail
ip urlfilter alert
!
!--------------------------------------------------------------------
! The command configures the N2H2 URL filtering server installed
! on 192.168.3.1.
!--------------------------------------------------------------------
ip urlfilter server vendor n2h2 192.168.3.1
!
!----------------------------------------------------------------------
! Create Access Control List 102:
! ACL 102 denies all IP protocol traffic except for ICMP traffic.
! This means that only the return traffic for protocols defined in the
! inspection rule and the ICMP traffic is allowed access through the
! interface where this rule is applied.  
!  
! Note that ACL is given here for an example; it is not relevant  
! to the URL filtering. The URL filtering will work without ACL also.  
!-------------------------------------------------------------------------------  
! access-list 102 permit icmp any any  
access-list 102 deny tcp any any  
access-list 102 deny udp any any  
access-list 102 deny ip any any  
!  
interface FastEthernet0/0  
ip address 192.168.3.254 255.255.255.0  
ip nat inside  
no ip route-cache  
no ip mroute-cache  
!  
interface Ethernet1/0  
no ip route-cache  
no ip mroute-cache  
shutdown  
duplex half  
!  
interface Ethernet1/1  
no ip address  
no ip mroute-cache  
shutdown  
duplex half  
!  
!-------------------------------------------------------------------------------  
! The ACL and CBAC inspection rules are applied to the Serial2/0 interface.  
! In this example, the ACL is applied IN, meaning that it applies to traffic  
! inbound from the internet. The CBAC inspection rule myfw is applied OUT,  
! meaning that CBAC inspects the traffic that goes out through the interface  
! and controls return traffic to the router for an existing connection.  
!-------------------------------------------------------------------------------  
interface Serial2/0  
ip address 10.6.9.7 255.255.0.0  
ip access-group 102 in  
ip nat outside  
ip inspect myfw out  
no ip directed-broadcast  
no ip mroute-cache  
!  
ip nat inside source static 192.168.3.1 10.6.243.1  
ip nat inside source static 192.168.3.2 10.6.243.2  
ip nat inside source static 192.168.3.3 10.6.243.3  
ip classless  
ip route 192.168.0.30 255.255.255.255 10.6.0.1  
!  
!  
line con 0  
exec-timeout 0 0  
stopbits 1  
line aux 0  
stopbits 1  
line vty 0 4  
password letmein  
login  
!  
end
Example 2:

! In the above example, the CBAC can also be configured on the inbound
! FastEthernet0/0 interface as IN, in which case the CBAC inspects all
! the traffic that comes in on FastEthernet0/0 and controls return traffic
! that leaves out of this interface for an existing connection.

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

New Commands

- clear ip urlfilter cache
- debug ip urlfilter
- ip urlfilter alert
- ip urlfilter allowmode
- ip urlfilter audit-trail
- ip urlfilter cache
- ip urlfilter exclusive-domain
- ip urlfilter max-request
- ip urlfilter max-resp-pak
- ip urlfilter server vendor
- ip urlfilter urlf-server-log
- show ip urlfilter cache
- show ip urlfilter config
- show ip urlfilter statistics
Modified Command

- ip inspect name
Glossary

ACL—Access Control List.

CSIS—Cisco Secure Integrated Software. CSIS is a content-based firewall that currently inspects application data, checks for protocol conformance, extracts the relevant port information to create dynamic access list entries that successfully allows return traffic, and closes the ports at the end of the session.

ICMP—Internet Control Message Protocol. ICMP is a network layer Internet protocol that reports errors and provides other information relevant to IP packet processing. ICMP is documented in RFC 792.

UFC—URL filter client. UFC is a separate process that accepts URLs from CSIS, forwards the URL to the Websense server, and processes the replies from the vendor server (Websense or N2H2).

UFS—URL filter server. UFS is a generic name given to the vendor server (Websense or N2H2), which processes URLs and decides whether to allow or deny web traffic based on a given policy.

Refer to the Internetworking Terms and Acronyms for terms not included in this glossary.

Firewall Stateful Inspection of ICMP

The Firewall Stateful Inspection of ICMP feature addresses the limitation of qualifying Internet Control Management Protocol (ICMP) messages into either a malicious or benign category by allowing the Cisco IOS firewall to use stateful inspection to “trust” ICMP messages that are generated within a private network and to permit the associated ICMP replies. Thus, network administrators can debug network issues by using ICMP without concern that possible intruders may enter the network.

Feature Specifications for the Firewall Stateful Inspection of ICMP feature

Feature History

- Additional References, page 7
- Command Reference, page 9
Restrictions for Firewall Stateful Inspection of ICMP

- To enable this feature, your Cisco IOS image must contain the Cisco IOS firewall.
- This feature does not work for the User Datagram Protocol (UDP) traceroute, in which UDP datagrams are sent instead of ICMP packets. The UDP traceroute is typically the default for UNIX systems. To use ICMP inspection with a UNIX host, use the “I” option with the traceroute command. This functionality will cause the UNIX host to generate ICMP traceroute packets, which will be inspected by the Cisco IOS firewall ICMP.

Information About Firewall Stateful Inspection of ICMP

The following sections provide information about Cisco IOS Firewall Stateful Inspection of ICMP:

- Feature Design of Firewall Stateful Inspection of ICMP, page 2
- ICMP Inspection Checking, page 3

Feature Design of Firewall Stateful Inspection of ICMP

ICMP is used to report errors and information about a network. It is a useful tool for network administrators who are trying to debug network connectivity issues. Unfortunately, intruders can also use ICMP to discover the topology of a private network. To guard against a potential intruder, ICMP messages can be blocked from entering a private network; however, a network administrator may then be unable to debug the network. Although a Cisco IOS router can be configured using access lists to selectively allow certain ICMP messages through the router, the network administrator must still guess which messages are potentially malicious and which messages are benign. With the introduction of this feature, a user can now configure a Cisco IOS firewall for stateful inspection to “trust” that the ICMP messages are generated within the private network and to permit the associated ICMP replies.

Note

Access lists can still be used to allow unsolicited error messages along with Cisco IOS firewall inspection. Access lists complement Cisco IOS firewall ICMP inspection.

Stateful inspection of ICMP packets is limited to the most common types of ICMP messages that are useful to network administrators who are trying to debug their networks. That is, ICMP messages that do not provide a valuable tool for the internal network administrator will not be allowed. For the Cisco IOS firewall-supported ICMP message request types, see Table 29.

<table>
<thead>
<tr>
<th>ICMP Packet Type</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Echo Reply</td>
<td>Reply to Echo Request (Type 8)</td>
</tr>
<tr>
<td>3</td>
<td>Destination Unreachable</td>
<td>Possible reply to any request</td>
</tr>
</tbody>
</table>

Note

This packet is included because it is a possible response to any ICMP packet request.
ICMP packet types 0 and 8 are used for pinging: the source sends out an Echo Request packet, and the destination responds with an Echo Reply packet.

Packet types 0, 8, and 11 are used for ICMP traceroute: Echo Request packets are sent out starting with a TTL packet of 1, and the TTL is incremented for each hop. The intermediate hops respond to the Echo Request packet with a Time Exceeded packet; the final destination responds with an Echo Reply packet.

**ICMP Inspection Checking**

Return packets are checked by the inspect code, not by ACLs. The inspect code tracks each destination address from outgoing packets and checks each return packet. For ECHO REPLY and TIMESTAMP REPLY packets, the return address is checked. For UNREACHABLE and TIME EXCEEDED packets, the intended destination address is extracted from the packet data and checked.

For more information, see Checking for ICMP Inspection Example, page 7.

**How to Use Firewall Stateful Inspection of ICMP**

This section contains the following procedures:

- Configuring Firewall Stateful Inspection for ICMP, page 3
- Verifying Firewall and ICMP Session Information, page 4
- Monitoring Firewall and ICMP Session Information, page 5

**Configuring Firewall Stateful Inspection for ICMP**

To enable the Cisco IOS Firewall to start inspection ICMP messages, perform the following steps:

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **ip inspect name inspection-name icmp [alert [on | off]] [audit-trail [on | off]] [timeout seconds]**

---

<table>
<thead>
<tr>
<th>ICMP Packet Type</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>Echo Request</td>
<td>Ping or traceroute request</td>
</tr>
<tr>
<td>11</td>

## Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
   * Enter your password if prompted. |
| **Example:**
   Router> enable | |
| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:**
   Router# configure terminal | |
| **Step 3** ip inspect name inspection-name icmp [alert (on | off)] [audit-trail (on | off)] [timeout seconds] | Turns on inspection for ICMP.  
   * alert—Alert messages are generated. This function is on by default.  
   * audit-trail—Audit trail messages are generated. This function is off by default.  
   * timeout—Overrides the global channel inactivity timeout value. The default value of the seconds argument is 10. |
| **Example:**
   Router(config)# ip inspect name test icmp alert on audit-trail on timeout 30 | |

## Verifying Firewall and ICMP Session Information

To display active ICMP session and IP access list information, perform the following optional steps:

### Summary Steps

1. enable
2. show ip inspect session [detail]
3. show ip access-list
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1  enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2  show ip inspect session</td>
<td>(Optional) Displays existing sessions that are currently being tracked</td>
</tr>
<tr>
<td></td>
<td>and inspected by the Cisco IOS firewall.</td>
</tr>
<tr>
<td></td>
<td>• The optional detail keyword causes additional details about</td>
</tr>
<tr>
<td></td>
<td>these sessions to be shown.</td>
</tr>
<tr>
<td></td>
<td>Example: Router# show ip inspect session</td>
</tr>
<tr>
<td>Step 3  show ip access-list</td>
<td>(Optional) Displays the contents of all current IP access lists.</td>
</tr>
<tr>
<td></td>
<td>For a sample output example, see the section “ICMP Session</td>
</tr>
<tr>
<td></td>
<td>Verification Example.”</td>
</tr>
<tr>
<td></td>
<td>Example: Router# show ip access-list</td>
</tr>
</tbody>
</table>

Monitoring Firewall and ICMP Session Information

To monitor debugging messages related to ICMP inspection, perform the following optional steps:

Note Effective with Cisco IOS Release 12.4(20)T, the debug ip inspect command is replaced by the debug policy-firewall command. See the Cisco IOS Debug Command Reference for more information.

SUMMARY STEPS

1. enable
2. debug ip inspect icmp

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1  enable</td>
<td>Enables privileged EXEC mode.</td>

- Checking for ICMP Inspection Example, page 7
- ICMP Session Verification Example, page 7

Firewall Stateful Inspection for ICMP Configuration Example

The default ICMP timeout is deliberately short (10 seconds) due to the security hole that is opened by allowing ICMP packets with a wild-carded source address back into the inside network. The timeout will occur 10 seconds after the last outgoing packet from the originating host. For example, if you send a set of 10 ping packets spaced 1 second apart, the timeout will expire in 20 seconds or 10 seconds after the last outgoing packet. However, the timeout is not extended for return packets. If a return packet is not seen within the timeout window, the hole will be closed and the return packet will not be allowed in. Although the default timeout can be made longer if desired, it is recommended that this value be kept relatively short.

The following example shows how to configure a firewall for stateful inspection of ICMP packets:

no service pad
service timestamps debug uptime
service timestamps log uptime
service password-encryption
!
hostname UUT
!
ip subnet-zero
no ip domain lookup
!
ip inspect audit-trail
ip inspect name test icmp alert on audit-trail on timeout 30
!
interface Ethernet0
ip address 192.168.10.2 255.255.255.0
ip inspect test in
!
interface Ethernet1
ip address 192.168.20.2 255.255.255.0
ip access-group 101 in
!
ip classless
ip route 0.0.0.0 0.0.0.0 192.168.20.3
no ip http server
!
access-list 101 deny ip any any
!
line con 0
exec-timeout 0
!
end
Checking for ICMP Inspection Example

In the following example, three destinations were pinged. The example shows that the inspect code tracked each destination address in the inspect session information.

```
fw_1751#sh ip insp sess detail
Established Sessions
Session 813A1808 (192.168.156.5:0)=>(0.0.0.0:0) icmp SIS_OPEN
   Created 00:04:20, Last heard 00:00:00
   Destinations: 3
      Dest addr [192.168.131.3]
      Dest addr [192.168.131.7]
      Dest addr [192.168.131.31]
   Bytes sent (initiator:responder) [8456:5880] acl created 4
Inbound access-list 102 applied to interface Ethernet0/0
Inbound access-list 102 applied to interface Ethernet0/0
Inbound access-list 102 applied to interface Ethernet0/0
Inbound access-list 102 applied to interface Ethernet0/0
```

ICMP Session Verification Example

The following example is sample output from the `show ip access-list` command. In this example, Access Control Lists (ACLs) are created for an ICMP session on which only ping packets were issued from the host.

```
Router# show ip access-list 101
Extended IP access list 101
   permit icmp any host 192.168.133.3 time-exceeded
   permit icmp any host 192.168.133.3 unreachable
   permit icmp any host 192.168.133.3 timestamp-reply
   permit icmp any host 192.168.133.3 echo-reply (4 matches)
```

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

- debug ip inspect
- ip inspect name
**Glossary**

**ACL**—access control list. An ACL is a list kept by routers to control access to or from the router for a number of services (for example, to prevent packets with a certain IP address from leaving a particular interface on the router).

**CBAC**—Context-Based Access Control. CBAC is the name given to the Cisco IOS Firewall subsystem.

**firewall**—A firewall is a networking device that controls access to the network assets of your organization. Firewalls are positioned at the entrance points into your network. If your network has multiple entrance points, you must position a firewall at each point to provide effective network access control.

The most basic function of a firewall is to monitor and filter traffic. Firewalls can be simple or elaborate, depending on your network requirements. Simple firewalls are usually easier to configure and manage. However, you might require the flexibility of a more elaborate firewall.

**ICMP**—Internet Control Message Protocol. An ICMP is a network layer Internet protocol that reports errors and provides other information relevant to IP packet processing.

**RPC**—remote-procedure call. A RPC is the technological foundation of client or server computing. RPCs are procedure calls that are built or specified by clients and are executed on servers, with the results returned over the network to the clients.

**RTSP**—Real Time Streaming Protocol. RTSP enables the controlled delivery of real-time data, such as audio and video. Sources of data can include both live data feeds, such as live audio and video, and stored content, such as prerecorded events. RTSP is designed to work with established protocols, such as RTP and HTTP.

**SIP**—Session Initiation Protocol. SIP is a protocol developed by the IETF MUSIC Working Group as an alternative to H.323. SIP features are compliant with IETF RFC 2543, published in March 1999. SIP equips platforms to signal the setup of voice and multimedia calls over IP networks.

**SMTP**—simple mail transfer protocol. SMTP is an Internet protocol providing e-mail services.

**UDP**—User Datagram Protocol. A UDP is a connectionless transport layer protocol in the TCP/IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, requiring that error processing and retransmission be handled by other protocols. UDP is defined in RFC 768.

**Note**

Refer to the *Internetworking Terms and Acronyms* for terms not included in this glossary.
Firewall Support for SIP

The Firewall Support for SIP feature integrates Cisco IOS firewalls, Voice over IP (VoIP) protocol, and Session Initiation Protocol (SIP) within a Cisco IOS-based platform, enabling better network convergence.

Some Cisco IOS versions earlier than 12.2(11)YU and 12.2(15)T may accept the configuration commands for SIP that are shown in this document; however, those earlier versions will not function properly.

Feature Specifications for Firewall Support for SIP

Restrictions for Firewall Support for SIP

DNS Name Resolution
Although SIP methods can have Domain Name System (DNS) names instead of raw IP addresses, this feature currently does not support DNS names.

SIP UDP Support Only
This feature supports only the SIP User Datagram Protocol (UDP) format for signaling; the TCP format is not supported.

SIP Abbreviated Header
This feature does not support the compact form of SIP header fields.

Earlier Versions of Cisco IOS
Some Cisco IOS versions earlier than 12.2(11)YU and 12.2(15)T may accept the configuration commands for SIP that are shown in this document; however, those earlier versions will not function properly.

Information About Firewall Support for SIP

To configure the Cisco IOS Firewall Support for SIP feature, you must understand the following concepts:

- Firewall and SIP Overviews, page 2
- Firewall for SIP Functionality Description, page 5
- SIP Message Treatment by the Firewall, page 6
- Call Database, page 7

Firewall and SIP Overviews

This section contains the following concepts:

- Cisco IOS Firewall, page 2
- SIP (Session Initiation Protocol), page 3

Cisco IOS Firewall

The Cisco IOS firewall extends the concept of static access control lists (ACLs) by introducing dynamic ACL entries that open on the basis of the necessary application ports on a specific application and close these ports at the end of the application session. The Cisco IOS firewall achieves this functionality by inspecting the application data, checking for conformance of the application protocol, extracting the
relevant port information to create the dynamic ACL entries, and closing these ports at the end of the session. The Cisco IOS firewall is designed to easily allow a new application inspection whenever support is needed.

**SIP (Session Initiation Protocol)**

SIP is an ASCII-based, application-layer control protocol that can be used to establish, maintain, and terminate calls between two or more endpoints. Like other VoIP protocols, SIP is designed to address the functions of signaling and session management within a packet telephony network. Signaling allows call information to be carried across network boundaries. Session management provides the ability to control the attributes of an end-to-end call.

**SIP Messages**

SIP has two types of messages—requests and responses—that have the following generic structure:

```
generic-message = Request-Line | Status-Line
                   * ( general-header | request-header
                   | response-header | entity-header )
                   CRLF
                   [ message-body]
```

*Note* Any of these message components may contain embedded IP addresses.

Table 30 identifies the six available SIP request messages.

<table>
<thead>
<tr>
<th>SIP Message</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACK</td>
<td>Confirms receipt of a final response to INVITE</td>
</tr>
<tr>
<td>BYE</td>
<td>Is sent by either side to end the call</td>
</tr>
<tr>
<td>CANCEL</td>
<td>Is sent to end a call that has not yet been connected</td>
</tr>
<tr>
<td>INVITE</td>
<td>Is a request from a User Agent Client (UAC) to initiate a session</td>
</tr>
<tr>
<td>OPTIONS</td>
<td>Are sent to query capabilities of the user agents and network servers</td>
</tr>
<tr>
<td>REGISTER</td>
<td>Is sent by the client to register the address with a SIP proxy</td>
</tr>
</tbody>
</table>

Table 31 identifies the available SIP response methods.

Firewall Support for SIP Functionality Description

The Firewall for SIP Support feature allows SIP signaling requests to traverse directly between gateways or through a series of proxies to the destination gateway or phone. After the initial request, if the Record-Route header field is not used, subsequent requests can traverse directly to the destination gateway address as specified in the Contact header field. Thus, the Cisco IOS firewall is aware of all surrounding proxies and gateways and allows the following functionality:

- SIP signaling responses can travel the same path as SIP signaling requests.
- Subsequent signaling requests can travel directly to the endpoint (destination gateway).
- Media endpoints can exchange data between each other.

See Figure 28 for a sample topology that displays these functionalities.
SIP Message Treatment by the Firewall

See Table 32 for information on the treatment of SIP methods by the Cisco IOS firewall.

### Table 32  Treatment of SIP Methods by the Cisco IOS Firewall

<table>
<thead>
<tr>
<th>SIP Message</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>200 OK</td>
<td>Signifies the end of the call creation phase. The packet is checked for validity against the call database, and the contact information of the server is taken from it. Temporary call-flow–based openings in the firewall are created for allowing the BYE message, which can be initiated from the inside or outside.</td>
</tr>
<tr>
<td>200 OK for BYE</td>
<td>Signifies the graceful termination of the call and is in response to the BYE message. The same action as the CANCEL message is taken.</td>
</tr>
<tr>
<td>ACK</td>
<td>Signifies that the message is passed after checking for validity.</td>
</tr>
<tr>
<td>BYE</td>
<td>Signifies the intent to terminate the call. The database state is updated and temporary openings in the firewall are created for response to the BYE message.</td>
</tr>
<tr>
<td>CANCEL</td>
<td>Signifies abnormal data termination. The signaling sessions, media sessions, pregenerated temporary openings in the firewall, and the call database entry for the call are removed.</td>
</tr>
</tbody>
</table>
A call database, which contains the details of a call leg, is maintained for all call flows. A call database is created and maintained because there can be numerous signaling sessions for each call. Table 33 identifies the information available in the call database.

<table>
<thead>
<tr>
<th>Type</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>call_int_over</td>
<td>Checks to see whether or not call initialization is over, and if so, checks to see if the call is in the teardown phase</td>
</tr>
<tr>
<td>C con ip &amp; C con port</td>
<td>Signifies the IP address and port in the contact field of the initiator; for example, “Contact:<a href="">sip:1111@172.16.0.3:5060;user=phone</a>”</td>
</tr>
<tr>
<td>C media ip &amp; C media port</td>
<td>Signifies the IP address in the media field of the initiator; for example, “c=IN IP4 172.16.0.3”</td>
</tr>
<tr>
<td>C media port</td>
<td>Signifies the port in the media field of the initiator; for example, “m=audio 20758 RTP/AVP 0”</td>
</tr>
<tr>
<td>C src ip &amp; C src port</td>
<td>Signifies the actual IP address and port of the initiator</td>
</tr>
<tr>
<td>C via ip &amp; C via port</td>
<td>Signifies the IP address and port in the via field of the initiator (the first via line); for example, “Via: SIP/2.0/UDP 172.16.0.3:5060”</td>
</tr>
<tr>
<td>current sip state</td>
<td>Is the current state of the call (which helps to avoid retransmission)</td>
</tr>
<tr>
<td>from/to/callid</td>
<td>Is extracted from the “INVITE” SIP request message to identify the call</td>
</tr>
<tr>
<td>media header</td>
<td>Keeps the list of media sessions for the call</td>
</tr>
</tbody>
</table>
How to Configure Your Firewall for SIP

To configure a Cisco IOS Firewall for SIP support, perform the following tasks:

- Configuring Firewall for SIP Support, page 8 (required)
- Verifying Firewall for SIP Support, page 9 (optional)
- Monitoring Firewall for SIP Support, page 10 (optional)

### Configuring Firewall for SIP Support

To enable a firewall to support SIP, use the following commands.

#### Prerequisite

Before you configure Cisco IOS firewall support for SIP on your router, you first need to configure access lists, whose purpose normally is to block SIP traffic from unprotected networks for which the firewall will create temporary openings for specific traffic. For information about configuring access lists and the `access-list` command, see the chapter “Configuring IPsec Network Security” in the Cisco IOS Security Configuration Guide, Release 12.2, and the Cisco IOS Command Reference, Release 12.2 T, respectively.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip inspect name inspection-name sip [alert {on | off}] [audit-trail {on | off}] [timeout seconds]`
4. `interface type number`
5. `ip inspect inspection-name {in | out}`
6. Repeat Steps 3 through 5 (Optional)

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ip inspect name</td>
<td>Turns on inspection for SIP.</td>
</tr>
<tr>
<td>inspection-name sip</td>
<td></td>
</tr>
<tr>
<td>[alert (on</td>
<td>off)] [audit-trail (on</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router(config)# ip inspect name voip sip</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> interface type number</td>
<td>Configures an interface type and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router(config)# interface FastEthernet 0/0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> ip inspect</td>
<td>Applies inspection configurations to an interface and for a particular traffic direction.</td>
</tr>
<tr>
<td>inspection-name (in</td>
<td>out)</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router(config-if)# ip inspect voip in</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>The inspection of protocols other than SIP may not be desirable for traffic that comes from external networks, so it may be necessary to configure an additional inspection rule specifying only SIP.</td>
</tr>
<tr>
<td>If SIP calls are coming from other interfaces, repeat Steps 3 through 5 and apply SIP inspections for the calls that are coming from those interfaces.</td>
<td></td>
</tr>
</tbody>
</table>

### Verifying Firewall for SIP Support

To verify Cisco IOS firewall session information, perform the following optional steps:

### SUMMARY STEPS

1. enable
2. show ip inspect name inspection-name
3. show ip inspect session [detail]
4. show ip access-list
**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2 show ip inspect name inspection-name</td>
<td>(Optional) Displays the configured inspection rule.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router# show ip inspect name voip</td>
</tr>
<tr>
<td>Step 3 show ip inspect session [detail]</td>
<td>(Optional) Displays existing sessions that are currently being tracked and inspected by the Cisco IOS firewall.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router# show ip inspect session</td>
</tr>
<tr>
<td>Step 4 show ip access-list</td>
<td>(Optional) Displays the contents of all current IP access lists.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router# show ip access-list</td>
</tr>
</tbody>
</table>

**Monitoring Firewall for SIP Support**

To monitor firewall events, perform the following optional steps:

*Note* Effective with Cisco IOS Release 12.4(20)T, the `debug ip inspect` command is replaced by the `debug policy-firewall` command. See the *Cisco IOS Debug Command Reference* for more information.

**SUMMARY STEPS**

1. enable
2. debug ip inspect sip

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Step 2 debug ip inspect sip</td>
<td>(Optional) Displays the operations of the SIP inspection engine for debugging purposes.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router# debug ip inspect sip</td>
</tr>
</tbody>
</table>
Configuration Examples for Firewall SIP Support

This section provides the following configuration example:

- Firewall and SIP Configuration Example, page 11

Firewall and SIP Configuration Example

The following example shows how to allow outside initiated calls and internal calls. For outside initiated calls, an ACL needs to be punched to allow for the traffic from the initial signaling packet from outside. Subsequent signaling and media channels will be allowed by the inspection module.

```conf
ip inspect name voip sip
interface FastEthernet0/0
  ip inspect voip in
  !
interface FastEthernet0/1
  ip inspect voip in
  ip access-group 100 in
  !
  !
access-list 100 permit udp host <gw_ip> any eq 5060
access-list 100 permit udp host <proxy_ip> any eq 5060
access-list deny ip any any
```

Firewall Websense URL Filtering

First Published: December 23, 2002
Last Updated: July 31, 2008

The Firewall Websense URL Filtering feature enables your Cisco IOS firewall (also known as Cisco Secure Integrated Software [CSIS]) to interact with the Websense URL filtering software, thereby allowing you to prevent users from accessing specified websites on the basis of some policy. The Cisco IOS firewall works with the Websense server to know whether a particular URL should be allowed or denied (blocked).

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the “Feature Information for Firewall Websense URL Filtering” section on page 17.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Catalyst OS, and Cisco IOS XE software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Firewall Websense URL Filtering

Websense Server Requirement
To enable this feature, you must have at least one Websense server; however, two or more Websense servers are preferred. Although there is no limit to the number of Websense servers you may have, and you can configure as many servers as you wish, only one server will be active at any given time—the primary server. URL look-up requests will be sent only to the primary server.

URL Filtering Support Restriction
This feature supports only one active URL filtering scheme at a time. (Before enabling Websense URL filtering, you should always ensure that there is not another URL filtering scheme configured, such as N2H2.)

Username Restriction
This feature does not pass the username and group information to the Websense server. However, the Websense server can work for user-based policies because it has another mechanism for getting the username to correspond to an IP address.

Exclusive Domain List Restriction
This feature does not resolve the domains before it searches an exclusive domain list. When a questionable URL is presented to the filtering server, this feature searches only for the value that was specified in the command-line interface (CLI). That is, if an exclusive domain list was configured via the `ip urlfilter exclusive-domain deny 198.168.1.1` command, a user entering http://198.168.1.1 into a browser will be denied access. However, a user who is trying to access this same domain and who enters http://www.cisco.com, will be allowed access because 198.168.1.1 was specified via the CLI, not www.cisco.com.

PISA URL Filtering Restrictions — Cisco IOS Release 12.2(18)ZYA
- Only one inspection rule is supported.
- Only HTTP filtering is supported. (HTTPS and FTP filtering are not supported.)
- HTTP over ports used by static Network Based Application Recognition (NBAR) protocols are not supported.
- Context-based Access Control (CBAC) is not supported.
- Only Layer 3 SVIs, Layer 3 routed ports, and Layer 3 subinterfaces are supported.
- The `clear ip urlfilter cache` and `show ip urlfilter cache` commands are not supported.
- Only the Websense URL filtering server is supported. (N2H2/SmartFilter/Trend Micro filtering servers are not supported.)
- Usernames are not passed on from PISA to Websense.
Information About Firewall Websense URL Filtering

To configure the Firewall Websense URL Filtering feature, you should understand the following concepts:

- Benefits of Firewall Websense URL Filtering, page 3
- Feature Design of Firewall Websense URL Filtering, page 4
- Supported Websense Server Features on a Cisco IOS Firewall, page 5

Benefits of Firewall Websense URL Filtering

The Cisco IOS Firewall Websense URL Filtering feature provides an Internet management application that allows you to control web traffic for a given host or user on the basis of a specified security policy. In addition, the following functions are available in this feature:

Primary and Secondary Servers

When users configure multiple Websense servers, the firewall will use only one server at a time—the primary server; all other servers are called secondary servers. When the primary server becomes unavailable for any reason, it becomes a secondary server and one of the secondary servers becomes the primary server.

A firewall marks a primary server as down when sending a request to or receiving a response from the server fails. When a primary server goes down, the system will go to the beginning of the configured servers list and try to activate the first server on the list. If the first server on the list is unavailable, it will try the second server on the list; the system will keep trying to activate a server until it is successful or until it reaches the end of the server list. If the system reaches the end of the server list, it will set a flag indicating that all of the servers are down, and it will enter allow mode.

When all the servers are down and the system is in allow mode, a periodic event that occurs for each minute will trace through the server list, trying to bring up a server by opening a TCP connection. If the TCP connection is successfully opened, the server is considered to be up, and the system will return to operational mode.

IP Cache Table

This function provides an IP cache table that contains the IP addresses of web servers whose underlying URLs can be accessed by all users and hosts.

The caching algorithm involves three parameters—the maximum number of IP addresses that can be cached, an idle time, and an absolute time. The algorithm also involves two timers—idle timer and absolute timer. The idle timer is a small periodic timer (1 minute) that checks to see whether the number of cached IP addresses in the cache table exceeds 80 percent of the maximum limit. If the cached IP addresses have exceeded 80 percent, it will start removing idle entries; if it has not exceeded 80 percent, it will quit and wait for the next cycle. The absolute timer is a large periodic timer (1 hour) that is used to remove all of the elapsed entries. (The age of an elapsed entry is greater than the absolute time.) An elapsed entry will also be removed during cache lookup.

The idle time value is fixed at 10 minutes. The absolute time value is taken from the Websense look-up response, which is often greater than 15 hours. The absolute value for cache entry made out of exclusive-domains is 12 hours. The maximum number of cache entries is configurable.

To configure cache table parameters, use the `ip urlfilter cache` command.
Packet Buffering
This function allows you to increase the maximum number of HTTP responses that a Cisco IOS firewall can hold. If the HTTP responses arrive prior to a Websense server reply, this buffering scheme allows your firewall to store a maximum of 200 HTTP responses. (After 200 responses have been reached, the firewall will drop further responses.) The responses will remain in the buffer until an allow or deny message is received from Websense: if the status indicates that the URL is allowed, the firewall will release the HTTP responses in the buffer to the browser of the end user; if the status indicates that the URL is blocked, the firewall will discard the HTTP responses in the buffer and close the connection to both ends. This function prevents numerous HTTP responses from overwhelming your system.

To configure the maximum number of HTTP responses for your firewall, use the `ip urlfilter max-resp-pak` command.

Exclusive Domains
This function provides a configurable list of domain names so that the Cisco IOS firewall does not have to send a lookup request to the Websense server for the HTTP traffic that is destined for one of the domains in the exclusive list. Thus, the Websense server does not have to deal with look-up requests for HTTP traffic that is destined for a host that has already been marked as “allowed.”

Flexibility when entering domain names is also provided; that is, the user can enter the complete domain name or a partial domain name. If the user adds a complete domain name, such as “www.cisco.com,” to the exclusive domain list, all HTTP traffic whose URLs are destined for this domain (such as www.cisco.com/news and www.cisco.com/index) will be excluded from the Websense URL filtering policies, and based on the configuration, the URLs will be permitted or blocked (denied).

If the user adds only a partial domain name to the exclusive domain list, such as “.cisco.com,” all URLs whose domain names end with this partial domain name (such as www.cisco.com/products and www.cisco.com/eng) will be excluded from the Websense URL filtering policies, and based on the configuration, the URLs will be permitted or blocked (denied).

To configure an exclusive domain list, use the `ip urlfilter exclusive-domain` command.

Allow Mode
The system will go into allow mode when connections to all the Websense servers are down. The system will return to normal mode when a connection to at least one Web Websense server is up. Allow mode directs your system to forward or drop all packets on the basis of the configurable allow mode setting. By default, allow mode is off, so all HTTP requests are forbidden if all Websense servers are down.

To configure allow mode for your system, use the `ip urlfilter allowmode` command.

Feature Design of Firewall Websense URL Filtering

Note
This feature assumes that the Websense server will be part of a protected network and that requests from the Cisco IOS firewall will not travel over any unprotected network to reach the Websense server.

Figure 29 and the corresponding steps explain a sample URL filtering network topology.
1. The end user browses a page on the web server, and the browser sends an HTTP request.

2. After the Cisco IOS firewall receives this request, it forwards the request to the web server while simultaneously extracting the URL and sending a look-up request to the Websense server.

3. After the Websense server receives the look-up request, it checks its database to see whether it should permit or deny the URL; it returns a permit or deny status via a look-up response to the Cisco IOS firewall.

4. After the Cisco IOS firewall receives this look-up response, it performs one of the following functions:
   - If the look-up response permits the URL, it sends the HTTP response to the end user.
   - If the look-up response denies the URL, the Websense server redirects the user to its own internal web server, which displays a message that describes the category under which the URL is blocked; thereafter, the connection is reset to both ends.

---

**Supported Websense Server Features on a Cisco IOS Firewall**

The Cisco IOS firewall supports all of the filtering and user authentication methods that are supported by the Websense server.

The following filtering methods are supported:

- Global filtering, which is applied to all users, groups, and IP addresses
- User- or group-based filtering, which is applied to a specific user or group
- Keyword-based filtering, which is applied on the basis of specific keywords (for example, a user can configure a policy for which all URLs with the keyword “dog” will be denied)
- Category-based filtering, which is applied on the basis of specific categories
- Customized filtering, which allows the user to apply a policy for customized URLs

The NT LAN Manager (NTLM) and Lightweight Directory Access Protocol (LDAP) user authentication methods are supported in this feature. Websense uses these methods to authenticate the user when the firewall does not pass the authenticated username along with the look-up request.
When the username is not passed along with the look-up request, the Websense server retrieves the username through one of the following methods:

- Manual authentication—Websense redirects the user to its own internal web server, which displays a challenge or response for the username and password. (This process is similar to when a user is blocked, but in this process, an authentication message is displayed instead of a blocked message.) Thereafter, Websense checks the NTLM or LDAP directory service to see if the username and password are a match. If there is a match, Websense associates the username with the source IP address and policies can be created for that username.

- Transparent ID (XID)—Websense has an agent that automatically associates users, when they log onto a Windows network, to their IP addresses. Unlike manual authentication, this method does not require an additional logon by the user. However, this method can be used only for Windows.

**Note**
Although Websense also supports user authentication via TACACS or RADIUS, this feature currently does not support these protocols for user authentication.

### How to Configure Websense URL Filtering

To configure your Cisco IOS firewall to interact with at least one Websense server to provide URL filtering, configure the following procedures:

- Configuring Firewall Websense URL Filtering, page 6 (required)
- Verifying Cisco IOS Firewall and Websense URL Filtering, page 11 (optional)
- Maintaining the Cache Table, page 12 (optional)
- Monitoring the URL Filter Subsystems, page 13 (optional)

### Configuring Firewall Websense URL Filtering

Websense is a third-party filtering software that can filter HTTP requests on the basis of the following policies: destination hostname, destination IP address, keywords, and username. The software maintains a URL database of more than 20 million sites organized into more than 60 categories and subcategories.

#### Prerequisites

Before enabling Websense URL filtering, you should always ensure that there is not another URL filtering scheme configured, such as N2H2. If you try to enter a new filtering scheme when one already exists, the new scheme will be ignored, and the system will display an error message that says, “different URL filtering scheme cannot co-exist.”

#### Restrictions

Enabling HTTP inspection (via the `ip inspect name` command) triggers the Java applet scanner, which is CPU intensive. The only way to stop the Java applet scanner is to specify the `java-list access-list` keyword and argument and configure a standard access list to allow any traffic. Configuring URL filtering without enabling the `java-list access-list` keyword and argument will severely impact performance.
SUMMARY STEPS

1. enable
2. configure terminal
3. `ip inspect name inspection-name http [java-list access-list] [urlfilter] [alert {on | off}] [audit-trail {on | off}] [timeout seconds]
4. `ip inspect inspection-name {in | out}
5. `ip urlfilter server vendor {websense | n2h2} ip-address [port port-number] [timeout seconds] [retransmit number]
6. `ip urlfilter alert
7. `ip urlfilter audit-trail
8. `ip urlfilter urlf-server-log
9. `ip urlfilter exclusive-domain {permit | deny} domain-name
10. `ip urlfilter cache number
11. `ip urlfilter allowmode [on | off]
12. `ip urlfilter max-resp-pak number
13. `ip urlfilter max-request number
14. `ip urlfilter truncate {script-parameters | hostname}
15. `ip urlfilter mode {per-session | per-uri | per-uri-proxy-only}

DETAILED STEPS

<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
### How to Configure Websense URL Filtering

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 3    | ip inspect name inspection-name http [java-list access-list] [urlfilter] [alert {on | off}] [audit-trail {on | off}] [timeout seconds] | Turns on HTTP inspection. The urlfilter keyword associates URL filtering with HTTP inspection.  
**Note** You may configure two or more inspections in a router, but URL filtering will work only with the inspections in which the urlfilter keyword is enabled.  
**Note** Enabling HTTP inspection with or without any options triggers the Java applet scanner, which is CPU intensive. The only way to stop the Java applet scanner is to specify the java-list access-list keyword and argument. Configuring URL filtering without enabling the java-list access-list keyword and argument will severely impact performance. |
| 4    | ip inspect inspection-name {in | out} | Applies a set of inspection rules to an interface.  
- The in keyword applies the inspection rules to inbound traffic. |
| 5    | ip urlfilter server vendor {websense | n2h2} ip-address [port port-number] [timeout seconds] [retransmit number] | Configures a Websense server to interact with the firewall to filter HTTP requests on the basis of a specified policy.  
- ip-address—IP address of the vendor server.  
- port port-number—Port number that the vendor server listens on. The default port number is 15868.  
- timeout seconds—Length of time that the firewall will wait for a response from the vendor server. The default timeout is 5 minutes.  
- retransmit number—Number of times the firewall will retransmit the request when a response does not arrive. The default value is 2 times. |
| 6    | ip urlfilter alert | (Optional) Enables the system alert, which displays system messages such as a server entering allow mode or going down.  
- The system alert is enabled by default. |
| 7    | ip urlfilter audit-trail | (Optional) Enables the logging of messages into the syslog server of router. This function is disabled by default. |
| 8    | ip urlfilter urlf-server-log | (Optional) Enables the logging of system messages on the URL filtering server (the Websense server).  
- This function is disabled by default. |
### Step 9

**Command or Action:**
```
ip urlfilter exclusive-domain {permit | deny} domain-name
```

**Example:**
```
Router(config)# ip urlfilter exclusive-domain permit www.cisco.com
```

**Purpose:**
(Optional) Adds a domain name to or from the exclusive domain list so that the firewall does not have to send look-up requests to the Websense server.

- **permit**—Permits all traffic destined for the specified domain name.
- **deny**—Denies all traffic destined for the specified domain name.
- **domain-name**—Domain name that is added or removed from the exclusive domain list.

### Step 10

**Command or Action:**
```
ip urlfilter cache number
```

**Example:**
```
Router(config)# ip urlfilter cache 4500
```

**Purpose:**
(Optional) Configures cache table parameters.

- **number**—Maximum number of destination IP addresses that can be cached into the cache table; the default is 5000.

### Step 11

**Command or Action:**
```
ip urlfilter allowmode [on | off]
```

**Example:**
```
Router(config)# ip urlfilter allowmode on
```

**Purpose:**
(Optional) Turns on the default mode of the filtering systems.

- **on**—Allows HTTP requests to pass to the end user if all Websense servers are down.
- **off**—Blocks all HTTP requests if all Websense servers are down; off is the default setting.

### Step 12

**Command or Action:**
```
ip urlfilter max-resp-pak number
```

**Example:**
```
Router(config)# ip urlfilter max-resp-pak 150
```

**Purpose:**
(Optional) Configures the maximum number of HTTP responses that the firewall can keep in its packet buffer.

The default value is 200 512-byte buffers.

### Step 13

**Command or Action:**
```
ip urlfilter max-request number
```

**Example:**
```
Router(config)# ip urlfilter maxrequest 500
```

**Purpose:**
(Optional) Sets the maximum number of outstanding requests that can exist at any given time. If the maximum number of requests is reached, all subsequent URLs are dropped.

- The default value is 1000.
Troubleshooting Tips

This feature introduces the following alert messages:

- **“%URLF-3-SERVER_DOWN: Connection to the URL filter server 10.92.0.9 is down”**
  
  This level three LOG_ERR-type message is displayed when a configured UFS goes down. When this happens, the firewall will mark the configured server as secondary and try to bring up one of the other secondary servers and mark that server as the primary server. If there is no other server configured, the firewall will enter allow mode and display the “URLF-3-ALLOW_MODE” message.

- **%URLF-3-ALLOW_MODE: Connection to all URL filter servers are down and ALLOW MODE is OFF**
  
  This LOG_ERR type message is displayed when all UFSs are down and the system enters allow mode.

  **Note** Whenever the system goes into allow mode (all filter servers are down), a periodic keepalive timer will be triggered that will try to bring up a server by opening a TCP connection.

- **“%URLF-5-SERVER_UP: Connection to an URL filter server 10.92.0.9 is made; the system is returning from ALLOW MODE”**
  
  This LOG_NOTICE-type message is displayed when the UFSs are detected as being up and the system is returning from allow mode.

- **“%URLF-4-URL_TOO_LONG: URL too long (more than 3072 bytes), possibly a fake packet?”**
  
  This LOG_WARNING-type message is displayed when the URL in a look-up request is too long; any URL longer than 3K will be dropped.
“%URLF-4-MAX_REQ: The number of pending request exceeds the maximum limit <1000>”

This LOG_WARNING-type message is displayed when the number of pending requests in the system exceeds the maximum limit and all further requests are dropped.

To display these alert messages, use the `ip urlfilter alert` command.

This feature introduces the following syslog messages:

- “%URLF-6-SITE_ALLOWED: Client 10.0.0.2:12543 accessed server 10.76.82.21:8080”
  This message is logged for each request whose destination IP address is found in the cache. It includes the source IP address, source port number, destination IP address, and destination port number. The URL is not logged because the IP address of the request is found in the cache, so parsing the request and extracting the URL is a waste of time.

  This message is logged when a request finds a match against one of the blocked domains in the exclusive-domain list or the corresponding entry in the IP cache.

  This message is logged for each URL request that is allowed by a UFS. It includes the allowed URL, source IP address, source port number, destination IP address, and destination port number. Longer URLs will be truncated to 300 bytes and then logged.

  This message is logged for each URL request that is blocked by a UFS. It includes the blocked URL, source IP address, source port number, destination IP address, and destination port number. Longer URLs will be truncated to 300 bytes and then logged.

To display these syslog messages, use the `ip urlfilter audit-trail` command.

**Verifying Cisco IOS Firewall and Websense URL Filtering**

To verify that the Firewall Websense URL Filtering feature is working, perform any of the following optional steps:

**SUMMARY STEPS**

1. enable
2. show ip urlfilter cache
3. show ip urlfilter config
4. show ip urlfilter statistics
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>enable</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Router&gt; enable</strong></td>
</tr>
<tr>
<td><strong>show ip urlfilter cache</strong></td>
<td>Displays the destination IP addresses that are cached into the cache table.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Router# show ip urlfilter cache</strong></td>
</tr>
<tr>
<td><strong>show ip urlfilter config</strong></td>
<td>Displays the size of the cache, the maximum number of outstanding requests, the allow mode state, and the list of configured Websense servers.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Router# show ip urlfilter config</strong></td>
</tr>
<tr>
<td><strong>show ip urlfilter statistics</strong></td>
<td>Displays information such as the number of requests that are sent to the Websense server, the number of responses received from the Websense server, the number of pending requests in the system, the number of failed requests, the number of blocked URLs.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Router# show ip urlfilter statistics</strong></td>
</tr>
</tbody>
</table>

Maintaining the Cache Table

To clear the cache table of a specified address or of all IP addresses, perform the following optional steps.

**SUMMARY STEPS**

1. **enable**
2. **clear ip urlfilter cache**

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>enable</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Router&gt; enable</strong></td>
</tr>
<tr>
<td>**clear ip urlfilter cache (ip-address</td>
<td>all)**</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Router# clear ip urlfilter cache all</strong></td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>This command is not supported on PISA in Cisco IOS Release 12.2(18)ZYA.</td>
</tr>
</tbody>
</table>
Monitoring the URL Filter Subsystems

To monitor the URL filter subsystems, perform the following optional steps:

**SUMMARY STEPS**

1. `enable`
2. `debug ip urlfilter {func-trace | detailed | events}`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>`debug ip urlfilter {func-trace</td>
<td>detailed</td>
</tr>
<tr>
<td></td>
<td>• <code>func-trace</code>—Prints a sequence of important functions that are called when configuring URL filtering.</td>
</tr>
<tr>
<td></td>
<td>• <code>detailed</code>—Prints detailed information about various activities that occur during URL filtering.</td>
</tr>
<tr>
<td></td>
<td>• <code>events</code>—Prints various events, such as queue event, timer event, and socket event.</td>
</tr>
</tbody>
</table>

Configuration Examples for the Firewall and Webserver

This section provides the following comprehensive configuration example:

- **URL Filter Client (Firewall) Configuration Example, page 13**

**URL Filter Client (Firewall) Configuration Example**

The following example shows how to configure the Cisco IOS firewall (also known as the URL filter client [UFC]) for Websense URL filtering:

```

Feature Information for Firewall Websense URL Filtering

Table 34 lists the release history for this feature. Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation. Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to [http://www.cisco.com/go/cfn](http://www.cisco.com/go/cfn). An account on Cisco.com is not required.

Note: Table 34 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Glossary

**CSIS**—Cisco Secure Integrated Software. CSIS is a content-based firewall that currently inspects application data, checks for protocol conformance, extracts the relevant port information to create dynamic access list entries that successfully allow return traffic, and closes the ports at the end of the session.

**UFC**—URL filter client. UFC is a separate process that accepts URLs from CSIS, forwards the URL to the Websense server, and processes the replies from the vendor server (Websense or N2H2).

**UFS**—URL filter server. UFS is a generic name given to the vendor server (Websense or N2H2), which processes URLs and decides whether to allow or deny web traffic on the basis of a given policy.

Refer to the *Internetworking Terms and Acronyms* for terms not included in this glossary.

The Firewall Support of Skinny Client Control Protocol (SCCP) feature enables Context-Based Access Control (CBAC) inspection to support the Voice over IP (VoIP) protocol, Skinny Client Control Protocol (SCCP). That is, CBAC inspects Skinny control packets that are exchanged between a Skinny client and the Call Manager (CM); CBAC then configures the router (also known as the Cisco IOS Firewall) to enable the Skinny data channels to traverse through the router.

### Feature Specifications for the Firewall Support of Skinny Client Control Protocol (SCCP) Feature

Prerequisites for Firewall Support of Skinny Client Control Protocol (SCCP)

The Skinny inspection module is part of the inspection subsystem; thus, your router must be running an image that has firewall support.

Restrictions for Firewall Support of Skinny Client Control Protocol (SCCP)

This feature has the following restrictions:

- Skinny inspection will inspect only the SCCP sessions that have been established after the firewall is configured with Skinny inspection. That is, any SCCP sessions that were established through the firewall before the Skinny inspection was configured will not be inspected.
- This feature does not support Music on Hold (MOH) when a device other than the CM is the music server. (This feature does support MOH when the CM is the music server.)
- This feature does not address either the multicast functionality of SCCP or the functionality of multiple active calls on a single Skinny client.

This feature does not support the following Skinny and firewall configurations:

- The firewall and CM cannot be in the same router. Skinny inspection does not support this configuration because the current firewall implementation does not inspect sessions that start or terminate at the router. Thus, Skinny inspection will work only with an external CM.
- The CM and the Skinny client cannot be on three different networks that are separated at the firewall. The current firewall implementation does not inspect sessions that have devices residing on more than two distinct networks that are segregated at the firewall. That is, if there are more than two interfaces at the firewall, session inspection is not supported.

Information About Firewall Support of Skinny Client Control Protocol (SCCP)

To configure the Firewall Support of SCCP feature, you must understand the following concepts:

- Context-Based Access Control Overview, page 3
- Skinny Overview, page 3
- CBAC and Skinny Functionality Overview, page 3
Context-Based Access Control Overview

CBAC extends the concept of static access control lists (ACLs) by introducing dynamic ACL entries that open the necessary application ports on the basis of a specific application and close these ports at the end of the application session. CBAC achieves this functionality by inspecting the application data, checking for conformance of the application protocol, extracting the relevant port information to create the dynamic ACL entries, and closing these ports at the end of the session. CBAC is designed to easily allow a new application inspection whenever support is needed.

Skinny Overview

Skinny enables voice communication between two Skinny clients through the use of a CM. Typically, the CM provides service to the Skinny clients on TCP Port 2000. Initially, a Skinny client connects to the CM by establishing a TCP connection; the client will also establish a TCP connection with a secondary CM, if available. After the TCP connection is established, the client will register with the primary CM, which will be used as the controlling CM until it reboots or there is a keepalive failure. Thus, the Skinny TCP connection between the client and the CM exists forever and is used to establish calls coming to or from the client. If a TCP connection failure is detected, the secondary CM is used. All data channels established with the previous CM remain active and will be closed after the end parties hang up the call.

Table 1 lists the set of messages that are necessary for the data sessions to open and close. Skinny inspection will examine the data sessions that are deemed for opening and closing the access list pin holes.

</tr>
</tbody>
</table>

CBAC and Skinny Functionality Overview

Figure 1 depicts typical deployment solutions that are supported by CBAC inspection for Skinny.

According to Figure 1, a firewall with Skinny inspection can be configured on Cisco IOS Router A, Cisco IOS Router B, or both routers, thereby addressing the following three scenarios:
A Cisco IOS router with a firewall on the customer premises equipment (CPE) side, supporting Skinny VoIP phone

A Cisco IOS router with a firewall on the CM side

A Cisco IOS router with a firewall at both ends of the connection

**Figure 1 CBAC Inspection for Skinny Sample Topology**

---

**How to Configure Your Firewall for Skinny Support**

To configure a Cisco IOS Firewall for SCCP support, perform the following tasks:

- Configuring Basic Skinny CBAC Inspection, page 4
- Setting Skinny CBAC Session Timeouts, page 6
- Configuring Port to Application Mapping, page 6
- Verifying Cisco IOS Firewall for Skinny Support, page 7
- Monitoring Cisco IOS Firewall for Skinny Support, page 8

**Configuring Basic Skinny CBAC Inspection**

Perform the following required steps to configure a basic Skinny CBAC configuration:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip inspect name inspection-name protocol [alert {on | off}] [audit-trail {on | off}] [timeout seconds]`

4. `ip inspect name inspection-name protocol [alert {on | off}] [audit-trail {on | off}] [timeout seconds]` (Optional. Required if the TFTP server is outside the firewall.)

5. `interface type number`

6. `ip access-group {access-list-number} {in | out}`

7. `ip inspect inspection-name {in | out}`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables higher privilege levels, such as privileged EXEC mode.  
- Enter your password if prompted. |
| Example: Router> enable | |
| **Step 2** configure terminal | Enters global configuration mode. |
| Example: Router# configure terminal | |
| **Step 3** ip inspect name inspection-name protocol [alert {on | off}] [audit-trail {on | off}] [timeout seconds] | Enables CBAC Skinny inspections. |
| Example: Router(config)# ip inspect name firewall skinny | |
| **Step 4** ip inspect name inspection-name protocol [alert {on | off}] [audit-trail {on | off}] [timeout seconds] | (Optional. Required if the TFTP server is outside the firewall.) Defines a set of inspection rules. |
| Example: Router(config)# ip inspect name firewall tftp | |
| **Step 5** interface type number | Configures an interface type and enters interface configuration mode. |
| Example: Router(config)# interface FastEthernet 0/0 | |
| **Step 6** ip access-group {access-list-number} {in | out} | Control access to an interface. Number of the access list that is blocking incoming traffic. |
| Example: Router(config-if)# ip access-group 100 in | |
| **Step 7** ip inspect inspection-name {in | out} | Applies a set of inspection rules to an interface. |
| Example: Router(config-if)# ip inspect firewall out | |
Setting Skinny CBAC Session Timeouts

Session timeouts are triggered when traffic is not seen on a particular session for a configured amount of time. (This value is configured via the `ip inspect name` command.) After the inactivity timeout is triggered, the firewall will clean up the session and deallocate all of the session data.

You must set the inactivity timeout value for Skinny to a greater value than the keepalive timeout value that is configured between the CM and Skinny clients. Otherwise, the Skinny connection may become inaccessible for inspection because the firewall might delete the session-related information due to inactivity.

After the inactivity timeout is triggered, the inspection module will send reset (RST packets) to both ends of the connection. Any data channels that are associated with the control channel will not be closed. After both end parties hang up, there will not be any traffic on the data channels and the connection will eventually timeout.

Note

If the inactivity timeout of the control channel that is connected to the primary CM is less than the keepalive timeout that is sent by the CM to the Skinny client, the firewall will set the inactivity timeout to three times the keepalive timeout. If a timeout is not configured, the default value of 3600 seconds will be used.

Configuring Port to Application Mapping

By default, the Skinny inspection will inspect SCCP messages to or from the CM on TCP port 2000. If you prefer to configure the CM to use a different port, the port to application mapping (PAM) feature should be used to specify the desired port to the Cisco IOS firewall. Thus, the firewall will inspect the SCCP messages in the desired port and in port 2000. To configure the CM to use a different port via PAM, use the `ip port-map` command.

Prerequisites

Before you can configure PAM, you must first configure the steps in the section, “Configuring Basic Skinny CBAC Inspection.”

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip port-map appl_name port port_num [list acl_num]`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
*enable* | Enables higher privilege levels, such as privileged EXEC mode.  
- Enter your password if prompted. |
| **Step 2**  
*configure terminal* | Enters global configuration mode. |
| **Step 3**  
*ip port map appl_name port port_num ([list acl_num]*)* | (Optional) Creates a port to address mapping for SCCP.  
This command allows you to indicate additional ports that need to be monitored for SCCP.  
*Example:*  
Router(config)# ip port map skinny port 2100 |

### Verifying Cisco IOS Firewall for Skinny Support

To display active Skinny session information, perform the following optional steps:

### SUMMARY STEPS

1. enable  
2. show ip inspect {name inspection-name | config | interfaces | session [detail] | all}  
3. show ip access-list  
4. show ip port-map [appl_name | port port_num]

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1**  
*enable* | Enables higher privilege levels, such as privileged EXEC mode.  
- Enter your password if prompted. |
| **Step 2**  
*show ip inspect* {name inspection-name | config | interfaces | session [detail] | all} | (Optional) Displays existing sessions that are currently being tracked and inspected by CBAC.  
The optional *detail* keyword causes additional details about these sessions to be shown.  
*Example:*  
Router# show ip inspect session detail |
### Configuration Examples for Firewall Skinny Support

#### Step 3

**Command or Action**: `show ip access-list`

**Example**: `Router# show ip access-list`

(Optional) Displays the contents of all current IP access lists, which includes the dynamic access lists created by Skinny inspection.

#### Step 4

**Command or Action**: `show ip port-map {appl_name | port port_num}`

**Example**: `Router# show ip port-map skinny`

(Optional) Displays information about the active port to application mappings on the router.

- `appl_name`—Displays Skinny-specific PAM information. (You must specify the `skinny` argument.)

---

### Monitoring Cisco IOS Firewall for Skinny Support

**Note**: Effective with Cisco IOS Release 12.4(20)T, the `debug ip inspect` command is replaced by the `debug policy-firewall` command. See the *Cisco IOS Debug Command Reference* for more information.

To monitor debugging messages related to Skinny inspection, perform the following optional steps:

#### SUMMARY STEPS

1. enable
2. `debug ip inspect {sccp | detailed}`

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables higher privilege levels, such as privileged EXEC mode.</td>

<td>detailed}`</td>
</tr>
<tr>
<td><strong>Example</strong>: <code>Router# debug ip inspect sccp</code></td>
<td></td>
</tr>
</tbody>
</table>

### Configuration Examples for Firewall Skinny Support

This section provides the following configuration example:

- Firewall and Skinny Configuration Example, page 9
Firewall and Skinny Configuration Example

Figure 2  Skinny and CBAC Configuration

The following is an example of how to configure a Cisco IOS firewall for Skinny support and includes PAM (see Figure 2):

! Define the name of the router as "CBAC-Firewall."
!
host CBAC-Firewall
!
! Create a DHCP server process to offer out 10.1.1.x addresses on the
! inside network. Option 150 is used by Cisco IP phones as where to
! look for their configuration file. A default router is required so that all
! the IP phones can talk to networks other than just to the local 10.1.1.x.
!
ip dhcp pool localnetwork
    network 10.1.1.0 255.255.255.0
    option 150 ip 192.168.1.100
    default-router 10.1.1.1
!
! Prevent the DHCP server process from assigning 10.1.1.1 -.9 as an IP
! address on the local network. This is done to hold the addresses .2 - .9 as static-
! defined addresses.
!
ip dhcp excluded-address 10.1.1.1 10.1.1.9
!
! Define firewall rules to all Skinny traffic in/out along with TFTP
! services.
!
ip inspect name fwout tftp
ip inspect name fwout skinny
!
! Prevent any traffic from coming in.
!
access-list 100 deny ip any any
!
interface ethernet 1
    ip access-group 100 in
    ip inspect firewall out

If the CallManager is requiring Skinny registration to happen on port tcp/2100, you will still need the above configuration plus the following additional step.

ip port map skinny port 2100

Granular Protocol Inspection

The Granular Protocol Inspection feature adds flexibility to the Cisco IOS Firewall by allowing it to perform a higher degree of inspection of TCP and User Data Protocol (UDP) traffic for most RFC 1700 application types.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the “Feature Information for Granular Protocol Inspection” section on page 10.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Catalyst OS, and Cisco IOS XE software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Contents

- Prerequisites for Granular Inspection Protocol, page 2
- Restrictions for Granular Inspection Protocol, page 2
- Information About Granular Protocol Inspection, page 2
- How to Configure Granular Protocol Inspection, page 3
- Configuration Examples for Granular Protocol Inspection, page 6
- Additional References, page 8
- Command Reference, page 9
- Feature Information for Granular Protocol Inspection, page 10
- Glossary, page 10
Prerequisites for Granular Inspection Protocol

- Cisco IOS Firewall software must be installed in your network.
- Access control lists (ACLs) must be applied to specified interfaces to enable the existing firewall software to function properly.

Restrictions for Granular Inspection Protocol

Port ranges cannot be specified directly in the `ip inspect name` command; use the port-to-application mapping (PAM) table.

Information About Granular Protocol Inspection

To use the Granular Protocol Inspection feature, you need to understand the following concepts:
- Cisco IOS Firewall, page 2
- Granular Protocol Inspection, page 2
- Benefits, page 3

Cisco IOS Firewall

The Cisco IOS Firewall is a security-specific option that provides inspection firewall functionality and intrusion detection for every network perimeter. By delivering state-of-the-art security features such as stateful, application-based filtering; dynamic per-user authentication and authorization; and URL filtering, the Cisco IOS Firewall adds greater depth and flexibility to existing Cisco IOS security solutions including authentication, encryption, and failover.

A firewall is a physical software or hardware barrier between one part of an internal network used to control access to and from external networks. This barrier is unique because it allows predefined traffic to pass through the firewall while being monitored for protocol anomalies. The difficult part is determining the criteria by which the packets are granted or denied access through the device.

As mentioned, a firewall blocks traffic and permits other types of traffic to traverse. Firewalls are not just access control lists (ACLs); rather, they are a stateful inspection application.

Granular Protocol Inspection

The Cisco IOS Firewall performs inspections for TCP and UDP traffic. For example, TCP inspections include Telnet traffic (port 23, by default) as well as all other applications on TCP such as Hypertext Transfer Protocol (HTTP), e-mail, instant message (IM) chatter, and so on. Therefore, there is no easy way to inspect Telnet traffic alone and deny all other TCP traffic.
The Granular Protocol Inspection feature allows you to specify TCP or UDP ports using the PAM table. As a result, the Cisco IOS Firewall can restrict traffic inspections to specific applications, thereby permitting a higher degree of granularity in selecting which protocols are to be permitted and denied as shown in Figure 32.

**Figure 32 Sample Topology**

Benefits

- Greater flexibility by allowing more granularity in the selection of protocols to be inspected
- Ease of use by providing for group inspection of multiple ports into a single, user-defined application keyword
- Enhanced functionality with the addition of more well-known ports, user-defined applications, and user-defined port ranges
- Improved performance and reduced CPU load resulting from focused inspection selections

**How to Configure Granular Protocol Inspection**

This section contains the following procedures:

- **Defining Applications, page 4** (required)
- **Setting Up Inspection Rules, page 5** (required)
- **Verifying the Configuration, page 5** (optional)
## Defining Applications

Perform the following task to define your applications in the PAM table by using the `ip port-map` command.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip port-map appl-name port [tcp | udp] [port_num | from begin_port_num to end_port_num] [list acl-num] [description description_string]`
4. `exit`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>enable</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Router&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code></td>
</tr>
</tbody>
</table>
| **Example:**      |         | When defining a user application in the PAM table, you must enter the prefix `user-`; otherwise, the following error message appears: “Unable to add port-map entry. Names for user-defined applications must start with 'user-'.

- **Note** Write the text string in the following format: “C description_string C,” where “C” is a delimiting character.

- **Note** Exits global configuration mode. |
| `Router(config)# ip port-map user-10 port udp from 3400 to 3433 list 22 description "test application"` | |
| **Step 3**        | `exit` | |
| **Example:**      |         | |
| `Router(config)# exit` | | |
## Setting Up Inspection Rules

Perform the following task to set up your inspection rules by using the `ip inspect name` command.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `ip inspect name inspection-name protocol [alert {on | off}] [audit-trail {on | off}] [timeout seconds]`
4. exit

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong> `ip inspect name inspection-name protocol [alert {on</td>
<td>off}] [audit-trail {on</td>
</tr>
<tr>
<td><strong>Step 4</strong> exit</td>
<td>Exits global configuration mode.</td>
</tr>
</tbody>
</table>

**Example:**

**Step 1**

Router> enable

**Step 2**

Router# configure terminal

**Step 3**

Router(config)# ip inspect name abc user-10

**Step 4**

Router(config)# exit

**Note** Replace the `protocol` argument with the application (PAM entry) that you just defined in the previous step. In this example, it is `user-10`.

---

## Verifying the Configuration

Perform the following task to verify your applications and inspection rules.

**SUMMARY STEPS**

1. enable
2. `show ip port-map [appl-name | port port-num [detail]]`
3. exit

**Example:**

Router> enable

Router# show ip port-map

Router(config)# exit
Configuration Examples for Granular Protocol Inspection

This section contains the following configuration examples:

- Defining an Application for the PAM Table: Example, page 6
- Setting Up an Inspection Rule: Example, page 6
- Verifying the Configuration: Example, page 8

Defining an Application for the PAM Table: Example

In the following example from the `ip port-map` command, a user-defined application named user-10 is defined in the PAM table for five ports using the TCP protocol. Standard access list 77 is applied to define host-specific port mapping and “TEST STRING” is the description.

Router# configure terminal

Enter configuration commands, one per line. End with CNTL/Z.

Router(config)# ip port-map user-10 port tcp 4000 5000 6000 7000 8000 list 77 description "TEST STRING"

Router(config)# end

Setting Up an Inspection Rule: Example

The following example from the `ip inspect name` command, lists user-10 as an application with the description “TEST STRING.”

Router# configure terminal

Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# `ip inspect name abc`?

user-10 TEST STRING<----- !user-defined application!

In the following example from the `ip inspect name` command, an inspection rule is established for user-10:

Router# configure terminal

Enter configuration commands, one per line. End with CNTL/Z.

Router(config)# `ip inspect name abc user-10`

Router(config)# end
Verifying the Configuration: Example

The following example verifies your port-map configuration:

Router# show running-config | include port-map

ip port-map user-10 port tcp 4000 5000 6000 7000 8000 list 77 description "TEST STRING"

The following example verifies your inspection rule configuration:

Router# show running-config | include inspect

ip inspect name abc user-10

The following example displays information about the user-defined application called user-10.

Router# show ip port-map user-10

Host specific:    user-10              tcp port 4000...8000    in list 77    user defined

The following example displays detailed information about the user-defined application called user-10.

Router# show ip port-map user-10 detail

IP port-map entry for application 'user-10':
    tcp 4000...8000                   list 77 "TEST STRING"                  user defined

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

- ip inspect name
- ip port-map
- show ip port-map
Feature Information for Granular Protocol Inspection

Table 35 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Note

Table 35 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Glossary

firewall—A router or access server, or several routers or access servers, designated as a buffer between any connected public networks and a private network. A firewall router uses access lists and other methods to ensure the security of the private network.

granular—Degree of componentization. Small, fine-grained components provide greater flexibility in assembling the right combination of functionality, but can be difficult to manage.

inspection rule—A rule that specifies what IP traffic (which application-layer protocols) will be inspected by CBAC at an interface.

PAM—port-to-application mapping. A flexible, per-application port mapping capability that allows the Cisco IOS Firewall to support applications running on nonstandard ports. This feature allows network administrators to customize access control for specific applications and services, in order to meet their distinct network needs.

traffic inspection—A way that CBAC inspects traffic that travels through the firewall to discover and manage state information for TCP and UDP sessions. This state information is used to create temporary openings in the firewall’s access lists to allow return traffic and additional data connections for permissible sessions (sessions that originated from within the protected internal network).

UDP—User Data Protocol. A connectionless service—there are no actual sessions, so the software approximates sessions by examining the information in the packet and determining if the packet is similar to other UDP packets (for example, similar source/destination addresses and port numbers) and if the packet was detected soon after another similar UDP packet. “Soon” means within the configurable UDP idle timeout period.

HTTP Inspection Engine

The HTTP Inspection Engine feature allows users to configure their Cisco IOS Firewall to detect and prohibit HTTP connections—such as tunneling over port 80, unauthorized request methods, and non-HTTP compliant file transfers—that are not authorized within the scope of the security policy configuration. Tunneling unauthorized protocols through port 80 and over HTTP exposes a network to significant security risks.

The Cisco IOS Firewall can now be configured with a security policy that adheres to the following tasks:

- Allowing specific traffic targeted for port 80 to traverse the firewall. The traffic is inspected for protocol conformance and for the types of HTTP commands that are allowed or disallowed.
- Denying specific traffic targeted for port 80 that does not comply to HTTP traffic standards. The firewall is enabled to drop the packet, reset the connection, and send a syslog message, as appropriate.

Feature History for HTTP Inspection Engine

Restrictions for HTTP Inspection Engine

The Cisco 831 router with 48M RAM does not have enough memory to support this feature.

Information About HTTP Inspection Engine

Before configuring an application firewall to detect and police specific traffic targeted for port 80, you should understand the following concepts:

- What Is a Security Policy?, page 2
- Cisco IOS HTTP Application Policy Overview, page 2

What Is a Security Policy?

The application firewall uses a security policy, which consists of a collection of static signatures, to detect security violations. A static signature is a collection of parameters that specify protocol conditions that must be met before an action is taken. (For example, a signature may specify that an HTTP data stream containing the POST method must reset the connection.) These protocol conditions and reactions are defined by the end user via the command-line interface (CLI) to form a security policy.

Cisco IOS HTTP Application Policy Overview

HTTP uses port 80 to transport Internet web services, which are commonly used on the network and rarely challenged with regards to their legitimacy and conformance to standards. Because port 80 traffic is typically allowed through the network without being challenged, many application developers are leveraging HTTP traffic as an alternative transport protocol in which to enable their application to travel through or even bypass the firewall.

Most firewalls provide only packet filtering capabilities that simply permit or deny port 80 traffic without inspecting the data stream; the Cisco IOS application firewall for HTTP performs packet inspection as follows:

- Detects HTTP connections that are not authorized within the scope of the security policy configuration.
- Detects users who are tunneling applications through port 80.

If the packet is not in compliance with the HTTP protocol, it will be dropped, the connection will be reset, and a syslog message will be generated, as appropriate.

How to Define and Apply an HTTP Application Policy to a Firewall for Inspection

This section contains the following procedures:

- Defining an HTTP Application Policy, page 3
Defining an HTTP Application Policy

Use this task to create an HTTP application firewall policy.

Restrictions

Although application firewall policies are defined in global configuration mode, only one global policy for a given protocol is allowed per interface.

SUMMARY STEPS

1. enable
2. configure terminal
3. appfw policy-name policy-name
4. application protocol
5. strict-http action {reset | allow} [alarm]
6. content-length {min bytes max bytes | min bytes | max bytes} action {reset | allow} [alarm]
7. content-type-verification [match-req-resp] action {reset | allow} [alarm]
8. max-header-length {request bytes response bytes} action {reset | allow} [alarm]
9. max-uri-length bytes action {reset | allow} [alarm]
10. request-method {rfc rfc-method | extension extension-method} action {reset | allow} [alarm]
11. port-misuse {p2p | tunneling | im | default} action {reset | allow} [alarm]
12. transfer-encoding type {chunked | compress | deflate | gzip | identity | default} action {reset | allow} [alarm]
13. timeout seconds
14. audit-trail {on | off}
15. exit
16. exit

• Applying an HTTP Application Policy to a Firewall for Inspection, page 7
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  - Enter your password if prompted. |
| **Example:** Router> enable | |
| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:** Router# configure terminal | |
| **Step 3** appfw policy-name policy-name | Defines an application firewall policy and puts the router in application firewall policy configuration mode. |
| **Example:** Router(config)# appfw policy-name mypolicy | |
| **Step 4** application protocol | Allows you to configure inspection parameters for a given protocol. Currently, only HTTP traffic can be inspected.  
  - **protocol**—Specify the **http** keyword.  
  This command puts you in appfw-policy-protocol configuration mode, where “protocol” is dependent upon the specified protocol. Because only HTTP can be specified, the configuration mode is appfw-policy-http. |
| **Example:** Router(cfg-appfw-policy)# application http | |
| **Step 5** strict-http action (reset | (Optional) Allows HTTP messages to pass through the firewall or resets the TCP connection when HTTP noncompliant traffic is detected. |
|  | allow) [alarm] | |
| **Example:** Router(cfg-appfw-policy-http)# strict-http action allow alarm | |
| **Step 6** content-length (min bytes | (Optional) Permits or denies HTTP traffic through the firewall on the basis of message size.  
  - **min** | **max** bytes—Minimum or maximum content length, in bytes, allowed per message. Number of bytes range: 0 to 65535. |
|  | max | action (reset | allow) [alarm] | |
| **Example:** Router(cfg-appfw-policy-http)# content-length max 1 action allow alarm | |
| **Step 7** content-type-verification | (Optional) Permits or denies HTTP traffic through the firewall on the basis of content message type. |
| [match-req-resp] | action (reset | allow) [alarm] | |
| **Example:** Router(cfg-appfw-policy-http)# content-type-verification match-req-resp action allow alarm | |
| **Step 8** max-header-length | (Optional) Permits or denies HTTP traffic on the basis of the message header length.  
  - **bytes**—Number of bytes ranging from 0 to 65535. |
| (request | response | bytes) | action (reset | allow) [alarm] | |
| **Example:** Router(cfg-appfw-policy-http)# max-header-length request 1 response 1 action allow alarm | |
### Command or Action

#### Step 9

**max-uri-length bytes action (reset | allow) [alarm]**

(Optional) Permits or denies HTTP traffic on the basis of the URI length in the request message.

**Example:**

Router(cfg-appfw-policy-http)# max-uri-length 1
action allow alarm

#### Step 10

**request method (rfc rfc-method | extension extension-method) action (reset | allow) [alarm]**

(Optional) Permits or denies HTTP traffic according to either the request methods or the extension methods.

- **rfc**—Specifies that the supported methods of RFC 2616, *Hypertext Transfer Protocol—HTTP/1.1*, are to be used for traffic inspection.
- **rfc-method**—Any one of the following RFC 2616 methods can be specified: connect, default, delete, get, head, options, post, put, trace.
- **extension**—Specifies that the extension methods are to be used for traffic inspection.
- **extension-method**—Any one of the following extension methods can be specified: copy, default, edit, getattribute, getproperties, index, lock, mkdir, move, revadd, revlabel, revlog, save, setattribute, startrev, stoprev, unedit, unlock.

**Example:**

Router(cfg-appfw-policy-http)# request-method rfc default action allow alarm

#### Step 11

**port-misuse (p2p | tunneling | im | default) action (reset | allow) [alarm]**

(Optional) Permits or denies HTTP traffic through the firewall on the basis of specified applications in the HTTP message.

- **p2p**—Peer-to-peer protocol applications subject to inspection: Kazaa and Gnutella.
- **tunneling**—Tunneling applications subject to inspection: HTTPPort/HTTPHost, GNU Httptunnel, GotoMyPC, Firethru, Http-tunnel.com Client
- **im**—Instant messaging protocol applications subject to inspection: Yahoo Messenger.
- **default**—All applications are subject to inspection.

**Example:**

Router(cfg-appfw-policy-http)# port-misuse default action allow alarm
## Command or Action

### Step 12
```
transfer-encoding type {chunked | compress | deflate | gzip | identity | default} action {reset | allow} [alarm]
```

**Example:**
```
Router(cfg-appfw-policy-http)# transfer-encoding type default action allow alarm
```

### Purpose
(Optional) Permits or denies HTTP traffic according to the specified transfer-encoding of the message.
- **chunked**—Encoding format (specified in RFC 2616, *Hypertext Transfer Protocol—HTTP/1*) in which the body of the message is transferred in a series of chunks; each chunk contains its own size indicator.
- **compress**—Encoding format produced by the UNIX “compress” utility.
- **gzip**—Encoding format produced by the “gzip” (GNU zip) program.
- **identity**—Default encoding, which indicates that no encoding has been performed.
- **default**—All of the transfer encoding types.

### Step 13
```
timeout seconds
```

**Example:**
```
Router(cfg-appfw-policy-http)# timeout 60
```

(Optional) Overrides the global TCP idle timeout value for HTTP traffic.

**Note**
If this command is not issued, the default value specified via the `ip inspect tcp idle-time` command will be used.

### Step 14
```
audit-trail {on | off}
```

**Example:**
```
Router(cfg-appfw-policy-http)# audit-trail on
```

(Optional) Turns audit trail messages on or off.

**Note**
If this command is not issued, the default value specified via the `ip inspect audit-trail` command will be used.

### Step 15
```
exit
```

**Example:**
```
Router(cfg-appfw-policy-http)# exit
```

Exits cfg-appfw-policy-http configuration mode.

### Step 16
```
exit
```

**Example:**
```
Router(cfg-appfw-policy)# exit
```

Exits cfg-appfw-policy configuration mode.

## What to Do Next

After you have successfully defined an application policy for HTTP traffic inspection, you must apply the policy to an inspection rule. Thereafter, the inspection rule must be applied to an interface. For information on completing this task, see the section “Applying an HTTP Application Policy to a Firewall for Inspection.”
Applying an HTTP Application Policy to a Firewall for Inspection

Use this task to apply an HTTP application policy to an inspection rule, followed by applying the inspection rule to an interface.

**Note**
An application policy can coexist with other inspection protocols (for example, an HTTP policy and an FTP policy can coexist).

**Prerequisites**
You must have already defined an application policy (as shown in the section “Defining an HTTP Application Policy”).

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip inspect name inspection-name appfw policy-name
4. ip inspect name inspection-name http [alert {on | off}] [audit-trail {on | off}] [timeout seconds]
5. interface type number
6. ip inspect inspection-name {in | out}
7. exit
8. exit
9. show appfw configuration [name]
   or
   show ip inspect {name inspection-name | config | interfaces | session [detail] | statistics | all}
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  - Enter your password if prompted. |
| **Example:**  
Router> enable | |
| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:**  
Router# configure terminal | |
| **Step 3** ip inspect name inspection-name appfw policy-name | Defines a set of inspection rules for the application policy.  
  - *policy-name*—Must match the policy name specified via the `appfw policy-name` command. |
| **Example:**  
Router(config)# ip inspect name firewall appfw mypolicy | |
| **Step 4** ip inspect name inspection-name http [alert {on | off}] [audit-trail {on | off}] [timeout seconds] | Defines a set of inspection rules that is to be applied to all HTTP traffic.  
  - The *inspection-name* argument must match the *inspection-name* argument specified in Step 3. |
| **Example:**  
Router(config)# ip inspect name firewall http | |
| **Step 5** interface type number | Configures an interface type and enters interface configuration mode. |
| **Example:**  
Router#(config)# interface FastEthernet0/0 | |
| **Step 6** ip inspect inspection-name {in | out} | Applies the inspection rules (defined in Step 3 and Step 4) to all traffic entering the specified interface.  
  - The *inspection-name* argument must match the inspection name defined via the `ip inspect name` command. |
| **Example:**  
Router#(config-if)# ip inspect firewall in | |
| **Step 7** exit | Exits interface configuration mode. |
| **Example:**  
Router#(config-if)# exit | |
HTTP Inspection Engine

How to Define and Apply an HTTP Application Policy to a Firewall for Inspection

Troubleshooting Tips

To help troubleshoot the application firewall configuration, issue the following application-firewall specific debug command: `debug appfw {application protocol | function-trace | object-creation | object-deletion | events | timers | detailed}`.

The following sample configuration shows how to configure an HTTP policy with application firewall debugging enabled:

```
Router(config)# appfw policy-name myPolicyAPPFW   FUNC:appfw_policy_find
APPFW  FUNC:appfw_policy_find -- Policy myPolicy is not found
APPFW  FUNC:appfw_policy_alloc
APPFW  FUNC:appfw_policy_alloc -- policy_alloc 0x65727278
APPFW  FUNC:appfw_policy_alloc -- Policy 0x65727278 is set to valid
APPFW  FUNC:appfw_policy_alloc -- Policy myPolicy has been created
APPFW  FUNC:appfw_policy_command -- memlock policy 0x65727278

! Debugging sample for application (HTTP) creation

Router(cfg-appfw-policy)# application httpAPPFW   FUNC:appfw_http_command
APPFW  FUNC:appfw_http_appl_find
APPFW  FUNC:appfw_http_appl_find -- Application not found
APPFW  FUNC:appfw_http_appl_alloc
APPFW  FUNC:appfw_http_appl_alloc -- appl_http 0x64D7A25C
APPFW  FUNC:appfw_http_appl_alloc -- Application HTTP parser structure 64D7A25C created

! Debugging sample for HTTP-specific application inspection

Router(cfg-appfw-policy-http)#

Router(cfg-appfw-policy-http)# strict-http action reset alarm
APPFW  FUNC:appfw_http_subcommand
APPFW  FUNC:appfw_http_subcommand -- strict-http cmd turned on

Router# debug appfw detailed

APPFW Detailed Debug debugging is on
```

Example:

```
Router(config)# exit
Exits global configuration mode.

Step 8

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>exit</td>
<td></td>
</tr>
</tbody>
</table>

Example:

```
Router(config)# exit
```

Step 9

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show appfw config</td>
<td></td>
</tr>
</tbody>
</table>

Example:

```
Router# show appfw configuration
```

or

```
show ip inspect {name inspection-name | config | interfaces | session [detail] | statistics | all}
```

Example:

```
Router# show ip inspect config
```

(Optional) Displays application firewall policy configuration information.

(Optional) Displays firewall-related configuration information.

Command or Action Purpose

Step 8

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>exit</td>
<td></td>
</tr>
</tbody>
</table>

Example:

```
Router(config)# exit
Exits global configuration mode.
```

Step 9

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>show appfw config</td>
<td></td>
</tr>
</tbody>
</table>

Example:

```
Router# show appfw configuration
```

or

```
show ip inspect {name inspection-name | config | interfaces | session [detail] | statistics | all}
```

Example:

```
Router# show ip inspect config
```

(Optional) Displays application firewall policy configuration information.

(Optional) Displays firewall-related configuration information.

Example:

```
Router(config)# exit
```

Exits global configuration mode.

Example:

```
Router# show appfw configuration
```

or

```
show ip inspect {name inspection-name | config | interfaces | session [detail] | statistics | all}
```

Example:

```
Router# show ip inspect config
```

(Optional) Displays application firewall policy configuration information.

(Optional) Displays firewall-related configuration information.

Example:

```
Router(config)# exit
```
Configuration Examples for Setting Up an HTTP Inspection Engine

This section contains the following configuration example:

- Setting Up and Verifying an HTTP Inspection Engine: Example, page 10

Setting Up and Verifying an HTTP Inspection Engine: Example

The following example show how to define the HTTP application firewall policy “mypolicy.” This policy includes all supported HTTP policy rules. This example also includes sample output from the `show appfw configuration` and `show ip inspect config` commands, which allow you to verify the configured setting for the application policy.

! Define the HTTP policy.
application http
  strict-http action allow alarm
  content-length maximum 1 action allow alarm
  content-type-verification match-req-rsp action allow alarm
  max-header-length request 1 response 1 action allow alarm
  max-uri-length 1 action allow alarm
  port-misuse default action allow alarm
  request-method rfc put action allow alarm
  transfer-encoding type default action allow alarm
!
!
! Apply the policy to an inspection rule.
ip inspect name firewall appfw mypolicy
ip inspect name firewall http
!
!
! Apply the inspection rule to all HTTP traffic entering the FastEthernet0/0 interface.
interface FastEthernet0/0
  ip inspect firewall in
!
!
! Issue the `show appfw configuration` command and the `show ip inspect config` command after the inspection rule “mypolicy” is applied to all incoming HTTP traffic on the FastEthernet0/0 interface.
!
Router# show appfw configuration

Application Firewall Rule configuration
  Application Policy name mypolicy
    Application http
      strict-http action allow alarm
      content-length minimum 0 maximum 1 action allow alarm
      content-type-verification match-req-rsp action allow alarm
      max-header-length request length 1 response length 1 action allow alarm
      max-uri-length 1 action allow alarm
      port-misuse default action allow alarm
      request-method rfc put action allow alarm
      transfer-encoding default action allow alarm

Router# show ip inspect config

Session audit trail is disabled
Session alert is enabled
one-minute (sampling period) thresholds are [400:500] connections
max-incomplete sessions thresholds are [400:500]
max-incomplete tcp connections per host is 50. Block-time 0 minute.
tcp synwait-time is 30 sec -- tcp finwait-time is 5 sec
tcp idle-time is 3600 sec -- udp idle-time is 30 sec
dns-timeout is 5 sec
Inspection Rule Configuration
Inspection name firewall
http alert is on audit-trail is off timeout 3600

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at
http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

New Commands
- `appfw policy-name`
- `application`
- `audit-trail`
- `content-length`
- `content-type-verification`
- `debug appfw`
- `max-header-length`
- `max-uri-length`
- `port-misuse`
- `request-method`
- `show appfw`
- `strict-http`
- `timeout`
- `transfer-encoding type`

Modified Command
- `ip inspect name`

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Inspection of Router-Generated Traffic

The Inspection of Router-Generated Traffic feature allows Context-Based Access Control (CBAC) to inspect traffic that is originated by or destined to the router on which CBAC is configured. Previously, inspection of Transmission Control Protocol (TCP), User Datagram Protocol (UDP), and H.323 connections initiated by or destined to the router were allowed.

Prerequisites for Inspection of Router-Generated Traffic

- Configure CBAC.
- Configure Cisco Call Manager Express (CCME) or H.323 Gateway to configure the inspection of H.323 connections to and from the router.

Restrictions for Inspection of Router-Generated Traffic

- Inspection of router-generated traffic is supported only on the following protocols: H.323, TCP, and UDP.
- The Cisco IOS Firewall supports only Version 2 of the H.323 protocol. If CCME or the H.323 Gateway has inspection of H.323 router traffic enabled, enter the following commands so that it is configured to support only Version 2 features:

  ```
  voice service voip
  h323
  session transport tcp calls-per-connection 1
  h245 tunnel disable
  h245 caps mode restricted
  h225 timeout tcp call-idle value 0
  ```

Information About Inspection of Router-Generated Traffic

To configure Inspection of Router-Generated Traffic, you need to understand the following concepts:

- CBAC, page 2
- Inspection of Router-Generated Traffic Overview, page 3

CBAC

CBAC is a Cisco IOS Firewall set feature that provides network protection by using the following functions:

- Traffic Filtering
- Traffic Inspection
- Alerts and Audit Trails
- Intrusion Detection

Traffic Filtering

CBAC filters TCP and UDP packets based on application-layer protocol session information. You can configure CBAC to permit specified TCP and UDP traffic through a firewall only when the connection is initiated from within the network you want to protect. CBAC can inspect traffic for sessions that originate from either side of the firewall, and CBAC can be used for intranet, extranet, and Internet perimeters of your network.
Traffic Inspection

CBAC inspects traffic that travels through the firewall to discover and manage state information for TCP and UDP sessions. This state information is used to create temporary openings in the firewall’s access lists to allow return traffic and additional data connections for permissible sessions.

Alerts and Audit Trails

CBAC generates real-time alerts and audit trails. Enhanced audit trail features use SYSLOG to track all network transactions; it records time stamps, the source host, the destination host, the ports used, and the total number of transmitted bytes, for advanced, session-based reporting. Real-time alerts send SYSLOG error messages to central management consoles upon detecting suspicious activity.

Using CBAC inspection rules, you can configure alerts and audit trail information on a per-application protocol basis. For example, if you want to generate audit trail information for HTTP traffic, you can specify that in the CBAC rule covering HTTP inspection.

Intrusion Detection

CBAC provides a limited amount of intrusion detection to protect against specific Simple Mail Transfer Protocol (SMTP) attacks. With intrusion detection, SYSLOG messages are reviewed and monitored for specific “attack signatures.” Certain types of network attacks have specific characteristics, or signatures. When CBAC detects an attack, it resets the offending connections and sends SYSLOG information to the SYSLOG server.

Inspection of Router-Generated Traffic Overview

Inspection of Router-Generated Traffic enhances CBAC’s functionality to inspect TCP, UDP, and H.323 connections that have a router or firewall as one of the connection endpoints. This enables CBAC to open pinholes for TCP, UDP, and H.323 control channel connections to and from the router, and to open pinholes for data and media channels negotiated over the H.323 control channels.

Inspection of TCP and UDP channels initiated from the router enables dynamic opening of pinholes on the interface access control list (ACL) to allow return traffic. You do not have to modify the ACL when a TCP connection such as Telnet is made from the router.

Inspection of local H.323 connections enables the deployment of CCME, H.323 gateway, and the Cisco IOS Firewall on the same router. This also simplifies ACL configuration on CCME’s interface through which H.323 connections are made. Before this feature, in addition to configuring ACLs to allow H.323 connections on a standard port (for example, port 1720), you had to configure ACLs to allow all dynamically negotiated data and media channels. With this feature you just configure the ACLs to allow H.323 control channels on port 1720. The Cisco IOS Firewall inspects all the traffic on the control channel and opens pinholes to allow dynamically negotiated data and media channels.

To enable Inspection of Router-Generated Traffic, specify the router-traffic keyword in the ip inspect name command of the appropriate protocol.

How to Configure Inspection of Router-Generated Traffic

This section contains the following procedures:

- Configuring H.323 Inspection, page 4 (required)
- Configuring CBAC, page 5 (required)
- Verifying the CBAC Configuration, page 7 (optional)
## Configuring H.323 Inspection

To configure the H.323 protocol, perform the following steps.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip inspect name inspection-name {TCP | UDP | H323} [alert {on | off}] [audit-trail {on | off}] [router-traffic] [timeout seconds]`
4. `interface type slot/port`
5. `exit`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Router&gt; enable</code></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Router# configure terminal</code></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Defines a set of inspection rules.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Router(config)# ip inspect name test H.323 router-traffic</code></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Configures an interface type.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Router(config)# interface FE 0/0</code></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>Exits global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td><code>Router(config)# exit</code></td>
</tr>
</tbody>
</table>
Configuring CBAC

To configure CBAC, perform the following steps.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. access-list access-list-number {deny | permit} source [source-wildcard] [log]
4. ip inspect name inspection-name {TCP | UDP | H323} [alert {on | off}] [audit-trail {on | off}] [router-traffic] [timeout seconds]
5. interface type slot/port
6. ip inspect inspection-name {in | out}
7. exit

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  • Enter your password if prompted. |
<p>| Example: Router&gt; enable |
| <strong>Step 2</strong> configure terminal | Enters global configuration mode. |
| Example: Router# configure terminal |
| <strong>Step 3</strong> access-list access-list-number {deny | permit} source [source-wildcard] [log] | Defines a standard IP access list. |
| Example: Router(config)# access-list 121 permit tcp host 100.168.11.1 any eq 1720 |
| <strong>Step 4</strong> ip inspect name inspection-name {TCP | UDP | H323} [alert {on | off}] [audit-trail {on | off}] [router-traffic] [timeout seconds] | Defines a set of inspection rules. |
| Example: Router(config)# ip inspect name here H323 router-traffic timeout 180 |
| <strong>Step 5</strong> interface type slot/port | Configures an interface type. |
| Example: Router(config)# Serial0/3/0 |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>

<td></td>
</tr>
<tr>
<td><code>Router(config-if)# ip inspect test in</code></td>
<td></td>
</tr>
<tr>
<td>Step 7: <code>exit</code></td>
<td>Exits global configuration mode and returns to privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Router(config)# exit</code></td>
<td></td>
</tr>
</tbody>
</table>
Verifying the CBAC Configuration

To verify the CBAC configuration, perform the following steps.

**SUMMARY STEPS**

1. `show ip inspect name inspection-name`
2. `show ip inspect config`
3. `show ip inspect interfaces`
4. `show ip inspect session [detail]`
5. `show ip inspect all`

**DETAILED STEPS**

**Step 1**

`show ip inspect name inspection-name`

Use this command to show a particular configured inspection rule. The following example configures the inspection rule `myinspectionrule`. The output shows the protocols that should be inspected by CBAC and the corresponding idle timeouts for each protocol.

```
Router# show ip inspect name myinspectionrule
Inspection Rule Configuration

inspection name myinspectionrule
tcp timeout 3600
udp timeout 30
ftp timeout 3600
```

**Step 2**

`show ip inspect config`

Use this command to show the CBAC configuration, including global timeouts, thresholds, and inspection rules.

```
Router# show ip inspect config
Session audit trail is disabled
one-minute (sampling period) thresholds are [400:500] connections
max-incomplete sessions thresholds are [400:500]
max-incomplete tcp connections per host is 50. Block-time 0 minute.
tcp synwait-time is 30 sec -- tcp finwait-time is 5 sec
tcp idle-time is 3600 sec -- udp idle-time is 30 sec
dns-timeout is 5 sec
Inspection Rule Configuration

inspection name myinspectionrule
tcp timeout 3600
udp timeout 30
ftp timeout 3600
```
### Step 3: `show ip inspect interfaces`

Use this command to show the interface configuration with respect to applied inspection rules and access lists.

```
Router# show ip inspect interfaces

Interface Configuration
  Interface Ethernet0
    Inbound inspection rule is myinspectionrule
    tcp timeout 3600
    udp timeout 30
    ftp timeout 3600
    Outgoing inspection rule is not set
    Inbound access list is not set
    Outgoing access list is not set
```

### Step 4: `show ip inspect session detail`

Use this command to display existing sessions that CBAC is currently tracking and inspecting. The following sample output shows that an outgoing ACL and an inbound ACL (dynamic ACLs) have been created to allow return traffic.

```
Router# show ip inspect session detail

Established Sessions
    Created 00:00:08, Last heard 00:00:04
    Bytes sent (initiator:responder) [140:298] acl created 2
    Outgoing access-list 102 applied to interface FastEthernet0/0
    Inbound access-list 101 applied to interface FastEthernet0/1
```

### Step 5: `show ip inspect all`

Use this command to show all CBAC configuration and all existing sessions that are currently being tracked and inspected by CBAC.

```
Router# show ip inspect all

Session audit trail is disabled
  one-minute (sampling period) thresholds are [400:500] connections
  max-incomplete sessions thresholds are [400:500]
  max-incomplete tcp connections per host is 50. Block-time 0 minute.
  tcp synwait-time is 30 sec -- tcp finwait-time is 5 sec
  tcp idle-time is 3600 sec -- udp idle-time is 30 sec
  dns-timeout is 5 sec

Inspection Rule Configuration
  Inspection name all
    tcp timeout 3600
    udp timeout 30
    ftp timeout 3600

Interface Configuration
  Interface Ethernet0
    Inbound inspection rule is all
    tcp timeout 3600
    udp timeout 30
    ftp timeout 3600
    Outgoing inspection rule is not set
    Inbound access list is not set
    Outgoing access list is not set

Established Sessions
  Session 25A6E1C (30.0.0.1:46065)=>(40.0.0.1:21) ftp SIS_OPEN
  Session 25A34A0 (40.0.0.1:20)=>(30.0.0.1:46072) ftp-data SIS_OPEN
```
Configuration Examples for Inspection of Router-Generated Traffic

This section provides the following configuration examples:

- Configuring CBAC with Inspection of H.323 Traffic: Example, page 9

Configuring CBAC with Inspection of H.323 Traffic: Example

These commands create the ACL. In this example, TCP traffic from subnet 100.168.11.1, 192.168.11.50, and 192.168.100.1 is permitted.

access-list 120 permit tcp host 100.168.11.1 any eq 1720
access-list 121 permit tcp host 192.168.11.50 host 100.168.11.1 eq 1720
access-list 121 permit tcp host 192.168.100.1 host 100.168.11.1 eq 1720

These commands create the CBAC inspection rule LOCAL-H323, allowing inspection of the protocol traffic specified by the rule. This inspection rule sets the timeout value to 180 seconds for each protocol (except for RPC). The timeout value defines the maximum time that a connection for a given protocol can remain active without any traffic passing through the router. When these timeouts are reached, the dynamic ACLs that are inserted to permit the returning traffic are removed, and subsequent packets (possibly even valid ones) are not permitted.

ip inspect name LOCAL-H323 tftp timeout 180
ip inspect name LOCAL-H323 h323 router-traffic timeout 180

These commands apply the inspection rule and ACL. In this example, the inspection rule LOCAL-H323 is applied to traffic at interface Serial0/3/0.

interface Serial0/3/0
ip address 11.168.11.2 255.255.255.0
ip access-group 121 in
ip access-group 120 out
ip inspect LOCAL-H323 in
ip inspect LOCAL-H323 out
encapsulation frame-relay
frame-relay map ip 11.168.11.1 168 broadcast
no frame-relay inverse-arp
frame-relay intf-type dce

- `ip inspect name`
Glossary

CBAC—Context-Based Access Control. Scrutinizes source and destination addresses to enhance security for TCP and UDP applications that use well-known ports, such as FTP and e-mail traffic.

firewall—one or more router or access servers designated as a buffer between any connected public networks and a private network. A firewall router uses access lists and other methods to ensure the security of the private network.

FTP—File Transfer Protocol. An application protocol, part of the TCP/IP protocol stack, for transferring files between network nodes.

H.323—a multimedia conferencing protocol that includes voice, video, and data conferencing for use over packet-switched networks. H.323 allows dissimilar communication devices to communicate with each other by using a standardized communication protocol.

IMAP—Internet Message Access Protocol. A method of accessing e-mail or bulletin board messages kept on a mail server that can be shared. IMAP permits client e-mail applications to access remote message stores as if they were local without actually transferring the message.

IP—Internet Protocol. Connectionless protocol at the network layer (Layer 3) of the OSI reference model. Provides features for addressing, type-of-service specification, fragmentation and reassemble, and security. IP works with TCP and is usually identified as TCP/IP.

POP—Post Office Protocol. A protocol that client e-mail applications use to retrieve mail from a mail server.

SMTP—Simple Mail Transfer Protocol. A simple ASCII protocol that describes the exchange of e-mail between two message-transfer agents using TCP/IP.

TCP/IP—Transmission Control Protocol/Internet Protocol. Common name for the suite of protocols developed by the U.S. Department of Defense in the 1970s to support the construction of worldwide internetworks. TCP and IP are the two best-known protocols in the suite.

UDP—User Datagram Protocol. A connectionless transport-layer protocol for exchanging datagrams without acknowledgments or guaranteed delivery.

VoIP—Voice over IP. Capability of carrying normal telephony-style voice over an IP network with circuit-based telephone-like functionality, reliability, and voice quality. VoIP generally refers to the Cisco standards-based (H.323 and so forth) approach to IP voice traffic.

Transparent Cisco IOS Firewall

The Transparent Cisco IOS Firewall feature allows users to “drop” a Cisco IOS Firewall in front of their existing network without changing the statically defined IP addresses of their network-connected devices. Thus, users can allow selected devices from a subnet to traverse the firewall while access to other devices on the same subnet is denied.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at http://www.cisco.com/go/fn. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.
Restrictions for Transparent Cisco IOS Firewall

Layer 3 IP Packet Support Only

Only IP packets (TCP, User Datagram Protocol [UDP], and Internet Control Message Protocol [ICMP]) are subjected to inspection by the transparent firewall. Non-IP traffic is bridged as usual without interference from the transparent firewall. However, if users wish to block non-IP traffic, the MAC access control lists (ACLs) can be applied on interfaces to filter out non-IP traffic and allow only IP traffic.

The following example shows how to configure an ACL that permits all IP packets (0x0800) into the Ethernet interface but denies all Internetwork Packet Exchange (IPX) packets (0x8137):

```
Router(config)# access-list 201 permit 0x0800
Router(config)# access-list 201 deny 0x8137
Router(config)# interface ethernet 0
Router(config-if)# bridge-group 1 input-type-list 201
```

VLAN Trunk Bridging

Bridging between VLAN trunks works only for dot1q encapsulation; Inter-Switch Link (ISL) encapsulation will not work. (However, ISL VLANs will work if subinterfaces are created and placed in a bridge group.)

Information About Transparent Cisco IOS Firewall

To use a transparent Cisco IOS Firewall in your network, you should understand the following concepts:

- Benefit of the Transparent Firewall, page 2
- Transparent Firewall Overview, page 2
- Layer 2 and Layer 3 Firewalls Configured on the Same Router, page 3

Benefit of the Transparent Firewall

Added Security with Minimum Configuration

Users can simply drop a transparent Cisco IOS Firewall into an existing network without having to reconfigure their statically defined devices. Thus, the tedious and costly overhead that is required to renumber devices on the trusted network is eliminated.

Transparent Firewall Overview

A typical Cisco IOS Firewall is a Layer 3 device with trusted and untrusted interfaces on different IP subnets. A Layer 3 firewall works well with Cisco IOS devices that function as routers with preexisting subnet separations. However, when a Layer 3 firewall is placed in an existing network, the network IP addresses must be reconfigured to accommodate the firewall.

A transparent Cisco IOS firewall acts as a Layer 2 transparent bridge with context-based access control (CBAC) and ACLs configured on the bridged interface. Because the Layer 2 firewall intercepts packets at Layer 2 and is “transparent” to the existing network, Layer 3 firewall limitations are not applicable.
Transparent Bridging Overview

If configured for bridging, a Cisco IOS device can bridge any number of interfaces. The device can complete basic bridging tasks such as learning MAC addresses on ports to restrict collision domains and running Spanning Tree Protocol (STP) to prevent looping in the topology.

Within bridging, a user can configure Integrated Routed Bridging (IRB), which allows a device to bridge on some interfaces while a Layer 3 Bridged Virtual Interface (BVI) is presented for routing. The bridge can determine whether the packet is to be bridged or routed on the basis of the destination of the Layer 2 or Layer 3 IP address in the packet. Configured with an IP address, the BVI can manage the device even if there is no interface configured for routing.

Layer 2 and Layer 3 Firewalls Configured on the Same Router

A transparent firewall supports a BVI for routing, so a packet that comes in on a bridged interface can be bridged or routed out of the BVI. This functionality allows a Layer 2 (transparent) firewall and a Layer 3 firewall to be configured on the same router: The transparent firewall operates on the bridged packets while the “normal” firewall operates on the routed packets. For example, if you have six interfaces on your router and two of them are in a bridge group, you can simultaneously configure and run normal inspection on the remaining four interfaces.

How to Configure a Transparent Cisco IOS Firewall

You configure a transparent firewall just as you would configure a Layer 3 firewall (via the ip inspect command, which can be configured on any of the bridged interfaces for the transparent firewall). Also, you configure transparent bridging for a firewall just as you would for any other Cisco IOS device.

This section contains the following procedures:
- Configuring a Bridge Group, page 3 (required)
- Configuring Inspection and ACLs, page 6 (required)
- Forwarding DHCP Traffic, page 8 (optional)
- Monitoring Transparent Firewall Events, page 8 (optional)

Configuring a Bridge Group

Use this task to configure a bridge group and to associate interfaces or subinterfaces in the configured bridge group.

BVI Configuration Requirements

- If a BVI is not configured, you must disable IP routing (via the no ip routing command) for the bridging operation to take effect.
- If configured, a BVI must be configured with an IP address in the same subnet.
- You must configure a BVI if more than two interfaces are placed in a bridge group.
Restrictions

- If more than two interfaces are assigned to a bridge group, any routers that are acting as first-hop gateways to hosts that are in the bridged network (the bridge group) must allow ICMP time-to-live (TTL) exceeded messages to pass.
- Spanning Tree Bridge Protocol Data Units (BPDU) and packets that are to be routed out of the bridge, if IRB is configured, are not inspected.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `bridge bridge-group protocol {dec | ibm | ieee | vlan-bridge}`
4. `interface type number`
5. `bridge-group bridge-group`
6. `exit`
7. `bridge irb`
8. `bridge bridge-group route protocol`
9. `interface type number`
10. `ip address ip-address mask`
11. `no shutdown`

DETAILED STEPS

<td>Restarts a disabled interface.</td>
</tr>
</tbody>
</table>

### Examples

The following example shows how to configure interfaces “ethernet0” and “ethernet1” in a bridge group. These interfaces are associated with the BVI interface “BVI1,” which can be reached from any host on either of the interfaces via the IP address 10.1.1.1.

```
Router(config)# bridge 1 protocol ieee
Router(config)# interface ethernet0
Router(config-if)# bridge-group 1
Router(config-if)# interface ethernet1
Router(config-if)# bridge-group 1
Router(config-if)# exit
! Configure the BVI.
Router(config)# bridge irb
Router(config)# bridge 1 route ip
Router(config)# interface BVI1
Router(config-if)# ip address 10.1.1.1 255.255.255.0
Router(config-if)# no shutdown
```
Troubleshooting Tips

To display the status of each bridge group, use the `show bridge-group` command or to display entries in the bridge table, use the `show bridge` command.

What to Do Next

After you have configured the bridge group, you must configure an inspection rule and at least one IP ACL. To complete this task, refer to the following section, “Configuring Inspection and ACLs.”

Note

If inspection is not configured on any interface in the bridge group, IP ACLs on bridged interfaces will not be active.

Configuring Inspection and ACLs

Use this task to configure an inspection rule and apply it on the appropriate interface. Also, use this task to configure at least one ACL and apply it on one or more of the interfaces that you configured in the bridge group.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `ip inspect name protocol [alert {on | off}] [audit-trail {on | off}] [timeout seconds]`
4. `interface type number`
5. `ip inspect inspection-name {in | out}`
6. `exit`
7. `access-list access-list-number {permit | deny} {type-code wild-mask | address mask}`
8. `interface type number`
9. `ip access-group {access-list-number | access-list-name} {in | out}`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>enable</strong></td>
<td></td>

<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>configure terminal</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Router# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

**Step 3**

```
ip inspect name protocol [alert {on | off}] [audit-trail {on | off}] [timeout seconds]
```

**Example:**
```
Router(config)# ip inspect name test tcp
```

- Defines a set of inspection rules.

**Step 4**

```
interface type number
```

**Example:**
```
Router(config)# interface Ethernet0
```

- Configures an interface type and enters interface configuration mode.

**Step 5**

```
ip inspect inspection-name {in | out}
```

**Example:**
```
Router(config-if)# ip inspect test in
```

- Applies a set of inspection rules to an interface.

**Step 6**

```
exit
```

**Step 7**

```
access-list access-list-number {permit | deny} {type-code wild-mask | address mask}
```

**Example:**
```
Router(config)# access-list 156 permit 10.1.1.0 0.0.0.255 any
```

- Configures the ACL.

**Note** Repeat this step for each ACL that you want to configure.

**Step 8**

```
interface type number
```

**Example:**
```
Router(config)# interface Ethernet0
```

- Configures an interface type and enters interface configuration mode.

**Note** Repeat Steps 8 and 9 for each ACL that you want to apply to inbound packets from a specific interface.

**Step 9**

```
ip access-group {access-list-number | access-list-name} {in | out}
```

**Example:**
```
Router(config-if) ip access-group 156 in
```

- Controls access to an interface.

### Examples

The following example shows how to configure an inspection rule on interface “ethernet0,” which is the inside interface. Policies can be specified via ACL 156 or 101; for example, ACL 156 can be used to specify that rlogin and rsh are not allowed for the internal users, and ACL 101 can be used to specify that an external host requires connectivity to a particular host in the internal domain.

```
Router(config)# ip inspect name test tcp
Router(config)# interface ethernet0
Router(config-if)# ip inspect test in
Router(config-if)# exit

! Configure the ACLs.
Router(config)# access-list 101 deny ip any any
Router(config)# access-list 156 permit 10.1.1.0 0.0.0.255 any
Router(config)# access-list 156 deny ip any any

Router(config)# interface ethernet0
Router(config-if) ip access-group 156 in
```
Forwarding DHCP Traffic

Use this task to enable a transparent firewall to forward DHCP packets across the bridge without inspection; that is, the `ip inspect L2-transparent dhcp-passthrough` command overrides the ACL for DHCP packets, so DHCP packets will be forwarded even if the ACL is configured to deny all IP packets. Thus, clients on one side of the bridge can get an IP address from a DHCP server on the opposite side of the bridge.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip inspect L2-transparent dhcp-passthrough`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router&gt; enable</td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>ip inspect L2-transparent dhcp-passthrough</code></td>
<td>Allows a transparent firewall to forward DHCP passthrough traffic.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router#(config) ip inspect L2-transparent dhcp-passthrough</td>
<td></td>
</tr>
</tbody>
</table>

**Monitoring Transparent Firewall Events**

Use either of these optional steps to monitor the activity of the transparent firewall.

*Note* Effective with Cisco IOS Release 12.4(20)T, the `debug ip inspect` command is replaced by the `debug policy-firewall` command. See the *Cisco IOS Debug Command Reference* for more information.

**SUMMARY STEPS**

1. `enable`
2. `debug ip inspect L2-transparent {packet | dhcp-passthrough}`
3. `show ip inspect {name inspection-name | config | interfaces | session [detail] | all}`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  - Enter your password if prompted. |
| Example: Router> enable | |
| **Step 2** debug ip inspect L2-transparent (packet | Enables debugging messages for transparent firewall events.  
  dhcp-passthrough) |  
  - **packet**—Displays messages for all debug packets that are inspected by the transparent firewall.  
  - **dhcp-passthrough**—Displays debug messages only for DHCP pass-through traffic that the transparent firewall forwards across the bridge. |
| Example: Router# debug ip inspect L2-transparent dhcp-passthrough | |
| **Step 3** show ip inspect {name inspection-name | config | interfaces | session [detail] | all} | Displays Cisco IOS Firewall configuration and session information.  
  - If the transparent firewall is configured, use the **all** keyword to display the bridging interface in the interface configuration section of the output. |
| Example: Router# show ip inspect all | |

**Examples**

The following sample output is a portion of the `show ip inspect all` command that shows the bridging interface:

```
Router# show ip inspect all
.
.
.
Interface Configuration
  ! Below is the bridging interface.
  Interface Ethernet1
  Inbound inspection rule is test
tcp alert is on audit-trail is off timeout 3600
ftp alert is on audit-trail is off timeout 3600
Outgoing inspection rule is not set
Inbound access list is not set
Outgoing access list is 156
.
.
```

**Configuration Examples for Transparent Cisco IOS Firewall**

This section contains the following configuration examples:

- Comprehensive Transparent Firewall Configuration: Example, page 10
- Monitoring Telnet Connections via debug and show Output: Examples, page 12
Comprehensive Transparent Firewall Configuration: Example

The following example and sample topology (see Figure 1) illustrate how to configure and debug a transparent Cisco IOS Firewall configuration between a client, a firewall, and a server. This example also includes show command output for additional configuration verification. After you have configured a transparent firewall, you can Telnet from the client to the server through the firewall. (See the section “Monitoring Telnet Connections via debug and show Output: Examples.”)

Figure 1 Sample Topology for Transparent Firewall Configuration

Note Effective with Cisco IOS Release 12.4(20)T, the debug ip inspect command is replaced by the debug policy-firewall command. See the Cisco IOS Debug Command Reference for more information.

  ! approximately 30 seconds to move to a forwarding after "bridge-group 1" is configured.

**Monitoring Telnet Connections via debug and show Output: Examples**

The following examples shows how to monitor established Telnet connections from the client to the server through the firewall (see Figure 1) and from the server to the client. In these example, the `debug ip inspect l2-transparent packet` command has been issued to generate the debug messages. Relevant `show` commands are also issued for additional verification.
Effective with Cisco IOS Release 12.4(20)T, the `debug ip inspect` command is replaced by the `debug policy-firewall` command. See the `Cisco IOS Debug Command Reference` for more information.

- Telnet Connection from the Client (97.0.0.2) to the Server (97.0.0.23), page 13

Telnet Connection from the Client (97.0.0.2) to the Server (97.0.0.23)

The following example is output from the initial Telnet connection between the client and the server. A subsequent connection is established to highlight differences in the debug output. Explanations are given inline.

! A packet is received by the firewall in the flood path because the bridge-table is ! initially empty. However, the client seems to have the server’s mac-address in its ARP ! cache, so the bridge floods the packet and it appears in the firewall’s “flood” path.

*Mar 1 00:26:12.367:L2FW:Packet punted up by Input ACL for logging
! The packet arrives at process level
*Mar 1 00:26:12.367:L2FW:insp_l2_inspection:input is Ethernet1 output is Ethernet0
*Mar 1 00:26:12.371:L2FW*:Src 97.0.0.23 dst 97.0.0.2 protocol tcp
! The ACL log is generated
*Mar 1 00:26:12.371:%SEC-6-IPACCESSLOGP:list 101 denied tcp 97.0.0.23(11045) -> 97.0.0.0.2(23), 1 packet
! The packet is dropped by the ACL
*Mar 1 00:26:12.371:L2FW:Packet processed and dropped by Input ACL
! The packet is dropped by the ACL and is therefore NOT sent to CBAC for inspection
*Mar 1 00:26:12.371:L2FW:Packet is dropped in insp_l2_inspection
Configuring and Verifying DHCP Pass-Through Traffic: Examples

The following examples show how to verify (via debug messages) DHCP pass-through that has been allowed and traffic that has not been allowed.

- Allowing DHCP Pass-Through Traffic: Example, page 16
- Denying DHCP Pass-Through Traffic: Example, page 17

Allowing DHCP Pass-Through Traffic: Example

In this example, the static IP address of the client is removed and the address is acquired via DHCP using the `ip address dhcp` command on the interface that is connected to the transparent firewall.

```
Router# show debug
ARP:
   ARP packet debugging is on
L2 Inspection:
   INSPECT L2 firewall debugging is on
   INSPECT L2 firewall DHCP debugging is on
Router#
Router(config)# ip insp l2-transparent dhcp-passthrough
* Mar 1 00:35:01.299:L2FW:insp_l2_flood:input is Ethernet0 output is Ethernet1
* Mar 1 00:35:01.299:L2FW*:Src 0.0.0.0 dst 255.255.255.255 protocol udp
* Mar 1 00:35:01.299:L2FW:udp ports src 68 dst 67
* Mar 1 00:35:01.299:L2FW:src 0.0.0.0 dst 255.255.255.255
* Mar 1 00:35:01.299:L2FW:DHCP packet seen. Pass-through flag allows the packet
* Mar 1 00:35:01.299:L2FW*:Packet is broadcast or multicast.PASS
* Mar 1 00:35:01.311:L2FW:insp_l2_flood:input is Ethernet1 output is Ethernet0
* Mar 1 00:35:01.311:L2FW*:Src 97.0.0.23 dst 255.255.255.255 protocol udp
* Mar 1 00:35:01.311:L2FW:udp ports src 67 dst 68
* Mar 1 00:35:01.311:L2FW:src 97.0.0.23 dst 255.255.255.255
* Mar 1 00:35:01.311:L2FW:DHCP packet seen. Pass-through flag allows the packet
* Mar 1 00:35:01.311:L2FW*:Packet is broadcast or multicast.PASS
* Mar 1 00:35:01.323:L2FW:insp_l2_flood:input is Ethernet0 output is Ethernet1
* Mar 1 00:35:01.323:L2FW*:Src 0.0.0.0 dst 255.255.255.255 protocol udp
* Mar 1 00:35:01.323:L2FW:udp ports src 68 dst 67
* Mar 1 00:35:01.323:L2FW:src 0.0.0.0 dst 255.255.255.255
* Mar 1 00:35:01.323:L2FW:DHCP packet seen. Pass-through flag allows the packet
* Mar 1 00:35:01.323:L2FW*:Packet is broadcast or multicast.PASS
! The client has an IP address (97.0.0.5) and has issued a G-ARP to let everyone know its address
* Mar 1 00:35:01.327:IP ARP:rcvd rep src 97.0.0.5 0008.a3b6.b603, dst 97.0.0.5 BV11
Router#
```
Denying DHCP Pass-Through Traffic: Example

In this example, DHCP pass-through traffic is not allowed (via the `no ip inspect L2-transparent dhcp-passthrough` command). The client is denied when it attempts to acquire a DHCP address from the server.

! Deny DHCP pass-through traffic
Router(config)# no ip inspect L2-transparent dhcp-passthrough

! The DHCP discover broadcast packet arrives from the client
*Mar 1 00:36:40.003:L2FW:insp_l2_flood:input is Ethernet0 output is Ethernet1
*Mar 1 00:36:40.003:L2FW*:Src 0.0.0.0 dst 255.255.255.255 protocol udp
*Mar 1 00:36:40.003:L2FW:udp ports src 68 dst 67
*Mar 1 00:36:40.007:L2FW:src 0.0.0.0 dst 255.255.255.255

! The pass-through flag is checked
*Mar 1 00:36:40.007:L2FW:DHCP packet seen. Pass-through flag denies the packet
! The packet is dropped because the flag does not allow DHCP passthrough traffic. Thus,
! the client cannot acquire an address, and it times out
*Mar 1 00:36:40.007:L2FW:FLOOD Dropping the packet after ACL check.
Router#

Virtual Fragmentation Reassembly

Currently, the Cisco IOS Firewall—specifically context-based access control (CBAC) and the intrusion detection system (IDS)—cannot identify the contents of the IP fragments nor can it gather port information from the fragment. These inabilities allow the fragments to pass through the network without being examined or without dynamic access control list (ACL) creation.

Virtual fragmentation reassembly (VFR) enables the Cisco IOS Firewall to create the appropriate dynamic ACLs, thereby, protecting the network from various fragmentation attacks.

Restrictions for Virtual Fragmentation Reassembly

Performance Impact
VFR will cause a performance impact on the basis of functions such as packet copying, fragment validation, and fragment reorder. This performance impact will vary depending on the number of concurrent IP datagram that are being reassembled.

VFR Configuration Restriction
VFR should not be enabled on a router that is placed on an asymmetric path. The reassembly process requires all of the fragments within an IP datagram. Routers placed in the asymmetric path may not receive all of the fragments, so the fragment reassembly will fail.

SIP and RTSP Limitation
The Session Initiation Protocol (SIP) and the Real-Time Streaming Protocol (RTSP) do not have the ability to parse port information across noncontiguous buffers. Thus, virtual fragmentation reassembly may fail. (If the application fails, the session will be blocked.)

Information About Virtual Fragmentation Reassembly

To use fragmentation support for Cisco IOS Firewall, you should understand the following concept:

- Detected Fragment Attacks, page 2
- Automatically Enabling or Disabling VFR, page 3

Detected Fragment Attacks

VFR is responsible for detecting and preventing the following types of fragment attacks:

- Tiny Fragment Attack—In this type of attack, the attacker makes the fragment size small enough to force Layer 4 (TCP and User Datagram Protocol (UDP)) header fields into the second fragment. Thus, the ACL rules that have been configured for those fields will not match.
  
  VFR drops all tiny fragments, and an alert message such as follows is logged to the syslog server: “VFR-3-TINY_FRAGMENTS.”

- Overlapping Fragment Attack—In this type of attack, the attacker can overwrite the fragment offset in the noninitial IP fragment packets. When the firewall reassembles the IP fragments, it might create wrong IP packets, causing the memory to overflow or your system to crash.
  
  VFR drops all fragments within a fragment chain if an overlap fragment is detected, and an alert message such as follows is logged to the syslog server: “VFR-3-OVERLAP_FRAGMENT.”

- Buffer Overflow Attack—In this type of denial-of-service (DoS) attack, the attacker can continuously send a large number of incomplete IP fragments, causing the firewall to lose time and memory while trying to reassemble the fake packets.

  To avoid buffer overflow and control memory usage, configure a maximum threshold for the number of IP datagrams that are being reassembled and the number of fragments per datagram. (Both of these parameters can be specified via the `ip virtual-reassembly` command.)
When the maximum number of datagrams that can be reassembled at any given time is reached, all subsequent fragments are dropped, and an alert message such as the following is logged to the syslog server: “VFR-4_FRAG_TABLE_OVERFLOW.”

When the maximum number of fragments per datagram is reached, subsequent fragments will be dropped, and an alert message such as the following is logged to the syslog server: “VFR-4_TOO_MANY_FRAGMENTS.”

In addition to configuring the maximum threshold values, each IP datagram is associated with a managed timer. If the IP datagram does not receive all of the fragments within the specified time, the timer will expire and the IP datagram (and all of its fragments) will be dropped.

Automatically Enabling or Disabling VFR

VFR is designed to work with any feature that requires fragment reassembly (such as Cisco IOS Firewall and NAT). Currently, NAT enables and disables VFR internally; that is, when NAT is enabled on an interface, VFR is automatically enabled on that interface.

If more than one feature attempts to automatically enable VFR on an interface, VFR will maintain a reference count to keep track of the number of features that have enabled VFR. When the reference count is reduced to zero, VFR is automatically disabled.

How to Use Virtual Fragmentation Reassembly

This section contains the following procedures:

- Configuring VFR, page 3

Configuring VFR

Use this task to enable VFR on an interface, specify maximum threshold values to combat buffer overflow and control memory usage, and verify any VFR configurations.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface type type number
4. ip virtual-reassembly [max-reassemblies number] [max-fragments number] [timeout seconds] [drop-fragments]
5. exit
6. exit
7. show ip virtual-reassembly [interface type]
## Detailed Steps

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong>    enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>
| **Example:**  
  Router> enable                                        | Enter your password if prompted.                                       |
| **Step 2**    configure terminal                       | Enters global configuration mode.                                       |
| **Example:**  
  Router# configure terminal                             |                                                                         |
| **Step 3**    interface type number                    | Configures an interface type and enters interface configuration mode.   |
| **Example:**  
  Router(config)# interface ethernet1/1                  |                                                                         |
| **Step 4**    ip virtual-reassembly [max-reassemblies number] [max-fragments number] [timeout seconds] [drop-fragments] | Enables VFR on an interface.                                           |
| **Example:**  
  Router(config-if)# ip virtual-reassembly max-reassemblies 64 max-fragments 16 timeout 5 |                                                                         |
| **Step 5**    exit                                      | Exits interface configuration mode.                                     |
| **Example:**  
  Router(config-if)# exit                                |                                                                         |
| **Step 6**    exit                                      | Exits global configuration mode.                                        |
| **Example:**  
  Router(config)# exit                                  |                                                                         |
| **Step 7**    show ip virtual-reassembly [interface type] | Displays the configuration and statistical information of the VFR.     |
| **Example:**  
  Router# show ip virtual-reassembly ethernet1/1         | If an interface is not specified, VFR information is shown for all configured interfaces. |

## Troubleshooting Tips

To view debugging messages related to the VFR subsystem, use the **debug ip virtual-reassembly** command.

## Configuration Examples for Fragmentation Reassembly

This section contains the following configuration example:

- **Configuring VFR and a Cisco IOS Firewall: Example, page 5**
Configuring VFR and a Cisco IOS Firewall: Example

The following example shows a typical scenario where the Virtual Fragment Reassembly module is enabled on interfaces ethernet2/1, ethernet2/2, and serial3/0 to facilitate the firewall that is enabled in the outbound direction on interface serial3/0. In this example, the firewall rules that specify the list of LAN1 and LAN2 originating protocols (FTP, HTTP and SMTP) are to be inspected.

![Figure 1 VFR and Cisco IOS Firewall Sample Topology](image)

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at [Command Reference](#).

- debug ip virtual-reassembly
- ip virtual-reassembly
- show ip virtual-reassembly
Glossary

**fragment**—Part of an IP datagram that is fragmented into multiple pieces. Each piece is called a fragment or an IP fragment.

**fragmentation**—Process of breaking down an IP datagram into smaller packets (fragments) that are transmitted over different types of network media.

**initial fragment**—First fragment within a fragment set. This fragment should have a Layer 4 header and should have an offset of zero.

**noninitial fragment**—All fragments within a fragment set, except the initial fragment.

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

Configuring Cisco IOS Intrusion Prevention System (IPS)

First Published: May 2, 2005
Last Updated: August 7, 2007

This module describes how to configure the Cisco IOS Intrusion Prevention System (IPS), which helps to protect a network from internal and external attacks and threats. Cisco IOS IPS restructures and replaces the existing Cisco IOS Intrusion Detection System (IDS).

Cisco IOS IPS allows customers to choose between any of the following options when loading IPS signatures onto a device:

- Loading the default, built-in signatures.
- Download the SDF on the router by using the Cisco Router and Security Device Manager (SDM) to have the latest available detection of security threats. Go to the following link to download the SDF:
  http://www.cisco.com/cgi-bin/tablebuild.pl/ios-sigup

Note

SDM automatically recommends which SDF that should be used the first time IPS in enabled on the router.

After the SDF is downloaded on to their router, the SDM can immediately begin scanning for new signatures.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the “Feature Information for Configuring Cisco IOS IPS” section on page 34.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Catalyst OS, and Cisco IOS XE software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.
Contents

- Prerequisites for Configuring Cisco IOS IPS, page 2
- Restrictions for Configuring Cisco IOS IPS, page 2

- How to Configure Cisco IOS IPS on a Device, page 16
- Configuration Examples, page 31
- Additional References, page 33
- Feature Information for Configuring Cisco IOS IPS, page 34

Prerequisites for Configuring Cisco IOS IPS

Compatibility with VMS IDS MC 2.3 and Cisco Router SDM

VMS IDS MC provides a web-based interface for configuring, managing, and monitoring multiple IDS sensors. SDM is a web-based device-management tool that allows users to import and edit SDFs from Cisco.com to the router. VMS IDS MC is for network-wide management while SDM is for single-device management. It is strongly recommended that customers download the SDF to an IDS MC 2.3 network management device or an SDM.

Customers can choose to download the SDF to a device other than VMS IDS MC or SDM (such as a router) via command-line interface (CLI); however, this approach is not recommended because it requires that the customer know which signatures come from which signature engines.

Restrictions for Configuring Cisco IOS IPS

Signature Support Deprecation

Effective Cisco IOS Release 12.3(8)T, the following signatures are no longer supported by Cisco IOS IPS:

- 1100 IP Fragment Attack (Attack, Atomic)
  Triggers when any IP datagram is received with the “more fragments” flag set to 1 or if there is an offset indicated in the offset field. (To scan for application layer signatures across fragments, you can enable virtual fragment reassembly.)
- 1105 Broadcast Source Address (Compound/Attack)
  Triggers when an IP packet with a source address of 255.255.255.255 is detected. This signature may be an indicator of an IP spoof attack or an attempt to subvert a firewall, proxy, or gateway.
- 1106 Multicast IP Source Address (Compound/Attack)
  Triggers when an IP packet with a source address of 224.x.x.x is detected. This signature may be an indicator of an IP spoof attack or an attempt to subvert a firewall, proxy, or gateway.
- 8000 FTP Retrieve Password File (Attack, Atomic) SubSig ID: 2101
  Triggers on string “passwd” issued during an FTP session. May indicate that someone is attempting to retrieve the password file from a machine to try and gain unauthorized access to system resources.
Memory Impact on Low-End to Midrange Routers
Intrusion detection configuration on certain routers may not support the complete list of signatures because of lack of sufficient memory. Thus, the network administrator may have to select a smaller subset of signatures or choose to use the standard 100 (built-in) signatures with which the routers are shipped.

Action Configuration via CLI No Longer Supported
Cisco IOS IPS actions (such as resetting the TCP connection) can no longer be configured via CLI. If you are using the attack-drop.sdf signature file, the signatures are preset with actions to mitigate the attack by dropping the packet and resetting the connection, if applicable. If you are using VMS or SDM to deploy signatures to the router, you must first tune the signatures to use the desired actions.

Any CLI that is issued to configure IPS actions will be silently ignored.

Restrictions for Transparent Cisco IOS IPS
- Mixed-media bridging configurations are not supported. Only Ethernet media is supported.
- Layer 2 signatures are not supported.
- Multicast traffic is not processed.

Information About Cisco IOS IPS
To help secure your network via a signature-based IPS, you should understand the following concepts:
- Cisco IOS IPS Overview, page 3
- Transparent Cisco IOS IPS Overview, page 4
- Benefits of Cisco IOS IPS, page 4
- The Signature Definition File, page 5
- Signature Microengines: Overview and Lists of Supported Engines, page 5
- Supported Cisco IOS IPS Signatures in the attack-drop.sdf File, page 7

Cisco IOS IPS Overview
The Cisco IOS IPS acts as an in-line intrusion detection sensor, watching packets and sessions as they flow through the router and scanning each packet to match any of the Cisco IOS IPS signatures. When Cisco IOS IPS detects suspicious activity, it responds before network security can be compromised and logs the event through Cisco IOS syslog messages or Security Device Event Exchange (SDEE). The network administrator can configure Cisco IOS IPS to choose the appropriate response to various threats. When packets in a session match a signature, Cisco IOS IPS can take any of the following actions, as appropriate:
- Send an alarm to a syslog server or a centralized management interface
- Drop the packet
- Reset the connection
- Deny traffic from the source IP address of the attacker for a specified amount of time
- Deny traffic on the connection for which the signature was seen for a specified amount of time
Cisco developed its Cisco IOS software-based intrusion-prevention capabilities and Cisco IOS Firewall with flexibility in mind, so that individual signatures can be disabled in case of false positives. Generally, it is preferable to enable both the firewall and Cisco IOS IPS to support network security policies. However, each of these features may be enabled independently and on different router interfaces.

**Transparent Cisco IOS IPS Overview**

If customers want to protect their network via a typical Cisco IOS IPS device, they must manually readdress each of the statically defined devices on the trusted network. A transparent Cisco IOS IPS device allows customers to “drop” a Layer 3 IPS device in front of the devices that need to be protected. Thus, the tedious and costly overhead that is required to renumber devices on the trusted network is eliminated.

A transparent Cisco IOS IPS device acts as a Layer 3 IPS between bridged interfaces. (The current implementation of the transparent IPS does not support Layer 2 IPS functionality; thus, IPS can act only as a Layer 3 device.)

**Transparent Bridging Overview**

If configured for bridging, a Cisco IOS device can bridge any number of interfaces. The device can complete basic bridging tasks such as learning MAC addresses on ports to restrict collision domains and running Spanning Tree Protocol (STP) to prevent looping in the topology.

Within bridging, a user can configure Integrated Routed Bridging (IRB), which allows a device to bridge on some interfaces while a Layer 3 Bridged Virtual Interface (BVI) is presented for routing. The bridge can determine whether the packet is to be bridged or routed on the basis of the destination of the Layer 2 or Layer 3 IP address in the packet. Configured with an IP address, the BVI can manage the device even if there is no interface configured for routing.

**Transparent and Non-Transparent IPS Devices Configured on the Same Router**

A transparent IPS device supports a BVI for routing, so a packet that comes in on a bridged interface can be bridged or routed out of the BVI. This functionality allows a transparent IPS device and a nontransparent IPS device to be configured on the same router. The transparent IPS device operates on the bridged packets while the “normal” IPS device operates on the routed packets. For example, if you have six interfaces on your router and two of them are in a bridge group, you can simultaneously configure and run normal IPS inspection on the remaining four interfaces.

Users can also configure transparent IPS and a transparent firewall on the same device. For more information on the transparent firewall, see the document “Transparent Cisco IOS Firewall.”

**Benefits of Cisco IOS IPS**

**Dynamic IPS Signatures**

IPS signatures are dynamically updated and posted to Cisco.com on a regular basis. Thus, customers can access signatures that help protect their network from the latest known network attacks.

**Parallel Signature Scanning**

Cisco IOS IPS uses a Parallel Signature Scanning Engine to scan for multiple patterns within a signature microengine (SME) at any given time. IPS signatures are no longer scanned on a serial basis.
Named and Numbered Extended ACL Support
Cisco IOS IPS supports both named and numbered extended access control lists (ACLs) by using at least one of the following commands—\texttt{ip ips ips-name list acl} or \texttt{ip ips signature signature-id list acl-list}. (Prior to Cisco IOS Release 12.3(8)T, only standard, numbered ACLs were supported.)

The Signature Definition File
An SDF has definitions for each signature it contains. After signatures are loaded and compiled onto a router running Cisco IOS IPS, IPS can begin detecting the new signatures immediately. If the default, built-in signatures that are shipped with the routers are not used, then one of three different types of SDFs can be selected for download, which are pre-configured for routers with memory requirements:

- \texttt{attack-drop.sdf} file (which is a static file that has 83 signatures) is used for routers with less than 128MB memory.
- \texttt{128MB.sdf} (which has about 300 signatures) is used for routers with 128 MB or more memory.
- \texttt{256MB.sdf} (which has about 500 signatures) is used for routers with 256 MB or more memory.

The \texttt{attack-drop.sdf}, \texttt{128MB.sdf}, and \texttt{256MB.sdf} are available in flash on all Cisco access routers that are shipped with Cisco IOS Release 12.4 or later. One of these files can then be loaded directly from flash into the Cisco IOS IPS system. If flash is erased, the SDF file may also be erased. If a Cisco IOS image is copied to flash and there is a prompt to erase the contents of flash before copying the new image, you might risk erasing the SDF file. If the SDF file is erased, the router refers to the built-in signatures within the Cisco IOS image.

The SDF file can also be downloaded onto your router from Cisco.com through SDM. SDF files can be loaded through IDS MC 2.3, which can be launched from CSM 3.0.

Note
SDF files can be used only with 12.4(9)Tx or earlier IOS Images and mainline images.

To help detect the latest vulnerabilities, Cisco provides signature updates on Cisco.com on a regular basis. Users can use VMS or SDM to download these signature updates, tune the signature parameters as necessary, and deploy the new SDF to a Cisco IOS IPS router.

Signature Microengines: Overview and Lists of Supported Engines
Cisco IOS IPS uses SMEs to load the SDF and scan signatures. Signatures contained within the SDF are handled by a variety of SMEs. The SDF typically contains signature definitions for multiple engines. The SME typically corresponds to the protocol in which the signature occurs and looks for malicious activity in that protocol.

A packet is processed by several SMEs. Each SME scans for various conditions that can lead to a signature pattern match. When an SME scans the packets, it extracts certain values, searching for patterns within the packet via the regular expression engine.

For a list of supported signature engines, see the section “Lists of Supported Signature Engines.”
Lists of Supported Signature Engines

Table 1 lists supported signature engines and engine-specific parameter exceptions, if applicable.

If the SDF contains a signature that requires an engine that is not supported, the engine is ignored and an error message will be displayed. If a signature within a supported engine contains a parameter that is not supported, the parameter will be ignored and an error message will be displayed.

</tbody>
</table>

¹ The following parameters, which are defined in all signature engines, are currently not supported: AlarmThrottle=Summarize (all other values are supported), MaxInspectLength, MaxTTL, Protocol, ResetAfterIdle, StorageKey, and SummaryKey.

Table 2 lists support for the 100 signatures that are available in Cisco IOS IDS prior to Cisco IOS Release 12.3(8)T. As of Cisco IOS Release 12.3(8)T, these 100 signatures are a part of the Cisco IOS IPS built-in SDF. By default, signatures are loaded from this built-in SDF. Table 2 lists support for these 100 signatures under Cisco IOS IPS.

Because Cisco IOS IPS counts signatures on the basis of signature-id and subsignature-id, the 100 signatures under Cisco IOS IDS are counted as 132 signatures under Cisco IOS IPS.

</tr>
</tbody>
</table>

1. The OTHER engine contains existing, hard-coded signatures. Although the standard SDF contains an entry for these signatures, the engine is not dynamically updated. If the SDF that is loaded onto the engine does not contain the signature, the signature will be treated as though it has been disabled.

**Supported Cisco IOS IPS Signatures in the attack-drop.sdf File**

Customers can choose to use Cisco IOS IPS in one of the following ways:

- Download new signatures that are posted on Cisco.com. These signatures can be obtained at the Cisco Intrusion Prevention Alert Center web page. (You must have a valid Cisco.com account to access this web page.)
- Download the attack-drop.sdf file, which contains the signatures that are identified in Table 3.
### Table 3: Cisco IOS IPS Signatures Supported in Cisco IOS Release 12.3(8)T

1. A = alarm, D = drop, R = reset
2. This signature requires port to application mapping (PAM) configuration via the command ip port-map http port 81.
3. This signature requires PAM configuration via the command ip port-map http port 81.
4. This signature requires PAM configuration via the command ip port-map http port 8200.
How to Configure Cisco IOS IPS on a Device

If you want to configure transparent Cisco IOS IPS, you must configure a bridge group before loading IPS onto a device. To configure a bridge group, see the section “Configuring a Bridge Group for Transparent Cisco IOS IPS, page 16.” If you do not want to configure transparent IPS, skip this task and immediately begin installing IPS onto your device as shown in the tasks below.

Before configuring Cisco IOS IPS on a router, you should determine which one of the following deployment scenarios best addresses your situation and configure the associated task, as appropriate:

- You are loading signatures onto a router via VMS IDS MC or SDM:
  To use VMS IDS MC, see the documents on the VMS index.
  To use SDM, see the chapter Intrusion Prevention System in the Cisco Router and Security Device Manager 2.5 User Guide.
- You are installing a new router with the latest version of Cisco IOS IPS.
  To perform this task, see the section “Installing Cisco IOS IPS on a New Router, page 19.”
- Your network is transitioning to Cisco IOS IPS in Cisco IOS Release 12.3(8)T or later.
  To perform this task, see the section “Upgrading to the Latest Cisco IOS IPS Signature Definition File (SDF), page 21.”
- You are merging the default (built-in) Cisco IOS IPS signatures with the latest version of the Cisco IOS IPS signature detection file, “attack-drop.sdf.”
  To perform this task, see the section “Merging Built-In Signatures with the attack-drop.sdf File, page 24”

After you have configured Cisco IOS IPS on your router, see the following optional sections:

- Monitoring Cisco IOS IPS Signatures via Syslog Messages or SDEE, page 27
- Troubleshooting Cisco IOS IPS, page 29

Configuring a Bridge Group for Transparent Cisco IOS IPS

Use this task to configure a bridge group and to associate interfaces or subinterfaces in the configured bridge group.

**Note**
You should configure a bridge group only if you want to configure transparent IPS.

BVI Configuration Requirements

- If a BVI is not configured, you must disable IP routing (via the `no ip routing` command) for the bridging operation to take effect.
- If configured, a BVI must be configured with an IP address in the same subnet.
- You *must* configure a BVI if more than two interfaces are placed in a bridge group.
- Bridging between VLAN trunks works only for dot1q encapsulation; Inter-Switch Link (ISL) encapsulation will not work.
Restrictions

- If more than two interfaces are assigned to a bridge group, any routers that are acting as first-hop gateways to hosts that are in the bridged network (the bridge group) must allow ICMP time-to-live (TTL) exceeded messages to pass.
- Spanning Tree Bridge Protocol Data Units (BPDU) and packets that are to be routed out of the bridge, if IRB is configured, are not inspected.

SUMMARY STEPS

1. enable
2. configure terminal
3. bridge bridge-group protocol {dec | ibm | ieee | vlan-bridge}
4. interface type number
5. bridge-group bridge-group
6. exit
7. bridge irb
8. bridge bridge-group route protocol
9. interface type number
10. ip address ip-address mask
11. no shutdown

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 3 bridge bridge-group protocol {dec</td>
<td>ibm</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config)# bridge 1 protocol ieee</td>
</tr>
<tr>
<td>Step 4 interface type number</td>
<td>Configures an interface type and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config)# interface Ethernet0</td>
</tr>
</tbody>
</table>
### Command or Action

**Step 5**
- `bridge-group bridge-group`

**Example:**
- `Router(config-if)# bridge-group 1`

**Purpose:** Assigns each network interface to a bridge group.

**Note:** Complete Step 4 and Step 5 for each interface you want to assign to a bridge group.

**Note:** You can also assign subinterfaces to a bridge group to control bridging between VLANs.

**Step 6**
- `exit`

**Example:**
- `Router(config-if)# exit`

**Purpose:** Exits interface configuration mode.

**Step 7**
- `bridge irb`

**Example:**
- `Router(config)# bridge irb`

**Purpose:** Enables the Cisco IOS software to route a given protocol between routed interfaces and bridge groups or to route a given protocol between bridge groups.

**Note:** Step 7 through Step 11 are necessary only if you want to configure a BVI.

**Step 8**
- `bridge bridge-group route protocol`

**Example:**
- `Router(config)# bridge 1 route ip`

**Purpose:** Enables the routing of a specified protocol in a specified bridge group.

**Step 9**
- `interface type number`

**Example:**
- `Router(config)# interface BVI1`

**Purpose:** Configures a BVI and enters interface configuration mode.

**Step 10**
- `ip address ip-address mask`

**Example:**
- `Router(config-if) ip address 10.1.1.1 255.255.255.0`

**Purpose:** Sets a primary IP address for an interface.

**Step 11**
- `no shutdown`

**Example:**
- `Router(config-if)# no shutdown`

**Purpose:** Restarts a disabled interface.

### Examples

The following example shows how to configure interfaces “ethernet0” and “ethernet1” in a bridge group. These interfaces are associated with the BVI interface “BVI1,” which can be reached from any host on either of the interfaces via the IP address 10.1.1.1.

```plaintext
Router(config)# bridge-group bridge-group
Router(config)# interface ethernet0
Router(config-if)# bridge-group 1
Router(config-if)# interface ethernet1
Router(config-if)# bridge-group 1
Router(config-if)# exit
! Configure the BVI.
Router(config)# bridge irb
Router(config)# bridge 1 route ip
Router(config)# interface BVI1
```
Router(config-if)# ip address 10.1.1.1 255.255.255.0
Router(config-if)# no shutdown

Troubleshooting Tips

To display the status of each bridge group, use the show bridge-group command or to display entries in the bridge table, use the show bridge command.

What to Do Next

After you have configured the bridge group, you must configure Cisco IOS IPS as shown in one of the following Cisco IOS IPS tasks, as appropriate to your network needs.

Installing Cisco IOS IPS on a New Router

Perform this task to install the latest Cisco IOS IPS signatures on a router for the first time.

This task allows you to load the default, built-in signatures or the SDF called “attack-drop.sdf”—but not both. If you want to merge the two signature files, you must load the default, built-in signatures as described in this task. Then, you can merge the default signatures with the attack-drop.sdf file as described in the task “Merging Built-In Signatures with the attack-drop.sdf File.”

Note

Installing the signatures provided in flash is the recommended method in Cisco IOS Release 12.3(8)T for IPS attack mitigation.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip ips sdf location url
4. ip ips name ips-name [list acl]
5. ip ips signature signature-id [:sub-signature-id] {delete | disable | list acl-list}
6. ip ips deny-action ips-interface
7. interface type name
8. ip ips ips-name {in | out}
9. exit
10. show ip ips configuration
# Configuring Cisco IOS Intrusion Prevention System (IPS)

Configuring Cisco IOS Intrusion Prevention System (IPS)

How to Configure Cisco IOS IPS on a Device

Upgrading to the Latest Cisco IOS IPS Signature Definition File (SDF)

Perform this task to replace the existing signatures on your router with the latest IPS signature file, attack-drop.sdf.

**Note**
The latest IPS image will read and convert all commands that begin with the words “ip audit” to “ip ips.” For example, the ip audit name command will become the ip ips name command.

Although IPS will accept the audit keyword, it will generate the ips keyword when you show the configuration. Also, if you issue the help character (?), the CLI will display the ips keyword instead of the audit keyword, and the Tab key used for command completion will not recognize the audit keyword.

**Prerequisites**
To install Cisco IOS IPS, you should load a new Cisco IOS image to your router.

**SUMMARY STEPS**
1. enable
2. configure terminal
3. `ip ips name ips-name`
4. `ip ips sdf location url`
5. `no ip ips location in builtin`
6. `ip ips fail closed`
7. `ip ips deny-action ips-interface`
8. `interface type name`
9. `ip ips ips-name {in | out} [list acl]`
10. `exit`
11. `show ip ips configuration`
12. `show ip ips signatures [detailed]`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| Example: | Router> enable |
| **Step 2** configure terminal | Enters global configuration mode. |
| Example: | Router# configure terminal |
| **Step 3** `ip ips name ips-name` | Creates an IPS rule. |
| Example: | Router(config)# ip ips name MIPS |
| **Step 4** `ip ips sdf location url` | (Optional) Specifies the location where the router will load the SDF.  
If this command is not issued, the router will load the default SDF. |
| Example: | Router(config)# ip ips sdf location disk2:attack-drop.sdf |
| **Step 5** `no ip ips location in builtin` | (Optional) Instructs the router not load the built-in signatures if it cannot find the specified signature file.  
If this command is not issued, the router will load the built-in signatures if the SDF is not found. |
<p>| Example: | Router(config)# no ip ips location in builtin |
| <strong>Caution</strong> | If this command is issued and IPS fails to load the SDF, you will receive an error message stating that IPS is completely disabled. |</p>

<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 6** ip ips fail closed | (Optional) Instructs the router to drop all packets until the signature engine is built and ready to scan traffic. If this command is issued, one of the following scenarios will occur:  
  - If IPS fails to load the SDF, all packets will be dropped—unless the user specifies an ACL for packets to send to IPS.  
  - If IPS successfully loads the SDF but fails to build a signature engine, all packets that are destined for that engine will be dropped.  
If this command is not issued, all packets will be passed without scanning if the signature engine fails to build. |
| **Example:** Router(config)# ip ips fail closed | |
| **Step 7** ip ips deny-action ips-interface | (Optional) Creates an ACL filter for the deny actions (denyFlowInline and denyConnectionInline) on the IPS interface rather than the ingress interface.  
**Note** You should configure this command only if at least one signature is configured to use the supported deny actions, if the input interface is configured for load balancing, and if IPS is configured on the output interface. |
| **Example:** Router(config)# ip ips deny-action ips-interface | |
| **Step 8** interface type number | Configures an interface type and enters interface configuration mode. |
| **Example:** Router(config)# interface GigabitEthernet0/1 | |
| **Step 9** ip ips ips-name (in | out) [list acl] | Applies an IPS rule at an interface and automatically loads the signatures and builds the signature engines.  
  - list acl—Packets that are permitted via a specified ACL will be scanned by IPS.  
**Note** Whenever signatures are replaced or merged, the router prompt is suspended while the signature engines for the newly added or merged signatures are being built. The router prompt will be available again after the engines are built. |
| **Example:** Router(config-if)# ip ips MYIPS in | |
| **Step 10** exit | Exits global configuration mode. |
| **Example:** Router(config)# exit | |
| **Step 11** show ip ips configuration | (Optional) Verifies that Cisco IOS IPS is properly configured. |
| **Example:** Router# show ip ips configuration | |
| **Step 12** show ip ips signatures [detailed] | (Optional) Verifies signature configuration, such as signatures that have been disabled. |
| **Example:** Router# show ip ips signatures | |
Merging Built-In Signatures with the attack-drop.sdf File

You may want to merge the built-in signatures with the attack-drop.sdf file if the built-in signatures are not providing your network with adequate protection from security threats. Perform this task to add the SDF and to change default parameters for a specific signature within the SDF or signature engine.

Prerequisites

Before you can merge the attack-drop.sdf file with the built-in signatures, you should already have the built-in signatures loaded onto the router as described in the task “Installing Cisco IOS IPS on a New Router.”

SUMMARY STEPS

1. enable
2. configure terminal
3. no ip ips location in builtin
4. ip ips fail closed
5. exit
6. copy [/erase] url ips-sdf
7. copy ips-sdf url
8. configure terminal
9. ip ips signature signature-id[:sub-signature-id] {delete | disable | list acl-list}
10. ip ips sdf location url
11. ip ips deny-action ips-interface
12. interface type name
13. ip ips ips-name {in | out}
14. exit
15. exit
16. show ip ips signatures [detailed]

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Router# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Command: <code>no ip ips location in builtin</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td><code>Router(config)# no ip ips location in builtin</code></td>
</tr>
</tbody>
</table>

(Optional) Instructs the router not to load the built-in signatures if it cannot find the specified signature file. If this command is not issued, the router will load the built-in signatures if the SDF is not found.

**Caution**
- If this command is issued and IPS fails to load the SDF, you will receive an error message stating that IPS is completely disabled.

<table>
<thead>
<tr>
<th>Step 4</th>
<th>Command: <code>ip ips fail closed</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td><code>Router(config)# ip ips fail closed</code></td>
</tr>
</tbody>
</table>

(Optional) Instructs the router to drop all packets until the signature engine is built and ready to scan traffic. If this command is issued, one of the following scenarios will occur:

- If IPS fails to load the SDF, all packets will be dropped—unless the user specifies an ACL for packets to send to IPS.
- If IPS successfully loads the SDF but fails to build a signature engine, all packets that are destined for that engine will be dropped.

If this command is not issued, all packets will be passed without scanning if the signature engine fails to build.

<table>
<thead>
<tr>
<th>Step 5</th>
<th>Command: <code>exit</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td><code>Router(config)# exit</code></td>
</tr>
</tbody>
</table>

Exits global configuration mode.

<table>
<thead>
<tr>
<th>Step 6</th>
<th>Command: <code>copy [/erase] url ips-sdf</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Example:</td>
<td><code>Router# copy disk2:attack-drop.sdf ips-sdf</code></td>
</tr>
</tbody>
</table>

Loads the SDF in the router. The SDF will merge with the signatures that are already loaded in the router, unless the `/erase` keyword is issued. The `/erase` keyword replaces the built-in signatures with the SDF.

**Note**
- The SDF location is not saved in the configuration. The next time the router is reloaded, it will refer to a previously specified SDF location in the configuration or it will load the built-in signatures.

**Note**
- Whenever signatures are replaced or merged, the router prompt is suspended while the signature engines for the newly added or merged signatures are being built. The router prompt will be available again after the engines are built.

Depending on your platform and how many signatures are being loaded, building the engine can take up to several seconds. It is recommended that you enable logging messages to monitor the engine building status.

Configuring Cisco IOS Intrusion Prevention System (IPS)

How to Configure Cisco IOS IPS on a Device

Monitoring Cisco IOS IPS Signatures via Syslog Messages or SDEE

Cisco IOS IPS provides two methods to report IPS intrusion alerts—Cisco IOS logging (syslog) and SDEE. Perform this task to enable SDEE to report IPS intrusion alerts.

To configure syslog messages, see the chapter “Troubleshooting and Fault Management” in the Cisco IOS Configuration Fundamentals Configuration Guide.

Note
Effective Cisco IOS Release 12.3(14)T, the Post Office Protocol is no longer supported. To configure the Post Office Protocol, see the chapter “Configuring Cisco IOS Firewall Intrusion Detection System” in the Cisco IOS Security Configuration Guide.

SDEE Overview

SDEE is an application-level communication protocol that is used to exchange IPS messages between IPS clients and IPS servers.

SDEE is always running, but it does not receive and process events from IPS unless SDEE notification is enabled. If SDEE notification is not enabled and a client sends a request, SDEE will respond with a fault response message, indicating that notification is not enabled.

Storing SDEE Events in the Buffer

When SDEE notification is enabled (via the `ip ips notify sdee` command), 200 events can automatically be stored in the buffer. When SDEE notification is disabled, all stored events are lost. A new buffer is allocated when the notifications are reenabled.

When specifying the size of an events buffer, note the following functionality:

- It is circular. When the end of the buffer is reached, the buffer will start overwriting the earliest stored events. (If overwritten events have not yet been reported, you will receive a buffer overflow notice.)
- If a new, smaller buffer is requested, all events that are stored in the previous buffer will be lost.
- If a new, larger buffer is requested, all existing events will be saved.

Prerequisites

To use SDEE, the HTTP server must be enabled (via the `ip http server` command). If the HTTP server is not enabled, the router cannot respond to the SDEE clients because it cannot not “see” the requests.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 15 <code>exit</code></td>
<td>Exits global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Router(config)# exit</code></td>
<td></td>
</tr>
<tr>
<td>Step 16 <code>show ip ips signatures [detailed]</code></td>
<td>(Optional) Verifies signature configuration, such as signatures that have been disabled or marked for deletion.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><code>Router# show ip ips signatures</code></td>
<td></td>
</tr>
</tbody>
</table>

Example:

Router(config)# exit
Exits global configuration mode.

Example:

Router# show ip ips signatures
(Optional) Verifies signature configuration, such as signatures that have been disabled or marked for deletion.
### SUMMARY STEPS

1. `enable`  
2. `configure terminal`  
3. `ip ips notify sdee`  
4. `ip sdee events events`  
5. `ip sdee subscriptions subscriptions`  
6. `exit`  
7. `show ip sdee [[alerts] [all] [errors] [events] [configuration] [status] [subscriptions]]`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| **Example:** Router> enable |
| **Step 2** `configure terminal` | Enters global configuration mode. |
| **Example:** Router# configure terminal |
| **Step 3** `ip ips notify sdee` | Enables SDEE event notification on a router. |
| **Example:** Router(config)# ip ips notify sdee |
| **Step 4** `ip sdee events events` | (Optional) Sets the maximum number of SDEE events that can be stored in the event buffer. Maximum value: 1000 events.  
   **Note** By default, 200 events can be stored in the buffer when SDEE is enabled. When SDEE is disabled, all stored events are lost; a new buffer is allocated when the notifications are reenabled. |
| **Example:** Router(config)# ip sdee events 500 |
| **Step 5** `ip sdee subscriptions subscriptions` | (Optional) Sets the maximum number of SDEE subscriptions that can be open simultaneously. Valid value ranges from 1 to 3. |
| **Example:** Router(config)# ip sdee subscriptions 1 |
| **Step 6** `exit` | Exits global configuration mode. |
| **Example:** Router(config)# exit |
| **Step 7** `show ip sdee [[alerts] [all] [errors] [events] [configuration] [status] [subscriptions]]` | (Optional) Verifies SDEE configuration information and notification functionality. |
| **Example:** Router# show ip sdee configuration |
Troubleshooting Tips

To print out new SDEE alerts on the router console, issue the `debug ip sdee` command.

To clear the event buffer or SDEE subscriptions from the router (which helps with error recovery), issue the `clear ip sdee` command.

Troubleshooting Cisco IOS IPS

This section contains the following information, which may help you troubleshoot Cisco IOS IPS:

- Interpreting Cisco IOS IPS System Messages, page 29
- Conditions of an SME Build Failure, page 31

Interpreting Cisco IOS IPS System Messages

Table 4 lists some of the alarm, status, and error messages that may be shown when using Cisco IOS IPS.

<table>
<thead>
<tr>
<th>System Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alarm Messages</td>
<td></td>
</tr>
<tr>
<td>%IPS-5-SIGNATURE:Sig:1107 Subsig:0 Global Summary:50 alarms in this interval</td>
<td>A flood of the specified IPS signature has been seen and summarized. (For example, signature 1107 has been seen 50 times.)</td>
</tr>
<tr>
<td>Status Messages</td>
<td></td>
</tr>
<tr>
<td>%IPS-6-ENGINE_READY:SERVICE.HTTP - 183136 ms - packets for this engine will be scanned</td>
<td>An IPS signature engine has been built and is ready to scan packets.</td>
</tr>
<tr>
<td>%IPS-6-ENGINE_BUILD_SKIPPED:STRING.UDP - there are no new signature definitions for this engine</td>
<td>There are not any signature definitions or changes to the existing signature definitions of an IPS signature engine, and the engine does not have to be rebuilt.</td>
</tr>
<tr>
<td>%IPS-5-PACKET_DROP:SERVICE.DNS - packets dropped while engine is building</td>
<td>Packets are being dropped because the specified IPS module is not functioning and the <code>ip ips fail closed</code> command is configured. The message is rate limited to 1 message per 60 seconds.</td>
</tr>
<tr>
<td>%IPS-5-PACKET_UNSCANNED:SERVICE.DNS - packets passed unscanned while engine is building</td>
<td>Packets are passing through the network but are not being scanned because the specified IPS module is not functioning and the <code>ip ips fail closed</code> command is not configured. The message is rate limited to 1 message per 60 seconds.</td>
</tr>
<tr>
<td>%IPS-6-SDF_LOAD_SUCCESS:SDF loaded successfully from flash:sdf_8http.xml</td>
<td>An SDF is successfully loaded from a given location.</td>
</tr>
</tbody>
</table>
Table 4  Cisco IOS IPS System Messages (continued)

<table>
<thead>
<tr>
<th>System Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%IPS-3-BUILTIN_SIGS:Configured to load builtin signatures</td>
<td>One of these three messages can be displayed when IPS loads the built-in signatures.</td>
</tr>
<tr>
<td>%IPS-3-BUILTIN_SIGS:Not Configured to load builtin signatures</td>
<td></td>
</tr>
<tr>
<td>%IPS-3-BUILTIN_SIGS:Failed to load builtin signatures</td>
<td></td>
</tr>
<tr>
<td>%IPS-5-ENGINE_UNKNOWN: SERVICE.GENERIC - unknown engine encountered while parsing SDF</td>
<td>The router has encountered an unknown and unsupported signature engine while parsing the SDF. To prevent this message from being generated again, ensure that the SDF being loaded on the router does not contain any engines that are not supported by IPS.</td>
</tr>
<tr>
<td>%IPS-5-UNSUPPORTED_PARAM: SERVICE.RPC 6275:1 isSweep=False - bad parameter - removing parameter</td>
<td>The router has encountered an unsupported parameter while parsing the SDF. The signature is deleted if the unsupported parameter is required for the signature. The parameter is removed from the signature if it is not required. To prevent this message from being generated again, ensure that the SDF being loaded on the router does not contain any parameters that are not supported by IPS.</td>
</tr>
<tr>
<td>%IPS-3-ENGINE_BUILD_FAILED: SERVICE.HTTP - 158560 ms - engine build</td>
<td>One of the signature engines fails to build after an SDF is loaded. A message is sent for each engine that fails. An engine typically fails to build because of low memory, so increasing router memory can alleviate the problem. Also, try to load the SDF immediately after a route reboots, which is when system resources are available.</td>
</tr>
<tr>
<td>%IPS-4-SDF_PARSE_FAILED: not well-formed (invalid token) at Line 1 Col 0 Byte 0 Len 1006</td>
<td>An SDF has not parsed correctly. The SDF might have been corrupt.</td>
</tr>
</tbody>
</table>
| %IPS-4-SDF_LOAD_FAILED: failed to parse SDF from tftp://tftp-server/sdf.xml | An SDF fails to load. The SDF may fail for any of the following reasons:  
   - Fails to load if it resides on a network server that cannot be reached  
   - Does not have the correct read permissions |
| %IPS-2-DISABLED: IPS removed from all interfaces - IPS disabled | IPS has been disabled. This message will indicate why IPS has been disabled. |
Conditions of an SME Build Failure

Sometimes an SME that is being built will fail. The SME can fail because it is attempting to load a corrupted SDF file or it exceeds memory limitations of the router. If a failure occurs, Cisco IOS IPS is designed to handle it. Possible failures are as follows:

- By default, IPS is designed to “fail open,” which means that if an SME does not build, all packets that are destined for that particular engine will pass traffic without scanning.
- If IPS cannot load the attack-drop.sdf file onto a router, the router will revert to the previously loaded available signatures. (In most cases, the previously loaded signatures are the Cisco IOS built-in signatures.)
- If an engine build fails when you are merging the attack-drop.sdf file with the built-in signatures, IPS will revert, by default, to the previously available engine (or engines).

The default behavior for engine failure allows for packets to be passed unscanned. To prevent traffic from being passed unscanned, issue the `ip ips fail closed` command, which forces the router to drop all packets if an SME build fails.

Note
If a signature or a signature parameter is not supported, Cisco IOS will print a syslog message, indicating that the signature or parameter is not supported.

Configuration Examples

This section contains the following configuration examples:

- Loading the Default Signatures: Example, page 31
- Loading the attack-drop.sdf: Example, page 32
- Merging the attack-drop.sdf File with the Default, Built-in Signatures: Example, page 32

Loading the Default Signatures: Example

The following example shows the Cisco IOS IPS commands required to load the default, built-in signatures. Note that a configuration option for specifying an SDF location is not necessary; built-in signatures reside statically in Cisco IOS.

```bash
! ip ips po max-events 100 ip ips name MYIPS ! interface GigabitEthernet0/1 ip address 10.1.1.16 255.255.255.0 ip ips MYIPS in duplex full speed 100 media-type rj45 no negotiation auto !
```
Loading the attack-drop.sdf: Example

The following example shows the basic configuration necessary to load the attack-drop.sdf file onto a router running Cisco IOS IPS. Note that the configuration is almost the same as loading the default signatures onto a router, except for the ip ips sdf location command, which specifies the attack-drop.sdf file.

```
! ip ips sdf location disk2:attack-drop.sdf
ip ips name MYIPS
!
interface GigabitEthernet0/1
  ip address 10.1.1.16 255.255.255.0
  ip ips MYIPS in
duplex full
speed 100
media-type rj45
no negotiation auto
!
```

Merging the attack-drop.sdf File with the Default, Built-in Signatures: Example

The following example shows how to configure the router to load and merge the attack-drop.sdf file with the default signatures. After you have merged the two files, it is recommended that you copy the newly merged signatures to a separate file. The router can then be reloaded (via the reload command) or reinitialized to recognize the newly merged file (as shown in the following example).

```
! ip ips name MYIPS
!
interface GigabitEthernet0/1
  ip address 10.1.1.16 255.255.255.0
  ip ips MYIPS in
duplex full
speed 100
media-type rj45
no negotiation auto
!
!
! Merge the flash-based SDF (attack-drop.sdf) with the built-in signatures.
Router# copy disk2:attack-drop.sdf ips-sdf
! Save the newly merged signatures to a separate file.
Router# copy ips-sdf disk2:my-signatures.sdf
!
! Configure the router to use the new file, my-signatures.sdf
Router# configure terminal
Router(config)# ip ips sdf location disk2:my-signatures.sdf
! Reinitialize the IPS by removing the IPS rule set and reapplying the rule set.
Router(config-if)# interface gig 0/1
Router(config-if)# no ip ips MYIPS in
!
*Apr 8 14:05:38.243:%IPS-2-DISABLED:IPS removed from all interfaces - IPS disabled
!
Router(config-if)# ip ips MYIPS in
!
Router(config-if)# exit
```

Feature Information for Configuring Cisco IOS IPS

Table 5 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Releases 12.2(1) or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to [http://www.cisco.com/go/cfn](http://www.cisco.com/go/cfn). An account on Cisco.com is not required.

Table 5 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.
Table 5  Feature Information for Configuring Cisco IOS IPS

<table>
<thead>
<tr>
<th>Feature Name</th>
<th>Software Releases</th>
<th>Feature Configuration Information</th>
</tr>
</thead>
</table>
| Cisco IOS Intrusion Prevention System (IPS) | 12.3(8)T          | This feature restructured the existing Cisco IDS by allowing users to choose between loading the default, built-in signatures; downloading dynamic SDFs; or loading the SDF “attack-drop.sdf” file onto their router. Also, SDEE (an application-level communication protocol that is used to exchange IPS messages between IPS clients and IPS servers) was introduced. The following sections provide information about this feature:  
  • **Information About Cisco IOS IPS**  
  • **How to Configure Cisco IOS IPS on a Device**  
    The following commands were introduced by this feature:  
    ```plaintext
    clear ip sdee, copy ips-sdf, debug ip ips, debug ip sdee, ip ips fail closed, ip ips sdf location, ip sdee events, ip sdee subscriptions, no ip ips sdf builtin, show ip sdee
    ```  

| Cisco IOS Intrusion Prevention System (IPS) | 12.3(14)T         | Cisco IOS IPS was enhanced to support the following additional functionality:  
  • Access to more recent virus and attack signatures via the addition of three more SMEs—STRING.TCP, STRING.ICMP, and STRING.UDP.  
  • Intelligent and local shunning, which allows Cisco IOS IPS to shun offending traffic on the same router that Cisco IOS IPS is configured.  
  • The **ip ips deny-action ips-interface** command, which allows users to choose between two available ACL filter settings for detecting offending packets.  
    Support for the Post Office Protocol was deprecated and the following commands were removed from the Cisco IOS software: **ip ips po local**, **ip ips po max-events**, **ip ips po protected**, and **ip ips po remote**. |

| Transparent Cisco IOS IPS             | 12.4(2)T          | Support was added for Layer 2 transparent bridging for Cisco IOS IPS. Transparent Cisco IOS IPS eases certain network and management deployment by allowing users to “drop” a device running Cisco IOS IPS in front of their existing network without changing the statically defined IP addresses of their network-connected devices. Thus, users can allow selected devices from a subnet to traverse the IPS while access to other devices on the same subnet is denied. The following sections provide information about this feature:  
  • **Transparent Cisco IOS IPS Overview**  
  • **Configuring a Bridge Group for Transparent Cisco IOS IPS**  
    No commands were introduced or modified for this feature. |
Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Network Admission Control

First Published: May 27, 2004
Last Updated: October 31, 2008

The Network Admission Control feature addresses the increased threat and impact of worms and viruses have on business networks. This feature is part of the Cisco Self-Defending Network Initiative that helps customers identify, prevent, and adapt to security threats.

In its initial phase, the Cisco Network Admission Control (NAC) functionality enables Cisco routers to enforce access privileges when an endpoint attempts to connect to a network. This access decision can be on the basis of information about the endpoint device, such as its current antivirus state. The antivirus state includes information such as version of antivirus software, virus definitions, and version of scan engine.

Network admission control systems allow noncompliant devices to be denied access, placed in a quarantined area, or given restricted access to computing resources, thus keeping insecure nodes from infecting the network.

The key component of the Cisco Network Admission Control program is the Cisco Trust Agent, which resides on an endpoint system and communicates with Cisco routers on the network. The Cisco Trust Agent collects security state information, such as what antivirus software is being used, and communicates this information to Cisco routers. The information is then relayed to a Cisco Secure Access Control Server (ACS) where access control decisions are made. The ACS directs the Cisco router to perform enforcement against the endpoint.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the “Feature Information for Network Admission Control” section on page 29.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Catalyst OS, and Cisco IOS XE software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.
Prerequisites for Network Admission Control

- The Cisco IOS router must be running Cisco IOS software Release 12.3(8)T or later.
- The Cisco Trust Agent must be installed on the endpoint devices (for example, on PCs and laptops).
- A Cisco Secure ACS is required for authentication, authorization, and accounting (AAA).
- A proficiency with configuring access control lists (ACLs) and AAA is necessary.

Restrictions for Network Admission Control

- This feature is available only on Cisco IOS firewall feature sets.

Information About Network Admission Control

Before configuring the Network Admission Control feature, the following concepts need to be understood:

- Virus Infections and Their Effect on Networks, page 3
- How Network Admission Control Works, page 3

Virus Infections and Their Effect on Networks

Virus infections are the single largest cause of serious security breaches for networks and often result in huge financial losses. Sources of virus infections are insecure endpoints (for example, PCs, laptops, and servers). Although the endpoints may have antivirus software installed, the software is often disabled. Even if the software is enabled, the endpoints may not have the latest virus definitions and scan engines. A larger security risk is from devices that do not have any antivirus software installed. Although antivirus vendors today are making it more difficult to disable the antivirus software, they are not addressing the risk of outdated virus definitions and scan engines.

How Network Admission Control Works

Endpoint systems, or clients, are normally hosts on the network, such as PCs, laptops, workstations, and servers. The endpoint systems are a potential source of virus infections, and their antivirus states have to be validated before they are granted network access. When an endpoint attempts an IP connection to a network through an upstream Cisco network access device (typically a Cisco IOS router), the router challenges the endpoint for its antivirus state. The endpoint systems run a client called Cisco Trust Agent, which collects antivirus state information from the end device and transports the information to the Cisco network access device. This information is then communicated to a Cisco Secure ACS where the antivirus state of the endpoint is validated and access control decisions are made and returned to Cisco network access devices. The network devices either permit, deny, or quarantine the end device. The Cisco Secure ACS may in turn use back-end antivirus vendor-specific servers for evaluating the antivirus state of the endpoint.

Figure 1 illustrates how Cisco Network Admission Control works.

Figure 1  Cisco IOS Network Admission Control System

Network Access Device

A network access device (NAD) is typically a Cisco IOS router (a Layer 3 Extensible Authentication Protocol over User Datagram Protocol [EAPoUDP] access point) that provides connectivity to external networks, such as the Internet or remote enterprise networks. Cisco Network Admission Control functionality may have an Intercept ACL, which determines connections that are intercepted for network...
admission. Connections from endpoints that match the access list are intercepted by Network Admission Control and are challenged for their antivirus states over a Layer 3 association before they are granted network access.

**Cisco Trust Agent**

Cisco Trust Agent is a specialized software that runs on endpoint systems. Cisco Trust Agent responds to challenges from the router about the antivirus state of an endpoint system. If an endpoint system is not running the Cisco Trust Agent, the network access device (router) classifies the endpoint system as “clientless.” The network access device uses the EOU clientless username and EOU clientless password that are configured on the network access device as the credentials of the endpoint system for validation with Cisco Secure ACS. The policy attributes that are associated with this username are enforced against the endpoint system.

**Cisco Secure ACS**

Cisco Secure ACS provides authentication, authorization, and accounting services for network admission control using industry-standard RADIUS authentication protocol. Cisco Secure ACS returns access control decisions to the network access device on the basis of the antivirus credentials of the endpoint system.

Using RADIUS cisco_av_pair vendor-specific attributes (VSAs), the following attribute-value pairs (AV pairs) can be set on the Cisco Secure ACS. These AV pairs are sent to the network access device along with other access-control attributes.

- **url-redirect**—Enables the AAA client to intercept an HTTP request and redirect it to a new URL. This redirection is especially useful if the result of posture validation indicates that the network access control endpoint requires an update or patch to be made available on a remediation web server. For example, a user can be redirected to a remediation web server to download and apply a new virus Directory Administration Tool (DAT) file or an operating system patch. (See the following example.)

  url-redirect=http://10.1.1.1

- **posture-token**—Enables Cisco Secure ACS to send a text version of a system posture token (SPT) that is derived by posture validation. The SPT is always sent in numeric format, and using the posture-token AV pair makes it easier to view the result of a posture validation request on the AAA client. (See the following example.)

  posture-token=Healthy

Valid SPTs, in order of best to worst, are as follows:

- Healthy
- Checkup
- Quarantine
- Infected
- Unknown

- **status-query-timeout**—Overrides the status-query default value of the AAA client with the user specified value, in seconds. (See the following example.)

  status-query-timeout=150
For more information about AV pairs that are supported by Cisco IOS software, see the documentation for the releases of Cisco IOS software that are implemented on your AAA clients.

**Remediation**

Network Admission Control supports HTTP redirection that redirects any HTTP request from the endpoint device to a specified redirect address. This support mechanism redirects all HTTP requests from a source to a specified web page (URL) to which the latest antivirus files can be downloaded. For the HTTP redirection to work, the value must be set for the “url-redirect” VSA on the ACS and, correspondingly, associate an access control entry in the downloadable ACL that permits the access of the endpoint system to the redirect URL address. After the value of the url-redirect VSA has been set and the access control entry has been associated, any HTTP request that matches the IP admission Intercept ACL are redirected to the specified redirect URL address.

**Network Admission Control and Authentication Proxy**

It is possible that network admission control and authentication proxy can be configured for the same set of hosts on a given interface. In each case, the Intercept ACL should be the same for IP admission EAPoUDP and authentication proxy. IP admission proxy with proxy authentication should be configured first, followed by IP admission control.

**NAC MIB**

The NAC MIB feature adds Simple Network Management Protocol (SNMP) support for the NAC subsystem. Using SNMP commands (get and set operations), an administrator can monitor and control NAC sessions on the network access device (NAD).

For more information about SNMP get and set operations, see the subsection “Related Documents” in the section “Additional References.”

**Correlation Between SNMP Get and Set Operations and the Cisco CLI**

Most of the objects in the object tables in the NAC MIB (CISCO-NAC-NAD-MIB.my) describe various EAPoUDP and session parameters that are applicable to the setup of a NAD. These properties can be viewed and modified by performing various SNMP get and set operations. Many of the values of the table objects can also be viewed or modified by configuring corresponding command-line interface (CLI) commands on a router. For example, an SNMP get operation can be performed on the cnnEOUGlobalObjectsGroup table or the `show eou` command can be configured on a router. The parameter information obtained from the SNMP get operation is the same as the output from the `show eou` command. Similarly, performing an SNMP get operation on the table cnnEouIfConfigTable provides interface-specific parameters that can also be viewed in output from the `show eou` command.

SNMP set operations are allowed for table objects that have corresponding CLI commands, which can be used to modify table object values. For example, to change the value range for the `cnnEouHostValidateAction` object in the `cnnEouHostValidateAction` MIB table to 2, you can either perform the SNMP set operation or configure the `eou initialize all` command on a router.

For examples of NAC MIB output, see the subsection “NAC MIB Output: Examples” in the section “Configuration Examples for Network Admission Control.”
**Initializing and Revalidating Sessions**

NAC allows administrators to initialize and revalidate sessions using the following CLI commands:

- `eou initialize all`
- `eou initialize authentication clientless`
- `eou initialize authentication eap`
- `eou initialize authentication static`
- `eou initialize ip {ip-address}`
- `eou initialize mac {mac-address}`
- `eou initialize posturetoken {string}`
- `eou revalidate all`
- `eou revalidate authentication clientless`
- `eou revalidate authentication eap`
- `eou revalidate authentication static`
- `eou revalidate ip {ip-address}`
- `eou revalidate mac {mac-address}`
- `eou revalidate posturetoken {string}`

The initialization and revalidation actions can also be accomplished by performing SNMP set operations on the objects of the `cnnEouHostValidateAction` table. For more information about initializing and revalidating sessions, see the section “CLI Commands That Correlate to `cnnEouHostValidateAction` Table Objects.”

For examples of CLI commands that correlate to changes that can be made to `cnnEouHostValidateAction` table objects, see the subsection “NAC MIB Output: Examples” in the section “Configuration Examples for Network Admission Control.”

**Session-Specific Information**

The NAC MIB provides a way to view session-specific details using the `cnnEouHostQueryTable` and `cnnEouHostResultTable`. The `cnnEouHostQueryTable` is used to build the query. The query is the same format as the `show eou ip {ip-address}` command (that is, the IP address would be shown as in the `show eou ip` command—for example, 10.1.1.1). Administrators must use the SNMP set operation on the objects of the `cnnEouHostQueryTable` to create the query. The results of the query are stored as a row in the `cnnEouHostResultTable`. For more information about viewing session-specific details, see the section “Viewing MIB Query Results.”

**Using show Commands to View MIB Object Information**

The CLI commands `show eou`, `show eou all`, `show eou authentication`, `show eou initialize`, `show eou ip`, `show eou mac`, `show eou posturetoken`, `show eou revalidate`, and `show ip device tracking all` provide the same output information as that in the CISCO-NAC-NAD-MIB tables using SNMP get operations.

For examples of `show` command output information that can also be viewed in MIB object tables, see the subsection “NAC MIB Output: Examples” in the section “Configuration Examples for Network Admission Control.”
How to Configure Network Admission Control

This section contains the following procedures:

- Configuring the ACL and Admission Control, page 7 (required)
- Configuring Global EAPoUDP Values, page 9 (optional)
- Configuring an Interface-Specific EAPoUDP Association, page 10 (optional)
- Configuring AAA for EAPoUDP, page 11 (optional)
- Configuring the Identity Profile and Policy, page 12 (required)
- Clearing EAPoUDP Sessions That Are Associated with an Interface, page 14 (optional)
- Verifying Network Admission Control, page 15 (optional)
- Troubleshooting Network Admission Control, page 15 (optional)
- Monitoring and Controlling NAC with the CISCO-NAC-NAD-MIB, page 16 (optional)

Configuring the ACL and Admission Control

Network admission control is applied in the inbound direction at any interface. Applying network admission control inbound at an interface causes network admission control to intercept the initial IP connections of the intercept end system through the router.

Figure 1 shows that IP admission control is applied at the LAN interface. All network devices must be validated for their antivirus states upon their initial IP connections through the router. Until then, all traffic from endpoint systems (except for EAPoUDP and Cisco Secure ACS traffic) is blocked at the interface.

The endpoint system is then challenged for its antivirus state over an EAPoUDP association. The endpoint system gains access to the network if it complies with the network admission control policy as evaluated by the Cisco Secure ACS. If the endpoint system does not comply, the device is either denied access or quarantined.

To configure an intercept ACL, perform the DETAILED STEPS below.

In this configuration, an intercept ACL is defined as “101,” and the Intercept ACL is associated with the IP admission control rule “greentree.” Any IP traffic that is destined to the 192.50.0.0 network are subjected to validation. In addition, beginning with Step 5, an intercept ACL is applied inbound to the interface that is associated with network admission control. This ACL typically blocks access to endpoint systems until they are validated. This ACL is referred to as the default access list.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. access-list access-list-number {permit | deny} protocol source destination
4. ip admission name admission-name [eapoudp | proxy {ftp | http | telnet}] [list {acl | acl-name}]
5. interface type slot/port
6. ip address ip-address mask
7. ip admission admission-name
8. exit
### Network Admission Control

**9. access-list access-list-number {permit | deny} protocol source destination**

**10. ip access-group {access-list-number | access-list-name} in**

Configuring an Interface-Specific EAPoUDP Association

To configure an EAPoUDP association that can be changed or customized for a specific interface that is associated with network admission control, perform the following steps.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface type slot/port
4. eou [default | max-retry | revalidate | timeout]
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| **Example:** | Router> enable |
| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:** | Router# configure terminal |
| **Step 3** interface type slot/port | Defines an interface and enters interface configuration mode. |
| **Example:** | Router (config)# interface ethernet 2/1 |
| **Step 4** eou [default | max-retry | revalidate | timeout] | Enables an EAPoUDP association for a specific interface.  
- For a breakout of available keywords and arguments for the eou command, see the following commands:  
  - eou default  
  - eou max-retry  
  - eou revalidate  
  - eou timeout |
| **Example:** | Router (config-if)# eou revalidate |

Configuring AAA for EAPoUDP

To set up AAA for EAPoUDP, perform the following steps.

SUMMARY STEPS

1. enable
2. configure terminal
3. aaa new-model
4. aaa authentication eou default enable group radius
5. aaa authorization network default group radius
6. radius-server host { hostname | ip-address }
7. radius-server key { 0 string | 7 string | string }
 Configuring the Identity Profile and Policy

Identity is a common infrastructure that is used to specify local profile and policy configurations. The identity profile allows you to statically authorize or validate individual devices on the basis of IP address, MAC address, or device type. Each statically authenticated device can be associated with a local policy that specifies the network access control attributes. Hosts are added to this “exception list” using the identity profile command, and corresponding policies are associated with these hosts using the identity policy command.

If the client is part of the identity (that is, the client is on the exception list), the status of the client is set on the basis of the identity configuration. The client does not have to go through the posture validation process, and the associated identity policy is applied for the client.
Summary Steps

1. enable
2. configure terminal
3. identity profile eapoudp
4. device { authorize { ip address ip-address { policy policy-name } | mac-address mac-address | type { cisco | ip | phone } } | not-authorize }
5. exit
6. identity policy policy-name [ access-group group-name | description line-of-description | redirect url | template { virtual-template interface-name } ]
7. access-group group-name
8. exit
9. exit
10. ip access-list extended access-list-name
11. { permit | deny } source source-wildcard destination destination-wildcard

Detailed Steps

<td></td>
</tr>
<tr>
<td><code>Router (config)# ip access-list extended exempt-acl</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 11</strong></td>
<td>Set conditions to allow a packet to pass a named IP access list.</td>
</tr>
<tr>
<td>`{permit</td>
<td>deny} source source-wildcard destination destination-wildcard`</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Router (config-ext-nacl)# permit ip any 192.50.0.0. 0.0.0.255</code></td>
<td></td>
</tr>
</tbody>
</table>

### Clearing EAPoUDP Sessions That Are Associated with an Interface

To clear EAPoUDP sessions that are associated with a particular interface or that are on the NAD, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `clear eou all`
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>
| **Example:** 
  Router> enable | • Enter your password if prompted. |

| Step 2 | clear eou all | Clears all EAPoUDP sessions on the NAD. |
| **Example:** 
  Router# clear eou all | |

**Verifying Network Admission Control**

To verify EAP and EAPoUDP messages or sessions, perform the following steps. The `show` commands may be used in any order or independent of the other `show` command.

**SUMMARY STEPS**

1. `enable`
2. `show eou all`
3. `show ip admission eapoudp`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
</tbody>
</table>
| **Example:** 
  Router> enable | • Enter your password if prompted. |

| Step 2 | show eou all | Displays information about EAPoUDP sessions on the network access device. |
| **Example:** 
  Router# show eou all | |

| Step 3 | show ip admission eapoudp | Displays the network admission control configuration or network admission cache entries. |
| **Example:** 
  Router# show ip admission eapoudp | |

**Troubleshooting Network Admission Control**

The following commands may be used to display information about EAP and EAPoUDP messages or sessions. The `debug` commands may be used in any order or independent of the other `debug` commands.
SUMMARY STEPS

1. **enable**
2. **debug eap {all | errors | packets | sm}**
3. **debug eou {all | eap | errors | packets | sm}**
4. **debug ip admission eapoudp**

Monitoring and Controlling NAC with the CISCO-NAC-NAD-MIB

This section includes the following tasks:
- CLI Commands That Correlate to cnnEouHostValidateAction Table Objects, page 17
- CLI Commands That Correlate to cnnEouiIfConfigTable Objects, page 17
- CLI Commands That Correlate to cnnEouHostValidateAction Table Objects, page 17
- Creating MIB Query Tables, page 18
- Viewing MIB Query Results, page 21

CLI Commands That Correlate to cnnEouGlobalObjectsGroup Table Objects

An SNMP get or set operation can be performed to obtain or change information about value ranges for objects in the cnnEouGlobalObjectsGroup table. The same information can be viewed in output from the **show eou** command. Table 1 displays examples of some global configuration objects and the SNMP get and set operations required to obtain or change their values.

For an example of **show eou** command output, see the section “**show eou**” section on page 24.
### CLI Commands That Correlate to cnnEouIfConfigTable Objects

An SNMP get operation is performed to obtain information about value ranges for objects in the cnnEouIfConfigTable. The same information can be viewed in output from the `show eou` command. Table 2 displays examples of some interface-specific configuration objects and the SNMP get operations required to obtain their values.

<table>
<thead>
<tr>
<th>Interface-Specific Object</th>
<th>SNMP Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>AAA timeout</td>
<td>Performs a get operation on the cnnEouIfTimeoutAAA object.</td>
</tr>
<tr>
<td></td>
<td>• Format: GET cnnEouIfTimeoutAAA.IfIndex</td>
</tr>
<tr>
<td></td>
<td>• You must specify the corresponding index number of the specific interface.</td>
</tr>
<tr>
<td>Maximum retries</td>
<td>Performs a get operation on the cnnEouIfMaxRetry object.</td>
</tr>
<tr>
<td></td>
<td>• Format: GET cnnEouIfMaxRetry.IfIndex</td>
</tr>
</tbody>
</table>

### CLI Commands That Correlate to cnnEouHostValidateAction Table Objects

EOU sessions can be initialized or revalidated by the CLI or by using the SNMP set operation on the table cnnEouHostValidateAction.

Following are some examples (listed by CLI command) that correlate to MIB objects.

**eou initialize all**

EOU initialization can be accomplished for all sessions by using the `eou initialize all` command or by using an SNMP set operation on the object cnnEouHostValidateAction. This object must be set to the numeric value 2.

**eou initialize authentication clientless**

EOU initialization can be accomplished for sessions having an authentication type “clientless” using the `eou initialize authentication clientless` command or an SNMP set operation on the object cnnEouHostValidateAction. This object must be set to the numeric value 3.

**eou initialize ip**

EOU initialization can be accomplished for a particular session using the `eou initialize ip {ip-address}` command.
To achieve the same result using an SNMP operation, three objects have to be set in the cnnEouHostValidateAction MIB table:

- **cnnEouHostValidateAction**—The value range must be set.
- **cnnEouHostValidateIpAddrType**—The IP address type must be set. This value must be set to IPv4 because IPv4 is currently the only address type supported by NAC. (This value is the type of address being set for the cnnEouHostValidateIPAddr object.)
- **cnnEouHostValidateIPAddr**—The IP address must be set.

**Note**

The three MIB objects should be set in a single SNMP set operation.

eou initialize posturetoken

All sessions having a particular posturetoken can be initialized using the `eou initialize posturetoken {string}` command. The default value range for this command is 8.

To achieve the same result using an SNMP set operation, you must set the following objects:

- **cnnEouHostValidateAction**—Set this value to 8.
- **cnnEouHostValidatePostureTokenStr**—Set the string value.

**Note**

The two MIB objects should be set in a single SNMP set operation.

### Creating MIB Query Tables

The MIB table cnnEouHostQueryTable is used to create, or build, MIB queries.

#### MIB Query Correlating to the CLI show eou all Command

To build a query that provides the same results as using the `show eou all` command, perform the following SNMP get operation.

The object `cnnEouHostQueryMask` in the table `cnnEouHostQueryTable` indicates the kind of query. The corresponding value of the `cnnEouHostQueryMask` object in output from the `show eou all` command is 8 (the integer value).

#### SUMMARY STEPS

1. Set the `cnnEouHostQueryStatus` object to `createandgo`.
2. Set the `cnnEouHostQueryMask` object to 8.
3. Set the `cnnEouHostQueryStatus` object to `active` to indicate that query creation is complete.

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> Set the <code>cnnEouHostQueryStatus</code> object to <code>createandgo</code>.</td>
<td>Creates a query row.</td>
</tr>
<tr>
<td><strong>Step 2</strong> Set the <code>cnnEouHostQueryMask</code> object to 8.</td>
<td>Corresponds in value to the <code>show eou all</code> command.</td>
</tr>
<tr>
<td><strong>Step 3</strong> Set the <code>cnnEouHostQueryStatus</code> object to <code>active</code>.</td>
<td>Indicates that you have finished building the query.</td>
</tr>
</tbody>
</table>
Examples are not shown in the previous table because the format differs depending on the software you are using.

**What to Do Next**

View the results. See the section “**Viewing MIB Query Results Correlating to the show eou all Command.**”

**Viewing MIB Query Results Correlating to the show eou all Command**

After the MIB query has been built and you have indicated that you are finished (with the “active” status), the results can be viewed. A query in the cnnEouHostQueryTable is represented by a row. The row number is the Query Index. Similarly, the cnnEouHostResultTable is composed of result rows. Each row in the cnnEouHostResultTable is uniquely identified by a combination of Query Index and Result Index. The results of the cnnEouHostQueryTable index and the cnnEouHostResultTable have to be matched. Match one row in the Query table to one of the rows in the Result table. For example, if a query that corresponds to a `show` command results in ten sessions, the Result table has ten rows, each row corresponding to a particular session. The first row in the Result table is R1.1. The second row is R1.2, and so on to R1.10. If another query is created in the Query table, and it results in five sessions, five rows are created in the Result table (R2.1, R2.2, R2.3, R2.4, and R2.5).

Table 3 illustrates how the Query table sessions are mapped to Result table rows.

<table>
<thead>
<tr>
<th>Query Table</th>
<th>Result Table Rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>Q1 (10 sessions)</td>
<td>R1.1, R1.2, R1.3, R1.4, R1.5, R1.6, R1.7, R1.8, R1.9, R1.10</td>
</tr>
<tr>
<td>Q2 (5 sessions)</td>
<td>R2.1, R2.2, R2.3, R2.4, R2.5</td>
</tr>
</tbody>
</table>

**Creating the SNMP Query**

To create an SNMP query that provides the same information as output from the `show eou ip {ip-address}` command, perform the following steps.

**SUMMARY STEPS**

1. Set cnnEouHostQueryStatus to createandgo.
2. Set cnnEouHostQueryIpAddrType to IPv4 and the IP address (for example, 10.2.3.4).
3. Set cnnEouHostQueryStatus to active.
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1  Set cnnEouHostQueryStatus to createandgo.</td>
<td>Creates a query row.</td>
</tr>
<tr>
<td>Step 2  Set cnnEouHostQueryIpAddrType to IPv4 and the IP</td>
<td>Sets the address type.</td>
</tr>
<tr>
<td>address (for example, 10.2.3.4).</td>
<td>• The only address type currently supported by NAC is IPv4.</td>
</tr>
<tr>
<td>Step 3  Set cnnEouHostQueryStatus to active.</td>
<td>Indicates you have finished building the query.</td>
</tr>
</tbody>
</table>

Note: Examples are not shown in the previous table because the format differs depending on the software you are using.

Viewing the Results
To view the results in the cnnEouHostResultTable, perform the following steps.

SUMMARY STEPS

1. Perform a get operation on cnnEouHostQueryRows.
2. Perform a get operation on the cnnEouHostResultTable objects in the format resultTableObjectName.QueryIndex.ResultIndex.

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1  Perform a get operation on cnnEouHostQueryRows.</td>
<td>Finds how many rows are created in a Result table for a particular query.</td>
</tr>
<tr>
<td></td>
<td>• If a query row is a negative number, the query is still being processed.</td>
</tr>
<tr>
<td>Step 2  Perform a get operation on the</td>

<td>particular query.</td>
</tr>
<tr>
<td>resultTableObjectName.QueryIndex.ResultIndex.</td>
<td>• For multiple rows in the Result table for a single query, the</td>
</tr>
<tr>
<td></td>
<td>ResultIndex ranges from 1 to the value of</td>
</tr>
<tr>
<td></td>
<td>cnnEouHostQueryRows.</td>
</tr>
</tbody>
</table>

Note: Examples are not shown in the above table because the format differs depending on the software you are using.

MIB Query Correlating to the show eou ip Command

To build a MIB query that provides the same results as the `show eou ip {ip-address}` command, perform the following SNMP get operation.
SUMMARY STEPS

1. Set the cnnEouHostQueryStatus object to createandgo.
2. Set the cnnEouHostQueryIpAddrType object to “IPv4”.
3. Set the cnnEouHostQueryIpAddr object to IP address (for example, 10.2.3.4).
4. Set the cnnEouHostQueryStatus object to active.

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 Set the cnnEouHostQueryStatus object to createandgo.</td>
<td>Sets the query status.</td>
</tr>
<tr>
<td>Step 2 Set the cnnEouHostQueryIpAddrType object to “IPv4”.</td>
<td>Sets the address type.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> The only address type currently supported by NAC is IPv4.</td>
</tr>
<tr>
<td>Step 3 Set the cnnEouHostQueryIpAddr object to IP address (for example, 10.2.3.4).</td>
<td>Sets the IP address.</td>
</tr>
<tr>
<td>Step 4 Set the cnnEouHostQueryStatus object to active.</td>
<td>Indicates that you have finished building the query.</td>
</tr>
</tbody>
</table>

**Note** Examples are not shown in the previous table because the format differs depending on the software you are using.

Viewing MIB Query Results

After the MIB query has been built, the results can be viewed in cnnEouHostResultTable. For information about how to review the results, see the subsection “Viewing MIB Query Results Correlating to the show eou all Command” in the previous section “Creating MIB Query Tables.”

Splitting a Query into Subqueries

If you are doing a MIB query that correlates to the show eou all command, there could possibly be as many as 2,000 rows of output. To ensure that you can view all the information in a MIB query, you can split the query into subqueries. For example, for a query having 2,000 rows of output, you could split the query into four subqueries to view the results in a page-by-page format. The first subquery would include rows 1 through 500 (the first 500 sessions); the second subquery would include rows 501 through 1,000; the third subquery would include rows 1,001 through 1,500; and the fourth subquery would include rows 1,501 through 2,000.

**Note** The cnnEouHostQueryTotalHosts object provides the total number of hosts (number of rows) that match a query criterion. By looking at this number, you can determine how many subqueries are necessary. However, you cannot get the cnnEouHostQueryTotalHosts object number until you have built your first query.

Build your query by performing the following steps.
SUMMARY STEPS

1. Set the cnnEouHostQueryStatus object to createandgo.
2. Set the cnnEouHostQueryMask object to 8.
3. Set cnnEouHostQueryRows to 500.
4. Set cnnEouHostQuerySkipNHosts to 0.
5. Set the cnnEouHostQueryStatus object to active.

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Set the cnnEouHostQueryStatus object to createandgo.</td>
</tr>
<tr>
<td>Step 2</td>
<td>Set the cnnEouHostQueryMask object to 8.</td>
</tr>
<tr>
<td>Step 3</td>
<td>Set cnnEouHostQueryRows to 500.</td>
</tr>
<tr>
<td>Step 4</td>
<td>Set cnnEouHostQuerySkipNHosts to 0.</td>
</tr>
<tr>
<td>Step 5</td>
<td>Set the cnnEouHostQueryStatus object to active.</td>
</tr>
</tbody>
</table>

Note

Examples are not shown in the previous table because the format differs depending on the software you are using. The table is on the basis of a query having 2,000 sessions (rows).

What to Do Next

After the above task is performed, information for the first 500 hosts (rows) is queried. To view query information for the next 500 hosts (rows), perform the same five steps, with the exception of changing the cnnEouHostQuerySkipNHosts object value to 500 in Step 4. This task results in query information for rows 501 through 1000. In the same way, to obtain query information for the remaining hosts (through 2000), perform the same five steps again, with the exception of changing the cnnEouHostQuerySkipNHosts object values in Step 4 to 1000 and 1500, respectively.
Configuration Examples for Network Admission Control

This section includes the following example.

- Network Admission Control: Example, page 23
- NAC MIB Output: Examples, page 24

Network Admission Control: Example

The following output example shows that IP admission control has been configured on a Cisco IOS router:

Router# show running-config

Building configuration...

Current configuration: 1240 bytes
!
version 12.3
service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption

!
The following lines configure an interface access list that allows EAPoUDP traffic and blocks the rest of the traffic until it is validated.

```
access-list 102 permit udp any any eq 21862
access-list 102 deny ip any any
```

The following line configures RADIUS.

```
radius-server host 10.13.11.105 auth-port 1645 acct-port 1646 key cisco
```

```
control-plane
```

```
line con 0
  exec-timeout 0 0
line aux 0
line vty 0 4
```

```
end
```

**NAC MIB Output: Examples**

The following are examples of `show` command output displaying MIB object information.

**show eou**

The `show eou` command provides output for information that can also be viewed in various CISCO-NAC-NAD-MIB tables. The information that follows the `show eou` command can also be found in the cnnEouGlobalObjectsGroup table and the information that follows the `show eou all` command can be found in the cnnEouIfConfigTable.

```
Router# show eou

Global EAPoUDP Configuration
--------------------------------
EAPoUDP Version = 1
EAPoUDP Port = 0x5566
Clientless Hosts = Enabled
IP Station ID = Disabled
Revalidation = Enabled
Revalidation Period = 36000 Seconds
ReTransmit Period = 3 Seconds
StatusQuery Period = 300 Seconds
Hold Period = 30 Seconds
AAA Timeout = 60 Seconds
Max Retries = 3
EAP Rate Limit = 20
EAPoUDP Logging = Enabled
Clientless Host Username = clientless
Clientless Host Password = clientless

Router# show eou all

Interface Specific EAPoUDP Configurations
------------------------------------------
Interface Vlan333
AAA Timeout = 60 Seconds
```
Max Retries = 3
eou initialize interface {interface-name}
eou revalidate interface {interface-name}

**show ip device tracking all**

The **show ip device tracking all** command provides output for information that can also be found in the cnnIpDeviceTrackingObjectsGroup MIB table. The following is an example of such **show** command output:

Router# **show ip device tracking all**

IP Device Tracking = Enabled
Probe Count: 2
Probe Interval: 10

Feature Information for Network Admission Control

Table 4 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Note

Table 4 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

default access policy—Set of ACLs that are applied to a client device until its credentials are validated by the AAA server.

EAPoUDP—Extensible Authentication Protocol over User Datagram Protocol. EAP is a framework that supports multiple, optional authentication mechanisms for PPP, including clear-text passwords, challenge-response, and arbitrary dialogue sequences. UDP is a connectionless transport layer protocol in the TCP/IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, and it requires that error processing and retransmission be handled by other protocols. UDP is defined in RFC 768.

ip admission rule—Named rule that defines how IP admission control is applied. The IP admission rule is associated with an Intercept ACL and provides control over which hosts can use the IP admission feature. To create an IP admission control rule, use the ip admission name command.

posture token—Status that is used to convey the result of the evaluation of posture credentials. The AAA server maps the posture token (its status can be Healthy, Checkup, Quarantine, Infected, or Unknown) to a network access policy (ACL, URL, redirect, or status query timer) for the peer that the client wants to reach.
Configuring Authentication Proxy

This chapter describes the Cisco IOS Firewall Authentication Proxy feature. Authentication proxy provides dynamic, per-user authentication and authorization, authenticating users against industry standard TACACS+ and RADIUS authentication protocols. Authenticating and authorizing connections by users provides more robust protection against network attacks.

For a complete description of the authentication proxy commands in this chapter, refer to the “Authentication Proxy Commands” chapter of the Cisco IOS Security Command Reference. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the “Identifying Supported Platforms” section in the chapter “Using Cisco IOS Software.”

In This Chapter

This chapter contains the following sections:

- About Authentication Proxy
- Authentication Proxy Configuration Task List
- Monitoring and Maintaining the Authentication Proxy
- Authentication Proxy Configuration Examples

About Authentication Proxy

The Cisco IOS Firewall authentication proxy feature allows network administrators to apply specific security policies on a per-user basis. Previously, user identity and related authorized access were associated with a user IP address, or a single security policy had to be applied to an entire user group or subnetwork. Now, users can be identified and authorized on the basis of their per-user policy. Tailoring of access privileges on an individual basis is possible, as opposed to applying a general policy across multiple users.
With the authentication proxy feature, users can log in to the network or access the Internet via HTTP, and their specific access profiles are automatically retrieved and applied from a CiscoSecure ACS, or other RADIUS, or TACACS+ authentication server. The user profiles are active only when there is active traffic from the authenticated users.

The authentication proxy is compatible with other Cisco IOS security features such as Network Address Translation (NAT), Context-based Access Control (CBAC), IP Security (IPSec) encryption, and Cisco Secure VPN Client (VPN client) software.

This section contains the following sections:

- How the Authentication Proxy Works
- Secure Authentication
- Using the Authentication Proxy
- When to Use the Authentication Proxy
- Applying the Authentication Proxy
- Operation with One-Time Passwords
- Compatibility with Other Security Features
- Compatibility with AAA Accounting
- Protection Against Denial-of-Service Attacks
- Risk of Spoofing with Authentication Proxy
- Comparison with the Lock-and-Key Feature
- Restrictions
- Prerequisites to Configuring Authentication Proxy

**How the Authentication Proxy Works**

When a user initiates an HTTP session through the firewall, the authentication proxy is triggered. The authentication proxy first checks to see if the user has been authenticated. If a valid authentication entry exists for the user, the connection is completed with no further intervention by the authentication proxy. If no entry exists, the authentication proxy responds to the HTTP connection request by prompting the user for a username and password.

*Figure 42* illustrates the authentication proxy HTML login page.
Users must successfully authenticate themselves with the authentication server by entering a valid username and password.

If the authentication succeeds, the user’s authorization profile is retrieved from the AAA server. The authentication proxy uses the information in this profile to create dynamic access control entries (ACEs) and add them to the inbound (input) access control list (ACL) of an input interface and to the outbound (output) ACL of an output interface, if an output ACL exists at the interface. This process enables the firewall to allow authenticated users access to the network as permitted by the authorization profile. For example, a user can initiate a Telnet connection through the firewall if Telnet is permitted in the user’s profile.

If the authentication fails, the authentication proxy reports the failure to the user and prompts the user with multiple retries. If the user fails to authenticate after five attempts, the user must wait two minutes and initiate another HTTP session to trigger authentication proxy.

The login page is refreshed each time the user makes requests to access information from a web server. The authentication proxy customizes each of the access list entries in the user profile by replacing the source IP addresses in the downloaded access list with the source IP address of the authenticated host.

At the same time that dynamic ACEs are added to the interface configuration, the authentication proxy sends a message to the user confirming that the login was successful. Figure 43 illustrates the login status in the HTML page.
About Authentication Proxy

The authentication proxy sets up an inactivity (idle) timer for each user profile. As long as there is activity through the firewall, new traffic initiated from the user’s host does not trigger the authentication proxy, and authorized user traffic is permitted access through the firewall.

If the idle timer expires, the authentication proxy removes the user’s profile information and dynamic access lists entries. When this happens, traffic from the client host is blocked. The user must initiate another HTTP connection to trigger the authentication proxy.

Secure Authentication

The authentication proxy uses JavaScript to help achieve secure authentication using the client browser. Secure authentication prevents a client from mistakenly submitting a username and password to a network web server other than the authentication proxy router.

This section contains the following sections:

- Operation with JavaScript
- Operation Without JavaScript

Operation with JavaScript

Users should enable JavaScript on the browser prior to initiating an HTTP connection. With JavaScript enabled on the browser, secure authentication is done automatically, and the user sees the authentication message shown in Figure 43. The HTTP connection is completed automatically for the user.

Operation Without JavaScript

If the client browser does not support JavaScript, or if site security policy prevents users from enabling JavaScript, any login attempt generates a popup window with instructions for manually completing the connection. Figure 44 illustrates the authentication proxy login status message with JavaScript disabled on the browser.
To close this window, click Close on the browser File menu.

After closing the popup window, the user should click Reload (Refresh for Internet Explorer) in the browser window in which the authentication login page is displayed. If the user’s last authentication attempt succeeds, clicking Reload brings up the web page the user is trying to retrieve. If the user’s last attempt fails, clicking Reload causes the authentication proxy to intercept the client HTTP traffic again, prompting the user with another login page that solicits the username and password.

If JavaScript is not enabled, it is strongly recommended that site administrators advise users of the correct procedure for closing the popup window as described in the section “Establishing User Connections Without JavaScript.”

### Using the Authentication Proxy

Unlike some Cisco IOS Firewall features that operate transparently to the user, the authentication proxy feature requires some user interaction on the client host. Table 40 describes the interaction of the authentication proxy with the client host.
When to Use the Authentication Proxy

Here are examples of situations in which you might use the authentication proxy:

- You want to manage access privileges on an individual (per-user) basis using the services provided by the authentication servers instead of configuring access control based on host IP address or global access policies. Authenticating and authorizing users from any host IP address also allows network administrators to configure host IP addresses using DHCP.

- You want to authenticate and authorize local users before permitting access to intranet or Internet services or hosts through the firewall.

- You want to authenticate and authorize remote users before permitting access to local services or hosts through the firewall.

- You want to control access for specific extranet users. For example, you might want to authenticate and authorize the financial officer of a corporate partner with one set of access privileges while authorizing the technology officer for that same partner to use another set of access privileges.

- You want to use the authentication proxy in conjunction with VPN client software to validate users and to assign specific access privileges.

- You want to use the authentication proxy in conjunction with AAA accounting to generate “start” and “stop” accounting records that can be used for billing, security, or resource allocation purposes, thereby allowing users to track traffic from the authenticated hosts.
Applying the Authentication Proxy

Apply the authentication proxy in the inbound direction at any interface on the router where you want per-user authentication and authorization. Applying the authentication proxy inbound at an interface causes it to intercept a user’s initial connection request before that request is subjected to any other processing by the firewall. If the user fails to gain authentication with the AAA server, the connection request is dropped.

How you apply the authentication proxy depends on your security policy. For example, you can block all traffic through an interface and enable the authentication proxy feature to require authentication and authorization for all user initiated HTTP connections. Users are authorized for services only after successful authentication with the AAA server.

The authentication proxy feature also allows you to use standard access lists to specify a host or group of hosts whose initial HTTP traffic triggers the proxy.

Figure 45 shows the authentication proxy applied at the LAN interface with all network users required to be authenticated upon the initial connection (all traffic is blocked at each interface).

Figure 46 shows the authentication proxy applied at the dial-in interface with all network traffic blocked at each interface.
Operation with One-Time Passwords

Given a one-time password, the user enters the username and one-time password in the HTML login page as usual.

The user must enter the correct token password within the first three attempts. After three incorrect entries, the user must enter two valid token passwords in succession before authentication is granted by the AAA server.

Compatibility with Other Security Features

The authentication proxy is compatible with Cisco IOS software and with Cisco IOS security features:

- Cisco IOS Firewall Intrusion Detection System (IDS)
- NAT
- CBAC
- IPSec encryption
- VPN client software

The authentication proxy works transparently with the Cisco IOS Firewall IDS and IPSec encryption features. The following sections describe the relationship of the NAT, CBAC, and VPN client software features with the authentication proxy:

- NAT Compatibility
- CBAC Compatibility
- VPN Client Compatibility

NAT Compatibility

The authentication proxy feature is compatible with NAT only if the ACL and authentication are completed prior to the NAT translation. Although NAT is compatible with the authentication proxy feature, NAT is not a requirement of the feature.
CBAC Compatibility

Although authentication proxy is compatible with CBAC security functions, CBAC is not required to use the authentication proxy feature.

Authentication proxy’s authorization returns Access Control Entries (ACEs) that are dynamically prepended into a manually created ACL. Thereafter, apply the ACL to the “protected side” inbound interface, allowing or disallowing an authorized user’s source IP address access to the remote networks.

VPN Client Compatibility

Using the authentication proxy, network administrators can apply an extra layer of security and access control for VPN client traffic. If a VPN client initiates an HTTP connection, the authentication proxy first checks for prior client authentication. If the client is authenticated, authorized traffic is permitted. If the client is not authenticated, the HTTP request triggers the authentication proxy, and the user is prompted for a username and password.

If the user authentication is successful, the authentication proxy retrieves the user profile from the AAA server. The source address in the user profile entries is replaced with the IP address of the authenticated VPN client from the decrypted packet.

Compatibility with AAA Accounting

Using the authentication proxy, you can generate “start” and “stop” accounting records with enough information to be used for billing and security auditing purposes. Thus, you can monitor the actions of authenticated hosts that use the authentication proxy service.

When an authentication proxy cache and associated dynamic access control lists are created, the authentication proxy will start to track the traffic from the authenticated host. Accounting saves data about this event in a data structure stored with the data of other users. If the accounting start option is enabled, you can generate an accounting record (a “start” record) at this time. Subsequent traffic from the authenticated host will be recorded when the dynamic ACL created by the authentication proxy receives the packets.

When an authentication proxy cache expires and is deleted, additional data, such as elapsed time, is added to the accounting information and a “stop” record is sent to the server. At this point, the information is deleted from the data structure.

The accounting records for the authentication proxy user session are related to the cache and the dynamic ACL usage.

---

Note

The accounting records must include RADIUS attributes 42, 46, and 47 for both RADIUS and TACACS+.

For more information on RADIUS attributes, refer to the appendix “RADIUS Attributes.”
Protection Against Denial-of-Service Attacks

The authentication proxy monitors the level of incoming HTTP requests. For each request, the authentication proxy prompts the user’s for login credentials. A high number of open requests could indicate that the router is the subject of a denial-of-service (DoS) attack. The authentication proxy limits the level of open requests and drops additional requests until the number of open requests has fallen below 40.

If the firewall is experiencing a high level of connection requests requiring authentication, legitimate network users may experience delays when making connections, or the connection may be rejected and the user must try the connection again.

Risk of Spoofing with Authentication Proxy

When the authentication proxy is triggered, it creates a dynamic opening in the firewall by temporarily reconfiguring an interface with user access privileges. While this opening exists, another host might spoof the authenticated users address to gain access behind the firewall. The authentication proxy does not cause the address spoofing problem; the problem is only identified here as a matter of concern to the user. Spoofing is a problem inherent to all access lists, and the authentication proxy does not specifically address this problem.

Comparison with the Lock-and-Key Feature

Lock-and-key is another Cisco IOS Firewall feature that uses authentication and dynamic access list to provide user access through the firewall. Table 41 compares the authentication proxy and lock-and-key features.

<table>
<thead>
<tr>
<th>Lock-and-Key</th>
<th>Authentication Proxy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Triggers on Telnet connection requests.</td>
<td>Triggers on HTTP connection requests.</td>
</tr>
<tr>
<td>TACACS+, RADIUS, or local authentication.</td>
<td>TACACS+ or RADIUS authentication and authorization.</td>
</tr>
<tr>
<td>Access lists are configured on the router only.</td>
<td>Access lists are retrieved from the AAA server only.</td>
</tr>
<tr>
<td>Access privileges are granted on the basis of the user’s host IP address.</td>
<td>Access privileges are granted on a per-user and host IP address basis.</td>
</tr>
<tr>
<td>Access lists are limited to one entry for each host IP address.</td>
<td>Access lists can have multiple entries as defined by the user profiles on the AAA server.</td>
</tr>
<tr>
<td>Associates a fixed IP addresses with a specific user. Users must log in from the host with that IP address.</td>
<td>Allows DHCP-based host IP addresses, meaning that users can log in from any host location and obtain authentication and authorization.</td>
</tr>
</tbody>
</table>

Use the authentication proxy in any network environment that provides a per-user security policy. Use lock-and-key in network environments that might benefit from local authentication and a limited number of router-based access control policies based on host addresses. Use lock-and-key in environments not using the Cisco Secure Integrated Software.
Restrictions

- The authentication proxy triggers only on HTTP connections.
- HTTP services must be running on the standard (well-known) port, which is port 80 for HTTP.
- Client browsers must enable JavaScript for secure authentication.
- The authentication proxy access lists apply to traffic passing through the router. Traffic destined to the router is authenticated by the existing authentication methods provided by Cisco IOS software.
- The authentication proxy does not support concurrent usage; that is, if two users try to log in from the same host at the same time, authentication and authorization applies only to the user who first submits a valid username and password.
- Load balancing using multiple or different AAA servers is not supported.

Prerequisites to Configuring Authentication Proxy

Prior to configuring authentication proxy, review the following:

- For the authentication proxy to work properly, the client host must be running the following browser software:
  - Microsoft Internet Explorer 3.0 or later
  - Netscape Navigator 3.0 or later
- The authentication proxy has an option to use standard access lists. You must have a solid understanding of how access lists are used to filter traffic before you attempt to configure the authentication proxy. For an overview of how to use access lists with the Cisco IOS Firewall, refer to the chapter “Access Control Lists: Overview and Guidelines.”
- The authentication proxy employs user authentication and authorization as implemented in the Cisco authentication, authorization, and accounting (AAA) paradigm. You must understand how to configure AAA user authentication, authorization, and accounting before you configure the authentication proxy. User authentication, authorization, and accounting are explained in the chapter “Authentication, Authorization, and Accounting (AAA).”
- To run the authentication proxy successfully with Cisco IOS Firewall, configure CBAC on the firewall. For complete information on the CBAC feature, refer to the chapter “Configuring Context-Based Access Control.”

Authentication Proxy Configuration Task List

To configure the authentication proxy feature, perform the following tasks:

- Configuring AAA (Required)
- Configuring the HTTP Server (Required)
- Configuring the Authentication Proxy (Required)
- Verifying the Authentication Proxy (Optional)

For authentication proxy configuration examples using the commands in this chapter, refer to the section “Authentication Proxy Configuration Examples” at the end of this chapter.
Configuring AAA

You must configure the authentication proxy for AAA services. Use the following commands in global configuration mode to enable authorization and to define the authorization methods:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> router(config)# aaa new-model</td>
<td>Enables the AAA functionality on the router.</td>
</tr>
<tr>
<td><strong>Step 2</strong> router(config)# aaa authentication login</td>
<td>Defines the list of authentication methods at login.</td>
</tr>
<tr>
<td>default TACACS+ RADIUS</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> router(config)# aaa authorization auth-proxy</td>
<td>Uses the auth-proxy keyword to enable authentication proxy for AAA methods.</td>
</tr>
<tr>
<td>default [method1 [method2...]]</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> router(config)# aaa accounting auth-proxy</td>
<td>Uses the auth-proxy keyword to set up the authorization policy as dynamic ACLs that can be downloaded. This command activates authentication proxy accounting.</td>
</tr>
<tr>
<td>default start-stop group tacacs+</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> router(config)# tacacs-server host hostname</td>
<td>Specifies an AAA server. For RADIUS servers, use the radius server host command.</td>
</tr>
<tr>
<td><strong>Step 6</strong> router(config)# tacacs-server key key</td>
<td>Sets the authentication and encryption key for communications between the router and the AAA server. For RADIUS servers use the radius server key command.</td>
</tr>
<tr>
<td><strong>Step 7</strong> router(config)# access-list access-list-number permit tcp host source eq tacacs host destination</td>
<td>Creates an ACL entry to allow the AAA server to return traffic to the firewall. The source address is the IP address of the AAA server, and the destination is the IP address of the router interface where the AAA server resides.</td>
</tr>
</tbody>
</table>

In addition to configuring AAA on the firewall router, the authentication proxy requires a per-user access profile configuration on the AAA server. To support the authentication proxy, configure the AAA authorization service **auth-proxy** on the AAA server as outlined here:

- Define a separate section of authorization for the **auth-proxy** keyword to specify the downloadable user profiles. This keyword does not interfere with other type of services, such as EXEC. The following example shows a user profile on a TACACS server:

  ```
  default authorization = permit
  key = cisco
  user = newuser1 {
  login = cleartext cisco
  service = auth-proxy
  
  priv-lvl=15
  proxyacl#1="permit tcp any eq 26"
  proxyacl#2="permit icmp any host 60.0.0.2"
  proxyacl#3="permit tcp any eq ftp"
  proxyacl#4="permit tcp any eq ftp-data"
  proxyacl#5="permit tcp any eq smtp"
  proxyacl#6="permit tcp any eq telnet"
  }
  ```

- The only supported attribute in the AAA server user configuration is proxyacl\#n. Use the proxyacl\#n attribute when configuring the access lists in the profile. The attribute proxyacl\#n is for both RADIUS and TACACS+ attribute-value (AV) pairs.

- The privilege level must be set to 15 for all users.
• The access lists in the user profile on the AAA server must have access commands that contain only the `permit` keyword.

• Set the source address to the `any` keyword in each of the user profile access list entries. The source address in the access lists is replaced with the source address of the host making the authentication proxy request when the user profile is downloaded to the firewall.

• The supported AAA servers are:
  – CiscoSecure ACS 2.1.x for Windows NT
  – CiscoSecure ACS 2.3 for Windows NT
  – CiscoSecure ACS 2.2.4 for UNIX
  – CiscoSecure ACS 2.3 for UNIX
  – TACACS+ server (vF4.02.alpha)
  – Ascend RADIUS server radius-980618 (required attribute-value pair patch)
  – Livingston RADIUS server (v1.16)

Refer to the section “AAA Server User Profile Example” for sample AAA server configurations.

### Configuring the HTTP Server

To use authentication proxy, you must also enable the HTTP server on the firewall and set the HTTP server authentication method to use AAA. Enter the following commands in global configuration mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1  router(config)# ip http server</td>
<td>Enables the HTTP server on the router. The authentication proxy uses the HTTP server to communicate with the client for user authentication.</td>
</tr>
<tr>
<td>Step 2  router(config)# ip http access-class access-list-number</td>
<td>Specifies the access list for the HTTP server. Use the standard access list number configured in the section “Interface Configuration Example.”</td>
</tr>
</tbody>
</table>

### Configuring the Authentication Proxy

**Note**

Set the `auth-cache-time` option for any authentication proxy rule to a higher value than the idle timeout value for any CBAC inspection rule. When the authentication proxy removes an authentication cache along with its associated dynamic user ACL, there may be some idle connections monitored by CBAC, and removal of user-specific ACLs could cause those idle connections to hang. If CBAC has a shorter idle timeout, CBAC resets these connections when the idle timeout expires; that is, before the authentication proxy removes the user profile.

To configure the authentication proxy, use the following commands, beginning in global configuration mode:
## Configuring Authentication Proxy

### Authentication Proxy Configuration Task List

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong>&lt;br&gt;router(config)# ip auth-proxy auth-cache-time min</td>
<td>Sets the global authentication proxy idle timeout value in minutes. If the timeout expires, user authentication entries are removed, along with any associated dynamic access lists. The default value is 60 minutes.</td>
</tr>
<tr>
<td><strong>Step 2</strong>&lt;br&gt;router(config)# ip auth-proxy auth-proxy-banner</td>
<td>(Optional) Displays the name of the firewall router in the authentication proxy login page. The banner is disabled by default.</td>
</tr>
</tbody>
</table>
| **Step 3**<br>router(config)# ip auth-proxy name auth-proxy-name http [auth-cache-time min] [list (acl | acl-name)] | Creates authentication proxy rules. The rules define how you apply authentication proxy. This command associates connections initiating HTTP protocol traffic with an authentication proxy name. You can associate the named rule with an access control list (ACL), providing control over which hosts use the authentication proxy feature. If no standard access list is defined, the named authentication proxy rule intercepts HTTP traffic from all hosts whose connection initiating packets are received at the configured interface.  
(Optional) The **auth-cache-time** option overrides the global authentication proxy cache timer. This option provides more control over timeout values for a specific authentication proxy rule. If no value is specified, the proxy rule assumes the value set with the **ip auth-proxy auth-cache-time** command.  
(Optional) The **list** option allows you to apply a standard, extended (1-199), or named access list to a named authentication proxy rule. HTTP connections initiated by hosts in the access list are intercepted by the authentication proxy. |
| **Step 4**<br>router(config)# interface type | Enters interface configuration mode by specifying the interface type on which to apply the authentication proxy. |
| **Step 5**<br>router(config-if)# ip auth-proxy auth-proxy-name | In interface configuration mode, applies the named authentication proxy rule at the interface. This command enables the authentication proxy rule with that name. |

## Verifying the Authentication Proxy

Verifying the authentication proxy configuration can have several components:

- **Checking the Authentication Proxy Configuration** (Optional)
- **Establishing User Connections with JavaScript** (Optional)
- **Establishing User Connections Without JavaScript** (Optional)
Checking the Authentication Proxy Configuration

To check the current authentication proxy configuration, use the `show ip auth-proxy configuration` command in privileged EXEC mode:

```
Configuration Command

Command | Purpose
---------|---------
router# show ip auth-proxy configuration | Displays the authentication proxy configuration.
```

In the following example, the global authentication proxy idle timeout value is set to 60 minutes, the named authentication proxy rule is “pxy”, and the idle timeout value for this named rule is one minute. The display shows that no host list is specified, meaning that all connections initiating HTTP traffic at the interface are subject to the authentication proxy rule.

```
router# show ip auth-proxy configuration
Authentication cache time is 60 minutes
Authentication Proxy Rule Configuration
Auth-proxy name pxy
http list not specified auth-cache-time 1 minutes
```

To verify that the authentication proxy is successfully configured on the router, ask a user to initiate an HTTP connection through the router. The user must have authentication and authorization configured at the AAA server. If the user authentication is successful, the firewall completes the HTTP connection for the user. If the authentication is unsuccessful, check the access list and the AAA server configurations.

```
router# show ip auth-proxy cache
```

The authentication proxy cache lists the host IP address, the source port number, the timeout value for the authentication proxy, and the state of the connection. If the authentication proxy state is HTTP_ESTAB, the user authentication was successful.

```
router# show ip auth-proxy cache
Authentication Proxy Cache
  Client IP 192.168.25.215 Port 57882, timeout 1, state HTTP_ESTAB
```

Wait for one minute, which is the timeout value for this named rule, and ask the user to try the connection again. After one minute, the user connection is denied because the authentication proxy has removed the user's authentication entry and any associated dynamic ACLs. The user is presented with a new authentication login page and must log in again to gain access through the firewall.

Establishing User Connections with JavaScript

To verify client connections using the authentication proxy with JavaScript enabled on the client browser, follow this procedure:

```
Step 1 | From a client host, initiate an HTTP connection through the firewall. This generates the authentication proxy login page.
Step 2 | At the authentication proxy login page, enter a username and password.
```
### Configuring Authentication Proxy

#### Authentication Proxy Configuration Task List

1. **Click OK** to submit the username and password to the AAA server.
   
   A popup window appears indicating whether the login attempt succeeded or failed. If the authentication is successful, the connection is completed automatically. If the authentication fails, the authentication proxy reports the failure to the user and prompts the user with multiple retries.

---

**Note**

If the authentication attempt is unsuccessful after five attempts, the user must wait two minutes and initiate another HTTP session to trigger authentication proxy.

---

### Establishing User Connections Without JavaScript

To ensure secure authentication, the authentication proxy design requires JavaScript. You can use the authentication proxy without enabling JavaScript on the browser, but this poses a potential security risk if users do not properly establish network connections. The following procedure provides the steps to properly establish a connection with JavaScript disabled. Network administrators are strongly advised to instruct users on how to properly establish connections using the procedure in this section.

---

**Note**

Failure to follow this procedure can cause user credentials to be passed to a network web server other than the authentication proxy or can cause the authentication proxy to reject the login attempt.

---

To verify client connections using the authentication proxy when JavaScript is not enabled on the client browser, follow this procedure:

1. **Step 1** Initiate an HTTP connection through the firewall.
   
   This generates the authentication proxy login page.

2. **Step 2** From the authentication proxy login page at the client, enter the username and password.

3. **Step 3** Click **OK** to submit the username and password to the AAA server.
   
   A popup window appears indicating whether the login attempt succeeded or failed. If the popup window indicates successful authentication, go to **Step 7**.

4. **Step 4** If the popup window displays a failed authentication message, click **Close** on the browser **File** menu.
   
   **Note** Do not click **Reload** (**Refresh** for Internet Explorer) to close the popup window.

5. **Step 5** From the original authentication login page, click **Reload** (**Refresh** for Internet Explorer) on the browser toolbar. The user login credentials are cleared from the form.
   
   **Note** Do not click **OK**. You must click **Reload** or **Refresh** to clear the username and password and to reload the form before attempting to log in again.

6. **Step 6** Enter the username and password again.
   
   If the authentication is successful, a window appears displaying a successful authentication message. If the window displays a failed authentication message, go to **Step 4**.

7. **Step 7** Click **Close** on the browser **File** menu.
Step 8  From the original authentication proxy login page, click **Reload** (Refresh for Internet Explorer) on the browser toolbar.

The authentication proxy completes the authenticated connection with the web server.

---

**Monitoring and Maintaining the Authentication Proxy**

This section describes how to view dynamic access list entries and how to manually remove authentication entries. This section contains the following sections:

- Displaying Dynamic ACL Entries
- Deleting Authentication Proxy Cache Entries

### Displaying Dynamic ACL Entries

You can display dynamic access list entries when they are in use. After an authentication proxy entry is cleared by you or by the idle timeout parameter, you can no longer display it. The number of matches displayed indicates the number of times the access list entry was hit.

To view dynamic access lists and any temporary access list entries that are currently established by the authentication proxy, use the `show ip access-lists` command in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>router# show ip access-lists</code></td>
<td>Displays the standard and extended access lists configured on the firewall, including dynamic ACL entries.</td>
</tr>
</tbody>
</table>

Consider the following example where ACL 105 is applied inbound at the input interface where you configure authentication proxy. The initial display shows the contents of the ACLs prior to authentication. The second display shows the same displays after user authentication with the AAA server.

**Note**

If NAT is configured, the `show ip access list` command might display the translated host IP address for the dynamic ACL entry or the IP address of the host initiating the connection. If the ACL is applied on the NAT outside interface, the translated address is displayed. If the ACL is applied on the NAT inside interface, the IP address of the host initiating the connection is displayed. The `show ip auth-proxy cache` command always displays the IP address of the host initiating the connection.

For example, the following is a list of ACL entries prior to the authentication proxy:

```
Router# show ip access-lists
.
.
.
Extended IP access list 105
   deny tcp any any eq telnet
   deny udp any any
   permit tcp any any (28 matches)
   permit ip any any
```
The following sample output shows a list of ACL entries following user authentication:

```
Router# show ip access-lists
.
.
.
Extended IP access list 105
!
permit tcp host 192.168.25.215 any eq 26
permit icmp host 192.168.25.215 host 60.0.0.2
permit tcp host 192.168.25.215 any eq telnet
permit tcp host 192.168.25.215 any eq ftp
permit tcp host 192.168.25.215 any eq ftp-data
permit tcp host 192.168.25.215 any eq smtp
deny tcp any any eq telnet
deny udp any any
permit tcp any any (76 matches)
permit ip any any
```

### Deleting Authentication Proxy Cache Entries

When the authentication proxy is in use, dynamic access lists dynamically grow and shrink as authentication entries are added and deleted. To display the list of authentication entries, use the `show ip auth-proxy cache` command. To manually delete an authentication entry, use the `clear ip auth-proxy cache` command in privileged EXEC mode:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>`router# clear ip auth-proxy cache (*</td>
<td>host ip address)`</td>
</tr>
</tbody>
</table>

### Authentication Proxy Configuration Examples

Configuring the authentication proxy feature requires configuration changes on both the router and the AAA server. The following sections provide authentication proxy configuration examples:

- **Authentication Proxy Configuration Example**
- **Authentication Proxy, IPSec, and CBAC Configuration Example**
- **Authentication Proxy, IPSec, NAT, and CBAC Configuration Example**
- **AAA Server User Profile Example**

Throughout these examples, the exclamation point (!) indicates a comment line. Comment lines precede the configuration entries being described.

### Authentication Proxy Configuration Example

The following examples highlight the specific authentication proxy configuration entries. These examples do not represent a complete router configuration. Complete router configurations using the authentication proxy are included later in this chapter.
This section contains the following examples:

- **AAA Configuration Example**
- **HTTP Server Configuration Example**
- **Authentication Proxy Configuration Example**
- **Interface Configuration Example**

**AAA Configuration Example**

```plaintext
aaa new-model
aaa authentication login default group tacacs group radius
! Set up the aaa new model to use the authentication proxy.
aaa authorization auth-proxy default group tacacs group radius
! Define the AAA servers used by the router.
aaa accounting auth-proxy default start-stop group tacacs+
! Set up authentication proxy with accounting.
tacacs-server host 172.31.54.143
tacacs-server key cisco
radius-server host 172.31.54.143
radius-server key cisco
```

**HTTP Server Configuration Example**

```plaintext
! Enable the HTTP server on the router.
ip http server
! Set the HTTP server authentication method to AAA.
ip http authentication aaa
! Define standard access list 61 to deny any host.
access-list 61 deny any
! Use ACL 61 to deny connections from any host to the HTTP server.
ip http access-class 61
```

**Authentication Proxy Configuration Example**

```plaintext
! Set the global authentication proxy timeout value.
ip auth-proxy auth-cache-time 60
! Apply a name to the authentication proxy configuration rule.
ip auth-proxy name HQ_users http
```

**Interface Configuration Example**

```plaintext
! Apply the authentication proxy rule at an interface.
interface e0
  ip address 10.1.1.210 255.255.255.0
  ip auth-proxy HQ_users
```

**Authentication Proxy, IPSec, and CBAC Configuration Example**

The following example shows a router configuration with the authentication proxy, IPSec, and CBAC features. Figure 47 illustrates the configuration.
If you are using this feature with Cisco IOS software release 12.3(8)T or later, see the document Crypto Access Check on Clear-Text Packets (feature module, release 12.3(8)T).

**Figure 47  Authentication Proxy, IPSec, and CBAC Configuration Example**

In this example, Host A initiates an HTTP connection with the web server (WWW). The HTTP traffic between Router 1 and Router 2 is encrypted using IPSec. The authentication proxy, IPSec, and CBAC are configured at interface Serial0 on Router 2, which is acting as the firewall. ACL 105 blocks all traffic at interface Serial0. ACL 102 is applied at interface Ethernet0 on Router 2 to block all traffic on that interface except traffic from the AAA server.

When Host A initiates an HTTP connection with the web server, the authentication proxy prompts the user at Host A for a username and password. These credentials are verified with the AAA server for authentication and authorization. If authentication is successful, the per-user ACLs are downloaded to the firewall to permit services.

The following examples provide both the Router 1 and Router 2 configurations for completeness:

- **Router 1 Configuration Example**
- **Router 2 Configuration Example**

## Router 1 Configuration Example

```
! Configure Router 1 for IPSec.
version 12.0
service timestamps debug uptime
service timestamps log uptime
no service password-encryption
!
hostname Router1
!
logging buffered 4096 debugging
no logging console
enable secret 5 $1$E0OB$AQF1vFZM3fLr3LQAOsudL/
enable password junk
!
username Router2 password 0 welcome
crypto isakmp policy 1
  authentication pre-share
```
crypto isakmp key cisco1234 address 10.0.0.2
!
crypto ipsec transform-set rule_1 ah-sha-hmac esp-des esp-sha-hmac
!
crypto map testtag 10 ipsec-isakmp
set peer 10.0.0.2
set transform-set rule_1
match address 155
!

Authentication Proxy, IPSec, NAT, and CBAC Configuration Example

The following example provides a router configuration with the authentication proxy, IPSec, NAT, and CBAC features. Figure 48 illustrates the configuration.

Figure 48 Authentication Proxy, IPSec, and CBAC Configuration Example

In this example, Host A initiates an HTTP connection with the web server (WWW). The HTTP traffic between router 1 (interface BRI0) and router 2 (interface Serial2) is encrypted using IPSec. The authentication proxy is configured on router 2, which is acting as the firewall. The authentication proxy, NAT, and CBAC are configured at interface Serial2, which is acting as the firewall. ACL 105 blocks all traffic at interface Serial2. ACL 102 is applied at interface Ethernet0 on router 2 to block all traffic on that interface except traffic from the AAA server. In this example, the authentication proxy uses standard ACL 10 to specify the hosts using the authentication proxy feature.

When any host in ACL 10 initiates an HTTP connection with the web server, the authentication proxy prompts the user at that host for a username and password. These credentials are verified with AAA server for authentication and authorization. If authentication is successful, the per-user ACLs are downloaded to the firewall to permit services.

The following examples provide both the router 1 and router 2 configurations for completeness:

AAA Server User Profile Example

This section includes examples of the authentication proxy user profile entries on the AAA servers. The “proxyacl” entries define the user access privileges. After the user has successfully used the authentication proxy to log in, these entries are transferred to the firewall router. Each entry in the profile must specify “permit” access for the service or application. The source address in each entry is set to “any”, which is replaced with the IP address of the authenticating host when the profile is downloaded to the firewall. The privilege level must be set to 15 for all AAA users.

This section contains the following sections:
- CiscoSecure ACS 2.3 for Windows NT
- CiscoSecure ACS 2.3 for UNIX
- TACACS+ Server
- Livingston Radius Server
- Ascend Radius Server

CiscoSecure ACS 2.3 for Windows NT

This section describes how to configure authentication proxy on CiscoSecure ACS 2.3 for Windows NT. For detailed information about CiscoSecure ACS, refer to the documentation for that product.

The following sample configuration is for the TACACS+ service of CiscoSecure ACS for Windows NT.

**Step 1**
Click the Interface Configuration icon and click **TACACS+ (Cisco)**.

a. Scroll down to New Services.
c. Select both the User and Group check boxes for the new service.
d. Scroll down to Advance Configuration Options and check the Per-user Advance TACACS+ features.
e. Click **Submit**.

**Step 2**
Click the Network Configuration icon.

a. Click the Add Entry icon for Network Access Servers and fill in the Network Access Server Hostname, IP address, and key (the key configured on the router) fields.
b. Select TACACS+ (Cisco) for the Authenticate Using option.
c. Click the Submit + Restart icon.

**Step 3**
Click the Group Setup icon.

a. Select a user group from the drop-down menu.
b. Select the Users in Group check box.
c. Select a user from the user list.
d. In the User Setup list, scroll down to TACACS+ Settings and select the “auth-proxy” check box.
e. Select the Custom Attributes check box.
f. Add the profile entries (do not use single or double quotes around the entries) and set the privilege level to 15.

```plaintext
priv-lvl=15
proxyacl#1=permit tcp any any eq 26
```
proxyacl#2=permit icmp any host 60.0.0.2
proxyacl#3=permit tcp any any eq ftp
proxyacl#4=permit tcp any any eq ftp-data
proxyacl#5=permit tcp any any eq smtp
proxyacl#6=permit tcp any any eq telnet

g. Click **Submit**.

### Step 4
Click the User Setup icon.

a. Click **List All Users**.
b. Add a username.
c. Scroll down to User Setup Password Authentication.
d. Select SDI SecurID Token Card from the Password Authentication drop-down menu.
e. Select the previous configured user group 1.
f. Click **Submit**.

### Step 5
Click Group Setup icon again.

a. Select the user group 1.
b. Click **Users in Group**.
c. Click **Edit Settings**.
d. Click the **Submit + Restart** icon to make sure the latest configuration is updated and sent to the AAA server.

---

**CiscoSecure ACS 2.3 for UNIX**

This section describes how to configure authentication proxy on CiscoSecure ACS 2.3 for UNIX. For detailed information regarding CiscoSecure ACS, refer to the documentation for that product.

To manage the CiscoSecure ACS using the Administrator program, you need a web browser that supports Java and JavaScript. You must enable Java in the browser application. You can start the Java-based CiscoSecure Administrator advanced configuration program from any of the CiscoSecure ACS Administrator web pages.

The following sample configuration procedure is for the TACACS+ service of CiscoSecure ACS 2.3 for UNIX.

### Step 1
On the CiscoSecure ACS web menu bar of the CiscoSecure ACS web interface, click **Advanced** and then click **Advanced** again.

The Java-based CiscoSecure Administrator advanced configuration program appears. It might require a few minutes to load.

### Step 2
In the CiscoSecure Administrator advanced configuration program, locate and deselect **Browse** in the Navigator pane of the tabbed Members page.

This displays the Create New Profile icon.

### Step 3
In the Navigator pane, do one of the following:
- Locate and click the group to which the user will belong.
- If you do not want the user to belong to a group, click the [Root] folder icon.
Step 4  Click Create Profile to display the New Profile dialog box.

Step 5  Make sure the Group check box is cleared.

Step 6  Enter the name of the user you want to create and click OK. The new user appears in the tree.

Step 7  Click the icon for the group or user profile in the tree that is displayed in the Navigator pane of the tabbed Members page.

Step 8  If necessary, in the Profile pane, click the Profile icon to expand it. A list or dialog box that contains attributes applicable to the selected profile or service appears in the window at the bottom right of the screen. The information in this window changes depending on what you have selected in the Profile pane.

Step 9  Click Service-String.

Step 10 Click string, enter auth-proxy in the text field, and click Apply.

Step 11 Select the Option menu.

Step 12 On the Option menu, click Default Attributes.

Step 13 Change the attribute from Deny to Permit.

Step 14 Click Apply.

Step 15 On the Option menu, click Attribute and enter the privilege level in the text field:

```
priv-lvl=15
```

Step 16 On the Option menu, click Attribute and enter the proxyacl entries in the text field:

```
proxyacl#1=“permit tcp any any eq 26”
proxyacl#2=“permit icmp any host 60.0.0.2”
proxyacl#3=“permit tcp any any eq ftp”
proxyacl#4=“permit tcp any any eq ftp-data”
proxyacl#5=“permit tcp any any eq smtp”
proxyacl#6=“permit tcp any any eq telnet”
```

Step 17 When you have finished making all your changes, click Submit.

---

### TACACS+ Server

```plaintext

default authorization = permit
key = cisco
user = Brian {
    login = cleartext cisco
    service = auth-proxy
    {
        priv-lvl=15
        proxyacl#1=‘permit tcp any any eq 26’
        proxyacl#2=‘permit icmp any host 60.0.0.2’
        proxyacl#3=‘permit tcp any any eq ftp’
        proxyacl#4=‘permit tcp any any eq ftp-data’
        proxyacl#5=‘permit tcp any any eq smtp’
        proxyacl#6=‘permit tcp any any eq telnet’
    }
}
```
Livingston Radius Server

Bob Password = "cisco" User-Service-Type=Outbound-User
cisco-avpair = "auth-proxy:priv-lvl=15",
cisco-avpair = "auth-proxy:proxyacl#1=permit tcp any any eq 26",

cisco-avpair = "auth-proxy:proxyacl#5=permit tcp any any eq smtp",
cisco-avpair = "auth-proxy:proxyacl#6=permit tcp any any eq telnet"
Firewall Support of HTTPS Authentication Proxy

The Firewall Support of HTTPS Authentication Proxy feature allows a user to encrypt the change of the username and password between the HTTP client and the Cisco IOS router via Secure Socket Layer (SSL) when authentication proxy is enabled on the Cisco IOS firewall, thereby ensuring confidentiality of the data passing between the HTTP client and the Cisco IOS router.

Feature Specifications for the Firewall Support of HTTPS Authentication Proxy feature

Prerequisites for Firewall Support of HTTPS Authentication Proxy

Before enabling this feature, ensure that your router is running a crypto image with k8 and k9 designations and that your Cisco IOS image supports SSL.

Restrictions for Firewall Support of HTTPS Authentication Proxy

- Although Port to Application Mapping (PAM) configuration is allowed in Cisco IOS Firewall processing, authentication proxy is limited to the server ports that are configured by the HTTP subsystem of the router.
- To conform to a proper TCP connection handshake, the authentication proxy login page will be returned from the same port and address as the original request. Only the postrequest, which contains the username and password of the HTTP client, will be forced to use HTTP over SSL (HTTPS).

Information About Firewall Support of HTTPS Authentication Proxy

To configure the Firewall Support of HTTPS Authentication Proxy feature, you must understand the following concepts:

- Authentication Proxy, page 2
- Feature Design for HTTPS Authentication Proxy, page 3

Authentication Proxy

Authentication proxy grants Internet access to an authorized user through the Cisco Secure Integrated Software (also known as a Cisco IOS firewall). Access is granted on a per-user basis after the proper identification process is completed and the user policies are retrieved from a configured authentication, authorization, and accounting (AAA) server.

When authentication proxy is enabled on a Cisco router, users can log into the network or access the Internet via HTTP(S). When a user initiates an HTTP(S) session through the firewall, the authentication proxy is triggered. Authentication proxy first checks to see if the user has been authenticated. If a valid authentication entry exists for the user, the connection is completed with no further intervention by authentication proxy. If no entry exists, the authentication proxy responds to the HTTP(S) connection request by prompting the user for a username and password. When authenticated, the specific access profiles are automatically retrieved and applied from a CiscoSecure Access Control Server (ACS), or other RADIUS or TACACS+ authentication server. The user profiles are active only when there is active traffic from the authenticated users.
Feature Design for HTTPS Authentication Proxy

Authentication proxy support using HTTPS provides encryption between the HTTPS client and the Cisco IOS router during the username and password exchange, ensuring secure communication between trusted entities.

Figure 49 and the corresponding steps explain how the data flows from the time the client issues a HTTP request to the time the client receives a response from the Cisco IOS router.

1. The HTTP or HTTPS client requests a web page.
2. The HTTP or HTTPS request is intercepted by the Cisco IOS router with authentication proxy.
3. The router marks the TCP/IP connection and forwards the request (with the client address) to the web server, if authentication is required.
4. The web server builds the authentication request form and sends it to the HTTP or HTTPS client via the original request protocol—HTTP or HTTPS.
5. The HTTP or HTTPS client receives the authentication request form.
6. The user enters his or her username and password in the HTTPS POST form and returns the form to the router. At this point, the authentication username and password form is sent via HTTPS. The web server will negotiate a new SSL connection with the HTTPS client.

Note: Your Cisco IOS image must support HTTPS, and HTTPS must be configured; otherwise, an HTTP request form will be generated.

7. The router receives the HTTPS POST form from the HTTPS client and retrieves the username and password.
8. The router sends the username and password to the AAA server for client authentication.
9. If the AAA server validates the username and password, it sends the configured user profile to the router. (If it cannot validate the username and password, an error is generated and sent to the router.)
10. If the router receives a user profile from the AAA server, it updates the access list with the user profile and returns a successful web page to the HTTPS client. (If the router receives an error from the AAA server, it returns an error web page to the HTTPS client.)
11. After the HTTPS client receives the successful web page, it retries the original request. Thereafter, HTTPS traffic will depend on HTTPS client requests; no router intervention will occur.

How to Use HTTPS Authentication Proxy

To enable HTTPS authentication proxy, you must enable AAA service, configure the HTTPS server, and enable authentication proxy. This section contains the following procedures:

- Configuring the HTTPS Server, page 4
- Verifying HTTPS Authentication Proxy, page 5

Configuring the HTTPS Server

To use HTTPS authentication proxy, you must enable the HTTPS server on the firewall and set the HTTPS server authentication method to use AAA.

Prerequisites

Before configuring the HTTPS server, you must perform the following procedures:

- Configure the authentication proxy for AAA services by enabling AAA and configuring a RADIUS or TACACS+ server. For information on completing these tasks, refer to the section “Configuring AAA” in the chapter “Configuring Authentication Proxy” of the Cisco IOS Security Configuration Guide, Release 12.2.
- Obtain a certification authority (CA) certificate. For information on completing this task, refer to the section “Configuring a Trustpoint CA” in the Trustpoint CLI, Cisco IOS Release 12.2(8)T feature module.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip http server
4. ip http authentication aaa
5. ip http secure-server
6. ip http secure-trustpoint name
DETAILED STEPS

What to Do Next

After you have finished configuring the HTTPS server, you must configure the authentication proxy (globally and per interface). For information on completing this task, refer to the section “Configuring the Authentication Proxy” in the chapter “Configuring Authentication Proxy” of the Cisco IOS Security Configuration Guide, Release 12.2.

Verifying HTTPS Authentication Proxy

To verify your HTTPS authentication proxy configuration, perform the following optional steps:

SUMMARY STEPS

1. enable
2. show ip auth-proxy configuration
3. show ip auth-proxy cache
4. show ip http server secure status
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>

RADIUS User Profile Example

The following example is a sample RADIUS user profile for Livingston RADIUS:

```plaintext
#--------------- Proxy user ---------------------------------
http                  Password = "test" User-Service-Type=Outbound-User
                     cisco-avpair = "auth-proxy:priv-lvl=15",
cisco-avpair = "auth-proxy:proxyacl#3=permit tcp any any eq 23"

http_1                Password = "test"
                     User-Service-Type = Shell-User,
                     User-Service-Type=Dialout-Framed-User,
                     cisco-avpair = "shell:priv-lvl=15",
                     cisco-avpair = "shell:inacl#4=permit tcp any host 192.168.134.216 eq 23"
                     cisco-avpair = "auth-proxy:priv-lvl=15",
                     cisco-avpair = "auth-proxy:proxyacl#3=permit tcp any any eq 23"

eq 23
                     cisco-avpair = "auth-proxy:priv-lvl=14",
                     cisco-avpair = "auth-proxy:proxyacl#3=permit tcp any any eq 23"

http_fail             Password = "test" User-Service-Type=Outbound-User
                     cisco-avpair = "auth-proxy:priv-lvl=14",
                     cisco-avpair = "auth-proxy:proxyacl#3=permit tcp any any eq 23"

proxy                Password = "cisco" User-Service-Type=Outbound-User
                     cisco-avpair = "auth-proxy:proxyacl#4=permit tcp any any eq 20"
```

TACACS User Profile Example

The following examples are sample TACACS user profiles:

```plaintext
default authorization = permit
key = cisco
user = http_1 {
    default service = permit
    login = cleartext test
    service = exec
    { 
        priv-lvl = 15
        inacl#4="permit tcp any host 192.168.134.216 eq 23"
        inacl#5="permit tcp any host 192.168.134.216 eq 20"
        inacl#6="permit tcp any host 192.168.134.216 eq 21"
        inacl#3="deny -1"
    }
    service = auth-proxy
    { 
        priv-lvl=15
        proxyacl#4="permit tcp any host 192.168.105.216 eq 23"
        proxyacl#5="permit tcp any host 192.168.105.216 eq 20"
        proxyacl#6="permit tcp any host 192.168.105.216 eq 21"
        proxyacl#7="permit tcp any host 192.168.105.216 eq 25"
    }
}
user = http {
    login = cleartext test
```
service = auth-proxy
{
  priv-lvl=15
  proxyacl#4="permit tcp any host 192.168.105.216 eq 23"
  proxyacl#5="permit tcp any host 192.168.105.216 eq 20"
  proxyacl#6="permit tcp any host 192.168.105.216 eq 21"
}
}
user = proxy_1 {
  login = cleartext test
  service = auth-proxy
  {
    priv-lvl=14
  }
}
user = proxy_3 {
  login = cleartext test
  service = auth-proxy
  {
    priv-lvl=15
  }

HTTPS Authentication Proxy Debug Example

Command Reference

This feature uses no new or modified commands. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the *Cisco IOS Master Commands List*. 
Glossary

ACL—access control list. An ACL is a list kept by routers to control access to or from the router for a number of services (for example, to prevent packets with a certain IP address from leaving a particular interface on the router).

Cisco IOS Firewall—The Cisco IOS Firewall is a protocol that provides advanced traffic filtering functionality and can be used as an integral part of your network’s firewall.

The Cisco IOS Firewall creates temporary openings in access lists at firewall interfaces. These openings are created when specified traffic exits your internal network through the firewall. The openings allow returning traffic (that would normally be blocked) and additional data channels to enter your internal network back through the firewall. The traffic is allowed back through the firewall only if it is part of the same session as the original traffic that triggered the Cisco IOS Firewall when exiting through the firewall.

firewall—A firewall is a networking device that controls access to the network assets of your organization. Firewalls are positioned at the entrance points into your network. If your network has multiple entrance points, you must position a firewall at each point to provide effective network access control.

The most basic function of a firewall is to monitor and filter traffic. Firewalls can be simple or elaborate, depending on your network requirements. Simple firewalls are usually easier to configure and manage. However, you might require the flexibility of a more elaborate firewall.

HTTPS—HTTP over SSL. HTTPS is client communication with a server by first negotiating an SSL connection and then transmitting the HTTP protocol data over the SSL application data channel.

SSL—Secure Socket Layer. SSL is encryption technology for the web used to provide secure transactions, such as the transmission of credit card numbers for e-commerce.

Refer to the Internetworking Terms and Acronyms for terms not included in this glossary.
Firewall Authentication Proxy for FTP and Telnet Sessions

Before the introduction of the Firewall Authentication Proxy for FTP and Telnet Sessions feature, users could enable only HTTP when configuring authentication proxy. This feature introduces support for FTP and Telnet, providing users with three protocol options when configuring authentication proxy.

Feature Specifications for the Firewall Authentication Proxy for FTP and Telnet Sessions Feature

Restrictions for Firewall Authentication Proxy for FTP and Telnet Sessions

- Authentication proxy is an IP-only feature; thus, it comes with only -o3 images.
- “proxyacl#<n>” is the only supported attribute in the authentication, authorization, and accounting (AAA) server’s user configuration.
- Authentication proxy is subjected only to the traffic that passes through the router; traffic that is destined for the router continues to be authenticated by the existing authentication methods that are provided by Cisco IOS.

Information About Firewall Authentication Proxy for FTP and Telnet Sessions

To configure the Authentication Proxy for FTP and Telnet Sessions feature, you must understand the following concepts:

- Feature Design for FTP and Telnet Authentication Proxy, page 2
- Absolute Timeout, page 7

Feature Design for FTP and Telnet Authentication Proxy

Authentication proxy for FTP and Telnet Sessions functions like authentication proxy for HTTP; that is, FTP and Telnet are independent components in the Cisco IOS software and can be enabled or disabled on the interface of an unauthenticated host.

Many of the authentication proxy for FTP or Telnet functions are similar to those used with HTTP, such as the interaction between the authentication proxy router and the AAA server during authentication. However, because of protocol differences, FTP and Telnet login methods are different from HTTP.

FTP and Telnet Login Methods

Figure 1 displays a typical authentication proxy topology.
Firewall Authentication Proxy for FTP and Telnet Sessions

Figure 1  Typical Authentication Proxy Topology

Just as with HTTP, the authentication proxy router intercepts traffic that is sent from the client host. Upon receiving a FTP or Telnet packet, the router will look into its authentication cache to check whether the client host has already been authenticated. If it has been authenticated, the router will forward the client host’s traffic to the FTP or Telnet server for additional authentication. If the IP address of the client host is not in the cache of the router, the router will try to authenticate the client host with the AAA server using the username and password of the router.

FTP Login

For FTP login, the client host will be prompted (by the authentication proxy router) for the username and password of the router; the client must respond with the username and password in the following format: “login: proxy_username@ftp_username” and “password: proxy_passwd@ftp_passwd:”. The authentication proxy will use the proxy username and password to verify the client’s profile against the AAA server’s user database. After the client is successfully authenticated with the AAA server, the authentication proxy will pass the FTP (remote) username and password to the FTP server (destination server) for the application server authentication.

A flow chart that depicts an overview of the FTP authentication proxy process is shown in Figure 2.
**Figure 2** FTP Authentication Proxy Overview

Client's user issues a FTP command in the form: 'ftp dest_host'

Router/Auth-Proxy intercepts the command

Auth-proxy initiates communication with FTP server

Is user already in authentication cache?

Yes: Auth-proxy solicits username and password

No: Client's user is expected to provide local_user@remote_user and local_password@remote_password

Auth-proxy parses the local username and password and attempts to authenticate with AAA server

Is user authenticated with the auth proxy?

No: Proxy issues error message to user and offers a retry

Yes: User's IP address is placed in the authentication cache. Proxy sends remote username and password to destination FTP server.

Client can communicate with server now.

Is user authenticated by the server?

Yes: end

No: Proxy issues error message to user
Telnet Login

For Telnet login, the client host will be prompted (by the authentication proxy router) for the username, followed by the password; the client must respond with the username and password in the following format: “login: proxy_username:” and “password: proxy_passwd:”. The username and password will be verified against the AAA server’s user database. After the client is successfully authenticated with the AAA server, the Telnet server (destination server) will prompt the client for the username and password of the Telnet server.

A flow chart that depicts an overview of the Telnet authentication proxy process is shown in Figure 3.
Figure 3  Telnet Authentication Proxy Overview

Client's user issues a Telnet command in the form: "telnet dest..host"

Router/Auth-proxy intercepts the command

Is user already in authentication cache?

Yes
Telnet server prompts for username and password

No
Auth-proxy solicits username and password

Proxy passes server's username and password

Upon the receipt of local username and password, auth proxy authenticates user with AAA server

Yes
User's IP address is placed in the authentication cache. Server queries its username and password.

Proxy issues error message to user

Client can communicate with telnet server now.

No

Proxy issues error message to user

end
If authentication with the AAA server fails, the proxy will inform the client accordingly. With Telnet, the proxy does not have any interest in the Telnet server’s username and password. If the client is authenticated with the AAA server but fails with the Telnet server, the client will not have to authenticate with the AAA server the next time he or she logs into the network; the client’s IP address will be stored in the authentication cache. The client will have to authenticate only with the Telnet server.

**Note**
With FTP, the client must always reenter the local and remote username and password combination every time he or she tries to log into the network—regardless of a successful AAA server authentication.

### Absolute Timeout

An absolute timeout value has been added to allow users to configure a window during which the authentication proxy on the enabled interface is active. After the absolute timer expires, the authentication proxy will be disabled regardless of any activity. The absolute timeout value can be configured per protocol (via the `ip auth-proxy name` command) or globally (via the `ip auth-proxy` command). The default value of the absolute timeout is zero; that is, the absolute timer is turned off by default, and the authentication proxy is enabled indefinitely and is subject only to the timeout specified by the `inactivity-timer` keyword.

**Note**
The `inactivity-timer` keyword deprecates the `auth-cache-time` keyword in the `ip auth-proxy name` and the `ip auth-proxy` commands.

### How to Configure FTP or Telnet Authentication Proxy

To enable FTP or Telnet authentication proxy, you must enable AAA services, configure the FTP or Telnet server, and enable authentication proxy. This section contains the following procedures:

- Configuring AAA, page 7
- Configuring the Authentication Proxy, page 9
- Verifying FTP or Telnet Authentication Proxy, page 11
- Monitoring and Maintaining FTP or Telnet Authentication Proxy Sessions, page 11

### Configuring AAA

To use authentication proxy, you must configure a AAA server for authentication. The authentication proxy service of the AAA server must also be configured for authorization. To configure these tasks, perform the following steps:

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `aaa new-model`
4. `aaa authentication login default group tacacs+ group radius`
How to Configure FTP or Telnet Authentication Proxy

5. `aaa authorization auth-proxy default [group tacacs+] [group radius]`
6. `aaa authorization exec default [group tacacs+] [group radius]`
7. `aaa accounting auth-proxy default stop-only [group tacacs+] [group radius]`
8. `access-list access-list-number {permit | deny} {tcp | ip | icmp} host source eq tacacs host destination`

Firewall Authentication Proxy for FTP and Telnet Sessions

How to Configure FTP or Telnet Authentication Proxy

What to Do Next

Ensure that your FTP or Telnet server is enabled and that the user credentials of the client (the username and password) are stored in the server’s database.

Configuring the Authentication Proxy

To configure the authentication proxy, perform the following steps:

**SUMMARY STEPS**

1. enable
2. configure terminal
3. ip auth-proxy inactivity-timer min | absolute-timer min
4. ip auth-proxy auth-proxy-banner [ftp | http | telnet] [banner-text]
5. ip auth-proxy name auth-proxy-name [ftp | http | telnet] [inactivity-timer min | absolute-timer min] [list {acl | acl-name}]
6. interface type
7. ip auth-proxy auth-proxy-name

### Command or Action

**Step 7**

`aaa accounting auth-proxy default stop-only [group tacacs+] [group radius]`

**Example:**

Router (config)# aaa accounting auth-proxy
default stop-only group tacacs+ group radius

**Step 8**

`access-list access-list-number (permit | deny) {tcp | ip | icmp} host source eq tacacs host destination`

**Example:**

Router (config)# access-list 111 permit tcp
host 209.165.200.225 eq tacacs host 209.165.200.254

or

Router (config)# access-list 111 deny ip any any

or

Router (config)# access-list 111 permit icmp any any

### Purpose

Activates authentication proxy accounting and uses the **auth-proxy** keyword to set up the authorization policy as dynamic access control lists (ACLs) that can be downloaded.

Creates an ACL entry to allow the AAA server to return traffic to the firewall.

The source address is the IP address of the AAA server, and the destination is the IP address of the router interface where the AAA server resides.

Command or Action

**Step 7**

`aaa accounting auth-proxy default stop-only [group tacacs+] [group radius]`

**Example:**

Router (config)# aaa accounting auth-proxy
default stop-only group tacacs+ group radius

**Step 8**

`access-list access-list-number (permit | deny) {tcp | ip | icmp} host source eq tacacs host destination`

**Example:**

Router (config)# access-list 111 permit tcp
host 209.165.200.225 eq tacacs host 209.165.200.254

or

Router (config)# access-list 111 deny ip any any

or

Router (config)# access-list 111 permit icmp any any

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables higher privilege levels, such as privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> `ip auth-proxy {inactivity-timer min</td>
<td>absolute-timer min}`</td>
</tr>
<tr>
<td><strong>Example:</strong> Router (config)# ip auth-proxy inactivity-timer 30</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>inactivity-timer min</strong>—Specifies the length of time in minutes that an authentication cache entry is managed after a period of inactivity. Enter a value in the range 1 to 2,147,483,647. The default value is 60 minutes.</td>
</tr>
<tr>
<td></td>
<td><strong>absolute-timer min</strong>—Specifies a window in which the authentication proxy on the enabled interface is active. Enter a value in the range 1 to 65,535 minutes (45 and a half days). The default value is 0 minutes.</td>
</tr>
<tr>
<td><strong>Step 4</strong> `ip auth-proxy auth-proxy-banner {ftp</td>
<td>http</td>
</tr>
<tr>

Firewall Authentication Proxy for FTP and Telnet Sessions

How to Configure FTP or Telnet Authentication Proxy

Verifying FTP or Telnet Authentication Proxy

To verify your FTP or Telnet authentication proxy configuration, perform the following optional steps:

SUMMARY STEPS

1. **enable**
2. **show ip auth-proxy configuration**
3. **show ip auth-proxy cache**

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables higher privilege levels, such as privileged EXEC mode. Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> show ip auth-proxy configuration</td>
<td>Displays the current authentication proxy configuration.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# show ip auth-proxy configuration</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> show ip auth-proxy cache</td>
<td>Displays the list of user authentication entries. The authentication proxy cache lists the host IP address, the source port number, the timeout value for the authentication proxy, and the state of the connection. If the authentication proxy state is ESTAB or INTERCEPT, the user authentication was successful.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# show ip auth-proxy cache</td>
<td></td>
</tr>
</tbody>
</table>

Monitoring and Maintaining FTP or Telnet Authentication Proxy Sessions

To monitor FTP or Telnet authentication proxy sessions, perform the following optional steps:
SUMMARY STEPS

1. enable
2. debug ip auth-proxy {detailed | ftp | function-trace | object-creation | object-deletion | telnet | timers}

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step 1</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
<td>Enables higher privilege levels, such as privileged EXEC mode. Enter your password if prompted.</td>
</tr>
</tbody>
</table>

| Example: | Router> enable |

| Step 2 | debug ip auth-proxy {detailed | ftp | function-trace | object-creation | object-deletion | telnet | timers} | Displays the authentication proxy configuration information on the router. |

| Example: | Router# debug ip auth-proxy ftp |

Configuration Examples for FTP and Telnet Authentication Proxy

This section provides the following configuration examples:

- Authentication Proxy Configuration Example, page 12
- AAA Server User Profile Examples, page 13

Authentication Proxy Configuration Example

The following example shows how to configure your router for authentication proxy:

```
aaa new-model
aaa authentication login default group tacacs+
aaa authorization exec default group tacacs+
aaa authorization auth-proxy default group tacacs+
enable password lab
!
ip inspect name pxy_test ftp
ip auth-proxy name pxy auth-cache-time 1

AAA Server User Profile Examples

This section includes examples of the authentication proxy user profile entries on the AAA servers. The "proxyacl" entries define the user access privileges. After the user has successfully used the authentication proxy to log in, these entries are transferred to the firewall router. Each entry in the profile must specify “permit” access for the service or application. The source address in each entry is set to “any”, which is replaced with the IP address of the authenticating host when the profile is downloaded to the firewall. The privilege level must be set to 15 for all AAA users.

This section contains the following examples:

- **TACACS+ User Profiles Example**
- **Livingston RADIUS User Profiles Example**
- **Ascend RADIUS User Profiles Example**

**TACACS+ User Profiles Example**

The following example are sample TACACS+ user profiles:

default authorization = permit
key = cisco
user = http_1 {
  default service = permit
  login = cleartext test
  service = exec
  {
    priv-lvl = 15
    inacl#4="permit tcp any host 209.165.200.234 eq 23"
    inacl#5="permit tcp any host 209.165.200.234 eq 20"
    inacl#6="permit tcp any host 209.165.200.234 eq 21"
    inacl#3="deny -1"
  }
}
service = auth-proxy
{
  priv-lvl=15
  proxyacl#4="permit tcp any host 209.165.201.1 eq 23"
  proxyacl#5="permit tcp any host 209.165.201.1 eq 20"
  proxyacl#6="permit tcp any host 209.165.201.1 eq 21"
  proxyacl#7="permit tcp any host 209.165.201.1 eq 25"
}
}

user = http {
  login = cleartext test
  service = auth-proxy {
    priv-lvl=15
    proxyacl#4="permit tcp any host 209.165.201.1 eq 23"
    proxyacl#5="permit tcp any host 209.165.201.1 eq 20"
    proxyacl#6="permit tcp any host 209.165.201.1 eq 21"
  }
}

user = proxy_1 {
  login = cleartext test
  service = auth-proxy {
    priv-lvl=14
  }
}

user = proxy_3 {
  login = cleartext test
  service = auth-proxy {
    priv-lvl=15
  }
}

Livingston RADIUS User Profiles Example

The following examples are sample user profiles for the Livingston RADIUS server:

#----------------- Proxy user -----------------------------

http                   Password = "test" User-Service-Type=Outbound-User
cisco-avpair = "auth-proxy:priv-lvl=15",
cisco-avpair = "auth-proxy:proxyacl#3=permit tcp any any eq 23"

http_1                   Password = "test"
  User-Service-Type = Shell-User,
  User-Service-Type=Dialout-Framed-User,
  cisco-avpair = "shell:priv-lvl=15",
  cisco-avpair = "shell:inacl#4=permit tcp any host 209.165.200.234 eq 23"
  cisco-avpair = "auth-proxy:priv-lvl=15",
  cisco-avpair = "auth-proxy:proxyacl#3=permit tcp any any eq 23"

eq 23

http_fail               Password = "test" User-Service-Type=Outbound-User
cisco-avpair = "auth-proxy:priv-lvl=14",
cisco-avpair = "auth-proxy:proxyacl#3=permit tcp any any eq 23"

proxy                 Password = "cisco" User-Service-Type=Outbound-User
cisco-avpair = "auth-proxy:proxyacl#4=permit tcp any any eq 20"
Ascend RADIUS User Profiles Example

The following examples are sample user profiles for the Ascend RADIUS server:

```
#---------------- Proxy user -----------------------------
http                   Password = "test" User-Service=Dialout-Framed-User
    cisco-avpair = "auth-proxy:priv-lvl=15",
    cisco-avpair = "auth-proxy:proxyacl#3=permit tcp any any eq 23"

http_2                  Password = "test"
 User-Service=Dialout-Framed-User
    cisco-avpair = "auth-proxy:priv-lvl=15",
    cisco-avpair = "auth-proxy:proxyacl#3=permit tcp any any eq 23",
    cisco-avpair = "shell:inacl#4=permit tcp any host 209.165.200.234 eq 23"

http_1                   Password = "test"
 User-Service=Dialout-Framed-User
    cisco-avpair = "auth-proxy:priv-lvl=15",
    cisco-avpair = "auth-proxy:proxyacl#3=permit tcp any any eq 23",
    cisco-avpair = "shell:inacl#4=permit tcp any host 209.165.200.234 eq 23"

http_fail               Password = "test" User-Service=Dialout-Framed-User
    cisco-avpair = "auth-proxy:priv-lvl=14",
    cisco-avpair = "auth-proxy:proxyacl#3=permit tcp any any eq 23"
    cisco-avpair = "auth-proxy:proxyacl#1=permit tcp any any eq 23",
    cisco-avpair = "auth-proxy:proxyacl#3=permit tcp any eq 25",
    cisco-avpair = "auth-proxy:proxyacl#2=permit tcp any eq 23",
    cisco-avpair = "auth-proxy:proxyacl#4=permit tcp any eq 20"

#-------------------------------------------------------------
proxy Password = "cisco" User-Service = Dialout-Framed-User
    cisco-avpair = "auth-proxy:priv-lvl=15",
    cisco-avpair = "auth-proxy:priv-lvl=15",
    cisco-avpair = "auth-proxy:proxyacl#1=permit tcp any any eq 23",
    cisco-avpair = "auth-proxy:proxyacl#3=permit tcp any any eq 23",
    cisco-avpair = "auth-proxy:proxyacl#2=permit tcp any eq 23",
    cisco-avpair = "auth-proxy:proxyacl#4=permit tcp any eq 20",
    cisco-avpair = "auth-proxy:proxyacl#5=permit tcp any eq 20"
```

Configuring Port to Application Mapping

This chapter describes the Cisco IOS Firewall Port to Application Mapping (PAM) feature. PAM enables CBAC-supported applications to be run on nonstandard ports. Using PAM, network administrators can customize access control for specific applications and services to meet the distinct needs of their networks.

For a complete description of the PAM commands in this chapter, refer to the chapter “Port to Application Mapping Commands” of the Cisco IOS Security Command Reference. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the “Identifying Supported Platforms” section in the chapter “Using Cisco IOS Software.”

In This Chapter

This chapter contains the following sections:

- About Port to Application Mapping
- PAM Configuration Task List
- Monitoring and Maintaining PAM
- PAM Configuration Examples

About Port to Application Mapping

Port to Application Mapping (PAM) is a feature of the Cisco IOS Firewall feature set. PAM allows you to customize TCP or UDP port numbers for network services or applications. PAM uses this information to support network environments that run services using ports that are different from the registered or well-known ports associated with an application.
Using the port information, PAM establishes a table of default port-to-application mapping information at the firewall. The information in the PAM table enables Context-based Access Control (CBAC) supported services to run on nonstandard ports. Previously, CBAC was limited to inspecting traffic using only the well-known or registered ports associated with an application. Now, PAM allows network administrators to customize network access control for specific applications and services.

PAM also supports host or subnet specific port mapping, which allows you to apply PAM to a single host or subnet using standard access control lists (ACLs). Host or subnet specific port mapping is done using standard ACLs.

This section contains the following sections:

- How PAM Works
- System-Defined Port Mapping
- PAM and CBAC
- When to Use PAM

**How PAM Works**

PAM generates a table of information that identifies specific applications with specific TCP or UDP port information. When the firewall router first starts up, the PAM table is populated with system-defined mapping information. As you customize the mapping information, the PAM table is modified with the new information. The information in the PAM table serves as the default port mapping for traffic passing through the firewall.

PAM works with CBAC to identify the applications associated with various port numbers, including services running on non-standard ports, as it inspect traffic passing through the firewall. Previously, CBAC was limited to inspecting traffic using only the well-known or registered ports associated with an application.

Entries in the PAM table provide three types of mapping information:

- System-Defined Port Mapping
- User-Defined Port Mapping
- Host-Specific Port Mapping

**System-Defined Port Mapping**

PAM creates a table, or database, of system-defined mapping entries using the well-known or registered port mapping information set up during the system start-up. The system-defined entries comprise all the services supported by CBAC, which requires the system-defined mapping information to function properly. The system-defined mapping information cannot be deleted or changed; that is, you cannot map HTTP services to port 21 (FTP) or FTP services to port 80 (HTTP).

---

**Note**

You can override the system-defined entries for specific hosts using the PAM host-specific option. Refer to the section “Host-Specific Port Mapping” in this chapter.

Table 42 lists the default system-defined services and applications in the PAM table.
About Port to Application Mapping

This section has the following sections:

- User-Defined Port Mapping
- Host-Specific Port Mapping

**User-Defined Port Mapping**

Network services or applications that use non-standard ports require user-defined entries in the PAM table. For example, your network might run HTTP services on the non-standard port 8000 instead of on the system-defined default port (port 80). In this case, you can use PAM to map port 8000 with HTTP services. If HTTP services run on other ports, use PAM to create additional port mapping entries. After you define a port mapping, you can overwrite that entry at a later time by simply mapping that specific port with a different application.

**Note**

If you try to map an application to a system-defined port, a message appears that warns you of a mapping conflict.

</tbody>
</table>
User-defined port mapping information can also specify a range of ports for an application by establishing a separate entry in the PAM table for each port number in the range. User-defined entries are saved with the default mapping information when you save the router configuration.

Host-Specific Port Mapping

User-defined entries in the mapping table can include host-specific mapping information, which establishes port mapping information for specific hosts or subnets. In some environments, it might be necessary to override the default port mapping information for a specific host or subnet.

With host-specific port mapping, you can use the same port number for different services on different hosts. This means that you can map port 8000 with HTTP services for one host, while mapping port 8000 with Telnet services for another host.

Host-specific port mapping also allows you to apply PAM to a specific subnet when that subnet runs a service that uses a port number that is different from the port number defined in the default mapping information. For example, hosts on subnet 192.168.21.0 might run HTTP services on non-standard port 8000, while other traffic through the firewall uses the default port for HTTP services, which is port 80.

Host-specific port mapping allows you to override a system-defined entry in the PAM table. For example, if CBAC finds an entry in the PAM table that maps port 25 (the system-defined port for SMTP) with HTTP for a specific host, CBAC identifies port 25 as HTTP protocol traffic on that host.

Note

If the host-specific port mapping information is the same as an existing system-defined or user-defined default entries, host-specific port changes have no effect.

PAM and CBAC

CBAC uses the information in the PAM table to identify a service or application from traffic flowing through the firewall. With PAM, CBAC can associate non-standard port numbers with specific protocols. For example, if you use PAM to map port 8000 with HTTP services, CBAC can determine that traffic using port 8000 is an HTTP application.

When to Use PAM

Here are a few examples of when you might want to use PAM:

- Use PAM to apply a non-standard port numbers for a service or application.
- Use PAM when a specific host or subnet uses a port number for an application that is different than the default port number established in the PAM table.
- Use PAM when different hosts use the same port number for different applications.

PAM Configuration Task List

See the following sections for PAM configuration tasks. Each task in the list indicates if it is optional or required:
- Configuring Standard ACLs (Optional)
- Configuring PAM (Required)
- Verifying PAM (Optional)

### Configuring Standard ACLs

If you require PAM for a specific host or subnet, use the `access-list` (standard) command in global configuration mode to define an ACL:

```
Router(config)# access-list access-list-number permit source [source-wildcard]
```

(Optional) Creates a standard ACL that defines the specific host or subnet for host-specific PAM.

For complete information on access-list command, refer to the *Cisco IOS IP Command Reference, Volume 1 of 3: Addressing and Services*.

### Configuring PAM

To configure PAM, use the `ip port-map` command in global configuration mode:

```
Router(config)# ip port-map appl_name port port_num [list acl_num]
```

Establishes a port mapping entry using the TCP or UDP port number and the application name.

(Optional) Use the list option to associate this port mapping to the specific hosts in the ACL. (PAM uses standard access lists only.) If an access list is included, the hosts defined in that ACL have the application `appl_name` running on port `port_num`.

### Verifying PAM

To verify the port mapping information, enter the `show ip port-map` command in privileged EXEC mode and review the entries:

```
Router# show ip port-map
```

This command displays all entries in the PAM table, including the system-defined entries.

For PAM configuration examples using the commands in this chapter, refer to the “PAM Configuration Examples” section at the end of this chapter.

### Monitoring and Maintaining PAM

The following commands can be used to monitor and maintain PAM:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Router(config)# access-list access-list-number permit source [source-wildcard]</td>
<td>(Optional) Creates a standard ACL that defines the specific host or subnet for host-specific PAM. For complete information on access-list command, refer to the <em>Cisco IOS IP Command Reference, Volume 1 of 3: Addressing and Services</em>.</td>
</tr>
<tr>
<td>Router(config)# ip port-map appl_name port port_num [list acl_num]</td>
<td>Establishes a port mapping entry using the TCP or UDP port number and the application name. (Optional) Use the list option to associate this port mapping to the specific hosts in the ACL. (PAM uses standard access lists only.) If an access list is included, the hosts defined in that ACL have the application <code>appl_name</code> running on port <code>port_num</code>.</td>
</tr>
</tbody>
</table>
PAM Configuration Examples

The following sections provide PAM configuration examples:

- Mapping an Application to a Non-Standard Port Example
- Mapping an Application with a Port Range Example
- Invalid Port Mapping Entry Example
- Mapping an Application to a Port for a Specific Host Example
- Mapping an Application to a Port for a Subnet Example
- Overriding a System-Defined Port Mapping Example
- Mapping Different Applications to the Same Port Example

### Mapping an Application to a Non-Standard Port Example

In this example, non-standard port 8000 is established as the user-defined default port mapping for HTTP services:

```
ip port-map http port 8000
```

### Mapping an Application with a Port Range Example

The following PAM entries establish a range of non-standard ports for HTTP services:

```
ip port-map http 8001
ip port-map http 8002
ip port-map http 8003
ip port-map http 8004
```

### Invalid Port Mapping Entry Example

This example is not valid because it tries to establish port 21, which is the system-defined default port for FTP, as the user-defined port for HTTP services:

```
ip port-map http port 21
```
Mapping an Application to a Port for a Specific Host Example

In this example, a specific host uses port 8000 for FTP services. ACL 10 identifies the server address (192.168.32.43), while port 8000 is mapped with FTP services.

```
access-list 10 permit 192.168.32.43
ip port-map ftp port 8000 list 10
```

Mapping an Application to a Port for a Subnet Example

In this example, a specific subnet runs HTTP services on port 8080. ACL 50 identifies the subnet, while port 8080 is mapped with HTTP services.

```
access-list 50 permit 192.168.92.0 0.0.0.255
ip port-map http 8080 list 50
```

Overriding a System-Defined Port Mapping Example

In this example, a specific host runs HTTP services on port 25, which is the system-defined port number for SMTP services. This requires a host-specific PAM entry that overrides the system-defined default port mapping for HTTP, which is port 80. ACL 15 identifies the host address (192.168.33.33), while port 25 is mapped with HTTP services.

```
access-list 15 permit 192.168.33.33
ip port-map http port 25 list 15
```

Mapping Different Applications to the Same Port Example

In this example, the same port number is required by different services running on different hosts. Port 8000 is required for HTTP services for host 192.168.3.4, while port 8000 is also required for FTP services for host 192.168.5.6. ACL 10 and ACL 20 identify the specific hosts, while the PAM entries map the ports with the services for each ACL.

```
access-list 10 permit 192.168.3.4
access-list 20 permit 192.168.5.6
ip port-map http port 8000 list 10
ip port-map http ftp 8000 list 20
```
coincidental.

The Call Admission Control for IKE feature describes the application of Call Admission Control (CAC) to the Internet Key Exchange (IKE) protocol in Cisco IOS. CAC limits the number of simultaneous IKE security associations (SAs) (that is, calls to CAC) that a router can establish.

### History for the Call Admission Control for IKE Feature

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at [http://www.cisco.com/go/fn](http://www.cisco.com/go/fn). You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.
Prerequisites for Call Admission Control for IKE

Information About Call Admission Control for IKE

To configure CAC for IKE, you need to understand the following concepts:

- IKE Session, page 2
- Security Association Limit, page 2
- System Resource Usage, page 3

IKE Session

There are two ways to limit the number of IKE SAs that a router can establish to or from another router:

- Configure the absolute IKE SA limit by entering the `crypto call admission limit` command. The router drops new IKE SA requests when the value has been reached.
- Configure the system resource limit by entering the `call admission limit` command. The router drops new IKE SA requests when the level of system resources that are configured in the unit of charge is being used.

For information about using these commands, see the “Command Reference” section on page 8.

CAC is applied only to new SAs (that is, when an SA does not already exist between the peers). Every effort is made to preserve existing SAs. Only new SA requests will ever be denied due to a lack of system resources or because the configured IKE SA limit has been reached.

Security Association Limit

An SA is a description of how two or more entities will utilize security services to communicate securely on behalf of a particular data flow. IKE requires and uses SAs to identify the parameters of its connections. IKE can negotiate and establish its own SA. An IKE SA is used by IKE only, and it is bidirectional. An IKE SA cannot limit IPsec.
IKE drops SA requests based on a user-configured SA limit. To configure an IKE SA limit, enter the `crypto call admission limit` command. When there is a new SA request from a peer router, IKE determines if the number of active IKE SAs plus the number of SAs being negotiated meets or exceeds the configured SA limit. If the number is greater than or equal to the limit, the new SA request is rejected and a syslog is generated. This log contains the source destination IP address of the SA request.

**Limit on Number of In-negotiation IKE Connections**

Effective with Cisco IOS Release 12.4(6)T, a limit on the number of in-negotiation IKE connections can be configured. This type of IKE connection represents either an aggressive mode IKE SA or a main mode IKE SA prior to its authentication and actual establishment.

Using the `crypto call admission limit ike in-negotiation-sa {number}` command allows the configured number of in-negotiation IKE SAs to start negotiation without contributing to the maximum number of IKE SAs allowed.

**System Resource Usage**

CAC polls a global resource monitor so that IKE knows when the router is running short of CPU cycles or memory buffers. You can configure a resource limit, from 1 to 100000, that represents the level of system resources that are configured in the unit of charge. When that level of resources is being used, IKE drops (will not accept new) SA requests. To configure the system resource usage, enter the `call admission control` command.

**How to Configure Call Admission Control for IKE**

This section contains the following procedures:

- Configure the IKE Security Association Limit, page 3 (optional)
- Configure the System Resource Limit, page 4 (optional)

**Note**

You must perform one of the procedures.

**Configure the IKE Security Association Limit**

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto call admission limit {ike {in-negotiation-sa number | sa number}}`
4. `exit`
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 enable     | Enables privileged EXEC mode.  
• Enter your password if prompted. |
| **Example:**      |         |
| Router> enable    |         |
| Step 2 configure terminal | Enters global configuration mode. |
| **Example:**      |         |
| Router# configure terminal |         |
| Step 3 crypto call admission limit {ike {in-negotiation-sa number | sa number)) | Specifies the maximum number of IKE SAs that the router can establish before IKE begins rejecting new SA requests. |
| **Note**          |         |
| An ISAKMP connection needs to be built in two directions. If you have 500 spokes in your network, you should set this value at a minimum of 1000 (500 x 2). |
| **Example:**      |         |
| Router(config)# crypto call admission limit ike sa 25 |         |
| Step 4 exit       | Returns to privileged EXEC mode. |
| **Example:**      |         |
| Router(config)# exit |         |

Configure the System Resource Limit

SUMMARY STEPS

1. enable
2. configure terminal
3. call admission limit charge
4. exit
## Verifying the Call Admission Control for IKE Configuration

To verify the CAC for IKE configuration, perform the following steps.

### SUMMARY STEPS

1. show call admission statistics
2. show crypto call admission statistics
DETAILED STEPS

For detailed field descriptions of the command output, see the “Command Reference” section on page 8.

Step 1  show call admission statistics
Use this command to monitor the global CAC configuration parameters and the behavior of CAC.

Router# show call admission statistics
Total Call admission charges: 0, limit 25
Total calls rejected 12, accepted 51
Load metric: charge 0, unscaled 0

Step 2  show crypto call admission statistics
Use this command to monitor Crypto CAC statistics.

Router# show crypto call admission statistics

-------------------------------------------
| Crypto Call Admission Control Statistics |
-------------------------------------------
System Resource Limit: 0    Max IKE SAs 0
Total IKE SA Count:    0    active:     0   negotiating: 0
Incoming IKE Requests: 0    accepted:   0   rejected:    0
Outgoing IKE Requests: 0    accepted:   0   rejected:    0
Rejected IKE Requests: 0    rsrc low:   0   SA limit:    0

Configuration Examples for Call Admission Control for IKE

This section provides the following configuration examples:

- Configuring the IKE Security Association Limit: Example, page 6
- Configuring the System Resource Limit: Example, page 6

Configuring the IKE Security Association Limit: Example

The following example shows how to specify that there can be a maximum of 25 SAs before IKE starts rejecting new SA requests:

Router(config)# crypto call admission limit ike sa 25

Configuring the System Resource Limit: Example

The following example shows how to specify that IKE should drop SA requests when the level of system resources that are configured in the unit of charge reaches 90000:

Router(config)# call admission limit 90000

Certificate to ISAKMP Profile Mapping

First Published: May 17, 2004
Last Updated: August 21, 2007

The Certificate to ISAKMP Profile Mapping feature enables you to assign an Internet Security Association and Key Management Protocol (ISAKMP) profile to a peer on the basis of the contents of arbitrary fields in the certificate. In addition, this feature allows you to assign a group name to those peers that are assigned an ISAKMP profile.

- Additional References, page 10
Prerequisites for Certificate to ISAKMP Profile Mapping

- You should be familiar with configuring certificate maps.
- You should be familiar with configuring ISAKMP profiles.

Restrictions for Certificate to ISAKMP Profile Mapping

This feature will not be applicable if you use Rivest, Shamir, and Adelman- (RSA-) signature or RSA-encryption authentication without certificate exchange. ISAKMP peers must be configured to do RSA-signature or RSA-encryption authentication using certificates.

Information About Certificate to ISAKMP Profile Mapping

To configure the Certificate to ISAKMP Profile Mapping feature, you should understand the following concepts:

- Certificate to ISAKMP Profile Mapping Overview, page 2
- How Certificate to ISAKMP Profile Mapping Works, page 2
- Assigning an ISAKMP Profile and Group Name to a Peer, page 3

Certificate to ISAKMP Profile Mapping Overview

Prior to Cisco IOS Release 12.3(8)T, the only way to map a peer to an ISAKMP profile was as follows. The ISAKMP identity field in the ISAKMP exchange was used for mapping a peer to an ISAKMP profile. When certificates were used for authentication, the ISAKMP identity payload contained the subject name from the certificate. If a certificate authority (CA) did not provide the required group value in the first Organizational Unit (OU) field of a certificate, an ISAKMP profile could not be assigned to a peer.

Effective with Cisco IOS Release 12.3(8)T, a peer can still be mapped as explained above. However, the Certificate to ISAKMP Profile Mapping feature enables you to assign an ISAKMP profile to a peer on the basis of the contents of arbitrary fields in the certificate. You are no longer limited to assigning an ISAKMP profile on the basis of the subject name of the certificate. In addition, this feature allows you to assign a group to a peer to which an ISAKMP profile has been assigned.

How Certificate to ISAKMP Profile Mapping Works

Figure 1 illustrates how certificate maps may be attached to ISAKMP profiles and assigned group names.
A certificate map can be attached to only one ISAKMP profile although an ISAKMP profile can have several certificate maps attached to it.

Certificate maps provide the ability for a certificate to be matched with a given set of criteria. ISAKMP profiles can bind themselves to certificate maps, and if the presented certificate matches the certificate map present in an ISAKMP profile, the peer will be assigned the ISAKMP profile. If the ISAKMP profile contains a client configuration group name, the same group name will be assigned to the peer. This ISAKMP profile information will override the information in the ID_KEY_ID identity or in the first OU field of the certificate.

### Assigning an ISAKMP Profile and Group Name to a Peer

To assign an ISAKMP profile to a peer on the basis of arbitrary fields in the certificate, use the `match certificate` command after the ISAKMP profile has been defined.

To associate a group name with an ISAKMP profile that will be assigned to a peer, use the `client configuration group` command, also after the ISAKMP profile has been defined.

### How to Configure Certificate to ISAKMP Profile Mapping

This section contains the following procedures:

- Mapping the Certificate to the ISAKMP Profile, page 4 (required)
- Verifying That the Certificate Has Been Mapped, page 4 (optional)
- Assigning the Group Name to the Peer, page 5 (required)
- Monitoring and Maintaining Your Certificate to ISAKMP Profile Mapping, page 6 (optional)
Mapping the Certificate to the ISAKMP Profile

To map the certificate to the ISAKMP profile, perform the following steps. This configuration will enable you to assign the ISAKMP profile to a peer on the basis of the contents of arbitrary fields in the certificate.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. crypto isakmp profile *profile-name*
4. match certificate *certificate-map*

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router# enable</td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>

Configuration Examples for Certificate to ISAKMP Profile Mapping

This section contains the following configuration examples:

- Certificates Mapped to the ISAKMP Profile on the Basis of Arbitrary Fields: Example, page 7
- Group Name Assigned to a Peer That Is Associated with an ISAKMP Profile: Example, page 7
- Mapping a Certificate to an ISAKMP Profile Verification: Example, page 8
- Group Name Assigned to a Peer Verification: Example, page 9

Certificates Mapped to the ISAKMP Profile on the Basis of Arbitrary Fields: Example

The following configuration example shows that whenever a certificate contains “ou = green,” the ISAKMP profile “cert_pro” will be assigned to the peer:

crypto pki certificate map cert_map 10
  subject-name co ou = green

crypto isakmp identity dn
crypto isakmp profile cert_pro
  ca trust-point 2315
  ca trust-point LaBcA
  initiate mode aggressive
  match certificate cert_map

Group Name Assigned to a Peer That Is Associated with an ISAKMP Profile: Example

The following example shows that the group “some_group” is to be associated with a peer that has been assigned an ISAKMP profile:

crypto isakmp profile id_profile
  ca trust-point 2315
match identity host domain cisco.com
client configuration group some_group

Mapping a Certificate to an ISAKMP Profile Verification: Example

The following examples show that a certificate has been mapped to an ISAKMP profile. The examples include the configurations for the responder and initiator, show command output verifying that the subject name of the certificate map has been configured, and debug command output showing that the certificate has gone through certificate map matching and been matched to the ISAKMP profile.

**Responder Configuration**
crypto pki certificate map cert_map 10
  ! The above line is the certificate map definition.
  subject-name co ou = green
  ! The above line shows that the subject name must have "ou = green."
  !
crypto isakmp profile certpro
  ! The above line shows that this is the ISAKMP profile that will match if the certificate of the peer matches cert_map (shown on third line below).
  ca trust-point 2315
  ca trust-point LaBcA
  match certificate cert_map
  initiate mode aggressive

**Initiator Configuration**
crypto ca trustpoint LaBcA
  enrollment url http://10.76.82.20:80/cgi-bin/openscep
  subject-name ou=green,c=IN
  ! The above line ensures that the subject name "ou = green" is set.
  revocation-check none

**show crypto ca certificates Command Output for the Initiator**

Router# show crypto ca certificates

Certificate
  Status: Available
  Certificate Serial Number: 21
  Certificate Usage: General Purpose
  Issuer:
    cn=blue-lab CA
    o=CISCO
    c=IN
  Subject:
    Name: Router1.cisco.com
    c=IN
    ou=green
    ! The above line is a double check that "ou = green" has been set as the subject name.
    hostname=Router1.cisco.com
  Validity Date:
    start date: 14:34:30 UTC Mar 31 2004
    end date: 14:34:30 UTC Apr 1 2009
    renew date: 00:00:00 UTC Jan 1 1970
  Associated Trustpoints: LaBcA

**debug crypto isakmp Command Output for the Responder**

Router# debug crypto isakmp
Certificate to ISAKMP Profile Mapping

Configuration Examples for Certificate to ISAKMP Profile Mapping

Group Name Assigned to a Peer Verification: Example

The following configuration and debug output show that a group has been assigned to a peer.

Initiator Configuration

crypto isakmp profile certpro
  ca trust-point 2315
  ca trust-point LaBcA
  match certificate cert_map
  client configuration group new_group

Note: The statement on the above line will assign the group "new_group" to any peer that matches the ISAKMP profile "certpro." initiate mode aggressive

debug crypto isakmp profile Command Output for the Responder

The following debug output example shows that the peer has been matched to the ISAKMP profile named “certpro” and that it has been assigned a group named “new_group.”

Router# debug crypto isakmp profile
6d23h: ISAKMP (0:268435461): received packet from 192.0.0.2 dport 500 sport 500 Global (R) MM_KEY_EXCH
6d23h: ISAKMP: Main Mode packet contents (flags 1, len 892):
  6d23h:     ID payload
  6d23h:       FQDN <Router1.cisco.com> port 500 protocol 17
  6d23h:     CERT payload
  6d23h:     SIG payload
  6d23h:     KEEAPLIVE payload
6d23h: ISAKMP:(0:4:HW:2): processing ID payload. message ID = 0
6d23h: ISAKMP (0:268435460): ID payload
  next-payload : 6
  type         : 2
  FQDN name    : Router1.cisco.com
  protocol     : 17
  port         : 500
  length       : 28
6d23h: ISAKMP:(0:4:HW:2): peer matches *none* of the profiles
6d23h: ISAKMP:(0:4:HW:2): processing CERT payload. message ID = 0
6d23h: ISAKMP:(0:4:HW:2): processing a CT_X509_SIGNATURE cert
6d23h: ISAKMP:(0:4:HW:2): peer's pubkey isn't cached
6d23h: ISAKMP:(0:4:HW:2): OU = green
6d23h: ISAKMP:(0:4:HW:2): certificate map matches certpro profile
! The above line shows that the certificate has gone through certificate map matching and that it matches the "certpro" profile.
6d23h: ISAKMP:(0:4:HW:2): Trying to re-validate CERT using new profile
6d23h: ISAKMP:(0:4:HW:2): Creating CERT validation list: 2315, LaBcA,

Encrypted Preshared Key

The Encrypted Preshared Key feature allows you to securely store plain text passwords in type 6 (encrypted) format in NVRAM.

Restrictions for Encrypted Preshared Key

- Old ROM monitors (ROMMONs) and boot images cannot recognize the new type 6 passwords. Therefore, errors are expected if you boot from an old ROMMON.
- For Cisco 836 routers, please note that support for Advanced Encryption Standard (AES) is available only on IP plus images.

Information About Encrypted Preshared Key

Before Using the Encrypted Preshared Key feature, you should understand the following concepts:

- Using the Encrypted Preshared Key Feature to Securely Store Passwords, page 2
- How to Configure an Encrypted Preshared Key, page 3

Using the Encrypted Preshared Key Feature to Securely Store Passwords

Using the Encrypted Preshared Key feature, you can securely store plain text passwords in type 6 format in NVRAM using a command-line interface (CLI). Type 6 passwords are encrypted. Although the encrypted passwords can be seen or retrieved, it is difficult to decrypt them to find out the actual password. Use the `key config-key password-encryption` command with the `password encryption aes` command to configure and enable the password (symmetric cipher AES is used to encrypt the keys). The password (key) configured using the `config-key password-encryption` command is the master encryption key that is used to encrypt all other keys in the router.

If you configure the `password encryption aes` command without configuring the `key config-key password-encryption` command, the following message is printed at startup or during any nonvolatile generation (NVGEN) process, such as when the `show running-config` or `copy running-config startup-config` commands have been configured:

"Can not encrypt password. Please configure a configuration-key with ‘key config-key’"

Changing a Password

If the password (master key) is changed, or reencrypted, using the `key config-key password-encryption` command), the list registry passes the old key and the new key to the application modules that are using type 6 encryption.

Deleting a Password

If the master key that was configured using the `key config-key password-encryption` command is deleted from the system, a warning is printed (and a confirm prompt is issued) that states that all type 6 passwords will become useless. As a security measure, after the passwords have been encrypted, they will never be decrypted in the Cisco IOS software. However, passwords can be reencrypted as explained in the previous paragraph.

⚠️ Caution

If the password configured using the `key config-key password-encryption` command is lost, it cannot be recovered. The password should be stored in a safe location.
Unconfiguring Password Encryption

If you later unconfigure password encryption using the \texttt{no password encryption aes} command, all existing type 6 passwords are left unchanged, and as long as the password (master key) that was configured using the \texttt{key config-key password-encryption} command exists, the type 6 passwords will be decrypted as and when required by the application.

Storing Passwords

Because no one can “read” the password (configured using the \texttt{key config-key password-encryption} command), there is no way that the password can be retrieved from the router. Existing management stations cannot “know” what it is unless the stations are enhanced to include this key somewhere, in which case the password needs to be stored securely within the management system. If configurations are stored using TFTP, the configurations are not standalone, meaning that they cannot be loaded onto a router. Before or after the configurations are loaded onto a router, the password must be manually added (using the \texttt{key config-key password-encryption} command). The password can be manually added to the stored configuration but is not recommended because adding the password manually allows anyone to decrypt all passwords in that configuration.

Configuring New or Unknown Passwords

If you enter or cut and paste cipher text that does not match the master key, or if there is no master key, the cipher text is accepted or saved, but an alert message is printed. The alert message is as follows:

\begin{verbatim}
ciphertext>[for username bar> is incompatible with the configured master key."
\end{verbatim}

If a new master key is configured, all the plain keys are encrypted and made type 6 keys. The existing type 6 keys are not encrypted. The existing type 6 keys are left as is.

If the old master key is lost or unknown, you have the option of deleting the master key using the \texttt{no key config-key password-encryption} command. Deleting the master key using the \texttt{no key config-key password-encryption} command causes the existing encrypted passwords to remain encrypted in the router configuration. The passwords will not be decrypted.

Enabling the Encrypted Preshared Key

The \texttt{password encryption aes} command is used to enable the encrypted password.

How to Configure an Encrypted Preshared Key

This section contains the following procedures:

\begin{itemize}
  \item Configuring an Encrypted Preshared Key, page 4 (required)
  \item Monitoring Encrypted Preshared Keys, page 5 (optional)
  \item Configuring an ISAKMP Preshared Key, page 6 (optional)
  \item Configuring an ISAKMP Preshared Key in ISAKMP Keyrings, page 7 (optional)
  \item Configuring ISAKMP Aggressive Mode, page 8 (optional)
  \item Configuring a Unity Server Group Policy, page 9 (optional)
\end{itemize}
• Configuring an Easy VPN Client, page 10 (optional)

Configuring an Encrypted Preshared Key

To configure an encrypted preshared key, perform the following steps.

SUMMARY STEPS

1. enable
2. configure terminal
3. key config-key password-encryption [text]
4. password encryption aes

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td>Step 2 configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3 key config-key password-encryption [text]</td>
<td>Stores a type 6 encryption key in private NVRAM.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router (config)# key config-key password-encryption</td>
<td></td>
</tr>
<tr>
<td>Step 4 password encryption aes</td>
<td>Enables the encrypted preshared key.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router (config)# password-encryption aes</td>
<td></td>
</tr>
</tbody>
</table>
Troubleshooting Tips

If you see the warning message “ciphertext >[for username bar]> is incompatible with the configured master key,” you have entered or cut and pasted cipher text that does not match the master key or there is no master key. (The cipher text will be accepted or saved.) The warning message will allow you to locate the broken configuration line or lines.

Monitoring Encrypted Preshared Keys

To get logging output for encrypted preshared keys, perform the following steps.

1. **enable**
2. **password logging**

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>enable</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>password logging</strong></td>
<td>Provides a log of debugging output for a type 6 password operation.</td>
</tr>
</tbody>
</table>

**Example:**

**Example:**

**Step 1**

`Router> enable`

Enter your password if prompted.

**Step 2**

`Router# password logging`

Examples

The following **password logging** debug output shows that a new master key has been configured and that the keys have been encrypted with the new master key:

```
Router (config)# key config-key password-encrypt
New key:
Confirm key:
Router (config)#
01:40:57: TYPE6_PASS: New Master key configured, encrypting the keys with the new master key

Router (config)# key config-key password-encrypt
Old key:
New key:
Confirm key:
Router (config)#
01:42:11: TYPE6_PASS: Master key change heralded, re-encrypting the keys with the new master key
01:42:11: TYPE6_PASS: Mac verification successful
01:42:11: TYPE6_PASS: Mac verification successful
01:42:11: TYPE6_PASS: Mac verification successful
```
What To Do Next

You can perform any of the following procedures. Each procedure is independent of the others.

- Configuring an ISAKMP Preshared Key, page 6
- Configuring an ISAKMP Preshared Key in ISAKMP Keyrings, page 7
- Configuring ISAKMP Aggressive Mode, page 8
- Configuring a Unity Server Group Policy, page 9
- Configuring an Easy VPN Client, page 10

Configuring an ISAKMP Preshared Key

To configure an ISAKMP preshared key, perform the following procedure.

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto isakmp key keystring address peer-address
4. crypto isakmp key keystring hostname hostname

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>enable</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>• Enter your password if prompted.</td>
<td></td>
</tr>
<tr>
<td>Step 2</td>
<td>configure terminal</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Step 3</td>
<td>crypto isakmp key keystring address peer-address</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router (config)# crypto isakmp key cisco address 10.2.3.4</td>
<td>Configures a preshared authentication key.</td>
</tr>
<tr>
<td>• The peer-address argument specifies the IP address of the remote peer.</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>crypto isakmp key keystring hostname hostname</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router (config)# crypto isakmp key foo hostname foo.com</td>
<td>Configures a preshared authentication key.</td>
</tr>
<tr>
<td>• The hostname argument specifies the fully qualified domain name (FQDN) of the peer.</td>
<td></td>
</tr>
</tbody>
</table>
Example

The following sample output shows that an encrypted preshared key has been configured:

```
crypto isakmp key 6 _Hg[^~ECgLGGPF`RXTQfDDNQ]YAAB address 10.2.3.4
crypto isakmp key 6 `eR\eTRaKCUPYYQfdX6wi_AAB hostname foo.com
```

Configuring an ISAKMP Preshared Key in ISAKMP Keyrings

To configure an ISAKMP preshared key in ISAKMP keyrings, which are used in IPSec Virtual Route Forwarding (VRF) configurations, perform the following procedure.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto keyring keyring-name`
4. `pre-shared-key address address key key`
5. `pre-shared-key hostname hostname key key`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| Step 1  | `enable` Enables privileged EXEC mode.  
  Example:  
  `Router# enable`  
  • Enter your password if prompted. |
| Step 2  | `configure terminal` Enters global configuration mode.  
  Example:  
  `Router# configure terminal` |
| Step 3  | `crypto keyring keyring-name` Defines a crypto keyring to be used during Internet Key Exchange (IKE) authentication and enters keyring configuration mode.  
  Example:  
  `Router (config)# crypto keyring foo` |
| Step 4  | `pre-shared-key address address key key` Defines a preshared key to be used for IKE authentication.  
  Example:  
  `Router (config-keyring)# pre-shared-key address 10.2.3.5 key cisco`  
  • The `address` argument specifies the IP address of the remote peer. |
| Step 5  | `pre-shared-key hostname hostname key key` Defines a preshared key to be used for IKE authentication.  
  Example:  
  `Router (config-keyring)# pre-shared-key hostname foo.com key cisco`  
  • The `hostname` argument specifies the FQDN of the peer. |
Example

The following `show-running-config` sample output shows that an encrypted preshared key in ISAKMP keyrings has been configured.

```
crypto keyring foo
  pre-shared-key address 10.2.3.5 key 6 `WHCJYR_Z\GRPF^RXTQfDcfZ\GPAAB
  pre-shared-key hostname foo.com key 6 aE_REHDcOfYCPF^RXTQfDJYVVNSAAB
```

Configuring ISAKMP Aggressive Mode

To configure ISAKMP aggressive mode, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto isakmp peer ip-address ip-address`
4. `set aggressive-mode client-endpoint client-endpoint`
5. `set aggressive-mode password password`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| **Example:**  
  **Router# enable** | |
| **Step 2** `configure terminal` | Enters global configuration mode. |
| **Example:**  
  **Router# configure terminal** | |
| **Step 3** `crypto isakmp peer ip-address ip-address` | To enable an IP Security (IPSec) peer for IKE querying of authentication, authorization, and accounting (AAA) for tunnel attributes in aggressive mode and to enter ISAKMP peer configuration mode. |
| **Example:**  
  **Router (config)# crypto isakmp peer ip-address 10.2.3.4** | |
| **Step 4** `set aggressive-mode client-endpoint client-endpoint` | Specifies the Tunnel-Client-Endpoint attribute within an ISAKMP peer configuration. |
| **Example:**  
  **Router (config-isakmp-peer)# set aggressive-mode client-endpoint fqdn cisco.com** | |
| **Step 5** `set aggressive-mode password password` | Specifies the Tunnel-Password attribute within an ISAKMP peer configuration. |
| **Example:**  
  **Router (config-isakmp-peer)# set aggressive-mode password cisco** | |
Example

The following `show-running-config` sample output shows that an encrypted preshared key in ISAKMP aggressive mode has been configured.

```
crypto isakmp peer address 10.2.3.4
set aggressive-mode password 6 ^aKPIQ_KJE_PPF^RXTQfDTIaLNeAAB
set aggressive-mode client-endpoint fqdn cisco.com
```

Configuring a Unity Server Group Policy

To configure a unity server group policy, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto isakmp client configuration group group-name`
4. `pool name`
5. `domain name`
6. `key name`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>

</tbody>
</table>
**How to Configure an Encrypted Preshared Key**

**Example**

The following `show-running-config` sample output shows that an encrypted key has been configured for a unity server group policy:

```
crypto isakmp client configuration group foo
  key 6 cZZgDZPOE\dDPF^RXTqfDTiaLNeAAB
  domain cisco.com
  pool foopool
```

**Configuring an Easy VPN Client**

To configure an Easy VPN client, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto isakmp client ezvpn name`
4. `peer ipaddress`
5. `mode client`
6. `group group-name key group-key`
7. `connect manual`

**DETAILED STEPS**

</table>
Encrypted Preshared Key

Configuration Examples for Encrypted Preshared Key

### Example

The following `show-running-config` sample output shows that an Easy VPN client has been configured. The key has been encrypted.

```
crypto ipsec client ezvpn foo
  connect manual
  group foo key 6 gdMI`S^^[GICPF^RXTQfDFKEO\RAAB
  peer 10.2.3.4
```

### Configuration Examples for Encrypted Preshared Key

This section provides the following configuration examples:

- Encrypted Preshared Key: Example, page 12
- No Previous Key Present: Example, page 12
- Key Already Exists: Example, page 12
- Key Already Exists But the User Wants to Key In Interactively: Example, page 12
- No Key Present But the User Wants to Key In Interactively: Example, page 12
- Removal of the Password Encryption: Example, page 13
Encrypted Preshared Key: Example

The following is an example of a configuration for which a type 6 preshared key has been encrypted. It includes the prompts and messages that a user might see.

```
Router (config)# crypto isakmp key cisco address 10.0.0.2
Router (config)# exit
```

```
Router#
show running-config | include crypto isakmp key
```

```
crypto isakmp key cisco address 10.0.0.2
Router#
```

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Router (config)# password encryption aes
```

```
Router (config)# key config-key password-encrypt
```

```
New key:
Confirm key:
```

```
Router (config)#
01:46:40: TYPE6_PASS: New Master key configured, encrypting the keys with the new master key
```

```
Router (config)# exit
```

```
Router # show running-config | include crypto isakmp key
crypto isakmp key 6 CXWdhVTZYB_Vcd^`cIHDOahiFTa address 10.0.0.2
```

No Previous Key Present: Example

In the following configuration example, no previous key is present:

```
Router (config)# key config-key password-encryption testkey 123
```

Key Already Exists: Example

In the following configuration example, a key already exists:

```
Router (config)# key config-key password-encryption testkey123
Old key:
```

```
Router (config)#
```

Key Already Exists But the User Wants to Key In Interactively: Example

In the following configuration example, the user wants to key in interactively, but a key already exists. The Old key, New key, and Confirm key prompts will show on your screen if you enter the `key config-key password-encryption` command and press the enter key to get into interactive mode.

```
Router (config)# key config-key password-encryption
Old key:
```

```
New key:
```

```
Confirm key:
```

No Key Present But the User Wants to Key In Interactively: Example

In the following example, the user wants to key in interactively, but no key is present. The New key and Confirm key prompts will show on your screen if you are in interactive mode.

```
Router (config)# key config-key password-encryption
New key:
```
Confirm key:

**Removal of the Password Encryption: Example**

In the following configuration example, the user wants to remove the encrypted password. The “WARNING: All type 6 encrypted keys will become unusable. Continue with master key deletion? [yes/no]:” prompt will show on your screen if you are in interactive mode.

```
Router (config)# no key config-key password-encryption
```

WARNING: All type 6 encrypted keys will become unusable. Continue with master key deletion? [yes/no]: y

**Where to Go Next**

Configure any other preshared keys.

Command Reference
The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the Cisco IOS Security Command Reference at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at http://tools.cisco.com/Support/CLILookup or to the Cisco IOS Master Commands List.

- crypto ipsec client ezvpn (global)
- crypto isakmp client configuration group
- crypto isakmp key
- key config-key password-encryption
- password encryption aes
- password logging
- pre-shared-key
- set aggressive-mode password
Configuring Internet Key Exchange for IPSec VPNs

This module describes how to configure the Internet Key Exchange (IKE) protocol for basic IP Security (IPSec) virtual private networks (VPNs). IKE is a key management protocol standard that is used in conjunction with the IPSec standard. IPSec is an IP security feature that provides robust authentication and encryption of IP packets.

IPSec can be configured without IKE, but IKE enhances IPSec by providing additional features, flexibility, and ease of configuration for the IPSec standard.

IKE is a hybrid protocol, which implements the Oakley key exchange and Skeme key exchange inside the Internet Security Association Key Management Protocol (ISAKMP) framework. (ISAKMP, Oakley, and Skeme are security protocols implemented by IKE.)

Module History
This module was first published on May 2, 2005, and last updated on May 2, 2005.

Finding Feature Information in This Module
Your Cisco IOS software release may not support all features. To find information about feature support and configuration, use the “Feature Information for Configuring IKE for IPSec VPNs” section on page 24.

Contents

- Where to Go Next, page 22
- Additional References, page 22
Prerequisites for IKE Configuration

- You should be familiar with the concepts and tasks explained in the module “Configuring Security for VPNs with IPSec.”
- Ensure that your access control lists (ACLs) are compatible with IKE. Because IKE negotiation uses User Datagram Protocol (UDP) on port 500, your ACLs must be configured so that UDP port 500 traffic is not blocked at interfaces used by IKE and IPSec. In some cases you might need to add a statement to your ACLs to explicitly permit UDP port 500 traffic.

Restrictions for IKE Configuration

The following restrictions are applicable when configuring IKE negotiation:

- The initiating router must not have a certificate associated with the remote peer.
- The preshared key must be fully qualified domain name (FQDN) on both peers. (To configure the preshared key, enter the `crypto isakmp key` command.)
- The communicating routers must have a FQDN host entry for each other in their configurations.
- The communicating routers must be configured to authenticate by hostname, not by IP address; thus, you should use the `crypto isakmp identity hostname` command.

Information About Configuring IKE for IPSec VPNs

To configure IKE for IPSec VPNs, you should understand the following concepts:

- Supported Standards for Use with IKE, page 2
- IKE Benefits, page 4
- IKE Main Mode and Aggressive Mode, page 4

Supported Standards for Use with IKE

Cisco implements the following standards:

- IPSec—IP Security Protocol. IPSec is a framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPSec provides these security services at the IP layer; it uses IKE to handle negotiation of protocols and algorithms based on local policy and to generate the encryption and authentication keys to be used by IPSec. IPSec can be used to protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.
- Oakley—A key exchange protocol that defines how to derive authenticated keying material.
- Skeme—A key exchange protocol that defines how to derive authenticated keying material, with rapid key refreshment.
The component technologies implemented for use by IKE include the following:

- **AES**—Advanced Encryption Standard. A cryptographic algorithm that protects sensitive, unclassified information. AES is privacy transform for IPSec and IKE and has been developed to replace the DES. AES is designed to be more secure than DES: AES offers a larger key size, while ensuring that the only known approach to decrypt a message is for an intruder to try every possible key. AES has a variable key length—the algorithm can specify a 128-bit key (the default), a 192-bit key, or a 256-bit key.

- **DES**—Data Encryption Standard. An algorithm that is used to encrypt packet data. IKE implements the 56-bit DES-CBC with Explicit IV standard. Cipher Block Chaining (CBC) requires an initialization vector (IV) to start encryption. The IV is explicitly given in the IPSec packet. Cisco IOS software also implements Triple DES (168-bit) encryption, depending on the software versions available for a specific platform. Triple DES (3DES) is a strong form of encryption that allows sensitive information to be transmitted over untrusted networks. It enables customers, particularly in the finance industry, to utilize network-layer encryption.

  **Note** Cisco IOS images that have strong encryption (including, but not limited to, 56-bit data encryption feature sets) are subject to United States government export controls, and have a limited distribution. Images that are to be installed outside the United States require an export license. Customer orders might be denied or subject to delay because of United States government regulations. Contact your sales representative or distributor for more information, or send e-mail to export@cisco.com.

- **SEAL**—Software Encryption Algorithm. An alternative algorithm to software-based DES, 3DES, and AES. SEAL encryption uses a 160-bit encryption key and has a lower impact to the CPU when compared to other software-based algorithms.

- **Diffie-Hellman**—A public-key cryptography protocol that allows two parties to establish a shared secret over an unsecure communications channel. Diffie-Hellman is used within IKE to establish session keys. 768-bit (the default), 1024-bit, and 1536-bit Diffie-Hellman groups are supported.

- **MD5** (HMAC variant)—Message Digest 5. A hash algorithm used to authenticate packet data. HMAC is a variant that provides an additional level of hashing.

- **SHA** (HMAC variant)—Secure Hash Algorithm. A hash algorithm used to authenticate packet data. HMAC is a variant that provides an additional level of hashing.

- **RSA signatures and RSA encrypted nonces**—RSA is the public key cryptographic system developed by Ron Rivest, Adi Shamir, and Leonard Adleman. RSA signatures provide nonrepudiation, and RSA encrypted nonces provide repudiation. (Repudiation and nonrepudiation have to do with traceability.)

IKE interoperates with the following standard:

**X.509v3 certificates**—Used with the IKE protocol when authentication requires public keys. This certificate support allows the protected network to scale by providing the equivalent of a digital ID card to each device. When two devices intend to communicate, they exchange digital certificates to prove their identity (thus removing the need to manually exchange public keys with each peer or to manually specify a shared key at each peer).
IKE Benefits

IKE automatically negotiates IPSec security associations (SAs) and enables IPSec secure communications without costly manual preconfiguration. Specifically, IKE provides the following benefits:

- Eliminates the need to manually specify all the IPSec security parameters in the crypto maps at both peers.
- Allows you to specify a lifetime for the IPSec SA.
- Allows encryption keys to change during IPSec sessions.
- Allows IPSec to provide anti-replay services.
- Permits certification authority (CA) support for a manageable, scalable IPSec implementation.
- Allows dynamic authentication of peers.

IKE Main Mode and Aggressive Mode

IKE has two phases of key negotiation: phase 1 and phase 2. Phase 1 negotiates a security association (a key) between two IKE peers. The key negotiated in phase 1 enables IKE peers to communicate securely in phase 2. During phase 2 negotiation, IKE establishes keys (security associations) for other applications, such as IPSec.

Phase 1 negotiation can occur using main mode or aggressive mode. Main mode tries to protect all information during the negotiation, meaning that no information is available to a potential attacker. When main mode is used, the identities of the two IKE peers are hidden. Although this mode of operation is very secure, it is relatively costly in terms of the time it takes to complete the negotiation. Aggressive mode takes less time to negotiate keys between peers; however, it gives up some of the security provided by main mode negotiation. For example, the identities of the two parties trying to establish a security association are exposed to an eavesdropper.

The two modes serve different purposes and have different strengths. Main mode is slower than aggressive mode, but main mode is more secure and more flexible because it can offer an IKE peer more security proposals than aggressive mode. Aggressive mode is less flexible and not as secure, but much faster.

In Cisco IOS software, the two modes are not configurable. The default action for IKE authentication (rsa-sig, rsa-encr, or preshared) is to initiate main mode; however, in cases where there is no corresponding information to initiate authentication, and there is a preshared key associated with the hostname of the peer, Cisco IOS software can initiate aggressive mode. Cisco IOS software will respond in aggressive mode to an IKE peer that initiates aggressive mode.

How to Configure IKE for IPSec VPNs

If you do not want IKE to be used with your IPSec implementation, you can disable it at all IPSec peers via the `no crypto isakmp` command, skip the rest of this chapter, and begin your IPSec VPN.

Note

If you disable IKE, you will have to manually specify all the IPSec SAs in the crypto maps at all peers, the IPSec SAs of the peers will never time out for a given IPSec session, the encryption keys will never change during IPSec sessions between the peers, anti-replay services will not be available between the peers, and public key infrastructure (PKI) support cannot be used.
IKE is enabled by default. IKE does not have to be enabled for individual interfaces, but it is enabled globally for all interfaces at the router.

Perform the following tasks to provide authentication of IPSec peers, negotiate IPSec SAs, and establish IPSec keys:

- Creating IKE Policies: Security Parameters for IKE Negotiation, page 5 (required)
- Configuring IKE Authentication, page 9 (required)
- Configuring IKE Mode Configuration, page 17

Creating IKE Policies: Security Parameters for IKE Negotiation

An IKE policy defines a combination of security parameters to be used during the IKE negotiation. You must create an IKE policy at each peer participating in the IKE exchange.

If you do not configure any IKE policies, your router will use the default policy, which is always set to the lowest priority and which contains the default value of each parameter.

About IKE Policies

Because IKE negotiations must be protected, each IKE negotiation begins by agreement of both peers on a common (shared) IKE policy. This policy states which security parameters will be used to protect subsequent IKE negotiations and mandates how the peers are authenticated.

After the two peers agree upon a policy, the security parameters of the policy are identified by an SA established at each peer, and these SAs apply to all subsequent IKE traffic during the negotiation.

You can configure multiple, prioritized policies on each peer—each with a different combination of parameter values. However, at least one of these policies must contain exactly the same encryption, hash, authentication, and Diffie-Hellman parameter values as one of the policies on the remote peer. For each policy that you create, you assign a unique priority (1 through 10,000, with 1 being the highest priority).

Tip

If you are interoperating with a device that supports only one of the values for a parameter, your choice is limited to the value supported by the other device. Aside from this limitation, there is often a trade-off between security and performance, and many of these parameter values represent such a trade-off. You should evaluate the level of security risks for your network and your tolerance for these risks.

IKE Peers Agreeing Upon a Matching IKE Policy

When the IKE negotiation begins, IKE searches for an IKE policy that is the same on both peers. The peer that initiates the negotiation will send all its policies to the remote peer, and the remote peer will try to find a match. The remote peer looks for a match by comparing its own highest priority policy against the policies received from the other peer. The remote peer checks each of its policies in order of its priority (highest priority first) until a match is found.

A match is made when both policies from the two peers contain the same encryption, hash, authentication, and Diffie-Hellman parameter values, and when the remote peer’s policy specifies a lifetime that is less than or equal to the lifetime in the policy being compared. (If the lifetimes are not identical, the shorter lifetime—from the remote peer’s policy—will be used.)

If a match is found, IKE will complete negotiation, and IPSec security associations will be created. If no acceptable match is found, IKE refuses negotiation and IPSec will not be established.
Depending on which authentication method is specified in a policy, additional configuration might be required (as described in the section “Configuring IKE Authentication”). If a peer’s policy does not have the required companion configuration, the peer will not submit the policy when attempting to find a matching policy with the remote peer.

**Restrictions**

If you are configuring an AES IKE policy, note the following restrictions:
- Your router must support IPSec and long keys (the “k9” subsystem).
- AES cannot encrypt IPSec and IKE traffic if an acceleration card is present.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto isakmp policy priority`
4. `encryption {des | 3des | aes | aes 192 | aes 256}`
5. `hash {sha | md5}`
6. `authentication {rsa-sig | rsa-encr | pre-share}`
7. `group {1 | 2 | 5}`
8. `lifetime seconds`
9. `exit`
10. `exit`
11. `show crypto isakmp policy`
## DETAILED STEPS

**Configuring Internet Key Exchange for IPSec VPNs**

### How to Configure IKE for IPSec VPNs

- **Note**: These parameters apply to the IKE negotiations after the IKE SA is established.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 7**
  group (1 | 2 | 5) | Specifies the Diffie-Hellman group identifier. By default, D-H group 1 is used.
  - 1—768-bit Diffie-Hellman
  - 2—1024-bit Diffie-Hellman
  - 5—1536-bit Diffie-Hellman
  **Note**: The 1024-bit and 1536-bit Diffie-Hellman options are harder to “crack,” but require more CPU time to execute. |
| **Example**:
  Router(config-isakmp)# group 1 |

- **Step 8**
  lifetime seconds | Specifies the lifetime of the IKE SA.
  - seconds—Time, in seconds, before each SA expires. Valid values: 60 to 86,400 seconds; default value: 86,400.
  **Note**: The shorter the lifetime (up to a point), the more secure your IKE negotiations will be. However, with longer lifetimes, future IPSec SAs can be set up more quickly. |
| **Example**:
  Router(config-isakmp)# lifetime 180 |

- **Step 9**
  exit | Exits config-isakmp configuration mode. |
| **Example**:
  Router(config-isakmp)# exit |

- **Step 10**
  exit | Exits the global configuration mode. |
| **Example**:
  Router(config)# exit |

- **Step 11**
  show crypto isakmp policy | (Optional) Displays all existing IKE policies. |
| **Example**:
  Router# show crypto isakmp policy |

- **Step 12**
  — | Repeat these steps for each policy you want to create. |

### Examples

The following sample output from the `show crypto isakmp policy` command displays a warning message after a user tries to configure an IKE encryption method that the hardware does not support:

```
Router# show crypto isakmp policy
Protection suite of priority 1
WARNING:encryption hardware does not support the configured encryption method for ISAKMP policy 1
  hash algorithm: Secure Hash Standard
  authentication method: Pre-Shared Key
```
Diffie-Hellman group:  #1 (768 bit)
lifetime:              3600 seconds, no volume limit

Troubleshooting Tips

- Clear (and reinitialize) IPSec SAs by using the `clear crypto sa` EXEC command.

  Using the `clear crypto sa` command without parameters will clear out the full SA database, which will clear out active security sessions. You may also specify the peer, map, or entry keywords to clear out only a subset of the SA database. For more information, see the `clear crypto sa` command in the *Cisco IOS Security Command Reference*, Release 12.4.

- The default policy and default values for configured policies do not show up in the configuration when you issue the `show running-config` command. To see the default policy and any default values within configured policies, use the `show crypto isakmp policy` command.

- Any IPSec transforms or IKE encryption methods that the current hardware does not support should be disabled; they are ignored whenever an attempt to negotiate with the peer is made.

  If a user enters an IPSec transform or an IKE encryption method that the hardware does not support, a warning message will be generated. These warning messages are also generated at boot time.

  When an encrypted card is inserted, the current configuration is scanned. If any IPSec transforms or IKE encryption methods are found that are not supported by the hardware, a warning message will be generated.

What to Do Next

Depending on which authentication method you specified in your IKE policies (RSA signatures, RSA encrypted nonces, or preshared keys), you must do certain additional configuration tasks before IKE and IPSec can successfully use the IKE policies. For information on completing these additional tasks, refer to the following section “Configuring IKE Authentication.”

To configure an AES-based transform set, see the module “Configuring Security for VPNs with IPSec.”

Configuring IKE Authentication

After you have created at least one IKE policy in which you specified an authentication method (or accepted the default method), you need to configure an authentication method. IKE policies cannot be used by IPSec until the authentication method is successfully configured.

To configure IKE authentication, you should perform one of the following tasks, as appropriate:

- Configuring RSA Keys Manually for RSA Encrypted Nonces, page 11
- Configuring Preshared Keys, page 13
- Configuring RSA Keys to Obtain Certificates from a CA. For information on completing this task, see the module “Deploying RSA Keys Within a PKI.”

IKE Authentication Methods: Overview

IKE authentication consists of three options—RSA signatures, RSA encrypted nonces, and preshared keys. Each authentication method requires additional configuration as follows:
RSA Signatures
With RSA signatures, you can configure the peers to obtain certificates from a CA. (The CA must be properly configured to issue the certificates.) Using a CA can dramatically improve the manageability and scalability of your IPSec network. Additionally, RSA signature-based authentication uses only two public key operations, whereas RSA encryption uses four public key operations, making it costlier in terms of overall performance. To properly configure CA support, see the chapter “Implementing and Managing a PKI.”

The certificates are used by each peer to exchange public keys securely. (RSA signatures requires that each peer has the public signature key of the remote peer.) When both peers have valid certificates, they will automatically exchange public keys with each other as part of any IKE negotiation in which RSA signatures are used.

You can also exchange the public keys manually, as described in the section “Configuring RSA Keys Manually for RSA Encrypted Nonces.”

RSA signatures provide nonrepudiation for the IKE negotiation. And, you can prove to a third party after the fact that you did indeed have an IKE negotiation with the remote peer.

RSA Encrypted Nonces
With RSA encrypted nonces, you must ensure that each peer has the public keys of the other peers.

Unlike RSA signatures, the RSA encrypted nonces method cannot use certificates to exchange public keys. Instead, you ensure that each peer has the others’ public keys by one of the following methods:

- Manually configuring RSA keys as described in the section “Configuring RSA Keys Manually for RSA Encrypted Nonces.”

or

- Ensuring that an IKE exchange using RSA signatures with certificates has already occurred between the peers. (The peers’ public keys are exchanged during the RSA-signatures-based IKE negotiations if certificates are used.)

To make that the IKE exchange happens, specify two policies: a higher-priority policy with RSA encrypted nonces and a lower-priority policy with RSA signatures. When IKE negotiations occur, RSA signatures will be used the first time because the peers do not yet have each other’s public keys. Then future IKE negotiations can use RSA encrypted nonces because the public keys will have been exchanged.

Note: This alternative requires that you already have CA support configured.

RSA encrypted nonces provide repudiation for the IKE negotiation; however, unlike RSA signatures, you cannot prove to a third party that you had an IKE negotiation with the remote peer.

Preshared Keys
With preshared keys, you must configure them as described in the section “Configuring Preshared Keys.”

Preshared keys are clumsy to use if your secured network is large, and they do not scale well with a growing network. However, they do not require use of a CA, as do RSA signatures, and might be easier to set up in a small network with fewer than ten nodes. RSA signatures also can be considered more secure when compared with preshared key authentication.
**Configuring Internet Key Exchange for IPSec VPNs**

**How to Configure IKE for IPSec VPNs**

Note

If RSA encryption is configured and signature mode is negotiated (and certificates are used for signature mode), the peer will request both signature and encryption keys. Basically, the router will request as many keys as the configuration will support. If RSA encryption is not configured, it will just request a signature key.

**Prerequisites**

You must have configured at least one IKE policy, which is where the authentication method was specified (or RSA signatures was accepted by default).

**Configuring RSA Keys Manually for RSA Encrypted Nonces**

To manually configure RSA keys, perform this task for each IPSec peer that uses RSA encrypted nonces in an IKE policy.

Note

This task can be performed only if a CA is not in use.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. crypto key generate rsa {general-keys | usage-keys} [label key-label] [exportable] [modulus modulus-size]
4. exit
5. show crypto key mypubkey rsa
6. configure terminal
7. crypto key pubkey-chain rsa
8. named-key key-name [encryption | signature]
   or
   addressed-key key-address [encryption | signature]
9. address ip-address
10. key-string key-string
11. quit
12. Repeat these steps at each peer that uses RSA encrypted nonces in an IKE policy.
13. exit
14. exit
15. show crypto key pubkey-chain rsa [name key-name | address key-address]
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
  - Enter your password if prompted. |
| **Example:**  
  Router> enable | |
| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:**  
  Router# configure terminal | |
| **Step 3** crypto key generate rsa {general-keys | usage-keys} [label key-label] [exportable] [modulus modulus-size] | Generates RSA keys.  
  - If a key-label argument is not specified, the default value, which is the fully qualified domain name (FQDN) of the router, is used. |
| **Example:**  
  Router(config)# crypto key generate rsa  
  general-keys modulus 360 | |
| **Step 4** exit | (Optional) Exits global configuration mode. |
| **Example:**  
  Router(config)# exit | |
| **Step 5** show crypto key mypubkey rsa | (Optional) Displays the generated RSA public keys. |
| **Example:**  
  Router# show crypto key mypubkey rsa | |
| **Step 6** configure terminal | Returns to global configuration mode. |
| **Example:**  
  Router# configure terminal | |
| **Step 7** crypto key pubkey-chain rsa | Enters public key configuration mode (so you can manually specify the RSA public keys of other devices). |
| **Example:**  
  Router(config)# crypto key pubkey-chain rsa | |
| **Step 8** named-key key-name [encryption | signature] | Indicates which remote peer’s RSA public key you are going to specify and enters public key configuration mode. |

How to Configure IKE for IPSec VPNs

### Configuring Preshared Keys

To configure preshared keys, perform these steps at each peer that uses preshared keys in an IKE policy.

#### Setting ISAKMP Identity for Preshared Keys

You should set the ISAKMP identity for each peer that uses preshared keys in an IKE policy.

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 9**
  - `address ip-address`
  - **Example:**
    - `Router(config-pubkey-key)# address 10.5.5.1`
  | Specifies the IP address of the remote peer. If you use the `named-key` command, you need to use this command to specify the IP address of the peer. |
| **Step 10**
  - `key-string key-string`
  - **Example:**
    - `Router(config-pubkey-key)# key-string`
    - `Router(config-pubkey)# 00302017 4A7D385B 1234EF29 335FC973`
    - `Router(config-pubkey)# 2DD50A37 C4F4B0FD 9DADE748 429618D5`
    - `Router(config-pubkey)# 18242BA3 2EDFBDD3 4296142A DDF7D3D8`
    - `Router(config-pubkey)# 08407585 2F2190A0 0B43F1BD 9A8A26DB`
    - `Router(config-pubkey)# 07953829 791FCDE9 A98420F0 6A82045B`
    - `Router(config-pubkey)# 90288A26 DBC64468 7789F76E EE21`
  | Specifies the RSA public key of the remote peer. (This key was previously viewed by the administrator of the remote peer when the RSA keys of the remote router were generated.) |
| **Step 11**
  - `quit`
  - **Example:**
    - `Router(config-pubkey-k)# quit`
  | Returns to public key chain configuration mode. |
| **Step 12**
  - `exit`
  - **Example:**
    - `Router(config-pubkey-c)# exit`
  | Repeat these steps at each peer that uses RSA encrypted nonces in an IKE policy. |
| **Step 13**
  - `exit`
  - **Example:**
    - `Router(config-pubkey-c)# exit`
  | Returns to global configuration mode. |
| **Step 14**
  - `exit`
  - **Example:**
    - `Router(config)# exit`
  | Returns to EXEC mode. |
| **Step 15**
  - `show crypto key pubkey-chain rsa [name key-name | address key-address]`
  - **Example:**
    - `Router# show crypto key pubkey-chain rsa`
  | (Optional) Displays either a list of all RSA public keys that are stored on your router or details of a particular RSA key that is stored on your router. |
When two peers use IKE to establish IPSec SAs, each peer sends its identity to the remote peer. Each peer sends either its host name or its IP address, depending on how you have set the ISAKMP identity of the router.

By default, a peer’s ISAKMP identity is the IP address of the peer. If appropriate, you could change the identity to be the peer’s host name instead. As a general rule, set the identities of all peers the same way—either all peers should use their IP addresses or all peers should use their hostnames. If some peers use their host names and some peers use their IP addresses to identify themselves to each other, IKE negotiations could fail if the identity of a remote peer is not recognized and a DNS lookup is unable to resolve the identity.

Mask Preshared Keys

A mask preshared key allows a group of remote users with the same level of authentication to share an IKE preshared key. The preshared key of the remote peer must match the preshared key of the local peer for IKE authentication to occur.

A mask preshared key is usually distributed through a secure out-of-band channel. In a remote peer-to-local peer scenario, any remote peer with the IKE preshared key configured can establish IKE SAs with the local peer.

If you specify the mask keyword with the crypto isakmp key command, it is up to you to use a subnet address, which will allow more peers to share the same key. That is, the preshared key is no longer restricted to use between two users.

Note: Using 0.0.0.0 as a subnet address is not recommended because it encourages group preshared keys, which allow all peers to have the same group key, thereby reducing the security of your user authentication.

Disable Xauth on a Specific IPSec Peer

Disabling Extended Authentication (Xauth) for static IPSec peers prevents the routers from being prompted for Xauth information—username and password.

Without the ability to disable Xauth, a user cannot select which peer on the same crypto map should use Xauth. That is, if a user has router-to-router IPSec on the same crypto map as a VPN-client-to-Cisco-IOS IPSec, both peers are prompted for a username and password. In addition, a remote static peer (a Cisco IOS router) cannot establish an IKE SA with the local Cisco IOS router. (Xauth is not an optional exchange, so if a peer does not respond to an Xauth request, the IKE SA is deleted.) Thus, the same interface cannot be used to terminate IPSec to VPN clients (that need Xauth) as well as other Cisco IOS routers (that cannot respond to Xauth) unless this feature is implemented.

Note: Xauth can be disabled only if preshared keys are used as the authentication mechanism for the given crypto map.

Restrictions

- Preshared do not scale well with a growing network.
- Mask preshared keys have the following restrictions:
  - The SA cannot be established between the IPSec peers until all IPSec peers are configured for the same preshared key.
- The mask preshared key must be distinctly different for remote users requiring varying levels of authorization. You must configure a new preshared key for each level of trust and assign the correct keys to the correct parties. Otherwise, an untrusted party may obtain access to protected data.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto isakmp identity {address | hostname}`
4. `ip host hostname address1 [address2...address8]`
5. `crypto isakmp key keystring address peer-address [mask] [no-xauth]`  
   or  
   `crypto isakmp key keystring hostname hostname [no-xauth]`
6. `crypto isakmp key keystring address peer-address [mask] [no-xauth]`  
   or  
   `crypto isakmp key keystring hostname hostname [no-xauth]`
7. Repeat these steps for each peer that uses preshared keys.
How to Configure IKE for IPSec VPNs

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Enter your password if prompted.</td>
</tr>
<tr>
<td></td>
<td>Router&gt; enable</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router# configure terminal</td>
</tr>
<tr>
<td><strong>Step 3</strong> crypto isakmp identity {address</td>
<td>hostname}</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>address—Typically used when there is only one interface (and therefore only one IP address) that will be used by the peer for IKE negotiations, and the IP address is known.</td>
</tr>
<tr>
<td></td>
<td>hostname—Should be used if there is more than one interface on the peer that might be used for IKE negotiations, or if the interface's IP address is unknown (such as with dynamically assigned IP addresses).</td>
</tr>
<tr>
<td></td>
<td>Router(config)# crypto isakmp identity address</td>
</tr>
<tr>
<td><strong>Step 4</strong> ip host hostname address1 [address2...address8]</td>
<td>If the local peer's ISAKMP identity was specified using a hostname, maps the peer's host name to its IP address(es) at all the remote peers.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>(This step might be unnecessary if the hostname or address is already mapped in a DNS server.)</td>
</tr>
<tr>
<td></td>
<td>Router(config)# ip host RemoteRouter.example.com 192.168.0.1</td>
</tr>
<tr>
<td><strong>Step 5</strong> crypto isakmp key keystring address peer-address [mask] [no-xauth]</td>
<td>Specifies at the local peer the shared key to be used with a particular remote peer.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>If the remote peer specified its ISAKMP identity with an address, use the address keyword in this step; otherwise use the hostname keyword in this step.</td>
</tr>
<tr>
<td></td>
<td>Router(config)# crypto isakmp key sharedkeystring address 192.168.1.33 no-xauth</td>
</tr>
<tr>
<td></td>
<td>or</td>
</tr>
<tr>
<td></td>
<td>crypto isakmp key keystring hostname hostname [no-xauth]</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Note According to the design of preshared key authentication in IKE main mode, preshared keys must be based on the IP address of the peers. Although you can send hostname as the identity of preshared key authentication, the key is searched on the IP address of the peer; if the key is not found (based on the IP address) the negotiation will fail.</td>
</tr>
<tr>
<td></td>
<td>Router(config) crypto isakmp key sharedKeystring hostname RemoteRouter.example.com</td>
</tr>
</tbody>
</table>
Configuring Internet Key Exchange for IPSec VPNs

How to Configure IKE for IPSec VPNs

Configuring IKE Mode Configuration

Perform the following task to configure IKE mode configuration.

About IKE Mode Configuration

IKE mode configuration, as defined by the Internet Engineering Task Force (IETF), allows a gateway to download an IP address (and other network level configuration) to the client as part of an IKE negotiation. Using this exchange, the gateway gives IP addresses to the IKE client to be used as an “inner” IP address encapsulated under IPSec. This method provides a known IP address for the client that can be matched against IPSec policy.

To implement IPSec VPNs between remote access clients that have dynamic IP addresses and a corporate gateway, you have to dynamically administer scalable IPSec policy on the gateway once each client is authenticated. With IKE Mode Configuration, the gateway can set up scalable policy for a very large set of clients irrespective of the IP addresses of those clients.

There are two types of IKE Mode Configuration:

- Gateway initiation—Gateway initiates the configuration mode with the client. Once the client responds, the IKE modifies the identity of the sender, the message is processed, and the client receives a response.
- Client initiation—Client initiates the configuration mode with the gateway. The gateway responds with an IP address that it has allocated for the client.

Restrictions

IKE Mode Configuration has the following restrictions:

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 6**

```plaintext
crypto isakmp key keystring
address peer-address [mask] [no-xauth]
```

**Example:**

```plaintext
Router(config) crypto isakmp key
sharedkeystring address 10.0.0.1
```

or

```plaintext
crypto isakmp key keystring hostname hostname
[no-xauth]
```

**Example:**

```plaintext
Router(config) crypto isakmp key
sharedkeystring hostname
LocalRouter.example.com
```

**Step 7**

Repeat these steps at each peer that uses preshared keys in an IKE policy.

---
• Interfaces with crypto maps that are configured for IKE Mode Configuration may experience a slightly longer connection setup time, which is true even for IKE peers that refuse to be configured or do not respond to the configuration mode request. In both cases, the gateway initiates the configuration of the client.

• This feature was not designed to enable the configuration mode for every IKE connection by default. Configure this feature at the global crypto map level.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip local pool pool-name start-addr end-addr
4. crypto isakmp client configuration address-pool local pool-name
5. crypto map tag client configuration address [initiate | respond]

## Configuration Examples for an IKE Configuration

This section contains the following configuration examples:

- Creating IKE Policies: Examples, page 19
- Configuring IKE Authentication: Example, page 21

## Creating IKE Policies: Examples

This section contains the following examples, which show how to configure a 3DES IKE policy and an AES IKE policy:

- Creating 3DES IKE Policies: Example, page 20
- Creating an AES IKE Policy: Example, page 20
Creating 3DES IKE Policies: Example

This example creates two IKE policies, with policy 15 as the highest priority, policy 20 as the next priority, and the existing default priority as the lowest priority. It also creates a preshared key to be used with policy 20 with the remote peer whose IP address is 192.168.224.33.

```
crypto isakmp policy 15
  encryption 3des
  hash md5
  authentication rsa-sig
  group 2
  lifetime 5000
!
crypto isakmp policy 20
  authentication pre-share
  lifetime 10000
!
crypto isakmp key 1234567890 address 192.168.224.33
```

In the example, the encryption des of policy 15 would not appear in the written configuration because this is the default value for the encryption algorithm parameter.

If the `show crypto isakmp policy` command is issued with this configuration, the output is as follows:

```
Protection suite priority 15
  encryption algorithm:3DES - Triple Data Encryption Standard (168 bit keys)
  hash algorithm:Message Digest 5
  authentication method:Rivest-Shamir-Adleman Signature
  Diffie-Hellman group:#2 (1024 bit)
  lifetime:5000 seconds, no volume limit
Protection suite priority 20
  encryption algorithm:DES - Data Encryption Standard (56 bit keys)
  hash algorithm:Secure Hash Standard
  authentication method:preshared Key
  Diffie-Hellman group:#1 (768 bit)
  lifetime:10000 seconds, no volume limit
Default protection suite
  encryption algorithm:DES - Data Encryption Standard (56 bit keys)
  hash algorithm:Secure Hash Standard
  authentication method:Rivest-Shamir-Adleman Signature
  Diffie-Hellman group:#1 (768 bit)
  lifetime:86400 seconds, no volume limit
```

Note that although the output shows “no volume limit” for the lifetimes, you can configure only a time lifetime (such as 86,400 seconds); volume-limit lifetimes are not configurable.

Creating an AES IKE Policy: Example

The following example is sample output from the `show running-config` command. In this example, the AES 256-bit key is enabled.

```
Current configuration : 1665 bytes
!
version 12.2
service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption
!
hostname "Router1"
!
!
ip subnet-zero

```

no ip domain lookup
!
ip audit notify log
ip audit po max-events 100
!
crypto isakmp policy 10
crypto isakmp key cisco123 address 10.0.110.1
!
crypto ipsec transform-set aesset esp-aes 256 esp-sha-hmac
mode transport
!
crypto map aesset 10 ipsec-isakmp
set peer 10.0.110.1
set transform-set aesset
match address 120
!
.
.
.

Configuring IKE Authentication: Example

The following example shows how to manually specify the RSA public keys of two IPSec peer—the peer at 10.5.5.1 uses general-purpose keys, and the other peer uses special-usage keys:

crypto key pubkey-chain rsa
named-key otherpeer.example.com
address 10.5.5.1
key-string
005C300D 06092A86 4886F70D 01010105

quit
exit
Where to Go Next

After you have successfully configured IKE negotiation, you can begin configuring IPSec. For information on completing these tasks, see the module “Configuring Security for VPNs With IPSec.”

Glossary
anti-replay—Security service in which the receiver can reject old or duplicate packets to protect itself against replay attacks. IPSec provides optional anti-replay services by use of a sequence number and the use of authentication.

data authentication—Verification of the integrity and origin of the data.

Data authentication can refer either to integrity alone or to both of these concepts (although data origin authentication is dependent upon data integrity).

peer—in the context of this chapter, a “peer” is a router or other device that participates in IPSec and IKE.

PFS—perfect forward secrecy. Cryptographic characteristic associated with a derived shared secret value. With PFS, if one key is compromised, previous and subsequent keys are not also compromised, because subsequent keys are not derived from previous keys.

repudiation—Quality that prevents a third party from being able to prove that a communication between two other parties ever took place. Repudiation is a desirable quality if you do not want your communications to be traceable.

nonrepudiation—Quality that allows a third party to prove that a communication between two other parties took place. Nonrepudiation is desirable if you want to be able to trace your communications and prove that they occurred.

SA—security association. How two or more entities utilize security services to communicate securely. For example, an IPSec SA defines the encryption algorithm (if used), the authentication algorithm, and the shared session key to be used during the IPSec connection. Both IPSec and IKE require and use SAs to identify the parameters of their connections. IKE can negotiate and establish its own SA. The IPSec SA is established either by IKE or by manual user configuration.

Note Refer to Internetworking Terms and Acronyms for terms not included in this glossary.

Feature Information for Configuring IKE for IPSec VPNs

Table 43 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For details on when support for a specific command was introduced, see the command reference documentation.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at http://www.cisco.com/go/fn. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.

Note Table 43 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.
### Table 43  Feature Information for Configuring IKE for IPSec VPNs

| Ability to Disable Extended Authentication for Static IPSec Peers | 12.2(4)T          | This feature allows a user to disable Xauth while configuring the preshared key for router-to-router IPSec. Thus, the router will not prompt the peer for a username and password, which are transmitted when Xauth occurs for VPN-client-to-Cisco-IOS IPSec. The following section provides information about this feature:  
  - Configuring Preshared Keys  
  The following command was modified by this feature: `crypto isakmp key` |
| Advanced Encryption Standard (AES)                | 12.2(8)T          | This feature adds support for the new encryption standard AES, which is a privacy transform for IPSec and IKE and has been developed to replace DES. The following sections provide information about this feature:  
  - Supported Standards for Use with IKE  
  - Creating IKE Policies: Security Parameters for IKE Negotiation  
  The following commands were modified by this feature: `crypto ipsec transform-set`, `encryption (IKE policy)`, `show crypto isakmp policy`, `show crypto ipsec transform-set` |
| SEAL Encryption                                   | 12.3(7)T          | This feature adds support for SEAL encryption in IPSec. The following section provides information about this feature:  
  - Supported Standards for Use with IKE  
  The following command was modified by this feature: `crypto ipsec transform-set` |
| IKE Extended Authentication (Xauth)               | Cisco IOS XE      | This feature was introduced on Cisco ASR 1000 Series Routers.                                                                                                                                                                      |
|                                                   | Release 2.1       |                                                                                                                                                                                                                                |
| Wildcard Pre-Shared Key                           | Cisco IOS XE      | This feature was introduced on Cisco ASR 1000 Series Routers.                                                                                                                                                                      |
|                                                   | Release 2.1       |                                                                                                                                                                                                                                |
| IKE - Diffie-Hellman (768 Bit or 1024 Bit) PKCS #3 Support | Cisco IOS XE      | This feature was introduced on Cisco ASR 1000 Series Routers.                                                                                                                                                                      |
|                                                   | Release 2.1       |                                                                                                                                                                                                                                    |

Configuring Security for VPNs with IPSec

This module describes how to configure basic IP Security (IPSec) virtual private networks (VPNs). IPSec is a framework of open standards developed by the Internet Engineering Task Force (IETF). It provides security for transmission of sensitive information over unprotected networks such as the Internet. IPSec acts at the network layer, protecting and authenticating IP packets between participating IPSec devices (“peers”), such as Cisco routers.

Module History
This module was first published on May 2, 2005, and last updated on May 2, 2005.

Finding Feature Information in This Module
Your Cisco IOS software release may not support all features. To find information about feature support and configuration, use the “Feature Information for Security for VPNs with IPSec” section on page 35.

Prerequisites for Configuring Security for VPNs with IPSec

**IKE Configuration**
You must configure Internet Key Exchange (IKE) as described in the module “Configuring Internet Key Exchange Security for IPSec VPNs.”

Even if you decide to not use IKE, you still must disable it as described in the module “Configuring Internet Key Exchange for IPSec VPNs.”

**Ensure Access Lists Are Compatible with IPSec**
IKE uses UDP port 500. The IPSec Encapsulating Security Payload (ESP) and Authentication Header (AH) protocols use protocol numbers 50 and 51. Ensure that your access lists are configured so that protocol 50, 51, and User Datagram Protocol (UDP) port 500 traffic is not blocked at interfaces used by IPSec. In some cases you might need to add a statement to your access lists to explicitly permit this traffic.

Restrictions for Configuring Security for VPNs with IPSec

**Unicast IP Datagram Application Only**
At this time, IPSec can be applied to unicast IP datagrams only. Because the IPSec Working Group has not yet addressed the issue of group key distribution, IPSec does not currently work with multicasts or broadcast IP datagrams.

**NAT Configuration**
If you use Network Address Translation (NAT), you should configure static NAT translations so that IPSec works properly. In general, NAT translation should occur before the router performs IPSec encapsulation; in other words, IPSec should be working with global addresses.

Information About Configuring Security for VPNs with IPSec

To configure basic IPSec VPNs, you should understand the following concepts:

- Supported Standards, page 2
- Supported Hardware, Switching Paths, and Encapsulation, page 4
- IPSec Functionality Overview, page 6
- IPSec Traffic Nested to Multiple Peers, page 8

Supported Standards

Cisco implements the following standards with this feature:

- IPSec—IP Security Protocol. IPSec is a framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPSec provides these security services at the IP layer; it uses IKE to handle negotiation of protocols and algorithms
based on local policy, and to generate the encryption and authentication keys to be used by IPSec. IPSec can be used to protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.

**Note** The term IPSec is sometimes used to describe the entire protocol of IPSec data services and IKE security protocols and is also sometimes used to describe only the data services.

- **IKE**—A hybrid protocol that implements Oakley and SKEME key exchanges inside the ISAKMP framework. While IKE can be used with other protocols, its initial implementation is with the IPSec protocol. IKE provides authentication of the IPSec peers, negotiates IPSec security associations, and establishes IPSec keys.

The component technologies implemented for IPSec include:

- **AES**—Advanced Encryption Standard. A cryptographic algorithm that protects sensitive, unclassified information. AES is privacy transform for IPSec and IKE and has been developed to replace the DES. AES is designed to be more secure than DES: AES offers a larger key size, while ensuring that the only known approach to decrypt a message is for an intruder to try every possible key. AES has a variable key length—the algorithm can specify a 128-bit key (the default), a 192-bit key, or a 256-bit key.

- **DES**—Data Encryption Standard. An algorithm that is used to encrypt packet data. Cisco IOS implements the mandatory 56-bit DES-CBC with Explicit IV. Cipher Block Chaining (CBC) requires an initialization vector (IV) to start encryption. The IV is explicitly given in the IPSec packet. For backwards compatibility, Cisco IOS IPSec also implements the RFC 1829 version of ESP DES-CBC.

Cisco IOS also implements Triple DES (168-bit) encryption, depending on the software versions available for a specific platform. Triple DES (3DES) is a strong form of encryption that allows sensitive information to be transmitted over untrusted networks. It enables customers to utilize network layer encryption.

**Note** Cisco IOS images with strong encryption (including, but not limited to, 56-bit data encryption feature sets) are subject to United States government export controls, and have a limited distribution. Images to be installed outside the United States require an export license. Customer orders might be denied or subject to delay due to United States government regulations. Contact your sales representative or distributor for more information, or send e-mail to export@cisco.com.

- **SEAL**—Software Encryption Algorithm. An alternative algorithm to software-based DES, 3DES, and AES. SEAL encryption uses a 160-bit encryption key and has a lower impact to the CPU when compared to other software-based algorithms.

- **MD5 (HMAC variant)**—MD5 (Message Digest 5) is a hash algorithm. HMAC is a keyed hash variant used to authenticate data.

- **SHA (HMAC variant)**—SHA (Secure Hash Algorithm) is a hash algorithm. HMAC is a keyed hash variant used to authenticate data.

IPSec as implemented in Cisco IOS software supports the following additional standards:

- **AH**—Authentication Header. A security protocol which provides data authentication and optional anti-replay services. AH is embedded in the data to be protected (a full IP datagram).
- ESP—Encapsulating Security Payload. A security protocol which provides data privacy services and optional data authentication, and anti-replay services. ESP encapsulates the data to be protected.

**Supported Hardware, Switching Paths, and Encapsulation**

IPSec has certain requirements for hardware, switching paths, and encapsulation methods as follows:

- **Supported Hardware**
- **Supported Switching Paths**
- **Supported Encapsulation**

**Supported Hardware**

This section contains the following subsections:

- **VPN Accelerator Module (VAM) Support**
- **AIMs and NM Support**

**VPN Accelerator Module (VAM) Support**

The VAM is a single-width acceleration module. It provides high-performance, hardware-assisted tunneling and encryption services suitable for VPN remote access, site-to-site intranet, and extranet applications. It also provides platform scalability and security while working with all services necessary for successful VPN deployments—security, quality of service (QoS), firewall and intrusion detection, service-level validation, and management. The VAM off-loads IPSec processing from the main processor, thus freeing resources on the processor engines for other tasks.

The VAM provides hardware-accelerated support for the following multiple encryption functions:

- 56-bit DES standard mode: CBC
- 3-Key Triple DES (168-bit)
- SHA-1 and MD5
- Rivest, Shamir, Adelman (RSA) public-key algorithm
- Diffie-Hellman key exchange RC4-40

For more information on VAMs, see the document “VPN Acceleration Module (VAM).”

**AIMs and NM Support**

The data encryption Advanced Integration Module (AIM) and Network Module (NM) provide hardware-based encryption.

The data encryption AIMs and NM are hardware Layer 3 (IPSec) encryption modules and provide DES and Triple DES IPSec encryption for multiple T1s or E1s of bandwidth. These products also have hardware support for Diffie-Hellman, RSA, and DSA key generation.

Before using either module, note that RSA manual keying is not supported.

See Table 44 to determine which VPN encryption module to use.
IPPCP Software for Use with AIMs and NM in Cisco 2600 and Cisco 3600 Series Routers

Software IPPCP with AIMs and NM allow customers to use Lempel-Ziv-Stac (LZS) software compression with IPSec when a VPN module is in Cisco 2600 and Cisco 3600 series routers, allowing users to effectively increase the bandwidth on their interfaces.

Without IPPCP software, compression is not supported with the VPN encryption hardware AIM and NM; that is, a user had to remove the VPN module from the router and run software encryption with software compression. IPPCP enables all VPN modules to support LZS compression in software when the VPN module is in the router, thereby, allowing users to configure data compression and increase their bandwidth, which is useful for a low data link.

Without IPPCP, compression occurs at Layer 2, and encryption occurs at Layer 3. After a data stream is encrypted, it is passed on for compression services. When the compression engine receives the encrypted data streams, the data expands and does not compress. This feature enables both compression and encryption of the data to occur at Layer 3 by selecting LZS with the IPSec transform set; that is, LZS compression occurs before encryption, and it is able to get better compression ratio.

Supported Switching Paths

Table 45 lists the supported switching paths that work with IPSec.
Supported Encapsulation

IPSec works with the following serial encapsulations: High-Level Data-Links Control (HDLC), PPP, and Frame Relay.

IPSec also works with the Generic Routing Encapsulation (GRE) and IP in IP Layer 3, Layer 2 Forwarding (L2F), Layer 2 Tunneling Protocol (L2TP), Data Link Switching+ (DLSw+), and SRB tunneling protocols; however, multipoint tunnels are not supported. Other Layer 3 tunneling protocols may not be supported for use with IPSec.

Because the IPSec Working Group has not yet addressed the issue of group key distribution, IPSec currently cannot be used to protect group traffic (such as broadcast or multicast traffic).

IPSec Functionality Overview

IPSec provides the following network security services. (In general, local security policy dictates the use of one or more of these services.)

- Data Confidentiality—The IPSec sender can encrypt packets before transmitting them across a network.
- Data Integrity—The IPSec receiver can authenticate packets sent by the IPSec sender to ensure that the data has not been altered during transmission.
- Data Origin Authentication—The IPSec receiver can authenticate the source of the IPSec packets sent. This service is dependent upon the data integrity service.

- Anti-Replay—The IPSec receiver can detect and reject replayed packets.

IPSec provides secure tunnels between two peers, such as two routers. You define which packets are considered sensitive and should be sent through these secure tunnels, and you define the parameters that should be used to protect these sensitive packets, by specifying characteristics of these tunnels. Then, when the IPSec peer recognizes such a sensitive packet, the peer sets up the appropriate secure tunnel and sends the packet through the tunnel to the remote peer. (The use of the term tunnel in this chapter does not refer to using IPSec in tunnel mode.)

More accurately, these tunnels are sets of security associations (SAs) that are established between two IPSec peers. The SAs define which protocols and algorithms should be applied to sensitive packets and specify the keying material to be used by the two peers. SAs are unidirectional and are established per security protocol (AH or ESP).

With IPSec you define what traffic should be protected between two IPSec peers by configuring access lists and applying these access lists to interfaces by way of crypto map sets. Therefore, traffic may be selected on the basis of source and destination address, and optionally Layer 4 protocol, and port. (The access lists used for IPSec are used only to determine which traffic should be protected by IPSec, not which traffic should be blocked or permitted through the interface. Separate access lists define blocking and permitting at the interface.)

A crypto map set can contain multiple entries, each with a different access list. The crypto map entries are searched in order—the router attempts to match the packet to the access list specified in that entry.

When a packet matches a permit entry in a particular access list, and the corresponding crypto map entry is tagged as cisco, connections are established if necessary. If the crypto map entry is tagged as ipsec-isakmp, IPSec is triggered. If no SA exists that IPSec can use to protect this traffic to the peer, IPSec uses IKE to negotiate with the remote peer to set up the necessary IPSec SAs on behalf of the data flow. The negotiation uses information specified in the crypto map entry as well as the data flow information from the specific access list entry. (The behavior is different for dynamic crypto map entries. See the section “Creating Dynamic Crypto Maps” section later in this module.)

If the crypto map entry is tagged as ipsec-manual, IPSec is triggered. If no SA exists that IPSec can use to protect this traffic to the peer, the traffic is dropped. In this case, the SAs are installed via the configuration, without the intervention of IKE. If the SAs did not exist, IPSec did not have all of the necessary pieces configured.

Once established, the set of SAs (outbound, to the peer) is then applied to the triggering packet and to subsequent applicable packets as those packets exit the router. “Applicable” packets are packets that match the same access list criteria that the original packet matched. For example, all applicable packets could be encrypted before being forwarded to the remote peer. The corresponding inbound SAs are used when processing the incoming traffic from that peer.

Multiple IPSec tunnels can exist between two peers to secure different data streams, with each tunnel using a separate set of SAs. For example, some data streams might be authenticated only while other data streams must both be encrypted and authenticated.

Access lists associated with IPSec crypto map entries also represent which traffic the router requires to be protected by IPSec. Inbound traffic is processed against the crypto map entries—if an unprotected packet matches a permit entry in a particular access list associated with an IPSec crypto map entry, that packet is dropped because it was not sent as an IPSec-protected packet.

Crypto map entries also include transform sets. A transform set is an acceptable combination of security protocols, algorithms, and other settings to apply to IPSec protected traffic. During the IPSec SA negotiation, the peers agree to use a particular transform set when protecting a particular data flow.
IPSect Traffic Nested to Multiple Peers

You can nest IPSec traffic to a series of IPSec peers. For example, in order for traffic to traverse multiple firewalls (these firewalls have a policy of not letting through traffic that they have not authenticated), the router must establish IPSec tunnels with each firewall in turn. The “nearer” firewall becomes the “outer” IPSec peer.

In the example shown in Figure 54, Router A encapsulates the traffic destined for Router C in IPSec (Router C is the inner IPSec peer). However, before Router A can send this traffic, it must first reencapsulate this traffic in IPSec in order to send it to Router B (Router B is the “outer” IPSec peer).

It is possible for the traffic between the “outer” peers to have one kind of protection (such as data authentication) and for traffic between the “inner” peers to have different protection (such as both data authentication and encryption).

How to Configure IPSec VPNs

Perform the tasks in the following sections to create IPSec VPNs:

- Creating Crypto Access Lists, page 8
- Creating Crypto Map Sets, page 17
- Applying Crypto Map Sets to Interfaces, page 30

Creating Crypto Access Lists

To create crypto access lists that define which traffic is protected via IPSec tunnels, you should understand the following concepts:

- Crypto Access List Overview
- When to Use the permit and deny Keywords in Crypto Access Lists
- Mirror Image Crypto Access Lists at Each IPSec Peer
- When to Use the any Keyword in Crypto Access Lists
Crypto Access List Overview

Crypto access lists are used to define which IP traffic is protected by crypto and which traffic is not protected by crypto. (These access lists are not the same as regular access lists, which determine what traffic to forward or block at an interface.) For example, access lists can be created to protect all IP traffic between Subnet A and Subnet Y or Telnet traffic between Host A and Host B.

The access lists themselves are not specific to IPSec. It is the crypto map entry referencing the specific access list that defines whether IPSec processing is applied to the traffic matching a permit in the access list.

Crypto access lists associated with IPSec crypto map entries have four primary functions:

- Select outbound traffic to be protected by IPSec (permit = protect).
- Indicate the data flow to be protected by the new SAs (specified by a single permit entry) when initiating negotiations for IPSec security associations.
- Process inbound traffic in order to filter out and discard traffic that should have been protected by IPSec.
- Determine whether or not to accept requests for IPSec security associations on behalf of the requested data flows when processing IKE negotiation from the IPSec peer.

Negotiation is performed only for ipsec-isakmp crypto map entries. In order to be accepted, if the peer initiates the IPSec negotiation, it must specify a data flow that is “permitted” by a crypto access list associated with an ipsec-isakmp crypto map entry.

If you want certain traffic to receive one combination of IPSec protection (for example, authentication only) and other traffic to receive a different combination of IPSec protection (for example, both authentication and encryption), you need to create two different crypto access lists to define the two different types of traffic. These different access lists are then used in different crypto map entries which specify different IPSec policies.

When to Use the permit and deny Keywords in Crypto Access Lists

Crypto protection can be permitted or denied for certain IP traffic in a crypto access list as follows:

- To protect IP traffic that matches the specified policy conditions in its corresponding crypto map entry, use the permit keyword in an access list.
- To refuse protection for IP traffic that matches the specified policy conditions in its corresponding crypto map entry, use the deny keyword in an access list.

Note

IP traffic is not protected by crypto if it is refused protection in all of the crypto map entries for an interface.

After the corresponding crypto map entry is defined and the crypto map set is applied to the interface, the defined crypto access list is applied to an interface the defined crypto access list is applied to an interface. Different access lists must be used in different entries of the same crypto map set. However, both inbound and outbound traffic is evaluated against the same “outbound” IPSec access list. Therefore, the access list’s criteria is applied in the forward direction to traffic exiting your router and in the reverse direction to traffic entering your router.

In Figure 55, IPSec protection is applied to traffic between Host 10.0.0.1 and Host 192.168.0.2 as the data exits Router A’s S0 interface en route to Host 192.168.0.2. For traffic from Host 10.0.0.1 to Host 192.168.0.2, the access list entry on Router A is evaluated as follows:
source = host 10.0.0.1
dest = host 192.168.0.2

For traffic from Host 192.168.0.2 to Host 10.0.0.1, that same access list entry on Router A is evaluated as follows:

source = host 192.168.0.2
dest = host 10.0.0.1

Figure 55 How Crypto Access Lists Are Applied for Processing IPSec

If you configure multiple statements for a given crypto access list that is used for IPSec, in general the first permit statement that is matched is the statement used to determine the scope of the IPSec SA. That is, the IPSec SA is set up to protect traffic that meets the criteria of the matched statement only. Later, if traffic matches a different permit statement of the crypto access list, a new, separate IPSec SA is negotiated to protect traffic matching the newly matched access list statement.

Any unprotected inbound traffic that matches a permit entry in the crypto access list for a crypto map entry flagged as IPSec is dropped, because this traffic was expected to be protected by IPSec.

Note

If you view your router’s access lists by using a command such as show ip access-lists, all extended IP access lists are shown in the command output. This display output includes extended IP access lists that are used for traffic filtering purposes and those that are used for crypto. The show command output does not differentiate between the different uses of the extended access lists.

The following example shows that if overlapping networks are used, then the most specific networks are defined in crypto sequence numbers before less specific networks are defined. In this example, the more specific network is covered by the crypto map sequence number 10, followed by the less specific network in the crypto map, which is sequence number 20.

crypto map mymap 10 ipsec-isakmp
set peer 192.168.1.1
set transform-set test
match address 101
crypto map mymap 20 ipsec-isakmp
set peer 192.168.1.2
set transform-set test
match address 102
access-list 101 permit ip 10.1.1.0 0.0.0.255 172.16.1.0 0.0.0.255
access-list 102 permit ip 10.0.0.0 0.255.255.255 172.16.0.0 0.15.255.255

The following example shows how having a deny keyword in one crypto map sequence number and having a permit keyword for the same subnet and IP range in another crypto map sequence number is not supported.

crypto map mymap 10 ipsec-isakmp
  set peer 192.168.1.1
  set transform-set test
  match address 101

access-list 101 deny ip 10.1.1.0 0.0.0.255 172.16.1.0 0.0.0.255
access-list 101 permit ip 10.0.0.0 0.255.255.255 172.16.0.0 0.15.255.255

Figure 56 shows some sample scenarios when you have mirror image access lists and when you do not have mirror image access lists.

**Mirror Image Crypto Access Lists at Each IPSec Peer**

Cisco recommends that for every crypto access list specified for a static crypto map entry that you define at the local peer, you define a “mirror image” crypto access list at the remote peer. This ensures that traffic that has IPSec protection applied locally can be processed correctly at the remote peer. (The crypto map entries themselves must also support common transforms and must refer to the other system as a peer.)
As Figure 56 indicates, IPSec SAs can be established as expected whenever the two peers’ crypto access lists are mirror images of each other. However, an IPSec SA can be established only some of the time when the access lists are not mirror images of each other. This can happen in the case where an entry in one peer’s access list is a subset of an entry in the other peer’s access list, such as shown in Cases 3 and 4 of Figure 56. IPSec SA establishment is critical to IPSec—without SAs, IPSec does not work, causing any packets matching the crypto access list criteria to be silently dropped instead of being forwarded with IPSec.

In Figure 56, an SA cannot be established in Case 4. This is because SAs are always requested according to the crypto access lists at the initiating packet’s end. In Case 4, Router N requests that all traffic between Subnet X and Subnet Y be protected, but this is a superset of the specific flows permitted by the crypto access list at Router M so the request is therefore not permitted. Case 3 works because Router M’s request is a subset of the specific flows permitted by the crypto access list at Router N.

Because of the complexities introduced when crypto access lists are not configured as mirror images at peer IPSec devices, Cisco strongly encourages you to use mirror image crypto access lists.

### When to Use the any Keyword in Crypto Access Lists

When you create crypto access lists, using the `any` keyword could cause problems. Cisco discourages the use of the `any` keyword to specify source or destination addresses.

The `any` keyword in a `permit` statement is discouraged when you have multicast traffic flowing through the IPSec interface; the `any` keyword can cause multicast traffic to fail.
Configuring Security for VPNs with IPSec

How to Configure IPSec VPNs

The `permit any any` statement is strongly discouraged, because this causes all outbound traffic to be protected (and all protected traffic sent to the peer specified in the corresponding crypto map entry) and requires protection for all inbound traffic. Then, all inbound packets that lack IPSec protection are silently dropped, including packets for routing protocols, Network Time Protocol (NTP), echo, echo response, and so on.

You need to be sure you define which packets to protect. If you must use the `any` keyword in a `permit` statement, you must preface that statement with a series of `deny` statements to filter out any traffic (that would otherwise fall within that `permit` statement) that you do not want to be protected.

Also, use of `any` keyword in access control lists (ACLs) with reverse route injection (RRI) is not supported. (For more information on RRI, see the section “Creating Crypto Map Sets.”)

**SUMMARY STEPS**

1. enable
2. configure terminal
3. `access-list access-list-number {deny | permit} protocol source source-wildcard destination destination-wildcard [log]`
   or
   `ip access-list extended name`
4. Repeat Step 3 for each crypto access list you want to create.

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 enable     | Enables privileged EXEC mode.  
| Example:          | • Enter your password if prompted. |
|Step 2 configure terminal | Enters global configuration mode. |
| Example:          | Router# configure terminal |
|Step 3 access-list access-list-number {deny | permit} protocol source source-wildcard destination destination-wildcard [log] | Specifies conditions to determine which IP packets are protected. Enable or disable crypto for traffic that matches these conditions.  
**Tip** Cisco recommends that you configure “mirror image” crypto access lists for use by IPSec and that you avoid using the `any` keyword. |
| Example: Router(config)# access-list 100 permit ip 10.0.68.0 0.0.0.255 10.1.1.0 0.0.0.255 | or \[ip access-list extended name\] |
| Step 4 — | Repeat Step 3 for each crypto access list you want to create. |
What to Do Next

After at least one crypto access list is created, a transform set needs to be defined as described in the section “Defining Transform Sets: A Combination of Security Protocols and Algorithms.”

Next the crypto access lists need to be associated to particular interfaces when you configure and apply crypto map sets to the interfaces are configured and applied (following instructions in the sections “Creating Crypto Map Sets” and “Applying Crypto Map Sets to Interfaces”).

Defining Transform Sets: A Combination of Security Protocols and Algorithms

Perform this task to define a transform set that is to be used by the IPSec peers during IPSec security association negotiations with IKE.

Restrictions

If you are specifying SEAL encryption, note the following restrictions:

- Your router and the other peer must not have hardware IPSec encryption.
- Your router and the other peer must support IPSec.
- Your router and the other peer must support the k9 subsystem.
- SEAL encryption is available only on Cisco equipment. Therefore, interoperability is not possible.

About Transform Sets

A transform set represents a certain combination of security protocols and algorithms. During the IPSec SA negotiation, the peers agree to use a particular transform set for protecting a particular data flow.

You can specify multiple transform sets, and then specify one or more of these transform sets in a crypto map entry. The transform set defined in the crypto map entry is used in the IPSec SA negotiation to protect the data flows specified by that crypto map entry’s access list.

During IPSec security association negotiations with IKE, the peers search for a transform set that is the same at both peers. When such a transform set is found, it is selected and is applied to the protected traffic as part of both peers’ IPSec SAs. (With manually established SAs, there is no negotiation with the peer, so both sides must specify the same transform set.)

If you change a transform set definition, the change is only applied to crypto map entries that reference the transform set. The change is not applied to existing security associations, but is used in subsequent negotiations to establish new SAs. If you want the new settings to take effect sooner, you can clear all or part of the SA database by using the `clear crypto sa` command.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto ipsec transform-set transform-set-name transform1 [transform2 [transform3]]`
4. `mode [tunnel | transport]`

5. `exit`

6. `clear crypto sa [peer {ip-address | peer-name} | sa map map-name | sa entry destination-address protocol spi]`

7. `show crypto ipsec transform-set [tag transform-set-name]`

### Detailed Steps

What to Do Next

After you have defined a transform set, you should create a crypto map as specified in the section “Creating Crypto Map Sets.”

Creating Crypto Map Sets

See one of the following sections, as appropriate, to help create crypto map sets:

- Creating Static Crypto Maps
- Creating Dynamic Crypto Maps
- Creating Crypto Map Entries to Establish Manual SAs

Prerequisites

Before you create crypto map entries, you should determine which type of crypto map—static, dynamic, or manual—best addresses the needs of your network. You should also understand the following concepts:

- About Crypto Maps
- Load Sharing Among Crypto Maps
- Crypto Map Guidelines

About Crypto Maps

Crypto map entries created for IPSec pull together the various parts used to set up IPSec SAs, including:

- Which traffic should be protected by IPSec (per a crypto access list)
- The granularity of the flow to be protected by a set of SAs
- Where IPSec-protected traffic should be sent (who the remote IPSec peer is)
- The local address to be used for the IPSec traffic (See the section “Applying Crypto Map Sets to Interfaces” for more details.)
- What IPSec SA should be applied to this traffic (selecting from a list of one or more transform sets)
- Whether SAs are manually established or are established via IKE
- Other parameters that might be necessary to define an IPSec SA

How Crypto Maps Work

Crypto map entries with the same crypto map name (but different map sequence numbers) are grouped into a crypto map set. Later, you apply these crypto map sets to interfaces; then, all IP traffic passing through the interface is evaluated against the applied crypto map set. If a crypto map entry sees outbound IP traffic that should be protected and the crypto map specifies the use of IKE, a SA is negotiated with the remote peer according to the parameters included in the crypto map entry; otherwise, if the crypto map entry specifies the use of manual SAs, an SA should have already been established via configuration. (If a dynamic crypto map entry sees outbound traffic that should be protected and no security association exists, the packet is dropped.)

The policy described in the crypto map entries is used during the negotiation of SAs. If the local router initiates the negotiation, it uses the policy specified in the static crypto map entries to create the offer to be sent to the specified IPSec peer. If the IPSec peer initiates the negotiation, the local router checks the policy from the static crypto map entries, as well as any referenced dynamic crypto map entries to decide whether to accept or reject the peer’s request (offer).

For IPSec to succeed between two IPSec peers, both peers’ crypto map entries must contain compatible configuration statements.

Compatible Crypto Maps: Establishing an SA

When two peers try to establish a SA, they must each have at least one crypto map entry that is compatible with one of the other peer’s crypto map entries. For two crypto map entries to be compatible, they must at least meet the following criteria:

- The crypto map entries must contain compatible crypto access lists (for example, mirror image access lists). In the case where the responding peer is using dynamic crypto maps, the entries in the local crypto access list must be “permitted” by the peer’s crypto access list.
- The crypto map entries must each identify the other peer (unless the responding peer is using dynamic crypto maps).
- The crypto map entries must have at least one transform set in common.

Load Sharing Among Crypto Maps

You can define multiple remote peers using crypto maps to allow for load sharing. Load sharing is useful because if one peer fails, there continues to be a protected path. The peer that packets are actually sent to is determined by the last peer that the router heard from (received either traffic or a negotiation request from) for a given data flow. If the attempt fails with the first peer, IKE tries the next peer on the crypto map list.

If you are not sure how to configure each crypto map parameter to guarantee compatibility with other peers, you might consider configuring dynamic crypto maps as described in the section “Creating Dynamic Crypto Maps.” Dynamic crypto maps are useful when the establishment of the IPSec tunnels is initiated by the remote peer (such as in the case of an IPSec router fronting a server). They are not useful if the establishment of the IPSec tunnels is locally initiated, because the dynamic crypto maps are policy templates, not complete statements of policy. (Although the access lists in any referenced dynamic crypto map entry are used for crypto packet filtering.)

Crypto Map Guidelines

You can apply only one crypto map set to a single interface. The crypto map set can include a combination of IPSec/IKE and IPSec/manual entries. Multiple interfaces can share the same crypto map set if you want to apply the same policy to multiple interfaces.
If you create more than one crypto map entry for a given interface, use the `seq-num` argument of each map entry to rank the map entries: the lower the `seq-num` argument, the higher the priority. At the interface that has the crypto map set, traffic is evaluated against higher priority map entries first.

You must create multiple crypto map entries for a given interface if any of the following conditions exist:

- If different data flows are to be handled by separate IPSec peers.
- If you want to apply different IPSec security to different types of traffic (to the same or separate IPSec peers); for example, if you want traffic between one set of subnets to be authenticated, and traffic between another set of subnets to be both authenticated and encrypted. In this case the different types of traffic should have been defined in two separate access lists, and you must create a separate crypto map entry for each crypto access list.
- If you are not using IKE to establish a particular set of security associations, and want to specify multiple access list entries, you must create separate access lists (one per `permit` entry) and specify a separate crypto map entry for each access list.

### Creating Static Crypto Maps

When IKE is used to establish SAs, the IPSec peers can negotiate the settings they use for the new security associations. This means that you can specify lists (such as lists of acceptable transforms) within the crypto map entry.

Perform this task to create crypto map entries that use IKE to establish the SAs.

### SUMMARY STEPS

1. enable
2. configure terminal
3. crypto map map-name seq-num ipsec-isakmp
4. match address access-list-id
5. set peer {hostname | ip-address}
6. set transform-set transform-set-name1 [transform-set-name2...transform-set-name6]
7. set security-association lifetime {seconds seconds | kilobytes kilobytes}
8. set security-association level per-host
9. set pfs [group1 | group2 | group5]
10. exit
11. exit
12. show crypto map [interface interface | tag map-name]
## How to Configure IPSec VPNs

### DETAILED STEPS

<table>

</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router&gt; enable</td>
</tr>
<tr>
<td>Enables privileged EXEC mode.</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>configure terminal</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router# configure terminal</td>
</tr>
<tr>
<td>Enters global configuration mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>crypto map map-name seq-num ipsec-isakmp</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router(config)# crypto map static-map 1 ipsec-isakmp</td>
</tr>
<tr>
<td>Names the crypto map entry to create (or modify), and enters crypto map configuration mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>match address access-list-id</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router(config-crypto-m)# match address vpn-tunnel</td>
</tr>
<tr>
<td>Names an extended access list. This access list determines which traffic should be protected by IPSec and which traffic should not be protected by IPSec security in the context of this crypto map entry.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td>set peer (hostname</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router(config-crypto-m)# set-peer 192.168.101.1</td>
</tr>
<tr>
<td>Specifies a remote IPSec peer, the peer to which IPSec protected traffic can be forwarded. Repeat for multiple remote peers.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td>set transform-set transform-set-name1 [transform-set-name2...transform-set-name6]</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router(config-crypto-m)# set transform-set aesset</td>
</tr>
<tr>
<td>Specifies which transform sets are allowed for this crypto map entry. List multiple transform sets in order of priority (highest priority first).</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>set security-association lifetime seconds seconds</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router (config-crypto-m)# set security-association lifetime seconds 2700</td>
</tr>
<tr>
<td>(Optional) Specifies a SA lifetime for the crypto map entry. By default, the SAs of the crypto map are negotiated according to the global lifetimes.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>set security-association level per-host</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Router(config-crypto-m)# set security-association level per-host</td>
</tr>
<tr>
<td>(Optional) Specifies that separate SAs should be established for each source and destination host pair. By default, a single IPSec “tunnel” can carry traffic for multiple source hosts and multiple destination hosts.</td>
<td></td>
</tr>
</tbody>
</table>

**Caution** Use this command with care, because multiple streams between given subnets can rapidly consume resources.
Troubleshooting Tips

Certain configuration changes take effect only when negotiating subsequent SAs. If you want the new settings to take immediate effect, you must clear the existing SAs so that they are re-established with the changed configuration. If the router is actively processing IPSec traffic, it is desirable to clear only the portion of the SA database that would be affected by the configuration changes (that is, clear only the SAs established by a given crypto map set). Clearing the full SA database should be reserved for large-scale changes, or when the router is processing very little other IPSec traffic.

To clear IPSec SAs, use the `clear crypto sa` command with appropriate parameters. (Omitting all parameters clears out the full SA database, which clears active security sessions.)

What to Do Next

After you have successfully created a static crypto map, you must apply the crypto map set to each interface through which IPSec traffic flows. To complete this task, see the section “Applying Crypto Map Sets to Interfaces.”

Creating Dynamic Crypto Maps

Dynamic crypto maps can ease IPSec configuration and are recommended for use with networks where the peers are not always predetermined. To create dynamic crypto maps, you should understand the following concepts:

- Dynamic Crypto Maps Overview
- Tunnel Endpoint Discovery (TED)
Dynamic Crypto Maps Overview

Dynamic crypto maps are only available for use by IKE.

A dynamic crypto map entry is essentially a static crypto map entry without all the parameters configured. It acts as a policy template where the missing parameters are later dynamically configured (as the result of an IPSec negotiation) to match a remote peer’s requirements. This allows remote peers to exchange IPSec traffic with the router even if the router does not have a crypto map entry specifically configured to meet all of the remote peer’s requirements.

Dynamic crypto maps are not used by the router to initiate new IPSec security associations with remote peers. Dynamic crypto maps are used when a remote peer tries to initiate an IPSec security association with the router. Dynamic crypto maps are also used in evaluating traffic.

A dynamic crypto map set is included by reference as part of a crypto map set. Any crypto map entries that reference dynamic crypto map sets should be the lowest priority crypto map entries in the crypto map set (that is, have the highest sequence numbers) so that the other crypto map entries are evaluated first; that way, the dynamic crypto map set is examined only when the other (static) map entries are not successfully matched.

If the router accepts the peer’s request, at the point that it installs the new IPSec security associations it also installs a temporary crypto map entry. This entry is filled in with the results of the negotiation. At this point, the router performs normal processing, using this temporary crypto map entry as a normal entry, even requesting new security associations if the current ones are expiring (based upon the policy specified in the temporary crypto map entry). Once the flow expires (that is, all of the corresponding security associations expire), the temporary crypto map entry is then removed.

For both static and dynamic crypto maps, if unprotected inbound traffic matches a permit statement in an access list, and the corresponding crypto map entry is tagged as “IPSec,” then the traffic is dropped because it is not IPSec-protected. (This is because the security policy as specified by the crypto map entry states that this traffic must be IPSec-protected.)

For static crypto map entries, if outbound traffic matches a permit statement in an access list and the corresponding SA is not yet established, the router initiates new SAs with the remote peer. In the case of dynamic crypto map entries, if no SA existed, the traffic would simply be dropped (because dynamic crypto maps are not used for initiating new SAs).

Note

Use care when using the any keyword in permit entries in dynamic crypto maps. If it is possible for the traffic covered by such a permit entry to include multicast or broadcast traffic, the access list should include deny entries for the appropriate address range. Access lists should also include deny entries for network and subnet broadcast traffic, and for any other traffic that should not be IPSec protected.

Restrictions for Dynamic Crypto Maps

Dynamic crypto map entries specify crypto access lists that limit traffic for which IPSec SAs can be established. A dynamic crypto map entry that does not specify an access list is ignored during traffic filtering. A dynamic crypto map entry with an empty access list causes traffic to be dropped. If there is only one dynamic crypto map entry in the crypto map set, it must specify acceptable transform sets.

Tunnel Endpoint Discovery (TED)

Defining a dynamic crypto map allows only the receiving router to dynamically determine an IPSec peer. TED allows the initiating router to dynamically determine an IPSec peer for secure IPSec communications.
Dynamic TED helps to simplify IPSec configuration on the individual routers within a large network. Each node has a simple configuration that defines the local network that the router is protecting and the required IPSec transforms.

To have a large, fully-meshed network without TED, each peer needs to have static crypto maps to every other peer in the network. For example, if there are 100 peers in a large, fully-meshed network, each router needs 99 static crypto maps for each of its peers. With TED, only a single dynamic crypto map with TED enabled is needed because the peer is discovered dynamically. Thus, static crypto maps do not need to be configured for each peer.

Note: TED helps only in discovering peers; otherwise, TED does not function any differently than normal IPSec. TED does not improve the scalability of IPSec (in terms of performance or the number of peers or tunnels).

Figure 57 and the corresponding steps explain a sample TED network topology.

**Figure 57**  
*Tunnel Endpoint Discovery Sample Network Topology*

---

**Step 1**  
Host A sends a packet that is destined for Host B.

**Step 2**  
Router 1 intercepts and reads the packet. According to the IKE policy, Router 1 contains the following information: the packet must be encrypted, there are no SAs for the packet, and TED is enabled. Thus, Router 1 drops the packet and sends a TED probe into the network. (The TED probe contains the IP address of Host A (as the source IP address) and the IP address of Host B (as the destination IP address) embedded in the payload.

**Step 3**  
Router 2 intercepts the TED probe and checks the probe against the ACLs that it protects; after the probe matches an ACL, it is recognized as a TED probe for proxies that the router protects. It then sends a TED reply with the IP address of Host B (as the source IP address) and the IP address of Host A (as the destination IP address) embedded in the payload.

**Step 4**  
Router 1 intercepts the TED reply and checks the payloads for the IP address and half proxy of Router 2. It then combines the source side of its proxy with the proxy found in the second payload and initiates an IKE session with Router 2; thereafter, Router 1 initiates an IPSec session with Router 2.

Note: IKE cannot occur until the peer is identified.
TED Versions

The following table lists the available TED versions:

<table>
<thead>
<tr>
<th>Version</th>
<th>First Available Release</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEDv1</td>
<td>12.0(5)T</td>
<td>Performs basic TED functionality on nonredundant networks.</td>
</tr>
<tr>
<td>TEDv2</td>
<td>12.1M</td>
<td>Enhanced to work with redundant networks with paths through multiple security gateways between the source and the destination.</td>
</tr>
<tr>
<td>TEDv3</td>
<td>12.2M</td>
<td>Enhanced to allow non-IP-related entries to be used in the access list.</td>
</tr>
</tbody>
</table>

TED Restrictions

TED has the following restrictions:

- It is Cisco proprietary.
- It is available only on dynamic crypto maps. (The dynamic crypto map template is based on the dynamic crypto map performing peer discovery. Although there are no access-list restrictions on the dynamic crypto map template, the dynamic crypto map template should cover data sourced from the protected traffic and the receiving router using the any keyword. When using the any keyword, include explicit deny statements to exempt routing protocol traffic prior to entering the permit any command.)
- TED works only in tunnel mode; that is, it does not work in transport mode.
- It is limited by the performance and scalability of limitation of IPSec on each individual platform.

**Note** Enabling TED slightly decreases the general scalability of IPSec because of the set-up overhead of peer discovery, which involves an additional “round-trip” of IKE messages (TED probe and reply). Although minimal, the additional memory used to store data structures during the peer discovery stage adversely affects the general scalability of IPSec.

- The IP addresses must be able to be routed within the network.
- The access list used in the crypto map for TED can only contain IP-related entries—TCP, UDP, or any other protocol cannot be used in the access list.

**Note** This restriction is no longer applicable in TEDv3.

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto dynamic-map dynamic-map-name dynamic-seq-num
4. set transform-set transform-set-name 1 [transform-set-name2...transform-set-name6]
5. match address access-list-id
6. set peer {hostname | ip-address}
7. set security-association lifetime {seconds seconds | kilobytes kilobytes}
8. `set pfs [group1 | group2 | group5]`
9. `exit`
10. `exit`
11. `show crypto dynamic-map [tag map-name]`
12. `configure terminal`
13. `crypto map map-name seq-num ipsec-isakmp dynamic dynamic-map-name [discover]`

**DETAILED STEPS**

### Command Purpose

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>match address access-list-id</td>
<td>(Optional) Accesses list number or name of an extended access list. This access list determines which traffic should be protected by IPSec and which traffic should not be protected by IPSec security in the context of this crypto map entry. <strong>Note</strong> Although access-lists are optional for dynamic crypto maps, they are highly recommended. If this is configured, the data flow identity proposed by the IPSec peer must fall within a <strong>permit</strong> statement for this crypto access list. If this is not configured, the router accepts any data flow identity proposed by the IPSec peer. However, if this is configured but the specified access list does not exist or is empty, the router drops all packets. This is similar to static crypto maps because they also require that an access list be specified. Care must be taken if the <strong>any</strong> keyword is used in the access list, because the access list is used for packet filtering as well as for negotiation. You must configure a match address; otherwise, the behavior is not secure, and you cannot enable TED because packets are sent in the clear (unencrypted.)</td>
</tr>
<tr>
<td>6</td>
<td>set peer {hostname</td>
<td>ip-address}</td>

</tbody>
</table>
Certain configuration changes take effect only when negotiating subsequent SAs. If you want the new settings to take immediate effect, you must clear the existing SAs so that they are reestablished with the changed configuration. If the router is actively processing IPSec traffic, it is desirable to clear only the portion of the SA database that would be affected by the configuration changes (that is, clear only the SAs established by a given crypto map set). Clearing the full SA database should be reserved for large-scale changes, or when the router is processing very little other IPSec traffic.

To clear IPSec SAs, use the `clear crypto sa` command with appropriate parameters. (Omitting all parameters clears the full SA database, which clears active security sessions.)

**Troubleshooting Tips**

**What to Do Next**

After you have successfully created a crypto map set, you must apply the crypto map set to each interface through which IPSec traffic flows. To complete this task, see the section “Applying Crypto Map Sets to Interfaces.”

**Creating Crypto Map Entries to Establish Manual SAs**

The use of manual security associations is a result of a prior arrangement between the users of the local router and the IPSec peer. The two parties may begin with manual SAs and then move to using SAs established via IKE, or the remote party’s system may not support IKE. If IKE is not used for establishing the SAs, there is no negotiation of SAs, so the configuration information in both systems must be the same in order for traffic to be processed successfully by IPSec.

The local router can simultaneously support manual and IKE-established SAs, even within a single crypto map set.
There is very little reason to disable IKE on the local router (unless the router only supports manual SAs, which is unlikely).

**Note**
Access lists for crypto map entries tagged as `ipsec-manual` are restricted to a single `permit` entry and subsequent entries are ignored. In other words, the SAs established by that particular crypto map entry are only for a single data flow. To be able to support multiple manually established SAs for different kinds of traffic, define multiple crypto access lists, and then apply each one to a separate `ipsec-manual` crypto map entry. Each access list should include one `permit` statement defining what traffic to protect.

To create crypto map entries to establish manual SAs (that is, when IKE is not used to establish the SAs), perform this task.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto map map-name seq-num ipsec-manual`
4. `match address access-list-id`
5. `set peer [hostname \ ip-address]`
6. `set transform-set transform-set-name`
7. `set session-key inbound ah spi hex-key-string`
   
   or
   
   `set session-key outbound ah spi hex-key-string`
8. `set session-key inbound esp spi cipher hex-key-string [authenticator hex-key-string]`
   
   or
   
   `set session-key outbound esp spi cipher hex-key-string [authenticator hex-key-string]`
9. `exit`
10. `exit`
11. `show crypto map [interface interface | tag map-name]`

Troubleshooting Tips

For manually established SAs, you must clear and reinitialize the SAs for the changes to take effect. To clear IPSec SAs, use the `clear crypto sa` command with appropriate parameters. (Omitting all parameters clears the full SA database, which clears active security sessions.)

What to Do Next

After you have successfully created a crypto map set, you must apply the crypto map set to each interface through which IPSec traffic flows. To complete this task, see the section “Applying Crypto Map Sets to Interfaces.”

Applying Crypto Map Sets to Interfaces

You need to apply a crypto map set to each interface through which IPSec traffic flows. Applying the crypto map set to an interface instructs the router to evaluate all the interface’s traffic against the crypto map set and to use the specified policy during connection or security association negotiation on behalf of traffic to be protected by crypto.

Perform this task to apply a crypto map to an interface.

Redundant Interfaces Sharing the Same Crypto Map

For redundancy, you could apply the same crypto map set to more than one interface. The default behavior is as follows:

- Each interface has its own piece of the security association database.
- The IP address of the local interface is used as the local address for IPSec traffic originating from or destined to that interface.

If you apply the same crypto map set to multiple interfaces for redundancy purposes, you need to specify an identifying interface. One suggestion is to use a loopback interface as the identifying interface. This has the following effects:

- The per-interface portion of the IPSec security association database is established one time and shared for traffic through all the interfaces that share the same crypto map.
The IP address of the identifying interface is used as the local address for IPSec traffic originating from or destined to those interfaces sharing the same crypto map set.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `crypto map map-name`
5. `exit`
6. `crypto map map-name local-address interface-id`
7. `exit`
8. `show crypto map [interface interface]`

Glossary

anti-replay—Security service where the receiver can reject old or duplicate packets to protect itself against replay attacks. IPSec provides this optional service by use of a sequence number combined with the use of data authentication. Cisco IOS IPSec provides this service whenever it provides the data authentication service, except for manually established SAs (that is, SAs established by configuration and not by IKE).

data authentication—Verification of the integrity and origin of the data.
Data authentication can refer either to integrity alone or to both of these concepts (although data origin authentication is dependent upon data integrity).

data confidentiality—Security service in which the protected data cannot be observed.
data flow—Grouping of traffic, identified by a combination of source address or mask; destination address or mask; IP next protocol field, and source and destination ports, where the protocol and port fields can have the values of any. IPSec protection is applied to data flows.

peer—in the context of this module, a “peer” is a router or other device that participates in IPSec.

PFS—perfect forward secrecy. Cryptographic characteristic associated with a derived shared secret value. With PFS, if one key is compromised, previous and subsequent keys are not compromised, because subsequent keys are not derived from previous keys.

SA—security association. Description of how two or more entities use security services in the context of a particular security protocol (AH or ESP) to communicate securely on behalf of a particular data flow. The transform and the shared secret keys are used for protecting the traffic.

SPI—security parameter index. A number which, together with a destination IP address and security protocol, uniquely identifies a particular security association. Without IKE, the SPI is manually specified for each security association.

transform—List of operations performed on a dataflow to provide data authentication, data confidentiality, and data compression. For example, one transform is the ESP protocol with the HMAC-MD5 authentication algorithm; another transform is the AH protocol with the 56-bit DES encryption algorithm and the ESP protocol with the HMAC-SHA authentication algorithm.

tunnel—in the context of this module, “tunnel” is a secure communication path between two peers, such as two routers. It does not refer to using IPSec in tunnel mode.

Refer to Internetworking Terms and Acronyms for terms not included in this glossary.

Feature Information for Security for VPNs with IPSec

Table 47 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For details on when support for a specific command was introduced, see the command reference documentation.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at http://www.cisco.com/go/fn. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.

Table 47 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Cisco Easy VPN Remote

First Published: November 25, 2002
Last Updated: November 4, 2008

This document provides information on configuring and monitoring the Cisco Easy VPN Remote feature to create IPsec Virtual Private Network (VPN) tunnels between a supported router and an Easy VPN server (Cisco IOS router, VPN 3000 concentrator, or Cisco PIX Firewall) that supports this form of IPsec encryption and decryption.

For the benefits of this feature, see the section “Benefits of the Cisco Easy VPN Remote Feature.”

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “Feature Information for Easy VPN Remote” section on page 108.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to http://www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites for Cisco Easy VPN Remote

Cisco Easy VPN Remote Feature

- A Cisco 800 series router running Cisco IOS Release 12.2(15)T, 12.3(2)T, 12.3(4)T, 12.3(7)T, or 12.3(7)XR2 configured as a Cisco Easy VPN remote.
- A Cisco 1700 series router running Cisco IOS Release 12.2(15)T, 12.3(2)T, 12.3(4)T, 12.3(7)T, or 12.3(7)XR, configured as a Cisco Easy VPN remote.
- A Cisco 1800 series fixed configuration router running Cisco IOS Release 12.3(8)YI.
- A Cisco uBR905 or Cisco uBR925 cable access router running Cisco IOS Release 12.2(15)T, configured as a Cisco Easy VPN remote.
- Another Cisco router or VPN concentrator that supports the Cisco Easy VPN Server feature and that is configured as a Cisco IOS Easy VPN server. See the “Required Easy VPN Servers” section for a detailed list.

Reactivate Primary Peer Feature

- An existing Easy VPN remote configuration can be enhanced to accommodate the Reactivate Primary Peer feature using the peer command (and default keyword) and the idle-time command. After the tunnel between the Easy VPN remote and a nondefault peer is working, the Reactivate Primary Peer features takes effect, that is, the Easy VPN remote periodically tries to check the connectivity with the primary peer. Any time the Easy VPN remote detects that the link is working, the Easy VPN remote tears down the existing connection and brings up the tunnel with the primary peer.

Restrictions for Cisco Easy VPN Remote

Required Easy VPN Servers
The Cisco Easy VPN Remote feature requires that the destination peer be a Cisco IOS Easy VPN server or VPN concentrator that supports the Cisco Easy VPN Server feature. At the time of publication, servers or concentrators that support this feature include the following platforms when running the indicated software releases:

- Cisco 806, Cisco 826, Cisco 827, Cisco 828, Cisco 831, Cisco 836, and Cisco 837 routers—Cisco IOS Release 12.2(8)T or later release. Cisco 800 series routers are not supported in Cisco IOS Release 12.3(7)XR, but they are supported in Cisco IOS Release 12.3(7)XR2.
- Cisco 870 series—Cisco IOS Release 12.3(8)YI.
- Cisco 1700 series—Cisco IOS Release 12.2(8)T or later release.
- Cisco 1800 series fixed configuration router—Cisco IOS Release 12.3(8)YI.
- Cisco 1812 router—Cisco IOS Release 12.3(8)YH.
- Cisco 2600 series—Cisco IOS Release 12.2(8)T or later release.
- Cisco 3620—Cisco IOS Release 12.2(8)T or later release.
- Cisco 3640—Cisco IOS Release 12.2(8)T or later release.
- Cisco 3660—Cisco IOS Release 12.2(8)T or later release.
- Cisco 7100 series VPN routers—Cisco IOS Release 12.2(8)T or later release.
- Cisco 7200 series routers—Cisco IOS Release 12.2(8)T or later release.
Cisco Easy VPN Remote

Restrictions for Cisco Easy VPN Remote

- Cisco 7500 series routers—Cisco IOS Release 12.2(8)T or later release.
- Cisco PIX 500 series—Software Release 6.2 or later release.
- Cisco VPN 3000 series—Software Release 3.11 or later release.

**Only ISAKMP Policy Group 2 Supported on Easy VPN Servers**
The Unity Protocol supports only Internet Security Association Key Management Protocol (ISAKMP) policies that use group 2 (1024-bit Diffie-Hellman) Internet Key Exchange (IKE) negotiation, so the Easy VPN server being used with the Cisco Easy VPN Remote feature must be configured for a group 2 ISAKMP policy. The Easy VPN server cannot be configured for ISAKMP group 1 or group 5 when being used with a Cisco Easy VPN client.

**Transform Sets Supported**
To ensure a secure tunnel connection, the Cisco Easy VPN Remote feature does not support transform sets that provide encryption without authentication (ESP-DES and ESP-3DES) or transform sets that provide authentication without encryption (ESP-NULL ESP-SHA-HMAC and ESP-NULL ESP-MD5-HMAC).

**Note**
The Cisco Unity Client Protocol does not support Authentication Header (AH) authentication, but Encapsulation Security Protocol (ESP) is supported.

**Dial Backup for Easy VPN Remotes**
Line-status–based backup is not supported in this feature.

**Network Address Translation Interoperability Support**
Network Address Translation (NAT) interoperability is not supported in client mode with split tunneling.

**Multicast and Static NAT**
Multicast and static NAT are supported only for Easy VPN remotes using dynamic virtual tunnel interfaces (DVTIs).

**Virtual IPsec Interface Restrictions**
- For the Virtual IPsec Interface Support feature to work, virtual templates support is needed.
- If you are using a virtual tunnel interface on the Easy VPN remote device, it is recommended that you configure the server for a virtual tunnel interface.

**Dual Tunnel Support**
The following restrictions apply if you are using dual tunnels that share common inside and outside interfaces:
- If dual tunnels are configured, one of the tunnels should have a split tunnel configured on the server.
- Web Intercept can be configured for only one of the tunnels. Web Intercept should not be used for the voice tunnel.
- Web Intercept cannot be used for IP phones until authorization proxy becomes aware of how to bypass the IP phone.
- Some features, such as Pushing a Configuration URL Through a Mode-Configuration Exchange, can be used only through a single tunnel.
cTCP Support on Easy VPN Clients

- cTCP listens on only up to 10 ports.
- If there are other applications registered for the port on which cTCP is enabled, those applications will not work.

Information About Cisco Easy VPN Remote

To configure the Cisco Easy VPN Remote features, you should understand the following concepts:

- Benefits of the Cisco Easy VPN Remote Feature, page 4
- Cisco Easy VPN Remote Overview, page 4
- Modes of Operation, page 5
- Authentication, page 8
- Tunnel Activation Options, page 17
- Dead Peer Detection Stateless Failover Support, page 18
- Cisco Easy VPN Remote Features, page 19

Benefits of the Cisco Easy VPN Remote Feature

- Allows dynamic configuration of end-user policy, requiring less manual configuration by end users and field technicians, thus reducing errors and further service calls.
- Allows the provider to change equipment and network configurations as needed, with little or no reconfiguration of the end-user equipment.
- Provides for centralized security policy management.
- Enables large-scale deployments with rapid user provisioning.
- Eliminates the need for end users to purchase and configure external VPN devices.
- Eliminates the need for end users to install and configure Easy VPN Client software on their PCs.
- Offloads the creation and maintenance of the VPN connections from the PC to the router.
- Reduces interoperability problems between the different PC-based software VPN clients, external hardware-based VPN solutions, and other VPN applications.
- Sets up a single IPsec tunnel regardless of the number of multiple subnets that are supported and the size of the split-include list.

Cisco Easy VPN Remote Overview

Cable modems, xDSL routers, and other forms of broadband access provide high-performance connections to the Internet, but many applications also require the security of VPN connections that perform a high level of authentication and that encrypt the data between two particular endpoints. However, establishing a VPN connection between two routers can be complicated and typically requires tedious coordination between network administrators to configure the VPN parameters of the two routers.
The Cisco Easy VPN Remote feature eliminates much of this tedious work by implementing Cisco Unity Client Protocol, which allows most VPN parameters to be defined at a Cisco IOS Easy VPN server. This server can be a dedicated VPN device, such as a Cisco VPN 3000 concentrator or a Cisco PIX Firewall or a Cisco IOS router that supports the Cisco Unity Client Protocol.

After the Cisco Easy VPN server has been configured, a VPN connection can be created with minimal configuration on an Easy VPN remote, such as a Cisco 800 series router or a Cisco 1700 series router. When the Easy VPN remote initiates the VPN tunnel connection, the Cisco Easy VPN server pushes the IPsec policies to the Easy VPN remote and creates the corresponding VPN tunnel connection.

The Cisco Easy VPN Remote feature provides for automatic management of the following details:

- Negotiating tunnel parameters, such as addresses, algorithms, and lifetime.
- Establishing tunnels according to the parameters that were set.
- Automatically creating the NAT or Port Address Translation (PAT) and associated access lists that are needed, if any.
- Authenticating users, that is, ensuring that users are who they say they are by way of usernames, group names, and passwords.
- Managing security keys for encryption and decryption.
- Authenticating, encrypting, and decrypting data through the tunnel.

**Modes of Operation**

The Cisco Easy VPN Remote feature supports three modes of operation: client, network extension, and network extension plus:

- **Client**—Specifies that NAT or PAT be done so that the PCs and other hosts at the remote end of the VPN tunnel form a private network that does not use any IP addresses in the IP address space of the destination server.

  An enhancement has been made so that the IP address that is received via mode configuration is automatically assigned to an available loopback interface. The IPsec Security Associations (SAs) for this IP address are automatically created by Easy VPN Remote. The IP address is typically used for troubleshooting (using ping, Telnet, and Secure Shell).

- **Network extension**—Specifies that the PCs and other hosts at the client end of the VPN tunnel should be given IP addresses that are fully routable and reachable by the destination network over the tunneled network so that they form one logical network. PAT is not used, which allows the client PCs and hosts to have direct access to the PCs and hosts at the destination network.

- **Network extension plus (mode network-plus)**—Identical to network extension mode with the additional capability of being able to request an IP address via mode configuration and automatically assign it to an available loopback interface. The IPsec SAs for this IP address are automatically created by Easy VPN Remote. The IP address is typically used for troubleshooting (using ping, Telnet, and Secure Shell).

All modes of operation also optionally support split tunneling, which allows secure access to corporate resources through the VPN tunnel while also allowing Internet access through a connection to an Internet service provider (ISP) or other service—thereby eliminating the corporate network from the path for web access.
Client Mode and Network Extension Mode Scenarios

Figure 1 illustrates the client mode of operation. In this example, the Cisco 831 router provides access to two PCs, which have IP addresses in the 10.0.0.0 private network space. These PCs connect to the Ethernet interface on the Cisco 831 router, which also has an IP address in the 10.0.0.0 private network space. The Cisco 831 router performs NAT or PAT translation over the VPN tunnel so that the PCs can access the destination network.

*Note* The diagram in Figure 1 could also represent a split tunneling connection, in which the client PCs can access public resources in the global Internet without including the corporate network in the path for the public resources.

Figure 2 also illustrates the client mode of operation, in which a VPN concentrator provides destination endpoints to multiple xDSL clients. In this example, Cisco 800 series routers provide access to multiple small business clients, each of which uses IP addresses in the 10.0.0.0 private network space. The Cisco 800 series routers perform NAT or PAT translation over the VPN tunnel so that the PCs can access the destination network.
Figure 3 illustrates the network extension mode of operation. In this example, the Cisco 831 router and Cisco 1700 series router both act as Cisco Easy VPN remote devices, connecting to a Cisco VPN 3000 concentrator.

The client hosts are given IP addresses that are fully routable by the destination network over the tunnel. These IP addresses could be either in the same subnet space as the destination network or in separate subnets, assuming that the destination routers are configured to properly route those IP addresses over the tunnel.

In this example, the PCs and hosts attached to the two routers have IP addresses that are in the same address space as the destination enterprise network. The PCs connect to the Ethernet interface of the Cisco 831 router, which also has an IP address in the enterprise address space. This scenario provides a seamless extension of the remote network.
Authentication

The Cisco Easy VPN Remote feature supports a two-stage process for authenticating the remote router to the central concentrator. The first step is Group Level Authentication and is part of the control channel creation. In this first stage, two types of authentication credentials can be used: either preshared keys or digital certificates. The following paragraphs provide details about these options.

The second authentication step is called Extended Authentication or Xauth. In this step, the remote side (in this case the Easy VPN router) submits a username and password to the central site router. This step is the same process as that which occurs when a user of the Cisco VPN software client on a PC enters his or her username and password to activate his or her VPN tunnel. When using the router, the difference is that the router itself is being authenticated to the network, not a PC with Cisco VPN Client software. Xauth is an optional step (it can be disabled) but is normally enabled to improve security. After Xauth is successful and the tunnel comes up, all PCs behind the Easy VPN remote router have access to the tunnel.

If Xauth is enabled, it is key to decide how to input the username and password. There are two options. The first option is to store the Xauth username and password in the configuration file of the router. This option is typically used if the router is shared between several PCs and the goal is to keep the VPN tunnel up all the time (see the section “Automatic Activation”) or to have the router automatically bring up the tunnel whenever there is data to be sent (see the section “Traffic-Triggered Activation”). An example of this application is a branch office situation, in which the users in the branch office want the VPN tunnel to be available whenever they have data to send and do not want to have to do anything special to activate the VPN tunnel. If the PCs in the branch office must be individually authenticated on the basis of the ID of each user, the correct configuration is to put the Easy VPN router in Automatic Activation mode to keep the tunnel “up” all the time and to use Cisco IOS Authentication Proxy or 802.1x to authenticate the individual PCs. Because the tunnel is always up, Authentication Proxy or 802.1x can access a central site user database such as AAA/RADIUS to authenticate the individual user requests as they are submitted by PC users. (See the “Related Documents” sections “General information on IPsec and VPN” for a reference to configuring Authentication Proxy and “802.1x authentication” for a reference to configuring 802.1x authentication.)
The second option for entry of the Xauth username and password is not to store it on the router. Instead, a PC user who is connected to the router is presented with a special web page that allows the user to manually enter the username and password (see the section “Manual Activation”). The router sends the username and password to the central site concentrator, and if the username and password are correct, the tunnel comes up. The typical application for this configuration is a teleworker network. The teleworker wants to control when the tunnel is up and has to enter his or her personal user credentials (which could include one-time passwords) to activate the tunnel. Also, the network administrator may want teleworker tunnels up only when someone is using them to conserve resources on the central concentrators. (See the section “Web-Based Activation” for details about this configuration.)

The Xauth username and password can also be manually entered from the command-line interface (CLI) of the router. This method is not recommended for most situations because the user must first log in to the router (and needs a user ID on the router to do so). However, it can be useful for network administrators during troubleshooting.

### Using Preshared Keys

Using preshared keys, each peer is aware of the key of the other peer. Preshared keys are displayed in running configurations, so they can be seen by anyone (referred to as clear format). When a more secure type of authentication is required, Cisco software also supports another type of preshared key: the encrypted preshared key.

Using an encrypted preshared key for authentication allows you to securely store plain-text passwords in type 6 (encrypted) format in NVRAM. A group preshared key can be preconfigured on both VPN-tunnel peers. The encrypted form of the keyword can be seen in the running configuration, but the actual keyword is not visible. (For more information about encrypted preshared keys, see Encrypted Preshared Key.)

### Using Digital Certificates

Digital certificates provide for the support of Rivest, Shamir, and Adelman (RSA) signatures on Easy VPN remote devices. The support is provided through a RSA certificate that can be stored on or off the remote device.

*Note*

The recommended timeout for Easy VPN using digital certificates is 40 seconds.

For more information about digital certificates, see the Easy VPN Remote RSA Signature Support feature guide, Release 12.3(7)T1.

### Using Xauth

Xauth is an additional level of authentication that can be used. Xauth is applicable when either group preshared keys or digital certificates are used. Xauth credentials can be entered using a web interface manager, such as Security Device Manager (SDM), or using the CLI. (See the section “Cisco Easy VPN Remote Web Managers.”)

The Save Password feature allows the Xauth username and password to be saved in the Easy VPN Remote configuration so that you are not required to enter the username and password manually. One-Time Passwords (OTPs) are not supported by the Save Password feature and must be entered manually when Xauth is requested. The Easy VPN server must be configured to “Allow Saved Passwords.” (For more information about how to configure the Save Password feature, see the section “Dead Peer Detection Periodic Message Option.”)
Xauth is controlled by the Easy VPN server. When the Cisco IOS Easy VPN server requests Xauth authentication, the following messages are displayed on the console of the router:

```
EZVPN: Pending XAuth Request, Please enter the following command:
crypto ipsec client ezvpn xauth
```

When you see this message, you can provide the necessary user ID, password, and other information by entering the `crypto ipsec client ezvpn connect` command and responding to the prompts that follow.

The recommended Xauth timeout is 50 seconds or fewer.

**Note**

The timeout for entering the username and password is determined by the configuration of the Cisco IOS Easy VPN server. For servers running Cisco IOS software, this timeout value is specified by the `crypto isakmp xauth timeout` command.

**Web-Based Activation**

Web-Based Activation provides a user-friendly method for a remote teleworker to authenticate the VPN tunnel between his or her remote Easy VPN router and the central site router. This feature allows administrators to set up their remote LANs so that the initial HTTP request that is coming from any of the remote PCs is intercepted by the remote Easy VPN router. A login page is returned to the user, whereby the user may enter credentials to authenticate the VPN tunnel. After the VPN tunnel comes up, all users behind this remote site can access the corporate LAN without being reprompted for the username and password. Alternatively, the user may choose to bypass the VPN tunnel and connect only to the Internet, in which case a password is not required.

A typical application for web-based activation is a home teleworker who brings up the Easy VPN tunnel only when he or she needs to connect to the corporate LAN. If the remote teleworker is not present, other members of the household (such as a spouse or children) can use the Internet Only option to browse the Internet without activating the VPN tunnel. **Figure 4** shows a typical scenario for web-based activation.

**Figure 4  Typical Web-Based Activation Scenario**

Entering the Xauth credentials brings up the tunnel for all users who are behind this remote site. After the tunnel is up, any additional PCs that are behind the remote site do not get prompted for Xauth credentials. Web-Based Activation is an authentication to bring up the VPN tunnel for all remote PCs and cannot be considered individual user authentication. Individual user authentication for VPN tunnel access is available using the Cisco IOS Authentication Proxy or 802.1x features, which can be
configured on the remote Easy VPN router. (See the “Related Documents” sections “General information on IPsec and VPN” for a reference to configuring Authentication Proxy and “802.1x authentication” for a reference to configuring 802.1x authentication.)

To configure web-based activation, see the section “Configuring Web-Based Activation.”

The following sections show the various screen shots that a remote teleworker sees when the Web-Based Activation feature is turned on:

- Web-Based Activation Portal Page, page 11
- VPN Authentication Bypass, page 12
- VPN Tunnel Authentication, page 13
- Successful Authentication, page 14
- Deactivation, page 15

### Web-Based Activation Portal Page

Figure 5 is an example of a web-based activation portal page. The user may choose to connect to the corporate LAN by clicking Connect Now or he or she may choose to connect only to the Internet by clicking Internet Only.

**Note**

If the user chooses to connect only to the Internet, a password is not required.

**Figure 5 Portal Page**
VPN Authentication Bypass

Figure 6 is an example of a web-based activation in which the user chose to connect only to the Internet by clicking the Internet Only option. This option is most useful for household members who need to browse the Internet while the remote teleworker is not available to authenticate the VPN tunnel for corporate use.

**Figure 6  VPN Authentication Bypass Page**
Note

If the Web-Based Activation window is mistakenly closed, to connect again, a user should follow this two-step process:

1. In a browser, type “http://routeripaddress/ezvpn/bypass” and try to connect to the URL. Entering this URL clears the bypass state that was created for your IP address (when the “Internet only” button was pressed). If you get a message saying that no such page is found, it does not matter because the only purpose of accessing the URL is to clear the bypass state.

2. After clearing the bypass state, you can browse to any external site. The Connect and Bypass page appears again. You can connect to VPN by pressing the Connect button.

VPN Tunnel Authentication

Figure 7 is an example of a web-based activation in which the user chose to connect to the corporate LAN by entering a username and password. After the user is successfully authenticated, the Easy VPN tunnel is brought up for this remote site. If there are multiple PCs behind this remote site, none of the additional users who are connecting to the corporate LAN will be requested for the Xauth credentials because the tunnel is already up.
**Figure 7**  VPN Tunnel Authentication

Successful Authentication

Figure 8 is an example of a successful activation. If the user chooses to deactivate the VPN tunnel, he or she should click the Disconnect button. After the IKE security association (SA) times out (the default value is 24 hours), the remote teleworker has to enter the Xauth credentials to bring up the tunnel.
**Figure 8  Successful Activation**

[Image of successful activation]

**Deactivation**

Figure 9 is an example of a VPN tunnel that has been deactivated successfully. The page automatically closes in 5 seconds.
802.1x Authentication

The 802.1x Authentication feature allows you to combine Easy VPN client mode operation with 802.1x authentication on Cisco IOS routers. For more information about this feature, see “802.1 Authentication” in the section “Additional References.”
Tunnel Activation Options

There are three tunnel activation options:

- Automatic activation
- Manual activation
- Traffic-triggered activation (not available in Cisco IOS Release 12.3(11)T)

Tunnel connect and disconnect options are available with SDM.

Automatic Activation

The Cisco Easy VPN tunnel is automatically connected when the Cisco Easy VPN Remote feature is configured on an interface. If the tunnel times out or fails, the tunnel automatically reconnects and retries indefinitely.

To specify automatic tunnel control on a Cisco Easy VPN remote device, you need to configure the `crypto ipsec client ezvpn` command and then the `connect auto` subcommand. However, you do not need to use these two commands when you are creating a new Easy VPN remote configuration because the default is “automatic.”

To disconnect or reset a particular tunnel, you should use the `clear crypto ipsec client ezvpn` command, or you can use SDM.

Manual Activation

The Cisco Easy VPN Remote software implements manual control of the Cisco Easy VPN tunnels so that you can establish and terminate the tunnel on demand.

To specify manual tunnel control on a Cisco Easy VPN remote device, you need to input the `crypto ipsec client ezvpn` command and then the `connect manual` command.

The manual setting means that the Cisco Easy VPN remote will wait for a command before attempting to establish the Cisco Easy VPN Remote connection. When the tunnel times out or fails, subsequent connections will also have to wait for the command.

If the configuration is manual, the tunnel is connected only after you issue the command `crypto ipsec client ezvpn connect`.

To disconnect or reset a particular tunnel, you should use the `clear crypto ipsec client ezvpn` command, or you can use SDM.

See the “Configuring Manual Tunnel Control” section for specific information on how to configure manual control of a tunnel.

Traffic-Triggered Activation

Note: This feature is not available in Cisco IOS Release 12.3(11)T.

The Traffic-Triggered Activation feature is recommended for transactional-based VPN applications. It is also recommended for use with the Easy VPN dial backup feature for the backup Easy VPN configuration so that backup is activated only when there is traffic to send across the tunnel.
To use Access Control List (ACL) tunnel control, you must first describe the traffic that is considered “interesting.” For more information about ACLs, see the chapter “Access Control Lists: Overview and Guidelines” in the “Traffic Filtering and Firewalls” section of the Cisco IOS Security Configuration Guide, Release 12.3. To actually configure an ACL-triggered tunnel, use the `crypto ipsec client ezvpn` command with the `connect acl` subcommand.

**Dead Peer Detection Stateless Failover Support**

Two options are available for configuring Dead Peer Detection Stateless Failover Support:

- Backup Server List Local Configuration
- Backup Server List Auto Configuration

**Backup Server List Local Configuration**

Backup Server List Local Configuration allows users to enter multiple peer statements. With this feature configured, if the client is connecting to a peer and the negotiation fails, Easy VPN fails over to the next peer. This failover continues through the list of peers. When the last peer is reached, Easy VPN rolls over to the first peer. The IKE and IPsec SAs to the previous peer are deleted. Multiple peer statements work for both IP addresses as well as for hostnames. Setting or unsetting the peer statements will not affect the order of the peer statements.

To use this feature, use the `peer` subcommand of the `crypto ipsec client ezvpn` command.

**Backup Server List Auto Configuration**

Easy VPN remote that is based on Cisco IOS software can have up to 10 backup servers configured for redundancy. The Backup Server feature allows the Easy VPN server to “push” the backup server list to the Easy VPN remote.

The backup list allows the administrator to control the backup servers to which a specific Easy VPN remote will connect in case of failure, retransmissions, or dead peer detection (DPD) messages.

---

**Note**

Before the backup server feature can work, the backup server list has to be configured on the server.

**How a Backup Server Works**

If remote A goes to server A and the connection fails, remote A goes to server B. If server B has a backup list configured, that list will override the backup server list of server A. If the connection to server B fails, remote A will continue through the backup servers that have been configured.

---

**Note**

If you are in auto mode and you have a failure, you will transition automatically from server A to server B. However, if you are in manual mode, you have to configure the transition manually. To configure the transition manually, use the `crypto ipsec client ezvpn` command with the `connect` keyword.

No new configuration is required at the Easy VPN remote to enable this feature. If you want to display the current server, you can use the `show crypto ipsec client ezvpn` command. If you want to find out which peers were pushed by the Easy VPN server, you can use the same command.
To troubleshoot this feature, use the `debug crypto ipsec client ezvpn` command. If more information is needed for troubleshooting purposes, use the `debug crypto isakmp` command. The `show crypto ipsec client ezvpn` command may also be used for troubleshooting.

**Cisco Easy VPN Remote Features**

The Cisco Easy VPN Remote feature is a collection of features that improves the capabilities of the Cisco Easy VPN Remote feature introduced in Cisco IOS Release 12.2(4)YA. The Cisco Easy VPN Remote feature includes the following:

- **Default Inside Interface, page 20**—This feature supports the autoconfiguration of the default Easy VPN inside interface for Cisco 800 series routers.
- **Multiple Inside Interfaces, page 21**—This feature allows you to configure up to eight inside interfaces on the Cisco Easy VPN remote.
- **Multiple Outside Interfaces, page 21**—This feature allows you to configure up to four outside tunnels for outside interfaces.
- **VLAN Support, page 21**—This feature allows VLANs to be configured as valid Easy VPN inside interfaces.
- **Multiple Subnet Support, page 22**—This feature allows multiple subnets from the Easy VPN inside interface to be included in the Easy VPN tunnel.
- **NAT Interoperability Support, page 22**—This feature automatically restores the NAT configuration when the IPsec VPN tunnel is disconnected.
- **Local Address Support, page 22**—The Cisco Easy VPN Remote feature is enhanced to support an additional `local-address` attribute that specifies which interface is used to determine the IP address used to source the Easy VPN tunnel traffic.
- **Peer Hostname, page 23**—When a peer is defined as a hostname, the hostname is stored and the Domain Name System (DNS) lookup is done at the time of tunnel connection.
- **Proxy DNS Server Support, page 23**—This feature allows you to configure the router in a Cisco Easy VPN remote configuration to act as a proxy DNS server for LAN-connected users.
- **Cisco IOS Firewall Support, page 23**—This feature supports Cisco IOS Firewall configurations on all platforms.
- **Easy VPN Remote and Server on the Same Interface, page 23**—The Easy VPN remote and Easy VPN server are supported on the same interface, which makes it possible to establish a tunnel to another Easy VPN server and terminate the Easy VPN software client on the same interface simultaneously.
- **Easy VPN Remote and Site to Site on the Same Interface, page 23**—The Easy VPN Remote and site to site (crypto map) are supported on the same interface, which makes it possible to establish a tunnel to another Easy VPN server and have another site to site on the same interface simultaneously.
- **Cisco Easy VPN Remote Web Managers, page 24**—Users can manage the Cisco Easy VPN Remote feature on the Cisco uBR905 and Cisco uBR925 cable access routers using a built-in web interface.
- **Dead Peer Detection Periodic Message Option, page 24**—This feature allows you to configure your router to query the liveness of its IKE peer at regular intervals.
- **Load Balancing, page 24**—If a remote device is loaded and unable to accept more traffic, the VPN 3000 will send a notify message that contains an IP address that represents the new IKE server to which the remote should connect.
• **Management Enhancements, page 25**—This feature allows for remote management of the VPN remote.

• **PFS Support, page 25**—The PFS configuration mode attribute is sent by the server if requested by the VPN remote device.

• **Dial Backup, page 25**—This feature allows you to configure a dial backup tunnel connection on your remote device.

• **Virtual IPsec Interface Support, page 27**—This feature allows you to selectively send traffic to different Easy VPN concentrators as well as to the Internet (includes a reference to the IPsec Virtual Tunnel Interface feature.)

• **Dual Tunnel Support, page 29**—This feature allows you to configure multiple Easy VPN tunnels that share common inside and outside interfaces to connect two peers to two different VPN servers simultaneously.

• **Banner, page 32**—The EasyVPN remote device can download a banner that has been pushed by the Easy VPN server. The banner can be used for Xauth and web-based activation. The banner is displayed when the Easy VPN tunnel is “up” on the Easy VPN remote console or as an HTML page in the case of web-based activation.

• **Configuration Management Enhancements (Pushing a Configuration URL Through a Mode-Configuration Exchange), page 33**—The Easy VPN remote device can download a URL that is pushed by the Easy VPN server, allowing the Easy VPN remote device to download configuration content and apply it to the running configuration.

• **Reactivate Primary Peer, page 33**—This feature allows you to designate a primary peer. When an Easy VPN device fails over from the primary peer to a backup peer and the primary peer is again available, connections with the backup peer are torn down and a connection is made with the primary peer.

• **Identical Addressing Support, page 33**—This feature integrates Network Address Translation (NAT) with Easy VPN to allow remotes with overlapping internal IP addressing to connect to the Easy VPN server.

• **cTCP Support on Easy VPN Clients, page 34**—When cTCP is enabled on a remote device (client) and headend device, IKE and ESP (Protocol 50) traffic is encapsulated in the TCP header so that the firewalls in between the client and the headend device permit this traffic (considering it the same as TCP traffic).

### Default Inside Interface

Easy VPN Remote supports the autoconfiguration of the default Easy VPN inside interface for Cisco 800 series routers. The interface Ethernet 0 is the default inside interface.

If you want to disable the default inside interface and configure another inside interface on the Cisco 800 series router, you must configure the other inside interface first and then disable the default inside interface. You can use the following command to disable the default inside interface:

```
no crypto ipsec client ezvpn name inside
```

If you did not configure the other inside interface first before disabling the default inside interface, you will receive a message such as the following (see lines three and four):

```
Router (config)# interface ethernet0
Router (config-if)# no crypto ipsec client ezvpn hw-client inside
Cannot remove the single inside interface unless
one other inside interface is configured
```
Multiple Inside Interfaces

Inside interface support is enhanced in the Cisco Easy VPN Remote feature to support multiple inside interfaces for all platforms. Inside interfaces can be configured manually with the enhanced command and subcommand:

```
interface interface-name
    crypto ipsec client ezvpn name [outside | inside]
```

See the “Configuring Multiple Inside Interfaces” section for information on how to configure more than one inside interface.

Multiple inside interfaces offer the following capabilities:

- Up to eight inside interfaces are supported on the Cisco 800 and Cisco 1700 series routers.
- At least one inside interface must be configured for each outside interface; otherwise, the Cisco Easy VPN Remote feature does not establish a connection.
- Adding a new inside interface or removing an existing inside interface automatically resets the Cisco Easy VPN Remote connection (the currently established tunnel). You must reconnect a manually configured tunnel, and if Xauth is required by the Cisco Easy VPN server, the user is reprompted. If you have set the Cisco Easy VPN Remote configuration to connect automatically and no Xauth is required, no user input is required.
- Inside interfaces that are configured or the default setting can be shown by using the `show crypto ipsec client ezvpn` command.

Multiple Outside Interfaces

The Easy VPN Remote feature supports one Easy VPN tunnel per outside interface. You can configure up to four Easy VPN tunnels per Cisco router. Each Easy VPN tunnel can have multiple inside interfaces configured, but they cannot overlap with another Easy VPN tunnel unless dial backup is configured. For more information about dial backup, see the section “Dial Backup.” To configure multiple outside interfaces, use the `crypto ipsec client ezvpn` command and `outside` keyword.

To disconnect or clear a specific tunnel, the `clear crypto ipsec client ezvpn` command specifies the IPsec VPN tunnel name. If there is no tunnel name specified, all existing tunnels are cleared.

See the “Configuring Multiple Outside Interfaces” section for more information on configuring more than one outside interface.

VLAN Support

Inside interface support on VLANs makes it possible to have valid Easy VPN inside interface support on a VLAN, which was not possible before Cisco IOS Release 12.3(7)XR. With this feature, SAs can be established at connection using the VLAN subnet address or mask as a source proxy.

For the inside interface support on VLANs to work, you must define each VLAN as an Easy VPN inside interface. In addition, IPsec SAs should be established for each inside interface in the same manner as for other inside interfaces. For more information about inside and outside interfaces, see the sections “Multiple Inside Interfaces” and “Multiple Outside Interfaces.”

Inside interface support on VLANs is supported only on Cisco routers that support VLANs.
Multiple Subnet Support

For situations in which you have multiple subnets connected to an Easy VPN inside interface, you can optionally include these subnets in the Easy VPN tunnel. First, you must specify the subnets that should be included by defining them in an ACL. To configure an ACL, see “Access control lists, configuring” in the “Additional References” section. Next, you have to use the `acl` subcommand of the `crypto ipsec client ezvpn` (global) command to link your ACL to the Easy VPN configuration. Easy VPN Remote will automatically create the IPsec SAs for each subnet that is defined in the ACL as well as for the subnets that are defined on the Easy VPN inside interface.

Note

Multiple subnet support is not supported in client mode.

NAT Interoperability Support

Cisco Easy VPN Remote supports interoperability with NAT. You can have a NAT configuration and a Cisco Easy VPN Remote configuration that coexist. When an IPsec VPN tunnel is down, the NAT configuration works.

In the Cisco Easy VPN Remote feature, the router automatically restores the previous NAT configuration when the IPsec VPN tunnel is torn down. The user-defined access lists are not disturbed. Users can continue to access nontunnel areas of the Internet when the tunnel times out or disconnects.

Note

NAT interoperability is not supported in client mode with split tunneling.

Local Address Support

The Cisco Easy VPN Remote feature is enhanced to support an additional `local-address` attribute. This attribute specifies which interface is used to determine the IP address that is used to source the Easy VPN Remote tunnel traffic. After specifying the interface with the `local-address` subcommand, you can manually assign a static IP address to the interface or use the `cable-modem dhcp-proxy interface` command to automatically configure the specified interface with a public IP address. See the “Configuring Proxy DNS Server Support” section for configuration information.

Local Address Support is available for all platforms, but it is more applicable to the Cisco uBR905 and Cisco uBR925 cable access routers in conjunction with the `cable-modem dhcp-proxy interface` command. Typically, the loopback interface is the interface used to source tunnel traffic for the Cisco uBR905 and Cisco uBR925 cable access routers.

In a typical DOCSIS network, the Cisco uBR905 and Cisco uBR925 cable access routers are normally configured with a private IP address on the cable modem interface. In the initial Cisco Easy VPN Remote feature, a public IP address was required on the cable modem interface to support the Easy VPN remote.

In the Cisco Easy VPN Remote feature, cable providers can use the Cable DHCP Proxy feature to obtain a public IP address and assign it to the cable modem interface, which is usually the loopback interface.

For more information on the `cable-modem dhcp-proxy interface` command, see the “Cable CPE Commands” chapter in the *Cisco Broadband Cable Command Reference Guide*.

Note

The `cable-modem dhcp-proxy interface` command is supported only for the Cisco uBR905 and Cisco uBR925 cable access routers.
**Peer Hostname**

The peer in a Cisco Easy VPN Remote configuration can be defined as an IP address or a hostname. Typically, when a peer is defined as a hostname, a DNS lookup is done immediately to get an IP address. In the Cisco Easy VPN Remote feature, the peer hostname operation is enhanced to support DNS entry changes. The text string of the hostname is stored so that the DNS lookup is done at the time of the tunnel connection, not when the peer is defined as a hostname.

See the “Configuring and Assigning the Easy VPN Remote Configuration” section for information on enabling the peer hostname functionality.

**Proxy DNS Server Support**

When the Easy VPN tunnel is down, the DNS addresses of the ISP or cable provider should be used to resolve DNS requests. When the WAN connection is up, the DNS addresses of the enterprise should be used.

As a way of implementing use of the DNS addresses of the cable provider when the WAN connection is down, the router in a Cisco Easy VPN Remote configuration can be configured to act as a proxy DNS server. The router, acting as a proxy DNS server for LAN-connected users, receives DNS queries from local users on behalf of the real DNS server. The DHCP server then can send out the LAN address of the router as the IP address of the DNS server. After the WAN connection comes up, the router forwards the DNS queries to the real DNS server and caches the DNS query records.

See the “Configuring Proxy DNS Server Support” section for information on enabling the proxy DNS server functionality.

**Cisco IOS Firewall Support**

The Cisco Easy VPN Remote feature works in conjunction with Cisco IOS Firewall configurations on all platforms.

**Easy VPN Remote and Server on the Same Interface**

This feature allows the Easy VPN remote and Easy VPN server to be supported on the same interface, making it possible to both establish a tunnel to another Easy VPN server and terminate the Easy VPN software client on the same interface simultaneously. A typical application would be a geographically remote location for which Easy VPN Remote is being used to connect to a corporate Easy VPN server and also to terminate local software client users.

For more information about the Easy VPN Remote and Server on the Same Interface feature, see “Easy VPN Remote and Server on the Same Interface” in the section “Additional References.”

**Easy VPN Remote and Site to Site on the Same Interface**

This feature allows the Easy VPN remote and site to site (crypto map) to be supported on the same interface, making it possible to both establish a tunnel to another Easy VPN server and have another site to site on the same interface simultaneously. A typical application would be a third-party VPN service provider that is managing a remote router via the site-to-site tunnel and using Easy VPN Remote to connect the remote site to a corporate Easy VPN server.

For more information about the Easy VPN Remote and Site to Site on the Same Interface feature, see “Easy VPN Remote and Site to Site on the Same Interface” in the section “Additional References.”
Cisco Easy VPN Remote Web Managers

Web interface managers may be used to manage the Cisco Easy VPN Remote feature. One such web interface manager is SDM, which is supported on the Cisco 830 series, Cisco 1700 series, Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers. SDM enables you to connect or disconnect the tunnel and provides a web interface for Xauth. For more information about SDM, see Cisco Security Device Manager.

A second web interface manager is the Cisco Router Web Setup (CRWS) tool, which is supported on the Cisco 806 router. The CRWS provides a similar web interface as SDM.

A third web interface manager, Cisco Easy VPN Remote Web Manager, is used to manage the Cisco Easy VPN Remote feature for Cisco uBR905 and Cisco uBR925 cable access routers. You do not need access to the CLI to manage the Cisco Easy VPN remote connection.

The web interface managers allow you to do the following:

- See the current status of the Cisco Easy VPN remote tunnel.
- Connect a tunnel that is configured for manual control.
- Disconnect a tunnel that is configured for manual control or reset a tunnel configured for automatic connection.
- Be prompted for Xauth information, if needed.

See the “Troubleshooting the VPN Connection” section for more information about Cisco Easy VPN Remote Web Manager.

Dead Peer Detection Periodic Message Option

The dead peer detection periodic message option allows you to configure your router to query the liveness of its IKE peer at regular intervals. The benefit of this approach over the default approach (on-demand dead peer detection) is earlier detection of dead peers. For more information about the dead peer detection periodic message option, see “Dead peer detection” in the section “Additional References.”

Load Balancing

When the Cisco VPN 3000 concentrator is configured for load balancing, the VPN 3000 will accept an incoming IKE request from the VPN remote on its virtual IP address. If the device is loaded and unable to accept more traffic, the VPN 3000 will send a notify message that contains an IP address that represents the new IKE server to which the remote should connect. The old connection will be torn down and a new connection established to the redirected VPN gateway.

There is no configuration required for load balancing to occur. If the VPN gateway is configured for load balancing, and it notifies the VPN remote that it is performing load balancing, the VPN remote has access to the load balancing feature.

To verify whether load balancing is occurring, use the debug crypto isakmp, debug crypto ipsec client ezvpn, and show crypto ipsec commands. To troubleshoot the load balancing process, use the show crypto ipsec command.
Management Enhancements

Management enhancements for Easy VPN remotes allow for the remote management of the VPN remote. The feature provides for the IPv4 address to be pushed by configuration mode to the VPN remote. The IPv4 address is assigned to the first available loopback interface on the VPN remote, and any existing statically defined loopbacks are not overridden. On disconnect, the address and loopback interface are removed from the list of active interfaces.

After the VPN remote is connected, the loopback interface should be accessible from the remote end of the tunnel. All PAT activities will be translated through this interface IP address.

If a loopback exists, and an IP address is associated with it and its state is unassigned, the interface is a good candidate for mode configuration address management.

Note

After you assign an address to the loopback interface, if you save the configuration to NVRAM and reboot the VPN remote, the configuration address is permanently contained in the configuration. If you saved the configuration to NVRAM and rebooted the VPN remote, you must enter configuration mode and remove the IP address from the loopback interface manually.

You can use the `show ip interface` command with the `brief` keyword to verify that a loopback has been removed. The output of this `show` command also displays the interface.

PFS Support

The PFS configuration mode attribute is sent by the server if requested by the VPN remote device. If any subsequent connection by the remote device shows that PFS is not received by the remote, PFS will not be sent in IPsec proposal suites.

Note

The PFS group that will be proposed in the IPsec proposal suites is the same as the group used for IKE.

You can use the `show crypto ipsec client ezvpn` command to display the PFS group and to verify that you are using PFS.

Dial Backup

Note

The Dial Backup feature is not available in Cisco IOS Release 12.3(11)T.

Dial backup for Easy VPN remotes allows you to configure a dial backup tunnel connection on your remote device. The backup feature is “brought up” only when real data has to be sent, eliminating the need for expensive dialup or ISDN links that must be created and maintained even when there is no traffic.

Figure 10 illustrates a typical Easy VPN remote-with-dial-backup scenario. In this scenario, a Cisco 1751 remote device is attempting to connect to another Cisco 1751 (acting as a server). There is a failure in the primary Easy VPN tunnel, and the connection is rerouted through the Easy VPN backup tunnel to the Cisco 1751 server.
Dial Backup Using a Dial-on-Demand Solution

IP static route tracking enable Cisco IOS software to identify when a Point-to-Point Protocol over Ethernet (PPPoE) or IPsec VPN tunnel “goes down” and initiates a Dial-on-Demand (DDR) connection to a preconfigured destination from any alternative WAN or LAN port (for example, a T1, ISDN, analog, or auxiliary port). The failure may be caused by several catastrophic events (for example, by Internet circuit failures or peer device failure). The remote route has only a static route to the corporate network. The IP static-route-tracking feature allows an object to be tracked (using an IP address or hostname) using Internet Control Message Protocol (ICMP), TCP, or other protocols, and it installs or removes the static route on the basis of the state of the tracked object. If the tracking feature determines that Internet connectivity is lost, the default route for the primary interface is removed, and the floating static route for the backup interface is enabled.

Dial Backup Using Object Tracking

IP static route tracking must be configured for dial backup on an Easy VPN remote device to work. The object tracking configuration is independent of the Easy VPN remote dial backup configuration. (For more information about object tracking, see the feature guide Reliable Static Routing Backup Using Object Tracking.)

Easy VPN Remote Dial Backup Support Configuration

You can configure dial backup for your Easy VPN remote using two Easy VPN remote options that allow a connection to the backup Easy VPN configuration and a connection to the tracking system.

- To specify the Easy VPN configuration that will be activated when backup is triggered, use the `backup` subcommand of the `crypto ipsec client ezvpn` (global) command.
- The Easy VPN remote device registers to the tracking system to get the notifications for change in the state of the object. Use the `track` subcommand to inform the tracking process that the Easy VPN remote device is interested in tracking an object, which is identified by the object number. The tracking process, in turn, informs the Easy VPN remote device when the state of this object changes. This notification prompts the Easy VPN remote device when the state of this object changes. This notification prompts the Easy VPN remote device to bring up the backup connection when the tracked object state is DOWN. When the tracked object is UP again, the backup connection is torn down and the Easy VPN remote device will switch back to using the primary connection.
Note

Only one backup configuration is supported for each primary Easy VPN configuration. Each inside interface must specify the primary and backup Easy VPN configuration.

Dynamically Addressed Environments

To allow dial backup to be deployed in dynamically addressed environments, use the IP SLA Pre-Routed ICMP Echo Probe feature. (For more information about this feature, see Cisco 1700 Series- Cisco IOS Release 12.3(7)XR release notes. To use the IP SLA Pre-Routed ICMP Echo Probe feature, use the icmp-echo command with the source-interface keyword.

Dial Backup Examples

For examples of dial backup configurations, see the section “Dial Backup: Examples.”

Virtual IPsec Interface Support

The Virtual IPsec Interface Support feature provides a routable interface to selectively send traffic to different Easy VPN concentrators as well as to the Internet.

Before Cisco IOS Release 12.4(4)T, at the tunnel-up/tunnel-down transition, attributes that were pushed during the mode configuration had to be parsed and applied. When such attributes resulted in the configurations being applied on the interface, the existing configuration had to be overridden. With the Virtual IPsec Interface Support feature, the tunnel-up configuration can be applied to separate interfaces, making it easier to support separate features at tunnel-up time. Features that are applied to the traffic going into the tunnel can be separate from the features that are applied to traffic that is not going through the tunnel (for example, split-tunnel traffic and traffic leaving the device when the tunnel is not up). When the Easy VPN negotiation is successful, the line protocol state of the virtual-access interface gets changed to up. When the Easy VPN tunnel goes down because the security association (SA) expires or is deleted, the line protocol state of the virtual-access interfaces changes to down.

Routes act as traffic selectors in an Easy VPN virtual interface, that is, the routes replace the access list on the crypto map. In a virtual-interface configuration, Easy VPN negotiates a single IPsec SA if the Easy VPN server has been configured with a dynamic virtual IPsec interface. This single SA is created irrespective of the Easy VPN mode that is configured.

After the SA is established, routes that point to the virtual-access interface are added to direct traffic to the corporate network. Easy VPN also adds a route to the VPN concentrator so that IPsec-encapsulated packets get routed to the corporate network. A default route that points to the virtual-access interface is added in the case of a nonsplit mode. When the Easy VPN server “pushes” the split tunnel, the split tunnel subnet becomes the destination to which the routes that point to the virtual access are added. In either case, if the peer (VPN concentrator) is not directly connected, Easy VPN adds a route to the peer.

Note

- Most routers that run the Cisco Easy VPN Client software have a default route configured. The default route that is configured should have a metric value greater than 1. The metric value must be greater than 1 because Easy VPN adds a default route that has a metric value of 1. The route points to the virtual-access interface so that all traffic is directed to the corporate network when the concentrator does not “push” the split tunnel attribute.
For more information about the IPsec Virtual Tunnel Interface feature, see the document *IPSec Virtual Tunnel Interface* (URL link provided in the “Related Documents” section of this document [General Information on IPsec and VPN]).

Table 1 presents the different methods of configuring a remote device and the corresponding headend IPsec aggregator configurations. Each row represents a way to configure a remote device. The third column shows the different headend configurations that can be used with IPsec interfaces. See Table 2 for a description of terms that are used in Table 1 and Table 3.

*Table 1 How Different Remote Device Configurations Interact with Various Headends and Configurations*

**Dual Tunnel Support**

Easy VPN now supports the ability to configure two easy VPN tunnels that have the same inside and outside interfaces. The feature is called the Easy VPN Dual Tunnel. Configuring multiple tunnels on a single remote device can be accomplished in a number of ways, which are listed below in Table 3 along with their configuration and usage considerations. Further discussion in this section refers to only one such method of configuring dual tunnels using Easy VPN tunnels that have virtual interfaces. This method will be referred to as Dual Tunnel Support.

In a dual-tunnel Easy VPN setup, each Easy VPN tunnel is configured using virtual IPsec interface support, as shown in the section “Virtual IPsec Interface Support.” Each Easy VPN tunnel has its unique virtual interface, which is created when the Easy VPN configuration is complete.

There are two possible combinations in which the dual tunnels can be used:

- Dual Easy VPN tunnels that have one tunnel using a nonsplit tunnel policy and the other tunnel using a split tunnel policy that has been pushed from the respective headend.
• Dual Easy VPN tunnel in which both tunnels are using an independent split tunnel policy that has been pushed from the respective headend.

**Note**

It is not permitted to have dual Easy VPN tunnels in which both tunnels are using a nonsplit tunnel policy.

The Easy VPN dual tunnel makes use of route injections to direct the appropriate traffic through the correct Easy VPN virtual tunnel interface. When the Easy VPN tunnel on the remote device “comes up,” it “learns” the split or nonsplit policy from the headend. The Easy VPN remote device injects routes in its routing table that correspond to the nonsplit networks that have been learned. If the headend pushes a nonsplit tunnel policy to the Easy VPN remote device, the Easy VPN remote device installs a default route in its routing table that directs all traffic out of the Easy VPN virtual interface that corresponds to this Easy VPN tunnel. If the headend pushes split-tunnel networks to the remote device, the remote device installs specific routes to the split networks in its routing table, directing the traffic to these networks out of the virtual tunnel interface.

**Note**

Dual Tunnel Easy VPN uses destination-based routing to send traffic to the respective tunnels.

Output features can be applied to this virtual interface. Examples of such output features are Cisco IOS Quality of Service and Cisco IOS Firewall. These features must be configured on the virtual template that is configured in the Easy VPN client configuration.

Table 3 explains how this feature should be used. See Table 2 for a description of terms that are used in Table 1 and Table 3.
### Table 3  Dual Tunnel Usage Guidelines

<table>
<thead>
<tr>
<th>Dual Tunnel Combinations</th>
<th>Headends Supported</th>
<th>Configuration and Usage Considerations on the Easy VPN Remote Device and Headend</th>
</tr>
</thead>
<tbody>
<tr>
<td>Two legacy Easy VPN tunnels</td>
<td>IOS, ASA, and VPN 3000</td>
<td>• Two tunnels cannot share a common outside interface.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Two tunnels cannot share a common inside interface.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The two tunnels should use separate inside and outside interfaces.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Traffic from an inside interface that belongs to one Easy VPN tunnel cannot be pushed into another tunnel.</td>
</tr>
<tr>
<td>One legacy Easy VPN tunnel and one crypto map</td>
<td>IOS, ASA, and VPN 3000</td>
<td>The crypto map can share the same outside interface as the legacy Easy VPN client configuration. However, the behavior of the two remote devices depends on the mode of Easy VPN as well as the IPsec selectors of the crypto map and the Easy VPN remote device. This is not a recommended combination.</td>
</tr>
<tr>
<td>One legacy Easy VPN tunnel and one static virtual interface</td>
<td>IOS</td>
<td>Both tunnels cannot terminate on the same headend. The static virtual interface remote device tunnel has to be terminated on a static virtual interface on the headend router. The legacy Easy VPN remote device tunnel can terminate on the virtual tunnel interface or crypto map that is configured on the headend.</td>
</tr>
</tbody>
</table>
Banner

The Easy VPN server pushes a banner to the Easy VPN remote device. The Easy VPN remote device can use the banner during Xauth and web-based activation. The Easy VPN remote device displays the banner the first time that the Easy VPN tunnel is brought up.

The banner is configured under group configuration on the Easy VPN server.

<table>
<thead>
<tr>
<th>Dual Tunnel Combinations</th>
<th>Headends Supported</th>
<th>Configuration and Usage Considerations on the Easy VPN Remote Device and Headend</th>
</tr>
</thead>
</table>
| One legacy Easy VPN tunnel and one Easy VPN virtual interface | IOS, ASA, and VPN 3000 | • Both tunnels cannot terminate on the same headend.  
• The legacy Easy VPN tunnel and the Easy VPN virtual interface can share a common inside and outside interface.  
• An Easy VPN virtual interface should be used only with split tunneling.  
• Legacy Easy VPN can use a split tunnel or no split tunnel.  
• The Web-Based Activation feature cannot be applied on both Easy VPN tunnels.  
• Using two Easy VPN virtual interfaces is preferable to using this combination. |
| One Easy VPN virtual interface and one static virtual interface | IOS | • Both tunnels cannot terminate on the same peer. The static virtual interface and the Easy VPN virtual interface can use the same outside interface.  
• The Easy VPN virtual interface should use split tunneling. |
| Two Easy VPN virtual interfaces | IOS, ASA, and VPN 3000 | • Both tunnels cannot terminate on the same peer.  
• At least one of the tunnels should use split tunneling.  
• Web-Based Activation cannot be applied to both Easy VPN tunnels. |
Configuration Management Enhancements (Pushing a Configuration URL Through a Mode-Configuration Exchange)

After this feature has been configured on the server using the commands `configuration url` and `configuration version` (subcommands under the `crypto isakmp client configuration group` command), the server can “push” the configuration URL and configuration version number to the Easy VPN remote device. With this information, the Easy VPN remote device can download the configuration content and apply it to its running configuration. For more information about this feature, see the section “Configuration Management Enhancements” in the *Easy VPN Server* feature module.

Reactivate Primary Peer

The Reactivate Primary Peer feature allows a default primary peer to be defined. The default primary peer (a server) is one that is considered better than other peers for reasons such as lower cost, shorter distance, or more bandwidth. With this feature configured, if Easy VPN fails over during Phase 1 SA negotiations from the primary peer to the next peer in its backup list, and if the primary peer is again available, the connections with the backup peer are torn down and the connection is again made with the primary peer.

Dead Peer Detection is one of the mechanisms that acts as a trigger for primary peer reactivation. Idle timers that are configured under Easy VPN is another triggering mechanism. When configured, the idle timer detects inactivity on the tunnel and tears it down. A subsequent connect (which is immediate in auto mode) is attempted with the primary preferred peer rather than with the peer last used.

---

**Note**

Only one primary peer can be defined.

Identical Addressing Support

The Identical Addressing Support feature supports identically addressed LANs on Easy VPN remotes. Network resources, such as printers and web servers on the LAN side of the EasyVPN remotes, that have overlapping addressing with other Easy VPN remotes are now reachable. The Easy VPN Remote feature was enhanced to work with NAT to provide this functionality.

- The Easy VPN server requires no changes to support the Identical Addressing Support feature.
- The Identical Addressing Support feature is supported only in network extension modes (network-extension and network-plus).
- Virtual tunnel interfaces must be configured on the Easy VPN remote before using the Identical Addressing Support feature.

*Figure 11* shows an example of the Identical Addressing Support feature configuration.
Figure 11 Identical Addressing Support

- Network behind Easy VPN remote 1 has the same IP addressing as that behind the Easy VPN remote 2.
- Printer 1 and Printer 3 have the same IP Address.
- Printer 2 and Printer 4 have the same IP Address.

The Identical Addressing Support feature can be configured with the following command and enhanced subcommands:

```
crypto ipsec client ezvpn <name>
```

**Enhanced subcommands**

- **nat acl** `{acl-name \ acl-number}`—Enables split tunneling for the traffic specified by the ACL name or the ACL number.
  - The `acl-name` argument is the name of the ACL.
  - The `acl-number` argument is the number of the ACL.
- **nat allow**—Allows NAT to be integrated with Cisco Easy VPN.

For detailed steps on how to configure Identical Addressing Support, see “Configuring Identical Addressing Support.”

**cTCP Support on Easy VPN Clients**

The Cisco Tunneling Control Protocol (cTCP) feature can be used for situations in which an Easy VPN client (remote device) is operating in an environment in which standard IPsec does not function or in which it does not function transparently without modification to existing firewall rules. These situations include the following:

- Small office or home office router performing Network Address Translation (NAT) or Port Address Translation (PAT)
- PAT-provided IP address behind a larger router (for example, in a corporation)
- Non-NAT firewall (packet filtering or stateful)
- Proxy server
Figure 12 illustrates how IPsec traffic that is tunneled inside the cTCP traverses Network Address Translation (NAT) and the firewall (see the dashed line).

For detailed steps on how to configure cTCP on Easy VPN remote devices, see the section “Configuring cTCP on an Easy VPN Client.”

For more information about cTCP support on Easy VPN remote devices, including configuration and troubleshooting examples, see “cTCP on Cisco Easy VPN remote devices” in the section “Related Documents.”

How to Configure Cisco Easy VPN Remote

This section includes the following required and optional tasks.

Remote Tasks

- Configuring and Assigning the Easy VPN Remote Configuration, page 36 (required)
- Verifying the Cisco Easy VPN Configuration, page 38 (optional)
- Configuring Save Password, page 39 (optional)
- Configuring Manual Tunnel Control, page 40 (optional)
- Configuring Automatic Tunnel Control, page 42 (optional)
- Configuring Multiple Inside Interfaces, page 43 (optional)
- Configuring Multiple Outside Interfaces, page 44 (optional)
- Configuring Multiple Subnet Support, page 45 (optional)
- Configuring Proxy DNS Server Support, page 47 (optional)
- Configuring Dial Backup, page 47 (optional)
- Configuring the DHCP Server Pool, page 48 (required)
- Resetting a VPN Connection, page 48 (optional)
- Monitoring and Maintaining VPN and IKE Events, page 49 (optional)
- Configuring a Virtual Interface, page 50 (optional)
- Troubleshooting Dual Tunnel Support, page 51 (optional)
- Configuring Reactivate (a Default) Primary Peer, page 52 (optional)
- Configuring Identical Addressing Support, page 53 (optional)
- Configuring cTCP on an Easy VPN Client, page 56 (optional)
- Restricting Traffic When a Tunnel Is Down, page 57 (optional)
Easy VPN Server Tasks

- Configuring a Cisco IOS Easy VPN Server, page 58 (required)
- Configuring an Easy VPN Server on a VPN 3000 Series Concentrator, page 58 (optional)
- Configuring an Easy VPN Server on a Cisco PIX Firewall, page 60 (optional)

Web Interface Tasks

- Configuring Web-Based Activation, page 61 (optional)
- Monitoring and Maintaining Web-Based Activation, page 61 (optional)
- Using SDM As a Web Manager, page 65 (optional)

Troubleshooting the VPN Connection

- Troubleshooting a VPN Connection Using the Cisco Easy VPN Remote Feature, page 65 (optional)
- Troubleshooting the Client Mode of Operation, page 65 (optional)
- Troubleshooting Remote Management, page 66 (optional)
- Troubleshooting Dead Peer Detection, page 66 (optional)

Remote Tasks

Configuring and Assigning the Easy VPN Remote Configuration

The router acting as the Easy VPN remote must create a Cisco Easy VPN Remote configuration and assign it to the outgoing interface. To configure and assign the remote configuration, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto ipsec client ezvpn name`
4. `group group-name key group-key`
5. `peer [ip-address | hostname]`
6. `mode {client | network-extension}`
7. `exit`
8. `interface interface`
9. `crypto ipsec client ezvpn name [outside]`
10. `exit`
11. `exit`
## Detailed Steps

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
| Example: Router> enable |  
| **Step 2** configure terminal | Enters global configuration mode. |
| Example: Router# configure terminal | |
| **Step 3** crypto ipsec client ezvpn name | Creates a remote configuration and enters Cisco Easy VPN Remote configuration mode. |
| Example: Router (config)# crypto ipsec client ezvpn easy client remote | |
| **Step 4** group group-name key group-key | Specifies the IPsec group and IPsec key value to be associated with this configuration.  
| Example: Router (config-crypto-ezvpn)# group easy-vpn-remote-groupname key easy-vpn-remote-password | Note | The value of the group-name argument must match the group defined on the Easy VPN server. On Cisco IOS routers, use the crypto isakmp client configuration group and crypto map dynmap isakmp authorization list commands. |
| **Step 5** peer [ip-address | hostname] | Specifies the IP address or hostname for the destination peer (typically the IP address on the outside interface of the destination route).  
| Example: Router (config-crypto-ezvpn)# peer 192.185.0.5 | Note | You must have a DNS server configured and available to use the hostname option. |
| **Step 6** mode {client | network-extension} | Specifies the type of VPN connection that should be made.  
| Example: Router (config-crypto-ezvpn)# mode client |  
| **Step 7** exit | Exits Cisco Easy VPN Remote configuration mode.  
| Example: Router (config-crypto-ezvpn)# exit | Note | The value of the group-key argument must match the key defined on the Easy VPN server. On Cisco IOS routers, use the crypto isakmp client configuration group command. |
How to Configure Cisco Easy VPN Remote

Verifying the Cisco Easy VPN Configuration

To verify that the Cisco Easy VPN Remote configuration has been correctly configured, that the configuration has been assigned to an interface, and that the IPsec VPN tunnel has been established, perform the following steps.

**SUMMARY STEPS**

1. `show crypto ipsec client ezvpn`
2. `show ip nat statistics`

**DETAILED STEPS**

**Step 8**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>interface interface</code></td>
<td>Enters interface configuration mode for the interface.</td>
</tr>
<tr>
<td>Example:</td>
<td>- This interface will become the outside interface for the NAT or PAT translation.</td>
</tr>
<tr>
<td>Router (config)# interface Ethernet1</td>
<td></td>
</tr>
</tbody>
</table>

**Step 9**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>crypto ipsec client ezvpn name [outside]</code></td>
<td>Assigns the Cisco Easy VPN Remote configuration to the interface.</td>
</tr>
<tr>
<td>Example:</td>
<td>- This configuration automatically creates the necessary NAT or PAT translation parameters and initiates the VPN connection (if you are in client mode).</td>
</tr>
<tr>
<td>Router (config-if)# crypto ipsec client ezvpn easy_vpn_remotel outside</td>
<td><strong>Note</strong> The inside interface must be specified on Cisco 1700 and higher platforms.</td>
</tr>
</tbody>
</table>

**Step 10**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>exit</code></td>
<td>Exits interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router (config-if)# exit</td>
<td></td>
</tr>
</tbody>
</table>

**Step 11**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>exit</code></td>
<td>Exits global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router (config)# exit</td>
<td></td>
</tr>
</tbody>
</table>
Step 2  Display the NAT or PAT configuration that was automatically created for the VPN connection using the `show ip nat statistics` command. The “Dynamic mappings” field of this display gives the details for the NAT or PAT translation that is occurring on the VPN tunnel.

Router# `show ip nat statistics`

Total active translations: 0 (0 static, 0 dynamic; 0 extended)
Outside interfaces:
  cable-modem0
Inside interfaces:
  Ethernet0
Hits: 1489  Misses: 1
Expired translations: 1
Dynamic mappings:
  -- Inside Source
  access-list 198 pool enterprise refcount 0
  pool enterprise: netmask 255.255.255.0
  start 192.168.1.90 end 192.168.1.90
  type generic, total addresses 1, allocated 0 (0%), misses 0

If you are seeing IPSEC_ACTIVE in your output at this point, everything is operating as expected.

---

**Configuring Save Password**

To configure the Save Password feature, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `password encryption aes`
4. `crypto ipsec client ezvpn name`
5. `username name password {0 | 6} {password}`
6. `exit`
7. `show running-config`
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> password encryption aes</td>
<td>Enables a type 6 encrypted preshared key.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router (config)# password encryption aes</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> crypto ipsec client ezvpn name</td>
<td>Creates a Cisco Easy VPN remote configuration and enters the Cisco Easy VPN remote configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router (config)# crypto ipsec client ezvpn ezvpn1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> username name password {0</td>
<td>6} (password)</td>
</tr>
<tr>
<td>Example:</td>
<td>• The 0 keyword specifies that an unencrypted password will follow.</td>
</tr>
<tr>
<td>Router (config-crypto-ezvpn)# username server_1 password 0 blue</td>
<td>• The 6 keyword specifies that an encrypted password will follow.</td>
</tr>
<tr>
<td></td>
<td>• The password argument is the unencrypted (cleartext) user password.</td>
</tr>
<tr>
<td><strong>Step 6</strong> exit</td>
<td>Exits the Cisco Easy VPN remote configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router (config-crypto-ezvpn)# exit</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> show running-config</td>
<td>Displays the contents of the configuration file that is currently running.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router (config)# show running-config</td>
<td></td>
</tr>
</tbody>
</table>

Configuring Manual Tunnel Control

To configure control of IPsec VPN tunnels manually so that you can establish and terminate the IPsec VPN tunnels on demand, perform the following steps.

**Note** CLI is one option for connecting the tunnel. The preferred method is via the web interface (using SDM).
### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto ipsec client ezvpn name`
4. `connect [auto | manual]`
5. `exit`
6. `exit`
7. `crypto ipsec client ezvpn connect name`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** `enable` | Enables privileged EXEC mode.  
* Enter your password if prompted. |
| **Example:**  
Router> enable | |
| **Step 2** `configure terminal` | Enters global configuration mode. |
| **Example:**  
Router# configure terminal | |
| **Step 3** `crypto ipsec client ezvpn name` | Assigns a Cisco Easy VPN remote configuration to an interface and enters Cisco Easy VPN Remote configuration mode.  
* The *name* argument specifies the configuration name to be assigned to the interface. |
| **Example:**  
Router (config)# crypto ipsec client ezvpn easy vpn remotel | |
| **Step 4** `connect [ auto | manual]` | Connects the VPN tunnel. Specify *manual* to configure manual tunnel control.  
* Automatic is the default; you do not need to use the *manual* keyword if your configuration is automatic. |
| **Example:**  
Router (config-crypto-ezvpn)# connect manual | |
| **Step 5** `exit` | Exits Cisco Easy VPN Remote configuration mode. |
| **Example:**  
Router (config-crypto-ezvpn)# exit | |
| **Step 6** `exit` | Exits global configuration mode and enters privileged EXEC mode. |
| **Example:**  
Router (config)# exit | |
| **Step 7** `crypto ipsec client ezvpn connect name` | Connects a given Cisco Easy VPN remote configuration.  
* The *name* argument specifies the IPsec VPN tunnel name.  
**Note** If the tunnel name is not specified, the active tunnel is connected. If there is more than one active tunnel, the command fails with an error requesting that you specify the tunnel name. |
| **Example:**  
Router# crypto ipsec client ezvpn connect easy vpn remotel | |
Configuring Automatic Tunnel Control

To configure automatic tunnel control, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto ipsec client ezvpn name`
4. `connect [auto | manual]`
5. `exit`
6. `exit`
7. `crypto ipsec client ezvpn connect name`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><strong>enable</strong> Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router&gt; enable</td>

<tr>
<td>Step 2</td>
<td><strong>configure terminal</strong> Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td><strong>crypto ipsec client ezvpn name</strong> Assigns a Cisco Easy VPN remote configuration to an interface and enters Cisco Easy VPN Remote configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router (config)# crypto ipsec client ezvpn easy vpn remotel</td>
<td>- Specify the configuration name to be assigned to the interface.</td>
</tr>
<tr>
<td>Step 4</td>
<td>**connect [auto</td>
</tr>
<tr>
<td><strong>Example:</strong> Router (config-crypto-ezvpn)# connect auto</td>
<td>- Specify <strong>auto</strong> to configure automatic tunnel control. Automatic is the default; you do not need to use this subcommand if your configuration is automatic.</td>
</tr>
<tr>
<td>Step 5</td>
<td><strong>exit</strong> Exits Cisco Easy VPN Remote configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router (config-crypto-ezvpn)# exit</td>
<td></td>
</tr>
<tr>
<td>Step 6</td>
<td><strong>exit</strong> Exits global configuration mode and enters privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router (config)# exit</td>
<td></td>
</tr>
</tbody>
</table>
Configuring Multiple Inside Interfaces

You can configure up to three inside interfaces for all platforms. You need to manually configure each inside interface using the following procedure.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-name`
4. `exit`
5. `crypto ipsec client ezvpn name [outside | inside]`
6. `interface interface-name`
7. `exit`
8. `crypto ipsec client ezvpn name [outside | inside]`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td><code>enable</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Router&gt; enable</code></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Router# configure terminal</code></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>interface interface-name</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Router (config)# interface Ethernet0</code></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>exit</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Router (config-if)# exit</code></td>
</tr>
</tbody>
</table>
Configuring Multiple Outside Interfaces

You can configure multiple tunnels for outside interfaces, setting up a tunnel for each outside interface. You can configure a maximum of four tunnels using the following procedure for each outside interface.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface interface-name`
4. `exit`
5. `crypto ipsec client ezvpn name [outside | inside]`
6. `interface interface-name`
7. `exit`
8. `crypto ipsec client ezvpn name [outside | inside]`
DETAILED STEPS

<table>
<thead>
<tr>

<td></td>
</tr>
<tr>
<td>Router (config)# interface Ethernet1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> exit</td>
<td>Exits interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router (config-if)# exit</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> crypto ipsec client ezvpn name [outside</td>
<td>inside]</td>
</tr>
<tr>
<td>Example:</td>
<td>• Specify outside (optional) for each outside interface. If neither outside nor inside is specified for the interface, the default is outside.</td>
</tr>
<tr>
<td>Router (config)# crypto ipsec client ezvpn easy vpn remotel2 outside</td>
<td>Repeat Step 3 through Step 4 to configure additional tunnels if desired.</td>
</tr>
</tbody>
</table>

Configuring Multiple Subnet Support

When configuring multiple subnet support, you must first configure an access list to define the actual subnets to be protected. Each source subnet or mask pair indicates that all traffic that is sourced from this network to any destination is protected by IPSec. For information about configuring ACLs, see “Access control lists, configuring” in the section “Additional References.”
After you have defined the subnets, you must configure the crypto IPsec client EZVPN profile to use the ACLs.

**Note**

Multiple subnets are not supported in client mode.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface interface-name**
4. **exit**
5. **crypto ipsec client ezvpn name**
6. **acl {acl-name | acl-number}**

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| Example:  
Router> enable |  |
| **Step 2** configure terminal | Enters global configuration mode. |
| Example:  
Router# configure terminal |  |
| **Step 3** interface interface-name | Selects the interface you want to configure by specifying the interface name and enters interface configuration mode. |
| Example:  
Router (config)# interface Ethernet1 |  |
| **Step 4** exit | Exits interface configuration mode. |
| Example:  
Router (config-if)# exit |  |
| **Step 5** crypto ipsec client ezvpn name | Creates a Cisco Easy VPN remote configuration and enters crypto Easy VPN configuration mode. |
| Example:  
Router (config)# crypto ipsec client ezvpn ez1 |  |
| **Step 6** acl {acl-name | acl-number} | Specifies multiple subnets in a VPN tunnel. |
| Example:  
Router (config-crypto-ezvpn)# acl acl-list1 |  |
Configuring Proxy DNS Server Support

As a way of implementing the use of the DNS addresses of the ISP when the WAN connection is down, the router in a Cisco Easy VPN remote configuration can be configured to act as a proxy DNS server. To enable the proxy DNS server functionality with the `ip dns server` command, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `ip dns server`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>enable</code></td>
</tr>
<tr>
<td>Example:</td>
<td>Router&gt; enable</td>
</tr>
<tr>
<td>Step 2</td>
<td><code>configure terminal</code></td>
</tr>
<tr>
<td>Example:</td>
<td>Router# configure terminal</td>
</tr>
<tr>
<td>Step 3</td>
<td><code>ip dns server</code></td>
</tr>
<tr>
<td>Example:</td>
<td>Router (config)# ip dns server</td>
</tr>
</tbody>
</table>

**Note** This definition is IOS specific.

**What to Do Next**

After configuring the router, you configure the Cisco IOS Easy VPN server as follows:

- Under the `crypto isakmp client configuration group` command, configure the `dns` subcommand as in the following example:
  
  ```
  ```

  These DNS server addresses should be pushed from the server to the Cisco Easy VPN remote and dynamically added to or deleted from the running configuration of the router.

For information about general DNS server functionality in Cisco IOS software applications, see *Configuring DNS* and *Configuring DNS on Cisco Routers*.

**Configuring Dial Backup**

**Note** The Dial Backup feature is not available in Cisco IOS Release 12.3(11)T.

To configure dial backup, perform the following steps.
SUMMARY STEPS

1. Create the Easy VPN backup configuration.
2. Add the backup subcommand details to the primary configuration.
3. Apply the backup Easy VPN configuration to the dial backup outside interface.
4. Apply the Easy VPN profile to the inside interfaces.

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Create the Easy VPN dial backup configuration. For details about the backup configuration, see the section “Dial Backup.”</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Add the backup subcommand details to the primary configuration. Use the backup subcommand and track keyword of the crypto ipsec client ezvpn command.</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Apply the backup Easy VPN configuration to the dial backup outside interface (for example, serial, async, or dialer). For details about applying the backup configuration to the dial backup outside interface, see the section “ Configuring Multiple Outside Interfaces.”</td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Apply the Easy VPN profile to the inside interfaces (there can be more than one). For details about applying the Easy VPN profile to the inside interfaces, see the section “ Configuring Multiple Inside Interfaces.”</td>
</tr>
</tbody>
</table>

Configuring the DHCP Server Pool

To configure the Dynamic Host Configuration Protocol (DHCP) server pool, see the chapter “Configuring DHCP” in the Cisco IOS IP Configuration Guide, Release 12.3.

Resetting a VPN Connection

To reset the VPN connection, perform the following steps. The clear commands can be configured in any order or independent of one another.

SUMMARY STEPS

1. enable
2. clear crypto ipsec client ezvpn
3. clear crypto sa
4. clear crypto isakmp
DETAILED STEPS

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> clear crypto ipsec client ezvpn</td>
<td>Resets the Cisco Easy VPN remote state machine and brings down the Cisco Easy VPN remote connection on all interfaces or on a given interface (tunnel).</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# clear crypto ipsec client ezvpn</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> clear crypto sa</td>
<td>Deletes IPsec SAs.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# clear crypto sa</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> clear crypto isakmp</td>
<td>Clears active IKE connections.</td>

How to Configure Cisco Easy VPN Remote

50

Configuring a Virtual Interface

To configure a virtual interface, perform the following steps.

**Note**
Before the virtual interface is configured, ensure that the Easy VPN profile is not applied on any outside interface. Remove the Easy VPN profile from the outside interface and then configure the virtual interface.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface virtual-template number type type-of-virtual-template`
4. `tunnel mode ipsec ipv4`
5. `exit`
6. `crypto ipsec client ezvpn name`  
7. `virtual-interface virtual-template-number`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td><strong>Step 7</strong></td>
<td><code>virtual-interface virtual-template-number</code></td>
</tr>
</tbody>
</table>
Troubleshooting Dual Tunnel Support

The following `debug` and `show` commands may be used to troubleshoot your dual-tunnel configuration.

### SUMMARY STEPS

1. `enable`
2. `debug crypto ipsec client ezvpn`
3. `debug ip policy`
4. `show crypto ipsec client ezvpn`
5. `show ip interface`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>debug crypto ipsec client ezvpn</code></td>
<td>Displays information about Cisco Easy VPN remote connections.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router# debug crypto ipsec client ezvpn</td>

</tbody>
</table>
### How to Configure Cisco Easy VPN Remote

#### Configuring Reactivate (a Default) Primary Peer

To configure a default primary peer, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto ipsec client ezvpn name`
4. `peer {ip-address | hostname} [default]`
5. `idle-time idle-time`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router&gt; enable</td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> <code>crypto ipsec client ezvpn name</code></td>
<td>Creates a Cisco Easy VPN remote configuration and enters crypto Easy VPN configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router (config)# crypto ipsec client ezvpn ez1</td>
<td></td>
</tr>
</tbody>
</table>
Configuring Identical Addressing Support

Configuring Identical Addressing Support comprises the following tasks:

- Defining the Easy VPN remote in network-extension mode and enabling `nat allow`.
- Assigning the Cisco Easy VPN Remote configuration to the Outside interface.
- Creating a loopback interface and assigning the Cisco Easy VPN Remote configuration to the Inside interface of the loopback interface.
- Configuring a one-to-one static NAT translation for each host that needs to be accessible from the EasyVPN server-side network or from other client locations.
- Configuring dynamic overloaded NAT or PAT using an access list for all the desired VPN traffic. The NAT or PAT traffic is mapped to the Easy VPN inside interface IP address.
- And, if split-tunneling is required, using the `nat acl` command to enable split-tunneling for the traffic specified by the `acl-name` or the `acl-number` argument. The ACL is the same as the ACL used by the NAT or PAT mapping in the preceding bullet item.

To configure Identical Addressing Support, perform the following steps on your router.

**Prerequisites**

Easy VPN Remote must be configured in network extension mode before you can configure the Identical Addressing Support feature.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto ipsec client ezvpn name`
4. `mode network-extension`
5. `nat allow`
6. `exit`
7. `interface interface`
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>enable</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Router&gt; enable</code></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td><code>configure terminal</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Router# configure terminal</code></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td><code>crypto ipsec client ezvpn name</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Router (config)# crypto ipsec client ezvpn easyclient</code></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td><code>mode network-extension</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Router (config-crypto-ezvpn)# mode network-extension</code></td>
</tr>
<tr>
<td><strong>Step 5</strong></td>
<td><code>nat allow</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Router (config-crypto-ezvpn)# nat allow</code></td>
</tr>
<tr>
<td><strong>Step 6</strong></td>
<td><code>exit</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Router (config-crypto-ezvpn)# exit</code></td>
</tr>
</tbody>
</table>
### Command Purpose

<table>
<thead>
<tr>
<th>Step</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 7    | ```interface interface``` | Enters interface configuration mode for the interface.  
- This interface will become the outside interface for the NAT or PAT translation. |
| 8    | ```crypto ipsec client ezvpn name outside``` | Assigns the Cisco Easy VPN Remote configuration to the outside interface.  
- This configuration automatically creates the necessary NAT or PAT translation parameters and initiates the VPN connection (if you are in client mode). |
| 9    | ```exit``` | Exits interface configuration mode. |
| 10   | ```interface interface``` | Enters interface configuration mode for the loopback interface.  
- This interface will become the inside interface for the NAT or PAT translation. |
| 11   | ```ip address ip mask``` | Assigns the IP address and mask to the loopback interface. |
| 12   | ```crypto ipsec client ezvpn name inside``` | Assigns the Cisco Easy VPN Remote configuration to the inside interface. |
| 13   | ```exit``` | Exits interface configuration mode. |
| 14   | ```ip nat inside source static local-ip global-ip``` | Configure a one-to-one static NAT translation for each host that needs to be accessible from the Easy VPN server side network, or from other client locations. |
| 15   | ```ip nat inside source list (acl-name | acl-number) interface overload``` | Configure dynamic overloaded NAT or PAT, which uses an ACL for all the desired VPN traffic. The NAT and PAT traffic is mapped to the Easy VPN inside interface IP address.  
- The `acl-name` argument is the name of the ACL.  
- The `acl-number` argument is the number of the ACL. |
How to Configure Cisco Easy VPN Remote

To configure cTCP on an Easy VPN client (remote device), perform the following steps.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto ctcp [keepalive number-of-seconds | port port-number]`
4. `crypto ipsec client ezvpn name`
5. `ctcp port port-number`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> <code>enable</code></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
Restricting Traffic When a Tunnel Is Down

To restrict the client from sending traffic in clear text when a tunnel is down, perform the following steps.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `crypto ipsec client ezvpn name`
4. `flow allow acl [name | number]`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 <code>enable</code></td>
<td>Enables privileged EXEC mode.&lt;br&gt;• Enter your password if prompted.</td>
</tr>
<tr>
<td>Example: <code>Router&gt; enable</code></td>
<td></td>
</tr>
<tr>
<td>Step 2 <code>configure terminal</code></td>
<td>Enters global configuration mode.</td>

</tbody>
</table>
How to Configure Cisco Easy VPN Remote

**Easy VPN Server Tasks**

**Configuring a Cisco IOS Easy VPN Server**

For information about configuring the Easy VPN Server, see the following document:

- *Easy VPN Server*

**Configuring an Easy VPN Server on a VPN 3000 Series Concentrator**

This section describes the guidelines required to configure the Cisco VPN 3000 series concentrator for use with the Cisco Easy VPN Remote feature. As a general rule, you can use the default configuration except for IP addresses, server addresses, routing configurations, and for the following parameters and options:

- Peer Configuration on a Cisco Easy VPN Remote Using the Hostname, page 59
- Interactive Hardware Client Authentication Version 3.5, page 59
- IPsec Tunnel Protocol, page 59
- IPsec Group, page 59
- Group Lock, page 59
- Xauth, page 59
- Split Tunneling, page 60
- IKE Proposals, page 60
- New IPsec SA, page 60

**Note**

You must be using Cisco VPN 3000 series concentrator software Release 3.11 or later to support Cisco Easy VPN software clients and remotes.

### Command Table

<table>
<thead>
<tr>
<th>Step 3</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>crypto ipsec client ezvpn name</td>
<td>Creates a Cisco Easy VPN remote configuration and enters Cisco Easy VPN remote configuration mode.</td>
<td></td>
</tr>
</tbody>
</table>

**Example:**

```
Router (config)# crypto ipsec client ezvpn ezvpn1
```

<table>
<thead>
<tr>
<th>Step 4</th>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>flow allow acl [name</td>
<td>number]</td>
<td>Restricts the client from sending traffic in clear text when the tunnel is down.</td>
</tr>
</tbody>
</table>

**Example:**

```
Router (config-crypto-ezvpn)# flow allow acl 102
```

- `name`— Access list name.
- `number`— Access list number. Value = 100 through 199.
Peer Configuration on a Cisco Easy VPN Remote Using the Hostname

After you have configured the Cisco Easy VPN server on the VPN 3000 concentrator to use hostname as its identity, you must configure the peer on the Cisco Easy VPN remote using the hostname. You can either configure DNS on the client to resolve the peer hostname or configure the peer hostname locally on the client using the `ip host` command. As an example, you can configure the peer hostname locally on an Easy VPN remote as follows:

```bash
ip host crypto-gw.cisco.com 10.0.0.1
```

Or you can configure the Easy VPN remote to use the hostname with the `peer` command and `hostname` argument, as follows:

```bash
peer crypto-gw.cisco.com.
```

Interactive Hardware Client Authentication Version 3.5

The Cisco Easy VPN Remote feature does not support the Interactive Hardware Client Authentication Version 3.5 feature. This feature must be disabled. You can disable the feature on the VPN 3000 series concentrator by clicking the `HW Client` tab on the Configuration | User Management | Base Group screen.

IPsec Tunnel Protocol

IPsec Tunnel Protocol enables the IPsec tunnel protocol so that it is available for users. The IPsec Tunnel Protocol is configured on the Cisco VPN 3000 series concentrator by clicking the `General` tab on the Configuration | User Management | Base Group screen.

IPsec Group

IPsec group configures the Cisco VPN 3000 series concentrator with a group name and password that match the values configured for the Cisco Easy VPN remote configuration on the router. These values are configured on the router with the `group group-name key group-key` subcommand and arguments. The values are configured on the Cisco VPN 3000 series concentrator using the Configuration | User Management | Groups screen.

Group Lock

If you are defining multiple users in multiple groups on the VPN 3000 series concentrator, you must check the `Group Lock` box in the IPsec tab to prevent users in one group from logging in with the parameters of another group. For example, if you have configured one group for split tunneling access and another group without split tunneling access, clicking the `Group Lock` box prevents users in the second group from gaining access to the split tunneling features. The Group Lock checkbox appears in the IPsec tab in the Configuration | User Management | Base Group screen and in the IPsec tab in the Configuration | User Management | Groups | Add/Modify screens.

Xauth

To use Xauth, set the `Authentication` parameter to `None`. The Authentication parameter appears in the IPsec tab in the Configuration | User Management | Base Group screen and in the IPsec tab in the Configuration | User Management | Groups | Add/Modify screens.
Split Tunneling

The Configuration | User Management | Base Group, Mode Configuration Parameters Tab screen includes a Split Tunnel option with a checkbox that says “Allow the networks in the list to bypass the tunnel.”

IKE Proposals

The Cisco VPN 3000 series concentrator is preconfigured with a default IKE proposal, CiscoVPNClient-3DES-MD5, that can be used with Cisco Easy VPN remotes. This IKE proposal supports preshared keys with Xauth using the MD5/HMAC-128 algorithm and Diffie-Hellman Group 2. This IKE proposal is active by default, but you should verify that it is still an active proposal using the Configuration | System | Tunneling Protocols | IPsec | IKE Proposals screen.

In addition, as part of configuring the Cisco VPN 3000 series concentrator—for the Cisco Easy VPN Remote image, you do not need to create a new IPsec SA. Use the default IKE and Easy VPN remote lifetime configured on the Cisco VPN 3000 series concentrator.

Note

You can also use the default IKE proposals IKE-DES-MD5 and IKE-3DES-MD5, but they do not enable Xauth support by default.

New IPsec SA

You can create a new IPsec SA. Cisco Easy VPN clients use a SA having the following parameters:

- Authentication Algorithm=ESP/MD5/HMAC-128
- Encryption Algorithm=DES-56 or 3DES-168 (recommended)
- Encapsulation Mode=Tunnel
- IKE Proposal=CiscoVPNClient-3DES-MD5 (preferred)

The Cisco VPN 3000 series concentrator is preconfigured with several default security associations (SAs), but they do not meet the IKE proposal requirements. To use an IKE proposal of CiscoVPNClient-3DES-MD5, copy the ESP/IKE-3DES-MD5 SA and modify it to use CiscoVPNClient-3DES-MD5 as its IKE proposal. An IKE proposal is configured on the VPN 3000 series concentrator using the Configuration | Policy Management | Traffic Management | Security Associations screen.

Configuring an Easy VPN Server on a Cisco PIX Firewall

For information about configuring an Easy VPN Server on a Cisco PIX Firewall, see the following document:

- Easy VPN Server
Web Interface Tasks

Configuring Web-Based Activation

To configure a LAN so that any HTTP requests coming from any of the PCs on the private LAN are intercepted, providing corporate users with access to the corporate Web page, perform the following steps.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **crypto ipsec client ezvpn name**
4. **xauth userid mode {http-intercept | interactive | local}**

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1 enable</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2 configure terminal</strong></td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3 crypto ipsec client ezvpn name</strong></td>
<td>Assigns a Cisco Easy VPN remote configuration to an interface and enters Cisco Easy VPN Remote configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> Router (config)# crypto ipsec client ezvpn easy vpn remote1</td>
<td>• The name argument specifies the configuration name to be assigned to the interface.</td>
</tr>
<tr>
<td>**Step 4 xauth userid mode {http-intercept</td>
<td>interactive</td>
</tr>
<tr>
<td><strong>Example:</strong> Router (config-crypto-ezvpn)# xauth userid mode http-intercept</td>
<td></td>
</tr>
</tbody>
</table>

Monitoring and Maintaining Web-Based Activation

To monitor and maintain web-based activation, perform the following steps. (The **debug** and **show** commands may be used independently, or they may all be configured.)

**SUMMARY STEPS**

1. **enable**
2. **debug crypto ipsec client ezvpn**
3. `debug ip auth-proxy ezvpn`
4. `show crypto ipsec client ezvpn`
5. `show ip auth-proxy config`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** enable | Enables privileged EXEC mode.  
- Enter your password if prompted. |
| Example: Router> enable | |
| **Step 2** `debug crypto ipsec client ezvpn` | Displays information about the Cisco Easy VPN connection. |
| Example: Router# debug crypto ipsec client ezvpn | |
| **Step 3** `debug ip auth-proxy ezvpn` | Displays information related to proxy authentication behavior for web-based activation. |
| Example: Router# debug ip auth-proxy ezvpn | |
| **Step 4** `show crypto ipsec client ezvpn` | Shows that the username and password used for user credentials during Xauth negotiations will be obtained by intercepting HTTP connections from the user. |
| Example: Router# show crypto ipsec client ezvpn | |
| **Step 5** `show ip auth-proxy config` | Displays the auth-proxy rule that has been created and applied by Easy VPN. |
| Example: Router# show ip auth-proxy config | |

**Examples**

**Debug Output**

The following is sample `debug` output for a typical situation in which a user has opened a browser and connected to the corporate website:

```
Router# debug ip auth-proxy ezvpn

Dec 10 12:41:13.335: AUTH-PROXY: New request received by EzVPN WebIntercept
The following line shows the ip address of the user.
from 10.4.205.205
Dec 10 12:41:13.335: AUTH-PROXY:GET request received
Dec 10 12:41:13.335: AUTH-PROXY:Normal auth scheme in operation
Dec 10 12:41:13.335: AUTH-PROXY:Ezvpn is NOT active. Sending connect-bypass page to user

At this point, the user chooses “connect” on his or her browser:

Dec 10 12:42:43.427: AUTH-PROXY: New request received by EzVPN WebIntercept
from 10.4.205.205
Dec 10 12:42:43.427: AUTH-PROXY:POST request received
Dec 10 12:42:43.639: AUTH-PROXY:Found attribute <connect> in form
Dec 10 12:42:43.639: AUTH-PROXY:Sending POST data to EzVPN
```
Request/Response from 10.4.205.205, via Ethernet0
Dec 10 12:42:43.639:         connect: Connect Now
Dec 10 12:42:43.639: EZVPN(tunnel22): Received CONNECT from 10.4.205.205!
Dec 10 12:42:43.643: EZVPN(tunnel22): ezvpn_connect_request

Easy VPN contacts the server:
Dec 10 12:42:43.643: EZVPN(tunnel22): Found valid peer 192.168.0.1
Dec 10 12:42:43.643: EZVPN(tunnel22): Added PSK for address 192.168.0.1
Dec 10 12:42:43.643: EZVPN(tunnel22): No state change
Dec 10 12:42:43.643: EZVPN(tunnel22): ezvpn_conn_up B8E86EC7 E88A8A18 D0D51422 8AFF32B7

The server requests Xauth information:
Dec 10 12:42:43.643: EZVPN(tunnel22): No state change
Dec 10 12:42:43.643: EZVPN(tunnel22): ezvpn_xauth_request
Dec 10 12:42:43.643: EZVPN(tunnel22): ezvpn_parse_xauth_msg
Dec 10 12:42:43.643: EZVPN(tunnel22): Attributes sent in xauth request message:
Dec 10 12:42:43.643:       XAUTH_TYPE_V2(tunnel22): 0
Dec 10 12:42:43.643:       XAUTH_USER_NAME_V2(tunnel22): Username:
Dec 10 12:42:43.643:       XAUTH_USER_PASSWORD_V2(tunnel22): Password:
Dec 10 12:42:43.643: EZVPN(tunnel22): Requesting following info for xauth
Dec 10 12:42:43.643:       username:(Null)
Dec 10 12:42:43.643:       password:(Null)

The username and password prompt are displayed in the browser of the user:
Dec 10 12:42:43.643: AUTH-PROXY: Response to POST is CONTINUE
Dec 10 12:42:43.643: AUTH-PROXY: Displayed POST response successfully
Dec 10 12:42:43.643: AUTH-PROXY: Served POST response to the user

When the user enters his or her username and password, the following is sent to the server:
Dec 10 12:42:43.643: AUTH-PROXY: New request received by EzVPN WebIntercept from 10.4.205.205

Dec 10 12:42:55.891: EZVPN(tunnel22): xauth status received: Success

After using the tunnel, the user chooses “Disconnect”:
Dec 10 12:48:17.267: EZVPN(tunnel22): Received authentic disconnect credential
Dec 10 12:48:17.275: EZVPN(): Received an HTTP request: disconnect
Dec 10 12:48:17.275: %CRYPTO-6-EZVPN_CONNECTION_DOWN: (Client) User=
Group=tunnel22  Client_public_addr=192.168.0.13  Server_public_addr=192.168.0.1
Assigned_client_addr=10.3.4.5

Show Output Before the User Is Connected to the Tunnel

The following output from the two show commands (show crypto ipsec client ezvpn and show ip auth-proxy config) displays what you might see before a user is connected to a VPN tunnel:

Router# show crypto ipsec client ezvpn tunnel22

Tunnel name : tunnel22
Inside interface list: Ethernet0
Outside interface: Ethernet1
Current State: CONNECT_REQUIRED
Last Event: RESET
Save Password: Disallowed
! Note the next line.
   XAuth credentials: HTTP intercepted
   HTTP return code : 200
   IP addr being prompted: 0.0.0.0
Current EZVPN Peer: 192.168.0.1

Router# show ip auth-proxy config

Authentication global cache time is 60 minutes
Authentication global absolute time is 0 minutes
Authentication Proxy Watch-list is disabled

Authentication Proxy Rule Configuration
! Note that the next line is the Easy VPN-defined internal rule.
   Auth-proxy name ezvpn401***
   Applied on Ethernet0
   http list not specified inactivity-timer 60 minutes

Show Output After the User Is Connected to the Tunnel

The following output from the two show commands (show crypto ipsec client ezvpn and show ip auth-proxy config) displays what you might see after the user has been connected to the tunnel:

Router# show crypto ipsec client ezvpn tunnel22

Tunnel name : tunnel22
Inside interface list: Ethernet0
Outside interface: Ethernet1
Current State: IPSSEC_ACTIVE
Last Event: SOCKET_UP
Address: 10.3.4.5
Mask: 255.255.255.255
Save Password: Disallowed
   XAuth credentials: HTTP intercepted
   HTTP return code : 200
   IP addr being prompted: 192.168.0.0
Current EzVPN Peer: 192.168.0.1

Router# show ip auth-proxy config

Authentication global cache time is 60 minutes
Authentication global absolute time is 0 minutes
Authentication Proxy Watch-list is disabled

Auth-proxy name ezvpnWeb*** (EzVPN-defined internal rule)
http list not specified inactivity-timer 60 minutes

Using SDM As a Web Manager

For information about the SDM web manager, see the following document:

• Cisco Security Device Manager

Troubleshooting the VPN Connection

Troubleshooting a VPN Connection Using the Cisco Easy VPN Remote Feature

To troubleshoot a VPN connection created using the Cisco Easy VPN Remote feature, use the following suggested techniques.

• Be aware that any changes to an active Cisco Easy VPN remote configuration or IP address changes to the involved interfaces, such as adding or removing an inside interface, result in a reset of the Cisco Easy VPN Remote connection.

• Enable debugging of the Cisco Easy VPN Remote feature using the debug crypto ipsec client ezvpn command.

• Enable debugging of IKE events using the debug crypto ipsec and debug crypto isakmp commands.

• Display the active IPsec VPN connections using the show crypto engine connections active command.

• To reset the VPN connection, use the clear crypto ipsec client ezvpn command. If you have debugging enabled, you might prefer to use the clear crypto sa and clear crypto isakmp commands.

Troubleshooting the Client Mode of Operation

The following information may be used to troubleshoot the Easy VPN Remote configuration for the client mode of operation.

In client mode, the Cisco Easy VPN Remote feature automatically configures the NAT or PAT translation and access lists that are needed to implement the VPN tunnel. These configurations are automatically created when the IPsec VPN connection is initiated. When the tunnel is torn down, the NAT or PAT and access list configurations are automatically deleted.

The NAT or PAT configuration is created with the following assumptions:

• The ip nat inside command is applied to all inside interfaces, including default inside interfaces. The default inside interface is the Ethernet 0 interface (for the Cisco 806, Cisco 826, Cisco 827, Cisco 828, Cisco 831, Cisco 836, and Cisco 837 routers).
• The **ip nat outside** command is applied to the interface that is configured with the Cisco Easy VPN Remote configuration. On the Cisco 800 series and Cisco 1700 series routers, the outside interface is configured with the Cisco Easy VPN Remote configuration. On the Cisco 1700 series routers, Cisco 2600 series routers, Cisco 3600 series routers, and Cisco 3700 series routers, multiple outside interfaces can be configured.

**Tip**

The NAT or PAT translation and access list configurations that are created by the Cisco Easy VPN Remote feature are not written to either the startup configuration or running configuration files. These configurations, however, can be displayed using the **show ip nat statistics** and **show access-list** commands.

**Troubleshooting Remote Management**

To troubleshoot remote management of the VPN remote, use the **show ip interface** command. Using the **brief** keyword, you can verify that the loopback has been removed and that the interface is shown correctly.

**Examples**

Following is a typical example of output from the **show ip interface** command.

```
Router# show ip interface brief

Interface   IP-Address      OK? Method Status                Protocol
Ethernet0   unassigned      YES NVRAM  administratively down down
Ethernet1   10.0.0.11       YES NVRAM  up                    up
Loopback0   192.168.6.1     YES manual up                    up
Loopback1   10.12.12.12     YES NVRAM  up                    up
```

```
Router# show ip interface brief

Interface   IP-Address      OK? Method Status                Protocol
Ethernet0   unassigned      YES NVRAM  administratively down down
Ethernet1   10.0.0.11       YES NVRAM  up                    up
Loopback1   10.12.12.12     YES NVRAM  up                    up
```

**Troubleshooting Dead Peer Detection**

To troubleshoot dead peer detection, use the **show crypto ipsec client ezvpn** command.

**Examples**

The following typical output displays the current server and the peers that have been pushed by the Easy VPN server:

```
Router# show crypto ipsec client ezvpn

Easy VPN Remote Phase: 4
Tunnel name : ez1
Inside interface list: Loopback1,
Outside interface: Ethernet1
```
Current State: IPSEC_ACTIVE
Last Event: CONNECT
Address: 192.168.6.5
Mask: 255.255.255.255

Cisco Easy VPN Remote Configuration Examples

Client Mode Configuration: Examples

The examples in this section show configurations for the Cisco Easy VPN Remote feature in client mode. Also shown are the Cisco IOS Easy VPN server configurations that correspond to these client configurations.

- Cisco Easy VPN Client in Client Mode (Cisco 831): Example, page 68
- Cisco Easy VPN Client in Client Mode (Cisco 837): Example, page 69
- Cisco Easy VPN Client in Client Mode (Cisco 1700 Series): Example, page 71

For more client-mode configuration examples, see IPSec VPN (under the “Technical Documents” and “Cisco IOS IPSec Configuration Documents” sections) and to Cisco Easy VPN Solutions.

Note

Typically, users configure the Cisco 800 series routers with the SDM or CRWS web interface, not by entering CLI commands. However, the configurations shown here for the Cisco 800 series routers display typical configurations that can be used if manual configuration is desired.

Cisco Easy VPN Client in Client Mode (Cisco 831): Example

In the following example, a Cisco 831 router is configured as an Easy VPN remote using the Cisco Easy VPN Remote feature in client mode. This example shows the following components of the Cisco Easy VPN Remote configuration:

- DHCP server pool—The ip dhcp pool command creates a pool of IP addresses to be assigned to the PCs connected to the Ethernet 0 interface of the router. The pool assigns addresses in the class C private address space (192.168.100.0) and configures each PC so that its default route is 192.168.100.1, which is the IP address assigned to the Ethernet interface of the router. The DHCP lease period is one day.

- Cisco Easy VPN remote configuration—The first crypto ipsec client ezvpn easy vpn remote command (global configuration mode) creates a Cisco Easy VPN remote configuration named “easy vpn remote.” This configuration specifies the group name “easy vpn remote-groupname” and the shared key value “easy vpn remote-password,” and it sets the peer destination to the IP address 192.185.0.5 (which is the address assigned to the interface connected to the Internet on the destination peer router). The Cisco Easy VPN Remote configuration is configured for the default client mode.

Note

If DNS is also configured on the router, the peer keyword option also supports a hostname instead of an IP address.

- The second crypto ipsec client ezvpn easy vpn remote command (interface configuration mode) assigns the Cisco Easy VPN Remote configuration to the Ethernet 1 interface so that all traffic that is received and transmitted on that interface is sent through the VPN tunnel.

Cisco Easy VPN Client in Client Mode (Cisco 837): Example

In the following example, a Cisco 837 router is configured as an Easy VPN remote using the Cisco Easy VPN Remote feature in the client mode of operation. This example shows the following components of the Cisco Easy VPN remote configuration:

- PPPoE configuration—The ATM 0 interface is configured to support PPPoE connections over the Dialer 1 virtual interface. Because the interfaces use PPPoE, a DHCP IP address pool is not required to provide IP addresses to the connected PCs.

- Cisco Easy VPN Remote configuration—The first `crypto ipsec client ezvpn` command (global configuration mode) creates a Cisco Easy VPN remote configuration named “easy vpn remote.” This configuration specifies the group name “easy vpn remote-groupname” and the shared key value of “easy vpn remote-password,” and it sets the peer destination to the IP address 10.0.0.5 (which is the address assigned to the interface connected to the Internet on the destination peer router). The Cisco Easy VPN remote configuration is configured for the default client mode.
Note  If DNS is also configured on the router, the **peer** keyword option also supports a hostname instead of an IP address.

- The second `crypto ipsec client ezvpn` command (interface configuration mode) assigns the Cisco Easy VPN remote configuration to the Dialer 1 interface so that all traffic received and transmitted on that interface is sent through the VPN tunnel.

Configuration Examples for Cisco Easy VPN Remote

Cisco Easy VPN Client in Client Mode (Cisco 1700 Series): Example

In the following example, a Cisco 1753 router is configured as an Easy VPN remote using the Cisco Easy VPN Remote feature in the client mode of operation. This example shows a running configuration of a Cisco 1753 that has two inside interfaces and one outside interface on one tunnel. The `connect auto` subcommand manually establishes the IPsec VPN tunnel.

Router# `show running-config`

Local Address Support for Easy VPN Remote: Example

The following example shows that the local-address command is used to specify the loopback 0
interface for sourcing tunnel traffic:

Router# configure terminal
Router(config)# crypto ipsec client ezvpn telecommuter-client
Router(config-crypto-ezvpn)# local-address loopback0
Network Extension Mode Configuration: Examples

In this section, the following examples demonstrate how to configure the Cisco Easy VPN Remote feature in the network extension mode of operation. Also shown are the Cisco IOS Easy VPN server configurations that correspond to these client configurations.

- Cisco Easy VPN Client in Network Extension Mode (Cisco 831): Example, page 74
- Cisco Easy VPN Client in Network Extension Mode (Cisco 837): Example, page 75
- Cisco Easy VPN Client in Network Extension Mode (Cisco 1700 Series): Example, page 77

For more network extension mode configuration examples, see IPSec VPN (under the “Technical Documents” and “Cisco IOS IPSec Configuration Documents” sections) and to Cisco Easy VPN Solutions.

Cisco Easy VPN Client in Network Extension Mode (Cisco 831): Example

In the following example, a Cisco 831 router is configured as an Easy VPN remote using the Cisco Easy VPN Remote feature. This example shows the following components of the Cisco Easy VPN remote configuration:

- The Ethernet 0 interface is assigned an address in the network address space of the Cisco IOS Easy VPN server. The `ip route` command directs all traffic for this network space from the Ethernet 1 interface to the destination server.

- Cisco Easy VPN Remote configuration—The first `crypto ipsec client ezvpn` command (global configuration mode) creates a Cisco Easy VPN remote configuration named “easy vpn remote.” This configuration specifies the group name “easy vpn remote-groupname” and the shared key value “easy vpn remote-password,” and it sets the peer destination to the IP address 192.185.0.5 (which is the address assigned to the interface connected to the Internet on the destination peer router). The Cisco Easy VPN remote configuration is configured for network extension mode.

  Note

  If DNS is also configured on the router, the `peer` keyword option also supports a hostname instead of an IP address.

- The second `crypto ipsec client ezvpn` command (interface configuration mode) assigns the Cisco Easy VPN Remote configuration to the Ethernet 1 interface so that all traffic that is received and transmitted on that interface is sent through the VPN tunnel.

Cisco Easy VPN Remote Configuration Examples for Cisco Easy VPN Remote

Cisco Easy VPN Client in Network Extension Mode (Cisco 1700 Series): Example

In the following example, a Cisco 1700 series router is configured as an Easy VPN remote using the Cisco Easy VPN Remote feature in the network extension mode of operation. This example shows the following components of the Cisco Easy VPN remote configuration:

- Cisco Easy VPN Remote configuration—The first `crypto ipsec client ezvpn` command (global configuration mode) creates a Cisco Easy VPN remote configuration that is named “easy vpn remote.” This configuration specifies the group name “easy vpn remote-groupname” and the shared key value “easy vpn remote-password,” and it sets the peer destination to the IP address 10.0.0.2 (which is the address assigned to the interface connected to the Internet on the destination peer router). The Cisco Easy VPN remote configuration is configured for network extension mode.

  **Note** If DNS is also configured on the router, the `peer` keyword option also supports a hostname instead of an IP address.

- The second `crypto ipsec client ezvpn easy vpn remote` command (interface configuration mode) assigns the Cisco Easy VPN remote configuration to the Ethernet 0 interface so that all traffic that is received and transmitted on that interface is sent through the VPN tunnel.

Save Password Configuration: Example

The following sample show running-config output shows that the Save Password feature has been configured (note the password encryption aes command and username keywords in the output):

Router# show running-config

133.CABLEMODEM.CISCO: Oct 28 18:42:07.115: %SYS-5-CONFIG_I: Configured from console by consolen
Building configuration...

Current configuration : 1269 bytes

**PFS Support: Examples**

The following `show crypto ipsec client ezvpn` command output shows the group name (“2”) and that PFS is being used:

```
Router# show crypto ipsec client ezvpn

Easy VPN Remote Phase: 4

Tunnel name : ez1
  Inside interface list: Loopback1,
  Outside interface: Ethernet1
  Current State: IPSEC_ACTIVE
  Last Event: SOCKET_UP
  Address: 192.168.6.6
  Mask: 255.255.255.255
  Using PFS Group: 2
  Save Password: Allowed
  Current EzVPN Peer:10.0.0.110
```

Note that on a Cisco IOS EasyVPN server, PFS must be included in IPsec proposals by adding to the crypto map, as in the following example:

```
crypto dynamic-map mode 1
  set security-association lifetime seconds 180
  set transform-set client
  set pfs group2
  set isakmp-profile fred
  reverse-route
```

**Dial Backup: Examples**

**Static IP Addressing**

The following example shows that static IP addressing has been configured for a Cisco 1711 router:

```

Web-Based Activation: Example

The following example shows that HTTP connections from the user are to be intercepted and that the
user can do web-based authentication (192.0.0.13 is the VPN client device and 192.0.0.1 is the server
device):

```
crypto ipsec client ezvpn tunnel22
   connect manual
   group tunnel22 key 22tunnel
   mode client
   peer 192.168.0.1
   xauth userid mode http-intercept
!
!
interface Ethernet0
   ip address 10.4.23.15 255.0.0.0
   crypto ipsec client ezvpn tunnel22 inside!
interface Ethernet1
   ip address 192.168.0.13 255.255.255.128
duplex auto
   crypto ipsec client ezvpn tunnel22
```

Easy VPN Remote with Virtual IPsec Interface Support Configuration: Examples

The following examples indicate that Virtual IPsec Interface Support has been configured on the Easy
VPN remote devices.
Virtual IPsec Interface: Generic Virtual Access

The following example shows an Easy VPN remote device with virtual-interface support using a generic virtual-access IPsec interface.

```plaintext

   no ip http secure-server
!
!
line con 0
line aux 0
line vty 0 4
   login
!
end
```
When the Tunnel Is Down

The result of a virtual-interface configuration on an Easy VPN profile is the creation of a virtual-access interface. This interface provides IPsec encapsulation. The output below shows the configuration of a virtual-access interface when Easy VPN is “down.”

Router# show running-config interface virtual-access 2

Building configuration...

Current configuration : 99 bytes
! interface Virtual-Access2
 no ip address
 tunnel source Ethernet1/0
 tunnel mode ipsec ipv4
end

A virtual-interface configuration results in the creation of a virtual-access interface. This virtual-access interface is made automatically outside the interface of the Easy VPN profile. The routes that are added later when the Easy VPN tunnels come up point to this virtual interface for sending the packets to the corporate network. If `crypto ipsec client ezvpn name outside (crypto ipsec client ezvpn name` command and `outside` keyword) is applied on a real interface, that interface is used as the IKE (IPsec) endpoint (that is, IKE and IPsec packets use the address on the interface as the source address).

Router# show crypto ipsec client ezvpn

Easy VPN Remote Phase: 5

Tunnel name : ez
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access2 (bound to Ethernet1/0)
Current State: CONNECT_REQUIRED
Last Event: TRACKED OBJECT UP
Save Password: Disallowed
Current EzVPN Peer: 10.3.0.2

Because a virtual interface, or for that matter any interface, is routable, routes act like traffic selectors. When the Easy VPN tunnel is “down,” there are no routes pointing to the virtual interface, as shown in the following example:

Router# show ip route

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
 D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
 N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
 E1 - OSPF external type 1, E2 - OSPF external type 2
 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
 IA - IS-IS inter area, * - candidate default, U - per-user static route
 o - ODR, p - periodic downloaded static route

Gateway of last resort is 10.2.0.2 to network 0.0.0.0

   10.0.0.0/24 is subnetted, 2 subnets
 C  10.2.0.0 is directly connected, Ethernet1/0
 C  10.1.0.0 is directly connected, Ethernet0/0
 S* 0.0.0.0/0 [2/0] via 10.2.0.2
When the Tunnel Is Up

In the case of client or network plus mode, Easy VPN creates a loopback interface and assigns the address that is pushed in mode configuration. To assign the address of the loopback to the interface, use the `ip unnumbered` command (ip unnumbered loopback). In the case of network extension mode, the virtual access will be configured as `ip unnumbered ethernet0` (the bound interface).

```
Router# show running-config interface virtual-access 2

Building configuration...

Current configuration : 138 bytes
!
interface Virtual-Access2
 ip unnumbered Loopback0
 tunnel source Ethernet1/0
 tunnel destination 10.3.0.2
 tunnel mode ipsec ipv4
end
```

```
Router# show crypto ipsec client ezvpn

Easy VPN Remote Phase: 5

Tunnel name : ez
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access2 (bound to Ethernet1/0)
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
Address: 10.5.0.2
Mask: 255.255.255.255
DNS Primary: 10.6.0.2
NBMS/WINS Primary: 10.7.0.1
Default Domain: cisco.com
Using PFS Group: 2
Save Password: Disallowed
Split Tunnel List: 1
 Address        : 10.4.0.0
 Mask           : 255.255.255.0
 Protocol       : 0x0
 Source Port    : 0
 Dest Port      : 0
Current EzVPN Peer: 10.3.0.2
```

When the tunnels come up, Easy VPN adds either a default route that points to the virtual-access interface or adds routes for all the split attributes of the subnets that point to the virtual-access interface. Easy VPN also adds a route to the peer (destination or concentrator) if the peer is not directly connected to the Easy VPN device.

The following `show ip route` command output examples are for virtual IPsec interface situations in which a split tunnel attribute was sent by the server and a split tunnel attribute was not sent, respectively.

```
Router# show ip route

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default, U - per-user static route

         10.4.0.0/24 is subnetted, 1 subnets
          R 10.4.0.0/24 [120/25] via 10.1.1.1, 00:00:00, Ethernet1/0
```
Gateway of last resort is 10.2.0.2 to network 0.0.0.0

10.0.0.0/8 is variably subnetted, 5 subnets, 2 masks
C 10.2.0.0/24 is directly connected, Ethernet1/0
S 10.3.0.2/32 [1/0] via 10.2.0.2, Ethernet1/0 <<< Route to peer (EzVPN server)
C 10.1.0.0/24 is directly connected, Ethernet0/0
C 10.5.0.2/32 is directly connected, Loopback0
S 10.4.0.0/24 [1/0] via 0.0.0.0, Virtual-Access2 <<< Split tunnel attr sent by the server
S* 10.0.0.0/0 [2/0] via 10.2.0.2

Split Tunnel Attribute Has Not Been Sent by the Server
All networks in the split attribute should be shown, as in the following example:

Router# show ip route

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
ia - IS-IS inter area, * - candidate default, U - per-user static route
o - ODR, P - periodic downloaded static route

Gateway of last resort is 0.0.0.0 to network 0.0.0.0

10.0.0.0/8 is variably subnetted, 4 subnets, 2 masks
C 10.2.0.0/24 is directly connected, Ethernet1/0

Dual Tunnel Show Output: Examples

The following `show` command examples display information about three phases of a dual tunnel that is coming up:

- First Easy VPN tunnel is up
- Second Easy VPN tunnel is initiated
- Both of the Easy VPN tunnels are up

Before the EzVPN Tunnels Are Up

Router# show crypto ipsec client ezvpn

Easy VPN Remote Phase: 6

Tunnel name : ezvpn1
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access2 (bound to Ethernet1/0)
Current State: CONNECT_REQUIRED
Last Event: TRACKED OBJECT UP
Save Password: Disallowed
Current EzVPN Peer: 10.75.1.2

Tunnel name : ezvpn2
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access3 (bound to Serial2/0)
Current State: CONNECT_REQUIRED
Last Event: TRACKED OBJECT UP
Save Password: Disallowed
Current EzVPN Peer: 10.75.2.2

Router# show ip route

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
IA - IS-IS inter area, * - candidate default, U - per-user static route
O - ODR, P - periodic downloaded static route

The gateway of last resort is 10.76.1.1 to network 0.0.0.0.

10.0.0.0/24 is subnetted, 2 subnets
C  10.76.2.0 is directly connected, Serial2/0
C  10.76.1.0 is directly connected, Ethernet1/0
C  192.168.1.0/24 is directly connected, Ethernet0/0
S* 0.0.0.0/0 [2/0] via 10.76.1.1

Note

The metric of the default route should be greater than 1 so that the default route that is added later by Easy VPN takes precedence and the traffic goes through the Easy VPN virtual-access interface.
Cisco Easy VPN Remote

Configuration Examples for Cisco Easy VPN Remote

Easy VPN “ezvpn2” Tunnel Is Up

Router# show crypto ipsec client ezvpn

Easy VPN Remote Phase: 6

Tunnel name: ezvpn1
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access2 (bound to Ethernet1/0)
Current State: CONNECT_REQUIRED
Last Event: TRACKED OBJECT UP
Save Password: Disallowed
Current EzVPN Peer: 10.75.1.2

Tunnel name: ezvpn2
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access3 (bound to Serial2/0)
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
DNS Ezvpn1: 10.6.0.2
NBMS/WINS Ezvpn1: 10.7.0.1
Default Domain: cisco.com
Save Password: Disallowed
Current EzVPN Peer: 10.75.2.2

Router# show ip route

Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
1a - IS-IS inter area, * - candidate default, U - per-user static route
O - ODR, P - periodic downloaded static route

The gateway of last resort is 0.0.0.0 to network 0.0.0.0.

10.0.0.0/8 is variably subnetted, 3 subnets, 2 masks
! The next line is the Easy VPN route.
S  10.75.2.2/32 [1/0] via 10.76.1.1
C  10.75.2.0/24 is directly connected, Serial2/0
C  10.76.1.0/24 is directly connected, Ethernet1/0
C  192.168.1.0/24 is directly connected, Ethernet0/0
! The next line is the Easy VPN route.
S* 0.0.0.0/0 [1/0] via 0.0.0.0, Virtual-Access3

One default route and one route to the peer is added as shown above.

Easy VPN “ezvpn2” Is Up and Easy VPN “ezvpn1” Is Initiated

Router# crypto ipsec client ezvpn connect ezvpn1

Router# show crypto ipsec client ezvpn

Easy VPN Remote Phase: 6

Tunnel name: ezvpn1
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access2 (bound to Ethernet1/0)
Current State: READY
Last Event: CONNECT
Save Password: Disallowed
Current EzVPN Peer: 10.75.1.2

Tunnel name : ezvpn2
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access3 (bound to Serial2/0)
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
DNS Ezvpn1: 10.6.0.2
NBMS/WINS Ezvpn1: 10.7.0.1
Default Domain: cisco.com
Save Password: Disallowed
Current EzVPN Peer: 10.75.2.2

Router# show ip route
Codes: C - connected, S - static, R - RIP, M - mobile, B - BGP
D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
ia - IS-IS inter area, * - candidate default, U - per-user static route
o - ODR, P - periodic downloaded static route

The gateway of last resort is 10.0.0.0 to network 10.0.0.0.

10.0.0.0/8 is variably subnetted, 4 subnets, 2 masks
S  10.75.2.2/32 [1/0] via 10.76.1.1
! The next line is the Easy VPN router.
S  10.75.1.2/32 [1/0] via 10.76.1.1
C  10.76.2.0/24 is directly connected, Serial2/0
C  10.76.1.0/24 is directly connected, Ethernet1/0
C  192.168.1.0/24 is directly connected, Ethernet0/0
S* 10.0.0.0/0 [1/0] via 10.0.0.0, Virtual-Access3

The route to 10.75.1.2 is added before the Easy VPN “ezvpn1” tunnel has come up. This route is for reaching the Easy VPN “ezvpn1” peer 10.75.1.2.

Both Tunnels Are Up

Router# show crypto ipsec client ezvpn

Easy VPN Remote Phase: 6

Tunnel name : ezvpn1
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access2 (bound to Ethernet1/0)
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
DNS Ezvpn1: 10.6.0.2
NBMS/WINS Ezvpn1: 10.7.0.1
Default Domain: cisco.com
Save Password: Disallowed
Split Tunnel List: 1
   Address   : 192.168.3.0
   Mask      : 255.255.255.255
   Protocol  : 0x0
   Source Port: 0
   Dest Port  : 0
Current EzVPN Peer: 10.75.1.2
Cisco Easy VPN Remote Configuration Examples for Cisco Easy VPN Remote

Tunnel name : ezvpn2
Inside interface list: Ethernet0/0
Outside interface: Virtual-Access3 (bound to Serial2/0)
Current State: IPSEC_ACTIVE
Last Event: SOCKET_UP
DNS Ezvpn1: 10.6.0.2
NBMS/WINS Ezvpn1: 10.7.0.1
Default Domain: cisco.com

Current EzVPN Peer: 10.75.2.2

Router# show ip route

Codes:  C - connected,  S - static,  R - RIP,  M - mobile,  B - BGP
        D - EIGRP,  EX - EIGRP external,  O - OSPF,  IA - OSPF inter area
        N1 - OSPF NSSA external type 1,  N2 - OSPF NSSA external type 2
        E1 - OSPF external type 1,  E2 - OSPF external type 2
        i - IS-IS,  su - IS-IS summary,  L1 - IS-IS level-1,  L2 - IS-IS level-2
        IA - IS-IS inter area,  * - candidate default,  U - per-user static route
        o - ODR,  P - periodic downloaded static route

The gateway of last resort is 10.0.0.0 to network 10.0.0.0.

10.0.0.0/8 is variably subnetted, 4 subnets, 2 masks
! The next line is the Easy VPN router (ezvpn2).
S 10.75.2.2/32 [1/0] via 10.76.1.1
! The next line is the Easy VPN router (ezvpn1).
S 10.75.1.2/32 [1/0] via 10.76.1.1
C 10.76.2.0/24 is directly connected, Serial2/0
C 10.76.1.0/24 is directly connected, Ethernet1/0
C 192.168.1.0/24 is directly connected, Ethernet0/0
! The next line is the Easy VPN route (ezvpn1).
S 192.168.3.0/24 [1/0] via 0.0.0.0, Virtual-Access2
! The next line is the Easy VPN (ezvpn2).
S* 10.0.0.0/0 [1/0] via 10.0.0.0, Virtual-Access3

The route to split tunnel “192.168.3.0/24” that points to Virtual-Access2 is added for the Easy VPN “ezvpn” tunnel as shown in the above show output.

Reactivate Primary Peer: Example

The following show output illustrates that the default primary peer feature has been activated. The primary default peer is 10.3.3.2.

Router# show crypto ipsec client ezvpn

Easy VPN Remote Phase: 6

Tunnel name : ezc
Inside interface list: Loopback0
Outside interface: Ethernet0/0
Current State: IPSEC_ACTIVE
Primary EzVPN Peer: 10.3.3.2, Last Tried: Dec 30 07:21:23.071
Last Event: CONN_UP
Address: 10.7.7.1
Mask: 255.255.255.255
DNS Primary: 10.1.1.1
NBMS/WINS Primary: 10.5.254.22
Identical Addressing Support Configuration: Example

In the following example, a Cisco router is configured for the Identical Addressing Support feature:

```plaintext
interface Virtual-Template1 type tunnel
    no ip address
    ip nat outside

crypto ipsec client ezvpn easy
    connect manual
    group easy key work4cisco
    mode network-extension
    peer 10.2.2.2
    virtual-interface 1
    nat allow
    nat acl 100

interface Ethernet1
    ip address 10.0.0.1 255.255.255.0
    ip nat outside
    crypto ipsec client ezvpn easy

interface Ethernet0
    ip address 10.0.0.2 255.255.255.0
    ip nat inside

interface Loopback0
    ip address 10.1.1.1 255.255.255.252
    ip nat enable
    crypto ipsec client ezvpn easy inside

    ip access-list 100 permit ip 10.0.0.0 0.0.0.255 any

    ip nat inside source list 100 interface Loopback0 overload

    ip nat inside source static 10.5.5.5 1.1.1.101
```

cTCP on an Easy VPN Client (Remote Device): Examples

For configuration and troubleshooting examples, see the topic “cTCP on Cisco Easy VPN remote devices” in the “Related Documents” section on page 102.

Easy VPN Server Configuration Examples

This section describes basic Cisco Easy VPN server configurations that support the Cisco Easy VPN remote configurations given in the previous sections. For complete information on configuring these servers, see Easy VPN Server for Cisco IOS Release 12.3(7)T, available on Cisco.com.
Cisco Easy VPN Server Without Split Tunneling: Example

The following example shows the Cisco Easy VPN server that is the destination peer router for the Cisco Easy VPN remote network extension mode configurations shown earlier in this section. In addition to the other IPSec configuration commands, the `crypto isakmp client configuration group` command defines the attributes for the VPN group that was assigned to the Easy VPN remote router. This includes a matching key value (easy vpn remote password), and the appropriate routing parameters, such as DNS server, for the Easy VPN remotes.

To support the network extension mode of operation, the `ip route` command instructs that incoming packets for the 172.168.0.0 network be directed from the cable modem interface to the Cisco Easy VPN remote. Other `ip route` commands might be needed, depending on the topology of your network.

```plaintext

Cisco Easy VPN Server Configuration with Split Tunneling: Example

The following example shows a Cisco Easy VPN server that is configured for a split tunneling configuration with a Cisco Easy VPN remote. This example is identical to that shown in the “Cisco Easy VPN Server Without Split Tunneling: Example” except for access list 150, which is assigned as part of the crypto isakmp client configuration group command. This access list allows the Cisco Easy VPN remote to use the server to access one additional subnet that is not part of the VPN tunnel without compromising the security of the IPsec connection.

To support network extension mode, the ip route command instructs that incoming packets for the 172.168.0.0 network be directed from the cable modem interface to the Cisco Easy VPN remote. Other ip route commands might be necessary, depending on the topology of your network.

Note
This example shows a Cisco uBR925 cable access router, but typically the destination Easy VPN remote will be a router, such as a VPN 3000 concentrator or a Cisco IOS router, that supports the Easy VPN Server feature.

Cisco Easy VPN Server Configuration with Xauth: Example

The following example shows a Cisco Easy VPN server configured to support Xauth with the Cisco Easy VPN Remote feature. This example is identical to that shown in the “Cisco Easy VPN Server Configuration with Split Tunneling: Example” except for the following commands that enable and configure Xauth:

- **aaa authentication login userlist local**—Specifies the local username database for authentication at login time. You could also specify the use of RADIUS servers by first using the `aaa authentication login userlist group radius` command and then by specifying the RADIUS servers using the `aaa group server radius` command.

- **crypto isakmp xauth timeout**—Specifies the amount of time, in seconds, that the user has to enter the appropriate username and password to authenticate the session.

- **crypto map dynmap client authentication list userlist**—Creates a crypto map named “dynmap” that enables Xauth.

- **username cisco password 7 cisco**—Creates an entry in the local username database for a user with the username of “cisco” and an encrypted password of “cisco.” This command should be repeated for each separate user that accesses the server.

The following commands, which are also present in the non-Xauth configurations, are also required for Xauth use:

- **aaa authorization network easy vpn remote-groupname local**—Requires authorization for all network-related service requests for users in the group named “easy vpn remote-groupname” using the local username database.

- **aaa new-model**—Specifies that the router should use the new AAA authentication commands.

- **aaa session-id common**—Specifies that a unique and common session ID should be used for AAA sessions.

- **crypto map dynmap 1 ipsec-isakmp dynamic dynmap**—Specifies that IKE should be used to establish the IPsec SAs, using the crypt map named “dynmap” as the policy template.

- **crypto map dynmap client configuration address respond**—Enables IKE negotiation, accepting requests from any requesting peers.

- **crypto map dynmap isakmp authorization list easy vpn remote-groupname**—Configures the crypto map named “dynmap” to use IKE Shared Secret using the group named “easy vpn remote-groupname.”

**Tip**

This configuration shows the server configured for split tunneling, but Xauth can also be used with nonsplit tunnel configurations as well.
This example shows a Cisco uBR925 cable access router, but typically the destination Easy VPN server is a router such as a VPN 3000 concentrator or a Cisco IOS router that supports the Easy VPN Server feature.
