New and Changed QoS Features

Table 1: QoS Features Added or Modified in IOS XR Release 7.5.x

Feature	Description	Changed in Release	Where Documented
Classifying Packets Based On MPLS Experimental Bits in MPLS Over GRE	For MPLS over GRE scenarios that tunnel MPLS traffic over non-MPLS networks, you can now perform QoS classification for specific traffic or applications based on MPLS EXP bit field values in the MPLS header.	Release 7.5.2	Classifying Packets Based On MPLS Experimental Bits in MPLS Over GRE, on page 68
Prioritization of IS-IS and ARP Packets to Manage Transit Traffic	This feature gives you the option to assign the highest priority to IS-IS and ARP packets in transit.	Release 7.5.1	Prioritization of IS-IS and ARP Packets to Manage Transit Traffic, on page 23
Layer 2 Ingress QoS Matching for IPv4 and IPv6 Destination Addresses	Using this feature, you can match class maps to IPv4 and IPv6 destination addresses on Layer 2 networks. The Layer 2 interface service policy has the relevant class maps, actioning them for ingress QoS operations.	Release 7.5.1	Layer 2 Ingress QoS Matching for IPv4 and IPv6 Destination Addresses , on page 35

CHAPTER 2

Configuring Modular QoS Service Packet Classification

This chapter covers these topics:

Packet Classification Overview

Table 2: Feature History Table

Feature Name	Release Information	Feature Description
Cisco NC57 Compatibility Mode: QoS Enablement on Layer 2 MPLS/BGP	Release 7.3.1	<p>This feature is now supported on routers that have the Cisco NC57 line cards installed and operate in the compatibility mode.</p> <p>The following Layer 2 services are supported:</p> <ul style="list-style-type: none"> • Local switching [xconnect or bridging] • Layer 2 VPN – Virtual Private Wire Service (VPWS) <p>Apart from packet classification, this feature is available for the following QoS operations:</p> <ul style="list-style-type: none"> • Modular QoS Congestion Avoidance , on page 81 • Configuring Modular QoS Congestion Management, on page 119 • QoS on Link Bundles, on page 155 • Configuring Hierarchical Modular QoS, on page 161

Feature Name	Release Information	Feature Description
Cisco NC57 Native Mode: QoS Enablement on Layer 2 Services	Release 7.4.1	<p>This feature is now supported on routers that have the Cisco NC57 line cards installed and operate in the native mode.</p> <p>The following Layer 2 services are supported:</p> <ul style="list-style-type: none"> • Local switching [xconnect or bridging] • Layer 2 VPN – Virtual Private Wire Service (VPWS) <p>Apart from packet classification, this feature is available for the following QoS operations:</p> <ul style="list-style-type: none"> • Modular QoS Congestion Avoidance , on page 81 • Configuring Modular QoS Congestion Management, on page 119 • QoS on Link Bundles, on page 155 • Configuring Hierarchical Modular QoS, on page 161

Packet classification involves categorizing a packet within a specific group (or class) and assigning it a traffic descriptor to make it accessible for QoS handling on the network. The traffic descriptor contains information about the forwarding treatment (quality of service) that the packet should receive. Using packet classification, you can partition network traffic into multiple priority levels or classes of service. The source agrees to adhere to the contracted terms and the network promises a quality of service. Traffic policers and traffic shapers use the traffic descriptor of a packet to ensure adherence to the contract.

Traffic policers and traffic shapers rely on packet classification features, such as IP precedence, to select packets (or traffic flows) traversing a router or interface for different types of QoS service. After you classify packets, you can use other QoS features to assign the appropriate traffic handling policies including congestion management, bandwidth allocation, and delay bounds for each traffic class.

The Modular Quality of Service (QoS) CLI (MQC) defines the traffic flows that must be classified, where each traffic flow is called a class of service, or class. Later, a traffic policy is created and applied to a class. All traffic not identified by defined classes fall into the category of a default class.

You can classify packets at the ingress on L3 subinterfaces for (CoS, DEI) for IPv4, IPv6, and MPLS flows. IPv6 packets are forwarded by paths that are different from those for IPv4. To enable classification of IPv6 packets based on (CoS, DEI) on L3 subinterfaces, run the `hw-module profile qos ipv6 short-l2qos-enable` command and reboot the line card for the command to take effect.

Starting with Cisco IOS XR Release 7.4.1 systems with Cisco NC57 line cards running in native mode support QoS over Layer 2 services for:

- Local switching [xconnect or bridging]
- L2 VPN – VPWS

Guidelines and Limitations

- Ingress CoS marking is not supported on Cisco NCS 5500 Series routers; however, it is supported on Cisco NCS 5700 Series routers.

Note

Ingress CoS marking is not supported on L3 interfaces because it can overwrite the Port Control Protocol (PCP) for traffic passing through the core network. To implement CoS marking, always configure it on egress L2 interfaces.

Traffic Class Elements

The purpose of a traffic class is to classify traffic on your router. Use the **class-map** command to define a traffic class.

A traffic class contains three major elements:

- A name
- A series of **match** commands - to specify various criteria for classifying packets.
- An instruction on how to evaluate these **match** commands (if more than one **match** command exists in the traffic class)

Packets are checked to determine whether they match the criteria that are specified in the **match** commands. If a packet matches the specified criteria, that packet is considered a member of the class and is forwarded according to the QoS specifications set in the traffic policy. Packets that fail to meet any of the matching criteria are classified as members of the default traffic class.

This table shows the details of match types that are supported on the router.

Match Type Supported	Min, Max	Max Entries	Support for Match NOT	Support for Ranges	Direction Supported on Interfaces
IPv4 DSCP IPv6 DSCP DSCP	(0,63)	64	Yes	Yes	Ingress
IPv4 Precedence IPv6 Precedence Precedence	(0,7)	8	Yes	No	Ingress
MPLS Experimental Topmost	(0,7)	8	Yes	No	Ingress

Match Type Supported	Min, Max	Max Entries	Support for Match NOT	Support for Ranges	Direction Supported on Interfaces
Access-group	Not applicable	8	No	Not applicable	Ingress
QoS-group	(1,7) (1,511) for peering profile	7	No	No	<ul style="list-style-type: none"> • Egress • Ingress for QoS Policy Propagation Using Border Gateway Protocol (QPPB) • Ingress for peering profile
Traffic-class	(1,7)	7	No	No	<ul style="list-style-type: none"> • Egress
Protocol	(0,255)	1	Yes	Not applicable	Ingress

Note Egress queue statistics are displayed only for those classes which have a corresponding match criteria in the egress. Therefore, if you have a **set traffic-class** *x* configured in the ingress, you must have a corresponding **match traffic-class** *x* in the egress, in order to see the statistics in the egress side.

Note A maximum value of up to 64 unique queues is supported. Each unique queue-limit consumes one rate profile in the Traffic manager. Out of 64 unique queues, few are reserved for default configs and the remaining are usable.

Depending on the interface speeds, default configurations consume some of the rate profiles. The remaining rate profiles can be exhausted in the following scenarios:

- Different shape rates without configuring queue limits could exhaust the rate profiles as 10ms of guaranteed service rate converts to a different value in bytes based on the shape rate.
- Configuring queue limits in units of time could exhaust the rate profiles. For example, 20 ms of 50 Mbps and 20 ms of 100 Mbps are two different values in bytes.

Tip You can avoid exhausting rate profiles by configuring queue limits in absolute units (such as bytes, kilobytes, or megabytes) for class maps and sharing these limits with the policy maps.

Default Traffic Class

Unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as belonging to the default traffic class.

If the user does not configure a default class, packets are still treated as members of the default class. However, by default, the default class has no enabled features. Therefore, packets belonging to a default class with no configured features have no QoS functionality. These packets are then placed into a first in, first out (FIFO) queue and forwarded at a rate determined by the available underlying link bandwidth. This FIFO queue is managed by a congestion avoidance technique called tail drop.

For egress classification, match on **traffic-class** (1-7) is supported. Match **traffic-class 0** cannot be configured. The class-default in the egress policy maps to **traffic-class 0**.

This example shows how to configure a traffic policy for the default class:

```
configure
policy-map ingress_policy1
class class-default
  police rate percent 30
!
```

Create a Traffic Class

To create a traffic class containing match criteria, use the **class-map** command to specify the traffic class name, and then use the **match** commands in class-map configuration mode, as needed.

Guidelines

- Users can provide multiple values for a match type in a single line of configuration; that is, if the first value does not meet the match criteria, then the next value indicated in the match statement is considered for classification.
- Use the **not** keyword with the **match** command to perform a match based on the values of a field that are not specified.
- All **match** commands specified in this configuration task are considered optional, but you must configure at least one match criterion for a class.
- If you specify **match-any**, one of the match criteria must be met for traffic entering the traffic class to be classified as part of the traffic class. This is the default. If you specify **match-all**, the traffic must match all the match criteria.
- From Release 7.7.1 onwards, for the **match access-group** command, QoS classification based on the packet length field in the IPv4 and IPv6 headers is supported. Prior to this, support was not available for packet length and TTL (time to live) fields.
- Deny action in the ACL or an empty ACL (contains no rules, only remarks) is not supported for the **match access-group command** when an ACL list is used within a **class-map**.
The configuration is rejected when you attach such a **policy-map** to an interface.
- The **traffic-class** and **discard-class** are supported only in egress direction, and these are the only match criteria supported in egress direction.
- The egress default class implicitly matches **qos-group 0** for marking policy and **traffic-class 0** for queuing policy.
- Multicast takes a system path that is different than unicast on router, and they meet later on the egress in a multicast-to-unicast ratio of 20:80 on a per interface basis. This ratio is maintained on the same priority level as that of the traffic.

- Egress QoS for multicast traffic treats traffic classes 0-5 as low-priority and traffic classes 6-7 as high priority. Currently, this is not user-configurable.
- Egress shaping does not take effect for multicast traffic in the high priority (HP) traffic classes. It only applies to unicast traffic.
- If you set a traffic class at the ingress policy and do not have a matching class at egress for the corresponding traffic class value, then the traffic at ingress with this class will not be accounted for in the default class at the egress policy map.
- Only traffic class 0 falls in the default class. A non-zero traffic class assigned on ingress but with no assigned egress queue, falls neither in the default class nor any other class.
- EDM timeouts for **show policy-map** CLI commands are expected during line card reload with scale configuration.

Configuration Example

You have to accomplish the following to complete the traffic class configuration:

1. Creating a class map
 2. Specifying the match criteria for classifying the packet as a member of that particular class
- (For a list of supported match types, see [Traffic Class Elements, on page 6](#).)

```
Router# configure
Router(config)# class-map match-any qos-1
Router(config-cmap)# match qos-group 1
Router(config-cmap)# end-class-map
Router(config-cmap)# commit
```

Use this command to verify the class-map configuration:

```
Router#show class-map qos-1
1) ClassMap: qos-1      Type: qos
   Referenced by 2 Policymaps
```

Also see, [Running Configuration, on page 14](#).

Also see, [Verification, on page 14](#).

- [match qos-group](#)

Traffic Policy Elements

A traffic policy contains three elements:

- Name
- Traffic class
- QoS policies

After choosing the traffic class that is used to classify traffic to the traffic policy, the user can enter the QoS features to be applied to the classified traffic.

The MQC does not necessarily require that the users associate only one traffic class to one traffic policy.

The order in which classes are configured in a policy map is important. The match rules of the classes are programmed into the TCAM in the order in which the classes are specified in a policy map. Therefore, if a packet can possibly match multiple classes, only the first matching class is returned and the corresponding policy is applied.

The router supports 32 classes per policy-map in the ingress direction and 8 classes per policy-map in the egress direction.

This table shows the supported class-actions on the router.

Supported Action Types	Direction supported on Interfaces
minimum-bandwidth	egress
bandwidth-remaining*	egress
mark	(See Packet Marking , on page 15)
police	ingress
priority	egress (level 1 to level 7)
queue-limit	egress
shape	egress
wred	egress

*Bandwidth and Bandwidth remaining configurations are not supported simultaneously within the same policy-map in H-QoS mode.

WRED supports **default** and **discard-class** options; the only values to be passed to the discard-class being 0 and 1.

Create a Traffic Policy

The purpose of a traffic policy is to configure the QoS features that should be associated with the traffic that has been classified in a user-specified traffic class or classes.

To configure a traffic class, see [Create a Traffic Class, on page 8](#).

After you define a traffic policy with the **policy-map** command, you can attach it to one, or more interfaces to specify the traffic policy for those interfaces by using the **service-policy** command in interface configuration mode. With dual policy support, you can have two traffic policies, one marking and one queuing attached at the output. See, [Attach a Traffic Policy to an Interface, on page 13](#).

Configuration Example

You have to accomplish the following to complete the traffic policy configuration:

1. Creating a policy map that can be attached to one or more interfaces to specify a service policy
2. Associating the traffic class with the traffic policy
3. Specifying the class-action(s) (see [Traffic Policy Elements, on page 10](#))

```
Router# configure
Router(config)# policy-map test-shape-1
Router(config-pmap)# class qos-1

/* Configure class-action ('shape' in this example).
Repeat as required, to specify other class-actions */
Router(config-pmap-c)# shape average percent 40
Router(config-pmap-c)# exit

/* Repeat class configuration as required, to specify other classes */

Router(config-pmap)# end-policy-map
Router(config)# commit
```

See, [Running Configuration, on page 14](#).

See, [Verification, on page 14](#).

Scaling of Unique Ingress Policy Maps

Table 3: Feature History Table

Feature Name	Release Information	Feature Description
Scaling of Unique Ingress Policy Maps	Release 7.4.1	This feature is now supported on routers that have Cisco NC57 line cards installed and operate in native mode.
Scaling of Unique Ingress Policy Maps	Release 7.3.1	With this feature, unique policy maps associated to the same template are shared in TCAM, thus enabling scaling of — or creating more number of — policy maps.

Traditionally, when unique policy maps were associated to the same template — that is, having the same match criteria and actions in the *same* order — each map was assigned a different TCAM entry. This resulted in inefficient TCAM entry management and also restricted the number of policy maps that could be created.

With this functionality, unique policy maps associated to the same template are shared in TCAM, thus enabling scaling of—in other words, creating more number of—policy maps. The other way to understand this functionality is that two policy maps with the same combination of criteria and actions use one template. This way, up to 250 templates are supported for association to policy map combinations.

As an example, consider the following policy maps (**policy-map ncs_input1** and **policy-map ncs_input2**) having the same class maps (**class COS7_DEI0** and **class COS7_DEI1**):

```
class-map match-all COS7_DEI0
  match cos 0
end-class-map
class-map match-all COS7_DEI1
  match cos 1
end-class-map

policy-map ncs_input1
  class COS7_DEI0
    set traffic class 1
```

```

    police rate 10 mbps
  !
  class COS7_DEI1
    set traffic class 2
    policer rate 20 mbps
  !

policy-map ncs_input2
  class COS7_DEI0
    set traffic class 1
    police rate 30 mbps
  !
  class COS7_DEI1
    set traffic class 2
    policer rate 40 mbps
  !

```

Earlier, when the policy maps were attached to interface, they used different TCAM entries, although the match criteria and actions were the same, except for the policer action.

With this functionality, both policy maps share the TCAM entry instead of selecting different entries, thus freeing up TCAM entries for more policy maps.

Limitations and Restrictions

- Policy Maps share TCAM entries only for the same match criteria and actions or template. However, the policer action can be different for the same template.
- For all unique policy maps the maximum number of templates supported is 250.

Attach a Traffic Policy to an Interface

After the traffic class and the traffic policy are created, you must attach the traffic policy to interface, and specify the direction in which the policy should be applied.

Note When a policy-map is applied to an interface, the transmission rate counter of each class is not accurate. This is because the transmission rate counter is calculated based on the exponential decay filter.

Configuration Example

You have to accomplish the following to attach a traffic policy to an interface:

1. Creating a traffic class and the associated rules that match packets to the class (see [#unique_25](#))
2. Creating a traffic policy that can be attached to one or more interfaces to specify a service policy (see [Create a Traffic Policy, on page 11](#))
3. Associating the traffic class with the traffic policy
4. Attaching the traffic policy to an interface, in the ingress or egress direction

```

Router# configure
Router(config)# interface HundredGigE 0/6/0/18

```

```
Router(config-int)# service-policy output test-shape-1
Router(config-int)# commit
```

Running Configuration

```
/* Class-map configuration */

class-map match-any traffic-class-1
  match traffic-class 1
end-class-map

Packet Marking

Note L2 packet marking is not supported on NC57-24DD and NC57-18DD-SE line cards for Cisco IOS XR Release 7.0.2.

The packet marking feature provides users with a means to differentiate packets based on the designated markings.

Egress packet marking

- The router supports egress packet marking. Match on **discard-class** on egress, if configured, can be used for a marking policy only.
- An egress policy is mandatory to create a user-defined header by stripping the initial 3 bits and copying the DSCP marking to the QoS group.

L2 ingress marking

- **Ingress marking limitations:** For the ingress pop operation, re-marking the customer VLAN tag (CoS, DEI) is not supported.
- **Egress traffic behavior:** The ingress 'pop VLAN' is translated to a 'push VLAN' for the egress traffic, and (CoS, DEI) marking is supported for newly pushed VLAN tags. If two VLAN tags are pushed to the packet header at the egress side, both inner and outer VLAN tags are marked. For example:

```
rewrite ingress tag pop 1 symmetric
rewrite ingress tag pop 2 symmetric
rewrite ingress tag translate 2-to-1 dot1q/dot1ad <> symmetric
```

VLAN tag details

- **Single tag operations:** When symmetrical pop 1 action is performed, the outer tag (CoS, DEI) is retained as the original frame.
- **Double tag operations:** When symmetrical pop 2 action is performed, the outer tag (CoS, DEI) is retained as the original frame and inner tag (CoS, DEI) is set to 0/0.

- **NC57 line card specifics:** In case of pop action, the outer VLAN tag (CoS, DEI) is retained on NC57 line cards.

Packet Marking Guidelines and Limitations

Avoid conflicting packet marking configurations: While marking a packet, ensure you don't set the IP DSCP (using the **set dscp** command) and the MPLS experimental imposition values (using the **set mpls experimental imposition** command) for the same class map. Else, neither the DSCP remarking nor the MPLS EXP values may take effect at the ingress. This will cause, per default QoS behavior, the IP precedence values to be copied to the EXP bits on the imposed packets. Such an action could lead to unintended packets marked as high-priority by your customer being forwarded as high-priority MPLS packets in the network.

Viewing statistics and counters for egress policies: The statistics and counters for the egress marking policy cannot be viewed on the router.

QoS EXP matching for Layer 2 and Layer 3 VPN traffic:

QoS EXP matching for egress doesn't work for Layer 2 VPN and Layer 3 VPN traffic flowing from:

- Cisco NCS 5700 series line cards at ingress to Cisco NCS 5500 series line cards at the egress and
- Cisco NCS 5500 series line cards at ingress to Cisco NCS 5700 series line cards at egress.

Policy map limits for egress marking:

- For QOS EXP-Egress marking applied on a Layer 3 interface on Cisco NCS550x and NCS55Ax routers, there is a limit of two unique policy maps per NPU. This limit is three unique policy maps per NPU for routers that have the Cisco NC57 line cards installed.

You can apply these policies to as many interfaces as your system resources allow. However, if you apply more than the permitted limit of unique policies, you may encounter unexpected failure.

- For QOS egress marking (CoS, DEI) applied on a Layer 2 interface, there is a limit of 13 unique policy-maps per NPU. If you exceed this number, you may encounter unexpected failure.

Supported Packet Marking Operations

This table shows the supported packet marking operations.

Table 4: Supported Ingress Marking Types

Supported Mark Types	Range	Layer	Supports Unconditional Marking	Supports Conditional Marking	Description
DSCP	0-63	L3	Ingress	No	Supported flows: IP to IP, IP to MPLS, MPLS to IP.
precedence	0-7	L3	Ingress	No	Supported flows: IP to IP, IP to MPLS, MPLS to IP.
mpls experimental topmost	0-7	L3	Ingress	No	Supported flows: MPLS to MPLS.

Supported Mark Types	Range	Layer	Supports Unconditional Marking	Supports Conditional Marking	Description
mpls experimental imposition	0-7	L2 L3	Ingress	No	Supported flows: L2 to MPLS, IP to MPLS.
DEI	0-1	L2	Ingress	No	Supported flows: L2 to L2, L2 to MPLS.
CoS	0-7	L2	Ingress	No	Supported flows: L2 to L2, L2 to MPLS.
discard-class	0-2	L2 L3	Ingress	No	Used in conjunction with random-detect for discard behavior identification.
qos-group	0-7	L2 L3	Ingress	No	Marks traffic for QoS management.
traffic-class	0-7	L2 L3	Ingress	No	Used for queuing purposes.

Class-based Unconditional Packet Marking

Table 5: Feature History Table

Feature Name	Release Information	Feature Description
Class-based Unconditional Packet Marking	Release 7.4.1	This feature is now supported on routers that have Cisco NC57 line cards installed and operate in native and compatibility modes.

The packet marking feature allows you to partition your network into multiple priority levels or classes of service, as follows:

- Use QoS unconditional packet marking to set the IP precedence or IP DSCP values for packets entering the network. Routers within your network can then use the newly marked IP precedence values to determine how the traffic should be treated.

On ingress direction, after matching the traffic based on either the IP Precedence or DSCP value, you can set it to a particular discard-class. Weighted random early detection (WRED), a congestion avoidance technique, thereby uses discard-class values to determine the probability that a packet is dropped.

If however, you set a discard-class of 3, the packet is dropped at ingress itself.

- Use QoS unconditional packet marking to assign MPLS packets to a QoS group. The router uses the QoS group to determine how to prioritize packets for transmission. To set the traffic class identifier on MPLS packets, use the **set traffic-class** command in policy map class configuration mode.

Note Setting the traffic class identifier does not automatically prioritize the packets for transmission. You must first configure an egress policy that uses the traffic class.

- Note**
- Unless otherwise indicated, the class-based unconditional packet marking for Layer 3 physical interfaces applies to bundle interfaces.
 - From IOS XR Release 7.2.1 onwards with NC57 line cards, propagation of PREC->COS marking happens by default on egress Layer 3 subinterfaces. This applies to single and double-tag L3 subinterfaces, and to NC57 line cards in Native mode.

Handling QoS for Locally Originated Packets

What are Locally Originated Packets?

Locally Originated Packets (LOPs) are packets generated and transmitted by the router itself. These differ from transit packets that pass through the router. LOPs include routing protocols, management protocols, and other locally initiated control messages.

Default QoS markings for protocols

The router assigns default precedence or Differentiated Services Code Point (DSCP) values to various locally originated protocols

Protocol or application	Precedence and DSCP value	L2 PCP value
BGP, OSPF, CCM (CSM), BFD, RSVP	<ul style="list-style-type: none"> • Precedence: 6 • DSCP: 48 	<ul style="list-style-type: none"> • BGP: 6 (with or without MPLS encap) • BFD: 7 (with or without MPLS encap)
Telnet, SSH	<ul style="list-style-type: none"> • Precedence: 2 • DSCP: 16 	Not applicable
SNMP	Precedence: 0	6 (with or without MPLS encap)
SSH, SFTP	Not applicable	7 (with or without MPLS encap)

Some protocols such as BGP, RSVP, CFM, and LDP and the management protocols allow setting explicit precedence or DSCP values.

Traffic class assignment by Cisco IOS XR release

Cisco IOS XR release	Traffic class value
Before Release 7.6.1	<ul style="list-style-type: none"> Locally generated control plane packets, such as IS-IS and BGP, are generated using traffic-class 6. Locally generated BFD over Bundle (IETF) packets, which are generated on the Network Processing Unit (NPU), are generated using traffic-class 6.
From Release 7.6.1 onwards	<ul style="list-style-type: none"> Locally generated control plane packets, such as IS-IS and BGP, are generated using traffic-class 7. Locally generated BFD over Bundle (IETF) packets, which are generated on the Network Processing Unit (NPU), are generated using traffic-class 7.

Note Bidirectional Forwarding Detection (BFD) uses a DSCP value of 48 (CS6) for single- and multi-hops sessions on NCS55xx.

Note Bidirectional Forwarding Detection (BFD) uses a DSCP value of 63 (IP-ToS 255) for single-hop sessions and IP-ToS 0 for multi-hop sessions on the NCS540 router. Due to an SDK limitation, a DSCP value of 48 is not supported.

Note Bidirectional Forwarding Detection (BFD) uses a DSCP value of 63 (IP-ToS 255) for single-hop sessions and IP-ToS 0 for multi-hop sessions on the NCS560 router. Due to an SDK limitation, a DSCP value of 48 is not supported.

Managing datapath and locally originated packets

On the router, datapath packets and injected packets aren't differentiated if both their traffic classes share the same Virtual Output Queues (VOQs). Therefore, in the case of a congested VOQ, the LOCP packets are dropped. To avoid the LOCP packets drop, Cisco recommends that you have a different traffic class for data path traffic. Alternatively, you can also specify a higher bandwidth for traffic-class 7 (if ingress traffic rate is predictable).

Optimizing traffic handling by early classification and marking

Classifying traffic helps the router to recognize traffic as a certain type and mark that traffic. By marking traffic early on its travel, you can prevent excessive reclassification later. You can mark traffic at the protocol level as shown in the following examples:

Ethernet

The following configuration shows that the outbound Control Hub packets are marked with a precedence value of 2 and EXP of 2, instead of a precedence and EXP value of 6. The SSH packets have a precedence value of 3 instead of 2.

```

ethernet cfm
  mep domain FOO service FOOBAR mep-id 1
  cos 2
ssh server dscp 24

```

BGP

```
neighbor x.x.x.x dscp
```

MPLS LDP

```
mpls ldp signalling dscp
```

Telnet

```
telnet ipv4 dscp
```

SNMP

```
snmp-server ipv4 precedence/dscp
```

Syslog

```

logging ipv4 precedence/dscp
netflow
flow exporter-map TEST dscp

```

NTP

```

ntp ipv4 precedence/dscp
ssh client dscp 56
ssh server dscp 56

```

Note By default, the router marks the Precision Time Protocol (PTP) traffic as high priority. Therefore, the need to prioritize PTP traffic in the QoS configuration is not required.

LOCPs and QoS policies

LOCPs are packets generated by the router itself, such as IS-IS, ARP, and other non-IP-based control packets. These packets are critical for network operations and are treated with high priority to ensure they are not dropped under normal circumstances.

Note By default, all LOCPs are assigned to traffic-class 7. Considering that LOCPs and LOMPs are generated by the RP, an Ingress QoS policy cannot be applied. Therefore, you must ensure that the egress QoS policy includes a class-map which matches traffic-class 7. By definition, the egress QoS policy matches all implicitly marked packets.

Key features of LOCPs

Discard priority

- LOCPs originating from the RP or LC CPU have a discard priority set in the appended Buffer Header (BHDR).
- This ensures LOCPs are not dropped internally under normal conditions.

- LOMPs do not have this discard priority and are treated as normal traffic.

Queue management

- LOCPs with discard priority are placed in an implicitly allocated high-priority queue for each physical egress interface.
- During congestion, LOCPs are not subject to Weighted Random Early Detection (WRED) or Tail-drop queue-limit operations.
- The tail-drop queue-limit must be hit before LOCP packets are dropped.

QoS policy configuration

- QoS policies can be attached to physical interfaces or sub-interfaces.
- If attached to sub-interfaces, the operator cannot attach a QoS policy to the physical interface.
- LOCPs are always sent out on the default high-priority queue of the physical interface.

Bandwidth reservation

- A minimum bandwidth of MIN (1% of interface bandwidth, 10 Mbps) is reserved for the default high-priority queue on physical interfaces without a QoS policy.
- If a QoS policy is applied, the minimum bandwidth for the high-priority queue is controlled by the configured policy.

Classification and re-marking

- LOCPs are not subject to traffic policing or re-marking.
- Non-IP LOCPs, such as IS-IS and ARP, are always sent to the high-priority queue, irrespective of the QoS policy.

Session termination prevention

- During over-subscription, LOCP drops may occur, leading to session termination.
- Proper bandwidth allocation and QoS configuration are essential to prevent such scenarios.

Protecting Locally Originated BFD Packets

For releases before Release 7.6.1, BFD packets are injected into traffic-class 6, with drop priority 0 (equivalent of discard-class 0). If transit traffic is also classified into traffic-class 7 and the associated egress queue is congested, BFD packets may be dropped.

From Release 7.6.1, BFD packets are injected into traffic-class 7, with drop priority 0 (equivalent of discard-class 0). If transit traffic is also classified into traffic-class 7 and the associated egress queue is congested, BFD packets may be dropped.

The recommendation is to configure transit traffic-class 7 in the ingress QoS policy with discard-class 1 or 2. You must then configure WRED in the egress QoS policy that drops these packets before dropping discard-class 0.

Note The default queue length is 16 ms.

Example

```
class-map match-any NC
  match traffic-class 6 (for releases before Release 7.6.1)
  match traffic-class 7 (from Release 7.6.1)
!
policy-map CORE-OUT
  class NC
    random-detect discard-class 1 7 ms 8 ms
```

Hardware Programming

```

WRED Max. Threshold = 0 bytes (0 ms)

WRED ECN = Disabled
```

Prioritization of IS-IS and ARP Packets to Manage Transit Traffic

Table 6: Feature History Table

Feature Name	Release Information	Feature Description
Prioritization of IS-IS and ARP Packets to Manage Transit Traffic	Release 7.5.1	<p>This feature gives you the option to assign the highest priority to IS-IS and Address Resolution Protocol (ARP) packets in transit. This feature is disabled by default.</p> <p>The feature provides more flexibility in transit traffic management on a per-hop basis and also fine-tunes the traffic profile management for transit traffic.</p> <p>This feature introduces the hw-module profile qos arp-isis-priority-enable command.</p>

Overview of IS-IS and ARP Traffic Prioritization

Transit traffic refers to all traffic that enters an ingress interface, is compared against the forwarding table entries, and forwarded out an egress interface toward its destination. While the exact path of the transit path may not be of interest to the sender or receiver, you may still want some of the Integrated Intermediate System-to-Intermediate System (IS-IS) and Address Resolution Protocol (ARP) transit traffic to be managed and routed efficiently between specific source and destination addresses. You can now achieve higher levels of flexibility and fine-tune the traffic profile management for transit traffic by enabling the ability to assign the highest priority level to IS-IS and ARP traffic on Layer 2 networks.

This feature is useful if you manage environments such as data centers where you have complete end-to-end control over your network, and you want to avoid any drops in IS-IS and ARP traffic during congestion.

Cisco IOS XR Release 7.5.1 introduces the **hw-module profile qos arp-isis-priority-enable** command to enable prioritization of IS-IS and ARP traffic in transit on Layer 2 networks. Configuring this command assigns a priority level of TC 7 to transit traffic.

Note Assigning highest priority levels to IS-IS and ARP traffic lead to higher volumes of ARP traffic and flood high-priority queues, which may cause other traffic to drop. It's best to assign priority levels based on your network configuration and traffic volume.

Guidelines

- This feature is disabled by default. Configure the **hw-module profile qos arp-isis-priority-enable** command to enable prioritization of IS-IS and ARP traffic in transit on Layer 2 networks.
- This feature is supported on routers that have the Cisco NC57 line cards installed and operate in the native and compatibility mode.
- Configuring **hw-module profile qos arp-isis-priority-enable** assigns a priority level of TC 7 for ISIS and ARP traffic. When this feature is in its default state of disabled, the default priority level is TC 0.

- This feature doesn't allow you to assign TC values.
- Reload the line card for the **hw-module** command to be functional.

Enabling IS-IS and ARP Traffic Prioritization

To enable IS-IS and ARP traffic prioritization, configure the **hw-module profile qos arp-isis-priority-enable** command.

```
Router#config
Router(config)#hw-module profile qos arp-isis-priority-enable
Router(config)#commit
Router(config)#exit
Router# reload location <lc location>
```

Prioritization is based on IS-IS destination MAC address (01:80:c2:00:00:14 and 01:80:c2:00:00:15) and ARP ether type 0x080. When you configure the **hw-module profile qos arp-isis-priority-enable** command, priority level for IS-IS and ARP and traffic is set as TC 7.

Verification

The following example shows the verification command for NC 57 line cards. The assigned priority level is **TC 07**.

```
RP/0/RP0/CPU0:ios#show controllers fia diag 0 "pp vis pkttm" location 0/0/CPU0
```

```
Node ID: 0/0/CPU0
```

```
R/S/I: 0/0/0

QoS Re-marking of IP Packets in Egress Direction

The router support the marking of IP DSCP bits of all IP packets to zero, in the egress direction. This feature helps to re-mark the priority of IP packets, which is mostly used in scenarios like IP over Ethernet over MPLS over GRE. This functionality is achieved using the ingress policy-map with **set dscp 0** option configured in class-default.

Configuration Example

```

Router# configure
Router(config)# policy-map ingress-set-dscp-zero-policy
Router(config-pmap)# class class-default
Router(config-pmap-c)# set dscp 0
Router(config-pmap-c)# end-policy-map
Router(config-pmap)# commit

```

Running Configuration

```

policy-map ingress-set-dscp-zero-policy
class class-default
    set dscp 0
!
end-policy-map
!

```

QoS Re-marking of Ethernet Packets in Egress Direction

The router supports Layer 2 marking of Ethernet packets in the egress direction.

QoS L2 Re-marking of Ethernet Packets in Egress Direction

The router supports Layer 2 marking of Ethernet packets in the egress direction.

To enable this feature, you must:

- Configure the policy maps for queuing and marking at the egress interface.
- Set traffic-class in the ingress and use **match traffic-class** in the egress for queuing.
- Ensure that the **set qos-group** command is configured in ingress policy and the corresponding **match qos-group** command is configured in the egress marking policy. If there is no corresponding QoS group, you will experience traffic failure.

The ingress ‘push VLAN’ is translated to ‘pop VLAN’ for the egress traffic. In this case, (CoS, DEI) re-marking is not supported for the VLAN tag. For example:

1. rewrite ingress tag push dot1q/dot1ad < symmetric
2. rewrite ingress tag push dot1q/dot1ad < second-dot1q < symmetric
3. rewrite ingress tag translate 1-to-2 dot1q/dot1ad < second-dot1q < symmetric

Running Configuration

```
policy-map egress-marking
class qos1
set cos 1
!
class qos2
set cos 2
set dei 1
!
class qos3
set cos 3
!
class class-default
set cos 7
!
end-policy-map
!
```

QoS L2 Re-Marking of Ethernet Packets on L3 Flows in Egress Direction

The router supports Layer 2 marking of Ethernet packets on Layer 3 flows in the egress direction.

To enable this feature, you must:

- Configure the policy maps for marking at the egress interface.
- Ensure that the **set qos-group** command is configured in ingress policy and the corresponding **match qos-group** command is configured in the egress marking policy. If there is no corresponding QoS group, you will experience traffic failure.

Restrictions

The following restrictions apply while configuring the Layer 2 marking of Ethernet packets on Layer 3 flows in the egress direction.

- **set discard-class** is not supported in ingress policy with peering mode.
- Egress marking statistics are not available.
- Layer 2 (802.1p) Egress marking is supported on Layer 3 flows for these types of traffic: IP-to-IP, IP-to-MPLS, and MPLS-to-IP traffic.
- Layer 2 marking of Ethernet packets on Layer 3 flows in the egress direction is supported only in the peering mode.

Running Configuration

Ingress Policy:

You must first set up the qos-group at ingress.

```
class-map match-any Class0
  match mpls experimental topmost 0
  match precedence routine
  match dscp 0-7
end-class-map
class-map match-any Class1
  match mpls experimental topmost 1

QoS L2 Re-Marking of Ethernet Packets on L3 Flows in Egress Direction on L3 sub-interfaces

Table 7: Feature History Table

Feature Name	Release Information	Feature Description
Cisco NC57 Native Mode: 802.1p marking	Release 7.4.1	This feature is now supported on routers that have the Cisco NC57 line cards installed and operate in the native mode.

The router supports Layer 2 marking of Ethernet packets on Layer 3 flows in the egress direction on L3 subinterfaces.

To enable this feature, you must:

- Configure the policy maps for marking at the egress interface.
- Ensure that the **set qos-group** command is configured in ingress policy and the corresponding **match qos-group** command is configured in the egress marking policy. If there is no corresponding QoS group, you experience traffic failure.

Restrictions

The following restrictions apply while configuring the Layer 2 marking of Ethernet packets on Layer 3 flows in the egress direction.

- **set discard-class** is not supported in ingress policy with peering mode.
- Egress marking statistics are not available.
- Layer 2 (CoS, DEI) Egress marking is supported on Layer 3 flows on L3 subinterfaces for these types of traffic: IP-to-IP, IP-to-MPLS, and MPLS-to-IP traffic.

Running Configuration

Ingress Policy:

You must first set up the qos-group at ingress. This is applicable only when you want to mark packets at the egress.

```
class-map match-all COS0_DEI0
match cos 0
match dei 0
end-class-map
class-map match-all COS0_DEI1
match cos 0

Layer 2 Ingress QoS Matching for IPv4 and IPv6 Destination Addresses

Table 8: Feature History Table

Feature Name	Release Information	Feature Description
Layer 2 Ingress QoS Matching for IPv4 and IPv6 Destination Addresses	Release 7.5.1	<p>Using this feature, you can match class maps to IPv4 and IPv6 destination addresses on Layer 2 networks. The Layer 2 interface service policy has the relevant class maps, actioning them for ingress QoS operations.</p> <p>This feature provides you with an additional level of classification for aggregated customer traffic at your ingress, thus giving you granular control on traffic flows.</p> <p>This feature introduces the following commands:</p> <ul style="list-style-type: none">• match destination-address• hw-module profile qos l2-match-dest-addr-v4v6

Overview

As a service provider, you provide Layer 2 connectivity for different classes of customer traffic across your network. With aggregated customer traffic arriving at your ingress, you need to provide differential treatment depending on specific destination addresses for the traffic. Such ability gives you granular control over traffic, allowing you to classify specific traffic flows depending on the type of services for which your customers have signed up.

You can match class maps to IPv4 and IPv6 destination addresses on Layer 2 networks to ensure such granular control. The interface service policy has the relevant class maps, actioning them for ingress QoS marking.

Guidelines and Limitations

- You can match up to 4 IPv4 and IPv6 addresses each in a class.
- For match on IPv6, only up to 64-bit prefix match is supported.
- The L2VPN traffic can be Virtual Private Wire Service (VPWS) or Virtual Private LAN Service (VPLS).
- Redundant and non-redundant pseudowires are supported.
- This feature isn't supported with egress ACL enabled.
- This feature isn't supported on NC57 line cards.
- Traffic classification for VLAN tags is supported as shown in the following table.

VLAN Tag Condition	IPv4 Addresses	IPv6 Addresses	Combination of IPv4 and IPv6 Addresses
With no VLAN tags	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
With a single VLAN tag	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
With a double VLAN tag	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>

Configure Layer 2 Ingress QoS Matching for IPv4 and IPv6 Destination Addresses

Perform the following steps to configure Layer 2 ingress QoS matching for IPv4 and IPv6 destination addresses. This example covers:

- **match-all** criteria for an IPv4 address and a Layer 2 classification (**match dscp**) in the same class map.

Note You can use the **match-all** criteria only when you want to match one specific destination address with other Layer 2 classification options such (CoS, DEI) or DSCP.

- **match-any** criteria for IPv4 and IPv6 addresses in the same class map.

1. Enable the ability to match class maps to IPv4 and IPv6 destination addresses on Layer 2 networks. Reload the router for the **hw-module** command to be functional.
2. Create a class map and specify **match-all** criteria for an IPv4 address and DSCP.
3. Create a class map and specify **match-any** criteria for IPv4 and IPv6 addresses.
4. Create a policy map and associate the class maps you created with the traffic policy and specify **class-action**.
5. Attach the policy map to the interface.

Configuration

```
/*Enable the ability to match class maps to IPv4 and IPv6 destination addresses on Layer 2
networks*/
Router(config)#hw-module profile qos l2-match-dest-addr-v4v6
Router(config)#commit
Router#reload

/*Create a class map and specify match-all criteria for an IPv4 address and DSCP*/
Router(config)#class-map match-all ipv4_dst_cs1
Router(config-cmap)#match destination-address ipv4 192.168.1.4 255.255.255.255
Router(config-cmap)#match dscp cs1

/*Create a class map and specify match-any criteria for IPv4 and IPv6 addresses*/
Router(config-cmap)#class-map match-any V4_V6_MATCH
Router(config-cmap)#match destination-address ipv4 10.0.0.0 255.0.0.0
Router(config-cmap)#match destination-address ipv4 20.1.0.0 255.255.0.0
Router(config-cmap)#match destination-address ipv4 20.1.1.1 255.255.255.255
Router(config-cmap)#match destination-address ipv4 30.1.0.1 255.255.255.0
Router(config-cmap)#match destination-address ipv6 101:1:12::1/64
```

```

Router(config-cmap)#match destination-address ipv6 201:1:1::1/32
Router(config-cmap)#match destination-address ipv6 201:1:3::2/64
Router(config-cmap)#match destination-address ipv6 301:1:3::2/64
Router(config-cmap)#commit

/*Create a policy map, associate the class maps with the traffic policy; specify class-action:
 police rate, in this example*/
Router(config-cmap)#policy-map PMAP_L2_V4_V6_MATCH
Router(config-pmap)#class ipv4_dst_cs1
Router(config-pmap-c)#police rate 10 mbps
Router(config-pmap-c-police)#class V4_V6_MATCH
Router(config-pmap-c)#police rate 10 mbps
Router(config-pmap-c-police)#commit

/*Attach the policy map with class-actions that you set in the class maps*/
Router(config-pmap-c-police)#int Bundle-Ether100.2
Router(config-if)#service-policy input PMAP_L2_V4_V6_MATCH
Router(config-if)#commit

```

You have successfully configured Layer 2 ingress QoS matching for IPv4 and IPv6 destination addresses.

Running Configuration

```

qos l2-match-dest-addr-v4v6
!

class-map match-all ipv4_dst_cs1
 match destination-address ipv4 192.168.1.4 255.255.255.255
 match dscp cs1
!

class-map match-any V4_V6_MATCH
 match destination-address ipv4 10.0.0.0 255.0.0.0
 match destination-address ipv4 20.1.0.0 255.255.0.0
 match destination-address ipv4 20.1.1.1 255.255.255.255
 match destination-address ipv4 30.1.0.1 255.255.255.0
 match destination-address ipv6 101:1:12::1/64
 match destination-address ipv6 201:1:1::1/32
 match destination-address ipv6 201:1:3::2/64
 match destination-address ipv6 301:1:3::2/64
!

policy-map PMAP_L2_V4_V6_MATCH
 class ipv4_dst_cs1
  police rate 10 mbps
  class V4_V6_MATCH
   police rate 10 mbps
!

```

Verification

To verify that the configuration was successful, run the **sh policy-map pmap-name** command for the policy map you created with all class maps associated. The output displays all the **match-any** and **match-all** configurations for IPv4 and IPv6 addresses.

```

Router#sh policy-map pmap-name PMAP_L2_V4_V6_MATCH detail
class-map match-all ipv4_dst_cs1
 match destination-address ipv4 192.168.1.4 255.255.255.255

```

```

match dscp cs1
end-class-map

!
class-map match-any V4_V6_MATCH
match destination-address ipv4 10.0.0.0 255.0.0.0
match destination-address ipv4 20.1.0.0 255.255.0.0
match destination-address ipv4 20.1.1.1 255.255.255.255
match destination-address ipv4 30.1.0.1 255.255.255.0
match destination-address ipv6 101:1:12::1/64
match destination-address ipv6 201:1:1::1/32
match destination-address ipv6 201:1:3::2/64
match destination-address ipv6 301:1:3::2/64
end-class-map

!
policy-map PMAP_L2_V4_V6_MATCH
class ipv4_dst_cs1
  police rate 10 mbps
!

!
class V4_V6_MATCH
  police rate 10 mbps
!
!
class class-default
!
end-policy-map
!
!

Router#sh run interface bundle-ether 100
interface Bundle-Ether100
service-policy input ipv4_dst_cs1
  ipv4 address 192.168.1.4 255.255.255.255
  dscp cs1
service-policy input PMAP_L2_V4_V6_MATCH
  ipv4 address 10.1.0.1 255.255.255.0
  ipv6 address 10:1::1/96
!

```

Bundle Traffic Policies

A policy can be bound to bundles. When a policy is bound to a bundle, the same policy is programmed on every bundle member (port). For example, if there is a policer or shaper rate, the same rate is configured on every port. Traffic is scheduled to bundle members based on the load balancing algorithm.

Both ingress and egress traffic is supported. Percentage-based policies, absolute rate-based policies, and time-based policies are supported.

Note Egress marking is not supported on BVI interfaces.

For details, see [Configure QoS on Link Bundles, on page 156](#).

Shared Policy Instance

Table 9: Feature History Table

Feature Name	Release Information	Feature Description
Shared Policy Instance	Release 7.3.1	This feature allows you to share a single instance of QoS policy across multiple subinterfaces, allowing for aggregate shaping of the subinterfaces to one rate. The ability to facilitate queue consumption in this manner offers the advantage of saving on QoS and hardware resources, while ensuring that the specified rate is not exceeded.
Shared Policy Instance	Release 7.4.1	This feature is now supported on routers that have Cisco NC57 line cards installed and operate in native and compatibility modes.

Traditionally, when services required by your end-customers mapped one-on-one to an interface, attaching the QoS policy-map directly to the interface was the way to meet customer SLAs. However, with increasing demand for triple play configurations—requiring the management of voice and video queues in addition to data queues—you may have several forwarding constructs. This scenario calls for the need to apply an aggregate QoS policy across interfaces to provide the necessary traffic.

After you create the traffic class and traffic policy, you can optionally use a shared policy instance to allocate a single set of QoS resources and share them across a group of subinterfaces.

With shared policy instance, you can share a single instance of a QoS policy across multiple subinterfaces, allowing for aggregate shaping, policing, and marking of the subinterfaces to one rate. All the subinterfaces that share the instance of a QoS policy must belong to the same main interface. The number of subinterfaces that share the QoS policy instance can range from 2 to the maximum number of subinterfaces on the main interface.

When a shared policy instance of a policy map is shared by several subinterfaces, QoS operations such as aggregate shaping, policing, and marking are applied for traffic on all the interfaces that use the same shared policy instance.

Traditionally, policies were bound to interfaces. However, different types of interfaces, such as Layer 2 and Layer 3, can use a single shared-policy-instance, which allows flexibility in the "attachment point" that binds the policy map.

As an example, consider the following policy configuration:

```
policy-map hqos_gold
  class class-default
    service-policy child_hqos_gold
    shape average 20 mbps
  !
end-policy-map
!
policy-map child_hqos_gold
```

```

class voice
  priority level 1
  shape average 64 kbps
!
class video
  priority level 1
  shape average 4 mbps
!
class data
  bandwidth 5 mbps
!
class class-default
!
end-policy-map
!

interface TenGigE 0/1/0/10.300 l2transport
  service-policy output hqos_gold shared-policy-instance hqos_gold_customer1
!
interface TenGigE 0/1/0/10.400 l2transport
  service-policy output hqos_gold shared-policy-instance hqos_gold_customer1
!

```

The keyword **shared-policy-instance** and the instance name **hqos_gold_customer1** identify the subinterfaces that share an aggregate SLA. These are shared on a physical main interface or a bundle member. In other words, in a mix of Layer 2 and Layer 3 subinterfaces in the same shared policy instance, both layers support classification criteria and action.

In the case of bundles, sharing is applicable within a bundle member and not the entire bundle. Depending on the traffic hashing, shared policy instance may or may not take effect across the subinterface under the bundle main interface.

All subinterfaces that share the same shared policy instance share resources as well. Hence, the **show policy-map** statistics values and **show qos** values for all the subinterfaces are the same.

Restrictions and Guidelines

The following restrictions and guidelines apply while configuring shared policy instance for a policy map.

- Subinterfaces that are part of the same shared policy must belong to the same main interface. In other words, subinterfaces of different main interfaces cannot be part of the same shared policy.
- There is no restriction on the number of unique shared policies across a system. However, the limit of maximum number of subinterfaces with QoS policies applies.
- There is no restriction on the number of unique shared policies per main interface, port, core, NPU, or line card.
- You cannot use the same shared policy name on the ingress and egress of the same subinterface.
- Shared policy instance is not supported with multi-policies. For example, on the egress, you cannot apply a marking policy and a queueing policy under a shared policy.
- A shared policy can include a combination of Layer 2 and Layer 3 subinterfaces.

Attaching a Shared Policy Instance to Multiple Subinterfaces

To attach a shared policy instance to multiple subinterfaces:

1. Enter interface configuration mode and configure a subinterface.

2. Attach a policy map to an input or output subinterface for it to be the service policy for that subinterface.

```
RP/0/RP0/CPU0:router(config)#interface HundredGigE0/3/0/0.1
RP/0/RP0/CPU0:router(config-subif)#service-policy output pm-out shared-policy-instance spi1
```

Running Configuration

```
interface HundredGigE0/3/0/0.1
service-policy output pm-out shared-policy-instance spi1
ipv4 address 20.0.0.1 255.255.255.0
encapsulation dot1q 1
!
```

Verification

The `show policy-map shared-policy-instance` command includes an option to display counters for the shared policy instance.

Note

- For bundle subinterfaces, use RP as the location keyword.
- For physical subinterfaces, use LC as the location keyword.

For example, for a physical interface:

```
RP/0/RP0/CPU0:ios#show policy-map shared-policy-instance spi1 output location 0/3/CPU0
```

Shared Policy Instance spi1 output: pm-out

```
Class cm-tc-1
  Classification statistics          (packets/bytes)          (rate - kbps)
    Matched                        :      772637560/1143503679080      9622860
    Transmitted                    :      731260312/1082265352040      5052880
    Total Dropped                  :      41377248/61238327040        4569980
  Queueing statistics
    Queue ID                       :      1433
    Taildropped(packets/bytes)     :      41377248/61238327040
Class class-default
  Classification statistics          (packets/bytes)          (rate - kbps)
    Matched                        :              0/0              0
    Transmitted                    :              0/0              0
    Total Dropped                  :              0/0              0
  Queueing statistics
    Queue ID                       :      1432
    Taildropped(packets/bytes)     :              0/0
Policy Bag Stats time: 1604675533816 [Local Time: 11/06/20 15:12:13.816]
```

Use the **`clear qos counters shared-policy-instance`** command to clear counters for the shared policy instance.

Note

- For bundle subinterfaces, use RP as the location keyword.
- For physical subinterfaces, use LC as the location keyword.

For example, for a physical interface:

```
RP/0/RP0/CPU0:ios#clear qos counters shared-policy-instance spil output location 0/3/CPU0
```

The **show qos shared-policy-instance** command allows you to display the QoS hardware programming values.

Note

- For bundle subinterfaces, use RP as the location keyword.
- For physical subinterfaces, use LC as the location keyword.

For example, for a physical interface:

```
RP/0/RP0/CPU0:ios#show qos shared-policy-instance spil output location 0/3/CPU0
Fri Nov  6 15:21:44.200 UTC
NOTE:- Configured values are displayed within parentheses

```

Ingress Short-Pipe

When QoS traffic leaves an MPLS network, the MPLS label stack is removed on the penultimate ingress Label Switch Router (LSR), leaving an IPv4 or IPv6 packet to be forwarded. MPLS experimental bits (or EXP or pipe mode) carries out this disposition process and the packet is marked with a Differentiated Services Code Point (DSCP) or precedence value (also called DSCP or Precedence-based classification).

Usually, QoS traffic supports DSCP and precedence-based classifications only when there is no MPLS label in the packet. Using the ingress short-pipe feature, however, you can classify a packet that contains one MPLS label using the type-of-service (ToS) field of the IPv4 or IPv6 header. This classification method is called ingress short-pipe. To classify an IP packet this way, you must:

1. Create a child class map.

2. Specify a ToS value in the child class map.
3. Attach the child class map to a parent class map.
4. Create a policy map containing the parent class map.
5. Set any ingress action such as traffic class or QoS group. From Release 7.1.1 onwards, you can also set ingress action DSCP (or precedence value).

With the ingress short-pipe feature, you get an increased visibility into traffic packets. Plus, the feature also removes the limitation of classifying MPLS packets that come into IPv4 or IPv6 networks.

Restrictions and Other Important Points

Ensure that you read these points before you configure the ingress short-pipe feature.

- This feature isn't supported on:
 - NC57-24DD
 - NC57-18DD-SE
 - NC57-36H-SE
 - NC57-36H6D-S
 - NC57-MOD-S
 - NCS-57B1-6D24-SYS
 - NCS-57B1-5DSE-SYS
 - NCS-57C3-MOD-SYS
 - NCS-57D2-18DD-SYS
- This feature works only when there is one MPLS header in the traffic packet. If there are two or more MPLS headers, the ingress-short pipe feature fails. For example, in case of Explicit Null where there are two labels at the disposition, this feature will not work.
- You can carry out ingress classification using either the MPLS experimental bits (or EXP or pipe mode) classification OR the DSCP/precedence (or short-pipe) classification. Ensure that you do not mix the classification methods, else it may result in an unknown behavior, and the classification may not work at all.
- This feature is supported only on L3VPN, and not supported on L2VPN.
- This feature works for regular IPv4/IPv6 traffic, but will not work for IPv6 VPN Provider Edge over MPLS (6VPE).
- You can add only one child class map to a parent class map.
- This feature supports the invocation of short-pipe and legacy DSCP classification for the same parent class map.
- The child class map can contain only match precedence and match dscp commands.
- This feature is not supported in peering mode.

Configure Ingress Short-Pipe

This section details a sample configuration for the ingress short-pipe feature and another sample to configure classification for labeled and non-labeled packets under the same parent class.

Sample configuration to classify a packet that contains one MPLS label using the type-of-service (ToS) field of the IPv4 or IPv6 header (or the ingress short-pipe method):

```
class-map match-any in_pipe
  match mpls disposition class-map child_pipe
end-class-map
!
class-map match-any child_pipe
  match precedence 1
  match dscp ipv4 af11
  end-class-map
!
class-map match-any ingress-business-high
  match dscp af21 af22
end-class-map

class-map match-any ingress-business-low
  match dscp af11 af12
end-class-map

policy-map ingress-classifier
  class in_pipe
    set traffic-class 5
    set dscp af31
  class ingress-business-high
    set traffic-class 4
  class ingress-business-low
    set traffic-class 2
  class class-default
    set traffic-class 0
  !
```

Note The **set dscp** option is available from Release 7.1.1 onwards.

You can configure classification for both labeled and non-labeled packets under the same parent class as in the following sample configuration. In this example, for MPLS labeled packets, DSCP configured under the child class is classified, while for non-labeled packets, DSCP/ToS configured in the **match dscp <value>** statement is classified.

DSCP value range is from 0 through 63. The range option is not supported. Up to 8 items per class are supported. Up to 64 **match dscp** values in total.

```
class-map match-any in_pipe
  match mpls disposition class-map child_pipe (labeled case)
  match dscp af11 (non-labeled case)
end-class-map
!
class-map match-any child_pipe
  match precedence 1
  match dscp ipv4 af11
  end-class-map
!
class-map match-any ingress-business-high
  match dscp af21 af22
```

```
end-class-map

class-map match-any ingress-business-low
match dscp af11 af12
end-class-map

policy-map ingress-classifier
class in_pipe
set traffic-class 5

class ingress-business-high
set traffic-class 4
class ingress-business-low
set traffic-class 2
class class-default
set traffic-class 0
!
```

Associated Commands

- match mpls disposition class-map

Selective Egress Policy-Based Queue Mapping

With selective egress policy-based queue mapping, you can combine traffic class (TC) maps in various permutations at the egress.

Note Modular chassis do not support this feature.

The primary aim of introducing the egress TC (traffic class) mapping is to classify the traffic in the ingress using a single policy and place the classified traffic into queues, by assigning the traffic classes. At the egress, you can support different groupings of TCs.

Based on different Service Level Agreements (SLAs) that each customer has signed up for, you can group some TCs into priority queues for real time (RT) traffic, other TCs into guaranteed bandwidth (BW) traffic, and the rest into best effort (BE) traffic delivery.

Let us consider an example where three customers have purchased these services, based on their requirements:

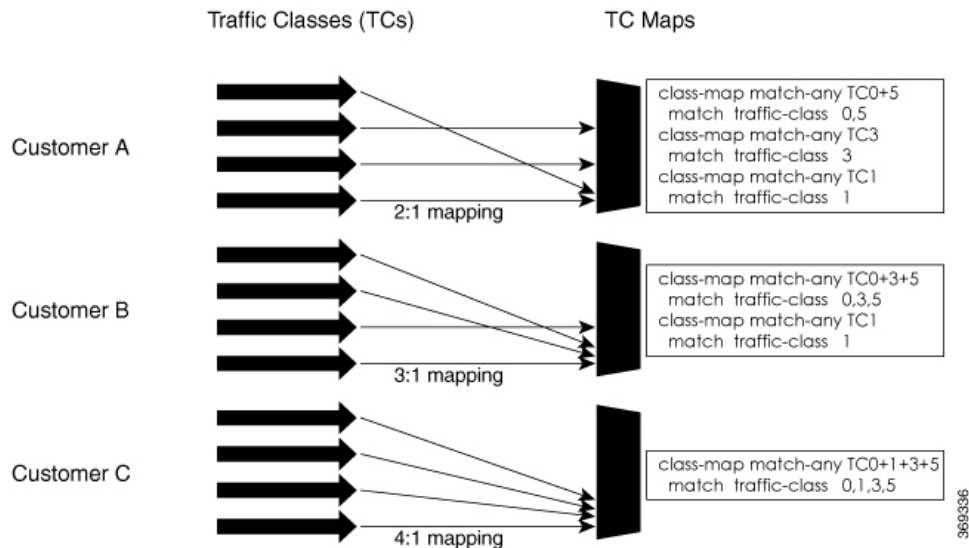

- Customer A - Requires RT traffic, reserved BW traffic and BE traffic delivery.
- Customer B – Requires reserved BW traffic and BE traffic delivery.
- Customer C – Needs only BE traffic delivery.

Using the selective egress policy-based queue mapping, you can create three profiles this way:

- Customer A – Priority queue RT traffic (TC1), Guaranteed BW traffic (TC3), Best effort traffic (TC0, TC5)
- Customer B – Guaranteed BW traffic (TC1), Best effort traffic (TC0, TC3, TC5)
- Customer C - Best effort traffic (TC0, TC1, TC3, TC5)

Using the egress TC-mapping, you can create three different profiles that you can use for each customer based on their SLAs with the provider.

Figure 1: Selective Egress Policy-Based Queue Mapping Helps Create Customer Profiles Based on Their SLAs

Restrictions and Other Important Points

- Ensure that you read these points before you configure the selective egress policy-based queue-mapping feature.
 - There can be only one TC (Traffic Class) mapped class to a PM (Policy Map).
 - You cannot use a TC that you used in a mapped class, in a non-mapped class under the same PM.
 - You can have a maximum of three unique TC mapped PMs or profiles per platform.
 - Every TC mapped class must include **traffic-class 0** in the range values.
 - The TC-mapping range is from 0 through 5.
 - When a TC-mapped class is present in a PM, the class default becomes a dummy class. This means that the class default statistics and QoS values are not applicable.
 - All the class default limitations apply to the TC-mapped class; for example, you cannot configure **priority** command under the TC mapped class.

Note A TC-mapped PM or profile is a PM that contains a TC-mapped class.

Example of a TC-mapped class:

match traffic-class 0 1 2 3

Example of a TC non-mapped class:

match traffic-class 1

Configure Selective Egress Policy-Based Queue Mapping

This section details a sample configuration for the selective egress policy-based queue-mapping feature and a use case to show how this feature works.

Sample configuration

```
class-map match-any <name>
  match traffic-class <value>
commit

policy-map tc_pmap
  class tc035
    shape average percent 1
  !
  class class-default
  !
end-policy-map
!
class-map match-any tc035
match traffic-class 0 3 5
end-class-map
!
```

Verification

Run the **show qos interface** and **show policy-map interface** commands.

When TC mapping class is present in a policy map, the class default does not have any values calculated.

show qos interface bundle-Ether 44 output sample

```
NOTE:- Configured values are displayed within parentheses

```

Use Case

With the ingress traffic matching the same match criteria, you can group the egress traffic up to three unique TC mapped profiles. Using this feature, you can provide differentiated services to customers based on the SLAs they have signed up for.

In the example that follows, the ingress policy-map sets the ingress match criteria for the traffic class from 0 through 5. Based on the SLAs, you can group the TC values at the egress PM to deliver differentiated services.

After you group the TC values, you can apply specific egress actions under that class.

Ingress match:

```

class EXP1
  set traffic-class 1
!
class EXP2
  set traffic-class 2

```

```

!
class EXP3
  set traffic-class 3
!
class EXP4
  set traffic-class 4
!
class EXP5
  set traffic-class 5
!
class class-default
!
end-policy-map
!

```

Egress match:**Sample TC mapped class for policy-map PM1**

```

class-map match-any TC2:1
match traffic-class 0 1
end-class-map

```

Sample TC mapped class for policy-map PM2

```

class-map match-any TC3:1
match traffic-class 0 1 2
end-class-map

```

Sample TC mapped class for policy-map PM3

```

class-map match-any TC6:1
match traffic-class 0 1 2 3 4 5
end-class-map

```

Configuring QoS Groups with an ACL

You can create QoS groups and configure ACLs to classify traffic into the groups based on a specified match condition. In this example, we match by the QoS group value (0-511).

Supported ACL Types

Your router supports the following ACL types.

Note If you configure QoS group with an unsupported ACL type, the system doesn't display any error message.

ACL Type	Example
IPv4 DSCP	permit ipv4 any any dscp af43
UDP DSCP	permit udp any any dscp af43
UDP Fragments IPv4	udp any any fragments - IPv4
UDP Fragments IPv6	udp any any fragments - IPv6
TCP Fragments IPv4	tcp any any fragments - IPv4

ACL Type	Example
TCP Fragments IPv6	tcp any any fragments - IPv6
IPv4 DSCP Fragments	permit ipv4 any any dscp af43 fragments
UDP DSCP Fragments	permit udp any any dscp af43 fragments
UDP Host Fragments	permit udp host <sip> host <dip> fragments
TCP Host Fragments	permit tcp host <sip> host <dip> dscp af43 fragments
TCP DSCP	permit tcp <source network > <destination network> dscp af43
TCP Port based	permit tcp any any eq <port>
UDP Port based	permit udp any any eq <port>
TCP Flags	permit tcp host <sip> host <dip> established fin psh syn urg

Restrictions

- ACLs with fragment match are supported on systems with only NC57 line cards, also referred to as native mode.
- IPv6 ACLs with fragment match are supported only in **short** and **short-l2-qos** mode.

Prerequisites

Before you can configure QoS groups with an ACL, the QoS peering profile must be enabled on the router or the line card. After enabling QoS peering, the router or line card must be reloaded, as shown in the following configuration.

Note If you enable QoS peering, the Source-based RTBH (S-RTBH) feature will not be supported due to hardware limitations related to copy engine availability.

Enabling QoS Peering Profile on the Router

Enter the global configuration mode and enable the QoS peering profile for the router as shown:

```
RP/0/RP0/CPU0:router(config)# hw-module profile qos ingress-model peering
RP/0/RP0/CPU0:router(config)# exit
RP/0/RP0/CPU0:router# reload
```

Enabling QoS Peering Profile on the Line Card

Enter the global configuration mode and enable the QoS peering profile for the line card as shown:

```
RP/0/RP0/CPU0:router(config)# hw-module profile qos ingress-model peering location 0/0/CPU0
RP/0/RP0/CPU0:router(config)# exit
RP/0/RP0/CPU0:router# reload location 0/0/CPU0
```

Configuration

Use the following set of configuration statements to configure an ACL with QoS groups.

```
/*
  Enter the global configuration mode, and configure an ACL with the required QoS groups.
*/
RP/0/RP0/CPU0:router# configure
RP/0/RP0/CPU0:router(config)# ipv4 access-list qos-acl
RP/0/RP0/CPU0:router(config-ipv4-acl)# 10 permit ipv4 host 5.0.0.1 any set qos-group 1
RP/0/RP0/CPU0:router(config-ipv4-acl)# 11 permit ipv4 host 6.0.0.1 any set qos-group 2
RP/0/RP0/CPU0:router(config-ipv4-acl)# 12 permit ipv4 host 7.0.0.1 any set qos-group 3
RP/0/RP0/CPU0:router(config-ipv4-acl)# 13 deny ipv4 any any

/* Create a policy map with the required classes.
In this example, we also create a default class for traffic that does not belong to any of
the specified
classes. */
RP/0/RP0/CPU0:router(config)# policy-map qos-acl-map
RP/0/RP0/CPU0:router(config-pmap)# class qos1
RP/0/RP0/CPU0:router(config-pmap-c)# set dscp af43
RP/0/RP0/CPU0:router(config-pmap-c)# set traffic-class 2
RP/0/RP0/CPU0:router(config-pmap-c)# exit

RP/0/RP0/CPU0:router(config-pmap)# class qos2
RP/0/RP0/CPU0:router(config-pmap-c)# set precedence critical
RP/0/RP0/CPU0:router(config-pmap-c)# set traffic-class 7
RP/0/RP0/CPU0:router(config-pmap-c)# exit

RP/0/RP0/CPU0:router(config-pmap)# class qos3
RP/0/RP0/CPU0:router(config-pmap-c)# set precedence 2
RP/0/RP0/CPU0:router(config-pmap-c)# set traffic-class 2
RP/0/RP0/CPU0:router(config-pmap-c)# exit

RP/0/RP0/CPU0:router(config-pmap)# class qos4
RP/0/RP0/CPU0:router(config-pmap-c)# set traffic-class 4
RP/0/RP0/CPU0:router(config-pmap-c)# set dscp cs4
RP/0/RP0/CPU0:router(config-pmap-c)# exit

RP/0/RP0/CPU0:router(config-pmap)# class class-default
RP/0/RP0/CPU0:router(config-pmap-c)# police rate percent 20
RP/0/RP0/CPU0:router(config-pmap-c-police)# exit

/* Create the class maps for specifying the match conditions. */
RP/0/RP0/CPU0:router(config)# class-map match-any qos1
RP/0/RP0/CPU0:router(config-cmap)# match qos-group 1
RP/0/RP0/CPU0:router(config-cmap)# end-class-map

RP/0/RP0/CPU0:router(config)# class-map match-any qos2
RP/0/RP0/CPU0:router(config-cmap)# match qos-group 2
RP/0/RP0/CPU0:router(config-cmap)# end-class-map

RP/0/RP0/CPU0:router(config)# class-map match-any qos3
RP/0/RP0/CPU0:router(config-cmap)# match qos-group 3
RP/0/RP0/CPU0:router(config-cmap)# end-class-map

RP/0/RP0/CPU0:router(config)# class-map match-any qos4
RP/0/RP0/CPU0:router(config-cmap)# match qos-group 4
RP/0/RP0/CPU0:router(config-cmap)# end-class-map
```

```

/* Apply the access list and the QoS map to the Gigabit interface, and commit your
configuration. */
RP/0/RP0/CPU0:router(config)# interface TenGigE0/0/0/1

You have successfully configured an ACL with QoS groups.

Configuring an ACL with Fragment Match

Usually, IP ACLs process non-fragmented packets and the first fragments of a packet using permit and deny actions. These packets may have Layer 3 and 4 information that the ACLs match for a permit or deny action. By default, however, ACLs permit noninitial fragments. This could lead to potential security issues with users with malicious intent using the noninitial fragments to launch denial of service (DoS) attacks.

With this feature, you can now to set QoS policies for noninitial fragment packets, thus having more granular control over noninitial IP fragments of a packet. Noninitial IP fragments have the fragment offset value non-zero. To know more about fragments, see the *IP Addresses and Services Configuration Guide for Cisco NCS 5500 Series Routers*.

Restrictions and Guidelines

The following restrictions and guidelines apply while configuring an ACL with fragment match.

- To enable IPv6 fragment classification support, configure **hw-module profile qos ipv6 short-l2qos-enable** or **hw-module profile qos ipv6 short**.
- IPv6 fragmentation is supported with only one Extension Header (EH).

Configuring an ACL with Fragment Match

For IPv4 and IPv6 ACLs

To configure an ACL with fragment match, you must:

1. Create IPv4 and IPv6 ACLs with fragment match.

Note To enable IPv6 fragment classification support, configure **hw-module profile qos ipv6 short-l2qos-enable** or **hw-module profile qos ipv6 short**.

2. Create two class maps, one for IPv4 and IPv6, and attach the respective ACLs to the class maps.
3. Create a policy map with these two class maps and set action.

```
Router(config)#ipv4 access-list v4_ace
Router(config-ipv4-acl)#permit ipv4 any any fragments
Router(config-ipv4-acl)#exit
Router(config)#
Router(config)#ipv6 access-list v6_ace
Router(config-ipv6-acl)#permit ipv6 any any fragments
Router(config-ipv6-acl)#exit
Router(config)#
Router(config)#class-map match-any v4_class
Router(config-cmap)#match access-group ipv4 v4_ace
Router(config-cmap)#exit
Router(config)#
Router(config)#class-map match-any v6_class
Router(config-cmap)#match access-group ipv6 v6_ace
Router(config-cmap)#exit
Router(config)#policy-map frag_policy

Restrictions

Refer to the following table for Ingress QoS Scale limitation.

Table 10: Ingress QoS Scale Limitation

QoS Mode	Class-Map Size	Maximum number of Interfaces with Ingress QoS Applied	
		Per Core	Per NPU
Normal	4	1023	2046
Normal	8	511	1022
Normal	16	255	510
Normal	32	127	254
Enhanced	4	871	1742
Enhanced	8	435	870
Enhanced	16	217	434
Enhanced	32	108	216

This is a tabular classification of NCS 540 series platform and related models, detailing their maximum supported policers and class-map entries. When enhanced mode is enabled, the number of supported policers is reduced by half compared to the standard mode.

Note If you apply an ingress policy map to a bundle that has bundle members only from a single core of an NPU, the QoS resources are consumed on both cores of that NPU.

Example: For Default Configuration, which is Normal (2 counter mode) QoS Mode & 32 Class Map-Size, you can configure 191 interfaces with Ingress Policy per core.

Other restrictions to follow:

- If you have a **set traffic class** statement explicitly configured in the ingress service policy, it's mandatory to have a corresponding **match traffic class** on egress for the traffic to be correctly matched and the stats to be accounted in **show policy-map interface <> output** command. To match the ingress traffic to the egress class-default, traffic class should be set to 0 on ingress.

- If you have a **set traffic class that is configured** in ingress service policy, and no corresponding **match traffic class** on egress, the traffic won't go to class default and the stats for this traffic flow won't be seen in **show policy-map interface <> output** command.
- If you don't have any **set traffic class** statement in ingress, then traffic will hit the default-class on egress.
- If you have a **set discard-class** statement configured in the ingress service policy, it's mandatory to have a corresponding **match discard-class** on egress for the traffic to be correctly matched and the stats to be accounted in **show policy-map interface <> output** command.
- If you have a **set discard-class** statement configured in the ingress service policy and don't have a corresponding **match discard-class** on egress, the traffic won't hit the class-default and the stats for this flow won't be accounted in **show policy-map interface <> output** command.
- The system doesn't support class-map size on peering mode.
- Even if you have an egress policy that has the drop action configured, the transmitted counter stats still shows an increment.
- Depending on the packet size, the traffic shaped value for low shaper rates, such as 10mbps, have greater deviation than 5% of tolerance from the shaper value. For higher shaper rates, the deviation is within the limit of 5% of tolerance from the shaper value for all packet sizes.
- If the shaper rate is less than 7 Mbps, the calculation of queue-limit is based on 10 ms of guaranteed service rate, and which leads to different queue-limit for each shaper value. This consumes the rate-profile for each queue-limit, and can also lead to a queue-limit of less than 1 MTU causing larger packets to drop.

Restrictions for Peering QoS Profile

- After enabling the QoS peering feature using the **hw-module profile qos ingress-model peering** command, you can set the Layer 2 class of service (CoS) or drop eligible indicator (DEI) values at the egress using the **set cos** or **set dei** commands, respectively. However, at the egress, ensure that you don't set the MPLS experimental imposition (EXP) values (using the **set mpls experimental imposition** command). Otherwise, when committing the policy map with these configurations at the egress, you will encounter an error. This error occurs because the internal fields required for egress EXP marking are not available with peering enabled.
- **explicit set discard-class** statement isn't supported.
- This feature is supported only on L3 interfaces and is limited to 1000 L3 interfaces per system.
- **set mpls exp topmost** statement isn't supported within QoS in peering mode.
- **access group** statement isn't supported.
- (Only in Release 6.2.x and Release 6.3.x) **set mpls exp imposition** statement isn't supported on ingress interface.
- 2-Level ingress policers isn't supported.
- (From Release 6.5.x) Egress H-QOS with peering profile support is enabled, but ingress H-QOS with peering profile isn't supported.
- Depending on the packet size, the traffic shaped value for low shaper rates, such as 10mbps, have greater deviation than 5% of tolerance from the shaper value. For higher shaper rates, the deviation is within the limit of 5% of tolerance from the shaper value for all packet sizes.

- (From Release 7.2.1) On NC57 line cards, QoS ingress peering profile isn't supported. This restriction is applicable for systems operating in compatibility mode and native mode.

Restrictions for QoS on BVI

- The system doesn't support the egress policy on Bridge-Group Virtual Interface (BVI), but BVI (CoS, DEI) marking is supported by applying the policy to its corresponding Layer 2 interface, which is part of the same bridge domain.
- If you apply L3 ingress QoS policy on L2 interface, which is a part of the same bridge-domain as BVI, the classification might not work if packets are destined to the BVI MAC address.
- If a QoS policy is attached to BVI, the policy is inherited by the L2 interfaces, which are part of the same bridge-domain. Hence, any other policy can't be applied on the L2 interfaces. Similarly, if a QoS policy is attached to any of the L2 interfaces, any QoS policy can't be applied on the BVI, which is part of the same bridge-domain.
- In the two-pass forwarding model for packets from Layer 2 to Layer 3 over BVI, where Layer 2 and Layer 3 forwarding are split across two paths and packet processing happens in two cycles, you can apply separate QoS policies for Layer 2 and BVI interfaces.

Restrictions for Egress Drop Action

- A maximum of 8 interfaces can have the drop action configured and a maximum of 8 classes in any single policy can have the drop action.
- A drop action in any particular class can't be combined with other actions.
- Drop action in a policy applied on the main interface isn't inherited onto sub-interfaces.
- Match condition for drop action PM can only be based on qos-group, discard class based match isn't supported.

In-Place Policy Modification

The In-Place policy modification feature allows you to modify a QoS policy even when the QoS policy is attached to one or more interfaces. A modified policy is subjected to the same checks that a new policy is subject to when it is bound to an interface. If the policy-modification is successful, the modified policy takes effect on all the interfaces to which the policy is attached. However, if the policy modification fails on any one of the interfaces, an automatic rollback is initiated to ensure that the pre-modification policy is in effect on all the interfaces.

You can also modify any class map used in the policy map. The changes made to the class map take effect on all the interfaces to which the policy is attached.

**Note**

- The QoS statistics for the policy that is attached to an interface are lost (reset to 0) when the policy is modified.
- When a QoS policy attached to an interface is modified, there might not be any policy in effect on the interfaces in which the modified policy is used for a short period of time.
- The system does not support the show policy-map statistics for marking policies.
- An in-place modification of an ACL does not reset the policy-map statistics counter.

**Note**

- For QOS EXP-Egress marking applied on a Layer 3 interface on Cisco NCS550x and NCS55Ax routers, there is a limit of two unique policy-maps per NPU. This limit is three unique policy maps per NPU for routers that have the Cisco NC57 line cards installed. When the maximum limit for policy-maps is reached and you try to modify a policy-map which is shared between different interfaces, you may get an error.
- For QOS egress marking (CoS, DEI) applied on a Layer 2 interface, there is a limit of 13 unique policy-maps per NPU. When the maximum limit for policy-maps is reached and you try to modify a policy-map which is shared between different interfaces, you may get an error.

Verification

If unrecoverable errors occur during in-place policy modification, the policy is put into an inconsistent state on target interfaces. No new configuration is possible until the configuration session is unblocked. It is recommended to remove the policy from the interface, check the modified policy and then re-apply accordingly.

References for Modular QoS Service Packet Classification

Specification of the CoS for a Packet with IP Precedence

Use of IP precedence allows you to specify the CoS for a packet. You can create differentiated service by setting precedence levels on incoming traffic and using them in combination with the QoS queuing features. So that, each subsequent network element can provide service based on the determined policy. IP precedence is usually deployed as close to the edge of the network or administrative domain as possible. This allows the rest of the core or backbone to implement QoS based on precedence.

Figure 2: IPv4 Packet Type of Service Field

You can use the three precedence bits in the type-of-service (ToS) field of the IPv4 header for this purpose. Using the ToS bits, you can define up to eight classes of service. Other features configured throughout the network can then use these bits to determine how to treat the packet in regard to the ToS to grant it. These other QoS features can assign appropriate traffic-handling policies, including congestion management strategy and bandwidth allocation. For example, queuing features such as LLQ can use the IP precedence setting of the packet to prioritize traffic.

IP Precedence Bits Used to Classify Packets

Use the three IP precedence bits in the ToS field of the IP header to specify the CoS assignment for each packet. You can partition traffic into a maximum of eight classes and then use policy maps to define network policies in terms of congestion handling and bandwidth allocation for each class.

Each precedence corresponds to a name. IP precedence bit settings 6 and 7 are reserved for network control information, such as routing updates. These names are defined in RFC 791.

IP Precedence Value Settings

By default, the routers leave the IP precedence value untouched. This preserves the precedence value set in the header and allows all internal network devices to provide service based on the IP precedence setting. This policy follows the standard approach stipulating that network traffic should be sorted into various types of service at the edge of the network and that those types of service should be implemented in the core of the network. Routers in the core of the network can then use the precedence bits to determine the order of transmission, the likelihood of packet drop, and so on.

Because traffic coming into your network can have the precedence set by outside devices, we recommend that you reset the precedence for all traffic entering your network. By controlling IP precedence settings, you prohibit users that have already set the IP precedence from acquiring better service for their traffic simply by setting a high precedence for all of their packets.

The class-based unconditional packet marking and LLQ features can use the IP precedence bits.

IP Precedence Compared to IP DSCP Marking

If you need to mark packets in your network and all your devices support IP DSCP marking, use the IP DSCP marking to mark your packets because the IP DSCP markings provide more unconditional packet marking options. If marking by IP DSCP is undesirable, however, or if you are unsure if the devices in your network support IP DSCP values, use the IP precedence value to mark your packets. The IP precedence value is likely to be supported by all devices in the network.

You can set up to 8 different IP precedence markings and 64 different IP DSCP markings.

Conditional Marking of MPLS Experimental bits for L3VPN Traffic

The conditional marking of MPLS experimental bits is achieved for Layer 3 Virtual Private Network (L3VPN) traffic by applying a combination of ingress and egress policy-maps on the Provider Edge (PE) router. In the ingress policy-map, the qos-group or discard-class is set either based on the result of the policing action or implicitly. The egress policy-map matches on qos-group or discard-class and sets the mpls experiment bits to the corresponding value.

This feature is supported on both IPv4 and IPv6 traffic in the L3VPN network. Conditional marking can be used to mark the MPLS experimental bits differently for in-contract and out-of-contract packets. In-contract packets are the confirmed packets with the color green and discard-class set to 0. Out-of-contract packets are the packets which have exceeded the limit and have the color yellow and discard-class set to 1.

Conditional marking of MPLS experimental bits for L3VPN traffic is supported on both physical and bundle main interfaces as well as sub-interfaces.

Restrictions for Conditional Marking of MPLS Experimental bits on L3VPN

1. In the case of two PE routers connected back-to-back and the only label that the traffic between the routers have is the BGP label, then the explicit null label should be configured.
2. A maximum of three policy-maps which perform conditional marking of MPLS experimental bits can be configured per Network Processor Unit (NPU) of the Cisco NCS 5500 Series Routers.
3. In the ingress policy-map if qos-group is being set for the incoming traffic packets, then setting of dscp and mpls experimental bits will not work.
4. Both the ingress and egress policy-maps must be applied in order to attain the expected behaviour. If either one of them is not applied then it may lead to undefined behaviour.
5. If the egress policy-map does not match on qos-group or discard-class and set the mpls experiment bits to the required value, then the mpls experimental bits will be set to a value of zero, by default.

QoS DSCP Preservation

Table 11: Feature History Table

Feature Name	Release Information	Feature Description
QoS DSCP Preservation	Release 7.2.1	This feature is now also supported on routers that have the Cisco NC57 line cards installed and operate in the native mode.

The DSCP value of the packet is preserved only for L3VPN networks when the packets are destined to the directly connected routes on the PE routers. To preserve the DSCP value for packets to destinations beyond the egress PE routers for L3VPN, you should use the **label mode per-vrf** command under the VRF at the PE routers. Similarly for MPLS networks, the default behaviour is uniform mode where the penultimate hop copies the MPLS EXP bit to IP DSCP and IP DSCP value is not preserved beyond the egress PE router. To preserve the IP DSCP value, you should use the **mpls ip-ttl-propagate disable** command at the penultimate hop.

DSCP value preservation is not supported on NC57-24DD and NC57-18DD-SE line cards for Cisco IOS XR Release 7.0.2.

Policy-map for conditional marking of incoming IPv4 and IPv6 traffic

The incoming packets are classified based on the ingress policy-map and the following actions are done.

- Set qos-group
- Discard class or drop precedence is set implicitly or as a result of a policing action.
- Packets that violate the configured policer are dropped in the ingress processing itself.

Running Configuration:

```

policy-map ingress
  class af11
    police rate percent 10 peak-rate percent 20
    !
    set qos-group 1
    !
  class af22
    police rate percent 30 peak-rate percent 50
    !
    set qos-group 2
    !
  class af32
    set qos-group 3
    police rate percent 30 peak-rate percent 60
    !
    !
  class class-default
    !
  end-policy-map
  !

```

Policy-map for conditional marking of outgoing MPLS traffic

The IPv4 or IPv6 ingress packet undergoes MPLS encapsulation during the egress processing in the PE router which performs the label imposition. The MPLS experimental bits are marked on the basis of egress policy-map which performs the following actions:

- Match on qos-group or discard class or both
- Set the MPLS experimental bits based on the match criteria

Running Configuration:

```

policy-map egress
  class qos1_disc0 # This class matches on qos-group 1 and discard-class 0
    set mpls experimental imposition 1
    !
  class qos1_disc1 # This class matches on qos-group 1 and discard-class 1
    set mpls experimental imposition 5
    !
  class qos2_disc0 # This class matches on qos-group 2 and discard-class 0
    set mpls experimental imposition 2
    !
  class qos2_disc1 # This class matches on qos-group 2 and discard-class 1
    set mpls experimental imposition 6
    !
  class qos3_disc0 # This class matches on qos-group 3 and discard-class 0
    set mpls experimental imposition 3
    !
  class qos3_disc1 # This class matches on qos-group 3 and discard-class 1
    set mpls experimental imposition 7
    !
  class class-default
    !
  end-policy-map
  !

```

Conditional Marking of MPLS Experimental bits for L2VPN Traffic

Note This feature is not available on NC57-24DD and NC57-18DD-SE line cards for Cisco IOS XR Release 7.0.2.

This feature is supported on Virtual Private Wire Service (VPWS), and Virtual Private LAN Service (VPLS) traffic in the L2VPN network, and currently not supported for Ethernet Virtual Private Network (EVPN).

The conditional marking of MPLS experimental bits is achieved for Layer 2 Virtual Private Network (L2VPN) traffic by applying a combination of ingress and egress policy-maps on the Provider Edge (PE) router. In the ingress policy-map, the qos-group or discard-class is set either based on the result of the policing action or implicitly. The egress policy-map matches on qos-group or on a combination of qos-group and discard-class and sets the mpls experiment bits to the corresponding value.

Conditional marking can be used to mark the MPLS experimental bits differently for in-contract and out-of-contract packets. In-contract packets are the confirmed packets with the color green and discard-class set to 0. Out-of-contract packets are the packets which have exceeded the limit and have the color yellow and discard-class set to 1.

Conditional marking of MPLS experimental bits for L2VPN traffic is supported on both physical and bundle main interfaces as well as sub-interfaces.

Restrictions for Conditional Marking of MPLS Experimental bits on L2VPN

1. In the case of two PE routers connected back-to-back and the only label that the traffic between the routers have is the BGP label, then the explicit null label should be configured.
2. A maximum of two policy-maps which perform conditional marking of MPLS experimental bits can be configured per Network Processor Unit (NPU) of the Cisco NCS 5500 Series Routers. However, the same policy can be applied on multiple interfaces on the same NPU.
3. In the ingress policy-map if qos-group is being set for the incoming traffic packets, then setting of dscp and mpls experimental bits will not work.
4. Both the ingress and egress policy-maps must be applied in order to attain the expected behaviour. If either one of them is not applied then it may lead to undefined behaviour.
5. If the egress policy-map does not match on qos-group or discard-class and set the mpls experiment bits to the required value, then the mpls experimental bits will be set to a value of zero, by default.

Policy-map for conditional marking of incoming traffic

The incoming packets on the Power Edge router are classified based on the ingress policy-map and these actions are taken.

- Set qos-group
- Discard class or drop precedence is set implicitly or as a result of a policing action.
- Set traffic class
- Packets that violate the configured policer are dropped in the ingress processing itself.

Running Configuration:

```

class-map af11
  match cos 1
!

policy-map ingress
  class af11
    police rate percent 10 peak-rate percent 20
    !
    set qos-group 1
    set Traffic-class 3
    !
  class class-default
  !
end-policy-map
!
```

Policy-map for conditional marking of outgoing MPLS traffic

The ingress packet undergoes MPLS encapsulation during the egress processing in the PE router which performs the label imposition. The MPLS experimental bits are marked on the basis of egress policy-map which performs the following actions:

- Match on qos-group or discard class or both
- Set the MPLS experimental bits based on the match criteria

Running Configuration:

```

class-map match-all qos-group2_0
  match qos-group 2
  match discard-class 0

policy-map egress-marking
  class qos-group2_0 # This class matches on qos-group 2 and discard-class 0
    set mpls experimental imposition 1
    !
  class class-default
  !
end-policy-map
!

policy-map Egress-Queuing
  class Traffic-class3
    shape average 500 mbps
    !
  class class-default
  !
end-policy-map
!
```

Conditional Marking of MPLS Experimental Bits for EVPN-VPWS Single-Homing Services

Table 12: Feature History Table

Feature Name	Release Information	Feature Description
Conditional Marking of MPLS Experimental Bits for EVPN-VPWS Single-Homing Services	Release 7.3.1	<p>This feature enables you to differentiate traffic in the MPLS forwarding domain and manage traffic from ingress PE to egress PE based on the MPLS EXP bit of the MPLS header.</p> <p>This feature is supported only for EVPN-VPWS single-homing services, and not supported for EVPN-VPWS multi-homing services.</p>

The conditional marking of MPLS experimental bits is achieved for EVPN-VPWS single-homing services by applying a combination of ingress and egress policy-maps on the provider edge (PE) router. In the ingress policy-map, the qos-group or discard-class is set either based on the result of the policing action or implicitly. The egress policy-map matches on qos-group or on a combination of qos-group and discard-class and sets the MPLS experiment bits to the corresponding value.

Conditional marking can be used to mark the MPLS experimental bits differently for in-contract and out-of-contract packets. In-contract packets are the confirmed packets with the color green and discard-class set to 0. Out-of-contract packets are the packets that have exceeded the limit and have the color yellow and discard-class set to 1.

Conditional marking of MPLS experimental bits for EVPN-VPWS single-homing services are supported on both physical and bundle main interfaces as well as sub-interfaces.

Configuration

- The ingress policing is applied on the UNI interface. It is with set qos-group and set traffic class.
- The marking policy is applied at the core facing NNI interface.
- MPLS EXP imposition is marked while packets egress from NNI Interface.

Running Configuration

```

interface TenGigE0/0/0/2.203 l2transport => This is UNI
encapsulation dot1q 203
service-policy input pol50-100

interface TenGigE0/0/0/10 =====> This is the core NNI

      neighbor evpn evi 1 service 203

policy-map pol50-100
class class-default
  set traffic-class 2
  set qos-group 4
  police rate 50 mbps peak-rate 100 mbps
!
!
end-policy-map
!

policy-map eg_mark
class qg4dc0
  set mpls experimental imposition 2
!
class qg4dc1
  set mpls experimental imposition 3
!
class class-default
!
end-policy-map
!
class-map match-all qg4dc0
match qos-group 4
match discard-class 0
end-class-map
!

class-map match-all qg4dc1
match qos-group 4
match discard-class 1
end-class-map

```

Verification

Verify that you have configured conditional marking of MPLS experimental bits for EVPN-VPWS single-homing services successfully.

```

Classifying Packets Based On MPLS Experimental Bits in MPLS Over GRE

Table 13: Feature History Table

Feature Name	Release Information	Feature Description
Classifying Packets Based On MPLS Experimental Bits in MPLS Over GRE	Release 7.5.2	<p>For MPLS over GRE scenarios that tunnel MPLS traffic over non-MPLS networks, you can now perform QoS classification for specific traffic or applications based on MPLS EXP bit field values in the MPLS header.</p> <p>In earlier releases, you could perform QoS classification only in the outer GRE IP header using DiffServ Code Point (DSCP) or IP precedence bits that helped you achieve the required line rate minus the granularity.</p> <p>This feature introduces the hw-module profile qos gre-exp-classification-enable command.</p>

You can now perform QoS classification based on the MPLS header that the GRE IP header encapsulates in a single-pass GRE scenario. This classification takes place on the MPLS labels (specifically the experimental bits or EXP) in the MPLS header after the GRE is decapsulated using Policy-Based Routing (PBR). Because the MPLS labels identify specific customer traffic and applications, the classification is more granular. As the traffic moves along the single-pass GRE, the POP tag removes the MPLS header, and the outgoing traffic with QoS classification has the inner IP header. (Also, see [Terms Used for Classifying Packets Based On MPLS Experimental Bits in MPLS Over GRE](#).)

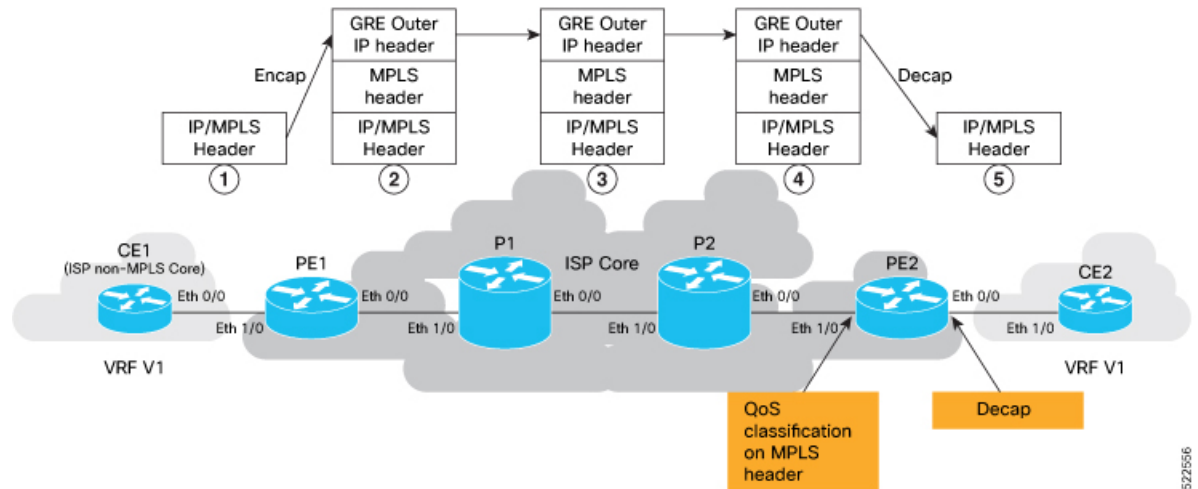

To enable QoS classification on the inner MPLS header, run the command **hw-module profile qos gre-exp-classification-enable**.

Note Ensure that you reload the line card for this command to take effect. If you don't reload the line card, QoS classification will continue on the outer GRE IP header with DSCP or IP precedence marking.

To understand how this functionality works, see the figure **QoS Classification on Inner MPLS Header for MPLS over GRE**.

Figure 3: QoS Classification on Inner MPLS Header for MPLS over GRE

1. The MPLS packet approaches the beginning of the GRE tunnel. The GRE tunnel is configured across a non-MPLS network on the provider edge (PE) devices, PE1 and PE2, which are at either end of the tunnel.
2. GRE encapsulation is added at tunnel entry point.
3. The MPLS packet traverses the non-MPLS network, where only the outer IP header is parsed by routers.
4. When the packet reaches the ingress interface (Eth 1/0) on router PE2, QoS classification is performed based on MPLS EXP bits. Before the packet reaches the egress interface (Eth 0/0) of PE2, the outer GRE header is removed.
5. The packet with the MPLS header now travels toward its ultimate destination to CE2.

Behavioral Specifications

- This feature is supported only in scenarios where you enable GRE single-pass. (You configure the **tunnel mode gre ipv4 encap** command in GRE single-pass. See [Set Up and Configuration for QoS Classification on MPLS Header](#), on page 69.)
- To preserve the inner DSCP markings and IP Time-to-Live (TTL) values, you must disable the propagation of IP Time-to-Live (TTL) to and from the MPLS header for forwarded and local packets. See [mpls ip-ttl-propagate](#).

Restrictions

This feature isn't supported on routers that have Cisco NC57 line cards installed and operate in the native and compatibility mode.

Set Up and Configuration for QoS Classification on MPLS Header

This section describes the configuration details for QoS classification on the MPLS header in a single pass GRE tunnel per the Figure **QoS Classification on Inner MPLS Header for MPLS over GRE**.

Configuration for PE1 (encap node) where you:

- enable GRE single-pass.

- assign the GRE tunnel source and destination addresses.
- assign IPv4 addresses for PE1 and PE2.

```
Router(config)#interface tunnel-ip_intf1
Router(config-if)#ipv4 address 203.0.113.1 255.255.255.252
Router(config-if)#tunnel mode gre ipv4 encaps
Router(config-if)#tunnel source 13.1.1.1
Router(config-if)#tunnel destination 11.1.1.1
Router(config-if)#root
Router(config)#interface Eth 1/0
Router(config-if)#ipv4 address 209.165.201.1 255.255.255.224
Router(config-if)#exit
Router(config-if)#interface Eth 0/0
Router(config-if)#ipv4 address 198.51.100.1 255.255.255.0
Router(config-if)#commit
```

Configuration for intermediate hop router (P1) where you configure the forwarding addresses for packets.

```
Router(config)#interface Eth1/0
Router(config-if)#ipv4 address 198.51.100.2 255.255.255.0
Router(config-if)#root
Router(config)#
Router(config)#interface Eth0/0
Router(config-if)#ipv4 address 203.0.113.1 255.255.255.0
Router(config-if)#root
Router(config)#commit
```

Configuration for intermediate hop router (P2) where you configure the forwarding addresses for packets.

```
Router(config)#interface Eth1/0
Router(config-if)#ipv4 address 203.0.113.2 255.255.255.0
Router(config-if)#root
Router(config)#
Router(config)#interface Eth0/0
Router(config-if)#ipv4 address 192.0.2.1 255.255.255.0
Router(config-if)#root
Router(config)#commit
```

Configuration for PE2 (decap node) where you:

- disable TTL to preserve the IP header DSCP and TTL.
- configure **hw-module profile qos gre-exp-classification-enable**.

Note Ensure that you reload the line card for this command to take effect. If you don't reload the line card, QoS classification will continue on the outer GRE IP header with DSCP or IP precedence marking. We recommend that you use the **hw-module location all reload** command in Sysadmin VM.

- configure MPLS EXP bits, class-map, and the policy-map before decapsulation.

```
Router(config)#mpls ip-ttl-propagate disable
Router(config)# hw-module profile qos gre-exp-classification-enable
NOTE:To activate this profile, you must manually reload the chassis/all line cards
Router(config)#
#reload the device to get effect of qos gre-exp-classification
/*We recommend that you use the hw-module location all reload command in Sysadmin VM*/
```

```

Router#admin
root connected from 192.0.108.4 using ssh on sysadmin-vm:0_RP0
sysadmin-vm:Router#hw-module location all reload
!

/*After reloading, configure MPLS exp bits, class-map, and the policy-map*/
Router(config)#class-map match-any exp1
Router(config-cmap)#match mpls experimental topmost 1
Router(config-cmap)#end-class-map
Router(config)#class-map match-any exp2
Router(config-cmap)#match mpls experimental topmost 2
Router(config-cmap)#end-class-map
Router(config)#class-map match-any cs1
Router(config-cmap)#match dscp cs1
Router(config-cmap)#end-class-map
Router(config)#policy-map gre-ip_in
Router(config-pmap)#class exp1
Router(config-pmap-c)#set traffic-class 1
Router(config-pmap-c)#exit
Router(config-pmap)#class exp2
Router(config-pmap-c)#set traffic-class 2
Router(config-pmap-c)#exit
Router(config-pmap)#class class-default
Router(config-pmap-c)#exit
Router(config-pmap)#end-policy-map
Router(config)#
Router(config)#interface Eth0/0
Router(config-if)#service-policy input gre-ip_in
Router(config-if)#ipv4 address 192.0.2.2 255.255.255.0
Router(config-if)#load-interval 30
Router(config)#
Router(config)#interface Eth1/0
Router(config-if)#ipv4 address 209.165.202.129 255.255.255.224
Router(config-if)#load-interval 30
Router(config-if)#root
Router(config-if)#commit

```

Running Configuration

```

```

Verification

Run the **show policy-map** command on PE2 (decapsulation node) to view the classification statistics that confirm QoS classification is on the MPLS header.

```

Router#show policy-map int Eth1/0
Eth1/0 input: gre-ip_in

```

```

Class exp1
  Classification statistics          (packets/bytes)      (rate - kbps)

```

```

    Matched      :          55436316/8426320032          504105
    Transmitted   :          55436316/8426320032          504105
    Total Dropped :          0/0                        0
Class exp2
  Classification statistics      (packets/bytes)      (rate - kbps)
    Matched      :          55436286/8426315472          504105
    Transmitted   :          55436286/8426315472          504105
    Total Dropped :          0/0                        0
Class class-default
  Classification statistics      (packets/bytes)      (rate - kbps)
    Matched      :          0/0                        0
    Transmitted   :          0/0                        0
    Total Dropped :          0/0                        0
Policy Bag Stats time: 1648011883484

```

When you don't enable QoS classification on the MPLS header, the **show policy-map** command on PE2 (decapsulation node) confirms that the classification is IP precedence (under **class-default**).

```

Router#show policy-map int Eth1/0
Eth1/0 input: gre-ip_in

```

```

```

Terms Used for Classifying Packets Based On MPLS Experimental Bits in MPLS Over GRE

Generic Routing Encapsulation (GRE)

A protocol used to encapsulate packets, GRE is useful when you need to transport packets across an unsupported network protocol, say IPv6 packets across an IPv4 network. In this case, IPv6 packets are encapsulated or wrapped around by packets that support the protocol (IPv4) and transported across the network. This is akin to cars being transported across oceans (unsupported protocol for cars) on cargo ships (the ocean being the supported protocol for the ships).

GRE Tunneling

The encapsulation of packets within other packets is called GRE tunneling. Here, if packets are to be transported from one router to another without any additional processing by intermediate routers and devices, you can configure a GRE tunnel between the two routers. As the packets flow across the network, the intermediate routers read the forwarding information on the packet headers and send them to their next hop. This is similar to the cars now being transported on a cargo truck on land, passing through a tunnel to reach the other end of the road faster, with no other action taking place on the cars as they are carried on the truck inside the tunnel. Without the tunnel, transport across this route would be impossible, akin to an unsupported network between the two ends of the GRE tunnel.

GRE Headers

Each packet consists of the payload—the actual packet content—and an IP header that contains information critical for the packet transportation: the source address, the destination address, packet number, packet length, and so on.

As with other network protocols, GRE adds its own headers to the packets: the GRE header that shows the protocol used by the encapsulated packet (the cars, in our preceding example) and an outer IP header that wraps the encapsulated packet's payload and IP header. A GRE header thus has two IP headers.

MPLS over GRE

A mechanism for tunneling MPLS packets over non-MPLS networks by creating a GRE tunnel across a non-MPLS network. The MPLS packets are encapsulated within the GRE tunnel packets, and the encapsulated packets traverse the non-MPLS network through the GRE tunnel. When GRE tunnel packets reach the other side of the non-MPLS network, the GRE tunnel packet header is removed and the inner MPLS packet is forwarded to its final destination.

QPPB

QoS Policy Propagation via BGP (QPPB) is a mechanism that allows propagation of quality of service (QoS) policy and classification by the sending party that is based on the following:

- Access lists
- Community lists
- Autonomous system paths in the Border Gateway Protocol (BGP)

Thus, helps in classification that is based on the destination address instead of the source address.

QoS policies that differentiate between different types of traffic are defined for a single enterprise network. For instance, one enterprise may want to treat important web traffic, not-important web traffic, and all other data traffic as three different classes. And thereafter, use the different classes for the voice and video traffic.

Hence, QPPB is introduced to overcome the following problems:

- The administrative challenges of classifying that is based on ACLs.
- The administrative problems of just listing the networks that need premium services.

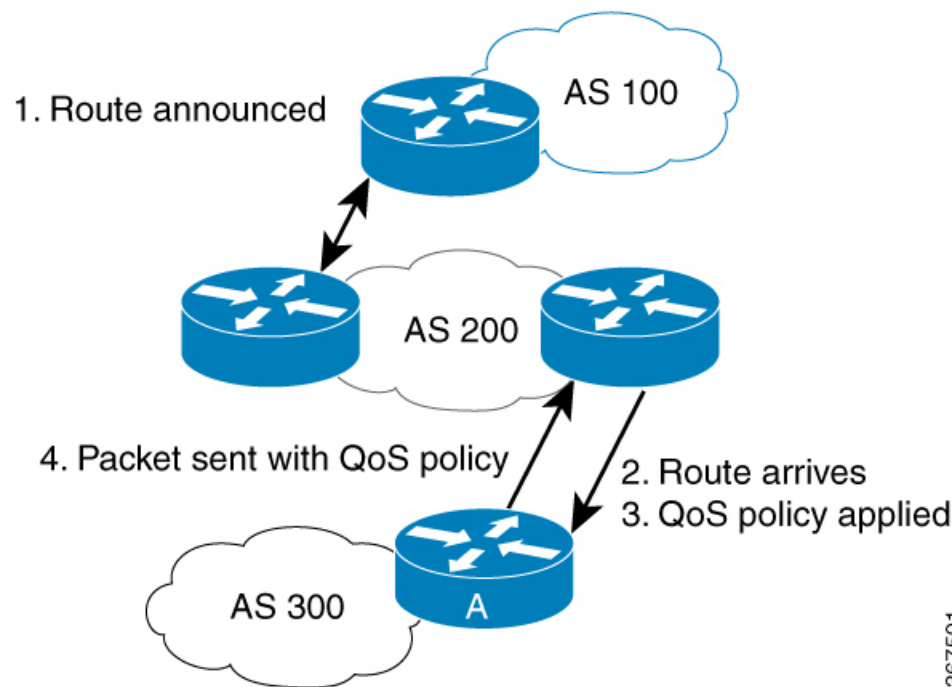

QPPB allows marking of packets that are based on QoS group value associated with a Border Gateway Protocol (BGP) route.

Benefits of QPPB

- QPPB provides an IP prefix-based QoS capability.
- Traffic to IP addresses that have specific IP prefixes can be prioritized above other IP addresses.
- IP prefixes of interest are tagged through the control plane that uses common BGP route-map techniques, including the community attribute.
- Traffic to the tagged BGP prefixes is then classified and prioritized via the data forwarding plane by using the IOS-XR MQC (Modular QoS CLI) mechanisms, such as re-marking.

- QPPB provides the glue between the BGP control plane and the IP data forwarding plane in support of IP prefix-based QoS.
- BGP configuration within QPPB uses a table map to match specific prefixes learned through BGP neighbors, and then sets the router's local QoS Group variable maintained within the Forwarding Information Base (FIB) for those specific prefixes.
- The router supports a subset of full QPPB options - only IP destination prefix mode on input policy is supported.

Figure 4: Sample Scenario

Router A learns routes from AS 200 and AS 100. QoS policy is applied to any ingress interface of Router A to match the defined route maps with destination prefixes of incoming packets. Matching packets on Router A to AS 200 or AS 100 are sent with the appropriate QoS policy from Router A.

BGP maintains a scalable database of destination prefixes, QPPB, by using BGP table maps. BGP adds the ability to map a qos-group value to desired IP destinations. These qos-group values are used in QoS policies applied locally on ingress interfaces. Whenever a packet bound for such destinations is encountered, the qos-group value matching that destination route looks up with work inside the policy classmap, and marks that packet for any configured policy actions.

QPPB: Guidelines and Limitations

- QPPB is supported only on the -SE variants of NCS 5700-line card-based routers and the following -SE variants of NCS 5500-line card-based routers:
 - NCS-55A1-36H-SE-S
 - NCS-55A2-MOD-SE-H-S

- NCS-55A2-MOD-SE-S
- NC55-36x100G-A-SE
- NC55-MOD-A-SE-S
- QPPB doesn't work for /32 IPv4 prefixes on NCS 5500 line card-based routers when you enable the **hw-module fib mpls label lsr-optimized** profile.
- You must configure the **hw-module profile qos ipv6 short** command for QPPB to work with IPv6 address families and packets.
- When you enable the peering mode (using the **hw-module profile qos ingress-model peering** command), the QPPB feature doesn't work.

Configuration Workflow

Use the following configuration workflow for QPPB:

- Define route policy.
- Put Route policy at table-policy attach point under BGP.
- Define classmaps and ingress policy to use the qos-groups that are used in table-policy.
- Enable ipv4/ipv6 QPPB configuration under the desired interfaces.
- Configure the QPPB hardware profile, *hw-module profile qos ipv6 short*.
- If you use ipv6 QPPB, you must reload that linecard. If you use only ipv4 QPPB, linecard reload is not mandatory.

Define route policy

A routing policy instructs the router to inspect routes, filter them, and potentially modify their attributes as they are accepted from a peer, advertised to a peer, or redistributed from one routing protocol to another.

The routing policy language (RPL) provides a language to express routing policy. You must set up destination prefixes either to match inline values or one of a set of values in a prefix set.

Example:

```
prefix-set prefix-list-v4
  70.1.1.1,
  70.2.1.0/24,
  70.2.2.0/24 ge 28,
  70.2.3.0/24 le 28
end-set
prefix-set prefix-list-v6
  2001:300::2,
  2003:200::3
end-set

route-policy qppb1
  if destination in (60.60.0.2) then
    set qos-group 5
  elseif destination in prefix-list-v4 then
    set qos-group 4
  else
```

```

        set qos-group 1
    pass
endif
end-policy

```

For NC57 line cards, the set qos-group value under the route policy for QPPB support is 0-15. Even though the set qos-group value option displays supported values <0-31> as show below, the configuration fails for any value above 15 for NC57 line cards.

```

RP/0/RP0/CPU0:Fretta(config-rpl-if)#set qos-group ?
<0-31>          decimal number

```

Put Route policy at table-policy attach point under BGP

The table-policy attach point permits the route policy to perform actions on each route as they are installed into the RIB routing table. QPPB uses this attachment point to intercept all routes as they are received from peers. Ultimately the RIB will update the FIB in the hardware forwarding plane to store destination prefix routing entries, and in cases where table policy matches a destination prefix, the qos-group value is also stored with the destination prefix entry for use in the forwarding plane.

Example:

```

router bgp 900
  [vrf <name>]
  bgp router-id 22.22.22.22
  address-family ipv4 unicast
    table-policy qppb1
  address-family ipv6 unicast
    table-policy qppb2
  neighbor 30.2.2.1
    remote-as 500
  address-family ipv4 unicast
    route-policy pass in
    route-policy pass out
  address-family ipv6 unicast
    route-policy pass in
    route-policy pass out

```

Ingress interface QOS and ipv4/ipv6 bgp configuration

QPPB would be enabled per interface and individually for V4 and V6. An ingress policy would match on the qos groups marked by QPPB and take desired action.

If a packet is destined for a destination prefix on which BGP route policy has stored a qos-group, but it ingresses on an interface on which qppb is not enabled, it would not be remarked with qos-group.

Earlier, router supported matching on qos-group only in peering profile 'hw-module profile qos ingress-model peering location <>'. QPPB now permits classmaps to match qos-group in the default "non peering mode qos" as well. Also QPPB and hierarchical QOS policy profiles can work together if Hqos is used.

Example:

```

class-map match-any qos-group5
  match qos-group 5
end-class-map

class-map match-any qos-group4
  match qos-group 4
end-class-map

policy-map ingress-marker-pol
  class qos-group5

```

```

        set precedence 0
        set discard-class 0
        set traffic-class 1

    class qos-group4
        set precedence 1
        set discard-class 1
        set traffic-class 2
    class class-default

end-policy-map

```

Configuring QPPB on an Interface

1. RP/0/RP0/CPU0:router # configure

Enters interface configuration mode and associates one or more interfaces to the VRF.

2.

```
RP/0/RP0/CPU0:router(config)# interface
type interface-path-id
```

Enters interface configuration mode and associates one or more interfaces to the VRF.

3. **ipv4 | ipv6 bgp policy propagation inputqos-groupdestination**

Example:

```
RP/0/RP0/CPU0:router(config-if)# ipv4 bgp policy propagation input qos-group destination
```

Enables QPPB on an interface

4. commit

Egress Interface Configuration

The traffic-class set on ingress has no existence outside the device. Also, traffic-class is not a part of any packet header but is associated internal context data on relevant packets. It can be used as a match criteria in an egress policy to set up various fields on the outgoing packet or shape flows.

Restrictions:

- No IP precedence marking.
- No policing on egress policy.

```

class-map match-any level1
    match traffic-class 1
end-class-map

class-map match-any level2
    match traffic-class 2
end-class-map

policy-map output-pol
    class level1
        bandwidth percent 50
    class level2

```

```
        bandwidth percent 20
        queue-limit 50 ms
    end-policy-map

    interface hun 0/5/0/0
        ipv4 address 30.1.1.1/24
        ipv6 address 2001:da8:b0a:12f0::1/64
        service-policy output output-pol
```

CHAPTER 3

Configuring Modular QoS Congestion Avoidance

This chapter covers the following topics:

- [Modular QoS Congestion Avoidance](#) , on page 81
- [Tail Drop and the FIFO Queue](#), on page 82
- [Random Early Detection and TCP](#), on page 84
- [Weighted Random Early Detection](#), on page 87
- [Explicit Congestion Notification \(ECN\)](#), on page 93

Modular QoS Congestion Avoidance

Congestion avoidance techniques monitor traffic flow to anticipate and avoid congestion at common network bottlenecks. Avoidance techniques are implemented before congestion occurs as compared with congestion management techniques that control congestion after it has occurred.

Note

From Cisco IOS XR Release 7.3.1 onwards, systems with Cisco NC57 line cards running in compatibility mode support QoS over Layer 2 services for:

- Local switching [xconnect or bridging]
- L2 VPN – VPWS

Starting with Cisco IOS XR Release 7.4.1 systems with Cisco NC57 line cards running in native mode support QoS over Layer 2 services for:

- Local switching [xconnect or bridging]
- L2 VPN – VPWS

Note For traffic requiring header decapsulation, the size of the header that is being removed is still included for the egress queuing actions. To offset this header size (required to achieve line rate for small frame sizes), configure an egress user policy with user overhead accounting on the egress interface. This policy can be a dummy policy configuration as well (allowing full traffic rate), if a policy isn't already in use or required on the egress interface.

You can enable user overhead accounting using the optional configuration of **accounting user-defined <overhead size in bytes>** while attaching the service policy on the egress interface.

Congestion avoidance is achieved through packet dropping. The router supports these QoS congestion avoidance techniques:

- [Tail Drop and the FIFO Queue, on page 82](#)
- [Random Early Detection and TCP, on page 84](#)
- [Weighted Random Early Detection, on page 87](#)

Tail Drop and the FIFO Queue

Tail drop is a congestion avoidance technique that drops packets when an output queue is full until congestion is eliminated. Tail drop treats all traffic flow equally and does not differentiate between classes of service. It manages the packets that are unclassified, placed into a first-in, first-out (FIFO) queue, and forwarded at a rate determined by the available underlying link bandwidth.

Tail Drop and the FIFO Queue: Tip to Optimize Hardware Resources

Tail drop is a congestion avoidance mechanism that works by discarding packets at the tail end of a queue when the queue length exceeds a certain threshold. These thresholds are critical in managing network congestion and are determined based on the Guaranteed Service Rate (GSR) of a traffic class, typically set at a value representing 10 milliseconds of the GSR.

Tail Drop Thresholds-Rate Class Profile Association and ASIC Limitations

When configuring tail drop thresholds, each threshold value is associated with a rate class profile, which defines the performance characteristics for that threshold. (A rate class profile typically includes bandwidth limits, priority levels, queueing policies, and drop policies like tail drop thresholds. These profiles manage how different types of traffic are treated as they traverse the network, ensuring that critical services get the bandwidth and latency treatment they require.)

However, there is a limitation: each ASIC can support only up to 64 rate class profiles. This hardware constraint necessitates efficient utilization of these profiles.

Resource Optimization Tip: Share Rate Class Profiles

Since multiple traffic classes can have the same tail drop threshold value, they can share a rate class profile. This sharing conserves hardware resources, allowing for a more scalable network design. Conversely, if each traffic class requires a unique tail drop threshold, more rate class profiles must be created, which can quickly exhaust the available hardware resources.

Therefore, to optimize network performance and resource utilization, we recommend that you strategically fine-tune tail drop threshold values so that more traffic classes share rate class profiles.

Configure Tail Drop

Packets satisfying the match criteria for a class accumulate in the queue reserved for the class until they are serviced. The **queue-limit** command is used to define the maximum threshold for a class. When the maximum threshold is reached, the enqueued packets to the class queue result in tail drop (packet drop).

Restrictions

- When configuring the **queue-limit** command, you must configure one of the following commands: **priority**, **shape average**, **bandwidth** or **bandwidth remaining**, except for the default class.

Configuration Example

You have to accomplish the following to complete the tail drop configuration:

1. Creating (or modifying) a policy map that can be attached to one or more interfaces to specify a service policy
2. Associating the traffic class with the traffic policy
3. Specifying the maximum limit the queue can hold for a class policy configured in a policy map.
4. Specifying priority to a class of traffic belonging to a policy map.
5. (Optional) Specifying the bandwidth allocated for a class belonging to a policy map or specifying how to allocate leftover bandwidth to various classes.
6. Attaching a policy map to an output interface to be used as the service policy for that interface.

```
Router# configure
Router(config)# class-map qos-1
Router(config-cmap)# match traffic-class 1
Router(config-cmap)# commit
Router(config-pmap)# exit

Router(config)# policy-map test-qlimit-1
Router(config-pmap)# class qos-1
Router(config-pmap-c)# queue-limit 100 us
Router(config-pmap-c)# priority level 7
Router(config-pmap-c)# exit
Router(config-pmap)# exit

Router(config)# interface HundredGigE 0/6/0/18
Router(config-if)# service-policy output test-qlimit-1
Router(config-if)# commit
```

Running Configuration

```
class-map qos-1
  match traffic-class 1
commit
```

```

policy-map test-qlimit-1
  class qos-1
    queue-limit 100 us
    priority level 7
  !
  class class-default
  !
end-policy-map
!

```

Verification

Router# **show qos int hundredGigE 0/6/0/18 output**

```

Random Early Detection and TCP

The Random Early Detection (RED) congestion avoidance technique takes advantage of the congestion control mechanism of TCP. By randomly dropping packets prior to periods of high congestion, RED tells the packet source to decrease its transmission rate. Assuming the packet source is using TCP, it decreases its transmission rate until all packets reach their destination, indicating that the congestion is cleared. You can use RED as a way to cause TCP to slow transmission of packets. TCP not only pauses, but it also restarts quickly and adapts its transmission rate to the rate that the network can support.

RED distributes losses in time and maintains normally low queue depth while absorbing traffic bursts. When enabled on an interface, RED begins dropping packets when congestion occurs at a rate you select during configuration.

Configure Random Early Detection

The **random-detect** command with the **default** keyword must be used to enable random early detection (RED).

Guidelines

If you configure the **random-detect default** command on any class including class-default, you must configure one of the following commands: **shape average**, **bandwidth**, and **bandwidth remaining**.

Configuration Example

You have to accomplish the following to complete the random early detection configuration:

1. Creating (or modifying) a policy map that can be attached to one or more interfaces to specify a service policy
2. Associating the traffic class with the traffic policy
3. Enabling RED with default minimum and maximum thresholds.
4. (Optional) Specifying the bandwidth allocated for a class belonging to a policy map or specifying how to allocate leftover bandwidth to various classes.
5. (Optional) Shaping traffic to the specified bit rate or a percentage of the available bandwidth.
6. Attaching a policy map to an output interface to be used as the service policy for that interface.

```
Router# configure
Router(config)# class-map qos-1
Router(config-cmap)# match traffic-class 1
Router(config-cmap)# commit
Router(config-pmap)# exit

Router# configure
Router(config)# policy-map test-wred-2
Router(config-pmap)# class qos-1
Router(config-pmap-c)# random-detect default
Router(config-pmap-c)# shape average percent 10
Router(config-pmap-c)# end-policy-map
Router(config)# commit
Router(config)# interface HundredGigE 0/6/0/18
Router(config-if)# service-policy output test-wred-2
Router(config-if)# commit
```

Running Configuration

```
class-map qos-1
  match traffic-class 1
commit
```

```

policy-map test-wred-2
  class qos-1
    random-detect default
    shape average percent 10
  !
  class class-default
  !
end-policy-map
!

interface HundredGigE 0/6/0/18
  service-policy output test-wred-2
!
```

Verification

Router# **show qos int hundredGigE 0/6/0/18 output**

```

Weighted Random Early Detection

The Weighted Random Early Detection (WRED) drops packets selectively based on any specified criteria, like discard-class. WRED uses this matching criteria to determine how to treat different types of traffic.

You can configure WRED using the **random-detect** command and different discard-class values. The value can be range or a list of values that are valid for that field. You can also use minimum and maximum queue thresholds to determine the dropping point. Ensure that the WRED maximum threshold value is close to the queue limit. When the maximum threshold value is reached, packets start to get dropped.

You can also configure WRED threshold values per discard class. Such an approach helps differentiate when to drop packets among different discard classes, helping prioritize packets among discard classes.

When a packet arrives, the following actions occur:

- The average queue size is calculated.
- If the average queue size is less than the minimum queue threshold, the arriving packet is queued.
- If the average queue size is between the minimum queue threshold for that type of traffic and the maximum threshold for the interface, the packet is either dropped or queued, depending on the packet drop probability for that type of traffic.
- If the average queue size is greater than the maximum threshold, the packet is dropped.

Average Queue Size for WRED

The router automatically determines the parameters to use in the WRED calculations. The average queue size is based on the previous average and current size of the queue. The formula is:

$$\text{average} = (\text{old_average} * (1 - 2^{-x})) + (\text{current_queue_size} * 2^{-x})$$

where x is the exponential weight factor.

For high values of x , the previous average becomes more important. A large factor smooths out the peaks and lows in queue length. The average queue size is unlikely to change very quickly, avoiding a drastic change in size. The WRED process is slow to start dropping packets, but it may continue dropping packets for a time after the actual queue size has fallen below the minimum threshold. The slow-moving average accommodates temporary bursts in traffic.

Note

- The exponential weight factor, x , is fixed and is not user configurable.
 - If the value of x gets too high, WRED does not react to congestion. Packets are sent or dropped as if WRED were not in effect.
 - If the value of x gets too low, WRED overreacts to temporary traffic bursts and drops traffic unnecessarily.
-

For low values of x , the average queue size closely tracks the current queue size. The resulting average may fluctuate with changes in the traffic levels. In this case, the WRED process responds quickly to long queues. Once the queue falls below the minimum threshold, the process stops dropping packets.

Configure Weighted Random Early Detection

This configuration task is similar to that used for RED except that the **random-detect** command is not configured in RED.

Restrictions

- You cannot use the **random-detect** command in a class configured with the **priority** command, because WRED cannot be configured in a class that has been set for priority queueing (PQ).
- When configuring the **random-detect** command, you must configure one of the following commands: **shape average**, **bandwidth**, and **bandwidth remaining**.

Configuration Example

You have to accomplish the following to complete the random early detection configuration:

1. Creating (or modifying) a policy map that can be attached to one or more interfaces to specify a service policy
2. Associating the traffic class with the traffic policy
3. Enabling WRED by specifying the match criteria (discard-class).
4. (Optional) Specifying the bandwidth allocated for a class belonging to a policy map or specifying how to allocate leftover bandwidth to various classes.
5. (Optional) Shaping traffic to the specified bit rate or a percentage of the available bandwidth.
6. (Optional) Changing queue limit to fine-tune the amount of buffers available for each queue.
7. Attaching a policy map to an output interface to be used as the service policy for that interface.

```
Router# configure
Router(config)# class-map qos-1
Router(config-cmap)# match traffic-class 1
Router(config-cmap)# commit
Router(config-pmap)# exit

Router# configure
Router(config)# policy-map test-wred-1

Router(config-pmap-c)# random-detect default
Router(config-pmap-c)# random-detect discard-class 0 10 ms 500 ms
Router(config-pmap-c)# shape average percent 10
Router(config-pmap-c)# commit

Router(config)# interface HundredGigE 0/6/0/18
Router(config-if)# service-policy output policy1
Router(config-if)# commit
```

Running Configuration

```
class-map qos-1
  match traffic-class 1
commit
```

```

policy-map test-wred-1
  class qos-1
    random-detect default
    random-detect discard-class 0 10 ms 500 ms
    shape average percent 10
  !
  class class-default
  !
end-policy-map
!

interface HundredGigE 0/6/0/18
  service-policy output test-wred-1
!

```

Verification

Configure WRED Counters by Class

Table 14: Feature History Table

Feature Name	Release Information	Feature Description
Configure WRED Counters by Class	Release 7.4.1	<p>This feature enables the display of WRED statistics per class, thus providing a more accurate and granular statistics profile for packet drops. Such insight allows you to monitor, anticipate, and avoid congestion at common bottlenecks on your network.</p> <p>This functionality introduces the hw-module profile qos wred-stats-enable command and modifies the output of the show policy-map interface command.</p>

- **Statistics profile**—Up until now, running the **show policy-map interface** command displayed the drop statistics per class under tail drop. Which meant that no matter what drop mechanism you deployed ([Tail Drop and the FIFO Queue, on page 82](#), [Random Early Detection and TCP, on page 84](#), or [Weighted Random Early Detection, on page 87](#)), the statistics profile that displayed was a number aggregated under the tail drop entry. Given that WRED provides a far more granular control over packet drops than the other mechanisms, the generic statistics profile didn't provide you with the validation that you required for your WRED actions.
- **WRED counters by class**—This functionality introduces a new command, **hw-module profile qos wred-stats-enable**. Configuring this command enables the display of WRED and RED statistics per class, thus providing a more accurate and granular statistic for packet drops.
- **Why WRED counters by class**—Prior to this functionality, you did not have visibility into the WRED drop counters and had no way to validate WRED actions. With this improvement, the **show policy-map interface** command provides the much-needed visibility by clearly depicting the drop counters per class for WRED. This visibility gives you the confidence that WRED is indeed in action and is providing the requisite congestion avoidance.
- **Guidelines and limitations**
 - WRED max-drop threshold statistics are unavailable.
 - WRED statistics are collected separately for each drop precedence value.
- **WRED counters support cheat-sheet**—Here's a quick look at some key support areas and their details for WRED counters by class.

Support	Details
Line card	Supported on Cisco NC57 line cards with external Ternary Content-Addressable Memory (TCAM) operating in native mode.
Statistics	WRED drop count is available for all the supported discard-values (from 0 through 2).

• **Configure WRED counters by class**—To configure WRED counters by class you must:

- Configure the **hw-module profile** for WRED statistics. Manually reload the chassis to activate the profile.
- Configure a class map.
- Create a service policy map.
- Attach the service policy to an interface.

```
/*Configure hw-module profile for wred stats*/
Router#conf
Router(config)#hw-module profile qos wred-stats-enable
Router(config)#commit
Router#reload

/*Configure a class map*/
Router(config)#class-map TC3
Router(config-cmap)#match traffic-class 3
Router(config-cmap)#commit
Router(config-cmap)#end-class-map

/*Create a service policy map*/
Router(config)#policy-map EGRESS_WRED
Router(config-pmap)#class TC3
Router(config-pmap-c)#shape average 1 gbps
Router(config-pmap-c)#random-detect discard-class 0 1 ms 2 ms
Router(config-pmap-c)#random-detect discard-class 1 3 ms 5 ms
Router(config-pmap-c)#random-detect discard-class 2 10 ms 20 ms
Router(config-pmap-c)#commit
Router(config-pmap)#end-policy-map

/*Attach the service policy to an interface*/
Router(config)#int hundredGigE 0/7/0/2
Router(config-if)#service-policy output EGRESS_WRED
Router(config-if)#commit
```

• **Running Configuration**

```
class-map match-any TC3

Explicit Congestion Notification (ECN)

Weighted Random Early Detection (WRED) is implemented at the core routers of a network. Edge routers assign IP precedences to packets, as the packets enter the network. With WRED, core routers then use these precedences to determine how to treat different types of traffic. WRED provides separate thresholds and weights for different IP precedences, enabling the network to provide different qualities of service, in regard

to packet dropping, for different types of traffic. Standard traffic may be dropped more frequently than premium traffic during periods of congestion.

ECN is an extension to WRED. ECN marks packets instead of dropping them when the average queue length exceeds a specific threshold value. When configured, ECN helps routers and end hosts to understand that the network is congested and slow down sending packets. However, if the number of packets in the queue is above the maximum threshold, packets are dropped based on the drop probability.

WRED starts dropping packets probabilistically before a queue becomes full, which means that it works during enqueueing. ECN marking with WRED (ECN-WRED) takes place as packets are about to be transmitted from the queue (during the dequeue process), when the router decides whether to forward, drop, or mark packets based on the congestion state of the queue. Also, WRED and ECN don't work together.

RFC 3168, *The Addition of Explicit Congestion Notification (ECN) to IP*, states that with the addition of active queue management (for example, WRED) to the Internet infrastructure, routers are no longer limited to packet loss as an indication of congestion.

Note You cannot use this feature when you have set qos-group or mpls experimental along with a traffic class in the ingress policy.

Implementing ECN

Implementing ECN requires an ECN-specific field that has 2 bits—the ECN-capable Transport (ECT) bit and the CE (Congestion Experienced) bit—in the IP header. The ECT bit and the CE bit can be used to make four ECN field combinations of 00 to 11. The first number is the ECT bit and the second number is the CE bit.

Table 15: ECN Bit Setting

ECT Bit	CE Bit	Combination Indicates
0	0	Not-ECN-capable.
0	1	Endpoints of the transport protocol are ECN-capable.
1	0	Endpoints of the transport protocol are ECN-capable.
1	1	Congestion experienced.

The ECN field combination 00 indicates that a packet is not using ECN. The ECN field combinations 01 and 10—Called ECT(1) and ECT(0), respectively—are set by the data sender to indicate that the endpoints of the transport protocol are ECN-capable. Routers treat these two field combinations identically. Data senders can use either one or both of these two combinations. The ECN field combination 11 indicates congestion to the endpoints. Packets arriving a full queue of a router will be dropped.

Packet Handling When ECN Is Enabled

When the number of packets in the queue is below the minimum threshold, packets are transmitted.

If the number of packets in the queue is above the maximum threshold:

- For traffic flows that are not ECN-enabled in only WRED-configured queues, packets are tail-dropped after the queue size exceeds the WRED maximum threshold.
- For traffic flows that are ECN-enabled in only WRED-configured queues, packets are tail-dropped when the queue size exceeds the tail-drop threshold.
- When you configure ECN remarking on your router, incoming packets with ECT bit settings 0 or 1 are marked as CE.

Note When the number of packets reaches the queue limit, all packets are dropped. This is the identical treatment that a packet receives when you enable WRED without ECN configured on the router.

Three different scenarios arise if the number of packets in the queue is between the minimum threshold and the maximum threshold:

- If the ECN field on the packet indicates that the endpoints are ECN-capable (that is, the ECT bit is set to 1 and the CE bit is set to 0, or the ECT bit is set to 0 and the CE bit is set to 1)—and the WRED algorithm determines that the packet should have been dropped based on the drop probability—the ECT and CE bits for the packet are changed to 1, and the packet is transmitted. This happens because ECN is enabled and the packet gets marked instead of dropped.
- If the ECN field on the packet indicates that neither endpoint is ECN-capable (that is, the ECT bit is set to 0 and the CE bit is set to 0), packet is dropped once the queue limit is reached.
- If the ECN field on the packet indicates that the network is experiencing congestion (that is, both the ECT bit and the CE bit are set to 1), the packet is transmitted. No further marking is required.

Note Applicable until Cisco IOS XR Release 7.11.1: When the incoming IP traffic with ECN bits set to 10 passes through the ingress qos-policy-map that has the class-map definition of `set DSCP/PREC <value>`, then the ECN bits in the IP header gets modified to 01. This is applicable to NC57 routers operating in the Native mode.

Applicable from Cisco IOS XR Release 7.11.2 : NC57 line cards operating in compatibility mode do not support ECN-bit preservation for terminated VXLAN packets when you configure ACL compression for ingress traffic.

Limitations

- ECN configuration is not supported per discard class but for all packets enqueued to a VOQ.
- **The following limitation is not applicable to NC57 routers:**

SRv6 Disposition Node — For the incoming traffic that has the outer SRv6 IP header having the ECN bits as non-zero value and the inner IP header ECN bits as zero value, then the ECN bits of the inner IP header will be overwritten to 01.

- **The following limitation is specific to NC57 routers operating in Native mode.**

Note ECN remarking functionality is not supported with SRv6 tunnels. The inner header in the following scenario is IP and the outer header is SRv6.

SRv6 Imposition Node — The ECN bits in outer header traffic class is set to 0 when SRv6 encapsulation is set to traffic-class propagate along with Ingress MQC set to any DSCP/PREC value. This scenario does not impact the inner header ECN bits.

SRv6 Disposition Node — The ECN bits in the inner packet header is reset to 0 when the Ingress MQC is set to any DSCP/PREC value.

Configuration Example

```
Router# configure
Router(config)# policy-map policy1
Router(config-pmap)# class class1
Router(config-pmap-c)# bandwidth percent 50
Router(config-pmap-c)# random-detect 1000 packets 2000 packets
Router(config-pmap-c)# random-detect ecn
Router(config-pmap-c)# exit
Router(config-pmap)# exit
Router(config)# commit
```

Verification

Use the **show policy-map interface** to verify the configuration.

```
Router# show policy-map interface tenGigE 0/0/0/6 output
TenGigE0/0/0/6 output: pm-out-queue

Note No ECN-specific statistics are displayed in the show output for this command. ECN is enabled if all rows indicate **N/A**, as highlighted in the example.

Configure ECN Maximum Marking Probability

Table 16: Feature History Table

Feature Name	Release Information	Feature Description
Configure ECN Maximum Marking Probability	Release 7.3.3	<p>This feature allows you to configure percentages for ECN maximum marking probability after considering your network congestion and end-to-end application needs. With this flexibility, you can fine-tune the network's reactivity to congestion according to the tolerance levels of your end-to-end applications.</p> <p>By controlling the probability of packets being ECN marked at the ECN maximum threshold, you can optimize the congestion notification from the traffic destination to the traffic source. This optimization avoids aggressive throttling at the source (from too high ECN maximum marking probability) or traffic drops in transit due to significantly less throttling at the source (from too low ECN maximum marking probability).</p> <p>This functionality modifies the existing random-detect command.</p>

- **First, something about packet drop probability and Explicit Congestion Notification (ECN)**—The probability that a packet will be ECN-marked is based on the minimum threshold, maximum threshold, and maximum mark probability percent.

When the average queue size is above the minimum threshold, ECN starts marking packets to indicate congestion. When an ECN-marked packet reaches the end host, the host transmits confirmation of receipt of this packet to the transmitting host. The confirmation indicates to the transmitting host that congestion has begun and that the transmission or packet rate must be reduced.

Maximum mark probability is the percentage of packets marked when the average queue size is at the maximum threshold. The ECN mark probability increases linearly from 0 when queue length is less than minimum threshold to 10% when the queue length equals or exceeds the maximum threshold. For example, when the average queue size is halfway between minimum-threshold and maximum-threshold the mark probability is 5%, and half the packets transmitted will be ECN marked.

- **Configurable ECN Maximum Marking Probability**—So far, the ECN maximum marking probability was not user-configurable and was fixed at 10%. The arrangement of preset marking probabilities meant that the router couldn't adapt the congestion notification to network characteristics and application tolerance. With the flexibility to configure maximum ECN marking probability, you can configure the

maximum marking probability to a higher or lower percent, depending on the requirements of congestion handling in the network for a given traffic flow and application type. This also allows you to choose a consistent ECN maximum marking probability across all network elements instead of operating them at the factory default values. The following table maps the linear increase in mark probability percentage as the queue length conditions change from 0 to the tail drop threshold.

Queue length conditions	Mark probability increases linearly...
Queue length is less than the minimum threshold value	from 0
Average queue length is between minimum-threshold and maximum-threshold	corresponding to the average queue length: $(\text{maximum mark probability}) * (\text{average queue length} - \text{minimum threshold value}) / (\text{maximum threshold value} - \text{minimum threshold value})$
Queue length equals the maximum threshold	to the configured maximum probability percentage
maximum threshold value < queue length < tail drop threshold	to 100%

• Some FAQs

• What if I set the ECN marking probability percentage to 10%?

In such a case, there's no change in traffic behavior from what it was for previously ECN-marked packets. Tail drop comes into play when the queue length exceeds the tail drop threshold.

• How does traffic behave beyond my configured value of maximum ECN marking probability?

Let's say you've set the maximum ECN marking probability to 5%. Any more increase in the average queue length beyond maximum ECN threshold shifts the marking probability to 100%, and once the queue length exceeds the tail drop threshold, [Tail Drop and the FIFO Queue, on page 82](#) comes into effect.

• How do I enable this functionality?

Create a policy with **random-detect ecn** and **random-detect** *<min-threshold>* *<max-threshold>* **probability percent** *<value>* configured on an interface.

• How do I disable this functionality?

To disable this functionality, do not configure the **probability percent** value.

• Are the user-configured values programmed precisely in the hardware?

The user-configured values are rounded off to the nearest granularity during programming in the hardware. The round-off is minimal when the 'Pmax/(ECNmax-ECNmin)' ratio is a power of 2, where Pmax is the user-configured maximum marking probability in percent and ECNmin and ECNmax are the user-configured minimum and maximum ECN thresholds.

The **show qos interface** command output displays the actual value programmed in hardware and the user-configured value for reference.

• Important Guidelines

- **Line Cards that support this functionality:**
 - NC55-36X100G
 - NC55-18H18F
 - NC55-24X100G-SE
 - NC55-36X100G-S
 - NC55-24H12F-SE
 - NC55-36X100G-A-SE
 - NCS-55A1-36H-SE-S
 - NCS-55A1-36H-S
 - NCS-55A1-24H
 - NCS-55A1-48Q6H
- **The following interface types** support this functionality:
 - Physical interfaces
 - Bundle interfaces
 - Subinterfaces
 - Bundle subinterfaces
- This functionality is **supported for all interface speeds**.
- If you have a **policy map with one or multiple classes with maximum ECN marking probability enabled**, you can:
 - Apply the map to any of the supported interface types.
 - Remove the map from any of the supported interface types.
 - Modify the map while you're attaching it to multiple interfaces.
- The probability percentage option is supported only with **random-detect ecn** configured in the same class. Else, the policy is rejected when applied on an interface
- **Configuring ECN Maximum Marking Probability**—After you have configured [Explicit Congestion Notification \(ECN\)](#), on [page 93](#), the **random-detect** command displays an option to add the probability in percent.

Configuration Example

```
Router#configure
Router(config)#policy-map policy1
Router(config-pmap)#class class1
Router(config-pmap-c)#bandwidth percent 50
Router(config-pmap-c)#random-detect 1 mbytes 2 mbytes probability percent 5
Router(config-pmap-c)#random-detect ecn
Router(config-pmap-c)#commit
```

Verification

Run the **show qos interface** command to view the configured ECN Maximum Marking Probability value (displayed as **ECN Mark Probability**).

```
Router#sh qos interface FourHundredGigE 0/1/0/4 output
```

NOTE:- Configured values are displayed within parentheses

```
Interface FourHundredGigE0/1/0/4 ifh 0x800150 -- output policy
```

```

  TailDrop Threshold                       =  390070272 bytes / 40 ms (default)

  Default RED profile
  WRED Min. Threshold                      =  9787392 bytes (1 ms)
  WRED Max. Threshold                      =  19580928 bytes (2 ms)
ECN Mark Probability                     =  4.99 (5)

  WRED ECN                                =  Enabled
```

CHAPTER 4

Link Level Flow Control

Link-level Flow Control (LLFC) is a congestion management technique that temporarily pauses data transmission to prevent system overload.

Table 17: Feature History Table

Feature Name	Release Information	Feature Description
LLFC	Release 7.5.1	Link-Level Flow Control (LLFC) helps prevent data loss by managing congestion on network links. By temporarily pausing data transmission when a receiving device becomes congested, LLFC ensures that the network can handle high traffic volumes without dropping packets, maintaining data integrity and performance.

LLFC in network congestion

When a receiving device experiences congestion, it sends a pause frame to the transmitter. Upon receiving this frame, the transmitter temporarily halts data transmission. The LLFC feature affects all traffic on the link and allows separate configuration for transmission and reception. By default, LLFC is disabled in both directions.

- [Guidelines and limitations for link level flow control, on page 101](#)
- [Configure LLFC egress, on page 102](#)
- [Mismatched LLFC configurations, on page 103](#)

Guidelines and limitations for link level flow control

LLFC includes specific configuration guidelines and limitations:

- Ethernet interfaces do not auto detect the LLFC capability. LLFC must be configured explicitly.
- Enabling LLFC requires a part of the buffer to be reserved. This reservation reduces the available shared buffer space.

- Configuration time quanta of the pause frames is not supported.
- On each Ethernet interface, the switch can enable either Priority Flow Control (PFC) or LLFC, but not both. For more information, see [PFC](#).

Note When both PFC and LLFC are enabled, LLFC is selected.

Configure LLFC egress

Follow these steps to configure LLFC egress on an interface.

Procedure

Step 1 Enable the privileged EXEC mode.

```
Device> enable
```

Enter your password if prompted.

Step 2 Enter the global configuration mode.

```
Device# configure terminal
```

Step 3 Enter the **interface** *<Gigabit Ethernet interface>* command to configure an interface type and enter interface configuration mode.

```
Device(config)#interface tenGigE 0/4/0/0
```

Step 4 Enter the **flow-control egress** command to enable the interface to receive and process pause frames.

```
Device(config-if)# flow-control egress
```

- Configuring LLFC on an interface causes the interface to flap which results in a momentary traffic loss.
- The **flow-control** keywords and their expected behaviour:
 - **egress**: Enables the receiving of flow control pause frames.
 - **ingress**: Enables the sending of flow control pause frames (unsupported).
 - **bidirectional**: Enables the receiving of flow control pause frames, but does not allow sending, as ingress flow control is not supported.

Step 5 Enter the **exit** command to exit the interface configuration mode.

```
Device(config-if)# exit
```

Step 6 Verify the **flow-control** configuration with the **show interfaces** *<interface-id>* **flow-control** command.

```
Device# show interfaces tenGigE 0/4/0/0 flow-control
Flow-control Send: off
Flow-control Receive: on
```

Mismatched LLFC configurations

The transmit and receive directions can be configured separately, and each device on the network can have a different LLFC configuration. The table demonstrates the interaction between devices with configurations that do not match.

Switch A	Switch B	Description
LLFC configured to receive and transmit PAUSE frames.	LLFC configured to receive PAUSE frames.	Switch A can transmit 802.3x PAUSE frames and honor 802.3x PAUSE frames. Switch B can only receive 802.3x PAUSE frames.
LLFC configured to receive and transmit PAUSE frames.	LLFC configured to transmit PAUSE frames.	Switch A can transmit 802.3x PAUSE frames and honor 802.3x PAUSE frames. Switch B can transmit 802.3x PAUSE frames but will drop all received PAUSE frames.

CHAPTER 5

Priority Flow Control Overview

Table 18: Feature History Table

Feature Name	Release Information	Feature Description
Priority Flow Control	Release 7.3.2	Previously available in Release 6.6.3, this feature is a link-level flow control mechanism that enables you to selectively pause traffic based on its class of service (CoS).

Priority flow control (PFC; IEEE 802.1Qbb), which is also referred to as Class-based Flow Control (CBFC) or Per Priority Pause (PPP), is a mechanism that prevents frame loss that is due to transient congestion. PFC is similar to 802.3x Flow Control (pause frames) or link-level flow control (LLFC). However, instead of pausing all traffic on a link, PFC functions on a per class-of-service (CoS) basis.

During congestion, PFC sends a pause frame that indicates which CoS value must be paused. When the congestion is mitigated, the router stops sending the PFC frames to the upstream node.

For details about the Priority Flow Control feature, see the *Interface and Hardware Component Configuration Guide for Cisco NCS 5500 Series Routers*.

- [Restrictions, on page 105](#)
- [Configuring Priority Flow Control Thresholds, on page 107](#)
- [Priority Flow Control Watchdog Overview, on page 113](#)
- [Configure a Priority Flow Control Watchdog Interval, on page 113](#)
- [Monitoring and Logging Packet Drops on Lossless PFC-Enabled Queues, on page 116](#)

Restrictions

The following restrictions apply while configuring PFC thresholds, PFC watchdog and QoS policies in PFC profile.

- The PFC feature is only supported in the non-HQoS profile.
- The PFC feature is only supported on the following line card or fixed chassis PIDs of the NCS5500 Series:
 - NC55-36X100G

- NC55-18H18F
 - NC55-24X100G-SE
 - NC55-36X100G-S
 - NC55-24H12F-SE
 - NC55-36X100G-A-SE
 - NCS-55A1-36H-SE-S
 - NCS-55A1-36H-S
 - NCS-55A1-24H
 - NCS-55A1-48Q6H
- When PFC is enabled, only two parameter scheduling is supported. So, the egress actions could have either priority or weighted fair queue (WFQ) scheduling apart from a shaper action. For WFQ scheduling, either bandwidth remaining ratio (BRR) or bandwidth is supported and a mix of the two in the same policy-map is rejected. With PFC, BRR has a weight range of 1 to 256 as against 1 to 4096 for the non PFC, non-HQoS case.
 - The hw-module profile for enabling PFC per queue and defining PFC Tx thresholds are global configurations per line card location. So, only one set of pause, resume thresholds and headroom sizes per traffic-class can be configured for all ports on a given line card location. With the introduction of this new configuration model, the pause action under an egress policy class-map is deprecated.
 - While a line card reload is required for any addition or removal of traffic classes in the hw-module profile, you can update the pause, resume thresholds and buffer / headroom sizes on already configured traffic-classes without requiring a line card reload.
 - PFC watchdog (PFCWD) interval has a minimum granularity of 100ms. When you configure higher values, they are rounded up to the nearest multiple of 100ms.
 - There is no XML schema or yang model for the new hw-module profile. Only CLI configuration and show commands are available.
 - In the PFC profile, only monotonically increasing priority levels with traffic-class are supported. For example, TC7 should be p1, TC6 should be p2, and so on, until TC1 is p7 with class-default being lowest priority. Rate classes can be mixed anywhere.
 - When an egress queue is disabled as part of a watchdog queue shutdown action and once the pause frames stop, the queue drains the enqueued packets on the wire while it waits to be restored back.
 - If PFCWD is disabled and a traffic-class experiences sustained PFC storm beyond 7s, then the traffic on that queue continues to be dropped even when the PFC storm stops. Traffic needs to be stopped and restarted or all the incoming ports involved in sending traffic to this egress port needs to be flapped (shut and no shut) to manually recover the egress port.
 - The class-map actions of queue-limit and WRED thresholds without ECN enabled have no impact on PFC-enabled queues. Queue-limit is redundant because packet is buffered based on pause or x-off and headroom configured per source port.
 - Even when PFCWD shuts down an egress queue experiencing storm, if the ingress traffic was already causing a congestion due to the application of sub-rate shapers or BRR policy, then the ingress buffers build up and PFC Tx is still generated towards the sender. In other words, PFCWD only removes the

source of a storm. It does not suppress PFC Tx generated from sustained congestion due to user configuration.

- In the PFC profile, there is a 25% reduction in available buffer descriptors. Further, 20% of the remaining buffer space is reserved for headroom. This leads to only 80% of the 75% buffers being available in the shared pool for all ingress VoQs on that NP core.

Configuring Priority Flow Control Thresholds

You can set values for pause threshold (x-off), resume threshold (x-on) and headroom for a traffic class on all PFC enabled ports on a given line card location using the hw-module profile priority-flow-control command.

The existing queue-limit for that traffic class on an egress queuing policy on that line card will have no impact and the effective queue limit is pause threshold + headroom.

Note For optimal functionality in hardware, for a given traffic class, the resume threshold should not be more than 10% of the pause threshold and the headroom should be at least 100KB.

For details on how to configure PFC on an interface, see the *Interface and Hardware Component Configuration Guide for Cisco NCS 5500 Series Routers*.

Configuration Example

Apart from the line card level PFC parameters configured through the hw-module profile, PFC Receive functionality requires an egress policy to be applied and egress traffic to be mapped to unique queues per CoS value on all PFC enabled interfaces.

You can accomplish this with the following sequence of configuration.

1. Configure ingress classification policy to map incoming traffic to the right CoS / priority queue.
2. Configure egress queuing policy with the relevant shaping, priority and weighted fair queue scheduling actions
3. Attach the ingress policy on all interfaces where traffic can come in.
4. Attach the egress policy on all PFC enabled interfaces in the system.
5. Configure hw-module priority-flow-control profile and configure pause, resume and headroom for all PFC traffic-classes on all line card locations requiring PFC feature.

Reload the line card for all traffic-class addition and deletions. Parameters within an already configured traffic-class can be edited 'in place' without requiring a line card reload.

```

Verification

Incoming PFC frames are displayed on the PFC Rx statistics that are shown in the command below. If the interface is enabled for PFC and has an egress queuing policy applied to it, then the queue corresponding to the incoming CoS value on the PFC frames is paused.

When PFC pause thresholds are crossed, PFC Tx frames are sent out of the PFC enabled interfaces sourcing such traffic on that network processing core. This can be verified against the PFC Tx statistics that are shown on this command. After the congestion condition ceases and the buffer resource usage goes below the PFC resume thresholds, a PFC resume frame is sent and the PFC Tx frames are stopped.

```
RP/0/RP1/CPU0:NCS5504#show controllers hundredGigE 0/0/0/0 priority-flow-control statistics
```

```

Priority Flow Control Watchdog Overview

PFC Watchdog is a mechanism to identify any PFC storms (queue-stuck condition) in the network, and to prevent the PFC from propagating on the network and running in a loop. You can configure a PFC watchdog interval to detect whether packets in a no-drop queue are being drained within a specified time period. When the time period is exceeded, all outgoing packets are dropped on interfaces that match the PFC queue that is not being drained.

This requires monitoring PFC receiving on each port and detecting ports seeing an unusual amount of sustained pause frames. Once detected, the watchdog module can enforce several actions on such ports, which include generating a syslog message for network management systems, shutting down the queue, and auto-restoring the queue (after the PFC storm stops).

Related Topics

- [Priority Flow Control Overview, on page 105](#)

Configure a Priority Flow Control Watchdog Interval

You can configure PFC Watchdog parameters (Watchdog interval, shutdown multiplier, auto-restore multiplier) at the global or interface levels. Note that:

- When global Watchdog mode is disabled or off, Watchdog is disabled on all interfaces. This condition is regardless of the interface level Watchdog mode settings.
- When global Watchdog mode is enabled or on, the interface level Watchdog mode configuration settings override the global Watchdog mode values.
- When you configure interface level Watchdog attributes such as interval, shutdown multiplier, and auto-restore multiplier, they override the global Watchdog attributes.

Note

Configuring the PFC mode and its policies is a prerequisite for PFC Watchdog.

Note PFC Watchdog also monitors, detects, and generates a syslog message every 5 minutes if global pause frames or link level flow control frames are received on a PFC-enabled port.

Such frames are ignored and discarded on the PFC-enabled port.

Configuration Example

You can configure the Watchdog at the global or at the interface level.

Note Watchdog is enabled by default, with system default values of:

Watchdog interval = 100 ms

Shutdown multiplier = 1

Auto-restore multiplier = 10

Monitoring and Logging Packet Drops on Lossless PFC-Enabled Queues

Table 19: Feature History Table

Feature Name	Release Information	Feature Description
Monitoring and Logging Packet Drops on Lossless PFC-Enabled Queues	Release 7.3.2	<p>In case of packet drops on lossless PFC-enabled queues that also have the PFC Watchdog feature enabled, this functionality generates syslogs in 10-minute intervals.</p> <p>Such timely alerts help you troubleshoot quickly, isolate issues, and reroute traffic if necessary, with minimal impact on end-user services.</p>

A Brief Background

Lossless PFC-enabled queues avoid queue tail drops during temporary congestion by sending PFC pause frames back to the previous network element to transmit lesser packets. Depending on the duration of the congestion, the previous network element may send PFC pause frames further upstream, hence triggering subsequent network elements to pause all the way up to the sender. Suppose that the congestion lasts longer or is persistent. In that case, the buffers on some of these network elements may still overflow, causing some packet drops eventually. PFC watchdog isolates such cases of persistent congestion and excessive PFC pause frames. PFC watchdog (enabled by default on all PFC enabled queues) monitors neighboring network elements that send excessive PFC pause frames and shuts down such queues until the PFC storm subsides. This action isolates the issue to just those queues, stops new PFC pause frame generation, and frees up the device buffers for other traffic flows, thus preventing the PFC storm from propagating throughout the network and affecting all other traffic flows.

From IOS XR Release 7.3.2, the PFC watchdog also monitors and periodically reports packet drops that occur due to excessive pausing, congestion, or PFC watchdog-triggered queue shutdown. While the **show controller** commands continue to provide an on-demand display of the total number of packets dropped for a given PFC enabled queue, the new logging mechanism provides timely alerts for proactive user intervention when drops occur on lossless PFC-enabled queues.

Highlights of Logging and Monitoring Packet Drops

From Release 7.3.2 onwards, packet drops on lossless PFC-enabled queues trigger syslog messages that record the drop statistics, alerting you about the event. These syslog messages enable monitoring of such queues and provide timely updates and alerts that help you take proactive action. You can troubleshoot quickly, isolate issues, and reroute traffic if necessary, with minimal impact on end-user services.

Here are some important highlights of the monitoring and logging of packet drops:

- *Only PFC-enabled queues* that also have the PFC Watchdog enabled are monitored.
- The syslog generation is event-based, where the event trigger is a packet drop on PFC Watchdog-monitored lossless queue between two consecutive measurement polls at a 10-minute interval. If the drop counters increment between such polls within a 10-minute interval, then this monitoring and logging functionality generates a syslog.
- Syslogs are generated for the following monitored parameters:
 - **Rx Data Frames Dropped** under **show controllers priority-flow-control statistics**. This counter accounts for virtual output queue (VOQ) tail drop statistics from all network processors across all ingress line cards in the system for a given egress port. VOQ tail drops occur when the PFC-enabled lossless queues build up beyond the user-configured headroom.
 - **Dropped Packets** under **show controllers priority-flow-control watchdog statistics**. This parameter accounts for all queue drops on the PFC-enabled lossless queues in the network processor on the egress line card.
- The **show controllers** command continues to display the total number of packets dropped.
- A typical syslog output looks like this:

```
%PLATFORM-PFC_WATCHDOG-5-PACKETDROP : PFC watchdog detected 150 packet drops on lossless
priority 3 of interface HundredGigE0_7_0_30. Total drops 5678 packets.
```

Restrictions for Monitoring and Logging Packet Drops

The following restrictions apply to the monitoring and logging of packet drops for lossless PFC-enabled queues:

- The 10-minute polling interval is fixed, and you can't modify it.
- The monitoring and logging functionality is enabled by default on all PFC Watchdog-enabled queues, and you can't disable it.

CHAPTER 6

Configuring Modular QoS Congestion Management

- [Traffic Shaping, on page 130](#)
- [4K Pseudowire on Bundle with QoS Enhancement , on page 134](#)
- [Traffic Policing, on page 136](#)
- [References for Modular QoS Congestion Management, on page 152](#)

Congestion Management Overview

Congestion management features allow you to control congestion by determining the order in which a traffic flow (or packets) is sent out an interface based on priorities assigned to packets. Congestion management entails the creation of queues, assignment of packets to those queues based on the classification of the packet, and scheduling of the packets in a queue for transmission.

Note

From Cisco IOS XR Release 7.3.1 onwards, systems with Cisco NC57 line cards running in compatibility mode support QoS over Layer 2 services for:

- Local switching [xconnect or bridging]
- L2 VPN – VPWS

Starting with Cisco IOS XR Release 7.4.1 systems with Cisco NC57 line cards running in native mode support QoS over Layer 2 services for:

- Local switching [xconnect or bridging]
- L2 VPN – VPWS

Table 20: Feature History Table

Feature Name	Release Information	Feature Description
Set Peak Burst Size for Egress Shaping	Release 7.4.1	<p>This feature is now supported on routers that have Cisco NC57 line cards installed and operate in native and compatibility modes.</p> <p>With this feature you can configure the burst size along with the existing egress shaper bandwidth, using the "shape average shaper bandwidth burst size burst unit" command.</p> <p>This feature is used to control higher bursts of traffic being transmitted to the devices that have lower queue length configured to receive traffic. For more information, see Configure VOQ-Level Traffic Shaping, on page 130.</p>
Absolute Rates for Bundle Interfaces for Traffic Shapers and Traffic Policers	Release 7.4.1	<p>This feature is now supported on routers that have Cisco NC57 line cards installed and operate in native and compatibility modes. For more information, see Configure VOQ-Level Traffic Shaping, on page 130 and Configure Traffic Policing (Two-Rate Three-Color), on page 142.</p>
Ingress Policing on BVI (Bridge Group Virtual Interface) and Low-Latency Queueing (LLQ)	Release 7.4.1	<p>This feature is now supported on routers that have Cisco NC57 line cards installed and operate in native and compatibility modes. For more information, see "Restrictions for QoS on BVI" under Restrictions , on page 56 and Low-Latency Queueing with Strict Priority Queueing, on page 124</p>

The types of traffic regulation mechanisms supported are:

- [Class-based Weighted Fair Queueing, on page 122](#)
- [Low-Latency Queueing with Strict Priority Queueing, on page 124](#)
- [Traffic Shaping, on page 130](#)
- [Traffic Policing, on page 136](#)

Ingress Traffic Management Model

The ingress traffic management model relies on packet queueing on the egress interface using Virtual Output Queueing (VOQ) on the ingress. In this model, buffering takes place at ingress. Here's how the VOQ process works.

Your routers support up to eight output queues per main interface or physical port. For every egress output queue, the VOQ model earmarks buffer space on every ingress pipeline. This buffer space is in the form of

dedicated VOQs. These queues are called virtual because the queues physically exist on the ingress interface only when the line card actually has packets enqueued to it. To support the modular model of packet distribution, each network processing unit (NPU) core at the ingress needs connectors to every egress main interface and subinterface. The ingress traffic management model thus requires a mesh of connectors to connect the ingress NPU cores to the egress interfaces, as shown in **The Ingress Traffic Management Model**.

Figure 5: The Ingress Traffic Management Model

In the figure, every ingress interface (LC 0 through LC n) port has eight VOQs for the single egress line card LC 10.

Here's how packet transmission takes place:

1. When a packet arrives at an ingress port (say on LC 0), the forwarding lookup on the ingress line card points to the egress interface. Based on the egress interface (say it is on LC10), the packet is enqueued to the VOQ of the LC 10 egress port. The egress interface is always mapped to a physical port.
2. Credits are requested from the egress port based on the scheduling mechanism. Once credits are available, the LC 10 will receive the packets (based on the packet marking and distribution model) and send grants to the ingress ports via the connectors. (The figure shows a separate line for the grant for the sake of visual representation. In reality, the same connector is used for requests, grants, and transmission between an NPU core at the ingress and the egress port on LC 10.)
3. The ingress ports respond to this permission by transmitting the packets via FC to the LC 10 ports. (The time it takes for the ingress ports to request for egress port access, the egress port to grant access, and the packet to travel across FC is the round-trip time.)

The VOQ model thus operates on the principle of storing excess packets in buffers at ingress until bandwidth becomes available. Based on the congestion that builds up and the configured threshold values, packets begin to drop at the ingress itself, instead of having to travel all the way to the egress interface and then getting dropped.

Tell me why this doesn't work as expected

Learn about the underlying limitations that lead to unexpected traffic drops, affect shaping behavior, or result in buffer-related constraints.

Why traffic drops occur even below VOQ shaper rate in high-scale QoS

This happens when buffer resources run out in high-scale deployments. If you create over 1,000 Virtual Output Queues (VOQs) with active traffic flows, the router may exhaust its on-chip buffer, resulting in unexpected packet drops.

Why egress queuing statistics are missing for unknown unicast traffic on Cisco NCS 5700 line cards

When unknown unicast traffic is flooded through a bridge domain on routers that have Cisco NCS 5700 series line cards, it is forwarded through the Fabric Multicast Queuing (FMQ) path.

FMQ does not support queuing features or providing queuing statistics at the egress. Egress policies such as shaping do not take effect for this traffic, resulting in null egress statistics. Ingress classification still works as expected.

- Unknown unicast traffic: traffic sent to a destination MAC address that the router doesn't have in its MAC table.
- Fabric multicast queuing path: an internal forwarding path used for multicast, broadcast, and unknown unicast traffic

Class-based Weighted Fair Queueing

Class-based Weighted Fair Queueing (CBWFQ) allows definition of traffic classes based on customer match criteria. With CBWFQ you can define traffic classes and assign guaranteed amount of minimum bandwidth to them. CBWFQ also allows for a strict priority queue for delay-sensitive traffic.

Bandwidth Remaining

The CBWFQ algorithm derives the weight for each class from the bandwidth remaining value allocated to the class. The **bandwidth remaining** option specifies a weight for the class to the CBWFQ. After the priority-queue is serviced, the leftover bandwidth is distributed as per bandwidth remaining ratio (BWRR) or percentage. If you do not configure this command for any class, the default value of the BWRR is considered as 1 (one). In the case of **bandwidth remaining percent**, the remaining bandwidth is equally distributed among other classes, to make it 100 percentage (100%).

Restrictions

- The **bandwidth remaining** command is supported only for egress policies.

Configure Minimum Bandwidth and Bandwidth Remaining

Guidelines

- The **priority** command cannot be configured along with **bandwidth**, **bandwidth remaining** commands, but can be configured with **shaping**, **queue-limit** and **random-detect** commands in the same class. Also see [Restrictions, Limitations, and Requirements for Configuring H-QoS](#), on page 162.

Configuration Example

You have to accomplish the following to complete the minimum bandwidth and bandwidth remaining configuration:

1. Creating or modifying a policy-map that can be attached to one or more interfaces
2. Specifying the traffic class whose policy has to be created or changed
3. Allocating the minimum bandwidth and leftover bandwidth for the class
4. Attaching the policy-map to an output interface

```
Router# configure
Router(config)# policy-map test-bw-bw-rem
Router(config-pmap)# class qos-6
Router(config-pmap-c)# bandwidth percent 60
Router(config-pmap-c)# bandwidth remaining percent 60
Router(config-pmap-c)# exit
Router(config-pmap)# exit
Router(config)# interface HundredGigE 0/6/0/18
Router(config-if)# service-policy output test-bw-bw-rem
Router(config-if)# commit
```

Running Configuration

```
policy-map test-bw-bw-rem
class qos-6
  bandwidth percent 60
  bandwidth remaining percent 60
!
class qos-5
  bandwidth percent 20
  bandwidth remaining percent 40
!
class class-default
!
end-policy-map
!

interface HundredGigE0/6/0/18
  service-policy input 100g-s1-1
  service-policy output test-bw-bw-rem
!
```

Verification

Low-Latency Queuing with Strict Priority Queuing

The Low-Latency Queuing (LLQ) feature brings strict priority queuing (PQ) to the CBWFQ scheduling mechanism. Priority queuing (PQ) in strict priority mode ensures that one type of traffic is sent, possibly at the expense of all others. For PQ, a low-priority queue can be detrimentally affected, and, in the worst case,

never allowed to send its packets if a limited amount of bandwidth is available or the transmission rate of critical traffic is high.

Configuring Low Latency Queuing with Strict Priority queuing

Configuring low latency queuing (LLQ) with strict PQ allows delay-sensitive data such as voice to be de-queued and sent before the packets in other queues are de-queued.

Support information

Supported priority levels

- Priority levels 1 to 7 are supported, with 1 being the highest and 7 the lowest.
- The default Class of Service Queue (CoSQ) 0 has the lowest priority among all levels.

Profile-based priority support

- For non-H-QoS profiles, priority levels 1 to 7 are supported.
- For H-QoS profiles, only priority levels 1 to 4 are supported.
- Regardless of the profile type, class-default always maps to CoSQ 0, which has the lowest priority.

Queue assignment for priority Level 1

- Any one of the eight egress class-maps (queues) can have priority level 1 configured.

Guidelines

Queue configuration commands

- You can configure these commands along with the **priority** command:
 - **shape average**
 - **queue-limit**
 - **random-detect**

Priority queue oversubscription

- A PQ can oversubscribe bandwidth when other queues do not fully utilize the port bandwidth.
- Oversubscription is supported only for a single priority level.

Limitations

Egress policing

- Egress policing is not supported. Hence, in strict priority queuing scenarios, lower-priority queues may not be serviced if the priority queue consumes the available bandwidth.

Multiple priority level oversubscription

- Bandwidth over-subscription with multiple priority levels is not a supported configuration.

- Starting with Cisco IOS XR Release 7.0.1, if multiple priority levels are configured for oversubscription:
 - the configuration is accepted, and a warning message is displayed
 - fair queuing is applied across all configured priority levels and,
 - higher-priority traffic is not guaranteed precedence over lower-priority traffic.

Traffic Disruption Risk

- There can be minimal traffic disruption when priority level 1 configuration is applied to any of the 8 queues.

Configuration Example

You have to accomplish the following to complete the LLQ with strict priority queuing:

1. Creating or modifying a policy-map that can be attached to one or more interfaces
2. Specifying the traffic class whose policy has to be created or changed.
3. Specifying priority to the traffic class
4. (Optional) Shaping the traffic to a specific bit rate
5. Attaching the policy-map to an output interface

```
Router# configure
Router(config)#class-map qos-1
Router(config-cmap)#match traffic-class 1
Router(config-cmap)#commit

Router(config)#class-map qos-2
Router(config-cmap)#match traffic-class 2
Router(config-cmap)#commit

Router(config)# policy-map test-priority-1
Router(config-pmap)# class qos1
Router(config-pmap-c)# priority level 7
Router(config-pmap-c)# shape average percent 2
Router(config-pmap-c)# class qos-2
Router(config-pmap-c)# priority level 6
Router(config-pmap-c)# shape average percent 1
Router(config-pmap-c)# commit
Router(config-pmap-c)# exit
Router(config-pmap)# exit

Router(config)# interface HundredGigE 0/0/0/20
Router(config-if)# service-policy output test-priority-1
Router(config-if)# commit
```

Running Configuration

```
policy-map test-priority-1
class qos-1
priority level 7
shape average percent 2
```

```

!
class qos-2
  priority level 6
  shape average percent 1
!
class class-default
!
end-policy-map
!

interface HundredGigE0/0/0/20
  service-policy output test-priority-1
!

```

Verification

Router# **show qos int hundredGigE 0/0/0/20 output**

```

Overhead Accounting

Traffic shapers and policers use packet traffic descriptors to ensure adherence to the service level agreement in QoS. However, when traffic flows from one hop to another in a network, headers added or removed at interim hops affect the packet bytes being accounted for by QoS at each hop. When your end-user network measures the packet bytes to ensure they receive the payload as agreed, these additional header bytes cause a discrepancy.

QoS overhead accounting provides the flexibility to operators to decide which header bytes can be excluded by the traffic shaper and policer and which can be included, depending on the end user's requirements and device capabilities, to meet the committed payload in units of bytes.

For example, if the QoS commitment includes the additional header bytes, the overhead accounting feature allows your router to account for this overhead and reduces the traffic policing and shaping rates accordingly. This is also called a **positive accounting overhead**.

If however, the committed rate doesn't include the additional bytes, overhead accounting allows your router to adjust the core stream traffic such that the traffic policing and shaping rates are increased. This is also called a **negative accounting overhead**.

To summarize, QoS overhead accounting enables the router to account for packet overhead when shaping and policing traffic to a specific rate. This accounting ensures that the router runs QoS features on the actual bandwidth that the subscriber traffic consumes.

Any interface that supports QoS policies supports overhead accounting.

Note You can enable user overhead accounting using the optional configuration of **accounting user-defined** *<overhead size in bytes>* while attaching the service policy on the egress interface.

Guidelines and Restrictions

- Overhead accounting for ingress shaping is not supported.

The following restrictions apply for routers that have Cisco NC57 line cards installed and operate in native and compatibility modes.

- More than one compensation value can be programmed, provided you configure egress policy maps on different egress ports.
- You must configure a unique compensation value for a main interface and all sub-interfaces belonging to that main interface. You can't program different compensation values on different sub-interfaces sharing a common main interface.
- You can configure different compensation values on different sub-interfaces if they belong to other main interfaces.
- Compensation value programmed on egress queues (but not on VoQs) will remain active until the last egress policy map (with header compensation) is removed from main or sub-interfaces. This may impact traffic flow on main and sub-interfaces even though no compensation is set for them.

The following restrictions apply for routers that have line cards other than Cisco NC57 line cards.

- You can't program more than one compensation value per NPU or router, even if they're on different egress ports.
- You can configure the same egress compensation for different egress ports.
- NPUs can have different compensation values configured on different line cards in a modular system.
- Compensation value programmed on egress queues (but not on VoQs) will remain active until the last egress policy map (with header compensation) is removed from main or sub-interfaces. This may impact traffic flow on main and sub-interfaces even though no compensation is set for them.

Configuring for Overhead Accounting

To configure overhead accounting, you must:

1. Create a policy map and configure QoS actions for that map.
2. Configure overhead accounting and attach the map to an egress interface.

```
/* create QoS policy */
Router#configure terminal
Router(config)#policy-map policer
Router(config-pmap)#class class-default
Router(config-pmap-c)#police rate percent 10
Router(config-pmap-c-police)#commit

/* configure account overhead value while attaching the QoS policy to an egress interface */
Router(config)#int hundredGigE 0/0/0/2
Router(config-if)#service-policy output policer account user-defined 12
Router(config-if)#commit
Router(config-if)#root
Router(config)#end
```

Running Configuration

```
Router#sh run int hundredGigE 0/0/0/2
interface HundredGigE0/0/0/2
service-policy output policer account user-defined 12
!
```

The following example shows how to **configure a negative overhead accounting value**:

```
Router#conf
Router(config)#int hundredGigE 0/0/0/2
Router(config-if)#service-policy output policer account user-defined -12
Router(config-if)#commit
```

To **modify an overhead accounting value**, you must:

1. Remove the existing QoS policy and re-add it.
2. Configure the new overhead accounting value.

```
Router#conf
Router(config)#int hundredGigE 0/0/0/2
Router(config-if)#no service-policy input policer
Router(config-if)#service-policy output policer account user-defined -20
Router(config-if)#commit
Router#sh run int hundredGigE 0/0/0/2
```

```
interface HundredGigE0/0/0/2
service-policy output policer account user-defined -20
!
```

Positive Accounting Use Case

If QoS commitment includes Preamble, Frame Delimiter & Interframe Gap and has the following configuration:

```
service-policy output <foo> account user-defined +20
```

For QoS purposes, your router treats this packet as a packet of size = Actual Packet size + 20. Hence, the effective policing and shaping is *reduced* to match the downstream interface.

Negative Accounting Use Case

If QoS commitment to your router does not include VLAN header information, and has the following configuration:

```
service-policy output <foo> account user-defined -4
```

For QoS purposes, your router treats this packet as a packet of size = Actual Packet size – 4. Hence, the effective policing and shaping is *increased* to match the downstream interface.

Associated Commands

```
service-policy (overhead accounting)
```

Traffic Shaping

Traffic shaping allows you to control the traffic flow exiting an interface to match its transmission to the speed of the remote target interface and ensure that the traffic conforms to policies contracted for it. Traffic adhering to a particular profile can be shaped to meet downstream requirements, hence eliminating bottlenecks in topologies with data-rate mismatches.

Note

If you apply a policy map that has configured traffic policing and traffic shaping on the basis of a percentage of bandwidth available on the interface and you change the speed of the interface, you must delete that policy map and reattach it to the interface. Else, QoS programming for the earlier speed remains in effect and does not change with change in the port speed.

You can configure traffic shaping at the VOQ level (see [Ingress Traffic Management Model, on page 120](#) Ingress Traffic Management Model to know how the VOQ model works), meaning you can apply shaping policies individually to each VOQ or output port. You can thus achieve fine-grained control over traffic shaping, enabling differentiated treatment of various types of traffic or destinations.

Configure VOQ-Level Traffic Shaping

The traffic shaping performed on outgoing interfaces is done at the Layer 1 level and includes the Layer 1 header in the rate calculation.

Guidelines

- You can configure **shape average** command along with **priority** command.

- From Cisco IOS XR Release 6.6.25 onwards, a shaper on a bundle interface also allows absolute rates apart from the already supported units of percentage, per-thousand and per-million.

From Cisco IOS XR Release 7.4.1 onwards, this is also supported on routers that have Cisco NC57 line cards installed and operate in native and compatibility modes.

Configuration Example

You have to accomplish the following to complete the traffic shaping configuration:

1. Creating or modifying a policy-map that can be attached to one or more interfaces
2. Specifying the traffic class whose policy has to be created or changed
3. Shaping the traffic to a specific bit rate and set peak burst size
4. Attaching the policy-map to an output interface

```
Router# configure
Router(config)#class-map c5
Router(config-cmap)#match traffic-class 5
Router(config-cmap)#commit

Router(config)# policy-map egress_policy1
Router(config-pmap)# class c5
Router(config-pmap-c)# shape average percent 50 1000
Router(config-pmap-c)# exit
Router(config-pmap)# exit
Router(config)# interface HundredGigE 0/1/0/0
Router(config-if)# service-policy output egress_policy1
Router(config-if)# commit
```

Running Configuration

```
class-map c5
  match traffic-class 5
commit

policy-map egress_policy1
  class c5
    shape average percent 50 1000
  !
  class class-default
  !
end-policy-map
!

interface HundredGigE0/6/0/18
  service-policy output egress_policy1
!
```

Verification

```
Router# show qos interface tenGigE 0/0/0/0 output

Wed Jul 10 14:18:37.783 UTC
```

```

NOTE:- Configured values are displayed within parentheses

Port Shaping

Port shaping, or port-based traffic shaping, is a technique used in QoS to control and manage network traffic on specific ports. Port shaping allows you to prioritize or limit the bandwidth on specific ports to ensure that critical applications receive sufficient network resources while non-critical traffic is restricted.

By implementing port shaping, you can define rules and policies to control the bandwidth allocated to specific ports.

Port shaping can help prevent network congestion, optimize network performance, and ensure that bandwidth is allocated efficiently to meet the requirements of different applications or services.

Key Differences Between VOQ-Level and Port-Level Shapers

Table 21: Differences Between VOQ-level and Port-level Shapers

Parameter	VOQ-Level Shaper	Port-Level Shaper
Granularity	Operates at the individual output queue level within a network device. It shapes the traffic on a per-queue basis.	Operates at a network device's interface or port level. It shapes the overall traffic on the port, affecting all the traffic passing through that interface.
Operational	Helps manage bandwidth usage for different traffic flows or classes within the device.	Helps manage the aggregate bandwidth usage for the entire port.

Parameter	VOQ-Level Shaper	Port-Level Shaper
Traffic control	Allows for granular control and shaping of traffic at the queue level.	Provides high-level control over the shaping of traffic, as it shapes all the traffic passing through the port without differentiating between individual flows or classes.
When to use	Useful when you need to manage and shape traffic per-flow or per-class basis, providing more precise control.	Helpful when you want to manage the overall bandwidth utilization of a port without the need for fine-grained control or differentiation between specific traffic types.

Burst Size for VOQ-Level Shaper

Virtual Output Queue (VOQ)-level shaper burst refers to the burst size or capacity set in a VOQ-level shaper.

A VOQ level shaper within a switch or router regulates the rate at which packets are transmitted from the VOQs to the output ports in a given time interval.

The burst size or capacity in a VOQ-level shaper determines the maximum number of packets or bytes transmitted from a VOQ during a traffic burst. It defines the burst size allowed before the shaper starts limiting the traffic to conform to the specified rate.

The burst setting is thus essential in VOQ-level shaping as it affects the burstiness or the ability to handle traffic bursts. A larger burst size allows larger traffic bursts to be transmitted before the shaping mechanism restricts the flow to conform to the desired rate. Similarly, a smaller burst size limits the burstiness of the traffic and ensures a smoother and more controlled transmission.

Configure Burst Size for VOQ-Level Shaper

See [Configure VOQ-Level Traffic Shaping](#), on page 130 for details.

4K Pseudowire on Bundle with QoS Enhancement

Table 22: Feature History Table

Feature Name	Release Information	Feature Description
4K Pseudowire on Bundle with QoS Enhancement	Release 7.3.1	<p>With this feature you can configure a desired traffic policy, to which your network complies, by using the bandwidth management technique of two-level traffic shaping. You can also increase the Link Aggregation Group (LAG) sub-interface scale or pseudowires up to 4K.</p> <p>This increased scale value enables you to increase the number of devices connected to your router, resulting in benefits such as increased bandwidth and cost-effective operations.</p>

Your router supports two modes of egress traffic shaping:

- The **default non-Hierarchical QoS (H-QoS) mode**, where the egress traffic shaping is configured only on main interfaces and no hierarchical policies are supported. In other words, egress traffic shaping on subinterfaces isn't supported in this mode.
- The **H-QoS mode**, where egress traffic shaping is also supported on subinterfaces. This mode also supports hierarchical policies on the main and subinterfaces.

Prior to Cisco IOS XR Release 7.3.1, the H-QoS mode restricted the scale of subinterfaces you could configure. For example, the maximum Link Aggregation Group (LAG) subinterface scale or pseudowires is 1K in the H-QoS mode.

The enhancement described in this section, available from Cisco IOS XR Release 7.3.1 is applicable for the default non-H-QoS mode for egress QoS. It involves configuring two-level traffic shaper policy on the main interface, while enabling you to increase the LAG subinterface scale or pseudowires to as much as 4K. What this means is that you can also scale up the number of access devices you want to connect through LAG to your router, thus enabling:

- Increased reliability and availability
- Better use of physical resources
- Increased bandwidth
- Cost-effective operations

Restrictions and Guidelines

The following restrictions and guidelines apply while configuring two-level traffic shaper policy on the main interface in (default) non-H-QoS mode:

- The hierarchical egress policy support is only for main interfaces.
- Subinterface behavior remains the same in non-H-QoS mode. No egress QoS support is available for subinterfaces.
- This enhancement is applicable only for egress QoS, and there are no changes in ingress QoS behavior.
- There's no change to the current non-H-QoS flat policy behavior.
- The minimum shaper rate varies between different ASICs.

Configure Two-Level Shaper Policy on Main Interface

To configure two-level shaper policy on main interface, you must:

1. Enter global configuration mode and create a two-level policy map.
2. Attach this policy map to the main interface.

```
/* Enter the global configuration mode and create the two-level policy map */
Router#configure
Router(config)# policy-map two-level-pm
Router(config-pmap)#class class-default
Router(config-pmap-c)#shape average percent 20
Router(config-pmap-c)#service-policy child
Router(config-pmap-c)#root
Router(config)#policy-map child
Router(config-pmap)#class class-default
Router (config-pmap-c)#shape average percent 5
Router(config-pmap-c)#commit

/* Apply policy-map under interface */
Router(config)#interface hundredGigE 0/0/0/3
Router(config-intf)#service-policy output policy
Router(config-intf)#commit
```

Running Configuration

```
Router#show running-config policy-map two-level-pm
policy-map two-level-pm
  class class-default
    service-policy child
    shape average percent 20
  !
end-policy-map
!

Router#show running-config interface hundredGigE 0/0/0/3
interface HundredGigE0/0/0/3
service-policy output two-level-pm
!
```

Verification

Verify that the maximum bandwidth (shaping rate) for the parent policy (Level 1) is greater than the rate for the child policy at Level 2.

```
Router#show qos interface hundredGigE 0/0/0/3 output
NOTE:- Configured values are displayed within parentheses
Interface HundredGigE0/0/0/3 ifh 0x68 -- output policy
NPU Id: 0
Total number of classes: 2
Interface Bandwidth: 100000000 kbps

Inverse Weight / Weight = 1 / (BWR not configured)

Level2 Class = class-default
Egressq Queue ID = 1048 (Default LP queue)
Queue Max. BW. = 1000000 kbps (5 %)
Queue Min. BW. = 0 kbps (default)
Inverse Weight / Weight = 1 / (BWR not configured)
Guaranteed service rate = 1000000 kbps
Peak burst = 36864 bytes (default)
TailDrop Threshold = 1249792 bytes / 10 ms (default)
WRED not configured for this class
```

Traffic Policing

Traffic policing allows you to control the maximum rate of traffic sent or received on an interface and to partition a network into multiple priority levels or class of service (CoS). Traffic policing manages the maximum rate of traffic through a token bucket algorithm. The token bucket algorithm uses user-configured values to determine the maximum rate of traffic allowed on an interface at a given moment in time. The token bucket algorithm is affected by all traffic entering or leaving the interface (depending on where the traffic policy with traffic policing is configured) and is useful in managing network bandwidth in cases where several large packets are sent in the same traffic stream. By default, the configured bandwidth value takes into account the Layer 2 encapsulation that is applied to traffic leaving the interface.

Traffic policing also provides a certain amount of bandwidth management by allowing you to set the burst size (Bc) for the committed information rate (CIR). See, [Committed Bursts and Excess Bursts](#), on page 137.

The router supports the following traffic policing mode(s):

- Single-Rate Two-Color (SR2C) in color-blind mode. See [Single-Rate Policer](#), on page 138.
- Single-Rate Three-Color (SR3C) in color-blind mode.
- Two-Rate Three-Color (2R3C) in color-blind mode. See [Two-Rate Policer](#), on page 142 .

Note In NC57-18DD-SE, QoS enhanced stats is enabled by default.

Restrictions

- If you apply a policy map that has configured traffic policing and traffic shaping on the basis of a percentage of bandwidth available on the interface and you change the speed of the interface, you must delete that policy map and reattach it to the interface. Else, QoS programming for the earlier speed remains in effect and does not change with change in the port speed.
- Traffic policing is supported only in ingress direction, and only color-blind mode is supported.
- The policing rate accuracy may vary up to +/-2% from the configured policer value.
- Ensure that you don't configure a policer and match criteria for **discard-class** in the same class. Even though the configuration is allowed, the policer doesn't work and allows all traffic without dropping packets.
- Policer marking is not supported.
- Policers are configured in the interface at the core level and "show qos int <>" value is displayed at the NPU level.

For policers configured in a bundle interface where bundle members are from the same NPU but different cores (NPU cores), each member sends the traffic up to the core level policer configuration, but "show qos int <>" displays the NPU level policer output.

- Example:

For bundle interface with two 10GE members (same NPU, but one interface from core0, one interface from core1) 2R3C policer applied on bundle interface (1G confirm rate, 1G exceed rate – total 2G policer rate) will be shown on the "show qos int <>" output):

Interface in core0 – 500 Mbps confirm rate, 500 Mbps exceed rate

Interface in core1 – 500 Mbps confirm rate, 500 Mbps exceed rate

For traffic in one out of two interfaces, the policed rate will be 1Gbps. For traffic on two interfaces, policed rate will be 2Gbps.

Committed Bursts and Excess Bursts

Unlike a traffic shaper, a traffic policer does not buffer excess packets and transmit them later. Instead, the policer executes a "send or do not send" policy without buffering. Policing uses normal or committed burst (bc) values and excess burst values (be) to ensure that the router reaches the configured committed information rate (CIR). Policing decides if a packet conforms or exceeds the CIR based on the burst values you configure. Burst parameters are based on a generic buffering rule for routers, which recommends that you configure buffering to be equal to the round-trip time bit-rate to accommodate the outstanding TCP windows of all connections in times of congestion. During periods of congestion, proper configuration of the excess burst parameter enables the policer to drop packets less aggressively.

For more details, see [Committed Bursts, on page 152](#) and [Excess Bursts, on page 152](#).

Single-Rate Policer

Single-Rate Two-Color Policer

A single-rate two-color (SR2C) policer provides one token bucket with two actions for each packet: a conform action and an exceed action.

Figure 6: Workflow of Single-Rate Two-Color Policer

Based on the committed information rate (CIR) value, the token bucket is updated at every refresh time interval. The T_c token bucket can contain up to the B_c value, which can be a certain number of bytes or a period of time. If a packet of size B is greater than the T_c token bucket, then the packet exceeds the CIR value and a default action is performed. If a packet of size B is less than the T_c token bucket, then the packet conforms and a different default action is performed.

Single-Rate Three-Color Policer

A single-rate three-color (SR3C) policer provides one token bucket with three actions for each packet: a conform action, an exceed action and a violate action. The packet is marked based on the CIR value and the two associated burst size - committed burst size (CBS) and excess burst size (EBS). If a packet does not exceed the CBS, it is marked as conformed packet. The packet is marked as exceeded if it exceeds CBS, but not the EBS. If it exceeds the EBS as well, it is marked as violate packet.

Configure Traffic Policing (Single-Rate Two-Color)

Traffic policing is often configured on interfaces at the edge of a network to limit the rate of traffic entering or leaving the network. The default conform action for single-rate two color policer is to transmit the packet and the default exceed action is to drop the packet. Users cannot modify these default actions.

Configuration Example

You have to accomplish the following to complete the traffic policing configuration:

1. Creating or modifying a policy-map that can be attached to one or more interfaces
2. Specifying the traffic class whose policy has to be created or changed
3. (Optional) Specifying the marking action
4. Specifying the policy rate for the traffic
5. Attaching the policy-map to an input interface

```
Router# configure
Router(config)# policy-map test-police-1
Router(config-pmap)# class ipv6-6
Router(config-pmap-c)# set dscp cs2 (optional)
Router(config-pmap-c)# set qos-group 7 (optional)
Router(config-pmap-c)# police rate percent 20 burst 10000 bytes
Router(config-pmap-c-police)# exit
Router(config-pmap-c)# exit
Router(config-pmap)# exit
Router(config)# interface HundredGigE 0/6/0/18
Router(config-if)# service-policy input test-police-1
Router(config-if)# commit
```

Running Configuration

```
class-map match-any ipv6-6
  match precedence 3
end-class-map
!

policy-map test-police-1
  class ipv6-6
    set dscp cs2
    set qos-group 7
    police rate percent 20 burst 10000 bytes
  !
  !
  class class-default
  !
end-policy-map
!

interface HundredGigE0/6/0/18

Two-Rate Policer

The two-rate policer manages the maximum rate of traffic by using two token buckets: the committed token bucket and the peak token bucket. The dual-token bucket algorithm uses user-configured values to determine the maximum rate of traffic allowed on a queue at a given moment. In this way, the two-rate policer can meter traffic at two independent rates: the committed information rate (CIR) and the peak information rate (PIR).

The dual-token bucket algorithm provides users with three actions for each packet—a conform action, an exceed action, and an optional violate action. Traffic entering a queue with the two-rate policer configured is placed into one of these categories. The actions are pre-determined for each category. The default conform and exceed actions are to transmit the packet, and the default violate action is to drop the packet.

This figure shows how the two-rate policer marks a packet and assigns a corresponding action to the packet.

Figure 7: Marking Packets and Assigning Actions—Two-Rate Policer

Also, see [Two-Rate Policer Details](#), on page 153.

The router supports Two-Rate Three-Color (2R3C) policer.

Configure Traffic Policing (Two-Rate Three-Color)

The default conform and exceed actions for two-rate three-color (2R3C) policer are to transmit the packet and the default violate action is to drop the packet. Users cannot modify these default actions.

Configuration Example

You have to accomplish the following to complete the two-rate three-color traffic policing configuration:

1. Creating or modifying a policy-map that can be attached to one or more interfaces
2. Specifying the traffic class whose policy has to be created or changed
3. Specifying the packet marking
4. Configuring two rate traffic policing
5. Attaching the policy-map to an input interface

```

Router# configure
Router(config)# policy-map policy1
Router(config-pmap)# class ipv4-7
Router(config-pmap-c)# set qos-group 4
Router(config-pmap-c)# police rate percent 20 burst 100000 bytes peak-rate percent 50
peak-burst 200000 bytes
Router(config-pmap-c-police)# exit
Router(config-pmap-c)# exit
Router(config-pmap)# exit
Router(config)# interface HundredGigE 0/6/0/18
Router(config-if)# service-policy input policy1
Router(config-if)# commit

```

Running Configuration

```

policy-map policy1
  class ipv4-7
    set qos-group 4
    police rate percent 20 burst 100000 bytes peak-rate percent 50 peak-burst 200000 bytes
  !
!

interface HundredGigE 0/6/0/18
  service-policy input policy1
!

```

Policer conform burst          = 4194304 bytes (default)

```

Important Notes

- From Cisco IOS XR Release 6.6.25 onwards:
 - a committed information rate of 0 kbps is supported, which is the only exception to the minimum rate of 22 kbps for both commit and excess rates.
 - a policer on a bundle interface also allows absolute rates apart from the already supported units of percent, per-thousand and per-million. From Cisco IOS XR Release 7.4.1 onwards, this is also supported on routers that have Cisco NC57 line cards installed and operate in native and compatibility modes.
- A policer is programmed per NPU core on a bundle interface. So, all members on a bundle interface from the same core share the policer.

Packets-Per-Second-Based Policer

Table 23: Feature History Table

Feature Name	Release Information	Feature Description
Packets-Per-Second-Based Policer	Release 7.4.1	<p>Prior to this functionality, when configuring policers, the only available option for policer rates was bit-rate measured in units of bits per second (bps). With this release, you can configure policer rates in units of packets per second (pps) as well. pps-based policer is critical in fending off malicious attacks—when attackers target your specific resources with a vast amount of traffic that contain higher number of packets, but move at a slower packet rate. Protection from such attacks is possible because pps-based policers ensure that regardless of the packet size and rate, the policer only accepts a fixed number of packets per second.</p> <p>This functionality modifies the police rate command.</p>

- **Policer rates so far**—You used the **police rate** command to configure policers based on two parameters:
 - bit-rates (default unit: bits per second or bps)
 - Burst size (default unit: bytes)
- **packets-per-second (pps)-based policer**—With this additional functionality, you can use the **police rate** command to configure policers in units of packets per second (pps). The pps configuration option is available as **police rate <pps-value> pps**. When you configure the pps option, ensure that you configure burst size in packets. (See **Restrictions and guidelines**.) Thus, the parameters for pps-based policer are:
 - packets per second (pps)
 - burst size (packets)
- **Why pps-based-policer**—Networks face newer types of attacks, and these days malicious operators don't necessarily employ aggressive tactics that involve overwhelming your bandwidth with large amount of traffic to cause distributed denial of service (DDoS). Now, some attackers go the 'softer' route, where they send smaller packet sizes at slower traffic rates. During such malicious network activity, a bandwidth-based policer can still aggregate up to many packets to be processed if the packet size is small. Attackers tend to use this behavior to bypass bandwidth-based policers to exploit vulnerabilities or try to hit performance limitations by increasing the packet rates.

Packets-per-second-based policers ensure that regardless of the packet size and traffic rate, the policer only accepts a fixed number of packets per second.

pps-based-policer support cheat-sheet—Here’s a quick look at some key support areas and their details for pps-based policer.

Support	Details
Classification and marking support	Same as that for bps-based-policer
Units	Equivalent kbps values display for QoS programming and statistics.
H-QoS	Support for parent and child policers
Bursts	Support for confirm burst (bc) and exceed burst (be) values in units of packets. The default value is in multiple of 128 bytes equivalent to 10 milliseconds.
Minimum pps value	For better granularity, recommended minimum value is 100 pps.

• **Restriction and guidelines**

- This functionality is **applicable only for ingress**.
- When using a pps-based policer, **ensure that you configure the burst-size value in number of packets as well**. This is because a policer burst rate determines whether a specific number of packets out of contract would be subject to the next action (that is, exceed or violate).
- **Within a QoS policy, configure the parent and child policies policers to either bps or pps**. Else, the configuration displays an error when you try attaching the policy to an interface.
- **For single-level policy maps:** under the same policy map, you can configure one class map with bps-based policer and the other class map with a pps-based policer.
- **For two-level hierarchical policy maps:**
 - The parent and child-level policy maps must use the same unit-based policer. That is, both must have either pps-based or bps-based policers.
 - If you configure the child-level policy map with pps-based policer, ensure that the parent policy-map class default has a pps-based policer.

• **Configure pps-based policer**—To configure pps-based policer, you must:

1. Configure a class map.
2. Create a service policy for the map and configure the pps values.
3. Attach the service policy to an interface.

```
/*Configure a class map*/

Router(config)#class-map prec1
Router(config-cmap)#match precedence 1
Router(config-cmap)# exit
Router(config)# commit
```

```

/*Create a service policy map*/

Router(config)# policy-map policy1
Router(config-pmap)# class prec1
Router(config-pmap-c)#police rate 1000 pps burst 300 packets
Router(config-pmap-c-police)#exit
Router(config-pmap-c)#exit
Router(config-pmap)#exit
Router(config)# commit

/*Attach the service policy to an interface*/

[police rate](#)

Per-thousand and Per-million Units

Shaper and policer rates can be configured in units of per-thousand and per-million on bundle interfaces. This provides the ability to provision shape and police rates down to 100 kbps on bundle or link aggregation (LAG) interfaces even with 100 GE bundle members.

For example, consider a 100GE interface and simple policy.

```
Interface HundredGig0/0/0/0
Service-policy output TEST
Policy-map TEST
Class C
  Shape average per-thousand 5
End-policy
```

Per thousand represents 0.1% of the link bandwidth and per million represents 0.0001% of the link bandwidth.

Which means that for a 100G link, 5 parts per thousand is 0.5% of the link bandwidth. Hence, the shape average per thousand of 5 in the above example enforces a shaper of 500 Mbps.

Shared Policer

Table 24: Feature History Table

Feature Name	Release Information	Feature Description
Shared Policer	Release 7.4.1	This feature is now supported on routers that have Cisco NC57 line cards installed and operate in native and compatibility modes.

The classification of the incoming packet occurs only once. However, based on the different classification criteria, the shared policer feature allows sharing of the policer bucket amongst two or more classes in a QoS policy map. That is, the same token bucket is used for a traffic flow matching against any of the classes sharing the policer.

For example, let us say a policer of 10 Mbps is shared among two classes C1 and C2. This feature ensures that both C1 and C2 get traffic flow assigned on First Come First Serve (FCFS) basis. Also that, if C2 does not have any traffic, C1 uses all of the 10 Mbps for transmission.

This feature includes two components:

- Policer Bucket Shared
- Policer Bucket Referred

Policer Bucket Shared

The policer bucket shared feature defines and shares a policer bucket instance among multiple classes.

Here is a sample configuration that defines and shares policer bucket instance sp1 :

```
policy-map parent
  class long-distance
    police bucket shared sp1 rate 1 mbps
```

In this configuration, a policy-map for class long-distance traffic type is created to police at 1Mbps rate and the policer bucket is shared.

Policer Bucket Referred

The policer bucket referred feature refers a defined policer bucket instance. Shared policer is not supported across policy levels. This means for example, that parent and child policy cannot share a common bucket.

Here is a sample configuration that refers shared policer bucket instance sp1 :

```
policy-map voip-child
  class long-distance-voip
    police bucket referred sp1
```

In this configuration, a policy-map for class long-distance-voip traffic type is created and the shared policer bucket sp1 is referred.

Shared Policer Statistics

Currently, individual class statistics are not available as a default option for shared policer. You can access statistics in the following modes.

Aggregate Mode

In this mode the policer bucket is shared among two or more classes. However, statistics are not available for every individual class. You can view the aggregate statistics that combine the numbers for all the classes sharing the policer bucket.

Per-Class Mode

In this mode the policer bucket is shared among two or more classes, and you can also view individual class statistics. However, when this mode is active, the Policy-Based Tunnel Selection (PBTS) mechanism is disabled. To enable the per-class mode, you must configure the **hw-module profile qos shared-policer-per-class-stats** command.

Restrictions and Guidelines

The following restrictions and guidelines apply while configuring the shared policer feature.

- When shared policer is enabled in per-class mode, Policy-Based Tunnel Selection (PBTS) mechanism is disabled. In other words, shared policer-per-class-mode and PBTS are mutually exclusive features.
- Shared policer is not supported across policy levels. This means, for example, that parent and child policies cannot share a common policer bucket.
- Shared policer is not supported in ingress peering mode.
- Shared policer is supported within classes of the same policy. However, cross-policy bucket sharing is not supported.
- There are no limitations on the number of classes that can share policer.
- There are no changes in policer scale numbers in the aggregate and per-class modes.
- All the existing policer types (1R2C, 1R3C and 2R3C) are supported.
- You must reload the affected line card to enable the per-class-stats mode.

Configuring Shared Policer

To configure shared policer, you must:

1. Create a class map to be used for matching packets to the specified class.
2. Create a policy map to be used for matching packets to the specified class.
3. Specify a class name.
4. Define and share a policer bucket.
5. Specify a class name.
6. Refer a shared policer bucket.

References for Modular QoS Congestion Management

Committed Bursts

The committed burst (bc) parameter of the police command implements the first, conforming (green) token bucket that the router uses to meter traffic. The bc parameter sets the size of this token bucket. Initially, the token bucket is full and the token count is equal to the committed burst size (CBS). Thereafter, the meter updates the token counts the number of times per second indicated by the committed information rate (CIR).

The following describes how the meter uses the conforming token bucket to send packets:

- If sufficient tokens are in the conforming token bucket when a packet arrives, the meter marks the packet green and decrements the conforming token count by the number of bytes of the packet.
- If there are insufficient tokens available in the conforming token bucket, the meter allows the traffic flow to borrow the tokens needed to send the packet. The meter checks the exceeding token bucket for the number of bytes of the packet. If the exceeding token bucket has a sufficient number of tokens available, the meter marks the packet.

Green and decrements the conforming token count down to the minimum value of 0.

Yellow, borrows the remaining tokens needed from the exceeding token bucket, and decrements the exceeding token count by the number of tokens borrowed down to the minimum value of 0.

- If an insufficient number of tokens is available, the meter marks the packet red and does not decrement either of the conforming or exceeding token counts.

Note When the meter marks a packet with a specific color, there must be a sufficient number of tokens of that color to accommodate the entire packet. Therefore, the volume of green packets is never smaller than the committed information rate (CIR) and committed burst size (CBS). Tokens of a given color are always used on packets of that color.

Excess Bursts

The excess burst (be) parameter of the police command implements the second, exceeding (yellow) token bucket that the router uses to meter traffic. The exceeding token bucket is initially full and the token count is equal to the excess burst size (EBS). Thereafter, the meter updates the token counts the number of times per second indicated by the committed information rate (CIR).

The following describes how the meter uses the exceeding token bucket to send packets:

- When the first token bucket (the conforming bucket) meets the committed burst size (CBS), the meter allows the traffic flow to borrow the tokens needed from the exceeding token bucket. The meter marks the packet yellow and then decrements the exceeding token bucket by the number of bytes of the packet.
- If the exceeding token bucket does not have the required tokens to borrow, the meter marks the packet red and does not decrement the conforming or the exceeding token bucket. Instead, the meter performs the exceed-action configured in the police command (for example, the policer drops the packets).

Two-Rate Policer Details

The committed token bucket can hold bytes up to the size of the committed burst (bc) before overflowing. This token bucket holds the tokens that determine whether a packet conforms to or exceeds the CIR as the following describes:

- A traffic stream is conforming when the average number of bytes over time does not cause the committed token bucket to overflow. When this occurs, the token bucket algorithm marks the traffic stream green.
- A traffic stream is exceeding when it causes the committed token bucket to overflow into the peak token bucket. When this occurs, the token bucket algorithm marks the traffic stream yellow. The peak token bucket is filled as long as the traffic exceeds the police rate.

The peak token bucket can hold bytes up to the size of the peak burst (be) before overflowing. This token bucket holds the tokens that determine whether a packet violates the PIR. A traffic stream is violating when it causes the peak token bucket to overflow. When this occurs, the token bucket algorithm marks the traffic stream red.

For example, if a data stream with a rate of 250 kbps arrives at the two-rate policer, and the CIR is 100 kbps and the PIR is 200 kbps, the policer marks the packet in the following way:

- 100 kbps conforms to the rate
- 100 kbps exceeds the rate
- 50 kbps violates the rate

The router updates the tokens for both the committed and peak token buckets in the following way:

- The router updates the committed token bucket at the CIR value each time a packet arrives at the interface. The committed token bucket can contain up to the committed burst (bc) value.
- The router updates the peak token bucket at the PIR value each time a packet arrives at the interface. The peak token bucket can contain up to the peak burst (be) value.
- When an arriving packet conforms to the CIR, the router takes the conform action on the packet and decrements both the committed and peak token buckets by the number of bytes of the packet.
- When an arriving packet exceeds the CIR, the router takes the exceed action on the packet, decrements the committed token bucket by the number of bytes of the packet, and decrements the peak token bucket by the number of overflow bytes of the packet.
- When an arriving packet exceeds the PIR, the router takes the violate action on the packet, but does not decrement the peak token bucket.

See [Two-Rate Policer](#), on page 142.

CHAPTER 7

Configuring Modular QoS on Link Bundles

This chapter covers the following topics:

- [QoS on Link Bundles, on page 155](#)

QoS on Link Bundles

A bundle is a group of one or more ports that are aggregated together and treated as a single link. The router supports Ethernet interfaces and VLAN interfaces (bundle sub-interfaces) bundles. All QoS features currently supported on physical interfaces, are also supported on all link bundle interfaces. Applying QoS on bundle members is not supported.

Note From Cisco IOS XR Release 7.3.1 onwards, systems with Cisco NC57 line cards running in compatibility mode support QoS over Layer 2 services for:

- Local switching [xconnect or bridging]
- L2 VPN – VPWS

Starting with Cisco IOS XR Release 7.4.1 systems with Cisco NC57 line cards running in native mode support QoS over Layer 2 services for:

- Local switching [xconnect or bridging]
- L2 VPN – VPWS

Restrictions for Link Bundles

- Only Ethernet link bundling is supported.
- A bundle interface can only contain physical interface.
- All links within a single bundle must be configured either to run 802.3ad (LACP) or Etherchannel (non-LACP). Mixed links within a single bundle are not supported.
- MAC accounting is not supported on Ethernet link bundles.
- Maximum number of links supported in each link bundle is 64.

- The maximum number of link bundles supported is 128.

Load Balancing

Load balancing function is a forwarding mechanism to distribute traffic over multiple links based on Layer 3 routing information in the router. Per-destination load balancing is only supported on the router, where the router is allowed to distribute packets over one of the links in the bundle. When the per-destination load balancing is enabled, all packets for a certain source-destination pair go through the same link, though there are multiple links available. In other words, per-destination load balancing can ensure that packets for a certain source-destination pair could arrive in order.

Layer 3 Load Balancing on Link Bundles

Layer 3 load balancing for link bundles is done on Ethernet Flow Points (EFPs) and is based on the IPv4 source and destination addresses in the packet. When Layer 3 service-specific load balancing is configured, all egress bundles are load balanced based on the IPv4 source and destination addresses. When packets do not have IPv4 addresses, default load-balancing (based on the MAC SA/DA fields in the packet header) is used.

Configure QoS on Link Bundles

QoS is configured on link bundles in the same way that it is configured on individual interfaces.

Guidelines

- When a QoS policy is applied on a bundle in the egress direction, it's also applied at each member interface.
- When a QoS policy is applied on a bundle (ingress direction), it's replicated at each NPU core.
- If a QoS policy is not applied to a bundle interface, both the ingress and egress traffic use the default queue of the per link member port.
- The shape rate that is specified in the bundle policy-map is not an aggregate for all bundle members. The shape rate applied to the bundle depends on the load balancing of the links. For example, if a policy map with a shape rate of 10 Mbps is applied to a bundle with two member links, and if the traffic is always load-balanced to the same member link, then an overall rate of 10 Mbps applies to the bundle. However, if the traffic is load-balanced evenly between the two links, the overall shape rate for the bundle becomes 20 Mbps.
- If a member is deleted from a bundle, the total bundle statistics change because the statistics that belongs to the detached link is lost.
- The QoS policy that is applied on bundle is inherited to all its member links and the reference bandwidth that is used to calculate shaper/bandwidth is applied as per the physical member interface bandwidth, and not the bundle as a whole.

Configuration Example

You have to accomplish the following to complete the QoS configuration on link bundles:

Note The policy works only if it is applied on the ingress direction. The egress is supported on COS, DEI and MPLS exp marking. So the below policy may not work when it is applied on egress.

1. Creating a class-map
2. Creating a policy-map and specifying the respective class-map
3. Specifying the action type for the traffic

Refer [Attach a Traffic Policy to an Interface, on page 13](#) for details on step 1, 2 and 3.

4. Creating a link bundle
5. Applying traffic policy to the link bundle

```
/* Configure Ether-Bundle and apply traffic policy */
Router(config)# interface Bundle-Ether 12000
Router(config-if)# mtu 9100
Router(config-if)# service-policy input ingress
Router(config-if)# service-policy output egress
Router(config-if)# ipv4 address 100.12.0.0 255.255.255.254
Router(config-if)# bundle maximum-active links 64
Router(config-if)# commit
```

Running Configuration

This example shows how a traffic policy is applied on an Ethernet link bundle. The policy is applied to all interfaces that are members of the Ethernet link bundle.

```
/* Policy-map */

policy-map ingress
  class inet4-classifier-af1
    set qos-group 1
  !
  class inet4-classifier-af2
    set qos-group 2
  !
  class inet4-classifier-af3
    set qos-group 3
  !
  class inet4-classifier-af4
    set qos-group 4
  !
  class inet4-classifier-bel
    set qos-group 5
  !
  class inet4-classifier-ncl
    set qos-group 6
  !
  class class-default
  !
end-policy-map
!

/* Ether Bundle */
```

```

interface Bundle-Ether12000
mtu 9100
service-policy input ingress
service-policy output egress
ipv4 address 100.12.0.0 255.255.255.254
load-interval 30
flow ipv4 monitor FMM-V4 sampler SM ingress
flow ipv6 monitor FMM-V6 sampler SM ingress
flow mpls monitor FMM-MPLS sampler SM ingress
ipv4 access-group IPV4ACL_101 ingress
ipv6 access-group IPV6ACL_101 ingress
!

```

Verification

- Verify that the bundle status is UP.

```

router# show bundle bundle-ether 1200
Wed Dec 16 19:55:49.974 PST

```

```

Bundle-Ether12000
Status: Up
Local links <active/standby/configured>: 35 / 0 / 35
Local bandwidth <effective/available>: 35000000000 (35000000000) kbps
MAC address (source): ea3b.745f.c4b0 (Chassis pool)
Inter-chassis link: No
Minimum active links / bandwidth: 1 / 1 kbps
Maximum active links: 64
Wait while timer: 2000 ms
Load balancing: Default
LACP: Operational
Flap suppression timer: Off
Cisco extensions: Disabled
Non-revertive: Disabled
mLACP: Not configured
IPv4 BFD: Not configured

```

Port	Device	State	Port ID	B/W, kbps
Hu0/4/0/0	Local	Active	0x8000, 0x0009	100000000
Link is Active				
Hu0/4/0/1	Local	Active	0x8000, 0x000a	100000000
Link is Active				
- - -				
Hu0/4/0/35	Local	Active	0x8000, 0x002b	100000000
Link is Active				

- Verify the bundle statistics:

```

router# show policy-map interface bundle-ether 12000

Bundle-Ether12000 input: ingress

CHAPTER 8

Configuring Hierarchical Modular QoS

Hierarchical QoS (H-QoS) is a QoS model that enables you to specify QoS behavior at multiple levels of hierarchy. This chapter provides information about this feature and the different steps involved in configuring it.

Table 25: Feature History for Hierarchical Modular QoS

Release	Modification
Release 6.3.1	Initial Release

This chapter covers the following topics:

- [Overview of Hierarchical Modular QoS, on page 161](#)
- [Restrictions, Limitations, and Requirements for Configuring H-QoS, on page 162](#)
- [Configuring Hierarchical Queuing, on page 164](#)
- [Conform Aware Hierarchical Policy Overview, on page 169](#)

Overview of Hierarchical Modular QoS

Hierarchical QoS (H-QoS) allows you to specify QoS behavior at multiple policy levels, which provides a high degree of granularity in traffic management.

H-QoS is applied on the router interface using nested traffic policies. The first level of traffic policy, the parent traffic policy, is used for controlling the traffic at the main interface or sub-interface level. The second level of traffic policy, the child traffic policy, is used for more control over a specific traffic stream or class. The child traffic policy, is a previously defined traffic policy, that is referenced within the parent traffic policy using the **service-policy** command.

Two-level H-QoS is supported on both ingress and egress directions on all line cards and on physical or bundle main interfaces and sub-interfaces.

Three-level Hierarchical QoS (H-QoS) enables enforcement of class/service, group/ Ethernet Flow Point (EFP), and port level SLAs. You can apply regular two-level egress H-QoS policies on the sub-interfaces to achieve class and EFP SLAs at child and parent levels. In addition, you can apply a port shaper policy on the main interface to achieve an aggregated port level SLA in a 1+2 H-QoS or three-level H-QoS model.

An important point to note is that before Release 6.6.25 (where the three-level H-QoS capability was introduced), when you applied class-default shaper on a main interface, it was enforced *only* on the traffic going through the main interface. With three-level H-QoS, a class default shaper that is applied on the main

interface is considered as a port shaper and enforced on *all* traffic going out of that physical port. The advantage of three-level H-QoS is that the parent shaper on the sub-interfaces is allowed to oversubscribe, thus enabling best effort sharing of the aggregate port shaper at the third level.

Note From Cisco IOS XR Release 7.3.1 onwards, systems with Cisco NC57 line cards running in compatibility mode support QoS over Layer 2 services for:

- Local switching [xconnect or bridging]
- L2 VPN – VPWS

Starting with Cisco IOS XR Release 7.4.1 systems with Cisco NC57 line cards running in native mode support QoS over Layer 2 services for:

- Local switching [xconnect or bridging]
- L2 VPN – VPWS

Restrictions, Limitations, and Requirements for Configuring H-QoS

There are some key restrictions, limitations, and requirements for configuring H-QoS on your router to ensure optimal performance and compliance.

Parent Traffic Policy Restrictions

- The parent traffic policy only supports the traffic class of type class-default.
- The parent traffic policy only supports the class-action shape, and no other queuing action can be configured in it.
- For congestion avoidance and management, the traffic shaper in the parent traffic policy calculates the queue limit and drop priority

Child Policy Requirements

- While configuring on the router, it is mandatory that the priority class must have a traffic shaper in the child traffic policy.
- The sum of the bandwidth of the child policies must be less than the parent policy's traffic shaper.

H-QoS Profile Limitations

- H-QoS profile and ingress peering profile don't work simultaneously. Hence, features requiring a peering profile also do not work with the H-QoS profile enabled.
- The PBTS feature does not work when the H-QoS profile is enabled. This is due to TCAM limitations.

- A maximum of 896 bundle subinterfaces are supported in the system, even if there are no QoS policies applied. This is due to an internal LAG_ID resource consumption in H-QoS profile mode for bundle subinterfaces with or without QoS policies being applied.
- A maximum of 4 priority levels are supported in H-QoS profile mode, unlike the default mode where 7-priority levels are supported. The restriction also applies to physical and bundle main interface policies where 7-level priorities were previously used in non-H-QoS profile mode.

Bandwidth Configuration Limitations

- Bandwidth and Bandwidth remaining configurations are not supported simultaneously within the same policy-map. If a class has bandwidth (CIR), other classes must also have only bandwidth configuration. If a class-map has bandwidth remaining percent/ratio (EIR), other classes should also have only the bandwidth remaining configuration. Shaping is applied on any class.
- In H-QoS mode, if multiple queues are configured with BRR and there is high congestion in the LP (low-priority) queues, one BRR queue receives more credits than the others. The deviation is proportional to the congestion in the LP queues.
- The granularity of bandwidth or the bandwidth remaining ratio (BRR) is 1:64, compared to 1:4096 in non-H-QoS mode. Consequently, there may be differences in bandwidth performance accuracy depending on the values used.

Priority Classes Requirements

Priority classes must be rate-limited using a shaping configuration. The effective shaper value is used as the priority bandwidth reservation. The total priority bandwidth reservations across all subinterfaces and main interfaces must not exceed the network interface (NIF) port speed to prevent oversubscription of priority traffic. Non-priority class rates and parent shaping can be oversubscribed.

Multicast Traffic Restriction

Filtering egress IPv4 and IPv6 multicast traffic is not supported when H-QoS is configured on the router.

Three-Level H-QoS Restrictions

- There is no support for bandwidth action at the EFP parent level. All EFP and subinterface policies get a fair share of the port shaper.
- Three-level H-QoS does not apply to ingress policies or egress marking policies.
- Executing clear qos counters on the main interface clears only the main interface policy statistics. Use the all option to clear all sub-interface statistics, or alternatively, clear the sub-interface policy statistics individually.
- Main interface policy statistics do not reflect the subinterface packet or byte counters, although the port shaper is enforced on all logical ports for a given physical interface. The subinterface policy-map statistics reflect the transmitted and dropped packet or byte count post-port shaper enforcement.

Configuring Hierarchical Queuing

Before you configure H-QoS, you must enable the H-QoS profile on the router. After enabling H-QoS profile, reload the router, as shown in the following configuration.

```
admin
hw-module location all reload
Router# configure
Router(config)# hw-module profile qos hqos-enable
Router(config)# commit
Router# admin
sysadmin-vm:0_RP0# hw-module location all reload
```

The steps that are involved in configuring hierarchical queuing are as follows:

1. Configure a class-map.
2. Configure a child traffic policy using the class-map that was configured in the previous step.
3. Configure a parent traffic policy and add the child traffic policy in it.

The parent traffic policy is the H-QoS traffic policy and it can be applied on physical or bundle main interfaces and sub-interfaces.

Configuration Example

Configuration of a class-map is as follows:

```
Router# configure
Router(config)# class-map match-any tc2
Router(config-cmap)# match traffic-class 1
Router(config-cmap)# end-class-map
Router(config)# commit
```

Configuration of a child traffic policy is as follows:

```
Router# configure
Router(config)# policy-map child
Router(config-pmap)# class tc2
Router(config-pmap-c)# shape average percent 20
Router(config-pmap-c)# exit
Router(config-pmap)# class class-default
Router(config-pmap-c)# shape average percent 1
Router(config-pmap)# end-policy-map
Router(config)# commit
```

Configuration of a parent traffic policy is as follows:

```
Router# configure
Router(config)# policy-map parent
Router(config-pmap)# class class-default
Router(config-pmap-c)# service-policy child
Router(config-pmap-c)# shape average percent 50
Router(config-pmap)# end-policy-map
Router(config)# commit
```

Running Configuration

```

/* Configuration of a Class-map */
class-map match-any tc2
  match traffic-class 1
end-class-map
!
/* Configuration of a Child Traffic Policy */
policy-map child
  class tc2
    shape average percent 20
  !
  class class-default
    shape average percent 1
  !
end-policy-map
!
/* Configuration of a Parent Traffic Policy */
policy-map parent
  class class-default
    service-policy child
    shape average percent 50
  !
end-policy-map
!

```

Applying the Parent Traffic Policy on a Main Interface

```

Router# configure
Router(config)# interface TenGigE 0/0/0/10
Router(config-int)# service-policy output parent
Router(config-int)# commit

```

Applying the Parent Traffic Policy on a Sub-interface

```

Router# configure
Router(config)# interface TenGigE 0/0/0/10.1
Router(config-int)# service-policy output parent
Router(config-int)# commit

```

Verification

Verify if the H-QoS traffic policy is applied correctly on the interface using the commands **show qos interface interface-name output**. In the following example, the **Level1 Class** gives information about the class-map that is associated with the parent traffic policy and the **Level2 Class** gives information about the class-maps that are associated with the child traffic policy.

```
RP/0/RP0/CPU0:ios#show qos interface ten0/0/0/10 output
```

```

The statistics for the packets that have matched the different traffic classes of the parent and child traffic policies can be viewed using the command **show policy-map interface interface-name output**. Also, this command also shows the number of packets that are transmitted or dropped when the specified action is applied on the packets that have matched the respective traffic class.

```
Router# show policy-map interface ten0/0/0/10 output
```

```

```

When using hierarchical policers, there is no independent set of hardware counters to store the parent policer statistics. Instead, parent policer statistics are manipulated in the software to be the sum of all child policers under the same policy-map.

This is shown in the following example where two streams of traffic, with CoS value of 1 and 2 are sent at a speed of 3.5 Gbps each.

```

/*Hierarchical Policy Map Configuration*/
=====
Router# show running-config policy-map Hingress
policy-map Hingress
  class class-default

```

```

service-policy ingress
police rate 5 gbps peak-rate 9 gbps
!
!
end-policy-map
!
/*Ingress Policy Map Configuration*/
=====
Router#show running-config policy-map ingress
policy-map ingress
class cos1
  set traffic-class 1
  police rate 5 gbps
  !
!
class cos2
  set traffic-class 2
  police rate 5 gbps
  !
!
class class-default
!
end-policy-map
!
/*Policy Map applied at TenGigE0/0/0/6.100 Interface*/

Configuration Example for Three-Level H-QoS

To configure three-level H-QoS:

1. Configure the port shaper or EFP group shaper.
2. Configure the two-level H-QoS policy with an EFP parent shaper and class or service level actions
3. Enable the port or EFP group shaper on the main interface to become the root policy.
4. Enable the two-level H-QoS policy on each EFP instance, thus providing a three-level hierarchy of service, EFP and EFP group or port SLAs.

A sample configuration for three-level H-QoS is as follows.

```

policy-map port_shaper
  class class-default
    shape average 6 gbps
  !
end-policy-map
!

policy-map efp_policy
  class class-default
    service-policy efp_policy_child
    shape average 4 gbps
  !
end-policy-map

!
policy-map efp_policy_child
  class tc1
    shape average 50 mbps
    priority level 1
  !
  class tc2
    bandwidth percent 50
  !
  class tc3
    bandwidth percent 30
  !
  class class-default
  !
end-policy-map
!

interface TenGigE0/5/0/4
  service-policy output port_shaper
!

interface TenGigE0/5/0/4.1
  service-policy output efp_policy
  encapsulation dot1q 11

```

```

!
interface TenGigE0/5/0/4.2
 service-policy output efp_policy
 encapsulation dot1q 12
!

```

Verification

Run the **show policy-map interface** command in XR EXEC mode to display the packet/byte count and rate post port shaper enforcement on each of the sub-interface/EFM policies.

Conform Aware Hierarchical Policy Overview

Hierarchical QoS (H-QoS), while allowing for granular and multi-level management of traffic, does not allow for conform traffic from a child-level policy to a parent-level policy to get priority. This means that in case of excess traffic, the parent policer drops conform traffic packets from the child level as well.

The conform-aware hierarchical policy feature enables the parent-level policy to prioritize conform traffic from child-level policy over exceed and violate traffic.

Here is how it works: the child-level policer initially marks its packets as red, yellow, or green. Packets are marked based on the committed information rate (CIR) value and the two associated burst sizes - committed burst size (CBS) and excess burst size (EBS). If a packet does not exceed the CBS, it is marked as conform packet (green). The packet is marked as exceeded if it exceeds CBS, but not the EBS (yellow). If it exceeds the EBS as well, it is marked as violate packet (red).

When the packets arrive at the parent level policer (which is color aware), the policer prioritizes the packets marked green over the packets marked yellow. After all the conform traffic (green) is transmitted and there are tokens available still, the yellow packets are transmitted next, instead of being marked as violate traffic (red).

To enable the conform-aware hierarchical policy feature run the command.

```
hw-module profile qos conform-aware-policer
```

Conform Aware Hierarchical Policy Restrictions

The parent-policy traffic police rate must be greater than or equal to the sum of child conform rates.

Configuring Conform Aware Hierarchy Policy

To enable and configure shared policer:

1. Run the **hw-module profile qos conform-aware-policer** command.
2. Reload the affected line card.
3. Configure class maps to be used for matching packets to the class specified.
4. Create a child policy map.
5. Configure traffic policing for the classes in the child policy map.
6. Attach the child policy-map to the parent's class-default class.
7. Configure traffic policing for the parent policy map.

```
RP/0/RP0/CPU0:ios(config)#hw-module profile qos conform-aware-policer
RP/0/RP0/CPU0:router# reload location 0/0/CPU0
RP/0/RSP0/CPU0:ios(config)#class-map match-any c1
RP/0/RSP0/CPU0:ios(config-cmap)#match precedence 1
RP/0/RSP0/CPU0:ios(config-cmap)#end-class-map
RP/0/RSP0/CPU0:ios(config)#class-map match-any c2
RP/0/RSP0/CPU0:ios(config-cmap)#match precedence 2
RP/0/RSP0/CPU0:ios(config-cmap)#end-class-map
RP/0/RSP0/CPU0:ios(config-pmap)# policy-map child
RP/0/RSP0/CPU0:ios(config-pmap-c)#class class1
RP/0/RSP0/CPU0:ios(config-pmap-c-police)#police rate 20 mbps peak-rate 50 mbps
RP/0/RSP0/CPU0:ios(config-pmap-c)#class class2
RP/0/RSP0/CPU0:ios(config-pmap-c-police)#police rate 30 mbps peak-rate 60 mbps
RP/0/RSP0/CPU0:ios(config-pmap)#policy-map parent
RP/0/RSP0/CPU0:ios(config-pmap-c)#class class-default
RP/0/RSP0/CPU0:ios(config-pmap-c)#service-policy child
RP/0/RSP0/CPU0:ios(config-pmap-c-police)#police rate 60 mbps
RP/0/RSP0/CPU0:ios(config-pmap-c-police)#exit
RP/0/RSP0/CPU0:ios(config-pmap-c)#exit
RP/0/RSP0/CPU0:ios(config-pmap)#exit
RP/0/RSP0/CPU0:ios(config-if)#commit
```

Running Configuration

```
class-map match-any class1
match precedence 1
end-class-map

class-map match-any class2
match precedence 2
end-class-map

policy-map child
class class1
    police rate 20 mbps peak-rate 50 mbps
    !
class class2
    police rate 30 mbps peak-rate 60 mbps
    !

policy-map parent
class class-default
    service-policy child
    police rate 60 mbps
```

```
!
```

In this example, the 20 mbps rate in child class1 and 30 mbps rate in child class2 are guaranteed as conform traffic and the parent will not drop them.

Verification

Run the **show policy-map interface** command in XR EXEC mode to confirm that the committed information rate (CIR) is prioritized over the peak information rate (PIR).

In the example below, **Policed (conform)** or CIR from each class is prioritized over **Policed (exceed)** or PIR.

```
RP/0/RP0/CPU0:ios(config-if)#do show running-config policy-map parent_conform
Tue Apr 28 11:19:09.785 UTC
policy-map parent_conform
class class-default
  service-policy child_conform
  police rate 80 mbps peak-rate 120 mbps
  !
end-policy-map
!
```

```
RP/0/RP0/CPU0:ios(config-if)#do show running-config policy-map child_conform
Tue Apr 28 11:19:14.219 UTC
policy-map child_conform
class match_prec1
  police rate 30 mbps peak-rate 35 mbps
  !
  set qos-group 3
!
class match_prec2
  police rate 20 mbps peak-rate 25 mbps
  !
  set qos-group 4
!
class class-default
  police rate 20 mbps peak-rate 30 mbps
  !
end-policy-map
!
```

```
RP/0/RP0/CPU0:ios(config-if)#do show policy-map interface tenGigE 0/0/0/11/2 input
Tue Apr 28 11:23:48.915 UTC
```

```
TenGigE0/0/0/11/2 input: parent_conform
```

```
