Implementing Secure Shell

Secure Shell (SSH) is an application and a protocol that provides a secure replacement to the Berkeley r-tools. The protocol secures sessions using standard cryptographic mechanisms, and the application can be used similarly to the Berkeley **rexec** and **rsh** tools.

Two versions of the SSH server are available: SSH Version 1 (SSHv1) and SSH Version 2 (SSHv2). SSHv1 uses Rivest, Shamir, and Adelman (RSA) keys and SSHv2 uses either Digital Signature Algorithm (DSA) keys or RSA keys, or Elliptic Curve Digital Signature Algorithm (ECDSA) keys. Cisco IOS XR software supports both SSHv1 and SSHv2.

This module describes how to implement Secure Shell on Cisco 8000 Series Routers.

Note Cisco IOS XR does not support X11 forwarding through an SSH connection.

Note Any reference to CiscoSSH in this chapter implies OpenSSH-based implementation of SSH that is available on this platform from Cisco IOS XR Software Release 7.3.2 and later. CiscoSSH replaces Cisco IOS XR SSH, which is the older SSH implementation that existed prior to this release.

Note For a complete description of the Secure Shell commands used in this chapter, see the *Secure Shell and Secure Socket Layer Commands* chapter in *System Security Command Reference for Cisco 8000 Series Routers*.

Release	Modification
Release 7.3.2	Introduced CiscoSSH.
Release 7.3.2	Introduced SSH port forwarding feature with CiscoSSH.
Release 7.3.15	Introduced SSH port forwarding feature with Cisco IOS XR SSH.

Release	Modification
Release 7.3.1	Introduced these features: • Ed25519 Public-Key Algorithm Support for SSH • User Configurable Maximum Authentication Attempts for SSH • X.509v3 Certificate-based Authentication for SSH
Release 7.0.12	This chapter was introduced.

• Information About Implementing Secure Shell, on page 2
• Prerequisites for Implementing Secure Shell, on page 12
• Restrictions for Implementing Secure Shell, on page 12
• How to Implement Secure Shell, on page 13

Information About Implementing Secure Shell

To implement SSH, you should understand the following concepts:

SSH Server

The SSH server feature enables an SSH client to make a secure, encrypted connection to a Cisco router. This connection provides functionality that is similar to that of an inbound Telnet connection. Before SSH, security was limited to Telnet security. SSH allows a strong encryption to be used with the Cisco IOS XR software authentication. The SSH server in Cisco IOS XR software works with publicly and commercially available SSH clients.

SSH Client

The SSH client feature is an application running over the SSH protocol to provide device authentication and encryption. The SSH client enables a Cisco router to make a secure, encrypted connection to another Cisco router or to any other device running the SSH server. This connection provides functionality that is similar to that of an outbound Telnet connection except that the connection is encrypted. With authentication and encryption, the SSH client allows for a secure communication over an insecure network.

The SSH client in the Cisco IOS XR software works with publicly and commercially available SSH servers. The SSH client supports the ciphers of AES, 3DES, the hash algorithm SHA1, and password authentication. The user authentication mechanisms supported for SSH are RADIUS, TACACS+, and the use of locally stored usernames and passwords.

The SSH client supports setting DSCP value in the outgoing packets using this command:

ssh client dscp *dscp-value*

The *dscp-value* ranges from 0 to 63. If not configured, 16 is set as the default DSCP value in the packets (for both client and server).

You can use the **ssh client** command in the XR Config mode to configure various SSH client options.

SSH also supports remote command execution as follows:

```
Router#ssh 192.0.2.1 username admin command "show redundancy sum"
Password:

Wed Jan  9 07:05:27.997 PST
    Active Node    Standby Node
    -----------    ------------
       0/4/CPU0        0/5/CPU0 (Node Ready, NSR: Not Configured)
Router#
```

SFTP Feature Overview

SSH includes support for secure file transfer protocol (SFTP) , a new standard file transfer protocol introduced in SSHv2. This feature provides a secure and authenticated method for copying router configuration or router image files.

The SFTP client functionality is provided as part of the SSH component and is always enabled on the router. Therefore, a user with the appropriate level can copy files to and from the router. Like the **copy** command, the **sftp** command can be used only in XR EXEC mode.

The SFTP client is VRF-aware, and you may configure the secure FTP client to use the VRF associated with a particular source interface during connections attempts. The SFTP client also supports interactive mode, where the user can log on to the server to perform specific tasks via the Unix server.

The SFTP Server is a sub-system of the SSH server. In other words, when an SSH server receives an SFTP server request, the SFTP API creates the SFTP server as a child process to the SSH server. A new SFTP server instance is created with each new request.

The SFTP requests for a new SFTP server in the following steps:

- The user runs the **sftp** command with the required arguments
- The SFTP API internally creates a child session that interacts with the SSH server
- The SSH server creates the SFTP server child process
- The SFTP server and client interact with each other in an encrypted format
- The SFTP transfer is subject to LPTS policer "SSH-Known". Low policer values will affect SFTP transfer speeds

Note The default policer value for SSH-Known is set to 300pps. Slower transfers are expected due to this. You can adjust the lpts policer value for this punt cause to higher values that allows faster transfers.

You can increase the throughput of SCP or SFTP over inband using the **ssh server tcp-window-scale** command.

When the SSH server establishes a new connection with the SSH client, the server daemon creates a new SSH server child process. The child server process builds a secure communications channel between the SSH client and server via key exchange and user authentication processes. If the SSH server receives a request for the sub-system to be an SFTP server, the SSH server daemon creates the SFTP server child process. For each incoming SFTP server subsystem request, a new SSH server child and SFTP server instances are created. The

SSH server authenticates the user session and initiates a connection. It sets the environment for the client and the default directory for the user.

Once the initialization occurs, the SFTP server waits for the SSH_FXP_INIT message from the client, which is essential to start the file communication session. This message may then be followed by any message based on the client request. Here, the protocol adopts a 'request-response' model, where the client sends a request to the server; the server processes this request and sends a response.

The SFTP server displays the following responses:

- Status Response
- Handle Response
- Data Response
- Name Response

Note The server must be running in order to accept incoming SFTP connections.

RSA Based Host Authentication

Verifying the authenticity of a server is the first step to a secure SSH connection. This process is called the host authentication, and is conducted to ensure that a client connects to a valid server.

The host authentication is performed using the public key of a server. The server, during the key-exchange phase, provides its public key to the client. The client checks its database for known hosts of this server and the corresponding public-key. If the client fails to find the server's IP address, it displays a warning message to the user, offering an option to either save the public key or discard it. If the server’s IP address is found, but the public-key does not match, the client closes the connection. If the public key is valid, the server is verified and a secure SSH connection is established.

The IOS XR SSH server and client had support for DSA based host authentication. But for compatibility with other products, like IOS, RSA based host authentication support is also added.

RSA Based User Authentication

One of the method for authenticating the user in SSH protocol is RSA public-key based user authentication. The possession of a private key serves as the authentication of the user. This method works by sending a signature created with a private key of the user. Each user has a RSA key pair on the client machine. The private key of the RSA key pair remains on the client machine.

The user generates an RSA public-private key pair on a unix client using a standard key generation mechanism such as ssh-keygen. The max length of the keys supported is 4096 bits, and the minimum length is 512 bits. The following example displays a typical key generation activity:

```
bash-2.05b$ ssh-keygen -b 1024 -t rsa
Generating RSA private key, 1024 bit long modulus
```

The public key must be in base64 encoded (binary) format for it to be imported correctly into the box. You can use third party tools available on the Internet to convert the key to the binary format.

Once the public key is imported to the router, the SSH client can choose to use the public key authentication method by specifying the request using the "-o" option in the SSH client. For example:

```
client$ ssh -o PreferredAuthentications=publickey 1.2.3.4
```

If a public key is not imported to a router using the RSA method, the SSH server initiates the password based authentication. If a public key is imported, the server proposes the use of both the methods. The SSH client then chooses to use either method to establish the connection. The system allows only 10 outgoing SSH client connections.

Currently, only SSH version 2 supports the RSA based authentication. For more information on how to import the public key to the router, see the *Implementing Certification Authority Interoperability* chapter in this guide.

Note The preferred method of authentication would be as stated in the SSH RFC. The RSA based authentication support is only for local authentication, and not for TACACS/RADIUS servers.

Authentication, Authorization, and Accounting (AAA) is a suite of network security services that provides the primary framework through which access control can be set up on your Cisco router or access server. For more information on AAA, the *Configuring AAA Services* chapter in this guide.

SSHv2 Client Keyboard-Interactive Authentication

An authentication method in which the authentication information is entered using a keyboard is known as keyboard-interactive authentication. This method is an interactive authentication method in the SSH protocol. This type of authentication allows the SSH client to support different methods of authentication without having to be aware of their underlying mechanisms.

Currently, the SSHv2 client supports the keyboard-interactive authentication. This type of authentication works only for interactive applications.

Note The password authentication is the default authentication method. The keyboard-interactive authentication method is selected if the server is configured to support only the keyboard-interactive authentication.

SSH and SFTP in Baseline Cisco IOS XR Software Image

The SSH and SFTP components are present in the baseline Cisco IOS XR software image. The management and control plane components (such as the IPSec control plane) are also present in the base package. However, the data plane components (such as the MACSec and the IPSec data plane) are part of the security package as per the export compliance regulations. This segregation of package components makes the software more modular. It also gives you the flexibility of including or excluding the security package as per your requirements.

The base package and the security package allow FIPS, so that the control plane can negotiate FIPS-approved algorithms.

CiscoSSH

Table 1: Feature History Table

Feature Name	Release Information	Feature Description
CiscoSSH	Release 7.3.2	This release introduces CiscoSSH, a newer implementation of SSH on this platform. CiscoSSH leverages OpenSSH implementation, by using the Linux TCP/IP stack to transmit and receive SSH packets over the management Ethernet interface and line card interfaces on the router. CiscoSSH provides additional security features like FIPS compliance and X.509 digital certification. It supports packet path features like MPP, ACL and VRF support, and ensures interoperability with various existing SSH implementations. **Note** Cisco IOS XR SSH, the SSH implementation that existed prior to this release, is now deprecated.

Note Any reference to CiscoSSH in this chapter implies OpenSSH-based implementation of SSH that is available on this platform from Cisco IOS XR Software Release 7.3.2 and later. CiscoSSH replaces Cisco IOS XR SSH, which is the older SSH implementation that existed prior to this release.

OpenSSH is a stable, widely deployed open-source implementation of SSH. CiscoSSH implementation leverages the key features of openSSH such as strong authentication, cryptography, encryption, port forwarding, and so on, to provide secured management access to the router. CiscoSSH provides additional security features like FIPS compliance and support for X.509 digital certificate.

For more details on SSH in general, see Information About Implementing Secure Shell, on page 2 and How to Implement Secure Shell, on page 13.

The CiscoSSH implementation also ensures backward compatibility for all the existing Cisco IOS XR SSH configuration and management. You can continue to use SSH the way it was existing before. The functionality and configuration commands of CiscoSSH and Cisco IOS XR SSH remain the same for majority of the part. However, certain behavioral changes exist between CiscoSSH and Cisco IOS XR SSH. For details, see the subsequent sections.

This table lists the behavioral changes introduced by CiscoSSH as compared to Cisco IOS XR SSH. Also, see Guidelines for Using CiscoSSH, on page 8.

Table 2: Behavioral Changes Introduced by CiscoSSH in Comparison to Cisco IOS XR SSH

Functionality	CiscoSSH	Cisco IOS XR SSH
Port number for Netconf server	The system uses the port numbers 830 (the default IANA-assigned TCP port number for Netconf over SSH) or 22 (the default port number for SSH) for the Netconf server. You cannot configure this value.	You can explicitly configure the desired port number for Netconf server using the **ssh server netconf port** command.
Username syntax	Because CiscoSSH considers ':' (*colon*) as a delimiter in certain types of user authentication, it does not support authentication of usernames having ':' (*colon*) in it.	No restriction for using ':' (*colon*) in username syntax.
Configuring unsupported algorithms	You cannot enable unsupported algorithms using any configuration command.	You can explicitly enable unsupported algorithms using the **ssh server enable cipher** command.
SSH session timeout	The SSH session initiated from the router to an unreachable host times out after 120 seconds.	The SSH session initiated from the router to an unreachable host times out after 60 seconds.
SSH session timeout criteria	The SSH timeout configuration considers the total timeout value for the maximum number of login attempts allowed.	The SSH timeout configuration considers the timeout value for individual login attempt.
Time-based rekey of SSH sessions	The router triggers time-based rekey of SSH sessions only when it receives a packet after the timer expiry.	The router triggers time-based rekey of SSH sessions immediately after the timer expiry.
LPTS policer rate for port-forwarded SSH sessions	When using SSH port forwarding feature, the router considers the traffic flows corresponding to port-forwarded SSH sessions as third party applications. Hence, the LPTS polices those traffic flows at a medium rate.	The LPTS polices the traffic flows corresponding to port-forwarded SSH sessions at a high rate.
Port-forwarded channels	No limit to the number of port-forwarded channels supported with CiscoSSH. But, the **show ssh command** displays a maximum of only 16 entries.	Supports a maximum of 16 port-forwarded channels.
File transfer through SCP	While using SCP with CiscoSSH, the router checks for the presence of system files after authentication.	The router checks for the presence of system files before authentication.

Functionality	CiscoSSH	Cisco IOS XR SSH
File transfer through SFTP	With non-interactive SFTP session initiated from the router, you can transfer files from an external device to the router; not from the router to external device.	You can transfer files from an external device to the router, and the other way round.

Restrictions for Cisco SSH

- Does not support SSH version 1
- Does not support back up SSH server
- Does not support management access to the router over the standby management Ethernet interface.
- Does not allow to use secondary IPv4 addresses because they are not currently synchronized to Linux
- Does not support BVI interfaces as source or destination for the SSH connections (prior to Cisco IOS XR Software Release 7.7.1)
- Does not support these algorithms:
  - The cipher algorithms, *aes128-cbc*, *aes192-cbc*, *aes256-cbc*, and *3des-cbc*
  - The key-exchange algorithm, *diffie-hellman-group1-sha1*
- Does not support these commands:
  - **show ssh history**
  - **show ssh history details**
  - **clear ssh stale sessions**

Guidelines for Using CiscoSSH

The following section lists certain functionality aspects and guidelines for using CiscoSSH.

- **Netconf Request**: You must follow a specific syntax when you send Netconf request over CLI. Add the subsystem (*netconf* or *sftp*) name as the last argument while issuing an SSH command.

  For example,

  ```
  ssh username@ipaddress -p 830 -s netconf ---> Correct usage
  ssh username@ipaddress netconf -p 830 -s ---> Incorrect usage
  ```

- **Configuring unsupported algorithms**: Configuring CiscoSSH server only with unsupported algorithms (*3des-cbc* or *diffie-hellman-group1-sha1*) results in commit failure. Hence, you must remove such configurations on your router as a part of the pre-upgrade procedure.

  For example,

  ```
  Router(config)#ssh server algorithms cipher 3des-cbc

  !!% Operation not permitted: 3des-cbc is not supported in ciscossh, SSH cannot work
  with this option only
  ```

Similarly, if you configure CiscoSSH server with both supported and unsupported algorithms, then the router issues the following warning and removes the unsupported algorithm:

```
Router(config)#ssh server algorithms cipher aes128-ctr aes192-ctr 3des-cbc

ssh_conf_proxy[1193]: %SECURITY-SSHD_CONF_PRX-3-ERR_GENERAL : 3des-cbc is not supported,
 will be removed
```

- **SSH session keep alive:** By default, the SSH session keep alive functionality is enabled in CiscoSSH, to detect and terminate unresponsive sessions. The default keep alive time is 60 seconds, with a maximum of three attempts allowed, so that the detection time for unresponsive sessions is 180 seconds. These keep alive parameters are not configurable.
- **TCP window scale**: Although the router accepts the configuration to change the TCP window scale parameter, the configuration does not have any effect with CiscoSSH. This is because, CiscoSSH uses Linux TCP/IP stack that has dynamic window scaling, and hence it does not require applications to specify the window scale.
- **SSH session limit and rate limit**: Although the configuration for SSH session limit and rate limit applies to all VRFs where SSH is enabled, the router enforces the limit for each VRF. However, the maximum number of virtual teletype (VTY) sessions across all VRFs still remains as 99. This in turn limits the total number of SSH sessions that require a VTY interface, across all VRFs. As a result, when upgrading from a release version having Cisco IOS XR SSH to a version having CiscoSSH, the system applies the session limit and rate limit configurations to all VRFs where SSH is enabled. Hence, as part of the post-upgrade procedure, you must reconfigure these limits to achieve the same limit as that of Cisco IOS XR SSH.
- **SSH session limit enforcement**: Information on the number of active SSH sessions on the router is not persistent across SSH server process restarts. Hence, SSH session limit enforcement does not consider the existing sessions after an SSH server restart.
- **SSH with ACL or MPP configuration**: With SSH ACL or MPP configured on the router, the attempt for client connection that is now allowed as per that configuration times out. The router does not send TCP reset for such blocked SSH connections. This implementation is to enhance security.
- **Default VRFs**: Configuring the default SSH VRF using the **ssh vrf default** command enables only version 2 of CiscoSSH, because version 1 is not supported.
- **Non-default VRFs**: If SSH service is enabled on any of the non-default VRFs that is configured on the router, and if you restart the *ssh_conf_proxy* process, there might be a delay in allowing incoming SSH sessions on that non-default VRF. The session establishment might even timeout in such a scenario. This behavior is due to the delay in programming the LPTS entries for those sessions.
- **Public key-based authentication**: In CiscoSSH, the router negotiates public key-based authentication even if there is no public key imported on to the router. So, the authentication attempt from the client using public key fails in such scenarios. The router displays a syslog on the console for this authentication failure. However, the client and server proceed with subsequent authentication methods like keyboard-interactive and password methods. If the router does not have a public key imported, you may choose to disable public key-based authentication from the client side. For details on public key-based authentication, see the *Implementing Certification Authority Interoperability* chapter in this guide.
- **Modifying SSH configuration**: Any change to the SSH configuration results in process restart of SSH server process. However, it does not impact the existing SSH, SCP, SFTP, or Netconf sessions.
- **Clearing SSH sessions**: The **clear ssh all** command clears all incoming sessions and restarts the SSH server process.

- **Line-feed option**: Adding a line-feed option for Gossh-based clients results in SSH session establishment failure. This is because, the SSH client checks for non-zero window size for session establishment. Whereas CiscoSSH sends window size as 0. The workaround for this issue is to use the option to ignore the window size while initiating an SSH connection from such clients.
- **Virtual IP addresses**: After a process restart of *xlncd* or *ip_smiap*, there might be a delay in restoring the virtual IP addresses.
- **More-specific Routes**: Routes that are more specific than a connected route will not be available through Linux.

  For example:

```
XR routing table:

10.0.0.0/24   via 10.0.0.2 (connected route)
10.0.0.192/28 via 20.0.0.1 (static route)
```

  The expected behavior is as follows:

Table 3: Expected Behavior of More-specific Routes with CiscoSSH

Destination IP Range	Cisco IOS XR OS Sends to:	Linux Sends to:	Match (Yes/No)
10.0.0.1 - 10.0.0.191	10.0.0.2	10.0.0.2	Yes
10.0.0.193 - 10.0.0.206	20.0.0.1	10.0.0.2	No
10.0.0.207 - 10.0.0.255	10.0.0.2	10.0.0.2	Yes

- **Verification commands**: During stress test on the router, certain show commands like **show ssh**, **show ssh session details**, and **show ssh rekey** might time out. The console displays the following error message in such cases:

```
"Error: Timed out to obtain information about one or more incoming/outgoing session.
please retry."
```

- **Process restart**:
  - You cannot restart the CiscoSSH server process using the **process restart ssh_server** command, because it is a Linux process. Use the **kill** command on the Linux shell to restart the process.
  - CiscoSSH has *ssh_conf_proxy* and *ssh_syslog_proxy* processes that are responsible for processing the SSH configuration and logging syslog messages respectively. You can restart these processes using the **process restart** command.
  - A restart of *XR-TCP* process does not have any impact on CiscoSSH functionality, because CiscoSSH uses Linux TCP.
- **Debuggability**:
  - You can enable 3 levels of debugs for CiscoSSH using the **debug ssh server l1/l2/l3** command. Similarly, you can use the **debug ssh client l1/l2/l3** command for CiscoSSH client.

- The SSH server process restarts every time you enable or disable the debugs, because enabling the debugs results in updating the LOGLEVEL in the internal *sshd_config* file.

Syslogs for CiscoSSH

CiscoSSH introduces new syslogs for various SSH session events. The following table gives a comparison of syslogs between CiscoSSH and Cisco IOS XR SSH:

Table 4: Syslogs for CiscoSSH and Cisco IOS XR SSH

Session Event	Syslogs on CiscoSSH	Syslogs on Cisco IOS XR SSH
Session login	RP/0/RP0/CPU0:Sep 22 11:06:33.467 IST: ssh_syslog_proxy[1204]: %SECURITY-SSHD_SYSLOG_PRX-6-INFO_GENERAL : sshd[32504]: Accepted authentication/pam for admin from 203.0.113.1 port 62015 ssh2 RP/0/RP0/CPU0:Sep 22 11:06:33.472 IST: ssh_syslog_proxy[1204]: %SECURITY-SSHD_SYSLOG_PRX-6-INFO_GENERAL : sshd[32504]: User child is on pid 32564 RP/0/RP0/CPU0:Sep 22 11:06:33.519 IST: ssh_syslog_proxy[1204]: %SECURITY-SSHD_SYSLOG_PRX-6-INFO_GENERAL : sshd[32564]: Starting session: shell on pts/1 for admin from 203.0.113.1 port 62015 id 0	RP/0/RP0/CPU0:Sep 22 11:46:13.475 IST: SSHD_[67274]: %SECURITY-SSHD-6-INFO_SUCCESS : Successfully authenticated user 'root' from '192.0.2.1' on 'vty0'(cipher 'aes128-ctr', mac 'hmac-sha2-256')

Prerequisites for Implementing Secure Shell

The following prerequisites are required to implement Secure Shell:

- You must be in a user group associated with a task group that includes the proper task IDs. The command reference guides include the task IDs required for each command. If you suspect user group assignment is preventing you from using a command, contact your AAA administrator for assistance.
- To run an SSHv2 server, you must have a VRF. This may be the default VRF or a specific VRF. VRF changes are applicable only to the SSH v2 server.
- Configure user authentication for local or remote access. You can configure authentication with or without authentication, authorization, and accounting (AAA). For more information, see the *Configuring AAA Services* chapter in the this guide.
- AAA authentication and authorization must be configured correctly for Secure Shell File Transfer Protocol (SFTP) to work.

Restrictions for Implementing Secure Shell

The following are some basic SSH restrictions and limitations of the SFTP feature:

- In order for an outside client to connect to the router, the router needs to have an RSA (for SSHv2) or DSA (for SSHv2) or ECDSA (for SSHv2) key pair configured. ECDSA, DSA and RSA keys are not required if you are initiating an SSH client connection from the router to an outside routing device. The same is true for SFTP: ECDSA, DSA and RSA keys are not required because SFTP operates only in client mode.

Note The RSA, DSA and ECDSA keys are auto-generated during the boot if there is no key present.

- In order for SFTP to work properly, the remote SSH server must enable the SFTP server functionality. For example, the SSHv2 server is configured to handle the SFTP subsystem with a line such as **/etc/ssh2/sshd2_config**:
- **subsystem-sftp /usr/local/sbin/sftp-server**
- The SFTP server is usually included as part of SSH packages from public domain and is turned on by default configuration.
- SFTP is compatible with sftp server version OpenSSH_2.9.9p2 or higher.
- RSA-based user authentication is supported in the SSH, SFTP and SCP servers. The support however, is not extended to the SSH client.
- Execution shell, SFTP, SCP and Netconf are the only applications supported.
- The cipher preference for the SSH server follows the order AES128, AES192, AES256, aes128-gcm, aes256-gcm, and chacha20-poly1305. The server rejects any requests by the client for an unsupported cipher, and the SSH session does not proceed.
- Use of a terminal type other than vt100 is unsupported, and the software generates a warning message in this case.
- Password messages of “none” are unsupported on the SSH client.
- Because the router infrastructure does not provide support for UNIX-like file permissions, files created on the local device lose the original permission information. For files created on the remote file system, the file permission adheres to the umask on the destination host and the modification and last access times are the time of the copy.

How to Implement Secure Shell

To configure SSH, perform the tasks described in the following sections:

Configure SSH

Note For SSHv1 configuration, Step 1 to Step 4 are required. For SSHv2 configuration, these steps are optional.

Perform this task to configure SSH.

Step 1 **configure**

Example:

```
RP/0/RP0/CPU0:router# configure
```

Enters mode.

Step 2 **hostname** *hostname*

Example:

```
Router(config)# hostname router1
```

Configures a hostname for your router.

Step 3 **domain name** *domain-name*

Example:

```
Router(config)# domain name cisco.com
```

Defines a default domain name that the software uses to complete unqualified host names.

Step 4 Use the **commit** or **end** command.

commit —Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- **Yes** — Saves configuration changes and exits the configuration session.
- **No** —Exits the configuration session without committing the configuration changes.
- **Cancel** —Remains in the configuration session, without committing the configuration changes.

Step 5 **configure**

Step 6 **ssh server tcp-window-scale** *scale*

Example:

```
Router(config)# ssh server tcp-window-scale 10
```

(Optional) Configures the TCP window scale for increased throughput for SCP or SFTP.

Step 7 **ssh timeout** *seconds*

Example:

```
Router(config)# ssh timeout 60
```

(Optional) Configures the timeout value for user authentication to AAA.

- If the user fails to authenticate itself to AAA within the configured time, the connection is terminated.
- If no value is configured, the default value of 30 seconds is used. The range is from 5 to 120.

Step 8 Do one of the following:

- **ssh server** [**vrf** *vrf-name* [**ipv4 access-list** *ipv4-access-list name*] [**ipv6 access-list** *ipv6-access-list name*]]
- **ssh server v2**

Example:

```
Router(config)# ssh server v2
```

- (Optional) Brings up an SSH server using a specified VRF of up to 32 characters. If no VRF is specified, the default VRF is used. To stop the SSH server from receiving any further connections for the specified VRF, use the no form of this command. If no VRF is specified, the default is assumed. Optionally ACLs for IPv4 and IPv6 can be used to restrict access to the server before the port is opened. To stop the SSH server from receiving any

further connections for the specified VRF, use the **no** form of this command. If no VRF is specified, the default is assumed.

Note The SSH server can be configured for multiple VRF usage.

- (Optional) Forces the SSH server to accept only SSHv2 clients if you configure the SSHv2 option by using the **ssh server v2** command. If you choose the **ssh server v2** command, only the SSH v2 client connections are accepted.

Step 9 **ssh** {**client** | **server**} **dscp** *dscp-value*

Example:

```
Router(config)# ssh server dscp 63
```

```
Router(config)# ssh client dscp 63
```

(optional) Sets the DSCP value in the outgoing packets. If not configured, 16 is set as the default DSCP value for the packets (for both client and server).

Step 10 Use the **commit** or **end** command.

commit —Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- **Yes** — Saves configuration changes and exits the configuration session.
- **No** —Exits the configuration session without committing the configuration changes.
- **Cancel** —Remains in the configuration session, without committing the configuration changes.

Step 11 **show ssh**

Example:

```
Router# show ssh
```

(Optional) Displays all of the incoming and outgoing SSHv1 and SSHv2 connections to the router.

Step 12 **show ssh session details**

Example:

```
Router# show ssh session details
```

(Optional) Displays a detailed report of the SSHv2 connections to and from the router.

Step 13 **show ssh history**

Example:

```
Router# show ssh history
```

(Optional) Displays the last hundred SSH connections that were terminated.

Step 14 **show ssh history details**

Example:

```
Router# show ssh history details
```

(Optional) Displays the last hundred SSH connections that were terminated with additional details. This command is similar to **show ssh session details** command but also mentions the start and end time of the session.

Step 15 **show tech-support ssh**

Example:

```
Router# show tech-support ssh
```

(Optional) Automatically runs the `show` commands that display system information.

Note The order of priority while doing negotiation for a SSH connection is as follows:

1. ecdsa-nistp-521
2. ecdsa-nistp-384
3. ecdsa-nistp-256
4. rsa
5. dsa

Automatic Generation of SSH Host-Key Pairs

This feature brings in the functionality of automatically generating the SSH host-key pairs for the DSA, ECDSA (such as **ecdsa-nistp256**, **ecdsa-nistp384**, and **ecdsa-nistp521**) and RSA algorithms. This in turn eliminates the need for explicitly generating each SSH host-key pair after the router boots up. Because the keys are already present in the system, the SSH client can establish connection with the SSH server soon after the router boots up with the basic SSH configuration. This is useful especially during zero touch provisioning (ZTP) and Golden ISO boot up scenarios.

Although the host keys are auto-generated with the introduction of this feature, you still have the flexibility to select only the required algorithms on the SSH server. You can use the **ssh server algorithms host-key** command in XR Config mode to achieve the same. Alternatively, you can also use the **crypto key zeroize** command in XR EXEC mode to remove the algorithms that are not required.

Note In a system upgrade scenario from version 1 to version 2, the system does not generate the SSH host-key pairs automatically if they were already generated in version 1. The host-key pairs are generated automatically only if they were not generated in version 1.

If the SSH host-key pairs are not present in some scenarios, you can execute the **crypto key generate** command in XR EXEC mode to generate the required host-key pairs.

Configure the Allowed SSH Host-Key Pair Algorithms

When the SSH client attempts a connection with the SSH server, it sends a list of SSH host-key pair algorithms (in the order of preference) internally in the connection request. The SSH server, in turn, picks the first matching algorithm from this request list. The server establishes a connection only if that host-key pair is already generated in the system, and if it is configured (using the **ssh server algorithms host-key** command) as the allowed algorithm.

Note If this configuration of allowed host-key pairs is not present in the SSH server, then you can consider that the SSH server allows all host-key pairs. In that case, the SSH client can connect with any one of the host-key pairs. Not having this configuration also ensures backward compatibility in system upgrade scenarios.

Configuration Example

You may perform this (optional) task to specify the allowed SSH host-key pair algorithm (in this example, **ecdsa**) from the list of auto-generated host-key pairs on the SSH server:

```
/* Example to select the ecdsa algorithm */
Router(config)#ssh server algorithms host-key ecdsa-nistp521
```

Similarly, you may configure other algorithms.

Running Configuration

```
ssh server algorithms host-key ecdsa-nistp521
!
```

Verify the SSH Host-Key Pair Algorithms

Note With the introduction of the automatic generation of SSH host-key pairs, the output of the **show crypto key mypubkey** command displays key information of all the keys that are auto-generated. Before its introduction, the output of this show command displayed key information of only those keys that you explicitly generated using the **crypto key generate** command.

```
Router#show crypto key mypubkey ecdsa

Ed25519 Public-Key Signature Algorithm Support for SSH

Table 5: Feature History Table

Feature Name	Release Information	Feature Description
Ed25519 Public-Key Signature Algorithm Support for SSH	Release 7.3.1	This algorithm is now supported on Cisco IOS XR 64-bit platforms when establishing SSH sessions. It is a modern and secure public-key signature algorithm that provides several benefits, particularly resistance against several side-channel attacks. Prior to this release, DSA, ECDSA, and RSA public-key algorithms were supported. This command is modified for this feature: ssh server algorithms host-key

This feature introduces the support for Ed25519 public-key algorithm, when establishing SSH sessions, on Cisco IOS XR 64-bit platforms. This algorithm offers better security with faster performance when compared to DSA or ECDSA signature algorithms.

The order of priority of public-key algorithms during SSH negotiation between the client and the server is:

- ecdsa-sha2-nistp256
- ecdsa-sha2-nistp384
- ecdsa-sha2-nistp521
- ssh-ed25519
- ssh-rsa
- ssh-dsa

Restrictions for ED25519 Public Key for SSH

The Ed25519 public key algorithm is not FIPS-certified. That is, if FIPS mode is enabled on the router, the list of public-key algorithms sent during the SSH key negotiation phase does not contain the Ed25519 key. This behavior is applicable only for new SSH connections. Any existing SSH session that has already negotiated Ed25519 public-key algorithm remains intact and continues to execute until the session is disconnected.

Further, if you have configured the router to negotiate only the Ed25519 public-key algorithm (using the **ssh server algorithms host-key** command), and if FIPS mode is also enabled, then the SSH connection to the router fails.

How to Generate Ed25519 Public Key for SSH

To generate Ed25519 public key for SSH, see Generate Crypto Key for Ed25519 Signature Algorithm.

You must also specify Ed25519 as the permitted SSH host-key pair algorithm from the list of auto-generated host-key pairs on the SSH server. For details, see Configure the Allowed SSH Host-Key Pair Algorithms, on page 17.

To remove the Ed25519 key from the router, use the **crypto key zeroize ed25519** command in XR EXEC mode.

Configure the SSH Client

Perform this task to configure an SSH client.

Step 1 **configure**

Example:

```
RP/0/RP0/CPU0:router# configure
```

Enters mode.

Step 2 **ssh client knownhost** *device* **:** /*filename*

Example:

```
Router(config)# ssh client knownhost slot1:/server_pubkey
```

(Optional) Enables the feature to authenticate and check the server public key (pubkey) at the client end.

Note The complete path of the filename is required. The colon (:) and slash mark (/) are also required.

Step 3 Use the **commit** or **end** command.

commit —Saves the configuration changes and remains within the configuration session.

end —Prompts user to take one of these actions:

- **Yes** — Saves configuration changes and exits the configuration session.
- **No** —Exits the configuration session without committing the configuration changes.
- **Cancel** —Remains in the configuration session, without committing the configuration changes.

Step 4 **ssh** {*ipv4-address* | *hostname*} [**username** *user- id* | **cipher des** | **source-interface** *type instance*]

Example:

```
Router# ssh remotehost username user1234
```

Enables an outbound SSH connection.

- To run an SSHv2 server, you must have a VRF. This may be the default or a specific VRF. VRF changes are applicable only to the SSH v2 server.
- The SSH client tries to make an SSHv2 connection to the remote peer. If the remote peer supports only the SSHv1 server, the peer internally spawns an SSHv1 connection to the remote server.
- The **cipher des** option can be used only with an SSHv1 client.

- The SSHv1 client supports only the 3DES encryption algorithm option, which is still available by default for those SSH clients only.
- If the *hostname* argument is used and the host has both IPv4 and IPv6 addresses, the IPv6 address is used.

- If you are using SSHv1 and your SSH connection is being rejected, the reason could be that the RSA key pair might have been zeroed out. Another reason could be that the SSH server to which the user is connecting to using SSHv1 client does not accept SSHv1 connections. Make sure that you have specified a hostname and domain. Then use the **crypto key generate rsa** command to generate an RSA key pair, and then enable the SSH server.
- If you are using SSHv2 and your SSH connection is being rejected, the reason could be that the DSA or RSA or ECDSA key pair might have been zeroed out. Make sure you follow similar steps as mentioned above to generate the required key pairs, and then enable the SSH server.
- When configuring the ECDSA, RSA or DSA key pair, you might encounter the following error messages:
  - No hostname specified

  You must configure a hostname for the router using the **hostname** command in that case.

  - No domain specified

  You must configure a host domain for the router using the **domain-name** command in that case.
- The number of allowable SSH connections is limited to the maximum number of virtual terminal lines configured for the router. Each SSH connection uses a vty resource. The default number of VTYs is 5. So, you must configure the number of VTYs in the VTY pool. The default value for the maximum number of SSH sessions is 64.
- For FIPS compliance,the weaker ciphers like 3DES and AES CBC are not supported; only AES-CTR cipher is supported.
- SSH uses either local authentication or remote authentication that is configured through AAA on your router for user authentication. When configuring AAA, you must ensure that the console is not running under AAA by applying a keyword in the global configuration mode to disable AAA on the console.

Note If you are using Putty version 0.63 or higher to connect to the SSH client, set the 'Chokes on PuTTYs SSH2 winadj request' option under SSH > Bugs in your Putty configuration to 'On.' This helps avoid a possible breakdown of the session whenever some long output is sent from IOS XR to the Putty client.

Order of SSH Client Authentication Methods

The default order of authentication methods for SSH clients on Cisco IOS XR routers is as follows:

- On routers running Cisco IOS XR SSH:
  - **public-key**, **password** and **keyboard-interactive**

- On routers running CiscoSSH (open source-based SSH):
  - **public-key**, **keyboard-interactive** and **password**

How to Set the Order of Authentication Methods for SSH Clients

To set the preferred order of authentication methods for SSH clients on Cisco IOS XR routers, use the **ssh client auth-method** command in the XR Config mode. This command is available from Cisco IOS XR Software Release 7.9.2/Release 7.10.1and later.

Configuration Example

In this example, we set the order of SSH client authentication methods in such a way that public key authentication is negotiated first, followed by keyboard-interactive, and then password-based authentication.

```
Router#configure
Router(config)#ssh client auth-method public-key keyboard-interactive password
Router(config-ssh)#commit
```

Running Configuration

```
Router#show run ssh client auth-methods
Tue Nov 21 17:55:44.688 IST
ssh client auth-methods public-key keyboard-interactive password
Router#
```

Configure Secure Shell: Example

This example shows how to configure SSHv2 by creating a hostname, defining a domain name, enabling the SSH server for local and remote authentication on the router by generating a DSA key pair, bringing up the SSH server, and saving the configuration commands to the running configuration file.

After SSH has been configured, the SFTP feature is available on the router.

```
configure
hostname router1
domain name cisco.com
exit
configure
ssh server
end
```

Multi-channeling in SSH

The multi-channeling (also called multiplexing) feature on the Cisco IOS XR software server allows you to establish multiple channels over the same TCP connection from the SSH clients originating from the same host. Thus, rather than opening a new TCP socket for each SSH connection, all the SSH connections are multiplexed into one TCP connection and a single SSH session. For example, with multiplexing support on your XR software server, on a single SSH connection you can simultaneously open a pseudo terminal, remotely execute a command and transfer a file using any file transfer protocol. Multiplexing offers the following benefits:

- You are required to authenticate only once at the time of creating the session. After that, all the SSH clients associated with a particular session use the same TCP socket to communicate to the server.
- Saves time consumed otherwise wasted in creating a new connection each time.

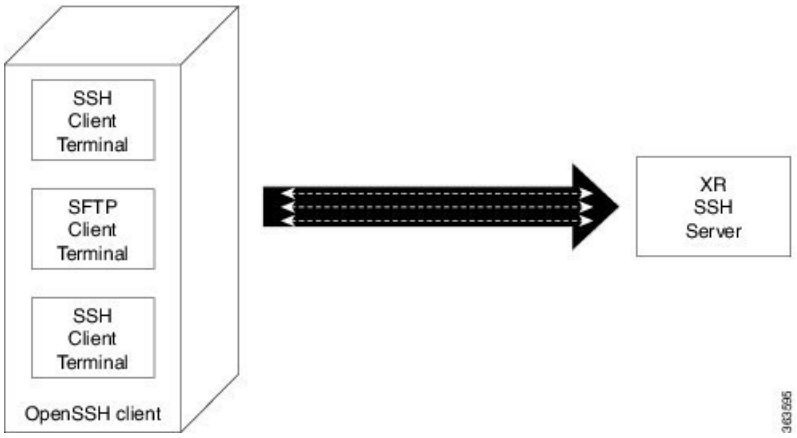
Multiplexing is enabled by default in the Cisco IOS XR software server. If your client supports multiplexing, you must explicitly set up multiplexing on the client for it to be able to send multi-channel requests to the server. You can use OpenSSH, Perl, WinSCP, FileZilla, TTSSH, Cygwin or any other SSH-based tool to set up multiplexing on the client. See Configure Client for Multiplexing, on page 23 provides an example of how you can configure the client for multiplexing using OpenSSH.

Restrictions for Multi-channeling Over SSH

- Do not use client multiplexing for heavy transfer of data as the data transfer speed is limited by the TCP speed limit. Hence, for a heavy data transfer it is advised that you run multiple SSH sessions, as the TCP speed limit is per connection.
- Client multiplexing must not be used for more than 15 concurrent channels per session simultaneously.

Client and Server Interaction Over Multichannel Connection

The figure below provides an illustration of a client-server interaction over a SSH multichannel connection.



As depicted in the illustration,

- The client multiplexes the collection of channels into a single connection. This allows different operations to be performed on different channels simultaneously. The dotted lines indicate the different channels that are open for a single session.
- After receiving a request from the client to open up a channel, the server processes the request. Each request to open up a channel represents the processing of a single service.

Note The Cisco IOX software supports server-side multiplexing only.

Configure Client for Multiplexing

The SSH client opens up one TCP socket for all the connections. In order to do so, the client multiplexes all the connections into one TCP connection. Authentication happens only once at the time of creating the session.

After that, all the SSH clients associated with the particular session uses the same TCP socket to communicate to the server. Use the following steps to configure client multiplexing using OpenSSH:

Step 1 Edit the ssh_config file.

Open the ssh_config file with your favorite text editor to configure values for session multiplexing. The system-wide SSH configuration file is located under /etc/ssh/ssh_config. The user configuration file is located under ~/.ssh/config or $HOME/.ssh/config.

Step 2 Add entries **ControlMaster auto** and **ControlPath**

Add the entry ControlMaster auto and ControlPath to the ssh_config file, save it and exit.

- ControlMaster determines whether SSH will listen for control connections and what to do about them. Setting the ControlMaster to 'auto' creates a primary session automatically but if there is a primary session already available, subsequent sessions are automatically multiplexed.
- ControlPath is the location for the control socket used by the multiplexed sessions. Specifying the ControlPath ensures that any time a connection to a particular server uses the same specified primary connection.

Example:

```
Host *
ControlMaster auto
ControlPath ~/.ssh/tmp/%r@%h:%p
```

Step 3 Create a temporary folder.

Create a temporary directory inside the /.ssh folder for storing the control sockets.

SSH Configuration Option to Restrict Cipher Public Key and HMAC Algorithm

The Cisco IOS XR software provides a new configuration option to control the key algorithms to be negotiated with the peer while establishing an SSH connection with the router. With this feature, you can enable the insecure SSH algorithms on the SSH server, which are otherwise disabled by default. A new configuration option is also available to restrict the SSH client from choosing the HMAC, or hash-based message authentication codes algorithm while trying to connect to the SSH server on the router.

You can also configure a list of ciphers as the default cipher list, thereby having the flexibility to enable or disable any particular cipher.

Caution Use caution in enabling the insecure SSH algorithms to avoid any possible security attack.

To disable the HMAC algorithm, use the **ssh client disable hmac** command or **ssh server disable hmac** command in XR Config mode.

To enable the required cipher, use the **ssh client enable cipher** command or the **ssh server enable cipher** command in XR Config mode.

The supported encryption algorithms (in the order of preference) are:

1. aes128-ctr
2. aes192-ctr

3. aes256-ctr
4. aes128-gcm@openssh.com
5. aes256-gcm@openssh.com
6. aes128-cbc
7. aes192-cbc
8. aes256-cbc
9. 3des-cbc

In SSH, the CBC-based ciphers are disabled by default. To enable these, you can use the **ssh client enable cipher** command or the **ssh server enable cipher** command with the respective CBC options (aes-cbc or 3des-cbc). All CTR-based and GCM-based ciphers are enabled by default.

Disable HMAC Algorithm

Configuration Example to Disable HMAC Algorithm

```
Router(config)# ssh server disable hmac hmac-sha1
Router(config)#commit

Router(config)# ssh client disable hmac hmac-sha1
Router(config)#commit
```

Running Configuration

```
ssh server disable hmac hmac-sha1
!

ssh client disable hmac hmac-sha1
!
```

Associated Commands

- **ssh client disable hmac**
- **ssh server disable hmac**

Enable Cipher Public Key

Configuration Example to Enable Cipher Public Key

To enable all ciphers on the client and the server:

Router 1:

```
Router(config)# ssh client algorithms cipher aes256-cbc aes256-ctr aes192-ctr aes192-cbc
aes128-ctr aes128-cbc aes128-gcm@openssh.com aes256-gcm@openssh.com 3des-cbc
```

Router 2:

```
Router(config)# ssh server algorithms cipher aes256-cbc aes256-ctr aes192-ctr aes192-cbc
aes128-ctr aes128-cbc aes128-gcm@openssh.com aes256-gcm@openssh.com 3des-cbc
```

To enable the CTR cipher on the client and the CBC cipher on the server:

Router 1:

```
Router(config)# ssh client algorithms cipher aes128-ctr aes192-ctr aes256-ctr
```

Router 2:

```
Router(config)# ssh server algorithms cipher aes128-cbc aes256-cbc aes192-cbc 3des-cbc
```

Without any cipher on the client and the server:

Router 1:

```
Router(config)# no ssh client  algorithms  cipher
```

Router 2:

```
Router(config)# no ssh server  algorithms  cipher
```

Enable only deprecated algorithms on the client and the server:

Router 1:

```
Router(config)# ssh client algorithms cipher aes128-cbc aes192-cbc aes256-cbc 3des-cbc
```

Router 2:

```
Router(config)# ssh server algorithms cipher aes128-cbc aes192-cbc aes256-cbc 3des-cbc
```

Enable deprecated algorithm (using **enable cipher** command) and enable the CTR cipher (using **algorithms cipher** command) on the client and the server:

Router 1:

```
Router(config)# ssh client enable cipher aes-cbc 3des-cbc
Router(config)# ssh client algorithms cipher aes128-ctr aes192-ctr aes256-ctr
```

Router 2:

```
Router(config)# ssh server enable cipher aes-cbc 3des-cbc
```

```
Router(config)# ssh server algorithms cipher aes128-ctr aes192-ctr aes256-ctr
```

Running Configuration

All ciphers enabled on the client and the server:

Router 1:

```
ssh client algorithms cipher aes256-cbc aes256-ctr aes192-ctr aes192-cbc aes128-ctr aes128-cbc
 aes128-gcm@openssh.com aes256-gcm@openssh.com 3des-cbc
!
```

Router 2:

```
ssh client algorithms cipher aes256-cbc aes256-ctr aes192-ctr aes192-cbc aes128-ctr aes128-cbc
 aes128-gcm@openssh.com aes256-gcm@openssh.com 3des-cbc
!
```

User Configurable Maximum Authentication Attempts for SSH

Table 6: Feature History Table

Feature Name	Release Information	Feature Description
User Configurable Maximum Authentication Attempts for SSH	Release 7.3.1	This feature allows you to set a limit on the number of user authentication attempts allowed for SSH connection, using the three authentication methods that are supported by Cisco IOS XR. The limit that you set is an overall limit that covers all the authentication methods together. If the user fails to enter the correct login credentials within the configured number of attempts, the connection is denied and the session is terminated. This command is introduced for this feature: ssh server max-auth-limit

The three SSH authentication methods that are supported by Cisco IOS XR are public-key (which includes certificate-based authentication), keyboard-interactive, and password authentication. The limit count that you set as part of this feature comes into effect whichever combination of authentication methods you use. The limit ranges from 3 to 20; default being 20 (prior to Cisco IOS XR Software Release 7.3.2, the limit range was from 4 to 20).

Restrictions for Configuring Maximum Authentication Attempts for SSH

These restrictions apply to configuring maximum authentication attempts for SSH:

- This feature is available only for Cisco IOS XR routers functioning as SSH server; not for the ones functioning as SSH clients.
- This configuration is not user-specific; the limit remains same for all the users.
- Due to security reasons, the SSH server limits the number of authentication attempts that explicitly uses the password authentication method to a maximum of 3. You cannot change this particular limit of 3 by configuring the maximum authentication attempts limit for SSH.

  For example, even if you configure the maximum authentication attempts limit as 5, the number of authentication attempts allowed using the password authentication method still remain as 3.

Configure Maximum Authentication Attempts for SSH

You can use the **ssh server max-auth-limit** command to specify the maximum number of authentication attempts allowed for SSH connection.

Configuration Example

```
Router#configure
Router(config)#ssh server max-auth-limit 5
Router(config)#commit
```

Running Configuration

```
Router#show running-configuration ssh
ssh server max-auth-limit 5
ssh server v2
!
```

Verification

The system displays the following SYSLOG on the router console when maximum authentication attempts is reached:

```
RP/0/RP0/CPU0:Oct 6 10:03:58.029 UTC: SSHD_[68125]: %SECURITY-SSHD-3-ERR_GENERAL : Max
authentication tries reached-exiting
```

Associated Commands

- **ssh server max-auth-limit**

X.509v3 Certificate-based Authentication for SSH

Table 7: Feature History Table

Feature Name	Release Information	Feature Description
X.509v3 Certificate-based Authentication for SSH	Release 7.3.1	This feature adds new public-key algorithms that use X.509v3 digital certificates for SSH authentication. These certificates use a chain of signatures by a trusted certification authority to bind a public key to the digital identity of the user who is authenticating with the SSH server. These certificates are tough to falsify and are therefore used for identity management and access control across many applications and networks. Commands introduced for this feature are: ssh server certificate ssh server trustpoint This command is modified for this feature: ssh server algorithms host-key

This feature support is available for the SSH server for the server authentication and the user authentication.

The X.509v3 certificate-based authentication for SSH feature supports the following public-key algorithms:

- **x509v3-ssh-dss**
- **x509v3-ssh-rsa**
- **x509v3-ecdsa-sha2-nistp256**
- **x509v3-ecdsa-sha2-nistp384**
- **x509v3-ecdsa-sha2-nistp521**

Note While user authentication by using X.509v3 certificate-based authentication for the SSH server is supported using all algorithms listed above, server authentication is supported only with the **x509v3-ssh-rsa** algorithm.

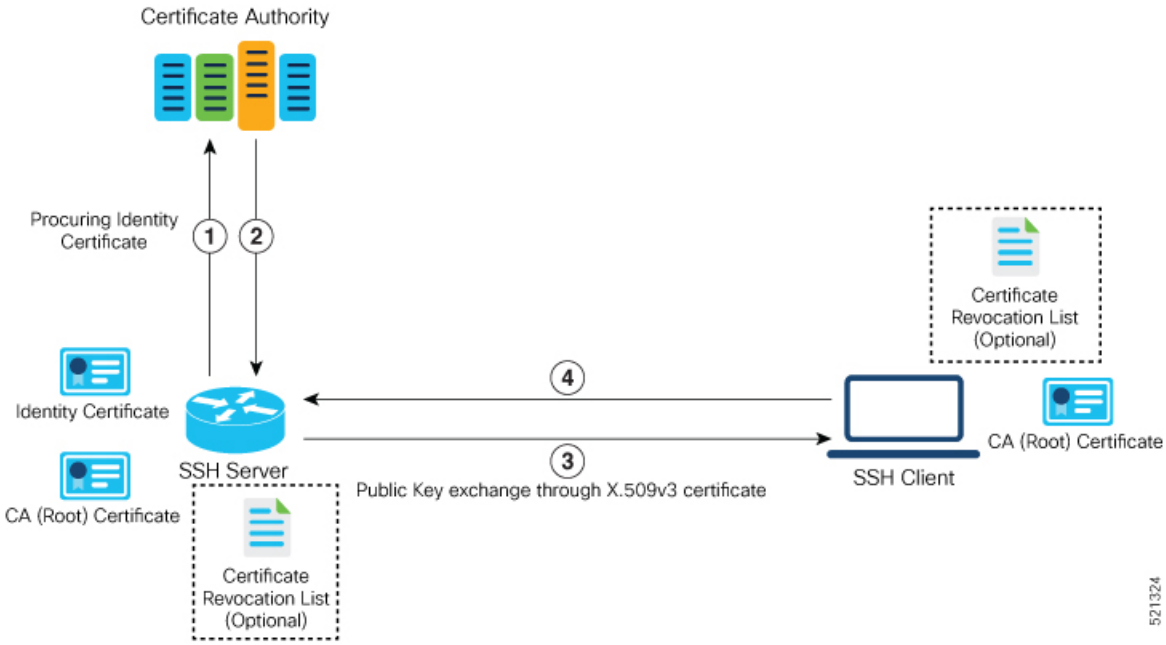
There are two SSH protocols that use public-key cryptography for authentication:

- Transport Layer Protocol (TLP) described in RFC4253—this protocol mandates that you use a digital signature algorithm (called the public-key algorithm) to authenticate the server to the client.

- User Authentication Protocol (UAP) described in RFC4252—this protocol allows the use of a digital signature to authenticate the client to the server (public-key authentication).

For TLP, the Cisco IOS XR SSH server provides its server certificate to the client, and the client verifies the certificate. Similarly, for UAP, the client provides an X.509 certificate to the server. The peer checks the validity and revocation status of the certificate. Based on the result, access is allowed or denied.

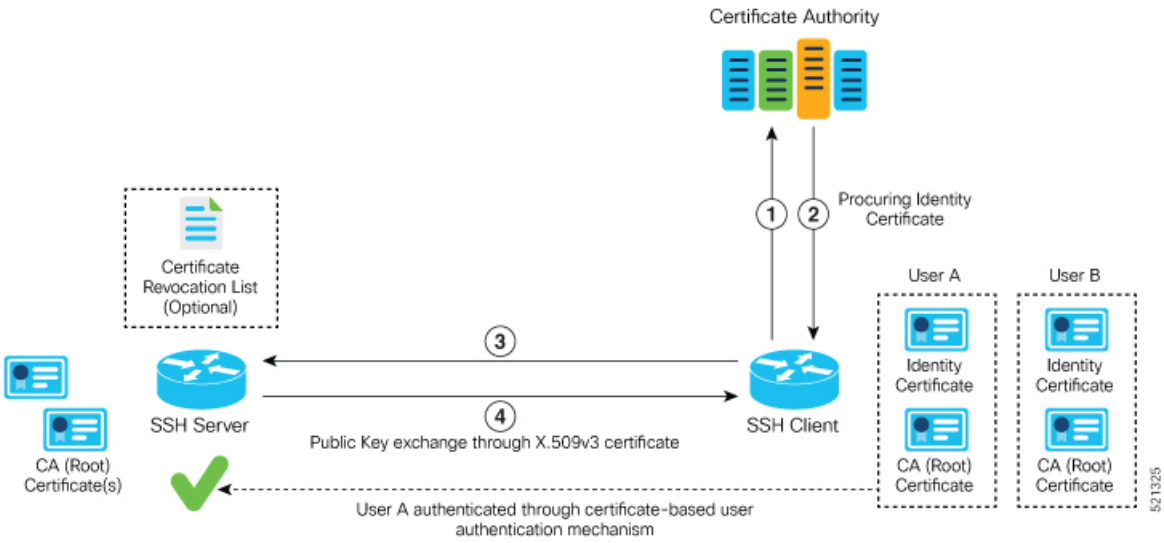
Server Authentication using X.509v3 Certificate



The server authentication process involves these steps:

1. The SSH server procures a valid identity certificate from a well-known certificate authority. This certificate can be obtained manually (through cut-and-paste mechanism) or through protocol implementations such as Simple Certificate Enrollment Protocol (SCEP).
2. The certificate authority provides valid identity certificates and associated root certificates. The requesting device stores these certificates locally.
3. The SSH server presents the certificate to the SSH client for verification.
4. The SSH client validates the certificate and starts the next phase of the SSH connection.

User Authentication using X.509v3 Certificate



The user authentication phase starts after the SSH transport layer is established. At the beginning of this phase, the client sends the user authentication request to the SSH server with required parameters. The user authentication process involves these steps:

1. The SSH client requests a valid identity certificate from a well-known certificate authority.
2. The certificate authority provides valid identity certificates and associated root certificates. The requesting device stores these certificates locally.
3. The SSH client presents the certificate to the SSH server for verification.
4. The SSH server validates the certificate and starts the next phase of the SSH connection.

The certificate-based authentication uses public key as the authentication method. The certificate validation process by the SSH server involves these steps:

- The SSH server retrieves the user authentication parameters, verifies the certificate, and also checks for the certificate revocation list (CRL).
- The SSH server extracts the *username* from the certificate attributes, such as *subject name* or *subject alternate name* (SAN) and presents them to the AAA server for authorization.
- The SSH server then takes the extracted *username* and validates it against the incoming *username* string present in the SSH connection parameter list.

Restrictions for X.509v3 Certificate-based Authentication for SSH

These restrictions apply to the X.509v3 certificate-based authentication feature for SSH:

- Supported only for Cisco IOS XR devices acting as the SSH server; not for the Cisco IOS XR devices acting as the SSH client.
- Supported only for local users because TACACS and RADIUS server do not support public-key authentication. As a result, you must include the **local** option for AAA authentication configuration.

Note Although this feature supports only local authentication, you can enforce remote authorization and accounting using the TACACS server.

- Certificate verification using the Online Certificate Status Protocol (OCSP) is currently not supported. The revocation status of certificates is checked using a certificate revocation list (CRL).
- To avoid user authentication failure, the chain length of the user certificate must not exceed the maximum limit of 9.

Configure X.509v3 Certificate-based Authentication for SSH

To enable X.509v3 certificate-based authentication for SSH, these tasks for server and user authentication:

Server Authentication:

- Configure the list of host key algorithms—With this configuration, the SSH server decides the list of host keys to be offered to the client. In the absence of this configuration, the SSH server sends all available algorithms to the user as host key algorithms. The SSH server sends these algorithms based on the availability of the key or the certificate.
- Configure the SSH trust point for server authentication—With this configuration, the SSH server uses the given trust point certificate for server authentication. In the absence of this configuration, the SSH server does not send **x509v3-ssh-rsa** as a method for server verification. This configuration is not VRF-specific; it is applicable to SSH running in all VRFs.

  The above two tasks are for server authentication and the following ones are for user authentication.

User Authentication:

- Configure the trust points for user authentication—With this configuration, the SSH server uses the given trust point for user authentication. This configuration is not user-specific; the configured trust points are used for all users. In the absence of this configuration, the SSH server does not authenticate using certificates. This configuration is not specific to a VRF; it is applicable to SSH running in all VRFs.

  You can configure up to ten user trust points.
- Specify the *username* to be picked up from the certificate—This configuration specifies which field in the certificate is to be considered as the *username*. The **common-name** from the **subject name** or the **user-principle-name(othername)** from the **subject alternate name**, or both can be configured.
- Specify the maximum number of authentication attempts allowed by the SSH server—The value ranges from 4 to 20. The default value is 20. The server closes the connection if the number of user attempts exceed the configured value.
- AAA authentication configuration—The AAA configuration for public key is the same as that for the regular or keyboard-interactive authentication, except that it mandates local method in the authentication method list.

Configuration Example

In this example, the **x509v3-ssh-rsa** is specified as the allowed host key algorithm to be sent to the client. Similarly, you can configure other algorithms, such as **ecdsa-sha2-nistp521, ecdsa-sha2-nistp384, ecdsa-sha2-nistp256, ssh-rsa**, and **ssh-dsa**.

```
/* Configure the lits of host key algorithms */
Router#configure
Router(config)#ssh server algorithms host-key x509v3-ssh-rsa
Router(config)#commit

/* Configure the SSH trustpoint for server authentication */
Router#configure
Router(config)#ssh server certificate trustpoint host tp1
Router(config)#commit

/* Configure the trustpoints to be used for user authentication */
Router#configure
Router(config)#ssh server trustpoint user tp1
Router(config)#ssh server trustpoint user tp2
Router(config)#commit

/* Specifies the username to be picked up from the certificate.
In this example, it specifies the user common name to be picked up from the subject name
field */
Router#configure
Router(config)#ssh server certificate username common-name
Router(config)#commit

/* Specifies the maximum authentication limit for the SSH server */
Router#configure
Router(config)#ssh server max-auth-limit 5
Router(config)#commit

/* AAA configuration for local authentication with certificate and
remote authorization with TACACS+ or RADIUS */
Router#configure
Router(config)#aaa authentication login default group tacacs+ local
Router(config)#aaa authorization exec default group radius group tacacs+
Router(config)#commit
```

Running Configuration

```
ssh server algorithms host-key x509v3-ssh-rsa
!
ssh server certificate trustpoint host tp1
!
ssh server trustpoint user tp1
ssh server trustpoint user tp2
!
ssh server certificate username common-name
!
ssh server max-auth-limit 5
!
```

Verification of Certificate-based Authentication for SSH

You can use the **show ssh server** command to see various parameters of the SSH server. For certificate-based authentication for SSH, the **Certificate Based** field displays *Yes*. Also, the two new fields, **Host Trustpoint** and **User Trustpoints**, display the respective trust point names.

```
Router#show ssh server
```

```
Wed Feb 19 15:23:38.752 IST
---------------------
SSH Server Parameters
---------------------

Current supported versions := v2
                 SSH port := 22
                 SSH vrfs := vrfname:=default(v4-acl:=, v6-acl:=)
             Netconf Port := 830
             Netconf Vrfs := vrfname:=default(v4-acl:=, v6-acl:=)

 Algorithms
---------------
        Hostkey Algorithms := x509v3-ssh-rsa,
ecdsa-sha2-nistp521,ecdsa-sha2-nistp384,ecdsa-sha2-nistp256,ssh-rsa,ssh-dsa
   Key-Exchange Algorithms :=
ecdh-sha2-nistp521,ecdh-sha2-nistp384,ecdh-sha2-nistp256,diffie-hellman-group14-sha1
     Encryption Algorithms :=
aes128-ctr,aes192-ctr,aes256-ctr,aes128-gcm@openssh.com,aes256-gcm@openssh.com
            Mac Algorithms := hmac-sha2-512,hmac-sha2-256,hmac-sha1

 Authetication Method Supported
-----------------------------------
                PublicKey := Yes
                 Password := Yes
      Keyboard-Interactive := Yes
         Certificate Based := Yes

 Others
------------
                     DSCP  := 16
                Ratelimit  := 60
             Sessionlimit  := 100
                Rekeytime  := 60
       Server rekeyvolume  := 1024
  TCP window scale factor  := 1
            Backup Server  := Enabled, vrf:=default, port:=11000
Host Trustpoint            := tp1
User Trustpoints           := tp1 tp2
```

You can use the **show ssh session details** command to see the chosen algorithm for an SSH session:

```
Router#show ssh session details
Wed Feb 19 15:33:00.405 IST
SSH version : Cisco-2.0

id      key-exchange           pubkey               incipher    outcipher   inmac
outmac
-------------------------------------------------------------------------------------------------

Incoming Sessions
1       ecdh-sha2-nistp256     x509v3-ssh-rsa       aes128-ctr  aes128-ctr  hmac-sha2-256
hmac-sha2-256
```

Similarly, you can use the **show ssh** command to verify the authentication method used. In this example, it shows as *x509-rsa-pubkey*:

```
Router#show ssh
Sun Sep 20 18:14:04.122 UTC
SSH version : Cisco-2.0
```

```
id  chan pty  location   state        userid    host          ver authentication connection
 type

client tried to access a nonexistent item or list an empty directory', x509 host auth
will not be used
RP/0/RP1/CPU0:Aug 10 00:23:30.442 IST: locald_DLRSC[326]: %SECURITY-PKI-3-ERR_ERRNO :
Error:='Crypto Engine' detected the 'warning' condition 'Invalid trustpoint or trustpoint
 not exist'(0x4214c000), Failed to get trustpoint name from
```

How to Disable X.509v3 Certificate-based Authentication for SSH

- Server Authentication — You can disable X.509v3 certificate-based server authentication for SSH by using the **ssh server algorithms host-key** command. From the list of auto-generated host-key pairs algorithms on the SSH server, this command configures allowed SSH host-key pair algorithms. Hence, if you have this configuration without specifying the **x509-ssh-rsa** option in the preceding command, it is equivalent to disabling the X.509v3 certificate-based server authentication for the SSH server.
- User Authentication — You can remove the user trust point configuration (**ssh server trustpoint user**) so that the SSH server does not allow the X.509v3 certificate-based authentication.

Failure Modes for X.509v3 Certificate-based Authentication for SSH

If the **ssh server certificate trustpoint host** configuration is missing, or if the configuration is present, but the router certificate is not present under the trust point, then the SSH server does not add **x509-ssh-rsa** to the list of supported host key methods during key exchange.

Also, the user authentication fails with an error message if:

- User certificate is in an incorrect format.

- The chain length of the user certificate is more than the maximum limit of 9.
- Certificate verification fails due to any reason.

Validating X.509v3 Certificate Extensions over Mutual Transport Layer Security (mTLS)

Table 8: Feature History Table

Feature Name	Release Information	Feature Description
Validating X.509v3 Certificate Extensions over Mutual Transport Layer Security (mTLS)	Release 7.9.1	With this feature, the router can handle the X.509v3 Certificates Extensions defined in RFC 5280 while validating the client certificate over mTLS. Here, the router acknowledges all extensions in X.509v3 Certificates of the user while validating it. Previously, the router failed to process certification extensions when the severity was critical and resulting in authentication failure. This feature permits users to configure any certificate extensions with different severity in their X.509v3 Certificates.

Starting with IOS XR Release 7.9.1, you can add any Certificate Extensions available in RFC 5280 to your X.509v3 client certificates validations over Mutual Transport Layer Security (mTLS). While validating such client certificate, the router acknowledges all extensions available in the certificate presented and processes it. With this, the router allows the user to configure any number of extensions with different severity in their X.509v3 client certificates.

OpenSSH Certificate based Authentication for Router

Table 9: Feature History Table

Feature Name	Release Information	Feature Description
OpenSSH Certificate based Authentication for Router	Release 7.5.3	You can now use OpenSSH certificates to authenticate to the remote routers from a client machine. This feature uses the ssh-keygen utility, a standard SSH component to generate and manage authentication keys, available in OpenSSH to create a CA (Certificate Authority) like infrastructure for logging into the router. In this feature, the certificates that are used to authenticate router and client are both signed by the same CA. This automatically establishes trust between router and client, and eliminates the need to establish trust, while using the client for remote logging to router for the first time.

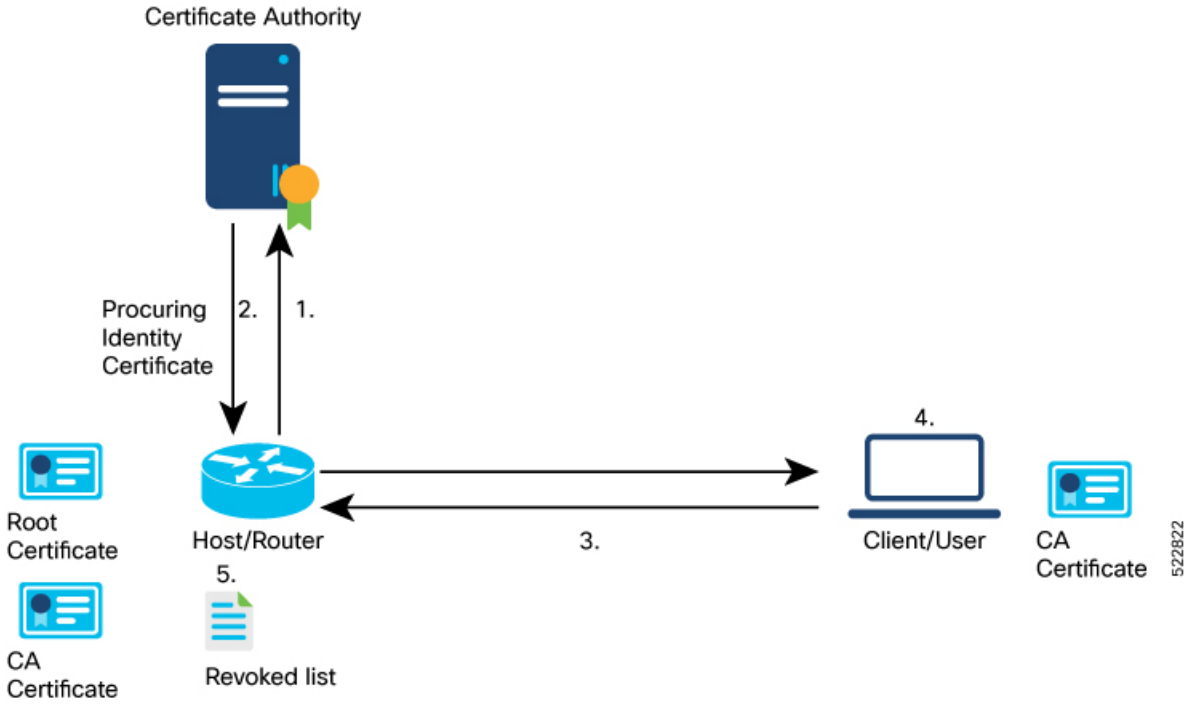
OpenSSH is the open-source implementation of the SSH Protocol. In OpenSSH certificate-based authentication, you can use the ssh-keygen utility to create a certificate signing infrastructure. A digital certificate with public and private key pair, created using the ssh-keygen utility, authenticates the host and the user certificates. The user certificate authenticates the client machine to the router. The client machine is a system that the user utilizes to establish remote access to the router. When a user attempts to log in to the router using the client machine, the client machine presents its certificate to the router. The router checks for the identity and validity of the certificate to decide whether to allow or deny the connection request. The host certificate in the router authenticates the router to the client. Overall, the host and user certificates together establish a two-way secure communication channel.

The OpenSSH based authentication for the router has the following major phases:

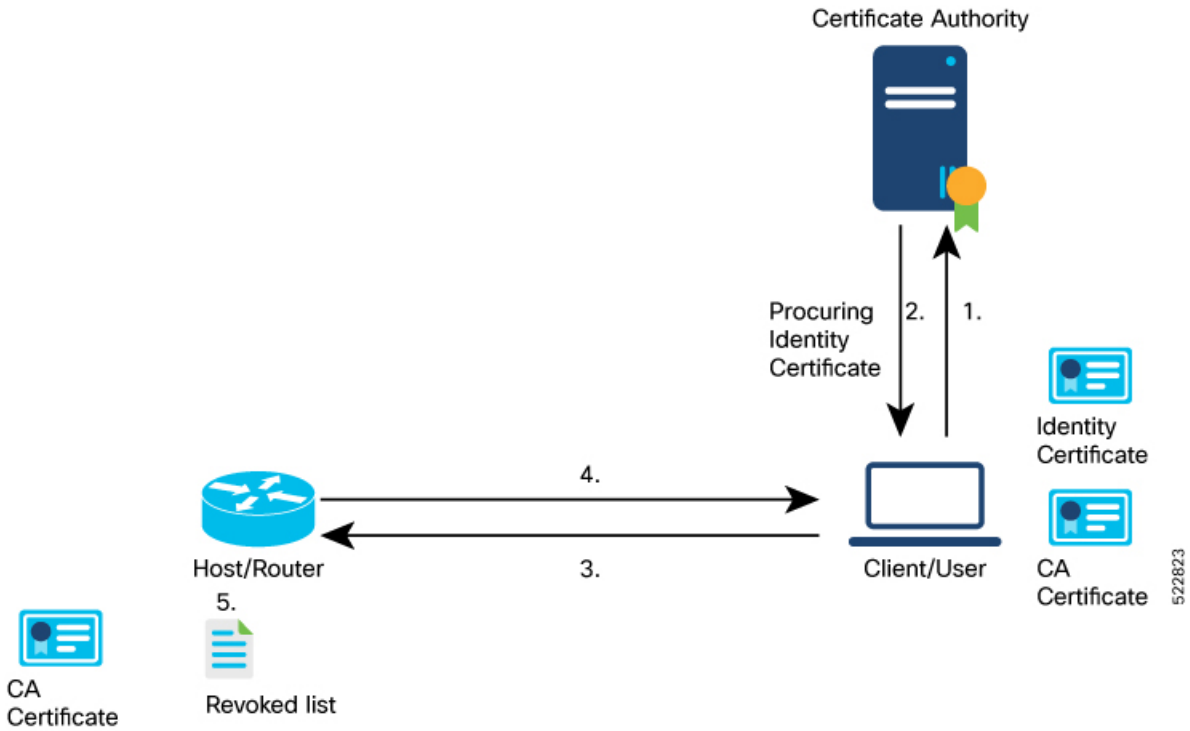
Establishing the trustpoints: In the router, you must create a trustpoint and configure the router to use this trustpoint for the host and user authentication. You can have a same or different trustpoints for these entities. While the router can have only one trustpoint, the user can have up to ten trustpoints.

Creating the CA: Any system with the OpenSSH feature acts like the CA. The ssh-keygen creates the CA certificate and utilizes it to sign the router and user certificate.

Router authentication: You must copy the CA public key in the CA server to the router and ensure to create a CSR (Certificate Signing Request) in the router. The CSR file is further copied to the CA server and signed using the CA certificate. The CA signed certificate is copied back to the router to complete its authentication with CA.



User authentication: You must create a digital certificate for the user using the ssh-keygen utility and sign the public key using the CA certificate. The CA signed user certificate must be copied to the client system using which you would log into the router using the specified user.



Remote access to the router: After the host and user authentication, you can access the router using SSH in the client system that is used to authenticate the user.

Feature Highlights

- OpenSSH certificates use the Certificate Authority (CA) infrastructure to act as a trusted entity while signing the host or user certificates.
- OpenSSH certificates contain a public and private key pair, including identity and validity information. These are signed using a standard SSH public key using the ssh-keygen utility.
- The router certificate includes information such as the host public key, public key of the signing CA, type (host), certificate validity, Key ID, serial number of the certificate, and so on.
- The user certificate contains the user's public key, the public key of the signing CA, Key ID, type (user), serial number, certificate validity, principals matched against the login username, and so forth.
- The CA is just another SSH key created using the ssh-keygen utility. However, rather than utilizing it for authenticating the router or user directly, it's used to sign and validate the other keys that are used for authenticating the router and the user.
- You can view the router and user certificate properties using the ssh-keygen.
- The OpenSSH certificates support the following encryptions:
  - RSA
  - DSA
  - ECDSA
  - ED25519

Prerequisites

- You must have a client machine which has OpenSSH feature with the **ssh-keygen** utility to act as CA.

Configuration Example

The following high-level steps help you set up OpenSSH based Authentication:

1. Create a trustpoint in the router and configure the router to use this trustpoint for the host and user authentication.
2. Creating CA, the CA here is a dedicated system with OpenSSH feature that provides a certificate signing infrastructure using the ssh-keygen utility.
3. Host authentication, the host here is the Cisco IOS XR router.
4. User authentication, a user is any entity attempting to access the router. Generally refers to system to access the router CLI remotely. User is also referred to as client.
5. Access the router in the client using the OpenSSH authentication

This section contains the detailed procedure to enable this feature in your router.

1. Create a trustpoint in the router and configure the router to use this trustpoint for the host and user authentication.

   a. [Router Config mode] Create a trustpoint in the router.

   ```
   Router# config
   Router(config)# crypto ca openssh trustpoint test
   Router(config)# commit
   ```

   b. [Router Config mode] Configure the trustpoint for host authentication.

   ```
   Router# config
   Router(config)# ssh server openssh trustpoint host test
   Router(config)# commit
   ```

   c. [Router Config mode] Configure the trustpoint for user authentication

   ```
   Router# config
   Router(config)# ssh server openssh trustpoint user test
   Router(config)# commit
   ```

2. Creating CA

   a. [CA Server] In the dedicated machine with OpenSSH feature to act as CA, generate a certificate using the **ssh-keygen** utility:

   ```
   [root@CAServer test]# ssh-keygen -t rsa -f cacert
   Generating public/private rsa key pair.
   Enter passphrase (empty for no passphrase):
   Enter same passphrase again:
   Your identification has been saved in cacert.
   Your public key has been saved in cacert.pub.
   The key fingerprint is:
   SHA256:/B2b8V7jKXwGphf75fkO74U/mpuHgDHmvF4okexdKhY root@CAServer
   The key's randomart image is:
   +---[RSA 2048]----+
   |                 |
   |                 |
   |                 |
   |      ...+       |
   |       ES +.o    |
   |      . +=+o X . |
   |       = +o.O O.+|
   |      . o... B+@*|
   |        ..  .=XBX|
   +----[SHA256]-----+

   [root@CAServer test]# ls
   cacert  cacert.pub
   ```

Note Leave the passphrase empty.

3. Host (Router) authentication

   a. [CA Server] Open the CA public key from CA server and copy it contents.

   ```
   [root@CAServer test]# cat cacert.pub
   ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQCigl/zhyjuGOBYz5bu+GL76
   HBaROV0pVS4Lx3pf1jcjrFkVibPKKkVeX/lE7sZIJ0anU9vYSJZW8zrl8z06G

hNj1BdH3/Hha4x root@CAServer
```

b. [Router EXEC mode] Add the contents of the CA public key to router trustpoint.

```
Router#crypto ca openssh authenticate test
Enter the CA pubkey.
End with a blank line or the word "quit" on a line by itself
ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQCigl/zhyjuGOBYz5bu+GL7

---End - This line not part of hostkey---
Redisplay enrollment request? [yes/no]: n
```

e. [Router EXEC mode] Select the hostkey contents of the CSR file and copy the hostkey of the CSR.

f. [CA server] Create a .pub file in the CA server for the CSR hostkey and paste the copied hostkey contents in this file.

```
[root@CAServer test]# vim host.pub
/* Here we are using the vim text editor to create the host.pub file */
/* You can use any text editor of your choice  */
```

g. [CA server] Execute the following block to sign the CSR file using the CA certificate

```
[root@CAServer test]# ssh-keygen -h -s cacert -I "server" -V +10w -z 10 host.pub
Signed host key host-cert.pub: id "server" serial 10 valid from 2022-09-16T12:26:00
 to 2022-11-25T12:27:17
```

Note Use the following command to sign the CSR file using the CA certificate:

ssh-keygen -h -s <CACert> -I <IdentityOfCSRSys> -V <CertValidity> -z <CertSerialNo> <CopiedCSRFile>

Parameter	Description
CACert	Specify the filename of the CA Server private key
CertValidity	Specify the validity period for the certificate.
CertSerialNo	Specify a serial number for the certificate.
CopiedCSRFile	Specify the name of the file created to copy the contents of CSR in the router.

h. [CA server] Open the signed host certificate and copy the contents.

```
[root@CAServer test]# cat host-cert.pub

sfjFscCP0kzU1gX root@userclient.cisco.com
```

c. [CA server] Create a .pub file in the CA server for the user certificate public key and paste the public key contents from the previous step in this file.

```
[root@CAServer test]# vim user.pub
/* Here we are using the vim text editor to create the user.pub file */
/* You can use any text editor of your choice  */
```

d. [CA server] Sign the user public key using the CA certificate private key.

```
[root@CAServer test]# ssh-keygen -s cacert -I "user" -V +10w -n testuser -z 20 user.pub

Signed user key user-cert.pub: id "user" serial 20 valid from 2022-09-16T12:42:00 to
 2022-11-25T12:43:24
```

Note The command to sign the CSR file using the CA certificate:

`ssh-keygen -s <CACert> -I <IdentityOfSysReqCert> -V <CertValidity> -n <Username> -z <CertSerialNo> <CopiedUserCertName>`

Note In addition to the mandatory fields specified for the user certificate, you can also configure critical options and extensions for the user certificate. For detailed information on the critical options and extensions, refer ssh-keygen.

Parameter	Description
`CACert`	Specify the filename of the CA Server private key/
`IdentityOfSysReqCert`	Specify the identity of the certificate as User
`CertValidity`	Specify the validity period for the certificate.

Parameter	Description
<Username>	Specify the principals that you want to add to the certificate. **Note** During authentication to the router, the principal in the user certificate is matched against the login username and requests with matching principal and username are permitted for further communication. **Note** You can have multiple principals that are associated with the same certificate. The principals must be separated by commas in the **IdentityOfSysReqCert** field in command to sign the user certificate file using CA certificate.
CertSerialNo	Specify a serial number for the certificate.
CopiedUserCertName	Specify the name of the file created to copy the contents of the user certificate file in the client machine.

e. [CA server] Open the signed user certificate in the CA server and copy the contents.

```
[root@CAServer test]# cat user-cert.pub

```

i. [Router Config mode] Configure the username in the router

```
Router# config
Router(config)# username testuser
Router(config-un)# group root-lr
Router(config-un)# commit
```

5. [Client machine] Access the router in the client using the OpenSSH certificate.

```
[root@userclient test]# ssh -o CertificateFile=user-cert.pub -i user testuser@192.0.2.2
 -o StrictHostKeyChecking=yes
Router#
```

Note The command to access the router in the client machine remotely:

ssh -o CertificateFile=<CA_Signed_User_Certificate_Name> -i <User_Certificate_Private_Key> <Username >@<Router_IP> -o StrictHostKeyChecking=yes

Certificate-based user authentication using TACACS+ server

Table 10: Feature History Table

Feature Name	Release Information	Feature Description
Certificate-based user authentication using TACACS+ server	Release 7.5.4	This feature enables the router login for users in the remote TACACS+ server using the certificate-based authentication methods. Here, the router authenticates a user using the OpenSSH certificates and authorizes access according to the configurations available for that user in the external TACACS+ server. This feature provides an option to configure the users in a centralized TACACS+ server and use them across multiple routers in a network. Thus, it helps you overcome the hassles of configuring users in each router individually while authenticating users based on certificates. This feature introduces the **aaa enable-cert-authentication** command.

In certificate-based authentication methods, the router permits a login by matching the OpenSSH user certificate with the user configurations available locally in the router database. It leads to the need to configure multiple user profiles across all the individual routers in a network when using certificate-based authentication methods. In turn, it locally creates a configuration overhead for the network administrators.

With this feature, you can configure the users in a centralized TACACS+ server and instruct the router to allow authentication to these users through the certificate using the **aaa enable-cert-authentication** command. On enabling this feature, when the router receives a certificate-based authentication request, the router validates the user certificate using the host certificate. Once validation is successful, the router further queries the external TACACS+ server to check if the user requesting access is a TACACS+ user. The router uses the functionality of the **aaa authorization exec** command to make this query to the external TACACS+ server. If there is a match between the user profiles in the external TACACS+ server and the user requesting access, then the TACACS+ server processes the authorization. And the TACACS+ server sends the user group associated with this user to the router. Else, the router checks its local database depending on the authorization configuration, and further permits or denies the authentication for such a request.

Note The Router supports certificate-based authentication for users profiles in the external TACACS+ server.

Restrictions

- Certificate based authentication for users in an external TACACS+ server is supported only in OpenSSH implementation.

Prerequisites

- Enable certificate-based authentication for the Router. For more information, see OpenSSH Certificate based Authentication for Router, on page 38.
- Configure the user profiles in the external TACACS+ Server.
- Configure the TACACS+ Server or TACACS+ Server Groups. For more information, see Configure TACACS+ Server and Configure TACACS+ Server Groups.
- Configure user authorization using the TACACS+. For more information, see aaa authorization exec.

Configuration Example

This section contains the detailed procedure to enable the Certificate based authentication for users in an external TACACS+ server in your router:

Configuration

```
Router#config

Router(config)#aaa enable-cert-authentication
/* Enables certificate based authentication for users in external TACACS+ Server */

Router(config)#aaa authorization exec default group tacacs+ local
/* Enables authorization for user list in TACACS+ and router database */

Router(config)#commit
```

Running Configuration

```
Router:ios#show running-config
 ...
    aaa enable-cert-authentication
    aaa authorization exec default group tacacs+ local
    !
```

Public Key-Based Authentication of SSH Clients

Table 11: Feature History Table

Feature Name	Release Information	Feature Description

Public Key-Based Authentication of SSH Clients on Cisco IOS XR Routers	Release 7.10.1	You are now assured of cryptographic strength even as you avail of automated password-less login while establishing SSH connections with the server. With the password and keyboard-interactive authentication, Cisco IOS XR routers configured as SSH clients now support public key-based authentication. In this authentication method, passwords need not be sent over the network; hence, it provides an additional layer of security and aids in automation processes. This feature is available only for users locally configured on the router; not those configured on remote servers.
		
		Previous releases supported SSH public key-based authentication only for Cisco IOS XR routers configured as SSH servers.
		
		The feature introduces these changes:
		
		• **CLI**:
		  • **crypto key generate authentication-ssh rsa**
		  • **crypto key zeroize authentication-ssh rsa**
		  • **show crypto key mypubkey authentication-ssh rsa**
		
		• **Yang Data Models**:
		  New Xpaths for:
		  • `Cisco-IOS-XR-crypto-act.yang`
		  • `Cisco-IOS-XR-crypto-oepki-new-oper.yang`
		
		  (see GitHub, YANG Data Models Navigator)

Cisco IOS XR routers configured as SSH clients supported only password authentication and keyboard-interactive authentication for establishing SSH connection with the SSH server. Whereas those IOS XR routers that are configured as SSH servers supported public key-based user authentication as well. From Cisco IOS XR Software Release 7.10.1 and later, you can use public-key based user authentication for Cisco

IOS XR routers configured as SSH clients as well. This feature thereby allows you to use password-less authentication for secure file transfer and copy operations using SFTP and SCP protocols.

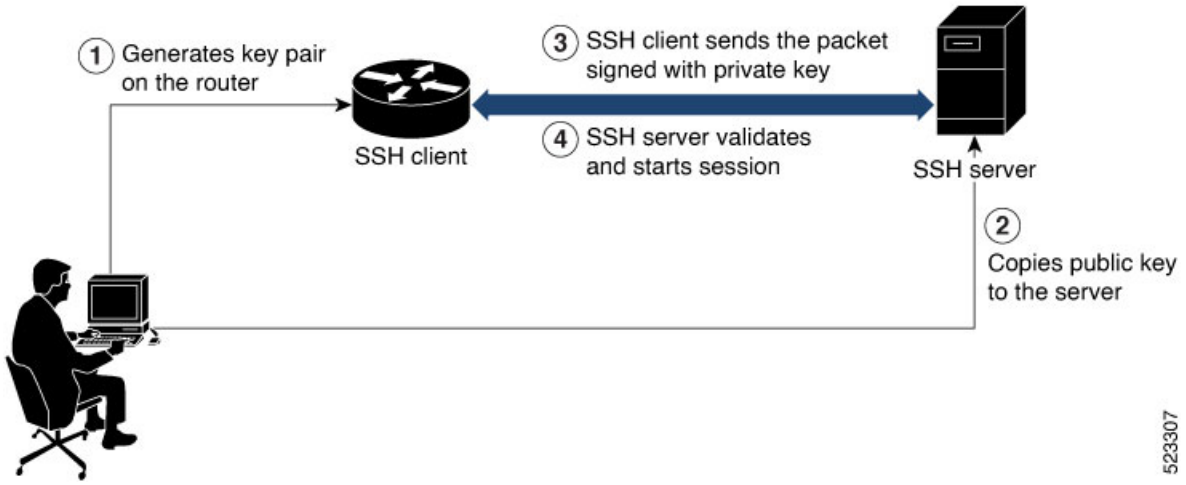
Remote AAA servers such as RADIUS and TACACS+ servers do not support public-key based authentication. Hence this functionality is available only for users who are configured locally on the router and not for users who are configured remotely.

How Does it Work

Public key encryption algorithm works with two keys—a public key and a private key. These keys form a key pair that is specific to a user. They are cryptographically related. The public key is used to encrypt the data and the private key is used to decrypt the data. The data encrypted by the SSH server that holds the public key can then only be read by the entity who holds the corresponding private key.

This image shows the work flow of public key-based authentication of SSH clients.

Figure 1: Public Key-Based Authentication of SSH Clients: Work Flow



You can generate the key pair on the router that is configured as the SSH client. Once it is generated, copy the public key to the SSH server that the user wants to connect to. When the user tries to log in to the server, the SSH client sends a connection request to the SSH server. The SSH server allows access only to users who can confirm that they have the corresponding private key. For this. the SSH server uses the public key of the user to issue a challenge that can be rightly answered by the SSH client using the corresponding private key. The SSH client thus automatically authenticates the user who is logging in to the server using the unique copy of the private key. This process thereby establishes a secure SSH connection to the server in a way that does not require the user to enter the password each time.

Enable Public Key-Based Authentication of SSH Client

Guidelines

These guidelines apply to enabling public key-based SSH authentication on Cisco IOS XR routers that are configured as SSH clients.

- Supports only RSA key.

- Remote AAA servers such as RADIUS and TACACS+ servers do not support public key-based authentication. Hence this functionality is available only for users who are configured locally on the router and not for users who are configured remotely.
- A user with root privileges has permission to create and delete keys for other users.
- If authentication keys are not created, then the SSH client does not proceed with public key-based authentication.
- If user adds the incorrect public key in the SSH server, then the user authentication fails.

Configuration Example

Establishing SSH connection using public key-based authentication on SSH client involves these high-level tasks:

1. Generate RSA key pair on the router that is configured as the SSH client.

   Use the **cyrpto key generate authentication-ssh rsa** command to generate the RSA key pair:

```
Router#crypto key generate authentication-ssh rsa
Wed Dec 21 10:02:57.684 UTC
The name for the keys will be: cisco
  Choose the size of the key modulus in the range of 512 to 4096. Choosing a key modulus
 greater than 512 may take a few minutes.

How many bits in the modulus [2048]:
Generating RSA keys ...
Done w/ crypto generate keypair
[OK]

Router#
```

2. View the details of the generated key.

   Use the **show crypto key mypubkey authentication-ssh rsa** command to view the details of the RSA key. The key value starts with *ssh-rsa* in this output.

```
Router#show crypto key mypubkey authentication-ssh rsa
Wed Dec 21 10:24:34.226 UTC
Key label: cisco
Type     : RSA Authentication
Size     : 2048
Created  : 10:02:59 UTC Wed Dec 21 2022
Data     :
 30820122 300D0609 2A864886 F70D0101 01050003 82010F00 3082010A 02820101
 00A292B0 E45ACBB9 47B9EDA8 47E4664E 58FC3EA5 CE0F6B7A 3C6B7A73 537E6CEB
 .
 .
 .
 FF6BAF95 D9617CF6 65C058CC 7C6C22A9 9E48CC43 FDFF0EB7 ABADEB77 55A274DB
 15020301 0001

OpenSSH Format:
ssh-rsa
AAAAB3NzaC1yc2EAAAADAQABAAABAQCikrDkWsu5R7ntqEfkZk5Y/.../2uvldlhfPZlwFjMfGwiqZ5IzEP9/w63q63rd1WidNsV

Router#
```

3. Copy the RSA public key from the SSH client to the SSH server.

You can do this either by logging in to the remote SSH server with your established user credentials, or have a system administrator on the remote system add the key on the SSH server.

If the SSH server is a Cisco IOS XR router, then you can use the **crypto key import authentication rsa** command on the router prompt of the server to import the key from the SSH client. You will then be prompted to enter the public key.

If the SSH server is a Linux server, then you must add the public key to the `~/.ssh/authorized_keys` file of the respective user account in that server. This file contains a list of all authorized public keys on that server.

4. The user configured on the SSH client can now log in to the remote SSH server (*209.165.200.225* in this example) without providing the user account password.

```
Router#ssh user1@209.165.200.225
```

This process establishes a successful SSH connection between the client and the server using public key-based authentication.

How to Delete the SSH Public Keys

Use the **crypto key zeroize authentication-ssh rsa username** command to delete the RSA keys.

```
Router#crypto key zeroize authentication-ssh rsa username user1
```

Public key-based Authentication to SSH Server on Routers

Table 12: Feature History Table

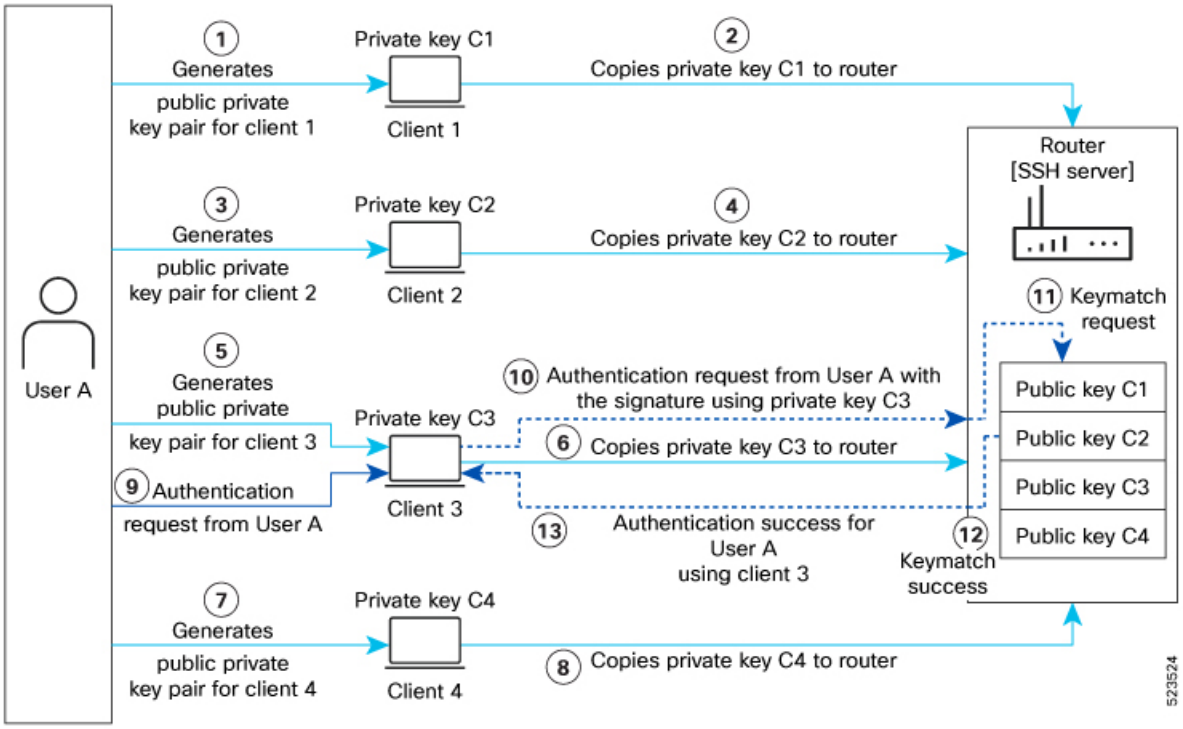
Feature Name	Release Information	Feature Description
Multiple Public Keys per User for Public Key-based Authentication	Release 7.11.1	We provide greater flexibility to access secure routers by allowing four public keys to be used for authentication. With the ability to associate multiple public keys with your user account on the router, we've also simplified the authentication process by eliminating the need to create unique users for each SSH client device. The feature introduces these changes: **CLI:** • The **second**, **third**, and **fourth** keywords are introduced in the **crypto key import authentication rsa** command. • The **second**, **third**, and **fourth** keywords are introduced in the **crypto key zeroize authentication rsa** command. • The **second**, **third**, and **fourth** keywords are introduced in the **keystring** command.` **YANG Data Models:** • `Cisco-IOS-XR-crypto-act` • `Cisco-IOS-XR-um-ssh-cfg` (See GitHub, YANG Data Models Navigator)

Public key-based authentication provides password-less authentication to the routers. In this method, the user authentication relies on a cryptographic key pair: a public key and a private key. The user generates a key pair in the client device using utilities such as ssh-keygen. The public key is imported and stored in the router(SSH server), while the private key is in the user device(SSH client). While attempting public key-based authentication from the client, the user presents a signature created using the private key to the router. The router verifies the authenticity of that signature using the public key associated with that user in its database. The authentication is successful when the signature matches the public key and user access is permitted.

Otherwise, the authentication fails, and the router denies the user access. With public key-based authentication, the routers offer a more secure authentication method than traditional password-based authentication because it is less vulnerable to brute force attacks and password theft.

From Cisco IOS XR Software Release 7.11.1, the routers support up to four public keys per user for public key-based authentication to the routers. Previously, the users could have a single key pair. This constraint restricts an individual user in the router from having multiple systems to access the routers. Also, it necessitates creating a unique user in the router for each device to be an authorized SSH client to the router. However, the multiple public keys per user for public key-based authentication feature overcome these restrictions by allowing up to four public keys per user. As a result, the users can employ any corresponding private key to access the router.

Figure 2: Multiple Public Keys per User for Public Key-based Authentication



You can generate the key pair on each of the SSH clients. You must then copy the public keys to the router. When the user tries to log in to the router, the SSH client sends a connection request with a signature created using the private key. The router then checks the authenticity of the request by matching it against the public keys associated with that user in its database. Suppose one of the multiple public keys associated with that user matches the signature; the router authenticates such user, confirming that the user has the corresponding private key. This process thereby establishes a secure SSH connection to the router.

Guidelines and Restrictions for Public key-based authentication to Routers

- You can add public keys by importing the public key file or directly adding the public keystring to the router.
- The maximum number of public keys supported per user is four.

- The router supports importing or adding only one public key at a time. Even though the router supports up to four keys per user, you can only import or add them to the router one after the other and not simultaneously.
- To import the public key files to the router, use the **crypto key import authentication rsa** command.
- The router supports importing public keys in the following formats:
  - RSA
  - Base 64
  - PEM PKCS1
  - PEM PKCS8
- To delete the public key files in the router, use the **crypto key zeroize authentication rsa** command.
- You can import the public keys using the **crypto key import authentication rsa** command in the XR Config mode and XR EXEC mode. However, use the same operation mode to import and delete the public keys. That is, if you import the public keys in the XR Config mode, delete such keys in XR Config mode only. Similarly, if you import the public keys in the XR EXEC mode, delete such keys in XR EXEC mode only.
- You can use SSH configurations to add or delete a public key in the router.
- The router supports only the RSA key format while using SSH configurations to add a public key for public key-based authentication to the router.

Configure Public key-based Authentication to Routers

This section details different methods of enabling flexible public key-based authentication and importing public keys to the router:

Configurations

Using public-key import:

1. [Router] Create a user in the router:

```
Router# config
Router(config)# username testuser1
Router(config)# commit
```

2. [Client] Generate RSA key pairs on the SSH clients.
3. [Router] Copy the public keys from the clients to the router.

Note You can skip step 3 while using the tftp filepath in step 4. For more details, **crypto key import authentication rsa** command.

4. [Router] Import public keys to the router:

```
Router# configure
Router(config)# crypto key import authentication rsa username testuser1
disk0:/id_rsa_key1.pub
```

```
Router(config)# crypto key import authentication rsa username testuser1 second
disk0:/id_rsa_key2.pub
Router(config)# crypto key import authentication rsa username testuser1 third
disk0:/id_rsa_key3.pub
Router(config)# crypto key import authentication rsa username testuser1 fourth
disk0:/id_rsa_key4.pub
Router(config)# commit
```

You can now access the router from any of the four SSH clients using the same user.

5. [Client] Access the router in the client:

```
[root@userclient test]# ssh testuser1@192.0.2.2
```

Using SSH configurations:

1. [Router] Create a user in the router:

```
Router# config
Router(config)# ssh server username testuser2
Router((config-user-key))# commit
```

2. [Client] Generate RSA key pair on the SSH clients.

3. [Router] Add public keys from the SSH clients for a user to the router:

```
Router# configure
Router(config)# ssh server username testuser2
Router(config-user-key)# keystring ssh-rsa
[redacted]
Router(config-user-key)# keystring ssh-rsa second
[redacted]
Router(config-user-key)# keystring ssh-rsa third
[redacted]
Router(config-user-key)# keystring ssh-rsa fourth
[redacted]
Router(config)# commit
```

You can now access the router from any of the four SSH clients using the same user.

4. [Client] Access the router in the client:

```
[root@userclient test]# ssh testuser2@192.0.2.2
```

Verification

Public-key import:

```
Router# show crypto key authentication rsa testuser1 all

  password      Command-Line-Interface
```

Delete Public Keys in the Routers

This section details different methods to delete public keys in the router:

```
Router# configure
Router(config)# crypto key zeroize authentication rsa all
Thu Sep 21 21:45:23.260 IST
Do you really want to remove all these keys ?? [yes/no]: yes
Router# commit
/* Deleting public keys for the user logged in to the router */

Router# configure
```

```
Router(config)# crypto key zeroize authentication rsa username testuser all
Thu Sep 21 21:45:23.260 IST
Do you really want to remove all these keys ?? [yes/no]: yes
Router# commit
/* Deleting public keys for any user in the router */

Router# configure
Router(config)#  no ssh server username testuser
Router# commit
/* Deleting all SSH configurations for a user in the router */

Router# configure
Router(config)# no ssh server username testuser keystring third
Router# commit
/* Deleting a specific public-key for a user using SSH configurations in the router */
```

Multi-Factor Authentication for SSH

Table 13: Feature History Table

Feature Name	Release Information	Feature Description
Multi-Factor Authentication for SSH	Release 24.1.1	You can now deploy robust authentication mechanisms for SSH connections to your routers and reduce security risks due to compromised or weak passwords. We now support multi-factor authentication (MFA)—a secure access management solution that verifies the identity of a user using multiple verification factors—for SSH login on Cisco IOS XR routers. These verification factors include a combination of login credentials such as username and password and a token, a cryptographic device, or a mobile phone with MFA application installed. No new commands or data models were introduced or modified as part of this feature.

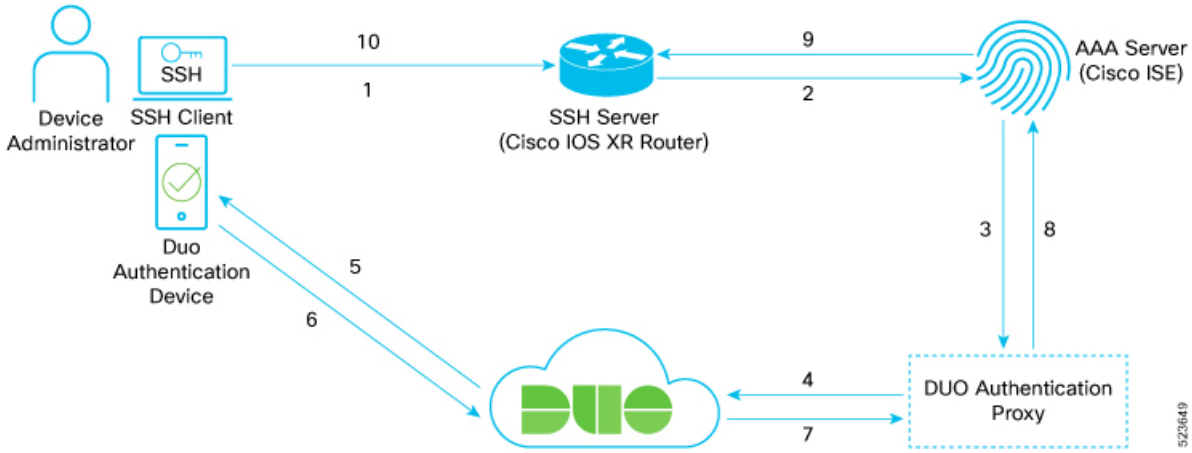
Multi-factor authentication is a multi-step authentication process that requires users to enter two or more verification factors to gain access to a system. These verification factors include something you know—such as a username and a password, and something you have—such as a token, a cryptographic authentication device, or a mobile phone with MFA application installed. MFA thereby enables stronger authentication mechanism and reduces security risk to the network devices arising due to compromised or weak passwords.

To achieve MFA for SSH, the SSH server as well as the client must support keyboard-interactive authentication method. The default order of SSH client authentication methods to support MFA in Cisco IOS XR routers is public-key, keyboard-interactive, and password-based authentication. You can change this default order as per your requirement using the **ssh client auth-method** command.

Multi-Factor Authentication Workflow

This is a sample topology to demonstrate the MFA workflow to establish SSH connection on a Cisco IOS XR router. In this example we have considered Cisco IOS XR router as the SSH server, Cisco ISE as the AAA server, and Cisco DUO authentication proxy and cloud services for MFA.

Figure 3: Multi-Factor Authentication Set-up for SSH Connection: Sample Topology



Key Components

The key components in this sample Duo MFA topology for SSH include:

- SSH client—from where the admin user initiates SSH connection to the SSH server.
- SSH server—which is the network device or router to which SSH connection is to be established.
- Cisco identity services engine (ISE)—that acts as the RADIUS or TACACS+ Server for AAA.
- DUO authentication proxy—is an on-premises software service that receives authentication requests from your local devices and applications through RADIUS or LDAP, optionally performs primary authentication against your existing LDAP directory or RADIUS authentication server, and then contacts Duo to perform secondary authentication.
- DUO cloud service—Cisco cloud-based security platform that provides secure access to any device or application.
- DUO authentication device—such as a mobile phone which has the Duo application installed.

The detailed workflow of Duo MFA for SSH is as follows:

1. The admin user initiates an SSH connection to the SSH server (Cisco IOS XR router, in this case) using the login credentials of the users that are already configured on ISE.
2. The router forwards the request to the TACACS+ AAA server (Cisco ISE, in this case).
3. The Cisco ISE sends the authentication request to Duo authentication proxy. The proxy forwards the request back to ISE for the 1st factor authentication. ISE informs the authentication proxy if the local authentication was successful.
4. Upon successful ISE authentication, the authentication proxy sends an authentication request to Duo cloud for 2nd factor authentication.
5. Duo cloud sends a *PUSH* notification to the DUO authentication device of the admin user.
6. The admin user approves the *PUSH* notification.
7. The Duo cloud informs the authentication proxy of the successful *PUSH* notification.

8. The authentication proxy informs ISE of a successful authentication.
9. The ISE authorizes the admin user.
10. The admin user successfully establishes an SSH connection with the router.

Set Up Multi-Factor Authentication for SSH

This section describes how to set up a sample topology for establishing SSH connection with Cisco IOS XR router using Duo MFA.

Prerequisites

- The Cisco IOS XR router installed with Cisco IOS XR Software Release 24.1.1 or later, that acts as the server to the SSH client, and as the client to the ISE server. The router must be already configured for AAA with ISE.
- Cisco identity services engine (ISE) server that acts as the RADIUS or TACACS+ AAA server.
- Duo MFA proxy application must be installed on either Windows or on Linux machine. For details, see https://duo.com/docs/authproxy-reference.
- DUO application must be installed on the DUO authentication device.

The procedure to set up MFA for SSH involves these high-level tasks:

- Configure Duo System
- Configure Duo Authentication Proxy
- Configure ISE
- Configure RADIUS Server Attributes on the Router
- Verify Duo MFA Set-up

Configure Duo System for MFA

Configuring Duo system for MFA involves these key steps:

1. Create a Duo account in https://duo.com/
2. Perform these Duo system configurations (for details, see the *First Steps* listed in https://duo.com/docs/radius):
   - Login to your Duo account and click on **Applications**.
   - Search for **Cisco ISE server** and click on **Protect This Application**.
   - In a notepad copy and paste your **Integration Key**, **Secret Key**, and **API Hostname**.
3. Add Duo mobile device:

   Select **Dashboard** > **Users** > ***username*** > **Add Phone**
4. Activate Duo mobile:

   Select **Dashboard** > **2FA Devices** > ***phone-number*** > **Activate Duo Mobile**

Configure Duo Authentication Proxy for MFA

Configuring Duo authentication proxy for MFA involves these key steps (For more details, see https://duo.com/docs/authproxy-reference)

1. Download and install the latest Duo authentication proxy on your Windows or Linux machine.

   In this example, we have installed the primary authentication proxy on a Windows 2016 machine and the secondary proxy on an Ubuntu server.

2. Configure the proxy for your primary authenticator.

   Edit the Duo authentication proxy configuration file, authproxy.cfg, located in the conf subdirectory of the proxy installation path in the server using a text editor. You can add multiple ISE servers as RADIUS clients and multiple router subnets/IP addresses as part of the router.

3. Start the proxy server(s) and check the proxy logs for any configuration or connectivity error.

Note For installation on Windows, ensure sure that the Windows firewall is configured to allow connections for the authentication proxy.

Configure ISE for MFA

Configuring ISE for MFA involves these key steps (for more details, see Configure Duo Two Factor Authentication for ISE Management Access)

1. Integrate ISE with Duo authentication proxy:
   a. Add a new RADIUS token server:

      Administration > **Identity Management** > **External Identity Sources** > **RADIUS Token**, and click **Add**

      Ensure that the **Shared Secret** matches the one that you already defined in the *Configure Duo Authentication Proxy* task.

      For details, see step1 listed under ISE Configuration.

   b. Set the authentication method for the identity source:

      Navigate to **Administration** > **System** > **Admin Access** > **Admin Access** > **Authentication Method**, and select previously configured RADIUS token server (for example, **RADIUS:DUO**) as the **Identity Source**.

      For details, see Step 2 listed under ISE Configuration.

2. Create device admin policies:
   a. Create a policy set:

      Navigate to **Work Centers** > **Device Administration** > **Device Admin Policy Sets**.

      In this example, we created a policy set that matches on both protocols (RADIUS and TACACS+) with the **Allowed Protocols** set to **Default Device Admin**.

   b. Set the following policies inside the policy set:

- **Authentication Policy**: In this example, we have set a default rule to check the Identity Source Sequence that we defined in the steps above which contains the RADIUS Token Servers (Duo Authentication Proxies) and Active Directory.
- **Authorization Policy**: In this example, we have set a rule that checks if the authenticated user belongs either to the **Domain Users** or **NS-ISE-IOS-Admins** groups that we have configured in active directory (AD). If the user belongs to one of these groups, then the system returns the pre-configured **Command Sets** and **Shell Profile**.

3. Add and onboard users in Duo:

   You can configure Duo to automatically sync with your AD or manually add the user in Duo (for details, see Enroll user with Duo).

Configure RADIUS Server Attributes for MFA

This topic describes how to configure RADIUS server attributes for MFA on the Cisco IOS XR router (for more details, see configure-your-radius-client(s)).

Set the IP address of the RADIUS server to the IP address of your authentication proxy, the RADIUS server port to 1812, and the RADIUS secret to the appropriate secret that you configured in the *radius_server_auto* section in the authproxy.cfg file.

```
Router#configure
Router(config)#radius-server host 209.165.200.225auth-port 1812 acct-port 1813
Router(config-radius-host)#key test@1234
Router(config-radius-host)#commit
```

Verify MFA Set-up for SSH Connection

Once you complete the Duo MFA configurations, follow these steps to verify the set-up:

- Initiate an SSH connection from the SSH client router that is already added in the ISE, using the **ssh** command.
- Use the AD credentials for the admin user to log in.
- Upon successful authentication, confirm that the user received a **Duo Push/Passcode** notification on the Duo authentication device based on what is set in the Duo authentication proxy configuration file, authproxy.cfg.
- After approving the **Duo Push** or entering the correct Passcode, the admin user must be authenticated and authorized to access the router through the SSH connection.
- The live logs of RADIUS in the ISE server must show authentication requests against the Duo authentication proxies.
- Check the authproxy log file in your authentication proxy for any errors or issues.

Selective Authentication Methods for SSH Server

Table 14: Feature History Table

Feature Name	Release Information	Feature Description
Selective Authentication Methods for SSH Server	Release 7.8.1	You now have the flexibility to choose the preferred SSH server authentication methods on the router. These methods include password authentication, keyboard-interactive authentication, and public-key authentication. This feature allows you to selectively disable these authentication methods. By allowing the SSH clients to connect to the server only through these permitted authentication methods, this functionality brings in additional security for router access through SSH. Before this release, by default, the SSH server allowed all these authentication methods for establishing SSH connections. The feature introduces these changes: • **CLI**: New **disable auth-methods** command • **YANG Data Model**: New XPaths for `Cisco-IOS-XR-crypto-ssh-cfg.yang` Cisco native model (see GitHub)

By default, the SSH server on the Cisco IOS XR routers allowed various authentication methods such as password authentication, keyboard-interactive authentication, and public-key authentication (including certificate-based authentication) for the SSH connections on the router. The SSH clients could use any of these authentication methods while attempting a connection to the SSH server on the router. From Cisco IOS XR Software Release 7.8.1, you can selectively disable these authentication methods, and allow connection attempts from the SSH client only through the remaining authentication methods. If the SSH client tries to establish a connection to the server using nonpermitted authentication methods (the ones that are disabled), then the login attempt fails.

Disable SSH Server Authentication Methods

Use the **disable auth-methods** command in ssh server configuration mode to disable the specific authentication method for the SSH server.

Public-key authentication includes certificate-based authentication as well. Hence, disabling public-key authentication automatically disables the certificate-based authentication.

Configuration Example

This example shows how to disable the keyboard-interactive authentication method for the SSH server on the router using CLI. Similarly, you can disable other authentication methods.

```
Router#configure
Router(config)# ssh server
Router(config-ssh)# disable auth-methods keyboard-interactive
Router(config-ssh)# commit
```

Running Configuration

```
!
ssh server
 disable auth-methods keyboard-interactive
!
```

Verification

Use the **show ssh server** command to see the list of authentication methods that the SSH server on the router supports. In this example, the keyboard-interactive method is disabled and the SSH server allows all other authentication methods.

```
Router#show ssh server

Wed Feb 23 10:38:37.716 UTC
Authentication Method Supported
-----------------------------------
                 PublicKey := Yes
                  Password := Yes
      Keyboard-Interactive := No
         Certificate Based := Yes
```

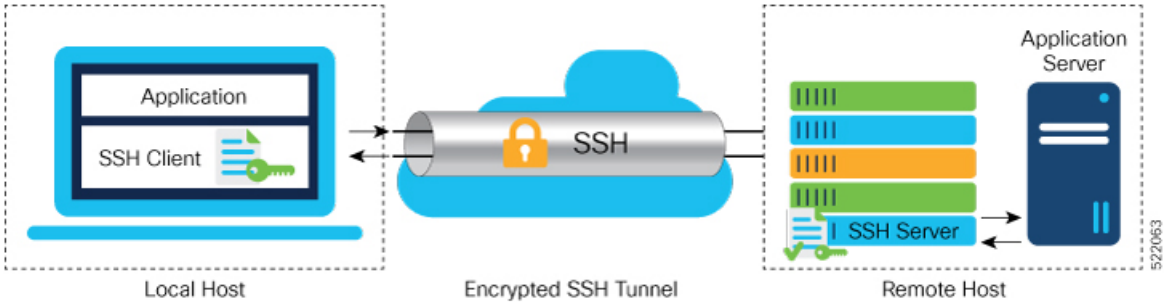
SSH Port Forwarding

Table 15: Feature History Table

Feature Name	Release Information	Feature Description
SSH Port Forwarding with CiscoSSH	Release 7.3.2	This release introduces SSH port forwarding with CiscoSSH, an OpenSSH-based implementation of SSH. CiscoSSH replaces Cisco IOS XR SSH, which is the older SSH implementation that existed prior to this release.
SSH Port Forwarding with Cisco IOS XR SSH	Release 7.3.15	With this feature enabled, the SSH client on a local host forwards the traffic coming on a given port to the specified host and port on a remote server, through an encrypted SSH channel. Legacy applications that do not otherwise support data encryption can leverage this functionality to ensure network security and confidentiality to the traffic that is sent to remote application servers. This feature introduces the ssh server port-forwarding local command.

SSH port forwarding or SSH tunneling is a method of forwarding the otherwise insecure TCP/IP connections from the SSH client to server, or the other way around, through a secure SSH channel. Since the traffic is directed to flow through an encrypted SSH connection, it is tough to snoop or intercept this traffic while in transit. This SSH tunneling provides network security and confidentiality to the data traffic, and hence legacy applications that do not otherwise support encryption can mainly benefit out of this feature. You can also use this feature to implement VPN and to access intranet services across firewalls.

Figure 4: SSH Port Forwarding

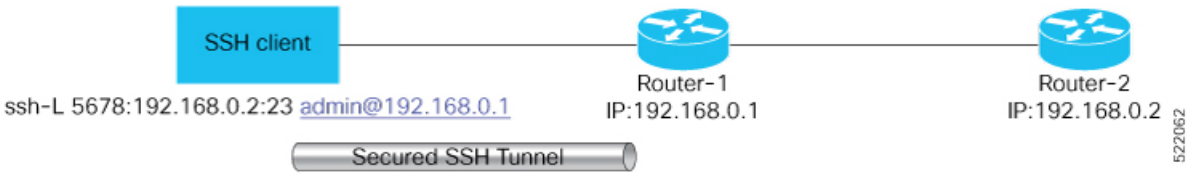


Consider an application on the SSH client residing on a local host, trying to connect to an application server residing on a remote host. The remote host can either be a single router where both the SSH server and application server reside, or, it can host the SSH server on one router and application server on a different device, like in case of a data center. With port forwarding or tunneling enabled, the application on the SSH client connects to a port on the local host that the SSH client listens to. The SSH client then forwards the data traffic of the application to the SSH server over an encrypted tunnel. The SSH server then connects to the actual application server that is either residing on the same router or on the same data center as the SSH server. The entire communication of the application is thus secured, without having to modify the application or the work flow of the end user.

The SSH port forwarding feature is disabled, by default. You can enable the feature by using the **ssh server port-forwarding local** command in the XR Config mode.

How Does SSH Port Forwarding Work?

Figure 5: Sample Topology for SSH Port Forwarding



Consider a scenario where port forwarding is enabled on the SSH server running on Router-1, in this topology. An SSH client running on a local host tries to create a secure tunnel to the SSH server, for a local application to eventually reach the remote application server running on Router-2.

The client tries to establish an SSH connection to Router-1 using the following command:

```
ssh -L local-port:remote-server-hostname:remote-port username@sshserver-hostname
```

where,

local-port is the local port number of the host where the SSH client and the application reside. Port 5678, in this example.

remote-server-hostname:remote-port is the TCP/IP host name and port number of the remote application server where the recipient (SSH server) must connect the channel from the SSH client to. 192.168.0.2 and port 23, in this example.

sshserver-hostname is the domain name or IP address of the SSH server that receives the SSH client request. It must the SSH IP address or domain name to access the router that hosts the SSH server. That is, 192.168.0.1 of Router-1, in this example.

For example,

```
ssh -L 5678:192.168.0.2:23 admin@192.168.0.1
```

When the SSH server receives a TCP/IP packet from the SSH client, it accepts the packet and opens a socket to the remote server and port specified in that packet. Once the connection between SSH client and server is established, the SSH server connects that communication channel to the newly created socket. From then onwards, SSH server forwards all the incoming data from the client on that channel to that socket. This type of connection is known as port-forwarded local connection. When the client closes the connection, the SSH server closes the socket and the forwarded channel.

How to Enable SSH Port Forwarding

Guidelines for Enabling SSH Port Forwarding Feature

- The Cisco IOS XR software supports SSH port forwarding only on SSH server; not on SSH client. Hence, to utilize this feature, the SSH client running at the end host must already have the support for SSH port forwarding or tunneling.
- The application server must be reachable on the same VRF where the current SSH connection between the server and the client is established.
- Port numbers need not match for SSH port forwarding to work. You can map any port on the SSH server to any port on the client.
- If the SSH client tries to do port forwarding without the feature being enabled on the SSH server, the port forwarding fails, and displays an error message on the console. Similarly the port-forwarded channel closes in case there is any connectivity issue or if the server receives an SSH packet from the client in an improper format.

Configuration Example

```
Router#configure
Router(config)#ssh server port-forwarding local
Router(config)#commit
```

Running Configuration

```
Router#show running-configuration

ssh server port-forwarding local
!
```

Verification

Use the **show ssh** command to see the details of the SSH sessions. The **connection type** field shows as **port-forwarded-local** for the port-forwarded session.

```
Router#show ssh

Wed Oct 14 11:22:05.575 UTC
SSH version : Cisco-2.0

id chan pty  location   state        userid host          ver authentication connection
type
-----------------------------------------------------------------------------------------
Incoming sessions
15 1    XXX  0/RP0/CPU0 SESSION_OPEN  admin  192.168.122.1 v2  password
port-forwarded-local

Outgoing sessions

Router#
```

Use the **show ssh server** command to see the details of the SSH server. The **Port Forwarding** column shows as **local** for the port-forwarded session. Whereas, for a regular SSH session, the field displays as **disabled**.

```
Router#show ssh server
Tue Sep  7 17:43:22.483 IST
---------------------
SSH Server Parameters
---------------------

Current supported versions := v2
                  SSH port := 22
                  SSH vrfs := vrfname:=default(v4-acl:=, v6-acl:=)
              Netconf Port := 830
              Netconf Vrfs := vrfname:=default(v4-acl:=, v6-acl:=)

 Algorithms
---------------
        Hostkey Algorithms :=
x509v3-ssh-rsa,ecdsa-sha2-nistp521,ecdsa-sha2-nistp384,ecdsa-sha2-nistp256,rsa-sha2-512,rsa-sha2-256,ssh-rsa,ssh-dsa,ssh-ed25519

   Key-Exchange Algorithms :=
ecdh-sha2-nistp521,ecdh-sha2-nistp384,ecdh-sha2-nistp256,diffie-hellman-group14-sha1
     Encryption Algorithms :=
aes128-ctr,aes192-ctr,aes256-ctr,aes128-gcm@openssh.com,aes256-gcm@openssh.com
            Mac Algorithms := hmac-sha2-512,hmac-sha2-256,hmac-sha1

 Authentication Method Supported
------------------------------------
                 PublicKey := Yes
                  Password := Yes
      Keyboard-Interactive := Yes
         Certificate Based := Yes

 Others
------------
                     DSCP  := 0
                Ratelimit  := 600
             Sessionlimit  := 110
                Rekeytime  := 30
       Server rekeyvolume  := 1024
  TCP window scale factor  := 1
```

```
           Backup Server  := Disabled
          Host Trustpoint  :=
          User Trustpoint  := tes,test,x509user
          Port Forwarding  := local
Max Authentication Limit  := 16
     Certificate username  := Common name(CN) User principle name(UPN)
Router#
```

Syslogs for SSH Port Forwarding Feature

The router console displays the following syslogs at various SSH session establishment events.

- When SSH port forwarding session is successfully established:

```
RP/0/RP0/CPU0:Aug 24 13:10:15.933 IST: SSHD_[66632]:
%SECURITY-SSHD-6-PORT_FWD_INFO_GENERAL : Port Forwarding, Target:=10.105.236.155,
Port:=22, Originator:=127.0.0.1,Port:=41590, Vrf:=0x60000000, Connection forwarded
```

- If SSH client tries to establish a port forwarding session without SSH port forwarding feature being enabled on the SSH server:

```
RP/0/RP0/CPU0:Aug 24 13:20:31.572 IST: SSHD_[65883]: %SECURITY-SSHD-3-PORT_FWD_ERR_GENERAL
 : Port Forwarding, Port forwarding is not enabled
```

Associated Command

- **ssh server port-forwarding local**

DSCP Marking for SSH Packets

Table 16: Feature History Table

Feature Name	Release Information	Feature Description
DSCP Marking from TCP Connection Phase for SSH Packets	Release 24.1.1	We now prevent SSH client packet drops in the TCP connection (initial handshake) phase as they travel across transit routers in the network. This is because you can mark the DSCP values for SSH client packets in the TCP connection phase, which overrides the transit routers' policies to filter and drop packets with no DSCP value marked. Using a new command, you can also set the DSCP value from the TCP connection phase for SSH server packets. The feature introduces these changes: **CLI:** • **ssh server set-dscp-connection-phase** **YANG Data Model:** • New XPath, `set-dscp-connection-phase`, for `Cisco-IOS-XR-crypto-ssh-cfg.yang` (see GitHub, YANG Data Models Navigator)

CiscoSSH is based on OpenSSH version 8.0 in which the DSCP marking of the SSH packets is done only after the authentication phase of session establishment. Hence, the SSH packets originating from the CiscoSSH routers did not have the DSCP value set in the initial handshake or the TCP connection phase. This led to SSH packet drops during the TCP connection phase if routers in the transit network have specific rules or filters to drop packets with zero or incorrect DSCP value.

From OpenSSH version 8.5 and later, the DSCP marking of SSH client packets is done from the TCP connection phase itself. Cisco IOS XR Software Release 24.1.1 brings in this behavior change for CiscoSSH. Whereas there is no change in behavior of the marking for SSH server packets. The CiscoSSH routers that function as SSH servers continue to mark the DSCP value for the packets only after the authentication phase. You can use the **ssh server set-dscp-connection-phase** command to set the DSCP value for the SSH server packets from the TCP connection phase.

Set DSCP Marking for SSH Packets from TCP Connection Phase

To set the DSCP marking for SSH server packets from TCP connection phase, use the **ssh server set-dscp-connection-phase** command in XR Config mode.

Note Although the **ssh server set-dscp-connection-phase** command is available on routers with CiscoSSH and routers with Cisco IOS XR SSH, this configuration is relevant only on routers with CiscoSSH.

Configuration Example

```
Router#configure
Router(config)#ssh server set-dscp-connection-phase
Router(config-ssh)#commit
```

Running Configuration

```
Router#show run ssh
!
ssh server set-dscp-connection-phase
!
```
