Implementing Network Stack IPv4 and IPv6

The Network Stack IPv4 and IPv6 features are used to configure and monitor Internet Protocol Version 4 (IPv4) and Internet Protocol Version 6 (IPv6).

Restrictions

In any Cisco IOS XR software release with IPv6 support, multiple IPv6 global addresses can be configured on an interface. However, multiple IPv6 link-local addresses on an interface are not supported.

Network Stack IPv4 and IPv6 Exceptions

The Network Stack feature in the Cisco IOS XR software has the following exceptions:

- In Cisco IOS XR software, the `clear ipv6 neighbors` and `show ipv6 neighbors` commands include the `location node-id` keyword. If a location is specified, only the neighbor entries in the specified location are displayed.

- The `ipv6 nd scaveng-timeout` command sets the lifetime for neighbor entries in the stale state. When the scavenge-timer for a neighbor entry expires, the entry is cleared.

- In Cisco IOS XR software, the `show ipv4 interface` and `show ipv6 interface` commands include the `location node-id` keyword. If a location is specified, only the interface entries in the specified location are displayed.

- Cisco IOS XR software allows conflicting IP address entries at the time of configuration. If an IP address conflict exists between two interfaces that are active, Cisco IOS XR software brings down the interface according to the configured conflict policy, the default policy being to bring down the higher interface instance. For example, if TenGigE 0/0/0/1 conflicts with TenGigE 0/0/0/2, then the IPv4 protocol on TenGigE 0/0/0/2, is brought down and IPv4 remains active on TenGigE 0/0/0/1.
IPv4 and IPv6 Functionality

When Cisco IOS XR software is configured with both an IPv4 and an IPv6 address, the interface can send and receive data on both IPv4 and IPv6 networks.

The architecture of IPv6 has been designed to allow existing IPv4 users to make the transition easily to IPv6 while providing services such as end-to-end security, quality of service (QoS), and globally unique addresses. The larger IPv6 address space allows networks to scale and provide global reachability. The simplified IPv6 packet header format handles packets more efficiently. IPv6 prefix aggregation, simplified network renumbering, and IPv6 site multihoming capabilities provide an IPv6 addressing hierarchy that allows for more efficient routing. IPv6 supports widely deployed routing protocols such as Open Shortest Path First (OSPF), and multiprotocol Border Gateway Protocol (BGP).

The IPv6 neighbor discovery (nd) process uses Internet Control Message Protocol (ICMP) messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), verify the reachability of a neighbor, and keep track of neighboring routers.

IPv6 for Cisco IOS XR Software

IPv6, formerly named IPng (next generation) is the latest version of the Internet Protocol (IP). IP is a packet-based protocol used to exchange data, voice, and video traffic over digital networks. IPv6 was proposed when it became clear that the 32-bit addressing scheme of IP version 4 (IPv4) was inadequate to meet the demands of Internet growth. After extensive discussion, it was decided to base IPng on IP but add a much larger address space and improvements such as a simplified main header and extension headers. IPv6 is described initially in RFC 2460, Internet Protocol, Version 6 (IPv6) Specification issued by the Internet Engineering Task Force (IETF). Further RFCs describe the architecture and services supported by IPv6.

How to Implement Network Stack IPv4 and IPv6

This section contains the following procedures:

Configuring IPv4 Addressing

A basic and required task for configuring IP is to assign IPv4 addresses to network interfaces. Doing so enables the interfaces and allows communication with hosts on those interfaces using IPv4. An IP address identifies a location to which IP datagrams can be sent. An interface can have one primary IP address and multiple secondary addresses. Packets generated by the software always use the primary IPv4 address. Therefore, all networking devices on a segment should share the same primary network number.

Associated with this task are decisions about subnetting and masking the IP addresses. A mask identifies the bits that denote the network number in an IP address. When you use the mask to subnet a network, the mask is then referred to as a subnet mask.

Note

Cisco supports only network masks that use contiguous bits that are flush left against the network field.
## Configuration Example

An IPv4 address of 192.168.1.27 and a network mask of "/8" is assigned to the TenGigE interface-0/0/0.

---

**Note**

The network mask can be a four-part dotted decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means the corresponding address bit belongs to the network address. The network mask can be indicated as a slash (/) and a number- a prefix length. The prefix length is a decimal value that indicates how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address). A slash must precede the decimal value, and there is no space between the IP address and the slash.

---

**Running Configuration**

Router# configure
Router(config)# interface TenGigE 0/0/0/0
Router(config-if)# ipv4 address 192.168.1.27/8
Router(config-if)# commit

**Verification**

Verify that the TenGigE interface is active and IPv4 is enabled.

Router# show ipv4 interface tenGigE 0/0/0/0
TenGigE0/0/0/0 is Up, ipv4 protocol is Up
Vrf is default (vrfid 0x60000000)
Internet address is 192.168.1.27/8
MTU is 1514 (1500 is available to IP)
Helper address is not set
Multicast reserved groups joined: 224.0.0.2 224.0.0.1
Directed broadcast forwarding is disabled
Outgoing access list is not set
Inbound access list is not set
Proxy ARP is disabled
ICMP redirects are never sent
ICMP unreachables are always sent
ICMP mask replies are never sent
Table Id is 0xe0000000

**Associated Commands**

- ipv4 address
- show ipv4 interface

---

### Configuring IPv6 Addressing

IPv6 addresses are configured to individual router interfaces in order to enable the forwarding of IPv6 traffic globally on the router. By default, IPv6 addresses are not configured.
IPv6 Multicast Groups

An IPv6 address must be configured on an interface for the interface to forward IPv6 traffic. Configuring a global IPv6 address on an interface automatically configures a link-local address and activates IPv6 for that interface.

Additionally, the configured interface automatically joins the following required multicast groups for that link:

- Solicited-node multicast group FF02:0:0:0:0:1:FF00::/104 for each unicast address assigned to the interface
- All-nodes link-local multicast group FF02::1
- All-routers link-local multicast group FF02::2

The solicited-node multicast address is used in the neighbor discovery process.

Configuration Example

An IPv6 address of 2001:0DB8:0:1::1/64 is assigned to the TenGigE interface 0/0/0/0:

Router# configure
Router(config)# interface TenGigE 0/0/0/0
Router(config-if)# ipv6 address 2001:0DB8:0:1::1/64
Router(config-if)# commit

Running Configuration

Router# show running-config interface tenGigE 0/0/0/0
interface TenGigE0/0/0/0
  ipv4 address 192.168.1.27 255.0.0.0
  ipv4 address 1.0.0.1 255.255.255.0 secondary
  ipv4 address 2.0.0.1 255.255.255.0 secondary
ipv6 address 2001:0DB8:0:1::1/64

Verification

Verify that the 10-Gigabit Ethernet interface is active and IPv6 is enabled.

Router# show ipv6 interface tenGigE 0/0/0/0
TenGigE0/0/0/0 is Up, ipv6 protocol is Up, Vrfid is default (0x60000000)
IPv6 is enabled, link-local address is fe80::c672:95ff:fea6:1c75
Global unicast address(es):
  2001:db8:0:1::1, subnet is 2001:db8:0:1::/64
Joined group address(es): ff02::1:ff00:1 ff02::1:ffa6:1c75 ff02::2 ff02::1
MTU is 1514 (1500 is available to IPv6)
ICMP redirects are disabled
ICMP unreachables are enabled
ND DAD is enabled, number of DAD attempts 1
ND reachable time is 0 milliseconds
ND cache entry limit is 1000000000
ND advertised retransmit interval is 0 milliseconds
Hosts use stateless autoconfig for addresses.
Outgoing access list is not set
Inbound access list is not set
Table Id is 0xe0800000
Complete protocol adjacency: 0
Complete glean adjacency: 0
Incomplete protocol adjacency: 0
Incomplete glean adjacency: 0
Dropped protocol request: 0
Dropped glean request: 0

Associated Commands

- ipv6 address
- show ipv6 interface

Configuration Example

An IPv6 address of 2001:0DB8:0:1::/64 is assigned to the TenGigE interface 0/0/0/0. The eui-64 keyword configures site-local and global IPv6 addresses with an interface identifier (ID) in the low-order 64 bits of the IPv6 address. Only the 64-bit network prefix for the address needs to be specified; the last 64 bits are automatically computed from the interface ID.

```
Router# configure
Router(config)# interface tenGigE 0/0/0/0
Router(config-if)# ipv6 address 2001:0DB8:0:1::/64 eui-64
Router(config-if)# commit
```

Running Configuration

```
Router# show running-config interface tenGigE 0/0/0/0
interface TenGigE0/0/0/0
  ipv4 address 192.168.1.27 255.0.0.0
  ipv4 address 1.0.0.1 255.255.255.0 secondary
  ipv4 address 2.0.0.1 255.255.255.0 secondary
  ipv6 address 2001:db8:0:1::/64 eui-64
!
```

Verification

Verify that the TenGigE interface is active and IPv6 is enabled.

```
Router# show ipv6 interface tenGigE 0/0/0/0
TenGigE0/0/0/0 is Up, ipv6 protocol is Up, VrfId is default (0x60000000)
  IPv6 is enabled, link-local address is fe80::c672:95ff:fea6:1c75
  Global unicast address(es):
    2001:db8:0:1::c672:95ff:fea6:1c75, subnet is 2001:db8:0:1::/64
    Joined group address(es): ff02::1:ffa6:1c75 ff02::2 ff02::1
```
MTU is 1514 (1500 is available to IPv6)
ICMP redirects are disabled
ICMP unreachables are enabled
ND DAD is enabled, number of DAD attempts 1
ND reachable time is 0 milliseconds
ND cache entry limit is 100000000
ND advertised retransmit interval is 0 milliseconds
Hosts use stateless autoconfig for addresses.
Outgoing access list is not set
Inbound access list is not set
Table Id is 0xe0800000
Complete protocol adjacency: 0
Complete glean adjacency: 0
Incomplete protocol adjacency: 0
Incomplete glean adjacency: 0
Dropped protocol request: 0
Dropped glean request: 0

Associated Commands
- ipv6 address
- show ipv6 interface

Configuration Example
An IPv6 address of FE80::260:3EFF:FE11:6770 is assigned to the TenGigE interface 0/0/0/0. The link-local keyword configures a link-local address on the interface that is used instead of the link-local address that is automatically configured when IPv6 is enabled on the interface.

Router#configure
Router(config)#interface TenGigE 0/0/0/0
Router(config-if)#ipv6 address FE80::260:3EFF:FE11:6770 link-local
Router(config-if)#commit

Running Configuration
Router#show running-config interface tenGigE 0/0/0/0
interface TenGigE0/0/0/0
 ipv6 address fe80::260:3eff:fe11:6770 link-local
!

Verification
Verify that the TenGigE interface is active and IPv6 is enabled with link-local address.

Router#show ipv6 interface tenGigE 0/0/0/0
TenGigE0/0/0/0 is Up, ipv6 protocol is Up, VrfId is default (0x60000000)
IPv6 is enabled, link-local address is fe80::260:3eff:fe11:6770
Global unicast address(es):
  2001:db8:0:1:260:3eff:fe11:6770, subnet is 2001:db8:0:1::/64
Joined group address(es): ff02::1:ff11:6770 ff02::2 ff02::1
MTU is 1514 (1500 is available to IPv6)
ICMP redirects are disabled
ICMP unreachables are enabled
ND DAD is enabled, number of DAD attempts 1
ND reachable time is 0 milliseconds
ND cache entry limit is 100000000
ND advertised retransmit interval is 0 milliseconds
Hosts use stateless autoconfig for addresses.
Outgoing access list is not set
Inbound access list is not set
Table Id is 0xe0800000
Complete protocol adjacency: 0
Complete glean adjacency: 0
Incomplete protocol adjacency: 0
Incomplete glean adjacency: 0
Dropped protocol request: 0
Dropped glean request: 0

Associated Commands

- ipv6 address
- show ipv6 interface

Configuration Example

Enable IPv6 processing on the TenGigE interface 0/0/0/0; that has not been configured with an explicit IPv6 address.

Router#configure
Router(config)#interface tenGigE 0/0/0/0
Router(config-if)#ipv6 enable
Router(config-if)#commit

Running Configuration

Router#show running-config interface tenGigE 0/0/0/0
interface TenGigE0/0/0/0
ipv6 enable
!

Verification

Verify that the TenGigE interface is active and IPv6 is enabled.

Router#show ipv6 interface tenGigE 0/0/0/0
TenGigE0/0/0/0 is Up, ipv6 protocol is Up, Vrfid is default (0x60000000)
IPv6 is enabled, link-local address is fe80::c672:95ff:fea6:1c75
No global unicast address is configured
Joined group address(es): ff02::1:fffe:1c75 ff02::2 ff02::1
MTU is 1514 (1500 is available to IPv6)
ICMP redirects are disabled
ICMP unreachables are enabled
ND DAD is enabled, number of DAD attempts 1
ND reachable time is 0 milliseconds
ND cache entry limit is 1000000000
ND advertised retransmit interval is 0 milliseconds
Hosts use stateless autoconfig for addresses.
Outgoing access list is not set
Inbound access list is not set
Table Id is 0xe0800000
Complete protocol adjacency: 0
Complete glean adjacency: 0
Incomplete protocol adjacency: 0
Incomplete glean adjacency: 0
Dropped protocol request: 0
Dropped glean request: 0
Assigning Multiple IP Addresses to Network Interfaces

The Cisco IOS XR software supports multiple IP addresses (secondary addresses) per interface. You can specify an unlimited number of secondary addresses. Secondary IP addresses can be used in a variety of situations. The following are the most common applications:

- There might not be enough host addresses for a particular network segment. For example, suppose your subnetting allows up to 254 hosts per logical subnet, but on one physical subnet you must have 300 host addresses. Using secondary IP addresses on the routers or access servers allows you to have two logical subnets using one physical subnet.

- Many older networks were built using Level 2 bridges, and were not subnetted. The judicious use of secondary addresses can aid in the transition to a subnetted, router-based network. Routers on an older, bridged segment can easily be made aware that many subnets are on that segment.

- Two subnets of a single network might otherwise be separated by another network. You can create a single network from subnets that are physically separated by another network by using a secondary address. In these instances, the first network is extended, or layered on top of the second network. Note that a subnet cannot appear on more than one active interface of the router at a time.

**Note**

If any router on a network segment uses a secondary IPv4 address, all other routers on that same segment must also use a secondary address from the same network or subnet.

**Caution**

Inconsistent use of secondary addresses on a network segment can quickly cause routing loops.

**Configuration Example**

A secondary IPv4 address of 192.168.1.27 is assigned to the TenGigE interface-0/0/0/1.

Note: For IPv6, an interface can have multiple IPv6 addresses without specifying the secondary keyword.

```
Router#configure
Router(config)#interface TenGigE 0/0/0/1
Router(config-if)#ipv4 address 192.168.1.27 255.255.255.0 secondary
Router(config-if)#commit
```

**Running Configuration**

```
Router#show running-config interface TenGigE 0/0/0/1
interface TenGigE0/0/0/1
  ipv4 address 192.168.1.27 255.255.255.0 secondary
```

Associated Commands

- `ipv6 address`
- `show ipv6 interface`
Verification

Router# show ipv4 interface TenGigE 0/0/0/0
TenGigE0/0/0/0 is up, ipv4 protocol is up
Vrf is default (vrfid 0x60000000)
Internet address is unassigned
Secondary address 192.168.1.27/24
MTU is 1514 (1500 is available to IP)
Helper address is not set
Multicast reserved groups joined: 224.0.0.2 224.0.0.1
Directed broadcast forwarding is disabled
Outgoing access list is not set
Inbound access list is not set
Proxy ARP is disabled
ICMP redirects are never sent
ICMP unreachables are always sent
ICMP mask replies are never sent
Table Id is 0xe000000

Associated Commands

• ipv4 address
• show ipv4 interface

Configuring IPv4 and IPv6 Protocol Stacks

This task configures an interface in a Cisco networking device to support both the IPv4 and IPv6 protocol stacks.

When an interface in a Cisco networking device is configured with both an IPv4 and an IPv6 address, the interface forwards both IPv4 and IPv6 traffic—the interface can send and receive data on both IPv4 and IPv6 networks.

Configuration Example

An IPv4 address of 192.168.99.1 and an IPv6 address of 2001:0DB8:c18:1::3/64 is configured on the TenGigE interface 0/0/0/0.

Router# configure
Router(config)# interface TenGigE 0/0/0/0
Router(config-if)# ipv4 address 192.168.99.1 255.255.255.0
Router(config-if)# ipv6 address 2001:0DB8:c18:1::3/64
Router(config-if)# commit

Running Configuration

Router# show running-config interface tenGigE 0/0/0/0
interface TenGigE0/0/0/0
ipv4 address 192.168.99.1 255.255.255.0
ipv6 address 2001:0DB8:c18:1::3/64
!

Verification

Verify that the TenGigE interface is active and IPv4 and IPv6 are enabled.

Router# show ipv4 inter tenGigE 0/0/0/0
TenGigE0/0/0/0 is up, ipv4 protocol is up
Vrf is default (vrfid 0x60000000)

**Internet address is 192.168.99.1/24**

MTU is 1514 (1500 is available to IP)
Helper address is not set
Multicast reserved groups joined: 224.0.0.2 224.0.0.1
Directed broadcast forwarding is disabled
Outgoing access list is not set
Inbound access list is not set
Proxy ARP is disabled
ICMP redirects are never sent
ICMP unreachables are always sent
ICMP mask replies are never sent
Table Id is 0xe0000000

Router# show ipv6 inter tenGigE 0/0/0/0

TenGigE0/0/0/0 is Up, ipv6 protocol is Up,
Vrf id is default (0x60000000)
IPv6 is enabled, link-local address is fe80::c672:95ff:fea6:1c75
Global unicast address(es):
  2001:db8:c18:1::3, subnet is 2001:db8:c18:1::/64
Joined group address(es):
  ff02::1:ff00:3 ff02::1:ffa6:1c75 ff02::2 ff02::1
MTU is 1514 (1500 is available to IPv6)
ICMP redirects are disabled
ICMP unreachables are enabled
ND DAD is enabled, number of DAD attempts 1

**Enabling IPv4 Processing on an Unnumbered Interface**

This section describes the process of enabling an IPv4 point-to-point interface without assigning an explicit IP address to the interface. Whenever the unnumbered interface generates a packet (for example, for a routing update), it uses the address of the interface you specified as the source address of the IP packet. It also uses the specified interface address in determining which routing processes are sending updates over the unnumbered interface. Restrictions are as follows:

- Interfaces using High-Level Data Link Control (HDLC), PPP, and Frame Relay encapsulations can be unnumbered. Serial interfaces using Frame Relay encapsulation can also be unnumbered, but the interface must be a point-to-point sub-interface.
• You cannot use the `ping` EXEC command to determine whether the interface is up, because the interface has no IP address. The Simple Network Management Protocol (SNMP) can be used to remotely monitor interface status.

• You cannot support IP security options on an unnumbered interface.

If you are configuring Intermediate System-to-Intermediate System (IS-IS) across a serial line, you should configure the serial interfaces as unnumbered, which allows you to conform with RFC 1195, which states that IP addresses are not required on each interface.

**Configuration Example**

Enables an IPv4 point-to-point interface without assigning an explicit IP address to the interface.

```
Router# configure
Router(config)# interface TenGigE 0/0/0/1
Router(config-if)# ipv4 unnumbered loopback 0
Router(config-if)# commit
```

**Running Configuration**

```
Router# show running-config interface tenGigE 0/0/0/1
interface TenGigE0/0/0/1
   ipv4 point-to-point
   ipv4 unnumbered Loopback0
!
```

**Verification**

```
Router# show int tenGigE 0/0/0/1
TenGigE0/0/0/1 is up, line protocol is up
   Interface state transitions: 5
   Hardware is TenGigE, address is 00e2.2a33.445b (bia 00e2.2a33.445b)
   Layer 1 Transport Mode is LAN
   Internet address is 10.0.0.2/32
   MTU 1514 bytes, BW 1000000 Kbit (Max: 1000000 Kbit)
   reliability 255/255, txload 194/255, rxload 0/255
   Encapsulation ARPA,
   Full-duplex, 10000Mb/s, link type is force-up
   output flow control is off, input flow control is off
   Carrier delay (up) is 10 msec
   loopback not set,

Router # show run int lo 0
```
interface Loopback0
  ipv4 address 10.0.0.2 255.255.255.255

Associated Commands
  • ipv4 unnumbered
  • show ipv4 interface

Selecting Flexible Source IP

You can select flexible source IP address in the Internet Control Message Protocol (ICMP) response packet to respond to a failure.

Configuration Example
Enables RFC compliance for source address selection.

Router# configure
Router(config)# icmp ipv4 source rfc
Router(config)# commit

Running Configuration

Router# show running-config | in source rfc
Building configuration...
icmp ipv4 source rfc

Associated Commands
  • icmp ipv4 source vrf

Configuring IPARM Conflict Resolution

This task sets the IP Address Repository Manager (IPARM) address conflict resolution parameters:
  • Static Policy Resolution
  • Longest Prefix Address Conflict Resolution
  • Highest IP Address Conflict Resolution
  • Route-Tag Support for Connected Routes

Static Policy Resolution

The static policy resolution configuration prevents new address configurations from affecting interfaces that are currently running.

Configuration Example
Sets the conflict policy to static, that is, prevents new interface addresses from affecting the currently running interface.
Longest Prefix Address Conflict Resolution

This conflict resolution policy attempts to give highest precedence to the IP address that has the longest prefix length, that is, all addresses within the conflict-set that do not conflict with the longest prefix address of the currently running interface are allowed to run as well.

Configuration Example

Configures longest prefix address conflict resolution.

Router# configure
Router(config)# ipv4 conflict-policy longest-prefix
/*/For IPv6, use the ipv6 conflict-policy longest-prefix command*/
Router(config)# commit

Running Configuration

Router# show running-config | in longest-prefix
Building configuration...
ipv4 conflict-policy longest-prefix

Verification

Router# show arm ipv4 conflicts
F Forced down
| Down interface & addr | Up interface & addr | VRF
F Te0/0/0/19 192.85.1.2/24 | Te0/0/0/1 10.0.0.2/24 | default
Forced down interface
Up interface | VRF

Associated Commands

- ipv4 conflict-policy
- ipv6 conflict-policy

Longest Prefix Address Conflict Resolution

This conflict resolution policy attempts to give highest precedence to the IP address that has the longest prefix length, that is, all addresses within the conflict-set that do not conflict with the longest prefix address of the currently running interface are allowed to run as well.

Configuration Example

Configures longest prefix address conflict resolution.

Router# configure
Router(config)# ipv4 conflict-policy longest-prefix
/*/For IPv6, use the ipv6 conflict-policy longest-prefix command*/
Router(config)# commit

Running Configuration

Router# show running-config | in longest-prefix
Building configuration...
ipv4 conflict-policy longest-prefix

Verification

Router# show arm ipv4 conflicts
F Forced down
| Down interface & addr | Up interface & addr | VRF
F Te0/0/0/19 192.85.1.2/24 | HundredGigE0/0/0/1 | 192.85.1.1/24 | default
Forced down interface
Up interface | VRF
**Highest IP Address Conflict Resolution**

This conflict resolution policy attempts to give highest precedence to the IP address that has the highest value, that is, the IP address with the highest value gets precedence.

**Configuration**

Configures highest IP address conflict resolution.

Router# configure
Router(config)#ipv4 conflict-policy highest-ip
"For IPv6, use the ipv6 conflict-policy highest-ip command/*
Router(config)#commit

**Running Configuration**

Router#show running-config | in highest-ip
Building configuration...
ipv4 conflict-policy highest-ip

**Verification**

Router#show arm ipv4 conflicts
F Forced down
| Down interface & addr | Up interface & addr VRF

Forced down interface

**Route-Tag Support for Connected Routes**

The Route-Tag Support for Connected Routes feature attaches a tag with all IPv4 and IPv6 addresses of an interface. The tag is propagated from the IPv4 and IPv6 management agents (MA) to the IPv4 and IPv6 address repository managers (ARM) to routing protocols, thus enabling the user to control the redistribution of connected routes by looking at the route tags, by using routing policy language (RPL) scripts. This prevents the redistribution of some interfaces, by checking for route tags in a route policy. The route tag feature is already available for static routes and connected routes (interfaces) wherein the route tags are matched to policies and redistribution can be prevented.

**Configuration Example**

Specifies an IPv4 address 192.168.1.27 that has a route tag of 20 to the TenGigE interface 0/0/0/1.
Router# configure
Router(config)# interface TenGigE 0/0/0/1
Router(config-if)# ipv4 address 192.168.1.27 255.0.0.0
Router(config-if)# route-tag 20
Router(config)# commit

Running Configuration
Router# show running-config interface TenGigE 0/0/0/1
interface TenGigE0/0/0/1
 ipv4 address 192.168.1.27 255.0.0.0 route-tag 20
!

Verification
Verify the parameters of the route.
Router# show route 192.168.1.27
Routing entry for 192.168.1.27
  Known via "local", distance 0, metric 0 (connected)
  Tag 20
Routing Descriptor Blocks
  directly connected, via TenGige 0/0/0/1
  Route metric is 0
  No advertising protos.

Associated Commands
  • route-tag

Larger IPv6 Address Space

The primary motivation for IPv6 is the need to meet the anticipated future demand for globally unique IP addresses. Applications such as mobile Internet-enabled devices (such as personal digital assistants [PDAs], telephones, and cars), home-area networks (HANs), and wireless data services are driving the demand for globally unique IP addresses. IPv6 quadruples the number of network address bits from 32 bits (in IPv4) to 128 bits, which provides more than enough globally unique IP addresses for every networked device on the planet. By being globally unique, IPv6 addresses inherently enable global reachability and end-to-end security for networked devices, functionality that is crucial to the applications and services that are driving the demand for the addresses. Additionally, the flexibility of the IPv6 address space reduces the need for private addresses and the use of Network Address Translation (NAT); therefore, IPv6 enables new application protocols that do not require special processing by border routers at the edge of networks.

IPv6 Address Formats

IPv6 addresses are represented as a series of 16-bit hexadecimal fields separated by colons (:). Following are two examples of IPv6 addresses:

2001:0DB8:0:0:8:800:200C:417A

It is common for IPv6 addresses to contain successive hexadecimal fields of zeros. To make IPv6 addresses less cumbersome, two colons (::) can be used to compress successive hexadecimal fields of zeros at the
beginning, middle, or end of an IPv6 address. (The colons represent successive hexadecimal fields of zeros.)

Table 3: Compressed IPv6 Address Formats, on page 18 lists compressed IPv6 address formats.

A double colon may be used as part of the `ipv6-address` argument when consecutive 16-bit values are denoted as zero. You can configure multiple IPv6 addresses per interfaces, but only one link-local address.

Two colons (::) can be used only once in an IPv6 address to represent the longest successive hexadecimal fields of zeros.

The hexadecimal letters in IPv6 addresses are not case-sensitive.

Table 3: Compressed IPv6 Address Formats

<td>::</td>
</tr>
</tbody>
</table>

The loopback address listed in Table 3: Compressed IPv6 Address Formats, on page 18 may be used by a node to send an IPv6 packet to itself. The loopback address in IPv6 functions the same as the loopback address in IPv4 (127.0.0.1).

The IPv6 loopback address cannot be assigned to a physical interface. A packet that has the IPv6 loopback address as its source or destination address must remain within the node that created the packet. IPv6 routers do not forward packets that have the IPv6 loopback address as their source or destination address.

The unspecified address listed in Table 3: Compressed IPv6 Address Formats, on page 18 indicates the absence of an IPv6 address. For example, a newly initialized node on an IPv6 network may use the unspecified address as the source address in its packets until it receives its IPv6 address.

The IPv6 unspecified address cannot be assigned to an interface. The unspecified IPv6 addresses must not be used as destination addresses in IPv6 packets or the IPv6 routing header.

An IPv6 address prefix, in the format `ipv6-prefix/prefix-length`, can be used to represent bit-wise contiguous blocks of the entire address space. The `ipv6-prefix` argument must be in the form documented in RFC 2373, in which the address is specified in hexadecimal using 16-bit values between colons. The prefix length is a decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). For example, 2001:0DB8:8086:6502::/32 is a valid IPv6 prefix.
IPv6 Address Type: Unicast

An IPv6 unicast address is an identifier for a single interface, on a single node. A packet that is sent to a unicast address is delivered to the interface identified by that address. Cisco IOS XR software supports the following IPv6 unicast address types:

- Global aggregatable address
- Site-local address (proposal to remove by IETF)
- Link-local address
- IPv4-compatible IPv6 address

Aggregatable Global Address

An aggregatable global address is an IPv6 address from the aggregatable global unicast prefix. The structure of aggregatable global unicast addresses enables strict aggregation of routing prefixes that limits the number of routing table entries in the global routing table. Aggregatable global addresses are used on links that are aggregated upward through organizations, and eventually to the Internet service providers (ISPs).

Aggregatable global IPv6 addresses are defined by a global routing prefix, a subnet ID, and an interface ID. Except for addresses that start with binary 000, all global unicast addresses have a 64-bit interface ID. The current global unicast address allocation uses the range of addresses that start with binary value 001 (2000::/3). This figure below shows the structure of an aggregatable global address.

Figure 1: Aggregatable Global Address Format

Addresses with a prefix of 2000::/3 (001) through E000::/3 (111) are required to have 64-bit interface identifiers in the extended universal identifier (EUI)-64 format. The Internet Assigned Numbers Authority (IANA) allocates the IPv6 address space in the range of 2000::/16 to regional registries.

The aggregatable global address typically consists of a 48-bit global routing prefix and a 16-bit subnet ID or Site-Level Aggregator (SLA). In the IPv6 aggregatable global unicast address format document (RFC 2374), the global routing prefix included two other hierarchically structured fields named Top-Level Aggregator (TLA) and Next-Level Aggregator (NLA). The IETF decided to remove the TLS and NLA fields from the RFCs, because these fields are policy-based. Some existing IPv6 networks deployed before the change might still be using networks based on the older architecture.

A 16-bit subnet field called the subnet ID could be used by individual organizations to create their own local addressing hierarchy and to identify subnets. A subnet ID is similar to a subnet in IPv4, except that an organization with an IPv6 subnet ID can support up to 65,535 individual subnets.

An interface ID is used to identify interfaces on a link. The interface ID must be unique to the link. It may also be unique over a broader scope. In many cases, an interface ID is the same as or based on the link-layer address of an interface. Interface IDs used in aggregatable global unicast and other IPv6 address types must be 64 bits long and constructed in the modified EUI-64 format.

Interface IDs are constructed in the modified EUI-64 format in one of the following ways:
• For all IEEE 802 interface types (for example, Ethernet interfaces and FDDI interfaces), the first three octets (24 bits) are taken from the Organizationally Unique Identifier (OUI) of the 48-bit link-layer address (MAC address) of the interface, the fourth and fifth octets (16 bits) are a fixed hexadecimal value of FFFE, and the last three octets (24 bits) are taken from the last three octets of the MAC address. The construction of the interface ID is completed by setting the Universal/Local (U/L) bit—the seventh bit of the first octet—to a value of 0 or 1. A value of 0 indicates a locally administered identifier; a value of 1 indicates a globally unique IPv6 interface identifier.

• For tunnel interface types that are used with IPv6 overlay tunnels, the interface ID is the IPv4 address assigned to the tunnel interface with all zeros in the high-order 32 bits of the identifier.

If no IEEE 802 interface types are in the router, link-local IPv6 addresses are generated on the interfaces in the router in the following sequence:

1. The router is queried for MAC addresses (from the pool of MAC addresses in the router).
2. If no MAC address is available, the serial number of the Route Processor (RP) or line card (LC) is used to form the link-local address.

**Link-Local Address**

A link-local address is an IPv6 unicast address that can be automatically configured on any interface using the link-local prefix FE80::/10 (1111 1110 10) and the interface identifier in the modified EUI-64 format. Link-local addresses are used in the neighbor discovery protocol and the stateless autoconfiguration process. Nodes on a local link can use link-local addresses to communicate; the nodes do not need site-local or globally unique addresses to communicate. This figure below shows the structure of a link-local address.

IPv6 routers must not forward packets that have link-local source or destination addresses to other links.

**Figure 2: Link-Local Address Format**

**IPv4-Compatible IPv6 Address**

An IPv4-compatible IPv6 address is an IPv6 unicast address that has zeros in the high-order 96 bits of the address and an IPv4 address in the low-order 32 bits of the address. The format of an IPv4-compatible IPv6 address is 0:0:0:0:0::A.B.C.D or ::A.B.C.D. The entire 128-bit IPv4-compatible IPv6 address is used as the
IPv6 address of a node and the IPv4 address embedded in the low-order 32 bits is used as the IPv4 address of the node. IPv4-compatible IPv6 addresses are assigned to nodes that support both the IPv4 and IPv6 protocol stacks and are used in automatic tunnels. This figure below shows the structure of an IPv4-compatible IPv6 address and a few acceptable formats for the address.

**Figure 3: IPv4-Compatible IPv6 Address Format**

The basic IPv4 packet header has 12 fields with a total size of 20 octets (160 bits). The 12 fields may be followed by an Options field, which is followed by a data portion that is usually the transport-layer packet. The variable length of the Options field adds to the total size of the IPv4 packet header. The shaded fields of the IPv4 packet header are not included in the IPv6 packet header.

**Figure 4: IPv4 Packet Header Format**

The basic IPv6 packet header has 8 fields with a total size of 40 octets (320 bits). Fields were removed from the IPv6 header because, in IPv6, fragmentation is not handled by routers and checksums at the network layer are not used. Instead, fragmentation in IPv6 is handled by the source of a packet and checksums at the data link layer and transport layer are used. (In IPv4, the User Datagram Protocol (UDP) transport layer uses an optional checksum. In IPv6, use of the UDP checksum is required to check the integrity of the inner packet.) Additionally, the basic IPv6 packet header and Options field are aligned to 64 bits, which can facilitate the processing of IPv6 packets.
This table lists the fields in the basic IPv6 packet header.

**Table 4: Basic IPv6 Packet Header Fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>Similar to the Version field in the IPv4 packet header, except that the field lists number 6 for IPv6 instead of number 4 for IPv4.</td>
</tr>
<tr>
<td>Traffic Class</td>
<td>Similar to the Type of Service field in the IPv4 packet header. The Traffic Class field tags packets with a traffic class that is used in differentiated services.</td>
</tr>
<tr>
<td>Flow Label</td>
<td>A new field in the IPv6 packet header. The Flow Label field tags packets with a specific flow that differentiates the packets at the network layer.</td>
</tr>
<tr>
<td>Payload Length</td>
<td>Similar to the Total Length field in the IPv4 packet header. The Payload Length field indicates the total length of the data portion of the packet.</td>
</tr>
<tr>
<td>Next Header</td>
<td>Similar to the Protocol field in the IPv4 packet header. The value of the Next Header field determines the type of information following the basic IPv6 header. The type of information following the basic IPv6 header can be a transport-layer packet, for example, a TCP or UDP packet, or an Extension Header.</td>
</tr>
<tr>
<td>Hop Limit</td>
<td>Similar to the Time to Live field in the IPv4 packet header. The value of the Hop Limit field specifies the maximum number of routers that an IPv6 packet can pass through before the packet is considered invalid. Each router decrements the value by one. Because no checksum is in the IPv6 header, the router can decrement the value without needing to recalculate the checksum, which saves processing resources.</td>
</tr>
<tr>
<td>Source Address</td>
<td>Similar to the Source Address field in the IPv4 packet header, except that the field contains a 128-bit source address for IPv6 instead of a 32-bit source address for IPv4.</td>
</tr>
</tbody>
</table>
Following the eight fields of the basic IPv6 packet header are optional extension headers and the data portion of the packet. If present, each extension header is aligned to 64 bits. There is no fixed number of extension headers in an IPv6 packet. Together, the extension headers form a chain of headers. Each extension header is identified by the Next Header field of the previous header. Typically, the final extension header has a Next Header field of a transport-layer protocol, such as TCP or UDP. This figure below shows the IPv6 extension header format.

Figure 6: IPv6 Extension Header Format

This table lists the extension header types and their Next Header field values.

Table 5: IPv6 Extension Header Types

<table>
<thead>
<tr>
<th>Header Type</th>
<th>Next Header Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hop-by-hop options header</td>
<td>0</td>
<td>This header is processed by all hops in the path of a packet. When present, the hop-by-hop options header always follows immediately after the basic IPv6 packet header.</td>
</tr>
<tr>
<td>Destination options header</td>
<td>60</td>
<td>The destination options header can follow any hop-by-hop options header, in which case the destination options header is processed at the final destination and also at each visited address specified by a routing header. Alternatively, the destination options header can follow any Encapsulating Security Payload (ESP) header, in which case the destination options header is processed only at the final destination.</td>
</tr>
<tr>
<td>Routing header</td>
<td>43</td>
<td>The routing header is used for source routing.</td>
</tr>

<tr>
<td>---------------------------------</td>
<td>-------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Fragment header</td>
<td>44</td>
<td>The fragment header is used when a source must fragment a packet that is larger than the maximum transmission unit (MTU) for the path between itself and a destination. The Fragment header is used in each fragmented packet.</td>
</tr>
<tr>
<td>Authentication header and ESP header</td>
<td>51 50</td>
<td>The Authentication header and the ESP header are used within IP Security Protocol (IPSec) to provide authentication, integrity, and confidentiality of a packet. These headers are identical for both IPv4 and IPv6.</td>
</tr>
<tr>
<td>Upper-layer header</td>
<td>6 (TCP) 17 (UDP)</td>
<td>The upper-layer (transport) headers are the typical headers used inside a packet to transport the data. The two main transport protocols are TCP and UDP.</td>
</tr>
<tr>
<td>Mobility header</td>
<td>To be done by IANA</td>
<td>Extension headers used by mobile nodes, correspondent nodes, and home agents in all messaging related to the creation and management of bindings.</td>
</tr>
</tbody>
</table>

### Path MTU Discovery for IPv6

As in IPv4, path MTU discovery in IPv6 allows a host to dynamically discover and adjust to differences in the MTU size of every link along a given data path. In IPv6, however, fragmentation is handled by the source of a packet when the path MTU of one link along a given data path is not large enough to accommodate the size of the packets. Having IPv6 hosts handle packet fragmentation saves IPv6 router processing resources and helps IPv6 networks run more efficiently.

In IPv4, the minimum link MTU is 68 octets, which means that the MTU size of every link along a given data path must support an MTU size of at least 68 octets. In IPv6, the minimum link MTU is 1280 octets. We recommend using an MTU value of 1500 octets for IPv6 links.

**Note**

Path MTU discovery is supported only for applications using TCP.

### IPv6 Neighbor Discovery

The IPv6 neighbor discovery process uses ICMP messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), verify the reachability of a neighbor, and keep track of neighboring routers.

### IPv6 Neighbor Solicitation Message

A value of 135 in the Type field of the ICMP packet header identifies a neighbor solicitation message. Neighbor solicitation messages are sent on the local link when a node wants to determine the link-layer address of another node on the same local link. When a node wants to determine the link-layer address of another node, the source address in a neighbor solicitation message is the IPv6 address of the node sending the neighbor solicitation message. The destination address in the neighbor solicitation message is the solicited-node multicast address.
address that corresponds to the IPv6 address of the destination node. The neighbor solicitation message also includes the link-layer address of the source node.

*Figure 7: IPv6 Neighbor Discovery—Neighbor Solicitation Message*

After receiving the neighbor solicitation message, the destination node replies by sending a neighbor advertisement message, which has a value of 136 in the Type field of the ICMP packet header, on the local link. The source address in the neighbor advertisement message is the IPv6 address of the node (more specifically, the IPv6 address of the node interface) sending the neighbor advertisement message. The destination address in the neighbor advertisement message is the IPv6 address of the node that sent the neighbor solicitation message. The data portion of the neighbor advertisement message includes the link-layer address of the node sending the neighbor advertisement message.

After the source node receives the neighbor advertisement, the source node and destination node can communicate.

Neighbor solicitation messages are also used to verify the reachability of a neighbor after the link-layer address of a neighbor is identified. When a node wants to verifying the reachability of a neighbor, the destination address in a neighbor solicitation message is the unicast address of the neighbor.

Neighbor advertisement messages are also sent when there is a change in the link-layer address of a node on a local link. When there is such a change, the destination address for the neighbor advertisement is the all-nodes multicast address.

Neighbor solicitation messages are also used to verify the reachability of a neighbor after the link-layer address of a neighbor is identified. Neighbor unreachability detection identifies the failure of a neighbor or the failure of the forward path to the neighbor, and is used for all paths between hosts and neighboring nodes (hosts or routers). Neighbor unreachability detection is performed for neighbors to which only unicast packets are being sent and is not performed for neighbors to which multicast packets are being sent.

A neighbor is considered reachable when a positive acknowledgment is returned from the neighbor (indicating that packets previously sent to the neighbor have been received and processed). A positive acknowledgment—from an upper-layer protocol (such as TCP)—indicates that a connection is making forward progress (reaching its destination) or that a neighbor advertisement message in response to a neighbor solicitation message has been received. If packets are reaching the peer, they are also reaching the next-hop neighbor of the source. Therefore, forward progress is also a confirmation that the next-hop neighbor is reachable.

For destinations that are not on the local link, forward progress implies that the first-hop router is reachable. When acknowledgments from an upper-layer protocol are not available, a node probes the neighbor using unicast neighbor solicitation messages to verify that the forward path is still working. The return of a solicited
A neighbor advertisement message from the neighbor is a positive acknowledgment that the forward path is still working. (Neighbor advertisement messages that have the solicited flag set to a value of 1 are sent only in response to a neighbor solicitation message.) Unsolicited messages confirm only the one-way path from the source to the destination node; solicited neighbor advertisement messages indicate that a path is working in both directions.

A neighbor advertisement message that has the solicited flag set to a value of 0 must not be considered as a positive acknowledgment that the forward path is still working.

Neighbor solicitation messages are also used in the stateless autoconfiguration process to verify the uniqueness of unicast IPv6 addresses before the addresses are assigned to an interface. Duplicate address detection is performed first on a new, link-local IPv6 address before the address is assigned to an interface. (The new address remains in a tentative state while duplicate address detection is performed.) Specifically, a node sends a neighbor solicitation message with an unspecified source address and a tentative link-local address in the body of the message. If another node is already using that address, the node returns a neighbor advertisement message that contains the tentative link-local address. If another node is simultaneously verifying the uniqueness of the same address, that node also returns a neighbor solicitation message. If no neighbor advertisement messages are received in response to the neighbor solicitation message and no neighbor solicitation messages are received from other nodes that are attempting to verify the same tentative address, the node that sent the original neighbor solicitation message considers the tentative link-local address to be unique and assigns the address to the interface.

Every IPv6 unicast address (global or link-local) must be checked for uniqueness on the link; however, until the uniqueness of the link-local address is verified, duplicate address detection is not performed on any other IPv6 addresses associated with the link-local address. The Cisco implementation of duplicate address detection in the Cisco IOS XR software does not check the uniqueness of anycast or global addresses that are generated from 64-bit interface identifiers.

### IPv6 Router Advertisement Message

Router advertisement (RA) messages, which have a value of 134 in the Type field of the ICMP packet header, are periodically sent out each configured interface of an IPv6 router. The router advertisement messages are sent to the all-nodes multicast address.

**Figure 8: IPv6 Neighbor Discovery—Router Advertisement Message**

Router advertisement messages typically include the following information:

- One or more onlink IPv6 prefixes that nodes on the local link can use to automatically configure their IPv6 addresses
- Lifetime information for each prefix included in the advertisement
• Sets of flags that indicate the type of autoconfiguration (stateless or statefull) that can be completed
• Default router information (whether the router sending the advertisement should be used as a default router and, if so, the amount of time, in seconds, that the router should be used as a default router)
• Additional information for hosts, such as the hop limit and MTU a host should use in packets that it originates

Router advertisements are also sent in response to router solicitation messages. Router solicitation messages, which have a value of 133 in the Type field of the ICMP packet header, are sent by hosts at system startup so that the host can immediately autoconfigure without needing to wait for the next scheduled router advertisement message. Given that router solicitation messages are usually sent by hosts at system startup (the host does not have a configured unicast address), the source address in router solicitation messages is usually the unspecified IPv6 address (0:0:0:0:0:0:0:0). If the host has a configured unicast address, the unicast address of the interface sending the router solicitation message is used as the source address in the message. The destination address in router solicitation messages is the all-routers multicast address with a scope of the link. When a router advertisement is sent in response to a router solicitation, the destination address in the router advertisement message is the unicast address of the source of the router solicitation message.

The following router advertisement message parameters can be configured:
• The time interval between periodic router advertisement messages
• The “router lifetime” value, which indicates the usefulness of a router as the default router (for use by all nodes on a given link)
• The network prefixes in use on a given link
• The time interval between neighbor solicitation message retransmissions (on a given link)
• The amount of time a node considers a neighbor reachable (for use by all nodes on a given link)

The configured parameters are specific to an interface. The sending of router advertisement messages (with default values) is automatically enabled on Ethernet and FDDI interfaces. For other interface types, the sending of router advertisement messages must be manually configured by using the `no ipv6 nd suppress-ra` command in interface configuration mode. The sending of router advertisement messages can be disabled on individual interfaces by using the `ipv6 nd suppress-ra` command in interface configuration mode.

For stateless autoconfiguration to work properly, the advertised prefix length in router advertisement messages must always be 64 bits.

**IPv6 Neighbor Redirect Message**

A value of 137 in the Type field of the ICMP packet header identifies an IPv6 neighbor redirect message. Routers send neighbor redirect messages to inform hosts of better first-hop nodes on the path to a destination.
IPv6 Neighbor Redirect Message

Figure 9: IPv6 Neighbor Discovery—Neighbor Redirect Message

A router must be able to determine the link-local address for each of its neighboring routers to ensure that the target address (the final destination) in a redirect message identifies the neighbor router by its link-local address. For static routing, the address of the next-hop router should be specified using the link-local address of the router; for dynamic routing, all IPv6 routing protocols must exchange the link-local addresses of neighboring routers.

After forwarding a packet, a router should send a redirect message to the source of the packet under the following circumstances:

- The destination address of the packet is not a multicast address.
- The packet was not addressed to the router.
- The packet is about to be sent out the interface on which it was received.
- The router determines that a better first-hop node for the packet resides on the same link as the source of the packet.
- The source address of the packet is a global IPv6 address of a neighbor on the same link, or a link-local address.

Use the `ipv6 icmp error-interval` global configuration command to limit the rate at which the router generates all IPv6 ICMP error messages, including neighbor redirect messages, which ultimately reduces link-layer congestion.

Note

A router must not update its routing tables after receiving a neighbor redirect message, and hosts must not originate neighbor redirect messages.
Address Repository Manager

IPv4 and IPv6 Address Repository Manager (IPARM) enforces the uniqueness of global IP addresses configured in the system, and provides global IP address information dissemination to processes on route processors (RPs) and line cards (LCs) using the IP address consumer application program interfaces (APIs), which includes unnumbered interface information.

Address Conflict Resolution

There are two parts to conflict resolution; the conflict database and the conflict set definition.

Conflict Database

IPARM maintains a global conflict database. IP addresses that conflict with each other are maintained in lists called conflict sets. These conflict sets make up the global conflict database.

A set of IP addresses are said to be part of a conflict set if at least one prefix in the set conflicts with every other IP address belonging to the same set. For example, the following four addresses are part of a single conflict set.

address 1: 10.1.1.1/16
address 2: 10.2.1.1/16
address 3: 10.3.1.1/16
address 4: 10.4.1.1/8

When a conflicting IP address is added to a conflict set, an algorithm runs through the set to determine the highest precedence address within the set.

This conflict policy algorithm is deterministic, that is, the user can tell which addresses on the interface are enabled or disabled. The address on the interface that is enabled is declared as the highest precedence ip address for that conflict set.

The conflict policy algorithm determines the highest precedence ip address within the set.
Configuring ARP

Address resolution is the process of mapping network addresses to Media Access Control (MAC) addresses, which is typically done dynamically by the system using the ARP protocol, but can also be done by Static ARP entry configuration. This process is accomplished using the Address Resolution Protocol (ARP).

ARP is used to associate IP addresses with media or MAC addresses. Taking an IP address as input, ARP determines the associated media address. After a media or MAC address is determined, the IP address or media address association is stored in an ARP cache for rapid retrieval. Then the IP datagram is encapsulated in a link-layer frame and sent over the network.

For more details on ARP, see Information About Configuring ARP, on page 38

ARP and Proxy ARP

Two forms of address resolution are supported by Cisco IOS XR software: Address Resolution Protocol (ARP) and proxy ARP, as defined in RFC 826 and RFC 1027, respectively. Cisco IOS XR software also supports a form of ARP called local proxy ARP.

For more details on Proxy ARP and Local Proxy ARP, see Proxy ARP and Local Proxy ARP, on page 32

Restrictions

The following restrictions apply to configuring ARP:

• Reverse Address Resolution Protocol (RARP) is not supported.

• ARP throttling, which is the rate limiting of ARP packets in Forwarding Information Base (FIB), is not supported.

ARP Cache Entries

ARP establishes correspondences between network addresses (an IP address, for example) and Ethernet hardware addresses. A record of each correspondence is kept in a cache for a predetermined amount of time and then discarded.
You can also add a static (permanent) entry to the ARP cache that persists until explicitly removed.

Defining a Static ARP Cache Entry

ARP and other address resolution protocols provide a dynamic mapping between IP addresses and media addresses. Because most hosts support dynamic address resolution, generally you need not specify static ARP entries. If you must define them, you can do so globally. Performing this task installs a permanent entry in the ARP cache. Cisco IOS XR software uses this entry to translate 32-bit IP addresses into 48-bit hardware addresses.

Optionally, you can specify that the software responds to ARP requests as if the software was identified by the specified IP address, by making an alias entry in the ARP cache.

Configuration Example

A cache entry is created to establish connection between an IP address 20.0.0.2 and the MAC address 20.0.2. Additionally, the cache entry is created as an alias entry such that the interface to which the entry is attached will respond to ARP request packets for this network layer address with the data link layer address in the entry.

Router# config
Router(config)# arp 20.0.0.2 20.0.2 arpA alias

Running Configuration

Router# show running-config interface tenGigE 0/0/0/0
arp 1.0.0.2 1.0.2 arpa
arp vrf default 1.0.0.2 0001.0000.0002 ARPA

Verification

Verify that the State is static for proper functioning:

Router# show arp 20.0.0.2

<table>
<thead>
<tr>
<th>Address</th>
<th>Age</th>
<th>Hardware Addr</th>
<th>State</th>
<th>Type</th>
<th>Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>20.0.0.2</td>
<td>-</td>
<td>0020.0000.0002</td>
<td>Static</td>
<td>ARPA</td>
<td>TenGigE0/0/0/0</td>
</tr>
</tbody>
</table>

Proxy ARP and Local Proxy ARP

When proxy ARP is disabled, the networking device responds to ARP requests received on an interface only if one of the following conditions is met:
• The target IP address in the ARP request is the same as the interface IP address on which the request is received.

• The target IP address in the ARP request has a statically configured ARP alias.

When proxy ARP is enabled, the networking device also responds to ARP requests that meet all the following conditions:

• The target IP address is not on the same physical network (LAN) on which the request is received.

• The networking device has one or more routes to the target IP address.

• All of the routes to the target IP address go through interfaces other than the one on which the request is received.

When local proxy ARP is enabled, the networking device responds to ARP requests that meet all the following conditions:

• The target IP address in the ARP request, the IP address of the ARP source, and the IP address of the interface on which the ARP request is received are on the same Layer 3 network.

• The next hop for the target IP address is through the same interface as the request is received.

Typically, local proxy ARP is used to resolve MAC addresses to IP addresses in the same Layer 3 network. Local proxy ARP supports all types of interfaces supported by ARP and unnumbered interfaces.

Enabling Proxy ARP

Cisco IOS XR software uses proxy ARP (as defined in RFC 1027) to help hosts with no knowledge of routing determine the media addresses of hosts on other networks or subnets. For example, if the router receives an ARP request for a host that is not on the same interface as the ARP request sender, and if the router has all of its routes to that host through other interfaces, then it generates a proxy ARP reply packet giving its own local data-link address. The host that sent the ARP request then sends its packets to the router, which forwards them to the intended host. Proxy ARP is disabled by default; this task describes how to enable proxy ARP if it has been disabled.

Configuration Example

Proxy ARP is enabled on the TenGigE interface-0/0/0/0:

Router# configure
Router(config)# interface TenGigE 0/0/0/0
Router(config-if)# proxy-arp
Router(config-if)# commit

Running Configuration

Router# show running-config interface tenGigE 0/0/0/0
interface TenGigE0/0/0/0
mtu 4000
ipv4 address 1.0.0.1 255.255.255.0
proxy-arp
!
Verification

Verify that proxy ARP is configured and enabled:

```
Router# show arp idb tenGigE 0/0/0/0 location 0/RP0/CPU0
  TenGigE0/0/0/0 (0x08000038):
  IPv4 address 1.0.0.1, Vrf ID 0x60000000
  VRF Name default
  Dynamic learning: Enable
  Dynamic entry timeout: 14400 secs
  Purge delay: off
  IPv4 caps added (state up)
  MPLS caps not added
  Interface not virtual, not client fwd ref,
  Proxy arp is configured, is enabled
  Local Proxy arp not configured
  Packet IO layer is NetIO
  Srg Role : DEFAULT
  Idb Flag : 262332
  IDB is Complete
```

Enabling Local Proxy ARP

Local proxy ARP is used to resolve MAC addresses to IP addresses in the same Layer 3 network such as, private VLANs that are Layer 2-separated. Local proxy ARP supports all types of interfaces supported by ARP and unnumbered interfaces.

Configuration Example

Local proxy ARP is enabled on the TenGigE interface-0/0/0/0

```
Router# configure
Router(config)# interface tenGigE 0/0/0/0
Router(config-if)# local-proxy-arp
Router(config-if)# commit
```

Running Configuration

```
Router# show running-config interface tenGigE 0/0/0/0
interface TenGigE0/0/0/0
ipv4 address 1.0.0.1 255.255.255.0
local-proxy-arp

```

Verification

Verify that local proxy ARP is configured:

```
Router# show arp idb tenGigE 0/0/0/0 location 0/RP0/CPU0
  TenGigE0/0/0/0 (0x08000038):
  IPv4 address 1.0.0.1, Vrf ID 0x60000000
```
Configure Learning of Local ARP Entries

You can configure an interface or a sub-interface to learn only the ARP entries from its local subnet. Use the following procedure to configure local ARP learning on an interface.

1. Enter the interface configuration mode.

```
Router(config)# interface GigabitEthernet 0/0/0/1
```

2. Configure the IPv4/IPv6 address for the interface.

```
Router(config-if)# ipv4 address 12.1.3.4 255.255.255.0
```

3. Configure local ARP learning on the interface.

```
Router(config-if)# arp learning local
```

4. Enable the interface and commit your configuration.

```
Router(config-if)# no shut
Router(config-if)# commit
```

```
RP/0/0/CFU0:Dec 12 13:41:16.580 : ifmgr[397]: %PKT_INFRA-LINK-3-UPDOWN : interface GigabitEthernet 0/0/0/1, changed state to Down
RP/0/0/CFU0:Dec 12 13:41:16.683 : ifmgr[397]: %PKT_INFRA-LINK-3-UPDOWN : interface GigabitEthernet 0/0/0/1 changed state to Up
```

5. Confirm your configuration.

```
Router(config-if)# show running-configuration
```

```
!! IOS XR Configuration 0.0.0
!! Last configuration change at Mon Dec 12 13:41:16 2016
!interface GigabitEthernet 0/0/0/1
  ipv4 address 12.1.3.4 255.255.255.0
  arp learning local
```

6. Verify if local ARP learning is working as configured on the interface.

```
Router(config-if)# do show arp idb gigabitEthernet 0/0/0/1 location 0/0/CFU0
Thu Dec 15 10:00:11.733 IST
GigabitEthernet 0/0/0/1 (0x00000040):
```
IPv4 address 12.1.3.4, Vrf ID 0x60000000
VRF Name default

**Dynamic learning: Local**
Dynamic entry timeout: 14400 secs
Purge delay: off
IPv4 caps added (state up)
MPLS caps not added
Interface not virtual, not client fwd ref,
Proxy arp not configured, not enabled
Local Proxy arp not configured
Packet IO layer is NetIO
Srg Role : DEFAULT
Idb Flag : 2146444
IDB is Complete

7. (Optional) You can monitor the ARP traffic on the interface.

Router(config-if)# do show arp idb gigabitEthernet 0/0/0/1 location 0/0/CPU0
Thu Dec 15 10:13:28.964 IST

**ARP statistics:**
Recv: 0 requests, 0 replies
Sent: 0 requests, 1 replies (0 proxy, 0 local proxy, 1 gratuitous)
Subscriber Interface:
  0 requests recv, 0 replies sent, 0 gratuitous replies sent
Resolve requests rcvd: 0
Resolve requests dropped: 0
Errors: 0 out of memory, 0 no buffers, 0 out of sunbet

**ARP cache:**
Total ARP entries in cache: 1
Dynamic: 0, Interface: 1, Standby: 0
Alias: 0, Static: 0, DHCP: 0

IP Packet drop count for GigabitEthernet0_0_0_1: 0

---

**Direct Attached Gateway Redundancy**

Direct Attached Gateway Redundancy (DAGR) allows third-party redundancy schemes on connected devices to use gratuitous ARP as a failover signal, enabling the ARP process to advertise a new type of route in the Routing Information Base (RIB). These routes are distributed by Open Shortest Path First (OSPF).

Sometimes part of an IP network requires redundancy without routing protocols. A prime example is in the mobile environment, where devices such as base station controllers and multimedia gateways are deployed in redundant pairs, with aggressive failover requirements (subsecond or less), but typically do not have the capability to use native Layer 3 protocols such as OSPF or Intermediate System-to-Intermediate System (IS-IS) protocol to manage this redundancy. Instead, these devices assume they are connected to adjacent IP devices over an Ethernet switch, and manage their redundancy at Layer 2, using proprietary mechanisms similar to Virtual Router Redundancy Protocol (VRRP). This requires a resilient Ethernet switching capability, and depends on mechanisms such as MAC learning and MAC flooding.

DAGR is a feature that enables many of these devices to connect directly to without an intervening Ethernet switch. DAGR enables the subsecond failover requirements to be met using a Layer 3 solution. No MAC learning, flooding, or switching is required.
Since mobile devices' 1:1 Layer 2 redundancy mechanisms are proprietary, they do not necessarily conform to any standard. So although most IP mobile equipment is compatible with DAGR, interoperability does require qualification, due to the possibly proprietary nature of the Layer 2 mechanisms with which DAGR interfaces.

**Restrictions**

The following additional restrictions apply when configuring the Direct Attached Gateway Redundancy (DAGR) feature:

- IPv6 is not supported.
- Ethernet bundles are not supported.
- Non-Ethernet interfaces are not supported.
- Hitless ARP Process Restart is not supported.
- Hitless RSP Failover is not supported.

**Enabling DAGR**

**Configuration Example**

DAGR is enabled on the TenGigE interface 0/0/0/10 with the peer router having ipv4 address of 5.10.10.1. The failover attributes set are priority-timeout, route distance, route metric, and timers query.

```
Router# configure
Router(config)# interface TenGigE 0/0/0/10
outer(config-if)# arp dagr
Router(config-if-dagr)# peer ipv4 5.10.10.1
Router(config-if-dagr-peer)# priority-timeout 1
Router(config-if-dagr-peer)# route distance normal 1 priority 1
Router(config-if-dagr-peer)# route metric normal 1 priority 1
Router(config-if-dagr-peer)# timers query 2 standby 1
Router(config-if-dagr-peer)# commit
```

**Running Configuration**

```
Router# show running-config interface TenGigE 0/0/0/10
mtu 9216
ipv4 address 10.0.0.1 255.255.255.0
arp dagr
peer ipv4 1.0.0.1
  route metric normal 1 priority 1
timers query 2 standby 1
  priority-timeout 1
  route distance normal 1 priority 1
!
peer ipv4 10.0.0.3
!
!```
### Information About Configuring ARP

#### Addressing Resolution Overview

A device in the IP can have both a local address (which uniquely identifies the device on its local segment or LAN) and a network address (which identifies the network to which the device belongs). The local address is more properly known as a **data link address**, because it is contained in the data link layer (Layer 2 of the OSI model) part of the packet header and is read by data-link devices (bridges and all device interfaces, for example). The more technically inclined person will refer to local addresses as **MAC addresses**, because the MAC sublayer within the data link layer processes addresses for the layer.

To communicate with a device on Ethernet, for example, Cisco IOS XR software first must determine the 48-bit MAC or local data-link address of that device. The process of determining the local data-link address from an IP address is called address resolution.

#### Address Resolution on a Single LAN

The following process describes address resolution when the source and destination devices are attached to the same LAN:

---

**Verification**

```
Router# show arp dagr
```

<table>

</table>

**Related Topics**

- Direct Attached Gateway Redundancy, on page 36

**Associated Commands**

- `arp dagr`
- `route distance`
- `route metric`
- `priority-timeout`
- `peer (DAGR)`
- `show arp dagr`
1. End System A (Node A) broadcasts an ARP request onto the LAN, attempting to learn the MAC address of End System B (Node B).

2. The broadcast is received and processed by all devices on the LAN, including End System B.

3. Only End System B replies to the ARP request. It sends an ARP reply containing its MAC address to End System A (Node A).

4. End System A (Node A) receives the reply and saves the MAC address of End System B in its ARP cache. (The ARP cache is where network addresses are associated with MAC addresses.)

5. Whenever End System A (Node A) needs to communicate with End System B, it checks the ARP cache, finds the MAC address of System B, and sends the frame directly, without needing to first use an ARP request.

Address Resolution When Interconnected by a Router

The following process describes address resolution when the source and destination devices are attached to different LANs that are interconnected by a router (only if proxy-arp is turned on):

1. End System Y (Node A) broadcasts an ARP request onto the LAN, attempting to learn the MAC address of End System Z (Node B).

2. The broadcast is received and processed by all devices on the LAN, including Router X.
3. Router X checks its routing table and finds that End System Z (Node B) is located on a different LAN.

4. Router X therefore acts as a proxy for End System Z (Node B). It replies to the ARP request from End System Y (Node A), sending an ARP reply containing its own MAC address as if it belonged to End System Z (Node B).

5. End System Y (Node A) receives the ARP reply and saves the MAC address of Router X in its ARP cache, in the entry for End System Z (Node B).

6. When End System Y (Node A) needs to communicate with End System Z (Node B), it checks the ARP cache, finds the MAC address of Router X, and sends the frame directly, without using ARP requests.

7. Router X receives the traffic from End System Y (Node A) and forwards it to End System Z (Node B) on the other LAN.
Implementing DHCP

• Implementing DHCP Relay Agent, on page 41

Implementing DHCP Relay Agent

Understanding DHCP

This topic provides an overview of DHCP related components.

DHCP Relay Agent

A DHCP relay agent is a host that forwards DHCP packets between clients and servers that do not reside on a shared physical subnet. Relay agent forwarding is distinct from the normal forwarding of an IP router where IP datagrams are switched between networks transparently.

DHCP clients use User Datagram Protocol (UDP) broadcasts to send DHCPDISCOVER messages when they lack information about the network to which they belong.

If a client is on a network segment that does not include a server, a relay agent is needed on that network segment to ensure that DHCP packets reach the servers on another network segment. UDP broadcast packets are not forwarded, because most routers are not configured to forward broadcast traffic. You can configure a DHCP relay agent to forward DHCP packets to a remote server by configuring a DHCP relay profile and configure one or more helper addresses in it. You can assign the profile to an interface or a VRF.

The figure below demonstrates the process. The DHCP client broadcasts a request for an IP address and additional configuration parameters on its local LAN. Acting as a DHCP relay agent, Router B picks up the broadcast, changes the destination address to the DHCP server's address and sends the message out on another interface. The relay agent inserts the IP address of the interface, on which the DHCP client’s packets are received into the gateway address (giaddr) field of the DHCP packet, which enables the DHCP server to determine which subnet should receive the offer and identify the appropriate IP address range. The relay agent unicasts the messages to the server address, in this case 172.16.1.2 (which is specified by the helper address in the relay profile).
DHCPv4 Server

DHCP server accepts address assignment requests and renewals and assigns the IP addresses from predefined groups of addresses contained within Distributed Address Pools (DAPS). DHCP server can also be configured to supply additional information to the requesting client such as subnet mask, domain-name, the IP address of the DNS server, the default router, and other configuration parameters. DHCP server can accept broadcasts from locally attached LAN segments or from DHCP requests that have been forwarded by other DHCP relay agents within the network.

DHCPv4 Client

The DHCP client functionality enables the router interfaces to dynamically acquire the IPv4 address using DHCP.

The DHCP provides configuration parameters to Internet hosts. DHCP consists of two components:

- a protocol to deliver host-specific configuration parameters from a DHCP server to a host.
- a mechanism to allocate network addresses to hosts.

DHCP is built on a client-server model, where designated DHCP server hosts allocate network addresses, and deliver configuration parameters to dynamically configured hosts.

A relay agent is required if the client and server are not on the same Layer 2 network. The relay agent usually runs on the router, and is required because the client device does not know its own IP address initially. The agent sends out a Layer 2 broadcast to find a server that has this information. The router relays these broadcasts to the DHCP server, and forwards the responses back to the correct Layer 2 address so that the correct device gets the correct configuration information.

DHCP has the ability to allocate IP addresses only for a configurable period of time, called the lease period. If the client is required to retain this IP address for a longer period beyond the lease period, the lease period must be renewed before the IP address expires. The client renews the lease based on configuration that was sent from the server. The client unicasts a REQUEST message using the IP address of the server. When a server receives the REQUEST message and responds with an ACK message. The lease period of the client is extended by the lease time configured in the ACK message.

Restrictions
- DHCP client can be enabled only on management interfaces.
- Either DHCP or static IP can be configured on an interface.

DHCP IPv4 Service-based Mode Selection

As part of DHCP IPv4 service based mode selection feature, a new mode called DHCP base is introduced. If an interface is configured in the DHCP base mode, then the DHCP selects the DHCP server mode to process
the client request by matching option 60 (class-identifier) value of the client request with the configured value under the DHCP base profile.

For example:

```
dhcp ipv4
profile DHCP_BASE base
  match option 60 41424355 profile DHCP_SERVER server
  default profile DEFAULT_PROFILE server
  relay information authenticate inserted

profile DHCP_relay relay
  helper-address vrf default 10.10.10.1 giaddr 0.0.0.0

profile DHCP_SERVER server
  lease 1 0 0
  pool IP_POOL

profile DEFAULT_PROFILE server
  lease 1 0 0
  pool IP_POOL

interface gigabitEthernet 0/0/0 base profile DHCP_BASE
```

The pool is configured under server-profile-mode and server-profile-class-sub-mode. The class-based pool selection is always given priority over profile pool selection. The DHCPv4 server profile class sub-mode supports configuring DHCP options except few (0, 12, 50, 53, 54, 58, 59, 61, 82, and 255).

### Configuring and Enabling DHCP Relay Agent with DHCP MAC Address Verification

This section discusses how to configure and enable DHCP Relay Agent with DHCP MAC address verification.

#### Configuration Example

```bash
Router# configure

Router(config)# dhcp ipv4
/* Configures DHCP for IPv4 and enters the DHCPv4 configuration submode. */

Router(config-dhcpv4)# profile client relay
/* Enables DHCP relay profile */

Router(config-dhcpv4)# client-mac-mismatch action drop
/* Enables MAC address verification. If MAC address in the DHCPv4 protocol header does not match the L2 header source MAC address in the DHCPv4 relay profile, the frame is dropped */

Router(config-dhcpv4-relay-profile)# relay information option
/* Inserts the DHCP relay agent information option (option-82 field) in forwarded BOOTREQUEST messages to a DHCP server. */

Router(config-dhcpv4-relay-profile)# relay information check
/* (Optional) Configures DHCP to check the validity of the relay agent information option in forwarded BOOTREPLY messages. */

Router(config-dhcpv4-relay-profile)# relay information policy drop
/* (Optional) Configures the reforwarding policy for a DHCP relay agent; */
```
Enabling DHCP Relay Agent on an Interface

This section describes how to enable the Cisco IOS XR DHCP relay agent on an interface.
Configuration Example

The DHCP relay agent is disabled by default.

```
router#configure

router(config)#dhcp_ipv4
/* Configures DHCP for IPv4 and enters the DHCPv4 configuration submode. */

router(config-dhcpv4)#interface HundredGigE 0/2/0/2 relay profile client
/* Attaches a relay profile to an interface.
To disable the DHCP relay on the interface, use the 'no interface HundredGigE 0/2/0/2 none'
command. */

router(config-dhcpv4-if)#commit
```

Running Configuration

```
Router#show running-config dhcp ipv4
dhcp ipv4
interface HundredGigE 0/2/0/2 relay profile client
!
```

Support for DHCP Option 82 on Bridge-Group Virtual Interface (BVI) Interface

DHCP option 82 provides additional security when DHCP is used to allocate network addresses. It enables the DHCP relay agent to prevent DHCP client requests from untrusted source. You can configure the relay agent to insert the Option 82 circuit ID in the DHCP packet before the relay agent sends the packet to the DHCP server. When the DHCP relay profile is attached to a bridge virtual interface (BVI), you can assign the name of the ingress Layer 2 interface as the value of Option 82 circuit ID. The DHCP packet that is sent from the relay agent to the server carries the packet’s ingress Layer 2 interface name as Option 82 circuit ID.

*Figure 11: DHCP Option 82 on BVI Interface*

Configuration Example

```
router#configure

router(config)#dhcp_ipv4
/* The 'dhcp_ipv4' command configures DHCP for IPv6 and enters the DHCPv6 configuration submode. */
```
```
router(config-dhcpv4)#profile bv1_profile relay
/* Enters the relay profile configuration mode. */

router(config-dhcpv4-relay-profile)#helper-address vrf default 10.1.1.2
/* Forwards UDP broadcasts, including DHCP. */

router(config-dhcpv4-relay-profile)#relay information option
/* Enables adding both circuit-id and remote-id to the DHCP packet */

router(config-dhcpv4-relay-profile)#interface BVI1 relay information option format-type
circuit-id format-string "%s" l2-interface
/* Enables the DHCP relay agent to add the value of Option 82 Circuit ID field to the DHCP
packet and assigns the ingress Layer 2 interface
as the value of Option 82 Circuit ID field. */

router(config-dhcpv4-relay-profile)# interface BVI1 relay profile bv1_profile
/* Enables DHCP for IPV4 on a BVI interface and attaches the profile as the relay profile
for the BVI interface. */
```

### Running Configuration

```
Router#show running-config dhcp ipv4
dhcp ipv4
  profile irb relay
    helper-address vrf default 10.1.1.2
    relay information option
! interface BVI1 relay information option format-type circuit-id format-string "%s"
l2-interface
  interface BVI1 relay profile irb
```

### Configuring DHCPv4 Server Profile on Bridge-Group Virtual Interface (BVI) Interface

DHCP server accepts address assignment requests and renewals and assigns the IP addresses from predefined
groups of addresses contained within Distributed Address Pools (DAPS). DHCP server can also be configured
to supply additional information to the requesting client. DHCP server can accept broadcasts from locally
attached LAN segments or from DHCP requests that have been forwarded by other DHCP relay agents within
the network.

**DHCP IPv4 service-based mode selection**

As part of DHCP IPv4 service-based mode selection feature, a new mode called DHCP base is introduced. If
an interface is configured in the DHCP base mode, then the DHCP selects the DHCP server mode to process
the client request by matching option 60 (class-identifier) value of the client request with the configured value
under the DHCP base profile.

The pool is configured under server-profile-mode and server-profile-class-sub-mode. The class-based pool
selection is always given priority over profile pool selection. The DHCPv4 server profile class sub-mode
supports configuring DHCP options except few (0, 12, 50, 52, 54, 58, 59, 61, 82, and 255 ).
Configuration Example

Router# configure

Router(config)# dhcp ipv4

Router(config-dhcpv4)# profile bvi1_server server
// Enters the server profile configuration mode. */

Router(config-dhcpv4)# lease 0 0 0
// Also use 'days minutes seconds' to specify lease for an IP address assigned from the pool. */

Router(config-dhcpv4)# bootfile http://10.1.1.1/auto/images/server_bvi.iso
// Configures the boot file b1. */

Router(config-dhcpv4)# pool bvi_pool
// Configures the DAPS pool name. */

Router(config-dhcpv4)# broadcast-flag policy unicast-always
// Broadcasts only BOOTREPLY packets if the DHCP IPv4 broadcast flag is set in the DHCP IPv4 header */

  option 160 ascii http://10.1.1.1/image.iso
Configuring Multiple Classes with a Pool

This section discusses configuring multiple classes with a pool.

Configuration Example

```
router#configure

router(config)#dhcp ipv4
/* Enables DHCP for IPv4 and enters DHCP IPv4 configuration mode. */

router(config-dhcpv4)#profile TEST server
/* Enters the server profile configuration mode. */

router(config-dhcpv4-server-profile)#pool POOL_TEST
/* Configures the DAPS pool name. */

router(config-dhcpv4-server-profile)#class Class_A
/* Creates and enters server profile class configuration submode. */

router(config-dhcpv4-server-profile-class)#pool pool_A
/* Configures the pool name. */

router(config-dhcpv4-server-profile-class)#match option 60 hex abcd
/* DHCP server selects a pool from a class by matching options in the received DISCOVER packet with the match option. */

router(config-dhcpv4-server-profile-class)#exit
/* Exits the server profile class submode. */

router(config-dhcpv4-server-profile)#class Class_B
/* Creates and enters the server profile class. */

router(config-dhcpv4-server-profile-class)#pool pool_B
/* Configures the pool name. */

router(config-dhcpv4-server-profile-class)#match vrf VRF1
/* The DHCP server selects a pool from a class by matching the options in the received DISCOVER packet with the match command. 
none of the classes match, then pools configured under the profile mode are selected. The 
DHCP server requests DAPS to allocate 
an address from that pool. */

router(config-dhcpv4-server-profile-class)#commit
```

Running Configuration

```
Router#show running-config dhcp ipv4
dhcp ipv4
profile TEST server
pool POOL_TEST
class Class_A
pool pool_A
match option 60 hex abcd
exit
```
class Class_B
pool pool_B
match vrf VRF1
!

### Configuring a Server Profile DAPS with Class Match Option

This section discusses configuring a server profile DAPS with class match option.

#### Configuration Example

```
routing#configure

router(config)#dhcp ipv4
/* The 'dhcp ipv6' command configures DHCP for IPv6 and enters the DHCPv6 configuration submode. */

router(config-dhcpv4)#profile ISP1 server
/* Enters the server profile configuration mode. */

router(config-dhcpv4-server-profile)#pool ISP1_POOL
/* Configures the DAPS pool name. */

router(config-dhcpv4-server-profile)#class ISP1_CLASS
/* Creates and enters server profile class configuration submode. */

router(config-dhcpv4-server-profile-class)#pool ISP1_CLASS_POOL
/* Configures the pool name. */

router(config-dhcpv4-server-profile-class)#match option 60 hex PXEClient_1
/* DHCP server selects a pool from a class by matching options in the received DISCOVER packet with the match option. */

router(config-dhcpv4-server-profile-class)#exit

router(config-dhcpv4-server-profile)#exit

router(config-dhcpv4)#profile ISP2 server
/* Enters the server profile configuration mode. */

router(config-dhcpv4-server-profile)#dns-server 10.20.3.4
/* Configures the name of the DNS server or the IP address. */

router(config-dhcpv4-server-profile)#pool ISP2_POOL
/* Configures the pool name. */

router(config-dhcpv4-server-profile)#class ISP2_CLASS
/* Creates and enters the server profile class. */

router(config-dhcpv4-server-profile-class)#pool ISP2_CLASS_POOL
/* Configures the pool name. */

router(config-dhcpv4-server-profile-class)#match option 60 hex PXEClient_2
/* DHCP server selects a pool from a class by matching options in the received DISCOVER packet with the match option. */

router(config-dhcpv4-server-profile-class)#exit

router(config-dhcpv4-server-profile)#exit
```
Configuring Server Profile without DAPS Pool Match Option

This section discusses configuring a server profile without DAPS pool match option.

Configuration Example

```
router(config)#configure

router(config)#dhcpc
/* The 'dhcpc' command configures DHCP for IPv6 and enters the DHCPv6 configuration
   submode. */

router(config-dhcpcv4)#profile ISP1 server
/* Enters the server profile configuration mode. */

router(config-dhcpcv4-server-profile)#dns-server ISP1.com
/* Configures the name of the DNS server or IP address. */

router(config-dhcpcv4-server-profile)#exit

router(config-dhcpcv4)#profile ISP2 server
/* Enters the server profile configuration mode. */

router(config-dhcpcv4-server-profile)#dns-server ISP2.com
/* Configures the name of the DNS server or IP address. */

router(config-dhcpcv4-server-profile)#exit

router(config-dhcpcv4)#commit
```

Running Configuration

```
Router#show running-config dhcp ipv4
dhcpc ipv4
profile ISP1 server
pool ISP1_POOL
class ISP1_CLASS
pool ISP1_CLASS_POOL
match option 60 hex PXEClient_1
exit
exit
profile ISP2 server
dns-server 10.20.3.4
pool ISP2_POOL
class ISP2_CLASS
pool ISP2_CLASS_POOL
match option 60 hex PXEClient_2
exit
exit
```

Configuring an Address Pool for Each ISP on DAPS

This section discusses configuring an address pool for each ISP on DAPS.

**Configuration Example**

```
router#configure
router(config)#pool vrf ISP_1 ipv4 ISP1_POOL
   /* Configures an IPv4 pool for the specified VRF or all VRFs. Use the 'ipv6' keyword for IPv6 pool. */
router(config-pool-ipv4)#network 10.10.10.0
   /* Specifies network for allocation. */
router(config-pool-ipv4)#exit

router(config)#pool vrf ISP_2 ipv4 ISP2_POOL
   /* Configures an IPv4 pool for the specified VRF or all VRFs. */
router(config-pool-ipv4)#network 10.20.20.0
   /* Specifies network for allocation. */
router(config-pool-ipv4)#exit

router(config-dhcpv4)#commit
```

**Running Configuration**

```
Router#show running-config pool
pool vrf ISP_1 ipv4 ISP1_POOL
   network 10.10.10.0
   exit
pool vrf ISP_2 ipv4 ISP2_POOL
   network 10.20.20.0
   !
```
Implementing DHCP

Configuring an Address Pool for Each ISP on DAPS
Implementing Host Services and Applications

Cisco IOS XR software Host Services and Applications features on the router are used primarily for checking network connectivity and the route a packet follows to reach a destination, mapping a hostname to an IP address or an IP address to a hostname, and transferring files between routers and UNIX workstations.

Network Connectivity Tools

Network connectivity tools enable you to check device connectivity by running traceroutes and pinging devices on the network:

Ping

The ping command is a common method for troubleshooting the accessibility of devices. It uses two Internet Control Message Protocol (ICMP) query messages, ICMP echo requests, and ICMP echo replies to determine whether a remote host is active. The ping command also measures the amount of time it takes to receive the echo reply.

The ping command first sends an echo request packet to an address, and then it waits for a reply. The ping is successful only if the echo request gets to the destination, and the destination is able to get an echo reply (hostname is alive) back to the source of the ping within a predefined time interval.

The bulk option has been introduced to check reachability to multiple destinations. The destinations are directly input through the CLI. This option is supported for ipv4 destinations only.
Checking Network Connectivity

As an aid to diagnosing basic network connectivity, many network protocols support an echo protocol. The protocol involves sending a special datagram to the destination host, then waiting for a reply datagram from that host. Results from this echo protocol can help in evaluating the path-to-host reliability, delays over the path, and whether the host can be reached or is functioning.

Configuration for Checking Network Connectivity

The following configuration shows an extended ping command sourced from the Router A TenGigE interface and destined for the Router B TenGigE interface. If this ping succeeds, it is an indication that there is no routing problem. Router A knows how to get to the TenGigE interface of Router B, and Router B knows how to get to the TenGigE interface of Router A. Also, both hosts have their default gateways set correctly.

If the extended ping command from Router A fails, it means that there is a routing problem. There could be a routing problem on any of the three routers: Router A could be missing a route to the subnet of Router B's interface, or to the subnet between Router C and Router B; Router B could be missing a route to the subnet of Router A's subnet, or to the subnet between Router C and Router A; and Router C could be missing a route to the subnet of Router A's or Router B's Ethernet segments. You should correct any routing problems, and then Host 1 should try to ping Host 2. If Host 1 still cannot ping Host 2, then both hosts' default gateways should be checked. The connectivity between the TenGigE interface of Router A and the TenGigE interface of Router B is checked with the extended ping command.

With a normal ping from Router A to Router B's TenGigE interface, the source address of the ping packet would be the address of the outgoing interface; that is the address of the TenGigE interface, (10.0.0.2). When Router B replies to the ping packet, it replies to the source address (that is, 10.0.0.2). This way, only the connectivity between the TenGigE interface of Router A (10.0.0.2) and the 10gige interface of Router B (10.0.0.1) is tested.

To test the connectivity between Router A's TenGigE interface (10.0.0.2) and Router B's TenGigE interface (10.0.0.1), we use the extended ping command. With extended ping, we get the option to specify the source address of the ping packet.

Configuration Example

In this use case, the extended ping command verifies the IP connectivity between the two IP addresses Router A (10.0.0.2) and Router B (10.0.0.1).

Router# ping 10.0.0.1
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.0.0.1, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5)
Router#!!!!!

*/If you do not enter a hostname or an IP address on the same line as the ping command, the system prompts you to specify the target IP address and several other command parameters. After specifying the target IP address, you can specify alternate values for the remaining parameters or accept the displayed default for each parameter /*

Router# ping
Protocol [ipv4]:
Target IP address: 10.0.0.1
Repeat count [5]: 5
Datagram size [100]: 1000
Timeout in seconds [2]: 1
Interval in milliseconds [10]: 1
Extended commands? [no]: no
Sweep range of sizes? [no]:
Type escape sequence to abort.
Sending 5, 1000-byte ICMP Echos to 10.0.0.1, timeout is 1 seconds:
!!!!!
Success rate is 100 percent (5/5)
Router#!!!!!

Associated Commands

• ping

Checking Network Connectivity for Multiple Destinations

The bulk option enables you to check reachability to multiple destinations. The destinations are directly input through the CLI. This option is supported for ipv4 destinations only.

Configuration Example

Check reachability and network connectivity to multiple hosts on IP networks with the following IP addresses:

• 1: 1.1.1.1
• 2: 2.2.2.2
• 3: 3.3.3.3

Router# ping bulk ipv4 input cli batch
*/You must hit the Enter button and then specify one destination address per line*/
Please enter input via CLI with one destination per line and when done Ctrl-D/(exit) to initiate pings:
1: 1.1.1.1
2: 2.2.2.2
3: 3.3.3.3
4:
Starting pings...
Target IP address: 1.1.1.1
Repeat count [5]: 5
Datagram size [100]: 1
% A decimal number between 36 and 18024.
Datagram size [100]: 1
% A decimal number between 36 and 18024.
Datagram size [100]: 1000
Timeout in seconds [2]: 1
Interval in milliseconds [10]: 10
Extended commands? [no]: no
Sweep range of sizes? [no]: q
% Please answer 'yes' or 'no'.
Sweep range of sizes? [no]: q
% Please answer 'yes' or 'no'.
Sweep range of sizes? [no]:
Type escape sequence to abort.
Sending 5, 1000-byte ICMP Echos to 1.1.1.1, vrf is default, timeout is 1 seconds:
!!!!!!
Success rate is 100 percent (5/5),
Target IP address: 2.2.2.2
Repeat count [5]:
Datagram size [100]: q
% A decimal number between 36 and 18024.
Datagram size [100]:
Timeout in seconds [2]:
Interval in milliseconds [10]:
Extended commands? [no]:
Sweep range of sizes? [no]:
Sending 5, 100-byte ICMP Echos to 1.1.1.1, vrf is default, timeout is 2 seconds:
!!!!!!
Success rate is 100 percent (5/5),
Target IP address: 3.3.3.3
Repeat count [5]: 4
Datagram size [100]: 100
Timeout in seconds [2]: 1
Interval in milliseconds [10]: 10
Extended commands? [no]: no
Sweep range of sizes? [no]: no
Sending 4, 100-byte ICMP Echos to 1.1.1.1, vrf is default, timeout is 1 seconds:
!!!!!!
Success rate is 100 percent (4/5),

Associated Commands

- ping bulk ipv4

Traceroute

Where the ping command can be used to verify connectivity between devices, the traceroute command can be used to discover the paths packets take to a remote destination and where routing breaks down.

The traceroute command records the source of each ICMP "time-exceeded" message to provide a trace of the path that the packet took to reach the destination. You can use the IP traceroute command to identify the path that packets take through the network on a hop-by-hop basis. The command output displays all network layer (Layer 3) devices, such as routers, that the traffic passes through on the way to the destination.

The traceroute command uses the Time To Live (TTL) field in the IP header to cause routers and servers to generate specific return messages. The traceroute command sends a User Datagram Protocol (UDP) datagram to the destination host with the TTL field set to 1. If a router finds a TTL value of 1 or 0, it drops the datagram and sends back an ICMP time-exceeded message to the sender. The traceroute facility determines the address of the first hop by examining the source address field of the ICMP time-exceeded message.

To identify the next hop, the traceroute command sends a UDP packet with a TTL value of 2. The first router decrements the TTL field by 1 and sends the datagram to the next router. The second router sees a TTL value of 1, discards the datagram, and returns the time-exceeded message to the source. This process continues until the TTL increments to a value large enough for the datagram to reach the destination host (or until the maximum TTL is reached).
To determine when a datagram reaches its destination, the `traceroute` command sets the UDP destination port in the datagram to a very large value that the destination host is unlikely to be using. When a host receives a datagram with an unrecognized port number, it sends an ICMP port unreachable error to the source. This message indicates to the traceroute facility that it has reached the destination.

## Checking Packet Routes

The `traceroute` command allows you to trace the routes that packets actually take when traveling to their destinations.

### Configuration Example

Trace the route from 10.0.0.2 to 20.1.1.1:

```
Router# traceroute 20.1.1.1
Type escape sequence to abort.
Tracing the route to 20.1.1.1
  1  10.0.0.1  39 msec  *  3 msec

/* If you do not enter a hostname or an IP address on the same line as the traceroute command, the system prompts you to specify the target IP address and several other command parameters. After specifying the target IP address, you can specify alternate values for the remaining parameters or accept the displayed default for each parameter/*

Router #traceroute
Protocol [ipv4]:
Target IP address: 20.1.1.1
Source address: 10.0.0.2
Numeric display? [no]:
Timeout in seconds [3]:
Probe count [3]:
Minimum Time to Live [1]:
Maximum Time to Live [30]:
Port Number [33434]:
Loose, Strict, Record, Timestamp, Verbose[none]:

Type escape sequence to abort.
Tracing the route to 20.1.1.1
  1  10.0.0.1  3 msec  *  3 msec
```

### Associated Commands

- `traceroute`

## Domain Services

Cisco IOS XR software domain services acts as a Berkeley Standard Distribution (BSD) domain resolver. The domain services maintains a local cache of hostname-to-address mappings for use by applications, such as Telnet, and commands, such as `ping` and `traceroute`. The local cache speeds the conversion of host names to addresses. Two types of entries exist in the local cache: static and dynamic. Entries configured using the `domain ipv4 host` or `domain ipv6 host` command are added as static entries, while entries received from the name server are added as dynamic entries.

The name server is used by the World Wide Web (WWW) for translating names of network nodes into addresses. The name server maintains a distributed database that maps hostnames to IP addresses through the
DNS protocol from a DNS server. One or more name servers can be specified using the **domain name-server** command.

When an application needs the IP address of a host or the hostname of an IP address, a remote-procedure call (RPC) is made to the domain services. The domain service looks up the IP address or hostname in the cache, and if the entry is not found, the domain service sends a DNS query to the name server.

You can specify a default domain name that Cisco IOS XR software uses to complete domain name requests. You can also specify either a single domain or a list of domain names. Any IP hostname that does not contain a domain name has the domain name you specify appended to it before being added to the host table. To specify a domain name or names, use either the **domain name** or **domain list** command.

### Configuring Domain Services

DNS-based hostname-to-address translation is enabled by default. If hostname-to-address translation has been disabled using the **domain lookup disable** command, re-enable the translation using the **no domain lookup disable** command.

### Configuration Example

Define a static hostname-to-address mapping. Associate (or map) the IPv4 addresses (192.168.7.18 and 10.2.0.2 192.168.7.33) with two hosts. The host names are host1 and host2.

#### Defining the Domain Host

```plaintext
Router# configure
Router(config)# domain ipv4 host host1 192.168.7.18
Router(config)# domain ipv4 host host2 10.2.0.2 192.168.7.33
Router(config)# commit
```

#### Defining the Domain Name

```plaintext
*Define cisco.com as the default domain name/*
Router# configure
Router(config)# domain name cisco.com
Router(config)# commit
```

#### Specifying the Addresses of the Name Servers

```plaintext
*Specify host 192.168.1.111 as the primary name server and host 192.168.1.2 as the secondary server/*
Router# configure
Router(config)# domain name-server 192.168.1.111
Router(config)# domain name-server 192.168.1.2
Router(config)# commit
```

### Verification

```plaintext
Router# show hosts
Default domain is cisco.com
Name/address lookup uses domain service
Name servers: 192.168.1.111, 192.168.1.2

<table>
<thead>
<tr>

- domain ipv6 host

TFTP Server

It is too costly and inefficient to have a machine that acts only as a server on every network segment. However, when you do not have a server on every segment, your network operations can incur substantial time delays across network segments. You can configure a router to serve as a TFTP server to reduce costs and time delays in your network while allowing you to use your router for its regular functions.

Typically, a router that is configured as a TFTP server provides other routers with system image or router configuration files from its flash memory. You can also configure the router to respond to other types of services requests.

Configuring a Router as a TFTP Server

The server and client router must be able to reach each other before the TFTP function can be implemented. Verify this connection by testing the connection between the server and client router (in either direction) using the `ping` command.

This task allows you to configure the router as a TFTP server so other devices acting as TFTP clients are able to read and write files from and to the router under a specific directory, such as slot0:, /tmp, and so on (TFTP home directory).

Note

For security reasons, the TFTP server requires that a file must already exist for a write request to succeed.

The server and client router must be able to reach each other before the TFTP function can be implemented. Verify this connection by testing the connection between the server and client router (in either direction) using the `ping` command.

Configuration Example

Configure the router (home directory disk0:) as the TFTP server.

```
Router#configure
Router(config)#tftp ipv4 server homedir disk0
Router(config)#commit
```

Running Configuration

```
Router#show running-config tftp ipv4 server homedir disk0:
tftp vrf default ipv4 server homedir disk0:
```
Verification

Router#show cinetd services

File Transfer Services

File Transfer Protocol (FTP), Trivial File Transfer Protocol (TFTP), remote copy protocol (rcp) rcp clients, and Secure Copy Protocol (SCP) are implemented as file systems or resource managers. For example, path names beginning with tftp:// are handled by the TFTP resource manager.

The file system interface uses URLs to specify the location of a file. URLs commonly specify files or locations on the WWW. However, on Cisco routers, URLs also specify the location of files on the router or remote file servers.

When a router crashes, it can be useful to obtain a copy of the entire memory contents of the router (called a core dump) for your technical support representative to use to identify the cause of the crash. SCP, FTP, TFTP, rcp can be used to save the core dump to a remote server.

FTP

File Transfer Protocol (FTP) is part of the TCP/IP protocol stack, which is used for transferring files between network nodes. FTP is defined in RFC 959.

Configuring a Router to Use FTP Connections

You can configure the router to use FTP connections for transferring files between systems on the network. You can set the following FTP characteristics:

- Passive-mode FTP
- Password
- IP address

Configuration Example

Enable the router to use FTP connections. Configure the software to use passive FTP connections, a password for anonymous users, and also specify the source IP address for FTP connections.

Router# configure
Router(config)# ftp client passive
Router(config)# ftp client anonymous-password xxxx
Router(config)# ftp client source-interface TenGigE 0/0/0/0
Router(config)# commit
Associated Commands

- ftp client passive
- ftp client anonymous-password
- ftp client source-interface

TFTP

Trivial File Transfer Protocol (TFTP) is a simplified version of FTP that allows files to be transferred from one computer to another over a network, usually without the use of client authentication (for example, username and password).

Configuring a Router to Use TFTP Connections

**Configuration Example**

Configure the router to use TFTP connections and set the IP address of the TenGigE interface 0/0/0/0 as the source address for TFTP connections:

```
Router# configure
Router (config)# tftp client source-interface TenGigE 0/0/0/0
Router (config)# commit
```

**Verification**

```
Router# show cinetd services
Vrf Name Family Service Proto Port ACL max_cnt curr_cnt wait Program Client Option
default v4 tftp udp 69 unlimited 0 wait tftpd sysdb disk0:
default v4 telnet tcp 23 10 0 nowait telnetd sysdb
```

Associated Commands

- tftp client source-interface type
- show cinetd services

SCP

Secure Copy Protocol (SCP) is a file transfer protocol which provides a secure and authenticated method for transferring files. SCP relies on SSHv2 to transfer files from a remote location to a local location or from local location to a remote location.

Cisco IOS XR software supports SCP server and client operations. If a device receives an SCP request, the SSH server process spawns the SCP server process which interacts with the client. For each incoming SCP subsystem request, a new SCP server instance is spawned. If a device sends a file transfer request to a destination device, it acts as the client.

When a device starts an SSH connection to a remote host for file transfer, the remote device can either respond to the request in Source Mode or Sink Mode. In Source Mode, the device is the file source. It reads the file
Transferring Files Using SCP

Secure Copy Protocol (SCP) allows you to transfer files between source and destination devices. You can transfer one file at a time. If the destination is a server, SSH server process must be running.

Configuration Example

Transfers the file "file1.txt" from the local directory to the remote directory and the "file2.txt" from vice-versa.

```
Router# scp /usr/file1.txt root@209.165.200.1:/root/file1.txt
** Transfers a file from a local directory to a remote directory**
Router# commit

Router# scp root@209.165.200.1:/root/file2.txt /usr/file2.txt
** Transfers a file from a remote directory to a local directory**
Router# commit
```

Associated Commands

- scp

Cisco inetd

Cisco Internet services process daemon (Cinetd) is a multithreaded server process that is started by the system manager after the system has booted. Cinetd listens for Internet services such as Telnet service, TFTP service, and so on. Whether Cinetd listens for a specific service depends on the router configuration. For example, when the `tftp server` command is entered, Cinetd starts listening for the TFTP service. When a request arrives, Cinetd runs the server program associated with the service.

Telnet

Enabling Telnet allows inbound Telnet connections into a networking device.

Configuration Example

Enable telnet and limit the number of simultaneous users that can access the router to 10.

```
Router# configure
Router(config)# telnet ipv4 server max-servers 10
Router(config)# commit
```
Verification

Router# show cinetd services

Syslog source-interface

You can configure the logging source interface to identify the syslog traffic, originating in a VRF from a particular router, as coming from a single device.

Configuration Example

Enable a source interface for the remote syslog server. Configure interface loopback 1 to be the logging source interface for the default vrf.

Router# configure
Router(config)# logging source-interface loopback 1 vrf default
Router(config)# commit

Running Configuration

Router# show running-config logging
logging source-interface Loopback1

Associated Commands

- logging source-interface
CHAPTER 6

Implementing Access Lists and Prefix Lists

• Understanding Access Lists, on page 65
• Understanding Access Lists and Prefix Lists, on page 78
• Atomic ACL Updates By Using the Disable Option, on page 78

Understanding Access Lists

Access lists perform packet filtering to control which packets move through the network and where. Such controls help to limit network traffic and restrict the access of users and devices to the network. Access lists have many uses, and therefore many commands accept a reference to an access list in their command syntax. Access lists can be used to do the following:

An access control list (ACL) consists of one or more access control entries (ACE) that collectively define the network traffic profile. This profile can then be referenced by Cisco IOS XR software features such as traffic filtering, route filtering, QoS classification, and access control. There are 2 types of ACLs:

• Standard ACLs- Verifies only the source IP address of the packets. Traffic is controlled by the comparison of the address or prefix configured in the ACL, with the source address found in the packet.

• Extended ACLs- Verifies more than just the source address of the packets. Attributes such as destination address, specific IP protocols, UDP or TCP port numbers, DSCP, and so on are validated. Traffic is controlled by a comparison of the attributes stated in the ACL with those in the incoming or outgoing packets.

Cisco IOS XR does not differentiate between standard and extended access lists. Standard access list support is provided for backward compatibility.

Purpose of IP Access Lists

• Filter incoming or outgoing packets on an interface.

• Filter packets for mirroring.

• Redirect traffic as required.

• Restrict the contents of routing updates.

• Limit debug output based on an address or protocol.

• Control vty access.
• Identify or classify traffic for advanced features, such as congestion avoidance, congestion management, and priority and custom queueing.

How an IP Access List Works

An access list is a sequential list consisting of permit and deny statements that apply to IP addresses and possibly upper-layer IP protocols. The access list has a name by which it is referenced. Many software commands accept an access list as part of their syntax.

An access list can be configured and named, but it is not in effect until the access list is referenced by a command that accepts an access list. Multiple commands can reference the same access list. An access list can control traffic arriving at the router or leaving the router, but not traffic originating at the router.

Source address and destination addresses are two of the most typical fields in an IP packet on which to base an access list. Specify source addresses to control packets from certain networking devices or hosts. Specify destination addresses to control packets being sent to certain networking devices or hosts.

You can also filter packets on the basis of transport layer information, such as whether the packet is a TCP, UDP, ICMP, or IGMP packet.

ACL Workflow

The following image illustrates the workflow of an ACL.

IP Access List Process and Rules

Use the following process and rules when configuring an IP access list:

• The software tests the source or destination address or the protocol of each packet being filtered against the conditions in the access list, one condition (permit or deny statement) at a time.

• If a packet does not match an access list statement, the packet is then tested against the next statement in the list.

• If a packet and an access list statement match, the remaining statements in the list are skipped and the packet is permitted or denied as specified in the matched statement. The first entry that the packet matches determines whether the software permits or denies the packet. That is, after the first match, no subsequent entries are considered.

• If the access list denies the address or protocol, the software discards the packet and returns an Internet Control Message Protocol (ICMP) Host Unreachable message. ICMP is configurable in the Cisco IOS XR software.

• If no conditions match, the software drops the packet because each access list ends with an unwritten or implicit deny statement. That is, if the packet has not been permitted or denied by the time it was tested against each statement, it is denied.

• The access list should contain at least one permit statement or else all packets are denied.

• Because the software stops testing conditions after the first match, the order of the conditions is critical. The same permit or deny statements specified in a different order could result in a packet being passed under one circumstance and denied in another circumstance.

• Only one access list per interface, per protocol, per direction is allowed.

• Inbound access lists process packets arriving at the router. Incoming packets are processed before being routed to an outbound interface. An inbound access list is efficient because it saves the overhead of
routing lookups if the packet is to be discarded because it is denied by the filtering tests. If the packet is permitted by the tests, it is then processed for routing. For inbound lists, permit means continue to process the packet after receiving it on an inbound interface; deny means discard the packet.

• Outbound access lists process packets before they leave the router. Incoming packets are routed to the outbound interface and then processed through the outbound access list. For outbound lists, permit means send it to the output buffer; deny means discard the packet.

• An access list can not be removed if that access list is being applied by an access group in use. To remove an access list, remove the access group that is referencing the access list and then remove the access list.

• Before removing an interface, which is configured with an ACL that denies certain traffic, you must remove the ACL and commit your configuration. If this is not done, then some packets are leaked through the interface as soon as the **no interface <interface-name>** command is configured and committed.

• An access list must exist before you can use the **ipv4 access group** command.

**ACL Filtering by Wildcard Mask and Implicit Wildcard Mask**

Address filtering uses wildcard masking to indicate whether the software checks or ignores corresponding IP address bits when comparing the address bits in an access-list entry to a packet being submitted to the access list. By carefully setting wildcard masks, an administrator can select a single or several IP addresses for permit or deny tests.

Wildcard masking for IP address bits uses the number 1 and the number 0 to specify how the software treats the corresponding IP address bits. A wildcard mask is sometimes referred to as an inverted mask, because a 1 and 0 mean the opposite of what they mean in a subnet (network) mask.

• A wildcard mask bit 0 means **check** the corresponding bit value.

• A wildcard mask bit 1 means **ignore** that corresponding bit value.

You do not have to supply a wildcard mask with a source or destination address in an access list statement. If you use the **host** keyword, the software assumes a wildcard mask of 0.0.0.0.

Unlike subnet masks, which require contiguous bits indicating network and subnet to be ones, wildcard masks allow noncontiguous bits in the mask.

You can also use CIDR format (/x) in place of wildcard bits. For example, the IPv4 address 1.2.3.4 0.255.255.255 corresponds to 1.2.3.4/8 and for IPv6 address 2001:db8:abcd:0012:0000:0000:0000:0000 corresponds to 2001:db8:abcd:0012::/64.

**Restrictions for Configuring Access Lists**

You must be aware of the following restrictions for configuring access lists.

• IPv4 and IPv6 ACLs are not supported for loopback and interflex interfaces.

• If the TCAM utilization is high and large ACLs are modified, then an error may occur. During such instances, remove the ACL from the interface and reconfigure the ACL. Later, reapply the ACL to the interface.

• Filtering of MPLS packets through interface ACL is not supported.
Including Comments in Access Lists

You can include comments (remarks) about entries in any named IP access list using the remark access list configuration command. The remarks make the access list easier for the network administrator to understand and scan. Each remark line is limited to 255 characters.

The remark can go before or after a permit or deny statement. You should be consistent about where you put the remark so it is clear which remark describes which permit or deny statement. For example, it would be confusing to have some remarks before the associated permit or deny statements and some remarks after the associated statements. Remarks can be sequenced.

Remember to apply the access list to an interface or terminal line after the access list is created.

Implementing Access Lists

Implementing ACLs involve:

1. Creating Standard or Extended ACLs-
   Create an ACL that includes an action element (permit or deny) and a filter element based on criteria such as source address, destination address, protocol, and protocol-specific parameters.

2. Applying the ACL to specific interfaces-
   After configuring an access list, you must reference the access list to make it work. Access lists can be applied on inbound interfaces. After receiving a packet, Cisco IOS XR software checks the source address of the packet against the access list. If the access list permits the address, the software continues to process the packet. If the access list rejects the address, the software discards the packet and returns an ICMP host unreachable message. The ICMP message is configurable.

   When you apply an access list that has not yet been defined to an interface, the software acts as if the access list has not been applied to the interface and accepts all packets. Note this behavior if you use undefined access lists as a means of security in your network.

The other actions that can be performed on an ACL are:

- Copying Access Lists—
  Users can create a copy of an existing access list using the copy access-list ipv4 | ipv6 command.

- Adding or Deleting Access-List Entries
If there is no match to either permit or deny the packets, then the default action is to drop the packet.

### Configuring Extended Access Lists

#### Configuration Example

Creates an IPv4 named access list "acl_1". This access list permits ICMP protocol packets with any source and destination IPv4 address and denies TCP protocol packets with any source and destination IPv4 address and port greater than 5000.

```
Router# configure
Router(config)# ipv4 access-list acl_1

Router(config-ipv4-acl)# 20 permit icmp any any
Router(config-ipv4-acl)# 30 deny tcp any any gt 5000
Router(config-ipv4-acl)# commit
```

#### Running Configuration

```
Router# show running-config ipv4 access-list acl_1
ipv4 access-list acl_1
  20 permit icmp any any
  30 deny tcp any any gt 5000
!
```

#### Verification

Verify that the permit and deny settings are according to the set configuration.

```
Router# show access-lists acl_1
ipv4 access-list acl_1
  20 permit icmp any any
  30 deny tcp any any gt 5000
Router#
```

**Associated Commands**

IPv4 Commands:
- `ipv4 access-list`
- `permit (IPv4)`
- `remark(IPv4)`
- `deny (IPv4)`

**What to Do Next**

After creating an access list, you must apply it to a line or an interface. ACL commit fails while adding and removing unique Access List Entries (ACE). This happens due to the absence of an assigned manager process. The user has to exit the ACL configuration mode and re-enter it before adding the first ACE.

### Configuring Standard Access Lists

**Configuration Example**

Creates an IPv4 named access list "acl_1" with a remark "Do not allow user1 to telnet out". This access list permits packets from the source address of "172.16.0.0" with a wild-card mask of "0.0.255.255"

Router# `configure`  
Router(config)# `ipv4 access-list acl_1`

Router(config-ipv4-acl)# `10 remark Do not allow user1 to telnet out`  
Router(config-ipv4-acl)# `20 permit 172.16.0.0 0.0.255.255`  
/* Repeat the above step as necessary, adding statements by sequence number where you planned.*/  
Use the no sequence-number command to delete an entry */

Router(config-ipv4-acl)# `commit`

**Running Configuration**

Router# `show running-config ipv4 access-list acl_1`  
ipv4 access-list acl_1  
10 remark Do not allow user1 to telnet out  
20 permit ipv4 172.16.0.0 0.0.255.255 any

**Verification**

Verify that the permit and remark settings are according to the set configuration.

Router# `show access-lists ipv4 acl_1`  
ipv4 access-list acl_1  
10 remark Do not allow user1 to telnet out  
20 permit ipv4 172.16.0.0 0.0.255.255 any

**Associated Commands**

IPv4 Commands:
- ipv4 access-list
- remark(IPv4)
- permit (IPv4)
- deny (IPv4)
- show access-lists ipv4

What to Do Next

After creating an access list, you must apply it to a line or an interface. ACL commit fails while adding and removing unique Access List Entries (ACE). This happens due to the absence of an assigned manager process. The user has to exit the config-ipv4-acl or config-ipv6-acl mode to configuration mode and re-enter the same mode before adding the first ACE.

Applying Access Lists

Configuration Example

Applies the access lists on the interface, which acts as filters on packets inbound from TenGigE interface 0/0/0/2.

Router# configure
Router(config)# interface TenGigE 0/0/0/2
Router(config-if)# ipv4 access-group acl_1 ingress

Router(config-ipv4-acl)# commit

Verification

Verify that the ACL applied (acl_1) on the interface is listed:

Router #show access-lists interface TenGigE 0/0/0/2
Input ACL
(common): N/A
(interface): acl_1
Output ACL: N/A
Router#

Associated Commands

IPv4 Commands:

- ipv4 access-group
- show access-lists ipv4

Ingress ACL over BVI

You can configure ACL over Bridge Virtual Interface (BVI). If you configure ACLs over BVIs, L3 traffic flows are filtered based on the ACLs applied on BVI interfaces and L2 traffic flows are filtered based on the ACLs applied on bridge domain interfaces. Otherwise, both L2 and L3 traffic are filtered based on the ACLs applied on bridge domain interfaces. Therefore, configuration of ACL over BVI reduces load on core traffic for routing and improves overall performance of the network.
BVI can have bridge association ports from different TCAM pipes. Therefore, ACL rules are replicated and programmed on all the TCAM pipes.

**Restrictions**

Consider the following restrictions when you configure ACL over BVI:

- On a BVI interface, Multicast packets cannot be filtered using ACL rules. So, the Multicast packets would not be accounted in the ACL rules. To overcome this discrepancy, the same ACL rule can be configured as a bridge domain ACL to do corresponding actions (permit/deny).

- Though the multicast packets are not filtered on the basis of ACL over BVI, you need to configure an ACL rule to prevent OSPF packets from hitting the implicit deny rule and be dropped in the control plane. If you do not configure an ACL rule over BVI to handle OSPF packets, OSPF sessions wouldn’t be established.

- ACL TCAM region is shared among interfaces, but configuration of BVI over ACL cannot be shared to other interfaces (physical/sub-interface/Bundle-interface/Bundle-Sub Interface) or vice-versa.

**Configure ACL over BVI**

Use the following steps to configure ACL over BVI.

1. Enter the global configuration mode and configure an ACL.

2. Configure ACL over BVI.

**Configuration Example**

/* Enter the global configuration mode and configure an ACL */
Router# configure
Router(config)# ipv4 access-list alpha-acl
Router(config-ipv4-acl)# permit ipv4 any any
Router(config-ipv4-acl)# commit
Router(config-ipv4-acl)# exit

/* Configure ACL over BVI */
Router(config)# int BVI 1
Router(config-if)# ipv4 access-group alpha-acl ingress
Router(config-12vpn-bg-bd-bvi)# commit

**Verification**

Use the following command to verify the ACL applied on hardware (L3 interfaces):

Router# show access-lists alpha-acl hardware ingress location 0/RP0/CPU0

ipv4 access-list alpha-acl
10 permit ipv4 any any (100 hw matches)

Use the following command to get detailed information about ACL applied on hardware:

Router# show feature-mgr client pfilter-ea feature-info feature-name alpha-acl direction ingress lookup ipv4 interface BVI 1 location 0/RP0/CPU0

*Feature name*: alpha-acl
*Lookup Type*: IPV4_PFILTER (L3)
**Sequencing Access List Entries and Revising the Access List**

**Configuration Example**

Assigns sequence numbers to entries in an access list and explains how to add or delete an entry to or from an access list. In this configuration, it is assumed that a user wants to revise an access list.

Resequences entries in the access list “acl_1”. The starting value in the resequenced access list is 20, and increment value is 15.

When an ACL is configured under an interface and its resequenced and rolled back, the interface experiences traffic loss for a short period of time.

```plaintext
Router# configure
Router(config)# ipv4 access-list acl_1

Router(config-ipv4-acl)# 10 permit 10.1.1.1
*/Repeat the above step as necessary adding statements by sequence number where you planned*/
Router(config-ipv4-acl)# 20 permit 10.2.0.0 0.0.255.255
Router(config-ipv4-acl)# no 25
*/Use the no sequence-number command to delete an entry with that specific sequence number*/
Router(config-ipv4-acl)# 30 permit tcp host 10.2.2.2 255.255.0.0 any eq telnet
Router(config-ipv4-acl)# commit
d

Router# resequence access-list ipv4 acl_1 20 15
```
Running Configuration

Before resequencing:
Router# show running-config ipv4 access-list acl_1
ipv4 access-list acl_1
10 remark Do not allow user1 to telnet out
20 permit ipv4 172.16.0.0 0.0.255.255 any
!

/*After resequencing using the resequence access-list ipv4 acl_1 20 15 command*/:

Router# show running-config ipv4 access-list acl_1
ipv4 access-list acl_1
20 permit ipv4 host 10.1.1.1 any
35 permit ipv4 10.2.0.0 0.0.255.25 any
50 permit ipv4 10.1.1.1/24 any
65 permit tcp host 10.2.2.2 any eq telnet
!

Verification

Verify that the access list (acl_1) contains all permit and deny options (after resequencing) that were configured:

Router# show access-lists ipv4 acl_1
ipv4 access-list acl_1
20 permit ipv4 host 10.1.1.1 any
35 permit ipv4 10.2.0.0 0.0.255.25 any
50 permit ipv4 10.1.1.1/24 any
65 permit tcp host 10.2.2.2 any eq telnet

Associated Commands

IPv4 Commands:

• resequence access-list ipv4
• ipv4 access-list
• permit (IPv4)
• show access-lists ipv4

Use case

This use case explains how to create, resequence, add new entries, delete an entry and verify the ACL:

/* Create an Access List*/
Router(config)# ipv4 access-list acl_1
/* Add entries (ACEs) to the ACL */
Router(config-ipv4-acl)# 10 permit ip host 10.3.3.3 host 172.16.5.34
Router(config-ipv4-acl)# 20 permit icmp any any
Router(config-ipv4-acl)# 30 permit tcp any host 10.3.3.3
Router(config-ipv4-acl)# end

/* Verify the entries of the ACL */
Router# show access-lists ipv4 acl_1
ipv4 access-list acl_1
10 permit ip host 10.3.3.3 host 172.16.5.34
20 permit icmp any any
30 permit tcp any host 10.3.3.3
/* Resequence the ACL */
Router(config)#resequence ipv4 access-list acl_1 10 20
/* 10 indicates the starting value in the resequenced ACL and the subsequent entries in the
original ACL are incremented by 20 */

/* Verify the entries of the ACL */
Router#show access-lists ipv4 acl_1
10 permit ip host 10.3.3.3 host 172.16.5.34
30 permit icmp any any
50 permit tcp any host 10.3.3.3

/* Add new entries, one with a sequence number "15" and another without a sequence number
to the ACL. Delete an entry with the sequence number "30" */
Router(config)#ipv4 access-list acl_1
Router(config-ipv4-acl)# 15 permit 10.5.5.5 0.0.0.255
Router(config-ipv4-acl)# no 30
Router(config-ipv4-acl)# permit 10.4.4.4 0.0.0.255

/* When an entry is added without a sequence number, it is automatically given a sequence
number that puts it at the end of the access list. Because the default increment is 10, the entry
will have a sequence number 10 higher than the last entry in the existing access list */

/* Verify the entries of the ACL */
Router(config)#show access-lists ipv4 acl_1
10 permit ip host 10.3.3.3 host 172.16.5.34
15 permit 10.5.5.5 0.0.0.255---/* newly added ACE (with the sequence number) */
50 permit tcp any host 10.3.3.3
60 permit 10.4.4.4 0.0.0.255---/* newly added ACE (without the sequence number) */
/* The entry with the sequence number 30, that is, "30 permit icmp any any" is deleted from
the ACL */

Understanding Prefix Lists

Prefix lists are used in route maps and route filtering operations and can be used as an alternative to access
lists in many Border Gateway Protocol (BGP) route filtering commands. A prefix is a portion of an IP address,
starting from the far left bit of the far left octet. By specifying exactly how many bits of an address belong to
a prefix, you can then use prefixes to aggregate addresses and perform some function on them, such as
redistribution (filter routing updates).

BGP Filtering Using Prefix Lists

Prefix lists can be used as an alternative to access lists in many BGP route filtering commands. It is configured
under the Global configurations of the BGP protocol. The advantages of using prefix lists are as follows:

- Significant performance improvement in loading and route lookup of large lists.
- Incremental updates are supported.
- More user friendly CLI. The CLI for using access lists to filter BGP updates is difficult to understand
  and use because it uses the packet filtering format.
- Greater flexibility.

Before using a prefix list in a command, you must set up a prefix list, and you may want to assign sequence
numbers to the entries in the prefix list.
How the System Filters Traffic by Prefix List

Filtering by prefix list involves matching the prefixes of routes with those listed in the prefix list. When there is a match, the route is used. More specifically, whether a prefix is permitted or denied is based upon the following rules:

- An empty prefix list permits all prefixes.
- An implicit deny is assumed if a given prefix does not match any entries of a prefix list.
- When multiple entries of a prefix list match a given prefix, the longest, most specific match is chosen.

Sequence numbers are generated automatically unless you disable this automatic generation. If you disable the automatic generation of sequence numbers, you must specify the sequence number for each entry using the `sequence-number` argument of the `permit` and `deny` commands in IPv4 prefix list configuration command. Use the `no` form of the `permit` or `deny` command with the `sequence-number` argument to remove a prefix-list entry.

The `show` commands include the sequence numbers in their output.

Configuring Prefix Lists

Configuration Example

Creates a prefix-list "pfx_2" with a remark "Deny all routes with a prefix of 10/8". This prefix-list denies all prefixes matching /24 in 128.0.0.0/8.

```
Router#configure
Router(config)#ipv4 prefix-list pfx_2

Router(config-ipv4_pfx)#10 remark Deny all routes with a prefix of 10/8
Router(config-ipv4_pfx)#20 deny 128.0.0.0/8 eq 24

/* Repeat the above step as necessary. Use the no sequence-number command to delete an entry. */

Router(config-ipv4_pfx)#commit
```

Running Configuration

```
Router#show running-config ipv4 prefix-list pfx_2
ipv4 prefix-list pfx_2
  10 remark Deny all routes with a prefix of 10/8
  20 deny 128.0.0.0/8 eq 24

! 
```

Verification

Verify that the permit and remark settings are according to the set configuration.

```
Router# show prefix-list pfx_2
ipv4 prefix-list pfx_2
  10 remark Deny all routes with a prefix of 10/8
  20 deny 128.0.0.0/8 eq 24
RP/0/RP0/CPU0:ios# 
```
Associated Commands

IPv4 Commands:

- `ipv4 prefix-list`
- `show prefix-list ipv4`

Sequencing Prefix List Entries and Revising the Prefix List

Configuration Example

Assigns sequence numbers to entries in a named prefix list and how to add or delete an entry to or from a prefix list. It is assumed a user wants to revise a prefix list. Resequencing a prefix list is optional.

```
Router# config
Router(config)# ipv4 prefix-list cl_1

Router(config)# 10 permit 172.16.0.0 0.0.255.255
/* Repeat the above step as necessary adding statements by sequence number where you planned; use the no sequence-number command to delete an entry */

Router(config)# commit
end
Router# resequence prefix-list ipv4 cl_1 20 15
```

Running Configuration

/* Before resequencing */
```
Router# show running-config ipv4 prefix-list cl_1
ipv4 prefix-list cl_1
  10 permit 172.16.0.0/16
!
/* After resequencing using the resequence prefix-list ipv4 cl_1 20 15 command: */
Router# show running-config ipv4 prefix-list cl_1
ipv4 prefix-list cl_1
  35 permit 172.16.0.0/16
!
```

Verification

Verify that the prefix list has been resequenced:
```
Router# show prefix-list cl_1
ipv4 prefix-list cl_1
  35 permit 172.16.0.0/16
```

Associated Commands

IPv4 Commands:

- `resequence prefix-list ipv4`
- `ipv4 prefix-list`
- `show prefix-lists ipv4`
Understanding Access Lists and Prefix Lists

Atomic ACL Updates By Using the Disable Option

Atomic ACL updates involve the insertion, modification, or removal of Access List Entries (ACEs) on an interface that is in operation. Such atomic updates consume up to 50% of TCAM resources. There can be an instance where multiple modifications are required and the available resources are not sufficient. The solution to this problem is to disable atomic ACL updates such that the old ACEs are deleted before the new ACEs are added.

Note
When you configure the `atomic-disable` statement in an ACL, any ACE modification detaches the ACL, until the modification is complete. In addition to this, the ACL rules are not applied during the modification process. Hence, it is recommended to configure to either permit or deny all traffic until the modification is complete.

Configuration for Disabling Atomic ACL Updates

To disable atomic updates on the hardware, by permitting packets that match the ACE rule, use the following configuration.

```
RP/0/RP0/CPU0:router# hardware access-list atomic-disable default-action permit
```

To disable atomic updates on the hardware, by denying all packets until the modification is complete, use the following configuration.

```
RP/0/RP0/CPU0:router# hardware access-list atomic-disable
```

Modifying ACLs when Atomic ACL Updates are Disabled

On disabling atomic ACL updates on the hardware, use the steps in this section to modify ACLs.

Add an ACE

Use the following steps to add an ACE.

1. Locate the ACL you want to modify.

```
RP/0/RP0/CPU0:router(config)# do show access-lists
...
ipv4 access-list list1
10 permit ipv4 10.1.1.0/24 any
20 permit ipv4 20.1.1.0/24 any
```

2. Add the ACE to the ACL.
3. Verify if your ACE was added successfully.

```
RP/0/RP0/CPU0:router(config)# do show access-lists
...!
ipv4 access-list list1
 10 permit ipv4 10.1.1.0/24 any
 20 permit ipv4 20.1.1.0/24 any
 30 permit ipv4 30.1.1.0/24 any
!
```

You have successfully added an ACE.

**Delete an ACE**

Use the steps in this section to delete an ACE.

1. Locate the ACL containing the ACE that you want deleted.

```
RP/0/RP0/CPU0:router(config)# do show access-lists
...!
ipv4 access-list list1
 10 permit ipv4 10.1.1.0/24 any
 20 permit ipv4 20.1.1.0/24 any
 30 permit ipv4 30.1.1.0/24 any
!
```

2. Delete the ACE.

```
RP/0/RP0/CPU0:router(config)# ipv4 access-list list1
RP/0/RP0/CPU0:router(config-ipv4-acl)# no 30
RP/0/RP0/CPU0:router(config-ipv4-acl)# commit
```

3. Verify if the ACE has been removed from the ACL.

```
RP/0/RP0/CPU0:router(config-ipv4-acl)# do show access-lists
...!
ipv4 access-list list1
 10 permit ipv4 10.1.1.0 0.0.0.255 any
 20 permit ipv4 20.1.1.0 0.0.0.255 any
!
```

You have successfully deleted an ACE.

**Replace an ACE**

Use the steps in this section to replace an ACE.

1. Locate the ACL you want to modify.

```
RP/0/RP0/CPU0:router(config-ipv4-acl)#do show access-lists
...!
ipv4 access-list list1
 10 permit ipv4 10.1.1.0 0.0.0.255 any
 20 permit ipv4 20.1.1.0 0.0.0.255 any
```

2. Configure the new ACE to replace the existing ACE.
3. Verify if the ACE replacement is successful.

```
RP/0/RP0/CPU0:router(config)# do show access-lists
...  
ipv4 access-list list1
   10 permit ipv4 11.1.1.0 0.0.0.255 any
   20 permit ipv4 20.1.1.0 0.0.0.255 any
```

You have successfully replaced an ACE.

Delete an ACE and Add a New ACE

Use the following steps to delete an ACE and add a new ACE.

1. Locate the ACL you want to modify.

```
RP/0/RP0/CPU0:router(config)# do show access-lists
...  
ipv4 access-list list1
   10 permit ipv4 11.1.1.0 0.0.0.255 any
   20 permit ipv4 20.1.1.0 0.0.0.255 any
```

2. Delete the required ACE, and add the new ACE.

```
RP/0/RP0/CPU0:router(config)# ipv4 access-list list1
RP/0/RP0/CPU0:router(config-ipv4-acl)# no 20
RP/0/RP0/CPU0:router(config-ipv4-acl)# permit ipv4 12.1.1.0/24 any
RP/0/RP0/CPU0:router(config-ipv4-acl)# commit
```

3. Verify if the modification is successful.

```
RP/0/RP0/CPU0:router(config)# do show access-lists
...  
ipv4 access-list list1
   10 permit ipv4 11.1.1.0 0.0.0.255 any
   20 permit ipv4 12.1.1.0 0.0.0.255 any
```

You have successfully deleted an ACE, and added a new ACE.

Similarly, you can combine the addition, removal, and replacement of ACEs.
Implementing Cisco Express Forwarding

Cisco Express Forwarding (CEF) is an advanced, Layer 3 IP switching technology. CEF optimizes network performance and scalability for networks with large and dynamic traffic patterns, such as the Internet, on networks characterized by intensive web-based applications, or interactive sessions. CEF is an inherent feature and the users need not perform any configuration to enable it. If required, the users can change the default route purge delay and static routes.

Components

Cisco IOS XR software CEF always operates in CEF mode with two distinct components:

- Forwarding Information Base (FIB) database: The protocol-dependent FIB process maintains the forwarding tables for IPv4 and IPv6 unicast in the route processor. The FIB on each node processes Routing Information Base (RIB) updates, performing route resolution and maintaining FIB tables independently in the route processor. FIB tables on each node can be slightly different.
- Adjacency table—a protocol-independent adjacency information base (AIB)

Adjacency FIB entries are maintained only on a local node, and adjacency entries linked to FIB entries could be different.

CEF is a primary IP packet-forwarding database for Cisco IOS XR software. CEF is responsible for the following functions:

- Software switching path
- Maintaining forwarding table and adjacency tables (which are maintained by the AIB) for software and hardware forwarding engines

The following features are supported for CEF on Cisco IOS XR software:
- Bundle interface support
- Multipath support
- Route consistency
- High availability features such as packaging, restartability, and Out of Resource (OOR) handling
- OSPFv2 SPF prefix prioritization
- BGP attributes download

**CEF Benefits**

- Improved performance—CEF is less CPU-intensive than fast-switching route caching. More CPU processing power can be dedicated to Layer 3 services such as quality of service (QoS) and encryption.
- Scalability—CEF offers full switching capacity at each line card.
- Resilience—CEF offers an unprecedented level of switching consistency and stability in large dynamic networks. In dynamic networks, fast-switched cache entries are frequently invalidated due to routing changes. These changes can cause traffic to be process switched using the routing table, rather than fast switched using the route cache. Because the Forwarding Information Base (FIB) lookup table contains all known routes that exist in the routing table, it eliminates route cache maintenance and the fast-switch or process-switch forwarding scenario. CEF can switch traffic more efficiently than typical demand caching schemes.

The following CEF forwarding tables are maintained in Cisco IOS XR software:

- IPv4 CEF database—Stores IPv4 Unicast routes for forwarding IPv4 unicast packets
- IPv6 CEF database—Stores IPv6 Unicast routes for forwarding IPv6 unicast packets
- MPLS LFD database—Stores MPLS Label table for forwarding MPLS packets

**Verifying CEF**

To view the details of the IPv4 or IPv6 CEF tables, use the following commands:

- `show cef {ipv4 address|ipv6 address} hardware egress`

Displays the IPv4 or IPv6 CEF table. The next hop and forwarding interface are displayed for each prefix. The output of the `show cef` command varies by location.
Displays a summary of the IPv4 or IPv6 CEF table.

Router# show cef ipv4 summary
Router ID is 0.0.0.0
IP CEF with switching (Table Version 0) for node0_RP0_CPU0
Load balancing: L4
Tableid 0xe0000000 (0x8a2d7380), Vrfid 0x60000000, Vrid 0x20000000, Flags 0x1019
Vrfname default, Refcount 88
39 routes, 0 protected, 0 reresolve, 0 unresolved (0 old, 0 new), 9048 bytes
11 rib, 0 lsd, 17:0 aib, 0 internal, 8 interface, 4 special, 1 default routes
39 load sharing elements, 32176 bytes, 2 references
2 shared load sharing elements, 1600 bytes
37 exclusive load sharing elements, 30576 bytes
0 route delete cache elements
24 local route bufs received, 0 remote route bufs received, 0 mix bufs received
11 local routes, 0 remote routes
26 total local route updates processed
0 total remote route updates processed
0 pkts pre-routed to cust card
0 pkts pre-routed to rp card
0 pkts received from core card
0 CEF route update drops, 2 revisions of existing leaves
0 CEF route update drops due to version mis-match
Resolution Timer: 15s
0 prefixes modified in place
0 deleted stale prefixes
0 prefixes with label imposition, 0 prefixes with label information
0 LISP EID prefixes, 0 merged, via 0 rlocs
20 next hops
0 incomplete next hops
0 PD backwalks on LDIs with backup path

Displays the details of the IPv4 or IPv6 CEF table.

• show cef {ipv4 address|ipv6 address} detail
Unicast Reverse Path Forwarding

Configuration of Unicast IPv4 and IPv6 Reverse Path Forwarding (uRPF) enables a router to verify the reachability of the source address in packets being forwarded. Configuring uRPF, both strict and loose modes, helps to mitigate problems caused by the introduction of spoofed IP source addresses into a network. Configuration of uRPF discards IP packets that lack a verifiable IP source address after a reverse lookup in the CEF table.

When strict uRPF is enabled, the source address of the packet is checked in the FIB. If the packet is received on the same interface that would be used to forward the traffic to the source of the packet, the packet passes...
the check and is further processed. Otherwise, the packet is dropped. Configure strict uRPF only where there is natural or configured symmetry. Internal interfaces are likely to have a routing asymmetry, that is, multiple routes to the source of a packet. Therefore, you should not implement strict uRPF on interfaces that are internal to the network.

Implementation of strict mode uRPF requires maintenance of a uRPF interfaces list for the prefixes. The list contains only the interfaces configured with strict mode uRPF. The interfaces are provided by the prefix path. The uRPF interface list is shared among the prefixes wherever possible.

When loose uRPF is enabled, the source address of the packet is checked in the FIB. If the source address exists and matches a valid forwarding entry, the packet passes the check and is further processed. Otherwise, the packet is dropped.

**Note**

The behavior of strict uRPF varies slightly on the basis of platforms, the number of recursion levels, and the number of paths in Equal-Cost Multipath (ECMP) scenarios. A platform may switch to loose uRPF check for some or all prefixes, even though strict uRPF is configured. For example, if ECMP Path is eight or more, strict mode is converted to loose mode.

Loose and strict uRPF supports two options: allow self-ping and allow default. The allow self-ping option allows the source of the packet to ping itself. The allow default option allows the lookup result to match a default routing entry. When the allow default option is enabled with the strict mode of the uRPF, the packet is processed further only if it arrives through the default interface.

**Restrictions**

Consider the following restrictions when you configure uRPF:

- Global configuration followed by cold reload is required to enable or disable uRPF on the router.
- Configuration of uRPF per interface enables or disables uRPF mode in the hardware of the corresponding interface.
- Configuration of uRPF reduces the route scale to half. Half of the routing table is used for destination lookup and the other half is used for source lookup of received packets.
- Unicast RPF allows packets with 0.0.0.0 source addresses and 255.255.255.255 destination addresses to pass so that Bootstrap Protocol and Dynamic Host Configuration Protocol (DHCP) functions properly.
- Unicast RPF allows packets whose destination IP address is not a unicast address.
- The behavior of strict uRPF varies slightly on the basis of platforms, the number of recursion levels, and the number of paths in Equal-Cost Multipath (ECMP) scenarios. A platform may switch to loose uRPF check for some or all prefixes, even though strict uRPF is configured.
- The allow self-ping option is the default option in uRPF configuration for both strict and loose mode. You cannot disable the allow-self-ping option. The allow-default option needs to be configured specifically per interface.
In Figure 1, uRPF is enabled on Router R2 and R2 has the following FIB table entries:

- 10.1.1.0/24 [110/3] via 10.25.24.1, 2d08h, HundredGigE0/0/0/24
- 12.1.1.0/24 [110/3] via 10.25.24.1, 2d08h, HundredGigE0/0/0/25
- 14.0.5.0/24 [110/3] via 20.0.0.2, 2d08h, HundredGigE0/0/0/1

R2 allows the packet from Host 1 to be routed because Host 1 subnet is available in R2’s FIB table. However, R2 does not allow Host 3 to be routed because Host 3 subnet is not available in R2’s FIB table. If strict uRPF is enabled on R2, then the source address 10.1.1.1/24 should be reachable through the same interface from which it is received. If loose uRPF is enabled on R2, then it is not mandatory that the source address 10.1.1.1/24 be reachable through the same interface from which it is received. The only criteria for a packet to be forwarded is that the host address should be present in R2’s FIB table.

Configure Unicast Reverse Path Forwarding

Configuring Unicast Reverse Path Forwarding (uRPF) enables a router to verify the reachability of the source address of packets being forwarded. If the source IP address is not valid, the packet is discarded. This capability can limit the appearance of spoofed addresses in a network.

To configure uRPF on a hardware module, use the following steps:

1. Configure a hardware module in the global configuration mode and enable uRPF.
2. Reboot the router.
3. Configure an interface.
4. Configure IPv4 or IPv6 uRPF through strict or loose mode under the interface.

Configuration

Use the following configuration to configure uRPF in strict mode:

```bash
/* Configure a hardware module in the global configuration mode and enable uRPF. */
Router# configure
Router(config)# hw-module urpf enable
Mon Sep 17 09:34:00.945 UTC
In order to activate/deactivate urpf, you must manually reboot the box.
Router(config)# commit

/* Reboot the router manually. */
```

```bash
/* Configure an interface. */
```
Per-Flow Load Balancing

The system inherently supports the 5-tuple hash algorithm. Load balancing describes the functionality in a router that distributes packets across multiple links based on Layer 3 (network layer) and Layer 4 (transport layer) routing information. If the router discovers multiple paths to a destination, the routing table is updated with multiple entries for that destination.

Per-flow load balancing performs these functions:
Incoming data traffic is evenly distributed over multiple equal-cost connections.

Incoming data traffic is evenly distributed over multiple equal-cost connections member links within a bundle interface.

Layer 2 bundle and Layer 3 (network layer) load balancing decisions are taken on IPv4, IPv6, and MPLS flows which are supported for the 5-tuple hash algorithm.

A 5-tuple hash algorithm provides more granular load balancing and used for load balancing over multiple equal-cost Layer 3 (network layer) paths. The Layer 3 (network layer) path is on a physical interface or on a bundle interface. In addition, load balancing over member links can occur within a Layer 2 bundle interface.

The 5-tuple load-balance hash calculation contains:

- Source IP address
- Destination IP address
- Router ID
- Source port
- Destination port

Configuring Static Route

Routers forward packets using either route information from route table entries that you manually configure or the route information that is calculated using dynamic routing algorithms. Static routes, which define explicit paths between two routers, cannot be automatically updated; you must manually reconfigure static routes when network changes occur. Static routes use less bandwidth than dynamic routes. Use static routes where network traffic is predictable and where the network design is simple. You should not use static routes in large, constantly changing networks because static routes cannot react to network changes. Most networks use dynamic routes to communicate between routers but might have one or two static routes configured for special cases. Static routes are also useful for specifying a gateway of last resort (a default router to which all unroutable packets are sent).

Configuration Example

Create a static route between Router A and B over a TenGigE interface. The destination IP address is 37.37.37.37/32 and the next hop address is 1.0.0.2.

```
Router(config)# router static address-family ipv4 unicast
Router(config-static-afi)# 37.37.37.37/32 tengige 0/0/0/0 1.0.0.2
Router(config-static-afi)# commit
```

Running Configuration

```
Router# show running-config router static address-family ipv4 unicast
router static
  address-family ipv4 unicast
```
Verification

Verify that the Next Hop Flags fields indicate COMPLETE for accurate functioning of the configuration.

```
show cef 37.37.37.32 hardware egress
```

Next Hop Flags: COMPLETE—This indicates that the router can forward traffic.

**Associated Commands**

- `show cef`
Implementing LPTS

LPTS Overview

Local Packet Transport Services (LPTS) maintains tables describing all packet flows destined for the secure domain router (SDR), making sure that packets are delivered to their intended destinations.

LPTS uses two components to accomplish this task: the port arbitrator and flow managers. The port arbitrator and flow managers are processes that maintain the tables that describe packet flows for a logical router, known as the Internal Forwarding Information Base (IFIB). The IFIB is used to route received packets to the correct Route Processor for processing.

LPTS interfaces internally with all applications that receive packets from outside the router. LPTS functions without any need for customer configuration. However, the policer values can be customized if required. The LPTS show commands are provided that allow customers to monitor the activity and performance of LPTS flow managers and the port arbitrator.

LPTS Policers

In Cisco IOS XR, the control packets, which are destined to the Route Processor (RP), are policed using a set of ingress policers in the incoming ports. These policers are programmed statically during bootup by LPTS components. The policers are applied based on the flow type of the incoming control traffic. The flow type is determined by looking at the packet headers. The policer rates for these static ingress policers are defined in a configuration file, which are programmed on the route processor during bootup. You can change the policer values based on the flow types of these set of ingress policers. You are able to configure the rate per policer per node.

Configuration Example

Configure the LPTS policer for the OSPF and BGP flowtypes with the following values:

- ospf unicast default rate 200
- bgp configured rate 200
• bgp default rate 100

Router#configure
Router(config)#lpts pifib hardware police
Router(config-pifib-policer-global)#flow ospf unicast default rate 200
Router(config-pifib-policer-global)#flow bgp configured rate 200
Router(config-pifib-policer-global)#flow bgp default rate 100
Router (config-pifib-policer-global)#commit

Running Configuration
lpts pifib hardware police
flow ospf unicast default rate 200
flow bgp configured rate 200
flow bgp default rate 100
!

Verification
Router#show run lpts pifib hardware police
lpts pifib hardware police
flow ospf unicast default rate 200
flow bgp configured rate 200
flow bgp default rate 100
!

The show lpts pifib hardware police location 0/RP0/CPU0 command displays pre-Internal Forwarding Information Base (IFIB) information for the designated node.

Configuration Example

Configure the LPTS policer for the OSPF and BGP flow types with the following values:

• ospf unicast default rate 100

• bgp configured rate 300

Router#configure
Router(config)#lpts pifib hardware police
Router(config-pifib-policer-per-node)#flow ospf unicast default rate 200
Router(config-pifib-policer-per-node)#flow bgp configured rate 200
Router(config-pifib-policer-per-node)#flow bgp default rate 100
Router(config-pifib-policer-per-node)#commit

Running Configuration
lpts pifib hardware police location 0/RP0/CPU0
flow ospf unicast default rate 100
flow bgp configured rate 300
!

Verification
Router#show run lpts pifib hardware police
lpts pifib hardware police
flow ospf unicast default rate 100
flow bgp configured rate 300
!
### Verification

The `show controllers npu stats traps-all instance all location 0/0/CPU0` command displays packets that are locally processed and packets that are dropped by the CPU.

```
Router# show controllers npu stats traps-all instance all location 0/0/CPU0
```

**Understanding ACL-based Policers**

ACL-based LPTS policers are session-based policers that provide secure network access for each session.

**Benefits**

These are the benefits of ACL-based policer:

- Provides rate limit on incoming packets based on session.
- Modifies policer rates depending on traffic load.
- Blocks entire traffic based on a specific session without impacting other sessions with the same flow.

**Restrictions**

- It is recommended to have up to 10 prefixes in a single ACL. The ACEs in an ACL should be managed such that there is no overlap of prefixes.
- Up to 50 ACL-based LPTS policers can be configured on a router.
ACL-based LPTS policers can be configured to an IPv4 LPTS session that has a particular flow type and that matches the default VRF.

ACL-based LPTS policers can be configured to an IPv4 or IPv6 LPTS session that has a particular flow type and that matches the VRF ID.

**Configure IPv4 ACL-based LPTS Policers**

This section describes how you can configure IPv4 ACL-based LPTS policers.

**Configuration Example**

To configure ACL-based LPTS policers for IPv4 sessions, complete the following configurations:

1. Configure an ACL.
2. Configure LPTS policer for a particular IPv4 session matching an ACL and VRF.

**Configuration**

/* Enter the global configuration mode and configure an ACL */
Router# configure
Router(config)# ipv4 access-list ACL1_OSPF
Router(config-ipv4-acl)# 10 permit ipv4 host 192.168.1.5 any
Router(config-ipv4-acl)# commit
Router(config-ipv4-acl)# exit

/* Configure LPTS policer for a particular IPv4 session matching an ACL and VRF. */
Router(config)# lpts pifib hardware police
Router(config-pifib-policer-global)# acl ACL1_OSPF rate 2000 vrf red8
Router(config-if)# commit

**Verification**

Use the following command to display the ACL-based LPTS policer entries attached to matching entries:

```
Router# show lpts pifib hardware entry statistics location 0/RP0/CPU0
```

Configure IPv6 ACL-based LPTS Policers

This section describes how you can configure IPv6 ACL-based LPTS policers.
Configuration Example

To configure ACL-based LPTS policers for IPv6 sessions, complete the following configurations:

1. Configure a VRF.
2. Configure an ACL.
3. Configure LPTS policer for a particular IPv6 session matching an ACL and VRF ID.

Configuration

/* Enter the global configuration mode and configure an VRF */
Router# configure
Router(config)# vrf red83
Router(config)# commit

/* Configure an ACL */
Router(config)# ipv6 access-list ACL33
Router(config-ipv6-acl)# 10 permit ipv6 host 4000:21::1 host 4000:21::2
Router(config-ipv6-acl)# 60 permit ipv6 host 4000:53::1 host 4000:53::2
Router(config-ipv6-acl)# commit
Router(config-ipv6-acl)# exit

/* Configure LPTS policer for a particular IPv6 session matching an ACL and VRF ID. */
Router(config)# lpts pifib hardware police
Router(config-pifib-policer-global)# acl ACL33 rate 5000 vrf red83 ipv6
Router(config-pifib-policer-global)# commit

Verification

Use the following command to display the ACL-based LPTS policer entries attached to matching entries:

Router# show lpts pifib hardware entry statistics location 0/RP0/CPU0

Implementing VRRP

- Configuring VRRP, on page 99
- Enabling Multiple Group Optimization (MGO) for VRRP, on page 107
- Configuring SNMP Server Notifications for VRRP Events, on page 108

Configuring VRRP

The Virtual Router Redundancy Protocol (VRRP) feature allows for transparent failover at the first-hop IP router, enabling a group of routers to form a single virtual router. For more information on VRRP and related concepts, see Understanding VRRP, on page 99.

Restrictions for Configuring VRRP

- Upto 64 VRRP sessions are permitted on Cisco NCS 5001 and NCS 5002 routers (including Hot Standby Router Protocol [HSRP] sessions, if any).
- Upto 16 VRRP sessions are permitted on Cisco NCS 5011 routers (including Hot Standby Router Protocol [HSRP] sessions, if any).
- ICMP redirects are not supported.
- VRRP is not supported over BVI interface.

Understanding VRRP

The Virtual Router Redundancy Protocol (VRRP) feature allows for transparent failover at the first-hop IP router, enabling a group of routers to form a single virtual router.

VRRP Overview

A LAN client can use a dynamic process or static configuration to determine which router should be the first hop to a particular remote destination. The client examples of dynamic router discovery are as follows:

- Proxy ARP—The client uses Address Resolution Protocol (ARP) to get the destination it wants to reach, and a router responds to the ARP request with its own MAC address.
- Routing protocol—The client listens to dynamic routing protocol updates (for example, from Routing Information Protocol [RIP]) and forms its own routing table.
• IRDP (ICMP Router Discovery Protocol) client—The client runs an Internet Control Message Protocol (ICMP) router discovery client.

The drawback to dynamic discovery protocols is that they incur some configuration and processing overhead on the LAN client. Also, in the event of a router failure, the process of switching to another router can be slow.

An alternative to dynamic discovery protocols is to statically configure a default router on the client. This approach simplifies client configuration and processing, but creates a single point of failure. If the default gateway fails, the LAN client is limited to communicating only on the local IP network segment and is cut off from the rest of the network.

The Virtual Router Redundancy Protocol (VRRP) feature can solve the static configuration problem. VRRP is an IP routing redundancy protocol designed to allow for transparent failover at the first-hop IP router. VRRP enables a group of routers to form a single virtual router. The LAN clients can then be configured with the virtual router as their default gateway. The virtual router, representing a group of routers, is also known as a VRRP group.

For example, Figure 13: Basic VRRP Topology, on page 100 shows a LAN topology in which VRRP is configured. In this example, Routers A, B, and C are VRRP routers (routers running VRRP) that compose a virtual router. The IP address of the virtual router is the same as that configured for the interface of Router A (10.0.0.1).

**Figure 13: Basic VRRP Topology**

![Figure 13: Basic VRRP Topology](image)

Because the virtual router uses the IP address of the physical interface of Router A, Router A assumes the role of the master virtual router and is also known as the IP address owner. As the master virtual router, Router A controls the IP address of the virtual router and is responsible for forwarding packets sent to this IP address. Clients 1 through 3 are configured with the default gateway IP address of 10.0.0.1.

Routers B and C function as backup virtual routers. If the master virtual router fails, the router configured with the higher priority becomes the master virtual router and provides uninterrupted service for the LAN hosts. When Router A recovers, it becomes the master virtual router again.
We recommend that you disable Spanning Tree Protocol (STP) on switch ports to which the virtual routers are connected. Enable RSTP or rapid-PVST on the switch interfaces if the switch supports these protocols.

**Note**

Multiple Virtual Router Support

You can configure up to 100 virtual routers on a router interface. You can configure up to 256 virtual routers on a router interface. The actual number of virtual routers that a router interface can support depends on the following factors:

- Router processing capability
- Router memory capability
- Router interface support of multiple MAC addresses

In a topology where multiple virtual routers are configured on a router interface, the interface can act as a master for one or more virtual routers and as a backup for one or more virtual routers.

VRRP Router Priority

An important aspect of the VRRP redundancy scheme is VRRP router priority. Priority determines the role that each VRRP router plays and what happens if the master virtual router fails.

If a VRRP router owns the IP address of the virtual router and the IP address of the physical interface, this router functions as a master virtual router.

If no VRRP router owns the IP address, the priority of a VRRP router, combined with the preempt settings, determines if a VRRP router functions as a master or a backup virtual router. By default, the highest priority VRRP router functions as master, and all the others function as backups. Priority also determines the order of ascendancy to becoming a master virtual router if the master virtual router fails. You can configure the priority of each backup virtual router with a value of 1 through 254, using the `vrrp priority` command.

For example, if Router A, the master virtual router in a LAN topology, fails, an election process takes place to determine if backup virtual Routers B or C should take over. If Routers B and C are configured with the priorities of 101 and 100, respectively, Router B is elected to become master virtual router because it has the higher priority. If Routers B and C are both configured with the priority of 100, the backup virtual router with the higher IP address is elected to become the master virtual router.

By default, a preemptive scheme is enabled whereby a higher-priority backup virtual router that becomes available takes over from the current master virtual router. You can disable this preemptive scheme using the `vrrp preempt disable` command. If preemption is disabled, the backup virtual router that is elected to become master upon the failure of the original higher priority master, remains the master even if the original master virtual router recovers and becomes available again.

VRRP Advertisements

The master virtual router sends VRRP advertisements to other VRRP routers in the same group. The advertisements communicate the priority and state of the master virtual router. The VRRP advertisements are encapsulated in IP packets and sent to the IP Version 4 multicast address assigned to the VRRP group. The advertisements are sent every second by default; the interval is configurable.
Benefits of VRRP

The benefits of VRRP are as follows:

- **Redundancy**—VRRP enables you to configure multiple routers as the default gateway router, which reduces the possibility of a single point of failure in a network.

- **Load Sharing**—You can configure VRRP in such a way that traffic to and from LAN clients can be shared by multiple routers, thereby sharing the traffic load more equitably among available routers.

- **Multiple Virtual Routers**—VRRP supports up to 100 virtual routers (VRRP groups) on a router interface, subject to the platform supporting multiple MAC addresses. You can configure up to 256 virtual routers on a router interface. Multiple virtual router support enables you to implement redundancy and load sharing in your LAN topology.

- **Multiple IP Addresses**—The virtual router can manage multiple IP addresses, including secondary IP addresses. Therefore, if you have multiple subnets configured on an Ethernet interface, you can configure VRRP on each subnet.

- **Preemption**—The redundancy scheme of VRRP enables you to preempt a backup virtual router that has taken over for a failing master virtual router with a higher-priority backup virtual router that has become available.

- **Text Authentication**—You can ensure that VRRP messages received from VRRP routers that comprise a virtual router are authenticated by configuring a simple text password.

- **Advertisement Protocol**—VRRP uses a dedicated Internet Assigned Numbers Authority (IANA) standard multicast address (224.0.0.18) for VRRP advertisements. This addressing scheme minimizes the number of routers that must service the multicasts and allows test equipment to accurately identify VRRP packets on a segment. The IANA assigns VRRP the IP protocol number 112.

Hot Restartability for VRRP

In the event of failure of a VRRP process in one group, forced failovers in peer VRRP master router groups should be prevented. Hot restartability supports warm RP failover without incurring forced failovers to peer VRRP routers.

Configuring VRRP for IPv4 Networks

This section describes the procedure for configuring and verifying VRRP for IPv4 networks.

**Configuration**

Use the following configuration for configuring VRRP for IPv4 networks.

```
/* Enter the interface configuration mode and configure an IPv4 address for the interface. */
Router(config)# interface gigabitEthernet 0/0/0/1
Router(config-if)# ipv4 address 10.10.10.1 255.255.255.0
```

**Note**

Certain customizations (as mentioned) are recommended to control the behavior of the VRRP group on committing the VRRP configuration on the Router. If the following customizations are not configured, then the Router seizes control of the VRRP group, and immediately assumes the role of the master virtual Router.
Router(config-if)# **no shut**
Router(config-if)# **commit**

Configuring VRRP for IPv6 Networks

This section describes the procedure for configuring and verifying VRRP for IPv6 networks.

Configuration

The following sample includes the configuration and customization of VRRP for IPv6 networks.
Certain customizations (as mentioned) are recommended to control the behavior of the VRRP group on committing the VRRP configuration on the Router. If the following customizations are not configured, then the Router seizes control of the VRRP group, and immediately assumes the role of the master virtual Router.

/* Enter the interface configuration mode and configure an IPv6 address */
Router# interface GigabitEthernet 0/0/0/2
Router(config-if)# ipv6 address 10::1/64
Router(config-if)# no shut

/* Exit the interface configuration mode and enter the vrrp configuration mode */
Router(config-if)# exit
Router(config)# Router vrrp

/* Add the configured interface for VRRP */
Router(config-vrrp)# interface GigabitEthernet 0/0/0/2

/* CUSTOMIZATION: Configure a delay for the startup of the state machine when the interface comes up. */
Router(config-vrrp)# delay minimum 2 reload 10 *

/* Enable the IPv6 global and link local address family on the interface */
Router(config-vrrp-if)# address-family ipv6 vrrp 50
Router(config-vrrp-virtual-Router)# address linklocal autoconfig

/* CUSTOMIZATION: Disable the installation of routes for the VRRP virtual addresses. */
Router(config-vrrp-virtual-Router)# accept-mode disable

/* CUSTOMIZATION: Set a priority for the virtual Router. */
Router(config-vrrp-virtual-Router)# priority 254

/* CUSTOMIZATION: Configure a preempt delay value that controls the selection of the master virtual Router. */
Router(config-vrrp-virtual-Router)# preempt delay 15

/* CUSTOMIZATION: Configure the interval between successive advertisements by the master virtual Router. */
Router(config-vrrp-virtual-Router)# timer 4

/* CUSTOMIZATION: Configure VRRP to track an interface. */
Router(config-vrrp-virtual-Router)# track interface GigabitEthernet0/0/0/2 30

/* Commit the configuration */
Router(config-vrrp-virtual-Router)# commit

You have successfully configured VRRP for IPv6 networks.

Validation

Use the following commands to validate the configuration.

/* Validate the configuration */
Router(config-vrrp-virtual-router)# do show run interface GigabitEthernet 0/0/0/2
Fri Dec 8 14:55:48.378 IST

You have successfully validated VRRP for IPv6 networks.

Disabling State Change Logging

Configuration Example

Disables the task of logging the VRRP state change events via syslog.
Enabling Multiple Group Optimization (MGO) for VRRP

Configuration Examples

Multiple Group Optimization for Virtual Router Redundancy Protocol (VRRP) provides a solution for reducing control traffic in a deployment consisting of many subinterfaces. By running the VRRP control traffic for just one session, the control traffic is reduced for the subinterfaces with identical redundancy requirements. All other sessions are slaves of this primary session, and inherit their states from it.

VRRP Session Name

Router#configure
Router(config)#router vrrp
router(config-vrrp)#interface TenGigE 0/0/0/2
router(config-vrrp-if)#address-family ipv4
router(config-vrrp-address-family)#vrrp 1
/* Enables VRRP group configuration mode on a specific interface. */

router(config-vrrp-virtual-router)#name s1
/* Specifies the VRRP session name. */

router(config-vrrp-gp)#commit

Slave Follow

Router#configure
Router(config)#router vrrp
router(config-vrrp)#interface TenGigE 0/0/0/2
router(config-vrrp-if)#address-family ipv4

router(config-vrrp-address-family)#vrrp 2 slave
/* Enables VRRP slave configuration mode on a specific interface. */

router(config-vrrp-slave)#follow m1
/* Configures a slave follow. Instructs the slave group to inherit its state from the specified group, m1 (MGO session name). */

router(config-vrrp-slave)#address 10.2.3.2
/* Specifies the primary virtual IPv4 address for slave group. */

router(config-vrrp-slave)#address 10.2.3.3 secondary
/* Specifies the secondary virtual IPv4 address for slave group. */

router(config-vrrp-gp)#commit

Primary and Secondary Virtual IPv4 Addresses for the Slave Group

Router#configure
Router(config)#router vrrp
router(config-vrrp)#interface TenGigE 0/0/0/2
router(config-vrrp-if)#address-family ipv4

router(config-vrrp-address-family)#vrrp 2 slave
/* Enables VRRP slave configuration mode on a specific interface. */
Configuring SNMP Server Notifications for VRRP Events

MIB support for VRRP

VRRP enables one or more IP addresses to be assumed by a router when a failure occurs. For example, when IP traffic from a host reaches a failed router because the failed router is the default gateway, the traffic is transparently forwarded by the VRRP router that has assumed control. VRRP does not require configuration of dynamic routing or router discovery protocols on every end host. The VRRP router controlling the IP address(es) associated with a virtual router is called the master, and forwards packets sent to these IP addresses. The election process provides dynamic fail over (standby) in the forwarding responsibility should the master become unavailable. This allows any of the virtual router IP addresses on the LAN to be used as the default first hop router by end-hosts.

The advantage gained from using VRRP is a higher availability default path without requiring configuration of dynamic routing or router discovery protocols on every end-host. Simple Network Management Protocol (SNMP) traps provide information of the state changes, when the virtual routers (in standby) are moved to master state or if the standby router is made master.

Configuration Example

Enables SNMP server notifications (traps) for VRRP.

Router#configure
Router(config)#snmp-server traps vrrp events
Router(config)#commit

Use the show snmp traps details command to view details of SNMP server notifications.
