Preface xvii

Changes to This Document xvii

Communications, Services, and Additional Information xvii

CHAPTER 1

New and Changed Information for Segment Routing Features 1

New and Changed Segment Routing Features-24.x.x 1

CHAPTER 2

YANG Data Models for Segment Routing Features 5

Using YANG Data Models 5

CHAPTER 3

About Segment Routing 7

Scope 7

Need 8

Benefits 8

Workflow for Deploying Segment Routing 9

CHAPTER 4

Configure Segment Routing over IPv6 (SRv6) with Micro-SIDs 11

Segment Routing over IPv6 Overview 12

SRv6 Micro-Segment (uSID) 16

SRv6 uSID Terminology 18

SRv6 uSID Carrier Format 18

SRv6 uSID Allocation Within a uSID Block 19

SRv6 Endpoint Behaviors Associated with uSID 20

SRv6 uSID in Action - Example 20

Usage Guidelines and Limitations 25

Configuring SRv6 27

Configuring SRv6 under IS-IS	35
Configuring SRv6 Flexible Algorithm under IS-IS	36
Configuring SRv6 Locator Prefix Summarization	38
Configuring TI-LFA with SRv6 IS-IS	38
Configuring SRv6 IS-IS Microloop Avoidance	41
Configuring Static SIDs	42
Configuring Static Adjacency SIDs	42
Configuring SRv6 BGP-Based Services	44
SRv6 Services: IPv4 L3VPN	46
SRv6 Services: IPv6 L3VPN	58
SRv6 Services: IPv4 BGP Global	70
SRv6 Services: IPv6 BGP Global	73
BGP Signaling for co-existence of IP routes with or without SRv6 SID	80
Configure BGP Signaling over SRv6 Core	81
SRv6 Services: IPv4 L3VPN Active-Standby Redundancy using Port-Active Mode	85
SRv6 Services for L3VPN Active-Standby Redundancy using Port-Active Mode: Operation	86
Configure SRv6 Services L3VPN Active-Standby Redundancy using Port-Active Mode	86
SRv6 Services: IPv4 L3VPN Active-Active Redundancy	89
SRv6 Services: EVPN VPWS — All-Active Multi-Homing	91
SRv6-Services: EVPN ELAN Layer 2 Gateway With Automated Steering To Flexible Algorithm Paths	95
SRv6 ESI Filtering	101
SRv6 Services: L3 EVPN	102
SRv6 Services: L2 and L3 Services with Remote SIDs from W-LIB	106
SRv6-Services: L3 Services with Local SIDs from W-LIB	108
SRv6/MPLS L3 Service Interworking Gateway	113
L3 EVPN/SRv6 and L3 EVPN/MPLS Interworking Gateway	118
L3 EVPN/SRv6 and L3VPN/MPLS Interworking Gateway	121
SRv6/MPLS Dual-Connected PE	124
SRv6 SID Information in BGP-LS Reporting	125
DHCPv4 Relay Agent and Proxy Support over SRv6	126
DHCPv6 Relay Agent Support over SRv6	127
Full-Replace Migration to SRv6 Micro-SID	128
Full-Replace Migration to SRv6 Micro-SID Restrictions	132

SRv6 Traffic Accounting	132
Usage Guidelines and Limitations	136
Configure SRv6 Traffic Accounting	137
Path Maximum Transmission Unit (MTU) Discovery for SRv6 Encapsulated Packets	141
Usage Guidelines and Limitations	143
Enabling Path MTU discovery for SRv6 encapsulated packets	143
VRF-to-VRF route leaking in SRv6 core	144
SRv6 VRF-to-VRF route leaking workflow	145
Usage guidelines and limitations for VRF-to-VRF route leaking in SRv6	146
Configure VRF-to-VRF route leaking in SRv6	146

CHAPTER 5

Configure Segment Routing over IPv6 (SRv6) with Full-Length SIDs	151
Segment Routing over IPv6 Overview	152
Configuring SRv6 under IS-IS	162
Configuring SRv6 IS-IS Flexible Algorithm	163
Configuring SRv6 IS-IS TI-LFA	166
Configuring SRv6 IS-IS Microloop Avoidance	170
SRv6 Services: IPv4 L3VPN	171
SRv6 Services: IPv6 L3VPN	179
SRv6 Services: IPv4 L3VPN Active-Standby Redundancy using Port-Active Mode	189
SRv6 Services for L3VPN Active-Standby Redundancy using Port-Active Mode: Operation	190
Configure SRv6 Services L3VPN Active-Standby Redundancy using Port-Active Mode	190
Configuration Example	190
Running Configuration	191
Verification	191
SRv6 Services: IPv4 L3VPN Active-Active Redundancy	193
SRv6 Services: BGP Global IPv4	194
SRv6 Services: BGP Global IPv6	197
SRv6 Services: EVPN VPWS — All-Active Multi-Homing	203
SRv6 Services: EVPN VPWS — IPv6 QoS Traffic-Class Marking	205
SRv6 Services: SRv6 Services TLV Type 5 Support	206
SRv6/MPLS L3 Service Interworking Gateway	207
SRv6/MPLS Dual-Connected PE	212
SRv6 SID Information in BGP-LS Reporting	213

DHCPv4 Relay Agent and Proxy Support over SRv6	214
DHCPv6 Relay Agent Support over SRv6	215
Dual-Stack with SRv6 Unicast and IPv4 Multicast Core	216
Usage Guidelines and Limitations for Dual-Stack with SRv6 and IPv4	217
Enable Dual-Stack with SRv6 Unicast and IPv4 Multicast Core	217

CHAPTER 6

Configure SRv6 Traffic Engineering	219
SRv6-TE Overview	220
Usage Guidelines and Limitations	221
Traffic Steering	223
SRv6 Flexible Algorithm	223
Automated Steering	227
SRv6-TE Policy Path Types	228
Explicit Paths	229
Configure SRv6-TE Policy with Explicit Path	229
SRv6-TE Explicit Segment List SID Validation	233
Dynamic Paths	235
Optimization Objectives	235
Constraints	237
Configure SRv6 Policy with Dynamic Path	240
Protocols	244
Path Computation Element Protocol	244
Configure the Head-End Router as PCEP PCC	245
SR-TE Application Programming Interface (API)	252
Reporting of SR-TE Policies Using BGP- Link State	261
Restrictions to Reporting of SRTE Policies using BGP-LS	263
Configure Reporting of SRTE Policies using BGP-LS	263

CHAPTER 7

Configure Segment Routing Global Block and Segment Routing Local Block	273
About the Segment Routing Global Block	273
About the Segment Routing Local Block	275
Understanding Segment Routing Label Allocation	276
Setup a Non-Default Segment Routing Global Block Range	279
Setup a Non-Default Segment Routing Local Block Range	280

CHAPTER 8

Configure Segment Routing for IS-IS Protocol	283
Enabling Segment Routing for IS-IS Protocol	283
Configuring a Prefix-SID on the IS-IS Enabled Loopback Interface	286
Configuring an Adjacency SID	288
Manually Configure a Layer 2 Adjacency SID	291
Configuring Bandwidth-Based Local UCMP	294
IS-IS Multi-Domain Prefix SID and Domain Stitching: Example	295
Configure IS-IS Multi-Domain Prefix SID	296
Configure Common Router ID	297
Distribute IS-IS Link-State Data	297
IS-IS Unreachable Prefix Announcement	298
Configuration Steps	299
IS-IS Partition Detection and Leakage of Specific Route Advertisement	301
Conditional Prefix Advertisement	306
Segment Routing ECMP-FEC Optimization	308
Verify the SR ECMP-FEC Optimization	310

CHAPTER 9

Configure Segment Routing for OSPF Protocol	313
Enabling Segment Routing for OSPF Protocol	314
Configuring a Prefix-SID on the OSPF-Enabled Loopback Interface	316
Configuring an Adjacency SID	318
Protected Adjacency SID Backup Timer	320
Conditional Prefix Advertisement	321
Segment Routing ECMP-FEC Optimization	323
Display Neighbor Router Capabilities in OSPF Networks	323
Usage Guidelines and Limitations to Display Neighbor Router Capabilities	325
Verify the Neighbor Router Capabilities	325

CHAPTER 10

Configure Segment Routing for BGP	327
Segment Routing for BGP	327
Configure BGP Prefix Segment Identifiers	328
Segment Routing Egress Peer Engineering	329
Usage Guidelines and Limitations	330

Configure Segment Routing Egress Peer Engineering	330
Configuring Manual BGP-EPE Peering SIDs	332
Configure BGP Link-State	335
Configurable Filters for IS-IS Advertisements to BGP-Link State	339
Configure Filters for IS-IS Advertisements to BGP-LS	340
Use Case: Configuring SR-EPE and BGP-LS	341
Configure BGP Proxy Prefix SID	343
BGP-LU Inter-AS Option-C Interworking with LDP and IGP SR-MPLS using Proxy BGP-SR	345
BGP Best Path Computation using SR Policy Paths	350
Optimal Utilization of ECMP FEC Resources	356
SRv6 double recursion for multilayer BGP underlay	359
Usage guidelines and limitations for SRv6 double recursion	360
Configure SRv6 double recursion for multilayer BGP underlay	361

CHAPTER 11
Configure SR-TE Policies 367

SR-TE Policy Overview	367
Usage Guidelines and Limitations	369
Instantiation of an SR Policy	370
On-Demand SR Policy – SR On-Demand Next-Hop	370
SR-ODN Configuration Steps	373
Configuring SR-ODN: Examples	375
Configuring SR-ODN for EVPN-VPWS: Use Case	384
Manually Provisioned SR Policy	405
PCE-Initiated SR Policy	405
Cumulative Metric Bounds (Delay-Bound Use-Case)	406
SR-TE BGP Soft Next-Hop Validation For ODN Policies	408
SR-TE Policy Path Types	411
Dynamic Paths	411
Optimization Objectives	412
Constraints	413
Configure SR Policy with Dynamic Path	416
Anycast SID-Aware Path Computation	418
Explicit Paths	419
SR-TE Policy with Explicit Path	419

Explicit Path with a BGP Prefix SID as First Segment	423
Configuring Explicit Path with Affinity Constraint Validation	427
Configure Explicit Path with Segment Protection-Type Constraint	429
SR-TE policy with enhanced flexible algorithm metric types	431
Benefits of SR-TE policy with enhanced flexible algorithm metric types	432
Guidelines and restrictions for SR-TE policy with enhanced flexible algorithm metric types	432
Configure SR-TE policy with enhanced flexible algorithm metric types	433
Optional administrative distance configuration for flexible algorithm metric types	434
Protocols	436
Path Computation Element Protocol	436
Configure the Head-End Router as PCEP PCC	436
Configure SR-TE PCE Groups	441
BGP SR-TE	446
Configure BGP SR Policy Address Family at SR-TE Head-End	446
Traffic Steering	449
Automated Steering	449
Color-Only Automated Steering	450
Setting CO Flag	451
Address-Family Agnostic Automated Steering	451
Per-Flow Automated Steering	452
Using Binding Segments	458
Stitching SR-TE Policies Using Binding SID: Example	459
L2VPN Preferred Path	463
Static Route over Segment Routing Policy	463
Autoroute Include	465
SR-TE Automated Steering Without BGP Prefix Path Label	468
Use Case: Centralized BGP EPE for 6PE in an SR-MPLS Network	470
Miscellaneous	476
SR Policy Liveness Monitoring	476
Programming Non-Active Candidate Paths of an SR Policy	477
LDP over Segment Routing Policy	483
SR-TE MPLS Label Imposition Enhancement	486
SR-TE Head-End IPv4 Unnumbered Interface Support	488
Path invalidation drop	490

SR-TE Reoptimization Timers	492
Circuit-Style SR-TE Policies	494
Reporting of SR-TE Policies Using BGP- Link State	508
Restrictions to Reporting of SRTE Policies using BGP-LS	509
Configure Reporting of SRTE Policies using BGP-LS	509
SR-TE Policy Path Protection	517
SR Policy Path Computation for IPv6	522
Usage Guidelines and Limitations	522

CHAPTER 12

Segment Routing Tree Segment Identifier	525
Usage Guidelines and Limitations	529
Bud Node Support	530
Configure Static Segment Routing Tree-SID via CLI at SR-PCE	530
Running Config	532
Multicast VPN: Dynamic Tree-SID MVPN (with TI-LFA)	534
Multicast VPN IPv6: Dynamic Tree-SID Multicast VPN IPv6	549
Prerequisites for Tree-SID mVPN IPv6	556
Restrictions to Tree-SID mVPN IPv6	557
Configure Tree-SID mVPN IPv6	557
Verify Tree-SID mVPN IPv6	560
Multicast: Cisco Nonstop Forwarding for Tree-SID	566
Multicast: SR-PCE High Availability (HA) Support for Dynamic Tree-SID (mVPN)	567
Limitations and Guidelines	577
Configuration Steps	578
Segment routing Tree-SID interoperability and SR-P2MP enhancements	583
Usage guidelines and limitations for SR Tree-SID interoperability	585
PCE upgrade recommendations	586
Verify the SR P2MP enhancements	586

CHAPTER 13

Enabling Segment Routing Flexible Algorithm	591
Prerequisites for Flexible Algorithm	591
Building Blocks of Segment Routing Flexible Algorithm	591
Flexible Algorithm Definition	591
Flexible Algorithm Membership	592

Flexible Algorithm Definition Advertisement	592
Flexible Algorithm Link Attribute Advertisement	592
Flexible Algorithm Prefix-SID Advertisement	593
Calculation of Flexible Algorithm Path	593
Installation of Forwarding Entries for Flexible Algorithm Paths	596
Flexible Algorithm Prefix-SID Redistribution	597
Flexible Algorithm Prefix Metric	599
Configuring Flexible Algorithm	600
Flexible Algorithm Link Attribute Advertisement Behavior	603
Strict IS-IS ASLA Link Attribute	605
Flexible Algorithm-Specific TE Metric	605
Flexible Algorithm with Exclude SRLG Constraint	606
Flexible Algorithm with Exclude Minimum Bandwidth Constraint	610
Flexible Algorithm with Exclude Maximum Delay Constraint	612
Maximum Paths Per IS-IS Flexible Algorithm	613
Maximum Paths Per IS-IS Flexible Algorithm Per Prefix	615
Flexible algorithm with bandwidth optimization	617
Usage guidelines for flexible algorithm with bandwidth optimization	619
Configure flexible algorithm with bandwidth optimization	619
Example: Configuring IS-IS Flexible Algorithm	621
Example: Configuring OSPF Flexible Algorithm	622
Example: Traffic Steering to Flexible Algorithm Paths	623
BGP Routes on PE – Color Based Steering	623
User-Defined Generic Metric Support for IS-IS Flex Algo	626
Usage Guidelines and Limitations for User-Defined Generic Metrics	629
Configure User-Defined Generic Metrics	629
IS-IS Flexible Algorithm UCMP Support	631
Configure IS-IS Flexible Algorithm UCMP Support	631

CHAPTER 14

Configure Segment Routing Path Computation Element	635
About SR-PCE	635
Usage Guidelines and Limitations	637
Configure SR-PCE	637
Configure the Disjoint Policy (Optional)	639

Global Maximum-delay Constraint	641
PCE override of SR-TE policies	641
Usage guidelines	642
Limitations	642
Prerequisites	643
PCE override of PCC-initiated SR-TE policies	643
Configure PCE override of PCC-initiated SR-TE policies	644
PCE-Initiated SR Policies	647
SR-PCE Flexible Algorithm Multi-Domain Path Computation	648
Example: SR-PCE Flexible Algorithm Multi-Domain Path Computation Use Case	650
Exclude Network Resources during Path Computation over SR-TE Policies	654
Configuration to exclude network resources during Path Computation	656
Configure the Shortest Path for Disjoint Candidate Paths	659
Configure the shortest path for disjoint candidate paths	660
Enable Strict Disjointness for SR-TE policies in the PCE	662
Configure Strict Disjointness in the PCE	663
ACL Support for PCEP Connection	664
Anycast SID-Aware Path Computation	664
SR-PCE IPv4 Unnumbered Interface Support	669
Inter-Domain Path Computation Using Redistributed SID	671
Example: Inter-Domain Path Computation Using Redistributed SID	673
PCE Support for MPLS-TE LSPs	674
Configuring the North-Bound API on SR-PCE	677

CHAPTER 15

Configure Performance Measurement	681
Usage Guidelines and Limitations	682
Liveness Monitoring	683
IP Endpoint Liveness Monitoring	684
IP Endpoint Liveness Detection in an SR MPLS Network	688
IP Endpoint Liveness in an SRv6 Network	690
SR Policy Liveness Monitoring	693
Configure SR Policy Liveness Monitoring in an MPLS Network	696
Configure Segment Lists to Activate Candidate Paths in SRv6 for PM Liveness	701
Configure Flow Labels in SRv6 Header for PM Liveness	705

Hardware offload of SR policy liveness monitoring	708
Usage Guidelines and Limitations	709
Configuration Example	709
Delay Measurement	711
Measurement Modes	711
Link Delay Measurement	715
Delay Normalization	729
Link Anomaly Detection with IGP Penalty	732
Delay Measurement for IP Endpoint	733
IP Endpoint Delay Measurement over MPLS Network Usecases	735
IP Endpoint Delay Measurement over SRv6 Network Usecase	744
SR Policy End-to-End Delay Measurement	746
Fallback delay advertisement	753
Configure interface fallback delay value	754
Path Tracing in SRv6 Network	756
Limitations and Guidelines	757
Configure Midpoint, Sink, and Source Nodes	757
Two-Way Active Measurement Protocol Light Source Address Filtering	761
Usage Guidelines and Limitations	762
Configure IP address on querier and responder nodes	762
Synthetic Loss Measurement	765
Configure Synthetic Loss measurement	766
Delay and synthetic loss measurement for GRE tunnel interfaces	771
Usage guidelines and limitations for delay and synthetic loss measurement for GRE tunnels	772
Configure delay and synthetic loss measurement for GRE tunnel interfaces	773
Delay Measurement Using Software Timestamp	775
Key Concepts	776
Benefits of Software Timestamp	776
How Delay is Measured Using Software Timestamp?	777
Guidelines and Limitations for Software Timestamp	777
Configure Software Timestamp for Delay Measurement	777
 CHAPTER 16	
Configure Topology-Independent Loop-Free Alternate (TI-LFA)	783
Usage guidelines and limitations for TI-LFA	786

Configuring TI-LFA for IS-IS	788
Configuring TI-LFA for OSPF	789
TI-LFA Node and SRLG Protection: Examples	791
Configuring Global Weighted SRLG Protection	792
SR-MPLS over GRE as TI-LFA Backup Path	795
Limitations	798
Example: SR-MPLS over GRE as TI-LFA Backup Path	799
Unlabeled IPv6 Traffic Protection	806

CHAPTER 17

Configure Segment Routing Microloop Avoidance	809
About Segment Routing Microloop Avoidance	809
Usage Guidelines and Limitations	812
Configure Segment Routing Microloop Avoidance for IS-IS	812
Microloop Avoidance for IS-IS with Per-Prefix Filtering	814
Configure Segment Routing Microloop Avoidance for OSPF	818

CHAPTER 18

Configure Segment Routing Mapping Server	821
Segment Routing Mapping Server	821
Usage Guidelines and Restrictions	822
Segment Routing and LDP Interoperability	823
Example: Segment Routing LDP Interoperability	823
Configuring Mapping Server	826
Enable Mapping Advertisement	828
Configure Mapping Advertisement for IS-IS	828
Configure Mapping Advertisement for OSPF	829
Enable Mapping Client	830

CHAPTER 19

Using Segment Routing OAM	833
MPLS Ping and Traceroute for BGP and IGP Prefix-SID	833
Examples: MPLS Ping, Traceroute, and Tree Trace for Prefix-SID	834
MPLS LSP Ping and Traceroute Nil FEC Target	836
Examples: LSP Ping and Traceroute for Nil_FEC Target	837
Segment Routing Ping and Traceroute	838
Segment Routing Ping	839

Segment Routing Traceroute	841
Segment Routing TreeTrace Enhancements	844
Segment Routing Ping and Traceroute for Flexible Algorithm	847
Segment Routing Ping for Flexible Algorithm	847
Segment Routing Traceroute for Flexible Algorithm	848
Segment Routing over IPv6 OAM	848
Data Plane Validation Support for SR-MPLS IPv6-based LSPs	850
Examples: SR-MPLS Data Plane Validation over IPv6-based LSPs	851
MPLS OAM support for SR-TE Policies using MPLS IPv6-based LSPs	852
Usage Guidelines and Limitations	853
Examples: MPLS OAM support for SR-TE Policies with IPv6-based LSPs	854

Preface

The *Segment Routing Configuration Guide for Cisco NCS 5500 Series Routers* preface contains these sections:

- [Changes to This Document, on page xvii](#)
- [Communications, Services, and Additional Information, on page xvii](#)

Changes to This Document

This table lists the changes made to this document since it was first printed.

Date	Change Summary
December 2024	Republished for Release 24.4.1.
September 2024	Republished for Release 24.3.1.
June 2024	Republished for Release 24.2.1.
March 2024	Initial release of this document.

Communications, Services, and Additional Information

- To receive timely, relevant information from Cisco, sign up at [Cisco Profile Manager](#).
- To get the business results you're looking for with the technologies that matter, visit [Cisco Services](#).
- To submit a service request, visit [Cisco Support](#).
- To discover and browse secure, validated enterprise-class apps, products, solutions and services, visit [Cisco DevNet](#).
- To obtain general networking, training, and certification titles, visit [Cisco Press](#).
- To find warranty information for a specific product or product family, access [Cisco Warranty Finder](#).

Cisco Bug Search Tool

[Cisco Bug Search Tool](#) (BST) is a web-based tool that acts as a gateway to the Cisco bug tracking system that maintains a comprehensive list of defects and vulnerabilities in Cisco products and software. BST provides you with detailed defect information about your products and software.

CHAPTER 1

New and Changed Information for Segment Routing Features

This table summarizes the new and changed feature information for the *Segment Routing Configuration Guide for Cisco NCS 5500 Series Routers*, and lists where they are documented.

- [New and Changed Segment Routing Features-24.x.x](#), on page 1

New and Changed Segment Routing Features-24.x.x

Segment Routing Features Added or Modified in IOS XR Release 24.x.x

Feature	Description	Introduced/Changed in Release	Where Documented
Flexible algorithm with bandwidth optimization	This feature is introduced.	Release 24.4.1	Flexible algorithm with bandwidth optimization, on page 617
SR-TE policy with enhanced flexible algorithm metric types	This feature is introduced.	Release 24.4.1	SR-TE policy with enhanced flexible algorithm metric types, on page 431
Segment routing Tree-SID interoperability and SR-P2MP enhancements	This feature is introduced.	Release 24.4.1	Segment routing Tree-SID interoperability and SR-P2MP enhancements, on page 583
VRF-to-VRF route leaking in SRv6 core	This feature is introduced.	Release 24.4.1	VRF-to-VRF route leaking in SRv6 core, on page 144
Delay and synthetic loss measurement for GRE tunnel interfaces	This feature is introduced.	Release 24.4.1	Delay and synthetic loss measurement for GRE tunnel interfaces, on page 771

Feature	Description	Introduced/Changed in Release	Where Documented
Fallback delay advertisement	This feature is introduced.	Release 24.4.1	Fallback delay advertisement, on page 753
Far-end delay metrics in one-way measurement mode	This feature is introduced.	Release 24.4.1	Measurement Modes, on page 711
SRv6 double recursion for multilayer BGP underlay	This feature is introduced.	Release 24.4.1	SRv6 double recursion for multilayer BGP underlay , on page 359
BGP Signaling for co-existence of IP routes	This feature is introduced.	Release 24.3.1	BGP Signaling for co-existence of IP routes with or without SRv6 SID, on page 80
SRv6 Traffic Accounting for NCS 5700	This feature is introduced.	Release 24.3.1	SRv6 Traffic Accounting, on page 132
Delay Measurement Using Software Timestamp	This feature was introduced.	Release 24.3.1	Delay Measurement Using Software Timestamp, on page 775
Liveness Monitoring for IP Endpoint over SRv6 Network on Cisco NCS 5508 and Cisco NCS 5700 Series Routers	This feature was introduced.	Release 24.3.1	IP Endpoint Liveness Monitoring, on page 684
Delay Measurement for IP Endpoint over SRv6 Network on Cisco NCS 5508 and Cisco NCS 5700 Series Routers	This feature was introduced.	Release 24.3.1	Delay Measurement for IP Endpoint, on page 733
SRv6 Traffic Class DSCP Marking Enhancement for QoS	This feature was introduced.	Release 24.2.1	Configuring SRv6
User-Defined Generic Metric Support for IS-IS Flex Algo	This feature is introduced.	Release 24.2.1	User-Defined Generic Metric Support for IS-IS Flex Algo, on page 626
Display Neighbor Router Capabilities in OSPF Networks	This feature is introduced.	Release 24.2.1	Display Neighbor Router Capabilities in OSPF Networks, on page 323
Data Plane Validation for SR-MPLS IPv6-based Controller Instantiated LSPs	This feature is introduced.	Release 24.2.1	Data Plane Validation Support for SR-MPLS IPv6-based LSPs, on page 850

Feature	Description	Introduced/Changed in Release	Where Documented
SR ECMP-FEC Optimization for IPv6 Prefixes	This feature is introduced.	Release 24.2.1	Segment Routing ECMP-FEC Optimization, on page 308
MPLS OAM support for SR-TE Policies using MPLS IPv6-based LSPs	This feature is introduced.	Release 24.2.1	MPLS OAM support for SR-TE Policies using MPLS IPv6-based LSPs, on page 852
Liveness Monitoring for IP Endpoint over SRv6 Network	This feature is introduced.	Release 24.2.1	IP Endpoint Liveness Monitoring, on page 684
Delay Measurement for IP Endpoint over SRv6 Network	This feature is introduced.	Release 24.2.1	Delay Measurement for IP Endpoint
Dual-Stack Support with SRv6 Unicast and IPv4 Multicast Core	This feature is introduced.	Release 24.2.1	Dual-Stack with SRv6 Unicast and IPv4 Multicast Core, on page 216
Reporting of SR-TE Policies Using BGP-Link State for SRv6	This feature is introduced.	Release 24.1.1	Reporting of SR-TE Policies Using BGP-Link State for SRv6
Path Maximum Transmission Unit (MTU) Discovery for SRv6 Encapsulated Packets	This feature is introduced.	Release 24.1.1	Path Maximum Transmission Unit (MTU) Discovery for SRv6 Encapsulated Packets
ISIS Flexible Algorithm UCMP Support	This feature is introduced.	Release 24.1.1	IS-IS Flexible Algorithm UCMP Support, on page 631
Synthetic Loss Measurement	This feature is introduced.	Release 24.1.1	Synthetic Loss Measurement, on page 765
SR-MPLSv6 Traffic Engineering	This feature is introduced.	Release 24.1.1	SR Policy Path Computation for IPv6, on page 522
Delay Measurement on NCS-57C3-MOD Fixed Port Routers	This feature is introduced.	Release 24.1.1	Link Delay Measurement, on page 715
Exclude Network Resources during Path Computation over SR-TE Policies	This feature was introduced.	Release 24.1.1	Exclude Network Resources during Path Computation over SR-TE Policies, on page 654

Feature	Description	Introduced/Changed in Release	Where Documented
Configure the Shortest Path for Disjoint Candidate Paths	This feature was introduced.	Release 24.1.1	Configure the Shortest Path for Disjoint Candidate Paths, on page 659
Enable Strict Disjointness for SR-TE Policies in the PCE	This feature was introduced.	Release 24.1.1	Enable Strict Disjointness for SR-TE policies in the PCE, on page 662
Identical Route Distinguisher on MPLS and SRv6 L3 Services between MPLS and SRv6 Domains	This feature was modified.	Release 24.1.1	SRv6/MPLS L3 Service Interworking Gateway

CHAPTER 2

YANG Data Models for Segment Routing Features

This chapter provides information about the YANG data models for Segment Routing features.

- [Using YANG Data Models, on page 5](#)

Using YANG Data Models

Cisco IOS XR supports a programmatic way of configuring and collecting operational data of a network device using YANG data models. Although configurations using CLIs are easier and human-readable, automating the configuration using model-driven programmability results in scalability.

The data models are available in the release image, and are also published in the [Github](#) repository. Navigate to the release folder of interest to view the list of supported data models and their definitions. Each data model defines a complete and cohesive model, or augments an existing data model with additional XPaths. To view a comprehensive list of the data models supported in a release, navigate to the **Available-Content.md** file in the repository.

You can also view the data model definitions using the [YANG Data Models Navigator](#) tool. This GUI-based and easy-to-use tool helps you explore the nuances of the data model and view the dependencies between various containers in the model. You can view the list of models supported across Cisco IOS XR releases and platforms, locate a specific model, view the containers and their respective lists, leaves, and leaf lists presented visually in a tree structure. This visual tree form helps you get insights into nodes that can help you automate your network.

To get started with using the data models, see the *Programmability Configuration Guide*.

CHAPTER 3

About Segment Routing

- [Scope, on page 7](#)
- [Need, on page 8](#)
- [Benefits, on page 8](#)
- [Workflow for Deploying Segment Routing, on page 9](#)

Scope

Segment routing is a method of forwarding packets on the network based on the source routing paradigm. The source chooses a path and encodes it in the packet header as an ordered list of segments. Segments are an identifier for any type of instruction. For example, topology segments identify the next hop toward a destination. Each segment is identified by the segment ID (SID) consisting of a flat unsigned 20-bit integer.

Segments

Interior gateway protocol (IGP) distributes two types of segments: prefix segments and adjacency segments. Each router (node) and each link (adjacency) has an associated segment identifier (SID).

- A prefix SID is associated with an IP prefix. The prefix SID is manually configured from the segment routing global block (SRGB) range of labels, and is distributed by IS-IS or OSPF. The prefix segment steers the traffic along the shortest path to its destination. A node SID is a special type of prefix SID that identifies a specific node. It is configured under the loopback interface with the loopback address of the node as the prefix.

A prefix segment is a global segment, so a prefix SID is globally unique within the segment routing domain.

- An adjacency segment is identified by a label called an adjacency SID, which represents a specific adjacency, such as egress interface, to a neighboring router. An adjacency SID can be allocated dynamically from the dynamic label range or configured manually from the segment routing local block (SRLB) range of labels. The adjacency SID is distributed by IS-IS or OSPF. The adjacency segment steers the traffic to a specific adjacency.

An adjacency segment is a local segment, so the adjacency SID is locally unique relative to a specific router.

By combining prefix (node) and adjacency segment IDs in an ordered list, any path within a network can be constructed. At each hop, the top segment is used to identify the next hop. Segments are stacked in order at the top of the packet header. When the top segment contains the identity of another node, the receiving node

uses equal cost multipaths (ECMP) to move the packet to the next hop. When the identity is that of the receiving node, the node pops the top segment and performs the task required by the next segment.

Dataplane

Segment routing can be directly applied to the Multiprotocol Label Switching (MPLS) architecture with no change in the forwarding plane. A segment is encoded as an MPLS label. An ordered list of segments is encoded as a stack of labels. The segment to process is on the top of the stack. The related label is popped from the stack, after the completion of a segment.

Services

Segment Routing integrates with the rich multi-service capabilities of MPLS, including Layer 3 VPN (L3VPN), Virtual Private Wire Service (VPWS), Virtual Private LAN Service (VPLS), and Ethernet VPN (EVPN).

Segment Routing for Traffic Engineering

Segment routing for traffic engineering (SR-TE) takes place through a policy between a source and destination pair. Segment routing for traffic engineering uses the concept of source routing, where the source calculates the path and encodes it in the packet header as a segment. Each segment is an end-to-end path from the source to the destination, and instructs the routers in the provider core network to follow the specified path instead of the shortest path calculated by the IGP. The destination is unaware of the presence of the policy.

Need

With segment routing for traffic engineering (SR-TE), the network no longer needs to maintain a per-application and per-flow state. Instead, it simply obeys the forwarding instructions provided in the packet.

SR-TE utilizes network bandwidth more effectively than traditional MPLS-TE networks by using ECMP at every segment level. It uses a single intelligent source and relieves remaining routers from the task of calculating the required path through the network.

Benefits

- **Ready for SDN:** Segment routing was built for SDN and is the foundation for Application Engineered Routing (AER). SR prepares networks for business models, where applications can direct network behavior. SR provides the right balance between distributed intelligence and centralized optimization and programming.
- **Minimal configuration:** Segment routing for TE requires minimal configuration on the source router.
- **Load balancing:** Unlike in RSVP-TE, load balancing for segment routing can take place in the presence of equal cost multiple paths (ECMPs).
- **Supports Fast Reroute (FRR):** Fast reroute enables the activation of a pre-configured backup path within 50 milliseconds of path failure.
- **Plug-and-Play deployment:** Segment routing policies are interoperable with existing MPLS control and data planes and can be implemented in an existing deployment.

Workflow for Deploying Segment Routing

Follow this workflow to deploy segment routing.

1. Configure the Segment Routing Global Block (SRGB)
2. Enable Segment Routing and Node SID for the IGP
3. Configure Segment Routing for BGP
4. Configure the SR-TE Policy
5. Configure the SR-PCE
6. Configure TI-LFA and Microloop Avoidance
7. Configure the Segment Routing Mapping Server

CHAPTER 4

Configure Segment Routing over IPv6 (SRv6) with Micro-SIDs

Note IOS XR release 7.3.2 supports SRv6 with Full-length SID and Micro-SID formats; however, only one format is supported in the network at a time.

To use SRv6 Micro-SID (uSID), enter the **hw-module profile segment-routing srv6 mode micro-segment format f3216** command in config mode, then reload the router or line card. See [Configuring SRv6, on page 27](#) for more information.

To use SRv6 Full-length SID, see the [Configure Segment Routing over IPv6 \(SRv6\) with Full-Length SIDs, on page 151](#).

Segment Routing for IPv6 (SRv6) is the implementation of Segment Routing over the IPv6 dataplane.

Segment Routing over IPv6 Overview

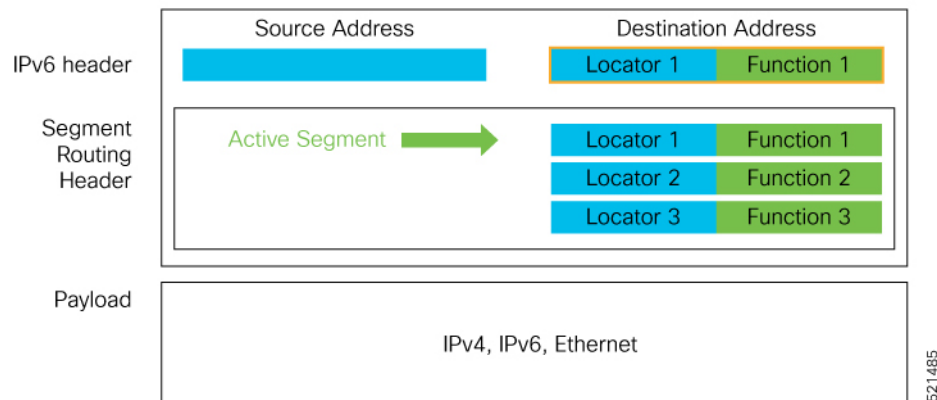

Segment Routing (SR) can be applied on both MPLS and IPv6 data planes. Segment Routing over IPv6 (SRv6) extends Segment Routing support with IPv6 data plane.

In an SR-MPLS enabled network, an MPLS label represents an instruction. The source nodes programs the path to a destination in the packet header as a stack of labels.

SRv6 introduces the Network Programming framework that enables a network operator or an application to specify a packet processing program by encoding a sequence of instructions in the IPv6 packet header. Each instruction is implemented on one or several nodes in the network and identified by an SRv6 Segment Identifier (SID) in the packet. The SRv6 Network Programming framework is defined in [IETF RFC 8986 SRv6 Network Programming](#).

In SRv6, an IPv6 address represents an instruction. SRv6 uses a new type of IPv6 Routing Extension Header, called the Segment Routing Header (SRH), in order to encode an ordered list of instructions. The active segment is indicated by the destination address of the packet, and the next segment is indicated by a pointer in the SRH.

Figure 1: Network Program in the Packet Header

The SRv6 SRH is documented in IETF RFC [IPv6 Segment Routing Header \(SRH\)](#).

The SRH is defined as follows:

```

0          1          2          3
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
| Next Header | Hdr Ext Len | Routing Type | Segments Left |
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
| Last Entry  | Flags      | Tag          |
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
|
|           Segment List[0] (128-bit IPv6 address)
|
|
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+

```

```

|
|
|                                     ...
|
|
+-----+
|
|          Segment List[n] (128-bit IPv6 address)
|
|
+-----+
//
//          Optional Type Length Value objects (variable)
//
+-----+

```

The following list explains the fields in SRH:

- **Next header**—Identifies the type of header immediately following the SRH.
- **Hdr Ext Len (header extension length)**—The length of the SRH in 8-octet units, not including the first 8 octets.
- **Segments left**—Specifies the number of route segments remaining. That means, the number of explicitly listed intermediate nodes still to be visited before reaching the final destination.
- **Last Entry**—Contains the index (zero based) of the last element of the segment list.
- **Flags**— Contains 8 bits of flags.
- **Tag**—Tag a packet as part of a class or group of packets like packets sharing the same set of properties.
- **Segment list**—128-bit IPv6 addresses representing the n th segment in the segment list. The segment list encoding starts from the last segment of the SR policy (path). That means the first element of the segment list (Segment list [0]) contains the last segment of the SR policy, the second element contains the penultimate segment of the SR policy and so on.

In SRv6, a SID represents a 128-bit value, consisting of the following three parts:

- **Locator:** This is the first part of the SID with most significant bits and represents an address of a specific SRv6 node.
- **Function:** This is the portion of the SID that is local to the owner node and designates a specific SRv6 function (network instruction) that is executed locally on a particular node, specified by the locator bits.
- **Args:** This field is optional and represents optional arguments to the function.

The locator part can be further divided into two parts:

- **SID Block:** This field is the SRv6 network designator and is a fixed or known address space for an SRv6 domain. This is the most significant bit (MSB) portion of a locator subnet.
- **Node Id:** This field is the node designator in an SRv6 network and is the least significant bit (LSB) portion of a locator subnet.

SRv6 Node Roles

Each node along the SRv6 packet path has a different functionality:

- Source node—A node that can generate an IPv6 packet with an SRH (an SRv6 packet), or an ingress node that can impose an SRH on an IPv6 packet.
- Transit node—A node along the path of the SRv6 packet (IPv6 packet and SRH). The transit node does not inspect the SRH. The destination address of the IPv6 packet does not correspond to the transit node.
- Endpoint node—A node in the SRv6 domain where the SRv6 segment is terminated. The destination address of the IPv6 packet with an SRH corresponds to the end point node. The segment endpoint node executes the function bound to the SID

SRv6 Head-End Behaviors

The SR Headend with Encapsulation behaviors are documented in the [IETF RFC 8986 SRv6 Network Programming](#).

The SR Headend with Insertion head-end behaviors are documented in the following IETF draft:

<https://datatracker.ietf.org/doc/draft-filsfils-spring-srv6-net-pgm-insertion/>

This section describes a set of SR Policy headend behaviors. The following list summarizes them:

- H.Encaps—SR Headend Behavior with Encapsulation in an SRv6 Policy
- H.Encaps.Red—H.Encaps with Reduced Encapsulation
- H.Insert—SR Headend with insertion of an SRv6 Policy
- H.Insert.Red—H.Insert with reduced insertion

SRv6 Endpoint Behaviors

The SRv6 endpoint behaviors are documented in the [IETF RFC 8986 SRv6 Network Programming](#).

The following is a subset of defined SRv6 endpoint behaviors that can be associated with a SID.

- End—Endpoint function. The SRv6 instantiation of a Prefix SID [[RFC8402](#)].
- End.X—Endpoint with Layer-3 cross-connect. The SRv6 instantiation of an Adj SID [[RFC8402](#)].
- End.DX6—Endpoint with decapsulation and IPv6 cross-connect (IPv6-L3VPN - equivalent to per-CE VPN label).
- End.DX4—Endpoint with decapsulation and IPv4 cross-connect (IPv4-L3VPN - equivalent to per-CE VPN label).
- End.DT6—Endpoint with decapsulation and IPv6 table lookup (IPv6-L3VPN - equivalent to per-VRF VPN label).
- End.DT4—Endpoint with decapsulation and IPv4 table lookup (IPv4-L3VPN - equivalent to per-VRF VPN label).
- End.DT46—Endpoint with decapsulation and specific IP table lookup (IP-L3VPN - equivalent to per-VRF VPN label).
- End.DX2—Endpoint with decapsulation and L2 cross-connect (L2VPN use-case).
- End.B6.Encaps—Endpoint bound to an SRv6 policy with encapsulation. SRv6 instantiation of a Binding SID.

- **End.B6.Encaps.RED**—End.B6.Encaps with reduced SRH. SRv6 instantiation of a Binding SID.

SRv6 Endpoint Behavior Variants

Depending on how the SRH is handled, different behavior variants are defined for the End and End.X behaviors. The End and End.X behaviors can support these variants, either individually or in combinations.

- **Penultimate Segment Pop (PSP) of the SRH variant**—An SR Segment Endpoint Nodes receive the IPv6 packet with the Destination Address field of the IPv6 Header equal to its SID address.

A penultimate SR Segment Endpoint Node is one that, as part of the SID processing, copies the last SID from the SRH into the IPv6 Destination Address and decrements the Segments Left value from one to zero.

The PSP operation takes place only at a penultimate SR Segment Endpoint Node and does not happen at non-penultimate endpoint nodes. When a SID of PSP-flavor is processed at a non-penultimate SR Segment Endpoint Node, the PSP behavior is not performed since Segments Left would not be zero.

The SR Segment Endpoint Nodes advertise the SIDs instantiated on them via control plane protocols. A PSP-flavored SID is used by the Source SR Node when it needs to instruct the penultimate SR Segment Endpoint Node listed in the SRH to remove the SRH from the IPv6 header.

- **Ultimate Segment Pop (USP) of the SRH variant**—The SRH processing of the End and End.X behaviors are modified as follows:

If Segments Left is 0, then:

1. Update the Next Header field in the preceding header to the Next Header value of the SRH
2. Decrease the IPv6 header Payload Length by $8 * (\text{Hdr Ext Len} + 1)$
3. Remove the SRH from the IPv6 extension header chain
4. Proceed to process the next header in the packet

One of the applications of the USP flavor is when a packet with an SRH is destined to an application on hosts with smartNICs implementing SRv6. The USP flavor is used to remove the consumed SRH from the extension header chain before sending the packet to the host.

- **Ultimate Segment Decapsulation (USD) variant**—The Upper-layer header processing of the End and End.X behaviors are modified as follows:

- **End** behavior: If the Upper-layer Header type is 41 (IPv6), then:

1. Remove the outer IPv6 Header with all its extension headers
2. Submit the packet to the egress IPv6 FIB lookup and transmission to the new destination
3. Else, if the Upper-layer Header type is 4 (IPv4)
4. Remove the outer IPv6 Header with all its extension headers
5. Submit the packet to the egress IPv4 FIB lookup and transmission to the new destination
6. Else, process as per Section 4.1.1 (Upper-Layer Header) of [IETF RFC 8986 SRv6 Network Programming](#)

- **End.X** behavior: If the Upper-layer Header type is 41 (IPv6) or 4 (IPv4), then:

1. Remove the outer IPv6 Header with all its extension headers
2. Forward the exposed IP packet to the L3 adjacency J
3. Else, process as per Section 4.1.1 (Upper-Layer Header) of [IETF RFC 8986 SRv6 Network Programming](#)

One of the applications of the USD flavor is the case of TI-LFA in P routers with encapsulation with H.Encaps. The USD flavor allows the last Segment Endpoint Node in the repair path list to decapsulate the IPv6 header added at the TI-LFA Point of Local Repair and forward the inner packet.

SRv6 Micro-Segment (uSID)

Table 1: Feature History Table

Feature Name	Release Information	Feature Description
Cisco NC57 Native Mode: SRv6 Micro-Segment (uSID)	Release 7.5.2	<p>SRv6 Micro-Segment (uSID) is an extension of the SRv6 architecture. It leverages the existing SRv6 Network Programming architecture to encode up to six SRv6 Micro-SID (uSID) instructions within a single 128-bit SID address. Such a SID address is called a uSID Carrier.</p> <p>The following features are now supported on Cisco NCS 5700 series fixed port routers and the Cisco NCS 5500 series routers that have Cisco NC57 line cards installed and operating in the native mode:</p> <ul style="list-style-type: none"> • SRv6 Micro SID (uSID) • IS-IS: TI-LFA, Microloop Avoidance, Flexible Algorithm • SRv6 BGP Services: IPv4 Layer-3 VPNs, IPv6 Layer-3 VPNs, IPv4 BGP global, IPv6 BGP global • SRv6 Services: Dual-Stack L3 Services (IPv4 BGP global, IPv6 BGP global), EVPN VPWS (ELINE) • SRv6/MPLS L3 Service Interworking Gateway

Feature Name	Release Information	Feature Description
SRv6 Micro-Segment (uSID)	Release 7.3.1	<p>This feature is an extension of the SRv6 architecture. It leverages the existing SRv6 Network Programming architecture to encode up to six SRv6 Micro-SID (uSID) instructions within a single 128-bit SID address. Such a SID address is called a uSID Carrier.</p> <p>In addition, this feature leverages the existing SRv6 data plane and control plane with no changes. It also provides low MTU overhead; for example, 6 uSIDs per uSID carrier results in 18 source-routing waypoints in only 40 bytes of overhead (in SRH).</p>

The SRv6 micro-segment (uSID) is an extension of the SRv6 architecture. It leverages the SRv6 Network Programming architecture to encode several SRv6 Micro-SID (uSID) instructions within a single 128-bit SID address. Such a SID address is called a uSID Carrier.

SRv6 uSID is documented in the IETF drafts [Network Programming extension: SRv6 uSID instruction](#) and [Compressed SRv6 Segment List Encoding in SRH](#).

Throughout this chapter, we will refer to SRv6 micro-segment as “uSID”.

The SRv6 uSID provides the following benefits:

- Leverages the SRv6 Network Programming with no change. SRv6 uSID is a new pseudo code in the existing SRv6 network programming framework.
- Leverages the SRv6 data plane (SRH) with no change. Any SID in the destination address or SRH can be an SRv6 uSID carrier.
- Leverages the SRv6 control plane with no change.
- Ultra-Scale—Scalable number of globally unique nodes in the domain, for example:
 - 16-bit uSID ID size: 65k uSIDs per domain block
 - 32-bit uSID ID size: 4.3M uSIDs per domain block
- Lowest MTU overhead
 - 6 uSIDs per uSID carrier
 - For example, 18 source-routing waypoints in only 40 bytes of overhead
- Hardware-friendliness:
 - Leverages mature hardware capabilities (inline IP Destination Address edit, IP Destination Address longest match).
 - Avoids any extra lookup in indexed mapping tables.
 - A micro-program with 6 or fewer uSIDs requires only legacy IP-in-IP encapsulation behavior.
- Scalable Control Plane:
 - Summarization at area/domain boundary provides massive scaling advantage.

- No routing extension is required, a simple prefix advertisement suffices.
- Seamless Deployment:
 - A uSID may be used as a SID (the carrier holds a single uSID).
 - The inner structure of an SR Policy can stay opaque to the source. A carrier with uSIDs is just seen as a SID by the policy headend Security.
 - Leverages SRv6's native SR domain security.

SRv6 uSID Terminology

The SRv6 Network Programming is extended with the following terms:

- **uSID**—An identifier that specifies a micro-segment.

A uSID has an associated behavior that is the SRv6 function (for example, a node SID or Adjacency SID) associated with the given ID. The node at which an uSID is instantiated is called the “Parent” node.

- **uSID Carrier**—A 128-bit IPv6 address (carried in either in the packet destination address or in the SRH) in the following format:

```
<uSID-Block><Active-uSID><Next-uSID>...<Last-uSID><End-of-Carrier>...<End-of-Carrier>
```

where:

- **uSID Block**—An IPv6 prefix that defines a block of SRv6 uSIDs.
- **Active uSID**—The first uSID that follows the uSID block.
- **Next uSID**—The next uSID after the Active uSID.
- **Last uSID**—The last uSID in the carrier before the End-of-Carrier uSID.
- **End-of-Carrier**—A globally reserved uSID that marks the end of a uSID carrier. The End-of-Carrier ID is **0000**. All empty uSID carrier positions must be filled with the End-of-Carrier ID; therefore, a uSID carrier can have more than one End-of-Carrier.

The following is an example of an SRH with 3 Micro-SID carriers for a total of up to 18 micro-instructions:

Micro-SID Carrier1: {uInstruction1, uInstruction2... uInstruction6}
Micro-SID Carrier2: {uInstruction7, uInstruction8... uInstruction12}
Micro-SID Carrier3: {uInstruction13, uInstruction14... uInstruction18}

SRv6 uSID Carrier Format

The uSID carrier format specifies the type of uSID carrier supported in an SRv6 network. The format specification includes Block size and ID size.

- **uSID Block**

The uSID block is an IPv6 prefix that defines a block of SRv6 uSIDs. This can be an IPv6 prefix allocated to the provider (for example, /22, /24, and so on.), or it can be any well-known IPv6 address block generally available for private use, such as the ULA space FC/8, as defined in IETF draft [RFC4193](#).

An SRv6 network may support more than a single uSID block.

The length of block [prefix] is defined in bits. From a hardware-friendliness perspective, it is expected to use sizes on byte boundaries (16, 24, 32, and so on).

• uSID ID

The length of uSID ID is defined in bits. From a hardware-friendliness perspective, it is expected to use sizes on byte boundaries (8, 16, 24, 32, and so on).

The uSID carrier format is specified using the notation "Fbbuu", where "bb" is size of block and "uu" is size of ID. For example, "F3216" is a format with a 32-bit uSID block and 16-bit uSID IDs.

Note F3216 is the default format, and the only format that is supported in IOS XR 7.3.1 release.

SRv6 uSID Allocation Within a uSID Block

The architecture for uSID specifies both globally scoped and locally scoped uSIDs, where a globally scoped uSID is the type of uSID that provides reachability to the node.

On the other hand, a locally scoped uSID is associated to a local behavior, and therefore *must* be preceded by a globally scoped uSID of the parent node when relying on routing to forward the packet.

The Global ID block (GIB) is the set of IDs available for globally scoped uSID allocation. The Local ID block (LIB) is the set of IDs available for locally scoped uSID allocation.

A globally scoped uSID is a uSID from the GIB. A globally scoped uSID typically identifies a shortest path to a node in the SR domain. An IP route (for example, /48) is advertised by the parent node to each of its globally scoped uSIDs, under the associated uSID block. The parent node executes a variant of the END behavior.

The "Nodal" uSID (uN) is an example of a globally scoped behavior defined in uSID architecture.

A node can have multiple globally scoped uSIDs under the same uSID blocks (for example, one per IGP flex-algorithm). Multiple nodes may share the same globally scoped uSID (Anycast).

A locally scoped uSID is a uSID from the LIB. A locally scoped uSID identifies a local micro-instruction on the parent node; for example, it may identify a cross-connect to a direct neighbor over a specific interface or a VPN context. Locally scoped uSIDs are not routeable.

For example, if N1 and N2 are two different physical nodes of the uSID domain and *L* is a locally scoped uSID value, then N1 and N2 may bind two different behaviors to *L*.

The uSIDs are allocated in one of following ways: auto, dynamic, or explicit.

- The request to allocate locally scoped uSIDs comes from SRv6 clients (such as IS-IS or BGP). The request can be to allocate any available ID (dynamic allocation) or to allocate a specific ID (explicit allocation).

SRv6 Endpoint Behaviors Associated with uSID

The SRv6 Network Programming is extended with new types of SRv6 SID endpoint behaviors:

- **uN**—A short notation for the NEXT-CSID (Compressed SID) End behavior with a pseudocode of shift-and-lookup, and PSP/USD flavors
- **uA**—A short notation for the NEXT-CSID End.X behavior with a pseudocode of shift-and-xconnect, and PSP/USD flavors
- **uDT**—A short notation for the NEXT-CSID End.DT behavior with the same pseudocode as End.DT4/End.DT6/End.DT46/End.DT2U/End.DT2M
- **uDX**—A short notation for the NEXT-CSID End.DX behavior with the same pseudocode as End.DX4/End.DX6/End.DX2

SRv6 uSID in Action - Example

This example highlights an integrated VPN and Traffic Engineering use-case leveraging SRv6 uSID.

VPNv4 site A connected to Node 1 sends packets to VPNv4 site B connected to Node 2 alongside a traffic engineered path via Node 8 and Node 7 using a single 128-bit SRv6 SID.

Node 1 is the ingress PE; Node 2 is the egress PE.

Nodes 3, 4, 5, and 6 are classic IPv6 nodes. Traffic received on these nodes use classic IP forwarding without changing the outer DA.

Nodes 1, 8, 7 and 2 are SRv6 capable configured with:

- 32-bit SRv6 block = fcbb:bb01
- 16-bit SRv6 ID

For example:

- Node 7 uN = fcbb:bb01:0700::/48
- Node 8 uN = fcbb:bb01:0800::/48

The following IGP routes are advertised:

- Node 8 advertises the IGP route fcbb:bb01:**0800**::/48
- Node 7 advertises the IGP route fcbb:bb01:**0700**::/48
- Node 2 advertises the IGP route fcbb:bb01:**0200**::/48

Figure 2: Integrated VPN and Traffic Engineering SRv6 uSID Use-case

- Node 1 encapsulates IPv4 packet from Site A and sends an IPv6 packet with DA = `fcbb:bb01:0800:0700:0200:f001:0000:0000`
- Traffic engineered path via 8 and 7 using a single 128-bit SRv6 SID
- One single micro-program in the DA is enough

521410

Node 1 encapsulates an IPv4 packet from VPN Site A and sends an IPv6 packet with destination address `fcbb:bb01:0800:0700:0200:f001:0000:0000`. This is a uSID carrier, with a list of micro-instructions (uSIDs) (0800, 0700, 0200, f001, and 0000 – indicating the end of the instruction).

uSIDs (uNs) 0800, 0700, 0200 are used to realize the traffic engineering path to Node 2 with way points at Nodes 8 and 7. uSID f001 is the BGP-signalled instruction (uDT4) advertised by Node 2 for the VPNv4 service

Figure 3: Node 1: End.B6.Encaps Behavior

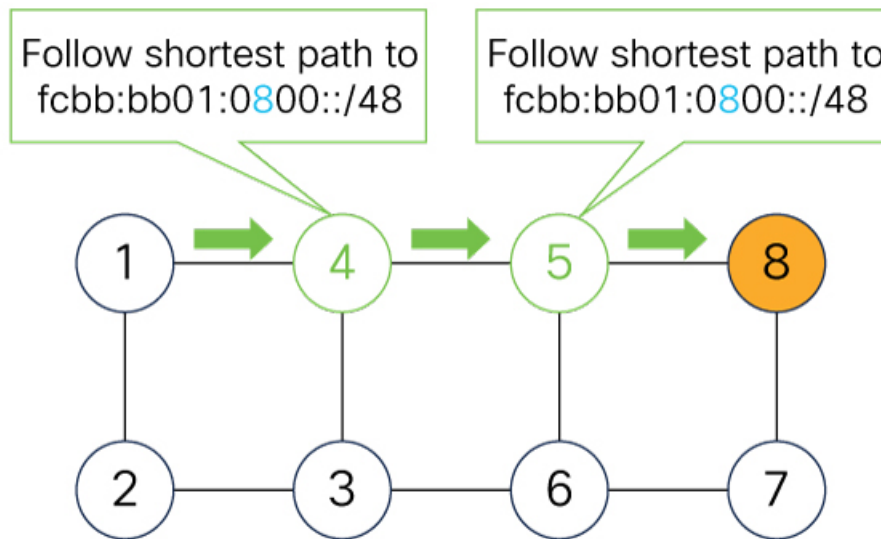

DA = fcbb:bb01:0800:0700:0200:f001:0000:0000

521411

Nodes 4 and 5 simply forward the packet along the shortest path to Node 8, providing seamless deployment through classic IPv6 nodes.

Figure 4: Node 4 and Node 5: Classic IPv6 Nodes

DA = fcbb:bb01:0800:0700:0200:f001:0000:0000

521412

When Node 8 receives the packet, it performs SRv6 uN behavior (shift-and-lookup with PSP/USD). It removes its outer DA (0800) and advances the micro program to the next micro instruction by doing the following:

1. Pops its own uSID (0800)

2. **Shifts** the remaining DA by 16-bits to the left
3. Fills the remaining bits with 0000 (End-of-Carrier)
4. Performs a **lookup** for the shortest path to the next DA (fcbb:bb01:0700::/48)
5. Forwards it using the new DA fcbb:bb01:0700:0200:f001:0000:0000:0000

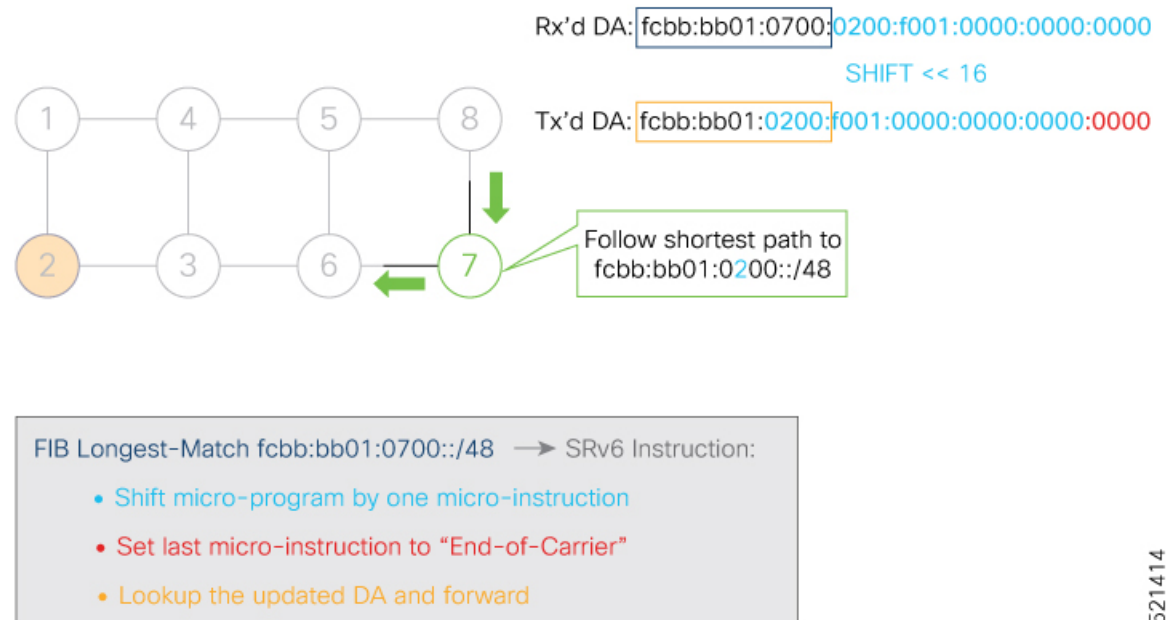

Figure 5: Node 8: SRv6 uN Behavior (Shift and Forward)

521413

When Node 7 receives the packet, it performs the same SRv6 uN behavior (shift-and-lookup with PSP/USD), forwarding it using the new DA fcbb:bb01:0200:f001:0000:0000:0000:0000

Figure 6: Node 7: SRv6 uN Behavior (Shift and Forward)

521414

Nodes 6 and 3 simply forward the packet along the shortest path to Node 2, providing seamless deployment through classic IPv6 nodes.

Figure 7: Node 6 and Node 3: Classic IPv6 Nodes

DA = fcbb:bb01:0200:f001:0000:0000:0000:0000

When Node 2 receives the packet, it performs an SRv6 uDT4 behavior (End.DT4—Endpoint with decapsulation and IPv4 table lookup) to VPNv4 Site B.

Figure 8: Node 2: SRv6 uDT4 Behavior

FIB Longest-Match fcbb:bb01:0200:f001::/64 → SRv6 Instruction:

- Decapsulate and Lookup of inner IPv4 packet

To recap, this example showed an integrated VPN and Traffic Engineering use-case, where VPNv4 site A connected to Node 1 sent packets to VPNv4 site B connected to Node 2 alongside a traffic engineered path via Node 8 and Node 7 using a single 128-bit SRv6 SID:

- @1: inner packet P encapsulated with outer DA fcbb:bb01:0800:0700:0200:f001:0000:0000

- @4 & @5: classic IP forwarding, outer DA unchanged
- @8: SRv6 uN behavior: shift and lookup, outer DA becomes fcbb:bb01:**0700:0200**:f001:0000:0000:0000
- @7: SRv6 uN behavior: shift and lookup, outer DA becomes fcbb:bb01:**0200**:f001:0000:0000:0000:0000
- @6 & @3: classic IP forwarding, outer DA unchanged
- @2: SRv6 End.DT4: Decapsulate and IPv4 table lookup

Usage Guidelines and Limitations

General Guidelines and Limitations

- Cisco IOS XR supports uSIDs with 32-bit uSID block and 16-bit uSID IDs (3216).
A single UCF format must be used for uSID locators in a SRv6 uSID domain.
- Cisco IOS XR supports up to 8 uSID locator prefixes.
Multiple locator prefixes are used when configuring Anycast locators or SRv6 Flexible Algorithm instances, for example.
- Cisco IOS XR supports uSID locator prefixes from different uSID blocks.
Up to 64 uSID blocks can be used across all uSID locators in the network.
- Cisco IOS XR Release 7.3.1 and later supports the following SRv6 uSID behaviors and variants:
 - uN with PSP/USD
 - uA with PSP/USD
 - uDT4
 - uDT6
- SRv6 Underlay support includes:
 - IGP redistribution/leaking between levels
 - Prefix Summarization on ABR routers
 - IS-IS TI-LFA
 - Microloop Avoidance
 - Flex-algo
- SRv6 over GRE interface is not supported

uSID Allocation Recommendation

We recommend that the uSID block allocation is made from the IPv6 Unique Local Address (ULA) range.

Note Allocation from the public Global Unicast Addresses (GUA) range is also supported.

- Use ULA /24 base from FC00::/8 space
 - FCBB:BB/24, with *B* indicating a nibble value picked by operator
- 256 uSID blocks possible from this allocation
 - In this release, 64 uSID blocks are supported
 - FCBB:BBVV/32, with *VV* two variable nibbles. The supported values for *VV* in Cisco IOS XR Release 7.3.1 are 0x00 to 0x3F.

For example:

- ULA /24 base = FC00:01/24
- uSID block space = 64 uSID blocks (from FC00:0100/32 to FC00:013F/32)

Platform-Specific Guidelines and Limitations

SRv6 is supported on NCS 5500 series routers and NCS 5700 series routers/NC57 line cards.

This release supports the following SID Encap budget:

- P role:
 - Underlay H-Insert: 6 sids (1 carrier with 6 sids per carrier)
- PE role:
 - Underlay H-Insert: 3 sids (1 carrier with 3 sids per carrier)
 - Overlay H-Encaps: 3 sids (1 carrier with 3 sids per carrier)

SRv6 is supported on NCS 5500 series routers and NCS 5700 series routers/NC57 line cards.

This release supports the following SID Encap budget:

- P role:
 - Underlay H-Insert: 6 sids (1 carrier with 6 sids per carrier)
- PE role:
 - Underlay H-Insert: 3 sids (1 carrier with 3 sids per carrier)
 - Overlay H-Encaps: 3 sids (1 carrier with 3 sids per carrier)

Configuring SRv6

Table 2: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 Traffic Class DSCP Marking Enhancement for QoS	Release 24.2.1	<p><i>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers</i></p> <p>This feature allows you to set the traffic class values to use the full range of DSCP (6 bits) for SRv6 packets that are encapsulated.</p> <p>The feature extends the existing policy-map setting of 3-bit traffic class DSCP marking to 6 bits using the new policy-map-extend option in the configuration for L2 and L3 traffic for SRv6.</p> <p>This is a mutually inclusive feature for L2 and L3 traffic. Therefore, this feature cannot be used in the individual configuration for L2 and L3 traffic.</p> <p>This feature introduces this change:</p> <p>CLI: The policy-map-extend keyword is introduced in the hw-module profile segment-routing srv6 mode microsegment f3216 encapsulation traffic-class command.</p>
SRv6 Traffic Class QoS Enhancement	Release 7.7.1	<p>The modified hw-module profile segment-routing srv6 mode command option provides you with better flexibility to customize the optional SRv6 encapsulation parameters. The updated command supports both L2 and L3 traffic types of SRv6 parameters.</p> <p>Encapsulation is a sub-mode from Release 7.7.1.</p> <p>The l3-traffic configuration supports the additional policy-map option that sets SRv6 traffic-class DSCP based on qos-group selected by input policy-map.</p> <p>The following commands are updated:</p> <ul style="list-style-type: none"> hw-module profile segment-routing srv6 mode: Mode is a mandatory parameter <p>The following commands are introduced:</p> <ul style="list-style-type: none"> encapsulation l2-traffic encapsulation l3-traffic

Enabling SRv6 involves the following high-level configuration steps:

- Enable SRv6 on the platform
- Configure SRv6 locator(s)
- Enable SRv6 under IS-IS
- Enable SRv6 Services under BGP

Enable SRv6 on the Platform

Before configuring SRv6 on the Cisco NCS 5500 Series Routers router, you must first use the following command:

- **hw-module profile segment-routing srv6 mode micro-segment format f3216**

Note You must reload the router after enabling this command.

(Optional) Configure Network Role

By default, after enabling SRv6 on the platform, the node can serve as both edge (services) and core roles.

Optionally, you can customize the node role as "core-only" using the following command:

- **hw-module profile network-role core-only**

Note You must reload the router after enabling this command.

Given that there is different budget for underlay SID encap based on the node role in the network (P-only vs Edge), an operator can use this configuration to provide a hint to the platform and control plane to use a larger SID encap budget when operating as a P-only node.

(Optional) Configure Merge Overlay/Underlay SID Mode

One of the main benefits of SRv6 uSID is compression (or packing) of multiple uSIDs into a uSID carrier. This is possible when they share the same uSID block and when there is enough space in the carrier.

The underlay SIDs are always programmed in compressed form, if possible. The overlay SID is programmed separately.

The **segment-routing srv6 micro-segment merge-overlay-underlay-sids** command is used to enable the platform to merge overlay/underlay SIDs.

Note From Cisco IOS XR Release 7.7.1 and later, the compression/merging of uSID lists is automatically done in the dataplane during imposition. This configuration option is ignored by the dataplane.

When there is a need to send overlay traffic, the data path implementation attempts to merge the underlay SIDs and overlay SIDs into a single carrier, if possible. With H.Encaps.Red encapsulation, this yields a packet with no SRH.

Note If the overlay and underlay use different uSID blocks, this merge is not possible.

By default, the Cisco NCS platform does not automatically merge the overlay/underlay SIDs.

To enable the platform to merge overlay/underlay SIDs, use the following command:

- **segment-routing srv6 micro-segment merge-overlay-underlay-sids**

Caution This command should only be enabled when a single block is required.

After you enable this command, this CLI will modify the behavior for all new overlay routes being programmed afterwards.

If you enable this command after SRv6 overlay routes are already programmed, we recommend that you clear the SRv6 overlay routes (using the **clear route [vrf WORD]** command) in order to trigger the re-programming in the “merge” mode.

If you do not to clear the overlay routes, those routes would continue to be programmed in the “non-merge” mode.

(Optional) Customize SRv6 Encapsulation Parameters

From Cisco IOS XR Release 7.7.1, the **hw-module profile segment-routing srv6 mode** command has been updated to support both L2 and L3 traffic types of SRv6 parameters. The existing traffic-class CLI (common to L2 and L3) is still accepted in the ASCII format, but will be converted into the new **l2-traffic** and **l3-traffic** submode format after the config is committed.

From Cisco IOS XR Release 7.7.1, ensure that you use mandatory keyword **mode**. Note that **encapsulation** is now a sub-mode and not a configuration option.

The following example shows how to configure the traffic-class field settings on the IPv6 header:

```
Router(config)#hw-module profile segment-routing srv6 mode micro-segment format f3216
Router(config-srv6)#encapsulation
Router(config-srv6-encap)#l2-traffic
Router(config-srv6-encap-l2)#traffic-class propagate
```

```
Router(config)#hw-module profile segment-routing srv6 mode micro-segment format f3216
Router(config-srv6)#encapsulation
Router(config-srv6-encap)#l3-traffic
Router(config-srv6-encap-l3)#traffic-class policy-map
```

```
Router(config)#hw-module profile segment-routing srv6 mode micro-segment format f3216
Router(config-srv6)#encapsulation
Router(config-srv6-encap)#traffic-class policy-map-extend
```

The **l2-traffic** and **l3-traffic** are SRv6 parameters for L2 traffic type and L3 traffic type respectively. The **traffic-class** parameter controls the traffic-class field of SRv6 IPv6 header for inner L2 and L3 traffic. Use **propagate** to set the traffic-class value by propagation (from incoming packet/frame). Use **policy-map** to set traffic-class DSCP to qos-group selected by input policy-map.

The **l3-traffic** configuration supports the additional **policy-map** option that sets SRv6 traffic-class DSCP based on qos-group selected by input **policy-map**.

The **l2-traffic** configuration continues to support the **propagate** option that sets the SRv6 traffic-class based on either the inner packet (default) or input **policy-map** (if match action found).

Starting with Cisco IOS XR Software Release 24.2.1, both the L2 and L3 traffic configurations support the **policy-map-extend** option to set the SRv6 traffic-class DSCP marking to 6 bits. This is a mutually inclusive feature for L2 and L3 traffic. Therefore, this feature cannot be used in the individual configuration for L2 and L3 traffic.

When you use the **policy-map-extend** keyword in the **hw-module profile segment-routing srv6 mode microsegment f3216 encapsulation traffic-class** CLI, the existing 3-bit DSCP marking set by the **hw-module profile segment-routing srv6 mode microsegment f3216 encapsulation traffic-class l3-traffic policy-map** CLI in the L3 traffic configuration is modified to 6-bits.

Go through the following topics for more information on the CLI:

- [hw-module profile segment-routing srv6 mode](#)
- [encapsulation l2-traffic](#)
- [encapsulation l3-traffic](#)
- [traffic-class policy-map-extend](#)

Specify the *value* (as 2 hexadecimal nibbles) for traffic class; valid values are from 0x0 to 0xff.

Configure SRv6 Locator Name, Prefix, and uSID-Related Parameters

This section shows how to globally enable SRv6 and configure locator.

- **segment-routing srv6 locators locator** *locator*—Globally enable SRv6 and configure the locator.
- **segment-routing srv6 locators locator** *locator* **prefix** *ipv6_prefix/length*—Configure the locator prefix value.
- **segment-routing srv6 locators locator** *locator* **micro-segment behavior unode psp-usd**—Specifies the locator as a micro-segment (uSID) locator as well as specifies that IGP underlay uSID (uN/uA) variant is PSP-USD for this locator.

(Optional) Configure Algorithm Associated with Locator

- **segment-routing srv6 locators locator** *locator* **algorithm** *algo*—(Optional) Configure Algorithm associated with the locator. Valid values for *algo* are from 128 to 255.

For additional information about SRv6 Flexible Algorithm, see [Configuring SRv6 Flexible Algorithm under IS-IS, on page 36](#).

For detailed information about Flexible Algorithm, see [Enabling Segment Routing Flexible Algorithm, on page 591](#).

(Optional) Configure Anycast Locator

An SRv6 Anycast locator is a type of locator that identifies a set of nodes (uN SIDs). SRv6 Anycast Locators and their associated uN SIDs may be provisioned at multiple places in a topology.

The set of nodes (Anycast group) is configured to advertise a shared Anycast locator and uN SID. Anycast routing enables the steering of traffic toward multiple advertising nodes. Packets addressed to an Anycast address are forwarded to the topologically nearest nodes.

One use case is to advertise Anycast uN SIDs at exit points from an SRv6 network. Any of the nodes that advertise the common uN SID could be used to forward traffic out of the SRv6 portion of the network to the topologically nearest node.

The following behaviors apply to Anycast Locator:

- Unlike a normal locator, IS-IS does not program or advertise uA SIDs associated with an Anycast locator.
- uN SIDs allocated from Anycast locators will not be used in constructing TI-LFA backup paths or Microloop Avoidance primary paths. TI-LFA backup and Microloop Avoidance paths for an Anycast locator prefix may terminate on any node advertising that locator, which may be different from the node terminating the original primary path.
- SRv6 anycast locators may have non-zero algorithm (Flexible Algorithm) values.

Use the following commands to configure the Anycast locator and advertise Anycast prefixes associated with an interface.

- **segment-routing srv6 locators locator *locator* anycast**—Configure the Anycast locator
- **router isis *instance-id* interface Loopback *instance* prefix-attributes anycast level *level***—Advertise the Anycast prefixes associated with an interface.

Example 1:

The following example shows how to globally enable SRv6 and configure a locator.

```
Router(config)# segment-routing srv6
Router(config-srv6)# locators
Router(config-srv6-locators)# locator myLoc1
Router(config-srv6-locator)# micro-segment behavior unode psp-usd
Router(config-srv6-locator)# prefix 2001:0:8::/48
```

Example 2:

The following example shows how to configure Flexible Algorithm associated with locator.

```
Router(config)# segment-routing srv6
Router(config-srv6)# locators
Router(config-srv6-locators)# locator myLocAlg128
Router(config-srv6-locator)# algorithm 128
Router(config-srv6-locator)# micro-segment behavior unode psp-usd
Router(config-srv6-locator)# prefix 2001:0:88::/48
```

Example 3:

The following example shows how to configure Anycast locator.

```
Router(config)# segment-routing srv6
Router(config-srv6)# locators
Router(config-srv6-locators)# locator myLocAnycast
Router(config-srv6-locator)# anycast
Router(config-srv6-locator)# micro-segment behavior unode psp-usd
Router(config-srv6-locator)# prefix 2001:0:100::/48
```

The following example shows how to advertise the Anycast prefixes associated with an interface.

```
Router(config)# router isis core
Router(config-isis)# interface Loopback100
```

```
Router(config-isis-if) # prefix-attributes anycast level 1
```

(Optional) Customize SRv6 Encapsulation Parameters

This section describes the configurable SRv6 encapsulation parameters. These optional parameters include:

- **segment-routing srv6 encapsulation source-address** *ipv6-addr*—Source Address of outer encapsulating IPv6 header. The default source address for encapsulation is one of the loopback addresses.
- **segment-routing srv6 encapsulation hop-limit** {*count* | **propagate**}—The hop limit of outer-encapsulating IPv6 header. The range for *count* is from 1 to 254 for NCS 5500 and from 1 to 255 for NCS 5700; the default value for hop-limit is 254. Use **propagate** to set the hop-limit value by propagation (from incoming packet/frame).

Note On NCS 5700 hardware, hop-limit propagation is not applied for packets going to P2P services.

- **segment-routing srv6 encapsulation evpn next-header** *protocol-number*—The protocol number to use in the Next-header field of the IPv6 or SRH header. The range for *protocol-number* is from 59 to 252.

(Optional) Customize SRv6 Logging for Locator Status Changes

- **segment-routing srv6 logging locator status**—Enable the logging of locator status.

(Optional) Customize SRv6 SID Parameters

- **segment-routing srv6 sid holdtime** *minutes*—The holdtime for a stale or freed SID. The range of *minutes* is from 0 (disabled) to 60 minutes.

Example 4:

The following example shows how to configure optional SRv6 parameters:

```
RP/0/RSP0/CPU0:Node1(config) # segment-routing srv6 encapsulation
RP/0/RSP0/CPU0:Node1(config-srv6-encap) # source-address 1::1
RP/0/RSP0/CPU0:Node1(config-srv6-encap) # hop-limit 60
RP/0/RSP0/CPU0:Node1(config-srv6-encap) # evpn next-header 65
RP/0/RSP0/CPU0:Node1(config-srv6-encap) # exit
RP/0/RSP0/CPU0:Node1(config-srv6) # logging locator status
RP/0/RSP0/CPU0:Node1(config-srv6) # sid holdtime 10
RP/0/RSP0/CPU0:Node1(config-srv6) # micro-segment merge-overlay-underlay-sids
```

This config applies to only new SRv6 micro-segment overlay routes and does not update already programmed routes.

Please flap any existing SRv6 micro-segment overlay routes after making this configuration change.

```
RP/0/RSP0/CPU0:Node1(config-srv6) #
```

Verifying SRv6 Manager

This example shows how to verify the overall SRv6 state from SRv6 Manager point of view. The output displays parameters in use, summary information, and platform specific capabilities.

```
Router# show segment-routing srv6 manager
Parameters:
  SRv6 Enabled: Yes
  SRv6 Operational Mode:
    Micro-segment:
      SID Base Block: 2001::/24
  Encapsulation:
    Source Address:
      Configured: ::
      Default: ::
    Hop-Limit: Default
    Traffic-class: Default
Summary:
  Number of Locators: 3 (3 operational)
  Number of SIDs: 3 (0 stale)
  Max SIDs: 64000
  OOR:
    Thresholds: Green 3200, Warning 1920
    Status: Resource Available
      History: (0 cleared, 0 warnings, 0 full)
    Block 2001::/32:
      Number of SIDs free: 7680
      Max SIDs: 7680
      Thresholds: Green 384, Warning 231
      Status: Resource Available
        History: (0 cleared, 0 warnings, 0 full)
Platform Capabilities:
  SRv6: Yes
  TILFA: Yes
  Microloop-Avoidance: Yes
  Endpoint behaviors:
    End (PSP)
    End.X (PSP)
    End.DX6
    End.DX4
    End.DT6
    End.DT4
    End.OP
    uN (PSP/USD)
    uA (PSP/USD)
    uDT6
    uDT4
    uDX2
    uB6 (Insert.Red)
  Headend behaviors:
    T
    H.Insert.Red
    H.Encaps.Red
  Security rules:
    SEC-1
    SEC-2
    SEC-3
  Counters:
    CNT-1
    CNT-3
  Signaled parameters:
    Max-SL : 3
    Max-End-Pop-SRH : 3
    Max-H-Insert : 3 sids
```

```

Max-H-Encap      : 3 sids
Max-End-D        : 4
Configurable parameters (under srv6):
Encapsulation:
  Source Address: Yes
  Hop-Limit     : value=Yes, propagate=No
  Traffic-class  : value=Yes, propagate=Yes
Max SIDs: 64000
SID Holdtime: 3 mins

```

Verifying SRv6 Locator

This example shows how to verify the locator configuration and its operational status.

```
Router# show segment-routing srv6 locator myLoc1 detail
```

Name	ID	Algo	Prefix	Status	Flags
myLoc1	3	0	2001:0:8::/48	Up	U

```

(U): Micro-segment (behavior: uN (PSP/USD))
Interface:
  Name: srv6-myLoc1
  IFH : 0x02000120
  IPv6 address: 2001:0:8::/48
  Number of SIDs: 1
  Created: Dec 10 21:26:54.407 (02:52:26 ago)

```

Verifying SRv6 SIDs

This example shows how to verify the allocation of SRv6 local SIDs off locator(s).

```
Router# show segment-routing srv6 locator myLoc1 sid
```

SID	State	RW	Behavior	Context	Owner
2001:0:8::	InUse	Y	uN (PSP/USD)	'default':1	sidmgr

The following example shows how to display detail information regarding an allocated SRv6 local SID.

```
Router# show segment-routing srv6 locator myLoc1 sid 2001:0:8:: detail
```

SID	State	RW	Behavior	Context	Owner
2001:0:8::	InUse	Y	uN (PSP/USD)	'default':8	sidmgr

```

SID Function: 0x8
SID context: { table-id=0xe0800000 ('default':IPv6/Unicast), opaque-id=8 }
Locator: 'myLoc1'
Allocation type: Dynamic
Created: Dec 10 22:10:51.596 (02:10:05 ago)

```

Similarly, you can display SID information across locators by using the **show segment-routing srv6 sid** command.

Configuring SRv6 under IS-IS

Table 3: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 under IS-IS	Release 7.5.1	This feature is now supported on Cisco NCS 5700 series fixed port routers and the Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native mode.

Intermediate System-to-Intermediate System (IS-IS) protocol already supports segment routing with MPLS dataplane (SR-MPLS). This feature enables extensions in IS-IS to support Segment Routing with IPv6 data plane (SRv6). The extensions include advertising the SRv6 capabilities of nodes and node and adjacency segments as SRv6 SIDs.

SRv6 IS-IS performs the following functionalities:

1. Interacts with SID Manager to learn local locator prefixes and announces the locator prefixes in the IGP domain.
2. Learns remote locator prefixes from other IS-IS neighbor routers and installs the learned remote locator IPv6 prefix in RIB or FIB.
3. Allocate or learn prefix SID and adjacency SIDs, create local SID entries, and advertise them in the IGP domain.

Usage Guidelines and Restrictions

The following usage guidelines and restrictions apply for SRv6 IS-IS:

- An IS-IS address-family can support either SR-MPLS or SRv6, but both at the same time is not supported.

Configuring SRv6 under IS-IS

To configure SRv6 IS-IS, use the **router isis** command. Enable SRv6 under the IS-IS IPv6 address-family and assign SRv6 locator(s) to it. Use the **level {1 | 2}** keywords to advertise the locator only in the specified IS-IS level.

Note If no level is specified, local locators will be advertised into all configured ISIS levels. Ensure that locators are included in the redistribution or propagation policy to prevent potential loops when redistributing between multiple instances or propagating between Level 2 and Level 1.

The following example shows how to configure SRv6 under IS-IS.

```
Router(config)# router isis core
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# segment-routing srv6
```

```
Router(config-isis-srv6) # locator myLoc1 level 1
Router(config-isis-srv6-loc) # exit
```

For more information about configuring IS-IS, refer to the ["Implementing IS-IS"](#) chapter in the *Routing Configuration Guide for Cisco NCS 5500*.

Configuring SRv6 Flexible Algorithm under IS-IS

This feature introduces support for implementing Flexible Algorithm using IS-IS SRv6.

SRv6 Flexible Algorithm allows operators to customize IGP shortest path computation according to their own needs. An operator can assign custom SR prefix-SIDs to realize forwarding beyond link-cost-based SPF. As a result, Flexible Algorithm provides a traffic-engineered path automatically computed by the IGP to any destination reachable by the IGP.

For detailed information about Flexible Algorithm, see [Enabling Segment Routing Flexible Algorithm, on page 591](#).

Usage Guidelines and Restrictions

Observe the following usage guidelines and restrictions:

- You can configure up to 8 locators to support SRv6 Flexible Algorithm.
- The Flexible Algorithm locator prefix follows the same usage guidelines and restrictions of algo-0 locator prefixes. See [Usage Guidelines and Limitations, on page 25](#).
- The Locator Algorithm value range is 128 to 255.

Configuring SRv6 Flexible Algorithm under IS-IS

The following sections show you the steps to enable SRv6 Flexible Algorithm. The example highlights a delay-based Flexible Algorithm instance.

1. Configure SRv6 locators
2. Assign SRv6 locators under IS-IS
3. Configure Flexible Algorithm definition and associated metric (for example, delay)
4. Configure the delay probe under the interface. For more information on SR performance measurement, see [Configure performance measurement](#).

The following section shows how to configure two SRv6 locators: one associated with Algo 0, and the other associated with Algo 128.

```
Router(config)# segment-routing srv6
Router(config-srv6)# locators
Router(config-srv6-locators)# locator myLocBestEffort // best-effort locator
Router(config-srv6-locator)# micro-segment behavior unode psp-usd
Router(config-srv6-locator)# prefix 2001:0:1::/48
Router(config-srv6-locator)# exit

Router(config-srv6-locators)# locator myLocLowLat // low-latency (flex algo 128) locator
Router(config-srv6-locator)# micro-segment behavior unode psp-usd
```

```

Router(config-srv6-locator)# prefix 2001:0:2::/48
Router(config-srv6-locator)# algorithm 128
Router(config-srv6-locator)# exit
Router(config-srv6)# exit

```

The following section shows how to assign multiple SRv6 locators under IS-IS.

```

Router(config)# router isis core
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# segment-routing srv6
Router(config-isis-srv6)# locator myLocBestEffort
Router(config-isis-srv6-loc)# exit
Router(config-isis-srv6)# locator myLocLowLat
Router(config-isis-srv6-loc)# exit

```

The following section shows how to configure the Flexible Algorithm definition.

```

Router(config)# router isis core
Router(config-isis)# flex-algo 128
Router(config-isis-flex-algo)# metric-type delay
Router(config-isis-flex-algo)# exit
Router(config-isis)# interface GigabitEthernet0/0/0/0
Router(config-isis-if)# address-family ipv6 unicast

```

The following section shows how to configure the delay probe under the interface.

```

Router(config)# performance-measurement
Router(config-perf-meas)# interface GigabitEthernet0/0/0/0
Router(config-pm-intf)# delay-measurement
Router(config-pm-intf-dm)# commit

```

Verification

```
Router# show segment-routing srv6 locator
```

Configuring SRv6 Locator Prefix Summarization

SRv6 leverages longest-prefix-match IP forwarding. Massive-scale reachability can be achieved by summarizing locators at ABRs and ASBRs.

Use the **summary-prefix locator** [**algorithm algo**] [**explicit**] command in IS-IS address-family configuration mode to specify that only locators from the specified algorithm contribute to the summary. The **explicit** keyword limits the contributing prefixes to only those belonging to the same algorithm.

The following example shows how to configure SRv6 IS-IS Algorithm Summarization for regular algorithm and Flexible Algorithm (128).

```
Router(config)# router isis core
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# summary-prefix 2001:0:1::/48
Router(config-isis-af)# summary-prefix 2001:0:2::/48 algorithm 128 explicit
```

Configuring TI-LFA with SRv6 IS-IS

This feature introduces support for implementing Topology-Independent Loop-Free Alternate (TI-LFA) using SRv6 IS-IS.

TI-LFA provides link protection in topologies where other fast reroute techniques cannot provide protection. The goal of TI-LFA is to reduce the packet loss that results while routers converge after a topology change due to a link failure. TI-LFA leverages the post-convergence path which is planned to carry the traffic and ensures link and node protection within 50 milliseconds. TI-LFA with IS-IS SR-MPLS is already supported.

TI-LFA provides link, node, and Shared Risk Link Groups (SRLG) protection in any topology.

For more information, see [Configure Topology-Independent Loop-Free Alternate \(TI-LFA\), on page 783](#).

Usage Guidelines and Limitations

The following usage guidelines and limitations apply:

- TI-LFA provides link protection by default. Additional tiebreaker configuration is required to enable node or SRLG protection.
- Usage guidelines for node and SRLG protection:
 - TI-LFA node protection functionality provides protection from node failures. The neighbor node is excluded during the post convergence backup path calculation.
 - Shared Risk Link Groups (SRLG) refer to situations in which links in a network share a common fiber (or a common physical attribute). These links have a shared risk: when one link fails, other

links in the group might also fail. TI-LFA SRLG protection attempts to find the post-convergence backup path that excludes the SRLG of the protected link. All local links that share any SRLG with the protecting link are excluded.

- When you enable link protection, you can also enable node protection, SRLG protection, or both, and specify a tiebreaker priority in case there are multiple LFAs.
- Valid priority values are from 1 to 255. The lower the priority value, the higher the priority of the rule. Link protection always has a lower priority than node or SRLG protection.

Configuring SRv6 IS-IS TI-LFA

The following example shows how to configure different types of TI-LFA protection for SRv6 IS-IS.

```
Router(config)# router isis core
Router(config-isis)# interface bundle-ether 1201
Router(config-isis-if)# address-family ipv6 unicast
Router(config-isis-if-af)# fast-reroute per-prefix
Router(config-isis-if-af)# fast-reroute per-prefix ti-lfa
Router(config-isis-if-af)# exit
Router(config-isis-if)# exit
Router(config-isis)# interface bundle-ether 1301
Router(config-isis-if)# address-family ipv6 unicast
Router(config-isis-if-af)# fast-reroute per-prefix
Router(config-isis-if-af)# fast-reroute per-prefix ti-lfa
Router(config-isis-if-af)# fast-reroute per-prefix tiebreaker node-protecting index 100
Router(config-isis-if-af)# fast-reroute per-prefix tiebreaker srlg-disjoint index 200
Router(config-isis-if-af)# exit
```

Configuring SRv6 IS-IS TI-LFA with Flexible Algorithm

TI-LFA backup paths for particular Flexible Algorithm are computed using the same constraints as the calculation of the primary paths for such Flexible Algorithm. These paths use the locator prefix advertised specifically for such Flexible Algorithm in order to enforce a backup path.

By default, LFA/TI-LFA for SRv6 Flexible Algorithm uses the LFA/TI-LFA configuration of Algo 0.

Use the **fast-reroute disable** command to disable the LFA/TI-LFA calculation on a per-algorithm basis:

```
Router(config)# router isis core
Router(config-isis)# flex-algo 128
Router(config-isis-flex-algo)# fast-reroute disable
```

Verification

This example shows how to verify the SRv6 IS-IS TI-LFA configuration using the **show isis ipv6 fast-reroute ipv6-prefix detail** command.

```
Router# show isis ipv6 fast-reroute cafe:0:2::2/128 detail

Configuring SRv6 IS-IS Microloop Avoidance

This feature introduces support for implementing microloop avoidance using IS-IS SRv6.

Microloops are brief packet loops that occur in the network following a topology change (link down, link up, or metric change events). Microloops are caused by the non-simultaneous convergence of different nodes in the network. If nodes converge and send traffic to a neighbor node that has not converged yet, traffic may be looped between these two nodes, resulting in packet loss, jitter, and out-of-order packets.

The SRv6 Microloop Avoidance feature detects if microloops are possible following a topology change. If a node computes that a microloop could occur on the new topology, the node creates a loop-free SR-TE policy path to the destination using a list of segments. After the RIB update delay timer expires, the SR-TE policy is replaced with regular forwarding paths.

Usage Guidelines and Limitations

The following usage guidelines and limitations apply:

- The Routing Information Base (RIB) update delay value specifies the amount of time the node uses the microloop avoidance policy before updating its forwarding table. The *delay-time* range is from 1 to 60000 milliseconds; the default value is 5000.

Configuring SRv6 IS-IS Microloop Avoidance

The following example shows how to configure SRv6 IS-IS Microloop Avoidance and set the Routing Information Base (RIB) update delay value.

Note Complete the [Configuring SRv6, on page 27](#) before performing these steps.

```

Router(config)# router isis test-igp
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# microloop avoidance segment-routing
Router(config-isis-af)# microloop avoidance rib-update-delay 2000
Router(config-isis-af)# commit

```

Configuring SRv6 IS-IS Microloop Avoidance with Flexible Algorithm

Microloop Avoidance paths for particular Flexible Algorithm are computed using the same constraints as the calculation of the primary paths for such Flexible Algorithm. These paths use the Locator prefix advertised specifically for such Flexible Algorithm in order to enforce a microloop avoidance path.

By default, Microloop Avoidance for SRv6 Flexible Algorithm uses the Microloop Avoidance configuration of Algo 0.

Use the **microloop avoidance disable** command to disable the microloop calculation on a per-algorithm basis:

```
Router(config)# router isis test-tilfa
Router(config-isis)# flex-algo 128
Router(config-isis-flex-algo)# microloop avoidance disable
```

Configuring Static SIDs

Manually allocated (static) SIDs are persistent over reloads and restarts, making them a reliable option to be used in explicit paths.

Configuring Static Adjacency SIDs

An adjacency SID (Adj-SID) is associated with an adjacency to a neighboring node. The adjacency SID steers the traffic to a specific adjacency. Adjacency SIDs have local significance and are only valid on the node that allocates them.

Adjacency SIDs that are dynamically allocated do not require any special configuration, however there are some limitations:

- A dynamically allocated Adj-SID value is not known until it has been allocated, and a controller will not know the Adj-SID value until the information is flooded by the IGP.
- Dynamically allocated Adj-SIDs are not persistent and can be reallocated after a reload or a process restart.
- Each link is allocated a unique Adj-SID, so the same Adj-SID cannot be shared by multiple links.

Manually allocated (static) Adj-SIDs are persistent over reloads and restarts, making them a reliable option to be used in explicit paths. They can be provisioned for multiple adjacencies to the same neighbor or to different neighbors.

You can specify that the Adj-SID is protected. If the Adj-SID is protected on the primary interface and a backup path is available, a backup path is installed. By default, static Adj-SIDs are not protected.

Usage Guidelines and Limitations

- Static Adj-SIDs are allocated from the explicit Local ID block (LIB). The default range for explicit SID allocation is 0xFE00 to 0xFEFF (256 IDs).
- Static Adj-SIDs are allocated independent of IS-IS. If a static Adj-SID is successfully allocated, then the SID Manager notifies IS-IS. IS-IS then claims the allocated static Adj-SID and installs the Adj-SID in RIB or FIB.

- If you remove the static Adj-SID configuration, the SID Manager does not clear the allocated static Adj-SID; IS-IS will continue to use the allocated static Adj-SID. This is expected behavior. If you configure a different static Adj-SID, SID manager resolves the conflict and installs the new Adj-SID and notifies IS-IS.
- Static Adj-SID allocation does not follow the interface manager (IM) interface state. The static Adj-SID will be allocated even if the interface is down or doesn't exist in the system. However, the static Adj-SID is not installed in forwarding, since IS-IS didn't claim this Adj-SID.
- Static Adj-SID follows the locator state. Static Adj-SID allocation will fail if the locator is down or invalid.
- Static Adj-SID can be allocated as a protected Adj-SID.
- Static Adj-SID can be allocated to a specific algorithm.

Configuration

Use the **segment-routing srv6 static endpoint** command to configure static adjacency SID and SID allocation context.

Use the **sid <srv6-sid> behavior end-ua-psp-usd** command in srv6-static-endpoint config mode to configure the static Adj SID and endpoint behavior.

Use the **allocation-context nexthop <nhop-int> [algo-id <algo> | protected]** command in srv6-static-sid config mode to configure the next-hop interface. You can also configure the following options:

- **algo-id algo** — Specify a Flex Algo value for the static Adj-SID. Valid values for *algo* are 128 to 255; the default is 0 (SPF).
- **protected** — Specify if the static Adj-SID is protected

Example

```
Router(config)# segment-routing
Router(config-sr)# srv6
Router(config-srv6)# static
Router(config-srv6-static)# endpoint
Router(config-srv6-static-endpoint)# sid fccc:0:200:fe01:: behavior end-ua-psp-usd
Router(config-srv6-static-sid)# allocation-context nexthop TenGigE0/1/0/30/1
Router(config-srv6-static-sid)# exit
Router(config-srv6-static-endpoint)# sid fccc:0:200:fe88:: behavior end-ua-psp-usd
Router(config-srv6-static-sid)# allocation-context nexthop TenGigE0/1/0/0/3 protected
Router(config-srv6-static-sid)# exit
Router(config-srv6-static-endpoint)# sid fccc:3a:200:fe01:: behavior end-ua-psp-usd
Router(config-srv6-static-sid)# allocation-context nexthop TenGigE0/1/0/0/3 algo-id 132
protected
Router(config-srv6-static-sid)#
```

Running Configuration

```
segment-routing

```

Configuring SRv6 BGP-Based Services

Building on the messages and procedures defined in IETF draft "[BGP/MPLS IP Virtual Private Networks \(VPNs\)](#)", BGP has been extended to provide services over an SRv6 network, such as:

- IPv4 Layer-3 VPNs
- IPv6 Layer-3 VPNs
- IPv4 BGP global
- IPv6 BGP global
- Layer-2 VPNs - Ethernet VPNs (EVPN)

For more information about BGP, refer to the *BGP Configuration Guide for Cisco NCS 5500 Series Routers* BGP Configuration Guide.

In SRv6-based services, the egress PE signals an SRv6 Service SID with the BGP service route. The ingress PE encapsulates the payload in an outer IPv6 header where the destination address is the SRv6 Service SID advertised by the egress PE. BGP messages between PEs carry SRv6 Service SIDs as a means to interconnect PEs and form VPNs. SRv6 Service SID refers to a segment identifier associated with one of the SRv6 service-specific behaviors advertised by the egress PE router, such as:

- uDT4 (Endpoint with decapsulation and IPv4 table lookup)
- uDT6 (Endpoint with decapsulation and IPv6 table lookup)
- uDX4 (Endpoint with decapsulation and IPv4 cross-connect)
- uDX6 (Endpoint with decapsulation and IPv6 cross-connect)

Based on the messages and procedures defined in IETF draft "[SRv6 BGP based Overlay services](#)", BGP encodes the SRv6 Service SID in the prefix-SID attribute of the corresponding BGP Network Layer Reachability Information (NLRI) and advertises it to its IPv6 BGP peers.

Usage Guidelines and Restrictions

- The following SRv6 BGP-based services are supported:
 - [IPv4 Layer-3 VPNs](#)
 - [IPv6 Layer-3 VPNs](#)
 - [IPv4 BGP global](#)
 - [IPv6 BGP global](#)

- uDT4 and uDT6 for L3VPN and BGP global are supported.
- Dual-Stack L3 Services (IPv4 L3VPN, IPv6 L3VPN, IPv4 BGP global, IPv6 BGP global) are supported.

SRv6 Locator Inheritance Rules

SRv6 locators can be assigned at different levels inside the BGP routing process. BGP allocates SRv6 Service SIDs from configured locator spaces according to the following inheritance rules:

1. Use the locator as defined under the service.
If not defined under the specific service, then:
2. Use the locator as defined under the corresponding address-family.
If not defined under the corresponding address-family, then:
3. Use the locator as defined globally under BGP.

Enabling SRv6 Globally under BGP

Use the **router bgp *as-number* segment-routing srv6** command to enable SRv6 globally under the BGP routing process. The *as-number* is from 1-65535.

```
RP/0/0/CPU0:Node1(config)# router bgp 100 segment-routing srv6
```

Assigning SRv6 Locator Globally under BGP

Use the **router bgp *as-number* segment-routing srv6 locator *WORD*** command to assign an SRv6 locator globally under the BGP routing process. The *as-number* is from 1-65535.

This example shows how to assign a locator:

```
RP/0/0/CPU0:Node1(config)# router bgp 100 segment-routing srv6 locator Node1-locator
```

For more information on how to configure an SRv6 locator, see [Configuring SRv6, on page 27](#).

For more information on how to assign an SRv6 locator under the BGP service or BGP address-family, see the following SRv6 Services sections.

SRv6 Services: IPv4 L3VPN

Table 4: Feature History Table

Feature Name	Release	Description
Per-Prefix SRv6 Locator Assignment	Release 7.5.1	This feature provides the ability to assign a specific SRv6 locator for a given prefix or a set of prefixes (IPv4/IPv6 GRT, IPv4/IPv6 VPN). The egress PE advertises the prefix with the specified locator. This allows for per-prefix steering into desired transport behaviors, such as Flex Algo.
Support for iBGP as PE-CE protocol	Release 7.5.1	This feature introduces support for iBGP as PE-CE protocol.
BGP Route Leaking	Release 7.5.1	This feature adds support for importing routes from default-VRF to non-default VRF and routes from non-default VRF to default VRF.

Table 5: Feature History Table

Feature Name	Release	Description
Dual-Stack L3VPN Services (IPv4, IPv6) (SRv6 Micro-SID)	Release 7.3.2	This feature introduces support for Dual-stack (VPNv4/VPNv6) VRFs. VPNv4/VPNv6 Dual-stack supports both IPv4 (uDT4) and IPv6 (uDT6) based SRv6 L3VPN service on the same interface, sub-interface, or VRF.

This feature provides IPv4 L3VPNs (VPNv4) over an SRv6 network.

Usage Guidelines and Limitations

- SRv6 locator can be assigned globally, for all VRFs, for an individual VRF, or per-prefix.
- Per-VRF allocation mode is supported (uDT4 behavior)
- Dual-Stack L3VPN Services (IPv4, IPv6) are supported
- Equal-Cost Multi-path (ECMP) and Unequal Cost Multipath (UCMP) are supported.
- BGP (iBGP, eBGP), OSPF, Static are supported as PE-CE protocol.
- BGP route leaking between BGP Global and L3VPN is supported. Refer to the [Implementing BGP](#) chapter in the *BGP Configuration Guide for Cisco NCS 5500 Series Routers*.

- MPLS L3VPN and SRv6 L3VPN interworking gateway is supported.
- Per-CE allocation mode is not supported (uDX4 behavior)

Configuring SRv6 based IPv4 L3VPN

To enable SRv6-based L3VPN, you need to enable SRv6 under BGP, specify the locator, and configure the SID allocation mode. The assignment of the locator can be done in different places under the **router bgp** configuration. See [SRv6 Locator Inheritance Rules, on page 45](#).

Use Case 1: Assigning SRv6 Locator Globally

This example shows how to enable SRv6 and configure the SRv6 locator name under BGP Global:

```
Node1(config)# router bgp 100
Node1(config-bgp)# segment-routing srv6
Node1(config-bgp-gbl-srv6)# locator Node1-locator
Node1(config-bgp-gbl-srv6)# exit
Node1(config-bgp)# address-family vpnv4 unicast
Node1(config-bgp-af)# exit
Node1(config-bgp)# neighbor 3001::1:1:1:4
Node1(config-bgp-nbr)# remote-as 100
Node1(config-bgp-nbr)# address-family vpnv4 unicast
Node1(config-bgp-nbr-af)# exit
Node1(config-bgp-nbr)# exit
Node1(config-bgp)# vrf vrf_cust1
Node1(config-bgp-vrf)# rd 100:1
Node1(config-bgp-vrf)# address-family ipv4 unicast
Node1(config-bgp-vrf-af)# commit
```

Running Config

```
router bgp 100
  segment-routing srv6
    locator Node1-locator
  !
  address-family vpnv4 unicast
  !
  neighbor 3001::1:1:1:4
    remote-as 100
    address-family vpnv4 unicast
  !
  !
  vrf vrf_cust1
    rd 100:1
    address-family ipv4 unicast
  !
  !
end
```

Use Case 2: Assigning SRv6 Locator for All VRFs

To configure the SRv6 locator for all VRFs under VPNv4 Address Family and specify the allocation mode, use the following commands:

- **router bgp *as-number* address-family vpnv4 unicast vrf all segment-routing srv6:** Enable SRv6
- **router bgp *as-number* address-family vpnv4 unicast vrf all segment-routing srv6 alloc mode {per-vrf}:** Specify the SID behavior (allocation mode)

- Use the **per-vrf** keyword to specify that the same service SID (uDT4 behavior) be used for all the routes advertised from a unique VRF.
- **router bgp as-number address-family vpnv4 unicast vrf all segment-routing srv6 locator WORD:** Specify the locator

This example shows how to enable SRv6 and configure the SRv6 locator for all VRFs under VPNv4 Address Family, with per-VRF label allocation mode:

```
Node1(config)# router bgp 100
Node1(config-bgp)# address-family vpnv4 unicast
Node1(config-bgp-af)# vrf all
Node1(config-bgp-af-vrfall)# segment-routing srv6
Node1(config-bgp-af-vrfall-srv6)# locator Node1-locator
Node1(config-bgp-af-vrfall-srv6)# alloc mode per-vrf
Node1(config-bgp-af-vrfall-srv6)# exit
Node1(config-bgp-af-vrfall)# exit
Node1(config-bgp-af)# exit
Node1(config-bgp)# neighbor 3001::1:1:1:4
Node1(config-bgp-nbr)# remote-as 100
Node1(config-bgp-nbr)# address-family vpnv4 unicast
Node1(config-bgp-nbr-af)# exit
Node1(config-bgp-nbr)# exit
Node1(config-bgp)# vrf vrf_cust1
Node1(config-bgp-vrf)# rd 100:1
Node1(config-bgp-vrf)# address-family ipv4 unicast
Node1(config-bgp-vrf-af)# commit
```

Running Config

```
router bgp 100
 address-family vpnv4 unicast
   vrf all
     segment-routing srv6
       locator Node1-locator
       alloc mode per-vrf
   !
 !
 !
 neighbor 3001::1:1:1:4
  remote-as 100
  address-family vpnv4 unicast
  !
 !
 vrf vrf_cust1
  rd 100:1
  address-family ipv4 unicast
  !
 !
 !
end
```

Use Case 3: Assigning SRv6 Locator for a specific VRF

To configure the SRv6 locator for a specific VRF under IPv4 Address Family and specify the allocation mode, use the following commands:

- **router bgp as-number vrf WORD address-family ipv4 unicast segment-routing srv6:** Enable SRv6
- **router bgp as-number vrf WORD address-family ipv4 unicast segment-routing srv6 alloc mode { per-vrf }:** Specify the SID behavior (allocation mode)

- Use the **per-vrf** keyword to specify that the same service SID (uDT4 behavior) be used for all the routes advertised from a unique VRF.
- **router bgp** *as-number* **vrf** *WORD* **address-family** **ipv4** **unicast** **segment-routing** **srv6** **locator** *WORD*: Specify the locator

This example shows how to configure the SRv6 locator for an individual VRF, with per-VRF label allocation mode:

```
Node1(config)# router bgp 100
Node1(config-bgp)# address-family vpnv4 unicast
Node1(config-bgp-af)# exit
Node1(config-bgp)# neighbor 3001::1:1:1:4
Node1(config-bgp-nbr)# remote-as 100
Node1(config-bgp-nbr)# address-family vpnv4 unicast
Node1(config-bgp-nbr-af)# exit
Node1(config-bgp-nbr)# exit
Node1(config-bgp)# vrf vrf_cust1
Node1(config-bgp-vrf)# rd 100:1
Node1(config-bgp-vrf)# address-family ipv4 unicast
Node1(config-bgp-vrf-af)# segment-routing srv6
Node1(config-bgp-vrf-af-srv6)# locator Node1-locator
Node1(config-bgp-vrf-af-srv6)# alloc mode per-vrf
Node1(config-bgp-vrf-af-srv6)# commit
```

Running Config

```
router bgp 100
 address-family vpnv4 unicast
 !
 neighbor 3001::1:1:1:4
  remote-as 100
  address-family vpnv4 unicast
  !
 !
vrf vrf_cust1
 rd 100:1
  address-family ipv4 unicast
   segment-routing srv6
    locator Node1-locator
    alloc mode per-vrf
  !
 !
 !
end
```

Use Case 4: Assigning SRv6 Locator for a Specific Prefix

This use case provides the ability to assign a specific SRv6 locator for a given prefix or a set of prefixes. The egress PE advertises the prefix with the specified locator. This allows for per-prefix steering into desired transport behaviors, such as Flex Algo.

To assign an SRv6 locator for a specific prefix, configure a route policy to specify the SID allocation mode based on match criteria. Examples of match criteria are destination-based match or community-based match.

- Supported SID allocation mode is per-VRF.
- For per-VRF allocation mode, you can also specify the SRv6 locator.

- If an SRv6 locator is specified in the route policy, BGP will use that to allocate per-VRF SID. If the specified locator is invalid, the SID will not be allocated.
- If an SRv6 locator is not specified in the route policy, the default locator configured under BGP is used to allocate the SID. If the default locator is not configured, then the SID will not be allocated.

For more information on configuring routing policies, refer to the "Implementing Routing Policy" chapter in the *Routing Configuration Guide*.

The following example shows a route policy specifying the SID allocation mode with destination-based match:

```
Node1(config)# route-policy set_per_prefix_locator_rpl
Node1(config-rpl)# if destination in (10.1.1.0/24) then
Node1(config-rpl-if)# set srv6-alloc-mode per-vrf locator locator1
Node1(config-rpl-if)# elseif destination in (2.2.2.0/24) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf locator locator2
Node1(config-rpl-elseif)# elseif destination in (3.3.3.0/24) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf
Node1(config-rpl-elseif)# else
Node1(config-rpl-else)# drop
Node1(config-rpl-else)# endif
Node1(config-rpl)# end-policy
Node1(config)#
```

To specify per-prefix allocation mode for a specific VRF under IPv4 address family, use the following command:

- **router bgp** *as-number* **vrf** *WORD* **address-family ipv4 unicast segment-routing srv6 alloc mode** **route-policy** *policy_name*

This example shows how to configure per-prefix allocation mode for a specific VRF (vrf_cust1) under IPv4 address family

```
Node1(config)# router bgp 100
Node1(config-bgp)# vrf vrf_cust1
Node1(config-bgp-vrf)# address-family ipv4 unicast
Node1(config-bgp-vrf-af)# segment-routing srv6
Node1(config-bgp-vrf-af-srv6)# alloc mode route-policy set_per_prefix_locator_rpl
```

Running Configuration

```
route-policy set_per_prefix_locator_rpl
  if destination in (10.1.1.0/24) then
    set srv6-alloc-mode per-vrf locator locator1
  elseif destination in (2.2.2.0/24) then
    set srv6-alloc-mode per-vrf locator locator2
  elseif destination in (3.3.3.0/24) then
    set srv6-alloc-mode per-vrf
  else
    drop
  endif
end-policy
!
router bgp 100
  vrf vrf_cust1
    address-family ipv6 unicast
      segment-routing srv6
        alloc mode route-policy set_per_prefix_locator_rpl
    !
  !
```

!
!

Verify that the local and received SIDs have been correctly allocated under VPNv4 and specific VRF (vrf_cust1):

```

Verification

The following figure shows a VPNv4 scenario. The sequence of commands included correspond to router Node1 acting as Ingress PE, and routers Node4 and Node5 acting as Egress PEs.

The following example shows how to verify the SRv6 based L3VPN configuration using the **show segment-routing srv6 sid** command.

In this example, we can observe the uDT4 SIDs associated with the IPv4 L3VPN; where uDT4 behavior represents Endpoint with decapsulation and IPv4 table lookup.

```
Node1# show segment-routing srv6 sid
```

```
*** Locator: 'Node1-locator' ***
```

SID	State	RW	Behavior	Context	Owner
cafe:0:1::	InUse	Y	uN (PSP/USD)	'default':1	sidmgr
cafe:0:1:e000::	InUse	Y	uA (PSP/USD)	[Hu0/0/0/0, Link-Local]:0	isis-1
cafe:0:1:e001::	InUse	Y	uA (PSP/USD)	[Hu0/0/0/1, Link-Local]:0	isis-1
cafe:0:1:e002::	InUse	Y	uDT4	'vrf_cust1'	bgp-100
cafe:0:1:e003::	InUse	Y	uDT4	'vrf_cust2'	bgp-100
cafe:0:1:e004::	InUse	Y	uDT4	'vrf_cust3'	bgp-100
cafe:0:1:e005::	InUse	Y	uDT4	'vrf_cust4'	bgp-100
cafe:0:1:e006::	InUse	Y	uDT4	'vrf_cust5'	bgp-100

The following example shows how to verify the SRv6 based L3VPN configuration using the **show segment-routing srv6SID-prefixdetail** command.

```
Node1# show segment-routing srv6 sid cafe:0:1:e002:: detail
Tue Feb 9 17:50:40.621 UTC
```

```
*** Locator: 'Node1-locator' ***

SRv6 Services: IPv6 L3VPN

Table 6: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 Services: IPv6 L3VPN	Release 7.3.1	With this feature, the egress PE can signal an SRv6 Service SID with the BGP overlay service route. The ingress PE encapsulates the IPv4/IPv6 payload in an outer IPv6 header where the destination address is the SRv6 Service SID provided by the egress PE. BGP messages between PEs carry SRv6 Service SIDs as a means to interconnect PEs and form VPNs.

This feature provides IPv6 L3VPNs (VPNv6) over an SRv6 network.

Usage Guidelines and Limitations

- SRv6 locator can be assigned globally, for all VRFs, for an individual VRF, or per-prefix.
- Per-VRF allocation mode is supported (uDT6 behavior)
- Dual-Stack L3VPN Services (IPv4, IPv6) are supported
- Equal-Cost Multi-path (ECMP) and Unequal Cost Multipath (UCMP) are supported.
- BGP (iBGP, eBGP), OSPF, Static are supported as PE-CE protocol.
- BGP route leaking between BGP Global and L3VPN is supported. Refer to the [Implementing BGP](#) chapter in the *BGP Configuration Guide for Cisco NCS 5500 Series Routers*.
- MPLS L3VPN and SRv6 L3VPN interworking gateway is supported.
- Per-CE allocation mode is not supported (uDX6 behavior)

Configuring SRv6-based IPv6 L3VPN

To enable SRv6-based L3VPN, you need to enable SRv6 under BGP, specify the locator, and configure the SID allocation mode. The assignment of the locator can be done in different places under the **router bgp** configuration. See [SRv6 Locator Inheritance Rules, on page 45](#).

Use Case 1: Assigning SRv6 Locator Globally

This example shows how to configure the SRv6 locator name under BGP Global:

```

Node1(config)# router bgp 100
Node1(config-bgp)# segment-routing srv6
Node1(config-bgp-gbl-srv6)# locator Node1-locator
Node1(config-bgp-gbl-srv6)# exit
Node1(config-bgp)# address-family vpnv6 unicast
Node1(config-bgp-af)# exit
Node1(config-bgp)# neighbor 3001::12:1:1:4
Node1(config-bgp-nbr)# remote-as 100
Node1(config-bgp-nbr)# address-family vpnv6 unicast
Node1(config-bgp-nbr-af)# exit
Node1(config-bgp-nbr)# exit
Node1(config-bgp)# vrf vrf_cust6
Node1(config-bgp-vrf)# rd 100:6
Node1(config-bgp-vrf)# address-family ipv6 unicast
Node1(config-bgp-vrf-af)# commit

```

Running Configuration

```

router bgp 100
  segment-routing srv6
    locator Node1-locator
  !
  address-family vpnv6 unicast
  !
  neighbor 3001::12:1:1:4
    remote-as 100
    address-family vpnv6 unicast
  !
  !
  vrf vrf_cust6
    rd 100:6
    address-family ipv6 unicast
  !
  !
end

```

Use Case 2: Assigning SRv6 Locator for All VRFs

To configure the SRv6 locator for all VRFs under VPNv6 Address Family and specify the allocation mode, use the following commands:

- **router bgp *as-number* address-family vpnv6 unicast vrf all segment-routing srv6:** Enable SRv6
- **router bgp *as-number* address-family vpnv6 unicast vrf all segment-routing srv6 alloc mode {per-vrf}:** Specify the SID behavior (allocation mode)
 - Use the **per-vrf** keyword to specify that the same service SID (uDT6 behavior) be used for all the routes advertised from a unique VRF.
- **router bgp *as-number* address-family vpnv6 unicast vrf all segment-routing srv6 locator *WORD*:** Specify the locator

This example shows how to configure the SRv6 locator for all VRFs under VPNv6 Address Family, with per-VRF label allocation mode:

```

Node1(config)# router bgp 100
Node1(config-bgp)# address-family vpnv6 unicast
Node1(config-bgp-af)# vrf all

```

```

Node1(config-bgp-af-vrfall)# segment-routing srv6
Node1(config-bgp-af-vrfall-srv6)# locator Node1-locator
Node1(config-bgp-af-vrfall-srv6)# alloc mode per-vrf
Node1(config-bgp-af-vrfall-srv6)# exit
Node1(config-bgp-af-vrfall)# exit
Node1(config-bgp-af)# exit
Node1(config-bgp)# neighbor 3001::12:1:1:4
Node1(config-bgp-nbr)# remote-as 100
Node1(config-bgp-nbr)# address-family vpnv6 unicast
Node1(config-bgp-nbr-af)# exit
Node1(config-bgp-nbr)# exit
Node1(config-bgp)# vrf vrf_cust6
Node1(config-bgp-vrf)# rd 100:6
Node1(config-bgp-vrf)# address-family ipv6 unicast
Node1(config-bgp-vrf-af)# commit

```

Running Configuration

```

router bgp 100
 address-family vpnv6 unicast
   vrf all
     segment-routing srv6
       locator Node1-locator
       alloc mode per-vrf
   !
 !
 !
 neighbor 3001::12:1:1:4
 remote-as 100
 address-family vpnv6 unicast
 !
 !
 vrf vrf_cust6
 rd 100:6
 address-family ipv6 unicast
 !
 !
 !
end

```

Use Case 3: Assigning SRv6 Locator for a specific VRF

To configure the SRv6 locator for a specific VRF under IPv6 Address Family and specify the allocation mode, use the following commands:

- **router bgp *as-number* vrf *WORD* address-family ipv6 unicast segment-routing srv6:** Enable SRv6
- **router bgp *as-number* vrf *WORD* address-family ipv6 unicast segment-routing srv6 alloc mode { *per-vrf* }:** Specify the SID behavior (allocation mode)
 - Use the **per-vrf** keyword to specify that the same service SID (uDT6 behavior) be used for all the routes advertised from a unique VRF.
- **router bgp *as-number* vrf *WORD* address-family ipv6 unicast segment-routing srv6 locator *WORD*:** Specify the locator

This example shows how to configure the SRv6 locator for an individual VRF, with per-VRF label allocation mode:

```

Node1(config)# router bgp 100
Node1(config-bgp)# address-family vpnv6 unicast

```

```

Node1(config-bgp-af)# exit
Node1(config-bgp)# neighbor 3001::12:1:1:4
Node1(config-bgp-nbr)# remote-as 100
Node1(config-bgp-nbr)# address-family vpnv6 unicast
Node1(config-bgp-nbr-af)# exit
Node1(config-bgp-nbr)# exit
Node1(config-bgp)# vrf vrf_cust6
Node1(config-bgp-vrf)# rd 100:6
Node1(config-bgp-vrf)# address-family ipv6 unicast
Node1(config-bgp-vrf-af)# segment-routing srv6
Node1(config-bgp-vrf-af-srv6)# locator Node1-locator
Node1(config-bgp-vrf-af-srv6)# alloc mode per-vrf
Node1(config-bgp-vrf-af-srv6)# commit

```

Running Configuration

```

router bgp 100
 address-family vpnv6 unicast
 !
 neighbor 3001::12:1:1:4
  remote-as 100
 address-family vpnv6 unicast
 !
 !
 vrf vrf_cust6
  rd 100:6
 address-family ipv6 unicast
  segment-routing srv6
  locator Node1-locator
  alloc mode per-vrf
 !
 !
 !
 !
end

```

Use Case 4: Assigning SRv6 Locator for a Specific Prefix

This use case provides the ability to assign a specific SRv6 locator for a given prefix or a set of prefixes. The egress PE advertises the prefix with the specified locator. This allows for per-prefix steering into desired transport behaviors, such as Flex Algo.

To assign an SRv6 locator for a specific prefix, configure a route policy to specify the SID allocation mode based on match criteria. Examples of match criteria are destination-based match or community-based match.

- Supported SID allocation mode is per-VRF.
- For per-VRF allocation mode, you can also specify the SRv6 locator.
 - If an SRv6 locator is specified in the route policy, BGP will use that to allocate per-VRF SID. If the specified locator is invalid, the SID will not be allocated.
 - If an SRv6 locator is not specified in the route policy, the default locator is used to allocate the SID. If the default locator is not configured in BGP, then the SID will not be allocated.

For more information on configuring routing policies, refer to the "Implementing Routing Policy" chapter in the *Routing Configuration Guide*.

The following example shows a route policy specifying the SID allocation mode with destination-based match:

```

Node1(config)# route-policy set_per_prefix_locator_rpl
Node1(config-rpl)# if destination in (3001::1:1:1:1/128) then

```

```

Node1(config-rpl-if)# set srv6-alloc-mode per-vrf locator locator1
Node1(config-rpl-if)# elseif destination in (3001::2:2:2:2/128) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf locator locator2
Node1(config-rpl-elseif)# elseif destination in (3001::3:3:3:3/128) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf
Node1(config-rpl-elseif)# else
Node1(config-rpl-elseif)# drop
Node1(config-rpl-elseif)# endif
Node1(config-rpl)# end-policy

```

To specify per-prefix allocation mode for a specific VRF under IPv6 Address Family, use the following command:

- **router bgp** *as-number* **vrf** *WORD* **address-family ipv6 unicast segment-routing srv6 alloc mode** **route-policy** *policy_name*

This example shows how to specify per-prefix allocation mode for a specific VRF (vrf_cust6) under the IPv6 address family:

```

Node1(config)# router bgp 100
Node1(config-bgp)# vrf vrf_cust6
Node1(config-bgp-vrf)# address-family ipv6 unicast
Node1(config-bgp-vrf-af)# segment-routing srv6
Node1(config-bgp-vrf-af-srv6)# alloc mode route-policy set_per_prefix_locator_rpl

```

Running Configuration

```

route-policy set_per_prefix_locator_rpl
  if destination in (3001::1:1:1:1/128) then
    set srv6-alloc-mode per-vrf locator locator1
  elseif destination in (3001::2:2:2:2/128) then
    set srv6-alloc-mode per-vrf locator locator2
  elseif destination in (3001::3:3:3:3/128) then
    set srv6-alloc-mode per-vrf
  else
    drop
  endif
end-policy
!
router bgp 100
  vrf vrf_cust6
    address-family ipv6 unicast
      segment-routing srv6
        alloc mode route-policy set_per_prefix_locator_rpl
    !
  !
!

```

Verify that the local and received SIDs have been correctly allocated under VPNv6 and specific VRF (vrf_cust6):

```

Node1# show bgp vpnv6 unicast local-sids

```

Verification

The following figure shows a VPNv6 scenario. The sequence of commands included correspond to router Node1 acting as Ingress PE, and routers Node4 and Node5 acting as Egress PEs.

The following examples shows how to verify the SRv6 based L3VPN configurations for an Individual VRF with per VRF label allocation mode.

In this example, we can observe the uDT6 SID associated with the IPv6 L3VPN, where uDT6 behavior represents Endpoint with decapsulation and IPv6 table lookup.

```
Node1# show segment-routing srv6 sid
Fri Jan 29 19:31:53.293 UTC
```

```
*** Locator: 'Node1-locator' ***
```

SRv6 Services: IPv4 BGP Global

This feature extends support of SRv6-based BGP services to include IPv4 global BGP by implementing uDT4 SRv6 functions at the PE node ([draft-ietf-bess-srv6-services](#)).

Usage Guidelines and Limitations

- SRv6 locator can be assigned globally or under IPv4 unicast address family
- Equal-Cost Multi-path (ECMP) and Unequal Cost Multipath (UCMP) are supported.
- BGP, OSPF, Static are supported as PE-CE protocol.
- BGP route leaking between BGP Global and L3VPN is supported. Refer to the [Implementing BGP](#) chapter in the *BGP Configuration Guide for Cisco NCS 5500 Series Routers*.
- Dual-Stack L3 Services (IPv4 BGP global, IPv6 BGP global) are supported.

BGP Global IPv4 Over SRv6 with Per-AFI SID Allocation Mode (uDT4)

To configure BGP global IPv4 over SRv6, use the following commands:

- **router bgp *as-number* address-family ipv4 unicast segment-routing srv6**: Enable SRv6
- **router bgp *as-number* address-family ipv4 unicast segment-routing srv6 alloc mode {*per-vrf* | *route-policy policy_name*}**: Specify the SID behavior (allocation mode).
 - **per-vrf**: Specifies that the same label is be used for all the routes advertised from a unique VRF.
 - **route-policy *policy_name***: Uses a route policy to determine the SID allocation mode and locator (if provided) for given prefix.
- **router bgp *as-number* address-family ipv4 unicast segment-routing srv6 locator *WORD***: Specify the locator
- **router bgp *as-number* {*af-group WORD* | *neighbor-group WORD* | *neighbor ipv6-addr*} address-family ipv4 unicast encapsulation-type srv6**: Specify the encapsulation type for SRv6.
 - Use **af-group *WORD*** to apply the SRv6 encapsulation type to the address family group for BGP neighbors.
 - Use **neighbor-group *WORD*** to apply the SRv6 encapsulation type to the neighbor group for BGP neighbors.
 - Use **neighbor *ipv6-addr*** to apply the SRv6 encapsulation type to the specific BGP neighbor.

Use Case 1: BGP Global IPv4 over SRv6 with Per-AFI SID Allocation

The following example shows how to configure BGP global IPv4 over SRv6 with per-AFI SID allocation.

```
Node1(config)# router bgp 1
Node1(config-bgp)# bgp router-id 10.1.0.1
Node1(config-bgp)# address-family ipv4 unicast
Node1(config-bgp-af)# segment-routing srv6
```

```

Node1(config-bgp-af-srv6)# locator Node1
Node1(config-bgp-af-srv6)# alloc mode per-vrf
Node1(config-bgp-af-srv6)# exit
Node1(config-bgp-af)# exit
Node1(config-bgp)# neighbor 60::2
Node1(config-bgp-nbr)# remote-as 1
Node1(config-bgp-nbr)# update-source Loopback1
Node1(config-bgp-nbr)# address-family ipv4 unicast
Node1(config-bgp-nbr-af)# encapsulation-type srv6
Node1(config-bgp-nbr-af)# exit
Node1(config-bgp-nbr)# exit
Node1(config-bgp)# neighbor 52.52.52.1
Node1(config-bgp-nbr)# remote-as 3
Node1(config-bgp-nbr)# address-family ipv4 unicast
Node1(config-bgp-nbr-af)# route-policy passall in
Node1(config-bgp-nbr-af)# route-policy passall out
Node1(config-bgp-nbr-af)# commit

```

Running Configuration

```

router bgp 1
  bgp router-id 10.1.0.1
  address-family ipv4 unicast
    segment-routing srv6
      locator Node1
      alloc mode per-vrf
  !
!

  remote-as 3
  address-family ipv4 unicast
    route-policy passall in
    route-policy passall out
  !
!
!

```

Use Case 2: BGP Global IPv4 over SRv6 with Per-Prefix SID Allocation

This use case provides the ability to assign a specific SRv6 locator for a given prefix or a set of prefixes. The egress PE advertises the prefix with the specified locator. This allows for per-prefix steering into desired transport behaviors, such as Flex Algo.

To assign an SRv6 locator for a specific prefix, configure a route policy to specify the SID allocation mode based on match criteria. Examples of match criteria are destination-based match or community-based match.

- Supported SID allocation mode is per-VRF.
- For per-VRF allocation mode, you can also specify the SRv6 locator.
 - If an SRv6 locator is specified in the route policy, BGP will use that to allocate per-VRF SID. If the specified locator is invalid, the SID will not be allocated.

- If an SRv6 locator is not specified in the route policy, the default locator is used to allocate the SID. If the default locator is not configured in BGP, then the SID will not be allocated.

For more information on configuring routing policies, refer to the "Implementing Routing Policy" chapter in the *Routing Configuration Guide*.

The following example shows a route policy specifying the SID allocation mode with destination-based match:

```
Nodel(config)# route-policy set_per_prefix_locator_rpl
Nodel(config-rpl)# if destination in (10.1.1.0/24) then
Nodel(config-rpl-if)# set srv6-alloc-mode per-vrf locator locator1
Nodel(config-rpl-if)# elseif destination in (2.2.2.0/24) then
Nodel(config-rpl-elseif)# set srv6-alloc-mode per-vrf locator locator2
Nodel(config-rpl-elseif)# elseif destination in (3.3.3.0/24) then
Nodel(config-rpl-elseif)# set srv6-alloc-mode per-vrf
Nodel(config-rpl-elseif)# else
Nodel(config-rpl-else)# drop
Nodel(config-rpl-else)# endif
Nodel(config-rpl)# end-policy
Nodel(config)#
```

The following example shows how to configure BGP global IPv4 over SRv6 with a route policy to determine the SID allocation mode for given prefix.

```
Nodel(config)# router bgp 100
Nodel(config-bgp)# address-family ipv4 unicast
Nodel(config-bgp-af)# segment-routing srv6
Nodel(config-bgp-af-srv6)# alloc mode route-policy set_per_prefix_locator_rpl
```

Running Configuration

```
route-policy set_per_prefix_locator_rpl
  if destination in (10.1.1.0/24) then
    set srv6-alloc-mode per-vrf locator locator1
  elseif destination in (2.2.2.0/24) then
    set srv6-alloc-mode per-vrf locator locator2
  elseif destination in (3.3.3.0/24) then
    set srv6-alloc-mode per-vrf
  else
    drop
  endif
end-policy
!
router bgp 100
  address-family ipv4 unicast
    segment-routing srv6
      alloc mode route-policy set_per_prefix_locator_rpl
    !
  !
!
```

Verify that the local and received SIDs have been correctly allocated under BGP IPv4 address family:

```

SRv6 Services: IPv6 BGP Global

Table 7: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 Services: BGP Global IPv6	Release 7.3.1	With this feature, the egress PE can signal an SRv6 Service SID with the BGP global route. The ingress PE encapsulates the IPv4/IPv6 payload in an outer IPv6 header where the destination address is the SRv6 Service SID provided by the egress PE. BGP messages between PEs carry SRv6 Service SIDs as a means to interconnect PEs.

This feature extends support of SRv6-based BGP services to include IPv6 global BGP by implementing uDT6 SRv6 functions at the PE node ([draft-ietf-bess-srv6-services](#)).

Usage Guidelines and Limitations

- SRv6 locator can be assigned globally or under IPv6 unicast address family
- Equal-Cost Multi-path (ECMP) and Unequal Cost Multipath (UCMP) are supported.
- BGP, OSPF, Static are supported as PE-CE protocol.
- BGP route leaking between BGP Global and L3VPN is supported. Refer to the [Implementing BGP](#) chapter in the *BGP Configuration Guide for Cisco NCS 5500 Series Routers*.
- Dual-Stack L3 Services (IPv4 BGP global, IPv6 BGP global) are supported.

BGP Global IPv6 Over SRv6 with Per-AFI SID Allocation Mode (uDT6)

To configure BGP global IPv6 over SRv6, use the following commands:

- **router bgp *as-number* address-family ipv6 unicast segment-routing srv6:** Enable SRv6

- **router bgp** *as-number* **address-family ipv6 unicast segment-routing srv6 alloc mode** {*per-vrf* | *route-policy policy_name*}: Specify the SID behavior (allocation mode).
 - **per-vrf**: Specifies that the same label is be used for all the routes advertised from a unique VRF.
 - **route-policy** *policy_name*: Uses a route policy to determine the SID allocation mode and locator (if provided) for given prefix.
- **router bgp** *as-number* **address-family ipv6 unicast segment-routing srv6 locator** *WORD*: Specify the locator
- **router bgp** *as-number* {**af-group** *WORD* | **neighbor-group** *WORD* | **neighbor** *ipv6-addr*} **address-family ipv6 unicast encapsulation-type srv6**: Specify the encapsulation type for SRv6.
 - Use **af-group** *WORD* to apply the SRv6 encapsulation type to the address family group for BGP neighbors.
 - Use **neighbor-group** *WORD* to apply the SRv6 encapsulation type to the neighbor group for Border Gateway Protocol (BGP) neighbors.
 - Use **neighbor** *ipv6-addr* to apply the SRv6 encapsulation type to the specific BGP neighbor.

Use Case 1: BGP Global IPv6 over SRv6 with Per-AFI SID Allocation

The following example shows how to configure BGP global IPv6 over SRv6 with per-AFI SID allocation.

```

Node1(config)# router bgp 100
Node1(config-bgp)# bgp router-id 10.1.1.1
Node1(config-bgp)# segment-routing srv6
Node1(config-bgp-gbl-srv6)# locator Node1
Node1(config-bgp-gbl-srv6)# exit
Node1(config-bgp)# address-family ipv6 unicast
Node1(config-bgp-af)# segment-routing srv6

Use Case 2: BGP Global IPv6 over SRv6 with Per-Prefix SID Allocation

This use case provides the ability to assign a specific SRv6 locator for a given prefix or a set of prefixes. The egress PE advertises the prefix with the specified locator. This allows for per-prefix steering into desired transport behaviors, such as Flex Algo.

To assign an SRv6 locator for a specific prefix, configure a route policy to specify the SID allocation mode based on match criteria. Examples of match criteria are destination-based match or community-based match.

- Supported SID allocation modes are per-VRF and per-CE.
- For per-VRF allocation mode, you can also specify the SRv6 locator.
 - If an SRv6 locator is specified in the route policy, BGP will use that to allocate per-VRF SID. If the specified locator is invalid, the SID will not be allocated.
 - If an SRv6 locator is not specified in the route policy, the default locator is used to allocate the SID. If the default locator is not configured in BGP, then the SID will not be allocated.
- Per-CE allocation mode always uses the default locator to allocate the SID.

For more information on configuring routing policies, refer to the "Implementing Routing Policy" chapter in the *Routing Configuration Guide*.

The following example shows a route policy specifying the SID allocation mode with destination-based match:

```

Node1(config)# route-policy set_per_prefix_locator_rpl
Node1(config-rpl)# if destination in (3001::1:1:1:1/128) then
Node1(config-rpl-if)# set srv6-alloc-mode per-vrf locator locator1
Node1(config-rpl-if)# elseif destination in (3001::2:2:2:2/128) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf locator locator2
Node1(config-rpl-elseif)# elseif destination in (3001::3:3:3:3/128) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf
Node1(config-rpl-elseif)# elseif destination in (3001::4:4:4:4/128) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-ce
Node1(config-rpl-elseif)# else
Node1(config-rpl-else)# drop
Node1(config-rpl-else)# endif
Node1(config-rpl)# end-policy

```

The following example shows how to configure BGP global IPv6 over SRv6 with a route policy to determine the SID allocation mode for given prefix.

```

Node1(config)# router bgp 100
Node1(config-bgp)# address-family ipv6 unicast
Node1(config-bgp-af)# segment-routing srv6
Node1(config-bgp-af-srv6)# alloc mode route-policy set_per_prefix_locator_rpl

```

Running Configuration

```

route-policy set_per_prefix_locator_rpl
  if destination in (3001::1:1:1:1/128) then
    set srv6-alloc-mode per-vrf locator locator1
  elseif destination in (3001::2:2:2:2/128) then
    set srv6-alloc-mode per-vrf locator locator2
  elseif destination in (3001::3:3:3:3/128) then
    set srv6-alloc-mode per-vrf
  else
    drop
  endif
end-policy
!
router bgp 100
  address-family ipv6 unicast
    segment-routing srv6
      alloc mode route-policy set_per_prefix_locator_rpl
    !
  !

```

Verify that the local and received SIDs have been correctly allocated under BGP IPv6 address family:

```
Node1# show bgp ipv6 unicast local-sids
```

```

BGP Signaling for co-existence of IP routes with or without SRv6 SID

Table 8: Feature History Table

Feature Name	Release Information	Feature Description
BGP Signaling for co-existence of IP routes	Release 24.3.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>SRv6 with BGP supports the coexistence of IP routes with or without SRv6 SID over an SRv6-enabled core network. This support enables integrating SRv6 capabilities into existing network infrastructures without replacing IP routing completely.</p> <p>This feature enables flexibility and scalability, transition to new technologies, and enhanced network efficiency, making it easier to migrate from MPLS to SRv6.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> • encapsulation-type srv6 relax-sid

Need for BGP Signaling Over SRv6 core

BGP now supports sending internet service over an SRv6 core, assuming that all Global Routing Table (GRT) routes are advertised with an SRv6-SID.

To differentiate between the SRv6 core and non-SRv6 core sides, an **encapsulation-type SRv6** was introduced under the IPv6 BGP peer for the IPv4 unicast address-family. When the "encapsulation-type srv6" is enabled, routes without an SRv6-SID are not sent to the neighbor sessions during update generation. For more information, see [Configuring SRv6 BGP-Based Services, on page 44](#) and <https://datatracker.ietf.org/doc/rfc9252/>.

However, in some networks, there may be a mix of GRT routes with SRv6 SID encapsulation and without SRv6 encapsulation. Hence, there is a need for BGP to allow SRv6-enabled GRT to support the co-existence and signaling of IP routes with or without an SRv6-SID on the same IPv6 neighbor session.

Co-existence of IP routes with or without SRv6 SID

This feature adds a new BGP encapsulation type called **SRv6 relax-SID**, which allows the advertisement of prefixes with or without SRv6 SID over the same BGP session. This is in contrast to the existing encapsulation type "srv6", which did not advertise prefixes without an SRv6 SID. The configuration allows for the specification of route policies that set the SRv6 allocation mode based on the destination prefix, enabling the coexistence of IP routes with or without SRv6 SID.

Benefits

The benefits of the co-existence of IP routes with or without SRv6 SID over an SRv6 core are numerous and significant for network operations as listed.

- **Enhanced Network Efficiency:** Allows seamless integration of SRv6 capabilities into existing network infrastructures, which can lead to more efficient routing and resource utilization.
- **Simplified Operations:** By supporting the coexistence of IP routes with or without SRv6 SID, network operators can manage their networks better without maintaining separate BGP peer sessions to support advertising both type of routes.
- **Future-Proofing the Network:** As networks evolve, the ability to support IP routes with or without SRv6 SID ensures that the network is prepared to enable customer to support use cases such as overlay and underlay route separation in a GRT table.
- **Cost Savings:** Reduce operations cost by streamlining network efficiency by optimizing BGP session management.
- **Flexibility and Scalability:** The feature provides the flexibility to apply SRv6 where it is needed while maintaining IP routing, allowing the network to scale efficiently.
- **Transition to New Technologies:** It facilitates a smoother transition to newer routing technologies like SRv6, which is designed to meet the demands of modern network applications and services.

These benefits contribute to a more robust, agile, and cost-effective network that can adapt to the changing needs of service providers and their customers.

Configure BGP Signaling over SRv6 Core

The purpose of this task is to enable SRv6 with BGP to support the co-existence of IP routes with or without SRv6 SID.

Follow these steps to configure BGP signaling over SRv6 Core.

Procedure

Step 1 Execute the **encapsulation-type srv6 relax-sid** command on neighbor to configure the neighbor.

Summary of this configuration: Set up BGP to use SRv6 for IPv4 unicast routes, with specific rules for SID allocation based on the destination prefixes. It also configures a BGP neighbor and specifies how SRv6 encapsulation should be handled for that neighbor.

Example:

```
Router(config)# route-policy alloc-sid-policy
Router(config-rpl)# if destination in prefix-set-1 then
Router(config-rpl-if)# set srv6-alloc-mode per-vrf locator LOC2
Router(config-rpl-if)# else if destination is prefix-set-2 then
Router(config-rpl-else)# drop
Router(config-rpl-if)# else
Router(config-rpl-else)# set srv6-alloc-mode per-vrf
Router(config-rpl-else)# endif
Router(config-rpl)# end-policy

Router(config)# router bgp 2
```

```

Router(config-bgp)# address-family ipv4 unicast
Router(config-bgp-af)# segment-routing srv6
Router(config-bgp-af-srv6)# locator LOC1
Router(config-bgp-af-srv6)# alloc mode route-policy alloc-sid-policy
Router(config-bgp-af-srv6)# exit
Router(config-bgp-af)# exit
Router(config-bgp)# neighbor 12:100::1
Router(config-bgp-nbr)# address-family ipv4 unicast
Router(config-bgp-nbr-af)# encapsulation-type srv6 relax-sid
Router(config-bgp-nbr-af)# exit
Router(config-bgp-nbr)# exit

```

Step 2 Execute the **encapsulation-type srv6 relax-sid** command on the neighbor group to configure the neighbor-group.

Example:

```

Router(config-bgp)# neighbor-group srv6-core-relax
Router(config-bgp-nbr)# address-family ipv4 unicast
Router(config-bgp-nbr-af)# encapsulation-type srv6 relax-sid
Router(config-bgp-nbr-af)# exit
Router(config-bgp-nbr)# exit
Router(config-bgp)# neighbor 12:100::1
Router(config-bgp-nbr)# remote-as 1
Router(config-bgp-nbr)# use neighbor-group srv6-core-relax
Router(config-bgp-nbr)# exit

```

Step 3 Execute the **encapsulation-type srv6 relax-sid** command, on the address family group to configure the Address- Family Group .

Example:

```

Router(config-bgp)# af-group srv6-core-af address-family ipv4 unicast
Router(config-bgp-nbr-af)# encapsulation-type srv6 relax-sid
Router(config-bgp-nbr)# exit
Router(config-bgp-nbr)# address-family ipv4 unicast
Router(config-bgp-nbr-af)# neighbor 12:100::1
Router(config-bgp-nbr-af)# remote-as 1
Router(config-bgp-nbr-af)# address-family ipv4 unicast
Router(config-bgp-nbr-af)# use af-group srv6-core-af
Router(config-bgp-nbr)# exit

```

Step 4 Run the show commands to verify the encapsulation type is updated to SRv6 Relax-SID in all neighbor sessions.

You can see that 192::4 has **encapsulation-type srv6 relax-sid** configured.

Example:

```

Router#show bgp neighbor 192::4
For Address Family: IPv4 Unicast
  BGP neighbor version 155
  Update group: 0.1 Filter-group: 0.3 No Refresh request being processed
  Encapsulation type SRv6 Relax-SID
  NEXT_HOP is always this router
  Default information originate: default sent
  AF-dependent capabilities:
    Graceful Restart capability advertised
      Local restart time is 120, RIB purge time is 600 seconds
      Maximum stalepath time is 360 seconds
    Graceful Restart capability received
      Remote Restart time is 120 seconds
  Neighbor preserved the forwarding state during latest restart

```

```

    Extended Nexthop Encoding: advertised and received
    Route refresh request: received 0, sent 0
    3 accepted prefixes, 3 are bestpaths
...

```

```

Router#show bgp update-group neighbor 192::4
Update group for IPv4 Unicast, index 0.1:
  Attributes:
    Neighbor sessions are IPv6
    Internal
    Common admin
    First neighbor AS: 100
    Send communities
    Send GSHUT community if originated
    Send extended communities
    Next-hop-self enabled
    4-byte AS capable
    Advertise routes with local-label via Unicast SAFI
    Send AIGP
    Encapsulation type SRv6 Relax-SID
    Send multicast attributes
    Extended Nexthop Encoding
    Minimum advertisement interval: 0 secs
  Update group desynchronized: 0
  Sub-groups merged: 0
  Number of refresh subgroups: 0
  Messages formatted: 7, replicated: 7
  All neighbor are assigned to sub-group(s)
    Neighbors in sub-group: 0.3, Filter-Groups num:1
    Neighbors in filter-group: 0.3(RT num: 0)
    192::4

```

In the following example, 158.158.58.1/32 is without SRv6 SID but advertised to 192::4 and 157.157.57.1/32 with SRv6 SID, which is also advertised to 192::4. To allow IP route without SRv6 SID, you must include it in **prefix-set-2**.

Example:

```

Router#show bgp 158.158.58.1/32
BGP routing table entry for 158.158.58.1/32

SRv6 Services: IPv4 L3VPN Active-Standby Redundancy using Port-Active Mode

The Segment Routing IPv6 (SRv6) Services: IPv4 L3VPN Active-Standby Redundancy using Port-Active Mode feature provides all-active per-port load balancing for multihoming. The forwarding of traffic is determined based on a specific interface rather than per-flow across multiple Provider Edge routers. This feature enables efficient load-balancing and provides faster convergence. In an active-standby scenario, the active PE router is detected using designated forwarder (DF) election by modulo calculation and the interface of the standby PE router brought down. For Modulo calculation, byte 10 of the Ethernet Segment Identifier (ESI) is used.

Usage Guidelines and Restrictions

- This feature can only be configured for bundle interfaces.
- When an EVPN Ethernet Segment (ES) is configured with port-active load-balancing mode, you cannot configure ACs of that bundle on bridge-domains with a configured EVPN instance (EVI). EVPN Layer 2 bridging service is not compatible with port-active load-balancing.

SRv6 Services for L3VPN Active-Standby Redundancy using Port-Active Mode: Operation

Under port-active operational mode, EVPN Ethernet Segment (ES) routes are exchanged across BGP for the routers servicing the multihomed ES. Each PE router then builds an ordered list of the IP addresses of all PEs connected to the ES, including itself, and assigns itself an ordinal for its position in the list. The ordinals are used with the modulo calculation to determine which PE will be the Designated Forwarder (DF) for a given ES. All non-DF PEs will take the respective bundles out of service.

In the case of link or port failure, the active DF PE withdraws its ES route. This re-triggers DF election for all PEs that service the ES and a new PE is elected as DF.

Configure SRv6 Services L3VPN Active-Standby Redundancy using Port-Active Mode

This section describes how you can configure SRv6 services L3VPN active-standby redundancy using port-active mode under an Ethernet Segment (ES).

Configuration Example

```
/* Configure Ethernet Link Bundles */
Router# configure
Router(config)# interface Bundle-Ether10
Router(config-if)# ipv4 address 10.0.0.2 255.255.255.0
Router(config-if)# ipv6 address 2001:DB8::1
Router(config-if)# lacp period short
Router(config-if)# mac-address 1.2.3
Router(config-if)# bundle wait-while 0
Router(config-if)# exit
Router(config)# interface GigabitEthernet 0/2/0/5
Router(config-if)# bundle id 14 mode active
Router(config-if)# commit

/* Configure load balancing. */
Router# configure
Router(config)# evpn
Router(config-evpn)# interface Bundle-Ether10
Router(config-evpn-ac)# ethernet-segment
Router(config-evpn-ac-es)# identifier type 0 11.11.11.11.11.11.11.14
Router(config-evpn-ac-es)# load-balancing-mode port-active
Router(config-evpn-ac-es)# commit
!

/* Configure address family session in BGP. */
Router# configure
Router(config)# router bgp 100
Router(config-bgp)# bgp router-id 192.168.0.2
Router(config-bgp)# address-family l2vpn evpn
Router(config-bgp)# neighbor 192.168.0.3
Router(config-bgp-nbr)# remote-as 200
Router(config-bgp-nbr)# update-source Loopback 0
Router(config-bgp-nbr)# address-family l2vpn evpn
Router(config-bgp-nbr)# commit
```

Running Configuration

```

interface Bundle-Ether14
  ipv4 address 14.0.0.2 255.255.255.0
  ipv6 address 14::2/64
  lacp period short
  mac-address 1.2.3
  bundle wait-while 0
!
interface GigabitEthernet0/2/0/5
  bundle id 14 mode active
!
evpn
  interface Bundle-Ether14
    ethernet-segment
      identifier type 0 11.11.11.11.11.11.11.14
      load-balancing-mode port-active
    !
  !
!
router bgp 100
  bgp router-id 192.168.0.2
  address-family l2vpn evpn
  !
  neighbor 192.168.0.3
    remote-as 100
    update-source Loopback0
    address-family l2vpn evpn
  !
!
!

```

Verification

Verify the SRv6 services L3VPN active-standby redundancy using port-active mode configuration.

```

/* Verify ethernet-segment details on active DF router */
Router# show evpn ethernet-segment interface Bundle-Ether14 detail

```

Ethernet Segment Id	Interface	Nexthops
0011.1111.1111.1111.1114	BE14	192.168.0.2 192.168.0.3

```

SRv6 Services: IPv4 L3VPN Active-Active Redundancy

This feature provides active-active connectivity to a CE device in a L3VPN deployment. The CE device can be Layer-2 or Layer-3 device connecting to the redundant PEs over a single LACP LAG port.

Depending on the bundle hashing, an ARP or IPv6 Network Discovery (ND) packet can be sent to any of the redundant routers. As a result, not all entries will exist on a given PE. In order to provide complete awareness, Layer-3 local route learning is augmented with remote route-synchronization programming.

Route synchronization between service PEs is required in order to provide minimum interruption to unicast and multicast services after failure on a redundant service PE. The following EVPN route-types are used for Layer-3 route synchronization:

- EVPN route-type 2 for synchronizing ARP tables
- EVPN route-type 7/8 for synchronizing IGMP JOINS/LEAVES

In a Layer-3 CE scenario, the router that connects to the redundant PEs may establish an IGP adjacency on the bundle port. In this case, the adjacency will be formed to one of the redundant PEs, and IGP customer routes will only be present on that PE. To synchronize Layer-3 customer subnet routes (IP Prefixes), the EVPN route-type 5 is used to carry the ESI and ETAG as well as the gateway address (prefix next-hop address).

Note Gratuitous ARP (GARP) or IPv6 Network Advertisement (NA) replay is not needed for CEs connected to the redundant PEs over a single LAG port.

The below configuration enables Layer-3 route synchronization for routes learned on the Ethernet-segment sub-interfaces.

```
evpn
  route-sync vrf default
  !
vrf RED
  evi route-sync 10
  !
vrf BLUE
  evi route-sync 20
  !
```

Note EVPN does not support untagged interfaces.

SRv6 Services: EVPN VPWS — All-Active Multi-Homing

Table 9: Feature History Table

Feature Name	Release	Description
SRv6 Services: EVPN VPWS — All-Active Multi-Homing (SRv6 Micro SID)	Release 7.3.2	<p>This feature provides an ELINE (P2P) service with all-active multihoming capability over an SRv6 network.</p> <p>All-Active Multi-Homing enables an operator to connect a customer edge (CE) device to two or more provider edge (PE) devices to provide load balancing and redundant connectivity. With All-Active Multi-Homing, all the PEs can forward traffic to and from the multi-homed device.</p>

EVPN VPWS All-Active Multi-Homing over SRv6 provides an ELINE (P2P) service with all-active multihoming capability over an SRv6 network.

All-Active Multi-Homing enables an operator to connect a customer edge (CE) device to two or more provider edge (PE) devices to provide load balancing and redundant connectivity. With All-Active Multi-Homing, all the PEs can forward traffic to and from the multi-homed device.

Note For information about EVPN VPWS, refer to the "EVPN Virtual Private Wire Service (VPWS)" chapter in the *L2VPN and Ethernet Services Configuration Guide for Cisco NCS 5500 Series Routers*.

Configuring EVPN VPWS over SRv6

Note Complete the steps in [Configuring SRv6, on page 27](#) before performing these steps.

An SRv6 Locator for an EVPN VPWS service can be configured at 3 different levels independently:

- `global_locator` is the default locator for all EVPN-VPWS services
- `evi_locator` is applied to all EVPN-VPWS services for the specific EVI
- `evi_service_locator` is applied to an individual EVI service

When locators are configured at different levels at the same time, the following priority is implemented:

1. `evi_service_locator`
2. `evi_locator`
3. `global_locator`

This example shows how to configure an EVPN VPWS over SRv6 using a global locator for EVPN:

```
evpn
 segment-routing srv6
  locator sample_global_loc

l2vpn
 xconnect group sample_xcg
  p2p sample-vpws-12001-2002
    interface Bundle-Ether12001.2002
  neighbor evpn evi 12001 service 2002 segment-routing srv6
```

This example shows how to configure EVPN VPWS over SRv6 using specific EVI locator:

```
evpn
 evi 11001 segment-routing srv6
  locator sample_evi_loc

l2vpn
 xconnect group sample_xcg
  p2p sample-vpws-11001-2002
    interface Bundle-Ether11001.2002
  neighbor evpn evi 11001 service 2002 segment-routing srv6
```

This example shows how to configure an EVPN VPWS over SRv6 using a locator for an individual EVI service:

```
l2vpn
 xconnect group sample_xcg
  p2p sample-vpws-11001-2001
    interface Bundle-Ether11001.2001
  neighbor evpn evi 11001 service 2001 segment-routing srv6
    locator sample_evi_service_loc
```

Feature Name	Release Information	Feature Description
SRv6-Services: EVPN ELAN Layer 2 Gateway With Automated Steering To Flexible Algorithm Paths	Release 7.5.2	<p>This feature builds upon EVPN BGP signaling to provide Emulated Local Area Network (ELAN) multipoint-to-multipoint Ethernet services over an SRv6-based network.</p> <p>You can enable automated steering of EVPN ELAN traffic into the path associated with a best-effort or Flex- Algorithm locator.</p> <p>This feature combines the benefits of EVPN ELAN service and SRv6 Micro-SIDs.</p> <p>For this feature, the segment-routing srv6 option was added to the evi command:</p> <p>evi (bridge-domain)</p>

You can transport EVPN ELAN bridged unicast and broadcast, unknown unicast, and multicast (BUM) traffic over an SRv6 network in the Micro-SID format. Relevant SRv6 headend and endpoint definitions are noted below:

- **H.Encaps.L2.Red**: This headend router operation involves reduced encapsulation of Layer 2 or Ether frames using an SRv6 Policy.
- **uDT2U**: This endpoint router operation involves traffic decapsulation and unicast MAC L2 table lookup. This is used for the EVPN bridging unicast traffic use case.
- **uDT2M**: This endpoint router operation involves traffic decapsulation and L2 table flooding. This is used for the EVPN bridging BUM traffic with ESI filtering use case.

Note For more information on SRv6 headend and endpoint behaviors, refer to Segment Routing over IPv6 Overview.

The following topology is used to explain this feature.

Topology pointers:

- Customer edge (CE) devices send traffic between each other over the SRv6 network. The CE devices are CE-A, CE-B, and CE-C.
- The SRv6 network devices transport customer traffic, and they are R1, R2 .. till R8.
- The provider edge (PE) devices, R1, R3 and R8, are displayed in green. The SRv6 EVPN configurations must be enabled on the PE devices since they participate in the EVPN EVI.

This is a high-level overview of the traffic flow from CE-A to CE-C:

1. CE-A sets the source and destination addresses of the L2 frame and sends it to the connected PE device, R1.
2. R1 looks up the destination MAC address in the frame. Based on its forwarding table, R1 performs an H.Encaps.L2.Red operation and adds the destination DT2U SRv6 SID (say, fccc:ccc1:a1:e000::) to the packet.
3. From R1, traffic is sent over the SRv6 network to destination PE device R8.
4. When R8 receives the traffic, it performs the uDT2U function - It decapsulates the packet, performs a destination MAC address lookup in its forwarding table, and sends the frame through the local interface to CE-C.

Guidelines and Limitations

- For transporting BUM traffic, the BGP Route Reflector device should have an IOS XR release version 7.5.2 or later.

Configure SRv6 EVPN Bridging

Enable the following configurations on the PE routers R1, R3 and R8 since they participate in the EVPN EVI.

Note Complete the steps in Segment Routing over IPv6 Overview before performing these steps.

Associate SRv6 with EVPN

```
Router# configure terminal
Router(config)# evpn
```

Enable SRv6 under the EVPN mode and associate a global locator (**sample**, in this case) with EVPN.

```
Router(config-evpn)# segment-routing srv6
Router(config-evpn-srv6)# locator sample
Router(config-evpn-srv6)# exit
```

Associate an EVI-specific locator (**sample_evi_loc**) with EVI 1.

```
Router(config-evpn)# evi 1 segment-routing srv6
Router(config-evpn-instance)# locator sample_evi_loc
Router(config-evpn-instance)# commit
```

Associate SRv6 with L2VPN

Associate the sub-interface to the bridge domain:

```
Router(config)# l2vpn
Router(config-l2vpn)# bridge group bg1
Router(config-l2vpn-bg)# bridge-domain bd1
Router(config-l2vpn-bg-bd)# interface Hu0/0/0/0.1
Router(config-l2vpn-bg-bd-ac)# exit
```

Enable the **evi 1 segment-routing srv6** command under L2VPN bridge domain **bd1**.

```
Router(config-l2vpn-bg-bd)# evi 1 segment-routing srv6
Router(config-l2vpn-bg-bd-evi-srv6)# commit
```

Verification

In this sample output, SRv6 EVPN ELAN traffic unicast and multicast SID information is displayed.

```
Router# show evpn evi vpn-id 1 detail
```

VPN-ID	Encap	Bridge Domain	Type
1	SRv6	bd1	EVPN

```
..
    Stitching: Regular
    Unicast SID: fccc:cccl:a1:e000::
    Multicast SID: fccc:cccl:a1:e001::
..
```

In this sample output, EVI 1 details, including the corresponding SID and EVPN MAC address details are displayed.

```
Router# show evpn evi vpn-id 1 mac
```

VPN-ID	Encap	MAC address	IP address	Nexthop	Label	SID
1	SRv6	0010.3000.01d0	::	Hu0/0/0/0.1	0	fccc:cccl:a1:e000::

In this sample output, for the specified EVI and EVPN MAC address, SRv6 EVPN ELAN traffic details are displayed.

```
Router# show evpn evi vpn-id 1 mac 0010.3000.01d0 detail
```

VPN-ID	Encap	MAC	IP	Nexthop	Label	SID
--------	-------	-----	----	---------	-------	-----

```

      Source: Local
      E-Tree: Root
..

```

In this sample output, for the specified MAC address, bridge domain information is displayed.

```
Router# show l2route evpn mac all | i ee03.0500.0130
```

```

Topo ID      Mac Address      Producer      Next Hop(s)
-----      -
1          ee03.0500.0130      L2VPN        ::ffff:10.0.0.10/IID/v6, N/A

```

In this sample output, SRv6 network locator and corresponding SID information are displayed.

uDT2U and **uDT2M** refer to SRv6 network endpoint operations. **uDT2U** indicates SRv6 traffic decapsulation, wherein EVPN bridged unicast traffic is forwarded out of the SR network. **uDT2M** indicates SRv6 traffic decapsulation, wherein EVPN bridged multicast traffic is forwarded out of the SR network.

```
Router# show segment-routing srv6 sid
```

```
*** Locator: 'sample_evi_loc' ***
```

```

SID          Behavior      Context      Owner      State      RW

SRv6 ESI Filtering

Table 11: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 ESI Filtering	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards)</p> <p>Split Horizon Group (SHG) labels and Ethernet Segment Identifier (ESI) filtering functionalities exist on MPLS underlay networks.</p> <p>This feature introduces ESI filtering functionality to SRv6 underlay networks, using the End.DT2M SRv6 endpoint behavior. This behavior uses the "Arg.FE2" argument for SRv6, which is similar to the SHG label for MPLS.</p> <p>This feature allows nodes to identify BUM traffic based on the advertised ESI and prevent a loop by avoiding re-broadcasting the same traffic back towards the access node.</p> <p>This functionality is enabled by default.</p>

Consider the below network topology where CE1 is attached to PE1 and PE2.

When broadcast, unknown unicast, and multicast (BUM) traffic is received by PE1 from CE1, PE1 floods this traffic on the core network. This results in a copy of the BUM traffic being sent to PE2. PE2 in turn floods it to the core and access network, and the BUM traffic would be received at CE1. This is undesirable as we are flooding the same traffic to the source from which it originated, thus causing a loop.

SRv6 ESI Filtering

A unique 16-bit ID is generated by all nodes in an Ethernet Segment and is transmitted to all nodes in the same EVPN instance via ES/EAD Route Type 1 NLRI (see ["EVPN Route Types"](#) for description of Route Type 1: Ethernet Auto-Discovery (AD) Route). This unique label functions in a similar way as the Split

Horizon group label (SHG label). Ethernet Segment Identifier (ESI) filtering is the mechanism that controls which nodes to re-broadcast BUM traffic.

Note For more information, see “[Split Horizon Groups](#)” in the *L2VPN and Ethernet Services Configuration Guide*.

When PE1 receives BUM traffic from an attachment circuit (AC), it floods the traffic to all nodes in its core network, where PE2 is also member node. The traffic flooded to PE2 is sent with its previously advertised ID. When PE2 decodes the packet and examines the label, it recognizes this to be the label that it had generated. In this mechanism, PE2 will not flood the BUM traffic back towards the access. PE2 has successfully prevented a loop by avoiding re-broadcasting the same traffic back towards the source (CE1).

This feature introduces ESI filtering to SRv6 underlay networks, using the End.DT2M SRv6 endpoint behavior. This behavior uses the "Arg.FE2" argument, as defined in [IETF RFC 8986 SRv6 Network Programming](#) and [IETF draft SRv6 Argument Signaling for BGP Services](#). This argument provides a local mapping to ESI for split-horizon filtering of the received traffic to exclude a specific outgoing L2 interface (OIF), or a set of OIFs, from L2 table T flooding. The allocation of the argument values is local to the SR Segment Endpoint Node instantiating this behavior, and the signaling of the argument to other nodes for the EVPN functionality occurs via the control plane.

Usage Guidelines and Limitations

This feature is supported on NCS 5500 Series routers.

This feature is not supported on NCS 5700 Series routers or NC57 line cards.

Verification

The output of the **show evpn ethernet-segment interface** *interface-name* now displays both the SHG label information for MPLS EVPN instances (EVIs) and the Arg.FE2 information for SRv6 EVIs:

```
Router# show evpn ethernet-segment interface Bundle-Ether 1

Ethernet Segment Id      Interface                               Nexthops
-----

                                                                    192.168.0.3
. . .

Peering timer : 3 sec [not running]
Recovery timer : 30 sec [not running]
Local SHG label : 34251
Remote SHG labels : 2
38216 : nexthop 192.168.0.1
Arg.FE2 1:16 : nexthop 192.168.0.2
```

SRv6 Services: L3 EVPN

EVPN Route Type 5 (RT5) is used for the advertisement of EVPN routes using IP prefixes (refer to [IETF RFC 9136 - IP Prefix Advertisement in Ethernet VPN \(EVPN\)](#)) to provide end-to-end L3 connectivity

This feature adds support for carrying L3VPN routes in L2VPN EVPN EVPN RT5 address family instead of VPNv4 unicast and/or VPNv6 unicast address-family across SRv6 core (EVPN over SRv6 underlay).

Usage Guidelines and Limitations

BGP does not support dual VPNv4/v6 address family and EVPN RT5 address family on the same BGP session. For the route reflector (RR) to receive both Type-5 EVPN route and VPNv4/v6 address family, we recommend that you configure two pairs of loopback interfaces and configure two BGP loopback sessions between the RR and the PE: one session for VPNv4/v6 address family and one session for EVPN address family.

BGP sends all VRF routes via either VPNv4/v6 or EVPN address family. We recommend that you mark the VRF route via export route-policy and use neighbor out policy to either drop or pass the route for an address family to achieve the same net effect.

The following behaviors are supported:

- IPv4, IPv6, and IPv4/IPv6 (dual stack) L3 EVPN over SRv6
- uDT4
- uDT6
- uDT46
- Automated Steering to Flex-Algo (BGP per-VRF locator Flex-Algo (per-prefix))
- Automated Steering to SRv6 Policy (ODN/AS)

Configuring SRv6-based L3 EVPN

To enable SRv6-based L3 EVPN, you must enable SRv6 under BGP, specify the locator, and configure the SID allocation mode. The assignment of the locator can be done in multiple ways under the **router bgp** configuration. See [SRv6 Locator Inheritance Rules](#).

Figure 9: Configuration Example: Dual Stack L3 EVPN over SRv6

Configure the VRF (Dual-Stack IPv4/IPv6)

```
Router(config)# vrf VPN1
Router(config-vrf)# address-family ipv4 unicast
Router(config-vrf-af)# import route-target
Router(config-vrf-import-rt)# 1:1
Router(config-vrf-import-rt)# exit
Router(config-vrf-af)# export route-target
Router(config-vrf-export-rt)# 1:1
Router(config-vrf-export-rt)# exit
Router(config-vrf)# address-family ipv6 unicast
```

```

Router(config-vrf-af) # import route-target
Router(config-vrf-import-rt) # 1:1
Router(config-vrf-import-rt) # exit
Router(config-vrf-af) # export route-target
Router(config-vrf-export-rt) # 1:1
Router(config-vrf-export-rt) # exit
Router(config-vrf-af) #

```

Configure the SRv6 Locator for an Individual VRF, with Per-VRF Label Allocation Mode

```

Router(config) # router bgp 100
Router(config-bgp) # address-family vpnv4 unicast

SRv6 Services: L2 and L3 Services with Remote SIDs from W-LIB

Table 12: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 Services: L2 and L3 Services with Remote SIDs from Wide Local ID Block	Release 7.9.1	<p>This feature enables an SRv6 headend node to receive and install remote SIDs with Wide (32-bit) functions (Remote W-LIB).</p> <p>The Remote W-LIB is supported for Layer 3 (VPN/BGP global) and Layer 2 EVPN services (ELINE/ELAN).</p> <p>This capability is enabled by default.</p>

This capability is enabled by default; there is no CLI to configure this capability at the ingress PE.

An SRv6 Service SID is used to identify a specific service function. This Service SID inserted into the packet header by the source node is used to steer the packet along a specific path that includes the service function.

The Service SID signaled by transposing a variable part of the SRv6 SID value (function, argument, or both) and carrying them in the existing label fields to achieve more efficient compression of those service prefix NLRIs in BGP update messages. The SRv6 SID Structure Sub-Sub-TLV (SSTLV) contains appropriate length fields when the SRv6 Service SID is signaled in split parts to enable the receiver to put together the SID accurately.

The Transposition Offset indicates the bit position. The Transposition Length indicates the number of bits that are being taken out of the SRv6 SID value and put into high order bits of label field.

For example, a remote W-LIB uSID **fcbb:bb00:0200:fff0:0001::** with a SRv6 SID SSTLV of **BL=32; NL=16; FL=32; AL=0, TPOS len/offset=16/64** is defined as follows:

- Block length (BL) of 32 bits = fcbb:bb00
- Node length (NL) of 16 bits = 0200
- Function length (FL) of 32 bits = fff0:0001
- Argument length (AL) of 0
- Transposition length (TPOS len) of 16 bits = 0001
- Transposition offset (TPOS offset) of 64 bits = fcbb:bb00:0200:fff0:

This results in a SID value of **fcbb:bb00:0200:fff0::** and Label value of **0x0001**.

Example

The following example shows output of a BGP route table for a VPNv4 prefix learned from three egress PEs:

- BGP Path 1 from next-hop 7::1 and a 32-bit uDT4 function (0xfff0 4002) allocated from W-LIB

- BGP Path 2 from next-hop 9::1 and a 16-bit uDT4 function (0x4002) allocated from LIB
- BGP Path 3 from next-hop 8::1 and a 16-bit uDT4 function (0x4002) allocated from LIB

Note the following fields in the output:

- Function length of 16 bits for LIB and 32 bits for W-LIB
- Transposition offset value of 48 bits for LIB and 64 bits for W-LIB
- Transposition length value of 16 bits for LIB/W-LIB

```

SRv6-Services: L3 Services with Local SIDs from W-LIB

Table 13: Feature History Table

Feature Name	Release	Description
SRv6-Services: L3 Services with Local SIDs from W-LIB	Release 7.11.1	<p>Introduced in this release on: NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5700 line cards [Mode: Native])</p> <p>This feature enables an SRv6 headend node to allocate and advertise local SIDs with Wide (32-bit) functions (Local W-LIB).</p> <p>The headend router utilizes the local W-LIB functionality to define and implement SR policies using SRv6 SIDs.</p> <p>The Local W-LIB is supported for Layer 3 (VPNv4/VPNv6/BGPv4/BGPv6 global) services.</p> <p>This feature introduces the usid allocation wide-local-id-block command.</p>

An SRv6 Service SID is used to identify a specific service function. This Service SID inserted into the packet header by the source node is used to steer the packet along a specific path that includes the service function. This capability enhances flexibility and control over how packets are processed and enables efficient delivery of services within the network.

Note See [SRv6 uSID Allocation Within a uSID Block](#) for more information about W-LIB.

By default, BGP specifies to SID-Manager that allocation of uSIDs is from LIB space only. With this feature enabled, BGP can indicate to the SID-Manager that uSID allocation is to be enforced from W-LIB.

BGP performs transposition when encoding the service SID for VPN services to the label part of the NLRI, as described in IETF [RFC 9252](#). In the current LIB implementation, BGP transposes the 16-bit function to the label field in the NLRI.

For W-LIB, BGP transposes the last 16-bits of the W-LIB 32-bit function to the label part of the NLRI for VPNv4 and VPNv6 routes. For more information on transposition, see the [SRv6 Services: L2 and L3 Services with Remote SIDs from W-LIB](#) section.

Note There is no transposition for BGPv4/BGPv6 global routing table.

Usage Guidelines and Limitations

This feature is supported on NCS 5700 Series routers or NC57 line cards.

This feature is not supported on NCS 5500 Series routers.

Configuration

Use the **usid allocation wide-local-id-block** command to enable the allocation and advertisement of an SRv6 Service SID with wide function (W-LIB) for L3 services.

The precedence rules for the W-LIB allocation mode are applied at different levels:

- W-LIB uSID Allocation Applied Globally under BGP:

```
router bgp 1
  segment-routing srv6
    usid allocation wide-local-id-block
  !
```

- W-LIB uSID Allocation Applied at the IPv4/v6 Address Family under BGP:

```
router bgp 1
  address-family ipv4 unicast
    segment-routing srv6
      usid allocation wide-local-id-block
  !
  address-family ipv6 unicast
    segment-routing srv6
      usid allocation wide-local-id-block
```

- W-LIB uSID Allocation Applied for all VPNv4/v6 Address Family:

```
router bgp 1
  address-family vpnv4 unicast
    vrf all
      segment-routing srv6
        usid allocation wide-local-id-block
  !
  address-family vpnv6 unicast
    vrf all
      segment-routing srv6
        usid allocation wide-local-id-block
```

- W-LIB uSID Allocation Applied at the VRF IPv4/v6 Address Family:

```
router bgp 1
  vrf foo
    address-family ipv4 unicast
      segment-routing srv6
        usid allocation wide-local-id-block
```

```

!
address-family ipv6 unicast
segment-routing srv6
    usid allocation wide-local-id-block

```

Verification

The following output shows the W-LIB uSID allocation:

```
RP/0/0/CPU0:PE1# show bgp ipv4 unicast process
```

```

SRv6/MPLS L3 Service Interworking Gateway

Table 14: Feature History Table

Feature Name	Release	Description
Identical Route Distinguisher (RD) for Interworking Gateways between MPLS and SRv6 Domains	Release 24.1.1	<p>Introduced in the release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native]).</p> <p>You can now configure the same Route Distinguisher (RD) for interworking gateways catering to both MPLS and SRv6 domains that help conserve hardware resources, reduce the BGP table scale and minimize the processing load on routers. At the same time, it ensures seamless connectivity across SRv6 and MPLS L3 EVPN domains, thus promoting interoperability and efficiency in modern network environments.</p> <p>Previously, a unique RD was required to extend L3 services between MPLS and SRv6 domains resulting in higher router load and resource consumption, which could have affected performance.</p>
SRv6/MPLS L3 Service Interworking Gateway (SRv6 Micro-SID)	Release 7.3.2	<p>This feature enables you to extend L3 services between MPLS and SRv6 domains by providing service continuity on the control plane and data plane.</p> <p>This feature allows for SRv6 L3VPN domains to interwork with existing MPLS L3VPN domains. The feature also allows a way to migrate from MPLS L3VPN to SRv6 L3VPN.</p>

SRv6/MPLS L3 Service Interworking Gateway enables you to extend L3 services between MPLS and SRv6 domains by providing service continuity on the control plane and data plane.

This feature allows for SRv6 L3VPN domains to interwork with existing MPLS L3VPN domains. The feature also allows a way to migrate from MPLS L3VPN to SRv6 L3VPN.

The SRv6/MPLS L3 Service Interworking Gateway provides both transport and service termination at the gateway node. The gateway generates both SRv6 VPN SIDs and MPLS VPN labels for all prefixes under the VRF configured for re-origination. The gateway supports traffic forwarding from MPLS domain to SRv6 domain by popping the MPLS VPN label, looking up the destination prefix, and pushing the appropriate SRv6 encapsulation. From SRv6 domain to MPLS domain, the gateway removes the outer IPv6 header, looks up the destination prefix, and pushes the VPN and next-hop MPLS labels.

VRFs on the gateway node are configured with 2 sets of route targets (RTs):

- MPLS L3VPN RTs
- SRv6 L3VPN RTs (called *stitching RTs*)

The gateway performs the following actions:

- Imports service routes received from one domain (MPLS or SRv6)
- Re-advertises exported service routes to the other domain (next-hop-self)
- Stitches the service on the data plane (uDT4/H.Encaps.Red ↔ service label)

SRv6/MPLS L3 Service Interworking Gateway Scenarios

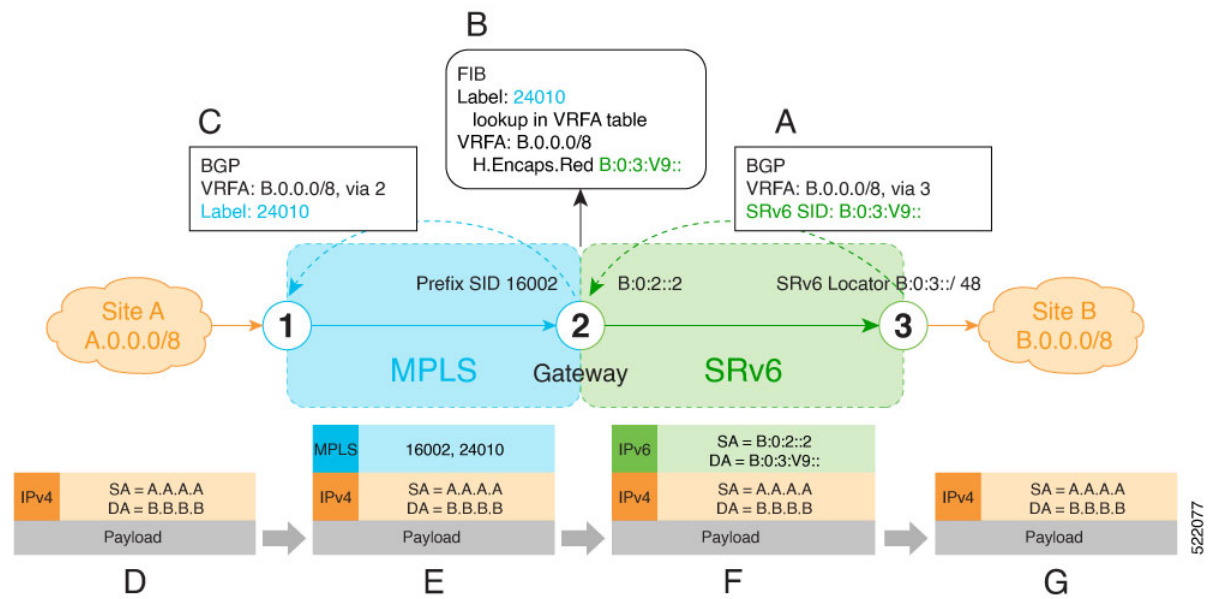

The following scenario is used to describe the gateway functionality:

- Node 1 is an L3VPN PE in the MPLS domain with an SR prefix SID label of 16001 for its Loopback interface 10.1.1.1/32.
- Node 2 is the SRv6/MPLS L3 Service Interworking Gateway. In the MPLS domain, it has an SR prefix SID label of 16002 for its Loopback interface 10.1.1.2/32. In the SRv6 domain, it has an SRv6 locator of B:0:2::/48 and Loopback interface B:0:2::2/128.
- Node 3 is an L3VPN PE in the SRv6 domain with SRv6 locator of B:0:3::/48 and Loopback interface B:0:3::3/128.

Scenario 1: SRv6-to-MPLS Control-Plane Direction/MPLS-to-SRv6 Data-Plane Direction

The figure below describes the associated control-plane behaviors in the SRv6-to-MPLS direction for traffic in the MPLS-to-SRv6 data-plane direction.

A. Node 3 advertises a BGP L3VPN update for prefix B.0.0.0/8 with RD corresponding to VRFA, including the SRv6 VPN SID (B:0:3:V9::) assigned to this VRF, in the SRv6 domain.

Note SRv6 uDT4 function value "V9" is not a valid hex number, however it is used for illustration purposes to remind you of its connection to a VRF.

B. Node 2 (gateway) imports the BGP L3VPN update and programs its FIB:

- MPLS label 24010 is allocated for VRFA
- Prefix B.0.0.0/8 is programmed with an "SR Headend Behavior with Reduced Encapsulation in an SR Policy" function (H.Encaps.Red) of B:0:3:V9::

Note The gateway follows per-VRF label and per-VRF SID allocation methods.

C. Node 2 re-originates a BGP L3VPN update for the same prefix, including the MPLS VPN label (24010) allocated for the VRF, in the MPLS domain.

D. Site A sends traffic to an IPv4 prefix (B.B.B.B) of Site B

E. Node 1 encapsulates incoming traffic with the MPLS VPN label (24010) and the prefix SID MPLS label (16002) of the BGP next-hop (Node 2).

F. Node 2 performs the following actions:

- Pops the MPLS VPN label and looks up the destination prefix
- Encapsulates the payload in an outer IPv6 header with destination address (DA) equal to the H.Encaps.Red function (B:0:3:V9::)

G. Node 3 removes the outer IPv6 header, looks up the payload destination address (B.B.B.B), and forwards to Site B.

Scenario 2: MPLS-to-SRv6 Control-Plane Direction/SRv6-to-MPLS Data-Plane Direction

The figure below describes the associated control-plane behaviors in the MPLS-to-SRv6 direction for traffic in the SRv6-to-MPLS data-plane direction.

A. Node 1 advertises a BGP L3VPN update for prefix A.0.0.0/8 with RD corresponding to VRFA, including the MPLS VPN label (24055) assigned to this VRF, in the MPLS domain.

B. Node 2 (gateway) imports the BGP L3VPN update and programs its FIB:

- Prefix A.0.0.0/8 is programmed to impose an MPLS VPN label (24055) and the prefix SID MPLS label (16001) of the BGP next-hop (Node 1)
- "Endpoint with decapsulation and IPv4 table lookup" function (uDT4) of B:0:2:V8:: is allocated to VRFA

Note SRv6 uDT4 function value "V8" is not a valid hex number, however it is used for illustration purposes to remind you of its connection to a VRF.

Note The gateway follows per-VRF label and per-VRF SID allocation methods.

C. Node 2 re-originates a BGP L3VPN update for the same prefix, including the uDT4 function (B:0:2:V8::) allocated for the VRF, in the SRv6 domain.

D. Site B sends traffic to an IPv4 prefix (A.A.A.A) of Site A.

E. Node 3 Encapsulates the payload in an outer IPv6 header with destination address (DA) equal to the uDT4 function (B:0:2:V8::).

F. Node 2 performs the following actions:

- Removes the outer IPv6 header and looks up the destination prefix
- Pushes the MPLS VPN label (24055) and the prefix SID MPLS label (16001) of the BGP next-hop (Node 1)

G. Node 1 pops the MPLS VPN label, looks up the payload destination address (A.A.A.A), and forwards to Site A.

Example

Leveraging the topology described in the above use-case, this example shows the SRv6/MPLS L3 Service Interworking Gateway configuration required at Node 2.

The following configuration shows how to enable SRv6 with locator and configure encapsulation parameters:

```
segment-routing
  srv6
    encapsulation
      source-address B:0:2::2
    !
    locators
      locator LOC1
        prefix B:0:2::/48
      !
    !
  !
```

The following configuration shows how to configure a VPNv4 VRF with the following route targets (RTs):

- 1111:1, RT used for MPLS L3VPN
- 2222:1, RT used for SRv6 L3VPN (stitching RT)

```
vrf ACME
  address-family ipv4 unicast
    import route-target
      1111:1
      2222:1 stitching
    !
    export route-target
      1111:1
      2222:1 stitching
    !
  !
```

The following configuration shows how to configure SRv6/SRv6 VPNs under BGP:

```
router bgp 100
  segment-routing srv6
    locator LOC1
  !
  neighbor 10.1.1.1
    address-family vpnv4 unicast
      import re-originate stitching-rt
      route-reflector-client
      advertise vpnv4 unicast re-originated
    !
  neighbor B:0:3::1
    address-family vpnv4 unicast
```

```

import stitching-rt re-originate
route-reflector-client
encapsulation-type srv6
advertise vpnv4 unicast re-originated stitching-rt
!
vrf ACME
address-family ipv4 unicast
enable label-mode
segment-routing srv6

```

You can configure same route distinguisher (RD) on the Node 1, Node 2 and GW. This example shows how to configure same route distinguisher (RD) on the Node 1, Node 2 and GW. In this example, **rd 5000:2** is used on Node 1, Node 2 and GW.

```

/* Configuration on Node 1*/
vrf ACMErd 5000:2
address-family ipv4 unicast
import route-target
1111:1
!
export route-target
1111:1
!
!
!

/* Configuration on Node 2*/
vrf ACMErd 5000:2
address-family ipv4 unicast
import route-target
2222:1
!
export route-target
2222:1
!
!
!

/* Configuration on GW*/
vrf ACMErd 5000:2
address-family ipv4 unicast
import route-target
1111:1
2222:1 stitching
!
export route-target
1111:1
2222:1 stitching
!
!
!

```

L3 EVPN/SRv6 and L3 EVPN/MPLS Interworking Gateway

This feature adds support for L3 EVPN interworking between SRv6 and MPLS.

L3 EVPN/SRv6 and L3 EVPN/MPLS Interworking Gateway enables you to extend L3 EVPN services between MPLS and SRv6 domains by providing service continuity on the control plane and data plane.

This feature allows for SRv6 L3 EVPN domains to interwork with existing MPLS L3 EVPN domains. The feature also allows a way to migrate from MPLS L3 EVPN to SRv6 L3 EVPN.

The L3 EVPN/SRv6 and L3 EVPN/MPLS Interworking Gateway provides both transport and service termination at the gateway node.

VRFs on the gateway node are configured with 2 sets of route targets (RTs):

- L3 EVPN/MPLS RTs
- L3 EVPN/SRv6 RTs (called *stitching RTs*)

The gateway performs the following actions:

- Imports service routes received from one domain (L3 EVPN/MPLS or L3 EVPN/SRv6)
- Re-originates exported service routes to the other domain and setting next-hop-self
- Stitches the service routes in the data plane (uDT4/H.Encaps.Red ↔ MPLS service label)

The gateway generates both L3 EVPN/SRv6 SIDs and L3 EVPN/MPLS labels for all prefixes under the VRF configured for re-origination:

- MPLS-to-SRv6 Control Plane Direction

The gateway imports routes received from the MPLS side (via EVPN RT5) and re-originates them in L3VPN VRF with a per-VRF SRv6 SID.

- SRv6-to-MPLS Control Plane Direction

The gateway imports routes received from the SRv6 side (via EVPN RT5) and re-originates them in L3VPN VRF with a per-VRF label.

In the data plane, the gateway forwards traffic from the MPLS domain to the SRv6 domain by popping the MPLS L3 EVPN label, looking up the destination prefix, and pushing the appropriate SRv6 encapsulation. In the opposite direction, the gateway removes the outer IPv6 header, looks up the destination prefix, and pushes the L3 EVPN and next-hop MPLS labels.

Usage Guidelines and Limitations

L3 EVPN/SRv6 and L3 EVPN/MPLS Interworking Gateway is supported for IPv4 and IPv6.

Configuration Example

Leveraging the topology described above, this example shows the SRv6/MPLS L3 EVPN Service Interworking Gateway configuration required at Node 2.

The following configuration shows how to enable SRv6 with locator and configure encapsulation parameters.

```
segment-routing
srv6
  encapsulation
    source-address b:0:2::2
  !
  locators
    locator LOC1
    prefix b:0:2::/48
  !
!
!
!
```

The following configuration shows how to configure a VPNv4/VPNv6 VRF with the following route targets (RTs):

- 1111:1, RT used for MPLS L3 EVPN
- 2222:1, RT used for SRv6 L3 EVPN (stitching RT)

```
vrf VPN1
address-family ipv4 unicast
  import route-target
    1111:1
    2222:1 stitching
  !
  export route-target
    1111:1
    2222:1 stitching
  !
!
address-family ipv6 unicast
  import route-target
    1111:1
    2222:1 stitching
  !
  export route-target
    1111:1
    2222:1 stitching
  !
!
!
```

The following configuration shows how to configure SRv6/SRv6 VPNs under BGP:

```
router bgp 100
segment-routing srv6
  locator LOC1
!
address-family vpnv4 unicast
!
address-family vpnv6 unicast

L3 EVPN/SRv6 and L3VPN/MPLS Interworking Gateway

This feature adds support for EVPN L3VPN interworking between SRv6 and MPLS.

L3 EVPN/SRv6 and L3VPN/MPLS Interworking Gateway enables you to extend L3 services between MPLS and SRv6 domains by providing service continuity on the control plane and data plane.

This feature allows for SRv6 L3 EVPN domains to interwork with existing MPLS L3VPN domains. The feature also allows a way to migrate from MPLS L3VPN to SRv6 L3 EVPN.

The L3 EVPN/SRv6 and L3VPN/MPLS Interworking Gateway provides both transport and service termination at the gateway node.

VRFs on the gateway node are configured with 2 sets of route targets (RTs):

- L3VPN/MPLS RTs
- L3 EVPN/SRv6 RTs (called *stitching RTs*)

The gateway performs the following actions:

- Imports service routes received from one domain (L3VPN/MPLS or L3 EVPN/SRv6)
- Re-originate exported service routes to the other domain and setting next-hop-self
- Stitches the service routes in the data plane (uDT4/H.Encaps.Red ↔ MPLS service label)

The gateway generates both L3 EVPN/SRv6 SIDs and L3VPN/MPLS labels for all prefixes under the VRF configured for re-origination:

- MPLS to SRv6 Control Plane Direction

The gateway imports routes received from the MPLS side (via EVPN RT5) and re-originate them in L3 EVPN VRF with a per-VRF SRv6 SID.

- SRv6 to MPLS Control Plane Direction

The gateway imports routes received from the SRv6 side (via EVPN RT5) and re-originate them in L3VPN VRF with a per-VRF label.

In the data plane, the gateway forwards traffic from the MPLS domain to the SRv6 domain by popping the MPLS L3VPN label, looking up the destination prefix, and pushing the appropriate SRv6 encapsulation. In the opposite direction, the gateway removes the outer IPv6 header, looks up the destination prefix, and pushes the L3VPN and next-hop MPLS labels.

Usage Guidelines and Limitations

L3 EVPN/SRv6 and L3 EVPN/MPLS Interworking Gateway is supported for IPv4 and IPv6.

Configuration Example

The following configuration shows how to enable SRv6 with locator and configure encapsulation parameters:

```
segment-routing
  srv6
    encapsulation
      source-address b:0:2::2
    !
  locators
    locator LOC1
      prefix b:0:2::/48
    !
  !
!
```

The following configuration shows how to configure a VPNv4/VPNv6 VRF with the following route targets (RTs):

- **1111:1**, RT used for MPLS L3 EVPN
- **2222:1**, RT used for SRv6 L3 EVPN (stitching RT)

```

vrf VPN1
 address-family ipv4 unicast
  import route-target
    1111:1
    2222:1 stitching
  !
 export route-target
  1111:1
  2222:1 stitching
  !
 !
 address-family ipv6 unicast
  import route-target
    1111:1
    2222:1 stitching
  !
 export route-target
  1111:1
  2222:1 stitching
  !
 !
 !

```

The following configuration shows how to configure SRv6/SRv6 VPNs under BGP:

```

router bgp 100
 segment-routing srv6
  locator LOC1
  !
 address-family vpnv4 unicast
  !
 address-family vpnv6 unicast
  !
 address-family l2vpn evpn
  !
 neighbor 2222::2
  remote-as 100
  description SRv6 side peering

SRv6/MPLS Dual-Connected PE

Table 15: Feature History Table

Feature Name	Release	Description
SRv6/MPLS Dual-Connected PE (SRv6 Micro SID)	Release 7.3.2	This feature allows a PE router to support IPv4 L3VPN services for a given VRF with both MPLS and SRv6. This is MPLS and SRv6 L3VPNv4 co-existence scenario and is sometimes referred to as dual-connected PE.

A PE router can support IPv4 L3VPN service for a given VRF with both MPLS and SRv6. This is MPLS and SRv6 L3VPNv4 co-existence scenario and is sometimes referred to as dual-connected PE.

In the figure below, node 2 is a dual-connected PE to Site C, providing:

- MPLS/IPv4 L3VPN between Site A and Site C
- SRv6/IPv4 L3VPN between Site B and Site C

Configure BGP to Support Dual-Mode

Enable MPLS Label Allocation

Use the **router bgp as-number vrf WORD address-family ipv4 unicast mpls alloc enable** command under the VRF address-family to enable per-prefix mode for MPLS labels. Additionally, use the **router bgp as-number vrf WORD address-family ipv4 unicast label mode {per-ce | per-vrf}** command to choose the type of label allocation.

```
Router(config)# router bgp 100
Router(config-bgp)# vrf blue
Router(config-bgp-vrf)# rd 1:10
Router(config-bgp-vrf)# address-family ipv4 unicast
Router(config-bgp-vrf-af)# mpls alloc enable
Router(config-bgp-vrf-af)# label mode per-ce
Router(config-bgp-vrf-af)# segment-routing srv6
Router(config-bgp-vrf-af-srv6)# alloc mode per-ce
Router(config-bgp-vrf-af-srv6)# exit
Router(config-bgp-vrf-af)# exit
Router(config-bgp-vrf)# exit
Router(config-bgp)#
```

Configure Encaps on Neighbor to Send the SRv6 SID Toward the SRv6 Dataplane

By default, if a VRF prefix has both an MPLS label and an SRv6 SID, the MPLS label is sent when advertising the prefix to the PE. To advertise a VRF prefix with an SRv6 SID to an SRv6 session, use the **encapsulation-type srv6** command under the neighbor VPN address-family.

```
Router(config-bgp)# neighbor 192::6
Router(config-bgp-nbr)# remote-as 1
Router(config-bgp-nbr)# address-family ipv4 unicast
Router(config-bgp-nbr-af)# encapsulation-type srv6
Router(config-bgp-nbr-af)# exit
```

Running Config

```
router bgp 100
 neighbor 192::6
   remote-as 1
   address-family ipv4 unicast
     encapsulation-type srv6
   !
!
vrf blue
 rd 1:10
 address-family ipv4 unicast
   mpls alloc enable
   label mode per-ce
   segment-routing srv6
   alloc mode per-ce
 !
!
!
```

SRv6 SID Information in BGP-LS Reporting

BGP Link-State (BGP-LS) is used to report the topology of the domain using nodes, links, and prefixes. This feature adds the capability to report SRv6 Segment Identifier (SID) Network Layer Reachability Information (NLRI).

The following NLRI has been added to the BGP-LS protocol to support SRv6:

- Node NLRI: SRv6 Capabilities, SRv6 MSD types
- Link NLRI: End.X, LAN End.X, and SRv6 MSD types
- Prefix NLRI: SRv6 Locator
- SRv6 SID NLRI (for SIDs associated with the node): Endpoint Function, BGP-EPE Peer Node/Set

This example shows how to distribute IS-IS SRv6 link-state data using BGP-LS:

```
Router(config)# router isis 200
Router(config-isis)# distribute link-state instance-id 200
```

Note It is still possible to ping or trace a SID:

- **ping** B:k:F::
- **traceroute** B:k:F::

It is possible to use a list of packed carriers to ping or trace a SID, to ping or trace route, use **<destination SID> via srv6-carriers <list of packed carriers>**

DHCPv4 Relay Agent and Proxy Support over SRv6

This feature introduces support for DHCPv4 Relay Agent and Proxy over SRv6.

An IOS XR router can act as a DHCPv4 relay agent/proxy with a DHCPv4 server connected over an SRv6 network.

The following functionality is supported:

- DHCPv4 relay agent/proxy over SRv6 with DHCPv4 server (helper-address) located in default VRF (global)
- DHCPv4 relay agent/proxy over SRv6 with DHCPv4 server (helper-address) located in non-default VRF
- DHCPv4 relay agent/proxy on interfaces associated with a default VRF (global)
- DHCPv4 relay agent/proxy on interfaces associated with a non-default VRF
- DHCPv4 relay agent/proxy on Ethernet physical interfaces
- DHCPv4 relay agent/proxy on Ethernet bundle interfaces

For information on configuring DHCPv4 relay agent and proxy, refer to the “Implementing the Dynamic Host Configuration Protocol” chapter in the *IP Addresses and Services Configuration Guide for Cisco NCS 5500 Series Routers*.

DHCPv6 Relay Agent Support over SRv6

Table 16: Feature History Table

Feature Name	Release Information	Feature Description
DHCPv6 Relay Agent Support on SRv6	Release 7.2.2	<p>An IOS XR router can act as a DHCPv6 relay agent with a DHCPv6 server connected over an SRv6 network.</p> <p>A DHCP relay agent is a host that forwards DHCP packets between clients and servers that do not reside on a shared physical subnet.</p>

This feature introduces support for DHCPv6 Relay Agent over SRv6.

An IOS XR router can act as a DHCPv6 relay agent with a DHCPv6 server connected over an SRv6 network.

The following functionality is supported:

- DHCPv6 relay agent over SRv6 with DHCPv6 server (helper-address) located in default VRF (global)
- DHCPv6 relay agent over SRv6 with DHCPv6 server (helper-address) located in non-default VRF
- DHCPv6 relay agent on interfaces associated with a default VRF (global)
- DHCPv6 relay agent on interfaces associated with a non-default VRF
- DHCPv6 relay agent on Ethernet physical interfaces
- DHCPv6 relay agent on Ethernet bundle interfaces

For information on configuring DHCPv6 relay agent, refer to the “Implementing the Dynamic Host Configuration Protocol” chapter in the *IP Addresses and Services Configuration Guide for Cisco NCS 5500 Series Routers*.

Full-Replace Migration to SRv6 Micro-SID

Table 17: Feature History Table

Feature Name	Release	Description
Full-Replace Migration to SRv6 Micro-SID	Release 7.8.1	<p>This feature enables migration of existing SRv6 SID format1 to SRv6 Micro-SIDs (f3216) formats.</p> <p>Earlier, only one format was supported at a time, and you had to choose either format1 or Micro-SID format for the deployment of services. Migration from Full-length SIDs to SRv6 Micro-SIDs was not possible.</p> <p>The hw-module profile segment-routing srv6 mode base-and-micro-segment-f3216 subcommand is introduced under hw-module profile segment-routing srv6 mode.</p>

During the Full-Replace migration, both underlay and services are migrated from format1 to f3216. The underlay migration is done using the *Ship in the night* strategy, where updates into your environment are incremental, thereby phasing out your existing transport protocols when ready. This method minimizes the service disruption, and is recommended for seamless migration. The services migration is done using *swap* procedures, where the incoming transport label is swapped with an outgoing transport label.

The format1 to f3216 migration is seamless, requires minimal configurations, and no IETF signaling extensions. The migration enables preference of Micro-SID f3216 over format1, and minimizes traffic drop with faster convergence.

EVPN supports migration of the following services from format1 to f3216:

- IS-IS underlay (TILFA, uLoop, FlexAlgo)
- L2 overlay (EVPN VPWS - All-Active Multi-Homing)
- SRv6-MPLS IW Gateway, dual-connected PE

The following modes are supported in the context of migration:

- **Base:** SRv6 classic with format1 only.
- **Dual:** SRv6 classic with format1 and SRv6 Micro-SID with f3216 will both coexist.
- **f3216:** Micro-segment format. f3216 represents the format 3216, which is 32-bit block and 16-bit IDs.

The migration process involves the following steps:

1. **Prepare for migration:** Upgrade the network nodes to an image that is Micro-SID f3216 capable, and allows the coexistence of format1 and f3216.

Use the **hw-module profile segment-routing srv6 mode base-and-micro-segment-f3216** command to change the hardware module profile to SRv6 dual-mode.

2. **Migrate the underlay to f3216:** Enable IS-IS as an underlay protocol on PE nodes. The IS-IS configuration adds f3216 locators to format1 locators. Both format1 and f3216 endpoint SIDs are allocated, installed, and announced during this stage. f3216 is the preferred option over format1 for underlay paths.

The IS-IS SR headends provide faster convergence to f3216. Faster convergence to f3216 is done on the per-prefix per-path level, does not need any new CLI, and avoids packet drops. The format1 locators are removed after underlay traffic convergence to f3216 on all nodes. The format1 locators are unconfigured from IS-IS, and deleted from SRv6.

Change the hardware profile to SRv6 *f3216* mode.

At the end of this step, the migration status of the following P Nodes are:

- Locator reachability: f3216 only
- Underlay endpoint/headends: f3216 only
- The mode is f3216

At the end of this step, the migration status of the following PE Nodes are:

- Locator reachability: format1 and f3216
- Underlay endpoint/headends: f3216 only
- Overlay endpoint/headends: format1
- The mode is base-and-f3216

3. **Migrate the overlay to f3216:** Enables overlay f3216 under BGP and EVPN on all PE nodes. The BGP and EVPN configuration replaces format1 by f3216 locators. During this stage, the f3216 Micro-SIDs are allocated, installed, and announced, while the format1 SIDs are deallocated, uninstalled, and withdrawn.

The format1 locators are removed after overlay traffic convergence to f3216 on all nodes. The format1 locators are unconfigured from BGP and EVPN, and deleted from SRv6. For a transient period, BGP and EVPN might have some paths with format1 and some with f3216.

At the end of this step, the migration status of the following is:

- For P/PE Nodes:
 - Locator reachability: f3216 only
 - Underlay endpoint/headends: f3216 only
 - Overlay endpoint/headends: f3216 only
 - The mode is f3216

The migration starts with SRv6 base format1, and ends with SRv6 Micro-SID f3216. The migration states are:

1. **Initial state:** This is the early migration state of a deployment, for the supported features. This state comprises SRv6 base with format1.

You must use the **hw-module profile srv6 mode base** command for the initial state.

This example shows the initial state of migration with SRv6 and configure locator:

```
Router(config)# segment-routing srv6
Router(config-srv6)# locators
Router(config-srv6-locators)# locator myLoc0
Router(config-srv6-locators)# prefix flbb:bbbb:bb00:0001::/64
```

This example shows the initial state of migration with SRv6 and IS-IS:

```
Router(config)# router isis 100
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# segment-routing srv6
Router(config-isis-srv6)# locator myLoc0
```

This example shows the initial state of migration with SRv6 and BGP/EVPN:

```
Router(config)# router bgp 100
Router(config-bgp)# bgp router-id 10
Router(config-bgp)# segment-routing srv6
Router(config-bgp-srv6)# locator myLoc0
```

```
Router(config)# evpn
Router(config-evpn)# segment-routing srv6
Router(config-evpn-srv6)# locator myLoc0
```

2. **In-migration state:** The migration procedures are initiated, and are in progress. This state comprises SRv6 in dual mode (base with format1, and Micro-SID with f3216).

You must use the **hw-module profile segment-routing srv6 mode base-and-micro-segment-f3216** command for the in-migration state.

This example shows the in-migration state with SRv6 and configure locator:

```
Router(config)# segment-routing srv6
Router(config-srv6)# locators
Router(config-srv6-locators)# locator myLoc0
Router(config-srv6-locators)# prefix flbb:bbbb:bb00:0001::/64
Router(config-srv6-locators)# delayed-delete
Router(config-srv6-locators)# locator myuLoc0
Router(config-srv6-locators)# micro-segment behavior unode psp-usd
Router(config-srv6-locators)# prefix fcbb:bb00:0001::/48
```

This example shows the in-migration state with SRv6 and IS-IS:

```
Router(config)# router isis 100
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# segment-routing srv6
Router(config-isis-srv6)# locator myLoc0
Router(config-isis-srv6)# locator myuLoc0
```

This example shows the in-migration state with SRv6 and BGP/EVPN:

```
Router(config)# router bgp 100
Router(config-bgp)# bgp router-id 10
Router(config-bgp)# segment-routing srv6
Router(config-bgp-srv6)# locator myuLoc0
```

```
Router(config)# evpn
```

```
Router(config-evpn)# segment-routing srv6
Router(config-evpn-srv6)# locator myuLoc0
```

3. **End state:** This is the state of deployment at the end of the migration. At the end state, you can update the network and add new features. The Full-Replace migration end state can be of two modes:
- **Full-Replace:** Both underlay and overlay are migrated to Micro-SID f3216. Full-Replace is the Cisco recommended migration type.
 - **uF1:** Underlay migrated to Micro-SID f3216, overlay remains format1. The uF1 migration is a transient state of the Full-Replace migration type.

You need to use the **hw-module profile srv6 mode f3216** command for the end migration state.

This example shows the end state with SRv6 and configure locator:

```
Router(config)# segment-routing srv6
Router(config-srv6)# locators
Router(config-srv6-locators)# locator myuLoc0
Router(config-srv6-locators)# micro-segment behavior unode psp-usd
Router(config-srv6-locators)# prefix fcbb:bb00:0001::/48
```

This example shows the end state with SRv6 and IS-IS:

```
Router(config)# router isis 100
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# segment-routing srv6
Router(config-isis-srv6)# locator myuLoc0
```

This example shows the end state with SRv6 and BGP/EVPN:

```
Router(config)# router bgp 100
Router(config-bgp)# bgp router-id 10
Router(config-bgp)# segment-routing srv6
Router(config-bgp-srv6)# locator myuLoc0
```

```
Router(config)# evpn
Router(config-evpn)# segment-routing srv6
Router(config-evpn-srv6)# locator myuLoc0
```

Run the following command to check the result of migration, as shown in the example:

```
RP/0/RSP0/CPU0:Router# sh route ipv6 fc00:cc30:600:e004:: detail
Wed Nov 10 18:57:56.645 UTC

```

Full-Replace Migration to SRv6 Micro-SID Restrictions

You need to reload the the line cards as the hardware profiles go through multiple transitions during the Full-Replace migration to SRv6 Micro-SID.

You can overcome the traffic drop duration at time of swap of format1 by f3216 on a PE node depending on the BGP/EVPN convergence using the **delayed_delete** command. When the **delayed_delete** command is configured against the format1 SID locator, RIB notifies EVPN about this change. The EVPN in turn stores the delayed flag in its RIB locator database.

SRv6 Traffic Accounting

Table 18: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 Traffic Accounting for NCS 5700	Release 24.3.1	Introduced in this release on: NCS 5700 fixed port routers (NCS 5700 line cards [Mode: Native]). SRv6 Traffic Accounting is now supported on the Cisco NCS 5700 series routers and line cards in Native mode.

Feature Name	Release Information	Feature Description
SRv6 Traffic Accounting	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers, NCS 5500 modular routers (NCS 5500 line cards).</p> <p>You can now enable the router to record the number of packets and bytes transmitted on a specific egress interface for IPv6 traffic using the SRv6 locator counter.</p> <p>You can use this data to create deterministic data tools to anticipate and plan for future capacity planning solutions.</p> <p>This feature introduces or modifies the following changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> accounting prefixes ipv6 mode per-prefix per-nexthop srv6-locators <p>YANG Data Models:</p> <ul style="list-style-type: none"> Cisco-IOS-XR-accounting-cfg Cisco-IOS-XR-fib-common-oper.yang <p>(see GitHub, YANG Data Models Navigator)</p>

SRv6 traffic accounting is an integral part of today's network for planning and forecasting traffic. Traffic accounting is the volume of aggregated traffic flows that enter, traverse, and leave the network in a given time. Traffic accounting is a solution to monitor the traffic that helps to measure traffic flows and record how much customer traffic is passing through the SR network.

To design a network topology and meet the defined Service-Level Agreement (SLA), capacity planning becomes essential for forecasting traffic load and failures. A complete view of the traffic in your network enables you to anticipate common failures, and provision for network expansion.

You can now monitor traffic on an ingress node of a domain that is SRv6 encapsulated towards an egress node of the domain. The traffic is recorded at the source using the per-locator, per-egress-interface (LOC.INT.E) counter, which is the locator per interface at egress to account the traffic. For a given locator (L) and interface (I), the router counts the number of packets and bytes for the traffic transmitted on the interface (I) with a destination address (DA) matching the locator L.

When this feature is enabled on routers, all traffic passing through the routers are accounted. These counters are periodically streamed through telemetry and you can retrieve the counters at any point.

To enable traffic accounting on PE and P routers, use the **accounting prefixes ipv6 mode per-prefix** command. You can retrieve the number of packets transmitted and received on the specific interface of a PE or P routers by using the following telemetry:

```
Cisco-IOS-XR-fib-common-oper:cef-accounting/vrfs/vrf[vrf-name='default']/afis/afi[afi-type=ipv6]/pfx/srv6locs/srv6loc
```

Benefits

Monitoring the traffic provides numerous benefits, and here are a few:

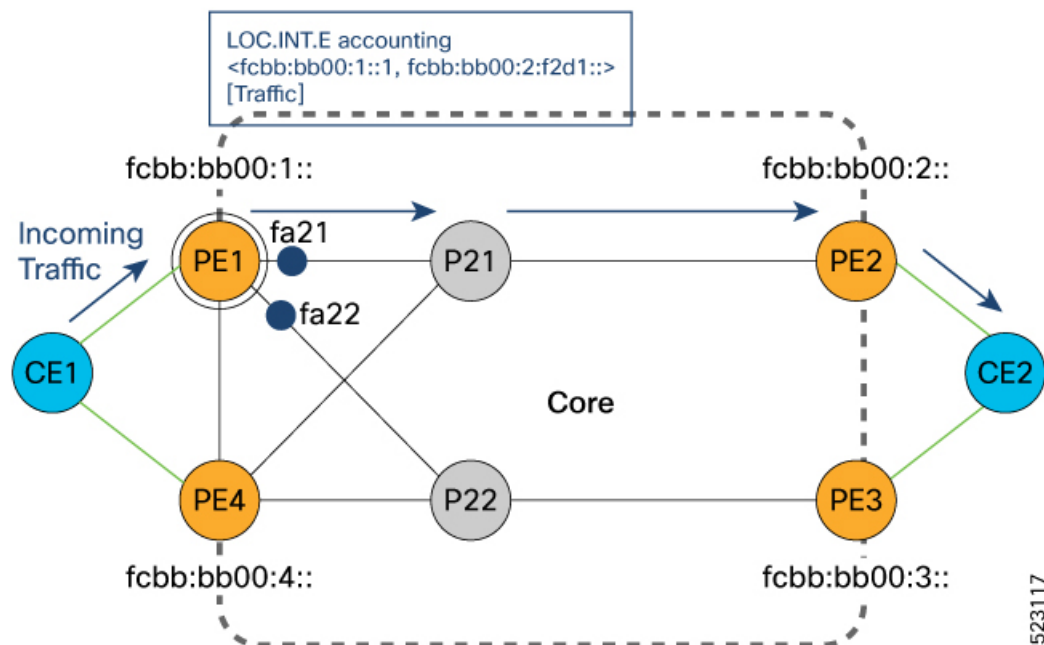

- To optimize network utilization and achieve a balance between underutilized and overutilized paths.
- To plan and optimize network capacity and avoid congestion.
- To plan the service provisioning and choose the right path and create an optimized backup path (for using SRLG's affinity, and so on).

Understanding SRv6 Locator Counters

Let's understand this feature with the following topology:

Consider the topology where traffic is passing from CE1 to CE2 through PE1. The traffic sent and received from CE1 is considered as the external traffic. The traffic from PE4 destined to PE2 is considered as the internal traffic.

Figure 10: Sample Topology for SRv6 Traffic Accounting

PE1 learns CE2 reachability through PE2. Consider PE1 has ECMP paths via P21 and P22 to reach PE2.

- When traffic reaches PE1, PE1 imposes traffic with the PE2 locator fcbb:bb00:2::.
- SRv6 traffic accounting LOC.INT.E is per prefix per egress interface accounting.

When traffic exits the PE1 interface (fa21) through P21, PE1 keeps the count of this traffic that is sent. Also, when traffic exits the PE1 interface (fa22) through P22, PE1 keeps the count of this traffic that is sent. The traffic is accounted irrespective of the path PE1 takes to send traffic.

Here is the SRv6 label of the outgoing traffic for PE2:

```
<fcbb:bb00:1::1, fcbb:bb00:2:f2d1::> [CUSTTraffic]
```

- When the next set of packets are received and passed through PE1, the counters are incremented on fa21 or fa22 interface based on the path the traffic sent through PE2.

The traffic from PE4 to PE1 is considered as internal traffic.

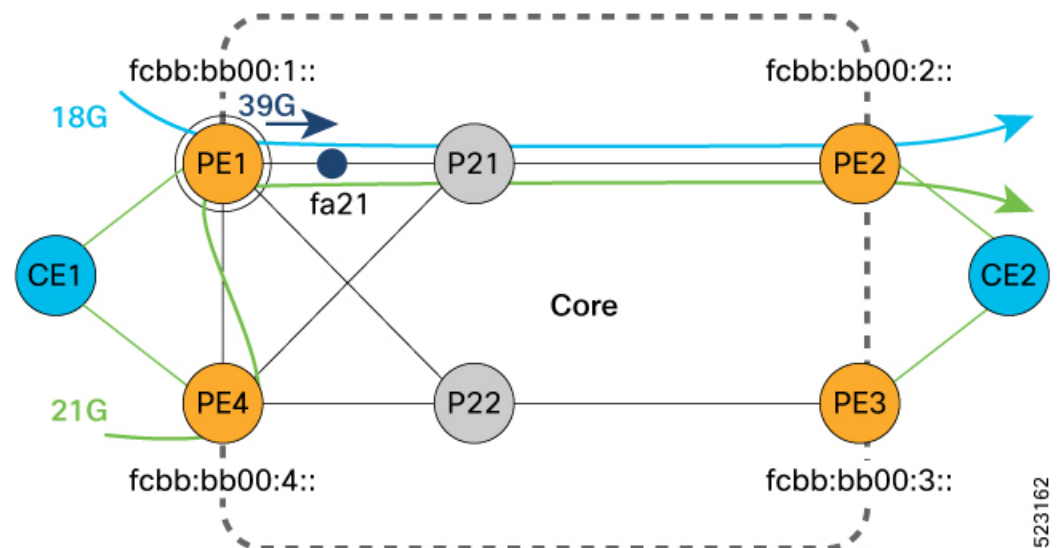

- When traffic is sent from PE4 to PE2 through PE1, PE4 imposes the traffic with the PE2 locator ID fcbb:bb00:2::. The traffic count is recorded at PE4 for this locator ID.
- When traffic reaches PE1, it looks for the PE2 locator ID and keeps the traffic count at PE1 when the traffic exit the fa21 interface.

Let's see how the SRv6 traffic is calculated using the demand matrix.

The Demand Matrix (DM) also known as a traffic matrix is a representation of the amount of data transmitted between every pair of routers. Each cell in the DM represents a traffic volume from one router to another. DM gives a complete view of the traffic in your network.

In the topology, the amount of external traffic destined for PE2 is a combination of external and internal traffic.

Figure 11: SampleTopology for Demand Matrix

- The traffic transmitted from PE1 is marked in **blue**.
- The traffic transmitted from PE4 is marked as in **green**.

The external traffic that PE2 receives is equal to the total traffic sent out from PE1 minus the received internal traffic.

```
External traffic to PE2
= (Total traffic sent out from PE1) - (Internal traffic received by PE1)
= (sum of all Loc.int.E counters on PE1) - (sum of the Loc.int.E counters of all neighbors
of PE1)
```

Let's try to calculate with this example.

- PE1 transmits a total of 39 gigabits per second towards PE2.
- PE1 receives 21 gigabits per second of internal traffic from PE4.
- PE1 receives 0 gigabits per second from P21 and P22.

You can calculate the external traffic to PE2 as follows:

```
External traffic to PE2
= (sum of all Loc.int.E counters on PE1) - ( sum of the Loc.int.E counters of all neighbors
  of PE1)
= 39 gigabits per second - (21 + 0 + 0) gigabits per second
= 18 gigabits per second external traffic
```

So, PE2 receives 18 gigabits per second external traffic from PE1.

The calculation for external traffic for routers follows a similar approach. Let's see few examples in the following demand matrix.

Table 19: Demand Matrix showing traffic transmitted from PE1 and PE4 to PE2

From/To	PE1	PE2
PE1	NA	39 - (21 + 0 + 0) = 18 gigabits per second
PE4	21 - (18 + 0 + 0) = 3 gigabits per second	39 - (18 + 0 + 0) = 21 gigabits per second

Usage Guidelines and Limitations

Supported Traffic Types

- IPv6 packets.
- SRv6 packets with the local SID as the top SID.
 - If the top SID is a local uN, traffic is counted against the remote locator prefix of the next SID.
 - Traffic is not counted if the top SID is a local uA.
- SRv6 VPNv4
- SRv6 VPNv6
- SRv6 INETv4
- SRv6 INETv6

Limitations

- Supports a minimum telemetry pull interval of 30 seconds.
- Supports only per path statistics and does not support summary of statistics of all the outgoing paths.
- SRv6 traffic accounting does not count locally generated control plane packets such as ping to the remote locator.

- Packets are not counted if the local uA is the top SID.
 - SRv6 traffic accounting is not supported with SRv6 TE policy.
 - No additional MIBs are supported to retrieve SRv6 traffic statistics. We recommend to use telemetry through the newly added sensor-path in `Cisco-IOS-XR-fib-common-oper` to retrieve these statistics.
 - ELINE or VPWS services over SRv6 undergo an extra recycle pass when SRv6 traffic accounting is enabled even when there is no additional IGP SID being added that reduces the overall throughput and increases switching latency accordingly.
 - When SRv6 traffic accounting is enabled, ECMP FEC sharing is automatically disabled. This increases the usage of ECMP with FEC where the FEC resource was shared without accounting.
 - Enabling SRv6 traffic accounting results in the allocation of two additional encapsulation resources per SRv6 locator prefix per path. As a result, the overall available scale of encapsulation resources is reduced accordingly.
 - SRv6 traffic accounting shares the statistics resources with other features such as MPLS label accounting. Therefore, even if accounting is enabled, when the statistics resources are fully utilized in a multi-dimensional scaled configuration, the statistics count displays as 0s for SRv6 locator prefixes that do not get dedicated statistics allocated in the hardware.
 - The convergence of the network is affected by enabling SRv6 traffic accounting because the same software thread handles the operations of reading statistics. The impact on convergence can vary depending on factors such as the frequency of statistics queries and the scale of locator prefixes with accounting enabled.
 - There is no support for clearing the counters used in SRv6 traffic accounting.
 - Prior to advertising the relevant SRv6 locator prefixes to the router, you must enable SRv6 traffic accounting. However, accounting will not be enabled for locator prefixes that are already programmed in the hardware.
- Similarly, when accounting is disabled, the associated hardware resources are freed when the SRv6 locator prefixes are withdrawn.
- SRv6 traffic accounting is only supported with micro-sids and we recommend you not to enable SRv6 traffic accounting on a router that has full-length SIDs.

Configure SRv6 Traffic Accounting

Before you begin ensure that you enable SRv6 and its services.

Configuration Example

To enable SRv6 traffic accounting:

```
Router#configure
Router(config)#accounting
Router(config-acct)#prefixes ipv6 mode per-prefix per-nexthop srv6-locators
Router(config-acct)#commit
```

Running Configuration

```
Router#show run
```

```

accounting
prefixes
  ipv6
    mode per-prefix per-nexthop srv6-locators
  !
!
!

```

Verification

Verify the Stats ID allocated for remote locator. The following example shows the SRv6 locator ID and the stats ID allocated for the prefixes with the locator ID.

```
Router#show route ipv6 fccc:cc00:1:: detail
```

```

Routing entry for fccc:cc00:1::/48

```

Configuring Telemetry Data

Configure the sensory path to retrieve the accounting data using telemetry:

```

Router#configure
Router(config)#grpc
Router(config-grpc)#port 57400
Router(config-grpc)#no-tls
Router(config-grpc)#commit
Router(config-grpc)#exit
Router(config)#telemetry model-driven
Router(config-model-driven)#sensor-group s1

```

```

Router(config-model-driven-snsr-grp)#sensor-path
Cisco-IOS-XR-fib-common-oper:cef-accounting/vrfs/vrf[vrf-name='default']/af$
Router(config-model-driven-snsr-grp)#exit
Router(config-model-driven)#subscription sub1
Router(config-model-driven-subs)#sensor-group-id s1 sample-interval 30000
Router(config-model-driven-subs)#commit
Router(config-model-driven-subs)#root
Router(config)#exit
Router#

```

Running Configuration for Configuring Telemetry Data

The following shows the show running configuration:

```

Router#show run
grpc
  port 57400
  no-tls
!
telemetry model-driven
  sensor-group s1
  sensor-path
Cisco-IOS-XR-fib-common-oper:cef-accounting/vrfs/vrf[vrf-name='default']/afis/afi[afi-type=ipv6]/pfx/srv6locs/srv6loc

!
subscription sub1
  sensor-group-id s1 sample-interval 30000
!
!

```

Verification for Configuring Telemetry Data

Verify the counters using the telemetry data. The following example shows the accounting data with the number of packets and the bytes transmitted through the interface.

```

Run **sh cef ipv6 accounting** command to display the packets per bytes:

Segment Routing Configuration Guide for Cisco NCS 5500 Series Routers, IOS XR Release 24.1.x, 24.2.x, 24.3.x, 24.4.x

Path Maximum Transmission Unit (MTU) Discovery for SRv6 Encapsulated Packets

Table 20: Feature History Table

Feature Name	Release Information	Feature Description
Path MTU Discovery for SRv6 Packets on Ingress Provider Edge (PE) Routers, and Egress (PE) Router	Release 24.1.1	<p>Introduced in this release on: NCS 5700 fixed port routers (NCS 5700 line cards [Mode: Native]).</p> <p>You can measure and monitor the packet loss information when one SRv6-enabled router sends an oversized packet to another. This functionality enables a router to send an ICMP error message to the source in such cases, prompting the sender to resend a packet whose size is within the MTU value, thus ensuring the packet moves ahead. The feature is critical for SRv6-enabled routers as these routers do not support packet fragmentation.</p> <p>This feature is enabled by default.</p>

Feature Name	Release Information	Feature Description
Path MTU Discovery for SRv6 Packets on Ingress Provider Edge (PE) Routers	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards).</p> <p>You can measure and monitor the packet loss information when one SRv6-enabled router sends an oversized packet to another. This functionality enables a router to send an ICMP error message to the source in such cases, prompting the sender to resend a packet whose size is within the MTU value, thus ensuring the packet moves ahead. The feature is critical for SRv6-enabled routers as these routers don't support packet fragmentation.</p> <p>Previously, a router dropped oversized packets without notifying the source, resulting in packet loss.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> The path-mtu keyword is introduced in the hw-module profile segment-routing srv6 mode command.

Earlier, routers did not account for the SRv6 encapsulated packets while checking the MTU of a link along a given data path in the egress core interface. When the path MTU of a link along a given data path was not large enough to accommodate the size of the encapsulated packets from a source, the router silently dropped the packets without notifying the source.

With this configuration, the ingress PE router supports Path MTU discovery for SRv6 encapsulated packets. The router does not drop the packets along a given data path without notifying the source. The router sends an ICMP type 3 or type 2 error message for IPv4 or IPv6 links respectively. The configuration enables the source to learn to use a smaller MTU for packets sent to a destination.

For example, the maximum allowed MTU for an IPv4 link is 1500 bytes. Consider a source that sends an IPv4 packet of size 1480 bytes with an SRv6 encapsulation of 40 bytes. The overall IPv4 packet size is increased to 1520 bytes, which is greater than the maximum MTU allowed on the IPv4 link. In this case, the router sends an ICMP Type 3 error message to the source to request the packet originator to adjust the size of the packet.

We calculate the maximum allowed MTU on IPv4 and IPv6 links using the following formula:

Maximum MTU = Egress Interface MTU + SRv6 Encapsulation Size (maximum 64 bytes) + size of L2 Header

Usage Guidelines and Limitations

The following usage guidelines and limitations apply:

- The SRv6 uSID (F3216) format supports the feature.
- Does not support L2 services over SRv6 (L2VPN).
- When ECMP paths have different MTU sizes configured for each of these paths, then the ICMP P2B generation is not guaranteed. This is due to the difference of the software and hardware load balance hashing algorithm. The MTU exceeded punt packet points to a different path due to this mismatch in the software and hardware hashing. This causes the P2B generation with a wrong MTU value or it gets re-injected to a different interface path.
- This feature is not supported on BVI interfaces.
- **Ingress**
 - The SRv6 Full-length SID format does not support Path MTU discovery.
 - Starting from Cisco IOS XR Release 24.1.1, Ingress, Egress, and Provider Core Router or Transit nodes with IPv6 are supported by Cisco NCS 5700 Series Routers and Cisco NC 57 line cards in native mode.
 - SRv6 encapsulation supports the following scenarios:
 - IPv4/IPv6 over SRv6
 - SRv6-TE
 - H insert
 - TI-LFA for Single Carrier and Multi Carrier
- **Egress**
 - Starting from Cisco IOS XR Release 24.1.1, you can configure this feature on the Egress PE router for Cisco NCS 5700 Series Routers and Cisco NC 57 line cards in native mode.
 - Supports the following functions:
 - Decapsulation and specific IPv4 table lookup (DT4), Decapsulation and specific IPv6 table lookup (DT6).
 - The decapsulated packet is punted to PI (after removing the SR6 headers).
 - SRv6 PMTUD cannot co-exist with LI and SPAN feature on NCS 5500 routers.

Enabling Path MTU discovery for SRv6 encapsulated packets

Perform this task in global configuration mode to enable Path MTU discovery for SRv6 encapsulated packets:

Note To enable the ingress Provider Edge (PE) routers on NCS 5500 Series line cards, run the **hw-module profile segment-routing srv6 mode micro-segment format f3216 path-mtu** command. It is enabled by default in the other platforms.

```
Router#configure
Router(config)#hw-module profile segment-routing srv6 mode micro-segment format f3216
path-mtu
In order to activate/deactivate this srv6 profile, you must manually reload the chassis/all
line cards
Router(config-srv6)#commit
```

Note After committing the configuration, you must reload the chassis or all line cards using the command **reload location all**.

Running Configuration

```
hw-module profile segment-routing srv6 mode micro-segment format f3216 path-mtu
!
```

VRF-to-VRF route leaking in SRv6 core

VRF-to-VRF route leaking is an SRv6 core feature that allows communication between separate VRFs by sharing specific routes while keeping others isolated. This is achieved by configuring import and export route targets in each VRF, ensuring that only the selected routes are exchanged.

Table 21: Feature History Table

Feature Name	Release Information	Feature Description
VRF-to-VRF route leaking in SRv6 core	Release 24.4.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>VRF-to-VRF route leaking enables sharing of routes between VRFs while maintaining their isolation. This feature allows the source VRF to send leaked routes to remote PEs or Route Reflectors (RRs) across an SRv6 core network, similar to an MPLS core network, enabling communication between different service tenants or administrative domains without compromising VRF isolation.</p>

Route leaking between VRFs in an SRv6 core network extends the MPLS-based VRF route leaking functionalities to SRv6, by taking advantage of the SRv6 flexibility for path selection and optimization. You can configure the destination VRF to send leaked routes to a remote PE or RR across an SRv6 core. The feature enables VRF-to-VRF communication in an SRv6-enabled environment while maintaining control over routing and traffic engineering decisions.

Benefits of VRF-to-VRF route leaking in SRv6

The key benefits of the feature are:

- **Improved Traffic Management:** The feature allows routes in the source VRF to use SRv6 SIDs from a best-effort locator and routes in the destination VRF to use SIDs from a low-latency locator. This setup enables differentiated traffic treatment in the SRv6 core.
- **Enhanced Flexibility:** The feature leaks routes between VRFs and advertises them as VPNv4 or VPNv6 or EVPN RT5 prefixes to remote PE routers, providing better flexibility in managing network traffic and inter-VRF communication.
- **Scalability:** The feature dynamically leaks routes that help to scale the network by automating the redistribution process between VRFs.
- **Security and Isolation:** The feature uses route targets and policies to control route leaking, ensuring that it only occurs between intended VRFs, maintaining both security and isolation.

SRv6 VRF-to-VRF route leaking workflow

The different steps in the VRF-to-VRF route leaking workflow are explained in detail:

- Route import: A VRF imports a prefix from another VRF, which belongs to another service and creates a route leak between them.
- SID allocation: The destination VRF allocates a unique SRv6 SID to the imported prefix. The SID ensures that the traffic to the imported prefix is correctly routed within the SRv6 core. The SID allocation type is either per-VRF or per-VRF-46 depending on the destination VRF configuration.
- Prefix advertisement: The destination VRF advertises the imported prefix, along with the associated SRv6 SID to remote neighbors in the SRv6 network through BGP VPNv4 or VPNv6 or EVPN RT5.
- Routing within the SRv6 core: The remote neighbors now have the information that is required to route traffic to the imported prefix using the SRv6 SID. The SRv6 SID allows for efficient routing and traffic engineering, ensuring the traffic reaches the correct VRF and destination.

Usage guidelines and limitations for VRF-to-VRF route leaking in SRv6

The usage guidelines and limitations that are listed apply:

- VRF-to-VRF route leaking does not support multicast routes.
- The feature supports both SRv6 Full-length SID and Micro-SIDs.
- Depending on the destination VRF configuration, the PE router assigns SIDs to the leaked route based on the SID allocation mode, which can be per-VRF or per-VRF-46.

Configure VRF-to-VRF route leaking in SRv6

Before you begin

Enable Segment Routing over IPv6 under BGP in the source and destination VRFs.

Procedure

Step 1 Run the **export route-policy** command to configure and attach route leaking in the source VRF.

- Configure the static export Route Target to leak all prefixes to the destination VRF. In the below configuration, the leaked Route Target is 1:12.

```
Router(config)#vrf vrf-be
Router(config-vrf)#address-family ipv4 unicast
Router(config-vrf-af)#import route-target 1:10
Router(config-vrf-af)#export route-target 1:10
Router(config-vrf-af)#export route-target 1:12
Router(config-vrf-af)#commit
```

- Configure a route policy that attaches appropriate Route Target to the leaked prefixes to leak specific prefixes to the destination VRF. Apply the IF condition in the Route Policy Language (RPL) to leak specific prefixes.

```
Route(config)#prefix-set allowed-leaked-route
Route(config-pfx)#192.168.1.0/32
Router(config-pfx)#end-set
Router(config)#route-policy export-policy
Router(config-rpl)#if destination in allowed-leaked-route then
```

```

Router(config-rpl-if)#set extcommunity rt 1:12
Router(config-rpl-if)#endif
Router(config-rpl)#end-policy
Router(config)#commit
Router(config)#vrf vrf-be
Router(config-vrf)#address-family ipv4 unicast
Router(config-vrf-af)#import route-target 1:10
Router(config-vrf-af)#export route-target 1:10
Router(config-vrf-af)#export route-policy export-policy
Router(config-vrf-af)#commit

```

Step 2 Configure the destination VRF to import routes from the source VRF.

Example:

```

Router(config)#vrf vrf-ef
Router(config-vrf)#address-family ipv4 unicast
Router(config-vrf-af)#import route-target 2:2
Router(config-vrf-af)#import route-target 1:12
Router(config-vrf-af)#export route-target 2:2

```

Step 3 Run the **show running-config** command to verify the running configuration.

Example:

```

vrf vrf-be
  address-family ipv4 unicast
    import route-target 1:10
    export route-target 1:10
    export route-target 1:12
  !
!
vrf vrf-ef
  address-family ipv4 unicast
    import route-target 2:2
    import route-target 1:12
    export route-target 2:2
  !
!

```

Step 4 Run the **import from vrf advertise-as-vpn** command to forward the imported routes to a remote PE or VPN RR peer through configuration.

Example:

```

Router(config)#vrf vrf-ef
Router(config-vrf)#address-family ipv4 unicast
Router(config-vrf-af)#import from vrf advertise-as-vpn
Router(config-vrf-af)#commit

```

Step 5 Run the **show bgp vrf** command to verify the route leaking from the source VRF vrf-be.

In the below show output, the source VRF vrf-be leaks the Route Target 1:12.

Example:

```

Router#show bgp vrf vrf-be 192.168.1.0/32 detail
Mon Aug 19 14:06:22.668 UTC

CHAPTER 5

Configure Segment Routing over IPv6 (SRv6) with Full-Length SIDs

Note IOS XR release 7.3.2 supports SRv6 with Full-length SID and Micro-SID formats; however, only one format is supported in the network at a time.

To use SRv6 Full-length SID, enter the **hw-module profile segment-routing srv6 mode base** command in config mode, then reload the router or line card. See [Configuring SRv6, on page 157](#) for more information.

To use SRv6 Micro-SID (uSID), see the [Configure Segment Routing over IPv6 \(SRv6\) with Micro-SIDs, on page 11](#) chapter.

Segment Routing for IPv6 (SRv6) is the implementation of Segment Routing over the IPv6 dataplane.

Segment Routing over IPv6 Overview

Table 22: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 Network Instructions	Release 7.5.1	This feature is now supported on Cisco NCS 5700 series fixed port routers and the Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native mode.

Segment Routing (SR) can be applied on both MPLS and IPv6 data planes. Segment Routing over IPv6 (SRv6) extends Segment Routing support with IPv6 data plane.

In an SR-MPLS enabled network, an MPLS label represents an instruction. The source nodes programs the path to a destination in the packet header as a stack of labels.

SRv6 introduces the Network Programming framework that enables a network operator or an application to specify a packet processing program by encoding a sequence of instructions in the IPv6 packet header. Each instruction is implemented on one or several nodes in the network and identified by an SRv6 Segment Identifier (SID) in the packet. The SRv6 Network Programming framework is defined in [IETF RFC 8986 SRv6 Network Programming](#).

In SRv6, an IPv6 address represents an instruction. SRv6 uses a new type of IPv6 Routing Extension Header, called the Segment Routing Header (SRH), in order to encode an ordered list of instructions. The active segment is indicated by the destination address of the packet, and the next segment is indicated by a pointer in the SRH.

Figure 12: Network Program in the Packet Header

The SRv6 SRH is documented in IETF RFC [IPv6 Segment Routing Header \(SRH\)](#).

The SRH is defined as follows:

```

0          1          2          3
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1

```

```

+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
| Next Header | Hdr Ext Len | Routing Type | Segments Left |
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
| Last Entry  | Flags        | Tag          |
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
|
|           Segment List[0] (128-bit IPv6 address)
|
|
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
|
|
|
|           ...
|
|
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
|
|           Segment List[n] (128-bit IPv6 address)
|
|
|
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+
//
//           Optional Type Length Value objects (variable)
//
//
+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+---+

```

The following list explains the fields in SRH:

- Next header—Identifies the type of header immediately following the SRH.
- Hdr Ext Len (header extension length)—The length of the SRH in 8-octet units, not including the first 8 octets.
- Segments left—Specifies the number of route segments remaining. That means, the number of explicitly listed intermediate nodes still to be visited before reaching the final destination.
- Last Entry—Contains the index (zero based) of the last element of the segment list.
- Flags—Contains 8 bits of flags.
- Tag—Tag a packet as part of a class or group of packets like packets sharing the same set of properties.
- Segment list—128-bit IPv6 addresses representing the *n*th segment in the segment list. The segment list encoding starts from the last segment of the SR policy (path). That means the first element of the segment list (Segment list [0]) contains the last segment of the SR policy, the second element contains the penultimate segment of the SR policy and so on.

In SRv6, a SID represents a 128-bit value, consisting of the following three parts:

- Locator: This is the first part of the SID with most significant bits and represents an address of a specific SRv6 node.
- Function: This is the portion of the SID that is local to the owner node and designates a specific SRv6 function (network instruction) that is executed locally on a particular node, specified by the locator bits.
- Args: This field is optional and represents optional arguments to the function.

The locator part can be further divided into two parts:

- SID Block: This field is the SRv6 network designator and is a fixed or known address space for an SRv6 domain. This is the most significant bit (MSB) portion of a locator subnet.

- Node Id: This field is the node designator in an SRv6 network and is the least significant bit (LSB) portion of a locator subnet.

SRv6 Node Roles

Each node along the SRv6 packet path has a different functionality:

- Source node—A node that can generate an IPv6 packet with an SRH (an SRv6 packet), or an ingress node that can impose an SRH on an IPv6 packet.
- Transit node—A node along the path of the SRv6 packet (IPv6 packet and SRH). The transit node does not inspect the SRH. The destination address of the IPv6 packet does not correspond to the transit node.
- Endpoint node—A node in the SRv6 domain where the SRv6 segment is terminated. The destination address of the IPv6 packet with an SRH corresponds to the end point node. The segment endpoint node executes the function bound to the SID

SRv6 Head-End Behaviors

The SR Headend with Encapsulation behaviors are documented in the [IETF RFC 8986 SRv6 Network Programming](#).

The SR Headend with Insertion head-end behaviors are documented in the following IETF draft:

<https://datatracker.ietf.org/doc/draft-filsfils-spring-srv6-net-pgm-insertion/>

This section describes a set of SR Policy headend behaviors. The following list summarizes them:

- H.Encaps—SR Headend Behavior with Encapsulation in an SRv6 Policy
- H.Encaps.Red—H.Encaps with Reduced Encapsulation
- H.Insert—SR Headend with insertion of an SRv6 Policy
- H.Insert.Red—H.Insert with reduced insertion

SRv6 Endpoint Behaviors

The SRv6 endpoint behaviors are documented in the [IETF RFC 8986 SRv6 Network Programming](#).

The following is a subset of defined SRv6 endpoint behaviors that can be associated with a SID.

- End—Endpoint function. The SRv6 instantiation of a Prefix SID [[RFC8402](#)].
- End.X—Endpoint with Layer-3 cross-connect. The SRv6 instantiation of an Adj SID [[RFC8402](#)].
- End.DX6—Endpoint with decapsulation and IPv6 cross-connect (IPv6-L3VPN - equivalent to per-CE VPN label).
- End.DX4—Endpoint with decapsulation and IPv4 cross-connect (IPv4-L3VPN - equivalent to per-CE VPN label).
- End.DT6—Endpoint with decapsulation and IPv6 table lookup (IPv6-L3VPN - equivalent to per-VRF VPN label).
- End.DT4—Endpoint with decapsulation and IPv4 table lookup (IPv4-L3VPN - equivalent to per-VRF VPN label).

- End.DT46—Endpoint with decapsulation and specific IP table lookup (IP-L3VPN - equivalent to per-VRF VPN label).
- End.DX2—Endpoint with decapsulation and L2 cross-connect (L2VPN use-case).
- End.B6.Encaps—Endpoint bound to an SRv6 policy with encapsulation. SRv6 instantiation of a Binding SID.
- End.B6.Encaps.RED—End.B6.Encaps with reduced SRH. SRv6 instantiation of a Binding SID.

SRv6 Endpoint Behavior Variants

Table 23: Feature History Table

Feature Name	Release Information	Feature Description
SRv6: Ultimate Segment Decapsulation (USD) on Full-length SIDs	Release 7.5.2	<p>The Ultimate Segment Decapsulation (USD) variant is supported on SRv6 endpoint nodes using full-length SIDs. One of the USD variant applications is the case of TI-LFA in P routers with encapsulation with H.Encaps. The USD variant allows the last Segment Endpoint Node in the repair path list to decapsulate the IPv6 header added at the TI-LFA Point of Local Repair and forward the inner packet.</p> <p>In earlier releases, the USD variant was supported on SRv6 endpoint nodes using Micro SIDs (uSIDs).</p>

Depending on how the SRH is handled, different behavior variants are defined for the End and End.X behaviors. The End and End.X behaviors can support these variants, either individually or in combinations.

- **Penultimate Segment Pop (PSP) of the SRH variant**—An SR Segment Endpoint Nodes receive the IPv6 packet with the Destination Address field of the IPv6 Header equal to its SID address.

A penultimate SR Segment Endpoint Node is one that, as part of the SID processing, copies the last SID from the SRH into the IPv6 Destination Address and decrements the Segments Left value from one to zero.

The PSP operation takes place only at a penultimate SR Segment Endpoint Node and does not happen at non-penultimate endpoint nodes. When a SID of PSP-flavor is processed at a non-penultimate SR Segment Endpoint Node, the PSP behavior is not performed since Segments Left would not be zero.

The SR Segment Endpoint Nodes advertise the SIDs instantiated on them via control plane protocols. A PSP-flavored SID is used by the Source SR Node when it needs to instruct the penultimate SR Segment Endpoint Node listed in the SRH to remove the SRH from the IPv6 header.

- **Ultimate Segment Pop (USP) of the SRH variant**—The SRH processing of the End and End.X behaviors are modified as follows:

If Segments Left is 0, then:

1. Update the Next Header field in the preceding header to the Next Header value of the SRH
2. Decrease the IPv6 header Payload Length by $8 * (\text{Hdr Ext Len} + 1)$
3. Remove the SRH from the IPv6 extension header chain
4. Proceed to process the next header in the packet

One of the applications of the USP flavor is when a packet with an SRH is destined to an application on hosts with smartNICs implementing SRv6. The USP flavor is used to remove the consumed SRH from the extension header chain before sending the packet to the host.

- **Ultimate Segment Decapsulation (USD) variant**—The Upper-layer header processing of the End and End.X behaviors are modified as follows:

- **End** behavior: If the Upper-layer Header type is 41 (IPv6), then:
 1. Remove the outer IPv6 Header with all its extension headers
 2. Submit the packet to the egress IPv6 FIB lookup and transmission to the new destination
 3. Else, if the Upper-layer Header type is 4 (IPv4)
 4. Remove the outer IPv6 Header with all its extension headers
 5. Submit the packet to the egress IPv4 FIB lookup and transmission to the new destination
 6. Else, process as per Section 4.1.1 (Upper-Layer Header) of [IETF RFC 8986 SRv6 Network Programming](#)
- **End.X** behavior: If the Upper-layer Header type is 41 (IPv6) or 4 (IPv4), then:
 1. Remove the outer IPv6 Header with all its extension headers
 2. Forward the exposed IP packet to the L3 adjacency J
 3. Else, process as per Section 4.1.1 (Upper-Layer Header) of [IETF RFC 8986 SRv6 Network Programming](#)

One of the applications of the USD flavor is the case of TI-LFA in P routers with encapsulation with H.Encaps. The USD flavor allows the last Segment Endpoint Node in the repair path list to decapsulate the IPv6 header added at the TI-LFA Point of Local Repair and forward the inner packet.

Usage Guidelines and Limitations

General Guidelines and Limitations

- Cisco IOS XR Release 7.5.2 and later supports the following SRv6 SID behaviors and variants:
 - END with PSP/USD
 - END.X with PSP/USD
 - END.DT4
 - END.DT6
- SRv6 Underlay support includes:

- IGP redistribution/leaking between levels
- Prefix Summarization on ABR routers
- IS-IS TI-LFA
- Microloop Avoidance
- Flex-algo

Configuring SRv6

To enable SRv6 globally, you should first configure a locator with its prefix. The IS-IS protocol announces the locator prefix in IPv6 network and SRv6 applications (like ISIS, BGP) use it to allocate SIDs.

The following usage guidelines and restrictions apply while configuring SRv6.

- All routers in the SRv6 domain should have the same SID block (network designator) in their locator.
- The locator length should be 64-bits long.
 - The SID block portion (MSBs) cannot exceed 40 bits. If this value is less than 40 bits, user should use a pattern of zeros as a filler.
 - The Node Id portion (LSBs) cannot exceed 24 bits.
- You can configure up to 8 locators to support SRv6 Flexible Algorithm. All locators prefix must share the same SID block (first 40-bits).

Enabling SRv6 on the Platform

Before configuring SRv6 on Cisco NCS 5500 Series Routers, you must first use the following command in config mode:

- **hw-module profile segment-routing srv6 mode base**

You must reload the router after enabling this command.

Note Starting from Release 7.10.1, the SRv6 mode is automatically set to **base-and-micro-segment-f3216 mode** (dual mode) even if you configure the base mode. The running configuration would still continue to reflect the user configured mode only.

You can verify the change using the following console log:

```
fia_driver[238]: %FABRIC-FIA_DRV-6-HW_MOD_PROFILE_AUTO_CONVERTED
:
Auto-converting SRv6 hw-module base profile to
base-and-micro-segment-f3216 profile
```

Enabling SRv6 with Locator

This example shows how to globally enable SRv6 and configure locator.

```
Router(config)# segment-routing srv6
Router(config-srv6)# locators
```

```
Router(config-srv6-locators)# locator myLoc1
Router(config-srv6-locator)# prefix 2001:db8:0:a2::/64
```

(Optional) Configuring SRv6 Anycast Locator

An SRv6 Anycast locator is a type of locator that identifies a set of nodes (END SIDs). SRv6 Anycast Locators and their associated END SIDs may be provisioned at multiple places in a topology.

The set of nodes (Anycast group) is configured to advertise a shared Anycast locator and END SID. Anycast routing enables the steering of traffic toward multiple advertising nodes. Packets addressed to an Anycast address are forwarded to the topologically nearest nodes.

One use case is to advertise Anycast END SIDs at exit points from an SRv6 network. Any of the nodes that advertise the common END SID could be used to forward traffic out of the SRv6 portion of the network to the topologically nearest node.

Unlike a normal locator, IS-IS does not program or advertise END.X SIDs associated with an anycast locator.

Note END SIDs allocated from Anycast locators will not be used in constructing TI-LFA backup paths or Microloop Avoidance primary paths. TI-LFA backup and Microloop Avoidance paths for an Anycast locator prefix may terminate on any node advertising that locator, which may be different from the node terminating the original primary path.

Note SRv6 anycast locators may have non-zero algorithm (Flexible Algorithm) values.

The following example shows how to globally enable SRv6 and configure Anycast locator.

Note For Cisco NCS 5500 Series Routers, you must first use the **hw-module profile segment-routing srv6** command to enable SRv6 functionality. Then, reload the line card after enabling this command.

```
Router(config)# hw-module profile segment-routing srv6
Router(config)# segment-routing srv6
Router(config-srv6)# locators
Router(config-srv6-locators)# locator myLoc1 anycast
Router(config-srv6-locator)# prefix 2001:db8:0:a2::/64
```

Optional: Configuring Encapsulation Parameters

This example shows how to configure encapsulation parameters when configuring SRv6. These optional parameters include:

- **segment-routing srv6 encapsulation source-address *ipv6-addr***—Source Address of outer encapsulating IPv6 header. The default source address for encapsulation is one of the loopback addresses.
- **segment-routing srv6 encapsulation hop-limit {*count* | **propagate**}**—The hop limit of outer-encapsulating IPv6 header. The range for *count* is from 1 to 254 for NCS 5500 and from 1 to 255 for NCS 5700; the default value for hop-limit is 254. Use **propagate** to set the hop-limit value by propagation (from incoming packet/frame).

Note On NCS 5700 hardware, hop-limit propagation is not applied for packets going to ELINE (P2P) services.

```
Router(config)# segment-routing srv6
Router(config-srv6)# encapsulation source-address 1::1
Router(config-srv6)# hop-limit 60
```

Optional: Enabling Syslog Logging for Locator Status Changes

This example shows how to enable the logging of locator status.

```
Router(config)# segment-routing srv6
Router(config-srv6)# logging locator status
```

Verifying SRv6 Manager

This example shows how to verify the overall SRv6 state from SRv6 Manager point of view. The output displays parameters in use, summary information, and platform specific capabilities.

```
Router# show segment-routing srv6 manager
Parameters:

SID Holdtime: 3 mins

```

Verifying SRv6 Locator

This example shows how to verify the locator configuration and its operational status.

```

Router# show segment-routing srv6 locator myLoc1 detail

```

Name	ID	Prefix	Status
myLoc1*	5	2001:db8:0:a2::/64	Up

```

(*) : is-default
Interface:
  Name: srv6-myLoc1
  IFH : 0x00000170
  IPv6 address: 2001:db8:0:a2::/64
Chkpt Obj ID: 0x2fc8
Created: Apr 25 06:21:57.077 (00:03:37 ago)

```

Verifying SRv6 Local SIDs

This example shows how to verify the allocation of SRv6 local SIDs off locator(s).

```

Router# show segment-routing srv6 locator myLoc1 sid

```

SID	State	RW	Function	Context	Owner
2001:db8:0:a2:1::	InUse	Y	End (PSP)	'default':1	sidmgr

```

2001:db8:0:a2:40::      End.DT4      'VRF1'      bgp-100
    InUse   Y
2001:db8:0:a2:41::      End.X (PSP)  [Hu0/1/0/1, Link-Local]  isis-srv6
    InUse   Y

```

The following example shows how to display detail information regarding an allocated SRv6 local SID.

```
Router# show segment-routing srv6 locator myLoc1 sid 2001:db8:0:a2:40:: detail
```

```

SID          State  RW          Function      Context          Owner
-----
2001:db8:0:a2:40::      End.DT4      'VRF1'      bgp-100
    InUse   Y
    SID context: { table-id=0xe0000011 ('VRF1':IPv4/Unicast) }
    Locator: myLoc1'
    Allocation type: Dynamic
    Created: Feb  1 14:04:02.901 (3d00h ago)

```

Similarly, you can display SID information across locators by using the **show segment-routing sid** command.

show Commands

You can use the following **show** commands to verify the SRv6 global and locator configuration:

Command	Description
show segment-routing srv6 manager	Displays the summary information from SRv6 manager, including platform capabilities.
show segment-routing srv6 locator <i>locator-name</i> [detail]	Displays the SRv6 locator information on the router.
show segment-routing srv6 locator <i>locator-name</i> sid [<i>[sid-ipv6-address]</i> [detail]]	Displays the information regarding SRv6 local SID(s) allocated from a given locator.
show segment-routing srv6 sid [<i>[sid-ipv6-address]</i> all stale] [detail]	Displays SID information across locators. By default, only “active” (i.e. non-stale) SIDs are displayed.
show route ipv6 local-srv6	Displays all SRv6 local-SID prefixes in IPv6 RIB.

Configuring SRv6 under IS-IS

Table 24: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 under IS-IS	Release 7.5.1	This feature is now supported on Cisco NCS 5700 series fixed port routers and the Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native mode.

Intermediate System-to-Intermediate System (IS-IS) protocol already supports segment routing with MPLS dataplane (SR-MPLS). This feature enables extensions in IS-IS to support Segment Routing with IPv6 data plane (SRv6). The extensions include advertising the SRv6 capabilities of nodes and node and adjacency segments as SRv6 SIDs.

SRv6 IS-IS performs the following functionalities:

1. Interacts with SID Manager to learn local locator prefixes and announces the locator prefixes in the IGP domain.
2. Learns remote locator prefixes from other IS-IS neighbor routers and installs the learned remote locator IPv6 prefix in RIB or FIB.
3. Allocate or learn prefix SID and adjacency SIDs, create local SID entries, and advertise them in the IGP domain.

Usage Guidelines and Restrictions

The following usage guidelines and restrictions apply for SRv6 IS-IS:

- An IS-IS address-family can support either SR-MPLS or SRv6, but both at the same time is not supported.

Configuring SRv6 under IS-IS

To configure SRv6 IS-IS, use the **router isis** command. Enable SRv6 under the IS-IS IPv6 address-family and assign SRv6 locator(s) to it. Use the **level {1 | 2}** keywords to advertise the locator only in the specified IS-IS level.

Note If no level is specified, local locators will be advertised into all configured ISIS levels. Ensure that locators are included in the redistribution or propagation policy to prevent potential loops when redistributing between multiple instances or propagating between Level 2 and Level 1.

The following example shows how to configure SRv6 under IS-IS.

```
Router(config)# router isis core
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# segment-routing srv6
```

```
Router(config-isis-srv6)# locator myLoc1 level 1
Router(config-isis-srv6-loc)# exit
```

For more information about configuring IS-IS, refer to the "[Implementing IS-IS](#)" chapter in the *Routing Configuration Guide for Cisco NCS 5500*.

Configuring SRv6 IS-IS Flexible Algorithm

Table 25: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 IS-IS Flexible Algorithm	Release 7.5.1	This feature is now supported on Cisco NCS 5700 series fixed port routers and the Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native mode.

This feature introduces support for implementing Flexible Algorithm using IS-IS SRv6.

SRv6 Flexible Algorithm allows operators to customize IGP shortest path computation according to their own needs. An operator can assign custom SRv6 locators to realize forwarding beyond link-cost-based SPF. As a result, Flexible Algorithm provides a traffic engineered path automatically computed by the IGP to any destination reachable by the IGP.

Restrictions and Usage Guidelines

The following restrictions and usage guidelines apply:

- You can configure up to 8 locators to support SRv6 Flexible Algorithm:
 - All locators prefix must share the same SID block (first 40-bits).
 - The Locator Algorithm value range is 128 to 255.

Configuring SRv6 IS-IS Flexible Algorithm

The following example shows how to configure SRv6 IS-IS Flexible Algorithm.

Note Complete the [SRv6 base configuration](#) before performing these steps.

Note For Cisco NCS5500 Series Routers, you must first use the **hw-module profile segment-routing srv6** command to enable SRv6 functionality. Then, reload the line card after enabling this command.

```
Router(config)# hw-module profile segment-routing srv6
```

```
Router(config)# segment-routing srv6
```

```

Router(config-srv6) # locators
Router(config-srv6-locators) # locator Loc1-BE // best-effort
Router(config-srv6-locator) # prefix 2001:db8:0:a2::/64
Router(config-srv6-locator) # exit
Router(config-srv6-locators) # locator Loc1-LL // low latency
Router(config-srv6-locator) # prefix 2001:db8:1:a2::/64
Router(config-srv6-locator) # algorithm 128
Router(config-srv6-locator) # exit
Router(config-srv6) # exit

```

Configuring SRv6 IS-IS

The following example shows how to configure SRv6 IS-IS.

```

Router(config) # router isis test-igp
Router(config-isis) # flex-algo 128
Router(config-isis-flex-algo) # exit
Router(config-isis) # address-family ipv6 unicast
Router(config-isis-af) # summary-prefix 2001:db8:0::/48
Router(config-isis-af) # summary-prefix 2001:db8:1::/48 algorithm 128 explicit
Router(config-isis-af) # segment-routing srv6
Router(config-isis-srv6) # locator Loc1-BE
Router(config-isis-srv6-loc) # exit
Router(config-isis-srv6) # locator Loc1-LL
Router(config-isis-srv6-loc) # exit

```

Configuring SRv6 IS-IS Prefix Summarization

SRv6 leverages longest-prefix-match IP forwarding. Massive-scale reachability can be achieved by summarizing locators at ABRs and ASBRs. Use the **summary-prefix locator [algorithm algo] [explicit]** command in IS-IS address-family configuration mode to specify that only locators from the specified algorithm contribute to the summary. The **explicit** keyword limits the contributing prefixes to only those belonging to the same algorithm.

The following example shows how to configure SRv6 IS-IS Algorithm Summarization for regular algorithm and Flexible Algorithm (128).

```

Router(config) # router isis test-igp
Router(config-isis) # flex-algo 128
Router(config-isis-flex-algo) # exit
Router(config-isis) # address-family ipv6 unicast
Router(config-isis-af) # summary-prefix 2001:db8:0::/48
Router(config-isis-af) # summary-prefix 2001:db8:1::/48 algorithm 128 explicit
Router(config-isis-af) # segment-routing srv6
Router(config-isis-srv6) # locator Loc1-BE
Router(config-isis-srv6-loc) # exit
Router(config-isis-srv6) # locator Loc1-LL
Router(config-isis-srv6-loc) # exit

```

Enable Flexible Algorithm for Low Latency

The following example shows how to enable Flexible Algorithm for low-latency:

- IS-IS: Configure Flexible Algorithm definition with **delay** objective
- Performance-measurement: Configure static delay per interface

```

Router(config)# router isis test-igp
Router(config-isis)# flex-algo 128
Router(config-isis-flex-algo)# metric-type delay
Router(config-isis-flex-algo)# exit
Router(config-isis)# interface GigabitEthernet0/0/0/0
Router(config-isis-if)# address-family ipv6 unicast
Router(config-isis-if-af)# root

Router(config)# performance-measurement
Router(config-perf-meas)# interface GigabitEthernet0/0/0/0
Router(config-pm-intf)# delay-measurement
Router(config-pm-intf-dm)# advertise-delay 100
Router(config-pm-intf-dm)# commit

```

Configuring SRv6 IS-IS TI-LFA

Table 26: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 IS-IS TI-LFA	Release 7.5.1	This feature is now supported on Cisco NCS 5700 series fixed port routers and the Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native mode.

This feature introduces support for implementing Topology-Independent Loop-Free Alternate (TI-LFA) using IS-IS SRv6.

TI-LFA provides link protection in topologies where other fast reroute techniques cannot provide protection. The goal of TI-LFA is to reduce the packet loss that results while routers converge after a topology change due to a link failure. TI-LFA leverages the post-convergence path which is planned to carry the traffic and ensures link and node protection within 50 milliseconds. TI-LFA with IS-IS SR-MPLS is already supported.

TI-LFA provides link, node, and Shared Risk Link Groups (SRLG) protection in any topology.

Usage Guidelines and Restrictions

The following usage guidelines and restrictions apply:

- TI-LFA provides link protection by default. Additional tiebreaker configuration is required to enable node or SRLG protection.
- Usage guidelines for node and SRLG protection:
 - TI-LFA node protection functionality provides protection from node failures. The neighbor node is excluded during the post convergence backup path calculation.
 - Shared Risk Link Groups (SRLG) refer to situations in which links in a network share a common fiber (or a common physical attribute). These links have a shared risk: when one link fails, other links in the group might also fail. TI-LFA SRLG protection attempts to find the post-convergence backup path that excludes the SRLG of the protected link. All local links that share any SRLG with the protecting link are excluded.
 - When you enable link protection, you can also enable node protection, SRLG protection, or both, and specify a tiebreaker priority in case there are multiple LFAs.
 - Valid priority values are from 1 to 255. The lower the priority value, the higher the priority of the rule. Link protection always has a lower priority than node or SRLG protection.

Configuring SRv6 IS-IS TI-LFA

The following example shows how to configure SRv6 IS-IS TI-LFA.

Note Complete the [SRv6 configuration](#) before performing these steps.

```
Router(config)# router isis core
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# segment-routing srv6
Router(config-isis-srv6)# locator locator1
Router(config-isis-srv6-loc)# exit
Router(config-isis)# interface loopback 0
Router(config-isis-if)# passive
Router(config-isis-if)# address-family ipv6 unicast
Router(config-isis-if-af)# exit
Router(config-isis)# interface bundle-ether 1201
Router(config-isis-if)# address-family ipv6 unicast
Router(config-isis-if-af)# fast-reroute per-prefix
Router(config-isis-if-af)# fast-reroute per-prefix ti-lfa
Router(config-isis-if-af)# exit
Router(config-isis)# interface bundle-ether 1301
Router(config-isis-if)# address-family ipv6 unicast
Router(config-isis-if-af)# fast-reroute per-prefix
Router(config-isis-if-af)# fast-reroute per-prefix ti-lfa
Router(config-isis-if-af)# fast-reroute per-prefix tiebreaker node-protecting index 100
Router(config-isis-if-af)# fast-reroute per-prefix tiebreaker srlg-disjoint index 200
Router(config-isis-if-af)# exit
```

Configuring SRv6 IS-IS TI-LFA with Flexible Algorithm

TI-LFA backup paths for particular Flexible Algorithm are computed using the same constraints as the calculation of the primary paths for such Flexible Algorithm. These paths use Prefix-SIDs advertised specifically for such Flexible Algorithm in order to enforce a backup path.

The following example shows how to configure SRv6 IS-IS TI-LFA with Flexible Algorithm.

```
Router(config)# router isis core
Router(config-isis)# flex-algo 128
Router(config-isis-flex-algo)# exit
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# segment-routing srv6
Router(config-isis-srv6)# locator locator1
Router(config-isis-srv6-loc)# exit
Router(config-isis)# interface bundle-ether 1201
Router(config-isis-if)# address-family ipv6 unicast
Router(config-isis-if-af)# fast-reroute per-prefix
Router(config-isis-if-af)# fast-reroute per-prefix ti-lfa
Router(config-isis-if-af)# exit
```

Use the **fast-reroute disable** command to disable the LFA calculation on a per-algorithm basis:

```
Router(config)# router isis core
Router(config-isis)# flex-algo 128
Router(config-isis-flex-algo)# fast-reroute disable
```

Verification

This example shows how to verify the SRv6 IS-IS TI-LFA configuration using the **show isis ipv6 fast-reroute ipv6-prefix detail** command.

```

Router# show isis ipv6 fast-reroute cafe:0:0:66::/64 detail
Thu Nov 22 16:12:51.983 EST

Configuring SRv6 IS-IS Microloop Avoidance

Table 27: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 IS-IS Microloop Avoidance	Release 7.5.1	This feature is now supported on Cisco NCS 5700 series fixed port routers and the Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native mode.

This feature introduces support for implementing microloop avoidance using IS-IS SRv6.

Microloops are brief packet loops that occur in the network following a topology change (link down, link up, or metric change events). Microloops are caused by the non-simultaneous convergence of different nodes in the network. If nodes converge and send traffic to a neighbor node that has not converged yet, traffic may be looped between these two nodes, resulting in packet loss, jitter, and out-of-order packets.

The SRv6 Microloop Avoidance feature detects if microloops are possible following a topology change. If a node computes that a microloop could occur on the new topology, the node creates a loop-free SR-TE policy path to the destination using a list of segments. After the RIB update delay timer expires, the SR-TE policy is replaced with regular forwarding paths.

Restrictions and Usage Guidelines

The following restrictions and usage guidelines apply:

- The Routing Information Base (RIB) update delay value specifies the amount of time the node uses the microloop avoidance policy before updating its forwarding table. The *delay-time* range is from 1 to 60000 milliseconds; the default value is 5000.

Configuring SRv6 IS-IS Microloop Avoidance

The following example shows how to configure SRv6 IS-IS Microloop Avoidance and set the Routing Information Base (RIB) update delay value.

Note Complete the [SRv6 configuration](#) before performing these steps.

```
Router(config)# router isis test-igp
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# microloop avoidance segment-routing
Router(config-isis-af)# microloop avoidance rib-update-delay 2000
Router(config-isis-af)# commit
```

Configuring SRv6 IS-IS Microloop Avoidance with Flexible Algorithm

Microloop Avoidance paths for particular Flexible Algorithm are computed using the same constraints as the calculation of the primary paths for such Flexible Algorithm. These paths use Prefix-SIDs advertised specifically for such Flexible Algorithm in order to enforce a microloop avoidance path.

The following example shows how to configure SRv6 IS-IS Microloop Avoidance with Flexible Algorithm.

```
Router(config)# segment-routing srv6
Router(config-srv6)# locators
Router(config-srv6-locators)# locator myLoc1
Router(config-srv6-locator)# prefix 2001:db8:1:a2::/64
Router(config-srv6-locator)# algorithm 128
Router(config-srv6-locator)# root

Router(config)# router isis test-uloop
Router(config-isis)# flex-algo 128
Router(config-isis-flex-algo)# exit
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# microloop avoidance segment-routing
Router(config-isis-af)# segment-routing srv6
Router(config-isis-srv6)# locator myLoc1
Router(config-isis-srv6-loc)# commit
```

Use the **microloop avoidance disable** command to disable the microloop calculation on a per-algorithm basis:

```
Router(config)# router isis test-tilfa
Router(config-isis)# flex-algo 128
Router(config-isis-flex-algo)# microloop avoidance disable
```

SRv6 Services: IPv4 L3VPN

Table 28: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 Services: IPv4 L3VPN	Release 7.5.1	This feature is now supported on Cisco NCS 5700 series fixed port routers and the Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native mode.

Table 29: Feature History Table

Feature Name	Release	Description
Dual-Stack L3VPN Services (IPv4, IPv6) (SRv6 Base)	Release 7.3.2	This feature introduces support for Dual-stack (VPNv4/VPNv6) VRFs. VPNv4/VPNv6 Dual-stack supports both IPv4 (End.DT4) and IPv6 (End.DT6) based SRv6 L3VPN service on the same interface, sub-interface, or VRF.

The SRv6-based IPv4 L3VPN feature enables deployment of IPv4 L3VPN over a SRv6 data plane. Traditionally, it was done over an MPLS-based system. SRv6-based L3VPN uses SRv6 Segment IDs (SIDs) for service segments instead of labels. SRv6-based L3VPN functionality interconnects multiple sites to resemble a private network service over public infrastructure. To use this feature, you must configure SRv6-base.

For this feature, BGP allocates an SRv6 SID from the locator space, configured under SRv6-base and VPNv4 address family. For more information on this, refer [Segment Routing over IPv6 Overview, on page 152](#). The BGP SID can be allocated in the following ways:

- Per-VRF mode that provides End.DT4 support. End.DT4 represents the Endpoint with decapsulation and IPv4 table lookup.
- Per-CE mode that provides End.DX4 cross connect support. End.DX4 represents the Endpoint with decapsulation and IPv4 cross-connect.

BGP encodes the SRv6 SID in the prefix-SID attribute of the IPv4 L3VPN Network Layer Reachability Information (NLRI) and advertises it to IPv6 peering over an SRv6 network. The Ingress PE (provider edge) router encapsulates the VRF IPv4 traffic with the SRv6 VPN SID and sends it over the SRv6 network.

Usage Guidelines and Limitations

- SRv6 locator can be assigned globally, for all VRFs, for an individual VRF, or per-prefix.
- Equal-Cost Multi-path (ECMP) and Unequal Cost Multipath (UCMP) are supported.
- BGP, OSPF, Static are supported as PE-CE protocol.
- Dual-Stack L3VPN Services (IPv4, IPv6) are supported.
- MPLS L3VPN and SRv6 L3VPN interworking gateway is supported.

Configuring SRv6 based IPv4 L3VPN

To enable SRv6-based L3VPN, you need to configure SRv6 under BGP and configure the SID allocation mode. The following example shows how to configure SRv6-based L3VPN:

Configure SRv6 Locator Under BGP Global

```
RP/0/0/CPU0:Router(config)# router bgp 100
RP/0/0/CPU0:Router(config-bgp)# bgp router-id 10.6.6.6
RP/0/0/CPU0:Router(config-bgp)# segment-routing srv6
RP/0/0/CPU0:Router(config-bgp-srv6)# locator my_locator
RP/0/0/CPU0:Router(config-bgp-srv6)# exit
```

Configure SRv6 Locator For All VRF Under VPNv4 AFI

```
RP/0/0/CPU0:Router(config)# router bgp 100
RP/0/0/CPU0:Router(config-bgp)# bgp router-id 10.6.6.6
RP/0/0/CPU0:Router(config-bgp)# address-family vpnv4 unicast
RP/0/0/CPU0:Router(config-bgp-af)# vrf all
RP/0/0/CPU0:Router(config-bgp-af-vrfall)# segment-routing srv6
RP/0/0/CPU0:Router(config-bgp-af-vrfall-srv6)# locator my_locator

```

Configure an Individual VRF with Per-VRF Label Allocation Mode

```
RP/0/0/CPU0:Router(config-bgp-af)# vrf vrf1
RP/0/0/CPU0:Router(config-bgp-vrf)# rd 106:1
RP/0/0/CPU0:Router(config-bgp-vrf)# address-family ipv4 unicast
RP/0/0/CPU0:Router(config-bgp-vrf-af)# segment-routing srv6
RP/0/0/CPU0:Router(config-bgp-vrf-af-srv6)# alloc mode per-vrf
RP/0/0/CPU0:Router(config-bgp-vrf-af-srv6)# exit
RP/0/0/CPU0:Router(config-bgp-vrf-af)# exit
RP/0/0/CPU0:Router(config-bgp-vrf)# neighbor 10.1.2.2
RP/0/0/CPU0:Router(config-bgp-vrf-nbr)# remote-as 100
RP/0/0/CPU0:Router(config-bgp-vrf-nbr)# address-family ipv4 unicast
```

Configure an Individual VRF with Per-CE Label Allocation Mode

```
RP/0/0/CPU0:Router(config-bgp-af)# vrf vrf2
RP/0/0/CPU0:Router(config-bgp-vrf)# rd 106:2
RP/0/0/CPU0:Router(config-bgp-vrf)# address-family ipv4 unicast
RP/0/0/CPU0:Router(config-bgp-vrf-af)# segment-routing srv6
RP/0/0/CPU0:Router(config-bgp-vrf-af-srv6)# alloc mode per-ce
RP/0/0/CPU0:Router(config-bgp-vrf-af-srv6)# exit
RP/0/0/CPU0:Router(config-bgp-vrf-af)# exit
RP/0/0/CPU0:Router(config-bgp-vrf)# neighbor 10.1.2.2
RP/0/0/CPU0:Router(config-bgp-vrf-nbr)# remote-as 100
RP/0/0/CPU0:Router(config-bgp-vrf-nbr)# address-family ipv4 unicast
```

Assigning SRv6 Locator for a Specific Prefix

This use case provides the ability to assign a specific SRv6 locator for a given prefix or a set of prefixes. The egress PE advertises the prefix with the specified locator. This allows for per-prefix steering into desired transport behaviors, such as Flex Algo.

To assign an SRv6 locator for a specific prefix, configure a route policy to specify the SID allocation mode based on match criteria. Examples of match criteria are destination-based match or community-based match.

- Supported SID allocation modes are per-VRF and per-CE.
- For per-VRF allocation mode, you can also specify the SRv6 locator.
 - If an SRv6 locator is specified in the route policy, BGP will use that to allocate per-VRF SID. If the specified locator is invalid, the SID will not be allocated.
 - If an SRv6 locator is not specified in the route policy, the default locator configured under BGP is used to allocate the SID. If the default locator is not configured, then the SID will not be allocated.
- Per-CE allocation mode always uses the default locator configured under BGP to allocate the SID.

For more information on configuring routing policies, refer to the "Implementing Routing Policy" chapter in the *Routing Configuration Guide for Series Routers*.

The following example shows a route policy specifying the SID allocation mode with destination-based match:

```
Node1(config)# route-policy set_per_prefix_locator_rpl
Node1(config-rpl)# if destination in (10.1.1.0/24) then
Node1(config-rpl-if)# set srv6-alloc-mode per-vrf locator locator1
Node1(config-rpl-if)# elseif destination in (2.2.2.0/24) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf locator locator2
Node1(config-rpl-elseif)# elseif destination in (3.3.3.0/24) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf
Node1(config-rpl-elseif)# elseif destination in (4.4.4.0/24) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-ce
Node1(config-rpl-elseif)# else
Node1(config-rpl-else)# drop
Node1(config-rpl-else)# endif
Node1(config-rpl)# end-policy
Node1(config)#
```

To specify per-prefix allocation mode for a specific VRF under IPv4 Address Family, use the following command:

- **router bgp** *as-number* **vrf** *WORD* **address-family ipv4 unicast segment-routing srv6 alloc mode** *route-policy policy_name*

This example shows how to configure per-prefix allocation mode for a specific VRF (vrf_cust1) under IPv4 address family

```
Node1(config)# router bgp 100
Node1(config-bgp)# vrf vrf_cust1
Node1(config-bgp-vrf)# address-family ipv4 unicast
Node1(config-bgp-vrf-af)# segment-routing srv6
Node1(config-bgp-vrf-af-srv6)# alloc mode route-policy set_per_prefix_locator_rpl
```

Running Configuration

```
route-policy set_per_prefix_locator_rpl
  if destination in (10.1.1.0/24) then
    set srv6-alloc-mode per-vrf locator locator1
  elseif destination in (2.2.2.0/24) then
    set srv6-alloc-mode per-vrf locator locator2
  elseif destination in (3.3.3.0/24) then
    set srv6-alloc-mode per-vrf
  elseif destination in (4.4.4.0/24) then
    set srv6-alloc-mode per-ce
  else
    drop
  endif
end-policy
!
router bgp 100
  vrf vrf_cust1
    address-family ipv4 unicast
      segment-routing srv6
        alloc mode route-policy set_per_prefix_locator_rpl
    !
  !
!
```

Verify that the local and received SIDs have been correctly allocated under IPv4 address family and specific VRF (vrf_cust1):

```

Verification

The following example shows how to verify the SRv6 based L3VPN configuration using the **show segment-routing srv6 sid** command.

In this example, End.X represents Endpoint function with Layer-3 cross-connect, End.DT4 represents Endpoint with decapsulation and IPv4 table lookup, and End.DX4 represents Endpoint with decapsulation and IPv4 cross-connect.

```

RP/0/0/CPU0:SRv6-Hub6# show segment-routing srv6 sid
*** Locator: 'my_locator' ***
SID          Function      Context                      Owner
  State  RW
-----
-----
cafe:0:0:66:1::      End (PSP)    'my_locator':1             sidmgr
    InUse  Y
cafe:0:0:66:40::     End.X (PSP)  [Te0/0/0/2, Link-Local]    isis-srv6

```

```

      InUse Y
cafe:0:0:66:41::      End.X (PSP) [BE6801, Link-Local]      isis-srv6
      InUse Y
cafe:0:0:66:42::      End.X (PSP) [BE5601, Link-Local]      isis-srv6
      InUse Y

SRv6 Services: IPv6 L3VPN

Building on the messages and procedures defined in IETF draft "[BGP/MPLS IP Virtual Private Networks \(VPNs\)](#)", this feature provides IPv6 L3VPNs (VPNv6) over an SRv6 network.

In SRv6-based L3VPNs, the egress PE signals an SRv6 Service SID with the BGP overlay service route. The ingress PE encapsulates the IPv4/IPv6 payload in an outer IPv6 header where the destination address is the

SRv6 Service SID provided by the egress PE. BGP messages between PEs carry SRv6 Service SIDs as a means to interconnect PEs and form VPNs.

SRv6 Service SID refers to a segment identifier associated with one of the SRv6 service-specific behaviors on the advertising VPNv6 PE router, such as END.DT6 (Endpoint with decapsulation and IPv6 table lookup) behaviors.

Based on the messages and procedures defined in IETF draft "[SRv6 BGP based Overlay services](#)", BGP encodes the SRv6 Service SID in the prefix-SID attribute of the IPv6 L3VPN Network Layer Reachability Information (NLRI) and advertises it to its IPv6 BGP peers.

BGP allocates an SRv6 Service SID from the locator space, configured under SRv6 and VPNv6 address family. For more information on this, see [Segment Routing over IPv6 Overview](#). The SRv6 Service SID can be allocated in the following ways:

- Per-VRF mode that provides End.DT6 support. End.DT6 represents the Endpoint with decapsulation and IPv6 table lookup.

Usage Guidelines and Restrictions

- SRv6 locator can be assigned globally, for all VRFs, for an individual VRF, or per-prefix.
- Equal-Cost Multi-path (ECMP) and Unequal Cost Multipath (UCMP) are supported.
- BGP, OSPF, Static are supported as PE-CE protocol.
- Dual-Stack L3VPN Services (IPv4, IPv6) are supported.
- MPLS L3VPN and SRv6 L3VPN interworking gateway is supported.

Configuring SRv6-based IPv6 L3VPN

To enable SRv6-based L3VPN, you need to configure SRv6 under BGP and configure the SID allocation mode.

The following examples show how to configure SRv6-based L3VPN.

Configure SRv6 Locator Under BGP Global

This example shows how to configure the SRv6 locator name under BGP Global:

```
RP/0/0/CPU0:Node1(config)# router bgp 100
RP/0/0/CPU0:Node1(config-bgp)# segment-routing srv6
RP/0/0/CPU0:Node1(config-bgp-gbl-srv6)# locator Node1-locator
RP/0/0/CPU0:Node1(config-bgp-gbl-srv6)# exit
RP/0/0/CPU0:Node1(config-bgp)# address-family vpnv6 unicast
RP/0/0/CPU0:Node1(config-bgp-af)# exit
RP/0/0/CPU0:Node1(config-bgp)# neighbor 3001::1:1:1:4
RP/0/0/CPU0:Node1(config-bgp-nbr)# remote-as 100
RP/0/0/CPU0:Node1(config-bgp-nbr)# address-family vpnv6 unicast
RP/0/0/CPU0:Node1(config-bgp-nbr-af)# exit
RP/0/0/CPU0:Node1(config-bgp-nbr)# exit
RP/0/0/CPU0:Node1(config-bgp)# vrf vrf_cust6
RP/0/0/CPU0:Node1(config-bgp-vrf)# rd 100:6
RP/0/0/CPU0:Node1(config-bgp-vrf)# address-family ipv6 unicast
RP/0/0/CPU0:Node1(config-bgp-vrf-af)# commit
```

Running Configuration

```

router bgp 100
  segment-routing srv6
    locator Node1-locator
  !
  address-family vpnv6 unicast
  !
  neighbor 3001::1:1:1:4
    remote-as 100
    address-family vpnv6 unicast
  !
  !
  vrf vrf_cust6
    rd 100:6
    address-family ipv6 unicast
  !
  !
end

```

Configure SRv6 Locator For All VRF Under VPNv6 AFI

This example shows how to configure the SRv6 locator for all VRFs under VPNv6 address family, with per-VRF label allocation mode:

```

RP/0/0/CPU0:Node1(config)# router bgp 100
RP/0/0/CPU0:Node1(config-bgp)# address-family vpnv6 unicast
RP/0/0/CPU0:Node1(config-bgp-af)# vrf all
RP/0/0/CPU0:Node1(config-bgp-af-vrfall)# segment-routing srv6
RP/0/0/CPU0:Node1(config-bgp-af-vrfall-srv6)# locator Node1-locator
RP/0/0/CPU0:Node1(config-bgp-af-vrfall-srv6)# alloc mode per-vrf
RP/0/0/CPU0:Node1(config-bgp-af-vrfall-srv6)# exit
RP/0/0/CPU0:Node1(config-bgp-af-vrfall)# exit
RP/0/0/CPU0:Node1(config-bgp-af)# exit
RP/0/0/CPU0:Node1(config-bgp)# neighbor 3001::1:1:1:4
RP/0/0/CPU0:Node1(config-bgp-nbr)# remote-as 100
RP/0/0/CPU0:Node1(config-bgp-nbr)# address-family vpnv6 unicast
RP/0/0/CPU0:Node1(config-bgp-nbr-af)# exit
RP/0/0/CPU0:Node1(config-bgp-nbr)# exit
RP/0/0/CPU0:Node1(config-bgp)# vrf vrf_cust6
RP/0/0/CPU0:Node1(config-bgp-vrf)# rd 100:6
RP/0/0/CPU0:Node1(config-bgp-vrf)# address-family ipv6 unicast
RP/0/0/CPU0:Node1(config-bgp-vrf-af)# commit

```

Running Configuration

```

router bgp 100
  address-family vpnv6 unicast
    vrf all
      segment-routing srv6
        locator Node1-locator
        alloc mode per-vrf
    !
  !
  neighbor 3001::1:1:1:4
    remote-as 100
    address-family vpnv6 unicast
  !
  !
  vrf vrf_cust6
    rd 100:6
    address-family ipv6 unicast

```

```

!
!
!
end

```

Configure an Individual VRF with Per-VRF Label Allocation Mode

This example shows how to configure the SRv6 locator for an individual VRF, with per-VRF label allocation mode:

```

RP/0/0/CPU0:Node1(config)# router bgp 100
RP/0/0/CPU0:Node1(config-bgp)# address-family vpnv6 unicast
RP/0/0/CPU0:Node1(config-bgp-af)# exit
RP/0/0/CPU0:Node1(config-bgp)# neighbor 3001::1:1:1:4
RP/0/0/CPU0:Node1(config-bgp-nbr)# remote-as 100
RP/0/0/CPU0:Node1(config-bgp-nbr)# address-family vpnv6 unicast
RP/0/0/CPU0:Node1(config-bgp-nbr-af)# exit
RP/0/0/CPU0:Node1(config-bgp-nbr)# exit
RP/0/0/CPU0:Node1(config-bgp)# vrf vrf_cust6
RP/0/0/CPU0:Node1(config-bgp-vrf)# rd 100:6
RP/0/0/CPU0:Node1(config-bgp-vrf)# address-family ipv6 unicast
RP/0/0/CPU0:Node1(config-bgp-vrf-af)# segment-routing srv6
RP/0/0/CPU0:Node1(config-bgp-vrf-af-srv6)# locator Node1-locator
RP/0/0/CPU0:Node1(config-bgp-vrf-af-srv6)# alloc mode per-vrf
RP/0/0/CPU0:Node1(config-bgp-vrf-af-srv6)# commit

```

Running Configuration

```

router bgp 100
 address-family vpnv6 unicast
!
 neighbor 3001::1:1:1:4
  remote-as 100
 address-family vpnv6 unicast
!
!
vrf vrf_cust6
 rd 100:6
 address-family ipv6 unicast
  segment-routing srv6
   locator Node1-locator
   alloc mode per-vrf
!
!
!
end

```

Assigning SRv6 Locator for a Specific Prefix

This use case provides the ability to assign a specific SRv6 locator for a given prefix or a set of prefixes. The egress PE advertises the prefix with the specified locator. This allows for per-prefix steering into desired transport behaviors, such as Flex Algo.

To assign an SRv6 locator for a specific prefix, configure a route policy to specify the SID allocation mode based on match criteria. Examples of match criteria are destination-based match or community-based match.

- Supported SID allocation modes are per-VRF and per-CE.
- For per-VRF allocation mode, you can also specify the SRv6 locator.

- If an SRv6 locator is specified in the route policy, BGP will use that to allocate per-VRF SID. If the specified locator is invalid, the SID will not be allocated.
- If an SRv6 locator is not specified in the route policy, the default locator is used to allocate the SID. If the default locator is not configured in BGP, then the SID will not be allocated.
- Per-CE allocation mode always uses the default locator to allocate the SID.

The following example shows a route policy specifying the SID allocation mode with destination-based match:

```
Node1(config)# route-policy set_per_prefix_locator_rpl
Node1(config-rpl)# if destination in (3001::1:1:1:1/128) then
Node1(config-rpl-if)# set srv6-alloc-mode per-vrf locator locator1
Node1(config-rpl-if)# elseif destination in (3001::2:2:2:2/128) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf locator locator2
Node1(config-rpl-elseif)# elseif destination in (3001::3:3:3:3/128) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf
Node1(config-rpl-elseif)# elseif destination in (3001::4:4:4:4/128) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-ce
Node1(config-rpl-elseif)# else
Node1(config-rpl-else)# drop
Node1(config-rpl-else)# endif
Node1(config-rpl)# end-policy
```

To specify per-prefix allocation mode for a specific VRF under IPv6 Address Family, use the following command:

- **router bgp** *as-number* **vrf** *WORD* **address-family ipv6 unicast segment-routing srv6 alloc mode route-policy** *policy_name*

This example shows how to specify per-prefix allocation mode for a specific VRF (vrf_cust1) under the IPv6 address family:

```
Node1(config)# router bgp 100
Node1(config-bgp)# vrf vrf_cust6
Node1(config-bgp-vrf)# address-family ipv6 unicast
Node1(config-bgp-vrf-af)# segment-routing srv6
Node1(config-bgp-vrf-af-srv6)# alloc mode route-policy set_per_prefix_locator_rpl
```

Running Configuration

```
route-policy set_per_prefix_locator_rpl
  if destination in (3001::1:1:1:1/128) then
    set srv6-alloc-mode per-vrf locator locator1
  elseif destination in (3001::2:2:2:2/128) then
    set srv6-alloc-mode per-vrf locator locator2
  elseif destination in (3001::3:3:3:3/128) then
    set srv6-alloc-mode per-vrf
  elseif destination in (3001::4:4:4:4/128) then
    set srv6-alloc-mode per-ce
  else
    drop
  endif
end-policy
!
router bgp 100
  vrf vrf_cust6
    address-family ipv6 unicast
      segment-routing srv6
        alloc mode route-policy set_per_prefix_locator_rpl
```

```

!
!
!
!

```

Verify that the local and received SIDs have been correctly allocated under IPv6 address family and specific VRF (vrf_cust6):

Node1# **show bgp vpnv6 unicast local-sids**

SRv6 Services: IPv4 L3VPN Active-Standby Redundancy using Port-Active Mode

The Segment Routing IPv6 (SRv6) Services: IPv4 L3VPN Active-Standby Redundancy using Port-Active Mode feature provides all-active per-port load balancing for multihoming. The forwarding of traffic is determined based on a specific interface rather than per-flow across multiple Provider Edge routers. This feature enables efficient load-balancing and provides faster convergence. In an active-standby scenario, the active PE router is detected using designated forwarder (DF) election by modulo calculation and the interface of the standby PE router brought down. For Modulo calculation, byte 10 of the Ethernet Segment Identifier (ESI) is used.

Usage Guidelines and Restrictions

- This feature can only be configured for bundle interfaces.
- When an EVPN Ethernet Segment (ES) is configured with port-active load-balancing mode, you cannot configure ACs of that bundle on bridge-domains with a configured EVPN instance (EVI). EVPN Layer 2 bridging service is not compatible with port-active load-balancing.

SRv6 Services for L3VPN Active-Standby Redundancy using Port-Active Mode: Operation

Under port-active operational mode, EVPN Ethernet Segment (ES) routes are exchanged across BGP for the routers servicing the multihomed ES. Each PE router then builds an ordered list of the IP addresses of all PEs connected to the ES, including itself, and assigns itself an ordinal for its position in the list. The ordinals are used with the modulo calculation to determine which PE will be the Designated Forwarder (DF) for a given ES. All non-DF PEs will take the respective bundles out of service.

In the case of link or port failure, the active DF PE withdraws its ES route. This re-triggers DF election for all PEs that service the ES and a new PE is elected as DF.

Configure SRv6 Services L3VPN Active-Standby Redundancy using Port-Active Mode

This section describes how you can configure SRv6 services L3VPN active-standby redundancy using port-active mode under an Ethernet Segment (ES).

Configuration Example

```
/* Configure Ethernet Link Bundles */
Router# configure
Router(config)# interface Bundle-Ether10
Router(config-if)# ipv4 address 10.0.0.2 255.255.255.0
Router(config-if)# ipv6 address 2001:DB8::1
Router(config-if)# lacp period short
Router(config-if)# mac-address 1.2.3
Router(config-if)# bundle wait-while 0
Router(config-if)# exit
Router(config)# interface GigabitEthernet 0/2/0/5
Router(config-if)# bundle id 14 mode active
Router(config-if)# commit

/* Configure load balancing. */
Router# configure
Router(config)# evpn
Router(config-evpn)# interface Bundle-Ether10
Router(config-evpn-ac)# ethernet-segment
Router(config-evpn-ac-es)# identifier type 0 11.11.11.11.11.11.11.14
Router(config-evpn-ac-es)# load-balancing-mode port-active
Router(config-evpn-ac-es)# commit
!
/* Configure address family session in BGP. */
Router# configure
Router(config)# router bgp 100
Router(config-bgp)# bgp router-id 192.168.0.2
Router(config-bgp)# address-family l2vpn evpn
Router(config-bgp)# neighbor 192.168.0.3
Router(config-bgp-nbr)# remote-as 200
Router(config-bgp-nbr)# update-source Loopback 0
Router(config-bgp-nbr)# address-family l2vpn evpn
Router(config-bgp-nbr)# commit
```

Running Configuration

```

interface Bundle-Ether14
  ipv4 address 14.0.0.2 255.255.255.0
  ipv6 address 14::2/64
  lacp period short
  mac-address 1.2.3
  bundle wait-while 0
!
interface GigabitEthernet0/2/0/5
  bundle id 14 mode active
!
evpn
  interface Bundle-Ether14
    ethernet-segment
      identifier type 0 11.11.11.11.11.11.11.14
      load-balancing-mode port-active
    !
  !
!
router bgp 100
  bgp router-id 192.168.0.2
  address-family l2vpn evpn
  !
  neighbor 192.168.0.3
    remote-as 100
    update-source Loopback0
    address-family l2vpn evpn
  !
!
!

```

Verification

Verify the SRv6 services L3VPN active-standby redundancy using port-active mode configuration.

```

/* Verify ethernet-segment details on active DF router */
Router# show evpn ethernet-segment interface Bundle-Ether14 detail

```

SRv6 Services: IPv4 L3VPN Active-Active Redundancy

This feature provides active-active connectivity to a CE device in a L3VPN deployment. The CE device can be Layer-2 or Layer-3 device connecting to the redundant PEs over a single LACP LAG port.

Depending on the bundle hashing, an ARP or IPv6 Network Discovery (ND) packet can be sent to any of the redundant routers. As a result, not all entries will exist on a given PE. In order to provide complete awareness, Layer-3 local route learning is augmented with remote route-synchronization programming.

Route synchronization between service PEs is required in order to provide minimum interruption to unicast and multicast services after failure on a redundant service PE. The following EVPN route-types are used for Layer-3 route synchronization:

- EVPN route-type 2 for synchronizing ARP tables
- EVPN route-type 7/8 for synchronizing IGMP JOINS/LEAVES

In a Layer-3 CE scenario, the router that connects to the redundant PEs may establish an IGP adjacency on the bundle port. In this case, the adjacency will be formed to one of the redundant PEs, and IGP customer routes will only be present on that PE. To synchronize Layer-3 customer subnet routes (IP Prefixes), the EVPN route-type 5 is used to carry the ESI and ETAG as well as the gateway address (prefix next-hop address).

Note Gratuitous ARP (GARP) or IPv6 Network Advertisement (NA) replay is not needed for CEs connected to the redundant PEs over a single LAG port.

The below configuration enables Layer-3 route synchronization for routes learned on the Ethernet-segment sub-interfaces.

```
evpn
 route-sync vrf default
!
vrf RED
 evi route-sync 10
!
vrf BLUE
 evi route-sync 20
!
```

Note EVPN does not support untagged interfaces.

SRv6 Services: BGP Global IPv4

Table 30: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 Services: BGP Global IPv4	Release 7.5.1	This feature is now supported on Cisco NCS 5700 series fixed port routers and the Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native mode.

This feature extends support of SRv6-based BGP services to include Internet (IPv4) services by implementing End.DT4 SRv6 functions at the PE node ([draft-ietf-bess-srv6-services](#)).

Usage Guidelines and Limitations

- SRv6 locator can be assigned globally or under IPv4 unicast address family
- Equal-Cost Multi-path (ECMP) and Unequal Cost Multipath (UCMP) are supported.
- BGP, OSPF, Static are supported as PE-CE protocol.
- Dual-Stack L3 Services (IPv4 BGP global, IPv6 BGP global) are supported.

Use Case 1: BGP Global IPv4 Over SRv6 with Per-VRF SID Allocation Mode (End.DT4)

The following example shows how to configure BGP global IPv4 over SRv6 with per-VRF SID allocation.

```

Node1(config)# router bgp 1
Node1(config-bgp)# bgp router-id 10.1.0.1
Node1(config-bgp)# address-family ipv4 unicast
Node1(config-bgp-af)# segment-routing srv6
Node1(config-bgp-af-srv6)# locator Node1
Node1(config-bgp-af-srv6)# alloc mode per-vrf
Node1(config-bgp-af-srv6)# exit
Node1(config-bgp-af)# exit
Node1(config-bgp)# neighbor 60::2
Node1(config-bgp-nbr)# remote-as 1
Node1(config-bgp-nbr)# update-source Loopback1
Node1(config-bgp-nbr)# address-family ipv4 unicast
Node1(config-bgp-nbr-af)# encapsulation-type srv6
Node1(config-bgp-nbr-af)# exit
Node1(config-bgp-nbr)# exit
Node1(config-bgp)# neighbor 52.52.52.1
Node1(config-bgp-nbr)# remote-as 3
Node1(config-bgp-nbr)# address-family ipv4 unicast
Node1(config-bgp-nbr-af)# route-policy passall in
Node1(config-bgp-nbr-af)# route-policy passall out
Node1(config-bgp-nbr-af)# commit

```

Running Configuration

```

router bgp 1
  bgp router-id 10.1.0.1
  address-family ipv4 unicast
    segment-routing srv6
      locator Node1
      alloc mode per-vrf
  !
!
neighbor 60::2
  remote-as 1
  update-source Loopback1
  address-family ipv4 unicast
    encapsulation-type srv6
  !
!
neighbor 52.52.52.1
  remote-as 3
  address-family ipv4 unicast
    route-policy passall in
    route-policy passall out
  !
!
!

```

Use Case 2: BGP Global IPv4 over SRv6 with Per-Prefix SID Allocation

This use case provides the ability to assign a specific SRv6 locator for a given prefix or a set of prefixes. The egress PE advertises the prefix with the specified locator. This allows for per-prefix steering into desired transport behaviors, such as Flex Algo.

To assign an SRv6 locator for a specific prefix, configure a route policy to specify the SID allocation mode based on match criteria. Examples of match criteria are destination-based match or community-based match.

- Supported SID allocation modes are per-VRF and per-CE.
- For per-VRF allocation mode, you can also specify the SRv6 locator.
 - If an SRv6 locator is specified in the route policy, BGP will use that to allocate per-VRF SID. If the specified locator is invalid, the SID will not be allocated.
 - If an SRv6 locator is not specified in the route policy, the default locator is used to allocate the SID. If the default locator is not configured in BGP, then the SID will not be allocated.
- Per-CE allocation mode always uses the default locator to allocate the SID.

For more information on configuring routing policies, refer to the "Implementing Routing Policy" chapter in the *Routing Configuration Guide for Series Routers*.

The following example shows a route policy specifying the SID allocation mode with destination-based match:

```

Node1(config)# route-policy set_per_prefix_locator_rpl
Node1(config-rpl)# if destination in (10.1.1.0/24) then
Node1(config-rpl-if)# set srv6-alloc-mode per-vrf locator locator1
Node1(config-rpl-if)# elseif destination in (2.2.2.0/24) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf locator locator2
Node1(config-rpl-elseif)# elseif destination in (3.3.3.0/24) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf
Node1(config-rpl-elseif)# elseif destination in (4.4.4.0/24) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-ce
Node1(config-rpl-elseif)# else
Node1(config-rpl-else)# drop
Node1(config-rpl-else)# endif
Node1(config-rpl)# end-policy
Node1(config)#

```

The following example shows how to configure BGP global IPv4 over SRv6 with a route policy to determine the SID allocation mode for given prefix.

```

Node1(config)# router bgp 100
Node1(config-bgp)# address-family ipv4 unicast
Node1(config-bgp-af)# segment-routing srv6
Node1(config-bgp-af-srv6)# alloc mode route-policy set_per_prefix_locator_rpl

```

Running Configuration

```

route-policy set_per_prefix_locator_rpl
  if destination in (10.1.1.0/24) then
    set srv6-alloc-mode per-vrf locator locator1
  elseif destination in (2.2.2.0/24) then
    set srv6-alloc-mode per-vrf locator locator2
  elseif destination in (3.3.3.0/24) then
    set srv6-alloc-mode per-vrf
  elseif destination in (4.4.4.0/24) then
    set srv6-alloc-mode per-ce

```

```

    else
    drop
    endif
end-policy
!
router bgp 100
  address-family ipv4 unicast
    segment-routing srv6
    alloc mode route-policy set_per_prefix_locator_rpl
  !
!
!

```

Verify that the local and received SIDs have been correctly allocated under BGP IPv4 address family:

Node1# **show bgp ipv4 unicast local-sids**

```

...

SRv6 Services: BGP Global IPv6

Table 31: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 Services: BGP Global IPv6	Release 7.5.1	This feature is now supported on Cisco NCS 5700 series fixed port routers and the Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native mode.

Table 32: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 Services: BGP Global IPv6	Release 7.2.2	With this feature, the egress PE can signal an SRv6 Service SID with the BGP overlay service route. The ingress PE encapsulates the IPv4/IPv6 payload in an outer IPv6 header where the destination address is the SRv6 Service SID provided by the egress PE. BGP messages between PEs carry SRv6 Service SIDs as a means to interconnect PEs.

This feature extends support of SRv6-based BGP services to include Internet (IPv6) services by implementing End.DT6 SRv6 functions at the PE node, as defined in IETF draft "[SRv6 BGP based Overlay services](#)".

Usage Guidelines and Limitations

- SRv6 locator can be assigned globally or under IPv4 unicast address family
- Equal-Cost Multi-path (ECMP) and Unequal Cost Multipath (UCMP) are supported.
- BGP, OSPF, Static are supported as PE-CE protocol.
- Dual-Stack L3 Services (IPv4 BGP global, IPv6 BGP global) are supported.

BGP Global IPv6 Over SRv6 with Per-VRF SID Allocation Mode (End.DT6)

To configure BGP global IPv6 over SRv6, use the following commands:

- **router bgp *as-number* address-family ipv6 unicast segment-routing srv6:** Enable SRv6
- **router bgp *as-number* address-family ipv6 unicast segment-routing srv6 alloc mode {*per-vrf* | *route-policy policy_name*}:** Specify the SID behavior (allocation mode).
 - **per-vrf:** Specifies that the same label is be used for all the routes advertised from a unique VRF.
 - **route-policy *policy_name*:** Uses a route policy to determine the SID allocation mode and locator (if provided) for given prefix.
- **router bgp *as-number* address-family ipv6 unicast segment-routing srv6 locator *WORD*:** Specify the locator
- **router bgp *as-number* {*af-group WORD* | *neighbor-group WORD* | *neighbor ipv6-addr*} address-family ipv6 unicast encapsulation-type srv6:** Specify the encapsulation type for SRv6.
 - Use **af-group *WORD*** to apply the SRv6 encapsulation type to the address family group for BGP neighbors.
 - Use **neighbor-group *WORD*** to apply the SRv6 encapsulation type to the neighbor group for Border Gateway Protocol (BGP) neighbors.
 - Use **neighbor *ipv6-addr*** to apply the SRv6 encapsulation type to the specific BGP neighbor.

Use Case 1: BGP Global IPv6 over SRv6 with Per-AFI SID Allocation

The following example shows how to configure BGP global IPv6 over SRv6 with per-VRF SID allocation.

```
Node1(config)# router bgp 100
Node1(config-bgp)# bgp router-id 10.1.1.1
Node1(config-bgp)# segment-routing srv6
Node1(config-bgp-gbl-srv6)# locator Node1
Node1(config-bgp-gbl-srv6)# exit
Node1(config-bgp)# address-family ipv6 unicast
Node1(config-bgp-af)# segment-routing srv6
Node1(config-bgp-af-srv6)# locator Node1
Node1(config-bgp-af-srv6)# alloc mode per-vrf
Node1(config-bgp-af-srv6)# exit
Node1(config-bgp-af)# exit
Node1(config-bgp)# neighbor 3001::1:1:1:4
Node1(config-bgp-nbr)# address-family ipv6 unicast
Node1(config-bgp-nbr-af)# encapsulation-type srv6
Node1(config-bgp-nbr-af)# exit
Node1(config-bgp-nbr)# exit
Node1(config-bgp)# neighbor 3001::1:1:1:5
Node1(config-bgp-nbr)# address-family ipv6 unicast
Node1(config-bgp-nbr-af)# encapsulation-type srv6
Node1(config-bgp-nbr-af)# commit
```

Running Configuration

```
router bgp 100
  bgp router-id 10.1.1.1
  segment-routing srv6
    locator Node1
  !
  address-family ipv6 unicast
    segment-routing srv6
      locator Node1
      alloc mode per-vrf
    !
  !
  neighbor 3001::1:1:1:4
    address-family ipv6 unicast
      encapsulation-type srv6
    !
  !
  neighbor 3001::1:1:1:5
    address-family ipv6 unicast
      encapsulation-type srv6
```

Use Case 2: BGP Global IPv6 over SRv6 with Per-Prefix SID Allocation

This use case provides the ability to assign a specific SRv6 locator for a given prefix or a set of prefixes. The egress PE advertises the prefix with the specified locator. This allows for per-prefix steering into desired transport behaviors, such as Flex Algo.

To assign an SRv6 locator for a specific prefix, configure a route policy to specify the SID allocation mode based on match criteria. Examples of match criteria are destination-based match or community-based match.

- Supported SID allocation modes are per-VRF and per-CE.
- For per-VRF allocation mode, you can also specify the SRv6 locator.
 - If an SRv6 locator is specified in the route policy, BGP will use that to allocate per-VRF SID. If the specified locator is invalid, the SID will not be allocated.

- If an SRv6 locator is not specified in the route policy, the default locator is used to allocate the SID. If the default locator is not configured in BGP, then the SID will not be allocated.
- Per-CE allocation mode always uses the default locator to allocate the SID.

For more information on configuring routing policies, refer to the "Implementing Routing Policy" chapter in the *Routing Configuration Guide for Series Routers*.

The following example shows a route policy specifying the SID allocation mode with destination-based match:

```
Node1(config)# route-policy set_per_prefix_locator_rpl
Node1(config-rpl)# if destination in (3001::1:1:1:1/128) then
Node1(config-rpl-if)# set srv6-alloc-mode per-vrf locator locator1
Node1(config-rpl-if)# elseif destination in (3001::2:2:2:2/128) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf locator locator2
Node1(config-rpl-elseif)# elseif destination in (3001::3:3:3:3/128) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-vrf
Node1(config-rpl-elseif)# elseif destination in (3001::4:4:4:4/128) then
Node1(config-rpl-elseif)# set srv6-alloc-mode per-ce
Node1(config-rpl-elseif)# else
Node1(config-rpl-else)# drop
Node1(config-rpl-else)# endif
Node1(config-rpl)# end-policy
```

The following example shows how to configure BGP global IPv6 over SRv6 with a route policy to determine the SID allocation mode for given prefix.

```
Node1(config)# router bgp 100
Node1(config-bgp)# address-family ipv4 unicast
Node1(config-bgp-af)# segment-routing srv6
Node1(config-bgp-af-srv6)# alloc mode route-policy set_per_prefix_locator_rpl
```

Running Configuration

```
route-policy set_per_prefix_locator_rpl
  if destination in (3001::1:1:1:1/128) then
    set srv6-alloc-mode per-vrf locator locator1
  elseif destination in (3001::2:2:2:2/128) then
    set srv6-alloc-mode per-vrf locator locator2
  elseif destination in (3001::3:3:3:3/128) then
    set srv6-alloc-mode per-vrf
  elseif destination in (3001::4:4:4:4/128) then
    set srv6-alloc-mode per-ce
  else
    drop
  endif
end-policy
!
router bgp 100
  address-family ipv6 unicast
    segment-routing srv6
      alloc mode route-policy set_per_prefix_locator_rpl
    !
  !
```

Verify that the local and received SIDs have been correctly allocated under BGP IPv6 address family:

```
Node1# show bgp ipv6 unicast local-sids
...
Status codes: s suppressed, d damped, h history, * valid, > best
```

```

SRv6 Services: EVPN VPWS — All-Active Multi-Homing

Table 33: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 Services: EVPN VPWS — All-Active Multi-Homing	Release 7.5.1	This feature is now supported on Cisco NCS 5700 series fixed port routers and the Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native mode.

EVPN VPWS All-Active Multi-Homing over SRv6 provides an ELINE (P2P) service with all-active multihoming capability over an SRv6 network.

All-Active Multi-Homing enables an operator to connect a customer edge (CE) device to two or more provider edge (PE) devices to provide load balancing and redundant connectivity. With All-Active Multi-Homing, all the PEs can forward traffic to and from the multi-homed device.

Note For information about EVPN VPWS, refer to the "EVPN Virtual Private Wire Service (VPWS)" chapter in the *L2VPN and Ethernet Services Configuration Guide for Cisco NCS 5500 Series Routers*.

Configuring EVPN VPWS over SRv6

An SRv6 Locator for an EVPN VPWS service can be configured at 3 different levels independently:

- `global_locator` is the default locator for all EVPN-VPWS services
- `evi_locator` is applied to all EVPN-VPWS services for the specific EVI
- `evi_service_locator` is applied to an individual EVI service

When locators are configured at different levels at the same time, the following priority is implemented:

1. `evi_service_locator`
2. `evi_locator`
3. `global_locator`

This example shows how to configure an EVPN VPWS over SRv6 using a global locator for EVPN:

```
evpn
 segment-routing srv6
  locator sample_global_loc

l2vpn
 xconnect group sample_xcg
  p2p sample-vpws-12001-2002
  interface Bundle-Ether12001.2002
  neighbor evpn evi 12001 service 2002 segment-routing srv6
```

This example shows how to configure EVPN VPWS over SRv6 using specific EVI locator:

```
evpn
 evi 11001 segment-routing srv6
  locator sample_evi_loc

l2vpn
 xconnect group sample_xcg
  p2p sample-vpws-11001-2002
  interface Bundle-Ether11001.2002
  neighbor evpn evi 11001 service 2002 segment-routing srv6
```

This example shows how to configure an EVPN VPWS over SRv6 using a locator for an individual EVI service:

```
l2vpn
 xconnect group sample_xcg
```

```
p2p sample-vpws-11001-2001
interface Bundle-Ether11001.2001
neighbor evpn evi 11001 service 2001 segment-routing srv6
locator sample_evi_service_loc
```

Verification

```
Router# show segment-routing srv6 locator sample_evi_loc sid
```

```
Mon Aug 12 20:57:07.759 EDT
```

Configured on EVIs <evi>:	11001			

SRv6 Services: EVPN VPWS — IPv6 QoS Traffic-Class Marking

This feature allows the ingress EVPN VPWS PE to copy the CoS value from the top-most VLAN header to the traffic-class (TC) field of the outer-most IPv6 header. This functionality enables prioritization of traffic in the IPv6 network.

The following configuration shows how to enable this feature:

Note This command requires you to reload the router for the configuration to take effect.

```
Router# configure
```

```
Router(config)# hw-module profile segment-routing srv6 encapsulation traffic-class propagate
```

The functionality covers the following scenarios:

- Use case 1: Without additional QoS configuration, the CoS in the outer VLAN tag of incoming Ethernet frames is propagated to the traffic-class field in the encapsulated IPv6 header.

- Use case 2: With additional QoS configuration, DSCP in the IPv4/IPv6 header of incoming IP packets is propagated to the traffic-class field in the encapsulated IPv6 header.

The following configuration shows how to define specific classification criteria:

```
class-map match-any prec-0
  match precedence ipv4 0
  match precedence ipv6 0
end-class-map
...
class-map match-any prec-7
  match precedence ipv4 7
  match precedence ipv6 7
end-class-map
```

The following configuration shows how to define a QoS policy map:

```
policy-map prec-to-tc
  class prec-0
    set qos-group 0
...
  class prec-7
    set qos-group 7
```

The following configuration shows how to apply a QoS policy-map to an attachment-circuit (AC) interface:

```
interface Bundle-Ether1.1 l2transport
  encapsulation untagged
  service-policy input prec-to-tc
```

SRv6 Services: SRv6 Services TLV Type 5 Support

IOS XR 6.6.1 supports IETF draft [draft-dawra-idr-srv6-vpn-04](#), in which the SRv6-VPN SID TLV (TLV Type 4) carries the SRv6 Service SID information. This SID TLV is inconsistent with the SRv6 SID Structure.

In IOS XR 7.0.2 and later releases, the implementation is compliant with [draft-ietf-bess-srv6-services-00](#), which defines a new SRv6 Services TLV (TLV Type 5/6) and SRv6 SID Structure Sub-Sub-TLV to address this inconsistency.

SRv6 SID Structure Sub-Sub-TLV describes mechanisms for signaling of the SRv6 Service SID by transposing a variable part of the SRv6 SID value (function and/or the argument parts) and carrying them in existing label fields to achieve more efficient packing of VPN and EVPN service prefix NLRIs in BGP update messages.

In order to allow backward compatibility between the newer software and the older software, use the **segment-routing srv6 prefix-sid-type4** command in Router BGP Neighbor VPNv4 Address-Family configuration mode to advertise BGP VPNv4 NLRIs in TLV Type 4 format. The newer software can receive either TLV Type 4 or TLV Type 5 formats.

The following configuration shows how to enable the advertisement of BGP VPNv4 NLRIs in TLV Type 4 format:

```
RP/0/RSP0/CPU0:Rtr-a(config)# router bgp 65000
RP/0/RSP0/CPU0:Rtr-a(config-bgp)# neighbor 6::6
RP/0/RSP0/CPU0:Rtr-a(config-bgp-nbr)# address-family vpnv4 unicast
RP/0/RSP0/CPU0:Rtr-a(config-bgp-nbr-af)# segment-routing srv6 prefix-sid-type4
```

```
RP/0/RSP0/CPU0:Rtr-a(config-bgp-nbr-af)#
```

SRv6/MPLS L3 Service Interworking Gateway

Table 34: Feature History Table

Feature Name	Release Information	Feature Description
SRv6/MPLS L3 Service Interworking Gateway	Release 7.5.1	This feature is now supported on Cisco NCS 5700 series fixed port routers and the Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native mode.

Table 35: Feature History Table

Feature Name	Release	Description
SRv6/MPLS L3 Service Interworking Gateway (SRv6 Full-Length SID)	Release 7.3.2	<p>This feature enables you to extend L3 services between MPLS and SRv6 domains by providing service continuity on the control plane and data plane.</p> <p>This feature allows for SRv6 L3VPN domains to interwork with existing MPLS L3VPN domains. The feature also allows a way to migrate from MPLS L3VPN to SRv6 L3VPN.</p>

SRv6/MPLS L3 Service Interworking Gateway enables you to extend L3 services between MPLS and SRv6 domains by providing service continuity on the control plane and data plane.

This feature allows for SRv6 L3VPN domains to interwork with existing MPLS L3VPN domains. The feature also allows a way to migrate from MPLS L3VPN to SRv6 L3VPN.

The SRv6/MPLS L3 Service Interworking Gateway provides both transport and service termination at the gateway node. The gateway generates both SRv6 VPN SIDs and MPLS VPN labels for all prefixes under the VRF configured for re-origination. The gateway supports traffic forwarding from MPLS domain to SRv6 domain by popping the MPLS VPN label, looking up the destination prefix, and pushing the appropriate SRv6 encapsulation. From SRv6 domain to MPLS domain, the gateway removes the outer IPv6 header, looks up the destination prefix, and pushes the VPN and next-hop MPLS labels.

VRFs on the gateway node are configured with 2 sets of route targets (RTs):

- MPLS L3VPN RTs
- SRv6 L3VPN RTs (called *stitching RTs*)

The gateway performs the following actions:

- Imports service routes received from one domain (MPLS or SRv6)
- Re-advertises exported service routes to the other domain (next-hop-self)
- Stitches the service on the data plane (End.DT4/H.Encaps.Red ↔ service label)

SRv6/MPLS L3 Service Interworking Gateway Scenarios

The following scenario is used to describe the gateway functionality:

- Node 1 is an L3VPN PE in the MPLS domain with an SR prefix SID label of 16001 for its Loopback interface 10.1.1.1/32.
- Node 2 is the SRv6/MPLS L3 Service Interworking Gateway. In the MPLS domain, it has an SR prefix SID label of 16002 for its Loopback interface 10.1.1.2/32. In the SRv6 domain, it has an SRv6 locator of B:0:0:2::/64 and Loopback interface B:0:0:2::1/128.
- Node 3 is an L3VPN PE in the SRv6 domain with SRv6 locator of B:0:0:3::/64 and Loopback interface B:0:0:3::1/128.

Scenario 1: SRv6-to-MPLS Control-Plane Direction/MPLS-to-SRv6 Data-Plane Direction

The figure below describes the associated control-plane behaviors in the SRv6-to-MPLS direction for traffic in the MPLS-to-SRv6 data-plane direction.

A. Node 3 advertises a BGP L3VPN update for prefix B.0.0.0/8 with RD corresponding to VRFA, including the SRv6 VPN SID (B:0:0:3:V9::) assigned to this VRF, in the SRv6 domain.

Note SRv6 End.DT4 function value "V9" is not a valid hex number, however it is used for illustration purposes to remind you of its connection to a VRF.

B. Node 2 (gateway) imports the BGP L3VPN update and programs its FIB:

- MPLS label 24010 is allocated for VRFA
- Prefix B.0.0.0/8 is programmed with an "SR Headend Behavior with Reduced Encapsulation in an SR Policy" function (H.Encaps.Red) of B:0:0:3:V9::

Note The gateway follows per-VRF label and per-VRF SID allocation methods.

C. Node 2 re-originates a BGP L3VPN update for the same prefix, including the MPLS VPN label (24010) allocated for the VRF, in the MPLS domain.

D. Site A sends traffic to an IPv4 prefix (B.B.B.B) of Site B

E. Node 1 encapsulates incoming traffic with the MPLS VPN label (24010) and the prefix SID MPLS label (16002) of the BGP next-hop (Node 2).

F. Node 2 performs the following actions:

- Pops the MPLS VPN label and looks up the destination prefix
- Encapsulates the payload in an outer IPv6 header with destination address (DA) equal to the H.Encaps.Red function (B:0:0:3:V9::)

G. Node 3 removes the outer IPv6 header, looks up the payload destination address (B.B.B.B), and forwards to Site B.

Scenario 2: MPLS-to-SRv6 Control-Plane Direction/SRv6-to-MPLS Data-Plane Direction

The figure below describes the associated control-plane behaviors in the MPLS-to-SRv6 direction for traffic in the SRv6-to-MPLS data-plane direction.

A. Node 1 advertises a BGP L3VPN update for prefix A.0.0.0/8 with RD corresponding to VRFA, including the MPLS VPN label (24055) assigned to this VRF, in the MPLS domain.

B. Node 2 (gateway) imports the BGP L3VPN update and programs its FIB:

- Prefix A.0.0.0/8 is programmed to impose an MPLS VPN label (24055) and the prefix SID MPLS label (16001) of the BGP next-hop (Node 1)
- "Endpoint with decapsulation and IPv4 table lookup" function (End.DT4) of B:0:0:2:V8:: is allocated to VRFA

Note

SRv6 End.DT4 function value "V8" is not a valid hex number, however it is used for illustration purposes to remind you of its connection to a VRF.

Note

The gateway follows per-VRF label and per-VRF SID allocation methods.

C. Node 2 re-originates a BGP L3VPN update for the same prefix, including the End.DT4 function (B:0:0:2:V8::) allocated for the VRF, in the SRv6 domain.

D. Site B sends traffic to an IPv4 prefix (A.A.A.A) of Site A.

E. Node 3 Encapsulates the payload in an outer IPv6 header with destination address (DA) equal to the End.DT4 function (B:0:0:2:V8::).

F. Node 2 performs the following actions:

- Removes the outer IPv6 header and looks up the destination prefix
- Pushes the MPLS VPN label (24055) and the prefix SID MPLS label (16001) of the BGP next-hop (Node 1)

G. Node 1 pops the MPLS VPN label, looks up the payload destination address (A.A.A.A), and forwards to Site A.

Example

Leveraging the topology described in the above use-case, this example shows the SRv6/MPLS L3 Service Interworking Gateway configuration required at Node 2.

The following configuration shows how to enable SRv6 with locator and configure encapsulation parameters:

```
segment-routing
  srv6
    encapsulation
      source-address b:0:0:2::1
    !
  locators
    locator LOC1
      prefix b:0:0:2::/64
    !
  !
  !
  !
```

The following configuration shows how to configure a VPNv4 VRF with the following route targets (RTs):

- 1111:1, RT used for MPLS L3VPN
- 2222:1, RT used for SRv6 L3VPN (stitching RT)

```
vrf ACME
  address-family ipv4 unicast
    import route-target
      1111:1
      2222:1 stitching
    !
  export route-target
    1111:1
    2222:1 stitching
  !
  !
  !
```

The following configuration shows how to configure SRv6/SRv6 VPNs under BGP:

```
router bgp 100
  segment-routing srv6
    locator LOC1
  !
  neighbor 10.1.1.1
  address-family vpnv4 unicast
    import re-originate stitching-rt
    route-reflector-client
    advertise vpnv4 unicast re-originated
```

```

!
neighbor b:0:0:3::1
address-family vpnv4 unicast
  import stitching-rt re-originate
  route-reflector-client
  encapsulation-type srv6
  advertise vpnv4 unicast re-originated stitching-rt
!
vrf ACME
address-family ipv4 unicast
  enable label-mode
  segment-routing srv6
  
```

SRv6/MPLS Dual-Connected PE

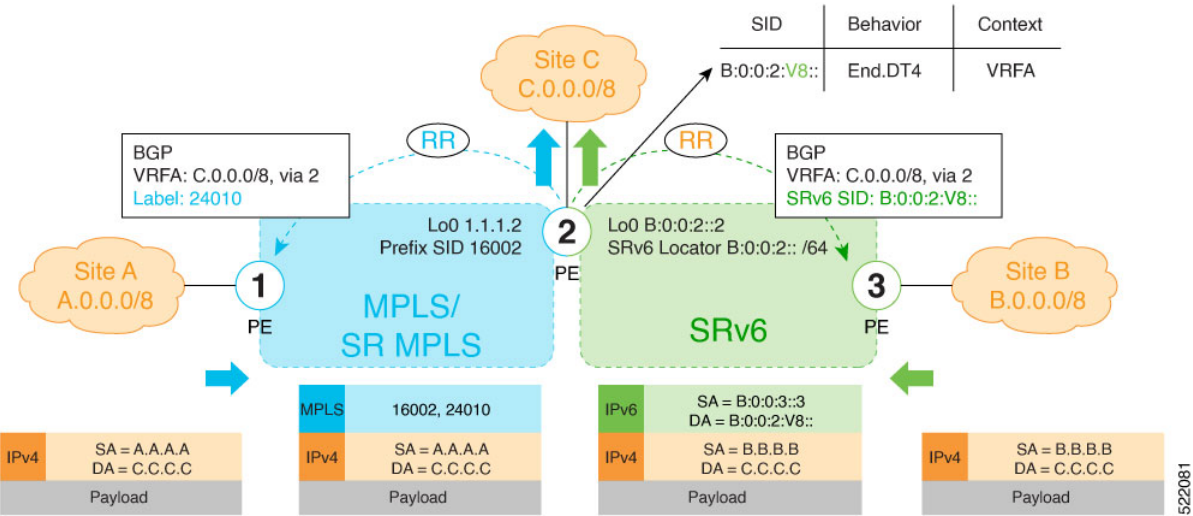

Table 36: Feature History Table

Feature Name	Release	Description
SRv6/MPLS Dual-Connected PE (SRv6 Full-Length SID)	Release 7.3.2	This feature allows a PE router to support IPv4 L3VPN services for a given VRF with both MPLS and SRv6. This is MPLS and SRv6 L3VPNv4 co-existence scenario and is sometimes referred to as dual-connected PE.

A PE router can support IPv4 L3VPN service for a given VRF with both MPLS and SRv6. This is MPLS and SRv6 L3VPNv4 co-existence scenario and is sometimes referred to as dual-connected PE.

In the figure below, node 2 is a dual-connected PE to Site C, providing:

- MPLS/IPv4 L3VPN between Site A and Site C
- SRv6/IPv4 L3VPN between Site B and Site C

Configure BGP to Support Dual-Mode

Enable MPLS Label Allocation

Use the **router bgp *as-number* vrf *WORD* address-family ipv4 unicast mpls alloc enable** command under the VRF address-family to enable per-prefix mode for MPLS labels. Additionally, use the **router bgp *as-number* vrf *WORD* address-family ipv4 unicast label mode {per-ce | per-vrf}** command to choose the type of label allocation.

```
Router(config)# router bgp 100
Router(config-bgp)# vrf blue
Router(config-bgp-vrf)# rd 1:10
Router(config-bgp-vrf)# address-family ipv4 unicast
Router(config-bgp-vrf-af)# mpls alloc enable
Router(config-bgp-vrf-af)# label mode per-ce
Router(config-bgp-vrf-af)# segment-routing srv6
Router(config-bgp-vrf-af-srv6)# alloc mode per-ce
Router(config-bgp-vrf-af-srv6)# exit
Router(config-bgp-vrf-af)# exit
Router(config-bgp-vrf)# exit
Router(config-bgp)#
```

Configure Encaps on Neighbor to Send the SRv6 SID Toward the SRv6 Dataplane

By default, if a VRF prefix has both an MPLS label and an SRv6 SID, the MPLS label is sent when advertising the prefix to the PE. To advertise a VRF prefix with an SRv6 SID to an SRv6 session, use the **encapsulation-type srv6** command under the neighbor VPN address-family.

```
Router(config-bgp)# neighbor 192::6
Router(config-bgp-nbr)# remote-as 1
Router(config-bgp-nbr)# address-family ipv4 unicast
Router(config-bgp-nbr-af)# encapsulation-type srv6
Router(config-bgp-nbr-af)# exit
```

Running Config

```
router bgp 100
 neighbor 192::6
   remote-as 1
   address-family ipv4 unicast
     encapsulation-type srv6
   !
!
vrf blue
 rd 1:10
 address-family ipv4 unicast
   mpls alloc enable
   label mode per-ce
   segment-routing srv6
   alloc mode per-ce
!
!
!
```

SRv6 SID Information in BGP-LS Reporting

BGP Link-State (BGP-LS) is used to report the topology of the domain using nodes, links, and prefixes. This feature adds the capability to report SRv6 Segment Identifier (SID) Network Layer Reachability Information (NLRI).

The following NLRI has been added to the BGP-LS protocol to support SRv6:

- Node NLRI: SRv6 Capabilities, SRv6 MSD types
- Link NLRI: End.X, LAN End.X, and SRv6 MSD types
- Prefix NLRI: SRv6 Locator
- SRv6 SID NLRI (for SIDs associated with the node): Endpoint Function, BGP-EPE Peer Node/Set

This example shows how to distribute IS-IS SRv6 link-state data using BGP-LS:

```
Router(config)# router isis 200
Router(config-isis)# distribute link-state instance-id 200
```

Note It is still possible to ping or trace a SID:

- **ping** B:k:F::
- **traceroute** B:k:F::

It is possible to use a list of packed carriers to ping or trace a SID, to ping or trace route, use **<destination SID> via srv6-carriers <list of packed carriers>**

DHCPv4 Relay Agent and Proxy Support over SRv6

This feature introduces support for DHCPv4 Relay Agent and Proxy over SRv6.

An IOS XR router can act as a DHCPv4 relay agent/proxy with a DHCPv4 server connected over an SRv6 network.

The following functionality is supported:

- DHCPv4 relay agent/proxy over SRv6 with DHCPv4 server (helper-address) located in default VRF (global)
- DHCPv4 relay agent/proxy over SRv6 with DHCPv4 server (helper-address) located in non-default VRF
- DHCPv4 relay agent/proxy on interfaces associated with a default VRF (global)
- DHCPv4 relay agent/proxy on interfaces associated with a non-default VRF
- DHCPv4 relay agent/proxy on Ethernet physical interfaces
- DHCPv4 relay agent/proxy on Ethernet bundle interfaces

For information on configuring DHCPv4 relay agent and proxy, refer to the “Implementing the Dynamic Host Configuration Protocol” chapter in the *IP Addresses and Services Configuration Guide for Cisco NCS 5500 Series Routers*.

DHCPv6 Relay Agent Support over SRv6

Table 37: Feature History Table

Feature Name	Release Information	Feature Description
DHCPv6 Relay Agent Support on SRv6	Release 7.2.2	<p>An IOS XR router can act as a DHCPv6 relay agent with a DHCPv6 server connected over an SRv6 network.</p> <p>A DHCP relay agent is a host that forwards DHCP packets between clients and servers that do not reside on a shared physical subnet.</p>

This feature introduces support for DHCPv6 Relay Agent over SRv6.

An IOS XR router can act as a DHCPv6 relay agent with a DHCPv6 server connected over an SRv6 network.

The following functionality is supported:

- DHCPv6 relay agent over SRv6 with DHCPv6 server (helper-address) located in default VRF (global)
- DHCPv6 relay agent over SRv6 with DHCPv6 server (helper-address) located in non-default VRF
- DHCPv6 relay agent on interfaces associated with a default VRF (global)
- DHCPv6 relay agent on interfaces associated with a non-default VRF
- DHCPv6 relay agent on Ethernet physical interfaces
- DHCPv6 relay agent on Ethernet bundle interfaces

For information on configuring DHCPv6 relay agent, refer to the “Implementing the Dynamic Host Configuration Protocol” chapter in the *IP Addresses and Services Configuration Guide for Cisco NCS 5500 Series Routers*.

Dual-Stack with SRv6 Unicast and IPv4 Multicast Core

Table 38: Feature History Table

Feature Name	Release Information	Feature Description
Dual-Stack Support with SRv6 Unicast and IPv4 Multicast Core	Release 24.2.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards).</p> <p>This feature introduces dual-stack support with SRv6 for unicast traffic and IPv4 for multicast communication.</p> <p>The dual-stack simplifies the routing process by combining the advantages of both IPv4 and SRv6 protocols, and facilitates smoother interoperability between the two protocols. The dual-stack enables efficient unicast communication through SRv6 by allowing precise control over the path that a packet takes through a network and streamlines the network routing, while using the deployment support of IPv4 for multicast traffic.</p>

Support Multiple IP Versions with Dual-Stack

Dual-stack is a feature that enables a device to simultaneously support multiple Internet Protocol (IP) versions within a network stack. The most commonly supported protocols are IPv4 and IPv6. Dual-stacking allows devices to support both IPv4 and IPv6 unicast addresses simultaneously, facilitating the transition to IPv6 while maintaining compatibility with existing IPv4 networks and applications.

Dual-stack support for SRv6 and IPv4 for Unicast and Multicast traffic

In the dual-stack support with SRv6 and IPv4 configuration, SRv6 is utilized for unicast traffic, where packets are sent from a single sender to a single receiver. On the other hand, IPv4 is used for multicast communication, which involves sending packets from one sender to multiple receivers.

Benefits of dual-stack with SRv6 Unicast and IPv4 Multicast

The key benefits of the feature are:

- The dual-stack combines the benefits of both IPv4 and SRv6 protocols, by providing a streamlined and optimized network experience for both unicast and multicast communication.
- It facilitates seamless interoperability between IPv4 and IPv6 protocols.

- Based on the availability and performance of the IPv4 and IPv6 services, dual-stack enables devices to use the optimal protocol for a specific network scenario.
- It provides a simple solution for data transfer from IPv4 to SRv6 without requiring complex tunneling or translation mechanisms.
- It preserves the end-to-end connectivity and security of IPv6 while ensuring compatibility with the existing IPv4 infrastructure and applications.

Usage Guidelines and Limitations for Dual-Stack with SRv6 and IPv4

The following usage guidelines and limitations apply:

- The dual-stack support is available on MVPN GRE-based profiles such as profile 0 and profile 11.
- The dual-stack supports only SRv6 micro-segments (uSIDs).
- The dual-stack uses Customer Edge (CE) label allocation for SRv6.

Enable Dual-Stack with SRv6 Unicast and IPv4 Multicast Core

This section includes only the BGP configuration required to enable dual-stack with SRv6 unicast and an IPv4 multicast core. For more information about SRv6 configuration, see *Configure Segment Routing over IPv6 (SRv6) with Micro-SIDs* chapter in the *Segment Routing Configuration Guide*.

For more information about profile-based multicast and IPv4 multicast configurations, see the *Multicast Configuration Guide*.

Procedure

- Step 1** Enable SRv6 globally under the BGP routing process using the **router bgp as-number segment-routing srv6** command. The *as-number* range is 1–65535.

Example:

```
Router(config)#router bgp 101
Router(config-bgp)#nsr
Router(config-bgp)#mvpn
Router(config-bgp)#bgp router-id 10.10.10.1
Router(config-bgp)#bgp graceful-restart
Router(config-bgp)#segment-routing srv6
```

- Step 2** Configure IPv4 for multicast communication under the BGP routing process.

Example:

```
Router(config-bgp)#address-family ipv4 multicast
Router(config-bgp-af)#redistribute connected
```

- Step 3** Configure SRv6 for unicast communication under the BGP routing process. The **address-family ipv6 unicast** and **segment-routing srv6** configurations indicate that SRv6 is used for unicast communication.

Example:

```
Router(config-bgp)#address-family ipv6 unicast
Router(config-bgp-af)#segment-routing srv6
Router(config-bgp-af)#redistribute connected
Router(config-bgp)#address-family ipv6 mvpn
Router(config-bgp)#address-family ipv4 mvpn
```

Step 4 Verify the running configuration using the **show running-config** command.

Example:

```
router bgp 101
 nsr
 mvpn
 bgp router-id 10.10.10.1
 bgp graceful-restart
 segment-routing srv6
 !
 address-family ipv4 multicast
  redistribute connected
 !
 address-family ipv6 unicast
  segment-routing srv6
  !
  redistribute connected
 !
 address-family ipv4 mvpn
 !
 address-family ipv6 mvpn
 !
 !
```

CHAPTER 6

Configure SRv6 Traffic Engineering

Table 39: Feature History Table

Feature Name	Release	Description
SRv6 Traffic Engineering	Release 7.3.2	<p>This feature introduces Segment Routing over IPv6 (SRv6) Traffic Engineering.</p> <p>This release supports the following features:</p> <ul style="list-style-type: none">• SRv6-TE with SRv6 micro-SIDs (uSIDs)• SRv6 policies• Manual SRv6 policies• Automated steering for Layer 3-based BGP services (IPv4 L3VPN, IPv6 L3VPN, IPv4 BGP global, IPv6 BGP global)• SRv6-aware Path Computation Element (PCE)• PCEPv6• Path computation optimization objectives (TE, IGP, latency)• Path computation constraints (affinity, disjointness)

This feature introduces Segment Routing over IPv6 (SRv6) Traffic Engineering.

- [SRv6-TE Overview](#), on page 220
- [Usage Guidelines and Limitations](#), on page 221
- [Traffic Steering](#), on page 223
- [SRv6-TE Policy Path Types](#), on page 228
- [Protocols](#), on page 244
- [SR-TE Application Programming Interface \(API\)](#), on page 252
- [Reporting of SR-TE Policies Using BGP- Link State](#) , on page 261

SRv6-TE Overview

Traffic engineering over SRv6 can be accomplished in the following ways:

- **End-to-End Flexible Algorithm:** This is used for traffic engineering intents achieved with Flexible Algorithm, including low latency, multi-plane disjointness, affinity inclusion/exclusion, and SRLG exclusion.
- **SRv6-TE Policy:** This is used for traffic engineering intents beyond Flex Algo capabilities, such as path disjointness that rely on path computation by a PCE. In addition, this is used for user-configured explicit paths.

End-to-End Flexible Algorithm

SRv6 Flexible Algorithm allows operators to customize IGP shortest path computation according to their own needs. An operator can assign custom SRv6 locators to realize forwarding beyond link-cost-based shortest path. As a result, Flexible Algorithm provides a traffic-engineered path automatically computed by the IGP to any destination reachable by the IGP.

SRv6-TE Policy

SRv6 for traffic engineering (SRv6-TE) uses a “policy” to steer traffic through the network. An SRv6-TE policy path is expressed as a list of micro-segments that specifies the path, called a micro-segment ID (uSID) list. Each segment list is an end-to-end path from the source to the destination, and instructs the routers in the network to follow the specified path instead of following the shortest path calculated by the IGP. If a packet is steered into an SRv6-TE policy, the uSID list is pushed on the packet by the head-end. The rest of the network executes the instructions embedded in the uSID list.

An SRv6-TE policy is identified as an ordered list (head-end, color, end-point):

- **Head-end** – Where the SRv6-TE policy is instantiated
- **Color** – A numerical value that distinguishes between two or more policies to the same node pairs (Head-end – End point)
- **End-point** – The destination of the SRv6-TE policy

Every SRv6-TE policy has a color value. Every policy between the same node pairs requires a unique color value.

An SRv6-TE policy uses one or more candidate paths. A candidate path can be made up of a single SID-list or a set of weighted SID-lists (for weighted equal cost multi-path [WECMP]).

A SID list can be either the result of a dynamic path computation by a PCE or a user-configured explicit path. See [SRv6-TE Policy Path Types](#) for more information.

Usage Guidelines and Limitations

Table 40: Feature History Table

Feature Name	Release	Description
Cisco NC57 Native Mode: Automated Steering of L3 BGP-based services	Release 7.8.1	<p>This feature is now supported on routers that have the Cisco NC57 line cards installed and operate in the native mode.</p> <p>To enable the native mode, use the hw-module profile npu native-mode-enable command in the configuration mode. Ensure that you reload the router after configuring the native mode.</p>

Observe the following usage guidelines and limitations for the platform.

This release supports the following SRv6 policy functionality:

- SRv6 policies with SRv6 uSID segments
- SRv6 policies with PCE-delegated dynamic paths
- SRv6 policies with explicit paths
- SRv6 policies with single or multiple candidate paths (CP)
- SRv6 policies with a single SID list per CP
- SRv6 policies with multiple (weighted ECMP) SID lists per CP
- Path delegation and reporting with PCEPv4
- Path delegation and reporting with PCEPv6
- PCEPv4 and PCEPv6 sessions with different PCEs
- PCEP path delegation with the following optimization objective (metric) types:
 - IGP metric
 - TE metric
 - Delay (latency)
 - Hop-count
- PCEP path delegation with the following constraint types:
 - Affinity (include-any, include-all, exclude-any)
 - Path disjointness (link, node, SRLG, SRLG+node)
 - Segment protection-type:
 - Protected-only
 - Protected-preferred

- Unprotected-only
- Unprotected-preferred
- SRv6 policy with TI-LFA (protection of the first segment in the segment list at the head-end)
- Steering over SRv6 policies with Automated Steering for the following services:
 - L3 BGP-based services (IPv4 L3VPN, IPv6 L3VPN, IPv4 BGP global, IPv6 BGP global)
 - L2 BGP-based service (EVPN VPWS)

The following functionalities are not supported:

- SRv6 policy counters
- PCE-initiated SRv6 policies via PCEP
- SRv6 policies with head-end computed dynamic paths
- PCE path delegation with segment-type Flex Algo constraint
- PCEPv4 and PCEPv6 sessions with same PCE
- Steering over SRv6 policies based on incoming BSID (remote automated steering)
- PCC with user-configured PCE groups
- SR-PM delay-measurement over SRv6 policies
- SR-PM liveness detection over SRv6 policies
- L3 services with BGP PIC over SRv6 policies
- SRv6 policy ping

SR-PCE and SRv6-TE head-end PCEP compatibility:

- A PCEP session between an SR-PCE running Cisco IOS XR release 7.8.1 and an SRv6-TE head-end running Cisco IOS XR release 7.8.1 is supported.
- A PCEP session between an SR-PCE running Cisco IOS XR release 7.8.1 and an SRv6-TE head-end running an earlier release is supported.
- A PCEP session between an SR-PCE running Cisco IOS XR release earlier than 7.8.1 and an SRv6-TE head-end running Cisco IOS XR release 7.8.1 is not supported.
- A PCEP session between an SR-PCE running Cisco IOS XR release 7.8.1 and another SR-PCE running an earlier Cisco IOS XR release is not supported.
- As a result of the above, prior to upgrading any SRv6-TE headend nodes in the network to Cisco IOS XR release 7.8.1, you must upgrade its SR-PCE to Cisco IOS XR release 7.8.1.

Note

When a pair of SR-PCEs part of the same redundancy group run different versions of Cisco IOS XR, they will lose their state-sync PCEP session until both SR-PCEs are upgraded to Cisco IOS XR release 7.8.1.

- To switch between an RSVP-TE or SR-TE configuration and an MPLS-TE configuration and vice versa, it is necessary to remove the configuration of the first process, say, RSVP-TE or SR-TE, in a separate commit operation and add the configuration of the next process, say, MPLS-TE, in another commit operation. This prevents any commit failures caused due to the delay in unconfiguring the first process before the next process configuration is applied.

Traffic Steering

SRv6 Flexible Algorithm

With SRv6 Flexible Algorithm, a PE can advertise BGP service routes (global, VPN) that include the SRv6 locator (Algo 0 or Flex Algo) of the intended transport SLA.

For information about configuring Flexible Algorithm, see [Configuring SRv6 IS-IS Flexible Algorithm, on page 163](#).

In the example below, the SR domain has 2 network slices. Each slice is assigned a /32 uSID Locator Block.

A slice can be realized with a user-defined Flex-Algo instances (for example, Flex Algo 128 = min-delay)

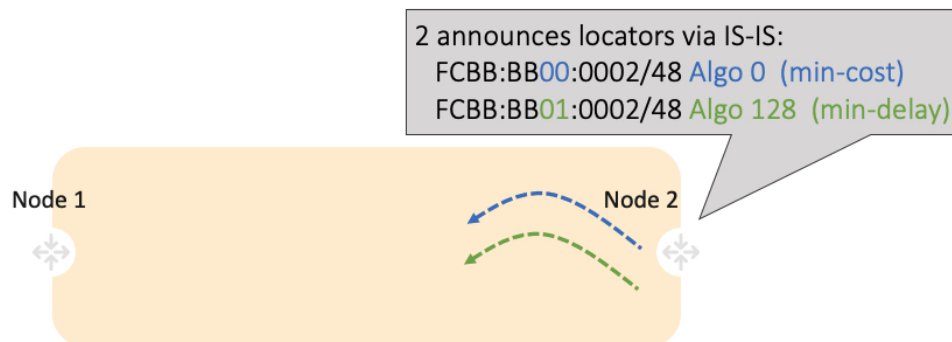

- Min-Cost Slice — FCBB:BB00/32
- Min-Delay Slice — FCBB:BB01/32

SR node2 gets a Shortest-Path Endpoint uSID (uN) from each slice:

- uN **min-cost** of Node2 — FCBB:BB00:0002/48
- uN **min-delay** of Node2 — FCBB:BB01:0002/48

Node2 announces locators via IS-IS:

- FCBB:BB00:0002/48 Algo **0** (min-cost)
- FCBB:BB01:0002/48 Algo **128** (min-delay)

IS-IS in Node1 computes shortest paths for each locator and programs them in the FIB:

Node1 and Node2 are PEs of a common VPN. PEs advertise VPN routes via BGP with different transport SLAs. For example, traffic to a set of prefixes is to be delivered over the min-cost slice, while for another set of prefixes is to be delivered over the min-delay slice. To achieve this, the egress PE's service route advertisement includes the locator of the intended transport SLA type.

Use-case: VPN over Min-Cost Slice (Control Plane Behavior)

- Intuitive uSID program for routes advertised by Node2:
 - Within the Min-Cost Slice (FCBB:BB00)
 - Follow the shortest-path to Node2 (0002)
 - Execute VPN9 decapsulation function at Node2 (F009)
- Hardware Efficiency
 - Egress PE Node2 processes multiple uSIDs with a single /64 lookup
 - FCBB:BB00:0002:F009/64

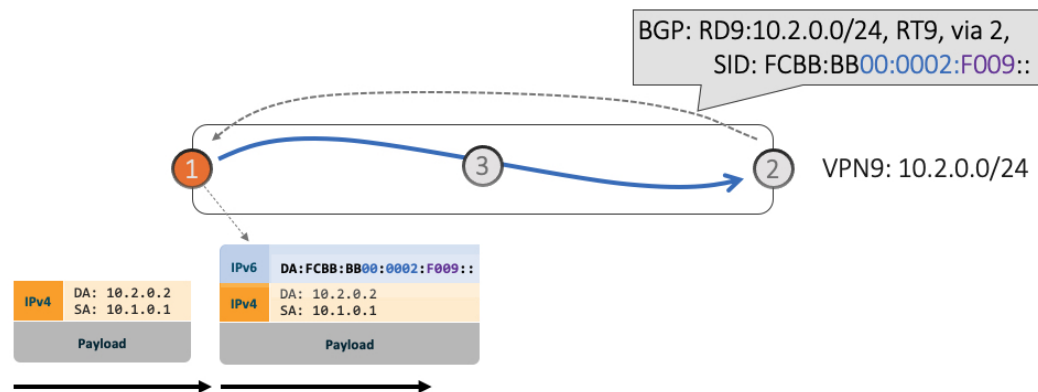

Use-case: VPN over Min-Delay Slice (Control Plane Behavior)

- Intuitive uSID program for routes advertised by Node2:
 - Within the Min-Delay Slice (FCBB:BB01)
 - Follow the shortest-path to Node2 (0002)
 - Execute VPN9 decapsulation at Node2 (F009)
- Hardware Efficiency
 - Egress PE 2 processes multiple uSIDs with a single /64 lookup
 - FCBB:BB01:0002:F009/64

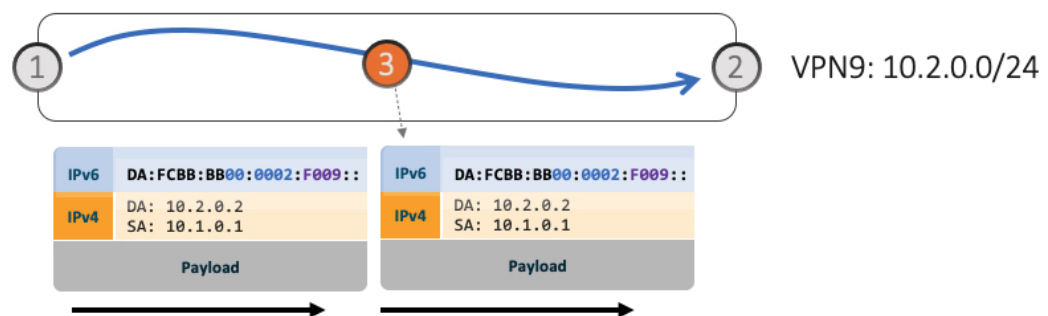

**Use-case: VPN over Min-Cost Slice (Data Plane Behavior)**

1. Ingress PE (Node 1) learns via BGP that prefix 10.2.0.0/24 in VPN9 is reachable via SID FCBB:BB00:0002:F009
2. Node 1 programs the prefix with “VPN Encaps” behavior
3. When receiving traffic with DA IP matching the prefix 10.2.0.0/24 FIB entry, Node 1 encapsulates the incoming packet into IPv6 with DA of FCBB:BB00:0002:F009

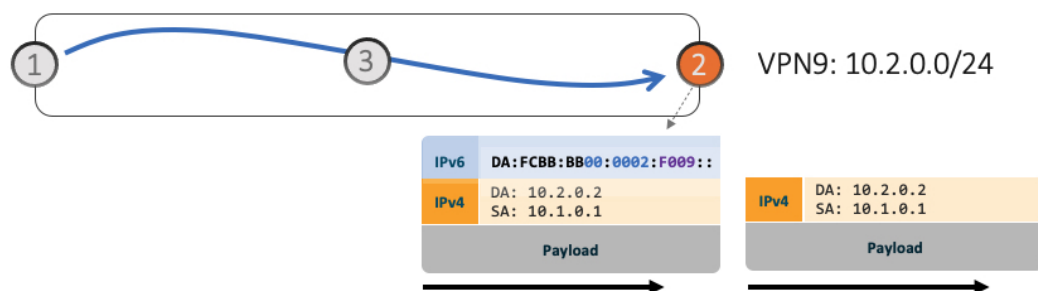

4. SRv6 allows for seamless deployment where any transit node (SRv6-capable or not) simply routes based on a /48 longest prefix match lookup.

For example, transit node (Node 3) forwards traffic along the Algo 0 (min-cost) shortest path for the remote prefix FCBB:BB00:0002::/48.

5. Egress PE (Node 2) matches local SID FCBB:BB00:0002:F009/64. Node 2 applies “VPN Decaps” behavior into VRF9 by removing the IPv6 encapsulation and looking up the payload’s DA on the corresponding VPN table.

Use-case: VPN over Min-Delay Slice (Data Plane Behavior)

1. Ingress PE (Node 1) learns via BGP that prefix 20.2.0.0/24 in VPN9 is reachable via SID FCBB:BB01:0002:F009

- Node 1 programs the prefix with “VPN Encaps” behavior
- When receiving traffic with DA IP matching the prefix 20.2.0.0/24 FIB entry, Node 1 encapsulates the incoming packet into IPv6 with DA of FCBB:BB01:0002:F009
- Transit node (Node 3) forwards traffic along the Algo 128 (min-delay) shortest path for the remote prefix FCBB:BB01:0002::/48.
- Egress PE (Node 2) matches local SID FCBB:BB01:0002:F009/64. Node 2 applies “VPN Decaps” behavior into VRF9 by removing the IPv6 encapsulation and looking up the payload’s DA on the corresponding VPN table.

Automated Steering

Automated steering (AS) allows service traffic to be automatically steered onto the required transport SLA path programmed by an SRv6 policy.

With AS, BGP automatically steers traffic onto an SRv6 policy based on the next-hop and color of a BGP service route. The color of a BGP service route is specified by a color extended community attribute. This color is used as a transport SLA indicator, such as min-delay or min-cost.

When the next-hop and color of a BGP service route matches the end-point and color of an SRv6 policy, BGP automatically installs the route resolving onto the BSID of the matching SRv6 policy. Recall that an SRv6 policy on a head-end is uniquely identified by an end-point and color.

When a BGP route has multiple extended-color communities, each with a valid SRv6 policy, the BGP process installs the route on the SRv6 policy giving preference to the color with the highest numerical value.

The granularity of AS behaviors can be applied at multiple levels, for example:

- At a service level—When traffic destined to all prefixes in a given service is associated to the same transport path type. All prefixes share the same color.
- At a destination/prefix level—When traffic destined to a prefix in a given service is associated to a specific transport path type. Each prefix could be assigned a different color.
- At a flow level—When flows destined to the same prefix are associated with different transport path types

SRv6-TE Policy Path Types

An **explicit** path is a specified SID-list or set of SID-lists.

A **dynamic** path is based on an optimization objective and a set of constraints. The head-end computes a solution, resulting in a SID-list or a set of SID-lists. When the topology changes, a new path is computed. If the head-end does not have enough information about the topology, the head-end might delegate the computation to a Segment Routing Path Computation Element (SR-PCE). For information on configuring SR-PCE, see *Configure Segment Routing Path Computation Element* chapter.

An SRv6-TE policy initiates a single (selected) path in RIB/FIB. This is the preferred valid candidate path.

A candidate path has the following characteristics:

- It has a preference – If two policies have same {color, endpoint} but different preferences, the policy with the highest preference is selected.
- It is associated with a single Binding SID (uB6) – A uB6 SID conflict occurs when there are different SRv6 policies with the same uB6 SID. In this case, the policy that is installed first gets the uB6 SID and is selected.
- It is valid if it is usable.

A path is selected when the path is valid and its preference is the best among all candidate paths for that policy.

Note The protocol of the source is not relevant in the path selection logic.

The following SRv6-TE policy path types are supported in this release:

- [Explicit Paths](#)
- [Dynamic Paths, on page 235](#)

Explicit Paths

Table 41: Feature History Table

Feature Name	Release	Description
Manual SRv6-TE Policies with Explicit Paths	Release 7.8.1	This feature allows you to create an explicit list of segment IDs (SID list) for a candidate path or multiple candidate paths. An explicit path can be a single SID list or set of SID lists.
Cisco NC57 Native Mode: Manual SRv6-TE Policies with Explicit Paths	Release 7.8.1	This feature is now supported on routers that have the Cisco NC57 line cards installed and operate in the native mode. To enable the native mode, use the hw-module profile npu native-mode-enable command in the configuration mode. Ensure that you reload the router after configuring the native mode.

Usage Guidelines and Limitations

A segment list can use uSIDs or uSID carrier, or a combination of both.

When configuring an explicit path using IP addresses of links along the path, the SRv6-TE process prefers the protected Adj-SID of the link, if one is available. In addition, when manual Adj-SIDs are configured, the SRv6-TE process prefers a manual protected Adj-SID over a dynamic protected Adj-SID.

You can configure the path to prefer the protected or unprotected Adj-SID, or to use only protected or unprotected Adj-SID. See [Segment Protection-Type Constraint, on page 238](#).

You can enable SRv6-TE explicit segment list SID validation to allow the head-end node to validate the SIDs in an explicit SRv6-TE segment list against the SR-TE topology database. See [SRv6-TE Explicit Segment List SID Validation, on page 233](#).

Configure SRv6-TE Policy with Explicit Path

To configure an SRv6-TE policy with an explicit path, complete the following configurations:

1. Create the segment lists with SRv6 segments.
2. Create the SRv6-TE policy.

Behaviors and Limitations

A segment list can use uSIDs or uSID carrier, or a combination of both.

Configure Local SRv6-TE Policy Using Explicit Paths

Create a segment list with SRv6 uSIDs:

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# segment-lists
Router(config-sr-te-segment-lists)# srv6
```

```

Router(config-sr-te-sl-global-srv6)# sid-format usid-f3216
Router(config-sr-te-sl-global-srv6)# exit
Router(config-sr-te-segment-lists)# segment-list p1_r8_1
Router(config-sr-te-sl)# srv6
Router(config-sr-te-sl-srv6)# index 10 sid FCBB:BB00:10:feff::
Router(config-sr-te-sl-srv6)# index 15 sid FCBB:BB00:100:fe00::
Router(config-sr-te-sl-srv6)# index 20 sid FCBB:BB00:1::
Router(config-sr-te-sl-srv6)# index 30 sid FCBB:BB00:1:fe00::
Router(config-sr-te-sl-srv6)# index 40 sid FCBB:BB00:fe00::
Router(config-sr-te-sl-srv6)# index 50 sid FCBB:BB00:5::
Router(config-sr-te-sl-srv6)# index 60 sid FCBB:BB00:6::

```

Create the SRv6-TE policy:

```

Router(config-sr-te)# policy POLICY1
Router(config-sr-te-policy)# srv6 locator loc1 binding-sid dynamic behavior ub6-insert-reduced
Router(config-sr-te-policy)# color 10 end-point ipv6 FCBB:BB00:2::1
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 100
Router(config-sr-te-policy-path-pref)# explicit segment-list p1_r8_1
Router(config-sr-te-pp-info)# exit
Router(config-sr-te-policy-path-pref)# exit

```

Running Configuration

```
Router# show running-config
```

```

. . .

segment-routing
traffic-eng
segment-lists

```

Candidate Paths with Weighted SID Lists

If a candidate path is associated with a set of segment lists, each segment list is associated with weight for weighted load balancing. Valid values for weight are from 1 to 4294967295; the default weight is 1.

If a set of segment lists is associated with the active path of the policy, then the steering is per-flow and weighted-ECMP (W-ECMP) based according to the relative weight of each segment list.

The fraction of the flows associated with a given segment list is w/S_w , where w is the weight of the segment list and S_w is the sum of the weights of the segment lists of the selected path of the SR policy.

When a composite candidate path is active, the fraction of flows steered into each constituent SR policy is equal to the relative weight of each constituent SR policy. Further load balancing of flows steered into a constituent SR policy is performed based on the weights of the segment list of the active candidate path of that constituent SR policy.

Configuration Example

```
Router(config)# segment-routing traffic-eng
```

```

Router(config-sr-te)# segment-lists
Router(config-sr-te-segment-lists)# srv6
Router(config-sr-te-sl-global-srv6)# sid-format usid-f3216
Router(config-sr-te-sl-global-srv6)# exit
Router(config-sr-te-segment-lists)# segment-list p1_r8_3

SRv6-TE Explicit Segment List SID Validation

Table 42: Feature History Table

Feature Name	Release Information	Feature Description
SRv6-TE Explicit Segment List SID Validation	Release 7.8.1	<p>This feature provides a way for the head-end node to validate the SIDs in an explicit SRv6-TE segment list against the SR-TE topology database.</p> <p>If any SID in the segment list is not found on the head-end, the validation fails, and the policy remains down.</p>

SRv6-TE explicit segment list SID validation evaluates whether the explicit segment list of an SR policy's candidate path is valid and therefore usable. The head-end node validates if the hops are in the SR-TE topology database.

When enabled, the segment list SID validation occurs before programming the SR policy and after an IGP topology change.

When the segment list validation fails, then the segment list is declared invalid. An SR policy candidate path is declared invalid when it has no valid segment lists. An SR policy is declared invalid when it has no valid candidate paths.

Usage Guidelines and Limitations

- Segment list SID validation can be enabled globally for all SRv6 explicit segment lists or for a specific SRv6 segment list.
- If SIDs in an explicit segment list are expected to not be found in the headend (for example, a multi-domain case), the topology check can be disabled for that segment list.
- The SR-TE topology should be distributed from IGP (for intra-domain paths) or from BGP-LS (for multi-domain paths).
- The SRv6 segment list in an explicit candidate path of an SRv6 policy cannot be empty.

- All segments in a segment list must be of same data plane type: SRv6 or SR-MPLS.
- Top SID validation occurs by performing path resolution using the top SID.
- All SIDs in segment list are validated against local SID block and SID format.
- A segment list is validated against MSD.

Configuration

Prior to enabling SRv6 explicit segment list SID validation, use the **show segment-routing traffic-eng topology** command to verify if the SR-TE topology is available on the headend PCC router.

To enable SID validation globally, use the **segment-routing traffic-eng segment-lists srv6 topology-check** command.

To enable SID validation for a specific explicit SID list, use the **segment-routing traffic-eng segment-lists segment-list name srv6 topology-check** command.

Configuration Example

The following example shows how to enable SID validation globally for all SRv6 explicit segment lists:

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# segment-lists
Router(config-sr-te-segment-lists)# srv6
Router(config-sr-te-sl-global-srv6)# topology-check
```

The following example shows how to enable SID validation for a specific SRv6 explicit segment list:

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# segment-lists
Router(config-sr-te-segment-lists)# segment-list p1_r8_1
Router(config-sr-te-sl)# srv6
Router(config-sr-te-sl-srv6)# topology-check
```

The following example shows how to enable SID validation globally and disable SID validation for a specific SRv6 explicit segment list:

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# segment-lists
Router(config-sr-te-segment-lists)# srv6
Router(config-sr-te-sl-global-srv6)# topology-check
Router(config-sr-te-sl-global-srv6)# exit
Router(config-sr-te-segment-lists)# segment-list p1_r8_1
Router(config-sr-te-sl)# srv6
Router(config-sr-te-sl-srv6)# no topology-check
```

Running Configuration

```
segment-routing
 traffic-eng
  segment-lists
   srv6
    topology-check
  !
 segment-list p1_r8_1
  srv6
   no topology-check
```

```

!
!
!
!
!

```

Verification

```
Router# show segment-routing traffic-eng policy name srte_c_10_ep_fcbb:bb00:2::1 detail
```

Dynamic Paths

Behaviors and Limitations

For a dynamic path that traverses a specific interface between nodes (segment), the algorithm may encode this segment using an Adjacency uSID (uA SID).

Optimization Objectives

Optimization objectives allow the head-end router to compute a uSID-list that expresses the shortest dynamic path according to the selected metric type:

- Hopcount — Use the least number of hops for path computation.

- IGP metric — Refer to the "Implementing IS-IS" and "Implementing OSPF" chapters in the *Routing Configuration Guide for Cisco NCS 5500 Series Routers*.
- TE metric — See the [Configure Interface TE Metrics, on page 412](#) section for information about configuring TE metrics.
- Delay (latency) — See the [Configure Performance Measurement, on page 681](#) chapter for information about measuring delay for links or SRv6 policies.

This example shows a dynamic path from head-end router 1 to end-point router 3 that minimizes IGP or TE metric:

Default IGP link metric: I:10
Default TE link metric T:10

520018

- The blue path uses the minimum IGP metric: Min-Metric (1 → 3, IGP) = uSID-list {cafe:0:3::}; cumulative IGP metric: 20
- The green path uses the minimum TE metric: Min-Metric (1 → 3, TE) = uSID-list {cafe:0:5:4:3::}; cumulative TE metric: 23

Configure Interface TE Metrics

Use the **metric value** command in SR-TE interface submode to configure the TE metric for interfaces. The **value** range is from 0 to 2147483647.

```
Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# interface type interface-path-id
Router(config-sr-te-if)# metric value
```

Configuring TE Metric: Example

The following configuration example shows how to set the TE metric for various interfaces:

```
segment-routing
traffic-eng
interface TenGigE0/0/0/0
metric 100
!
interface TenGigE0/0/0/1
metric 1000
!
interface TenGigE0/0/2/0
metric 50
```

```

!
!
end

```

Constraints

Constraints allow the head-end router to compute a dynamic path according to the selected metric type:

Note For path-computation on PCE, configuring both affinity and disjoint-path is not supported.

- **Affinity** — You can apply a color or name to links or interfaces by assigning affinity bit-maps to them. You can then specify an affinity (or relationship) between an SRv6 policy path and link colors. SRv6-TE computes a path that includes or excludes links that have specific colors, or combinations of colors. See the [Named Interface Link Admin Groups and SR-TE Affinity Maps, on page 413](#) section for information on named interface link admin groups and SRv6-TE Affinity Maps.
- **Disjoint** — SRv6-TE computes a path that is disjoint from another path in the same disjoint-group. Disjoint paths do not share network resources. Path disjointness may be required for paths between the same pair of nodes, between different pairs of nodes, or a combination (only same head-end or only same end-point).
- **Segment protection-type behavior** — You can control whether protected or unprotected segments are used when encoding the SID-list of an SRv6 policy candidate path. The types of segments that could be used when building a SID-list include uSIDs and adjacency SIDs (uA SID). See the [Segment Protection-Type Constraint, on page 238](#) for details and usage guidelines.

Named Interface Link Admin Groups and SRv6-TE Affinity Maps

Named Interface Link Admin Groups and SRv6-TE Affinity Maps provide a simplified and more flexible means of configuring link attributes and path affinities to compute paths for SRv6-TE policies.

In the traditional TE scheme, links are configured with attribute-flags that are flooded with TE link-state parameters using Interior Gateway Protocols (IGPs), such as Open Shortest Path First (OSPF).

Named Interface Link Admin Groups and SRv6-TE Affinity Maps let you assign, or map, up to 256 color names for affinity and attribute-flag attributes instead of 32-bit hexadecimal numbers. After mappings are defined, the attributes can be referred to by the corresponding color name in the CLI. Furthermore, you can define constraints using *include-any*, *include-all*, and *exclude-any* arguments, where each statement can contain up to 10 colors.

Note You can configure affinity constraints using attribute flags or the Flexible Name Based Policy Constraints scheme; however, when configurations for both schemes exist, only the configuration pertaining to the new scheme is applied.

Configure Named Interface Link Admin Groups and SRv6-TE Affinity Maps

Use the **segment-routing traffic-eng interface *interface* affinity name *NAME*** command to assign affinity to interfaces. Configure this on routers with interfaces that have an associated admin group attribute.

Use the **segment-routing traffic-eng affinity-map name *NAME* bit-position *bit-position*** command to define affinity maps. The *bit-position* range is from 0 to 255.

Configure affinity maps on the following routers:

- Routers with interfaces that have an associated admin group attribute.
- Routers that act as SRv6-TE head-ends for SR policies that include affinity constraints.

Configuring Link Admin Group: Example

The following example shows how to assign affinity to interfaces and to define affinity maps. This configuration is applicable to any router (SRv6-TE head-end or transit node) with colored interfaces.

```
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# interface HundredGigE0/0/0/0
Router(config-sr-if)# affinity
Router(config-sr-if-affinity)# name brown
Router(config-sr-if-affinity)# exit
Router(config-sr-if)# exit

Router(config-sr-te)# affinity-map
Router(config-sr-te-affinity-map)# name brown bit-position 1
```

Running Config

```
segment-routing
traffic-eng
interface HundredGigE0/0/0/0
affinity
name brown
!
!
affinity-map
name brown bit-position 1
!
end
```

Segment Protection-Type Constraint

Table 43: Feature History Table

Feature Name	Release Information	Feature Description
Segment Protection-Type Constraint	Release 7.4.1	<p>This feature introduces the ability to control whether protected or unprotected segments are used when encoding the SID-list of an SR policy candidate path.</p> <p>The types of segments that could be used when building a SID-list include prefix SIDs and adjacency SIDs.</p>

This feature introduces the ability to control whether protected or unprotected segments are used when encoding the SID-list of an SRv6 policy candidate path. The types of segments that could be used when building a SID-list include uSIDs and adjacency SIDs (uA SID).

A prefix SID is a global segment representing a prefix that identifies a specific node. A prefix SID is programmed with a backup path computed by the IGP using TI-LFA.

An adjacency SID is a local segment representing an IGP adjacency. An adjacency SID can be programmed with or without protection. Protected adjacency SIDs are programmed with a link-protectant backup path computed by the IGP (TI-LFA) and are used if the link associated with the IGP adjacency fails.

Prefix SIDs and adjacency SIDs can be leveraged as segments in a SID-list in order to forward a packet along a path traversing specific nodes and/or over specific interfaces between nodes. The type of segment used when encoding the SID-list will determine whether failures along the path would be protected by TI-LFA. Depending on the offering, an operator may want to offer either unprotected or protected services over traffic engineered paths.

The following behaviors are available with the segment protection-type constraint:

- **protected-only** — The SID-list must be encoded using protected segments.
- **protected-preferred** — The SID-list should be encoded using protected segments if available; otherwise, the SID-list may be encoded using unprotected Adj-SIDs. This is the default behavior when no segment protection-type constraint is specified.
- **unprotected-only** — The SID-list must be encoded using unprotected Adj-SID.
- **unprotected-preferred** — The SID-list should be encoded using unprotected Adj-SID if available, otherwise SID-list may be encoded using protected segments.

Usage Guidelines and Limitations

Observe the following guidelines and limitations for the platform:

- This constraint applies to candidate-paths of manual SR policies with dynamically computed paths.
- PCEP has been augmented (vendor-specific object) to allow a PCC to indicate the segment protection-type constraint to the PCE.
- When the segment protection type constraint is protected-only or unprotected-only, the path computation must adhere to the constraint. If the constraint is not satisfied, the SRv6 policy will not come up on such candidate path.
- When the segment protection-type constraint is unprotected-only, the entire SID-list must be encoded with unprotected Adj-SIDs.
- When the segment protection-type constraint is protected-only, the entire SID-list must be encoded with protected Adj-SIDs or Prefix SIDs.

Configuring Segment Protection-Type Constraint

Use the **constraints segments protection {protected-only | protected-preferred | unprotected-only | unprotected-preferred}** command to configure the segment protection-type behavior.

The following example shows how to configure the policy with a SID-list that must be encoded using protected segments:

```
Router(config-sr-te)# policy POLICY1
Router(config-sr-te-policy)# color 10 end-point ipv6 2:2::22
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 100
Router(config-sr-te-policy-path-pref)# constraints
```

```
Router(config-sr-te-path-pref-const)# segments
Router(config-sr-te-path-pref-const-seg)# protection protected-only
```

The following example shows how to configure the SRv6 ODN policy that must be encoded using protected segments:

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# on-demand color 20
Router(config-sr-te-color)# constraints
Router(config-sr-te-color-const)# segments
Router(config-sr-te-color-const-seg)# protection protected-only
```

Configure SRv6 Policy with Dynamic Path

To configure a SRv6-TE policy with a dynamic path, optimization objectives, and affinity constraints, complete the following configurations:

1. Define the optimization objectives. See the [Optimization Objectives, on page 412](#) section.
2. Define the constraints. See the [Constraints, on page 413](#) section.
3. Create the policy.

Behaviors and Limitations

For a dynamic path that traverses a specific interface between nodes (segment), the algorithm may encode this segment using an Adjacency micro-SID (uA SID).

Configuration

Create the SRv6-TE Policy

- Use the **segment-routing traffic-eng policy policy srv6 color color end-point ipv6 ipv6-address** command to configure the SRv6-TE policy color and IPv6 end-point address.

```
Node1(config)# segment-routing traffic-eng policy pol_node1_node4_te srv6 color 50
end-point ipv6 cafe:0:4::4
```

Specify Customized Locator and Source Address

- (Optional) Use the **segment-routing traffic-eng policy policy srv6 locator locator binding-sid dynamic behavior ub6-insert-reduced** command to specify the customized per-policy locator and BSID behavior. If you do not specify a customized per-policy locator and BSID behavior, the policy will use the global locator and BSID behavior.

```
Node1(config)# segment-routing traffic-eng policy pol_node1_node4_te srv6 locator node1
binding-sid dynamic behavior ub6-insert-reduced
```

- (Optional) Use the **segment-routing traffic-eng policy policy source-address ipv6 ipv6-address** command to specify the customized IPv6 source address for candidate paths. If you do not specify a customized per-policy source address, the policy will use the local IPv6 source address.

```
Node1(config)# segment-routing traffic-eng policy pol_node1_node4_te srv6 source-address
ipv6 cafe:0:1::1
```

Enable Dynamic Path Computed by the SR-PCE

- Use the **segment-routing traffic-eng policy policy candidate-paths preference preference dynamic pcep** command to specify the candidate path preference and enable dynamic path computed by the SR-PCE. The range for *preference* is from 1 to 65535.

```
Node1(config)# segment-routing traffic-eng policy pol_node1_node4_te candidate-paths
preference 100 dynamic pcep
```

Configure Dynamic Path Optimization Objectives

- Use the **segment-routing traffic-eng policy policy candidate-paths preference preference dynamic metric type {igp | te | latency}** command to configure the metric for use in path computation.

```
Node1(config)# segment-routing traffic-eng policy pol_node1_node4_te candidate-paths
preference 100 metric type te
```

- Use the **segment-routing traffic-eng policy policy candidate-paths preference preference dynamic metric margin {absolute value| relative percent}** command to configure the dynamic path metric margin. The range for *value* and *percent* is from 0 to 2147483647.

```
Node1(config)# segment-routing traffic-eng policy pol_node1_node4_te candidate-paths
preference 100 metric margin absolute 5
```

Configure Dynamic Path Constraints

Note Disjoint-path and affinity constraints cannot be configured at the same time.

- Use the **segment-routing traffic-eng policy policy candidate-paths preference preference constraints affinity {exclude-any | include-all | include-any} name** command to configure the affinity constraints.

```
Node1(config)# segment-routing traffic-eng policy pol_node1_node4_te candidate-paths
preference 100 constraints affinity exclude-any name brown
```

- Use the **segment-routing traffic-eng policy policy candidate-paths preference preference constraints disjoint-path group-id group-id type {link | node | srlg | srlg-node} [sub-id sub-id]** command to configure the disjoint-path constraints. The *group-id* and *sub-id* range is from 1 to 65535

```
Node1(config)# segment-routing traffic-eng policy pol_node1_node4_te candidate-paths
preference 100 constraints disjoint-path group-id 775 type link
```

- Use the **segment-routing traffic-eng policy policy candidate-paths preference preference constraints segments protection {protected-only | protected-preferred | unprotected-only | unprotected-preferred}** command to configure the segment protection-type behavior.

See [Segment Protection-Type Constraint, on page 238](#) for details about the segment protection-type constraint.

The following example shows how to configure the policy with a SID-list that must be encoded using protected segments:

```
Node1(config)# segment-routing traffic-eng policy pol_node1_node4_te candidate-paths
preference 100 constraints segments protection protected-only
```

Examples

The following example shows a configuration of an SRv6 policy at an SRv6-TE head-end router using the global locator and source address. The policy has a dynamic path with optimization objectives and affinity constraints computed by the SR-PCE.

```

Node1(config)# segment-routing
Node1(config-sr)# traffic-eng
Node1(config-sr-te)# srv6
Node1(config-sr-te-srv6)# locator Node1 binding-sid dynamic behavior ub6-insert-reduced

Protocols

Path Computation Element Protocol

The path computation element protocol (PCEP) describes a set of procedures by which a path computation client (PCC) can report and delegate control of head-end label switched paths (LSPs) sourced from the PCC to a PCE peer. The PCE can request the PCC to update and modify parameters of LSPs it controls. The stateful model also enables a PCC to allow the PCE to initiate computations allowing the PCE to perform network-wide orchestration.

Note Refer to the [Usage Guidelines and Limitations, on page 221](#) section for information about SR-PCE compatibility with different IOS XR releases.

A PCEP channel is established over TCP and has its own light-weight Keep-Alive (KA) mechanism

Upon configuring a PCE peer, a PCC opens a PCEP session to the PCE, and the PCE accepts the PCEP sessions if the following conditions are satisfied:

- The total number of PCEP sessions does not exceed the limit on the total number of PCEP sessions on the PCE.
- The KA interval indicated by PCC is acceptable to the PCE.

Sample Workflow with Stateful PCEP

1. The PCC is configured to instantiate an SRv6-TE policy.
2. The PCC sends a PCEP Path Computation Request (PCReq) to the PCE, requesting a path by specifying path attributes, optimization objectives, and constraints.
3. The PCE stores the request, computes a TE metric shortest-path, and returns the computed SID list in a PCEP Path Computation Reply (PCRepl).
4. The PCC allocates a BSID and activates the SR Policy using the SID list computed by the PCE. The PCC sends a Path Computation Report (PCRpt) to the PCE, delegating the SR Policy to the PCE and including BSID.
5. The PCE updates the paths when required (for example, following a multi-domain topology change that impacts connectivity).

Configure the Head-End Router as PCEP PCC

Configure the head-end router as PCEP Path Computation Client (PCC) to establish a connection to the PCE. The PCC and PCE addresses must be routable so that TCP connection (to exchange PCEP messages) can be established between PCC and PCE.

Configure the PCC to Establish a Connection to the PCE

Use the **segment-routing traffic-eng pcc** command to configure the PCC source address, the SR-PCE address, and SR-PCE options.

A PCE can be given an optional precedence. If a PCC is connected to multiple PCEs, the PCC selects a PCE with the lowest precedence value. If there is a tie, a PCE with the highest IP address is chosen for computing path. The precedence *value* range is from 0 to 255.

```
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# pcc
```

```
Router(config-sr-te-pcc) # source-address ipv6 ipv6-local-source-address
Router(config-sr-te-pcc) # pce address ipv6 ipv6-PCE-address[precedence value]
```

Configure PCEP Authentication

TCP Message Digest 5 (MD5) authentication has been used for authenticating PCEP (TCP) sessions by using a clear text or encrypted password. This feature introduces support for TCP Authentication Option (TCP-AO), which replaces the TCP MD5 option.

TCP-AO uses Message Authentication Codes (MACs), which provides the following:

- Protection against replays for long-lived TCP connections
- More details on the security association with TCP connections than TCP MD5
- A larger set of MACs with minimal system and operational changes

TCP-AO is compatible with Master Key Tuple (MKT) configuration. TCP-AO also protects connections when using the same MKT across repeated instances of a connection. TCP-AO protects the connections by using traffic key that are derived from the MKT, and then coordinates changes between the endpoints.

Note TCP-AO and TCP MD5 are never permitted to be used simultaneously. TCP-AO supports IPv6, and is fully compatible with the proposed requirements for the replacement of TCP MD5.

TCP Message Digest 5 (MD5) Authentication

Use the **password {clear | encrypted} LINE** command to enable TCP MD5 authentication for all PCEP peers. Any TCP segment coming from the PCC that does not contain a MAC matching the configured password will be rejected. Specify if the password is encrypted or clear text

```
Router(config-sr-te-pcc) # pce address ipv6 ipv6-PCE-address[password {clear | encrypted}
LINE]
```

TCP Authentication Option (TCP-AO)

Use the **tcp-ao key-chain [include-tcp-options]** command to enable TCP Authentication Option (TCP-AO) authentication for all PCEP peers. Any TCP segment coming from the PCC that does not contain a MAC matching the configured key chain will be rejected. Use the **include-tcp-options** keyword to include other TCP options in the header for MAC calculation.

```
Router(config-sr-te-pcc) # pce address ipv6 ipv6-PCE-address tcp-ao key-chain
[include-tcp-options]
```

Configure PCEP-Related Timers

Use the **timers keepalive** command to specify how often keepalive messages are sent from PCC to its peers. The range is from 0 to 255 seconds; the default value is 30.

```
Router(config-sr-te-pcc) # timers keepalive seconds
```

Use the **timers deadtimer** command to specify how long the remote peers wait before bringing down the PCEP session if no PCEP messages are received from this PCC. The range is from 1 to 255 seconds; the default value is 120.

```
Router(config-sr-te-pcc) # timers deadtimer seconds
```

Use the **timers delegation-timeout** command to specify how long a delegated SR policy can remain up without an active connection to a PCE. The range is from 0 to 3600 seconds; the default value is 60.

```
Router(config-sr-te-pcc)# timers delegation-timeout seconds
```

PCE-Initiated SR Policy Timers

Use the **timers initiated orphans** command to specify the amount of time that a PCE-initiated SR policy will remain delegated to a PCE peer that is no longer reachable by the PCC. The range is from 10 to 180 seconds; the default value is 180.

```
Router(config-sr-te-pcc)# timers initiated orphans seconds
```

Use the **timers initiated state** command to specify the amount of time that a PCE-initiated SR policy will remain programmed while not being delegated to any PCE. The range is from 15 to 14440 seconds (24 hours); the default value is 600.

```
Router(config-sr-te-pcc)# timers initiated state seconds
```

Note Multicast follows the same timer for Point-to-Multipoint (P2MP) policies:

- The default interval is 10 minutes.
- You can set the internal timer to '0' to ensure that forwarding states remain active indefinitely, even if the PCE is down for more than 5 minutes.
- If the PCE is down for more than 5 minutes, it is because the PCE is going down or the reachability to PCE going down.

To better understand how the PCE-Initiated SR policy timers operate, consider the following example:

- PCE A instantiates SR policy P at head-end N.
- Head-end N delegates SR policy P to PCE A and programs it in forwarding.
- If head-end N detects that PCE A is no longer reachable, then head-end N starts the PCE-initiated **orphan** and **state** timers for SR policy P.
- If PCE A reconnects before the **orphan** timer expires, then SR policy P is automatically delegated back to its original PCE (PCE A).
- After the **orphan** timer expires, SR policy P will be eligible for delegation to any other surviving PCE(s).
- If SR policy P is not delegated to another PCE before the **state** timer expires, then head-end N will remove SR policy P from its forwarding.

Enable SR-TE SYSLOG Alarms

Use the **logging policy status** command to enable SR-TE related SYSLOG alarms.

```
Router(config-sr-te)# logging policy status
```

Enable PCEP Reports to SR-PCE

Use the **report-all** command to enable the PCC to report all SR policies in its database to the PCE.

```
Router(config-sr-te-pcc) # report-all
```

Customize MSD Value at PCC

Use the **maximum-sid-depth** *value* command to customize the Maximum SID Depth (MSD) signaled by PCC during PCEP session establishment.

The MSD is expressed as a number uSIDs. The number of uSID is expressed as a number of carriers and the number of uSID per carrier.

The default MSD *value* is equal to the maximum MSD supported by the platform (6 — 1 carrier, 6 uSIDs per carrier).

```
Router(config-sr-te-srv6) # maximum-sid-depth value
```

For cases with path computation at PCE, a PCC can signal its MSD to the PCE in the following ways:

- During PCEP session establishment – The signaled MSD is treated as a node-wide property.
 - MSD is configured under **segment-routing traffic-eng maximum-sid-depth** *value* command
- During PCEP LSP path request – The signaled MSD is treated as an LSP property.
 - On-demand (ODN) SR Policy: MSD is configured using the **segment-routing traffic-eng on-demand color** *color* **maximum-sid-depth** *value* command
 - Local SR Policy: MSD is configured using the **segment-routing traffic-eng policy** *WORD* **candidate-paths preference** *preference* **dynamic metric sid-limit** *value* command.

Note If the configured MSD values are different, the per-LSP MSD takes precedence over the per-node MSD.

After path computation, the resulting uSID stack size is verified against the MSD requirement.

- If the uSID stack size is larger than the MSD and path computation is performed by PCE, then the PCE returns a "no path" response to the PCC.
- If the uSID stack size is larger than the MSD and path computation is performed by PCC, then the PCC will not install the path.

Note A sub-optimal path (if one exists) that satisfies the MSD constraint could be computed in the following cases:

- For a dynamic path with TE metric, when the PCE is configured with the **pce segment-routing te-latency** command or the PCC is configured with the **segment-routing traffic-eng te-latency** command.
- For a dynamic path with LATENCY metric
- For a dynamic path with affinity constraints

For example, if the PCC MSD is 4 and the optimal path (with an accumulated metric of 100) requires 5 uSIDs, but a sub-optimal path exists (with accumulated metric of 110) requiring 4 uSIDs, then the sub-optimal path is installed.

Customize the SR-TE Path Calculation

Use the **te-latency** command to enable ECMP-aware path computation for TE metric.

```
Router(config-sr-te) # te-latency
```

Note ECMP-aware path computation is enabled by default for IGP and LATENCY metrics.

Configure PCEP Redundancy Type

Use the **redundancy pcc-centric** command to enable PCC-centric high-availability model. The PCC-centric model changes the default PCC delegation behavior to the following:

- After LSP creation, LSP is automatically delegated to the PCE that computed it.
- If this PCE is disconnected, then the LSP is redelegated to another PCE.
- If the original PCE is reconnected, then the delegation fallback timer is started. When the timer expires, the LSP is redelegated back to the original PCE, even if it has worse preference than the current PCE.

```
Router(config-sr-te-pcc) # redundancy pcc-centric
```

Configuring Head-End Router as PCEP PCC and Customizing SR-TE Related Options: Example

The following example shows how to configure an SR-TE head-end router with the following functionality:

- Enable the SR-TE head-end router as a PCEP client (PCC) with 2 PCEP servers (PCE) with different precedence values. The PCE with IP address cafe:0:2::2 is selected as BEST.
- Enable SR-TE related syslogs.
- Set the Maximum SID Depth (MSD) signaled during PCEP session establishment to 5.
- Enable PCEP reporting for all policies in the node.

```
Node1(config) # segment-routing
Node1(config-sr) # traffic-eng
Node1(config-sr-te) # pcc
```

```

Node1(config-sr-te-pcc)# source-address ipv6 cafe:0:1::1
Node1(config-sr-te-pcc)# pce address ipv6 cafe:0:2::2
Node1(config-pcc-pce)# precedence 10
Node1(config-pcc-pce)# exit
Node1(config-sr-te-pcc)# pce address ipv6 cafe:0:3::3
Node1(config-pcc-pce)# precedence 20
Node1(config-pcc-pce)# exit
Node1(config-sr-te-pcc)# report-all
Node1(config-sr-te-pcc)# exit
Node1(config-sr-te)# srv6
Node1(config-sr-te-srv6)# maximum-sid-depth 5
Node1(config-sr-te-srv6)# exit
Node1(config-sr-te)# logging
Node1(config-sr-te-log)# policy status
Node1(config-sr-te-log)# exit
Node1(config-sr-te)#

```

SR-TE Application Programming Interface (API)

Table 44: Feature History Table

Feature Name	Release Information	Feature Description
SR-TE Application Programming Interface (API)	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards)</p> <p>This feature introduces an API solution that simplifies the task of building SR-TE controllers and managing SRTE policies. It does so by defining gRPC API services that allow applications to request SR policy operations.</p> <p>The solution leverages the gRPC Service API and GPB Data models, providing a unified, scalable, and secure method for network programming.</p> <p>This feature introduces these changes:</p> <p>New CLI</p> <ul style="list-style-type: none"> • grpc segment-routing traffic-eng policy-service <p>YANG Data Models:</p> <p>EMSD Yang model is updated to have this config under "segment-routing" container.</p> <ul style="list-style-type: none"> • Native model: Cisco-IOS-XR-man-ems-cfg.yang • UM model: Cisco-IOS-XR-um-grpc-cfg.yang <p>(see GitHub, YANG Data Models Navigator)</p>

SDN controllers and applications with SR traffic-engineering capabilities require a mechanism to create, monitor, and control SRv6-TE (IPv6) policies with different properties, such as optimization objectives, constraints, and segment-lists.

This feature introduces an API solution that simplifies building SR-TE controllers by defining gRPC API services to request SR policy operations. These services allow for SR policy operations, potentially including

the creation, modification, or deletion of such policies. It's a more efficient and modernized approach to managing and controlling SR-TE policies.

Google-defined remote procedure call (gRPC) is an open-source RPC framework. It is based on Protocol Buffers (Protobuf), which is an open-source binary serialization protocol. gRPC provides a flexible, efficient, automated mechanism for serializing structured data, like XML, but is smaller and simpler to use. You can define the structure using protocol buffer message types in `.proto` files. Each protocol buffer message is a small logical record of information, containing a series of name-value pairs.

The client applications use this protocol to request information from the router and make configuration changes to the router. The process for using data models involves:

- Obtaining the data models.
- Establishing a connection between the router and the client using gRPC communication protocol.
- Managing the configuration of the router from the client using data models.

Note Refer to [Use gRPC Protocol to Define Network Operations with Data Models](#) in the *Programmability Configuration Guide for Cisco NCS 5500 Series Routers*.

Usage Guidelines and Limitations

- The API is supported for SRv6-TE policies.
- The API is not supported on the SR PCE.

SR-TE gRPC API

The SR-TE gRPC API uses the protocol buffers definition interface language (IDL) to manage the lifecycle (creation, modification, deletion) of SR-TE policies signaled by a controller/PCE and programmed at a headend.

The gRPC requests are encoded and sent to the SR-TE headend router (gRPC server) using JSON. The router can invoke the RPC calls defined in the IDL to program the SR-TE policies.

The gRPC service specifications for SR-TE, including the definitions of messages and the data model, are housed in a proto file. This SR-TE gRPC API proto file and a sample client are available in the following Github repository: <https://github.com/ios-xr/SR-TE>

SR-TE gRPC API proto file provides the following RPCs:

gRPC Operation	Description
SRTEPolicyAdd	Create and modify an SR-TE policy and its identifiers and attributes (for ex: color, endpoint, head-end, candidate paths).
SRTEPolicyDelete	Delete an SR-TE policy or any of its candidate paths.

Enabling the SR-TE gRPC API on the Headend Router

Use the following commands to enable the SR-TE gRPC API:

```
RP/0/RP0/CPU0:ios(config)# grpc  
RP/0/RP0/CPU0:ios(config-grpc)# segment-routing
```

```
RP/0/RP0/CPU0:ios(config-grpc-sr)# traffic-eng
RP/0/RP0/CPU0:ios(config-grpc-sr-te)# policy-service
RP/0/RP0/CPU0:ios(config-grpc-sr-te)# commit
```

Note Refer to [Use gRPC Protocol to Define Network Operations with Data Models](#) in the *Programmability Configuration Guide for Cisco NCS 5500 Series Routers* for other gRPC parameters.

Verify

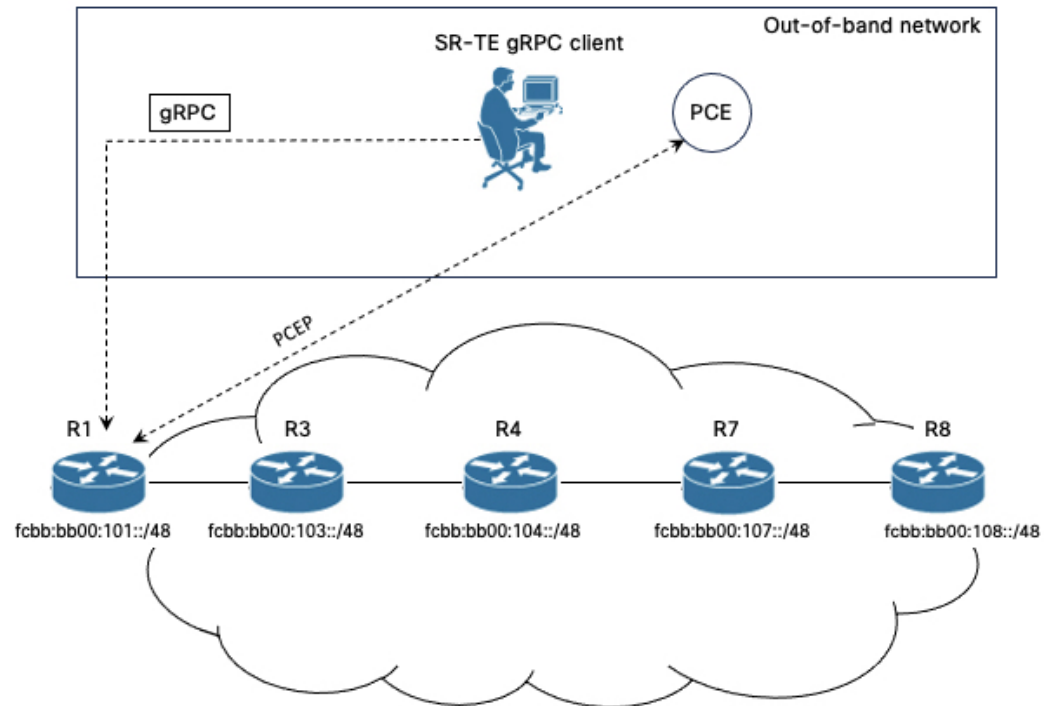

Use the show segment-routing traffic-eng service-api clients command to display the SR-TE gRPC API client and its status:

```
RP/0/RSP0/CPU0:ios# show segment-routing traffic-eng service-api clients
. . .
```

```
Client name: emsd (Protocol type: gRPC)
  Role: Active
  ID: 960268627
  State: Up
  Throttled: No
  Statistics:
    Client ever connected: Yes
    Connected: 00:00:12 (since Wed Nov 15 15:02:14 PST 2023)
    Number of add requests: 0
    Number of delete requests: 0
. . .
```

Examples

In the following examples, R1 is the SR-TE headend and the gRPC server. The headend router implements the server-side of the gRPC communication, handling requests from gRPC clients.

In these examples, an SR-TE gRPC client written in Python is used to emulate the controller node. These clients send commands to create, modify, or delete SRTE policies, and the headend router executes these commands and returns the responses.

Example 1: Programming an SRv6-TE Policy with Explicit Path via gRPC API

1. Configure the SRv6-TE policy.

In this example, the SRv6-TE policy uses explicit paths with a segment list. The following JSON file is passed as an input to the SR-TE gRPC client to program an SRv6-TE policy with an explicit path at the head-end router.

```
controller:grpc$ more sample_srv6_explicit_path_req.json
{
  "policies": [
    {
      "key": {
        "color": 6,
        "endpoint": "2001:0:108::1",
        "headend": "2001:0:101::1"
      },
      "CPs": [
        {
          "explicit": [
            {
              "segmentList": {
                "name": "test-srv6",
                "segments": {
                  "typeB": [
                    "fcbb:bb00:104::",
                    "fcbb:bb00:108::"
                  ]
                }
              }
            }
          ]
        }
      ]
    }
  ]
}
```

```

    }
  ],
  "preference": 10,
  "dataplane": 1,
  "key": {
    "originatorID": {
      "ASN": 64000,
      "nodeID": "1.1.1.101"
    },
    "discriminator": 100,
    "originatorProtocol": 40
  }
}
},
"bindingSIDAllocation": 1,
"srv6BindingSID": {
  "locatorName": "LOC_BEST_EFFORT",
  "behavior": 71
}
}
]
}

```

Execute the command/JSON file on the SR-TE gRPC client:

```

controller-grpc$ srte_client -u <user> -p <password> --policy-add
-j sample_srv6_explicit_path_req.json -a <sr-te-headend-ip-addr>:57400
Response: [{"ReturnCode": 0, "Key": {"Color": 6, "Headend": "2001:0:101::1",
"Endpoint": "2001:0:108::1"}}]

```

Note Observe the console message indicating the policy state is “UP”:

```

RP/0/RP0/CPU0:Nov 15 15:11:23.784 PST: xtc_agent[1304]: %OS-XTC-5-SR_POLICY_UPDOWN :
SR policy 'srte_c_6_ep_2001:0:108::1' (color 6, end-point 2001:0:108::1) state changed to
UP

```

2. Verify the configuration.

Use the following **show** commands to verify the configuration.

```
RP/0/RP0/CPU0:R1# show segment-routing traffic-eng policy color 6
```

```
SR-TE policy database
```

```

Example 2: Programming an SRv6-TE Policy with Dynamic Path (Delegated to PCE) via gRPC API

1. Configure the SRv6-TE policy.

In this example, the SRv6-TE policy uses dynamic paths delegated to the PCE.

The following JSON file is passed as an input to the SR-TE gRPC client to program an SRv6-TE policy with a dynamic path.

```

controller:grpc$ more sample_srv6_dynamic_path_req.json
{
  "policies": [
    {
      "key": {
        "color": 7,
        "endpoint": "2001:0:108::1",
        "headend": "2001:0:101::1"
      },
      "CPs": [
        {
          "dynamic": {
            "delegate": true,
            "omeric": 0
          },
          "preference": 10,
          "dataplane": 1,
          "key": {
            "originatorID": {
              "ASN": 64000,
              "nodeID": "1.1.1.101"
            },
            "discriminator": 100,
            "originatorProtocol": 40
          }
        }
      ],
      "bindingSIDAllocation": 1,
      "srv6BindingSID": {
        "locatorName": "LOC_BEST_EFFORT",
        "behavior": 71
      }
    }
  ]
}

```

Execute the command/JSON file on the SR-TE gRPC client:

```

controller-grpc$ srte_client -u <user> -p <password> --policy-add
-j sample_srv6_dynamic_path_req.json -a <sr-te-headend-ip-addr>:57400
Response: [{"ReturnCode": 0, "Key": {"Color": 7, "Headend": "2001:0:101::1",
"Endpoint": "2001:0:108::1"}}]

```

Note Observe the console message indicating the policy state is “UP”:

```

RP/0/RP0/CPU0:Nov 15 15:25:23.671 PST: xtc_agent[1304]: %OS-XTC-5-SR_POLICY_UPDOWN :
SR policy 'srte_c_7_ep_2001:0:108::1' (color 7, end-point 2001:0:108::1) state changed to
UP

```

2. Verify the configuration.

Use the following **show** commands to verify the configuration.

```
RP/0/RP0/CPU0:R1# show segment-routing traffic-eng pol color 7
```

```
SR-TE policy database
```

```

Reporting of SR-TE Policies Using BGP- Link State

Table 45: Feature History Table

Feature Name	Release Information	Feature Description
Reporting of SR-TE Policies Using BGP-Link State for SRv6	Release 24.1.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>You can gather the Traffic Engineering Policy information that is locally available in a node and advertise it in BGP-LS for SRv6. The configuration procedures from previous releases, which supported only SR-MPLS, are the same and apply to this feature.</p>

Feature Name	Release Information	Feature Description
Reporting of SR-TE Policies Using BGP-Link State for SR-MPLS	Release 7.10.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>BGP- Link State (LS) is a mechanism by which LS and Traffic Engineering (TE) information can be collected from networks and shared with external components (such as, Segment Routing Path Computation Element (SR-PCE) or Crossword Optimization Engine (COE)) using the BGP routing protocol.</p> <p>This feature gathers the Traffic Engineering Policy information that is locally available in a node and advertises it in BGP-LS for SR-MPLS.</p> <p>The operators can now take informed decisions based on the information that is gathered on their network's path computation, reoptimization, service placement, network visualization, and so on.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> • distribute link-state <p>YANG Data Model:</p> <ul style="list-style-type: none"> • New XPath for module <code>Cisco-IOS-XR-infra-xtc-agent-cfg.yang</code> (see GitHub, YANG Data Models Navigator)

This function is achieved using a BGP Network Layer Reachability Information (NLRI) encoding format. BGP-LS consumes structured IGP data (for example, router-id, remote-IP-address of a link, local-IP address of a link, link identifier, and so on). and creates BGP-LS (NLRI) or attributes that BGP or other components like Cisco IOS XR Traffic Controller (XTC) can consume. Current implementation of BGP-LS can report topology using Nodes, Links, and Prefixes.

**Note**

- Starting from Release 7.10.1 this feature supports MPLS.
- Starting from Release 24.1.1 this feature supports SRv6.

Modern Segment Routing (SR) networks often use SR Traffic Engineering (SR-TE) to influence the path that each specific traffic takes over the network. SR-TE tunnels can be provisioned manually on the tunnel head, but often they are calculated and provisioned by the central controller. Often operator of the network wants the ability to force the traffic over specific nodes and links.

Now the operators have the option to collect reports of the SR-TE and Policy information that is locally available in a node and advertise it into BGP-LS updates, which can be used by external components. Refer the [IEFT](#) for examples. This feature is implemented so that the operators have control over their network's path computation, reoptimization, service placement, network visualization, and so on.

Note Circuit Style (CS) SR policies are reported but without the CS policies' specific attributes, like the bidirectional constraints, per-hop behavior, and so on.

Restrictions to Reporting of SRTE Policies using BGP-LS

Some important points to be aware related to this feature are as follows:

- This feature has high availability, ensuring BGP-LS reporting at all times.
- This feature works with PCE State Sync. The policy information learned via the state-sync channel is not advertised in BGP-LS by the PCE.
- The feature works with PCE redundancy. Both PCEs advertise the BGP-LS policy information. The consumers can select only one policy based on the BGP best path logic.

Configure Reporting of SRTE Policies using BGP-LS

The reporting of policies to BGP-LS is disabled by default. Configuring the **distribute link-state** under the SR-PCE or SR-TE configuration enables this feature. Once enabled, all the existing SR policies or Candidate Path (CPs) are encoded to BGP-LS. You can disable this feature by removing the configuration and all the SR policies or CPs are withdrawn from BGP which deletes all of the previously encoded SR policies or CPs.

Note When SR policies that are reporting in BGP-LS are enabled by the operator, the Head End only reports the Active Candidate Path (CPs) (CPs installed in the forwarding). There are monitoring use cases that require reporting of inactive CPs. The following CLI is needed to report inactive CPs.

For both SR-TE and SR-PCE, you need to use the global CLI to enable the reporting of policies or Circuit Style (CS) to BGP-LS:

- Note**
- Starting from Release 7.10.1 this feature supports MPLS.
 - Starting from Release 24.1.1 this feature supports SRv6.

Configuration Example

Configure the following command to enable reporting and syncing of SR policies in BGP-LS at the Head End:

```
Router# config
```

```

Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# distribute link-state
Router(config-sr-te-distribute-ls)# report-candidate-path-inactive
Router(config-sr-te-distribute-ls)# commit
Router(config-sr-te-distribute-ls)# exit

```

Note The **report-candidate-path-inactive** command is an optional command to report inactive CPs.

Running Configuration

This is a sample running configuration which shows that you have configured BGP-LS reporting feature.

```

segment-routing
 traffic-eng
   distribute link-state
   report-candidate-path-inactive
!
!
!

```

Verification

Use the **show pce segment-routing traffic-eng policy private** and **show pce distributed-ls events** to verify the configuration.

Router#show pce segment-routing traffic-eng policy private

```

CHAPTER 7

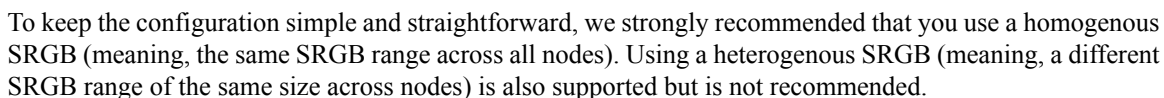

Configure Segment Routing Global Block and Segment Routing Local Block

Local label allocation is managed by the label switching database (LSD). The Segment Routing Global Block (SRGB) and Segment Routing Local Block (SRLB) are label values preserved for segment routing in the LSD.

- [About the Segment Routing Global Block, on page 273](#)
- [About the Segment Routing Local Block, on page 275](#)
- [Understanding Segment Routing Label Allocation, on page 276](#)
- [Setup a Non-Default Segment Routing Global Block Range, on page 279](#)
- [Setup a Non-Default Segment Routing Local Block Range, on page 280](#)

About the Segment Routing Global Block

The Segment Routing Global Block (SRGB) is a range of labels reserved for Segment Routing global segments. A prefix-SID is advertised as a domain-wide unique index. The prefix-SID index points to a unique label within the SRGB range. The index is zero-based, meaning that the first index is 0. The MPLS label assigned to a prefix is derived from the Prefix-SID index plus the SRGB base. For example, considering an SRGB range of 16,000 to 23,999, a prefix 10.1.1.65/32 with prefix-SID index of **65** is assigned the label value of **16065**.

- The default SRGB in IOS XR has a size of 8000 starting from label value 16000. The default range is 16000 to 23,999. With this size, and assuming one loopback prefix per router, an operator can assign prefix SIDs to a network with 8000 routers.
- There are instances when you might need to define a different SRGB range. For example:
 - Non-IOS XR nodes with a SRGB range that is different than the default IOS XR SRGB range.
 - The default SRGB range is not large enough to accommodate all required prefix SIDs.
- A non-default SRGB can be configured following these guidelines:
 - The SRGB starting value can be configured anywhere in the dynamic label range space (16,000 to 1,048,575).
 - In Cisco IOS XR release earlier than 6.6.3, the SRGB can have a maximum configurable size of 262,143.
 - In Cisco IOS XR release 6.6.3 and later, the SRGB can be configured to any size value that fits within the dynamic label range space.
- Allocating an SRGB label range does not mean that all the labels in this range are programmed in the forwarding table. The label range is just reserved for SR and not available for other purposes. Furthermore, a platform may limit the number of local labels that can be programmed.
- We recommend that the non-default SRGB be configured under the **segment-routing** global configuration mode. By default, all IGP instances and BGP use this SRGB.

- You can also configure a non-default SRGB under the IGP, but it is not recommended.

SRGB Label Conflicts

When you define a non-default SRGB range, there might be a label conflict (for example, if labels are already allocated, statically or dynamically, in the new SRGB range). The following system log message indicates a label conflict:

```
%ROUTING-ISIS-4-SRGB_ALLOC_FAIL : SRGB allocation failed: 'SRGB reservation not
successful for [16000,80000], SRGB (16000 80000, SRGB_ALLOC_CONFIG_PENDING, 0x2)
(So far 16 attempts). Make sure label range is free'
```

To remove this conflict, you must reload the router to release the currently allocated labels and to allocate the new SRGB.

After the system reloads, LSD does not accept any dynamic label allocation before IS-IS/OSPF/BGP have registered with LSD. Upon IS-IS/OSPF/BGP registration, LSD allocates the requested SRGB (either the default range or the customized range).

After IS-IS/OSPF/BGP have registered and their SRGB is allocated, LSD starts serving dynamic label requests from other clients.

Note To avoid a potential router reload due to label conflicts, and assuming that the default SRGB size is large enough, we recommend that you use the default IOS XR SRGB range.

Note Allocating a non-default SRGB in the upper part of the MPLS label space increases the chance that the labels are available and a reload can be avoided.

Caution Modifying a SRGB configuration is disruptive for traffic and may require a reboot if the new SRGB is not available entirely.

About the Segment Routing Local Block

A local segment is automatically assigned an MPLS label from the dynamic label range. In most cases, such as TI-LFA backup paths and SR-TE explicit paths defined with IP addresses, this dynamic label allocation is sufficient. However, in some scenarios, it could be beneficial to allocate manually local segment label values to maintain label persistency. For example, an SR-TE policy with a manual binding SID that is performing traffic steering based on incoming label traffic with the binding SID.

The Segment Routing Local Block (SRLB) is a range of label values preserved for the manual allocation of local segments, such as adjacency segment identifiers (adj-SIDs), Layer 2 adj-SIDs, binding SIDs (BSIDs), and BGP peering SIDs. These labels are locally significant and are only valid on the nodes that allocate the labels.

Behaviors and Limitations

- The default SRLB has a size of 1000 starting from label value 15000; therefore, the default SRLB range goes from 15000 to 15,999.
- A non-default SRLB can be configured following these guidelines:
 - The SRLB starting value can be configured anywhere in the dynamic label range space (16,000 to 1,048,575).
 - In Cisco IOS XR release earlier than 6.6.3, the SRLB can have a maximum configurable size of 262,143.
 - In Cisco IOS XR release 6.6.3 and later, the SRLB can be configured to any size value that fits within the dynamic label range space.

SRLB Label Conflicts

When you define a non-default SRLB range, there might be a label conflict (for example, if labels are already allocated, statically or dynamically, in the new SRLB range). In this case, the new SRLB range will be accepted, but not applied (pending state). The previous SRLB range (active) will continue to be in use.

To remove this conflict, you must reload the router to release the currently allocated labels and to allocate the new SRLB.

Caution

You can use the **clear segment-routing local-block discrepancy all** command to clear label conflicts. However, using this command is disruptive for traffic since it forces all other MPLS applications with conflicting labels to allocate new labels.

Note

To avoid a potential router reload due to label conflicts, and assuming that the default SRGB size is large enough, we recommend that you use the default IOS XR SRLB range.

Note

Allocating a non-default SRLB in the upper part of the MPLS label space increases the chance that the labels are available and a reload can be avoided.

Understanding Segment Routing Label Allocation

In IOS XR, local label allocation is managed by the Label Switching Database (LSD). MPLS applications must register as a client with the LSD to allocate labels. Most MPLS applications (for example: LDP, RSVP, L2VPN, BGP [LU, VPN], IS-IS and OSPF [Adj-SID], SR-TE [Binding-SID]) use labels allocated dynamically by LSD.

With Segment Routing-capable IOS XR software releases, the LSD *preserves* the default SRLB label range (15,000 to 15,999) and default SRGB label range (16,000 to 23,999), even if Segment Routing is not enabled.

This preservation of the default SRLB/SRGB label range makes future Segment Routing activation possible without a reboot. No labels are allocated from this preserved range. When you enable Segment Routing with the default SRLB/SRGB in the future, these label ranges will be available and ready for use.

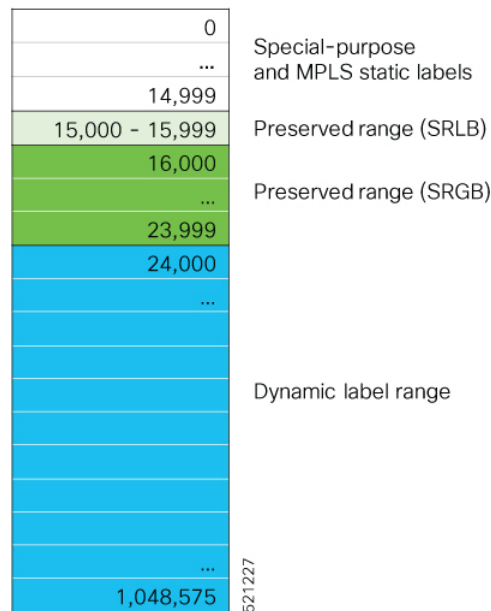

The LSD allocates dynamic labels starting from 24,000.

Note If an MPLS label range is configured and it overlaps with the default SRLB/SRGB label ranges (for example, **mpls label range 15000 1048575**), then the default SRLB/SRGB preservation is disabled.

Example 1: LSD Label Allocation When SR is not Configured

- Special use: 0-15
- MPLS static: 16 to 14,999
- SRLB (preserved): 15,000 to 15,999
- SRGB (preserved): 16,000 to 23,999
- Dynamic: 24,000 to max

Example 2: LSD Label Allocation When SR is Configured with Default SRGB and Default SRLB

- Special use: 0-15
- MPLS static: 16 to 14,999
- SRLB (reserved): 15,000 to 15,999
- SRGB (reserved): 16,000 to 23,999
- Dynamic: 24,000 to max

Example 3: LSD Label Allocation When SR is Configured with Non-default SRGB and Non-default SRLB

- Special use: 0-15
- MPLS static: 16 to 14,999
- SRLB (preserved): 15,000 to 15,999
- SRGB (preserved): 16,000 to 23,999
- Dynamic: 24000 to 28,999
- SRLB (reserved): 29,000 to 29,999
- SRGB (reserved): 30,000 to 39,999
- Dynamic: 40,000 to max

0	
...	Special-purpose and MPLS static labels

Setup a Non-Default Segment Routing Global Block Range

This task explains how to configure a non-default SRGB range.

SUMMARY STEPS

1. **configure**
2. **segment-routing global-block** *starting_value ending_value*
3. Use the **commit** or **end** command.

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.
Step 2	segment-routing global-block <i>starting_value ending_value</i> Example: RP/0/RP0/CPU0:router(config)# segment-routing global-block 16000 80000	Enter the lowest value that you want the SRGB range to include as the starting value. Enter the highest value that you want the SRGB range to include as the ending value.

	Command or Action	Purpose
Step 3	Use the commit or end command.	commit —Saves the configuration changes and remains within the configuration session. end —Prompts user to take one of these actions: <ul style="list-style-type: none"> • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • Cancel —Remains in the configuration session, without committing the configuration changes.

Use the **show mpls label table [label label-value]** command to verify the SRGB configuration:

```
Router# show mpls label table label 16000 detail
Table Label      Owner                               State Rewrite
-----
0      16000     ISIS(A):1                               InUse  No
      (Lbl-blk SRGB, vers:0, (start_label=16000, size=64001))
```

What to do next

Configure prefix SIDs and enable segment routing.

Setup a Non-Default Segment Routing Local Block Range

This task explains how to configure a non-default SRLB range.

SUMMARY STEPS

1. **configure**
2. **segment-routing local-block** *starting_value ending_value*
3. Use the **commit** or **end** command.

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.

	Command or Action	Purpose
Step 2	segment-routing local-block <i>starting_value ending_value</i> Example: <pre>RP/0/RP0/CPU0:router(config)# segment-routing local-block 30000 30999</pre>	Enter the lowest value that you want the SRLB range to include as the starting value. Enter the highest value that you want the SRLB range to include as the ending value.
Step 3	Use the commit or end command.	commit —Saves the configuration changes and remains within the configuration session. end —Prompts user to take one of these actions: <ul style="list-style-type: none"> • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • Cancel —Remains in the configuration session, without committing the configuration changes.

Use the **show mpls label table** [*label label-value*] [**detail**] command to verify the SRLB configuration:

```
Router# show mpls label table label 30000 detail

Table Label   Owner                               State Rewrite
-----
0      30000   LSD(A)                               InUse  No
(lbl-blk SRLB, vers:0, (start_label=30000, size=1000, app_notify=0)

Router# show segment-routing local-block inconsistencies

No inconsistencies
```

The following example shows an SRLB label conflict in the range of 30000 and 30999. Note that the default SRLB is active and the configured SRLB is pending:

```
Router(config)# segment-routing local-block 30000 30999

%ROUTING-MPLS_LSD-3-ERR_SRLB_RANGE : SRLB allocation failed: 'SRLB reservation not successfull
for [30000,30999]. Use with caution 'clear segment-routing local-block discrepancy all'
command
to force srlb allocation'
```

Caution You can use the **clear segment-routing local-block discrepancy all** command to clear label conflicts. However, using this command is disruptive for traffic since it forces all other MPLS applications with conflicting labels to allocate new labels.

```
Router# show mpls label table label 30000 detail
```

Setup a Non-Default Segment Routing Local Block Range

Table	Label	Owner	State	Rewrite
0	30000	LSD(A)	InUse	No

(Lbl-blk SRLB, vers:0, (start_label=30000, size=1000, app_notify=0)

```
Router# show segment-routing local-block inconsistencies
SRLB inconsistencies range: Start/End: 30000/30999
```

```
Router# show mpls lsd private | i SRLB
```

```
SRLB Lbl Mgr:
  Current Active SRLB block      = [15000, 15999]
  Configured Pending SRLB block = [30000, 30999]
```

Reload the router to release the currently allocated labels and to allocate the new SRLB:

```
Router# reload
```

```
Proceed with reload? [confirm]yes
```

After the system is brought back up, verify that there are no label conflicts with the SRLB configuration:

```
Router# show mpls lsd private | i SRLB
```

```
SRLB Lbl Mgr:
  Current Active SRLB block      = [30000, 30999]
  Configured Pending SRLB block = [0, 0]
```

```
Router# show segment-routing local-block inconsistencies
```

```
No inconsistencies
```

What to do next

Configure adjacency SIDs and enable segment routing.

CHAPTER 8

Configure Segment Routing for IS-IS Protocol

Integrated Intermediate System-to-Intermediate System (IS-IS), Internet Protocol Version 4 (IPv4), is a standards-based Interior Gateway Protocol (IGP). The Cisco IOS XR software implements the IP routing capabilities described in International Organization for Standardization (ISO)/International Engineering Consortium (IEC) 10589 and RFC 1995, and adds the standard extensions for single topology and multitopology IS-IS for IP Version 6 (IPv6).

This module provides the configuration information used to enable segment routing for IS-IS.

Note For additional information on implementing IS-IS on your Cisco NCS 5500 Series Router, see the *Implementing IS-IS* module in the *Routing Configuration Guide for Cisco NCS 5500 Series Routers*.

- [Enabling Segment Routing for IS-IS Protocol, on page 283](#)
- [Configuring a Prefix-SID on the IS-IS Enabled Loopback Interface, on page 286](#)
- [Configuring an Adjacency SID, on page 288](#)
- [Configuring Bandwidth-Based Local UCMP, on page 294](#)
- [IS-IS Multi-Domain Prefix SID and Domain Stitching: Example, on page 295](#)
- [IS-IS Unreachable Prefix Announcement, on page 298](#)
- [IS-IS Partition Detection and Leakage of Specific Route Advertisement, on page 301](#)
- [Conditional Prefix Advertisement, on page 306](#)
- [Segment Routing ECMP-FEC Optimization, on page 308](#)

Enabling Segment Routing for IS-IS Protocol

Segment routing on the IS-IS control plane supports the following:

- IPv4 and IPv6 control plane
- Level 1, level 2, and multi-level routing
- Prefix SIDs for host prefixes on loopback interfaces
- Adjacency SIDs for adjacencies
- MPLS penultimate hop popping (PHP) and explicit-null signaling

This task explains how to enable segment routing for IS-IS.

Before you begin

Your network must support the MPLS Cisco IOS XR software feature before you enable segment routing for IS-IS on your router.

Note You must enter the commands in the following task list on every IS-IS router in the traffic-engineered portion of your network.

SUMMARY STEPS

1. **configure**
2. **router isis** *instance-id*
3. **address-family** { **ipv4** | **ipv6** } [**unicast**]
4. **metric-style wide** [**level** { **1** | **2** }]
5. **router-id loopback** *loopback interface used for prefix-sid*
6. **segment-routing mpls** [**sr-prefer**]
7. **exit**
8. Use the **commit** or **end** command.

DETAILED STEPS**Procedure**

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.
Step 2	router isis <i>instance-id</i> Example: RP/0/RP0/CPU0:router(config)# router isis isp	Enables IS-IS routing for the specified routing instance, and places the router in router configuration mode. Note You can change the level of routing to be performed by a particular routing instance by using the is-type router configuration command.
Step 3	address-family { ipv4 ipv6 } [unicast] Example: RP/0/RP0/CPU0:router(config-isis)# address-family ipv4 unicast	Specifies the IPv4 or IPv6 address family, and enters router address family configuration mode.
Step 4	metric-style wide [level { 1 2 }] Example:	Configures a router to generate and accept only wide link metrics in the Level 1 area.

	Command or Action	Purpose
	<pre>RP/0/RP0/CPU0:router(config-isis-af)# metric-style wide level 1</pre>	
Step 5	<p>router-id loopback <i>loopback interface used for prefix-sid</i></p> <p>Example:</p> <pre>RP/0/RP0/CPU0:router(config-isis-af)# router-id loopback0</pre>	Configures router ID for each address-family (IPv4/IPv6). IS-IS advertises the router ID in TLVs 134 (for IPv4 address family) and 140 (for IPv6 address family). Required when traffic engineering is used.
Step 6	<p>segment-routing mpls [sr-prefer]</p> <p>Example:</p> <pre>RP/0/RP0/CPU0:router(config-isis-af)# segment-routing mpls</pre>	<p>Segment routing is enabled by the following actions:</p> <ul style="list-style-type: none"> • MPLS forwarding is enabled on all interfaces where IS-IS is active. • All known prefix-SIDs in the forwarding plain are programmed, with the prefix-SIDs advertised by remote routers or learned through local or remote mapping server. • The prefix-SIDs locally configured are advertised. <p>Use the sr-prefer keyword to set the preference of segment routing (SR) labels over label distribution protocol (LDP) labels.</p>
Step 7	<p>exit</p> <p>Example:</p> <pre>RP/0/RP0/CPU0:router(config-isis-af)# exit RP/0/RP0/CPU0:router(config-isis)# exit</pre>	
Step 8	Use the commit or end command.	<p>commit —Saves the configuration changes and remains within the configuration session.</p> <p>end —Prompts user to take one of these actions:</p> <ul style="list-style-type: none"> • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • Cancel —Remains in the configuration session, without committing the configuration changes.

What to do next

Configure the prefix SID.

Configuring a Prefix-SID on the IS-IS Enabled Loopback Interface

A prefix segment identifier (SID) is associated with an IP prefix. The prefix SID is manually configured from the segment routing global block (SRGB) range of labels. A prefix SID is configured under the loopback interface with the loopback address of the node as the prefix. The prefix segment steers the traffic along the shortest path to its destination.

A prefix SID can be a node SID or an Anycast SID. A node SID is a type of prefix SID that identifies a specific node. An Anycast SID is a type of prefix SID that identifies a set of nodes, and is configured with n-flag clear. The set of nodes (Anycast group) is configured to advertise a shared prefix address and prefix SID. Anycast routing enables the steering of traffic toward multiple advertising nodes. Packets addressed to an Anycast address are forwarded to the topologically nearest nodes.

The prefix SID is globally unique within the segment routing domain.

This task explains how to configure prefix segment identifier (SID) index or absolute value on the IS-IS enabled Loopback interface.

Before you begin

Ensure that segment routing is enabled on the corresponding address family.

SUMMARY STEPS

1. **configure**
2. **router isis** *instance-id*
3. **interface Loopback** *instance*
4. **address-family** { **ipv4** | **ipv6** } [**unicast**]
5. **prefix-sid** [**algorithm** *algorithm-number*] {**index** *SID-index* | **absolute** *SID-value*} [**n-flag-clear**] [**explicit-null**]
6. Use the **commit** or **end** command.

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.
Step 2	router isis <i>instance-id</i> Example: RP/0/RP0/CPU0:router(config)# router isis 1	Enables IS-IS routing for the specified routing instance, and places the router in router configuration mode. <ul style="list-style-type: none"> • You can change the level of routing to be performed by a particular routing instance by using the is-type router configuration command.

	Command or Action	Purpose
Step 3	interface <i>Loopback instance</i> Example: <pre>RP/0/RP0/CPU0:router(config-isis)# interface Loopback0</pre>	Specifies the loopback interface and instance.
Step 4	address-family { <i>ipv4</i> <i>ipv6</i> } [<i>unicast</i>] Example: The following is an example for ipv4 address family: <pre>RP/0/RP0/CPU0:router(config-isis-if)# address-family ipv4 unicast</pre>	Specifies the IPv4 or IPv6 address family, and enters router address family configuration mode.
Step 5	prefix-sid [<i>algorithm algorithm-number</i>] { <i>index SID-index</i> <i>absolute SID-value</i> } [<i>n-flag-clear</i>] [<i>explicit-null</i>] Example: <pre>RP/0/RP0/CPU0:router(config-isis-if-af)# prefix-sid index 1001</pre> <pre>RP/0/RP0/CPU0:router(config-isis-if-af)# prefix-sid absolute 17001</pre>	<p>Configures the prefix-SID index or absolute value for the interface.</p> <p>Specify algorithm <i>algorithm-number</i> to configure SR Flexible Algorithm.</p> <p>Specify index <i>SID-index</i> for each node to create a prefix SID based on the lower boundary of the SRGB + the index.</p> <p>Specify absolute <i>SID-value</i> for each node to create a specific prefix SID within the SRGB.</p> <p>By default, the n-flag is set on the prefix-SID, indicating that it is a node SID. For specific prefix-SID (for example, Anycast prefix-SID), enter the <i>n-flag-clear</i> keyword. IS-IS does not set the N flag in the prefix-SID sub Type Length Value (TLV).</p> <p>To disable penultimate-hop-popping (PHP) and add explicit-Null label, enter <i>explicit-null</i> keyword. IS-IS sets the E flag in the prefix-SID sub TLV.</p>
Step 6	Use the commit or end command.	<p>commit —Saves the configuration changes and remains within the configuration session.</p> <p>end —Prompts user to take one of these actions:</p> <ul style="list-style-type: none"> • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • Cancel —Remains in the configuration session, without committing the configuration changes.

Verify the prefix-SID configuration:

```
RP/0/RP0/CPU0:router# show isis database verbose
```

```

Configuring an Adjacency SID

An adjacency SID (Adj-SID) is associated with an adjacency to a neighboring node. The adjacency SID steers the traffic to a specific adjacency. Adjacency SIDs have local significance and are only valid on the node that allocates them.

An adjacency SID can be allocated dynamically from the dynamic label range or configured manually from the segment routing local block (SRLB) range of labels.

Adjacency SIDs that are dynamically allocated do not require any special configuration, however there are some limitations:

- A dynamically allocated Adj-SID value is not known until it has been allocated, and a controller will not know the Adj-SID value until the information is flooded by the IGP.
- Dynamically allocated Adj-SIDs are not persistent and can be reallocated after a reload or a process restart.
- Each link is allocated a unique Adj-SID, so the same Adj-SID cannot be shared by multiple links.

Manually allocated Adj-SIDs are persistent over reloads and restarts. They can be provisioned for multiple adjacencies to the same neighbor or to different neighbors. You can specify that the Adj-SID is protected. If the Adj-SID is protected on the primary interface and a backup path is available, a backup path is installed. By default, manual Adj-SIDs are not protected.

Adjacency SIDs are advertised using the existing IS-IS Adj-SID sub-TLV. The S and P flags are defined for manually allocated Adj-SIDs.

```

 0 1 2 3 4 5 6 7
+---+---+---+---+---+---+
| F | B | V | L | S | P |   |
+---+---+---+---+---+---+

```

Table 46: Adjacency Segment Identifier (Adj-SID) Flags Sub-TLV Fields

Field	Description
S (Set)	This flag is set if the same Adj-SID value has been provisioned on multiple interfaces.
P (Persistent)	This flag is set if the Adj-SID is persistent (manually allocated).

Manually allocated Adj-SIDs are supported on point-to-point (P2P) interfaces.

This task explains how to configure an Adj-SID on an interface.

Before you begin

Ensure that segment routing is enabled on the corresponding address family.

Use the **show mpls label table detail** command to verify the SRLB range.

SUMMARY STEPS

1. **configure**
2. **router isis** *instance-id*
3. **interface** *type interface-path-id*
4. **point-to-point**
5. **address-family** { **ipv4** | **ipv6** } [**unicast**]
6. **adjacency-sid** { **index** *adj-SID-index* | **absolute** *adj-SID-value* } [**protected**]
7. Use the **commit** or **end** command.

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.
Step 2	router isis <i>instance-id</i> Example: RP/0/RP0/CPU0:router(config)# router isis 1	Enables IS-IS routing for the specified routing instance, and places the router in router configuration mode. • You can change the level of routing to be performed by a particular routing instance by using the is-type router configuration command.
Step 3	interface <i>type interface-path-id</i> Example: RP/0/RP0/CPU0:router(config-isis)# interface GigabitEthernet0/0/0/7	Specifies the interface and enters interface configuration mode.

	Command or Action	Purpose
Step 4	point-to-point Example: <pre>RP/0/RP0/CPU0:router(config-isis-if)# point-to-point</pre>	Specifies the interface is a point-to-point interface.
Step 5	address-family { ipv4 ipv6 } [unicast] Example: The following is an example for ipv4 address family: <pre>RP/0/RP0/CPU0:router(config-isis-if)# address-family ipv4 unicast</pre>	Specifies the IPv4 or IPv6 address family, and enters router address family configuration mode.
Step 6	adjacency-sid {index <i>adj-SID-index</i> absolute <i>adj-SID-value</i> } [protected] Example: <pre>RP/0/RP0/CPU0:router(config-isis-if-af)# adjacency-sid index 10</pre> <pre>RP/0/RP0/CPU0:router(config-isis-if-af)# adjacency-sid absolute 15010</pre>	Configures the Adj-SID index or absolute value for the interface. Specify index <i>adj-SID-index</i> for each link to create an Adj-SID based on the lower boundary of the SRLB + the index. Specify absolute <i>adj-SID-value</i> for each link to create a specific Adj-SID within the SRLB. Specify if the Adj-SID is protected . For each primary path, if the Adj-SID is protected on the primary interface and a backup path is available, a backup path is installed. By default, manual Adj-SIDs are not protected.
Step 7	Use the commit or end command.	commit —Saves the configuration changes and remains within the configuration session. end —Prompts user to take one of these actions: <ul style="list-style-type: none"> • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • Cancel —Remains in the configuration session, without committing the configuration changes.

Verify the Adj-SID configuration:

```
RP/0/RP0/CPU0:router# show isis segment-routing label adjacency persistent
Mon Jun 12 02:44:07.085 PDT

IS-IS 1 Manual Adjacency SID Table

15010 AF IPv4
  GigabitEthernet0/0/0/3: IPv4, Protected 1/65/N, Active
  GigabitEthernet0/0/0/7: IPv4, Protected 2/66/N, Active
```

```
15100 AF IPv6
      GigabitEthernet0/0/0/3: IPv6, Not protected 255/255/N, Active
```

Verify the labels are added to the MPLS Forwarding Information Base (LFIB):

```
RP/0/RP0/CPU0:router# show mpls forwarding labels 15010
Mon Jun 12 02:50:12.172 PDT
Local  Outgoing  Prefix      Outgoing   Next Hop   Bytes
Label  Label        or ID      Interface  Hop        Switched
-----
15010  Pop          SRLB (idx 10)  Gi0/0/0/3  10.0.3.3   0
      Pop          SRLB (idx 10)  Gi0/0/0/7  10.1.0.5   0
      16004       SRLB (idx 10)  Gi0/0/0/7  10.1.0.5   0              (!)
      16004       SRLB (idx 10)  Gi0/0/0/3  10.0.3.3   0              (!)
```

Manually Configure a Layer 2 Adjacency SID

Typically, an adjacency SID (Adj-SID) is associated with a Layer 3 adjacency to a neighboring node, to steer the traffic to a specific adjacency. If you have Layer 3 bundle interfaces, where multiple physical interfaces form a bundle interface, the individual Layer 2 bundle members are not visible to IGP; only the bundle interface is visible.

You can configure a Layer 2 Adj-SID for the individual Layer 2 bundle interfaces. This configuration allows you to track the availability of individual bundle member links and to verify the segment routing forwarding over the individual bundle member links, for Operational Administration and Maintenance (OAM) purposes.

A Layer 2 Adj-SID can be allocated dynamically or configured manually.

- IGP dynamically allocates Layer 2 Adj-SIDs from the dynamic label range for each Layer 2 bundle member. A dynamic Layer 2 Adj-SID is not persistent and can be reallocated as the Layer 3 bundle link goes up and down.
- Manually configured Layer 2 Adj-SIDs are persistent if the Layer 3 bundle link goes up and down. Layer 2 Adj-SIDs are allocated from the Segment Routing Local Block (SRLB) range of labels. However, if the configured value of Layer 2 Adj-SID does not fall within the available SRLB, a Layer 2 Adj-SID will not be programmed into forwarding information base (FIB).

Restrictions

- Adj-SID forwarding requires a next-hop, which can be either an IPv4 address or an IPv6 address, but not both. Therefore, manually configured Layer 2 Adj-SIDs are configured per address-family.
- Manually configured Layer 2 Adj-SID can be associated with only one Layer 2 bundle member link.
- A SID value used for Layer 2 Adj-SID cannot be shared with Layer 3 Adj-SID.
- SR-TE using Layer 2 Adj-SID is not supported.

This task explains how to configure a Layer 2 Adj-SID on an interface.

Before you begin

Ensure that segment routing is enabled on the corresponding address family.

Use the **show mpls label table detail** command to verify the SRLB range.

SUMMARY STEPS

1. **configure**
2. **segment-routing**
3. **adjacency-sid**
4. **interface** *type interface-path-id*
5. **address-family** { **ipv4** | **ipv6** } [**unicast**]
6. **l2-adjacency sid** { **index** *adj-SID-index* | **absolute** *adj-SID-value* } [**next-hop** { *ipv4_address* | *ipv6_address* }]
7. Use the **commit** or **end** command.
8. **end**
9. **router isis** *instance-id*
10. **address-family** { **ipv4** | **ipv6** } [**unicast**]
11. **segment-routing bundle-member-adj-sid**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.
Step 2	segment-routing Example: Router(config)# segment-routing	Enters segment routing configuration mode.
Step 3	adjacency-sid Example: Router(config-sr)# adjacency-sid	Enters adjacency SID configuration mode.
Step 4	interface <i>type interface-path-id</i> Example: Router(config-sr-adj)# interface GigabitEthernet0/0/0/3	Specifies the interface and enters interface configuration mode.
Step 5	address-family { ipv4 ipv6 } [unicast] Example: Router(config-sr-adj-intf)# address-family ipv4 unicast	Specifies the IPv4 or IPv6 address family, and enters router address family configuration mode.

	Command or Action	Purpose
Step 6	<p>l2-adjacency sid {<i>index adj-SID-index</i> absolute <i>adj-SID-value</i> } [next-hop {<i>ipv4_address</i> <i>ipv6_address</i> }]</p> <p>Example:</p> <pre>Router(config-sr-adj-intf-af)# l2-adjacency sid absolute 15015 next-hop 10.1.1.4</pre>	<p>Configures the Adj-SID index or absolute value for the interface.</p> <p>Specify index <i>adj-SID-index</i> for each link to create an Adj-SID based on the lower boundary of the SRLB + the index.</p> <p>Specify absolute <i>adj-SID-value</i> for each link to create a specific Adj-SID within the SRLB.</p> <p>For point-to-point interfaces, you are not required to specify a next-hop. However, if you do specify the next-hop, the Layer 2 Adj-SID will be used only if the specified next-hop matches the neighbor address.</p> <p>For LAN interfaces, you must configure the next-hop IPv4 or IPv6 address. If you do not configure the next-hop, the Layer 2 Adj-SID will not be used for LAN interface.</p>
Step 7	Use the commit or end command.	<p>commit —Saves the configuration changes and remains within the configuration session.</p> <p>end —Prompts user to take one of these actions:</p> <ul style="list-style-type: none"> • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • Cancel —Remains in the configuration session, without committing the configuration changes.
Step 8	end	
Step 9	<p>router isis <i>instance-id</i></p> <p>Example:</p> <pre>Router(config)# router isis isp</pre>	Enables IS-IS routing for the specified routing instance, and places the router in router configuration mode.
Step 10	<p>address-family { <i>ipv4</i> <i>ipv6</i> } [unicast]</p> <p>Example:</p> <pre>Router(config-isis)# address-family ipv4 unicast</pre>	Specifies the IPv4 or IPv6 address family, and enters router address family configuration mode.
Step 11	<p>segment-routing bundle-member-adj-sid</p> <p>Example:</p> <pre>Router(config-isis-af)# segment-routing bundle-member-adj-sid</pre>	<p>Programs the dynamic Layer 2 Adj-SIDs, and advertises both manual and dynamic Layer 2 Adj-SIDs.</p> <p>Note This command is not required to program manual L2 Adj-SID, but is required to program the dynamic Layer</p>

	Command or Action	Purpose
		2 Adj-SIDs and to advertise both manual and dynamic Layer 2 Adj-SIDs.

Verify the configuration:

```
Router# show mpls forwarding detail | i "Pop|Outgoing Interface|Physical Interface"
Tue Jun 20 06:53:51.876 PDT
```

```
. . .
15001 Pop          SRLB (idx 1)      BE1          10.1.1.4          0
    Outgoing Interface: Bundle-Ether1 (ifhandle 0x000000b0)
    Physical Interface: GigabitEthernet0/0/0/3 (ifhandle 0x000000b0)
```

```
Router# show running-config segment-routing
Tue Jun 20 07:14:25.815 PDT

```

Configuring Bandwidth-Based Local UCMP

Bandwidth-based local Unequal Cost Multipath (UCMP) allows you to enable UCMP functionality locally between Equal Cost Multipath (ECMP) paths based on the bandwidth of the local links.

Bandwidth-based local UCMP is performed for prefixes, segment routing Adjacency SIDs, and Segment Routing label cross-connects installed by IS-IS, and is supported on any physical or virtual interface that has a valid bandwidth.

For example, if the capacity of a bundle interface changes due to the link or line card up/down event, traffic continues to use the affected bundle interface regardless of the available provisioned bundle members. If some bundle members were not available due to the failure, this behavior could cause the traffic to overload the bundle interface. To address the bundle capacity changes, bandwidth-based local UCMP uses the bandwidth of the local links to load balance traffic when bundle capacity changes.

Before you begin

SUMMARY STEPS

1. **configure**
2. **router isis** *instance-id*
3. **address-family** { **ipv4** | **ipv6** } [**unicast**]
4. **apply-weight** **ecmp-only** **bandwidth**
5. Use the **commit** or **end** command.

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.
Step 2	router isis <i>instance-id</i> Example: RP/0/RP0/CPU0:router(config)# router isis 1	Enables IS-IS routing for the specified routing instance, and places the router in router configuration mode. You can change the level of routing to be performed by a particular routing instance by using the is-type router configuration command.
Step 3	address-family { ipv4 ipv6 } [unicast] Example: The following is an example for ipv4 address family: RP/0/RP0/CPU0:router(config-isis)# address-family ipv4 unicast	Specifies the IPv4 or IPv6 address family, and enters IS-IS address family configuration mode.
Step 4	apply-weight ecmp-only bandwidth Example: RP/0/RP0/CPU0:router(config-isis-af)# apply-weight ecmp-only bandwidth	Enables UCMP functionality locally between ECMP paths based on the bandwidth of the local links.
Step 5	Use the commit or end command.	commit —Saves the configuration changes and remains within the configuration session. end —Prompts user to take one of these actions: <ul style="list-style-type: none"> • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • Cancel —Remains in the configuration session, without committing the configuration changes.

IS-IS Multi-Domain Prefix SID and Domain Stitching: Example

IS-IS Multi-Domain Prefix SID and Domain Stitching allows you to configure multiple IS-IS instances on the same loopback interface for domain border nodes. You specify a loopback interface and prefix SID under multiple IS-IS instances to make the prefix and prefix SID reachable in different domains.

This example uses the following topology. Node 5 and 9 are border nodes between two IS-IS domains (Domain1 and Domain2). Node 10 is configured as the Segment Routing Path Computation Element (SR-PCE).

Figure 13: Multi-Domain Topology

Configure IS-IS Multi-Domain Prefix SID

Specify a loopback interface and prefix SID under multiple IS-IS instances on each border node:

Example: Border Node 5

```
router isis Domain1
 interface Loopback0
  address-family ipv4 unicast
  prefix-sid absolute 16005
```

```
router isis Domain2
 interface Loopback0
  address-family ipv4 unicast
  prefix-sid absolute 16005
```

Example: Border Node 9

```
router isis Domain1
 interface Loopback0
  address-family ipv4 unicast
  prefix-sid absolute 16009
```

```
router isis Domain2
 interface Loopback0
  address-family ipv4 unicast
  prefix-sid absolute 16009
```

Border nodes 5 and 9 each run two IS-IS instances (Domain1 and Domain2) and advertise their Loopback0 prefix and prefix SID in both domains.

Nodes in both domains can reach the border nodes by using the same prefix and prefix SID. For example, Node 3 and Node 22 can reach Node 5 using prefix SID 16005.

Configure Common Router ID

On each border node, configure a common TE router ID under each IS-IS instance:

Example: Border Node 5

```
router isis Domain1
 address-family ipv4 unicast
   router-id loopback0

router isis Domain2
 address-family ipv4 unicast
   router-id loopback0
```

Example: Border Node 9

```
router isis Domain1
 address-family ipv4 unicast
   router-id loopback0

router isis Domain2
 address-family ipv4 unicast
   router-id loopback0
```

Distribute IS-IS Link-State Data

Configure BGP Link-state (BGP-LS) on Node 13 and Node 14 to report their local domain to Node 10:

Example: Node 13

```
router isis Domain1
 distribute link-state instance-id instance-id
```

Example: Node 14

```
router isis Domain2
  distribute link-state instance-id instance-id
```

Link-state ID starts from 32. One ID is required per IGP domain. Different domain IDs are essential to identify that the SR-TE TED belongs to a particular IGP domain.

Nodes 13 and 14 each reports its local domain in BGP-LS to Node 10.

Node 10 identifies the border nodes (Nodes 5 and 9) by their common advertised TE router ID, then combines (stitches) the domains on these border nodes for end-to-end path computations.

IS-IS Unreachable Prefix Announcement

Table 47: Feature History Table

Feature Name	Release	Description
IS-IS Unreachable Prefix Announcement	Release 7.8.1	<p>The Unreachable Prefix Announcement (UPA) notifies the loss of prefix reachability between areas or domains, for prefixes that are covered by the summary address range during inter-area or inter-domain summarization.</p> <p>This feature helps in identifying the routers that are facing prefix unreachability issues faster and fix it.</p> <p>The new commands introduced for this feature are:</p> <ul style="list-style-type: none"> • summary-prefix • prefix-unreachable

The organization of networks into levels or areas and/or IGP domains helps to limit the scope of link-state information within certain boundaries. However, the state that is related to prefix reachability often requires propagation across these areas (Level1/Level2) or domains (Autonomous System Boundary Router (ASBR)). An Autonomous System Boundary Router (ASBR) is a router that is running multiple protocols and serves as a gateway to routers outside the Open Shortest Path First (OSPF) domain and those operating with different protocols.

Route summarization, also known as route aggregation, is a method to minimize the number of routing tables in an IP network. It consolidates selected multiple routes into a single route advertisement.

Techniques such as summarization address the scale challenges associated with the advertisement of the individual prefix state outside of local area/domain. MPLS architecture did not allow for the effective use of the summarization due to its end-to-end Label Switched Path (LSP) requirement. With the introduction of the SRv6, which does not have such requirement, the use of summarization has become important again.

Summarization results in suppression of the individual prefix state that is useful for triggering fast-convergence mechanisms outside of the Interior Gateway Routing Protocols (IGPs) (for example - Border Gateway Protocol - Prefix Independent Convergence (BGP PIC) Edge).

This feature enables the notification of the individual prefixes becoming unreachable in its area/domain, when the summarization is used between areas/domains to advertise the reachability for these prefixes.

There are existing SRv6 deployments that use summarization and require fast detection of the egress Provider Edge (PE) going down. To address these deployments in timely manner, we use the existing Protocol Data Units (PDUs) and Tag-Length-Values (TLVs), which is based on the Prefix Unreachability Advertisement (UPA).

Configuration Steps

The configuration steps that are required to set up the Unreachable Prefix Announcement (UPA) feature are as follows:

• UPA Advertisement

An existing IS-IS address-family submode **summary-prefix** command was extended for UPA advertisement.

```
Router(config)#router isis 1
Router(config-isis)#address-family ipv6 unicast
Router(config-isis-af)#summary-prefix beef:10::/32 level 2 adv-unreachable
Router(config-isis-af)#summary-prefix beef:11::/32 level 2 algorithm 128 adv-unreachable
  unreachable-component-tag 777
Router(config-isis-af)#commit
```

• Prefix Unreachable

The new **prefix-unreachable** command includes new commands that control the UPA advertisement such as, lifetime, metric, limit the maximum number if UPAs and UPA processing. For more details see, [prefix-unreachable](#)

```
Router(config)#router isis 1
Router(config-isis)#address-family ipv6
Router(config-isis-af)#prefix-unreachable
Router(config-isis-prefix-unreachable)#adv-lifetime 500
Router(config-isis-prefix-unreachable)#adv-metric 4261412866
Router(config-isis-prefix-unreachable)#adv-maximum 77
Router(config-isis-prefix-unreachable)#rx-process-enable
Router(config-isis-prefix-unreachable)#commit
```

Running Configuration

Execute the following show commands to review the L1/L2 (area) or ASBR (domain) running configuration:

Run the **show run router isis 1 address-family ipv6 unicast** command to view the summary prefix under as well as UPA parameters under it.

```
Router#sh run router isis 1 address-family ipv6 unicast
router isis 1
address-family ipv6 unicast
  advertise application lfa link-attributes srlg
  advertise link attributes
  prefix-unreachable
    adv-lifetime 300
  !
  summary-prefix 10::/64
  summary-prefix beef:10::/32 adv-unreachable
  summary-prefix beef:11::/32 algorithm 128 adv-unreachable
  summary-prefix ceef:10::/32 adv-unreachable
  propagate level 2 into level 1 route-policy L2_TO_L1
  segment-routing srv6
```

```
locator USID_ALG0
!
locator USID_ALG128
!
!
!
```

IS-IS Partition Detection and Leakage of Specific Route Advertisement

Table 48: Feature History Table

Feature Name	Release	Description
IS-IS Partition Detection and Leakage of Specific Route Advertisements	Release 7.10.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>In an open ring topology, a single fiber cut may partition the area or domain into two pieces. With summarization enabled, the area (domain) partition may result in traffic drops. Depending on the configuration in the Area Border Routers (ABRs) or Autonomous System Boundary Routers (ASBRs) that is picked as an entry point to the partitioned area (domain), the traffic is delivered to its destination or dropped as unreachable at ABR or ASBR.</p> <p>IS-IS partition detection and leakage of specific route advertisements features are introduced to retain connectivity for the partitioned area (domain) when summarization is used.</p> <p>The ABRs or ASBRs detect a network partition within an area (domain) and upon detection, ensure that the summary route is replaced with specific route advertisements in IS-IS.</p> <p>The feature introduces these changes:</p> <p>New Command:</p> <ul style="list-style-type: none">• partition-detect <p>Modified Command:</p> <ul style="list-style-type: none">• The partition-repair keyword is introduced in the summary-prefix command. <p>YANG Data Model:</p> <ul style="list-style-type: none">• New XPaths for <code>Cisco-IOS-XR-um-router-isis-cfg.yang</code> (see GitHub, YANG Data Models Navigator)

In service provider networks, the Layer 1 (L1) area is often represented by a set of routers connected in a ring. Sometimes the ring is not closed (for example, Area Border Routers (ABRs) are not connected directly into the L1 area). In such cases, a single fiber cut partitions the area into two pieces. Route Summarization is

basically advertising many routes into one route, also called route aggregation. When the partition is detected, summarization is suppressed, and all previously summarized prefixes are advertised in IS-IS. The individual prefix advertisements preserve the connectivity end-to-end.

Figure 14: Interarea Topology with L1 Area in an Open Ring

This feature addresses the following summarization problems:

- **Area Partition Detection and Avoidance:** Area partition detection only works for summarization from L1 to L2. It is not supported for summarization from L2 to L1. Ensure you have router-id that is configured for the address-family (IPv4 or IPv6) for which you are enabling the partition detection and avoidance.

Note Router-id must be enabled for this feature to work. Area partition is tracked for each algorithm, algo 0, and any enabled flex-algo, independently. For flex-algo, the Area Border Router must participate in the algo for the tracking to work for such flex-algo

- **Domain Partition Detection and Avoidance:** Networks use multi-domain design, where they split their network into multiple IGP domains. They redistribute between domains and summarize during the redistribution. An IGP domain may represent an open ring and a single link cut may split it into two parts.

Configuration Steps

Configure IS-IS Partition Detection and Leakage of Specific as follows:

- **Area Partition Detection and Avoidance:** To configure the area partition detection and avoidance there are two configuration steps:
 1. For each summary prefix that you want the area partition and avoidance to work, enable it with the summary-prefix command:

```
Router(config)#router isis 1
Router(config-isis)#address-family ipv6 unicast
Router(config-isis-af)#summary-prefix 2001:DB8::/32 level 2 partition-repair
Router(config-isis-af)#summary-prefix 2001:DB9::/32 level 2 algorithm 128
partition-repair
Router(config-isis-af)#commit
```

2. Configure the tracking of the Area Border Router (ABR) reachability. Here, the example is for two ABRs, but you can enable the partition for as many ABRs in the area.

```
Router(config)#router isis 1
Router(config-isis)#address-family ipv6 unicast
Router(config-isis-af)#router-id 2001:DB8:1::1
Router(config-isis-af)#summary-prefix 2001:DB8::/32 level 2 partition-repair
Router(config-isis-af)#summary-prefix 2001:DB9::/32 level 2 algorithm 128
partition-repair
Router(config-isis-af)#partition-detect
Router(config-isis-af)#track 2001:DB8:4::4
Router(config-isis-af)#commit
```

```
Router(config)#router isis 1
Router(config-isis)#address-family ipv6 unicast
Router(config-isis-af)#router-id 2001:DB8:4::4
Router(config-isis-af)#summary-prefix 2001:DB8::/32 level 2 partition-repair
Router(config-isis-af)#summary-prefix 2001:DB9::/32 level 2 algorithm 128
partition-repair
Router(config-isis-af)#partition-detect
Router(config-isis-af)#track 2001:DB8:1::1
Router(config-isis-af)#commit
```

- **Domain Partition Detection and Avoidance:** It is similar to Area Partition and requires two configuration steps:

1. For each summary prefix that you want the area partition and avoidance to work, enable it with the summary-prefix command:

```
Router(config)#router isis 1
Router(config-isis)#address-family ipv6 unicast
Router(config-isis-af)#summary-prefix 2001:DB8::/32 level 2 partition-repair
Router(config-isis-af)#summary-prefix 2001:DB9::/32 level 2 algorithm 128
partition-repair
Router(config-isis-af)#commit
```

2. Configure the tracking of the Area Border Router reachability. The example is for two ABRs, but you can enable the partition for as many ABRs in the area.

To track ASBR, two identifiers are required:

- First is the internal router-id in the instance under which the configuration is done (similar to area partition).
- Second is the address of the ASBR in the other domain that is redistributed to the instance where the configuration is done.

Note

The implementation of the feature ensures that the reachability of the external-address is only tracked in algorithm 0. The loss of the external-address is used for algo 0 and all flex-algos. The reachability of the internal address is kept per flex-algo.

```
Router(config)#router isis 2
Router(config-isis)#address-family ipv6 unicast
```

```

Router(config-isis-af)#router-id 2001:DB8:1::1
Router(config-isis-af)#summary-prefix 2001:DB8::/32 level 2 partition-repair
Router(config-isis-af)#summary-prefix 2001:DB9::/32 level 2 algorithm 128
partition-repair
Router(config-isis-af)#partition-detect
Router(config-isis-af)#track 2001:DB8:4::4 external-address 2001:DB8:10::4
Router(config-isis-af)#commit

Router(config)#router isis 2
Router(config-isis)#address-family ipv6 unicast
Router(config-isis-af)#router-id 2001:DB8:4::4
Router(config-isis-af)#summary-prefix 2001:DB8::/32 level 2 partition-repair
Router(config-isis-af)#summary-prefix 2001:DB9::/32 level 2 algorithm 128
partition-repair
Router(config-isis-af)#partition-detect
Router(config-isis-af)#track 2001:DB8:1::1 external-address 2001:DB8:10::1
Router(config-isis-af)#commit

```

Verification

• For Area Partition Detection and Avoidance

Use the show command **show isis instance 1 flex-algo 128** to check if the area partition is detected:

```

Router# show isis instance 1 flex-algo 128
IS-IS 1 Flex-Algo Database
Flex-Algo 128:

Conditional Prefix Advertisement

In some situations, it's beneficial to make the IS-IS prefix advertisement conditional. For example, an Area Border Router (ABR) or Autonomous System Boundary Router (ASBR) that has lost its connection to one of the areas or autonomous systems (AS) might keep advertising a prefix. If an ABR or ASBR advertises the Segment Routing (SR) SID with this prefix, the label stack of the traffic routed toward the disconnected area or AS might use this SID, which would result in dropped traffic at the ABR or ASBR.

ABRs or ASBRs are often deployed in pairs for redundancy and advertise a shared Anycast prefix SID. Conditional Prefix Advertisement allows an ABR or an ASBR to advertise its Anycast SID only when connected to a specific area or domain. If an ABR or ASBR becomes disconnected from the particular area or AS, it stops advertising the address for a specified interface (for example, Loopback).

Configure the conditional prefix advertisement under a specific interface. The prefix advertisement on this interface is associated with the route-policy that tracks the presence of a set of prefixes (prefix-set) in the Routing Information Base (RIB).

For faster convergence, the route-policy used for conditional prefix advertisement uses the new event-based **rib-has-route async** condition to notify IS-IS of the following situations:

- When the last prefix from the prefix-set is removed from the RIB.
- When the first prefix from the prefix-set is added to the RIB.

Configuration

To use the conditional prefix advertisement in IS-IS, create a prefix-set to be tracked. Then create a route policy that uses the prefix-set.

```
Router(config)# prefix-set prefix-set-name
Router(config-pfx)# prefix-address-1/length[, prefix-address-2/length,,
prefix-address-16/length]
Router(config-pfx)# end-set

Router(config)# route-policy rpl-name
Router(config-rpl)# if rib-has-route async prefix-set-name then
Router(config-rpl-if)# pass
Router(config-rpl-if)# endif
Router(config-rpl)# end-policy
```

To advertise the loopback address in IS-IS conditionally, use the **advertise prefix route-policy** command under IS-IS interface address-family configuration sub-mode.

```
Router(config)# router isis 1
Router(config-isis)# interface Loopback0
Router(config-isis-if)# address-family ipv4 unicast
Router(config-isis-if-af)# advertise prefix route-policy rpl-name
Router(config-isis-if-af)# commit
```

Example

```
Router(config)# prefix-set domain_2
Router(config-pfx)# 2.3.3.3/32, 2.4.4.4/32
Router(config-pfx)# end-set
Router(config)# route-policy track_domain_2
```

```
Router(config-rpl)# if rib-has-route async domain_2 then
Router(config-rpl-if)# pass
Router(config-rpl-if)# endif
Router(config-rpl)# end-policy
Router(config)# router isis 1
Router(config-isis)# interface Loopback0
Router(config-isis-if)# address-family ipv4 unicast
Router(config-isis-if-af)# advertise prefix route-policy track_domain-2
Router(config-isis-if-af)# commit
```

Running Configuration

```
prefix-set domain_2
  2.3.3.3/32,
  2.4.4.4/32
end-set
!
route-policy track_domain_2
  if rib-has-route async domain_2 then
    pass
  endif
end-policy
!
router isis 1
  interface Loopback0
    address-family ipv4 unicast
    advertise prefix route-policy track_domain_2
  !
!
```

Segment Routing ECMP-FEC Optimization

Table 49: Feature History Table

Feature Name	Release Information	Feature Description
SR ECMP-FEC Optimization for IPv6 Prefixes	Release 24.2.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards).</p> <p>You can now minimize ECMP-FEC resource consumption and duplication of resources during underlay programming for an SR-MPLS network for IPv6 prefixes. The feature supports sharing the same ECMP-FEC, regular FEC, and Egress Encapsulation DB (EEDB) entries for all paths with the same outgoing MPLS label among IPv6 prefixes. This improvement is now possible by using the hw-module fib mpls label lsr-optimized command.</p> <p>In earlier releases, ECMP-FEC optimization for IPv4 prefixes was available.</p>
SR ECMP-FEC Optimization L2 and L3 Recursive Services	Release 7.4.1	This feature adds support for L2VPN service Label Edge Router (LER) and BGP PIC for Layer 3 BGP services when SR ECMP-FEC Optimization is enabled.

ECMP-FECs are used for any ECMP programming on the system, such as MPLS LSP ECMP, VPN multipath, and [EVPN multi-homing](#).

The SR ECMP-FEC optimization solution minimizes ECMP-FEC resource consumption and duplication, during underlay programming for an SR-MPLS network. This feature supports sharing the same ECMP-FEC, regular FEC, and Egress Encapsulation DB (EEDB) entries among Segment Routing prefixes with the same set of next hops.

ECMP-FEC optimization is triggered when all the out_labels associated with the ECMP paths for a given prefix have the same value. If this rule is not met, then the prefix is programmed with a dedicated ECMP-FEC.

Segment Routing Label Edge Router (LER) ECMP-FEC Optimization enables ECMP-FEC optimization originally developed for Label Switched Router (LSR) nodes (MPLS P) to be enabled on LER (Layer 3 MPLS PE) routers.

Usage Guidelines and Limitations

- SR ECMP-FEC Optimization is not supported on Cisco NCS 5700 series fixed port routers or Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native or compatible modes.
- For the labeled prefixes with ECMP across a combination of labeled and unlabeled (PHP) paths, the SR ECMP-FEC Optimization cannot be triggered since the paths associated with the prefix do not have the same outgoing label and/or label action.
- For prefixes with LFA backup paths, the SR ECMP-FEC Optimization is possible since these backup paths do not require an extra label to be pushed; all paths associated with the prefix (primary and backup) have the same outgoing label value.
- For prefixes with TI-LFA backup paths requiring extra labels to be pushed on to the backup, the SR ECMP-FEC Optimization is not possible since all the paths associated with the prefix do not have the same outgoing label value.
- For the duration of time that prefixes are programmed to avoid microloops (when SR MicroLoop Avoidance is triggered), SR ECMP-FEC Optimization is not possible since all the paths associated with the prefix do not have the same outgoing label value. After removal of the microloop-avoidance programming, the SR ECMP-FEC Optimization might be possible again.
- For scenarios with prefixes where the SR ECMP-FEC Optimization is not possible, dedicated ECMP-FEC is allocated per prefix. This could potentially lead to ECMP FEC out-of-resource (OOR) considering the baseline usage of ECMP FEC resources at steady state. During ECMP-FEC OOR, prefixes with multiple paths are programmed with a single path in order to avoid traffic disruption.
- SR ECMP-FEC optimization is applicable in the following instances:
 - Label Switched Router (LSR) nodes (MPLS P)
 - L3VPN Label Edge Router (LER) nodes
 - L2VPN LER nodes
 - ASBR node with BGP-LU swap
- BGP PIC is supported
- SR ECMP-FEC optimization should not be enabled in the following instances:
 - L2VPN/L3VPN LER nodes with VPN over BGP-LU over SR
- For the labeled prefixes, transitioning from TI-LFA to SR ECMP-FEC optimization can cause ECMP-FEC OOR due to different output labels (ECMP label vs backup path's label) at make-before-break. This results in a few second traffic loss depending on route scale

Enable SR ECMP-FEC Optimization

To enable SR ECMP-FEC optimization, use the **hw-module fib mpls label lsr-optimized** command in global configuration mode. After enabling this feature, reload the line card. For more information about the command, see the *MPLS Label Distribution Protocol Commands* chapter in the *MPLS Command Reference Guide*.

```
Router(config)# hw-module fib mpls label lsr-optimized
Router(config)# commit
```

```
LC/0/0/CPU0:Oct 11 20:19:12.540 UTC: fia_driver[185]:
%FABRIC-FIA_DRV-4-MPLS_HW_PROFILE_MISMATCH :
Mismatch found, reload LC to activate the new mpls profile
```

```
Router# reload location 0/0/CPU0
```

```
Proceed with reload? [confirm]
Reloading node 0/0/CPU0
```

Verify the SR ECMP-FEC Optimization

From Cisco IOS XR Release 24.2.1, in addition to IPv4 prefixes, you can view the ECMP-FEC optimization details for IPv6 prefixes using the **show controllers npu resources** command. In earlier releases, ECMP-FEC optimization for IPv4 prefixes was available.

The following example shows NPU usage before enabling SR ECMP-FEC optimization for IPv4 and IPv6 prefixes:

```
Router#show controllers npu resources ecmpfec location 0/0/CPU0
```

```
Tue May 14 17:17:40.306 UTC
```

```
HW Resource Information
```

```
    Name                : ecmp_fec
    Asic Type             : JerichoPlus
```

```
NPU-0
```

```
OOR Summary
```

```

CHAPTER 9

Configure Segment Routing for OSPF Protocol

Table 50: Feature History Table

Feature Name	Release Information	Feature Description
NC57 line cards in Native Mode: SR-MPLS - OSPFv2	Release 7.3.1	This feature is now supported on routers that have the Cisco NC57 line cards installed and operate in native mode. To enable the native mode, use the hw-module profile npu native-mode-enable command in the configuration mode. Ensure that you reload the router after configuring the native mode.

Open Shortest Path First (OSPF) is an Interior Gateway Protocol (IGP) developed by the OSPF working group of the Internet Engineering Task Force (IETF). Designed expressly for IP networks, OSPF supports IP subnetting and tagging of externally derived routing information. OSPF also allows packet authentication and uses IP multicast when sending and receiving packets.

This module provides the configuration information to enable segment routing for OSPF.

Note For additional information on implementing OSPF on your Cisco NCS 5500 Series Router, see the *Implementing OSPF* module in the *Routing Configuration Guide for Cisco NCS 5500 Series Routers*.

- [Enabling Segment Routing for OSPF Protocol, on page 314](#)

Enabling Segment Routing for OSPF Protocol

Segment routing on the OSPF control plane supports the following:

- OSPFv2 control plane
- Multi-area
- IPv4 prefix SIDs for host prefixes on loopback interfaces
- Adjacency SIDs for adjacencies
- MPLS penultimate hop popping (PHP) and explicit-null signaling

This section describes how to enable segment routing MPLS and MPLS forwarding in OSPF. Segment routing can be configured at the instance, area, or interface level.

Before you begin

Your network must support the MPLS Cisco IOS XR software feature before you enable segment routing for OSPF on your router.

Note You must enter the commands in the following task list on every OSPF router in the traffic-engineered portion of your network.

SUMMARY STEPS

1. **configure**
2. **router ospf** *process-name*
3. **segment-routing mpls**
4. **segment-routing sr-prefer**
5. **area** *area*
6. **segment-routing mpls**
7. **exit**
8. Use the **commit** or **end** command.

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.

	Command or Action	Purpose
Step 2	router ospf <i>process-name</i> Example: RP/0/RP0/CPU0:router(config)# router ospf 1	Enables OSPF routing for the specified routing process and places the router in router configuration mode.
Step 3	segment-routing mpls Example: RP/0/RP0/CPU0:router(config-ospf)# segment-routing mpls	<p>Enables segment routing using the MPLS data plane on the routing process and all areas and interfaces in the routing process.</p> <p>Enables segment routing forwarding on all interfaces in the routing process and installs the SIDs received by OSPF in the forwarding table.</p>
Step 4	segment-routing sr-prefer Example: RP/0/RP0/CPU0:router(config-ospf)# segment-routing sr-prefer	Sets the preference of segment routing (SR) labels over label distribution protocol (LDP) labels.
Step 5	area area Example: RP/0/RP0/CPU0:router(config-ospf)# area 0	Enters area configuration mode.
Step 6	segment-routing mpls Example: RP/0/RP0/CPU0:router(config-ospf-ar)# segment-routing mpls	(Optional) Enables segment routing using the MPLS data plane on the area and all interfaces in the area. Enables segment routing forwarding on all interfaces in the area and installs the SIDs received by OSPF in the forwarding table.
Step 7	exit Example: RP/0/RP0/CPU0:router(config-ospf-ar)# exit RP/0/RP0/CPU0:router(config-ospf)# exit	
Step 8	Use the commit or end command.	<p>commit —Saves the configuration changes and remains within the configuration session.</p> <p>end —Prompts user to take one of these actions:</p> <ul style="list-style-type: none"> • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • Cancel —Remains in the configuration session, without committing the configuration changes.

What to do next

Configure the prefix SID.

Configuring a Prefix-SID on the OSPF-Enabled Loopback Interface

A prefix segment identifier (SID) is associated with an IP prefix. The prefix SID is manually configured from the segment routing global block (SRGB) range of labels. A prefix SID is configured under the loopback interface with the loopback address of the node as the prefix. The prefix segment steers the traffic along the shortest path to its destination.

A prefix SID can be a node SID or an Anycast SID. A node SID is a type of prefix SID that identifies a specific node. An Anycast SID is a type of prefix SID that identifies a set of nodes, and is configured with n-flag clear. The set of nodes (Anycast group) is configured to advertise a shared prefix address and prefix SID. Anycast routing enables the steering of traffic toward multiple advertising nodes. Packets addressed to an Anycast address are forwarded to the topologically nearest nodes.

The prefix SID is globally unique within the segment routing domain.

This task describes how to configure prefix segment identifier (SID) index or absolute value on the OSPF-enabled Loopback interface.

Before you begin

Ensure that segment routing is enabled on an instance, area, or interface.

SUMMARY STEPS

1. **configure**
2. **router ospf** *process-name*
3. **area** *value*
4. **interface Loopback** *interface-instance*
5. **prefix-sid** [*algorithm algorithm-number*] {**index** *SID-index* | **absolute** *SID-value* } [**n-flag-clear**] [**explicit-null**]
6. Use the **commit** or **end** command.

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.
Step 2	router ospf <i>process-name</i> Example: RP/0/RP0/CPU0:router(config)# router ospf 1	Enables OSPF routing for the specified routing process, and places the router in router configuration mode.

	Command or Action	Purpose
Step 3	area <i>value</i> Example: RP/0/RP0/CPU0:router(config-ospf)# area 0	Enters area configuration mode.
Step 4	interface Loopback <i>interface-instance</i> Example: RP/0/RP0/CPU0:router(config-ospf-ar)# interface Loopback0 passive	Specifies the loopback interface and instance.
Step 5	prefix-sid [<i>algorithm algorithm-number</i>] { <i>index SID-index</i> <i>absolute SID-value</i> } [n-flag-clear] [explicit-null] Example: RP/0/RP0/CPU0:router(config-ospf-ar)# prefix-sid index 1001 RP/0/RP0/CPU0:router(config-ospf-ar)# prefix-sid absolute 17001	<p>Configures the prefix-SID index or absolute value for the interface.</p> <p>Specify algorithm <i>algorithm-number</i> to configure SR Flexible Algorithm.</p> <p>Specify index <i>SID-index</i> for each node to create a prefix SID based on the lower boundary of the SRGB + the index.</p> <p>Specify absolute <i>SID-value</i> for each node to create a specific prefix SID within the SRGB.</p> <p>By default, the n-flag is set on the prefix-SID, indicating that it is a node SID. For specific prefix-SID (for example, Anycast prefix-SID), enter the n-flag-clear keyword. OSPF does not set the N flag in the prefix-SID sub Type Length Value (TLV).</p> <p>To disable penultimate-hop-popping (PHP) and add an explicit-Null label, enter the explicit-null keyword. OSPF sets the E flag in the prefix-SID sub TLV.</p>
Step 6	Use the commit or end command.	<p>commit —Saves the configuration changes and remains within the configuration session.</p> <p>end —Prompts user to take one of these actions:</p> <ul style="list-style-type: none"> • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • Cancel —Remains in the configuration session, without committing the configuration changes.

Verify the prefix-SID configuration:

```
RP/0/RP0/CPU0:router# show ospf database opaque-area 7.0.0.1 self-originate
  OSPF Router with ID (10.0.0.1) (Process ID 1)
    Type-10 Opaque Link Area Link States (Area 0)
<...>
```

```

Extended Prefix TLV: Length: 20
Route-type: 1
AF       : 0
Flags    : 0x40
Prefix   : 10.0.0.1/32

SID sub-TLV: Length: 8
Flags    : 0x0
MTID     : 0
Algo     : 0
SID Index : 1001

```

Configuring an Adjacency SID

An adjacency SID (Adj-SID) is associated with an adjacency to a neighboring node. The adjacency SID steers the traffic to a specific adjacency. Adjacency SIDs have local significance and are only valid on the node that allocates them.

An adjacency SID can be allocated dynamically from the dynamic label range or configured manually from the segment routing local block (SRLB) range of labels.

Adjacency SIDs that are dynamically allocated do not require any special configuration, however there are some limitations:

- A dynamically allocated Adj-SID value is not known until it has been allocated, and a controller will not know the Adj-SID value until the information is flooded by the IGP.
- Dynamically allocated Adj-SIDs are not persistent and can be reallocated after a reload or a process restart.
- Each link is allocated a unique Adj-SID, so the same Adj-SID cannot be shared by multiple links.

Manually allocated Adj-SIDs are persistent over reloads and restarts. They can be provisioned for multiple adjacencies to the same neighbor or to different neighbors. You can specify that the Adj-SID is protected. If the Adj-SID is protected on the primary interface and a backup path is available, a backup path is installed. By default, manual Adj-SIDs are not protected.

Adjacency SIDs are advertised using the existing OSPF Adj-SID sub-TLV. The P-flag is defined for manually allocated Adj-SIDs.

```

 0 1 2 3 4 5 6 7
+---+---+---+---+---+---+
|B|V|L|G|P|   |
+---+---+---+---+---+---+

```

Table 51: Adjacency Segment Identifier (Adj-SID) Flags Sub-TLV Fields

Field	Description
P (Persistent)	This flag is set if the Adj-SID is persistent (manually allocated).

This task explains how to configure an Adj-SID on an interface.

Before you begin

Ensure that segment routing is enabled on the corresponding address family.

Use the **show mpls label table detail** command to verify the SRLB range.

SUMMARY STEPS

1. **configure**
2. **router ospf** *process-name*
3. **area** *area*
4. **interface** *type interface-path-id*
5. **adjacency-sid** {**index** *adj-SID-index* | **absolute** *adj-SID-value*} [**protected**]
6. Use the **commit** or **end** command.

DETAILED STEPS**Procedure**

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.
Step 2	router ospf <i>process-name</i> Example: RP/0/RP0/CPU0:router(config)# router ospf 1	Enables OSPF routing for the specified routing instance, and places the router in router configuration mode.
Step 3	area <i>area</i> Example: RP/0/RP0/CPU0:router(config-ospf)# area 0	Enters area configuration mode.
Step 4	interface <i>type interface-path-id</i> Example: RP/0/RP0/CPU0:router(config-ospf-ar)# interface HundredGigE0/0/0/1	Specifies the interface and enters interface configuration mode.
Step 5	adjacency-sid { index <i>adj-SID-index</i> absolute <i>adj-SID-value</i> } [protected] Example: RP/0/RP0/CPU0:router(config-config-ospf-ar-if)# adjacency-sid index 10 RP/0/RP0/CPU0:router(config-config-ospf-ar-if)#	Configures the Adj-SID index or absolute value for the interface. Specify index <i>adj-SID-index</i> for each link to create an Adj-SID based on the lower boundary of the SRLB + the index. Specify absolute <i>adj-SID-value</i> for each link to create a specific Adj-SID within the SRLB.

	Command or Action	Purpose
	<code>adjacency-sid absolute 15010</code>	Specify if the Adj-SID is protected . For each primary path, if the Adj-SID is protected on the primary interface and a backup path is available, a backup path is installed. By default, manual Adj-SIDs are not protected.
Step 6	Use the commit or end command.	<p>commit —Saves the configuration changes and remains within the configuration session.</p> <p>end —Prompts user to take one of these actions:</p> <ul style="list-style-type: none"> • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • Cancel —Remains in the configuration session, without committing the configuration changes.

What to do next

Configure the SR-TE policy.

Protected Adjacency SID Backup Timer

OSPF advertises a protected adjacency SID for an adjacency when a backup path is available. Primary and backup paths are programmed into the label switching database (LSD) as rewrites.

When an adjacency goes down, OSPF stops advertising the protected adjacency SID immediately, and the backup path is promoted and installed as LSD rewrite. After a specified amount of time, the LSD rewrite is deleted. If the installed path fails again, the protection ends there and traffic through the original protected adjacency SID is permanently lost.

The Protected Adjacency SID Backup Timer provides a configurable maintenance time period. During this time period, OSPF updates the LSD rewrite with primary and backup (if available) paths to the neighbor upon topology changes.

Configuration

Use the **segment-routing protected-adjacency-sid-delay** command in OSPF configuration mode. The range is from 30 to 3600 seconds; the default is 900 seconds (15 min).

```
Router(config)# router ospf 1
Router(config-ospf)# segment-routing protected-adjacency-sid-delay 360
```

Running Configuration

```
router ospf 1
 segment-routing protected-adjacency-sid-delay 360
 area 1
 interface HundredGigE0/0/0/1
 fast-reroute per-prefix
 fast-reroute per-prefix ti-lfa enable
```

Conditional Prefix Advertisement

Table 52: Feature History Table

Feature Name	Release Information	Feature Description
Segment Routing Conditional Prefix Advertisement for OSPF	Release 7.3.1	<p>In a typical Anycast scenario, if an advertising node becomes unavailable or unreachable while still advertising its Anycast SID, traffic could still be routed to the node and, as a result, get dropped.</p> <p>This feature allows a node to advertise its loopback address when it's connected to the domain, and to track the loopback addresses of the other nodes in the domain. If a node becomes unavailable or unreachable, it stops advertising its loopback address, allowing for a new path to be computed.</p>

In some situations, it's beneficial to make the OSPF prefix advertisement conditional. For example, an Area Border Router (ABR) or Autonomous System Boundary Router (ASBR) that has lost its connection to one of the areas or autonomous systems (AS) might keep advertising a prefix. If an ABR or ASBR advertises the Segment Routing (SR) SID with this prefix, the label stack of the traffic routed toward the disconnected area or AS might use this SID, which would result in dropped traffic at the ABR or ASBR.

ABRs or ASBRs are often deployed in pairs for redundancy and advertise a shared Anycast prefix SID. Conditional Prefix Advertisement allows an ABR or an ASBR to advertise its Anycast SID only when connected to a specific area or domain. If an ABR or ASBR becomes disconnected from the particular area or AS, it stops advertising the address for a specified interface (for example, Loopback).

Configure the conditional prefix advertisement under a specific interface. The prefix advertisement on this interface is associated with the route-policy that tracks the presence of a set of prefixes (prefix-set) in the Routing Information Base (RIB).

For faster convergence, the route-policy used for conditional prefix advertisement uses the new event-based **rib-has-route async** condition to notify OSPF of the following situations:

- When the last prefix from the prefix-set is removed from the RIB.
- When the first prefix from the prefix-set is added to the RIB.

Configuration

To use the conditional prefix advertisement in OSPF, create a prefix-set to be tracked. Then create a route policy that uses the prefix-set.

```

Router(config)# prefix-set prefix-set-name
Router(config-pfx)# prefix-address-1/length [, prefix-address-2/length [, ,
prefix-address-16/length]
Router(config-pfx)# end-set

Router(config)# route-policy rpl-name
Router(config-rpl)# if rib-has-route async prefix-set-name then
Router(config-rpl-if)# pass
Router(config-rpl-if)# endif
Router(config-rpl)# end-policy

```

To advertise the loopback address in OSPF conditionally, use the **advertise prefix route-policy** command under OSPF interface address-family configuration sub-mode.

```

Router(config)# router ospf 1
Router(config-ospf)# area 0
Router(config-ospf-ar)# interface Loopback0
Router(config-ospf-ar-if)# advertise prefix route-policy rpl-name
Router(config-ospf-ar-if)# commit

```

Example

```

Router(config)# prefix-set domain_2
Router(config-pfx)# 2.3.3.3/32, 2.4.4.4/32
Router(config-pfx)# end-set
Router(config)# route-policy track_domain_2
Router(config-rpl)# if rib-has-route async domain_2 then
Router(config-rpl-if)# pass
Router(config-rpl-if)# endif
Router(config-rpl)# end-policy
Router(config)# router ospf 1
Router(config-ospf)# area 0
Router(config-ospf-ar)# interface Loopback0
Router(config-ospf-ar-if)# advertise prefix route-policy track_domain_2
Router(config-ospf-ar-if)# commit

```

Running Configuration

```

prefix-set domain_2
  2.3.3.3/32,
  2.4.4.4/32
end-set
!
route-policy track_domain_2
  if rib-has-route async domain_2 then
    pass
  endif
end-policy
!
router ospf 1
  area 0
    interface Loopback0
      advertise prefix route-policy track_domain_2
    !
  !
!

```

Segment Routing ECMP-FEC Optimization

ECMP-FECs are used for any ECMP programming on the system, such as MPLS LSP ECMP, VPN multipath, and [EVPN multi-homing](#).

The SR ECMP-FEC optimization solution minimizes ECMP-FEC resource consumption during underlay programming for an SR-MPLS network. This feature supports sharing the same ECMP-FEC, regular FEC, and Egress Encapsulation DB (EEDB) entries for all IPv4 and IPv6 Segment Routing prefixes with the same set of next hops. ECMP-FEC optimization is triggered when all the out_labels associated with the ECMP paths for a given prefix have the same value. If this rule is not met, then the prefix is programmed with a dedicated ECMP-FEC. Other prefixes that meet the rule are candidates for optimization.

Segment Routing Label Edge Router (LER) ECMP-FEC Optimization enables ECMP-FEC optimization originally developed for Label Switched Router (LSR) nodes (MPLS P) to be enabled on LER (Layer 3 MPLS PE) routers.

For usage guidelines, limitations, and configuration options, see [Segment Routing ECMP-FEC Optimization, on page 308](#).

Display Neighbor Router Capabilities in OSPF Networks

Table 53: Feature History Table

Feature Name	Release Information	Feature Description
Display Neighbor Router Capabilities in OSPF Networks on NCS 5700 Fixed Port Routers	Release 24.2.11	Introduced in this release on: NCS 5700 fixed port routers The feature support is now extended to NCS 5700 fixed port routers.

Feature Name	Release Information	Feature Description
Display Neighbor Router Capabilities in OSPF Networks	Release 24.2.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native]).</p> <p>You can now improve the user experience, understand the features and functionalities supported by neighboring routers, reduce operational work hours and human errors by gaining better visibility into the routing capabilities of directly connected neighboring routers in an OSPF network. These improvements are now possible when you enable Segment Routing on a neighboring connected router.</p> <p>Previously, there was no straightforward method to display the segment routing and other capabilities of neighboring routers in an OSPF network.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> The capabilities keyword is introduced in the show ospf neighbor command. <p>YANG Data Models:</p> <ul style="list-style-type: none"> Cisco-IOS-XR-ipv4-ospf-oper.yang <p>See (GitHub, Yang Data Models Navigator)</p>

The feature enables you to access detailed information of a neighboring router capability from the Router Information Link State Advertisement (RI LSA). This includes details such as segment routing feature, graceful restart and helper operation modes, hostname, and traffic engineering capabilities.

For more information about graceful restart and helper operation modes, see *Implementing OSPF* chapter in the *Routing Configuration Guide*.

Key Benefits of Displaying Neighbor Router Capabilities

- The feature ensures optimal path selection for faster packet forwarding.
- Reduces operational complexity, and enables you to make informed decisions for network upgrades.

- Perform compatibility checks with neighboring routers.

Usage Guidelines and Limitations to Display Neighbor Router Capabilities

The following usage guidelines and limitations apply:

- The RI LSA includes the capabilities of a router, only when Segment Routing capability is enabled for that router. This means that if Segment Routing is not enabled, the router does not advertise any capability in the RI LSA.
- The feature is area-oriented, meaning that it is specific to an OSPF area. This suggests that the capabilities advertised by a neighboring router are relevant and visible only within the same OSPF area.
- You must enable traffic engineering at the OSPF or at the area level.
- You must configure graceful restart and helper capabilities at the OSPF level.

Verify the Neighbor Router Capabilities

You can use the **show ospf neighbor capabilities** command to display the traffic engineering support, hostname, and graceful restart and helper capabilities of neighboring connected routers, which are enabled for Segment Routing.

```
Router#show ospf neighbor capabilities
Mon Apr 29 08:27:07.289 UTC
```

Capabilities advertised in RI LSA

```
TE - Traffic Engineering
GR - Graceful Restart
GH - Graceful Restart Helper
```

```
NA - Capabilities TLV Not Advertised
```

Neighbors for OSPF 1

Area 1

Neighbor ID	Address	Interface	SR-Enabled	Capabilities
192.168.199.137	209.165.200.225/27	Gi100/0/0/0	Yes	TE, GR, GH
HostName: Device_3				
192.168.48.1	209.165.200.230/27	Gi100/0/0/4	No	NA
192.168.48.200	209.165.200.235/27	Gi10/0/0/0	Yes	TE, GR, GH
HostName: Device_0				

Total neighbor count: 3

In this scenario, Area 1 consists of three connected routers. Routers 192.168.199.137 and 192.168.48.200 support Segment Routing, so their RI LSA includes the TE, GH, and GR capabilities. When the TE and GR are not configured, only the GH capability is advertised by default. Router 192.168.48.1, which does not support Segment Routing, does not include any capabilities in its RI LSA.

When you use the **show ospf neighbor neighbor-id** command to view the summary information of a specific neighboring router, the summary information includes the capabilities of that neighbor router if Segment Routing is enabled for it.

The following example shows the capabilities of neighbor 192.168.199.130 listed in the summary information:

Verify the Neighbor Router Capabilities

```

Router#show ospf neighbor 192.168.199.130

CHAPTER 10

Configure Segment Routing for BGP

Border Gateway Protocol (BGP) is an Exterior Gateway Protocol (EGP) that allows you to create loop-free inter-domain routing between autonomous systems. An autonomous system is a set of routers under a single technical administration. Routers in an autonomous system can use multiple Interior Gateway Protocols (IGPs) to exchange routing information inside the autonomous system and an EGP to route packets outside the autonomous system.

This module provides the configuration information used to enable Segment Routing for BGP.

Note For additional information on implementing BGP on your router, see the *BGP Configuration Guide for Cisco NCS 5500 Series Routers*.

- [Segment Routing for BGP, on page 327](#)

Segment Routing for BGP

In a traditional BGP-based data center (DC) fabric, packets are forwarded hop-by-hop to each node in the autonomous system. Traffic is directed only along the external BGP (eBGP) multipath ECMP. No traffic engineering is possible.

In an MPLS-based DC fabric, the eBGP sessions between the nodes exchange BGP labeled unicast (BGP-LU) network layer reachability information (NLRI). An MPLS-based DC fabric allows any leaf (top-of-rack or border router) in the fabric to communicate with any other leaf using a single label, which results in higher packet forwarding performance and lower encapsulation overhead than traditional BGP-based DC fabric. However, since each label value might be different for each hop, an MPLS-based DC fabric is more difficult to troubleshoot and more complex to configure.

BGP has been extended to carry segment routing prefix-SID index. BGP-LU helps each node learn BGP prefix SIDs of other leaf nodes and can use ECMP between source and destination. Segment routing for BGP simplifies the configuration, operation, and troubleshooting of the fabric. With segment routing for BGP, you can enable traffic steering capabilities in the data center using a BGP prefix SID.

Note BGP flowspec support with SRv6 - Limitations

List of BGP address families interacts with SRv6. There are some supported and unsupported BGP address family for the interaction with SRv6.

Supported address family:

- address-families ipv6.

Unsupported address families:

- address-families ipv4
 - vpnv4
 - vpnv6
-

Configure BGP Prefix Segment Identifiers

Segments associated with a BGP prefix are known as BGP prefix SIDs. The BGP prefix SID is global within a segment routing or BGP domain. It identifies an instruction to forward the packet over the ECMP-aware best-path computed by BGP to the related prefix. The BGP prefix SID is manually configured from the segment routing global block (SRGB) range of labels.

Each BGP speaker must be configured with an SRGB using the **segment-routing global-block** command. See the [About the Segment Routing Global Block](#) section for information about the SRGB.

Note You must enable SR and explicitly configure the SRGB before configuring SR BGP. The SRGB must be explicitly configured, even if you are using the default range (16000 – 23999). BGP uses the SRGB and the index in the BGP prefix-SID attribute of a learned BGP-LU advertisement to allocate a local label for a given destination.

If SR and the SRGB are enabled after configuring BGP, then BGP is not aware of the SRGB, and therefore it allocates BGP-LU local labels from the dynamic label range instead of from the SRGB. In this case, restart the BGP process in order to allocate BGP-LU local labels from the SRGB.

Note Because the values assigned from the range have domain-wide significance, we recommend that all routers within the domain be configured with the same range of values.

To assign a BGP prefix SID, first create a routing policy using the **set label-index** *index* attribute, then associate the index to the node.

Note A routing policy with the **set label-index** attribute can be attached to a network configuration or redistribute configuration. Other routing policy language (RPL) configurations are possible. For more information on routing policies, refer to the "Implementing Routing Policy" chapter in the *Routing Configuration Guide for Cisco NCS 5500 Series Routers*.

Example

The following example shows how to configure the SRGB, create a BGP route policy using a \$SID parameter and **set label-index** attribute, and then associate the prefix-SID index to the node.

```
RP/0/RSP0/CPU0:router(config)# segment-routing global-block 16000 23999

RP/0/RSP0/CPU0:router(config)# route-policy SID($SID)
RP/0/RSP0/CPU0:router(config-rpl)# set label-index $SID
RP/0/RSP0/CPU0:router(config-rpl)# end policy

RP/0/RSP0/CPU0:router(config)# router bgp 1
RP/0/RSP0/CPU0:router(config-bgp)# bgp router-id 10.1.1.1
RP/0/RSP0/CPU0:router(config-bgp)# address-family ipv4 unicast
RP/0/RSP0/CPU0:router(config-bgp-af)# network 10.1.1.3/32 route-policy SID(3)
RP/0/RSP0/CPU0:router(config-bgp-af)# allocate-label all
RP/0/RSP0/CPU0:router(config-bgp-af)# commit
RP/0/RSP0/CPU0:router(config-bgp-af)# end

RP/0/RSP0/CPU0:router# show bgp 10.1.1.3/32

```

Segment Routing Egress Peer Engineering

Segment routing egress peer engineering (EPE) uses a controller to instruct an ingress provider edge, or a content source (node) within the segment routing domain, to use a specific egress provider edge (node) and a specific external interface to reach a destination. BGP peer SIDs are used to express source-routed inter-domain paths.

Below are the BGP-EPE peering SID types:

- **PeerNode SID**—To an eBGP peer. Pops the label and forwards the traffic on any interface to the peer.
- **PeerAdjacency SID**—To an eBGP peer via interface. Pops the label and forwards the traffic on the related interface.
- **PeerSet SID**—To a set of eBGP peers. Pops the label and forwards the traffic on any interface to the set of peers. All the peers in a set might not be in the same AS.

Multiple PeerSet SIDs can be associated with any combination of PeerNode SIDs or PeerAdjacency SIDs.

The controller learns the BGP peer SIDs and the external topology of the egress border router through BGP-LS EPE routes. The controller can program an ingress node to steer traffic to a destination through the egress node and peer node using BGP labeled unicast (BGP-LU).

EPE functionality is only required at the EPE egress border router and the EPE controller.

Usage Guidelines and Limitations

- When enabling BGP EPE, you must enable MPLS encapsulation on the egress interface connecting to the eBGP peer. This can be done by enabling either BGP labeled unicast (BGP-LU) address family or MPLS static for the eBGP peer.

For information about BGP-LU, refer to the “[Implementing BGP](#)” chapter in the *BGP Configuration Guide for Cisco NCS 5500 Series Routers*.

For information about MPLS static, refer to the “[Implementing MPLS Static Labeling](#)” chapter in the *MPLS Configuration Guide for NCS 5500 Series Routers*.

- When configuring SRv6 BGP with stitching and non-stitching VRFs between the same peers, you must enable the CLI knob **label mode per-nexthop-received-label** to avoid GRID full memory error while scaling the non-stitching VRFs. The stitching-VRF is used in SRv6 Interworking Gateway case (IW-GW)
- Note the following points related to the Ip-lookup backup support for EPEs:
 - This feature works only when you enable the **epe backup enable**, under the Global Address Family ID (AFI).
 - With this feature, an IP-Lookup backup is installed for each Egress Peer Engineering. This means, when all the paths of that EPE go down, the Forwarding Information Base (FIB) table searches in the IP table for the destination IP address in the data packet and forwards them accordingly.
 - The peer-set EPEs have a backup installed only when the mentioned CLI knob is enabled.

Configure Segment Routing Egress Peer Engineering

This task explains how to configure segment routing EPE on the EPE egress node.

SUMMARY STEPS

1. **router bgp** *as-number*
2. **neighbor** *ip-address*

3. **remote-as** *as-number*
4. **egress-engineering**
5. **exit**
6. **mpls static**
7. **interface** *type interface-path-id*
8. Use the **commit** or **end** command.

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	router bgp <i>as-number</i> Example: RP/0/RSP0/CPU0:router(config)# router bgp 1	Specifies the BGP AS number and enters the BGP configuration mode, allowing you to configure the BGP routing process.
Step 2	neighbor <i>ip-address</i> Example: RP/0/RSP0/CPU0:router(config-bgp)# neighbor 192.168.1.3	Places the router in neighbor configuration mode for BGP routing and configures the neighbor IP address as a BGP peer.
Step 3	remote-as <i>as-number</i> Example: RP/0/RSP0/CPU0:router(config-bgp-nbr)# remote-as 3	Creates a neighbor and assigns a remote autonomous system number to it.
Step 4	egress-engineering Example: RP/0/RSP0/CPU0:router(config-bgp-nbr)# egress-engineering	Configures the egress node with EPE for the eBGP peer.
Step 5	exit Example: RP/0/RSP0/CPU0:router(config-bgp-nbr)# exit RP/0/RSP0/CPU0:router(config-bgp)# exit RP/0/RSP0/CPU0:router(config)#	
Step 6	mpls static Example:	Configure MPLS static on the egress interface connecting to the eBGP peer.

	Command or Action	Purpose
	RP/0/RSP0/CPU0:router(config)# mpls static	
Step 7	interface <i>type interface-path-id</i> Example: RP/0/RSP0/CPU0:router(config-mpls-static)# interface GigabitEthernet0/0/1/2	Specifies the egress interface connecting to the eBGP peer.
Step 8	Use the commit or end command.	commit —Saves the configuration changes and remains within the configuration session. end —Prompts user to take one of these actions: <ul style="list-style-type: none"> • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • Cancel —Remains in the configuration session, without committing the configuration changes.

Example

Running Config:

```

router bgp 1
  neighbor 192.168.1.3
  remote-as 3
  egress-engineering
  !
  !
mpls static
  interface GigabitEthernet0/0/1/2
  !
  !

```

Configuring Manual BGP-EPE Peering SIDs

Configuring manual BGP-EPE Peer SIDs allows for persistent EPE label values. Manual BGP-EPE SIDs are advertised through BGP-LS and are allocated from the Segment Routing Local Block (SRLB). See [Configure Segment Routing Global Block and Segment Routing Local Block, on page 273](#) for information about the SRLB.

Each PeerNode SID, PeerAdjacency SID, and PeerSet SID is configured with an index value. This index serves as an offset from the configured SRLB start value and the resulting MPLS label (SRLB start label + index) is assigned to these SIDs. This label is used by CEF to perform load balancing across the individual BGP PeerSet SIDs, BGP PeerNode SID, or ultimately across each first-hop adjacency associated with that BGP PeerNode SID or BGP PeerSet SID.

Configuring Manual PeerNode SID

Each eBGP peer will be associated with a PeerNode SID index that is configuration driven.

```
RP/0/0/CPU0:PE1(config)# router bgp 10
RP/0/0/CPU0:PE1(config-bgp)# neighbor 10.10.10.2
RP/0/0/CPU0:PE1(config-bgp-nbr)# remote-as 20
RP/0/0/CPU0:PE1(config-bgp-nbr)# egress-engineering
RP/0/0/CPU0:PE1(config-bgp-nbr)# peer-node-sid index 600
```

Configuring Manual PeerAdjacency SID

Any first-hop for which an adjacency SID is configured needs to be in the resolution chain of at least one eBGP peer that is configured for egress-peer engineering. Otherwise such a kind of “orphan” first-hop with regards to BGP has no effect on this feature. This is because BGP only understands next-hops learnt by the BGP protocol itself and in addition only the resolving IGP next-hops for those BGP next-hops.

```
RP/0/0/CPU0:PE1(config)# router bgp 10
RP/0/0/CPU0:PE1(config-bgp)# adjacencies
RP/0/0/CPU0:PE1(config-bgp-adj)# 10.1.1.2
RP/0/0/CPU0:PE1(config-bgp-adj)# adjacency-sid index 500
```

Configuring Manual PeerSet SID

The PeerSet SID is configured under global Address Family. This configuration results in the creation of a Peer-Set SID EPE object.

```
RP/0/0/CPU0:PE1(config)# router bgp 10
RP/0/0/CPU0:PE1(config-bgp)# address-family ipv4 unicast
RP/0/0/CPU0:PE1(config-bgp-afi)# peer-set-id 1
RP/0/0/CPU0:PE1(config-bgp-peer-set)# peer-set-sid 300
```

Example

Topology

The example in this section uses the following topology.

In this example, BGP-EPE peer SIDs are allocated from the default SRLB label range (15000 – 15999). The BGP-EPE peer SIDs are configured as follows:

- PeerNode SIDs to 10.10.10.2 with index 600 (label 15600), and for 20.10.10.2 with index 700 (label 15700)
- PeerAdj SID to link 10.1.1.2 with index 500 (label 15500)
- PeerSet SID 1 to load balance over BGP neighbors 10.10.10.1 and 20.10.10.2 with SID index 300 (label 15300)
- PeerSet SID 2 to load balance over BGP neighbor 20.10.10.2 and link 10.1.1.2 with SID index 400 (label 15400)

Configuration on R1

```
router bgp 10
 address-family ipv4 unicast
   peer-set-id 1
     peer-set-sid index 300
   !
   peer-set-id 2
     peer-set-sid index 400
   !
 !
 adjacencies
 10.1.1.2
   adjacency-sid index 500
   peer-set 2
 !
 !
 neighbor 10.10.10.2
  remote-as 20
  egress-engineering
  peer-node-sid index 600
  peer-set 1
 !
 neighbor 20.10.10.2
  egress-engineering
  peer-node-sid index 700
  peer-set 1
  peer-set 2
 !
```

To further show the load balancing of this example:

- 15600 is load balanced over {10.1.1.1 and 2.1.1.1}
- 15700 is load balanced over {3.1.1.1 and 4.1.1.1}
- 15500 is load balanced over {10.1.1.1}
- 15300 is load balanced over {10.1.1.1, 2.1.1.1, 3.1.1.1 and 4.1.1.1}
- 15400 is load balanced over {10.1.1.1, 3.1.1.1 and 4.1.1.1}

Configure BGP Link-State

BGP Link-State (LS) is an Address Family Identifier (AFI) and Sub-address Family Identifier (SAFI) originally defined to carry interior gateway protocol (IGP) link-state information through BGP. The BGP Network Layer Reachability Information (NLRI) encoding format for BGP-LS and a new BGP Path Attribute called the BGP-LS attribute are defined in [RFC7752](#). The identifying key of each Link-State object, namely a node, link, or prefix, is encoded in the NLRI and the properties of the object are encoded in the BGP-LS attribute.

The BGP-LS Extensions for Segment Routing are documented in [RFC9085](#).

BGP-LS applications like an SR Path Computation Engine (SR-PCE) can learn the SR capabilities of the nodes in the topology and the mapping of SR segments to those nodes. This can enable the SR-PCE to perform path computations based on SR-TE and to steer traffic on paths different from the underlying IGP-based distributed best-path computation.

The following figure shows a typical deployment scenario. In each IGP area, one or more nodes (BGP speakers) are configured with BGP-LS. These BGP speakers form an iBGP mesh by connecting to one or more route-reflectors. This way, all BGP speakers (specifically the route-reflectors) obtain Link-State information from all IGP areas (and from other ASes from eBGP peers).

Usage Guidelines and Limitations

- BGP-LS supports IS-IS and OSPFv2.

- The identifier field of BGP-LS (referred to as the Instance-ID) identifies the IGP routing domain where the NLRI belongs. The NLRIs representing link-state objects (nodes, links, or prefixes) from the same IGP routing instance must use the same Instance-ID value.
- When there is only a single protocol instance in the network where BGP-LS is operational, we recommend configuring the Instance-ID value to **0**.
- Assign consistent BGP-LS Instance-ID values on all BGP-LS Producers within a given IGP domain.
- NLRIs with different Instance-ID values are considered to be from different IGP routing instances.
- Unique Instance-ID values must be assigned to routing protocol instances operating in different IGP domains. This allows the BGP-LS Consumer (for example, SR-PCE) to build an accurate segregated multi-domain topology based on the Instance-ID values, even when the topology is advertised via BGP-LS by multiple BGP-LS Producers in the network.
- If the BGP-LS Instance-ID configuration guidelines are not followed, a BGP-LS Consumer may see duplicate link-state objects for the same node, link, or prefix when there are multiple BGP-LS Producers deployed. This may also result in the BGP-LS Consumers getting an inaccurate network-wide topology.
- The following table defines the supported extensions to the BGP-LS address family for carrying IGP topology information (including SR information) via BGP. For more information on the BGP-LS TLVs, refer to [Border Gateway Protocol - Link State \(BGP-LS\) Parameters](#).

Exchange Link State Information with BGP Neighbor

The following example shows how to exchange link-state information with a BGP neighbor:

```
Router# configure
Router(config)# router bgp 1
Router(config-bgp)# neighbor 10.0.0.2
Router(config-bgp-nbr)# remote-as 1
Router(config-bgp-nbr)# address-family link-state link-state
Router(config-bgp-nbr-af)# exit
```

IGP Link-State Database Distribution

A given BGP node may have connections to multiple, independent routing domains. IGP link-state database distribution into BGP-LS is supported for both OSPF and IS-IS protocols in order to distribute this information on to controllers or applications that desire to build paths spanning or including these multiple domains.

To distribute IS-IS link-state data using BGP-LS, use the **distribute link-state** command in router configuration mode.

```
Router# configure
Router(config)# router isis isp
```

```
Router(config-isis)# distribute link-state instance-id 32
```

To distribute OSPFv2 link-state data using BGP-LS, use the **distribute link-state** command in router configuration mode.

```
Router# configure
Router(config)# router ospf 100
Router(config-ospf)# distribute link-state instance-id 32
```

Configurable Filters for IS-IS Advertisements to BGP-Link State

Table 55: Feature History Table

Feature Name	Release Information	Feature Description
Configurable Filters for IS-IS Advertisements to BGP-Link State	Release 7.10.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>This feature allows you to configure a route map to filter IS-IS route advertisements to BGP-Link State (LS). It also provides a per-area configuration knob to disable IS-IS advertisements for external and propagated prefixes. This configuration of filters hence reduces the amount of redundant data for external and interarea prefixes sent to the BGP - LS clients.</p> <p>The feature introduces exclude-external, exclude-interarea, and route-policy <i>name</i> optional keywords in the distribute link-state command.</p>

In a large IS-IS network, there are multiple routers in different areas distributing their link-state databases through BGP-LS. In addition, other protocols, such as OSPF do their own BGP-LS reporting and have routes that are redistributed into IS-IS. This can result in substantial amounts of redundant data for external and interarea prefixes which are sent to the BGP-LS clients only to be discarded.

Rather than sending redundant information, this feature provides the option of limiting the prefixes for which IS-IS TLV information is sent to BGP-LS.

There are three options to filter prefix Type-Length-Values (TLVs) that are reported in BGP-LS and the operators can specify these options on a per-level basis:

- **exclude-external**: Omits information for external prefixes that are redistributed from a different protocol or instance. These are identified by the “X” bit set in its Extended Reachability Attribute Flags or the ‘X’ bit of TLVs 236 and 237.
- **exclude-interarea**: Omits information for interarea prefixes and summaries. These are identified by the ‘R’ bit set in their Extended Reachability Attribute Flags or the ‘up or down’ bit set in TLVs 135, 235, 236, and 237.
- **route-policy** *name*: Allows specification of a route-policy to provide filtering based on a set of destination prefixes.

The filtering is implemented at the point where the individual prefix TLVs are read from a label-switched path to generate updates to BGP-LS. It does not affect the advertisement of a node or the link information.

Configure Filters for IS-IS Advertisements to BGP-LS

Configuration Example

You can configure any of these filters for IS-IS advertisements to BGP-LS:

```
Router#config
Router(config)#router isis 1
Router(config-isis)#distribute link-state exclude-external
Router(config-isis)#commit
```

```
Router#config
Router(config)#router isis 1
Router(config-isis)#distribute link-state exclude-interarea
Router(config-isis)#commit
```

```
Router# config
Router(config)# router isis 1
Router(config-isis)#distribute link-state route-policy isis-rp-1
Router(config-isis)#commit
```

Note This feature does not introduce any new failure modes to IS-IS.

Running Configuration

To check the filter for IS-IS advertisements to BGP-LS, you can run the following command:

```
Router# show running-config
router isis 1
  distribute link-state exclude-external
  commit
  !
!

router isis 1
  distribute link-state exclude-interarea
  commit
  !
!

router isis 1
  distribute link-state route-policy isis-rp-1
  commit
  !
!
```

Use Case: Configuring SR-EPE and BGP-LS

In the following figure, segment routing is enabled on autonomous system AS1 with ingress node A and egress nodes B and C. In this example, we configure EPE on egress node C.

Figure 15: Topology

Procedure

Step 1 Configure node C with EPE for eBGP peers D and E.

Example:

```
RP/0/RSP0/CPU0:router_C(config)# router bgp 1
RP/0/RSP0/CPU0:router_C(config-bgp)# neighbor 192.168.1.3
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# remote-as 3
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# description to E
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# egress-engineering
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# address-family ipv4 unicast
RP/0/RSP0/CPU0:router_C(config-bgp-nbr-af)# route-policy bgp_in in
RP/0/RSP0/CPU0:router_C(config-bgp-nbr-af)# route-policy bgp_out out
RP/0/RSP0/CPU0:router_C(config-bgp-nbr-af)# exit
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# exit
RP/0/RSP0/CPU0:router_C(config-bgp)# neighbor 192.168.1.2
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# remote-as 2
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# description to D
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# egress-engineering
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# address-family ipv4 unicast
RP/0/RSP0/CPU0:router_C(config-bgp-nbr-af)# route-policy bgp_in in
RP/0/RSP0/CPU0:router_C(config-bgp-nbr-af)# route-policy bgp_out out
RP/0/RSP0/CPU0:router_C(config-bgp-nbr-af)# exit
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# exit
```

Step 2 Configure node C to advertise peer node SIDs to the controller using BGP-LS.

Example:

```
RP/0/RSP0/CPU0:router_C(config-bgp)# neighbor 172.29.50.71
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# remote-as 1
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# description to EPE_controller
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# address-family link-state link-state
RP/0/RSP0/CPU0:router_C(config-bgp-nbr)# exit
RP/0/RSP0/CPU0:router_C(config-bgp)# exit
```

Step 3 Configure MPLS static on the egress interfaces connecting to the eBGP peer.

Example:

```
RP/0/RSP0/CPU0:router_C(config)# mpls static
RP/0/RSP0/CPU0:router_C(config-mpls-static)# interface TenGigE 0/3/0/0
RP/0/RSP0/CPU0:router_C(config-mpls-static)# interface TenGigE 0/1/0/0
RP/0/RSP0/CPU0:router_C(config-mpls-static)# exit
```

Step 4 Commit the configuration.

Example:

```
RP/0/RSP0/CPU0:router_C(config)# commit
```

Step 5 Verify the configuration.

Example:

```
RP/0/RSP0/CPU0:router_C# show bgp egress-engineering

Egress Engineering Peer Set: 192.168.1.2/32 (10b87210)
  Nexthop: 192.168.1.2
  Version: 2, rn_version: 2
  Flags: 0x00000002
  Local ASN: 1
  Remote ASN: 2
  Local RID: 10.1.1.3
  Remote RID: 10.1.1.4
  First Hop: 192.168.1.2
  NHID: 3
  Label: 24002, Refcount: 3
  rpc_set: 10b9d408

Egress Engineering Peer Set: 192.168.1.3/32 (10be61d4)
  Nexthop: 192.168.1.3
  Version: 3, rn_version: 3
  Flags: 0x00000002
  Local ASN: 1
  Remote ASN: 3
  Local RID: 10.1.1.3
  Remote RID: 10.1.1.5
  First Hop: 192.168.1.3
  NHID: 4
  Label: 24003, Refcount: 3
  rpc_set: 10be6250
```

The output shows that node C has allocated peer SIDs for each eBGP peer.

Example:

```
RP/0/RSP0/CPU0:router_C# show mpls forwarding labels 24002 24003
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
24002	Pop	No ID	Te0/3/0/0	192.168.1.2	0
24003	Pop	No ID	Te0/1/0/0	192.168.1.3	0

The output shows that node C installed peer node SIDs in the Forwarding Information Base (FIB).

Configure BGP Proxy Prefix SID

To support segment routing, Border Gateway Protocol (BGP) requires the ability to advertise a segment identifier (SID) for a BGP prefix. A BGP-Prefix-SID is the segment identifier of the BGP prefix segment in a segment routing network. BGP prefix SID attribute is a BGP extension to signal BGP prefix-SIDs. However, there may be routers which do not support BGP extension for segment routing. Hence, those routers also do not support BGP prefix SID attribute and an alternate approach is required.

BGP proxy prefix SID feature allows you to attach BGP prefix SID attributes for remote prefixes learnt from BGP labeled unicast (LU) neighbours which are not SR-capable and propagate them as SR prefixes. This allows an LSP towards non SR endpoints to use segment routing global block in a SR domain. Since BGP proxy prefix SID uses global label values it minimizes the use of limited resources such as ECMP-FEC and provides more scalability for the networks.

BGP proxy prefix SID feature is implemented using the segment routing mapping server (SRMS). SRMS allows the user to configure SID mapping entries to specify the prefix-SIDs for the prefixes. The mapping server advertises the local SID-mapping policy to the mapping clients. BGP acts as a client of the SRMS and uses the mapping policy to calculate the prefix-SIDs.

Configuration Example:

This example shows how to configure the BGP proxy prefix SID feature for the segment routing mapping server.

```
RP/0/RSP0/CPU0:router(config)# segment-routing
RP/0/RSP0/CPU0:router(config-sr)# mapping-server
RP/0/RSP0/CPU0:router(config-sr-ms)# prefix-sid-map
RP/0/RSP0/CPU0:router(config-sr-ms-map)# address-family ipv4
RP/0/RSP0/CPU0:router(config-sr-ms-map-af)# 10.1.1.1/32 10 range 200
RP/0/RSP0/CPU0:router(config-sr-ms-map-af)# 192.168.64.1/32 400 range 300
```

This example shows how to configure the BGP proxy prefix SID feature for the segment-routing mapping client.

```
RP/0/RSP0/CPU0:router(config)# router bgp 1
RP/0/RSP0/CPU0:router(config-bgp)# address-family ip4 unicast
RP/0/RSP0/CPU0:router(config-bgp-af)# segment-routing prefix-sid-map
```

Verification

These examples show how to verify the BGP proxy prefix SID feature.

```
RP/0/RSP0/CPU0:router# show segment-routing mapping-server prefix-sid-map ipv4 detail
Prefix
10.1.1.1/32
  SID Index:      10
  Range:          200
  Last Prefix:    10.1.1.200/32
  Last SID Index: 209
  Flags:
```

BGP-LU Inter-AS Option-C Interworking with LDP and IGP SR-MPLS using Proxy BGP-SR

Table 56: Feature History Table

Feature Name	Release	Description
BGP-LU Inter-AS Option-C Interworking with LDP and IGP SR-MPLS using Proxy BGP-SR	Release 7.3.2	<p>This feature extends the current Proxy BGP-SR functionality by allowing the BGP-LU ASBR router with Proxy BGP-SR configured to also interconnect attached LDP domains.</p> <p>The Proxy BGP-SR feature allows interconnection of IGP SR-MPLS domains and legacy domains via BGP-LU Inter-AS option-C. It provides a prefix-to-SID mapping for BGP-LU prefixes that are learned without a Prefix-SID.</p>

The Proxy BGP-SR feature allows interconnection of IGP SR-MPLS domains and legacy domains via BGP-LU Inter-AS option-C. It provides a prefix-to-SID mapping for BGP-LU prefixes that are learned without a Prefix-SID. This new feature extends the current functionality by allowing the BGP-LU ASBR router (configured with Proxy BGP-SR) to also interconnect attached LDP domains.

With this enhancement, when performing redistribution from BGP into IGP, LDP would use the same local label assigned by BGP for a prefix learned by BGP-LU. The local label value is based on the SR mapping server configuration (Proxy-BGP SR feature). This behavior allows incoming LDP traffic destined to a redistributed prefix to be switched over to the BGP-LU Inter-AS LSP.

Use Case

In the following figure, Router A does the following:

- Is an ASBR for BGP AS 100 running BGP-LU with BGP AS 200
- Interconnects two IS-IS processes: one running LDP and another running Segment Routing
- Redistributes prefixes learned by BGP-LU from AS 200 into both IS-IS instances
- Runs SR Mapping Server (SRMS) in order to assign mappings to prefixes learned by BGP LU from AS 200 without a prefix SID (proxy BGP-SR) and prefixes learned from the LDP domain

Configuration on Router A - ASBR for AS100

```
prefix-set pfxset-bgplu

BGP Best Path Computation using SR Policy Paths

Table 57: Feature History Table

Feature Name	Release Information	Feature Description
BGP Best Path Computation using SR Policy Paths	Release 7.5.2 Release 7.3.4	<p>BGP best-path selection is modified for a prefix when at least one of its paths resolves over the next hop using SR policies (SR policy in “up” state). Under this condition, paths not steered over an SR policy (those using native next-hop resolution) are considered ineligible during best-path selection.</p> <p>You can thus control the best path selection in order to steer traffic, preferably or exclusively, over SR policies with the desired SLA.</p> <p>This feature introduces the bgp bestpath sr-policy {force prefer} command.</p>

BGP selects the best path from the available pool of paths such as iBGP, eBGP, color, or noncolor paths with native next hop and SR policy next hop. BGP uses either native next hop or an SR policy next hop for best path computation. However, BGP might not consider SR policy next hop for best path computation due to other factors in best path selection. By default, BGP considers a native next hop for the best path computation during the failure.

For more information, see [Best path calculation algorithm](#).

When multiple advertisements of the same BGP prefix are received where some have extended community color, SRTE headend with BGP multi-path enabled installs multiple routes with or without extended community color. It may be required to exclude the path resolving over native next hop SR policy paths from BGP best path selection when a prefix has multiple paths in the presence of one BGP path with the extended community color that is resolved over the SR policy.

You may want to use the egress PE to exit a domain using local preference or other attributes before the next hop metric selection. In such scenarios, when SR policy of the primary path fails, the best path is resolved over a regular IGP next hop that is the default mode of operation. Traffic doesn't select the backup path with SR policy, instead traffic moves to native LSP on the primary path.

The BGP Best Path Computation using SR Policy Paths feature allows the BGP to use the path with SR policy as the best-path, backup, and multipath.

When this feature is enabled, some paths are marked as an ineligible path for BGP best path selection. Existing BGP best path selection order is applied to the eligible paths.

Use either of the following modes for the BGP to select the SR policy path as the best path for the backup path:

- Force mode: When force mode is enabled, only SR policy paths are considered for best path calculation. Use the **bgp bestpath sr-policy force** command to enable this mode.

In a network, when at least one path has an active SR policy, the following paths are marked as ineligible for best path selection:

- iBGP paths with noncolor or color paths with SR policy that isn't active.
- eBGP with color and SR policy isn't active.
- eBGP noncolor paths

Note Local and redistributed BGP paths are always eligible for best path selection.

- Prefer mode: When prefer mode is enabled, SR policy paths and eBGP noncolor paths are eligible for best path calculation.

Use the **bgp bestpath sr-policy prefer** command to enable this mode.

In a network, when at least one path has an active SR policy, the following paths are marked as ineligible for best path selection:

- iBGP paths with noncolor or color paths with SR policy that isn't active.
- eBGP with color and SR policy isn't active.

Note Local and redistributed BGP paths are always eligible for best path selection.

Configure BGP Best Path Computation using SR Policy Paths

To enable the feature, perform the following tasks on the ingress PE router that is the head-end of SR policy:

- Configure route policy.
- Configure SR policy.
- Configure BGP with either prefer or force mode.

Configuration Example

Configure route policies on the egress PE router:

```
Router(config)#extcommunity-set opaque color9001
Router(config-ext)#9001 co-flag 01
Router(config-ext)#end-set
Router(config)#extcommunity-set opaque color9002
Router(config-ext)#9002 co-flag 01
Router(config-ext)#end-set
Router(config)#commit

Router(config)#route-policy for9001
Router(config-rpl)#set extcommunity color color9001
```

```

Router(config-rpl)# pass
Router(config-rpl)#end-policy

Router(config)#route-policy for9002
Router(config-rpl)#set extcommunity color color9002
Router(config-rpl)#pass
Router(config-rpl)#end-policy
Router(config)#commit

Router#configure
Router(config)#route-policy add_path
Router(config-rpl)#set path-selection backup 1 install multipath-protect advertise
multipath-protect-advertise
Router(config-rpl)#end-policy

Router(config)#route-policy pass-all
Router(config-rpl)#pass
Router(config-rpl)#end-policy
Router(config)#commit

```

Configure SR policy on the egress PE router:

```

Router#configure
Router(config)#segment-routing
Router(config-sr)#traffic-eng
Router(config-sr-te)#segment-list SL201
Router(config-sr-te-sl)#index 1 mpls label 25000
Router(config-sr-te-sl)#policy POLICY_9001
Router(config-sr-te-policy)#binding-sid mpls 47700
Router(config-sr-te-policy)#color 9001 end-point ipv6 ::
Router(config-sr-te-policy)#candidate-paths
Router(config-sr-te-policy-path)#preference 10
Router(config-sr-te-policy-path-pref)#explicit segment-list SL201
Router(config-sr-te-sl)#policy POLICY_9002
Router(config-sr-te-policy)#binding-sid mpls 47701
Router(config-sr-te-policy)#color 9002 end-point ipv6 ::
Router(config-sr-te-policy)#candidate-paths
Router(config-sr-te-policy-path)#preference 10
Router(config-sr-te-policy-path-pref)#explicit segment-list SL201
Router(config-sr-te-policy-path-pref)#commit

```

Configure BGP on the Egress PE router:

```

Router(config)#router bgp 100
Router(config-bgp)#nsr
Router(config-bgp)#bgp router-id 10.1.1.2
Router(config-bgp)#bgp best-path sr-policy force
Router(config-bgp)#address-family ipv6 unicast
Router(config-bgp-af)#maximum-paths eibgp 25
Router(config-bgp-af)#additional-paths receive
Router(config-bgp-af)#additional-paths send
Router(config-bgp-af)#additional-paths selection route-policy add_path
Router(config-bgp-af)#redistribute connected
Router(config-bgp-af)#redistribute static
Router(config-bgp-af)#allocate-label all
Router(config-bgp-af)#commit
Router(config-bgp-af)#exit
Router(config-bgp)#neighbor 31::2
Router(config-bgp-nbr)#remote-as 2
Router(config-bgp-nbr)#address-family ipv6 unicast
Router(config-bgp-nbr-af)#route-policy for9001 in
Router(config-bgp-nbr-af)#route-policy pass-all out

```

```

Router(config-bgp-nbr-af)#commit
Router(config-bgp-nbr-af)#exit
Router(config-bgp)#neighbor 32::2
Router(config-bgp-nbr)#remote-as 2
Router(config-bgp-nbr)#address-family ipv6 unicast
Router(config-bgp-nbr-af)#route-policy for9002 in
Router(config-bgp-nbr-af)#route-policy pass-all out
Router(config-bgp-nbr-af)#commit

```

Verification

The following show output shows that when the **force** option is enabled, the configured SR policy path is selected as the best path instead of the default best path.

```

Router#show bgp ipv6 unicast 2001:DB8::1 brief

Optimal Utilization of ECMP FEC Resources

Table 58: Feature History Table

Feature Name	Release Information	Feature Description
Optimal Utilization of ECMP FEC Resources	Release 7.5.2	<p>BGP-SR multipath ECMP FEC optimization is enhanced to support 32k BGP-LU prefixes (from the earlier 4k BGP-LU prefixes) on multipath with the same outgoing label. This results in the consumption of lesser ECMP FEC resources, thus avoiding out-of-resource (OOR) situations for your router.</p> <p>In earlier releases, all 4k BGP-LU prefixes consumed all the 4k ECMP FEC resources.</p> <p>Use the hw-module fib mpls bgp-sr lsr-optimized command to enable BGP-SR multipath ECMP FEC optimization.</p>

The BGP-SR multipath ECMP FEC optimization solution minimizes the ECMP FEC resource consumption during underlay programming for an SR-MPLS network. BGP-LU prefix consumes one FEC resource for every path and one ECMP FEC resource for multipath. When you configure BGP-LU multipath, each BGP-LU prefix consumes one ECMP FEC resource for programming the prefix. This limits the BGP-LU prefix scale to only 4k. To support higher BGP-LU prefix scales of upto 32k, you need to conserve the ECMP FEC resources. With BGP-SR multipath ECMP FEC optimization feature, you can conserve the ECMP FEC resource usage when BGP-LU multipath is configured.

Enable the **hw-module fib mpls bgp-sr lsr-optimized** command, and ensure that all BGP-LU prefix paths advertise the same `out_label`. You can achieve this with BGP-SR or proxy BGP-SR by using same **prefix-sid-map** on the next hop routers.

After you enable ECMP FEC optimization, all BGP-LU prefix is assigned the same ECMP FEC key by conserving the ECMP FEC resources and supports scale of upto 32k BGP-LU prefixes.

Note

If the paths for BGP-LU prefixes don't have the same `out_label`, then each prefix whose `out_label` isn't the same, starts to consume ECMP FEC resources and may result in out-of-resource (OOR) when it exceeds 4k, and you may observe traffic drops. Also, the successive prefixes starts to consume FEC resources, which affect multipath support.

Usage Guidelines and Limitations

- BGP-SR multipath ECMP FEC optimization feature isn't supported on Cisco NCS 5700 series fixed port routers or Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native or compatible modes.
- All the prefixes advertised must be /32 (IPv4 only) and to enable optimization, all prefixes must have the same outgoing label.
- eBGP is always interface peering and iBGP is always loopback peering.
- Supports 32k LU prefix scale (IPv4 only) for loopback peering and 24k LU prefix scale for interface peering.
 - For eBGP interface peering, the maximum BGP next hops possible is only 2.
 - For iBGP loopback peering, the maximum BGP next hops possible is only 4.
- You can't configure the **hw-module fib mpls bgp-sr lsr-optimized** command, if **hw-module fib mpls label lsr-optimized** command is already configured.
- No ECMP FEC optimization is supported for L3VPN services over BGP-LU loopback peering.

Enable BGP-SR Multipath ECMP FEC Optimization

To enable BGP-SR multipath ECMP FEC optimization, you must configure the **hw-module fib mpls label lsr-optimized** command in global configuration mode. After enabling this feature, reload the chassis.

```
Router(config)#hw-module fib mpls bgp-sr lsr-optimized
Tue Nov 16 22:27:42.360 UTC
In order to activate this MPLS profile, you must manually reload the chassis/all line cards
Router(config)#commit

Router# reload location 0/0/CPU0

Proceed with reload? [confirm]
Reloading node 0/0/CPU0
```

Verification

The following example shows NPU ECMP FEC resource before enabling BGP-SR multipath ECMP FEC optimization, shows the OOR state and the ECMP FEC resource consumption.

SRv6 double recursion for multilayer BGP underlay

Table 59: Feature History Table

Feature Name	Release Information	Feature Description
SRv6 double recursion for multilayer BGP underlay	Release 24.4.1	<p>Introduced in this release on; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>The feature introduces support for SRv6 double recursion, where network services such as BGP VPNs (Layer 2 and Layer 3) require multiple resolution layers. Specifically, one routing layer resolves over another before reaching the final destination. Double recursion is achieved by collapsing the underlay, typically involving protocols like IGP or BGP in the packet forwarding chain. This enables three-level load balancing and an even distribution of traffic across multiple layers of the network stack.</p> <p>The feature is supported on the ingress Provider Edge (PE) router.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> • tag-map tag <value> map forwarding-hierarchy level-2-used-as-nexthop • The show cef ipv6 and show cef ipv4 commands now include the Layer 2 prefix information, which resolve as nexthop Layer 3 prefixes. <p>YANG Data Models:</p> <ul style="list-style-type: none"> • Cisco-IOS-XR-un-router-rib-cfg:router (see GitHub, Yang Data Models Navigator) data model.

SRv6 double recursion and load balancing

SRv6 double recursion refers to scenarios where network service such as BGP VPN (Layer 2/Layer 3) requires multiple layers of resolution, specifically where one routing layer resolves over another before reaching its final destination.

The SRv6 double recursion feature is designed to support three-level load balancing by collapsing the underlay, which typically involves protocols like IGP or BGP in the forwarding chain. This involves specific configurations in RIB, BGP, and static routes to indicate IPv4 and IPv6 unicast routes with Layer 2 prefixes, which resolve as nexthop Layer 3 prefixes.

Without this feature, the traffic drops the Layer 3 prefixes leading to packet loss.

Key benefits of SRv6 double recursion

- Support for complex network scenarios: In traditional service provider (SP) networks, BGP VPN services typically resolve directly over IGP reachability, meaning there is a straightforward, single-level resolution path from the service to the IGP underlay. However, with the evolution of networking, especially in data centers, new architectures have emerged where BGP underlay networks are used. In these scenarios, BGP VPN services resolve over a BGP underlay, which in turn resolves over IGP or directly connected routes.
- Support for enhanced load balancing: SRv6 double recursion allows the routing platform to balance traffic more efficiently across all available paths, enhancing overall network performance and reducing congestion. Proper load balancing at each level of recursion helps in distributing traffic evenly, avoiding bottlenecks, and ensuring that packets take optimal paths even in complex topologies.
- Improved network flexibility: Double recursion allows advanced routing solutions in SP and data center networks, accommodating complex use cases beyond single-layer limitations.

Single and double recursion in BGP VPN services

To optimize the network routing efficiency, it is important to understand the resolution processes of BGP VPN services.

- Single Recursion: BGP VPN service → IGP reachability. In a single recursion, the BGP VPN service directly resolves to IGP (Interior Gateway Protocol) reachability. Single recursion is required when a BGP VPN service can directly resolve to an IGP route without any intermediary steps.
- Double Recursion: BGP VPN service → BGP underlay reachability → IGP reachability. In double recursion, the BGP VPN service first resolves over a BGP underlay, which then leads to IGP reachability. Double recursion is necessary in cases where a BGP VPN service cannot resolve directly to an IGP route but instead must traverse a BGP underlay first. This creates a layered resolution process that standard single-level load balancing cannot handle effectively.

Usage guidelines and limitations for SRv6 double recursion

Limitations

You cannot use a combination of BGP-SU (BGP Service Unicast) and BGP-IP paths at Layer 2.

Usage guidelines

The usage guidelines that are listed apply:

- Configure the locator prefix for IPv6 prefixes that are Layer 2 prefixes.
- If the collapsed BGP paths are a combination of IGP IPv6 and SRv6, the router filters out only the IPv6 paths.
- In a collapsed chain scenario with SRv6 as the IGP, the router configures the encapsulation (Encap) ID, provided it supports SRv6 and BGP extensions for SRv6.

Configure SRv6 double recursion for multilayer BGP underlay

Before you begin

- For Layer 2 IPv6 prefixes, set the locator prefix using the **prefix-set** command in RIB.
- Configure the set of IPv4 and IPv6 Layer 2 prefixes, which resolve as nexthop Layer 3 prefixes using the **prefix-set** command.

Procedure

- Step 1** Enable the hardware support for BGP-LU to allow the ingress PE router to advertise and forward the MPLS-labelled unicast routes.

Example:

```
Router#config
Router(config)#hw-module profile cef bgplu enable
```

- Step 2** Configure the IPv4 and IPv6 unicast routes in the RIB to ensure that the Layer 2 prefixes can be used as nexthop for Layer 3 prefixes.

Example:

```
Router#config
Router(config)#router bgp 100
Router(config-bgp)#address-family ipv4 unicast
Router(config-bgp-af)#table-policy level2-ipv4-policy
Router(config-bgp-af)#exit
Router(config-bgp)#address-family ipv6 unicast
Router(config-bgp-af)#table-policy level2-ipv6-policy
Router(config-bgp-af)#commit
```

- Step 3** Assign the required tag to the IPv4 and IPv6 unicast routes to forward the route information to the Forwarding Information Base (FIB).

For the IPv4 and IPv6 routes, the RIB assigns the tags and forwards the route information to the FIB, indicating that these Layer 2 prefixes resolve as nexthop for Layer 3 prefixes.

Example:

IPv4 Layer 2 prefixes:

```
Router(config)#route-policy level2-ipv4-policy
Router(config-rpl)#if destination in level2_prefixes-ipv4 then
```

```
Router(config-rpl-if)#set tag 100
Router(config-rpl-if)#else
Router(config-rpl-else)#pass
Router(config-rpl-else)#endif
Router(config-rpl)#end-policy
Router(config)#commit
```

Example:

IPv6 Layer 2 prefixes:

```
Router(config)#route-policy level2-ipv6-policy
Router(config-rpl)#if destination in level2_prefixes-ipv6 then
Router(config-rpl-if)#set tag 100
Router(config-rpl-if)#endif
Router(config-rpl)#if destination in level2_locators then
Router(config-rpl-if)#set locator-prefix
Router(config-rpl-if)#else
Router(config-rpl-else)#pass
Router(config-rpl-else)#endif
Router(config-rpl)#end-policy
```

- Step 4** Map the tags in the RIB for the IPv4 and IPv6 unicast routes to ensure that the routes resolve as nexthop for Layer 3 prefixes.

In the following example, the RIB maps all the IPv4 and IPv6 routes tagged with the value 100, which indicates that these routes resolve as nexthop for Layer 3 prefixes. The RIB adds the *FIB_UPDATE_ROUTE_FLAG_EXTN_LVL2_HAS_DEPENDENT* flag when it sends the route update to the FIB.

Example:

```
Router#config
Router(config)#router rib
Router(config-rib)#tag-map tag 100 map forwarding-hierarchy level-2-used-as-nexthop
Router(config-rib)#commit
```

- Step 5** Run the **show running-config** command to verify the running configuration.

Example:

```
hw-module profile cef bgplu enable
!
router bgp 100
  address-family ipv4 unicast
    table-policy level2-ipv4-policy
  !
  address-family ipv6 unicast
    table-policy level2-ipv6-policy
  !
!
router rib
  tag-map tag 100 map forwarding-hierarchy level-2-used-as-nexthop
!
!
```

- Step 6** Run the **show cef ipv4** and **show cef ipv6** commands to verify the Layer 2 collapsed prefixes.

In the show output command example, the IPv6 Layer 2 prefixes, which resolve as nexthop for Layer 3 prefixes are collapsed. This is indicated by the **collapsed** keyword in the output. The SRv6 SID lists indicate the different encapsulation layers or hierarchy.

Example:

```
Router#show cef ipv6 2001:DB8:A:B::1/64
Thu Jun  6 12:48:52.399 EDT
```

```

2001:DB8:A:B::1/64, version 8, SRv6 Headend, internal 0x1000001 0x0 (ptr 0x63851c98) [1], 0x1400

CHAPTER 11

Configure SR-TE Policies

This module provides information about segment routing for traffic engineering (SR-TE) policies, how to configure SR-TE policies, and how to steer traffic into an SR-TE policy.

- [SR-TE Policy Overview, on page 367](#)
- [Usage Guidelines and Limitations, on page 369](#)
- [Instantiation of an SR Policy, on page 370](#)
- [SR-TE Policy Path Types, on page 411](#)
- [SR-TE policy with enhanced flexible algorithm metric types, on page 431](#)
- [Protocols, on page 436](#)
- [Traffic Steering, on page 449](#)
- [Miscellaneous, on page 476](#)

SR-TE Policy Overview

Table 60: Feature History Table

Feature Name	Release Information	Feature Description
Local ECMP Support on SR-TE	Release 7.10.1	<p>This feature supports the top segment identifier (SID) resolved route interior gateway protocol (IGP) path's weight to be used in relative weight computation of outgoing paths of the SRTE policy.</p> <p>Now ECMP supports SR-TE and computes per-egress-path relative weight using underlay (IGP) weight from Forwarding Information Base (FIB) / Routing Information Base (RIB) in addition to Segment List (SL) weight and number of primary egress paths for SL. Thus, IGP load balancing required at individual paths is also maintained.</p> <p>This feature is enabled by default and no configuration changes are required.</p>

Feature Name	Release Information	Feature Description
NC57 Native Mode: SR Policy	Release 7.3.1	<p>With this feature, NC57 line cards will support SR Policy in native mode.</p> <p>Native mode is used when the chassis contains only NC57 line cards. After you configure the native mode, ensure to reload the router.</p> <p>To enable the native mode, use the hw-module profile npu native-mode-enable command in the configuration mode.</p>

Segment routing for traffic engineering (SR-TE) uses a “policy” to steer traffic through the network. An SR-TE policy path is expressed as a list of segments that specifies the path, called a segment ID (SID) list. Each segment is an end-to-end path from the source to the destination, and instructs the routers in the network to follow the specified path instead of following the shortest path calculated by the IGP. If a packet is steered into an SR-TE policy, the SID list is pushed on the packet by the head-end. The rest of the network executes the instructions embedded in the SID list.

An SR-TE policy is identified as an ordered list (head-end, color, end-point):

- Head-end – Where the SR-TE policy is instantiated
- Color – A numerical value that distinguishes between two or more policies to the same node pairs (Head-end – End point)
- End-point – The destination of the SR-TE policy

Every SR-TE policy has a color value. Every policy between the same node pairs requires a unique color value.

An SR-TE policy uses one or more candidate paths. A candidate path is a single segment list (SID-list) or a set of weighted SID-lists (for weighted equal cost multi-path [WECMP]). A candidate path is either dynamic or explicit. See *SR-TE Policy Path Types* section for more information.

The NC57 line cards operate under the following modes in SR Policy:

- Compatible Mode - Used when the chassis contains combination of NC57 line card and older generation cards. This is the default mode.
- Native Mode - Used when the chassis contains only NC57 line cards.

To enable the native mode, use the **hw-module profile npu native-mode-enable** command in the configuration mode. Ensure that you reload the router after configuring the native mode.

Usage Guidelines and Limitations

Table 61: Feature History Table

Feature Name	Release Information	Feature Description
L3VPN BGP PIC over SR-TE	Release 7.3.2	<p>This feature provides BGP PIC support for L3VPN over SR policies. BGP PIC provides fast convergence when traffic switches from a primary path to a backup path.</p> <p>BGP PIC over SR-TE is supported when both primary and backup paths each resolve into the BSID of an SR policy.</p>
Cisco NC57 Compatible and Native Mode: BVI co-existence with SRTE on same NPU	Release 7.3.1	<p>This feature is supported on routers that have the Cisco NC57 line cards installed and operate in the native and compatible modes. To enable the native mode, use the hw-module profile npu native-mode-enable command in the configuration mode. Ensure that you reload the router after configuring the native mode.</p>

Observe the following guidelines and limitations for the platform.

- Broadcast links are not supported, configure IGP's interface as P2P (point-to-point).
- The ECMP path-set of an IGP route with a mix of SR-TE Policy paths (Autoroute Include) and unprotected native paths is supported.
- The ECMP path-set of an IGP route with a mix of SR-TE Policy paths (Autoroute Include) and protected (LFA/TI-LFA) native paths is not supported.
- Before configuring SR-TE policies, use the **distribute link-state** command under IS-IS or OSPF to distribute the link-state database to external services.
- L3VPN BGP PIC over SR-TE is supported.

BGP PIC over SR-TE is supported when both primary and backup paths each resolve into the BSID of an SR policy. BGP PIC over SR-TE is not supported when primary and backup paths are of different resolution types. For example, when a primary path resolves into the BSID of an SR policy, the backup path cannot point to a native LSP. When this happens, the backup path will not be programmed. For information about BGP PIC, refer to the [BGP PIC](#) chapter in the *BGP Configuration Guide for Cisco NCS 5500 Series Routers*.

- SR-TE over BVI is not supported. An SR-TE policy cannot be resolved over an MPLS-enabled BVI interface.

- **For NCS 5500:** Counter implications when BVI and SR-TE co-exist in same NPU—Counters for a BVI's logical interface are not allocated when the same NPU hosts layer-2 (sub)interface(s) associated with the BVI alongside other port(s) used as egress interface(s) for an SR policy
- **For routers that have Cisco NC57 line cards installed and operate in native or compatible modes:** Counter implications when BVI and SR-TE co-exist in same NPU—Counters for a BVI's logical interface are allocated when the same NPU hosts layer-2 (sub)interface(s) associated with the BVI alongside other port(s) used as egress interface(s) for an SR policy
- GRE tunnel as primary interface for an SR policy is not supported.
- GRE tunnel as backup interface for an SR policy with TI-LFA protection is not supported.
- Head-end computed inter-domain SR policy with Flex Algo constraint and IGP redistribution is not supported. This is supported with Flex Algo-aware path computation at SR-PCE, with or without IGP redistribution. See [SR-PCE Flexible Algorithm Multi-Domain Path Computation, on page 648](#).

Instantiation of an SR Policy

An SR policy is instantiated, or implemented, at the head-end router.

The following sections provide details on the SR policy instantiation methods:

- gRPC API Services
- [On-Demand SR Policy – SR On-Demand Next-Hop , on page 370](#)
- [Manually Provisioned SR Policy, on page 405](#)
- [PCE-Initiated SR Policy, on page 405](#)

On-Demand SR Policy – SR On-Demand Next-Hop

Table 62: Feature History Table

Feature Name	Release Information	Feature Description
SRTE-Services: 6PE/6VPE On-Demand Next Hop (ODN+AS)	Release 7.3.1	This feature is now supported on routers that have the Cisco NC57 line cards installed and operate in the native and compatible modes. To enable the native mode, use the hw-module profile npu native-mode-enable command in the configuration mode. Ensure that you reload the router after configuring the native mode.

Segment Routing On-Demand Next Hop (SR-ODN) allows a service head-end router to automatically instantiate an SR policy to a BGP next-hop when required (on-demand). Its key benefits include:

- **SLA-aware BGP service** – Provides per-destination steering behaviors where a prefix, a set of prefixes, or all prefixes from a service can be associated with a desired underlay SLA. The functionality applies equally to single-domain and multi-domain networks.
- **Simplicity** – No prior SR Policy configuration needs to be configured and maintained. Instead, operator simply configures a small set of common intent-based optimization templates throughout the network.
- **Scalability** – Device resources at the head-end router are used only when required, based on service or SLA connectivity needs.

The following example shows how SR-ODN works:

1. An egress PE (node H) advertises a BGP route for prefix T/t. This advertisement includes an SLA intent encoded with a BGP color extended community. In this example, the operator assigns color purple (example value = 100) to prefixes that should traverse the network over the delay-optimized path.
2. The route reflector receives the advertised route and advertises it to other PE nodes.
3. Ingress PEs in the network (such as node F) are pre-configured with an ODN template for color purple that provides the node with the steps to follow in case a route with the intended color appears, for example:
 - Contact SR-PCE and request computation for a path toward node H that does not share any nodes with another LSP in the same disjointness group.
 - At the head-end router, compute a path towards node H that minimizes cumulative delay.
4. In this example, the head-end router contacts the SR-PCE and requests computation for a path toward node H that minimizes cumulative delay.
5. After SR-PCE provides the compute path, an intent-driven SR policy is instantiated at the head-end router. Other prefixes with the same intent (color) and destined to the same egress PE can share the same on-demand SR policy. When the last prefix associated with a given [intent, egress PE] pair is withdrawn, the on-demand SR policy is deleted, and resources are freed from the head-end router.

An on-demand SR policy is created dynamically for BGP global or VPN (service) routes. The following services are supported with SR-ODN:

- IPv4 BGP global routes
- IPv6 BGP global routes (6PE)
- VPNv4
- VPNv6 (6vPE)
- EVPN-VPWS (single-homing)
- EVPN-VPWS (multi-homing)
- EVPN (single-homing/multi-homing)

Note For EVPN single-homing, you must configure an EVPN Ethernet Segment Identifier (ESI) with a non-zero value.

Note Colored per-ESI/per-EVI EVPN Ethernet Auto-Discovery route (route-type 1) and Inclusive Multicast Route (route-type 3) are used to trigger instantiation of ODN SR-TE policies.

Note The following scenarios involving virtual Ethernet Segments (vES) are also supported with EVPN ODN:

- VPLS VFI as vES for single-active Multi-Homing to EVPN
- Active/backup Pseudo-wire (PW) as vES for Single-Homing to EVPN
- Static Pseudo-wire (PW) as vES for active-active Multi-Homing to EVPN

SR-ODN Configuration Steps

Note If you are on a release before Cisco IOS XR Release 7.4.1, you can configure SR-ODN with Flexible Algorithm constraints using the **segment-routing traffic-eng on-demand color** *color* **dynamic sid-algorithm** *algorithm-number* command.

Starting with Cisco IOS XR release 7.4.1, you can also configure SR-ODN with Flexible Algorithm constraints using the new **segment-routing traffic-eng on-demand color** *color* **constraints segments sid-algorithm** *algorithm-number* command.

From Cisco IOS XR Release 7.9.1, the **segment-routing traffic-eng on-demand color** *color* **dynamic sid-algorithm** *algorithm-number* command is deprecated. Previous configurations stored in NVRAM will be rejected at boot-up.

Hence, for Cisco IOS XR Release 7.9.1, you must reconfigure all SR-ODN configurations with Flexible Algorithm constraints that use the **on-demand dynamic sid-algorithm** with the **on-demand constraints** command.

To configure SR-ODN, complete the following configurations:

1. Define the SR-ODN template on the SR-TE head-end router.
(Optional) If using Segment Routing Path Computation Element (SR-PCE) for path computation:
 - a. Configure SR-PCE. For detailed SR-PCE configuration information, see [Configure SR-PCE, on page 637](#).
 - b. Configure the head-end router as Path Computation Element Protocol (PCEP) Path Computation Client (PCC). For detailed PCEP PCC configuration information, see [Configure the Head-End Router as PCEP PCC](#).
2. Define BGP color extended communities. Refer to the "Implementing BGP" chapter in the [BGP Configuration Guide for NCS 5500 Series Routers](#).
3. Define routing policies (using routing policy language [RPL]) to set BGP color extended communities. Refer to the "Implementing Routing Policy" chapter in the [Routing Configuration Guide for NCS 5500 Series Routers](#).

The following RPL attach-points for setting/matching BGP color extended communities are supported:

Note The following table shows the supported RPL match operations; however, routing policies are required primarily to set BGP color extended community. Matching based on BGP color extended communities is performed automatically by ODN's on-demand color template.

Attach Point	Set	Match
VRF export	X	X
VRF import	—	X
EVI export	X	—
EVI import	X	X

Attach Point	Set	Match
Neighbor-in	X	X
Neighbor-out	X	X
Inter-AFI export	—	X
Inter-AFI import	—	X
Default-originate	X	—

4. Apply routing policies to a service. Refer to the "Implementing Routing Policy" chapter in the [Routing Configuration Guide for NCS 5500 Series Routers](#).

Configure On-Demand Color Template

- Use the **on-demand color** *color* command to create an ODN template for the specified color value. The head-end router automatically follows the actions defined in the template upon arrival of BGP global or VPN routes with a BGP color extended community that matches the color value specified in the template.

The *color* range is from 1 to 4294967295.

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# on-demand color 10
```

Note Matching based on BGP color extended communities is performed automatically via ODN's on-demand color template. RPL routing policies are not required.

- Use the **on-demand color** *color dynamic* command to associate the template with on-demand SR policies with a locally computed dynamic path (by SR-TE head-end router utilizing its TE topology database) or centrally (by SR-PCE). The head-end router will first attempt to install the locally computed path; otherwise, it will use the path computed by the SR-PCE.

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# on-demand color 10 dynamic
```

- Use the **on-demand color** *color dynamic pcep* command to indicate that only the path computed by SR-PCE should be associated with the on-demand SR policy. With this configuration, local path computation is not attempted; instead the head-end router will only instantiate the path computed by the SR-PCE.

```
Router(config-sr-te)# on-demand color 10 dynamic pcep
```

Configure Dynamic Path Optimization Objectives

- Use the **metric type** {*igp* | *te* | *latency*} command to configure the metric for use in path computation.

```
Router(config-sr-te-color-dyn)# metric type te
```

- Use the **metric margin** *{absolute value| relative percent}* command to configure the On-Demand dynamic path metric margin. The range for *value* and *percent* is from 0 to 2147483647.

```
Router(config-sr-te-color-dyn)# metric margin absolute 5
```

Configure Dynamic Path Constraints

- Use the **disjoint-path group-id** *group-id type {link | node | srlg | srlg-node} [sub-id sub-id]* command to configure the disjoint-path constraints. The *group-id* and *sub-id* range is from 1 to 65535.

```
Router(config-sr-te-color-dyn)# disjoint-path group-id 775 type link
```

- Use the **affinity** *{include-any | include-all | exclude-any} {name WORD}* command to configure the affinity constraints.

```
Router(config-sr-te-color-dyn)# affinity exclude-any name CROSS
```

- Use the **maximum-sid-depth** *value* command to customize the maximum SID depth (MSD) constraints advertised by the router.

The default MSD *value* is equal to the maximum MSD supported by the platform (12).

```
Router(config-sr-te-color)# maximum-sid-depth 5
```

See [Customize MSD Value at PCC, on page 438](#) for information about SR-TE label imposition capabilities.

- Use the **constraints segments sid-algorithm** *algorithm-number* command to configure the SR Flexible Algorithm constraints. The *algorithm-number* range is from 128 to 255.

```
Router(config-sr-te-color)# constraints segments sid-algorithm 128
```

- Use the **constraints segments protection** *{protected-only | protected-preferred | unprotected-only | unprotected-preferred}* command to configure the Adj-SID protection behavior constraints.

```
Router(config-sr-te-color)# constraints segments protection protected-only
```

See [Segment Protection-Type Constraint, on page 415](#) for information about Adj-SID protection behavior.

Configuring SR-ODN: Examples

Configuring SR-ODN: Layer-3 Services Examples

The following examples show end-to-end configurations used in implementing SR-ODN on the head-end router.

Configuring ODN Color Templates: Example

Configure ODN color templates on routers acting as SR-TE head-end nodes. The following example shows various ODN color templates:

- color 10: minimization objective = te-metric
- color 20: minimization objective = igp-metric
- color 21: minimization objective = igp-metric; constraints = affinity

- color 22: minimization objective = te-metric; path computation at SR-PCE; constraints = affinity
- color 30: minimization objective = delay-metric
- color 128: constraints = flex-algo

```

Configuring BGP Color Extended Community Set: Example

The following example shows how to configure BGP color extended communities that are later applied to BGP service routes via route-policies.

Note In most common scenarios, egress PE routers that advertise BGP service routes apply (set) BGP color extended communities. However, color can also be set at the ingress PE router.

```
extcommunity-set opaque color10-te
  10
end-set
!
extcommunity-set opaque color20-igp
  20
end-set
!
extcommunity-set opaque color21-igp-excl-cross

end-set
!
extcommunity-set opaque color128-fa128
  128
end-set
!
```

Configuring RPL to Set BGP Color (Layer-3 Services): Examples

The following example shows various representative RPL definitions that set BGP color community.

The first 4 RPL examples include the set color action only. The last RPL example performs the set color action for selected destinations based on a prefix-set.

```
route-policy SET_COLOR_LOW_LATENCY_TE
  set extcommunity color color10-te
  pass
end-policy
!
route-policy SET_COLOR_HI_BW
  set extcommunity color color20-igp
  pass
end-policy
!
route-policy SET_COLOR_LOW_LATENCY
  set extcommunity color color30-delay
  pass
end-policy
!
route-policy SET_COLOR_FA_128
  set extcommunity color color128-fa128
  pass
end-policy
!

prefix-set sample-set
  88.1.0.0/24
end-set
```

```

!
route-policy SET_COLOR_GLOBAL
  if destination in sample-set then
    set extcommunity color color10-te
  else
    pass
  endif
end-policy

```

Applying RPL to BGP Services (Layer-3 Services): Example

The following example shows various RPLs that set BGP color community being applied to BGP Layer-3 VPN services (VPNv4/VPNv6) and BGP global.

- The L3VPN examples show the RPL applied at the VRF export attach-point.
- The BGP global example shows the RPL applied at the BGP neighbor-out attach-point.

```

vrf vrf_cust1
  address-family ipv4 unicast
    export route-policy SET_COLOR_LOW_LATENCY_TE
  !
  address-family ipv6 unicast
    export route-policy SET_COLOR_LOW_LATENCY_TE
  !
!
vrf vrf_cust2
  address-family ipv4 unicast
    export route-policy SET_COLOR_HI_BW
  !
  address-family ipv6 unicast
    export route-policy SET_COLOR_HI_BW

  address-family ipv4 unicast
    export route-policy SET_COLOR_FA_128
  !
  address-family ipv6 unicast
    export route-policy SET_COLOR_FA_128
  !
!
router bgp 100
  neighbor-group BR-TO-RR
    address-family ipv4 unicast
      route-policy SET_COLOR_GLOBAL out
    !
  !
!
end

```

Verifying BGP VRF Information

Use the **show bgp vrf** command to display BGP prefix information for VRF instances. The following output shows the BGP VRF table including a prefix (88.1.1.0/24) with color 10 advertised by router 10.1.1.8.

```
RP/0/RP0/CPU0:R4# show bgp vrf vrf_cust1

BGP VRF vrf_cust1, state: Active

Verifying SR Policy

Use the **show segment-routing traffic-eng policy** command to display SR policy information.

The following outputs show the details of an on-demand SR policy that was triggered by prefixes with color 10 advertised by node 10.1.1.8.

```
RP/0/RP0/CPU0:R4# show segment-routing traffic-eng policy color 10 tabular
```

Color	Endpoint	Admin State	Oper State	Binding SID
10	10.1.1.8	up	up	24036

The following outputs show the details of the on-demand SR policy for BSID 24036.

Note There are 2 candidate paths associated with this SR policy: the path that is computed by the head-end router (with preference 200), and the path that is computed by the SR-PCE (with preference 100). The candidate path with the highest preference is the active candidate path (highlighted below) and is installed in forwarding.

```
RP/0/RP0/CPU0:R4# show segment-routing traffic-eng policy binding-sid 24036
```

```

Configuring SR-ODN: EVPN Services Examples

Configuring BGP Color Extended Community Set: Example

The following example shows how to configure BGP color extended communities that are later applied to BGP service routes via route-policies.

```

extcommunity-set opaque color-44
  44
end-set

extcommunity-set opaque color-55
  55
end-set

extcommunity-set opaque color-77
  77
end-set

extcommunity-set opaque color-88
  88
end-set

```

Configuring RPL to Set BGP Color (EVPN Services): Examples

The following examples shows various representative RPL definitions that set BGP color community.

The following RPL examples match on EVPN route-types and then set the BGP color extended community.

```

route-policy sample-export-rpl
  if evpn-route-type is 1 then
    set extcommunity color color-44
  endif

```

```

    if evpn-route-type is 3 then
        set extcommunity color color-55
    endif
end-policy

route-policy sample-import-rpl
    if evpn-route-type is 1 then
        set extcommunity color color-77
    elseif evpn-route-type is 3 then
        set extcommunity color color-88
    else
        pass
    endif
end-policy

```

The following RPL example sets BGP color extended community while matching on the following:

- Route Distinguisher (RD)
- Ethernet Segment Identifier (ESI)
- Ethernet Tag (ETAG)
- EVPN route-types

```

route-policy sample-bgpneighbor-rpl
    if rd in (10.1.1.1:3504) then
        set extcommunity color color3504
    elseif rd in (10.1.1.1:3505) then
        set extcommunity color color3505
    elseif rd in (10.1.1.1:3506) then
        set extcommunity color color99996
    elseif esi in (0010.0000.0000.0000.1201) and rd in (10.1.1.1:3508) then
        set extcommunity color color3508
    elseif etag in (30509) and rd in (10.1.1.1:3509) then
        set extcommunity color color3509
    elseif etag in (0) and rd in (10.1.1.1:2001) and evpn-route-type is 1 then
        set extcommunity color color82001
    elseif etag in (0) and rd in (10.1.1.1:2001) and evpn-route-type is 3 then
        set extcommunity color color92001
    endif
    pass
end-policy

```

Applying RPL to BGP Services (EVPN Services): Example

The following examples show various RPLs that set BGP color community being applied to EVPN services.

The following 2 examples show the RPL applied at the EVI export and import attach-points.

Note RPLs applied under EVI import or export attach-point also support matching on the following:

- Ethernet Segment Identifier (ESI)
- Ethernet Tag (ETAG)
- EVPN-Originator

```

evpn
 evi 101

```

```

bgp
  route-target 101:1
  route-target import 100:1
  route-target export 101:1
  route-policy import sample-import-rpl
  !
  advertise-mac
  !
  !
evi 102
  bgp
    route-target 102:1
    route-target import 100:2
    route-target export 102:1
    route-policy export sample-export-rpl
    !
    advertise-mac
    !
    !
  !

```

The following example shows the RPL applied at the BGP neighbor-out attach-point.

Note RPLs defined under BGP neighbor-out attach-point also support matching on the following:

- EVPN-Originator

```

router bgp 100
  bgp router-id 10.1.1.1
  address-family l2vpn evpn
  !
  neighbor-group evpn-rr
  remote-as 100
  update-source Loopback0
  address-family l2vpn evpn
  !
  neighbor 10.10.10.10
    use neighbor-group evpn-rr
    address-family l2vpn evpn
    route-policy sample-bgpneighbor-rpl out

```

Configuring SR-ODN for EVPN-VPWS: Use Case

This use case shows how to set up a pair of ELINE services using EVPN-VPWS between two sites. Services are carried over SR policies that must not share any common links along their paths (link-disjoint). The SR policies are triggered on-demand based on ODN principles. An SR-PCE computes the disjoint paths.

This use case uses the following topology with 2 sites: Site 1 with nodes A and B, and Site 2 with nodes C and D.

Figure 16: Topology for Use Case: SR-ODN for EVPN-VPWS

Table 63: Use Case Parameters

IP Addresses of Loopback0 (Lo0) Interfaces	SR-PCE Lo0: 10.1.1.207	
	Site 1: <ul style="list-style-type: none"> Node A Lo0: 10.1.1.5 Node B Lo0: 10.1.1.6 	Site 2: <ul style="list-style-type: none"> Node C Lo0: 10.1.1.2 Node D Lo0: 10.1.1.4

Configuration: SR-PCE

For cases when PCC nodes support, or signal, PCEP association-group object to indicate the pair of LSPs in a disjoint set, there is no extra configuration required at the SR-PCE to trigger disjoint-path computation.

Note SR-PCE also supports disjoint-path computation for cases when PCC nodes do not support PCEP association-group object. See [Configure the Disjoint Policy \(Optional\), on page 639](#) for more information.

Configuration: Site 1 Node A

This section depicts relevant configuration of Node A at Site 1. It includes service configuration, BGP color extended community, and RPL. It also includes the corresponding ODN template required to achieve the disjointness SLA.

Nodes in Site 1 are configured to set color 10000 on originating EVPN routes, while matching color 11000 on incoming EVPN routes from routers located at Site 2.

Since both nodes in Site 1 request path computation from SR-PCE using the same disjoint-path group-id (775), the PCE will attempt to compute disjointness for the pair of LSPs originating from Site 1 toward Site 2.

Verification: SR-PCE

Use the **show pce ipv4 peer** command to display the SR-PCE's PCEP peers and session status. SR-PCE performs path computation for the 4 nodes depicted in the use-case.

```

RP/0/0/CPU0:SR-PCE# show pce ipv4 peer
Mon Jul 15 19:41:43.622 UTC

PCE's peer database:
-----
Peer address: 10.1.1.2
  State: Up
  Capabilities: Stateful, Segment-Routing, Update, Instantiation

Peer address: 10.1.1.4
  State: Up
  Capabilities: Stateful, Segment-Routing, Update, Instantiation

Peer address: 10.1.1.5
  State: Up
  Capabilities: Stateful, Segment-Routing, Update, Instantiation

Peer address: 10.1.1.6
  State: Up
  Capabilities: Stateful, Segment-Routing, Update, Instantiation

```

Use the **show pce association group-id** command to display information for the pair of LSPs assigned to a given association group-id value.

Based on the goals of this use case, SR-PCE computes link-disjoint paths for the SR policies associated with a pair of ELINE services between site 1 and site 2. In particular, disjoint LSPs from site 1 to site 2 are identified by association group-id 775. The output includes high-level information for LSPs associated to this group-id:

- At Node A (10.1.1.5): LSP symbolic name = bgp_c_11000_ep_10.1.1.2_discr_100
- At Node B (10.1.1.6): LSP symbolic name = bgp_c_11000_ep_10.1.1.4_discr_100

In this case, the SR-PCE was able to achieve the desired disjointness level; therefore the Status is shown as "Satisfied".

```
RP/0/0/CPU0:SR-PCE# show pce association group-id 775
Thu Jul 11 03:52:20.770 UTC
```

PCE's association database:

Association: Type Link-Disjoint, Group 775, Not Strict

Associated LSPs:

LSP[0]:

PCC 10.1.1.6, tunnel name **bgp_c_11000_ep_10.1.1.4_discr_100**, PLSP ID 18, tunnel ID 17,
LSP ID 3, Configured on PCC

LSP[1]:

Verification: Site 1 Node A

This section depicts verification steps at Node A.

Use the **show bgp l2vpn evpn** command to display BGP prefix information for EVPN-VPWS EVI 100 (rd 10.1.1.5:100). The output includes an EVPN route-type 1 route with color 11000 originated at Node C (10.1.1.2).

```

RP/0/RSP0/CPU0:Node-A# show bgp l2vpn evpn rd 10.1.1.5:100
Wed Jul 10 18:57:57.704 PST
BGP router identifier 10.1.1.5, local AS number 65000
BGP generic scan interval 60 secs
Non-stop routing is enabled
BGP table state: Active
Table ID: 0x0 RD version: 0
BGP main routing table version 360
BGP NSR Initial initsync version 1 (Reached)
BGP NSR/ISSU Sync-Group versions 0/0
BGP scan interval 60 secs

Status codes: s suppressed, d damped, h history, * valid, > best
               i - internal, r RIB-failure, S stale, N Nexthop-discard
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network          Next Hop          Metric LocPrf Weight Path
Route Distinguisher: 10.1.1.5:100 (default for vrf VPWS:100)
*> [1][0000.0000.0000.0000.0000][11]/120
      0.0.0.0                                0 i
*>i [1][0000.0000.0000.0000.0000][21]/120
      10.1.1.2 C:11000                        100      0 i

```

The following output displays the details for the incoming EVPN RT1. Note the presence of BGP extended color community 11000, and that the prefix is associated with an SR policy with color 11000 and BSID value of 80044.

```
RP/0/RSP0/CPU0:Node-A# show bgp l2vpn evpn rd 10.1.1.5:100
[1][0000.0000.0000.0000.0000][21]/120

Use the **show segment-routing traffic-eng policy** command with **tabular** option to display SR policy summary information.

The following output shows the on-demand SR policy with BSID 80044 that was triggered by EVPN RT1 prefix with color 11000 advertised by node C (10.1.1.2).

```

RP/0/RSP0/CPU0:Node-A# show segment-routing traffic-eng policy color 11000 tabular
Wed Jul 10 18:58:00.732 PST

```

Color	Endpoint	Admin State	Oper State	Binding SID
-----	-----	-----	-----	-----
11000	10.1.1.2	up	up	80044

The following output shows the details for the on-demand SR policy. Note that the SR policy's active candidate path (preference 100) is computed by SR-PCE (10.1.1.207).

Based on the goals of this use case, SR-PCE computes link-disjoint paths for the SR policies associated with a pair of ELINE services between site 1 and site 2. Specifically, from site 1 to site 2, LSP at Node A (srte_c_11000_ep_10.1.1.2) is link-disjoint from LSP at Node B (srte_c_11000_ep_10.1.1.4).

```

RP/0/RSP0/CPU0:Node-A# show segment-routing traffic-eng policy color 11000

Verification: Site 2 Node D

This section depicts verification steps at Node D.

Use the **show bgp l2vpn evpn** command to display BGP prefix information for EVPN-VPWS EVI 101 (rd 10.1.1.4:101). The output includes an EVPN route-type 1 route with color 10000 originated at Node B (10.1.1.6).

```
RP/0/RSP0/CPU0:Node-D# show bgp l2vpn evpn rd 10.1.1.4:101
BGP router identifier 10.1.1.4, local AS number 65000
BGP generic scan interval 60 secs
Non-stop routing is enabled
BGP table state: Active
Table ID: 0x0 RD version: 0
BGP main routing table version 570
BGP NSR Initial initsync version 1 (Reached)
BGP NSR/ISSU Sync-Group versions 0/0
BGP scan interval 60 secs
```

```

Status codes: s suppressed, d damped, h history, * valid, > best

Use the **show segment-routing traffic-eng policy** command with **tabular** option to display SR policy summary information.

The following output shows the on-demand SR policy with BSID 80047 that was triggered by EVPN RT1 prefix with color 10000 advertised by node B (10.1.1.6).

```
RP/0/RSP0/CPU0:Node-D# show segment-routing traffic-eng policy color 10000 tabular
```

Color	Endpoint	Admin State	Oper State	Binding SID
10000	10.1.1.6	up	up	80047

The following output shows the details for the on-demand SR policy. Note that the SR policy's active candidate path (preference 100) is computed by SR-PCE (10.1.1.207).

Based on the goals of this use case, SR-PCE computes link-disjoint paths for the SR policies associated with a pair of ELINE services between site 1 and site 2. Specifically, from site 2 to site 1, LSP at Node D (srte_c_10000_ep_10.1.1.6) is link-disjoint from LSP at Node C (srte_c_10000_ep_10.1.1.5).

Manually Provisioned SR Policy

Manually provisioned SR policies are configured on the head-end router. These policies can use dynamic paths or explicit paths. See the [SR-TE Policy Path Types, on page 411](#) section for information on manually provisioning an SR policy using dynamic or explicit paths.

PCE-Initiated SR Policy

An SR-TE policy can be configured on the path computation element (PCE) to reduce link congestion or to minimize the number of network touch points.

The PCE collects network information, such as traffic demand and link utilization. When the PCE determines that a link is congested, it identifies one or more flows that are causing the congestion. The PCE finds a suitable path and deploys an SR-TE policy to divert those flows, without moving the congestion to another part of the network. When there is no more link congestion, the policy is removed.

To minimize the number of network touch points, an application, such as a Network Services Orchestrator (NSO), can request the PCE to create an SR-TE policy. PCE deploys the SR-TE policy using PCC-PCE communication protocol (PCEP).

For more information, see the [PCE-Initiated SR Policies, on page 647](#) section.

Cumulative Metric Bounds (Delay-Bound Use-Case)

Table 64: Feature History Table

Feature Name	Release Information	Feature Description
Cumulative Metric Bounds (Delay-Bound use-case)	Release 7.3.1	With this feature, SRTE calculates a shortest path that satisfies multiple metric bounds. This feature provides flexibility for finding paths within metric bounds, for parameters such as latency, hop count, IGP and TE.

SRTE can calculate a shortest path with cumulative metric bounds. For example, consider these metric bounds:

- IGP metric ≤ 10
- TE metric ≤ 60
- Hop count ≤ 4
- Latency ≤ 55

When an SR policy is configured on a head-end node with these metric bounds, a path is finalized towards the specified destination only if it meets each of these criteria.

You can set the maximum number of attempts for computing a shortest path that satisfies the cumulative metric bounds criteria, by using the **kshortest-paths** command in SR-TE configuration mode.

Restrictions

- PCE-based cumulative metric bounds computations are not supported. You must use non-PCE (SR-TE topology) based configuration for path calculation, for cumulative bounds.
- If you use PCE dynamic computation configuration with cumulative bounds, the PCE computes a path and validates against cumulative bounds. If it is valid, then the policy is created with this path on PCC. If the initial path doesn't respect the bounds, then the path is not considered, and no further K-shortest path algorithm is executed to find the path.

Configuring SRTE Shortest Path Calculation For Cumulative Metric Bounds

You can enable this feature for SR, and ODN SR policy configurations, as shown below.

SR Policy

SR Policy - A policy called **fromAtoB_XTC** is created towards destination IP address 192.168.0.2. Also, the candidate-paths preference, and other attributes are enabled.

```
Router# configure terminal
Router(config)# segment-routing traffic-eng policy fromAtoB_XTC
Router(config-sr-te-policy)# color 2 end-point ipv4 192.168.0.2
Router(config-sr-te-policy)# candidate-paths preference 100
Router(config-sr-te-policy-path-pref)# dynamic metric type te
```

Cumulative Metric bounds – IGP, TE, hop count, and latency metric bounds are set. SRTE calculates paths only when each criterion is satisfied.

```
Router(config-sr-te-policy-path-pref)# constraints bounds cumulative
Router(config-sr-te-pref-const-bounds-type)# type igp 10
Router(config-sr-te-pref-const-bounds-type)# type te 60
Router(config-sr-te-pref-const-bounds-type)# type hopcount 4
Router(config-sr-te-pref-const-bounds-type)# type latency 55
Router(config-sr-te-pref-const-bounds-type)# commit
```

ODN SR Policy

SR ODN Policy – An SR ODN policy with color 1000 is created. Also, the candidate-paths value is on-demand.

```
Router# configure terminal
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# on-demand color 1000 dynamic metric type te
Router(config-sr-te)# candidate-paths on-demand
Router(config-sr-te-candidate-path-type)# exit
Router(config-sr-te-candidate-path)# exit
```

Cumulative Metric bounds – IGP, TE, hop count, and latency metric bounds are set for the policy. SRTE calculates paths, only when each criterion is satisfied.

```
Router(config-sr-te)# on-demand color 1000 dynamic bounds cumulative
Router(config-sr-te-odc-bounds-type)# type igp 100
Router(config-sr-te-odc-bounds-type)# type te 60
Router(config-sr-te-odc-bounds-type)# type hopcount 6
Router(config-sr-te-odc-bounds-type)# type latency 1000
Router(config-sr-te-odc-bounds-type)# commit
```

To set the maximum number of attempts for computing paths that satisfy the cumulative metric bounds criteria, use the **kshortest-paths** command.

```
Router# configure terminal
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# kshortest-paths 120
Router(config-sr-te)# commit
```

Verification

Use this command to view SR policy configuration details. Pointers:

- The **Number of K-shortest-paths** field displays 4. It means that the K-shortest path algorithm took 4 computations to find the right path. The 4 shortest paths that are computed using K-shortest path algorithm did not respect the cumulative bounds. The fifth shortest path is valid against the bounds.
- The values for the metrics of the actual path (**TE, IGP, Cumulative Latency** and **Hop count** values in the **Dynamic** section) are within the configured cumulative metric bounds.

```
Router# show segment-routing traffic-eng policy color 2

SR-TE BGP Soft Next-Hop Validation For ODN Policies

Table 65: Feature History Table

Feature Name	Release Information	Feature Description
SR-TE BGP Soft Next-Hop Validation For ODN Policies	Release 7.3.2	<p>This feature addresses BGP Next-Hop reachability issues through BGP Next-Hop <i>soft</i> validation, and also enhances BGP best path selection.</p> <p>New commands:</p> <ul style="list-style-type: none"> • nexthop validation color-extcomm disable • nexthop validation color-extcomm sr-policy • bgp bestpath igp-metric sr-policy

Before a BGP router installs a route in the routing table, it checks its own reachability to the Next-Hop (NH) IP address of the route. In an SR-TE domain, a NH address may not be redistributed within the AS, or to a neighbor AS. So, BGP cannot reach the NH, and does not install the corresponding route into the routing table. The following workarounds are available, but they are tedious and might impact scalability:

1. Enable a non-default, static route to null0 covering the routes

2. Inject the routes into BGP using BGP-Labeled Unicast configuration
3. Redistribute routes between IGP domains

This feature introduces a more optimal design and solution - When you enable an SR policy on the SR-TE headend router, configure the `nexthop validation color-extcomm sr-policy` command in BGP configuration mode. It instructs BGP that, instead of NH reachability validation of BGP routes, the validation is done for SR policy-installed color NH addresses. When the NH address of such a route is reachable, the route is added to the routing table.

Also, this configuration on the ingress/headend PE router reduces the route scale for NH reachability, and service (VPN) routes automatically get NH reachability.

RR configuration – For intermediate router configuration, enable the RR with the `nexthop validation color-extcomm disable` command. When enabled, and L3VPN prefixes are associated with a color ID, BGP skips NH validation on the RR.

When the RR has no reachability to the color-extcomm NH, either enable this command, or use a legacy static route.

The following sequence occurs when the headend router receives L3VPN prefixes based on a color ID such as purple, green, etc.

1. The router checks/learns the local SR policy, or requests the ODN SR policy for color ID and NH
2. BGP does validation of the SR policy routes' NH addresses and applies the corresponding NH AD/metric. For a NH with a specific BGP-based color attribute, SR-PCE provides the AD/metric

With BGP NH reachability, traffic is transported smoothly

3. On the RR, BGP does not validate NH reachability

BGP Best Path Selection Based On SR Policy Effective Metric

BGP uses an algorithm to select the best path for installing the route in the RIB or for making a choice of which BGP path to propagate. At a certain point in the process, if there is IGP reachability to a BGP NH address, the algorithm chooses the path with the lowest IGP metric as the best path. The SR Policy path metric is not considered even if it has a better metric. This feature addresses the issue.

To ensure that BGP prefers the SR policy path metric over the IGP metric, enable `bgp bestpath igp-metric sr-policy` in BGP configuration mode.

Configurations

Configuring BGP Soft Next-Hop Validation (Headend Router)

```
Headend # configure
Headend (config) # router bgp 100
Headend (config-bgp) # nexthop validation color-extcomm sr-policy
Headend (config-bgp) # commit
Headend (config-bgp) # end
```

Configuring BGP Soft Next-Hop Validation (Route Reflector)

```
RR # configure
RR (config) # router bgp 100
RR (config-bgp) # nexthop validation color-extcomm disable
RR (config-bgp) # commit
RR (config-bgp) # end
```

Configuring BGP Best Path Selection Based on SR Policy Metric (Headend Router)

```
Headend # configure
Headend (config) # router bgp 100
Headend (config-bgp) # bgp bestpath igp-metric sr-policy
Headend (config-bgp) # commit
Headend (config-bgp) # end
```

Verification

Use this command to view BGP Soft Next-Hop Validation details.

```
Headend # show bgp process detail | i Nexthop
Use SR-Policy admin/metric of color-extcomm Nexthop during path comparison: enabled ExtComm
Color Nexthop validation: SR-Policy then RIB
```

Use this command to view BGP Best Path Selection Based on SR Policy Metric.

```
Headend # show bgp vrf VRF1002 ipv4 unicast 207.77.2.0

Details

- **10.1.1.33 C:1129** - BGP path is selected based on the SR policy with color ID C:1129
- If no SR policy is up, or if the SR policy metric is not configured, only the RIB metric is displayed
- **admin 20** and **metric 25** are SR policy references

SR-TE Policy Path Types

Table 66: Feature History Table

Feature Name	Release Information	Feature Description
SR-Policy (Explicit, Dynamic, affinity)	Release 7.3.1	This feature is now supported on routers that have the Cisco NC57 line cards installed and operate in native mode. To enable the native mode, use the hw-module profile npu native-mode-enable command in the configuration mode. Ensure that you reload the router after configuring the native mode.

A **dynamic** path is based on an optimization objective and a set of constraints. The head-end computes a solution, resulting in a SID-list or a set of SID-lists. When the topology changes, a new path is computed. If the head-end does not have enough information about the topology, the head-end might delegate the computation to a Segment Routing Path Computation Element (SR-PCE). For information on configuring SR-PCE, see *Configure Segment Routing Path Computation Element* chapter.

An **explicit** path is a specified SID-list or set of SID-lists.

An SR-TE policy initiates a single (selected) path in RIB/FIB. This is the preferred valid candidate path. A path is selected when the path is valid and its preference is the best among all candidate paths for that policy.

Note The protocol of the source is not relevant in the path selection logic.

A candidate path has the following characteristics:

- It has a preference – If two policies have the same {color, endpoint} but different preferences, the policy with the highest preference is selected.
- It is associated with a single binding SID (BSID) – A BSID conflict occurs when there are different SR policies with the same BSID. In this case, the policy that is installed first gets the BSID and is selected.
- It is valid if it is usable.

Dynamic Paths

Behaviors and Limitations

For a dynamic path that traverses a specific interface between nodes (segment), the algorithm may encode this segment using an Adj-SID. The SR-TE process prefers the protected Adj-SID of the link, if one is available. In addition, the SR-TE process prefers a manual protected Adj-SID over a dynamic protected Adj-SID.

You can configure the path to prefer the protected or unprotected Adj-SID, or to use only protected or unprotected Adj-SID. See [Segment Protection-Type Constraint, on page 415](#).

Optimization Objectives

Optimization objectives allow the head-end router to compute a SID-list that expresses the shortest dynamic path according to the selected metric type:

- IGP metric — Refer to the "Implementing IS-IS" and "Implementing OSPF" chapters in the *Routing Configuration Guide for Cisco NCS 5500 Series Routers*.
- TE metric — See the [Configure Interface TE Metrics, on page 412](#) section for information about configuring TE metrics.

This example shows a dynamic path from head-end router 1 to end-point router 3 that minimizes IGP or TE metric:

Default IGP link metric: I:10
Default TE link metric T:10

520018

- The blue path uses the minimum IGP metric: Min-Metric (1 → 3, IGP) = SID-list <16003>; cumulative IGP metric: 20
- The green path uses the minimum TE metric: Min-Metric (1 → 3, TE) = SID-list <16005, 16004, 16003>; cumulative TE metric: 23

Configure Interface TE Metrics

Use the **metric value** command in SR-TE interface submode to configure the TE metric for interfaces. The *value* range is from 0 to 2147483647.

```

Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# interface type interface-path-id
Router(config-sr-te-if)# metric value

```

Configuring TE Metric: Example

The following configuration example shows how to set the TE metric for various interfaces:

```

segment-routing
traffic-eng
interface TenGigE0/0/0/0
metric 100

```

```

!
interface TenGigE0/0/0/1
 metric 1000
!
interface TenGigE0/0/2/0
 metric 50
!
!
end

```

Constraints

Constraints allow the head-end router to compute a dynamic path according to the selected metric type:

- **Affinity** — You can apply a color or name to links or interfaces by assigning affinity bit-maps to them. You can then specify an affinity (or relationship) between an SR policy path and link colors. SR-TE computes a path that includes or excludes links that have specific colors, or combinations of colors. See the [Named Interface Link Admin Groups and SR-TE Affinity Maps, on page 413](#) section for information on named interface link admin groups and SR-TE Affinity Maps.
- **Disjoint** — SR-TE computes a path that is disjoint from another path in the same disjoint-group. Disjoint paths do not share network resources. Path disjointness may be required for paths between the same pair of nodes, between different pairs of nodes, or a combination (only same head-end or only same end-point).
- **Flexible Algorithm** — Flexible Algorithm allows for user-defined algorithms where the IGP computes paths based on a user-defined combination of metric type and constraint.
- **Protection type** — For a dynamic path that traverses a specific interface between nodes (segment), or for an explicit path using IP addresses of intermediate links, the algorithm may encode this segment using an Adj-SID. You can specify the path to prefer protected or unprotected Adj-SIDs, or to use only protected or unprotected Adj-SIDs. See [Segment Protection-Type Constraint, on page 415](#) for information about configuring the protection type.

Named Interface Link Admin Groups and SR-TE Affinity Maps

Named Interface Link Admin Groups and SR-TE Affinity Maps provide a simplified and more flexible means of configuring link attributes and path affinities to compute paths for SR-TE policies.

In the traditional TE scheme, links are configured with attribute-flags that are flooded with TE link-state parameters using Interior Gateway Protocols (IGPs), such as Open Shortest Path First (OSPF).

Named Interface Link Admin Groups and SR-TE Affinity Maps let you assign, or map, up to 256 color names for affinity and attribute-flag attributes instead of 32-bit hexadecimal numbers. After mappings are defined, the attributes can be referred to by the corresponding color name in the CLI. Furthermore, you can define constraints using *include-any*, *include-all*, and *exclude-any* arguments, where each statement can contain up to 10 colors.

Note

You can configure affinity constraints using attribute flags or the Flexible Name Based Policy Constraints scheme; however, when configurations for both schemes exist, only the configuration pertaining to the new scheme is applied.

Configure Named Interface Link Admin Groups and SR-TE Affinity Maps

Use the **affinity name NAME** command in SR-TE interface submode to assign affinity to interfaces. Configure this on routers with interfaces that have an associated admin group attribute.

```
Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# interface TenGigE0/0/1/2
Router(config-sr-if)# affinity
Router(config-sr-if-affinity)# name RED
```

Use the **affinity-map name NAME bit-position bit-position** command in SR-TE sub-mode to define affinity maps. The *bit-position* range is from 0 to 255.

Configure affinity maps on the following routers:

- Routers with interfaces that have an associated admin group attribute.
- Routers that act as SR-TE head-ends for SR policies that include affinity constraints.

```
Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# affinity-map
Router(config-sr-te-affinity-map)# name RED bit-position 23
```

Configuring Link Admin Group: Example

The following example shows how to assign affinity to interfaces and to define affinity maps. This configuration is applicable to any router (SR-TE head-end or transit node) with colored interfaces.

```
segment-routing
traffic-eng
interface TenGigE0/0/1/1
  affinity
    name CROSS
    name RED
  !
!
interface TenGigE0/0/1/2
  affinity
    name RED
  !
!
interface TenGigE0/0/2/0
  affinity
    name BLUE
  !
!
affinity-map
  name RED bit-position 23
  name BLUE bit-position 24
  name CROSS bit-position 25
!
end
```

Segment Protection-Type Constraint

Table 67: Feature History Table

Feature Name	Release Information	Feature Description
Segment Protection-Type Constraint	Release 7.4.1	<p>This feature introduces the ability to control whether protected or unprotected segments are used when encoding the SID-list of an SR policy candidate path.</p> <p>The types of segments that could be used when building a SID-list include prefix SIDs and adjacency SIDs.</p>

This feature introduces the ability to control whether protected or unprotected segments are used when encoding the SID-list of an SR policy candidate path. The types of segments that could be used when building a SID-list include prefix SIDs and adjacency SIDs.

A prefix SID is a global segment representing a prefix that identifies a specific node. A prefix SID is programmed with a backup path computed by the IGP using TI-LFA.

An adjacency SID is a local segment representing an IGP adjacency. An adjacency SID can be programmed with or without protection. Protected adjacency SIDs are programmed with a link-protectant backup path computed by the IGP (TI-LFA) and are used if the link associated with the IGP adjacency fails.

Prefix SIDs and adjacency SIDs can be leveraged as segments in a SID-list in order to forward a packet along a path traversing specific nodes and/or over specific interfaces between nodes. The type of segment used when encoding the SID-list will determine whether failures along the path would be protected by TI-LFA. Depending on the offering, an operator may want to offer either unprotected or protected services over traffic engineered paths.

The following behaviors are available with the segment protection-type constraint:

- **protected-only** — The SID-list must be encoded using protected segments.
- **protected-preferred** — The SID-list should be encoded using protected segments if available; otherwise, the SID-list may be encoded using unprotected Adj-SIDs. This is the default behavior when no segment protection-type constraint is specified.
- **unprotected-only** — The SID-list must be encoded using unprotected Adj-SID.
- **unprotected-preferred** — The SID-list should be encoded using unprotected Adj-SID if available, otherwise SID-list may be encoded using protected segments.

Usage Guidelines and Limitations

Observe the following guidelines and limitations for the platform:

- This constraint applies to candidate-paths of manual SR policies with either dynamically computed paths or explicit paths.
- This constraint applies to On-Demand SR policy candidate-paths.

- PCEP has been augmented (vendor-specific object) to allow a PCC to indicate the segment protection-type constraint to the PCE.
- When the segment protection type constraint is protected-only or unprotected-only, the path computation must adhere to the constraint. If the constraint is not satisfied, the SR policy will not come up on such candidate path.
- When the segment protection-type constraint is unprotected-only, the entire SID-list must be encoded with unprotected Adj-SIDs.
- When the segment protection-type constraint is protected-only, the entire SID-list must be encoded with protected Adj-SIDs or Prefix SIDs.

Configuring Segment Protection-Type Constraint

Use the **constraints segments protection** {**protected-only** | **protected-preferred** | **unprotected-only** | **unprotected-preferred**} command to configure the segment protection-type behavior.

The following example shows how to configure the policy with a SID-list that must be encoded using protected segments:

```
Router(config-sr-te)# policy POLICY1
Router(config-sr-te-policy)# color 10 end-point ipv4 10.1.1.4
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 100
Router(config-sr-te-policy-path-pref)# constraints
Router(config-sr-te-path-pref-const)# segments
Router(config-sr-te-path-pref-const-seg)# protection protected-only
```

Configure SR Policy with Dynamic Path

To configure a SR-TE policy with a dynamic path, optimization objectives, and affinity constraints, complete the following configurations:

1. Define the optimization objectives. See the [Optimization Objectives, on page 412](#) section.
2. Define the constraints. See the [Constraints, on page 413](#) section.
3. Create the policy.

Behaviors and Limitations

You can configure the path to prefer protected or unprotected segments, or to use only protected or unprotected segments.

Examples

The following example shows a configuration of an SR policy at an SR-TE head-end router. The policy has a dynamic path with optimization objectives and affinity constraints computed by the head-end router.

```
segment-routing
traffic-eng
policy foo
color 100 end-point ipv4 10.1.1.2
candidate-paths
preference 100
dynamic
metric
```

```

        type te
        !
        !
        constraints
        affinity
        exclude-any
        name RED
        !
        !
        !
        !
        !
        !

```

The following example shows a configuration of an SR policy at an SR-TE head-end router. The policy has a dynamic path with optimization objectives and affinity constraints computed by the SR-PCE.

```

Anycast SID-Aware Path Computation

This feature allows the SR-TE head-end or SR-PCE to compute a path that is encoded using Anycast prefix SIDs of nodes along the path.

An Anycast SID is a type of prefix SID that identifies a set of nodes and is configured with n-flag clear. The set of nodes (Anycast group) is configured to advertise a shared prefix address and prefix SID. Anycast routing enables the steering of traffic toward multiple advertising nodes, providing load-balancing and redundancy. Packets addressed to an Anycast address are forwarded to the topologically nearest nodes.

For more information about this feature, see the *Anycast SID-Aware Path Computation* topic in the *Configure Segment Routing Path Computation Element* chapter.

Note For information on configuring Anycast SID, see [Configuring a Prefix-SID on the IS-IS Enabled Loopback Interface, on page 286](#) and [Configuring a Prefix-SID on the OSPF-Enabled Loopback Interface, on page 316](#).

Explicit Paths

SR-TE Policy with Explicit Path

Table 68: Feature History Table

Feature Name	Release Information	Feature Description
SR-TE Explicit Segment Lists with Mix of IPv4 and IPv6 Segments	Release 7.9.1	<p>This feature allows you to configure an explicit segment list with IPv4 addresses and include an IPv6 address as a non-first SID.</p> <p>You can thus deploy a centralized BGP EPE solution for 6PE in an SR-MPLS network where the last segment is associated with an EPE-enabled BGPv6 neighbor.</p>

An explicit segment list is defined as a sequence of one or more segments. A segment can be configured as an IP address or an MPLS label representing a node or a link.

An explicit segment list can be configured with the following:

- IP-defined segments
- MPLS label-defined segments
- A combination of IP-defined segments and MPLS label-defined segments

Usage Guidelines and Limitations

- An IP-defined segment can be associated with an IPv4 or IPv6 address (for example, a link or a Loopback address).
- An IPv6 address cannot be the first segment of the segment list.
 - A segment defined with an IPv6 address (for example, IPv6 EPE SID) enables use-cases such as [centralized BGP EPE for 6PE in an SR-MPLS network](#) where the last segment of the explicit segment list is associated with an EPE-enabled BGPv6 neighbor.
- The BGP prefix SID label of an IPv4 /32 prefix learned via BGP-LU can be configured as the first segment of an explicit segment-list (see [Explicit Path with a BGP Prefix SID as First Segment, on page 423](#)).
 - The segment must be specified as an MPLS label (the local BGP-LU label allocated at the head-end for the target prefix).
 - The next-hop of the BGP Prefix SID advertisement must be reachable over a unipath route (either BGP loopback-peering reachable over unipath, or BGP interface-peering).
- When a segment of the segment list is defined as an MPLS label, subsequent segments can only be configured as MPLS labels.

- Prior to Cisco IOS XR release 7.2.1, a segment of an explicit segment list can be configured as an IPv4 address (representing a Node or a Link) using the **index index address ipv4 address** command.

Starting with Cisco IOS XR release 7.2.1, an IPv4-based segment (representing a Node or a Link) can also be configured with the new **index index mpls adjacency address** command. The configuration is stored in NVRAM in the same CLI format used to create it. There is no conversion from the old CLI to the new CLI.

Starting with Cisco IOS XR release 7.9.1, the old CLI has been deprecated. Old configurations stored in NVRAM will be rejected at boot-up.

As a result, explicit segment lists with IPv4-based segments using the old CLI must be re-configured using the new CLI.

There are no CLI changes for segments configured as MPLS labels using the **index index mpls label label** command.

- You can configure the path to prefer the protected or unprotected Adj-SID, or to use only protected or unprotected Adj-SID. See [Segment Protection-Type Constraint](#), on page 415.

Configure Local SR-TE Policy Using Explicit Paths

To configure an SR-TE policy with an explicit path, complete the following configurations:

1. Create the segment list.
2. Create the SR-TE policy.

Create a segment list with IPv4 addresses:

```
Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# segment-list name SIDLIST1
Router(config-sr-te-sl)# index 10 mpls adjacency 10.1.1.2
Router(config-sr-te-sl)# index 20 mpls adjacency 10.1.1.3
Router(config-sr-te-sl)# index 30 mpls adjacency 10.1.1.4
Router(config-sr-te-sl)# exit
```

Create a segment list with MPLS labels:

```
Router(config-sr-te)# segment-list name SIDLIST2
Router(config-sr-te-sl)# index 10 mpls label 16002
Router(config-sr-te-sl)# index 20 mpls label 16003
Router(config-sr-te-sl)# index 30 mpls label 16004
Router(config-sr-te-sl)# exit
```

Create a segment list with IPv4 addresses and MPLS labels:

```
Router(config-sr-te)# segment-list name SIDLIST3
Router(config-sr-te-sl)# index 10 mpls adjacency 10.1.1.2
Router(config-sr-te-sl)# index 20 mpls label 16003
Router(config-sr-te-sl)# index 30 mpls label 16004
Router(config-sr-te-sl)# exit
```

Create a segment list with IPv4 and IPv6 addresses:

```

Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# segment-list name SIDLIST4
Router(config-sr-te-sl)# index 10 mpls adjacency 10.1.1.2
Router(config-sr-te-sl)# index 20 mpls adjacency 10.1.1.3
Router(config-sr-te-sl)# index 30 mpls adjacency 10.1.1.4
Router(config-sr-te-sl)# index 40 mpls adjacency 2001:db8:10:1:1::100
Router(config-sr-te-sl)# exit

```

Create the SR-TE policy:

```

Router(config-sr-te)# policy POLICY2
Router(config-sr-te-policy)# color 20 end-point ipv4 10.1.1.4
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 200
Router(config-sr-te-policy-path-pref)# explicit segment-list SIDLIST2
Router(config-sr-te-pp-info)# exit
Router(config-sr-te-policy-path-pref)# exit
Router(config-sr-te-policy-path)# preference 100
Router(config-sr-te-policy-path-pref)# explicit segment-list SIDLIST1
Router(config-sr-te-pp-info)# exit
Router(config-sr-te-policy-path-pref)# exit

```

Running Configuration

```

Router# show running-configuration

segment-routing
traffic-eng
segment-list SIDLIST1
index 10 mpls adjacency 10.1.1.2
index 20 mpls adjacency 10.1.1.3
index 30 mpls adjacency 10.1.1.4
!
segment-list SIDLIST2
index 10 mpls label 16002
index 20 mpls label 16003
index 30 mpls label 16004
!
segment-list SIDLIST3
index 10 mpls adjacency 10.1.1.2
index 20 mpls label 16003
index 30 mpls label 16004
!
segment-list SIDLIST4
index 10 mpls adjacency 10.1.1.2
index 20 mpls adjacency 10.1.1.3
index 30 mpls adjacency 10.1.1.4
index 40 mpls adjacency 2001:db8:10:1:1::100
!
policy POLICY2
color 20 end-point ipv4 10.1.1.4
candidate-paths

Verification

Improved Segment List Information for Inactive or Invalid Policies

Feature Name	Release Information	Description
Improved Segment List Information for Inactive or Invalid Policies	Release 7.3.3	This feature provides for displaying detailed segment list information, and also lists information on invalid and inactive policies. This allows you to determine if the policies have been received correctly, to the SR-TE policies with explicit path.

This feature provides for displaying detailed segment list information. This is in addition to the current behavior of displaying segment list information from active policies. For active candidate paths, the status of segment list will either be valid or invalid. If the segment list is invalid, the reason for its invalidity along with the entire label/IP stack of segment list is displayed. For inactive candidate paths, the status of segment list will always be inactive. Since the validity of segment list under inactive path is not checked, it is always displayed inactive.

Verify the SR-TE policy configuration using:

```
Router# show segment-routing traffic-eng policy name srte_c_20_ep_10.1.1.4
```

```
SR-TE policy database

Explicit Path with a BGP Prefix SID as First Segment

Table 69: Feature History Table

Feature Name	Release Information	Feature Description
SR-TE Explicit Path with a BGP Prefix SID as First Segment	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>This feature allows you to configure an SR-TE policy with an explicit path that uses a remote BGP prefix SID as its first segment. This path is achieved by leveraging the recursive resolution of the first SID, which is a BGP-Label Unicast (BGP-LU) SID. BGP-LU labels are used as the first SID in the SR policy to determine the egress paths for the traffic and program the SR-TE forwarding chain accordingly.</p> <p>This allows users to enable Segment Routing to leverage their existing BGP infrastructure and integrate it with the required Segment Routing functionalities.</p>

The figure below shows a network setup where a PE router (PE1) is using BGP-SR as the routing protocol and is connected to a classic BGP-LU domain. The classic BGP-LU domain is also connected to other domains running BGP-SR.

In BGP-SR, a BGP Prefix-SID is advertised along with a prefix in BGP Labeled Unicast (BGP-LU). This Prefix-SID attribute contains information about the label value and index for the route. This allows for interworking between the classic BGP-LU and BGP-SR domains.

The figure below illustrates a best-effort BGP-LU Label Switched Path (LSP) from PE1 to PE6, passing through transit Label Switching Router (LSR) nodes 2, 3, and 5.

With this setup, the operator can create an alternate path using an SR-TE policy at the ingress BGP-SR PE (PE1). The explicit path for this alternate path will follow a different transit node, using the BGP prefix SID for that transit node as the first segment.

For example, in the figure below, the SID-list shows that the explicit path uses the BGP prefix SID of transit LSR node 4 (16004) followed by the BGP prefix SID of PE6 (16006). The PE1 router resolves the first segment of this explicit path to the outgoing interface towards Node 2, using the outgoing label advertised by Node 2 for the BGP-LU prefix 10.1.1.4/32.

Limitations for explicit Path with a BGP prefix SID as first segment

- SR-TE explicit path with a BGP prefix SID as the first segment does not support BGP peering on loopback interfaces. It is recommended to use interface peering for BGP sessions.

Example

The following output shows the BGP-LU routes learned at the head-end (PE1 in the illustration above). Consider the IP prefix 1.1.1.4/32. A BGP-LU local label is assigned from the SRGB with a prefix SID index of 4, resulting in the value 16004. Additionally, the classic BGP-LU upstream neighbor (P2) advertises an outgoing label of 78000 for this IP prefix.

Configuring Explicit Path with Affinity Constraint Validation

To fully configure SR-TE flexible name-based policy constraints, you must complete these high-level tasks in order:

1. Assign Color Names to Numeric Values
2. Associate Affinity-Names with SR-TE Links
3. Associate Affinity Constraints for SR-TE Policies

```

/* Enter the global configuration mode and assign color names to numeric values
Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# affinity-map
Router(config-sr-te-affinity-map)# blue bit-position 0
Router(config-sr-te-affinity-map)# green bit-position 1
Router(config-sr-te-affinity-map)# red bit-position 2
Router(config-sr-te-affinity-map)# exit

/* Associate affinity-names with SR-TE links
Router(config-sr-te)# interface Gi0/0/0/0
Router(config-sr-te-if)# affinity
Router(config-sr-te-if-affinity)# blue
Router(config-sr-te-if-affinity)# exit
Router(config-sr-te-if)# exit
Router(config-sr-te)# interface Gi0/0/0/1
Router(config-sr-te-if)# affinity
Router(config-sr-te-if-affinity)# blue
Router(config-sr-te-if-affinity)# green
Router(config-sr-te-if-affinity)# exit
Router(config-sr-te-if)# exit
Router(config-sr-te)#

/* Associate affinity constraints for SR-TE policies

```

```
Router(config-sr-te)# segment-list name SIDLIST1
Router(config-sr-te-sl)# index 10 mpls adjacency 10.1.1.2
Router(config-sr-te-sl)# index 20 mpls adjacency 2.2.2.23
Router(config-sr-te-sl)# index 30 mpls adjacency 10.1.1.4
Router(config-sr-te-sl)# exit
Router(config-sr-te)# segment-list name SIDLIST2
Router(config-sr-te-sl)# index 10 mpls adjacency 10.1.1.2
Router(config-sr-te-sl)# index 30 mpls adjacency 10.1.1.4
Router(config-sr-te-sl)# exit
Router(config-sr-te)# segment-list name SIDLIST3
Router(config-sr-te-sl)# index 10 mpls adjacency 10.1.1.5
Router(config-sr-te-sl)# index 30 mpls adjacency 10.1.1.4
Router(config-sr-te-sl)# exit

Router(config-sr-te)# policy POLICY1
Router(config-sr-te-policy)# color 20 end-point ipv4 10.1.1.4

Configure Explicit Path with Segment Protection-Type Constraint

For an SR policy with an explicit path that includes IP addresses of links, the SR-TE process encodes these segments using the corresponding adjacency SID (Adj-SID) for each link. The type of Adj-SID used (protected or unprotected) is determined by the segment protection-type constraint configured under the SR policy. See the [Segment Protection-Type Constraint, on page 415](#).

Configure Local SR-TE Policy Using Explicit Paths

Create a segment list with IP addresses:

```
Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# segment-list name SIDLIST1
Router(config-sr-te-sl)# index 10 mpls adjacency 10.1.1.2
Router(config-sr-te-sl)# index 20 mpls adjacency 10.1.1.3
Router(config-sr-te-sl)# index 30 mpls adjacency 10.1.1.4
Router(config-sr-te-sl)# exit
```

Create the SR-TE policy with segment protection-type constraint:

```
Router(config-sr-te)# policy POLICY1
Router(config-sr-te-policy)# color 20 end-point ipv4 10.1.1.4
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 100
Router(config-sr-te-policy-path-pref)# explicit segment-list SIDLIST1
Router(config-sr-te-pp-info)# exit
Router(config-sr-te-policy-path-pref)# constraints
Router(config-sr-te-path-pref-const)# segments
Router(config-sr-te-path-pref-const-seg)# protection protected-only
```

```
Router(config-sr-te-path-pref-const-seg) # commit
```

Running Configuration

```
Router# show running-configuration  
segment-routing  
traffic-eng  
  segment-list SIDLIST1  
    index 10 mpls adjacency 10.1.1.2  
    index 20 mpls adjacency 10.1.1.3  
    index 30 mpls adjacency 10.1.1.4  
  !

    !  
    constraints  
      segments  
        protection protected-only  
    !  
  !  
!
```

SR-TE policy with enhanced flexible algorithm metric types

Table 70: Feature History Table

Feature Name	Release Information	Feature Description
SR-TE policy with enhanced flexible algorithm metric types	Release 24.4.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>We have enhanced the SR-TE policy at headend with flexible algorithm that supports additional metric types, user-defined and bandwidth, ensuring consistent path computation across flexible algorithm metric types and constraints, on both intra-IGP and inter-IGP domains. The feature also supports headend computed inter-domain SR policies with Flex Algo constraints and IGP redistribution or leaking.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> The flex-algo-metric-type keyword is introduced in the effective-metric admin-distance command. <p>YANG Data Models:</p> <ul style="list-style-type: none"> New Xpaths are introduced for <code>Cisco-IOS-XR-segment-routing-ms-cfg.yang</code> (see GitHub, YANG Data Models Navigator)

Automated traffic steering in SR-MPLS

In SR-MPLS, automated traffic steering over flex-algo (FA) requires a Segment Routing Traffic Engineering (SR-TE) policy on the ingress PE (SR-TE Headend) to provide the FA path to the destination node. The service traffic is then steered over the SR-TE policy. Metric type, constraints, and other attributes for FA are configured in IGP. IGP computes and installs a route in RIB for the destination prefix along with the list of FA SIDs associated to the prefix and the corresponding metric for each FA SID. From IOS-XR Release 24.4.1, instead of performing path computation at the headend, the route information provided by IGP is utilized at the headend to determine the optimum path for routing.

To facilitate the usage of route information from IGP, SR-TE policy definition at SR-TE headend with FA now supports additional metric types, generic and bandwidth metric types. This ensures that any new metric or constraints added to FA in IGP is consistently used in SR-TE headend as well.

You can optionally adjust the default Administrative Distance (AD) for different metric types within SR-TE. The metric types available for configuration include IGP, TE, latency, bandwidth, and user-defined metric types. With optimal configuration of AD for specific metric types, you can ensure more precise routing decisions based on specific metrics, and enhanced control over path selection and traffic engineering. The augmented path computation procedure performs irrespective of the SR-TE policy being intra-IGP or inter-IGP domain.

Enhancements in SR-TE policy for improved metric support and path computation

To facilitate the usage of route information from IGP, SR-TE policy definition at SR-TE headend with FA now supports additional metric types, generic and bandwidth metric types. This ensures that any new metric or constraints added to FA in IGP is consistently used in SR-TE headend as well.

You can optionally adjust the default Administrative Distance (AD) for different metric types within SR-TE. The metric types available for configuration include IGP, TE, latency, bandwidth, and user-defined metric types. With optimal configuration of AD for specific metric types, you can ensure more precise routing decisions based on specific metrics, and enhanced control over path selection and traffic engineering. The augmented path computation procedure performs irrespective of the SR-TE policy being intra-IGP or inter-IGP domain.

Inter-IGP domain path computation is supported using either leaked or redistributed prefixes.

Inter-IGP domain with redistributed IPv4 and IPv6 prefixes between IGP instances

This involves sharing prefixes between different IGP instances, which could be different routing protocols or different instances of the same protocol.

Redistribution is the process of taking routes learned by one IGP and distributing them to another IGP. This allows for connectivity between networks that are running different IGPs.

Inter-IGP domain with leaked IPv4 and IPv6 prefixes between IGP areas

This involves sharing prefixes between different areas within the same IGP instance.

Route leaking is the process of allowing routes from one area to be visible in another area within the same IGP.

Benefits of SR-TE policy with enhanced flexible algorithm metric types

- Instead of using disjoint SR Policies or using FA with affinities to lay out disjoint topologies, you can assign user-defined metric type to the links and specify FA to use the defined metric type. For any given FA, the traffic follows the per-FA shortest path.
- Supports FA-specific AD configuration for IGP, TE, latency, user-defined, and bandwidth metric types.
- Supports SR-TE AD configuration of any newly defined FA metric type in IGP.

Guidelines and restrictions for SR-TE policy with enhanced flexible algorithm metric types

- In the Headend, SR-TE policy can be associated to a Flex-Algo (FA) with any metric type supported in IGP (ISIS or OSPF).
- In PCE, SR-TE policy can only be associated to FA with metric type IGP, TE, latency, or hop count.
- Existing configurations for FA constraints under manual policies and On-Demand Next-hop (ODN) templates remain unaffected.

Configure SR-TE policy with enhanced flexible algorithm metric types

This feature does not introduce or update any mandatory configuration. For details on creating SR-TE policy, see [Instantiation of an SR Policy, on page 370](#).

Procedure

Step 1 Use the following configuration to configure the SR-TE policy.

Example:

```
Router#configure
Router(config)#segment-routing traffic-eng
Router(config-sr-te)#policy policy_v4_igp_metric_0
Router(config-sr-te-policy)#no shutdown
Router(config-sr-te-policy)#binding-sid mpls 37000
Router(config-sr-te-policy)#color 37000 end-point ipv4 10.2.1.1
Router(config-sr-te-policy)#candidate-paths
Router(config-sr-te-policy-path)#preference 200
Router(config-sr-te-policy-path-pref)#dynamic
Router(config-sr-te-path-pref-info)#constraints
Router(config-sr-te-path-pref-const)#segments
Router(config-sr-te-path-pref-const-seg)#sid-algorithm 134
Router(config-sr-te-path-pref-const-seg)#commit
```

Step 2 Use the **show segment-routing traffic-eng policy** command to verify the configuration.

Example:

```
Router#show segment-routing traffic-eng policy
Color: 37000, End-point: 10.2.1.1
Name: srte_c_37000_ep_10.2.1.1
Status:
  Admin: up Operational: up for 00:00:01 (since Jul 28 18:33:58.296)
Candidate-paths:
  Preference: 200 (configuration) (active)
  Name: policy_v4_igp_metric_0
  Requested BSID: 37000
  Constraints:
    Prefix-SID Algorithm: 134
    Protection Type: protected-preferred
    Maximum SID Depth: 8
  Dynamic (valid)
    Metric Type: IGP, Path Accumulated Metric: 50
    SID[0]: 21292 [Prefix-SID: 10.2.1.1, Algorithm: 134]
Attributes:
  Binding SID: 37000
  Forward Class: Not Configured
  Steering labeled-services disabled: no
  Steering BGP disabled: no
  IPv6 caps enable: yes
  Invalidation drop enabled: no
  Max Install Standby Candidate Paths: 0
  Path Type: SRMPLSv4
```

Optional administrative distance configuration for flexible algorithm metric types

These are the guidelines for configuring Administrative Distance (AD).

- The default AD value for different FA metric types is as follows:

Table 71: Default AD value of FA metric types

Metric Type	Default AD Value
IANA-defined metric types 4 to 127	100
bandwidth	50
generic user-defined metric types 128 to 255	60
igp	30
latency	10
te	20

- The default AD value can be overridden by the global SR-TE command, **segment-routing traffic-eng effective-metric admin-distance**.
- The configured AD for IGP, TE, and Latency under *metric-type* applies to both Non-FA and FA policies, where FA is associated with one of these metric types.
- The configured AD for IGP, TE, and Latency metric types under *flex-algo-metric-type* overrides the configured AD for these metric types under *metric-type*.

This table lists the commands and corresponding parameters that help in configuring AD for various SR-TE metric types.

Table 72: Administrative distance configuration options for SR-TE metric types

Command	Keyword	Options for metric type	AD configuration	Additional information
segment-routing traffic-eng effective-metric admin-distance	metric-type	<ul style="list-style-type: none"> • igp • latency • te • unknown 	admin-distance <1-255>	Applicable for FA and non-FA metric types
	flex-algo-metric-type	<ul style="list-style-type: none"> • <4-127> IANA-defined • bandwidth • generic <128-255> user-defined • igp • latency • te 	admin-distance <1-255>	<ul style="list-style-type: none"> • Applicable for FA metric types • flex-algo-metric-type configuration overrides metric-type configuration

Procedure

Step 1 Use the **segment-routing traffic-eng effective-metric** command to configure the AD for SR-TE generic user-defined metric to 120.

Example:

```
Router(config)#segment-routing traffic-eng effective-metric admin-distance flex-algo-metric-type
generic 130 admin-distance 120
Router(config)#commit
```

Step 2 Use the **show segment-routing traffic-eng global** command to verify the administrative distance configuration.

Example:

```
Router#show segment-routing traffic-eng global
Mon Nov 18 06:19:06.831 UTC
Global admin distances
Metric type: NONE      admin distance: 100
Metric type: IGP       admin distance: 30
Metric type: TE        admin distance: 20
Metric type: LATENCY   admin distance: 10
Metric type: HOPCOUNT admin distance: 40

Flex-Algo admin distances
Metric type: IGP       admin distance: 30
Metric type: LATENCY   admin distance: 10
Metric type: TE        admin distance: 20
Metric type: BANDWIDTH admin distance: 50
```

```

Metric type: USER-DEFINED (Default)  admin distance: 60
Metric type: 130                    admin distance: 120
Metric type: UNKNOWN (Default)      admin distance: 100

Next-hop Separation: Disabled
Max Install Standby Candidate Paths: 0

MPLS Label Stack
Maximum Label Stack Limit 12
Number of Recycles: 1
Maximum Label Stack Limit Per Pass: 6
Maximum Label Stack Limit Per Pass with Service Labels: 3

```

Protocols

Path Computation Element Protocol

The path computation element protocol (PCEP) describes a set of procedures by which a path computation client (PCC) can report and delegate control of head-end label switched paths (LSPs) sourced from the PCC to a PCE peer. The PCE can request the PCC to update and modify parameters of LSPs it controls. The stateful model also enables a PCC to allow the PCE to initiate computations allowing the PCE to perform network-wide orchestration.

Configure the Head-End Router as PCEP PCC

Configure the head-end router as PCEP Path Computation Client (PCC) to establish a connection to the PCE. The PCC and PCE addresses must be routable so that TCP connection (to exchange PCEP messages) can be established between PCC and PCE.

Configure the PCC to Establish a Connection to the PCE

Use the **segment-routing traffic-eng pcc** command to configure the PCC source address, the SR-PCE address, and SR-PCE options.

A PCE can be given an optional precedence. If a PCC is connected to multiple PCEs, the PCC selects a PCE with the lowest precedence value. If there is a tie, a PCE with the highest IP address is chosen for computing path. The precedence *value* range is from 0 to 255.

```

Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# pcc
Router(config-sr-te-pcc)# source-address ipv4 local-source-address
Router(config-sr-te-pcc)# pce address ipv4 PCE-address[precedence value]
Router(config-sr-te-pcc)# pce address ipv4 PCE-address[keychain WORD]

```

Configure PCEP Authentication

TCP Message Digest 5 (MD5) authentication has been used for authenticating PCEP (TCP) sessions by using a clear text or encrypted password. This feature introduces support for TCP Authentication Option (TCP-AO), which replaces the TCP MD5 option.

TCP-AO uses Message Authentication Codes (MACs), which provides the following:

- Protection against replays for long-lived TCP connections
- More details on the security association with TCP connections than TCP MD5
- A larger set of MACs with minimal system and operational changes

TCP-AO is compatible with Master Key Tuple (MKT) configuration. TCP-AO also protects connections when using the same MKT across repeated instances of a connection. TCP-AO protects the connections by using traffic key that are derived from the MKT, and then coordinates changes between the endpoints.

Note TCP-AO and TCP MD5 are never permitted to be used simultaneously. TCP-AO supports IPv6, and is fully compatible with the proposed requirements for the replacement of TCP MD5.

TCP Message Digest 5 (MD5) Authentication

Use the **password {clear | encrypted} LINE** command to enable TCP MD5 authentication for all PCEP peers. Any TCP segment coming from the PCC that does not contain a MAC matching the configured password will be rejected. Specify if the password is encrypted or clear text

```
Router(config-sr-te-pcc)# pce address ipv4 PCE-address [password {clear | encrypted} LINE]
```

TCP Authentication Option (TCP-AO)

Use the **tcp-ao key-chain [include-tcp-options]** command to enable TCP Authentication Option (TCP-AO) authentication for all PCEP peers. Any TCP segment coming from the PCC that does not contain a MAC matching the configured key chain will be rejected. Use the **include-tcp-options** keyword to include other TCP options in the header for MAC calculation.

```
Router(config-sr-te-pcc)# pce address ipv4 PCE-address tcp-ao key-chain [include-tcp-options]
```

Configure PCEP-Related Timers

Use the **timers keepalive** command to specify how often keepalive messages are sent from PCC to its peers. The range is from 0 to 255 seconds; the default value is 30.

```
Router(config-sr-te-pcc)# timers keepalive seconds
```

Use the **timers deadtimer** command to specify how long the remote peers wait before bringing down the PCEP session if no PCEP messages are received from this PCC. The range is from 1 to 255 seconds; the default value is 120.

```
Router(config-sr-te-pcc)# timers deadtimer seconds
```

Use the **timers delegation-timeout** command to specify how long a delegated SR policy can remain up without an active connection to a PCE. The range is from 0 to 3600 seconds; the default value is 60.

```
Router(config-sr-te-pcc)# timers delegation-timeout seconds
```

PCE-Initiated SR Policy Timers

Use the **timers initiated orphans** command to specify the amount of time that a PCE-initiated SR policy will remain delegated to a PCE peer that is no longer reachable by the PCC. The range is from 10 to 180 seconds; the default value is 180.

```
Router(config-sr-te-pcc) # timers initiated orphans seconds
```

Use the **timers initiated state** command to specify the amount of time that a PCE-initiated SR policy will remain programmed while not being delegated to any PCE. The range is from 15 to 14440 seconds (24 hours); the default value is 600.

```
Router(config-sr-te-pcc) # timers initiated state seconds
```

To better understand how the PCE-initiated SR policy timers operate, consider the following example:

- PCE A instantiates SR policy P at head-end N.
- Head-end N delegates SR policy P to PCE A and programs it in forwarding.
- If head-end N detects that PCE A is no longer reachable, then head-end N starts the PCE-initiated **orphan** and **state** timers for SR policy P.
- If PCE A reconnects before the **orphan** timer expires, then SR policy P is automatically delegated back to its original PCE (PCE A).
- After the **orphan** timer expires, SR policy P will be eligible for delegation to any other surviving PCE(s).
- If SR policy P is not delegated to another PCE before the **state** timer expires, then head-end N will remove SR policy P from its forwarding.

Enable SR-TE SYSLOG Alarms

Use the **logging policy status** command to enable SR-TE related SYSLOG alarms.

```
Router(config-sr-te) # logging policy status
```

Enable PCEP Reports to SR-PCE

Use the **report-all** command to enable the PCC to report all SR policies in its database to the PCE.

```
Router(config-sr-te-pcc) # report-all
```

Customize MSD Value at PCC

Use the **maximum-sid-depth value** command to customize the Maximum SID Depth (MSD) signaled by PCC during PCEP session establishment.

The default MSD *value* is equal to the maximum MSD supported by the platform (12).

```
Router(config-sr-te) # maximum-sid-depth value
```

Note The platform's SR-TE label imposition capabilities are as follows:

- Up to 12 transport labels when no service labels are imposed
- Up to 9 transport labels when service labels are imposed

For cases with path computation at PCE, a PCC can signal its MSD to the PCE in the following ways:

- During PCEP session establishment – The signaled MSD is treated as a node-wide property.

- MSD is configured under **segment-routing traffic-eng maximum-sid-depth** *value* command
- During PCEP LSP path request – The signaled MSD is treated as an LSP property.
 - On-demand (ODN) SR Policy: MSD is configured using the **segment-routing traffic-eng on-demand color** *color* **maximum-sid-depth** *value* command
 - Local SR Policy: MSD is configured using the **segment-routing traffic-eng policy** *WORD* **candidate-paths preference** *preference* **dynamic metric sid-limit** *value* command.

Note If the configured MSD values are different, the per-LSP MSD takes precedence over the per-node MSD.

After path computation, the resulting label stack size is verified against the MSD requirement.

- If the label stack size is larger than the MSD and path computation is performed by PCE, then the PCE returns a "no path" response to the PCC.
- If the label stack size is larger than the MSD and path computation is performed by PCC, then the PCC will not install the path.

Note A sub-optimal path (if one exists) that satisfies the MSD constraint could be computed in the following cases:

- For a dynamic path with TE metric, when the PCE is configured with the **pce segment-routing te-latency** command or the PCC is configured with the **segment-routing traffic-eng te-latency** command.
- For a dynamic path with LATENCY metric
- For a dynamic path with affinity constraints

For example, if the PCC MSD is 4 and the optimal path (with an accumulated metric of 100) requires 5 labels, but a sub-optimal path exists (with accumulated metric of 110) requiring 4 labels, then the sub-optimal path is installed.

Customize the SR-TE Path Calculation

Use the **te-latency** command to enable ECMP-aware path computation for TE metric.

```
Router(config-sr-te) # te-latency
```

Note ECMP-aware path computation is enabled by default for IGP and LATENCY metrics.

Configure PCEP Redundancy Type

Use the **redundancy pcc-centric** command to enable PCC-centric high-availability model. The PCC-centric model changes the default PCC delegation behavior to the following:

- After LSP creation, LSP is automatically delegated to the PCE that computed it.
- If this PCE is disconnected, then the LSP is redelegated to another PCE.
- If the original PCE is reconnected, then the delegation fallback timer is started. When the timer expires, the LSP is redelegated back to the original PCE, even if it has worse preference than the current PCE.

```
Router(config-sr-te-pcc)# redundancy pcc-centric
```

Configuring Head-End Router as PCEP PCC and Customizing SR-TE Related Options: Example

The following example shows how to configure an SR-TE head-end router with the following functionality:

- Enable the SR-TE head-end router as a PCEP client (PCC) with 3 PCEP servers (PCE) with different precedence values. The PCE with IP address 10.1.1.57 is selected as BEST.
- Enable SR-TE related syslogs.
- Set the Maximum SID Depth (MSD) signaled during PCEP session establishment to 5.
- Enable PCEP reporting for all policies in the node.

```
segment-routing
traffic-eng
pcc
  source-address ipv4 10.1.1.2
  pce address ipv4 10.1.1.57
  precedence 150
  password clear <password>
  !
  pce address ipv4 10.1.1.58
  precedence 200
  password clear <password>
  !
  pce address ipv4 10.1.1.59
  precedence 250
  password clear <password>
  !
  !
logging
  policy status
  !
maximum-sid-depth 5
pcc
  report-all
  !
  !
end
```

Verification

```
RP/0/RSP0/CPU0:Router# show segment-routing traffic-eng pcc ipv4 peer
```

```
PCC's peer database:
-----
```

```
Peer address: 10.1.1.57, Precedence: 150, (best PCE)
State up
Capabilities: Stateful, Update, Segment-Routing, Instantiation
```

```

Peer address: 10.1.1.58, Precedence: 200
  State up
  Capabilities: Stateful, Update, Segment-Routing, Instantiation

Peer address: 10.1.1.59, Precedence: 250
  State up
  Capabilities: Stateful, Update, Segment-Routing, Instantiation

```

Configure SR-TE PCE Groups

Table 73: Feature History Table

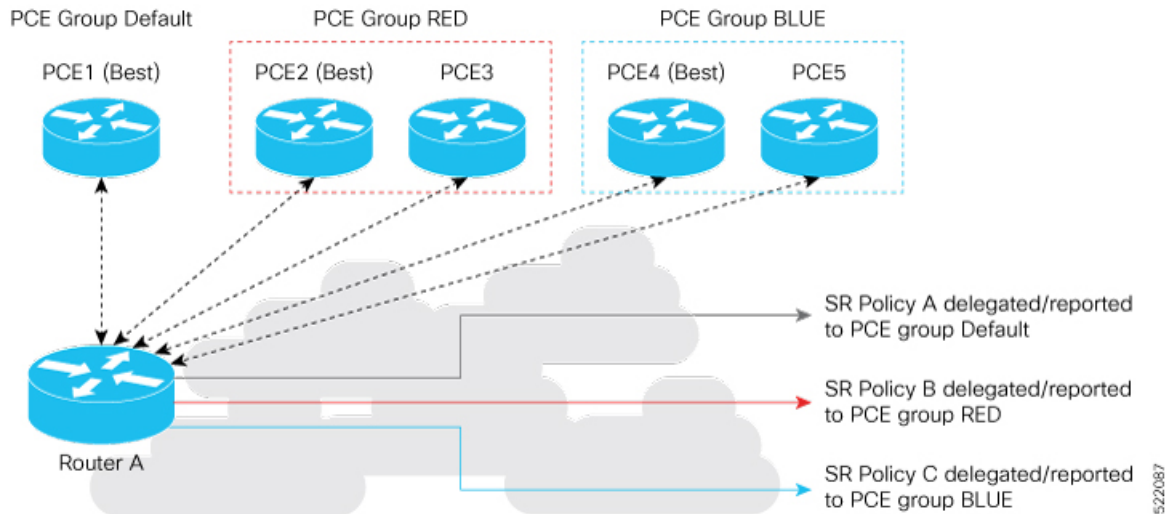

Feature Name	Release	Description
SR-TE PCE Groups	Release 7.3.2	<p>This feature allows an SR policy to be delegated to a set of PCE servers configured under a PCE group. Multiple PCE groups can be configured to allow SR policies on the same head-end to be delegated to different sets of PCEs.</p> <p>With this functionality, an operator can designate sets of PCEs for various purposes, such as PCE-per-service-type or PCE-per-wholesale-customers.</p>

This feature allows an SR policy to be delegated or reported to a set of PCE servers configured under a PCE group. Multiple PCE groups can be configured to allow different SR policies on the same head-end to be delegated or reported to different sets of PCEs.

With this functionality, an operator can designate sets of PCEs for various purposes, such as PCE-per-service-type or PCE-per-wholesale-customer.

In the figure below, Router A has a PCEP session with 5 PCEs. The PCEs are configured over 3 PCE groups. PCE1 is in the “default” group. PCE2 and PCE3 are in the RED group. PCE4 and PCE5 are in the BLUE group.

Figure 17: Example: PCE Groups

In case of PCE failure, each candidate path is re-delegated to the next-best PCE within the same PCE group. For example, if the best PCE in the RED group (PCE2) fails, then all candidate paths in the RED group fallback to the secondary PCE in the RED group (PCE3). If all the PCEs in the RED group fail, then all candidate paths in the RED group become undelegated; they are not delegated to the PCEs in the BLUE group. If there are no more available PCEs in the given PCE group, then the outcome is the same as when there are no available PCEs.

Configure PCE Groups

Use the **segment-routing traffic-eng pcc pce address {ipv4 ipv4_addr | ipv6 ipv6_addr} pce-group WORD** command to configure the PCE groups.

The following example shows how to configure the PCE groups

- PCE1 in the “default” group
- PCE2 and PCE3 in the “red” group
- PCE4 and PCE5 in the “blue” group

```
Router(config)# segment-routing traffic-eng pcc
Router(config-sr-te-pcc)# pce address ipv4 10.1.1.1
Router(config-pcc-pce)# precedence 10
Router(config-pcc-pce)# exit
```

```
Router(config-sr-te-pcc)# pce address ipv4 2.2.2.2
Router(config-pcc-pce)# precedence 20
Router(config-pcc-pce)# pce-group red
Router(config-pcc-pce)# exit
```

```
Router(config-sr-te-pcc)# pce address ipv4 3.3.3.3
Router(config-pcc-pce)# precedence 30
Router(config-pcc-pce)# pce-group red
Router(config-pcc-pce)# exit
```

```
Router(config-sr-te-pcc)# pce address ipv4 4.4.4.4
Router(config-pcc-pce)# precedence 40
Router(config-pcc-pce)# pce-group blue
```

```
Router(config-pcc-pce)# exit

Router(config-sr-te-pcc)# pce address ipv4 5.5.5.5
Router(config-pcc-pce)# precedence 50
Router(config-pcc-pce)# pce-group blue
Router(config-pcc-pce)# exit
```

Verification

```

```

Assign PCE Group to a Candidate Path or ODN Template

Use the **segment-routing traffic-eng policy *policy* pce-group *WORD*** command to assign the PCE group to all candidate paths of an SR policy.

Use the **segment-routing traffic-eng policy *policy* candidate-paths preference *pref* pce-group *WORD*** command to assign the PCE group to a specific candidate path of an SR policy.

Use the **segment-routing traffic-eng on-demand color *color* pce-group *WORD*** command to assign the PCE group to on-demand candidate paths triggered by an ODN template.

Note Only one PCE group can be attached to a given SR policy candidate path.

The following example shows how to configure a policy with all candidate paths delegated/reported to PCEs in the default group:

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# policy A
Router(config-sr-te-policy)# color 100 end-point ipv4 192.168.0.2
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 100
Router(config-sr-te-policy-path-pref)# dynamic
Router(config-sr-te-pp-info)# pcep
```

```

Router(config-sr-te-path-pcep)# exit
Router(config-sr-te-pp-info)# exit
Router(config-sr-te-policy-path-pref)# exit
Router(config-sr-te-policy-path)# exit
Router(config-sr-te-policy)# exit

```

The following example shows how to configure a policy with all candidate paths delegated/reported to PCEs in the red group:

```

Router(config-sr-te)# policy B
Router(config-sr-te-policy)# color 100 end-point ipv4 192.168.0.3
Router(config-sr-te-policy)# pce-group red
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 100
Router(config-sr-te-policy-path-pref)# dynamic
Router(config-sr-te-pp-info)# pcep
Router(config-sr-te-path-pcep)# exit
Router(config-sr-te-pp-info)# exit
Router(config-sr-te-policy-path-pref)# exit
Router(config-sr-te-policy-path)# exit
Router(config-sr-te-policy)# exit

```

The following example shows how to configure a policy with a specific candidate path (explicit path) reported to PCEs in the blue group:

```

Router(config-sr-te)# policy C
Router(config-sr-te-policy)# color 100 end-point ipv4 192.168.0.4
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 100
Router(config-sr-te-policy-path-pref)# pce-group blue
Router(config-sr-te-policy-path-pref)# explicit segment-list SLA
Router(config-sr-te-pp-info)# exit
Router(config-sr-te-policy-path-pref)# exit
Router(config-sr-te-policy-path)# exit
Router(config-sr-te-policy)# exit

```

The following example shows how to configure an ODN template with on-demand candidate paths delegated/reported to PCEs in the blue group:

```

Router(config-sr-te)# on-demand color 10
Router(config-sr-te-color)# pce-group blue
Router(config-sr-te-color)# dynamic
Router(config-sr-te-color-dyn)#pcep
Router(config-sr-te-color-dyn-pce)#

```

Running Config

```

BGP SR-TE

BGP may be used to distribute SR Policy candidate paths to an SR-TE head-end. Dedicated BGP SAFI and NLRI have been defined to advertise a candidate path of an SR Policy. The advertisement of Segment Routing policies in BGP is documented in the IETF draft <https://datatracker.ietf.org/doc/draft-ietf-idr-segment-routing-te-policy/>

SR policies with IPv4 and IPv6 end-points can be advertised over BGPv4 or BGPv6 sessions between the SR-TE controller and the SR-TE headend.

The Cisco IOS-XR implementation supports the following combinations:

- IPv4 SR policy advertised over BGPv4 session
- IPv6 SR policy advertised over BGPv4 session
- IPv4 SR policy advertised over BGPv6 session
- IPv6 SR policy advertised over BGPv6 session

Configure BGP SR Policy Address Family at SR-TE Head-End

Perform this task to configure BGP SR policy address family at SR-TE head-end:

SUMMARY STEPS

1. **configure**
2. **router bgp** *as-number*
3. **bgp router-id** *ip-address*

4. **address-family** {**ipv4** | **ipv6**} **sr-policy**
5. **exit**
6. **neighbor** *ip-address*
7. **remote-as** *as-number*
8. **address-family** {**ipv4** | **ipv6**} **sr-policy**
9. **route-policy** *route-policy-name* {**in** | **out**}

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	configure	
Step 2	router bgp <i>as-number</i> Example: RP/0/RSP0/CPU0:router(config)# router bgp 65000	Specifies the BGP AS number and enters the BGP configuration mode, allowing you to configure the BGP routing process.
Step 3	bgp router-id <i>ip-address</i> Example: RP/0/RSP0/CPU0:router(config-bgp)# bgp router-id 10.1.1.1	Configures the local router with a specified router ID.
Step 4	address-family { ipv4 ipv6 } sr-policy Example: RP/0/RSP0/CPU0:router(config-bgp)# address-family ipv4 sr-policy	Specifies either the IPv4 or IPv6 address family and enters address family configuration submenu.
Step 5	exit	
Step 6	neighbor <i>ip-address</i> Example: RP/0/RSP0/CPU0:router(config-bgp)# neighbor 10.10.0.1	Places the router in neighbor configuration mode for BGP routing and configures the neighbor IP address as a BGP peer.
Step 7	remote-as <i>as-number</i> Example: RP/0/RSP0/CPU0:router(config-bgp-nbr)# remote-as 1	Creates a neighbor and assigns a remote autonomous system number to it.

	Command or Action	Purpose
Step 8	address-family {ipv4 ipv6} sr-policy Example: <pre>RP/0/RSP0/CPU0:router(config-bgp-nbr)# address-family ipv4 sr-policy</pre>	Specifies either the IPv4 or IPv6 address family and enters address family configuration submode.
Step 9	route-policy route-policy-name {in out} Example: <pre>RP/0/RSP0/CPU0:router(config-bgp-nbr-af)# route-policy pass out</pre>	Applies the specified policy to IPv4 or IPv6 unicast routes.

Example: BGP SR-TE with BGPv4 Neighbor to BGP SR-TE Controller

The following configuration shows the an SR-TE head-end with a BGPv4 session towards a BGP SR-TE controller. This BGP session is used to signal both IPv4 and IPv6 SR policies.

```
router bgp 65000
bgp router-id 10.1.1.1
!
address-family ipv4 sr-policy
!
address-family ipv6 sr-policy
!
neighbor 10.1.3.1
remote-as 10
description *** eBGP session to BGP SRTE controller ***
address-family ipv4 sr-policy
route-policy pass in
route-policy pass out
!
address-family ipv6 sr-policy
route-policy pass in
route-policy pass out
!
!
```

Example: BGP SR-TE with BGPv6 Neighbor to BGP SR-TE Controller

The following configuration shows an SR-TE head-end with a BGPv6 session towards a BGP SR-TE controller. This BGP session is used to signal both IPv4 and IPv6 SR policies.

```
router bgp 65000
bgp router-id 10.1.1.1
address-family ipv4 sr-policy
!
address-family ipv6 sr-policy
!
neighbor 3001::10:1:3:1
remote-as 10
description *** eBGP session to BGP SRTE controller ***
address-family ipv4 sr-policy
route-policy pass in
route-policy pass out
!
```

```

address-family ipv6 sr-policy
  route-policy pass in
  route-policy pass out
!
!
!

```

Traffic Steering

Automated Steering

Automated steering (AS) allows service traffic to be automatically steered onto the required transport SLA path programmed by an SR policy.

With AS, BGP automatically steers traffic onto an SR Policy based on the next-hop and color of a BGP service route. The color of a BGP service route is specified by a color extended community attribute. This color is used as a transport SLA indicator, such as min-delay or min-cost.

When the next-hop and color of a BGP service route matches the end-point and color of an SR Policy, BGP automatically installs the route resolving onto the BSID of the matching SR Policy. Recall that an SR Policy on a head-end is uniquely identified by an end-point and color.

When a BGP route has multiple extended-color communities, each with a valid SR Policy, the BGP process installs the route on the SR Policy giving preference to the color with the highest numerical value.

The granularity of AS behaviors can be applied at multiple levels, for example:

- At a service level—When traffic destined to all prefixes in a given service is associated to the same transport path type. All prefixes share the same color.
- At a destination/prefix level—When traffic destined to a prefix in a given service is associated to a specific transport path type. Each prefix could be assigned a different color.
- At a flow level—When flows destined to the same prefix are associated with different transport path types

AS behaviors apply regardless of the instantiation method of the SR policy, including:

- On-demand SR policy
- Manually provisioned SR policy

- PCE-initiated SR policy

See the [Verifying BGP VRF Information, on page 379](#) and [Verifying Forwarding \(CEF\) Table, on page 380](#) sections for sample output that shows AS implementation.

Color-Only Automated Steering

Color-only steering is a traffic steering mechanism where a policy is created with given color, regardless of the endpoint.

You can create an SR-TE policy for a specific color that uses a NULL end-point (0.0.0.0 for IPv4 NULL, and ::0 for IPv6 NULL end-point). This means that you can have a single policy that can steer traffic that is based on that color and a NULL endpoint for routes with a particular color extended community, but different destinations (next-hop).

Note Every SR-TE policy with a NULL end-point must have an explicit path-option. The policy cannot have a dynamic path-option (where the path is computed by the head-end or PCE) since there is no destination for the policy.

You can also specify a color-only (CO) flag in the color extended community for overlay routes. The CO flag allows the selection of an SR-policy with a matching color, regardless of endpoint Sub-address Family Identifier (SAFI) (IPv4 or IPv6). See [Setting CO Flag, on page 451](#).

Configure Color-Only Steering

```
Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# policy P1
Router(config-sr-te-policy)# color 1 end-point ipv4 0.0.0.0
```

```
Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# policy P2
Router(config-sr-te-policy)# color 2 end-point ipv6 ::0
```

```
Router# show running-configuration
segment-routing
traffic-eng
policy P1
color 1 end-point ipv4 0.0.0.0
!
policy P2
color 2 end-point ipv6 ::
!
!
end
```

Setting CO Flag

The BGP-based steering mechanism matches BGP color and next-hop with that of an SR-TE policy. If the policy does not exist, BGP requests SR-PCE to create an SR-TE policy with the associated color, end-point, and explicit paths. For color-only steering (NULL end-point), you can configure a color-only (CO) flag as part of the color extended community in BGP.

Note See [Color-Only Automated Steering, on page 450](#) for information about color-only steering (NULL end-point).

The behavior of the steering mechanism is based on the following values of the CO flags:

co-flag 00	<ol style="list-style-type: none"> 1. The BGP next-hop and color <N, C> is matched with an SR-TE policy of same <N, C>. 2. If a policy does not exist, then IGP path for the next-hop N is chosen.
co-flag 01	<ol style="list-style-type: none"> 1. The BGP next-hop and color <N, C> is matched with an SR-TE policy of same <N, C>. 2. If a policy does not exist, then an SR-TE policy with NULL end-point with the same address-family as N and color C is chosen. 3. If a policy with NULL end-point with same address-family as N does not exist, then an SR-TE policy with any NULL end-point and color C is chosen. 4. If no match is found, then IGP path for the next-hop N is chosen.

Configuration Example

```
Router(config)# extcommunity-set opaque overlay-color
Router(config-ext)# 1 co-flag 01
Router(config-ext)# end-set
Router(config)#
Router(config)# route-policy color
Router(config-rpl)# if destination in (5.5.5.1/32) then
Router(config-rpl-if)# set extcommunity color overlay-color
Router(config-rpl-if)# endif
Router(config-rpl)# pass
Router(config-rpl)# end-policy
Router(config)#
```

Address-Family Agnostic Automated Steering

Address-family agnostic steering uses an SR-TE policy to steer both labeled and unlabeled IPv4 and IPv6 traffic. This feature requires support of IPv6 encapsulation (IPv6 caps) over IPV4 endpoint policy.

IPv6 caps for IPv4 NULL end-point is enabled automatically when the policy is created in Segment Routing Path Computation Element (SR-PCE). The binding SID (BSID) state notification for each policy contains an "ipv6_caps" flag that notifies SR-PCE clients (PCC) of the status of IPv6 caps (enabled or disabled).

An SR-TE policy with a given color and IPv4 NULL end-point could have more than one candidate path. If any of the candidate paths has IPv6 caps enabled, then all of the remaining candidate paths need IPv6 caps enabled. If IPv6 caps is not enabled on all candidate paths of same color and end-point, traffic drops can occur.

You can disable IPv6 caps for a particular color and IPv4 NULL end-point using the **ipv6 disable** command on the local policy. This command disables IPv6 caps on all candidate paths that share the same color and IPv4 NULL end-point.

Disable IPv6 Encapsulation

```
Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# policy P1
Router(config-sr-te-policy)# color 1 end-point ipv4 0.0.0.0
Router(config-sr-te-policy)# ipv6 disable
```

Per-Flow Automated Steering

Table 74: Feature History Table

Feature Name	Release Information	Feature Description
Per-Flow Automated Steering: L3 / L2 BGP Services + BSID Steering	Release 7.4.1	<p>This feature introduces support for BGP VPNv6 (6VPE) and BGP EVPN (single-home/multi-homed) over PFP, labeled traffic (Binding SID as top-most label in the stack) steering over per-flow policy (PFP).</p> <p>An ingress QoS policy applied to an input interface is used to classify flows and set corresponding MPLS experimental values.</p>

The steering of traffic through a Segment Routing (SR) policy is based on the candidate paths of that policy. For a given policy, a candidate path specifies the path to be used to steer traffic to the policy's destination. The policy determines which candidate path to use based on the candidate path's preference and state. The candidate path that is valid and has the highest preference is used to steer all traffic using the given policy. This type of policy is called a Per-Destination Policy (PDP).

Per-Flow Automated Traffic Steering using SR-TE Policies introduces a way to steer traffic on an SR policy based on the attributes of the incoming packets, called a Per-Flow Policy (PFP).

A PFP provides up to 8 "ways" or options to the endpoint. With a PFP, packets are classified by a classification policy and marked using internal tags called forward classes (FCs). The FC setting of the packet selects the "way". For example, this "way" can be a traffic-engineered SR path, using a low-delay path to the endpoint. The FC is represented as a numeral with a value of 0 to 7.

A PFP defines an array of FC-to-PDP mappings. A PFP can then be used to steer traffic into a given PDP based on the FC assigned to a packet.

As with PDPs, PFPs are identified by a {headend, color, endpoint} tuple. The color associated with a given FC corresponds to a valid PDP policy of that color and same endpoint as the parent PFP. So PFP policies contain mappings of different FCs to valid PDP policies of different colors. Every PFP has an FC designated as its default FC. The default FC is associated to packets with a FC undefined under the PFP or for packets with a FC with no valid PDP policy.

The following example shows a per-flow policy from Node1 to Node4:

Figure 18: PFP Example

- FC=0 -> shortest path to Node4
 - IGP shortest path = 16004
- FC=1 -> Min-delay path to Node4
 - SID list = {16002,16004}

The same on-demand instantiation behaviors of PDPs apply to PFPs. For example, an edge node automatically (on demand) instantiates Per-Flow SR Policy paths to an endpoint by service route signaling. Automated Steering steers the service route in the matching SR Policy.

Figure 19: PFP with ODN Example

Like PDPs, PFPs have a binding SID (BSID). Existing SR-TE automated steering (AS) mechanisms for labeled traffic (via BSID) and unlabeled traffic (via BGP) onto a PFP is similar to that of a PDP. For example, a packet having the BSID of a PFP as the top label is steered onto that PFP. The classification policy on the ingress interface marks the packet with an FC based on the configured class-map. The packet is then steered to the PDP that corresponds to that FC.

Usage Guidelines and Limitations

The following guidelines and limitations apply to the platform when acting as a head-end of a PFP policy:

- BGP IPv4 unicast over PFP (steered via ODN/AS) is supported
- BGP IPv6 unicast (with IPv4 next-hop [6PE]) over PFP (steered via ODN/AS) is supported
- BGP IPv6 unicast (with IPv6 next-hop) over PFP (steered via ODN/AS) is supported

- BGP VPNv4 over PFP (steered via ODN/AS) is supported
- BGP VPNv6 (6VPE) over PFP (steered via ODN/AS) is supported
- BGP EVPN (single-home/multi-homed) over PFP (steered via ODN/AS) is supported
- Pseudowire and VPLS over PFP (steered with preferred-path) are supported
- BGP multipath is supported
- BGP PIC is not supported
- Labeled traffic (Binding SID as top-most label in the stack) steered over PFP is supported
- When not explicitly configured, FC 0 is the default FC.
- A PFP is considered valid as long as its default FC has a valid PDP.
- An ingress QoS policy applied to an input interface is used to classify flows and set corresponding MPLS experimental values.
- PFP implementation is accomplished with a double-pass through the ASIC (recirculation).
 - In the first pass, an ingress QoS policy applied to an input interface is used to classify flows and set MPLS EXP values, alongside push of service label and PFP Binding SID label.
 - In the absence of any ingress QoS policy, the default behavior is to copy PREC/DSCP/EXP to PFP BSID MPLS EXP.
 - In the second pass, a forwarding lookup based on PFP Binding SID label plus MPLS EXP is used to resolve to a given PFP's PDP.
- The PFP's BSID is allocated from a user-configured MPLS label block; see [Configuring PFP BSID Label Block, on page 455](#).
- The following counters are supported:
 - PFP's BSID counter (packet, bytes)
 - Per-FC counters (packet, byte)
 - Collected from the PDP's segment-list-per-path egress counters
 - If an SR policy is used for more than one purpose (as a regular policy as well as a PDP under one or more PFPs), then the collected counters will represent the aggregate of all contributions. To preserve independent counters, it is recommended that an SR policy be used only for one purpose.
- Inbound packet classification, based on the following fields, is supported:
 - IP precedence
 - IP DSCP
 - L3 ACL-based (L3 source/destination IP; L4 source/destination port)
 - MPLS EXP
 - Layer 2 CoS

- MAC ACL
- A color associated with a PFP SR policy cannot be used by a non-PFP SR policy. For example, if a per-flow ODN template for color 100 is configured, then the system will reject the configuration of any non-PFP SR policy using the same color. You must assign different color value ranges for PFP and non-PFP SR policies.
- Per-Flow Automated Steering is not supported on Cisco NCS 5700 series fixed port routers or Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native or compatible modes.

Configuring PFP BSID Label Block

Implementation on NCS platforms requires that the BSID assigned to a PFP be allocated from a preconfigured label block. The BSID is a local segment.

This label range cannot overlap with the existing SRLB or SRGB ranges allocated on the platform.

To configure the MPLS label block for PFP BSID allocation, use the **block name name type pfp start starting-value {end ending-value | size size} [client word]** command.

This example shows how to allocate a block of labels based on the size of the block:

```
Router(config)# mpls label blocks
Router(config-mpls-lbl-blks)# block name sample-pfp-bsid-block type pfp start 40000 size 1000 client any
```

This example shows how to allocate a block of labels based on specific starting and ending values:

```
Router(config)# mpls label blocks
Router(config-mpls-lbl-blks)# block name sample-pfp-bsid-block type pfp start 40000 end 41000 client any
```

Configuring ODN Template for PFP Policies: Example

The following example depicts an ODN template for PFP policies that includes three FCs.

The example also includes the corresponding ODN templates for PDPs as follows:

- FC0 (default FC) mapped to color 10 = Min IGP path
- FC1 mapped to color 20 = Flex Algo 128 path
- FC2 mapped to color 30 = Flex Algo 129 path

```
segment-routing
traffic-eng
  on-demand color 10
  dynamic
    metric
      type igp
  !
  !
  on-demand color 20
  constraints
    segments
```

```

        sid-algorithm 128
    !
    !
    !
    on-demand color 30
    constraints
    segments
        sid-algorithm 129
    !
    !
    !
    on-demand color 1000
    per-flow
        forward-class 0 color 10
        forward-class 1 color 20
        forward-class 2 color 30

```

Manually Configuring a PFP and PDPs: Example

The following example depicts a manually defined PFP that includes three FCs and corresponding manually defined PDPs.

The example also includes the corresponding PDPs as follows:

- FC0 (default FC) mapped to color 10 = Min IGP path
- FC1 mapped to color 20 = Min TE path
- FC2 mapped to color 30 = Min delay path

```

mpls label blocks
block name sample-pfp-bsid-block type pfp start 400000 size 1000 client any

    color 30 end-point ipv4 10.1.1.4
    candidate-paths

```

```

preference 100
dynamic
metric type delay

```

Configuring Ingress Classification: Example

An MQC QoS policy is used to classify and mark traffic to a corresponding MPLS experimental value.

The following shows an example of such ingress classification policy:

```

class-map match-any MinDelay
match dscp 46
end-class-map
!
class-map match-any PremiumHosts
match access-group ipv4 PrioHosts
end-class-map
!
!
policy-map MyPerFlowClassificationPolicy
class MinDelay
set mpls experimental imposition 2
!
class PremiumHosts
set mpls experimental imposition 1
!
class class-default
!
end-policy-map
!
interface GigabitEthernet0/0/0/0
description PE_Ingress_Interface
service-policy input MyPerFlowClassificationPolicy
!

```

Determining Per-Flow Policy State

A PFP is brought down for the following reasons:

- The PDP associated with the default FC is in a down state.
- All FCs are associated with PDPs in a down state.
- The FC assigned as the default FC is missing in the forward class mapping.

Scenario 1—FC 0 (default FC) is not configured in the FC mappings below:

```

policy foo
color 1 end-point ipv4 10.1.1.1
per-flow
forward-class 1 color 10
forward-class 2 color 20

```

Scenario 2—FC 1 is configured as the default FC, however it is not present in the FC mappings:

```

policy foo
color 1 end-point ipv4 10.1.1.1
per-flow
forward-class 0 color 10
forward-class 2 color 20

```

```
forward-class default 1
```

Using Binding Segments

The binding segment is a local segment identifying an SR-TE policy. Each SR-TE policy is associated with a binding segment ID (BSID). The BSID is a local label that is automatically allocated for each SR-TE policy when the SR-TE policy is instantiated.

Note In Cisco IOS XR 6.3.2 and later releases, you can specify an explicit BSID for an SR-TE policy. See the following **Explicit Binding SID** section.

BSID can be used to steer traffic into the SR-TE policy and across domain borders, creating seamless end-to-end inter-domain SR-TE policies. Each domain controls its local SR-TE policies; local SR-TE policies can be validated and rerouted if needed, independent from the remote domain's head-end. Using binding segments isolates the head-end from topology changes in the remote domain.

Packets received with a BSID as top label are steered into the SR-TE policy associated with the BSID. When the BSID label is popped, the SR-TE policy's SID list is pushed.

BSID can be used in the following cases:

- Multi-Domain (inter-domain, inter-autonomous system)—BSIDs can be used to steer traffic across domain borders, creating seamless end-to-end inter-domain SR-TE policies.
- Large-Scale within a single domain—The head-end can use hierarchical SR-TE policies by nesting the end-to-end (edge-to-edge) SR-TE policy within another layer of SR-TE policies (aggregation-to-aggregation). The SR-TE policies are nested within another layer of policies using the BSIDs, resulting in seamless end-to-end SR-TE policies.
- Label stack compression—If the label-stack size required for an SR-TE policy exceeds the platform capability, the SR-TE policy can be seamlessly stitched to, or nested within, other SR-TE policies using a binding segment.

Explicit Binding SID

Use the **binding-sid mpls label** command in SR-TE policy configuration mode to specify the explicit BSID. Explicit BSIDs are allocated from the segment routing local block (SRLB) or the dynamic range of labels. A best-effort is made to request and obtain the BSID for the SR-TE policy. If requested BSID is not available (if it does not fall within the available SRLB or is already used by another application or SR-TE policy), the policy stays down.

Use the **binding-sid explicit {fallback-dynamic | enforce-srlb}** command to specify how the BSID allocation behaves if the BSID value is not available.

- Fallback to dynamic allocation – If the BSID is not available, the BSID is allocated dynamically and the policy comes up:

```
Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
```

```
Router(config-sr-te)# binding-sid explicit fallback-dynamic
```

- Strict SRLB enforcement – If the BSID is not within the SRLB, the policy stays down:

```
Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# binding-sid explicit enforce-srlb
```

This example shows how to configure an SR policy to use an explicit BSID of 1000. If the BSID is not available, the BSID is allocated dynamically and the policy comes up.

```
segment-routing
traffic-eng
binding-sid explicit fallback-dynamic
policy goo
binding-sid mpls 1000
!
!
!
```

Stitching SR-TE Policies Using Binding SID: Example

In this example, three SR-TE policies are stitched together to form a seamless end-to-end path from node 1 to node 10. The path is a chain of SR-TE policies stitched together using the binding-SIDs of intermediate policies, providing a seamless end-to-end path.

Figure 20: Stitching SR-TE Policies Using Binding SID

Table 75: Router IP Address

Router	Prefix Address	Prefix SID/Adj-SID
3	Loopback0 - 10.1.1.3	Prefix SID - 16003
4	Loopback0 - 10.1.1.4 Link node 4 to node 6 - 10.4.6.4	Prefix SID - 16004 Adjacency SID - dynamic
5	Loopback0 - 10.1.1.5	Prefix SID - 16005
6	Loopback0 - 10.1.1.6 Link node 4 to node 6 - 10.4.6.6	Prefix SID - 16006 Adjacency SID - dynamic
9	Loopback0 - 10.1.1.9	Prefix SID - 16009

Router	Prefix Address	Prefix SID/Adj-SID
10	Loopback0 - 10.1.1.10	Prefix SID - 16010

Procedure

Step 1 On node 5, do the following:

- Define an SR-TE policy with an explicit path configured using the loopback interface IP addresses of node 9 and node 10.
- Define an explicit binding-SID (**mpls label 15888**) allocated from SRLB for the SR-TE policy.

Example:

Node 5

```
segment-routing
traffic-eng
segment-list PATH-9_10
index 10 address ipv4 10.1.1.9
index 20 address ipv4 10.1.1.10
!
policy foo
binding-sid mpls 15888
color 777 end-point ipv4 10.1.1.10
candidate-paths
preference 100
explicit segment-list PATH5-9_10
!
!
!
!
!
```

```
RP/0/RSP0/CPU0:Node-5# show segment-routing traffic-eng policy color 777
```

```
SR-TE policy database
-----
```

```
Color: 777, End-point: 10.1.1.10
Name: srte_c_777_ep_10.1.1.10
Status:
  Admin: up Operational: up for 00:00:52 (since Aug 19 07:40:12.662)
Candidate-paths:
  Preference: 100 (configuration) (active)
  Name: foo
  Requested BSID: 15888
  PCC info:
    Symbolic name: cfg_foo_discr_100
    PLSP-ID: 70
  Explicit: segment-list PATH-9_10 (valid)
    Weight: 1, Metric Type: TE
    16009 [Prefix-SID, 10.1.1.9]
    16010 [Prefix-SID, 10.1.1.10]
Attributes:
  Binding SID: 15888 (SRLB)
  Forward Class: 0
  Steering BGP disabled: no
  IPv6 caps enable: yes
```

Step 2 On node 3, do the following:

a) Define an SR-TE policy with an explicit path configured using the following:

- Loopback interface IP address of node 4
- Interface IP address of link between node 4 and node 6
- Loopback interface IP address of node 5
- Binding-SID of the SR-TE policy defined in Step 1 (**mpls label 15888**)

Note

This last segment allows the stitching of these policies.

b) Define an explicit binding-SID (**mpls label 15900**) allocated from SRLB for the SR-TE policy.

Example:

Node 3

```
segment-routing
traffic-eng
segment-list PATH-4_4-6_5_BSID
index 10 address ipv4 10.1.1.4
index 20 address ipv4 10.4.6.6
index 30 address ipv4 10.1.1.5
index 40 mpls label 15888
!
policy baa
binding-sid mpls 15900
color 777 end-point ipv4 10.1.1.5
candidate-paths
preference 100
explicit segment-list PATH-4_4-6_5_BSID
!
!
!
!
!
!

RP/0/RSP0/CPU0:Node-3# show segment-routing traffic-eng policy color 777

SR-TE policy database
-----

Color: 777, End-point: 10.1.1.5
Name: srte_c_777_ep_10.1.1.5
Status:
  Admin: up Operational: up for 00:00:32 (since Aug 19 07:40:32.662)
Candidate-paths:
  Preference: 100 (configuration) (active)
    Name: baa
    Requested BSID: 15900
    PCC info:
      Symbolic name: cfg_baa_discr_100
      PLSP-ID: 70
    Explicit: segment-list PATH-4_4-6_5_BSID (valid)
      Weight: 1, Metric Type: TE
        16004 [Prefix-SID, 10.1.1.4]
        80005 [Adjacency-SID, 10.4.6.4 - 10.4.6.6]
        16005 [Prefix-SID, 10.1.1.5]
        15888
  Attributes:
```

```

Binding SID: 15900 (SRLB)
Forward Class: 0
Steering BGP disabled: no
IPv6 caps enable: yes

```

Step 3 On node 1, define an SR-TE policy with an explicit path configured using the loopback interface IP address of node 3 and the binding-SID of the SR-TE policy defined in step 2 (**mpls label 15900**). This last segment allows the stitching of these policies.

Example:

Node 1

```

segment-routing
traffic-eng
segment-list PATH-3_BSID
index 10 address ipv4 10.1.1.3
index 20 mpls label 15900
!
policy bar
color 777 end-point ipv4 10.1.1.3
candidate-paths
preference 100
explicit segment-list PATH-3_BSID
!
!
!
!
!
!

```

```
RP/0/RSP0/CPU0:Node-1# show segment-routing traffic-eng policy color 777
```

```
SR-TE policy database
```

```

-----

    Symbolic name: cfg_bar_discr_100
    PLSP-ID: 70
  Explicit: segment-list PATH-3_BSID (valid)
    Weight: 1, Metric Type: TE
    16003 [Prefix-SID, 10.1.1.3]
    15900
Attributes:
  Binding SID: 80021
  Forward Class: 0
  Steering BGP disabled: no
  IPv6 caps enable: yes

```

L2VPN Preferred Path

EVPN VPWS Preferred Path over SR-TE Policy feature allows you to set the preferred path between the two end-points for EVPN VPWS pseudowire (PW) using SR-TE policy.

L2VPN VPLS or VPWS Preferred Path over SR-TE Policy feature allows you to set the preferred path between the two end-points for L2VPN Virtual Private LAN Service (VPLS) or Virtual Private Wire Service (VPWS) using SR-TE policy.

Refer to the [EVPN VPWS Preferred Path over SR-TE Policy](#) and [L2VPN VPLS or VPWS Preferred Path over SR-TE Policy](#) sections in the "L2VPN Services over Segment Routing for Traffic Engineering Policy" chapter of the *L2VPN and Ethernet Services Configuration Guide*.

Static Route over Segment Routing Policy

This feature allows you to specify a Segment Routing (SR) policy as an interface type when configuring static routes for MPLS data planes.

For information on configuring static routes, see the "Implementing Static Routes" chapter in the *Routing Configuration Guide for Cisco NCS 5500 Series Routers*.

Configuration Example

The following example depicts a configuration of a static route for an IPv4 destination over an SR policy.

```
Router(config)# router static
Router(config-static)# address-family ipv4 unicast
Router(config-static-afi)# 10.1.100.100/32 sr-policy sample-policy
```

Running Configuration

```
Router# show run segment-routing traffic-eng

segment-routing
 traffic-eng
  segment-list sample-SL
    index 10 mpls adjacency 10.1.1.102
    index 20 mpls adjacency 10.1.1.103
  !
 policy sample-policy
  color 777 end-point ipv4 10.1.1.103
  candidate-paths
  preference 100
  explicit segment-list sample-SL

Router# show run segment-routing traffic-eng

router static
 address-family ipv4 unicast
  10.1.1.4/32 sr-policy srte_c_200_ep_10.1.1.4
 !
 !
```

Verification

```
Router# show segment-routing traffic-eng policy candidate-path name sample-policy
```

SR-TE policy database

```
Color: 777, End-point: 10.1.1.103
Name: srte_c_777_ep_10.1.1.103
Status:
  Admin: up Operational: up for 00:06:35 (since Jan 17 14:34:35.120)
Candidate-paths:
  Preference: 100 (configuration) (active)
  Name: sample-policy
  Requested BSID: dynamic
  PCC info:

Autoroute Include

Table 76: Feature History Table

Feature Name	Release	Description
Autoroute Include	Release 7.3.2	This feature allows you to steer specific IGP (IS-IS, OSPF) prefixes, or all prefixes, over non-shortest paths and to divert the traffic for those prefixes on to an SR-TE policy.

Feature Name	Release	Description
IPv6 'Autoroute Include' Support for an SR-TE Policy with an IPv4 Endpoint	Release 7.3.4	<p>You can configure an SR-TE policy for all IPv6 prefixes and automatically steer the incoming IPv6 traffic at the headend router into that SR-TE policy with an IPv4 endpoint. Compared to MPLS/RSVP-TE, SR-TE provides more granular and automated steering techniques.</p> <p>In earlier releases, you could automatically steer only incoming IPv4 traffic for specific or all prefixes.</p> <p>New command:</p> <p><code>autoroute include ipv6 all</code></p>

You can configure SR-TE policies with Autoroute Include to steer specific IGP (IS-IS, OSPF) prefixes, or all prefixes, over non-shortest paths and to divert the traffic for those prefixes on to the SR-TE policy.

The **autoroute include all** option applies Autoroute Announce functionality for all destinations or prefixes.

The **autoroute include ipv4 address** option applies Autoroute Destination functionality for the specified destinations or prefixes. This option is supported for IS-IS only; it is not supported for OSPF.

The Autoroute SR-TE policy adds the prefixes into the IGP, which determines if the prefixes on the endpoint or downstream of the endpoint are eligible to use the SR-TE policy. If a prefix is eligible, then the IGP checks if the prefix is listed in the Autoroute Include configuration. If the prefix is included, then the IGP downloads the prefix route with the SR-TE policy as the outgoing path.

Usage Guidelines and Limitations

- Autoroute Include supports three metric types:
 - Default (no metric): The path over the SR-TE policy inherits the shortest path metric.
 - Absolute (constant) metric: The shortest path metric to the policy endpoint is replaced with the configured absolute metric. The metric to any prefix that is Autoroute Included is modified to the absolute metric. Use the **autoroute metric constant** *constant-metric* command, where *constant-metric* is from 1 to 2147483647.
 - Relative metric: The shortest path metric to the policy endpoint is modified with the relative value configured (plus or minus). Use the **autoroute metric relative** *relative-metric* command, where *relative-metric* is from -10 to +10.

Note

To prevent load-balancing over IGP paths, you can specify a metric that is lower than the value that IGP takes into account for autorouted destinations (for example, **autoroute metric relative -1**).

- LDP over SR-TE not supported.
- LDP to SR-TE interworking is not supported.
- Static route over SR-TE is not supported.

Configuration Examples

The following example shows how to configure autoroute include for all prefixes:

```
Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)#policy P1
Router(config-sr-te-policy)# color 20 end-point ipv4 10.1.1.2
Router(config-sr-te-policy)# autoroute include all
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 100
Router(config-sr-te-pp-index)# explicit segment-list Plist-1
```

The following example shows how to configure autoroute include for the specified IPv4 prefixes:

Note This option is supported for IS-IS only; it is not supported for OSPF.

```
Router# configure
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)#policy P1
Router(config-sr-te-policy)# color 20 end-point ipv4 10.1.1.2
Router(config-sr-te-policy)# autoroute include ipv4 10.1.1.21/32
Router(config-sr-te-policy)# autoroute include ipv4 10.1.1.23/32
Router(config-sr-te-policy)# autoroute metric constant 1
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 100
Router(config-sr-te-pp-index)# explicit segment-list Plist-1
```

The following example shows how to configure the IPv6 autoroute function for an SR-TE policy with an IPv4 endpoint:

```
Router# configure
Router(config)# segment-routing traffic-eng policy pol12
Router(config-sr-te-policy)# autoroute include ipv6 all
Router(config-sr-te-policy)# commit
```

The following example shows how to configure the IPv6 autoroute function for a PCE-instantiated SR-TE policy with an IPv4 endpoint:

```
Router# configure
Router(config)# segment-routing traffic-eng pcc profile 10
Router(config-pcc-prof)# autoroute include ipv6 all
Router(config-pcc-prof)# commit
```

SR-TE Automated Steering Without BGP Prefix Path Label

Table 77: Feature History Table

Feature Name	Release Information	Feature Description
SR-TE Automated Steering Without BGP Prefix Path Label	Release 7.9.1	<p>This feature allows traffic to a BGP service route to be steered over an SR-TE policy using automated-steering principles without imposing the service route's prefix label.</p> <p>This feature allows you to deploy a centralized BGP EPE solution for 6PE in an SR-MPLS network.</p> <p>This feature introduces the bgp prefix-path-label ignore command.</p>

This feature allows traffic to a BGP service route to be steered over an SR-TE policy using automated-steering principles without imposing the service route's prefix label (see [Automated Steering, on page 449](#)). BGP ignores the programming of the label associated with a prefix path (for example, 6PE/VPN label) when recursing onto the BSID of an SR-TE policy with this feature enabled.

This feature allows you to deploy a [centralized BGP EPE solution for 6PE in an SR-MPLS network](#).

Usage Guidelines and Limitations

This functionality applies to local/manually configured SR-TE candidate-paths.

This functionality does not apply to on-demand SR-TE candidate-paths triggered by ODN.

This functionality does not apply to SR-TE candidate-paths instantiated via PCEP (PCE-initiated) or BGP-TE.

Configuration

Use the **bgp prefix-path-label ignore** command in SR-TE policy steering config mode to indicate BGP ignores the programming of the label associated with a prefix path (for example, 6PE/VPN label) when recursing onto the BSID of an SR-TE policy with this feature enabled.

```
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# policy FOO
Router(config-sr-te-policy)# steering
Router(config-sr-te-policy-steering)# bgp prefix-path-label ignore
Router(config-sr-te-policy-steering)# exit
Router(config-sr-te-policy)# color 100 end-point ipv4 0.0.0.0
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 100
Router(config-sr-te-policy-path-pref)# explicit segment-list sample-sl
```

Verification

The following output displays the SR-TE policy (SR policy color 100, IPv4 null end-point) details showing the ignore prefix label steering behavior:

```
Router# show segment-routing traffic-eng policy candidate-path name FOO private
```

```
SR-TE policy database
```

```

Use Case: Centralized BGP EPE for 6PE in an SR-MPLS Network

In this use case, an operator wants to control the egress peering router/egress transit autonomous system (AS) used by selected Internet IPv6 prefixes. To achieve this, SR policies with explicit paths are used to steer traffic to an intended egress peering router and intended egress transit AS. BGP-EPE SIDs are used in order to force traffic onto an intended egress transit AS. Traffic steering follows SR-TE automated-steering principles.

The following key features enable the use-case:

- [SR-TE Explicit Segment Lists with Mix of IPv4 and IPv6 Segments](#) — Allows the last segment of an SR policy's SID list to be associated with an EPE-enabled BGPv6 neighbor.
- [SR-TE Automated Steering Without BGP Prefix Path Label](#) — Allows traffic to an Internet IPv6 prefix to be steered over an SR-TE policy without imposing the 6PE label learned from the original advertising router.

Topology

The below topology shows a single-stack IPv4 SR-MPLS and BGP-free network that delivers Internet IPv6 connectivity using 6PE.

Peering routers 2 and 3 learn IPv6 reachability through transit AS's (ASBR routers 4, 5, 6) via eBGPv6 neighbors.

BGP EPE SIDs are enabled on external BGPv6 neighbors at router 2 (for example, EPE label 24024) and router 3 (for example, EPE labels 24035 and 24036).

Figure 21: Network Setup

BGP EPE Propagation via BGP-LS

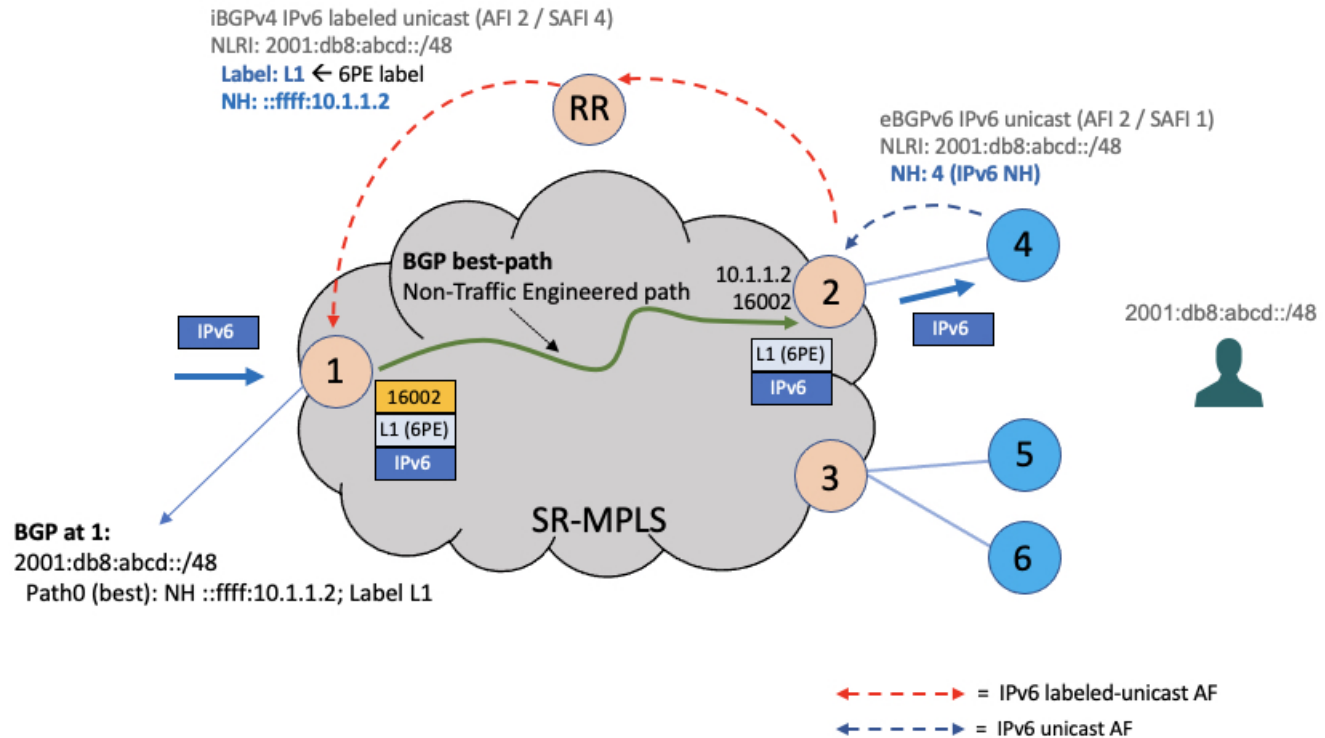

Peering routers 2 and 3 advertise their EPE-enabled neighbors via BGP-LS. As a result, ingress router node 1 learns those EPE-enabled neighbors via BGP-LS. This allows the SR-TE database at the ingress router to include the external links.

Figure 22: BGP-LS

**Steady State (Non-Traffic-Engineered)**

At steady state, router 1 selects (as BGP best-path) the path from router 2 for IPv6 prefix 2001:db8:abcd::/48. Traffic to this prefix is sent over the SR-native LSP associated with router 2 (prefix SID 16002) along side the advertised 6PE label.

Figure 23: Steady State

EPE Traffic-Engineered Path

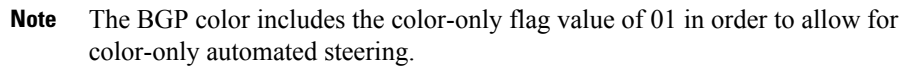

To create a traffic-engineered path that steers traffic to an intended egress peering router/egress transit AS (for example, node 3/ASBR node 6), an SR policy can be configured at ingress border router 1 with the following:

- An IPv4 null (0.0.0.0) end-point, in order to perform color-only automated steering (see [Color-Only Automated Steering](#), on page 450).
- An explicit segment list with SIDs corresponding to the intended egress node (for example, node 3) and the intended egress peering link (for example, ASBR node 6).
- The **bgp prefix-label ignore** steering command in order to indicate BGP to ignore the programming of the 6PE label associated with the prefix path.

```
segment-routing
traffic-eng
segment-list sl-to_3-epe_36
index 10 mpls adjacency 10.1.1.3
index 20 mpls adjacency 2001:db8:20:3:6::3
!
policy FOO
steering
  bgp prefix-label ignore
!
color 10 end-point ipv4 0.0.0.0
candidate-paths
preference 100
```

When a given IPv6 Internet destination needs to be steered over an intended egress peering router/egress AS, the operator can perform one of the following:

- Advertise a new BGP prefix path from a Route Server that includes a color extended community value equal to the color of the SR-TE policy for the intended egress peering router/egress AS, or
- Apply a color extended community value equal to the color of the SR-TE policy for the intended egress peering router/egress AS at the peering router advertising the best path (for example, node 2), as shown below.

The diagram illustrates an SR-MPLS network configuration and data flow. A central cloud represents the SR-MPLS network, with nodes 1, 2, 3, 4, 5, and 6. Node 1 is the ingress node, and Node 3 is the egress node. A red dashed arrow shows IPv6 labeled-unicast AF traffic from Node 1 to Node 2. A blue dashed arrow shows IPv6 unicast AF traffic from Node 2 to Node 3. Node 3 has a table with IPv6 addresses 16003 and 24036. Node 4 has a table with IPv6 address 24036. Node 5 has a table with IPv6 address 24036. Node 6 has a table with IPv6 address 24036. A user icon is shown with the address 2001:db8:abcd::/48. The diagram also shows a BGP configuration for Node 1, including a BGP policy FOO and a BGP neighbor 6.

IBGPv4 IPv6 labeled unicast (AFI 2 / SAFI 4)

Miscellaneous

SR Policy Liveness Monitoring

SR Policy liveness monitoring allows you to verify end-to-end traffic forwarding over an SR Policy candidate path by periodically sending performance monitoring (PM) packets. The head-end router sends PM packets to the SR policy's endpoint router, which sends them back to the head-end without any control-plane dependency on the endpoint router.

For more information about this feature, see [SR Policy Liveness Monitoring, on page 693](#).

Programming Non-Active Candidate Paths of an SR Policy

Table 78: Feature History Table

Feature Name	Release Information	Feature Description
Programming Non-Active Candidate Paths of an SR Policy	Release 7.6.1	<p>By programming non-active candidate paths (CPs) in the forwarding plane, you ensure that if the existing active CP is unavailable, the traffic switches quickly to the new CP, thus minimizing loss of traffic flow.</p> <p>In earlier releases, instantiating a non-active CP to the forwarding plane after the unavailability of the active CP could take a few seconds, resulting in potential loss of traffic flow.</p> <p>This feature introduces the following command:</p> <ul style="list-style-type: none">• <code>max-install-standby-cpaths</code>

An SR Policy is associated with one or more candidate paths (CP). A CP is selected as the active CP when it is valid and it has the highest preference value among all the valid CPs of the SR Policy. By default, only the active CP is programmed in the forwarding plane.

This feature allows the programming of multiple CPs of an SR policy in the forwarding plane. This minimizes traffic loss when a new CP is selected as active.

Usage Guidelines and Limitations

Observe the following usage guidelines and limitations:

- Up to three non-active CPs can be programmed in the forwarding plane.
- Manually configured CPs are supported. This includes CPs with explicit paths or dynamic (head-end computed or PCE-delegated) paths.
- On-Demand instantiated CPs (ODN) are supported.
- BGP-initiated CPs are supported.
- PCE-initiated CPs via PCEP are not supported. This applies to policies created via CLI or via north-bound HTTP-based API.
- Programming of non-active CPs is not supported with SRv6-TE policies, Per-Flow Policies (PFP), or point-to-multipoint SR policies (Tree-SID)
- PCEP reporting of additional CPs is supported, but the PCEP reporting does not distinguish between active and non-active CPs.

- Programming of non-active CPs can be enabled for all SR policies (global), for a specific policy (local), or ODN template.

If enabled globally and also locally or on ODN template, the local or ODN configuration takes precedence over the global configuration.

- Programming of non-active CPs under global SR-TE and configuring policy path protection of an SR policy is supported. In this case, policy path protection takes precedence.
- Programming of non-active CPs for a specific SR policy and configuring policy path protection of an SR policy is not supported.
- The number of policies supported could be impacted by the number of non-active CPs per policy. Programming non-active CPs in the forwarding plane consumes hardware resources (such as local label and ECMP FEC) when more candidate paths are pre-programmed in forwarding than are actually carrying traffic.
- The active CP will be in programmed state. The remaining CPs will be in standby programmed state.
- We recommend that you create separate PM sessions for active and standby candidate paths to monitor the health of the paths end-to-end.

The recommended PM timers should be different for active and standby PM profiles. The PM timers should be less aggressive for the standby PM profile compared to the active PM profile. See [Configure Performance Measurement, on page 681](#) for information about configuring PM sessions.

Note PM sessions for BGP-TE policies are not supported. PM profiles can be configured only under configured policies at the head-end.

- The protected paths for each CP is programmed in the respective LSPs. The protected paths of active CPs are programmed in the active LSP, and the protected paths of standby CPs are programmed in the standby LSP.
- If a candidate path with higher preference becomes available, the traffic will switch to it in Make-Before-Break (MBB) behavior.

Note When you update segment lists for Label Switched Paths (LSPs), the SRTE policy statistics show incorrect numbers. This happens because the system combines out-of-date cached data with new LSP data, causing misaligned counters and data loss during updates.

During updates, metrics like interface accounting and policy packets or bytes switched do not accurately reflect the real traffic flow.

Configuration

Programming of non-active CPs can be enabled for all SR policies (global), for a specific policy (local), or ODN template. If enabled globally, the local or ODN configuration takes precedence over the global configuration.

Global SR-TE

Use the **max-install-standby-cpaths** *value* command to configure standby candidate paths for all SR policies, for a specific policy, or for an ODN template. The range for *value* is from 1 to 3. Use **no max-install-standby-cpaths** command to return to the default behavior.

The following example shows how to configure standby candidate paths globally:

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# max-install-standby-cpaths 2
Router(config-sr-te)#
```

Running Config

```
segment-routing
 traffic-eng
  max-install-standby-cpaths 2
```

Local SR Policy

Use the **max-install-standby-cpaths** *value* command to configure standby candidate paths for a specific policy. The range for *value* is from 0 (disable) to 3.

If programming of non-active CPs is enabled for all SR policies (global), you can disable programming of non-active CPs for a specific policy using the **max-install-standby-cpaths 0** command.

The following example shows how to configure standby candidate paths for a specific SR policy:

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# policy MyBackupPolicy
Router(config-sr-te-policy)# max-install-standby-cpaths 2
Router(config-sr-te-policy)#
```

Running Config

```
segment-routing
 traffic-eng
  policy MyBackupPolicy
  max-install-standby-cpaths 2
```

SR ODN

When you create an ODN template, two CPs are created by default (PCE-delegated and head-end computed) with preference 100 and preference 200. You can use the **max-install-standby-cpaths 1** command to program the non-active CP in forwarding. If programming of non-active CPs is enabled for all SR policies (global), you can disable programming of non-active CPs on ODN template using the **max-install-standby-cpaths 0** command.

The following example shows how to configure standby candidate paths for an SR ODN template:

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# on-demand color 10
Router(config-sr-te-color)# max-install-standby-cpaths 1
Router(config-sr-te-color)#
```

Running Config

```
segment-routing
 traffic-eng
```

```
on-demand color 10
max-install-standby-cpaths 1
```

The following example shows how to enable three standby CPs globally and disable standby CPs on local SR policy and ODN template:

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# max-install-standby-cpaths 3
Router(config-sr-te)# policy MyBackupPolicy
Router(config-sr-te-policy)# max-install-standby-cpaths 0
Router(config-sr-te-policy)# exit
Router(config-sr-te)# on-demand color 10
Router(config-sr-te-color)# max-install-standby-cpaths 0
Router(config-sr-te-color)#
```

Verification

The following output shows the status of active and backup CPs:

```
Router# show segment-routing traffic-eng policy
```

```

LDP over Segment Routing Policy

The LDP over Segment Routing Policy feature enables an LDP-targeted adjacency over a Segment Routing (SR) policy between two routers. This feature extends the existing MPLS LDP address family neighbor configuration to specify an SR policy as the targeted end-point.

LDP over SR policy is supported for locally configured SR policies with IPv4 end-points.

For more information about MPLS LDP, see the "Implementing MPLS Label Distribution Protocol" chapter in the *MPLS Configuration Guide*.

For more information about Autoroute, see the *Autoroute Announce for SR-TE* section.

Note Before you configure an LDP targeted adjacency over SR policy name, you need to create the SR policy under Segment Routing configuration. The SR policy interface names are created internally based on the color and endpoint of the policy. LDP is non-operational if SR policy name is unknown.

The following functionality applies:

1. Configure the SR policy – LDP receives the associated end-point address from the interface manager (IM) and stores it in the LDP interface database (IDB) for the configured SR policy.
2. Configure the SR policy name under LDP – LDP retrieves the stored end-point address from the IDB and uses it. Use the auto-generated SR policy name assigned by the router when creating an LDP targeted adjacency over an SR policy. Auto-generated SR policy names use the following naming convention: **srte_c_color_val_ep_endpoint-address**. For example, **srte_c_1000_ep_10.1.1.2**

Configuration Example

```
/* Enter the SR-TE configuration mode and create the SR policy. This example corresponds
to a local SR policy with an explicit path. */
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# segment-list sample-sid-list
Router(config-sr-te-sl)# index 10 address ipv4 10.1.1.7
Router(config-sr-te-sl)# index 20 address ipv4 10.1.1.2
Router(config-sr-te-sl)# exit
Router(config-sr-te)# policy sample_policy
Router(config-sr-te-policy)# color 1000 end-point ipv4 10.1.1.2
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 100
Router(config-sr-te-policy-path-pref)# explicit segment-list sample-sid-list
Router(config-sr-te-pp-info)# end

/* Configure LDP over an SR policy */
Router(config)# mpls ldp
Router(config-ldp)# address-family ipv4
Router(config-ldp-af)# neighbor sr-policy srte_c_1000_ep_10.1.1.2 targeted
Router(config-ldp-af)#
```

Note Do one of the following to configure LDP discovery for targeted hellos:

- Active targeted hellos (SR policy head end):

```
mpls ldp
  interface GigabitEthernet0/0/0/0
  !
  !
```

- Passive targeted hellos (SR policy end-point):

```
mpls ldp
  address-family ipv4
    discovery targeted-hello accept
  !
  !
```

Running Configuration

```
segment-routing
traffic-eng
  segment-list sample-sid-list
    index 10 address ipv4 10.1.1.7
    index 20 address ipv4 10.1.1.2
  !
  policy sample_policy
    color 1000 end-point ipv4 10.1.1.2
    candidate-paths
      preference 100
      explicit segment-list sample-sid-list
    !
  !
  !
  !
  !
  !

mpls ldp
  address-family ipv4
    neighbor sr-policy srte_c_1000_ep_10.1.1.2 targeted
    discovery targeted-hello accept
  !
  !
```

Verification

SR-TE MPLS Label Imposition Enhancement

The SR-TE MPLS Label Imposition Enhancement feature increases the maximum label imposition capabilities of the platform.

In previous releases, the platform supported:

- Up to 5 MPLS transport labels when no MPLS service labels are imposed
- Up to 3 MPLS transport labels when MPLS service labels are imposed

With the SR-TE MPLS Label Imposition Enhancement feature, the platform supports the following:

- Up to 12 MPLS transport labels when no MPLS service labels are imposed
- Up to 9 MPLS transport labels when MPLS service labels are imposed

This enhancement is enabled and disabled dynamically, as the label count changes. For example, if a path requires only 3 MPLS transport labels, the MPLS Label Imposition Enhancement feature is not enabled.

You can disable labeled services for SR-TE policies. The label switching database (LSD) needs to know if labeled services are disabled on top of an SR-TE policy to perform proper label stack splitting.

Disable Labeled Services per Local Policy

Use the **labeled-services disable** command to disable steering for labeled services for a configured policy. This configuration applies per policy.

```

segment-routing
  traffic-eng
    policy policy name
      steering
        labeled-services disable

```

Disable Labeled Services per ODN color

Use the **labeled-services disable** command to disable steering of labeled-services for on-demand color policies. This configuration applies for a specific ODN color.

```

segment-routing
  traffic-eng
    on-demand color color
      steering
        labeled-services disable

```

Disable Labeled Services per Policy Type

Use the **labeled-services disable** command to disable steering of labeled services for all policies for the following policy types:

- **all** — all policies
- **local** — all locally configured policies
- **on-demand** — all BGP on-demand color policies
- **bgp-srte** — all controller-initiated BGP SR-TE policies
- **pcep** — all PCE-initiated policies

Note You can specify more than one policy type.

```
segment-routing
  traffic-eng
    steering
      labeled-services
        disable {all | local | on-demand | bgp-srte | pcep}
```

Verification

Use the **show segment-routing traffic-eng policy** command to display SR policy information. The following output shows that steering of labeled services for the on-demand SR policy are disabled.

```
Router# show segment-routing traffic-eng policy color 10
Thu Jul 18 11:35:25.124 PDT

```

SR-TE Head-End IPv4 Unnumbered Interface Support

Table 79: Feature History Table

Feature Name	Release Information	Feature Description
SR-PCE: IP Unnumbered in Path Computation (ZTP/ZTD use case)	Release 7.3.1	This feature is now supported on routers that have the Cisco NC57 line cards installed and operate in the native and compatible modes. To enable the native mode, use the hw-module profile npu native-mode-enable command in the configuration mode. Ensure that you reload the router after configuring the native mode.

This feature allows IPv4 unnumbered interfaces to be part of an SR-TE head-end router topology database.

An unnumbered IPv4 interface is not identified by its own unique IPv4 address. Instead, it is identified by the router ID of the node where this interfaces resides and the local SNMP index assigned for this interface.

This feature provides enhancements to the following components:

- IGPs (IS-IS and OSPF):
 - Support the IPv4 unnumbered interfaces in the SR-TE context by flooding the necessary interface information in the topology
- SR-PCE:

Note SR-PCE and path computation clients (PCCs) need to be running Cisco IOS XR 7.0.2 or later.

- Compute and return paths from a topology containing IPv4 unnumbered interfaces.
- Process reported SR policies from a head-end router that contain hops with IPv4 unnumbered adjacencies.

PCEP extensions for IPv4 unnumbered interfaces adhere to IETF RFC8664 “PCEP Extensions for Segment Routing” (<https://datatracker.ietf.org/doc/rfc8664/>). The unnumbered hops use a Node or Adjacency Identifier (NAI) of type 5. This indicates that the segment in the explicit routing object (ERO) is an unnumbered adjacency with an IPv4 ID and an interface index.

- SR-TE process at the head-end router:
 - Compute its own local path over a topology, including unnumbered interfaces.
 - Process PCE-computed paths that contain hops with IPv4 unnumbered interfaces.
 - Report a path that contains hops with IPv4 unnumbered interfaces to the PCE.

Configuration Example

The following example shows how to configure an IPv4 unnumbered interface:

```
RP/0/0/CPU0:rtrA(config)# interface GigabitEthernet0/0/0/0
RP/0/0/CPU0:rtrA(config-if)# ipv4 point-to-point
RP/0/0/CPU0:rtrA(config-if)# ipv4 unnumbered Loopback0
```

To bring up the IPv4 unnumbered adjacency under the IGP, configure the link as point-to-point under the IGP configuration. The following example shows how to configure the link as point-to-point under the IGP configuration:

```
RP/0/0/CPU0:rtrA(config)# router ospf one
RP/0/0/CPU0:rtrA(config-ospf)# area 0
RP/0/0/CPU0:rtrA(config-ospf-ar)# interface GigabitEthernet0/0/0/0
RP/0/0/CPU0:rtrA(config-ospf-ar-if)# network point-to-point
```

Verification

Use the **show ipv4 interface** command to display information about the interface:

```
RP/0/0/CPU0:rtrA# show ipv4 interface GigabitEthernet0/0/0/0 brief
Tue Apr  2 12:59:53.140 EDT
Interface                               IP-Address      Status          Protocol
GigabitEthernet0/0/0/0                 192.168.0.1     Up              Up
```

This interface shows the IPv4 address of Loopback0.

Use the **show snmp interface** command to find the SNMP index for this interface:

```
RP/0/0/CPU0:rtrA# show snmp interface
Tue Apr  2 13:02:49.190 EDT
ifName : Null0                ifIndex : 3
ifName : Loopback0            ifIndex : 10
ifName : GigabitEthernet0/0/0/0 ifIndex : 6
```

The interface is identified with the pair (IPv4:192.168.0.1, index:6).

Use the **show ospf neighbor** command to display the adjacency:

```
RP/0/0/CPU0:rtrA# show ospf neighbor gigabitEthernet 0/0/0/0 detail
...
Neighbor 192.168.0.4, interface address 192.168.0.4
  In the area 0 via interface GigabitEthernet0/0/0/0
  Neighbor priority is 1, State is FULL, 6 state changes
...
Adjacency SIDs:
  Label: 24001,      Dynamic, Unprotected
Neighbor Interface ID: 4
```

The output of the **show segment-routing traffic-eng ipv4 topology** command is enhanced to display the interface index instead of the IP address for unnumbered interfaces:

```
RP/0/0/CPU0:rtrA# show segment-routing traffic-eng ipv4 topology
...
Link[2]: Unnumbered local index 6, remote index 4
Local node:
  OSPF router ID: 192.168.0.1 area ID: 0 ASN: 0
Remote node:
  TE router ID: 192.168.0.4
  OSPF router ID: 192.168.0.4 area ID: 0 ASN: 0
```

```

Metric: IGP 1, TE 1, Latency 1 microseconds
Bandwidth: Total 125000000 Bps, Reservable 0 Bps
Admin-groups: 0x00000000
Adj SID: 24001 (unprotected)

```

The output of the **show segment-routing traffic-eng policy detail** command includes unnumbered hops:

```

RP/0/0/CPU0:rtrA# show segment-routing traffic-eng policy detail
...
Dynamic (pce 192.168.0.5) (valid)
Metric Type: TE, Path Accumulated Metric: 3
  24001 [Adjacency-SID, unnumbered 192.168.0.1(6) - 192.168.0.4(4)]
  24002 [Adjacency-SID, unnumbered 192.168.0.4(7) - 192.168.0.3(7)]
  24000 [Adjacency-SID, unnumbered 192.168.0.3(5) - 192.168.0.2(5)]
...

```

Path invalidation drop

Table 80: Feature History Table

Feature Name	Release Information	Feature Description
Path invalidation drop	Release 7.4.1	<p>By default, if an SR Policy becomes invalid (for example, if there is no valid candidate path available), traffic falls back to the native SR forwarding path. In some scenarios, a network operator may require that certain traffic be only carried over the path associated with an SR policy and never allow the native SR LSP to be used.</p> <p>This feature allows the SR policy to stay up in the control plane (to prevent prefixes mapped to the SR policy from falling back to the native SR LSP) but drop the traffic sent on the SR policy.</p>

By default, if an SR Policy becomes invalid, traffic would fall back to the native SR forwarding path.

In some scenarios, a network operator may require that certain traffic be only carried over the path associated with an SR policy and never allow the native SR LSP to be used. The SR-TE path invalidation drop feature is introduced to meet this requirement.

With the path invalidation drop feature enabled, an SR policy that would become invalid (with no existing valid candidate path) is programmed to drop traffic. At the same time, the SR policy remains operationally UP to prevent prefixes steered over this SR policy from falling back to the native SR path.

Forwarding over the SR policy path resumes without dropping traffic, when the SR policy path becomes valid.

Note This feature applies to an SR policy that transitions from valid to invalid; it does not apply to an SR policy that has never been declared valid.

Enable path invalidation drop for manual SR policy

Use the **segment-routing traffic-eng policy *name* steering path-invalidation drop** command to enable the dropping of traffic when all candidate paths of an SR Policy becomes invalid.

```
segment-routing
 traffic-eng
  policy foo
  steering
    path-invalidation drop
```

Enable path Invalidation Drop for On-Demand SR Policy

Use the **segment-routing traffic-eng on-demand color *color* steering path-invalidation drop** command (where *color* is from 1 to 4294967295) to enable the dropping of traffic when an On-Demand SR Policy becomes invalid.

```
segment-routing
 traffic-eng
  on-demand color 10
  steering
    path-invalidation drop
```

Enable Path invalidation drop for PCE-initiated SR policy

Use the **segment-routing traffic-eng pcc profile *profile* steering path-invalidation drop** command (where *profile* is from 1 to 65534) to enable the dropping of traffic when a PCE-Initiated SR Policy becomes invalid.

```
segment-routing
 traffic-eng
  pcc
  profile 7
  steering
    path-invalidation drop
```

SR Policy output with path invalidation drop enabled and active

This output shows a detailed SR policy with path invalidation drop enabled and valid candidate path:

Router# show segment-routing traffic-eng policy detail

```

Configure path invalidation drop with performance measurement liveness detection

The Path Invalidation Drop feature can work alongside the **invalidation-action down** configuration in the Performance Measurement Liveness Detection feature. The Performance Measurement Liveness Detection feature enables end-to-end SR policy liveness detection for all segment lists of the active and standby candidate paths that are in the forwarding table. When **invalidation-action down** is configured and a candidate path becomes invalid, the candidate path is immediately operationally brought down and becomes invalid.

See [SR Policy Liveness Monitoring, on page 693](#) for information about configuring liveness detection and the invalidation action.

When both **path-invalidation drop** and **performance-measurement liveness-detection invalidation-action down** are enabled, the following behavior is observed:

1. If the PM liveness session goes down, the current active candidate path of the SR policy becomes invalid.
2. SR-TE path re-optimization occurs immediately to find the next valid candidate path in the SR policy.
3. If there is no valid candidate path in the SR policy, the policy remains operationally UP, but is marked with the invalidation-drop state.

SR-TE Reoptimization Timers

SR-TE path re-optimization occurs when the head-end determines that there is a more optimal path available than the one currently used. For example, in case of a failure along the SR-TE LSP path, the head-end could detect and revert to a more optimal path by triggering re-optimization.

Re-optimization can occur due to the following events:

- The explicit path hops used by the primary SR-TE LSP explicit path are modified
- The head-end determines the currently used path-option are invalid due to either a topology path disconnect, or a missing SID in the SID database that is specified in the explicit-path
- A more favorable path-option (lower index) becomes available

For event-based re-optimization, you can specify various delay timers for path re-optimization. For example, you can specify how long to wait before switching to a reoptimized path

Additionally, you can configure a timer to specify how often to perform reoptimization of policies. You can also trigger an immediate reoptimization for a specific policy or for all policies.

SR-TE Reoptimization

To trigger an immediate SR-TE reoptimization, use the **segment-routing traffic-eng reoptimization** command in Exec mode:

```
Router# segment-routing traffic-eng reoptimization {all | name policy}
```

Use the **all** option to trigger an immediate reoptimization for all policies. Use the **name policy** option to trigger an immediate reoptimization for a specific policy.

Configuring SR-TE Reoptimization Timers

Use these commands in SR-TE configuration mode to configure SR-TE reoptimization timers:

- **timers candidate-path cleanup-delay seconds**—Specifies the delay before cleaning up candidate paths, in seconds. The range is from 0 (immediate clean-up) to 86400; the default value is 120
- **timers cleanup-delay seconds**—Specifies the delay before cleaning up previous path, in seconds. The range is from 0 (immediate clean-up) to 300; the default value is 10.
- **timers init-verify-restart seconds**—Specifies the delay for topology convergence after the topology starts populating due to a restart, in seconds. The range is from 10 to 10000; the default is 40.
- **timers init-verify-startup seconds**—Specifies the delay for topology convergence after topology starts populating for due to startup, in seconds. The range is from 10 to 10000; the default is 300
- **timers init-verify-switchover seconds**—Specifies the delay for topology convergence after topology starts populating due to a switchover, in seconds. The range is from 10 to 10000; the default is 60.
- **timers install-delay seconds**—Specifies the delay before switching to a reoptimized path, in seconds. The range is from 0 (immediate installation of new path) to 300; the default is 10.
- **timers periodic-reoptimization seconds**—Specifies how often to perform periodic reoptimization of policies, in seconds. The range is from 0 to 86400; the default is 600.

Example Configuration

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# timers
Router(config-sr-te-timers)# candidate-path cleanup-delay 600
Router(config-sr-te-timers)# cleanup-delay 60
Router(config-sr-te-timers)# init-verify-restart 120
```

```

Router(config-sr-te-timers) # init-verify-startup 600
Router(config-sr-te-timers) # init-verify-switchover 30
Router(config-sr-te-timers) # install-delay 60
Router(config-sr-te-timers) # periodic-reoptimization 3000

```

Running Config

```

segment-routing
traffic-eng
timers
install-delay 60
periodic-reoptimization 3000

Circuit-Style SR-TE Policies

Table 81: Feature History Table

Feature Name	Release Information	Feature Description
Circuit-Style SR-TE Policies	Release 7.8.1	<p>This solution allows Segment Routing to meet the requirements of a connection-oriented transport network, which was historically delivered over circuit-switched SONET/SDH networks.</p> <p>Circuit-style SR-TE policies allow a common network infrastructure to be used for both connection-oriented services and classic IP-based transport. This eliminates the need for multiple parallel networks, which greatly reduces both capital expenditures (CapEx) and operating expenditures (OpEx).</p>

Segment Routing provides an architecture that caters to both connectionless transport (such as IP) as well as connection-oriented transport (such as TDM). IP-centric transport uses the benefits of ECMP and automated/optimum protection from TI-LFA. On the other hand, connection-oriented transport, which was historically delivered over circuit-switched SONET/SDH networks, requires the following:

- End-to-end bidirectional transport that provides congruent forward and reverse paths, predictable latency, and disjointness
- Bandwidth commitment to ensure there is no impact on the SLA due to network load from other services
- Monitoring and maintenance of path integrity with end-to-end 50-msec path protection
- Persistent end-to-end paths regardless of control-plane state

An SR network can satisfy these requirements by leveraging Circuit-Style SR-TE policies (CS-SR policies).

Properties of Circuit-Style SR Policies

CS-SR policies have the following properties:

• Guaranteed Latency over Non-ECMP Paths

Consider the network below with three possible paths from node 1 to node 7. Of the three paths, the best end-to-end delay is provided by the blue path (1 -> 2 -> 3 -> 7). The chosen path is then encoded with Adj-SIDs corresponding to the traversed interfaces to avoid any ECMP, and therefore guarantee the latency over the path.

522677

• Control-Plane Independent Persistency

Adjacency SIDs can provide a persistent path independent from control-plane changes (such as IGP neighbor flaps), as well as network events (such as interface additions or interface flaps) and even the presence of IP on an interface. To achieve this, adjacency SIDs can be manually allocated to ensure persistent values, for example after a node reload event. In addition, adjacency SIDs can be programmed as non-protected to avoid any local TI-LFA protection.

With the Adj-SIDs depicted in the figure below, the path from node 1 to node 7 is encoded with the segment list of {24000, 24001, 24000}. By manually allocating the same Adj-SID values for other direction, the path from node 7 to node 1 is encoded with the same segment list of {24000, 24001, 24000}.

522676

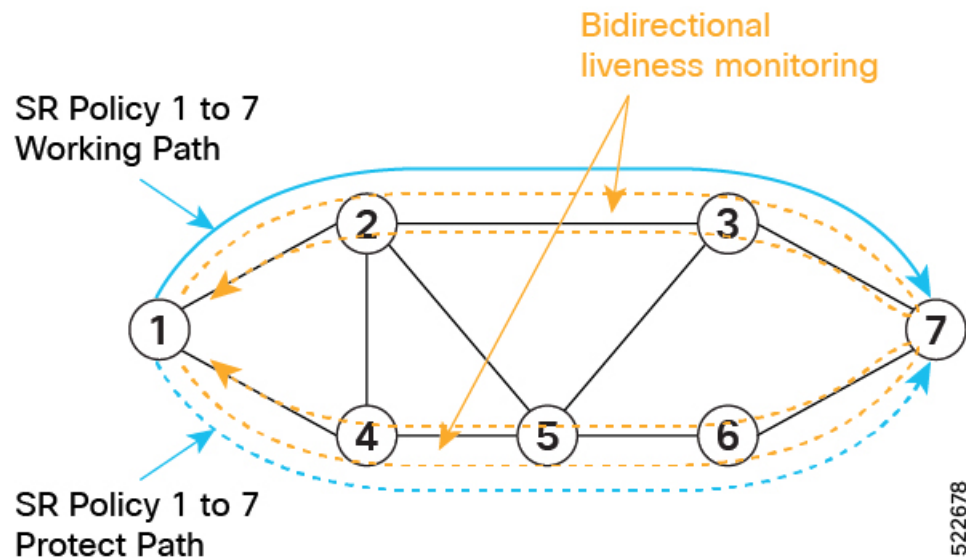

• Co-Routed Bidirectional Path

Forward and return SR Policies with congruent paths are routed along the same nodes/interfaces.

• Liveness Monitoring with Path Protection Switching

Bi-directional liveness monitoring on the working and protect paths ensures fast and consistent switchover, while a protect path is pre-programmed over disjoint facilities.

• Guaranteed Bandwidth

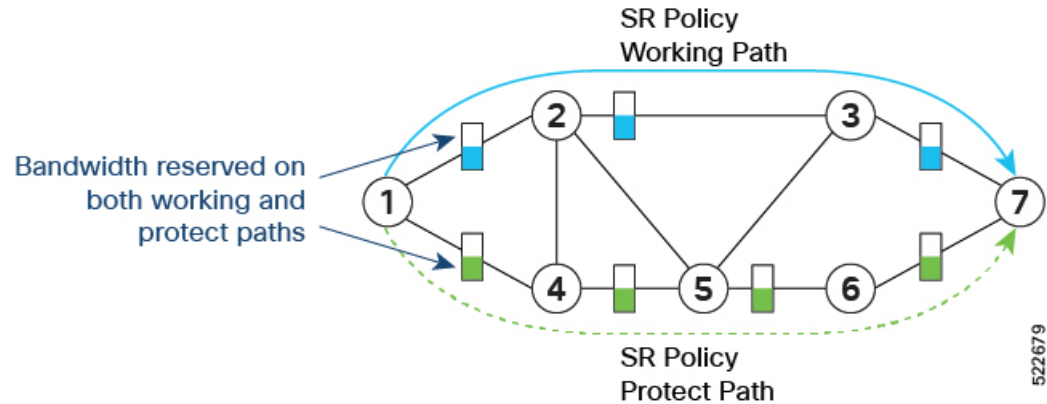

Most services carried over the CS-SR policy are constant-rate traffic streams. Any packet loss due to temporary congestion leads to bit errors at the service layer. Therefore, bandwidth must be managed very tightly and guaranteed to the services mapped to CS-SR policies.

A centralized controller manages the bandwidth reservation. The controller maintains the reserved bandwidth on each link based on the traffic usage:

- Monitors amount of traffic forwarded to each CS-SR policy in the network
- Uses knowledge of the active path used by the policy
- Computes the per-link reservable bandwidth accordingly

A per-hop behavior (as documented in [RFC3246](#) [Expedited Forwarding] or [RFC2597](#) [Assured Forwarding]) ensures that the specified bandwidth is available to CS-SR policies at all times independent of any other traffic.

Bandwidth is reserved on both the working and protect paths.

In addition, you can allocate one MPLS-EXP value for traffic steered over the CS SR-TE policies and use QoS (interface queueing) configuration to isolate the circuit traffic from the rest:

- QoS on headend nodes:
 - Define EXP value associated with CS services
 - Enforce rate limiting and perform EXP marking on service ingress interfaces
- QoS on transit nodes:
 - Classify incoming packets based on EXP value associated with CS services.
 - Enforce guaranteed bandwidth for the classified traffic on egress interfaces using bandwidth queues or priority queue with shaper.

Refer to [Configuring Modular QoS Service Packet Classification](#) chapter in the *Modular QoS Configuration Guide for Cisco NCS 5500 Series Routers*.

Components of the Circuit-Style Solution

CS-SR policy paths are computed and maintained by a stateful PCE. The stateful PCE has a centralized view of the network that it can leverage to compute the co-routed bidirectional end-to-end paths and perform bandwidth allocation control, as well as monitor capabilities to ensure SLA compliance for the life of the CS-SR Policy.

- Centralized Controller
 - Computes the path
 - Encodes the path in a list of Adj-SIDs
 - Monitors and controls bandwidth for SLA guarantee

- QoS configuration on every link to isolate guaranteed traffic

Usage Guidelines and Limitations

Observe the following guidelines and limitations:

- The maximum SID depth (MSD) is 610.
- CS SR policy end-point IP address must be the router-ID of the intended node.
- SR policy path protection is required for both directions.
- SR policy with dynamic path bandwidth constraint is required for both directions and must have the same value for both directions.
- Candidate path (CP) behavior:
 - The working path is associated with the candidate path of the highest preference value.
 - The protect path is associated with the candidate path of the second-highest preference value.
 - The restore path is associated with the candidate path of the third-highest preference value and is configured as "backup ineligible".
 - Candidate paths with the same role in both directions (working, protect, restore) must have the same preference value.
- Bi-directional path behavior:
 - All paths must be configured as co-routed.
 - All paths with the same role in both directions (working, protect, restore) must have the same bi-directional association ID value.
 - The bi-directional association ID value must be globally unique.
- Disjointness constraint:
 - The working and protect paths under the CS SR policy must be configured with a disjointness constraint using the same disjoint association ID and disjointness type.
 - The disjointness association ID for a working and protect path pair in one direction must be globally unique from the corresponding working and protect path pair in the opposite direction.
 - Node and link disjoint constraint types are supported.
 - The disjoint type used in both directions must be the same.
 - The restore path must not be configured with a disjointness constraint.
- Path optimization objectives supported are TE, IGP, and latency.
- The path optimization objective must match across working, protect, and restore paths in both directions.
- Segment type constraint:
 - Working, protect, and restore paths must all be configured with unprotected-only segment type constraint.

- Working, protect, and restore paths must all be configured with Adj-SID-only segment type constraint.
- To ensure persistency throughout link failure events, manual adjacency SIDs allocated from the SRLB range should be created on all interfaces used by CS policies.
- Revert/recovery behavior:
 - When both working and protect paths are down, the restore path becomes active.
 - The restore path remains active until the working or protect path recovers (partial recovery) and the lock duration timer expires.
 - The lock duration timer is configured under the protect and restore CPs.
- The following functionalities are not supported:
 - Affinity constraint
 - Flex-Algo constraint
 - Metric-bounds constraint
 - SR-TE Path Invalidation Drop

Configure Performance Measurement Liveness Profiles

Performance Measurement (PM) provides proper detection of candidate path liveness and effective path protection. See [SR Policy Liveness Monitoring, on page 693](#).

The following example shows how to create a liveness profile for the working and protect paths.

```
Router_1(config)# performance-measurement
Router_1(config-perf-meas)# liveness-profile name profile-WORKING
Router_1(config-pm-ld-profile)# liveness-detection
Router_1(config-pm-ld-profile-ld)# multiplier 3
```

```

Router_1(config-pm-ls-profile-ls)# exit
Router_1(config-pm-ls-profile)# probe
Router_1(config-pm-ls-probe)# tx-interval 30000
Router_1(config-pm-ls-probe)# exit
Router_1(config-pm-ls-profile)# exit
Router_1(config-perf-meas)# liveness-profile name profile-PROTECT
Router_1(config-pm-ls-profile)# liveness-detection
Router_1(config-pm-ls-profile-ls)# multiplier 3
Router_1(config-pm-ls-profile-ls)# exit
Router_1(config-pm-ls-profile)# probe
Router_1(config-pm-ls-probe)# tx-interval 100000

```

Configuring CS SR-TE Policy

The following example shows how to configure a circuit-style SR policy from node 1 to node 7 with three candidate paths: working, protect, and restore.

Create the SR-TE Policy

Configure the CS SR-TE policy.

Use the **bandwidth** *bandwidth* command in SR-TE policy configuration mode to configure the guaranteed reservable bandwidth for the policy. The range for *bandwidth* is from 1 to 4294967295 in kbps.

Use the **path-protection** command in SR-TE policy configuration mode to enable end-to-end path protection.

```

Router_1(config)# segment-routing
Router_1(config-sr)# traffic-eng
Router_1(config-sr-te)# policy cs-srte-to-node7
Router_1(config-sr-te-policy)# bandwidth 10000
Router_1(config-sr-te-policy)# color 10 end-point ipv4 10.1.1.7
Router_1(config-sr-te-policy)# path-protection
Router_1(config-sr-te-path-pref-protection)# exit
Router_1(config-sr-te-policy)#

```

Enable Liveness Monitoring Under SR Policy

The following example shows how to enable liveness monitoring under SR Policy and associate the working and protect (backup) liveness-profiles.

```
Router_1(config)# segment-routing
Router_1(config-sr)# traffic-eng
Router_1(config-sr-te)# policy cs-srte-to-node7
Router_1(config-sr-te-policy)# performance-measurement
Router_1(config-sr-te-policy-perf-meas)# liveness-detection
Router_1(config-sr-te-policy-live-detect)# liveness-profile name profile-WORKING
Router_1(config-sr-te-policy-live-detect)# liveness-profile backup name profile-PROTECT
Router_1(config-sr-te-policy-live-detect)# exit
Router_1(config-sr-te-policy-perf-meas)# exit
Router_1(config-sr-te-policy)#
```

Configure the Working Candidate Path

The working CP has the following characteristics:

- The working path is associated with the candidate path of the highest preference.
- The working CP uses unprotected-only Adj-SIDs in the segment list.
- The working CP is bidirectional and co-routed.
- The working CP in both directions must have the same bi-directional association ID value.
- The disjoint path constraint for the working CP must have the same group ID and disjoint type as the protect CP.

```
Router_1(config)# segment-routing
Router_1(config-sr)# traffic-eng
Router_1(config-sr-te)# policy cs-srte-to-node7
Router_1(config-sr-te-policy)# candidate-paths
Router_1(config-sr-te-policy-path)# preference 100
Router_1(config-sr-te-policy-path-pref)# dynamic
Router_1(config-sr-te-pp-info)# pcep
Router_1(config-sr-te-path-pcep)# exit
Router_1(config-sr-te-pp-info)# metric
Router_1(config-sr-te-path-metric)# type te
Router_1(config-sr-te-path-metric)# exit
Router_1(config-sr-te-pp-info)# exit
Router_1(config-sr-te-policy-path-pref)# constraints
Router_1(config-sr-te-path-pref-const)# segments
Router_1(config-sr-te-path-pref-const-seg)# protection unprotected-only
Router_1(config-sr-te-path-pref-const-seg)# adjacency-sid-only
Router_1(config-sr-te-path-pref-const-seg)# exit
Router_1(config-sr-te-path-pref-const)# disjoint-path group-id 3 type node
Router_1(config-sr-te-path-pref-const)# exit
Router_1(config-sr-te-policy-path-pref)# bidirectional
Router_1(config-sr-te-path-pref-bidir)# co-routed
Router_1(config-sr-te-path-pref-bidir)# association-id 1100
Router_1(config-sr-te-path-pref-bidir)# exit
Router_1(config-sr-te-policy-path-pref)# exit
Router_1(config-sr-te-policy-path)#
```

Configure the Protect Candidate Path

The protect CP has the following characteristics:

- The protect path is associated with the candidate path of the second-highest preference.
- The protect CP uses unprotected-only Adj-SIDs in the segment list.
- The protect CP is bidirectional and co-routed.
- The protect CP in both directions must have the same bi-directional association ID value.
- The disjoint path constraint for the protect CP must have the same group ID and disjoint type as the working CP.
- When the working path is invalid, the protect path becomes active. After the working path has recovered, the protect path remains active until the default lock duration (300 seconds) expires. You can configure a different lock duration using the **lock duration** *duration* command. The *duration* range is 0 (disabled) to 3000 seconds. If the lock duration is 0 (disabled), then the working path becomes active as soon as it recovers. If *duration* is not specified, the protect path remains active.

```

Router_1(config-sr-te-policy-path)# preference 50
Router_1(config-sr-te-policy-path-pref)# dynamic
Router_1(config-sr-te-pp-info)# pcep
Router_1(config-sr-te-path-pcep)# exit
Router_1(config-sr-te-pp-info)# metric
Router_1(config-sr-te-path-metric)# type te
Router_1(config-sr-te-path-metric)# exit
Router_1(config-sr-te-pp-info)# exit
Router_1(config-sr-te-policy-path-pref)# lock duration 30
Router_1(config-sr-te-policy-path-pref)# constraints
Router_1(config-sr-te-path-pref-const)# segments
Router_1(config-sr-te-path-pref-const-seg)# protection unprotected-only
Router_1(config-sr-te-path-pref-const-seg)# adjacency-sid-only
Router_1(config-sr-te-path-pref-const-seg)# exit
Router_1(config-sr-te-path-pref-const)# disjoint-path group-id 3 type node
Router_1(config-sr-te-path-pref-const)# exit
Router_1(config-sr-te-policy-path-pref)# bidirectional
Router_1(config-sr-te-path-pref-bidir)# co-routed
Router_1(config-sr-te-path-pref-bidir)# association-id 1050
Router_1(config-sr-te-path-pref-bidir)# exit
Router_1(config-sr-te-policy-path-pref)# exit
Router_1(config-sr-te-policy-path)#

```

Configure the Restore Candidate Path

The restore CP has the following characteristics:

- The restore path is associated with the candidate path of the the third-highest preference.
- The restore CP uses unprotected-only Adj-SIDs in the segment list.
- The restore CP is bidirectional and co-routed.
- The restore CP in both directions must have the same bidirectional association ID value.
- The restore CP must be configured with **backup-ineligible**. This configuration prevents the restore CP from being used as a fast reroute backup. The restore path is not computed until both working and protect paths become unavailable.
- Disjointness constraint is not configured on the restore CP.

- If both working and protect paths are unavailable, the restore path becomes active. After either the working or protect path has recovered, the restore path remains active until the default lock duration (300 seconds) expires. You can configure a different lock duration using the **lock duration** *duration* command. The *duration* range is 0 (disabled) to 3000 seconds. If the lock duration is 0 (disabled), then the working or protect path becomes active as soon as either recovers. If *duration* is not specified, the restore path remains active.

```

Router_1(config-sr-te-policy-path)# preference 10
Router_1(config-sr-te-policy-path-pref)# dynamic
Router_1(config-sr-te-pp-info)# pcep
Router_1(config-sr-te-path-pcep)# exit
Router_1(config-sr-te-pp-info)# metric
Router_1(config-sr-te-path-metric)# type te
Router_1(config-sr-te-path-metric)# exit
Router_1(config-sr-te-pp-info)# exit
Router_1(config-sr-te-policy-path-pref)# backup-ineligible
Router_1(config-sr-te-policy-path-pref)# lock duration 30
Router_1(config-sr-te-policy-path-pref)# constraints
Router_1(config-sr-te-path-pref-const)# segments
Router_1(config-sr-te-path-pref-const-seg)# protection unprotected-only
Router_1(config-sr-te-path-pref-const-seg)# adjacency-sid-only
Router_1(config-sr-te-path-pref-const-seg)# exit
Router_1(config-sr-te-path-pref-const)# exit
Router_1(config-sr-te-policy-path-pref)# bidirectional
Router_1(config-sr-te-path-pref-bidir)# co-routed
Router_1(config-sr-te-path-pref-bidir)# association-id 1010
Router_1(config-sr-te-path-pref-bidir)# exit
Router_1(config-sr-te-policy-path-pref)# exit
Router_1(config-sr-te-policy-path)#

Reporting of SR-TE Policies Using BGP- Link State

Table 82: Feature History Table

Feature Name	Release Information	Feature Description
Reporting of SR-TE Policies Using BGP-Link State for SRv6	Release 24.1.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>You can gather the Traffic Engineering Policy information that is locally available in a node and advertise it in BGP-LS for SRv6. The configuration procedures from previous releases, which supported only SR-MPLS, are the same and apply to this feature.</p>
Reporting of SR-TE Policies Using BGP-Link State for SR-MPLS	Release 7.10.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>BGP- Link State (LS) is a mechanism by which LS and Traffic Engineering (TE) information can be collected from networks and shared with external components (such as, Segment Routing Path Computation Element (SR-PCE) or Crossword Optimization Engine (COE)) using the BGP routing protocol.</p> <p>This feature gathers the Traffic Engineering Policy information that is locally available in a node and advertises it in BGP-LS for SR-MPLS.</p> <p>The operators can now take informed decisions based on the information that is gathered on their network's path computation, reoptimization, service placement, network visualization, and so on.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> • distribute link-state <p>YANG Data Model:</p> <ul style="list-style-type: none"> • New XPath for module <code>Cisco-IOS-XR-infra-xtc-agent-cfg.yang</code> (see GitHub, YANG Data Models Navigator)

This function is achieved using a BGP Network Layer Reachability Information (NLRI) encoding format. BGP-LS consumes structured IGP data (for example, router-id, remote-IP-address of a link, local-IP address

of a link, link identifier, and so on). and creates BGP-LS (NLRI) or attributes that BGP or other components like Cisco IOS XR Traffic Controller (XTC) can consume. Current implementation of BGP-LS can report topology using Nodes, Links, and Prefixes.

- Note**
- Starting from Release 7.10.1 this feature supports MPLS.
 - Starting from Release 24.1.1 this feature supports SRv6.

Modern Segment Routing (SR) networks often use SR Traffic Engineering (SR-TE) to influence the path that each specific traffic takes over the network. SR-TE tunnels can be provisioned manually on the tunnel head, but often they are calculated and provisioned by the central controller. Often operator of the network wants the ability to force the traffic over specific nodes and links.

Now the operators have the option to collect reports of the SR-TE and Policy information that is locally available in a node and advertise it into BGP-LS updates, which can be used by external components. Refer the [IEFT](#) for examples. This feature is implemented so that the operators have control over their network's path computation, reoptimization, service placement, network visualization, and so on.

- Note**
- Circuit Style (CS) SR policies are reported but without the CS policies' specific attributes, like the bidirectional constraints, per-hop behavior, and so on.

Restrictions to Reporting of SRTE Policies using BGP-LS

Some important points to be aware related to this feature are as follows:

- This feature has high availability, ensuring BGP-LS reporting at all times.
- This feature works with PCE State Sync. The policy information learned via the state-sync channel is not advertised in BGP-LS by the PCE.
- The feature works with PCE redundancy. Both PCEs advertise the BGP-LS policy information. The consumers can select only one policy based on the BGP best path logic.

Configure Reporting of SRTE Policies using BGP-LS

The reporting of policies to BGP-LS is disabled by default. Configuring the **distribute link-state** under the SR-PCE or SR-TE configuration enables this feature. Once enabled, all the existing SR policies or Candidate Path (CPs) are encoded to BGP-LS. You can disable this feature by removing the configuration and all the SR policies or CPs are withdrawn from BGP which deletes all of the previously encoded SR policies or CPs.

- Note**
- When SR policies that are reporting in BGP-LS are enabled by the operator, the Head End only reports the Active Candidate Path (CPs) (CPs installed in the forwarding). There are monitoring use cases that require reporting of inactive CPs. The following CLI is needed to report inactive CPs.

For both SR-TE and SR-PCE, you need to use the global CLI to enable the reporting of policies or Circuit Style (CS) to BGP-LS:

**Note**

- Starting from Release 7.10.1 this feature supports MPLS.
- Starting from Release 24.1.1 this feature supports SRv6.

Configuration Example

Configure the following command to enable reporting and syncing of SR policies in BGP-LS at the Head End:

```
Router# config
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# distribute link-state
Router(config-sr-te-distribute-ls)# report-candidate-path-inactive
Router(config-sr-te-distribute-ls)# commit
Router(config-sr-te-distribute-ls)# exit
```

**Note**

The **report-candidate-path-inactive** command is an optional command to report inactive CPs.

Running Configuration

This is a sample running configuration which shows that you have configured BGP-LS reporting feature.

```
segment-routing
 traffic-eng
  distribute link-state
  report-candidate-path-inactive
!
```

Verification

Use the **show pce segment-routing traffic-eng policy private** and **show pce distributed-ls events** to verify the configuration.

```
Router#show pce segment-routing traffic-eng policy private
```

```

SR-TE Policy Path Protection

Table 83: Feature History Table

Feature Name	Release Information	Feature Description
SR-TE Policy Path Protection	Release 7.4.2	<p>You can now configure pre-programmed SR-TE policy Working and Protect candidate paths, and provide fast failure detection through SR Policy Liveness Monitoring probes. If there is a liveness failure on the Working candidate path, the headend triggers a switchover to the Protect candidate path.</p> <p>With this release, you can operate IP-centric (with ECMP and TI-LFA) and TDM-centric (with circuits and path protection) services over a common SR network. This eliminates the need for multiple parallel networks and reduces capital expenditures (CapEx) and operating expenditures (OpEx).</p> <p>For this feature, the following commands/keywords are added:</p> <ul style="list-style-type: none"> • policy path-protection • policy candidate-paths preference lock duration • backup keyword is added to the performance-measurement liveness-detection command.

To provide SR policy path protection, headend router and liveness monitoring functions are introduced. The functions are explained with the *1:1 (one-to-one) path protection with SR policy liveness monitoring* use case for TDM-centric networks. Pointers:

Note Path protection and local TI-LFA FRR are mutually exclusive functions.

- An SR-TE policy is enabled on the headend router. The headend router 1 sends traffic to endpoint router 7. The Working candidate path **Blue** spans routers 1-2-3-7, and the Protect candidate path **Green** spans routers 1-4-5-6-7.
- The headend Router maintains an independent liveness session on each candidate path using loopback measurement mode. After verifying liveness, it pre-programs Working and Protect paths in forwarding.
- The paths are manually configured in explicit segment lists using MPLS labels to ensure that unprotected adjacency SIDs are utilized.
- The headend router sends traffic over the Working candidate path, and detects any liveness failure. When there is a failure, it sends direct switchover notifications to the FIB, and triggers a switchover to the protected path.
- In 1:1 (*one-to-one*) path protection, when the Working candidate path fails, the Protect candidate path sends traffic.

Note SR-TE policy path protection and SR-TE path invalidation drop inter-working is not supported.

Liveness Monitoring

- SR PM Liveness probes are performed over Working and Protect candidate paths.
- TWAMP Light (RFC 5357) is used for performance measurement and liveness monitoring.
- Separate PM liveness monitoring sessions are created for working and protect candidate-paths.
- Independent PM sessions are created at both endpoints of the SR Policy.

- Loopback measurement-mode (timestamps t1/t4) is used for liveness monitoring. Probe packets are not punted on the responder node. Round-trip delay is computed as (t4 – t1).
- From headend router 1, PM probe query packets are sent with forward and reverse (7->3->2->1) direction paths of the SR Policy's candidate-path in the header of the probe packet. Similarly, PM probe query packets are sent along the Protect path.
- For liveness monitoring:
 - Liveness is declared UP as soon as one probe packet is received back on all segment-lists of the candidate-path.
 - Liveness failure is detected when last N (user-configured value) consecutive probe packets are lost on any segment-list.
 - Fault in the forward and reverse direction of the segment-list (co-routed path) triggers liveness failure notification to SRTE and FIB. FIB triggers protection switchover upon PM notification (running on high priority thread).

Configuration

- In this example, an SR-TE policy **foo** is created on the headend router and path-protection is enabled for the policy.

```
RP/0/RSP0/CPU0:ios# configure
RP/0/RSP0/CPU0:ios(config)# segment-routing traffic-eng policy foo
RP/0/RSP0/CPU0:ios(config-sr-te-policy)# color 10 end-point ipv4 192.168.0.3
RP/0/RSP0/CPU0:ios(config-sr-te-policy)# path-protection
RP/0/RSP0/CPU0:ios(config-sr-te-path-pref-protection)#exit
```

- Under **candidate-paths**, the Protect and Working paths are specified through explicit segment lists.
- The Protect path's preference is 50, and it is lower than the Working path preference of 100. The forward (1->4->5->6->7) and reverse (7->6->5->4->1) Protect paths, and the forward (1->2->3->7) and reverse (7->3->2->1) Working paths are enabled as explicit segment lists.
- When the Working path is invalid, the Protect path becomes active. After the Working path has recovered, the Protect path remains active until the default lock duration (of 300 seconds) expires. You can configure a different lock duration using the **lock duration** command.

The duration range is 0 (disabled) to 3000 seconds. If the lock duration is 0 (disabled), then the Working path becomes active as soon as it recovers. If the duration is not specified, the Protect path remains active.

```
RP/0/RSP0/CPU0:ios(config-sr-te-policy)# candidate-paths
RP/0/RSP0/CPU0:ios(config-sr-te-policy-path)#preference 50
RP/0/RSP0/CPU0:ios(config-sr-te-policy-path-pref)#lock duration 30
RP/0/RSP0/CPU0:ios(config-sr-te-policy-path-pref)# explicit segment-list sl-protect-fw
```

Type **Exit** three times to go to the SR-TE policy configuration mode.

```
RP/0/RSP0/CPU0:ios(config-sr-te-policy)#candidate-paths
RP/0/RSP0/CPU0:ios(config-sr-te-policy-path)#preference 100
RP/0/RSP0/CPU0:ios(config-sr-te-policy-path-pref)# explicit segment-list sl-working-fw
RP/0/RSP0/CPU0:ios(config-sr-te-pp-info)# commit
```

Working and Protect Segment Lists Configuration

Configure explicit segment lists for the candidate paths.

Note Segment lists must use only unprotected (dynamic or manual) Adjacency SID and BSIDs (as non-first-SID).

```
RP/0/RSP0/CPU0:ios# configure
RP/0/RSP0/CPU0:ios(config)# segment-routing traffic-eng
RP/0/RSP0/CPU0:ios(config-sr-te)# segment-list sl-working-fw
RP/0/RSP0/CPU0:ios(config-sr-te-sl)# index 1 mpls label 24000
RP/0/RSP0/CPU0:ios(config-sr-te-sl)# index 2 mpls label 24004
RP/0/RSP0/CPU0:ios(config-sr-te-sl)# exit
RP/0/RSP0/CPU0:ios(config-sr-te)# segment-list sl-working-bck
RP/0/RSP0/CPU0:ios(config-sr-te-sl)# index 1 mpls label 24002
RP/0/RSP0/CPU0:ios(config-sr-te-sl)# index 2 mpls label 24006
RP/0/RSP0/CPU0:ios(config-sr-te-sl)# exit
RP/0/RSP0/CPU0:ios(config-sr-te)# segment-list sl-protect-fw
RP/0/RSP0/CPU0:ios(config-sr-te-sl)# index 1 mpls label 24000
RP/0/RSP0/CPU0:ios(config-sr-te-sl)# index 2 mpls label 30201
RP/0/RSP0/CPU0:ios(config-sr-te-sl)# exit
RP/0/RSP0/CPU0:ios(config-sr-te)# segment-list sl-protect-bck
RP/0/RSP0/CPU0:ios(config-sr-te-sl)# index 1 mpls label 24002
RP/0/RSP0/CPU0:ios(config-sr-te-sl)# index 2 mpls label 30201
RP/0/RSP0/CPU0:ios(config-sr-te-sl)# commit
```

Performance Measurement Configuration For SR-TE Policy

- Enable SR-TE policy specific performance measurement configurations.
- Create a liveness profile for the Working and Protect paths.

```
RP/0/RSP0/CPU0:ios# configure
RP/0/RSP0/CPU0:ios(config)# segment-routing traffic-eng policy foo
RP/0/RSP0/CPU0:ios(config-sr-te-policy)# performance-measurement
RP/0/RSP0/CPU0:ios(config-sr-te-policy-perf-meas)# liveness-detection
RP/0/RSP0/CPU0:ios(config-sr-te-policy-live-detect)# liveness-profile backup name
profile-PROTECT
RP/0/RSP0/CPU0:ios(config-sr-te-policy-live-detect)# liveness-profile name profile-WORKING
```

- The default Invalidation action is Down and it triggers path protection switching. The other action is None, which is enabled here.

```
RP/0/RSP0/CPU0:ios(config-sr-te-policy-live-detect)# invalidation-action none
RP/0/RSP0/CPU0:ios(config-sr-te-policy-live-detect)# commit
```

Performance Measurement Global Profile Configuration

- Create a Working candidate path liveness profile.

```
RP/0/RSP0/CPU0:ios(config)# performance-measurement
RP/0/RSP0/CPU0:ios(config-perf-meas)# liveness-profile sr-policy name profile-WORKING
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy)# probe
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy-probe)# tx-interval 30000
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy-probe)# commit
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy-probe)# exit
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy)# liveness-detection multiplier 4
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy)# commit
```

Type **Exit** to access the Performance Measurement config mode.

- Create a Protect candidate path liveness profile.

```
RP/0/RSP0/CPU0:ios(config-perf-meas)# liveness-profile sr-policy name profile-PROTECT
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy)# probe
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy-probe)# tx-interval 100000
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy-probe)# commit
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy-probe)# exit
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy)# liveness-detection multiplier 3
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy)# commit
```

Verification

Use the **show segment-routing traffic-eng policy candidate-path** command to display Working and Protect candidate-path details.

```
RP/0/RSP0/CPU0:ios# show segment-routing traffic-eng policy candidate-path name foo
```

```
SR-TE policy database
```

SR Policy Path Computation for IPv6

Table 84: Feature History Table

Feature Name	Release Information	Feature Description
SR Policy Path Computation for IPv6	Release 24.1.1	We have introduced the capability for SR Policy to support segment lists with IPv6 addresses, which can be either dynamically computed or explicitly set at the SRTE headend.

You can now use this feature when you want SR Policy to support segment lists with IPv6 addressed.

Note It uses the exiting configurations outlined in *Chapter: Configure SR-TE Policies* in *Segment Routing Configuration Guide for Cisco NCS 5500 Series Routers*, with the supported features detailed in the Usage Guidelines section that follows.

Usage Guidelines and Limitations

The supported features are listed below in the same order as the Table of Contents within the *Chapter: Configure SR-TE Policies* in *Segment Routing Configuration Guide for Cisco NCS 5500 Series Routers*

Supported Features

- Instantiation of SR Policy
 - On-Demand SR Policy – SR On-Demand Next-Hop
 - Manually Provisioned SR Policy
- SR-TE BGP Soft Next-Hop Validation For ODN Policies
- SR-TE Policy Path Types
 - Dynamic Paths
 - Optimization Objectives
 - Constraints
 - Configure SR Policy with Dynamic Path
 - Explicit Paths
 - SR-TE Policy with Explicit Path
 - Explicit Path with Affinity Constraint Validation
 - Explicit Path with Segment Protection-Type Constraint
- Traffic Steering
 - Automated Steering

- Color-Only Automated Steering
- Static Route over Segment Routing Policy
- Services Supported
 - IPv4 BGP Global Routes
 - IPv6 BGP Global Routes
- Miscellaneous
 - SR-TE Reoptimization Timers
 - Sharing the Extended Label Switch Path Array

CHAPTER 12

Segment Routing Tree Segment Identifier

Table 85: Feature History Table

Feature Name	Release Information	Feature Description
Segment Routing Tree SID	Release 7.4.1	<p>This feature is now supported on Cisco NCS 5700 series fixed-port routers and the Cisco NCS 5500 series routers that have the Cisco NC57 line cards installed and operating in the native mode.</p> <p>To enable the native mode, use the hw-module profile npu native-mode-enable command in the configuration mode. Ensure that you reload the router after configuring the native mode.</p>

Tree Segment Identifier (Tree-SID) is an SDN controller-based approach to build label switched multicast (LSM) Trees for efficient delivery of multicast traffic in an SR domain and without the need for multicast protocol running in the network. With Tree SID, trees are centrally computed and controlled by a path computation element (SR-PCE).

A Replication segment (as specified in IETF draft "[SR Replication segment for Multi-point Service Delivery](#)") is a type of segment which allows a node (Replication node) to replicate packets to a set of other nodes (Downstream nodes) in a Segment Routing Domain.

A Replication segment includes the following:

- Replication SID: The Segment Identifier of a Replication segment. This is an SR-MPLS label (Tree SID label).
- Downstream nodes: Set of nodes in Segment Routing domain to which a packet is replicated by the Replication segment.

A Point-to-Multipoint (P2MP) tree is formed by stitching Replication segments on the Root node, intermediate Replication nodes, and Leaf nodes. This is referred to as an SR P2MP Policy (as specified in IETF draft "[Segment Routing Point-to-Multipoint Policy](#)").

An SR P2MP policy works on existing MPLS data-plane and supports TE capabilities and single/multi routing domains. At each node of the tree, the forwarding state is represented by the same Replication segment (using a global Tree-SID specified from the SRLB range of labels).

An SR P2MP policy request contains the following:

- Policy name
- SID for the P2MP Tree (Tree-SID)
- Address of the root node
- Addresses of the leaf nodes
- Optimization objectives (TE, IGP, delay metric)
- Constraints (affinity)

The SR-PCE is responsible for the following:

1. Learning the network topology - *to be added*
2. Learning the Root and Leaves of a Tree - *describe dynamic and static Tree SIDs (16-17) - Tree SID Policy Types and Behaviors*
3. Computing the Tree
4. Allocating MPLS label for the Tree
5. Signaling Tree forwarding state to the routers
6. Re-optimizing Tree

Tree SID Policy Types and Behaviors

- Static P2MP Policies—can be configured in the following ways:
 - Tree SID parameters provided via Cisco Crosswork Optimization Engine (COE) UI
 - COE passes the policy configuration to the SR-PCE via REST API (no Tree-SID CLI at PCE). This method allows for SR-PCE High Availability (HA).

Note Refer to the *Traffic Engineering in Crosswork Optimization Engine* chapter in the [Cisco Crosswork Optimization Engine](#) documentation.

- Tree SID parameters configured via Tree-SID CLI at the SR-PCE

Caution With this method, SR-PCE HA is not supported. For this reason, this configuration method is not recommended.

- Dynamic P2MP Policies—can be configured in the following ways:

- A BGP mVPN is configured in the network (PE nodes) – service configuration via CLI or Cisco NSO
 - As a result, BGP control plane is used for PE auto-discovery and customer multicast signaling.
- Tree SID parameters are provided by mVPN PEs via PCEP to the PCE. This method allows for SR-PCE High Availability (HA).

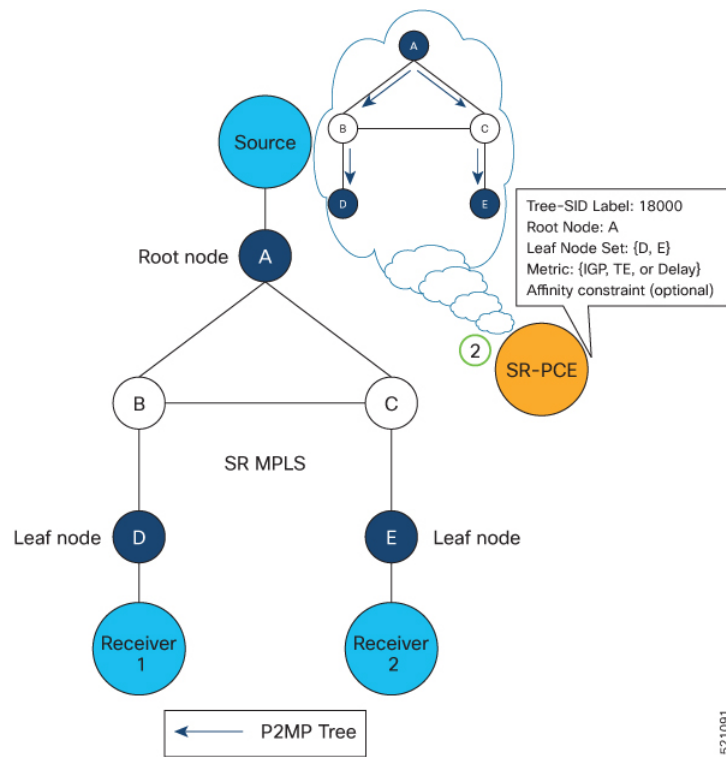

Tree SID Workflow Overview

This sections shows a basic workflow using a static Tree SID policy:

1. User creates a static Tree-SID policy, either via Crosswork Optimization Engine (preferred), or via CLI at the SR-PCE (not recommended).

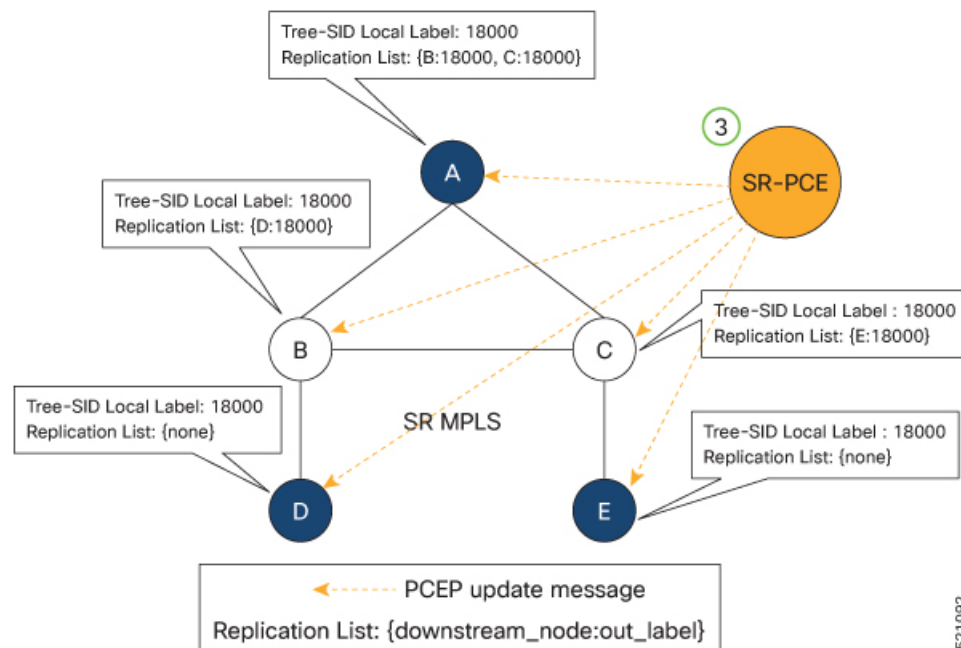

2. SR-PCE computes the P2MP Tree.

521091

3. SR-PCE instantiates the Tree-SID state at each node in the tree.

521092

4. The Root node encapsulates the multicast traffic, replicates it, and forwards it to the Transit nodes.

5. The Transit nodes replicate the multicast traffic and forward it to the Leaf nodes.
6. The Leaf nodes decapsulate the multicast traffic and forward it to the multicast receivers.

- [Usage Guidelines and Limitations, on page 529](#)
- [Bud Node Support, on page 530](#)
- [Configure Static Segment Routing Tree-SID via CLI at SR-PCE, on page 530](#)
- [Running Config, on page 532](#)
- [Multicast VPN: Dynamic Tree-SID MVPN \(with TI-LFA\), on page 534](#)
- [Multicast VPN IPv6: Dynamic Tree-SID Multicast VPN IPv6, on page 549](#)
- [Multicast: Cisco Nonstop Forwarding for Tree-SID, on page 566](#)
- [Multicast: SR-PCE High Availability \(HA\) Support for Dynamic Tree-SID \(mVPN\), on page 567](#)
- [Segment routing Tree-SID interoperability and SR-P2MP enhancements, on page 583](#)

Usage Guidelines and Limitations

- SR-PCE High Availability (HA) is supported for dynamic P2MP policies and for static P2MP policies configured via Cisco Crosswork Optimization Engine (COE) UI.

- SR-PCE HA is not supported for static Tree-SID policy configured via Tree-SID CLI at the SR-PCE. Tree-SID can only be controlled by a single PCE. Configure only one PCE on each PCC in the Tree-SID path.

Bud Node Support

In a multicast distribution tree, a Bud node is a node that acts as a leaf (egress) node as well as a mid-point (transit) node toward the downstream sub-tree.

In the below multicast distribution tree topology with Root node {A} and Leaf nodes set {B, C, D}, node D is a Bud node. Similarly, if node E is later added to the Leaf set, it would also become a Bud node.

The tree computation algorithm on SR-PCE has been enhanced to detect a Bud node based on knowledge of the Leaf set, and to handle Leaf/Transit node transitions to Bud node. The role of the Bud node is also explicitly signaled in PCEP.

Configure Static Segment Routing Tree-SID via CLI at SR-PCE

Caution

With this configuration method, SR-PCE HA is not supported. For this reason, this configuration method is not recommended.

To configure static Segment Routing Tree-SID for Point-to-Multipoint (P2MP) SR policies, complete the following configurations:

1. Configure Path Computation Element Protocol (PCEP) Path Computation Client (PCC) on all nodes involved in the Tree-SID path (root, mid-point, leaf)
2. Configure Affinity Maps on the SR-PCE
3. Configure P2MP SR Policy on SR-PCE
4. Configure Multicast on the Root and Leaf Nodes

Configure PCEP PCC on All Nodes in Tree-SID Path

Configure all nodes involved in the Tree-SID path (root, mid-point, leaf) as PCEP PCC. For detailed PCEP PCC configuration information, see [Configure the Head-End Router as PCEP PCC, on page 436](#).

Configure Affinity Maps on the SR-PCE

Use the **affinity bit-map** *COLOR bit-position* command in PCE SR-TE sub-mode to define affinity maps. The bit-position range is from 0 to 255.

```
Router# configure
Router(config)# pce
Router(config-pce)# segment-routing traffic-eng
Router(config-pce-sr-te)# affinity bit-map RED 23
Router(config-pce-sr-te)# affinity bit-map BLUE 24
Router(config-pce-sr-te)# affinity bit-map CROSS 25
Router(config-pce-sr-te)#
```

Configure P2MP SR Policy on SR-PCE

Configure the end-point name and addresses, Tree-SID label, and constraints for the P2MP policy.

Use the **endpoint-set** *NAME* command in SR-PCE P2MP sub-mode to enter the name of the end-point set and to define the set of end-point addresses.

```
Router(config-pce-sr-te)# p2mp
Router(config-pce-sr-te-p2mp)# endpoint-set BAR
Router(config-pce-p2mp-ep-set)# ipv4 10.1.1.2
Router(config-pce-p2mp-ep-set)# ipv4 10.1.1.3
Router(config-pce-p2mp-ep-set)# ipv4 10.1.1.4
Router(config-pce-p2mp-ep-set)# exit
Router(config-pce-sr-te-p2mp)#
```

Use the **policy** *policy* command to configure the P2MP policy name and enter P2MP Policy sub-mode. Configure the source address, endpoint-set color, Tree-SID label, affinity constraints, and metric type.

```
Router(config-pce-sr-te-p2mp)# policy FOO
Router(config-pce-p2mp-policy)# source ipv4 10.1.1.6
Router(config-pce-p2mp-policy)# color 10 endpoint-set BAR
Router(config-pce-p2mp-policy)# treesid mpls 15200
Router(config-pce-p2mp-policy)# candidate-paths
Router(config-pce-p2mp-policy-path)# constraints
Router(config-pce-p2mp-path-const)# affinity
Router(config-pce-p2mp-path-affinity)# exclude BLUE
Router(config-pce-p2mp-path-affinity)# exit
Router(config-pce-p2mp-path-const)# exit
Router(config-pce-p2mp-policy-path)# preference 100
```

```
Router(config-pce-p2mp-policy-path-preference)# dynamic
Router(config-pce-p2mp-path-info)# metric type te
Router(config-pce-p2mp-path-info)# root
Router(config)#
```

Configure Multicast on the Root and Leaf Nodes

On the root node of the SR P2MP segment, use the **router pim** command to enter Protocol Independent Multicast (PIM) configuration mode to statically steer multicast flows into an SR P2MP policy.

Note Enter this configuration only on an SR P2MP segment. Multicast traffic cannot be steered into a P2P policy.

```
Router(config)# router pim
Router(config-pim)# vrf name
Router(config-pim-name)# address-family ipv4
Router(config-pim-name-ipv4)# sr-p2mp-policy FOO
Router(config-pim-name-ipv4-srp2mp)# static-group 235.1.1.5 10.1.1.6
Router(config-pim-name-ipv4-srp2mp)# root
Router(config)#
```

On the root and leaf nodes of the SR P2MP tree, use the **mdt static segment-routing** command to configure the multicast distribution tree (MDT) core as Tree-SID from the multicast VRF configuration submode.

```
Router(config)# multicast-routing
Router(config-mcast)# vrf TEST
Router(config-mcast-TEST)# address-family ipv4
Router(config-mcast-TEST-ipv4)# mdt static segment-routing
```

On the leaf nodes of an SR P2MP segment, use the **static sr-policy p2mp-policy** command to configure the static SR P2MP Policy from the multicast VRF configuration submode to statically decapsulate multicast flows.

```
Router(config)# multicast-routing
Router(config-mcast)# vrf TEST
Router(config-mcast-TEST)# address-family ipv4
Router(config-mcast-TEST-ipv4)# static sr-policy FOO
```

Running Config

The following example shows how to configure the end point addresses and P2MP SR policy with affinity constraints on SR-PCE.

```
pce
segment-routing
traffic-eng
affinity bit-map
RED 23
BLUE 24
CROSS 25
!
p2mp
endpoint-set BAR
ipv4 10.1.1.2
ipv4 10.1.1.3
```

The following example shows how to statically decapsulate multicast flows on the leaf nodes.

The following example shows to configure the multicast distribution tree (MDT) core as Tree-SID on the root and leaf nodes.

The following example shows how to steer traffic to the SR P2MP policy on the root node.

Segment Routing Configuration Guide for Cisco NCS 5500 Series Routers, IOS XR Release 24.1.x, 24.2.x, 24.3.x, 24.4.x

Multicast VPN: Dynamic Tree-SID MVPN (with TI-LFA)

Table 86: Feature History Table

Feature Name	Release Information	Feature Description
Multicast VPN: Dynamic Tree-SID MVPN (with TI-LFA)	Release 7.3.1	<p>With this feature, you can use SR and MVPN for optimally transporting IP VPN multicast traffic over the SP network, using SR-PCE as a controller.</p> <p>With SR's minimal source router configuration requirement, its ability to implement policies with specific optimization objectives and constraints, protect against network failures using TI-LFA FRR mechanism, and use SR-PCE to dynamically generate optimal multicast trees (including when topology changes occur in the multicast tree), the SR-enabled SP network can transport IP multicast traffic efficiently.</p>

Prerequisites for Multicast VPN: Tree-SID MVPN With TI-LFA

- The underlay OSPF/IS-IS network is configured, and OSPF/IS-IS adjacency is formed between routers, across the network.
- BGP is configured for the network, and BGP adjacency is formed between routers. BGP MVPN configuration information is provided in this feature document.
- To understand the benefits, know-how, and configuration of SR and SR-TE policies, see About Segment Routing and Configure SR-TE Policies.

Information About Multicast VPN: Tree-SID MVPN With TI-LFA

Typically, a customer's IP VPN is spread across VPN sites. IP VPN customer traffic is sent from one site to another over a VPN Service Provider (SP) network.

When IP multicast traffic within a (BGP/MPLS) IP VPN is transported over an SP network (say, from **VPN1-Site-A** to **VPN1-Site-B**, as shown in the image), the SP network requires protocols and procedures to optimally transport multicast traffic from a multicast sender in Site-A to multicast receivers in Site-B.

This use case explains how to enable SR multicast for an SP network, and efficiently transport IP VPN multicast traffic (sent from **VPN1-Site-A** and) received at PE router A, through to PE routers D and E, towards receivers in sites **VPN1-Site-B** and **VPN1-Site-C**.

Figure 25: IP VPN Multicast Traffic Flow Over An SP Network

To enable the *Multicast VPN: Tree-SID MVPN With TI-LFA* feature, the following protocols and software applications are used.

OSPF/IS-IS - The underlay network is created with OSPF/IS-IS routing protocol, and reachability is established across the network. See *Configure Segment Routing for IS-IS Protocol* or *Configure Segment Routing for OSPF Protocol* chapter for details.

BGP Multicast VPN (MVPN) – The PE routers (A, D, and E) are IP VPN end-points for IP multicast traffic arriving at the SP network (at PE router A) and exiting the SP network (at PE routers D and E). So, BGP MVPN is enabled on the PE routers. NSO is used to configure BGP MVPN on the PE routers.

BGP Auto-Discovery (AD) - To enable distributed VPN end-point discovery and C-multicast flow mapping and signalling, BGP AD function is configured on the PE routers. A BGP Auto-Discovery route contains multicast router (loopback IP address) and tree identity (segment ID) information. It carries the information in the Provider Multicast Service Interface (PMSI) Tunnel Attribute (PTA).

C-multicast states are signaled using BGP.

SR - To transport IP multicast traffic between the VPN end-points (PE routers A, D, and E), Provider (or P-) tunnels are used. In a P-tunnel, the PE devices are the tunnel end-points. P-tunnels can be generated using different technologies (RSVP-TE, P2MP LSPs, PIM trees, mLDP P2MP LSPs, and mLDP MP2MP LSPs). In this use case, Segment Routing (SR) is used for its benefits that were noted earlier.

With SR and SR-PCE, a Tree-SID Point-to-Multipoint (P2MP) segment is used to create P-Tunnels for MVPN. You can specify SR policy optimization objectives (such as *metrics*) and constraints (such as *affinity*) in an SR policy and send it to the SR-PCE controller, so that it can dynamically create SR multicast trees for traffic flow.

SR-PCE - This is a controller which, based on the provided SR policy information, computes optimal paths for a multicast tree, and deploys the tree forwarding state on the multicast routers. When a topology change occurs, SR-PCE automatically computes a new, optimal multicast tree, and deploys the new tree forwarding state on the multicast routers.

Overview of Multicast VPN: Tree-SID MVPN With TI-LFA

Tree-SID MVPN Overview

- For multicast traffic, A is the root of the SR multicast tree, and D and E are leaf routers of the tree. B and C are the other multicast routers. The objective is to send the IP multicast traffic arriving at A to D and E, as needed

-
- The diagram illustrates the SR-P2MP algorithm. It shows a network topology with nodes A, B, C, D, and E. Node A is the source, and nodes B, C, D, and E are destinations. The algorithm steps are: 1. Create_P2MP(A, 10, {}), 2. Add_Leaf(A, 10, {D, E}), 3. SR-PCE, 4. SR-PCE, 5. SR-PCE. The diagram shows the flow of traffic from A to B, C, D, and E, with the SR-PCE node at the center.

6. SR-PCE assigns an SID for the SR multicast tree policy, and deploys the multicast tree forwarding state on the multicast routers.
7. When IP multicast traffic is sent from VPN1-SiteA to PE router A, it steers it into the SR policy, and sends it towards D and E, which forward it to multicast traffic receivers in the sites VPN1-SiteB and VPN1-SiteC.
8. When a leaf/multicast router is added or removed, PE router A updates the SR multicast policy and sends it to SR-PCE. SR-PCE computes new multicast routes, and deploys the multicast tree forwarding state information on the multicast routers.

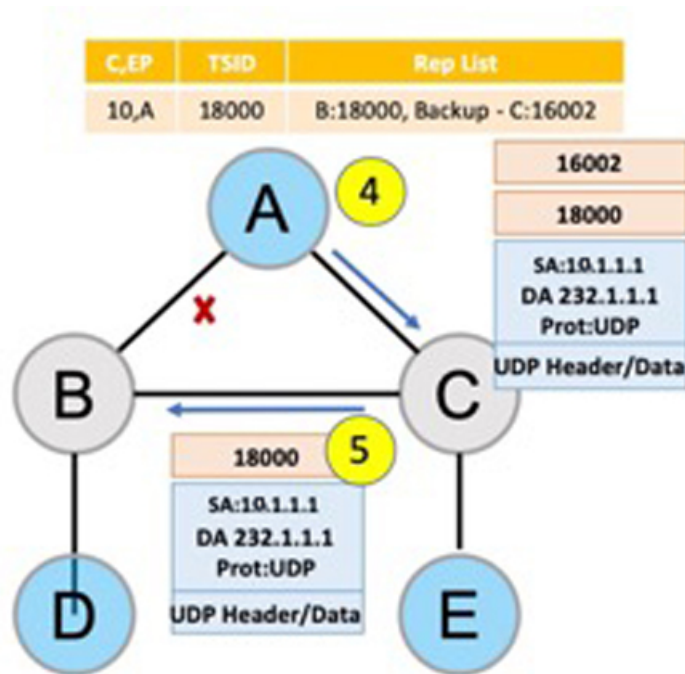

TI-LFA FRR Overview

High-level TI-LFA FRR function is depicted in these steps:

1. Tree-SID FRR state information.
 - The link from A to B is protected.
 - SID 16002 is the node SID of B.
 - A programs a backup path to B, through C.
2. IP multicast traffic arrives at A which steers the flow onto the tree.
3. A encapsulates and replicates to B, but the link to B is down.

4. A sends the traffic on the backup path, to C.
5. C sends the traffic to B where normal traffic processing resumes.

SR Multicast Tree Types

This is an overview of the types of SR multicast trees you can configure, depending on your requirement. You can create a full mesh, on-demand, or optimal multicast tree for IP VPN multicast flow in the SP network.

Figure 27: Full Mesh Multicast Tree

1. A assigns Tree-ID 10 and invokes a Create an SR multicast tree request by sending the multicast router and tree ID information (A, 10) towards SR-PCE.
2. A announces BGP AD Inclusive PMSI (I-PMSI) route with the PTA (A, 10). Inclusive PMSI - Traffic that is multicast by a PE router on an I-PMSI is received by all other PEs in the MVPN. I-PMSIs are generated by Inclusive P-tunnels.
3. A discovers VPN endpoints D and E from their BGP AD Type I-PMSI route messages.
4. A invokes an Add SR multicast leaf router request (for D and E) to SR-PCE.
5. SR-PCE computes and generates the multicast tree forwarding state information on all the routers that are part of the tree.

Figure 28: On-Demand SR Multicast Tree

1. A assigns Tree-ID 20 and invokes a Create an SR multicast tree request by sending the multicast router and tree ID information (A, 20) towards SR-PCE.
2. A announces BGP AD Selective PMSI (or S-PMSI) route with PTA (A, 20). A sets the leaf-info-required to discover endpoint interest set.

Selective PMSI - Traffic multicast by a PE on an S-PMSI is received by some PEs in the MVPN. S-PMSIs are generated by Selective P-tunnels.

3. E has a receiver behind it, and announces a BGP-AD leaf route towards A. A discovers service endpoint E for the on-demand tree.
4. A invokes an Add SR multicast leaf router request (for E) to SR-PCE.
5. SR-PCE computes and generates the multicast tree information for all the routers that are part of the tree.

Figure 29: Optimal Multicast Tree

1. A decides to optimize a flow and assigns Tree-ID 30 and invokes a Create an SR multicast tree request by sending the multicast router and tree ID information (A, 30) towards SR-PCE.
2. A announces BGP AD I-PMSI route with PTA (A,30). A sets the leaf-info-required to discover endpoint interest set.
3. D has a receiver behind it, and announces a BGP-AD leaf route towards A. A discovers service endpoint D for optimized flow.
4. A invokes an Add SR multicast leaf router request (for D) to SR-PCE.
5. SR-PCE computes and generates the multicast tree information for all the routers that are part of the tree.

Configurations

Head End Router Configuration (Router A) - The following configuration is specific to the head end router.

Configure TE Constraints and Optimization Parameters

```
Router# configure terminal
Router(config)# segment-routing traffic-engineering
```

An affinity bit-map is created so that it can be applied to a link or interface.

```
Router(config-sr-te)# affinity-map name 10 bit-position 24
Router(config-sr-te)# commit
```

An affinity (or relationship) is created between the SR policy path and the link color so that SR-TE computes a path that includes or excludes links, as specified. The head-end router automatically follows the actions defined in the ODN template (for color 10) upon the arrival of VPN routes with a BGP color extended community that matches color 10.

```
Router(config)# segment-routing traffic-engineering
Router(config-sr-te)# on-demand color 10 dynamic
Router(config-sr-te-color-dyn)# affinity include-all name red
```

```
Router(config-sr-te-color-dyn)# affinity include-any name blue
Router(config-sr-te-color-dyn)# affinity exclude-any name green
Router(config-sr-te-color-dyn)# metric type te
Router(config-sr-te-color-dyn)# commit
```

The SR policy configuration on the head-end router A will be sent to the SR-PCE server, after a connection is established between A and SR-PCE.

Multicast Router Configuration

Configure PCEP Client on Multicast Routers

Associate each multicast router as a client of the SR-PCE server. The **pce address ipv4** command specifies the SR-PCE server's IP address.

```
Router# configure terminal
Router(config)# segment-routing traffic-engineering
Router(config-sr-te)# pcc pce address ipv4 3.3.3.3
Router(config-pcc-pce)# commit
```

SR PCE Server Configuration

Configure Label Range for Multicast Trees

Configure the label range to be used for transporting IP multicast traffic in SP network.

```
Router(config)# pce segment-routing traffic-eng p2mp label-range min 30000 max 60000
Router(config)# commit
```

Configure FRR

The following configurations enable FRR for all SR multicast (P2MP) trees, including dynamic and static implementations.

The **lfa** keyword enables LFA FRR on the PCE server.

```
Router(config)# pce segment-routing traffic-eng p2mp fast-reroute lfa
Router(config)# commit
```

Alternatively, you can configure FRR for each individual tree using the following configuration. The **lfa** keyword under a specific multicast policy (**tree1** in this example) enables LFA FRR function for the specified SR multicast P2MP tree.

For dynamic trees, L-flag in LSP Attributes PCEP object controls FRR on a tree.

```
Router(config)# pce
Router(config-pce)# address ipv4 192.168.0.5
Router(config-pce)# segment-routing traffic-eng p2mp policy tree1 fast-reroute lfa
Router(config-pce)# commit
```

You can create FRR node sets using the **frr-node-set from ipv4 address** and **frr-node-set to ipv4 address** commands to specify the *from* and *to* paths on a multicast router that requires FRR protection. In this configuration, the PCE server is configured to manage the FRR function for traffic from 192.168.0.3 sent towards 192.168.0.4 and 192.168.0.5.

```
Router(config)# pce
Router(config-pce)# address ipv4 192.168.0.5
Router(config-pce)# segment-routing traffic-eng
Router(config-pce-sr-te)# p2mp
Router(config-pce-sr-te-p2mp)# frr-node-set from ipv4 192.168.0.3
Router(config-pce-sr-te-p2mp)# frr-node-set to ipv4 192.168.0.4
Router(config-pce-sr-te-p2mp)# frr-node-set to ipv4 192.168.0.5
Router(config-pce-sr-te-p2mp)# commit
```

Disable ECMP load splitting

To disable ECMP load splitting of different trees on the SR-PCE server, configure the **multipath-disable** command.

```
Router(config)# pce segment-routing traffic-eng p2mp multipath-disable
Router(config)# commit
```

Multicast Routing Configuration On PE Routers

The following MVPN configurations are required for VPN end-points, the 3 PE routers.

Configure Default MDT SR P2MP MVPN Profile

In this configuration, an MDT profile of the type *default* is created, and the SR multicast policy with color 10 will be used to send IP multicast traffic, as per the constraints and optimizations of the policy, through the multicast tree.

You can also specify the FRR LFA function with the **mdt default segment-routing mpls fast-reroute lfa** command.

```
Router(config)# multicast-routing vrf cust1
Router(config-mcast-cust1)# address-family ipv4
Router(config-mcast-cust1-ipv4)# mdt default segment-routing mpls color 10
Router(config-mcast-cust1-ipv4)# commit
```

Configure Partitioned MDT SR P2MP MVPN Profile

In this configuration, an MDT profile of the type *partitioned* is created, and the SR multicast policy with color 10 will be used to send IP multicast traffic, as per the constraints and optimizations of the policy, through the multicast tree.

You can also specify the FRR LFA function with the **mdt partitioned segment-routing mpls fast-reroute lfa** command.

```
Router(config)# multicast-routing vrf cust1
Router(config-mcast-cust1)# address-family ipv4
Router(config-mcast-cust1-ipv4)# mdt partitioned segment-routing mpls color 10
Router(config-mcast-cust1-ipv4)# commit
```

The following Data MVPN configuration is required at the Ingress PE (router A) where the multicast flows need to be steered onto the *data* MDT for SR multicast traffic flow.

Note - Data MDT can be configured for *Default* and *Partitioned* profiles.

Configure Data MDT for SR P2MP MVPN

In this configuration, an MDT profile of the type *data* is created, and the SR multicast policy with color 10 will be used to send IP multicast traffic, as per the constraints and optimizations of the policy, through the multicast tree.

- You can enable the FRR LFA function with the **mdt data segment-routing mpls fast-reroute lfa** command. This enables LFA FRR for SR multicast trees created for all data MDT profiles.
- As an alternative to the color keyword, you can specify a route policy in the **route-policy** command, and define the route policy separately (as mentioned in the next configuration).
- The **threshold** command specifies the threshold above which a multicast flow is switched onto the data MDT. The **immediate-switch** keyword enables an immediate switch of a multicast flow to the data MDT, without waiting for threshold limit to be crossed.
- The **customer-route-acl** keyword specifies an ACL to enable specific multicast flows to be put on to the data MDT.

- **color** and **fast-reroute lfa** keywords are mutually exclusive with the **route-policy** configuration. The objective is to apply constraints (through **color**) or FRR (through LFA protection) to either all data MDTs, or apply them selectively per data MDT, using the **set on-demand-color** and **set fast-reroute lfa** options in the route policy (configured in the **mdt data** configuration).

```
Router(config)# multicast-routing vrf cust1
Router(config-mcast-cust1)# address-family ipv4
Router(config-mcast-cust1-ipv4)# mdt data segment-routing mpls 2 color 10
Router(config-mcast-cust1-ipv4)# commit
```

Route Policy Example

The route policy designates multicast flow-to-SR multicast policy mapping, with different colors.

- With this configuration, IP multicast flows for the 232.0.0.1 multicast group are steered into the SR multicast policy created with the on-demand color 10, while flows for 232.0.0.2 are steered into the policy created with color 20.
- The *data* MDT SR multicast tree created for the 232.0.0.2 multicast group is enabled with FRR LFA protection.
- Route policies can also be used to match other parameters, such as source address.

```
Router(config)# route-policy TSID-DATA
Router(config-rpl)# if destination in (232.0.0.1) then
Router(config-rpl-if)# set on-demand-color 10
Router(config-rpl-if)# pass
Router(config-rpl-if)# elseif destination in (232.0.0.2) then
Router(config-rpl-elseif)# set on-demand-color 20
Router(config-rpl-elseif)# set fast-reroute lfa
Router(config-rpl-elseif)# pass
Router(config-rpl-elseif)# endif
Router(config-rpl)# end-policy
Router(config)# commit
```

Configure MVPN BGP Auto-Discovery for SR P2MP

The following configuration is required on all PE routers, and is mandatory for *default* MDT, *partitioned* MDT, and *data* MDT.

Configure the BGP Auto-Discovery function for transporting IP multicast traffic.

```
Router(config)# multicast-routing vrf cust1
Router(config-mcast-cust1)# address-family ipv4
Router(config-mcast-cust1-ipv4)# bgp auto-discovery segment-routing
Router(config-mcast-cust1-ipv4-bgp-ad)# commit
```

Verification

View MVPN Context Information - You can view MVPN VRF context information with these commands.

View Default MDT Configuration

This command displays SR multicast tree information, including the MDT details (of *default* type, etc), and customer VRF information (route target, route distinguisher, etc).

For dynamic SR multicast trees created for MVPN, the **show** command has filters to view root multicast router and Tree-ID information. When the root router is specified, all multicast trees from that root are displayed. When root and Tree-ID are specified, only the specified tree information is displayed.

```
Router# show pce lsp p2mp root ipv4 10.1.1.1 524289
```

```

Tree: sr_p2mp_root_10.1.1.1_tree_id_524289, Root: 10.1.1.1 ID: 524289

```

The following output shows that LFA FRR is enabled on the hop from rtrR to rtrM. Unlike typical multicast replication where the address displayed is the remote address on the link to a downstream router, the IP address 192.168.0.3 (displayed with an exclamation mark) is the router-ID of the downstream router rtrM. The output also displays the LFA FRR state for the multicast tree.

  Replication:
    Incoming label: 18001 CC-ID: 6

Policy: sr_p2mp_root_192.168.0.4_tree_id_524290  LSM-ID: 0x80002 (PCC-initiated)
  Color: 0
  LFA FRR: Disabled
  Role: Root
  Replication:
    Incoming label: 18000 CC-ID: 2
    Interface: None [192.168.0.3!]  Outgoing label: 18000 CC-ID: 2
  Endpoints:
    192.168.0.1, 192.168.0.2

```

For SR multicast policies originated locally on the router (root router of a dynamic MVPN multicast policy) additional policy information is displayed. The information includes color, end points, and whether LFA FRR is requested by the local application. When the SR-PCE server enables LFA FRR on a specific hop, the outgoing information shows the address of the next router with an exclamation mark and None is displayed for the outgoing interface.

For dynamic SR multicast trees created for MVPN, the **show** command has filters for displaying root multicast router and Tree-ID information. When the root router is specified, all multicast trees for that root are displayed. When root and Tree-ID are specified, only the specified tree information is displayed.

Router# **show segment-routing traffic-eng p2mp policy root ipv4 1.1\$**

Multicast VPN IPv6: Dynamic Tree-SID Multicast VPN IPv6

Table 87: Feature History Table

Feature Name	Release Information	Feature Description
Multicast VPN: Dynamic Tree-SID Multicast VPN IPv6	Release 7.10.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>This feature allows Dynamic Tree Segment Identifier (Tree-SID) deployment where IPv6 Multicast payload is used for optimally transporting IP VPN multicast traffic over the provider network, using SR-PCE as a controller. This implementation supports IPv6 only for the Dynamic Tree-SID. Currently, the Static Tree-SID supports IPV4 payloads only, not the IPv6 payloads.</p>

Overview of Multicast VPN: Tree-SID Multicast VPN

Typically, a customer's IP VPN is spread across VPN sites. IP VPN customer traffic is sent from one site to another over a VPN Service Provider (SP) network.

When IP Multicast traffic within a (BGP/MPLS) IP VPN is transported over a provider network (say, from **VPN1-Site-A** to **VPN1-Site-B**, as shown in the image), the provider network requires protocols and procedures to optimally transport multicast traffic from a multicast sender in Site-A to multicast receivers in Site-B.

This use case explains how to enable SR multicast for a provider network, and efficiently transport IP VPN multicast traffic (sent from **VPN1-Site-A** and) received at PE router A, through to PE routers D and E, toward receivers in sites **VPN1-Site-B** and **VPN1-Site-C**.

Figure 30: IP VPN Multicast Traffic Flow Over A Provider Network

To enable the *Multicast VPN: Tree-SID multicast VPN* feature, the following protocols and software applications are used:

- **OSPF/IS-IS** - The underlay network is created with OSPF/IS-IS routing protocol, and reachability is established across the network. See *Configure Segment Routing for IS-IS Protocol* or *Configure Segment Routing for OSPF Protocol* chapter for details, within this Guide.
- **BGP Multicast VPN (multicast VPN)** – The PE routers (A, D, and E) are IP VPN endpoints for IP Multicast traffic arriving at the provider network (at PE router A) and exiting the provider network (at PE routers D and E). So, BGP multicast VPN is enabled on the PE routers. NSO is used to configure BGP multicast VPN on the PE routers. See, *Configure Segment Routing for BGP* chapter for details, within this guide
- **BGP Auto-Discovery (AD)** - To enable distributed VPN endpoint discovery and C-multicast flow mapping and signaling, BGP AD function is configured on the PE routers. A BGP Auto-Discovery route contains multicast router (loopback IP address) and tree identity (segment ID) information. It carries the

information in the Provider Multicast Service Interface (PMSI) Tunnel Attribute (PTA). See, *Configure Segment Routing for BGP* chapter for details, within this guide

- **C-multicast states** are signaled using BGP. See, *Configure Segment Routing for BGP* chapter for details, within this guide
- **SR** - To transport IP Multicast traffic between the VPN endpoints (PE routers A, D, and E), Provider (or P-) tunnels are used. In a P-tunnel, the PE devices are the tunnel endpoints. P-tunnels can be generated using different technologies (RSVP-TE, point-to-multipoint LSPs, PIM trees, mLDP point-to-multipoint LSPs, and mLDP MP2MP LSPs). In this use case, Segment Routing (SR) is used for its benefits that were noted earlier.
- With SR and SR-PCE, a Tree-SID point-to-multipoint (P2MP) segment is used to create P-Tunnels for multicast VPN. You can specify SR policy optimization objectives (such as *metrics*) and constraints (such as *affinity*) in an SR policy and send it to the SR-PCE controller, so that it can dynamically create SR multicast trees for traffic flow.
- **SR-PCE** - This is a controller which, based on the provided SR policy information, computes optimal paths for a multicast tree, and deploys the tree forwarding state on the multicast routers. When a topology change occurs, SR-PCE automatically computes a new, optimal multicast tree, and deploys the new tree forwarding state on the multicast routers.

Tree-SID multicast VPN

The topology remains the same, with PE routers A, D, and E acting as VPN endpoints for carrying IP VPN multicast traffic.

1. For SR, A is designated as the SR headend router, and D and E are designated as the SR endpoints.

For multicast traffic, A is the root of the SR multicast tree, and D and E are leaf routers of the tree. B and C are the other multicast routers. The objective is to send the IP Multicast traffic arriving at A to D and E, as needed.

Figure 31: Multicast Tree

2. A discovers leaf routers' information through BGP multicast VPN.
3. Path Computation Element Protocol (PCEP) is used for the SR multicast policy communication between A and the SR-PCE server, and communication between PE routers and the SR-PCE server.

4. When the headend router SR policy is created on A, and PCEP configurations are enabled on the SR-PCE server and all multicast routers, SR-PCE receives the SR policy and leaf router identity information from A.
5. Based on the policy information it receives, including traffic engineering objectives and constraints, SR-PCE builds multicast distribution trees in the underlay for efficient VPN traffic delivery.

6. SR-PCE assigns an SID for the SR multicast tree policy, and deploys the multicast tree forwarding state on the multicast routers.
7. When IP Multicast traffic is sent from VPN1-SiteA to PE router A, it steers it into the SR policy, and sends it toward D and E, which forward it to multicast traffic receivers in the sites VPN1-SiteB and VPN1-SiteC.
8. When a leaf or multicast router is added or removed, PE router A updates the SR multicast policy and sends it to SR-PCE. SR-PCE computes new multicast routes, and deploys the multicast tree forwarding state information on the multicast routers.

SR Multicast Tree Types

This is an overview of the types of SR multicast trees that you can configure, depending on your requirement. You can create the following tree types for IP VPN multicast flow in the provider network:

- **Full Mesh Multicast Tree**

Figure 32: Full Mesh Multicast Tree

1. A assigns Tree-ID 10 and invokes a Create an SR multicast tree request by sending the multicast router and tree ID information (A, 10) toward SR-PCE.
2. A announces BGP AD Inclusive PMSI (I-PMSI) route with the PTA (A, 10). Inclusive PMSI - Traffic that is multicast by a PE router on an I-PMSI is received by all other PEs in the multicast VPN. I-PMSIs are generated by Inclusive P-tunnels.
3. A discovers VPN endpoints D and E from their BGP AD Type I-PMSI route messages.
4. A invokes an Add SR multicast leaf router request (for D and E) to SR-PCE.
5. SR-PCE computes and generates the multicast tree forwarding state information on all the routers that are part of the tree.

• On-Demand SR Multicast Tree

Figure 33: On-Demand SR Multicast Tree

1. A assigns Tree-ID 20 and invokes a Create an SR multicast tree request by sending the multicast router and tree ID information (A, 20) toward SR-PCE.
2. A announces BGP AD Selective PMSI (or S-PMSI) route with PTA (A, 20). A sets the leaf-info-required to discover endpoint interest set.
Selective PMSI - Traffic multicast by a PE on an S-PMSI is received by some PEs in the multicast VPN. S-PMSIs are generated by Selective P-tunnels.
3. E has a receiver behind it, and announces a BGP-AD leaf route toward A. A discovers service endpoint E for the on-demand tree.
4. A invokes an Add SR multicast leaf router request (for E) to SR-PCE.
5. SR-PCE computes and generates the multicast tree information for all the routers that are part of the tree.

• Optimal Multicast Tree

Figure 34: Optimal Multicast Tree

1. A decides to optimize a flow and assigns Tree-ID 30 and invokes a Create an SR multicast tree request by sending the multicast router and tree ID information (A, 30) toward SR-PCE.
2. A announces BGP AD I-PMSI route with PTA (A, 30). A sets the leaf-info-required to discover endpoint interest set.
3. D has a receiver behind it, and announces a BGP-AD leaf route toward A. A discovers service endpoint D for optimized flow.
4. A invokes an Add SR multicast leaf router request (for D) to SR-PCE.
5. SR-PCE computes and generates the multicast tree information for all the routers that are part of the tree.

Prerequisites for Tree-SID mVPN IPv6

Listed are the prerequisites for Tree-SID Multicast VPN IPv6:

- The underlay OSPF or IS-IS network is configured, and OSPF/IS-IS adjacency forms between routers, across the network.
- BGP is configured for the network, and BGP adjacency is formed between routers. BGP multicast VPN configuration information is provided in this feature document.

Restrictions to Tree-SID mVPN IPv6

Listed are the restrictions related to this feature:

- The following are not supported for MVPN SR P2MP:
 - SRv6 SR P2MP policies
 - Hitless RP failover
 - IPV6 Multicast payload
 - PCE redundancy
 - PIM Bidir is not supported
- The following are not supported for SR P2MP:
 - PCE server restart not supported for REST initiated SR P2MP policies
 - Co-existence of static MVPN SR P2MP profiles in a VRF of a PE.
 - Co-existence with other MVPN profiles (MLDP, P2MP RSVP-TE, Ingress Replication) that need BGP MVPN Auto-Discovery in a VRF of a PE.
 - PIM C-Multicast signaling (only BGP C-multicast is supported)

Configure Tree-SID mVPN IPv6

Configuration Examples

Following are examples to configure Tree-SID multicast VPN IPv6

- **Headend Router Configuration (Router A)** - The following configuration is specific to the headend router.

- **Configure traffic engineering Constraints and Optimization Parameters**

```
Router# configure terminal
Router(config)# segment-routing traffic-engineering
```

An affinity bit-map is created so that it can be applied to a link or interface.

```
Router(config-sr-te)# affinity-map name 10 bit-position 24
Router(config-sr-te)# commit
```

An affinity (or relationship) is created between the SR policy path and the link color so that SR-TE computes a path that includes or excludes links, as specified. The headend router automatically follows the actions that are defined in the ODN template (for color 10) upon the arrival of VPN routes with a BGP color extended community that matches color 10.

```
Router(config)# segment-routing traffic-engineering
Router(config-sr-te)# on-demand color 10 dynamic
Router(config-sr-te-color-dyn)# affinity include-all name red
Router(config-sr-te-color-dyn)# affinity include-any name blue
Router(config-sr-te-color-dyn)# affinity exclude-any name green
Router(config-sr-te-color-dyn)# metric type te
Router(config-sr-te-color-dyn)# commit
```

The SR policy configuration on the headend router A will be sent to the SR-PCE server, after a connection is established between A and SR-PCE.

- **Multicast Router Configuration**

- **Configure PCEP Client on Multicast Routers** - Associate each multicast router as a client of the SR-PCE server. The **pce address ipv6** command specifies the SR-PCE server's IP address.

```
Router# configure terminal
Router(config)# segment-routing traffic-engineering
Router(config-sr-te)# pcc pce address ipv6 10.3.3.3
Router(config-pcc-pce)# commit
```

- **SR PCE Server Configuration**

- **Configure Label Range for Multicast Trees** - Configure the label range to be used for transporting Cisco IOS IP Multicast traffic in provider network.

```
Router(config)# pce segment-routing traffic-eng p2mp label-range min 30000 max 60000
Router(config)# commit
```

- **Configure FRR**

The following configurations enable FRR for all SR multicast (point-to-multipoint) trees, including dynamic and static implementations.

The **lfa** keyword enables LFA FRR on the PCE server.

```
Router(config)# pce segment-routing traffic-eng p2mp fast-reroute lfa
Router(config)# commit
```

Alternatively, you can configure FRR for each individual tree using the following configuration.

The **lfa** keyword under a specific multicast policy (**tree1** in this example) enables LFA FRR function for the specified SR multicast point-to-multipoint tree.

For dynamic trees, L-flag in label-switched path Attributes, a PCEP object controls FRR on a tree.

```
Router(config)# pce
Router(config-pce)# address ipv6 192.168.0.5
Router(config-pce)# segment-routing traffic-eng p2mp policy tree1 fast-reroute lfa
Router(config-pce)# commit
```

The **frr-node-set from ipv6 address** and **frr-node-set to ipv6 address** commands specify the *from* and *to* paths on a multicast router that requires FRR protection. In this configuration, the PCE server is configured to manage the FRR function for traffic from 192.168.0.3 sent toward 192.168.0.4 and 192.168.0.5.

```
Router(config)# pce
Router(config-pce)# address ipv6 192.168.0.5
Router(config-pce)# segment-routing traffic-eng p2mp frr-node-set from ipv6
192.168.0.3
Router(config-pce)# commit

Router(config)# pce
Router(config-pce)# address ipv6 192.168.0.5
Router(config-pce)# segment-routing traffic-eng p2mp frr-node-set to ipv6 192.168.0.4

Router(config-pce)# segment-routing traffic-eng p2mp frr-node-set to ipv6 192.168.0.5
Router(config-pce)# commit
```

- **Disable ECMP load splitting** - To disable ECMP load splitting of different trees on the SR-PCE server, configure the **multipath-disable** command.

```
Router(config)# pce segment-routing traffic-eng p2mp multipath-disable
Router(config)# commit
```

- **Multicast Routing Configuration On PE Routers** - The following multicast VPN configurations are required for VPN endpoints, the 3 PE routers.

- **Configure Default MDT SR point-to-multipoint multicast VPN Profile** - In this configuration, an MDT profile of the type *default* is created, and the SR multicast policy with color 10 will be used to send Cisco IOS IP Multicast traffic, as per the constraints and optimizations of the policy, through the multicast tree.

You can also specify the FRR LFA function with the **mdt default segment-routing mpls fast-reroute lfa** command.

```
Router(config)# multicast-routing vrf cust1
Router(config-mcast-cust1)# address-family ipv6
Router(config-mcast-cust1-ipv6)# mdt default segment-routing mpls color 10
Router(config-mcast-cust1-ipv6)# commit
```

- **Configure Partitioned MDT SR point-to-multipoint multicast VPN Profile** - In this configuration, an MDT profile of the type *partitioned* is created, and the SR multicast policy with color 10 will be used to send Cisco IOS IP Multicast traffic, as per the constraints and optimizations of the policy, through the multicast tree.

You can also specify the FRR LFA function with the **mdt partitioned segment-routing mpls fast-reroute lfa** command.

```
Router(config)# multicast-routing vrf cust1
Router(config-mcast-cust1)# address-family ipv6
Router(config-mcast-cust1-ipv6)# mdt partitioned segment-routing mpls color 10
Router(config-mcast-cust1-ipv6)# commit
```

The following Data multicast VPN configuration is required at the Ingress PE (router A) where the multicast flows need to be steered onto the *data* MDT for SR multicast traffic flow.

Note - *Data* MDT can be configured for *Default* and *Partitioned* profiles.

Configure Data MDT for SR point-to-multipoint multicast VPN - In this configuration, an MDT profile of the type *data* is created, and the SR multicast policy with color 10 will be used to send Cisco IOS IP Multicast traffic, as per the constraints and optimizations of the policy, through the multicast tree.

- You can enable the FRR LFA function with the **mdt data segment-routing mpls fast-reroute lfa** command. This enables LFA FRR for SR multicast trees that are created for all data MDT profiles.
- As an alternative to the color keyword, you can specify a route policy in the **route-policy** command, and define the route policy separately (as mentioned in the next configuration).
- The **threshold** command specifies the threshold above which a multicast flow is switched onto the data MDT. The **immediate-switch** keyword enables an immediate switch of a multicast flow to the data MDT, without waiting for threshold limit to be crossed.
- The **customer-route-acl** keyword specifies an access control list to enable specific multicast flows to be put on to the data MDT.

- **color** and **fast-reroute lfa** keywords are mutually exclusive with the **route-policy** configuration. The objective is to apply constraints (through **color**) or FRR (through LFA protection) to either all data MDTs, or apply them selectively per data MDT, using the **set on-demand-color** and **set fast-reroute lfa** options in the route policy (configured in the **mdt data** configuration).

```
Router(config)# multicast-routing vrf cust1
Router(config-mcast-cust1)# address-family ipv6
Router(config-mcast-cust1-ipv6)# mdt data segment-routing mpls 2 color 10
Router(config-mcast-cust1-ipv6)# commit
```

Route Policy Example

The route policy designates multicast flow-to-SR multicast policy mapping, with different colors.

- With this configuration, Cisco IOS IP Multicast flows for the 232.0.0.1 multicast group are steered into the SR multicast policy that is created with the on-demand color 10, while flows for 232.0.0.2 are steered into the policy created with color 20.
- The *data* MDT SR multicast tree that is created for the 232.0.0.2 multicast group is enabled with FRR LFA protection.
- Route policies can also be used to match other parameters, such as source address.

```
Router(config)# route-policy TSID-DATA
Router(config-rpl)# if destination in (232.0.0.1) then
Router(config-rpl-if)# set on-demand-color 10
Router(config-rpl-if)# pass
Router(config-rpl-if)# elseif destination in (232.0.0.2) then
Router(config-rpl-elseif)# set on-demand-color 20
Router(config-rpl-elseif)# set fast-reroute lfa
Router(config-rpl-elseif)# pass
Router(config-rpl-elseif)# endif
Router(config-rpl)# end-policy
Router(config)# commit
```

Configure multicast VPN BGP Auto-Discovery for SR point-to-multipoint

The following configuration is required on all PE routers, and is mandatory for *default* MDT, *partitioned* MDT, and *data* MDT.

Configure the BGP Auto-Discovery function for transporting Cisco IOS IP Multicast traffic.

```
Router(config)# multicast-routing vrf cust1
Router(config-mcast-cust1)# address-family ipv6
Router(config-mcast-cust1-ipv6)# bgp auto-discovery segment-routing
Router(config-mcast-cust1-ipv6-bgp-ad)# commit
```

Verify Tree-SID mVPN IPv6

This section guides you through the verification options:

- **View multicast VPN Context Information** - You can view multicast VPN virtual routing and forwarding context information with these commands.
- **View Default MDT Configuration** - This command displays SR multicast tree information, including the MDT details (of *default* type, and so on), and customer virtual routing and forwarding information (route target, route distinguisher, and so on).

```
Router# show mvpn vrf vpn1 context
```

```
MVPN context information for VRF vpn1 (0x9541cf0)
```

```
RD: 1:10 (Valid, IID 0x1), VPN-ID: 0:0
```

```

Multicast: Cisco Nonstop Forwarding for Tree-SID

Table 88: Feature History Table

Feature Name	Release Information	Feature Description
Multicast: Cisco Nonstop Forwarding for Tree-SID	Release 7.10.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>Starting from this release, Multicast Nonstop Forwarding supports Tree-SID (Tree Segment Identifier). This ensures that traffic forwarding continues without interruptions whenever the active RSP fails over to the standby RSP.</p> <p>This feature prevents hardware or software failures on the control plane from disrupting the forwarding of existing packet flows through the router for Tree-SID. Thus, ensuring improved network availability, network stability, preventing routing flaps, and no loss of user sessions while the routing protocol information is being restored.</p> <p>The feature modifies the show mrib nsf private command.</p>

Note This section captures only the Cisco Nonstop Forwarding feature in relation with Tree-SID. For more information on the Cisco Nonstop Forwarding feature, see [Multicast Nonstop Forwarding](#).

Multicast now supports hitless Route Processor Fail Over (RPFO). During RPFO, the software deletes IP routes from the Static Tree-SID profile in the headend router. The Dynamic Tree-SID does not have this issue, because in this case, the BGP advertises the states that supports Nonstop Routing (NSR). To overcome this problem for static Tree-SID, there are checkpoints to check the feature in Protocol Independent Multicast (PIM). On switchover, the checkpoint reads to check if the feature is there or not and push Protocol Independent Multicast (PIM) to Cisco Nonstop Forwarding state.

Verification Steps

The **show mrib nsf private** command is enhanced to display the XTC info as well.

```
Router#show mrib nsf private

Multicast: SR-PCE High Availability (HA) Support for Dynamic Tree-SID (mVPN)

Table 89: Feature History Table

Feature Name	Release	Description
High Availability Support for Dynamic Tree-SID (Multicast VPN)	Release 7.8.1	<p>We have introduced more resilience for building multicast VPN (mVPN) dynamic tree-SIDs by providing High Availability (HA) for the Segment Routing Path Computation Element (SR-PCE). This HA is made possible by adding another SR-PCE to the network.</p> <p>As a result, there's a noncompute or standby PCE for the mVPN dynamic policies. The root Path Computation Element Client (PCC) elects the active SR-PCE. If an active PCE failure occurs, the root PCC delegates the compute role for the mVPN dynamic Tree-SID to the standby SR-PCE.</p>

Segment Routing Point-to-Multipoint policy (SR-P2MP) in Tree-SID is the solution for carrying multicast traffic in the Segment Routing Domain but it works in the presence of just one SR-PCE in the network. However, the SR-PCE HA feature supports the mVPN dynamic Tree-SID with more than one SR-PCE to manage the network.

For example, when PCE1 is unavailable due to a system failure or reboot, PCE2 uses the PCReport packet information sent by PCC and assumes the role of PCE1 ensuring the following:

- Avoid failure of the cluster with no or minimal data loss.
- PCE2 is a hot-standby PCE that detects the failure as they occur ensuring high availability of the cluster always.
- Recovery of the network occurs with minimal or with no data loss.

5. PCE1 forwards all the reports with D-bit set from PCCs to PCE2.

• PCE Failure

When PCE fails, the following events occur:

1. PCE1 fails.
2. Root re-delegate to PCE2 immediately and sends the PCReport with **D-bit** Set to 1
 - With the PCC-centric approach, Mid and Leaf nodes PCCs also re-delegate to PCE2 immediately and sends the PCReport with **D-bit** set to 1
3. PCE2 becomes the Compute PCE, recomputes Tree-SID and sends the update to PCCs.

• PCE Restore

Image

When PCE restores, the following events occur:

1. PCE1 is restored.
2. Root re-delegates to PCE1 after the delegation timer expires:
 - Sends the PCReport to PCE1 with **D-bit** set to **1**
 - Sends the PCReport to PCE2 with **D-bit** set to **0**
3. With the PCC-Centric approach, Mid and Leaf nodes PCCs also re-delegate to PCE1 after the Delegation timer expires.
 - Sends the PCReport to PCE2 with **D-bit** set to **0**
4. PCE1 becomes the compute PCE and recomputes the Tree-SID.
 - Sends PCUpdate to PCCs participating in Tree-SID creation

• **Redundant or Backup PCE Down or Up Event**

When the redundant or the backup PCE is down or up, the following events occur:

1. When the backup PCE fails or is down, it is a "No-Operation" event from the Tree's point of view.
2. When the backup PCE is back up then all the PCCs resend the PCReports with **D-bit** set to **0**.
3. PCE1 syncs all the delegated reports and locally computed Tree states with PCE2.

• **PCC Initiated PCEP Session with the Root is Down**

When the PCC initiated PCEP session with the Root is down, the following events occur:

1. PCEP session from the Root to PCE1 is down but the Mid and Leaf nodes continue to have the session with PCE1.
2. Root relegates to PCE2 immediately and sends the PCReport with **D-bit** set to **1**.
3. PCE2 takes the responsibility of the compute PCE, recomputes Tree, and sends the PCUpdate.

Note Mid or leaf nodes are still delegated to PCE1, any updates to these nodes are done through PCE1.

• PCC Initiated PCEP Session with the Root is Restored

When the PCC initiated PCEP session with the Root is back up, the following events occur:

1. PCEP session from the Root to PCE1 is restored.
2. Root redelegates to PCE1 immediately after the delegation timer expires:
 - Sends the PCReport to PCE1 with **D-bit** set to **1**
 - Sends the PCReport to PCE2 with **D-bit** set to **0**
3. PCE1 reclaims the responsibility of the compute PCE, recomputes Tree, and sends the PCUpdate.

• **PCC Initiated - PCEP session with Mid or Leaf node is Down**

When the PCC initiated PCEP session with the Mid or Leaf node is down, the following events occur:

1. PCEP session from Mid to PCE1 is down but the Root and Leaf node still has session to PCE1
 - PCE1 is still responsible for Tree compute.
 - PCE1 holds LSP state for Mid for sometime to allow redelegation and Report from PCE2 (60 seconds Tree-SID Peer Down Timer on PCE).
2. With PCC-Centric approach, Mid redelegates immediately to PCE2 and sends a PCReport with **D-bit** set to 1.
3. PCE2 forwards PCReport to PCE1.
4. PCE1 sends PCUpdate to PCE2 for Mid immediately.
5. PCE2 always forwards the PCUpdate to Mid (PCC) if the PCE2 still has delegation of LSP from the PCC.

**Note**

A node, which does not have PCEP session is considered for P2PM path compute for new Tree.

In this example, a new Tree from the Root to the same set of Leaf nodes cannot be brought up because PCE1 does not have a PCEP session to the Mid node.

- **PCC Initiated - PCEP session with Mid or Leaf node is Restored**

When the PCC initiated PCEP session with the Mid or Leaf node is restored, the following events occur:

1. PCEP session from Mid to PCE1 is restored.
 - Root and Leaf node still have the session to PCE1.
 - PCE1 is still responsible for path compute.
2. With PCC-centric approach, Mid node redelegates to PCE1 after the delegation timer expires.
 - Sends a PCReport with **D-bit** set to **1**.
3. PCE1 sends PCUpdate to Mid node.
4. Mid node sends a PCReport to PCE2 with **D-bit** set to **0**.
5. PCE2 withdraws "Interest" from PCE1.

Note Even after the session between PCE1 and Mid node is restored, PCE1 keeps pushing updates to PCE2 until the "interest" from LSP is withdrawn. The PCE to which the LSP is delegated push the update down to PCC.

It is possible that both OCEs have the **D-bit** set for the LSP momentarily. In such a case, both PCEs will push down the Updates. The PCC accepts the update from the PCE to which it has delegated to.

• PCC Initiated - Existing Tree Change with Split PCEP Session

When there is a PCC Initiated - Existing Tree Change with Split PCEP Session, the following events occur:

Root and Leaf node have PCEP session with PCE1 and the Mid-1 node has PCEP session restored and hence delegated to PCE2. The new mid node (Mid2) is introduced with PCEP sessions to both PCEs.

1. Root updates Tree to add Leaf1

- Sends PCReport to PCE1 with **D-bitset**

2. PCE1 computes Tree

- **Option 1:** PCE1 will not consider Mid-1 node because it does not have a direct PCEP session to it.
 - Sends PCInitiate to Mid-2 and Leaf1 node PCCs
 - **Cons:** This may not be the best path to Endpoint. The path to a given Endpoint may be different if it gets deleted and re-added.
- **Option 2 (Preferred):** PCE1 will consider reachability through Mid-1 node because it knows Mid-1 node is part of the Tree and delegated to PCE2 (Over State-Sync channel)
 - Sends PCUpdate to Mid-1 node through PCE2

• **PCC Initiated - New Tree with Split PCEP Session**

When there is a PCC Initiated - New Tree Change with Split PCEP Session, the following events occur:

Root, Mid-2, and Leaf nodes have PCEP session with PCE1 and the Mid-1 node has PCEP session UP with PCE2.

1. Root creates a new Tree to Leaf1 and Leaf2
 - Sends PCReport to PCE1 with **D-bit** set
2. PCE1 computes Tree
 - PCE1 will not consider Mid-1 node because it does not have a direct PCEP session to it
 - Sends PCInitiate to Mid-2 and Leaf node PCCs

Note Con: Another (Existing) tree to the same Endpoints may be programmed through Mid-1 node.

Limitations and Guidelines

This section lists the limitation and guidelines:

- The IOS-XR forwarding devices and the SR-PCE must be upgraded to IOSXR 7.8.1 release to enable this feature in the network.
- No support for PCE HA support for CLI-configured static TreeSID.

Configuration Steps

Captured below are the configuration steps required to set up the TreeSID PCE HA feature.

1. Configuration on forwarding device

This section guides you to configure the forwarding device.

a. PCE configuration on a PCC

The following configuration is required on the PCC routers to configure the PCE's that will provide the redundancy.

```
Router(config)# segment-routing
Router(config-sr)# traffic-eng
Router(config-sr-te)# pcc
Router(config-pcc)# pce address ipv4 2.2.2.1
Router(config-pcc)# precedence 200
Router(config-pcc)# pce-group pce-ha-group
Router(config-sr-te-pce)# pce address ipv4 4.4.4.2
Router(config-pce)# precedence 0
Router(config-pce)# pce-group pce-ha-group
```

Note To elect a Compute PCE, you must set the precedence. In the example above there are 2 PCEs configured with 200 and 0. The PCE with a lower precedence takes up the compute role.

b. Recommended steps for costing in a new SR-PCE in the network

If the network needs to be upgraded with a new SR-PCE, the operators can add the new SR-PCE as a more preferred PCE in the above configuration on the root of the SR-P2MP tree. Doing so results in the PCC re-delegating all the SR-P2MP LSPs to the newly configured SR-PCE. This delegation allows the new SR-PCE to assume the role of computation for the SR-P2MP trees. The older SR-PCE can be costed out of the network. Following these steps will allow the transition from one SR-PCE to another.

c. TreeSID with PCE groups

- **Associating a PCE with a PCE group:** A PCE can be associated to a PCE group using the below configuration. It must be noted that a PCE can only be associated to one PCE group

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# pcc
Router(config-pcc-pce)# pce address ipv4 192.168.0.5
Router(config-pcc-pce)# pce-group test
```

- **Associating a PCE group with on-demand color:** With a PCE now associated with a PCE group, the PCE group can be associated with an on-demand color (which you later associate with a P2MP policy) using the following configuration.

Note Note: While the same PCE group can be used across many on-demand colors, there can only be one PCE group associated with one on-demand color configuration.

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te-color)on-demand color 10
Router(config-sr-te-color)pce-group test
```

- **Associating a dynamic MVPN policy with color:** A dynamic SR P2MP policy is associated with an on-demand color, which provides an abstraction to the constraints or metrics that the policy must satisfy. The same structure will be used to associate a PCE group to the dynamic SR P2MP policy.

Default TreeSID

```
Router(config)# vrf vpn1
Router(config-vrf)# address-family ipv4
Router(config-vrf-af)# bgp auto-discovery segment-routing
Router(config-vrf-af)# mdt default segment-routing mpls color 10
Router(config-vrf-af)# mdt data segment-routing mpls 10 route-policy treesid
threshold 0
```

```
Router(config)# route-policy treesid
Router(config)# set on-demand-color 20
Router(config)# end-policy
```

Partitioned TreeSID

```
Router(config)# vrf vpn2
Router(config-vrf)# address-family ipv4
Router(config-vrf-af)# bgp auto-discovery segment-routing
Router(config-vrf-af)# mdt partitioned segment-routing mpls color 10
```

2. Configuration on SR-PCE

Note **PCE state-sync configuration:** The following configuration must be done on all PCEs participating in PCE state-sync. Configuring it on only one PCE will only enable that PCE to sync state uni-directionally.

```
Router(config)# pce state-sync ipv4 192.168.0.6
```

Running Configuration

Run the show command to review the running configuration:

```
pce

Segment routing Tree-SID interoperability and SR-P2MP enhancements

Tree-SID is a Segment Routing feature, which enables an SR-PCE to use PCEP to calculate the point-to-multipoint (P2MP) tree with SR policies.

Table 90: Feature History Table

Feature Name	Release Information	Feature Description
Segment routing Tree-SID interoperability and SR-P2MP enhancements	Release 24.4.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>The feature introduces enhancements to the SR Tree-SID functionality and SR-P2MP Policy, enabling full alignment with the Path Computation Element Protocol (PCEP) standard as per IETF specifications. These improvements enable interoperability between Path Computation Client (PCC) devices from different vendors connected to the PCE.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> The show pce ipv4 and show segment-routing traffic-eng pcc ipv4 commands are enhanced to display the SR-P2MP capability and the number of SR-P2MP instances.

Segment routing Tree-SID interoperability

The SR Tree-SID interoperability feature enables seamless integration and operation in heterogeneous network environments by allowing PCC devices from different manufacturers to interact with the PCE. In other words, you can combine Cisco proprietary and third-party devices as PCC devices. The feature enables seamless operation in a multivendor environment, expanding deployment options for service providers.

Network operators can fully leverage SR Tree-SID capabilities while ensuring compatibility with existing Cisco proprietary implementations. This feature is beneficial for networks that incorporate devices from various vendors and require consistent, optimized multicast routing.

Compliance with IETF PCEP standard

The feature ensures full compliance with the IETF PCEP standard, enabling broader interoperability across various network vendors. The feature facilitates more flexible network operations and efficiency.

SR P2MP enhancements

From Cisco IOS XR Release 24.4.1, the SR P2MP policy is enhanced to include a collection of candidate paths computed by the PCE for P2MP Tree redundancy.

Candidate paths

A candidate path represents a valid route from a root node to multiple leaf nodes. At any given time, only one candidate path remains active. If this path encounters issues, a router or a network device can switch to a new path without disrupting service.

Each candidate path contains the following information, which is crucial for accurate routing:

- Path originator
- Path discriminator
- Path preference
- Associated path instances

For more information about the enhancements to candidate path and path instances, see IETF drafts [Segment Routing Point-to-Multipoint Policy](#) and [PCEP Extensions for Segment Routing Policy Candidate Paths](#).

Path instances

Path instances facilitate load balancing, failover, and smooth switching between different paths. While a candidate path can contain multiple path instances, only one path instance remains active at any given time. A router or a network device establishes the forwarding states of these path instances using replication segments.

For information about configuring Tree-SID via CLI at SR-PCE, see [Configure Static Segment Routing Tree-SID via CLI at SR-PCE](#) section.

For more information about Tree-SID workflow, Tree SID policy types and behaviors, and additional details, see [Segment Routing Tree Segment Identifier, on page 525](#) section.

Usage guidelines and limitations for SR Tree-SID interoperability

Usage guidelines

These guidelines apply:

- To ensure compatibility between PCE and PCC, you must upgrade all PCEs before upgrading a PCC.
- For PCE High Availability, all PCEs must be the same version. It indicates the lack of interoperability between older, non-IETF compliant PCEs, and the newer IETF-compliant versions.

Limitations

These limitations apply:

- Only one candidate path is supported. This limitation reduces flexibility in switching paths.
- Only one instance within a candidate path is supported. Each candidate path can have only one active instance, which affects traffic balancing across multiple paths.

- Make-before-break is not supported. Switching paths may cause service disruptions as the old path becomes inactive before the new one is activated.
- Hitless In-Service Software Upgrade (ISSU) is not supported for PCCs. Software upgrades may require some downtime due to this limitation.
- IPv6 Tree-SID or SRv6 is not supported. Th12s limitation restricts the use of modern IPv6 routing techniques.
- SR P2MP Policy over Path Computation Element Protocol Version 6 (PCEPv6) is not supported.
- The SR P2MP Policy with Flex-Algo, also known as Tree-SID Flex-Algo, does not comply with IETF standards and remains nonstandard.

PCE upgrade recommendations

You should follow these upgrade recommendations when upgrading to the new IETF-compliant PCE.

- If you are using virtual machines (VMs) for your PCEs, create two new VMs (one at each PCE location) with the latest version of the PCE at each VM location. You must ensure that all network interfaces are shut down, and then switch over to the new VMs.
- Disable or remove the *state-sync* feature on both the older and newer PCE versions. Later, you can upgrade the older PCEs to the newer version and reconfigure the *state-sync* feature.
- If you do not use PCE-HA, you can upgrade a single PCE. It is best to upgrade both older and newer PCEs together to ensure compatibility.
- Increase the PCC state timer before the upgrade as switching from old VMs to new VMs might take time.
- When new PCE devices activate with their interfaces shut down, they do not learn the network topology right away. Each PCE starts a timer when it activates, blocking the PCEP session for a set period. If this timer expires before the interfaces open, the PCEP session establishes without any network data, leading to unnecessary cleanup of network trees. Adjusting the timer can help avoid this issue.

Verify the SR P2MP enhancements

You can use the **show pce ipv4 peer p2mp** command to view the status of the PCE in IPv4 networks.

In the following sample output, the **SR-P2MP Num Instances** field indicates the number of distinct paths that are currently active, and the **SR-P2MP** capability indicates the device functionality.

```
Router#show pce ipv4 peer p2mp

PCE's P2MP peer database:
-----
Peer address: 192.168.0.1
  Capabilities: SR-P2MP
  SR-P2MP Num Instances: 1
  Sync complete: yes
  Cleanup timer:
    Running: no
```

In the following sample output, the **SR-P2MP Num Instances** field indicates the number of distinct paths that are currently active, and the **ASSOC-Type-List** field indicates the types of associations that the PCE has

with peer devices. The PCEP extensions enable associating different types of LSPs or services through these association types.

```
Router#show pce ipv4 peer private
```

```
PCE's peer database:
```

```
-----

CHAPTER 13

Enabling Segment Routing Flexible Algorithm

Segment Routing Flexible Algorithm allows operators to customize IGP shortest path computation according to their own needs. An operator can assign custom SR prefix-SIDs to realize forwarding beyond link-cost-based SPF. As a result, Flexible Algorithm provides a traffic engineered path automatically computed by the IGP to any destination reachable by the IGP.

The SR architecture associates prefix-SIDs to an algorithm which defines how the path is computed. Flexible Algorithm allows for user-defined algorithms where the IGP computes paths based on a user-defined combination of metric type and constraint.

This document describes the IS-IS and OSPF extensions to support Segment Routing Flexible Algorithm on an MPLS data-plane.

- [User-Defined Generic Metric Support for IS-IS Flex Algo, on page 626](#)
- [IS-IS Flexible Algorithm UCMP Support, on page 631](#)

Prerequisites for Flexible Algorithm

Segment routing must be enabled on the router before the Flexible Algorithm functionality is activated.

Building Blocks of Segment Routing Flexible Algorithm

This section describes the building blocks that are required to support the SR Flexible Algorithm functionality in IS-IS and OSPF.

Flexible Algorithm Definition

Many possible constraints may be used to compute a path over a network. Some networks are deployed with multiple planes. A simple form of constraint may be to use a particular plane. A more sophisticated form of constraint can include some extended metric, like delay, as described in [RFC7810]. Even more advanced

case could be to restrict the path and avoid links with certain affinities. Combinations of these are also possible. To provide a maximum flexibility, the mapping between the algorithm value and its meaning can be defined by the user. When all the routers in the domain have the common understanding what the particular algorithm value represents, the computation for such algorithm is consistent and the traffic is not subject to looping. Here, since the meaning of the algorithm is not defined by any standard, but is defined by the user, it is called a Flexible Algorithm.

Flexible Algorithm Membership

An algorithm defines how the best path is computed by IGP. Routers advertise the support for the algorithm as a node capability. Prefix-SIDs are also advertised with an algorithm value and are tightly coupled with the algorithm itself.

An algorithm is a one octet value. Values from 128 to 255 are reserved for user defined values and are used for Flexible Algorithm representation.

Flexible Algorithm Definition Advertisement

To guarantee the loop free forwarding for paths computed for a particular Flexible Algorithm, all routers in the network must share the same definition of the Flexible Algorithm. This is achieved by dedicated router(s) advertising the definition of each Flexible Algorithm. Such advertisement is associated with the priority to make sure that all routers will agree on a single and consistent definition for each Flexible Algorithm.

Definition of Flexible Algorithm includes:

- Metric type
- Affinity constraints
- Exclude SRLG constraint
- Minimum bandwidth constraint
- Maximum delay constraint

To enable the router to advertise the definition for the particular Flexible Algorithm, **advertise-definition** command is used. At least one router in the area, preferably two for redundancy, must advertise the Flexible Algorithm definition. Without the valid definition being advertised, the Flexible Algorithm will not be functional.

Flexible Algorithm Link Attribute Advertisement

Various link attributes may be used during the Flexible Algorithm path calculation. For example, include or exclude rules based on link affinities can be part of the Flexible Algorithm definition, as defined in [RFC9350](#) (IGP Flexible Algorithm).

Link attribute advertisements used during Flexible Algorithm calculation must use the Application-Specific Link Attribute (ASLA) advertisements, as defined in [RFC8919](#) (IS-IS) and [RFC8920](#) (OSPF). In the case of IS-IS, if the L-Flag is set in the ASLA advertisement, then legacy advertisements (IS-IS Extended Reachability TLV) are used instead.

Flexible Algorithm Prefix-SID Advertisement

To be able to forward traffic on a Flexible Algorithm specific path, all routers participating in the Flexible Algorithm will install a MPLS labeled path for the Flexible Algorithm specific SID that is advertised for the prefix. Only prefixes for which the Flexible Algorithm specific Prefix-SID is advertised is subject to Flexible Algorithm specific forwarding.

Calculation of Flexible Algorithm Path

Table 91: Feature History Table

Feature Name	Release Information	Feature Description
OSPF: Microloop Avoidance for Flexible Algorithm	Release 7.4.1	This feature extends the current OSPF Flexible Algorithm functionality to support Microloop Avoidance.

Table 92: Feature History Table

Feature Name	Release Information	Feature Description
OSPF: Microloop Avoidance for Flexible Algorithm	Release 7.3.2	This feature extends the current OSPF Flexible Algorithm functionality to support Microloop Avoidance.
OSPF: TI-LFA for Flexible Algorithm	Release 7.3.1	This feature extends the current OSPF Flexible Algorithm functionality to support TI-LFA.

A router may compute path for multiple Flexible Algorithms. A router must be configured to support particular Flexible Algorithm before it can compute any path for such Flexible Algorithm. A router must have a valid definition of the Flexible Algorithm before Flexible Algorithm is used.

The router uses the following rules to prune links from the topology during the Flexible Algorithm computation:

- All nodes that don't advertise support for Flexible Algorithm are pruned from the topology.
- Affinities:
 - Check if any exclude affinity rule is part of the Flexible Algorithm Definition. If such exclude rule exists, check if any color that is part of the exclude rule is also set on the link. If such a color is set, the link must be pruned from the computation.
 - Check if any include-any affinity rule is part of the Flexible Algorithm Definition. If such include-any rule exists, check if any color that is part of the include-any rule is also set on the link. If no such color is set, the link must be pruned from the computation.
 - Check if any include-all affinity rule is part of the Flexible Algorithm Definition. If such include-all rule exists, check if all colors that are part of the include-all rule are also set on the link. If all such colors are not set on the link, the link must be pruned from the computation.

Note See [Flexible Algorithm Affinity Constraint](#).

- If the Flexible Algorithm definition includes an "exclude SRLG" rule, then all links that are part of such SRLG are pruned from the topology.

Note See [Flexible Algorithm with Exclude SRLG Constraint, on page 606](#).

- If the minimum bandwidth constraint is configured, any link that does not meet the minimum link bandwidth threshold is pruned from the topology.
- If the maximum delay constraint is configured, any link that exceeds the maximum unidirectional link delay is pruned from the topology.
- Router uses the metric that is part of the Flexible Algorithm definition. If the metric isn't advertised for the particular link, the link is pruned from the topology.

Loop Free Alternate (LFA) paths, TI-LFA backup paths, and Microloop Avoidance paths for particular Flexible Algorithm are computed using the same constraints as the calculation of the primary paths for such Flexible Algorithm. These paths use Prefix-SIDs advertised specifically for such Flexible Algorithm in order to enforce a backup or microloop avoidance path.

Configuring Microloop Avoidance for Flexible Algorithm

By default, Microloop Avoidance per Flexible Algorithm instance follows Microloop Avoidance configuration for algo-0. For information about configuring Microloop Avoidance, see [Configure Segment Routing Microloop Avoidance, on page 809](#).

You can disable Microloop Avoidance for Flexible Algorithm using the following commands:

```
router isis instance flex-algo algo microloop avoidance disable
router ospf process flex-algo algo microloop avoidance disable
```

Configuring LFA / TI-LFA for Flexible Algorithm

By default, LFA/TI-LFA per Flexible Algorithm instance follows LFA/TI-LFA configuration for algo-0. For information about configuring TI-LFA, see [Configure Topology-Independent Loop-Free Alternate \(TI-LFA\), on page 783](#).

You can disable TI-LFA for Flexible Algorithm using the following commands:

```
router isis instance flex-algo algo fast-reroute disable
router ospf process flex-algo algo fast-reroute disable
```

Flexible Algorithm Affinity Constraint

Table 93: Feature History Table

Feature Name	Release Information	Feature Description
IS-IS: Flexible Algorithm Reverse Affinity	Release 7.9.1	<p>This feature enhances the IS-IS Flexible Algorithm link admin group (affinity) constraint to include link colors on links in the reverse direction toward the calculating router.</p> <p>The ability to apply affinity constraints in the reverse direction provides additional control for IS-IS Flexible Algorithm path computation.</p> <p>This feature introduces the reverse keyword to the router isis instance flex-algo algo affinity command.</p>

You can apply a color or name to links or interfaces by assigning affinity bit-maps to them. You can then specify an affinity (or relationship) between a Flexible Algorithm path and link colors in the forwarding direction. Flexible Algorithm computes a path that includes or excludes links that have specific colors, or combinations of colors.

- Affinity “blue” is assigned to interface on node A; exclude affinity "blue": Link A-B is pruned from path calculation

FA 128: Metric IGP and Exclude Affinity “blue”

In Cisco IOS XR release 7.9.1, for IS-IS Flexible Algorithm, you can also specify a reverse affinity between a Flexible Algorithm path and link colors (in the direction toward the computing router). Flexible Algorithm computes a path that includes or excludes links in the reverse direction that have specific colors, or combinations of colors.

For example, on a point-to-point link between endpoints A and B and for the traffic flowing in the direction from A to B, the input errors can only be detected at node B. You may measure the rate of such input errors and set certain 'color' on a link locally on node B when the input error rate crosses a certain threshold.

- Affinity “blue” is assigned to interface on node B; exclude affinity "blue": Link A-B is not pruned from path calculation

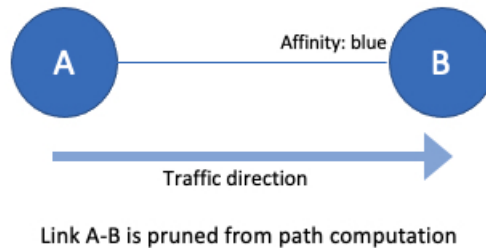

FA 128: Metric IGP and Exclude Affinity “blue”

With IS-IS Flexible Algorithm Reverse Affinity, when Flex-Algorithm calculation processes link A to B, it may look at the 'colors' of the link in the reverse direction (link B to A). This enables you to exclude this link from the Flex-Algorithm topology.

- Affinity “blue” is assigned to interface on node B; exclude reverse-affinity "blue": Link A-B is pruned from path calculation

FA 128: Metric IGP and Exclude-Reverse Affinity “blue”

Installation of Forwarding Entries for Flexible Algorithm Paths

Flexible Algorithm path to any prefix must be installed in the forwarding using the Prefix-SID that was advertised for such Flexible Algorithm. If the Prefix-SID for Flexible Algorithm is not known, such Flexible Algorithm path is not installed in forwarding for such prefix..

Only MPLS to MPLS entries are installed for a Flexible Algorithm path. No IP to IP or IP to MPLS entries are installed. These follow the native IGP paths computed based on the default algorithm and regular IGP metrics.

Flexible Algorithm Prefix-SID Redistribution

Table 94: Feature History Table

Feature Name	Release Information	Feature Description
Flexible Algorithm Prefix-SID Redistribution for External Route Propagation	Release 7.5.2	<p>You can now propagate flexible algorithm prefix-SIDs and their algorithm-specific metric between different IGP domains, such as OSPF to IS-IS RIP to OSPF. With this functionality enabling interdomain traffic engineering, you can export flexible algorithm labels from the OSPF domain to other domains and import the labels from other domains into OSPF.</p> <p>The show ospf route flex-algo command has been modified to include additional attributes to indicate the external routes.</p>

Prefix redistribution from IS-IS to another IS-IS instance or protocol was limited to SR algorithm 0 (regular SPF) prefix SIDs; SR algorithm 1 (Strict SPF) and SR algorithms 128-255 (Flexible Algorithm) prefix SIDs were not redistributed along with the prefix. The Segment Routing IS-IS Flexible Algorithm Prefix SID Redistribution feature allows redistribution of strict and flexible algorithms prefix SIDs from IS-IS to another IS-IS instance or protocols. This feature is enabled automatically when you configure redistribution of IS-IS Routes with strict or flexible algorithm SIDs.

Prefix redistribution from OSPF to another AS was limited to SR algorithm 0 (regular SPF) prefix SIDs; SR algorithm 1 (Strict SPF) and SR algorithms 128-255 (Flexible Algorithm) prefix SIDs were not redistributed along with the prefix. Starting from Cisco IOS XR Release 7.5.2, the Flexible Algorithm Prefix-SID Redistribution for External Route Propagation feature allows redistribution of strict and flexible algorithm prefixes SIDs from OSPF to another AS and also from another AS into OSPF.

Configuration Example

The following example shows how to configure redistribute and flexible algorithm to enable external routes.

```
RP/0/RP0/CPU0:ios(config)#router ospf 1
RP/0/RP0/CPU0:ios(config-ospf)#segment-routing mpls
RP/0/RP0/CPU0:ios(config-ospf)#segment-routing forwarding mpls
RP/0/RP0/CPU0:ios(config-ospf)#redistribute isis 2 route-policy loopback-type
RP/0/RP0/CPU0:ios(config-ospf)#flex-algo 240
RP/0/RP0/CPU0:ios(config-ospf-flex-algo)#metric-type delay
RP/0/RP0/CPU0:ios(config-ospf-flex-algo)#prefix-metric
RP/0/RP0/CPU0:ios(config-ospf-flex-algo)#advertise-definition
```

Verification

This following show output displays the route-type as 'Extern' for the external routes.

```
Router#show ospf routes flex-algo 240 route-type external detail
```

```

Route Table of ospf-1 with router ID 192.168.0.2 (VRF default)

Flexible Algorithm Prefix Metric

Table 95: Feature History Table

Feature Name	Release Information	Feature Description
Prefix Metric support for OSPF Flexible Algorithm	Release 7.5.1	This feature extends the current OSPF Flexible Algorithm functionality to introduce a Flexible Algorithm-specific prefix-metric in the OSPF prefix advertisement. The prefix-metric provides a way to compute the best end-to-end Flexible Algorithm optimized paths across multiple areas or domains.

A limitation of the existing Flexible Algorithm functionality in IS-IS and OSPF is the inability to compute the best path to a prefix in a remote area or remote IGP domain. Prefixes are advertised between IS-IS areas, OSPF processes, or between protocol domains, but the existing prefix metric does not reflect any of the constraints used for Flexible Algorithm path. Although the best Flexible Algorithm path can be computed to the inter-area or redistributed prefix inside the area, the path may not represent the overall best path through multiple areas or IGP domains.

The Flexible Algorithm Prefix Metric feature introduces a Flexible Algorithm-specific prefix-metric in the IS-IS and OSPF prefix advertisement. The prefix-metric provides a way to compute the best end-to-end Flexible Algorithm optimized paths across multiple areas or domains.

Note The Flexible Algorithm definition must be consistent between domains or areas. Refer to section 8 and section 9 in IETF draft <https://datatracker.ietf.org/doc/draft-ietf-lsr-flex-algo/>.

Configuring Flexible Algorithm

Table 96: Feature History Table

Feature Name	Release Information	Feature Description
IS-IS Enhancements: max-metric and data plane updates	Release 7.8.1	The new anomaly optional keyword is introduced to affinity flex-algo command. This keyword helps to advertise the flex-algo affinity when the performance measurement signals a link anomaly, such as an excessive delay on a link. You could use the anomaly option to exclude the link from flex-algo path computations. affinity flex-algo

Table 97: Feature History Table

Feature Name	Release Information	Feature Description
TE Metric Support for IS-IS Flex Algo	Release 7.4.1	Flexible Algorithm allows for user-defined algorithms where the IGP computes paths based on a user-defined combination of metric type (path optimization objective) and constraint. This feature adds support for TE metric as a metric type for IS-IS Flexible Algorithm. This allows the TE metric, along with IGP and delay metrics, to be used when running shortest path computations.

The following IS-IS and OSPF configuration sub-mode is used to configure Flexible Algorithm:

```
router isis instance flex-algo algo
router ospf process flex-algo algo
algo—value from 128 to 255
```

Configuring Flexible Algorithm Definitions

The following commands are used to configure Flexible Algorithm definition under the flex-algo sub-mode:

```
• router isis instance flex-algo algo metric-type {delay | te}

router ospf process flex-algo algo metric-type {delay | te-metric}
```

Note By default the IGP metric is used. If delay or TE metric is enabled, the advertised delay or TE metric on the link is used as a metric for Flexible Algorithm computation.

Note See [Flexible Algorithm Link Attribute Advertisement Behavior, on page 603](#) for TE metric behaviors.

```
• router isis instance flex-algo algo affinity [reverse] { include-any | include-all |
  exclude-any} name1, name2, ...

router ospf process flex-algo algo affinity { include-any | include-all | exclude-any}
  name1, name2, ...

name—name of the affinity map
```

Note See [Flexible Algorithm Affinity Constraint, on page 595](#) for information about affinity constraint behaviors.

```
• router isis instance flex-algo algo priority priority value

router ospf process flex-algo algo priority priority value

priority value—priority used during the Flexible Algorithm definition election.
```

The following command is used to include the Flexible Algorithm prefix metric in the advertised Flexible Algorithm definition in IS-IS and OSPF :

```
router isis instance flex-algo algo prefix-metric

router ospf process flex-algo algo prefix-metric
```

The following command is used to enable advertisement of the Flexible Algorithm definition in IS-IS:

```
router isis instance flex-algo algo advertise-definition
```

Configuring Affinity

The following command is used for defining the affinity-map. Affinity-map associates the name with the particular bit positions in the Extended Admin Group bitmask.

```
router isis instance flex-algo algo affinity-map name bit-position bit number

router ospf process flex-algo algo affinity-map name bit-position bit number
```

- *name*—name of the affinity-map.
- *bit number*—bit position in the Extended Admin Group bitmask.

With the IOS XR Release 7.8.1, the new optional keyword **anomaly** is introduced to the **interface** submode of **affinity flex-algo**. This keyword option helps to advertise flex-algo affinity on PM anomaly. The following command is used to associate the affinity with an interface:

```
router isis instance interface type interface-path-id affinity flex-algo anomaly name 1,
name 2, ...

router ospf process area area interface type interface-path-id affinity flex-algo anomaly
name 1, name 2, ...
```

name—name of the affinity-map

You can configure both normal and anomaly values. For the following example, the **blue** affinity is advertised. However, if a metric is received with the anomaly flag set, it will change to **red**:

```
Router# configure
Router(config)# router isis 1
Router(config-isis)# flex-algo 128
Router(config-isis-flex-algo)# interface GigabitEthernet0/0/0/2
Router(config-isis-flex-algo)# affinity flex-algo blue
Router(config-isis-flex-algo)# affinity flex-algo anomaly red
```

Configuring Prefix-SID Advertisement

The following command is used to advertise prefix-SID for default and strict-SPF algorithm:

```
router isis instance interface type interface-path-id address-family {ipv4 | ipv6} [unicast]
prefix-sid [strict-spf | algorithm algorithm-number] [index | absolute] sid value

router ospf process area area interface Loopback interface-instance prefix-sid [strict-spf
| algorithm algorithm-number] [index | absolute] sid value
```

- *algorithm-number*—Flexible Algorithm number
- *sid value*—SID value

Flexible Algorithm Link Attribute Advertisement Behavior

Table 98: Feature History Table

Feature Name	Release Information	Feature Description
Advertisement of Link Attributes for IS-IS Flexible Algorithm	Release 7.4.1	<p>Link attribute advertisements used during Flexible Algorithm path calculation must use the Application-Specific Link Attribute (ASLA) advertisements, as defined in IETF draft draft-ietf-lsr-flex-algo.</p> <p>This feature introduces support for ASLA advertisements during IS-IS Flexible Algorithm path calculation.</p>

The following tables explain the behaviors for advertising (transmitting) and processing (receiving) Flexible Algorithm link attributes.

Table 99: OSPF

Link Attribute	Transmit	Receive
Link Delay Metric	IOS XR OSPF Flex Algo implementation advertises the link delay metric value using the OSPF ASLA sub-TLV with the F-bit set.	<p>IOS XR OSPF only uses the link delay metric advertised in the ASLA sub-TLV for Flex Algo.</p> <p>ASLA sub-TLV is supported with non-zero-length or with zero-length Application Identifier Bit Masks.</p>
Link TE Metric	<p>IOS XR OSPF Flex Algo implementation advertises the link TE metric value using the OSPF ASLA sub-TLV with the F-bit set.</p> <p>The link TE metric values advertised are configured under SR-TE.</p>	<p>IOS XR OSPF only uses the TE metric advertised in the ASLA sub-TLV for Flex Algo.</p> <p>ASLA sub-TLV is supported with non-zero-length or with zero-length Application Identifier Bit Masks.</p>

Link Attribute	Transmit	Receive
Link Admin Group/Extended Admin Group	<p>IOS XR OSPF Flex Algo implementation advertises the link admin group value using both link admin group (AG) and link extended admin group (EAG) encoding using the OSPF ASLA sub-TLV with the F-bit set.</p> <p>The link admin group values advertised can be configured directly under the IGP and are therefore FA-specific. Otherwise, they will be derived from the link admin group values configured under SR-TE.</p>	<p>IOS XR OSPF only uses the AG/EAG (either one or both) advertised in the ASLA sub-TLV for Flex Algo.</p> <p>ASLA sub-TLV is supported with non-zero-length or with zero-length Application Identifier Bit Masks.</p>

Table 100: IS-IS

Link Attribute	Transmit	Receive
Link Delay Metric	IOS XR IS-IS Flex Algo implementation advertises the link delay metric value using both the IS-IS Extended Reachability TLV and the IS-IS ASLA.	<p>By default, IOS XR IS-IS Flex Algo implementation prefers the link delay metric value received in the IS-IS ASLA. Otherwise, it will use link delay metric value received in the IS-IS Extended Reachability TLV.</p> <p>ASLA sub-TLV is supported with non-zero-length or with zero-length Application Identifier Bit Masks.</p> <p>If the incoming ASLA includes the L-Flag, implementation derives the link delay metric value from the IS-IS Extended Reachability TLV.</p> <p>You can configure the IOS XR IS-IS Flex Algo implementation to strictly use the link delay metric value received in the IS-IS ASLA. See Strict IS-IS ASLA Link Attribute, on page 605.</p>
Link TE Metric	<p>IOS XR IS-IS Flex Algo implementation advertises the link TE metric value using the IS-IS ASLA.</p> <p>The link TE metric values advertised can be configured directly under the IGP and are therefore FA-specific. Link SRLG	<p>IOS XR IS-IS LFA implementation advertises the link SRLG value in the IS-IS ASLA.</p>	<p>IOS XR IS-IS LFA implementation processes the link SRLG value received in the IS-IS ASLA.</p> <p>If incoming ASLA includes the L-Flag, implementation derives the link SRLG value from the IS-IS Extended Reachability TLV.</p>

Strict IS-IS ASLA Link Attribute

Use the following command to configure the IOS XR IS-IS Flex Algo implementation to strictly use the link delay metric value received in the IS-IS ASLA:

```
router isis instance-id receive application flex-algo delay app-only
```

Flexible Algorithm-Specific TE Metric

Use the following command to configure the Flexible Algorithm-specific TE metric value under IS-IS, where *metric_value* is from 1 to 16777214:

- **router isis instance interface type interface-path-id address-family { ipv4 | ipv6 } [unicast] te-metric flex-algo metric_value [level {1 | 2}]**

The following example shows how to configure the IS-IS Flexible Algorithm-specific TE metric value to 50:

```
Router(config)# router isis 1
Router(config-isis)# interface HundredGigE 0/0/0/2
Router(config-isis-if)# address-family ipv4 unicast
Router(config-isis-if-af)# te-metric flex-algo 50
```

Use the following command to configure the Flexible Algorithm-specific TE metric value under OSPF, where *metric_value* is from 1 to 2147483647:

- **router ospf process-name area area interface type interface-path-id te-metric flex-algo metric_value**

The following example shows how to configure the OSPF Flexible Algorithm-specific TE metric value to 50:

```
Router(config)# router ospf 1
Router(config-ospf)# area 0
Router(config-ospf-ar)# interface HundredGigE 0/0/0/2
Router(config-ospf-ar-if# te-metric flex-algo 50
```

Flexible Algorithm with Exclude SRLG Constraint

Table 101: Feature History Table

Feature Name	Release Information	Feature Description
Flexible Algorithm to Exclude SRLGs for OSPF	Release 7.5.2	You can now configure the flexible algorithm to exclude any link belonging to the Shared Risk Link Groups (SRLGs) from the path computation for OSPF. The ability to exclude the at-risk links ensures that the rest of the links in the network remain unaffected.
IS-IS Flexible Algorithm: Exclude-SRLG Constraint	Release 7.5.1	<p>This feature allows the Flexible Algorithm definition to specify Shared Risk Link Groups (SRLGs) that the operator wants to exclude during the Flex-Algorithm path computation. The ability to exclude the at-risk links ensures that the rest of the links in the network remain unaffected.</p> <p>This allows the setup of disjoint paths between two or more Flex Algos by leveraging deployed SRLG configurations.</p>

This feature allows the Flexible Algorithm definition to specify Shared Risk Link Groups (SRLGs) that the operator wants to exclude during the Flex-Algorithm path computation. A set of links that share a resource whose failure can affect all links in the set constitute a SRLG. An SRLG provides an indication of which links in the network might be at risk from the same failure.

This allows the setup of disjoint paths between two or more Flex Algos by leveraging deployed SRLG configurations. For example, multiple Flex Algos could be defined by excluding all SRLGs except one. Each FA will prune the links belonging to the excluded SRLGs from its topology on which it computes its paths.

This provides a new alternative to creating disjoint paths with FA, in addition to leveraging FA with link admin group (affinity) constraints.

The Flexible Algorithm definition (FAD) can advertise SRLGs that you want to exclude during the Flexible Algorithm path computation. The IS-IS Flexible Algorithm Exclude SRLG Sub-TLV (FAESRLG) is used to

advertise the exclude rule that is used during the Flexible Algorithm path calculation, as specified in IETF draft <https://datatracker.ietf.org/doc/draft-ietf-lsr-flex-algo/>

The Flexible Algorithm path computation checks if an “exclude SRLG” rule is part of the FAD. If an “exclude SRLG” rule exists, it then checks if the link is part of an SRLG that is also part of the “exclude SRLG” rule. If the link is part of an excluded SRLG, the link is pruned from the path computation.

The figure below shows a topology configured with the following flex algos:

- Flex algo 128: metric IGP and exclude SRLG X constraint
- Flex algo 129: metric IGP and exclude SRLG Y constraint

The horizontal links between nodes 3 and 4 and between 2 and 5 are part of SRLG group X. The diagonal links between nodes 3 and 5 and between 2 and 4 are part of SRLG group Y. As a result, traffic from node 1 to node 6's FA 128 prefix SID (16806) avoids interfaces part of SRLG X. While traffic from node 1 to node 6's FA 129 prefix SID (16906) avoids interfaces part of SRLG Y.

Note See [Constraints, on page 413](#) section in the *Configure SR-TE Policies* chapter for information about configuring SR policies with Flex-Algo constraints.

Figure 35: Flex Algo with Exclude SRLG Constraint

Configuration

Use the **router isis instance address-family ipv4 unicast advertise application flex-algo link-attributes srlg** command to enable the Flexible Algorithm ASLA-specific advertisement of SRLGs.

Use the **router isis instance flex-algo algo srlg exclude-any srlg-name . . . srlg-name** command to configure the SRLG constraint which is advertised in the Flexible Algorithm definition (FAD) if the FAD advertisement is enabled under the flex-algo sub-mode. You can specify up to 32 SRLG names.

The SRLG configuration (value and port mapping) is performed under the global SRLG sub-mode. Refer to [MPLS Traffic Engineering Shared Risk Link Groups](#) for more information.

Example

The following example shows how to enable the Flexible Algorithm ASLA-specific advertisement of SRLGs and to exclude SRLG groups from Flexible Algorithm path computation:

```
RP/0/RP0/CPU0:router(config)# srlg
RP/0/RP0/CPU0:router(config-srlg)# interface HunGigE0/0/0/0
RP/0/RP0/CPU0:router(config-srlg-if)# name groupX
RP/0/RP0/CPU0:router(config-srlg-if)# exit
RP/0/RP0/CPU0:router(config-srlg)# interface TenGigE0/0/0/1

RP/0/0/CPU0:r1(config-ospf-flex-algo-srlg-exclude-any)#groupY
RP/0/0/CPU0:r1(config-ospf-flex-algo-srlg-exclude-any)#commit
```

Verification

The following example shows how to verify the number of SRLGs excluded for OSPF:

```
RP/0/RP0/CPU0:router# show ospf topology summary
Process ospf-1
Instance default
  Router ID      : 192.168.0.1
  Number of Areas : 1
  Number of Algos : 1
  Max Path count : 16
  Route count    : 10
  SR Global Block : 16000 - 23999

Area 0
  Number of Nodes : 6
  Algo 128
    FAD Advertising Router : 192.168.0.1
    FAD Area ID : 0
    Algo Type   : 0
    Metric Type : 0
      Number of Exclude SRLGs : (2)
        [1]: 100      [2]: 200
    FAPM supported : No
```

Flexible Algorithm with Exclude Minimum Bandwidth Constraint

Table 102: Feature History Table

Feature Name	Release Information	Feature Description
IS-IS Flexible Algorithm with Exclude Minimum Bandwidth Constraint	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>Traffic engineering in networks can be optimized by avoiding low-bandwidth links that may not be capable of handling high volumes of traffic.</p> <p>This feature allows you to use Flexible Algorithm to create topologies in your network that explicitly exclude high bandwidth traffic from utilizing links below a specified capacity. This constraint is achieved by introducing a new bandwidth-based metric type within the Flexible Algorithm framework. Links that do not satisfy the constraint are ignored when computing the associated Flexible Algorithm topology.</p> <p>This feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> The router isis <i>instance</i> flex-algo <i>algo</i> command is modified with the new minimum-bandwidth <i>value</i> option. <p>YANG Data Model:</p> <ul style="list-style-type: none"> This feature extends the native Cisco-IOS-XR-clns-isis-cfg.yang model (see GitHub, YANG Data Models Navigator)

This feature allows you to configure a minimum bandwidth value for computing a Flexible Algorithm path.

The IS-IS Flex-Algorithm Exclude Minimum Bandwidth sub-TLV (FAEMB) is a way to set a minimum bandwidth requirement for links in the Flex-Algorithm topology.

To determine if a link should be excluded based on this minimum bandwidth requirement, we compare the Minimum Bandwidth specified in the FAEMB sub-TLV with the Maximum Link Bandwidth advertised in the Area Supported by the Link Attribute (ASLA) sub-TLV.

If the Maximum Link Bandwidth is lower than the Minimum bandwidth specified, the link is excluded from the Flex-Algorithm topology. However, if the FAD includes the FAEMB sub-TLV but the Maximum Link Bandwidth is not advertised for the link, it should not be excluded based on the Minimum Bandwidth constraint.

Use the **router isis instance flex-algo algo minimum-bandwidth value** command to configure the minimum bandwidth value in kbps.

Example: Configuring IS-IS Flexible Algorithm with Minimum Bandwidth Constraint

```
router isis 1
 address-family ipv4 unicast
   segment-routing mpls
 !
 address-family ipv6 unicast
   segment-routing srv6
     locator L1_A129
   !
 !
 !
 flex-algo 129
   advertise-definition
     minimum-bandwidth 10000000
   !
 interface Loopback0
   address-family ipv4 unicast
     prefix-sid index 100
     prefix-sid algorithm 129 index 300
   !
   address-family ipv6 unicast
   !
 !
 segment-routing
   srv6
     locators
       locator L1_A129
         micro-segment behavior unode psp-usd
         prefix cafe:0:2100::/48
         algorithm 129
       !
     !
   !
 !
```

Flexible Algorithm with Exclude Maximum Delay Constraint

Table 103: Feature History Table

Feature Name	Release Information	Feature Description
IS-IS Flexible Algorithm with Exclude Maximum Delay Constraint	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>This feature enables you to configure topologies that exclude links that have delays over a specific threshold. This is especially critical for high-frequency trading applications, in satellite networks, or wherever there are fluctuations in link delays.</p> <p>This feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> The router isis instance flex-algo algo command is modified with the new maximum-delay value option. <p>YANG Data Model:</p> <ul style="list-style-type: none"> This feature extends the native Cisco-IOS-XR-clns-isis-cfg.yang model (see GitHub, YANG Data Models Navigator)

This feature allows you to configure a maximum delay value for computing a Flexible Algorithm path.

The Flexible Algorithm Exclude Minimum Delay (FAEMD) sub-TLV is used to specify the maximum delay requirement for links in a Flex-Algorithm topology. To ensure proper functioning, the FAEMD sub-TLV must appear only once in the FAD sub-TLV (Flexible Algorithm Definition). If it appears more than once, it should be ignored by the receiver. The maximum link delay advertised in the FAEMD sub-TLV is compared with the minimum unidirectional link delay advertised in the ASLA sub-TLV.

If the minimum unidirectional link delay is higher than the maximum link delay advertised in the FAEMD sub-TLV, the link must be excluded from the Flex-Algorithm topology.

However, if a link does not have the minimum unidirectional link delay advertised but the FAD contains the FAEMD sub-TLV, then based on the maximum delay constraint, that link should not be excluded from the topology.

Use the **router isis** *instance* **flex-algo algo maximum-delay delay** command to configure the maximum delay value in microseconds.

Example: Configuring IS-IS Flexible Algorithm with Maximum Delay Constraint

```
router isis 1
 address-family ipv4 unicast
   segment-routing mpls
 !
 address-family ipv6 unicast
   segment-routing srv6
     locator L1_A128
   !
 !
 flex-algo 128
   advertise-definition
     maximum-delay 300
 !
 interface Loopback0
   address-family ipv4 unicast
     prefix-sid index 100
     prefix-sid algorithm 128 index 200
   !
   address-family ipv6 unicast
   !
 !
 segment-routing
   srv6
     locators
       locator L1_A128
         micro-segment behavior unode psp-usd
         prefix cafe:0:1100::/48
         algorithm 128
       !
     !
   !
 !
```

Maximum Paths Per IS-IS Flexible Algorithm

Table 104: Feature History Table

Feature Name	Release	Description
IS-IS: Maximum Paths Per Flexible Algorithm	Release 7.8.1	This feature introduces a new subcommand under flex-algo command. This feature allows for maximum number of Equal-Cost Multi-path (ECMP) to be set for individual Flex Algorithms

A new subcommand under **flex-algo** is introduced.

The **flex-algo** command now includes the **address-family** <ipv4/ipv6> **unicast** subcommand, and the **maximum-paths** <maximum-paths> subcommand.

Note For information on IS-IS Algo0 Maximum Paths, refer to the "Implementing IS-IS" chapter in the *Routing Configuration Guide for Cisco NCS 5500 Series Routers*.

The new subcommands allow for maximum number of Equal-Cost Multi-path (ECMP) to be set for individual algorithms. The value that is configured on a per-flex-algo per address-family basis overrides any value that is configured under the IS-IS global address-family submode.

Usage Guidelines and Limitations

- The **maximum-paths** configuration is not part of the Flexible Algorithm Definitions (FAD). If the advertised definition is configured for the flexible algorithm, the **maximum-paths** will not be propagated by the IS-IS.
- The maximum-paths per algorithm takes precedence over maximum-paths per address-family.
- The maximum paths effective for each algorithm are as follows:
 - For Flex-Algo 128:
 - IPv4: 5
 - IPv6: 3
 - For Flex-Algos 129 through 255:
 - IPv4: 12
 - IPv6: 8

Configuration Example - Max Path

This example shows how you can set the maximum paths per-Flex-Algo:

```
Router(config)# router isis 10
Router(config-isis)# flex-algo 128
Router(config-isis-flex-algo)# metric-type te
Router(config-isis-flex-algo)# address-family ipv4 unicast
Router(config-isis-flex-algo-af)# maximum-paths 5
Router(config-isis-flex-algo)# exit
Router(config-isis-flex-algo-af)# address-family ipv6 unicast
Router(config-isis-flex-algo-af)# maximum-paths 3
Router(config-isis-flex-algo-af)# exit
```

Maximum Paths Per IS-IS Flexible Algorithm Per Prefix

Table 105: Feature History Table

Feature Name	Release	Description
Maximum Paths Per IS-IS Flexible Algorithm Per Prefix	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>Previously, you could configure a maximum number of Equal-Cost Multi-path (ECMP) to be set for individual Flex Algorithms.</p> <p>This feature provides additional granularity to the IS-IS Maximum Paths Per-Algorithm feature by allowing you to specify a set of prefixes for Flexible Algorithm.</p> <p>Now you can achieve a balance between path diversity and computational and memory requirements by controlling the number of paths for each specific algorithm and destination prefix combination.</p> <p>This feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> maximum-paths route-policy <i>name</i> <p>YANG Data Models:</p> <ul style="list-style-type: none"> This feature extends the native <code>Cisco-IOS-XR-clns-isis-cfg.yang</code> model <p>See GitHub, Yang Data Models Navigator</p>

Previously, you could set the maximum paths for a Flexible Algorithm per address-family.

With this feature, you can further refine the maximum paths configuration by associating it with specific prefixes for each Flexible Algorithm. The existing **maximum-paths** command is extended to include a **route-policy** qualifier to configure the maximum paths per algorithm per prefix-list.

When installing paths into the Routing Information Base (RIB) for Segment Routing with IPv6 (SRv6) or the Label Switched Database (LSD) for Segment Routing with MPLS (SR-MPLS), the system checks if a maximum paths value has been configured for the algorithm and the associated prefix. If such a configuration exists, it will be used instead of the existing address-family value to determine the number of paths to be installed.

Note Route policies that have the attribute **set maximum-paths number** are supported.

Note For information on maximum paths per prefix for IS-IS algo 0 (SPF), refer to the "Implementing IS-IS" chapter in the *Routing Configuration Guide for Cisco NCS 5500 Series Routers*.

Usage Guidelines and Limitations

- The **maximum-paths maximum-paths** and **maximum-paths route-policy name** configurations are mutually exclusive. You can configure either an unqualified number or a route-policy for any given IS-IS instance.
- The maximum paths per-algorithm per-prefix configuration takes precedence over maximum paths per-algorithm configuration. Likewise, the maximum paths per-algorithm configuration takes precedence over maximum paths per-address-family configuration. This hierarchy ensures that the most specific configuration is prioritized when determining the maximum paths for a given algorithm and prefix combination.

Example

The following example shows how to configure the maximum paths for Flex Algo 128:

• Define a Prefix Set:

```
prefix-set isis-ipv4-L1
 10.1.0.101/32
end-set
```

• Create a Route Policy:

```
route-policy isis-mp-if-L1
 if destination in isis-ipv4-L1 then
   set maximum-paths 2
 endif
end-policy
```

• Apply Route Policy to Configure Maximum Paths Per-Algo Per-Prefix:

```
router isis 10
 flex-algo 128
 address-family ipv4 unicast
   maximum-paths route-policy isis-mp-if-L1
```

Verification

```
Router# show isis route flex-algo 128
```

```
IS-IS 10 IPv4 Unicast routes Flex-Algo 128
```

Codes: L1 - level 1, L2 - level 2, ia - interarea (leaked into level 1)
 df - level 1 default (closest attached router), su - summary null
 C - connected, S - static, R - RIP, B - BGP, O - OSPF
 E - EIGRP, A - access/subscriber, M - mobile, a - application
 i - IS-IS (redistributed from another instance)

Maximum parallel path count: as defined in isis-mp-if-L1

```
L1 10.1.0.101/32 [121/115]
  via 15.15.15.2, GigabitEthernet0/0/0/5, hare, SRGB Base: 16000, Weight: 0
  via 16.16.16.2, GigabitEthernet0/0/0/6, hare, SRGB Base: 16000, Weight: 0
```

Flexible algorithm with bandwidth optimization

Table 106: Feature History Table

Feature Name	Release Information	Feature Description
Flexible algorithm with bandwidth optimization	Release 24.4.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>The enhanced IGP flexible algorithm path computation optimizes routing paths by automatically adjusting to changes in link bandwidth, which is especially beneficial for handling parallel L3 links and dynamic bandwidth variations, such as in L2 link bundles. The algorithm ensures optimal capacity paths by considering the cumulative bandwidth of parallel links and prefers paths with the highest available bandwidth, improving performance for high-bandwidth traffic flows. In addition to traditional metrics like link delay or monetary cost, the algorithm can also optimize paths based on the maximum available bandwidth of links, which can be locally configured or computed from advertised link bandwidth.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> • bandwidth-metric flex-algo • metric-type bandwidth • reference-bandwidth • group-mode <p>YANG Data Models:</p> <ul style="list-style-type: none"> • New Xpaths are introduced for Cisco-IOS-XR-um-router-isis-cfg.yang (see GitHub, YANG Data Models Navigator)

IGPs have traditionally computed paths by minimizing the sum of administratively defined link metrics, often inversely proportional to link bandwidth. In other cases, metrics are based on attributes like link delay or monetary cost. The enhanced Flexible Algorithm (FA) path computation provides an additional flex-algo

topology that is optimized purely on bandwidth, ensuring more efficient use of network resources by selecting paths based on physical bandwidth.

Challenges with traditional metrics on parallel links

The handling of parallel L3 links with administratively assigned metrics, even if these metrics are based on link bandwidth, does not always result in the best capacity path. This is because traditional metrics do not account for the cumulative bandwidth available across multiple parallel links.

FA bandwidth optimization for parallel links

FA bandwidth optimization provides a more accurate path selection by considering the most available bandwidth across these parallel links, ensuring that the chosen path can handle the required traffic load more effectively.

If the bandwidth of the interface changes, such as in the case of an L2 link bundle where a bundle member link goes up or down, the advertised link bandwidth will change accordingly. With bandwidth optimization, FA paths can be automatically adjusted. This dynamic adjustment ensures that the network can adapt to changes in real-time, maintaining optimal performance and avoiding potential bottlenecks. For instance, if a link within a bundle fails, the Flexible Algorithm can recalculate the paths to route traffic through the remaining available bandwidth, thereby maintaining service continuity and efficiency.

FA forwarding is available in multiple transport mechanisms:

- SR-MPLS: Utilizes algorithm-specific Segment Identifiers (SIDs)
- SRv6: Uses algorithm-specific locators
- IP Algorithm: Employs IP algorithm prefixes

All these methods support bandwidth-based computation.

Cumulative bandwidth over parallel links

Consider this topology, where PE1 is connected to PE2 via two different paths,

- Path 1: PE1-R1-R3-R4-R2-PE2
- Path 2: PE1-R1-R5-R6-R2-PE2

Figure 36: Example topology

In traditional path computation, if all links are of same capacity and all have the same metric 10, traffic from PE1 to PE2 is load balanced equally between Path 1 and Path 2, without considering the parallel links available in Path 1. Bandwidth based optimization considers the presence of these parallel links and computes the path

using the cumulative bandwidth. This is useful for traffic flows that involve a large volume of data being transferred over a long duration.

Cumulative bandwidth metric calculation can be enabled using the **group-mode** command.

Benefits of flexible algorithm with bandwidth optimization

- **Optimized path selection:** Ensures paths are selected based on physical bandwidth, leading to more efficient use of network resources.
- **Dynamic adjustment:** Automatically adjusts paths in real-time based on changes in link bandwidth, such as when a link in an L2 bundle goes up or down.
- **Improved handling of parallel links:** Considers cumulative bandwidth across parallel links, preferring paths with the best available bandwidth.

Usage guidelines for flexible algorithm with bandwidth optimization

Bandwidth metric

- Bandwidth metric can be manually computed and locally configured on a link using the **bandwidth-metric flex-algo** command. This is advertised similar to other metrics in IGP. Manual Bandwidth Metric is advertised in the ISIS Generic-Metric Sub-TLV, as type 3 metric.
- If no bandwidth metric is advertised, it is calculated for both local and remote links using the maximum physical link bandwidth from the interface attributes. This metric is derived from the maximum link bandwidth, using the Reference Bandwidth and Granularity Bandwidth provided by the Flexible Algorithm definition (FAD).

If Granularity Bandwidth is less than or equal to Maximum Link Bandwidth, this is the bandwidth metric calculation:

```
Bandwidth Metric = Reference Bandwidth / (Maximum Link Bandwidth - (MOD(Maximum Link Bandwidth , Granularity Bandwidth))
```

If Granularity Bandwidth is more than Maximum Link Bandwidth, this is the bandwidth metric calculation:

```
Bandwidth Metric = Reference Bandwidth / Maximum Link Bandwidth
```

- If there is only one link between nodes and bandwidth metric type is advertised for the link, the Flex-Algorithm calculation uses the advertised bandwidth metric.
- In interface group mode,
 - if all parallel links have a bandwidth metric advertised, the individual link bandwidth metric is used.
 - if none or only some parallel links have a bandwidth metric advertised, the advertised metrics are ignored, and the link metric is automatically calculated.
- If the calculated metric is zero, a metric of 1 is used.

Configure flexible algorithm with bandwidth optimization

This section includes configuration for bandwidth metrics for IS-IS flexible algorithms.

Procedure

- Step 1** Define the bandwidth metric value for an interface using the **bandwidth-metric flex-algo** command in the IS-IS interface address-family submode. In the following example, the metric value is configured as 100.

Example:

```
Router(config)#router isis 1
Router(config-isis)#interface GigabitEthernet 0/2/0/7
Router(config-isis-if)#address-family ipv4 unicast
Router(config-isis-if-af)#bandwidth-metric flex-algo 100
```

- Step 2** Define metric-type as bandwidth using the **metric-type** command in the IS-IS flex-algo submode.

Example:

```
Router(config)#router isis 1
Router(config-isis)#flex-algo 131
Router(config-isis-flex-algo)#metric-type bandwidth
```

- Step 3** Configure the parameters for automatic bandwidth metric calculation using the **reference-bandwidth** command in the IS-IS flex-algo auto-cost submode.

Example:

```
Router(config)#router isis 1
Router(config-isis)#flex-algo 131
Router(config-isis-flex-algo)#auto-cost reference
Router(config-isis-flex-algo-af-auto-cost)#reference-bandwidth 10000000 granularity 2000
```

- Step 4** Configure interface group mode using the **group-mode** command in the IS-IS flex-algo auto-cost submode.

Example:

```
Router(config)#router isis 1
Router(config-isis)#flex-algo 131
Router(config-isis-flex-algo)#auto-cost reference
Router(config-isis-flex-algo-af-auto-cost)#group-mode
Router(config-isis-flex-algo-af-auto-cost)#commit
```

- Step 5** Verify the running configuration using the **show running-config** command.

Example:

```
router isis 1
 flex-algo 131
  metric-type bandwidth
  auto-cost reference
  group-mode
  reference-bandwidth 10000000 granularity 2000
!
!
interface GigabitEthernet0/2/0/7
 address-family ipv4 unicast
  bandwidth-metric flex-algo 100
!
!
!
```

- Step 6** Verify the Flexible Algorithm Definition configuration using the **show isis flex-algo** command.

Example:

```
Router#show isis flex-algo 131
.....
Definition Source: plzen.00
Definition Equal to Local: No
Definition Metric Type: Bandwidth
Auto-cost Reference Bandwidth: 99999998 (kbits/sec), (12499999744 bytes/sec)
Auto-cost Granularity: 2000 (kbits/sec), (250000 bytes/sec)
Auto-cost Group Mode: No
Definition Flex-Algo Prefix Metric: No
Exclude Any Affinity Bit Positions:
Include Any Affinity Bit Positions:
Include All Affinity Bit Positions:
.....
```

Step 7 Verify the bandwidth metric configured for an interface using the **show isis interface** command.

Example:

```
Router#show isis interface GigabitEthernet 0/2/0/7

GigabitEthernet0/2/0/7 Enabled
Adjacency Formation: Enabled
Prefix Advertisement: Enabled
Bandwidth: 1000000
...
...
IPv4 Unicast Topology: Enabled
Adjacency Formation: Running
Prefix Advertisement: Running
Policy (L1/L2): -/-
Metric (L1/L2): 10/10
Metric fallback:
...
BW Metric (L1/L2): 100/100
```

Example: Configuring IS-IS Flexible Algorithm

```
router isis 1
  affinity-map red bit-position 65
  affinity-map blue bit-position 8
  affinity-map green bit-position 201

  flex-algo 128
    advertise-definition
    affinity exclude-any red
    affinity include-any blue
  !
  flex-algo 129
    affinity exclude-any green
  !
  !
address-family ipv4 unicast
  segment-routing mpls
!
interface Loopback0
  address-family ipv4 unicast
    prefix-sid algorithm 128 index 100
    prefix-sid algorithm 129 index 101
  !
```

```

!
interface GigabitEthernet0/0/0/0
  affinity flex-algo red
!
interface GigabitEthernet0/0/0/1
  affinity flex-algo blue red
!
interface GigabitEthernet0/0/0/2
  affinity flex-algo blue
!

```

Example: Configuring OSPF Flexible Algorithm

```

router ospf 1
  flex-algo 130
  priority 200
  affinity exclude-any
    red
    blue
  !
  metric-type delay
!
flex-algo 140
  affinity include-all
    green
  !
  affinity include-any
    red
  !
!

interface Loopback0
  prefix-sid index 10
  prefix-sid strict-spf index 40
  prefix-sid algorithm 128 absolute 16128
  prefix-sid algorithm 129 index 129
  prefix-sid algorithm 200 index 20
  prefix-sid algorithm 210 index 30
!
!

interface GigabitEthernet0/0/0/0
  flex-algo affinity
  color red
  color blue
!
!

affinity-map
  color red bit-position 10
  color blue bit-position 11
!

```

Example: Traffic Steering to Flexible Algorithm Paths

BGP Routes on PE – Color Based Steering

SR-TE On Demand Next-Hop (ODN) feature can be used to steer the BGP traffic towards the Flexible Algorithm paths.

The following example configuration shows how to setup BGP steering local policy, assuming two router: R1 (2.2.2.2) and R2 (4.4.4.4), in the topology.

Configuration on router R1:

```
vrf Test
address-family ipv4 unicast
  import route-target
  1:150
  !
  export route-policy SET_COLOR_RED_HI_BW
  export route-target
  1:150

User-Defined Generic Metric Support for IS-IS Flex Algo

Table 107: Feature History Table

Feature Name	Release Information	Feature Description
User-Defined Generic Metric Support for IS-IS Flex Algo on NCS 5700 Fixed Port Routers	Release 24.2.11	Introduced in this release on: NCS 5700 fixed port routers The feature support is now extended to NCS 5700 fixed port routers.

Feature Name	Release Information	Feature Description
User-Defined Generic Metric Support for IS-IS Flex Algo	Release 24.2.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>This feature adds support for user-defined generic metric as a metric type for IS-IS Flexible Algorithm.</p> <p>You can now have more control over traffic flows using user-defined generic metrics. You can define a family of user-defined generic metrics that can advertise different types of administrative metrics such as jitter, reliability, and fiscal cost depending on the traffic class for Flexible Algorithms. You can selectively define and assign semantics of these metrics as per the network requirement.</p> <p>The feature introduces the following changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> The feature introduces the generic-metric flex-algo and metric-type generic commands. <p>YANG Data Models:</p> <ul style="list-style-type: none"> Cisco-IOS-XR-un-router-isis-cfg.yang

Control Traffic Flow with User-Defined Generic Metrics

With the addition of different traffic types, the need for alternate types of metrics has evolved. Flexible Algorithm already supports IGP, TE, and delay metrics. However a network operator might want to minimize their operational costs and might want a metric that reflects the actual fiscal costs of using a link. Other traffic may require low jitter, leading to an entirely different set of metrics. With Flexible Algorithm, all these different metrics could be used concurrently on the same network. These improvements are possible as you can now define a family of user-defined generic metrics that can advertise various types of administratively assigned metrics. These metrics are not predefined, which provides network administrators with the flexibility to assign their own meanings and semantics to the metrics. This means you can create metrics tailored to specific operational goals or traffic requirements.

Apply User-Defined Generic Metrics in Flexible Algorithm Definition

You can apply the user-defined generic metrics within the Flexible Algorithm Definition (FAD) similar to how you would use TE or delay metrics. For example, you can assign specific user-defined generic metrics to individual Flex Algos, allowing for a customized path selection criteria. This capability enables different paths to use different metrics, ensuring that each path is optimized for the specific type of traffic it handles.

Split traffic with User-Defined Generic Metrics

Consider a scenario where for some networks, traffic engineering might require splitting east and west traffic for different Flexible Algorithms across multiple hardware data planes. In the following figure, the Flex Algo 128 (Orange) uses the upper primary path, while the Flex Algo 129 (Blue) uses the lower primary path. You can achieve this by defining specific user-defined generic metrics for the Flex Algo to determine the best path for each Flex Algo. The numbers 10 and 100 represent the user-defined generic metrics configured for the two different Flex Algos.

Figure 37: Splitting traffic using user-defined generic metrics for different Flex Algos

524029

Advantages of splitting traffic using user-defined generic metrics

This approach offers several advantages. You can use Equal-Cost Multi-Path (ECMP) routing within the backbone, allowing multiple links of the same color between core nodes. It also ensures efficient backup routes and prevents U-loops with Flex Algo specific Loop-Free Alternates (LFA) and Topology-Independent Loop-Free Alternates (TI-LFA).

In the above example, the vertical core links are used as backup paths for all Flex Algos, and you can activate them only if a core link or node fails. These links are part of all Flex Algos, and you can use user-defined generic metrics to configure and advertise such metrics for each individual Flex Algo to ensure smooth operation.

Benefits of User-Defined Generic Metrics

The key benefits of user-defined generic metrics are:

- You can ensure precise control over routing decisions based on the assigned metrics, as the links that do not advertise the user-defined generic metric are excluded from the Flex Algo topology.
- You can use the metrics to reduce operational expenses by choosing cost-effective paths.
- You can customize metrics to fit unique operational goals and traffic requirements, providing tailored solutions for different scenarios.
- You can simultaneously apply multiple metrics across the same network, enhancing overall network performance and reliability.

Usage Guidelines and Limitations for User-Defined Generic Metrics

The user-defined generic metric is disabled by default. In other words, the metric is not advertised unless it is configured.

Configure User-Defined Generic Metrics

This section includes configuration for user-defined generic metrics for IS-IS Flex Algos.

Procedure

- Step 1** Define the metric type and value for an interface using the **generic-metric flex-algo** command in the IS-IS interface address-family submode. In the following example, the user-defined generic metric type is 177 and the metric value as 100.

Example:

```
Router(config)#router isis 1
Router(config-isis)#interface GigabitEthernet 0/2/0/7
Router(config-isis-if)#address-family ipv4 unicast
Router(config-isis-if-af)#generic-metric flex-algo type 128 100
Router(config-isis-if-af)#generic-metric flex-algo type 177 100
Router(config-isis-if-af)#generic-metric flex-algo type 188 1000
```

- Step 2** Associate or advertise the configured metric type to a Flexible Algorithm Definition using the **metric-type generic** command. In the following example, the metric type advertised is 177.

```
Router(config)#router isis 1
Router(config-isis)#flex-algo 128
Router(config-isis-flex-algo)#priority 254
Router(config-isis-flex-algo)#metric-type generic 177
Router(config-isis-flex-algo)#advertise-definition
```

- Step 3** Verify the running configuration using the **show running-config** command.

Example:

```
router isis 1
flex-algo 128
priority 254
metric-type generic 177
advertise-definition
!
interface GigabitEthernet 0/2/0/7
address-family ipv4 unicast
```

```

generic-metric flex-algo type 128 100
generic-metric flex-algo type 177 100
generic-metric flex-algo type 188 1000
!
!
!

```

Step 4 Verify the Flexible Algorithm Definition configuration using the **show isis flex-algo** command.

Example:

```

Router#show isis flex-algo 128
Thu Dec 7 03:10:56.452 PST
IS-IS 1 Flex-Algo Database
Flex-Algo 128:
Level-2:
Definition Priority: 254
Definition Source: plzen.00, (Local)
Definition Equal to Local: Yes
Definition Metric Type: User-defined: 177.
Definition Flex-Algo Prefix Metric: No
Exclude Any Affinity Bit Positions:
Include Any Affinity Bit Positions:
Include All Affinity Bit Positions:
Reverse Exclude Any Affinity Bit Positions:
Reverse Include Any Affinity Bit Positions:
Reverse Include All Affinity Bit Positions:
Exclude SRLGs:
Minimum Link Bandwidth: 0 kbits/s
Maximum Link Delay: 0 us
Disabled: No
Topologies supported:
IPv4 Unicast
Local Priority: 254
FRR Disabled: No
Microloop Avoidance Disabled: No
UCMP Disabled: No
Data Plane Segment Routing: Yes
Data Plane IP: No

```

Step 5 Optionally, you can also verify the application-specific user-defined generic metric configured for an interface by using the **show isis interface** command.

Example:

```

Router#show isis interface GigabitEthernet 0/2/0/7
Thu Dec 7 03:13:34.140 PST
GigabitEthernet0/2/0/7 Enabled
Adjacency Formation: Enabled
Prefix Advertisement: Enabled
Bandwidth: 1000000
...
...
IPv4 Unicast Topology: Enabled
Adjacency Formation: Running
Prefix Advertisement: Running
Policy (L1/L2): -/-
Metric (L1/L2): 10/10
Metric fallback:
Bandwidth (L1/L2): Inactive/Inactive
Anomaly (L1/L2): Inactive/Inactive
Weight (L1/L2): 0/0
  L1 Flex-algo Generic-metrics:
    Type: 128           100
    Type: 177           100

```

```

Type: 188          1000
L2 Flex-algo Generic-metrics:
Type: 128          100
Type: 177          100
Type: 188          1000

```

IS-IS Flexible Algorithm UCMP Support

Table 108: Feature History Table

Feature Name	Release Information	Feature Description
IS-IS Flexible Algorithm UCMP Support	Release 24.1.1	<p>This feature enables UCMP at the IS-IS Address Family level and applies it to all the Flexible Algorithms. We have provided an option for you to disable UCMP for a specific Flexible Algorithm.</p> <p>This feature introduces the ucmp disable command</p>

Flexible Algorithm uses the Interior Gateway Protocol (IGP) to distribute the information about the network topology and the constraints for each algorithm. It operates in the context of Segment Routing with MPLS (SR-MPLS) and Segment Routing with IPv6 (SRv6).

Unequal-Cost Multiple Paths (UCMP) provides a way to distribute traffic across multiple unequal-cost paths. Traffic distributes proportionally to the cost of the paths. This increases network resiliency and optimizes bandwidth usage.

You can use UCMP with the Flexible Algorithm to create flexible and customizable routing policies. This feature can be useful in large, complex networks where it is crucial to optimize traffic flow, to enhance network performance, and ensure reliability. *For more information on UCMP, refer to the Implementing UCMP chapter in Routing Configuration Guide for Cisco NCS 5500 Series Routers*

Configure IS-IS Flexible Algorithm UCMP Support

The following example enables UCMP support on IS-IS Address Family.

Example configuration of UCMP at IS-IS Address Family submode for IPv4

```

Router(config)# router isis 1
Router(config-isis)# address-family ipv4 unicast
Router(config-isis-afi)# ucmp

```

Example configuration of UCMP at IS-IS Address Family submode for IPv6

```

Router(config)# router isis 1
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-afi)# ucmp

```

Example configuration to disable UCMP of specific Flexible Algorithm. Here, it is Flexible Algorithm 128

```

Router(config)# router isis 1

```

```
Router(config-isis)# flex-algo 128
Router(config-isis-flex-algo)# ucmp disable
```

Use the following command to disable specific Flexible Algorithms.

Example configuration to disable UCMP of specific Flexible Algorithm. Here, it is Flexible Algorithm 128

```
Router(config)# router isis 1
Router(config-isis)# flex-algo 128
Router(config-isis-flex-algo)# ucmp disable
```

Running Configuration

Example configuration of UCMP at IS-IS Address Family submode for IPv4

```
router isis 1
 address-family ipv4 unicast
   ucmp
   !
 !
 !
```

Example configuration of UCMP at IS-IS Address Family submode for IPv6

```
router isis 1
 address-family ipv6 unicast
   ucmp
   !
 !
 !
```

Example configuration to disable UCMP of specific Flexible Algorithm. Here, it is Flexible Algorithm 128

```
router isis 1
 flex-algo 128
   ucmp disable
   !
 !
 !
```

Verification

Run the **show isis route flex-algo <Flex-algo number>** command to verify if the UCMP is enabled or disabled for a specified Flexible Algorithm.

```
Router# sh isis flex-algo 128
```

```
IS-IS 1 Flex-Algo Database

CHAPTER 14

Configure Segment Routing Path Computation Element

The Segment Routing Path Computation Element (SR-PCE) provides stateful PCE functionality by extending the existing IOS-XR PCEP functionality with additional capabilities. SR-PCE is supported on the MPLS data plane and IPv4 control plane.

Table 109: Feature History Table

Feature Name	Release Information	Feature Description
SR-PCE: Single PCE scale enhancement	Release 7.5.1	With this feature, support for a single PCE is enhanced to 50000 nodes, 100000 LSPs, 500000 links, and 2000 PCEP sessions.

- [About SR-PCE, on page 635](#)
- [Usage Guidelines and Limitations, on page 637](#)
- [Configure SR-PCE, on page 637](#)
- [PCE override of SR-TE policies, on page 641](#)
- [PCE-Initiated SR Policies, on page 647](#)

- [PCE Support for MPLS-TE LSPs, on page 674](#)
- [Configuring the North-Bound API on SR-PCE, on page 677](#)

About SR-PCE

The path computation element protocol (PCEP) describes a set of procedures by which a path computation client (PCC) can report and delegate control of head-end label switched paths (LSPs) sourced from the PCC

to a PCE peer. The PCE can request the PCC to update and modify parameters of LSPs it controls. The stateful model also enables a PCC to allow the PCE to initiate computations allowing the PCE to perform network-wide orchestration.

SR-PCE learns topology information by way of IGP (OSPF or IS-IS) or through BGP Link-State (BGP-LS).

SR-PCE is capable of computing paths using the following methods:

- TE metric—SR-PCE uses the TE metric in its path calculations to optimize cumulative TE metric.
- IGP metric—SR-PCE uses the IGP metric in its path calculations to optimize reachability.
- LSP Disjointness—SR-PCE uses the path computation algorithms to compute a pair of disjoint LSPs. The disjoint paths can originate from the same head-end or different head-ends. Disjoint level refers to the type of resources that should not be shared by the two computed paths. SR-PCE supports the following disjoint path computations:
 - Link – Specifies that links are not shared on the computed paths.
 - Node – Specifies that nodes are not shared on the computed paths.
 - SRLG – Specifies that links with the same SRLG value are not shared on the computed paths.
 - SRLG-node – Specifies that SRLG and nodes are not shared on the computed paths.

When the first request is received with a given disjoint-group ID, the first LSP is computed, encoding the shortest path from the first source to the first destination. When the second LSP request is received with the same disjoint-group ID, information received in both requests is used to compute two disjoint paths: one path from the first source to the first destination, and another path from the second source to the second destination. Both paths are computed at the same time.

TCP Authentication Option

TCP Message Digest 5 (MD5) authentication has been used for authenticating PCEP (TCP) sessions by using a clear text or encrypted password. This feature introduces support for TCP Authentication Option (TCP-AO), which replaces the TCP MD5 option.

TCP-AO uses Message Authentication Codes (MACs), which provides the following:

- Protection against replays for long-lived TCP connections
- More details on the security association with TCP connections than TCP MD5
- A larger set of MACs with minimal system and operational changes

TCP-AO is compatible with Master Key Tuple (MKT) configuration. TCP-AO also protects connections when using the same MKT across repeated instances of a connection. TCP-AO protects the connections by using traffic key that are derived from the MKT, and then coordinates changes between the endpoints.

Note TCP-AO and TCP MD5 are never permitted to be used simultaneously. TCP-AO supports IPv6, and is fully compatible with the proposed requirements for the replacement of TCP MD5.

Usage Guidelines and Limitations

To ensure PCEP compatibility, we recommend that the Cisco IOS XR version on the SR-PCE be the same or later than the Cisco IOS XR version on the PCC or head-end.

Configure SR-PCE

This task explains how to configure SR-PCE.

SUMMARY STEPS

1. **configure**
2. **pce**
3. **address ipv4** *address*
4. **state-sync ipv4** *address*
5. **tcp-buffer size** *size*
6. **password** {**clear** | **encrypted**} *password*
7. **tcp-ao** *key-chain* [**include-tcp-options**] [**accept-ao-mismatch-connection**]
8. **segment-routing** {**strict-sid-only** | **te-latency**}
9. **timers**
10. **keepalive** *time*
11. **minimum-peer-keepalive** *time*
12. **reoptimization** *time*
13. **exit**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.
Step 2	pce Example: RP/0/RP0/CPU0:router(config)# pce	Enables PCE and enters PCE configuration mode.
Step 3	address ipv4 <i>address</i> Example:	Configures a PCE IPv4 address.

	Command or Action	Purpose
	RP/0/RP0/CPU0:router(config-pce)# address ipv4 192.168.0.1	
Step 4	state-sync ipv4 address Example: RP/0/RP0/CPU0:router(config-pce)# state-sync ipv4 192.168.0.3	Configures the remote peer for state synchronization.
Step 5	tcp-buffer size size Example: RP/0/RP0/CPU0:router(config-pce)# tcp-buffer size 1024000	Configures the transmit and receive TCP buffer size for each PCEP session, in bytes. The default buffer size is 256000. The valid range is from 204800 to 1024000.
Step 6	password {clear encrypted} password Example: RP/0/RP0/CPU0:router(config-pce)# password encrypted pwd1	<p>Enables TCP MD5 authentication for all PCEP peers. Any TCP segment coming from the PCC that does not contain a MAC matching the configured password will be rejected. Specify if the password is encrypted or clear text.</p> <p>Note TCP-AO and TCP MD5 are never permitted to be used simultaneously.</p>
Step 7	tcp-ao key-chain [include-tcp-options] [accept-ao-mismatch-connection] Example: RP/0/RP0/CPU0:router(config-pce)# tcp-ao pce_tcp_ao include-tcp-options	<p>Enables TCP Authentication Option (TCP-AO) authentication for all PCEP peers. Any TCP segment coming from the PCC that does not contain a MAC matching the configured key chain will be rejected.</p> <ul style="list-style-type: none"> • include-tcp-options—Includes other TCP options in the header for MAC calculation. • accept-ao-mismatch-connection—Accepts connection even if there is a mismatch of AO options between peers. <p>Note TCP-AO and TCP MD5 are never permitted to be used simultaneously.</p>
Step 8	segment-routing {strict-sid-only te-latency} Example: RP/0/RP0/CPU0:router(config-pce)# segment-routing strict-sid-only	<p>Configures the segment routing algorithm to use strict SID or TE latency.</p> <p>Note This setting is global and applies to all LSPs that request a path from this controller.</p>

	Command or Action	Purpose
Step 9	timers Example: RP/0/RP0/CPU0:router(config-pce)# timers	Enters timer configuration mode.
Step 10	keepalive time Example: RP/0/RP0/CPU0:router(config-pce-timers)# keepalive 60	Configures the timer value for locally generated keep-alive messages. The default time is 30 seconds.
Step 11	minimum-peer-keepalive time Example: RP/0/RP0/CPU0:router(config-pce-timers)# minimum-peer-keepalive 30	Configures the minimum acceptable keep-alive timer that the remote peer may propose in the PCEP OPEN message during session establishment. The default time is 20 seconds.
Step 12	reoptimization time Example: RP/0/RP0/CPU0:router(config-pce-timers)# reoptimization 600	Configures the re-optimization timer. The default timer is 1800 seconds.
Step 13	exit Example: RP/0/RP0/CPU0:router(config-pce-timers)# exit	Exits timer configuration mode and returns to PCE configuration mode.

Configure the Disjoint Policy (Optional)

This task explains how to configure the SR-PCE to compute disjointness for a pair of LSPs signaled by PCCs that do not include the PCEP association group-ID object in their PCEP request. This can be beneficial for deployments where PCCs do not support this PCEP object or when the network operator prefers to manage the LSP disjoint configuration centrally.

SUMMARY STEPS

1. **disjoint-path**
2. **group-id value type {link | node | srlg | srlg-node} [sub-id value]**
3. **strict**
4. **lsp {1 | 2} pcc ipv4 address lsp-name lsp_name [shortest-path]**

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	disjoint-path Example: <pre>RP/0/RP0/CPU0:router(config-pce)# disjoint-path</pre>	Enters disjoint configuration mode.
Step 2	group-id <i>value</i> type { link node srlg srlg-node } [sub-id <i>value</i>] Example: <pre>RP/0/RP0/CPU0:router(config-pce-disjoint)# group-id 1 type node sub-id 1</pre>	<p>Configures the disjoint group ID and defines the preferred level of disjointness (the type of resources that should not be shared by the two paths):</p> <ul style="list-style-type: none"> • link—Specifies that links are not shared on the computed paths. • node—Specifies that nodes are not shared on the computed paths. • srlg—Specifies that links with the same SRLG value are not shared on the computed paths. • srlg-node—Specifies that SRLG and nodes are not shared on the computed paths. <p>If a pair of paths that meet the requested disjointness level cannot be found, then the paths will automatically fallback to a lower level:</p> <ul style="list-style-type: none"> • If the requested disjointness level is SRLG or node, then link-disjoint paths will be computed. • If the requested disjointness level was link, or if the first fallback from SRLG or node disjointness failed, then the lists of segments encoding two shortest paths, without any disjointness constraint, will be computed.
Step 3	strict Example: <pre>RP/0/RP0/CPU0:router(config-pce-disjoint)# strict</pre>	(Optional) Prevents the automatic fallback behavior of the preferred level of disjointness. If a pair of paths that meet the requested disjointness level cannot be found, the disjoint calculation terminates and no new path is provided. The existing path is not modified.
Step 4	lsp { 1 2 } pcc ipv4 <i>address</i> lsp-name <i>lsp_name</i> [shortest-path] Example: <pre>RP/0/RP0/CPU0:router(config-pce-disjoint)# lsp 1 pcc ipv4 192.168.0.1 lsp-name rtrA_t1 shortest-path RP/0/RP0/CPU0:router(config-pce-disjoint)# lsp 2</pre>	<p>Adds LSPs to the disjoint group.</p> <p>The shortest-path keyword forces one of the disjoint paths to follow the shortest path from the source to the destination. This option can only be applied to the the first LSP specified.</p>

	Command or Action	Purpose
	<code>pcc ipv4 192.168.0.5 lsp-name rtrE_t2</code>	

Global Maximum-delay Constraint

This feature allows a PCE to compare the cumulative latency of a computed path against a global maximum-delay constraint value. If the latency of the computed path exceeds this global constraint, the path is not considered valid. This ensures that all latency-based paths computed by the PCE and signaled to the PCCs in the network do not exceed this maximum-delay constraint.

```
pce
  constraints
    bounds
      cumulative
      type
        latency <1-4294967295> Bound metric value in microseconds
```

Configuration

To configure a PCE for specifying maximum cumulative latency metric, you must complete the following configurations:

```
RP/0/RSP0/CPU0:ios(config)# pce
RP/0/RSP0/CPU0:ios(config-pce)# constraints
RP/0/RSP0/CPU0:ios(config-pce-constr)# bounds
RP/0/RSP0/CPU0:ios(config-pce-constr-bounds)# cumulative
RP/0/RSP0/CPU0:ios(config-pce-constr-bounds-type)# type latency 1000000
RP/0/RSP0/CPU0:ios(config-pce-constr-bounds-type)#
```

Verification

Verify using the **show** command:

```
RP/0/RSP0/CPU0:ios(config-pce-constr-bounds-type)# show
Wed Oct 12 22:18:22.962 UTC
pce
  constraints
    bounds
      cumulative
      type latency 1000000
    !
  !
!
```

PCE override of SR-TE policies

Segment routing for traffic engineering (SR-TE) uses a “policy” to steer traffic through the network. An SR-TE policy path is expressed as a list of segments that specifies the path, called a segment ID (SID) list. Each segment is an end-to-end path from the source to the destination, and instructs the routers in the network to follow the specified path instead of following the shortest path calculated by the IGP. If a packet is steered into an SR-TE policy, the SID list is pushed on the packet by the head-end. The rest of the network executes the instructions embedded in the SID list.

An SR-TE policy is identified as an ordered list (head-end, color, end-point):

- Head-end – Where the SR-TE policy is instantiated
- Color – An unsigned non-zero 32-bit integer value that associates the SR Policy with an intent or objective (e.g., low latency).
- End-point – The destination of the SR-TE policy.

There are fewer PCEs in the network compared to the PCCs. However, PCE versions may be newer than the PCC version because it is easy to update the lesser PCEs than the higher number of PCCs. This ensures PCE supports more features with the latest Internet Assigned Numbers Authority (IANA) code points than PCCs.

IOS-XR PCE implementation is based on the PCEP standards and the implementations of the PCEP vary leading to interoperability challenges. To overcome these challenges, you can configure PCE with the override-rules (OVR). These OVRs have a filter part and an overriding part. The matching criteria filter matches all the (Segment Routing) SR policies against these OVRs, suppose they match, then the overriding part applies to these SR policies attributes.

For example, suppose that a PCC is outdated and does not support reporting the latency metric type. In that case, PCC reports to the LSP with the metric-type that it supports and the PCE applies the OVRs that you configure to update the metric-type upon reception.

Usage guidelines

Some usage guidelines that apply to the PCE override of SR-TE policies feature.

- Lower sequence numbers have higher precedence. LSP can be matched to one override sequence at a time. It will be matched to the highest preference sequence and further matching stops.
- Show commands such as “show pce lsp” display values received from PCC, so applied changes are visible only in values, which are based on path-computation.
- In a PCE High Availability case, where there are multiple PCEs for a particular PCC, configure this feature likewise on all PCEs, to allow seamless transition of delegation between the PCEs.
- PCE (North Bound) NB-API clients only see overridden attributes in their communication with PCEs.
- The PCE OVR feature is seamless for PCCs. This means that PCCs will not know if the tunnel’s attributes are overridden. PCEs uses overridden attributes internally and sends only the original attributes to the PCCs.

Limitations

- Supports only Segment Routing (SR) setup type.
- Supports only ten override rules.
- Only one color or color range per override rule is supported.
- Does not support SRv6 policies.
- You cannot configure the filtration option "all" under peer and LSP with another filtration option under the same config submodule. For example, you cannot provide all and regex together under the LSP matching criteria.

- Only IPv4 Access Control Lists (ACL)s are supported for matching PCEP peers.
 - If the ACL is empty or there are no entries within the ACL, then it is implicit permit.
 - If the ACL is not configured but the name is specified, then it is implicit permit.
 - In all other cases, if no entries are matched in the ACL, then it is implicit deny.
 - The behavior aligns with ACL behavior in other areas on an XR router.

Prerequisites

Before you configure the PCE override of SR-TE policies, you can use the **try-regex** utility to test the regexes. This utility is an optional step and does not alter the system.

This example shows how to verify if the

override-rules sequence sequence-number [matching-criteria lsp { all | name lsp-name-regex }] works:

```
Router# pce try-regex ^cp_c_[0-9]+$ cp_c_5000
Regex verification utility
Regex:      ^cp_c_[0-9]+$
Test string: cp_c_5000
Result:     Matched
```

PCE override of PCC-initiated SR-TE policies

The Path Computation Element (PCE) is a key component of Software-Defined Networking (SDN) for Traffic Engineering (TE), which can dynamically compute and recompute paths for Segment Routing Traffic Engineering (SR-TE) policies. These computations are guided by specified path optimization metrics and constraints. By leveraging the PCE override feature, the PCE can modify certain attributes or constraints of these policies, enabling support for a broader range of use cases and enhanced functionality.

Table 110: Feature History Table

Feature Name	Release Information	Feature Description
PCE override of PCC-initiated policies	Release 7.7.1	<p>You can now override the LSP attributes in the PCEs based on the matching criteria of the path computation element protocol (PCEP) peer and LSP attributes. This feature improves the path computation of the PCC-initiated SR-TE policies.</p> <p>You can configure the PCE override rule for one, many, or all PCCs. This feature introduces the following commands:</p> <ul style="list-style-type: none"> • override-rules (PCE) • pce try-regex • show pce override-rules detail

Matching of SR-TE policies is done before PCInitiate is sent to PCC to allow modification of data included in messages sent to PCC before LSP is created.

The LSP matching is not re-evaluated again after receiving the next PCEP report message. Based on these matching criteria, you can override the values of the LSP attributes.

Configure PCE override of PCC-initiated SR-TE policies

This configuration defines an **override rule** for a PCE on a network router, which allows the PCE to modify certain attributes of Label Switched Paths (LSPs) that meet specific criteria for PCC-initiated SR-TE policies.

Procedure

Step 1 **configure**

Example:

```
Router# configure
```

Enters the global configuration mode.

Step 2 **pce**

Example:

```
Router(config)# pce
```

Enters the PCE configuration mode.

Step 3 **override-rules**

Example:

```
Router(config-pce)# override-rules
```

Enters the override rules submode.

Step 4 **sequence value**

Example:

```
Router(config-pce-ovr-rule)# sequence 100
```

Creates a rule with the sequence number 100.

Step 5 **matching-criteria**

Example:

```
Router(config-pce-ovr-rule-seq)# matching-criteria
```

Specifies a matching criteria. For example, **peer all**, **lsp all**, and so on.

Step 6 **peer all**

Example:

```
Router(config-pce-ovr-rule-crit)# peer
```

```
Router(config-pce-ovr-rule-peer)# all
```

```
Router(config-pce-ovr-rule-peer)# exit
```

Specifies that this rule applies to all peers.

Step 7 *lsp all range***Example:**

```
Router(config-pce-ovr-rule-crit)# lsp all
Router(config-pce-ovr-rule-crit)# exit
```

Specifies all LSPs in the PCE tunnel database.

Step 8 *colors range***Example:**

```
Router(config-pce-ovr-rule-crit)# colors 0-50
Router(config-pce-ovr-rule-crit)# exit
```

Defines that the colors in the 0 to 50 range to match this rule.

Step 9 *override metric type metric-type***Example:**

```
Router(config-pce-ovr-rule-seq)# override metric type igp
```

Specifies that the IGP (Interior Gateway Protocol) metric for matching LSPs is overridden by the PCE.

Step 10 *override constraints bandwidth value***Example:**

```
Router(config-pce-ovr-rule-seq)# override constraints bandwidth 1000
```

Specifies that the bandwidth constraint for matching LSPs is overridden and set to 1000.

Step 11 *commit***Example:**

```
Router(config-pce-ovr-rule-seq)# commit
```

Saves and apply these configuration changes.

Running configuration

These are the running configurations for the PCE override for the PCC-initiated SR-TE policies.

- Match all LSPs from all peers and modify metric type to latency:

```
pce
  override-rules
    sequence 1
      matching-criteria
        peer
          all
          lsp
          all
      override
        metric
          type latency
  !
```

- Match LSP name using regex and peer based on provided ACL and change metric type to IGP:

```
pce
  override-rules
    sequence 1
      matching-criteria
        peer
          access-list ipv4 PCC1
      !
      lsp
        name ^cfg_test2_.*$
      !
    override
      metric
        type igp
      !
  !
```

- Match policy using specified Segment Routing (SR) policy color from all peers and change bandwidth to 1000 kbps:

```
pce
  override-rules
    sequence 1
      matching-criteria
        peer
          all
      !
      lsp
        colors 10
      !
    override
      constraints
        bandwidth 1000
      !
  !
```

Verification

Show command displays operational values, which are applied during the override. For example, a bandwidth value is converted into IEEE float format. The value that is displayed in the show command may not be equal to the value configured, because of the limited precision of IEEE format used in PCEP.

Verify using the show command **show pce override-rules [sequence <sequence>]**

This is the show command output with two override rules that are configured and each matched one LSP are:

```
Router# show pce override-rules details

PCE's Override Rule database:
-----
Sequence number: 1
Matching criteria:
  Peer:
    IPv4 ACL name: PCC1
  LSP
    Regex: ^cfg_test1_.*$
Override:
  Metric type: Latency
  Constraints:
Matching LSPs:
  Peer: 192.168.0.1, Tunnel name: cfg_test1_xxx_discr_5
```

```

Sequence number: 2
Matching criteria:
  Peer:
    IPv4 ACL name: PCC1
  LSP
    Regex: ^cfg_test2_.*$
Override:
  Metric type: IGP
  Constraints:
Matching LSPs:
  Peer: 192.168.0.1, Tunnel name: cfg_test2_xxx_discr_5

```

PCE-Initiated SR Policies

Use cases based on centralized optimization, such as congestion mitigation solutions, rely on the ability of the PCE to signal and instantiate SR-TE policies in the network. We refer to this as PCE-initiated SR-TE policies.

PCE-initiated SR-TE policies can be triggered via Crossworks Network Controller (recommended approach) or via CLI at the PCE.

For more information on configuring SR-TE policies, see the [SR-TE Policy Overview, on page 367](#).

The PCE deploys the SR-TE policy using PCC-PCE communication protocol (PCEP).

1. PCE sends a PCInitiate message to the PCC.
2. If the PCInitiate message is valid, the PCC sends a PCRpt message; otherwise, it sends PCErr message.
3. If the PCInitiate message is accepted, the PCE updates the SR-TE policy by sending PCUpd message.

You can achieve high-availability by configuring multiple PCEs with SR-TE policies. If the head-end (PCC) loses connectivity with one PCE, another PCE can assume control of the SR-TE policy.

Configuration Example: PCE-Initiated SR Policy with Explicit SID List

To configure a PCE-initiated SR-TE policy, you must complete the following configurations:

1. Enter PCE configuration mode.
2. Create the segment list.

Note When configuring an explicit path using IP addresses of intermediate links, the SR-TE process prefers the protected Adj-SID of the link, if one is available.

3. Create the policy.

```

/* Enter PCE configuration mode and create the SR-TE segment lists */
Router# configure
Router(config)# pce

/* Create the SR-TE segment lists */
Router(config-pce)# segment-routing
Router(config-pce-sr)# traffic-eng
Router(config-pce-sr-te)# segment-list name addr2a

```

```

Router(config-pce-sr-te-sl)# index 10 address ipv4 10.1.1.2
Router(config-pce-sr-te-sl)# index 20 address ipv4 10.2.3.2
Router(config-pce-sr-te-sl)# index 30 address ipv4 10.1.1.4
Router(config-pce-sr-te-sl)# exit

/* Create the SR-TE policy */
Router(config-pce-sr-te)# peer ipv4 10.1.1.1
Router(config-pce-sr-te)# policy P1
Router(config-pce-sr-te-policy)# color 2 end-point ipv4 2.2.2.2
Router(config-pce-sr-te-policy)# candidate-paths
Router(config-pce-sr-te-policy-path)# preference 50
Router(config-pce-sr-te-policy-path-preference)# explicit segment-list addr2a
Router(config-pce-sr-te-pp-info)# commit
Router(config-pce-sr-te-pp-info)# end
Router(config)#

```

Running Config

```

pce
segment-routing
traffic-eng
segment-list name addr2a
index 10 address ipv4 10.1.1.2
index 20 address ipv4 10.2.3.2
index 30 address ipv4 10.1.1.4
!
peer ipv4 10.1.1.1
policy P1
color 2 end-point ipv4 2.2.2.2
candidate-paths
preference 50
explicit segment-list addr2a
!
!

```

SR-PCE Flexible Algorithm Multi-Domain Path Computation

Table 111: Feature History Table

Feature Name	Release Information	Feature Description
SR-PCE: Flex Algo Aware Policy Computation + Live-Live Disjointness Enhancements	Release 7.3.1	This feature is now supported on routers that have the Cisco NC57 line cards installed and operate in the native and compatible modes. To enable the native mode, use the hw-module profile npu native-mode-enable command in the configuration mode. Ensure that you reload the router after configuring the native mode.

Flexible Algorithm provides a traffic engineered path automatically computed by the IGP to any destination reachable by the IGP. With the SR-PCE Flexible Algorithm Multi-Domain Path Computation feature, SR-PCE can use Flexible Algorithms to compute multi-domain paths. See the [Enabling Segment Routing Flexible Algorithm, on page 591](#) chapter for information about Segment Routing Flexible Algorithm.

The SR-PCE Flexible Algorithm Multi-Domain Path Computation feature incorporates the following functionality:

- BGP-LS has been augmented to allow selected nodes to advertise the Flexible Algorithm definition (FAD) to the SR-PCE
- PCEP has been augmented (vendor-specific object) to allow a PCC to indicate SR policy constraint based on the Flexible Algorithm instance number
- SR-PCE algorithms have been augmented to compute paths based on a Flexible Algorithm constraint

The SR-PCE Flexible Algorithm multi-domain path computation requires the following:

- The same Flexible Algorithm instance ID is used across domains.
- The metric for those Flexible Algorithm instances must be the same across domains.
- The affinity constraints for those Flexible Algorithm instances may be different across domains.
- Multiple Flexible Algorithms can exist in a domain.

For example, considering a multi-domain topology (Domain 1 and Domain 2), the following scenarios meet the requirements listed above:

Scenario	Domain 1	Domain 2
Scenario 1	Flexible Algorithm 128, metric delay	Flexible Algorithm 128, metric delay
Scenario 2	Flexible Algorithm 128, metric delay	Flexible Algorithm 128, metric delay, exclude affinity blue
Scenario 3	Flexible Algorithm 128, metric delay, exclude affinity yellow	Flexible Algorithm 128, metric delay, exclude affinity blue
Scenario 4	Flexible Algorithm 128, metric delay Flexible Algorithm 129, metric IGP	Flexible Algorithm 128, metric delay Flexible Algorithm 129, metric IGP

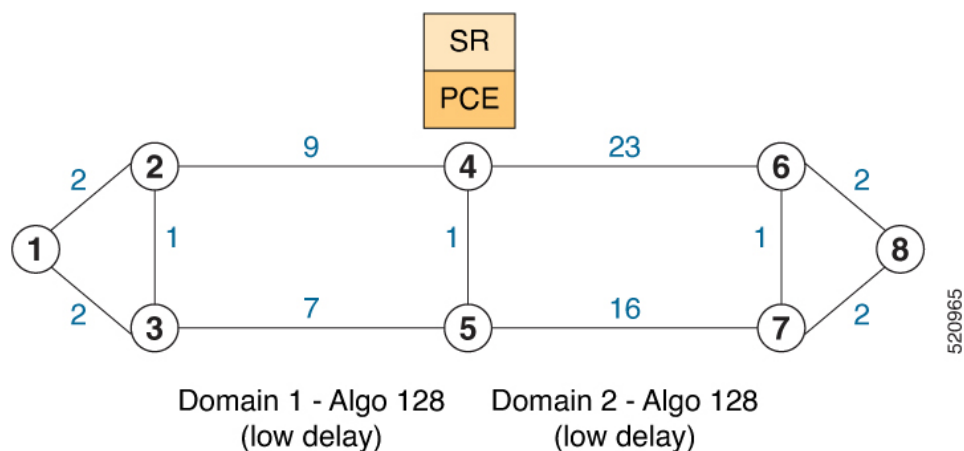

Note

The use of a Flexible Algorithm constraint in a multi-domain SR topology does not preclude the use of an SR policy that are optimized for a particular metric type. For example, a policy can request a PCE for a Multi Domain policy based on metric delay. SR-PCE computes the path and encodes it with regular prefix SIDs and Adj-SIDs as required. Alternatively, a policy can request to have a constraint for a Flexible Algorithm instance X, which is defined in multiple domains and it minimizes based on metric delay. In this case, the SR-PCE computes the multi-domain path and encodes it using only Flexible Algorithm prefix SIDs. This case benefits from the optimized label stack size that Flexible Algorithm provides (1 label per domain).

Example: SR-PCE Flexible Algorithm Multi-Domain Path Computation Use Case

The following use case depicts a multi-domain topology with two IS-IS processes, each with a Flexible Algorithm instance of 128 that minimizes metric delay. A multi-domain SR policy programmed at Node 1 leverages a Flexible Algorithm 128 path computed by the SR-PCE toward Node 8.

Exclude Network Resources during Path Computation over SR-TE Policies

Table 112: Feature History Table

Feature Name	Release Information	Feature Description
Exclude Network Resources during Path Computation over SR-TE Policies	Release 24.1.1	

Feature Name	Release Information	Feature Description
		<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native]).</p> <p>You can reduce the risk of attacks due to less secure network resources and IP addresses, improve network performance affected by overloaded or congested paths, and ensure higher levels of network stability and availability that could be impacted by resources experiencing issues and requiring maintenance. These improvements are possible because you can now exclude specific network resources using their IP addresses during path computation for traffic over SR-TE policies.</p> <p>Previously, you could not exclude network resources during path computation.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> The resources option is introduced in the segment-routing traffic-eng policy and segment-routing traffic-eng on-demand color commands. The resource-list keyword is introduced in the segment-routing traffic-eng command. <p>YANG Data Models:</p> <ul style="list-style-type: none"> Cisco-IOS-XR-infra-xtc-oper.yang Cisco-IOS-XR-infra-xtc-agent-oper.yang Cisco-IOS-XR-infra-xtc-agent-cfg.yang <p>See (GitHub, Yang Data Models Navigator)</p>

You can configure the SR-TE policies as either single or disjoint candidate paths that do not include certain IP addresses or subnets when traffic is routed through the network.

The key benefits of the feature are:

- **Security** - Excluding certain IP addresses or network resources can help protect sensitive resources from unauthorized access or attacks.
- **Performance** - By excluding certain resources, traffic can be directed away from congested parts of the network.
- **Isolation** - Excluding resources can help isolate different parts of the network, preventing issues in one part of the network from affecting others.

Configuration to exclude network resources during Path Computation

To exclude network resources during path computation for traffic, you must complete these high-level tasks in order:

1. Configure the network resources or IP addresses that you want to exclude from the network list.
2. Associate the excluded network resources to candidate paths for SR-TE or ODN SR-TE policies.

Configure the network resources or IP addresses to exclude from the network list

Perform the following task to configure a list of IPv4 addresses that you want to exclude from the network resource list:

```
Router(config)#segment-routing traffic-eng
Router(config-sr-te)#resource-list node_resc_list
Router(config-sr-te-rl)#index 1 ipv4 10.10.10.1
Router(config-sr-te-rl)#index 2 ipv4 10.10.10.8
```

Running Configuration

```
!
segment-routing
 traffic-eng
  resource-list node_resc_list
    index 1 ipv4 10.10.10.1
    index 2 ipv4 10.10.10.8
  !
!
```

Associate the excluded network resources to candidate paths for SR-TE policies

Perform the following task to associate the excluded IPv4 addresses to one or more candidate paths for SR-TE policies:

```
Router(config)#segment-routing traffic-eng
Router(config-sr-te)#policy dynamic pcep_policy
Router(config-sr-te-policy)#candidate-paths
Router(config-sr-te-policy-path)#preference 100
Router(config-sr-te-policy-path-pref)#constraints resources exclude resource-list
node_resc_list
```

Running Configuration

```

!
segment-routing
 traffic-eng
  policy dynamic_pcep_policy
    candidate-paths
      preference 100
      constraints
        resources
          exclude resource-list node_resc_list
    !
  !
!
!

Configure the Shortest Path for Disjoint Candidate Paths

Table 113: Feature History Table

Feature Name	Release Information	Feature Description
Configure the Shortest Path for Disjoint Candidate Paths	Release 24.1.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native]).</p> <p>You can now configure the available disjoint paths for Label Switched Paths (LSPs) to prefer the shortest path between two points in the network. This configuration ensures that traffic is routed along the most efficient route in the network.</p> <p>Previously, you could not configure the shortest path preference for disjoint LSPs.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <p>The shortest-path keyword is introduced in the policy candidate-paths constraints disjoint-path command.</p> <p>YANG Data Models:</p> <ul style="list-style-type: none"> • Cisco-IOS-XR-infra-xtc-oper.yang • Cisco-IOS-XR-infra-xtc-agent-oper.yang • Cisco-IOS-XR-infra-xtc-agent-cfg.yang <p>See (GitHub, Yang Data Models Navigator)</p>

The configuration enables the available disjoint paths to indicate preference for the shortest path between two points in the network. This way the traffic is contained within specific network planes as per the affinity constraints while still provisioning Label Switched Paths (LSPs) that are diverse from each other to meet the path disjointness requirement.

In earlier releases, if path disjointness was configured for LSPs, the Path Computation Element (PCE) prioritized finding disjoint paths for the LSPs over adhering to the affinity constraints.

Configure the shortest path for disjoint candidate paths

Perform the following task to indicate the disjoint path preference for the shortest path in the network:

```
Router(config)#segment-routing traffic-eng
Router(config-sr-te)#policy dynamic_pcep_policy_disjoint
Router(config-sr-te-policy)#candidate-paths
Router(config-sr-te-policy-path)#preference 100
Router(config-sr-te-policy-path-pref)#constraints disjoint-path group-id 1 type link
shortest-path
```

Running Configuration

```
!
segment-routing
 traffic-eng
   policy dynamic_pcep_policy
   candidate-paths
     preference 100
   constraints
     disjoint-path group-id 1 type link shortest-path
!
!
!
!
!
```

Verification

Enable Strict Disjointness for SR-TE policies in the PCE

Table 114: Feature History Table

Feature Name	Release Information	Feature Description
Enable Strict Disjointness for SR-TE Policies in the PCE	Release 24.1.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native]).</p> <p>You can now enforce strict disjoint constraints for Label Switched Paths (LSPs) and minimize the risk of a single point of failure that affects multiple LSPs. With this feature, if disjoint paths cannot be found for LSPs, the Path Computation Element (PCE) does not return any path.</p> <p>Previously, enforcing strict disjoint constraints for disjoint paths for LSPs was not possible.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <p>The fallback disable keyword is introduced in the segment-routing traffic-eng policy and segment-routing traffic-eng on-demand color commands.</p> <p>YANG Data Models:</p> <ul style="list-style-type: none"> • Cisco-IOS-XR-infra-xtc-oper.yang • Cisco-IOS-XR-infra-xtc-agent-qer.yang • Cisco-IOS-XR-infra-xtc-agent-cfg.yang <p>See (GitHub, Yang Data Models Navigator)</p>

When you enable fallback disable, the Path Computation Element (PCE) does not return any path for LSPs that are not disjoint if there are no disjoint candidate paths. In other words, when the PCE does not find multiple LSPs that satisfy the disjointness requirement, it returns no path. This indicates that there might be a networking issue that prevents the establishment of the desired redundancy, and you can investigate and address the underlying problem.

Without the option, the PCE can relax disjointness by applying an objective function or use a local policy when no objective function is requested.

Enforcing strict disjointness ensures that LSPs do not share any common links or nodes along their paths, minimizing the risk of a single point of failure affecting multiple LSPs. The feature is critical to maintain network reliability and ensures that traffic is properly routed in the event of a network failure.

Configure Strict Disjointness in the PCE

Enable strict disjointness for ODN SR-TE policies

Perform the following steps to enable strict disjointness for ODN SR-TE policies:

```
Router(config)#segment-routing traffic-eng
Router(config-sr-te)#on-demand color 4
Router(config-sr-te-color)#dynamic
Router(config-sr-te-color-dyn)#disjoint-path group-id 1 type node fallback disable
Router(config-sr-te-color-dyn)#commit
```

Running Configuration

```
segment-routing
 traffic-eng
   on-demand color 4
   dynamic
     disjoint-path group-id 1 type node fallback disable
   !
 !
 !
 !
```

Enable strict disjointness for SR-TE policies

Perform the following steps to enable strict disjointness for SR-TE policies:

```
Router(config)#segment-routing traffic-eng
Router(config-sr-te)#policy foo
Router(config-sr-te-policy)#color 1 end-point ipv4 10.10.10.1
Router(config-sr-te-policy)#candidate-paths preference 100
Router(config-sr-te-policy-path-pref)#constraints disjoint-path group-id 1 type node fallback
  disable
Router(config-sr-te-policy-path-pref)#commit
```

Running Configuration

```
segment-routing
 traffic-eng
   policy foo
     color 1 end-point ipv4 10.10.10.1
     candidate-paths
       preference 100

ACL Support for PCEP Connection

PCE protocol (PCEP) (RFC5440) is a client-server model running over TCP/IP, where the server (PCE) opens a port and the clients (PCC) initiate connections. After the peers establish a TCP connection, they create a PCE session on top of it.

The ACL Support for PCEP Connection feature provides a way to protect a PCE server using an Access Control List (ACL) to restrict IPv4 PCC peers at the time the TCP connection is created based on the source address of a client. When a client initiates the TCP connection, the ACL is referenced, and the client source address is compared. The ACL can either permit or deny the address and the TCP connection will proceed or not.

Refer to the Implementing Access Lists and Prefix Lists chapter in the *IP Addresses and Services Configuration Guide for Cisco NCS 5500 Series Routers* for detailed ACL configuration information.

To apply an ACL to the PCE, use the **pce peer-filter ipv4 access-list *acl_name*** command.

The following example shows how to configure an ACL and apply it to the PCE:

```

pce
 address ipv4 10.1.1.5
 peer-filter ipv4 access-list sample-peer-filter
!
ipv4 access-list sample-peer-filter
 10 permit ipv4 host 10.1.1.6 any
 20 permit ipv4 host 10.1.1.7 any
 30 deny ipv4 any any
!

```

Anycast SID-Aware Path Computation

This feature allows the SR-TE head-end or SR-PCE to compute a path that is encoded using Anycast prefix SIDs of nodes along the path.

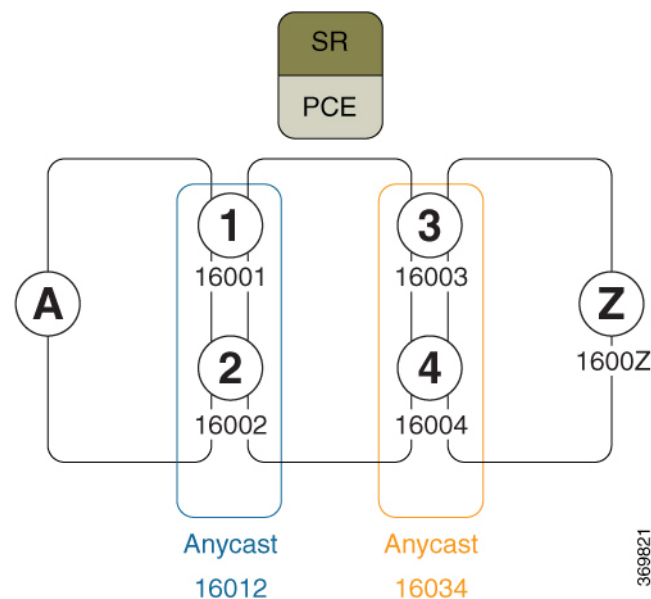

An Anycast SID is a type of prefix SID that identifies a set of nodes and is configured with n-flag clear. The set of nodes (Anycast group) is configured to advertise a shared prefix address and prefix SID. Anycast routing enables the steering of traffic toward multiple advertising nodes, providing load-balancing and redundancy. Packets addressed to an Anycast address are forwarded to the topologically nearest nodes.

Note For information on configuring Anycast SID, see [Configuring a Prefix-SID on the IS-IS Enabled Loopback Interface, on page 286](#) and [Configuring a Prefix-SID on the OSPF-Enabled Loopback Interface, on page 316](#).

This example shows how Anycast SIDs are inserted into a computed SID list.

The following figure shows 3 isolated IGP domains without redistribution and without BGP 3107. Each Area Border Router (ABR) 1 through 4 is configured with a node SID. ABRs 1 and 2 share Anycast SID 16012 and ABRs 3 and 4 share Anycast SID 16034.

Consider the case where nodes A and Z are provider edge (PE) routers in the same VPN. Node A receives a VPN route with BGP next-hop to node Z. Node A resolves the SR path to node Z based on ODN behaviors with delegation of path computation to SR-PCE.

Before considering Anycast SIDs, the head-end router or SR-PCE computes the SID list.

Assume that the computed path from node A to node Z traverses node 2 and node 4. This translates to SID list {16002, 16004, 1600Z} when node SIDs are leveraged to encode the path.

When an Anycast SID-aware path is requested, the path computation algorithm performs the following:

- **Path Computation**—Computes the path according to optimization objectives and constraints
- **Path Encoding**—Encodes the path in a SID list leveraging node-SIDs and adj-SIDs as applicable
- **Anycast SID Replacement**—Reiterates the original SID list by replacing node SIDs with Anycast SIDs present on the nodes along the computed path.

If a node has multiple Anycast SIDs, the algorithm considers them according to their weights. See [Weighted Anycast SIDs](#), on page 668.

- **Optimality Validation**—The new paths are validated against the original optimization objectives and constraints (maintain same cumulative metric as original SID list and do not violate path constraints).
- **Anycast SID Promotion**—If the optimality validation is successful, then the Anycast-encoded SID list is signaled and instantiated in the forwarding.

The following figure depicts cumulative metrics between nodes in the network.

Under these conditions, the optimality check is met, and therefore, the Anycast-encoded SID list from node A to node Z is {16012,16034,1600Z}.

The Anycast SID aware path computation also provides resiliency. For example, if one of the ABRs (in this case, ABR 1) becomes unavailable or unreachable, the path from node A to node Z {16012,16034,1600Z} will still be valid and usable.

Configuration Examples

1. Configure Prefix SIDs on the ABR nodes.
 - a. Configure each node with a node SID.
 - b. Configure each group of nodes with a shared Anycast SID.

See [Configuring a Prefix-SID on the IS-IS Enabled Loopback Interface, on page 286](#) and [Configuring a Prefix-SID on the OSPF-Enabled Loopback Interface, on page 316](#).

2. Configure SR policies to include Anycast SIDs for path computation using the **anycast-sid-inclusion** command.

This example shows how to configure a local SR policy to include Anycast SIDs for PCC-initiated path computation at the head-end router:

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# policy FOO
Router(config-sr-te-policy)# color 10 end-point ipv4 10.1.1.10
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 100
Router(config-sr-te-policy-path-pref)# dynamic
Router(config-sr-te-pp-info)# anycast-sid-inclusion
```

Running Configuration

Use the **anycast-sid-inclusion** command to request Anycast SID-aware path computation for the following SR policy types:

- Local SR policy with PCC-initiated path computation at the head-end router:

```
segment-routing
 traffic-eng
  policy FOO
    color 10 end-point ipv4 10.1.1.10
    candidate-paths
      preference 100
      dynamic
    anycast-sid-inclusion
```

- Local SR policy with PCC-initiated/PCE-delegated path computation at the SR-PCE:

```
segment-routing
traffic-eng
policy BAR
color 20 end-point ipv4 10.1.1.20
candidate-paths
preference 100
dynamic
pcep
anycast-sid-inclusion
```

- On-demand SR policies with a locally computed dynamic path at the head-end, or centrally computed dynamic path at the SR-PCE:

```
segment-routing
traffic-eng
on-demand color 10
dynamic
anycast-sid-inclusion
```

- On-demand SR policies with centrally computed dynamic path at the SR-PCE:

```
segment-routing
traffic-eng
on-demand color 20
dynamic
pcep
anycast-sid-inclusion
```

Weighted Anycast SIDs

Table 115: Feature History Table

Feature Name	Release Information	Feature Description
Weighted Anycast SID-Aware Path Computation	Release 7.3.1	<p>This feature extends Anycast SIDs with weighted nodes.</p> <p>Weighted Anycast nodes advertise a cost (weight) along with the Anycast SID. Traffic is then distributed according to the weights.</p> <p>Weighted Anycast SIDs allow for highly available paths with node redundancy and path optimality that provide Fast Re-Route (FRR) for node failure of service provider edge (PE) routers and ABR/ASBRs nodes in multi-domain networks.</p>

Weighted Anycast nodes advertise a cost along with the Anycast SID. This cost serves as a weight. The native SR path computation algorithms are augmented to compute optimum paths relying on Weighted Anycast SIDs during path encoding. Traffic to the SID is then distributed according to the weights.

The following example shows how node SID, Anycast SID, and Weighted Anycast SID are applied on node 1:

```

router isis 1
 interface Loopback0
  address-family ipv4 unicast
   prefix-sid absolute 16001 // Node SID
  !
 !
 interface Loopback1
  prefix-attributes anycast
  address-family ipv4 unicast
   prefix-sid absolute 16012 // Anycast SID - (prefer node 1 or 2)
  !
 !
 interface Loopback2
  prefix-attributes anycast
  address-family ipv4 unicast
   weight 1
   prefix-sid absolute 17012 // Weighted Anycast SID (prefer node 1)
  !
 !
 interface Loopback3
  prefix-attributes anycast
  address-family ipv4 unicast
   weight 100000
   prefix-sid absolute 18012 // Weighted Anycast SID (prefer node 2)
  !
 !
 !

```

SR-PCE IPv4 Unnumbered Interface Support

This feature allows IPv4 unnumbered interfaces to be part of an SR-PCE topology database.

An unnumbered IPv4 interface is not identified by its own unique IPv4 address. Instead, it is identified by the router ID of the node where this interfaces resides and the local SNMP index assigned for this interface.

This feature provides enhancements to the following components:

- IGP (IS-IS and OSPF):
 - Support the IPv4 unnumbered interfaces in the SR-TE context by flooding the necessary interface information in the topology
- SR-PCE:

Note

SR-PCE and path computation clients (PCCs) need to be running Cisco IOS XR 7.0.2 or later.

- Compute and return paths from a topology containing IPv4 unnumbered interfaces.
 - Process reported SR policies from a head-end router that contain hops with IPv4 unnumbered adjacencies.
- PCEP extensions for IPv4 unnumbered interfaces adhere to IETF RFC8664 “PCEP Extensions for Segment Routing” (<https://datatracker.ietf.org/doc/rfc8664/>). The unnumbered hops use a Node or

Adjacency Identifier (NAI) of type 5. This indicates that the segment in the explicit routing object (ERO) is an unnumbered adjacency with an IPv4 ID and an interface index.

- SR-TE process at the head-end router:
 - Compute its own local path over a topology, including unnumbered interfaces.
 - Process PCE-computed paths that contain hops with IPv4 unnumbered interfaces.
 - Report a path that contains hops with IPv4 unnumbered interfaces to the PCE.

Configuration Example

The following example shows how to configure an IPv4 unnumbered interface:

```
RP/0/0/CPU0:rtrA(config)# interface GigabitEthernet0/0/0/0
RP/0/0/CPU0:rtrA(config-if)# ipv4 point-to-point
RP/0/0/CPU0:rtrA(config-if)# ipv4 unnumbered Loopback0
```

To bring up the IPv4 unnumbered adjacency under the IGP, configure the link as point-to-point under the IGP configuration. The following example shows how to configure the link as point-to-point under the IGP configuration:

```
RP/0/0/CPU0:rtrA(config)# router ospf one
RP/0/0/CPU0:rtrA(config-ospf)# area 0
RP/0/0/CPU0:rtrA(config-ospf-ar)# interface GigabitEthernet0/0/0/0
RP/0/0/CPU0:rtrA(config-ospf-ar-if)# network point-to-point
```

Verification

Use the **show ipv4 interface** command to display information about the interface:

```
RP/0/0/CPU0:rtrA# show ipv4 interface GigabitEthernet0/0/0/0 brief
Tue Apr  2 12:59:53.140 EDT
Interface                               IP-Address      Status          Protocol
GigabitEthernet0/0/0/0                 192.168.0.1     Up              Up
```

This interface shows the IPv4 address of Loopback0.

Use the **show snmp interface** command to find the SNMP index for this interface:

```
RP/0/0/CPU0:rtrA# show snmp interface
Tue Apr  2 13:02:49.190 EDT
ifName : Null0                ifIndex : 3
ifName : Loopback0            ifIndex : 10
ifName : GigabitEthernet0/0/0/0 ifIndex : 6
```

The interface is identified with the pair (IPv4:192.168.0.1, index:6).

Use the **show ospf neighbor** command to display the adjacency:

```
RP/0/0/CPU0:rtrA# show ospf neighbor gigabitEthernet 0/0/0/0 detail
...
Neighbor 192.168.0.4, interface address 192.168.0.4
  In the area 0 via interface GigabitEthernet0/0/0/0
  Neighbor priority is 1, State is FULL, 6 state changes
...
Adjacency SIDs:
  Label: 24001,      Dynamic, Unprotected
```

Neighbor Interface ID: 4

The output of the **show pce ipv4 topology** command is enhanced to display the interface index instead of the IP address for unnumbered interfaces:

```
RP/0/0/CPU0:sr-pce# show pce ipv4 topology
...
Link[2]: unnumbered local index 6, remote index 4
Local node:
  OSPF router ID: 192.168.0.1 area ID: 0 ASN: 0
Remote node:
  TE router ID: 192.168.0.4
  OSPF router ID: 192.168.0.4 area ID: 0 ASN: 0
Metric: IGP 1, TE 1, Latency 1 microseconds
Bandwidth: Total 125000000 Bps, Reservable 0 Bps
Admin-groups: 0x00000000
Adj SID: 24001 (unprotected)
```

The output of **show pce lsp detail** command includes unnumbered hops:

```
RP/0/0/CPU0:sr-pce# show pce lsp detail
...
Reported path:
Metric type: TE, Accumulated Metric 3
SID[0]: Adj unnumbered, Label 24001, local 192.168.0.1(6), remote 192.168.0.4(4)
SID[1]: Adj unnumbered, Label 24002, local 192.168.0.4(7), remote 192.168.0.3(7)
SID[2]: Adj unnumbered, Label 24000, local 192.168.0.3(5), remote 192.168.0.2(5)
Computed path: (Local PCE)
Computed Time: Wed Apr 03 11:01:46 EDT 2019 (00:01:06 ago)
Metric type: TE, Accumulated Metric 3
SID[0]: Adj unnumbered, Label 24001, local 192.168.0.1(6), remote 192.168.0.4(4)
SID[1]: Adj unnumbered, Label 24002, local 192.168.0.4(7), remote 192.168.0.3(7)
SID[2]: Adj unnumbered, Label 24000, local 192.168.0.3(5), remote 192.168.0.2(5)
```

Inter-Domain Path Computation Using Redistributed SID

Table 116: Feature History Table

Feature Name	Release Information	Feature Description
SR-PCE: Inter-Domain Computation using Redistributed SID (SRTE - BGP-LU Domains Interworking)	Release 7.3.1	This feature is now supported on routers that have the Cisco NC57 line cards installed and operate in the native and compatible modes. To enable the native mode, use the hw-module profile npu native-mode-enable command in the configuration mode. Ensure that you reload the router after configuring the native mode.

A Path Computation Element (PCE) computes SR-TE paths based on SR topology database that stores connectivity, state, and TE attributes of SR network nodes and links. BGP Labeled Unicast (BGP-LU) provides

MPLS transport across IGP boundaries by advertising loopbacks and label binding of impact edge and border routers across IGP boundaries.

This feature adds new functionality to the SR-PCE that enables it to compute a path for remote non-SR end-point device distributed by BGP-LU.

The remote end-point device in the BGP-LU domain is unknown to the SR-PCE. For the SR-PCE to know about the end-point device, the gateway ABR/ASBR learns the end-point prefix via BGP-LU. The prefix is then redistributed to SR-PCE topology database from the gateway ABR/ASBR. SR-PCE then can compute the best path from the head-end device to the selected gateway router.

The following topology shows an SR domain and a BGP-LU domain, with a gateway ABR/ASBR between the two domains.

1. The gateway ABR/ASBR is configured with BGP/IGP helper to learn the remote prefix through BGP-LU and redistribute the remote prefix to the IGP helper, then to SR-PCE.
2. The SR-PCE selects the best gateway node to BGP-LU domain and computes the path to reach the remote prefix through the gateway node.
3. The head-end device in the SR domain requests a path to the remote destination and signals the SR profile interworking with the BGP-LU domain.

The BGP-LU prefix advertisement to SR-PCE Traffic Engineer Database (TED) is done by creating an IGP helper on the ABR/ASBR to redistribute BGP-LU prefix information to IGP. IGP then sends the prefix information to the SR-PCE via BGP-LS.

If there are multiple ABR/ASBRs advertising the same remote BGP-LU prefix, the SR-PCE selects the best gateway node to the BGP-LU domain using the accumulative metric from the head-end device to the gateway and the advertised metric from the gateway to the destination.

Example: Inter-Domain Path Computation Using Redistributed SID

The following examples show the configurations for the IGP helper, BGP-LU, and proxy BGP-SR:

Configuration on the End-Point Device

Configure the end-point device to allocate a label for the BGP-LU prefix on the end-point device:

```
router bgp 3107
  bgp router-id 1.0.0.8
  address-family ipv4 unicast
    network 1.0.0.8/32 route-policy bgplu-com
    allocate-label all

route-policy bgplu-com
  set community (65002:999)
end-policy
```

Configuration on the Gateway ABR/ASBR

1. Configure the remote prefix set and create the route policy for the BGP-LU domain:

```
prefix-set bgplu
  1.0.0.7/32,
  1.0.0.8/32,
  1.0.0.101/32,
  1.0.0.102/32
end-set
!

route-policy bgp2isis
  if destination in bgplu then
    pass
  else
    drop
  endif
```

```
end-policy
!
end
```

2. Configure the helper IGP instance on the Loopback interface:

```
router isis 101
 is-type level-2-only
 net 49.0001.0000.1010.1010.00
 distribute link-state instance-id 9999
 nsf cisco
 nsf lifetime 120
 address-family ipv4 unicast
 metric-style wide
 maximum-paths 64
 router-id Loopback10
 redistribute bgp 3107 metric 200 route-policy bgp2isis
 segment-routing mpls sr-prefer
!
interface Loopback10 >>> this loopback is for gateway SR-TE node-id
 passive
 address-family ipv4 unicast
 prefix-sid index 2001 explicit-null
```

3. Configure the gateway proxy BGP-SR and SR Mapping Server to allocate SR labels:

```
router bgp 3107
 address-family ipv4 unicast
 segment-routing prefix-sid-map
 allocate-label all

segment-routing
global-block 16000 23999
mapping-server
 prefix-sid-map
 address-family ipv4
 1.0.0.7/32 2007
 1.0.0.8/32 2008
 1.0.0.101/32 2101
 1.0.0.102/32 2102
```

PCE Support for MPLS-TE LSPs

This feature allows Cisco's SR-PCE to act as a Path Computation Element (PCE) for MPLS Traffic Engineering Label Switched Paths (MPLS-TE LSPs).

Note For more information about MPLS-TE, refer to the "Implementing MPLS Traffic Engineering" chapter in the *MPLS Configuration Guide for Cisco NCS 5500 Series Routers*.

The supported functionality is summarized below:

- PCE type: Active Stateful PCE
- MPLS-TE LSP initiation methods:
 - PCE Initiated—An active stateful PCE initiates an LSP and maintains the responsibility of updating the LSP.

- PCC Initiated—A PCC initiates the LSP and may delegate the control later to the Active stateful PCE.
- MPLS-TE LSP metric—Metric optimized by the path computation algorithm:
 - IGP metric
 - TE metric
 - Latency metric
- MPLS-TE LSP constraints—TE LSP attributes to be taken into account by the PCE during path computation:
 - Resource Affinities
 - Path Disjointness
- MPLS-TE LSP parameters:
 - Setup priority—The priority of the TE LSP with respect to taking resources
 - Hold priority—The priority of the TE LSP with respect to holding resources
 - FRR L flag—The "Local Protection Desired" bit. Can be set from an application instantiating an MPLS-TE LSP via SR-PCE. SR-PCE passes this flag to the PCC, and the PCC will enable FRR for that LSP.
 - Signaled Bandwidth—This value can be set from an application instantiating an MPLS-TE LSP via SR-PCE. SR-PCE passes this value to the PCC.
 - Binding SID—A segment identifier (SID) that a headend binds to an MPLS-TE LSP. When the headend receives a packet with active segment (top MPLS label) matching the BSID of a local MPLS-TE LSP, the headend steers the packet into the associated MPLS-TE LSP.

Cisco Crosswork Optimization Engine is an application that leverages the SR-PCE in order to visualize and instantiate MPLS-TE LSPs. For more information, refer to the [Visualize SR Policies and RSVP-TE Tunnels](#) chapter in the [Cisco Crosswork Optimization Engine 1.2.1 User Guide](#).

Note No extra configuration is required to enable MPLS-TE support at SR-PCE.

Example: Configuring a PCEP Session (Stateful Mode) on MPLS-TE PCC

The following example shows the configuration for an MPLS-TE PCC to establish a PCEP session with a PCE (IPv4 address 10.1.1.100).

Note MPLS-TE PCC must operate in the stateful PCEP mode when connecting to SR-PCE.

The **instantiation** keyword enables the PCC to support MPLS-TE LSP instantiation by PCE (PCE-initiated).

The **report** keyword enables the PCC to report all the MPLS-TE LSPs configured on that node.

Note PCE-initiated LSPs are automatically reported to all configured PCEs.

The **autoroute-announce** keyword enables autoroute-announce globally for all PCE-initiated LSPs on the PCC.

The **redundancy pcc-centric** keywords enable PCC-centric high-availability model for PCE-initiated LSPs. The PCC-centric model changes the default PCC delegation behavior to the following:

- After LSP creation, LSP is automatically delegated to the PCE that computed it.
- If this PCE is disconnected, then the LSP is redelegated to another PCE.
- If the original PCE is reconnected, then the delegation fallback timer is started. When the timer expires, the LSP is redelegated back to the original PCE, even if it has worse preference than the current PCE.

```
mpls traffic-eng
pce
  peer ipv4 10.1.1.100
  !
  stateful-client
  instantiation
  report
  autoroute-announce
  redundancy pcc-centric
  !
  !
end
```

Example: Configuring Multiple PCEP Sessions from a PCC Acting as MPLS-TE and SR-TE Headend Toward a Common PCE

The following example shows the configuration for a PCC (IPv4 addresses 10.1.1.1 and 10.1.1.2) to establish two PCEP sessions with a common PCE (IPv4 address 10.1.1.100). One session is configured under MPLS-TE, and the other under SR-TE.

Note The two PCEP sessions must use a different source address on the PCC when connecting to the same PCE.

For more information regarding PCEP configuration at SR-TE PCC, see the *Configure the Head-End Router as PCEP PCC* topic.

```
mpls traffic-eng
pce
  peer source ipv4 10.1.1.1
  peer ipv4 10.1.1.100
  !
  !
end

segment-routing
traffic-eng
```

```
pcc
 source-address ipv4 10.1.1.2
 pce address ipv4 10.1.1.100
 !
 !
 !
end
```

Configuring the North-Bound API on SR-PCE

Table 117: Feature History Table

Table 118: Feature History Table

Feature Name	Release Information	Feature Description
SR-PCE: Stateful North-Bound API for Tree-SID	Release 7.5.1	<p>The SR-PCE provides a north-bound HTTP-based API to allow communication between the SR-PCE and the Cisco Crosswork Optimization Engine.</p> <p>This release adds stateful north-bound APIs to support real-time monitoring of Tree-SID states on the SR-PCE using a subscription model.</p> <p>For more information, refer to the Cisco Crosswork Optimization Engine User Guides.</p>

Table 119: Feature History Table

Feature Name	Release Information	Feature Description
SR-PCE: North-Bound API for SRv6 and Flexible Algorithm in Cisco Optimization Engine (COE) v3.0 release	Release 7.3.2	<p>The SR-PCE provides a north-bound HTTP-based API to allow communication between the SR-PCE and the Cisco Crosswork Optimization Engine.</p> <p>This release adds support for the following:</p> <ul style="list-style-type: none"> • Reporting of Flexible Algorithm participation and definitions • SRv6 topology information (nodes, links, Node uSIDs and Adj uSIDs) • SRv6 uSID list and uB6 SIDs allocated for a policy <p>For more information, refer to the Cisco Crosswork Optimization Engine User Guides.</p>
SR-PCE: North-Bound API Enhancements for Cisco Optimization Engine (COE) v1.0 release	Release 7.3.1	<p>This feature is now supported on routers that have the Cisco NC57 line cards installed and operate in the native and compatible modes. To enable the native mode, use the hw-module profile npu native-mode-enable command in the configuration mode. Ensure that you reload the router after configuring the native mode.</p>

The SR-PCE provides a north-bound HTTP-based API to allow communication between SR-PCE and external clients and applications.

Over this API, an external application can leverage the SR-PCE for topology discovery, SR policy discovery, and SR policy instantiation.

The Cisco Crosswork Optimization Engine is an application that leverages the SR-PCE. For more information, refer to the [Cisco Crosswork Optimization Engine User Guides](#).

Use the following commands under PCE configuration mode to configure the API to allow communication between SR-PCE and external clients or applications.

Note The API server is enabled by default when SR-PCE is configured.

Command	Description
rest authentication basic	(Optional) Specify basic (plaintext) authentication. By default, authentication is disabled.
rest username <i>password</i> { clear encrypted } <i>password</i>	Add credentials when connecting to API. Note This command is used only if authentication is configured.
rest sibling ipv4 <i>address</i>	Opens a synchronization channel to another PCE in the same high availability (HA) pair. Note For more information regarding SR-PCE HA pairs, refer to the Multiple Cisco SR-PCE HA Pairs chapter of the Cisco Crosswork Optimization Engine 1.2.1 User Guide .

Command	Description
api authentication { basic digest }	Specify the type of authentication: <ul style="list-style-type: none"> • basic – Use HTTP Basic authentication (plaintext) • digest – Use HTTP Digest authentication (MD5)
api username <i>password</i> { clear encrypted } <i>password</i>	Add credentials when connecting to API.
api sibling ipv4 <i>address</i>	Opens a synchronization channel to another PCE in the same high availability (HA) pair. Note For more information regarding SR-PCE HA pairs, refer to the Multiple Cisco SR-PCE HA Pairs chapter of the Cisco Crosswork Optimization Engine 1.2.1 User Guide .

Example: Configuring API on SR-PCE

```

pce
 address ipv4 10.1.1.100
 rest
  user admin
  password encrypted 1304131F0202
  !
  authentication basic
  sibling ipv4 10.1.1.200
  !
!
end

```

```

pce
address ipv4 10.1.1.100
api
user admin
password encrypted 1304131F0202
!
authentication digest
sibling ipv4 10.1.1.200
!
!
end

```

The following example shows the current active connections:

```

RP/0/0/CPU0:pce1# show tcp brief | i 8080
Thu Aug  6 00:40:15.408 PDT
0xe9806fb8 0x60000000      0      0  :::8080                :::0                LISTEN
0xe94023b8 0x60000000      0      0  10.1.1.100:50487       10.1.1.200:8080     ESTAB
0xeb20bb40 0x60000000      0      0  10.1.1.100:8080        10.1.1.200:44401    ESTAB
0xe98031a0 0x60000000      0      0  0.0.0.0:8080           0.0.0.0:0           LISTEN

```

The first and fourth entries show the API server listening for IPv4 and IPv6 connections.

The second and third entries show the established sibling connection between PCE1 (10.1.1.100) and PCE2 (10.1.1.200).

CHAPTER 15

Configure Performance Measurement

Network performance metrics is a critical measure for traffic engineering (TE) in service provider networks. Network performance metrics include the following:

- Packet loss
- Delay
- Delay variation
- Bandwidth utilization

These network performance metrics provide network operators information about the performance characteristics of their networks for performance evaluation and help to ensure compliance with service level agreements. The service-level agreements (SLAs) of service providers depend on the ability to measure and monitor these network performance metrics. Network operators can use Segment Routing Performance Measurement (SR-PM) feature to monitor the network metrics for links and end-to-end TE label switched paths (LSPs).

The following table explains the functionalities supported by performance measurement feature for measuring delay for links or SR policies.

Table 120: Performance Measurement Functionalities

Functionality	Details
Profiles	You can configure different default profiles for different types of delay measurements. Use the "interfaces" delay profile type for link-delay measurement. The "sr-policy" delay profile type is used for SR policy delay measurements. Delay profile allows you to schedule probe and configure metric advertisement parameters for delay measurement.
Protocols	Two-Way Active Measurement Protocol (TWAMP) Light (using RFC 5357 with IP/UDP encap). The TWAMP Light from Appendix of RFC 5357 is standardized as Simple TWAMP in RFC 8762. Then it was extended with RFC 8972.
Probe and burst scheduling	Schedule probes and configure metric advertisement parameters for delay measurement.
Metric advertisements	Advertise measured metrics periodically using configured thresholds. Also supports accelerated advertisements using configured thresholds.

Functionality	Details
Measurement history and counters	Maintain packet delay and loss measurement history, session counters, and packet advertisement counters.

- [Usage Guidelines and Limitations, on page 682](#)
- [Liveness Monitoring, on page 683](#)
- [Delay Measurement, on page 711](#)
- [Path Tracing in SRv6 Network, on page 756](#)
- [Two-Way Active Measurement Protocol Light Source Address Filtering, on page 761](#)
- [Synthetic Loss Measurement, on page 765](#)
- [Delay and synthetic loss measurement for GRE tunnel interfaces, on page 771](#)
- [Delay Measurement Using Software Timestamp, on page 775](#)

Usage Guidelines and Limitations

The following usage guidelines and limitations apply:

- SR Performance Measurement is not supported on NCS5500 router in compatibility mode.
- SRv6 PM is not supported on routers that uses channelized ports.
- SR Performance Measurement is supported on hardware that supports Precision Time Protocol (PTP). This requirement applies to both one-way and two-way delay measurement.

See the [Configuring Precision Time Protocol](#) chapter in the *System Management Configuration Guide for Cisco NCS 5500 Series Routers* for Restrictions for PTP and the Timing Hardware Support Matrix.
- If the interface has two VLAN tags, such as QinQ, physical link delay with an IPv6 address is not supported.
- Performance Measurement (PM) probes typically follow the designated Segment Routing Traffic Engineering (SR-TE) path. However, in certain scenarios, the convergence of the PM probes and the SR-TE path may occur at different times. During this convergence period, PM probes may temporarily follow the IGP path and utilize an alternate egress interface until full convergence is achieved.
- In scenarios where you have
 - NCS 5500 modular routers (NCS 5500 line cards;NCS 5700 line cards [Mode: Compatibility]),
 - NCS 5700 fixed port routers or,
 - NCS 5500 modular routers with NCS 5700 line cards, and all the NCS 5700 line cards are reloaded at the same time.

Performance Measurement (PM) displays these syslog messages requesting you to restart the PM process.

```
Router: IST: perf_meas[1001]: %ROUTING-PERF_MEAS-6-PM_SYSTEM_INFO : System configuration
has changed. PM process restart on all locations recommended in order to enable PM
features.
Router: IST: perf_meas[1001]: %ROUTING-PERF_MEAS-2-PM_SYSTEM_INCONSISTENT : New PM
sessions cannot be created, existing sessions inconsistent. PM process restart on all
locations recommended.
Router: IST: perf_meas[1001]: %ROUTING-PERF_MEAS-2-PM_SYSTEM_INCONSISTENT : Unable to
create new SR policy session.
```

You must restart the PM process on all nodes using the **process restart perf_meas location all** command. This is necessary because the routers need to restart the PM process to initiate a new Segment Routing (SR) policy session.

Liveness Monitoring

Table 121: Feature History Table

Feature Name	Release	Description
Performance Measurement with Class-C mode on NC57-36H6D-S Line Cards	Release 24.4.1	<p>Introduced in this release on: NCS 5700 fixed port routers (NCS 5700 line cards [Mode: Native])</p> <p>The NC57-36H6D-S line card now supports Performance Measurement with Class-C mode of PTP, providing enhanced accuracy and a higher level of frequency precision. It also ensures that TWAMP functionality works seamlessly with Class-C mode.</p> <p>Note that from Release 7.6.1, the Cisco NCS 5700 routers support Performance Measurement in the default Class-B mode.</p>
Cisco NC57 Native Mode: SR Performance Measurement	Release 7.6.1	<p>The following features are now supported on Cisco Network Convergence System 5700 Series routers and routers with the Cisco NC57 line cards operating in native mode:</p> <ul style="list-style-type: none"> • Link Delay Measurement • Named Profiles • Static Delay Value on an Interface • IP Endpoint Delay Measurement and Liveness Monitoring • SR Policy End-to-End Delay Measurement • SR Policy Liveness Monitoring

Liveness refers to the ability of the network to confirm that a specific path, segment, or a node is operational and capable of forwarding packets. Liveness checks are essential for maintaining network availability and reliability. See *Configure PTP in System Management Configuration Guide* for more information on configuring PTP.

Benefits

- **Fault Detection:** You can quickly identify if a device is down, which allows for immediate response and troubleshooting.
- **Load Balancing:** You can identify if the devices in a network are live, so work can be distributed more evenly across the network, preventing overloading of specific components and improving overall performance.
- **System Health:** You can provide an ongoing snapshot of a system's health, helping to identify potential issues before they become significant problems.
- **Maintenance Planning:** Liveness information can also help with maintenance planning, as system administrators can understand which components are live or down and plan maintenance and downtime accordingly without significant disruption to services.
- **Security:** Regular liveness checks can also play a role in maintaining network security. Administrators can take proactive steps to mitigate the damage and prevent future incidents by identifying unusual activity that might indicate a security breach or attack.

You can determine liveness for SR Policy and IP Endpoint.

IP Endpoint Liveness Monitoring

Table 122: Feature History Table

Feature Name	Release Information	Feature Description
Liveness Monitoring for IP Endpoint over SRv6 Network on Cisco NCS 5508 and Cisco NCS 5700 Series Routers	Release 24.3.1	Introduced in this release on: NCS 5500 modular routers, NCS 5700 fixed port routers, NCS 5700 line cards [Mode: Native] . Liveness Monitoring for IP Endpoint over SRv6 Network is now supported on the NCS 5500 modular routers and NCS 5700 line cards in the Native mode.

Feature Name	Release Information	Feature Description
Liveness Monitoring for IP Endpoint over SRv6 Network	Release 24.2.1	<p>Introduced in the release on: NCS 5500 fixed port routers.</p> <p>In Segment Routing over an IPv6 network (SRv6), you can keep track of the operational status of both the forward and reverse paths of a particular node or IP endpoint. You can use this information for troubleshooting, network maintenance, and optimizing network performance.</p> <p>Additionally, you can use flow labels to verify the liveness of each subsequent hop path toward the IP endpoint of that path. So that, when network traffic is distributed across multiple available paths towards an IP endpoint, liveness detection tracks the operational status of each of these paths towards the IP endpoint.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> • The reverse-path and segment-list name keywords are introduced in the segment-routing traffic-eng explicit command. • The source-address ipv6 is introduced in the performance-measurement endpoint command. <p>YANG Data Model:</p> <ul style="list-style-type: none"> • <code>Cisco-IOS-XR-um-performance-measurement-cfg</code> • <code>Cisco-IOS-XR-perf-meas-oper.yang</code> <p>(see GitHub, YANG Data Models Navigator)</p>
IP Endpoint Delay Measurement and Liveness Monitoring	Release 7.4.1 Release 7.3.2	<p>This feature measures the end-to-end delay and monitors liveness of a specified IP endpoint node, including VRF-aware (awareness of multiple customers belonging to different VRFs).</p> <p>This feature is supported on IPv4, IPv6, and MPLS data planes.</p>

Note From Cisco IOS XR Release 7.6.1 onwards, this feature is supported on Cisco Network Convergence System 5700 Series routers and routers with the Cisco NC57 line cards operating in native mode.

The Segment Routing Performance Measurement (SR-PM) for IP endpoint liveness is a type of node liveness that involves testing whether an IP endpoint or a device identified by an IP address is available to send and receive data.

IP endpoint liveness is verified by sending a request to the IP address of the endpoint and waiting for a response. The probe could be an ICMP echo request (Ping), a TCP packet, a UDP packet, or any other type of packet that the endpoint would respond to.

- If a response is received, the endpoint is considered *live*.

- If no response is received within a certain time frame, the endpoint is considered *down* or *unreachable*.

IP endpoint dynamically measures the liveness towards a specified IP endpoint. IP endpoints can be located in a default or nondefault VRFs. IP endpoint is any device in the network a device identified by an IP address.

Liveness of an IP endpoint is verified by sending a request to the IP address of the endpoint and waiting for a response, which is referred to as a probe.

The endpoint of a probe is defined by an IP address, which can be either IPv4 or IPv6. This IP address can be any address that the sender can reach, such as a local interface or a remote node or host, either within an operator's network or accessible via a VRF.

The endpoint of a probe can be any IP address reachable by the sender. For example, a local interface or a remote node or host located within an operator's network or reachable through a VRF.

The IP address of the endpoint can be reached through an IP path, MPLS, LSP SRV6, or IP tunnel (GRE).

- When the endpoint is reachable using an MPLS LSP (for example, SR, LDP, RSVP-TE, SR Policy), the forwarding stage imposes the corresponding MPLS transport labels.
- When the endpoint is reachable via a GRE tunnel, the forwarding stage imposes the corresponding GRE header.
- When the endpoint is reachable via a VRF in an MPLS network, the forwarding stage imposes the corresponding MPLS service labels. In the forward path, the sender node uses the configured VRF for the endpoint address. In the return path, the reflector node derives the VRF based on which incoming VRF label the probe packet is received with.
- When the endpoint is reachable using SRv6, the forwarding stage imposes the SRv6 encapsulation.

You can configure the following parameters in the **performance-measurement** command:

- **Endpoint:** The endpoint of a probe is defined by an IP address, which can be either IPv4 or IPv6. This IP address can be any address that the sender can reach, such as a local interface or a remote node or host, either within an operator's network or accessible via a VRF.

The endpoint of a probe can be any IP address reachable by the sender. For example, a local interface or a remote node or host located within an operator's network or reachable through a VRF.

Use the **performance-measurement endpoint** command to configure a probe endpoint source and destination addresses on a sender node.

- **VRF:** You can define the endpoint point IP address belonging to a specific VRF. Use the **performance-measurement endpoint {ipv4 | ipv6} ip_addr [vrf WORD]** command to configure an endpoint to define the VRF. Endpoint segment list configuration is not supported under nondefault VRF.
 - VRF-awareness allows operators to deploy probes in the following scenarios:
 - Managed Customer Equipment (CE) scenarios:
 - PE to CE probes
 - CE to CE probes
 - Unmanaged Customer Equipment (CE) scenarios:
 - PE to PE probes
 - PE to PE (source from PE-CE interface) probes

- **Source address:** You can define the source of the endpoint using the endpoint specific source address and the global source address.

Global source address configuration is applied to all the endpoints when the endpoint specific source address configuration isn't specified. endpoint specific configuration overrides all the global source address configuration for those specific endpoints for which source addresses are configured.

For Micro-SID configuration for IPv4 endpoint sessions, if IPv6 global source address is configured, then it applies the configured global IPv6 source address for the IPv6 header in the SRv6 packet. If IPv6 global address is not configured, then It does not form a valid SRv6 packet.

You can use the **source-address** keyword under the **performance-measurement** command to define the global source address or use the keyword under **performance-measurement endpoint** to define endpoint specific source address.

- **Reverse Path:** To detect the liveness of the reverse of the segment, you can configure the reverse path using the **reverse-path** command.

The default reverse path configured under the endpoint submode is only used for sessions with segment list. The endpoint session without a segment list does not support reverse path configuration and will not use this reverse path.

The **reverse-path** under the **performance-measurement endpoint** is used as the default reverse path if there are no reverse paths configured under the segment list.

Use the **reverse-path** under the **performance-measurement endpoint segment-routing traffic-eng explicit segment-list name** to configure the reverse path under segment list.

The reverse type must be the same as the forward path. Using different types for forward and reverse paths is not supported. For example, uSID forward path and uSID reverse path; MPLS forward path and MPLS reverse path.

User-configured segment-list can also represent the reverse path (reflector to sender) when probe is configured in liveness detection mode. Up to 128 segment-lists can be configured under a probe. An additional PM session is created for each segment-list. Segment-lists are configured under **segment-routing traffic-eng segment-list** submode. See [SR-TE Policy with Explicit Path](#) for details about configuring segment lists.

- **Flow Label:** The flow label field in the IPv6 header is used to carry information that helps distribute traffic across multiple network paths. The flow label is a 20-bit field in the IPv6 header designed to carry information about the flow of packets, which routers can use to identify and differentiate between different traffic flows. Flow label sweeping uses a flow label to distribute the traffic load across multiple paths to the endpoint.

Use the **flow-label** keyword to configure flow label. See [Configure Flow Labels in SRv6 Header for PM Liveness, on page 705](#) for details.

Supported and Unsupported Features for IP Endpoint over SRv6 Network

The table lists supported and unsupported features for Liveness Monitoring for IP Endpoint over SRv6 Network.

Table 123: Supported and Unsupported Features for Liveness Monitoring for IP Endpoint over SRv6 Network

Supported Features	Unsupported Features
SRv6 Endpoint Liveness in Default VRF Example: <code>endpoint ipv6 fccc:2:: liveness-detection</code> In this example, the endpoint with the IPv6 address fccc:2:: is the SRv6 uSID format.	IPv6 Endpoint Liveness in Default VRF (over SRv6) Example: <code>endpoint ipv6 10::2 liveness-detection</code> In this example, the endpoint with the IPv6 address 10::2 is part of an underlay network using SRv6.
IPv6 Endpoint Liveness in VRF (static uDT6) Example: <code>endpoint ipv6 fccc:2:fe02:: liveness-detection</code> In this example, the endpoint with the IPv6 address fccc:2:fe02:: is the static uDT6 uSID carrier	IPv6 Endpoint Liveness in VRF (dynamic DT6 encap) Example: <code>endpoint ipv6 10::1 vrf purple source-address ipv6 10::2 liveness-detection</code>
IPv4 Endpoint Liveness in VRF or GRT (static uDT4) Example: <code>endpoint ipv4 10.5.56.1 source-address ipv4 10.1.17.1 segment-routing traffic-eng explicit segment-list name vrf-2-3-5-udt4 liveness-detection</code> The segment-list <code>vrf-2-3-5-udt4</code> here has static uDT4 SID.	IPv4 Endpoint Liveness in VRF or GRT (dynamic uDT4 encap) Example: <code>endpoint ipv4 10.0.0.1 vrf purple source-address ipv4 10.0.0.2 liveness-detection</code>

Usage Guidelines and Limitations

- Liveness session without segment list for an endpoint in a non-default VRF is not supported.
- Liveness on SRv6 is supported on Cisco NCS 5508 starting from Cisco IOS XR Release 24.3.1.
- IPv6 Endpoint Liveness in Default VRF over SRv6 is not supported.
- IP Endpoint in VRF without segment list, over SRv6 underlay (dynamic uDT6 or uDT4) is not supported
- SR Performance Measurement endpoint session over BVI interface is not supported.

IP Endpoint Liveness Detection in an SR MPLS Network

IP endpoint liveness detection leverages the loopback measurement-mode. The following workflow describes the sequence of events.

1. The sender creates and transmits the PM probe packets.
 The IP destination address (DA) on the probe packets is set to the loopback value of the sender itself.
 The transmit timestamp (T1) is added to the payload.
 The probe packet is encapsulated with the label corresponding to the endpoint.
2. The network delivers the PM probe packets following the LSP toward the endpoint.

3. The end-point receives the PM probe packets.

Packets are forwarded back to the sender based on the forwarding entry associated with the IP DA of the PM probe packet. If an LSP exists, the probe packet is encapsulated with the label of the sender.

4. The sender node receives the PM probe packets.

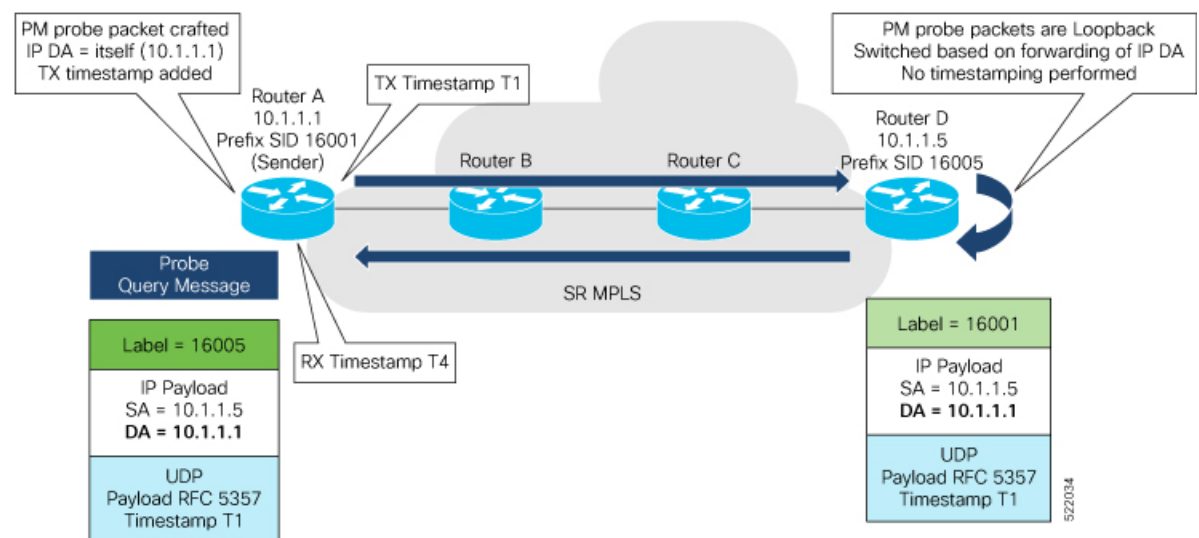

The received timestamp (T4) stored.

If the sender node doesn't receive the specified number of probe packets (based on the configured multiplier), the sender node declares the PM session as down.

The following figure illustrates a liveness detection probe toward an IP endpoint learned by the IGP. The network interconnecting the sender and reflector provides MPLS connectivity with Segment Routing.

The liveness detection multiplier is set to 5 to specify the number of consecutive missed probe packets before the PM session is declared as down.

Figure 39: IP Endpoint Liveness Detection

Configuration Example

```
RouterA(config)# performance-measurement
RouterA(config-perf-meas)# endpoint ipv4 10.1.1.5
RouterA(config-pm-ep)# source-address ipv4 10.1.1.1
RouterA(config-pm-ep)# liveness-detection
RouterA(config-pm-ep-ld)# exit
RouterA(config-pm-ep)# exit
RouterA(config-perf-meas)# liveness-profile endpoint default
RouterA(config-pm-ld-ep)# liveness-detection
RouterA(config-pm-ld-ep-ld)# multiplier 5
RouterA(config-pm-ld-ep-ld)# exit
```

Running Configuration

```
performance-measurement
 endpoint ipv4 10.1.1.5
 source-address ipv4 10.1.1.1
 liveness-detection
!
```

```

!
liveness-profile endpoint default
  liveness-detection
    multiplier 5
!

!
!
end

```

Verification

RouterA# **show performance-measurement endpoint ipv4 10.1.1.5**

Missed count: 0

```

IP Endpoint Liveness in an SRv6 Network

IP endpoint liveness detection leverages the loopback measurement-mode. The following workflow describes the sequence of events.

1. The sender creates and transmits the PM probe packets and sets the IP destination address (DA) on the probe packets to the loopback value of the sender itself. The sender adds the transmit timestamp (T1) to the payload and encapsulates the probe packet with the SRv6 labels corresponding to the endpoint.
2. The network delivers the PM probe packets by following the IPv6 or segment lists towards the endpoint.
3. The endpoint receives the PM probe packets.
4. The sender node receives the PM probe packets and stores the received timestamp. If the sender node doesn't receive the specified number of probe packets based on the configured multiplier, it declares the PM session down.

Figure 40: IP Endpoint Liveness In an SRv6 Network

523654

Note Liveness is not supported for non-default VRF.

Configuration Example

```
Router(config)#performance-measurement
Router(config-perf-meas)#source-address ipv6 2020:1::1
Router(config-perf-meas)#endpoint ipv6 FCBB:0::5::
Router(config-pm-ep)#exit
Router(config-perf-meas)#liveness-profile endpoint default
Router(config-pm-ld-ep)#probe
Router(config-pm-ld-ep-probe)#exit
Router(config-pm-ld-ep)#liveness-detection
Router(config-pm-ld-ep-ld)#multiplier 3
Router(config-pm-ld-ep-ld)#
```

The following example shows how to configure liveness with segment list and reverse path.

```
Router(config-sr)#traffic-eng
Router(config-sr-te)#segment-lists
Router(config-sr-te-segment-lists)#srv6
Router(config-sr-te-sl-global-srv6)#sid-format usid-f3216
Router(config-sr-te-sl-global-srv6)#exit
Router(config-sr-te-sl-global)#segment-list test
Router(config-sr-te-sl)#srv6
Router(config-sr-te-sl-srv6)#index 10 sid ff::2
Router(config-sr-te-sl-srv6)#index 20 sid ff::3
```

The following example shows how to configure liveness reverse path under segment list and under endpoint:

```
Router(config)#performance-measurement
Router(config-perf-meas)#endpoint ipv6 ff::2

/* Configure reverse path under segment list name */
Router(config-pm-ep)#segment-routing traffic-eng explicit segment-list name fwd-path
Router(config-pm-ep-sl)#reverse-path segment-list name rev-path
Router(config-pm-ep-sl)#exit

/* Configure reverse path under performance measurement endpoint */
```

```
Router(config-pm-ep) # segment-routing traffic-eng explicit reverse-path segment-list name
rev-path-name
```

The following example shows how to configure liveness with flow label:

```
Router(config-perf-meas) #liveness-profile endpoint default
Router(config-pm-ld-ep) #probe
Router(config-pm-ld-ep-probe) #flow-label from 1000 to 20000 increment 16
Router(config-pm-ld-ep-probe) #liveness-detection
Router(config-pm-ld-ep-ld) #multiplier 3
```

The following example shows how to configure liveness with flow label sweeping:

```
Router#configure
Router(config) #performance-measurement
Router(config-perf-meas) #liveness-profile name profile-sweeping
Router(config-pm-ld-profile) # flow-label from 1000 to 20000 increment 16
Router(config-pm-ld-profile) #commit
```

Verification

```

SR Policy Liveness Monitoring

Note From Cisco IOS XR Release 7.6.1 onwards, this feature is supported on Cisco Network Convergence System 5700 Series routers and routers with the Cisco NC57 line cards operating in native mode.

Table 124: Feature History Table

Feature Name	Release Information	Feature Description
SR Policy Liveness Monitoring on Segment Routing over IPv6 (SRv6)	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards).</p> <p>In segment routing over IPv6 (SRv6), you can now verify end-to-end traffic forwarding over an SR policy candidate path by periodically sending probe messages. Performance monitoring on an SRv6 network enables you to track and monitor traffic flows at a granular level.</p> <p>Earlier releases supported SR policy liveness monitoring over an SR policy candidate path on MPLS.</p>

Feature Name	Release Information	Feature Description
SR Performance Measurement Named Profiles	Release 7.3.1	<p>You can use this feature to create specific performance measurement delay and liveness profiles, and associate it with an SR policy.</p> <p>This way, a delay or liveness profile can be associated with a policy for which the performance measurement probes are enabled, and performance measurement is precise, and enhanced.</p> <p>The performance-measurement delay-profile sr-policy command was updated with the name profile keyword-argument combination.</p> <p>The performance-measurement liveness-profile sr-policy command was updated with the name profile keyword-argument combination.</p> <p>The performance-measurement delay-measurement command was updated with delay-profile name profile.</p> <p>The performance-measurement liveness-detection command was updated with liveness-profile name profile.</p>
SR Policy Liveness Monitoring	Release 7.3.1	This feature allows you to verify end-to-end traffic forwarding over an SR Policy candidate path by periodically sending performance monitoring (PM) packets.

SR Policy liveness monitoring allows you to verify end-to-end traffic forwarding over an SR Policy candidate path by periodically sending performance monitoring (PM) packets. The head-end router sends PM packets to the SR policy's endpoint router, which sends them back to the head-end without any control-plane dependency on the endpoint router.

For more information about the segment routing over IPv6, see [Segment Routing over IPv6](#) topic.

The following are benefits to using SR-PM liveness monitoring:

- Allows both liveness monitoring and delay measurement using a single-set of PM packets as opposed to running separate monitoring sessions for each purpose. This improves the overall scale by reducing the number of PM sessions required.

- Eliminates network and device complexity by reducing the number of monitoring protocols on the network (for example, no need for Bidirectional Failure Detection [BFD]). It also simplifies the network and device operations by not requiring any signaling to bootstrap the performance monitoring session.
- Improves interoperability with third-party nodes because signaling protocols aren't required. In addition, it leverages the commonly supported TWAMP protocol for packet encoding.
- Improves liveness detection time because PM packets aren't punted on remote nodes
- Provides a common solution that applies to data-planes besides MPLS, including IPv4, IPv6, and SRv6.

How it works?

The workflow associated with liveness detection over SR policy is described in the following sequence.

Consider an SR policy programmed at head-end node router 1 towards end-point node router 5. This SR policy is enabled for liveness detection using the loopback measurement-mode.

- **A:** The head-end node creates and transmits the PM probe packets.

The IP destination address (DA) on the probe packets is set to the loopback value of the head-end node itself.

A transmit (Tx) timestamp is added to the payload.

Optionally, the head-end node may also insert extra encapsulation (labels) to enforce the reverse path at the endpoint node.

Finally, the packet is injected into the data-plane using the same encapsulation (label stack) of that of the SR policy being monitored.

- **B:** The network delivers the PM probe packets as it would user traffic over the SR policy.
- **C:** The end-point node receives the PM probe packets.

Packets are switched back based on the forwarding entry associated with the IP DA of the packet. This would typically translate to the end-point node pushing the prefix SID label associated with the head-end node.

If the head-end node inserted label(s) for the reverse path, then the packets are switched back at the end-point node based on the forwarding entry associated with the top-most reverse path label.

- **D:** Headend node receives the PM probe packets.

A received (Rx) timestamp stored.

If the head-end node receives the PM probe packets, the head-end node assume that the SR policy active candidate path is up and working.

If the head-end node doesn't receive the specified number of consecutive probe packets (based on configured multiplier), the head-end node assumes the candidate path is down and a configured action is triggered.

Usage Guidelines and Limitations

The following usage guidelines and limitations apply:

- SR-PM liveness-detection over SR Policy is supported on manually configured SR Policies and On-Demand SR Policies (ODN).
- SR-PM liveness-detection over SR Policy is not supported on PCE-initiated SR Policies.
- SR-PM liveness-detection and delay-measurement aren't supported together
- When liveness-profile isn't configured, SR Policies use the default values for the liveness-detection profile parameters.
- The head-end router doesn't load-balance the liveness probes across bundle member links.
- SR-PM liveness-detection over SR Policy is not supported on NCS 5700 series fixed-port routers or NC57 line cards as head-end node when the probe packets contain more than 6 labels.

Configure SR Policy Liveness Monitoring in an MPLS Network

Configuring SR Policy liveness monitoring involves the following steps:

- Configuring a performance measurement liveness profile to customize generic probe parameters
- Enabling liveness monitoring under SR Policy by associating a liveness profile, and customizing SR policy-specific probe parameters

Liveness monitoring parameters are configured under **performance-measurement liveness-profile** sub-mode. The following parameters are configurable:

- **liveness-profile** {**sr-policy default** | **name** *name*}
Parameters defined under the **sr-policy default** liveness-profile apply to any SR policy with liveness monitoring enabled and that does not reference a non-default (named) liveness-profile.
- **probe**: Configure the probe parameters.
- **tx-interval**: Interval for sending probe packet. The default value is 3000000 microseconds and the range is from 30000 to 15000000 microseconds.
- **tos dscp value**: The default value is 48 and the range is from 0 to 63. You can modify the DSCP value of the probe packets, and use this value to prioritize the probe packets from headend to tailend.
- **sweep destination ipv4 127.x.x.x range range**: Configure SR Policy ECMP IP-hashing mode. Specify the number of IP addresses to sweep. The range is from 0 (default, no sweeping) to 128. The option is applicable to IPv4 packets.

Note The destination IPv4 headend address 127.x.x.x – 127.y.y.y is used in the Probe messages to take advantages of 3-tuple IP hashing (source-address, destination-address, and local router ID) for ECMP paths of SR-MPLS Policy.

The destination IPv4 address must be 127/8 range (loopback), otherwise it will be rejected.

Note One PM session is always created for the actual endpoint address of the SR Policy.

- **liveness-detection**: Configure the liveness-detection parameters:
- **multiplier**: Number of consecutive missed probe packets before the PM session is declared as down. The range is from 2 to 10, and the default is 3.

Note The detection-interval is equal to (tx-interval * multiplier).

Enabling Liveness Monitoring under SR Policy

Enable liveness monitoring under SR Policy, associate a liveness-profile, and configure SR Policy-specific probe parameters under the **segment-routing traffic-eng policy performance-measurement** sub-mode. The following parameters are configurable:

- **liveness-detection**: Enables end-to-end SR Policy Liveness Detection for all segment-lists of the active and standby candidate-path that are in the forwarding table.
- **liveness-profile name** *name*: Specifies the profile name for named profiles.
- **invalidation-action** {**down** | **none**}:

- **Down (default):** When the PM liveness session goes down, the candidate path is immediately operationally brought down.
- **None:** When the PM liveness session goes down, no action is taken. If logging is enabled, the failure is logged but the SR Policy operational state isn't modified.
- **logging session-state-change:** Enables Syslog messages when the session state changes.
- **reverse-path label {BSID-value | NODE-SID-value}:** Specifies the MPLS label to be used for the reverse path for the reply. If you configured liveness detection with ECMP hashing, you must specify the reverse path. The default reverse path uses IP Reply.
 - **BSID-value:** The Binding SID (BSID) label for the reverse SR Policy. (This is practical for manual SR policies with a manual BSID.)
 - **NODE-SID-value:** The absolute SID label of the (local) Sender Node to be used for the reverse path for the reply.

Configuration Examples

Configure a Default SR-Policy PM Liveness-Profile

The following example shows a default sr-policy liveness-profile:

```
RP/0/RSP0/CPU0:ios(config)# performance-measurement
RP/0/RSP0/CPU0:ios(config-perf-meas)# liveness-profile sr-policy default
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy)# probe

RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy-probe)# tx-interval 150000
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy-probe)# tos dscp 52
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy-probe)# exit
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy)# liveness-detection
RP/0/RSP0/CPU0:ios(config-pm-ld-srpolicy-ld)# multiplier 5
```

Running Configuration:

```
performance-measurement
 liveness-profile sr-policy default
 liveness-detection
  multiplier 5
!
probe
 tos dscp 52
 tx-interval 150000
!
!
end
```

Configure a Named (Non-Default) SR-Policy PM Liveness-Profile

The following example shows a named sr-policy liveness-profile:

```
Router(config)# performance-measurement
Router(config-perf-meas)# liveness-profile name sample-profile
Router(config-pm-ld-profile)# probe
Router(config-pm-ld-probe)# tx-interval 150000
Router(config-pm-ld-probe)# tos dscp 52
Router(config-pm-ld-probe)# exit
```

```
Router(config-pm-ld-profile)# liveness-detection
Router(config-pm-ld-profile-ld)# multiplier 5
Router(config-pm-ld-profile-ld)#commit
```

Running Configuration:

```
performance-measurement
  liveness-profile name sample-profile
    liveness-detection
      multiplier 5
    !
  probe
    tos dscp 52
    tx-interval 150000
  !
!
end
```

Configure a SR-Policy PM Liveness-Profile with Sweep Parameters

The following example shows a named liveness-profile with sweep parameters:

```
Router(config)# performance-measurement
Router(config-perf-meas)# liveness-profile name sample-profile
Router(config-pm-ld-profile)# probe
Router(config-pm-ld-probe)# tx-interval 150000
Router(config-pm-ld-probe)# tos dscp 52
Router(config-pm-ld-probe)# sweep
Router(config-pm-ld-probe-sweep)# destination ipv4 127.0.0.1 range 25
Router(config-pm-ld-probe-sweep)# exit
Router(config-pm-ld-probe)# exit

Router(config-pm-ld-profile)# liveness-detection
Router(config-pm-ld-profile-ld)# multiplier 5
Router(config-pm-ld-profile-ld)#commit
```

Running Configuration

```
performance-measurement
  liveness-profile name sample-profile
    liveness-detection
      multiplier 5
    !
  probe
    tos dscp 52
    sweep
      destination ipv4 127.0.0.1 range 25
    !
    tx-interval 150000
  !
!
end
```

Enable Liveness Monitoring Under SR Policy

The following example shows how to enable liveness monitoring under SR Policy, associate a liveness-profile, and configure the invalidation action:

```
RP/0/RSP0/CPU0:ios(config)# segment-routing traffic-eng
RP/0/RSP0/CPU0:ios(config-sr-te)# policy FOO
RP/0/RSP0/CPU0:ios(config-sr-te-policy)# performance-measurement
RP/0/RSP0/CPU0:ios(config-sr-te-policy-perf-meas)# liveness-detection
```

```
RP/0/RSP0/CPU0:ios(config-sr-te-policy-live-detect)# liveness-profile name sample-profile
RP/0/RSP0/CPU0:ios(config-sr-te-policy-live-detect)# invalidation-action none
```

Running Config

```
segment-routing
traffic-eng
policy FOO
performance-measurement
liveness-detection
liveness-profile name sample-profile
invalidation-action none
!
!
!
!
end
```

Enable Liveness Monitoring under SR Policy with Optional Parameters

The following example shows how to enable liveness monitoring under SR Policy, associate a liveness-profile, and configure reverse path label and session logging:

```
RP/0/RSP0/CPU0:ios(config)# segment-routing traffic-eng
RP/0/RSP0/CPU0:ios(config-sr-te)# policy BAA
RP/0/RSP0/CPU0:ios(config-sr-te-policy)# performance-measurement
RP/0/RSP0/CPU0:ios(config-sr-te-policy-perf-meas)# liveness-detection
RP/0/RSP0/CPU0:ios(config-sr-te-policy-live-detect)# liveness-profile name sample-profile
RP/0/RSP0/CPU0:ios(config-sr-te-policy-live-detect)# invalidation-action down
RP/0/RSP0/CPU0:ios(config-sr-te-policy-live-detect)# logging session-state-change
RP/0/RSP0/CPU0:ios(config-sr-te-policy-live-detect)# exit
RP/0/RSP0/CPU0:ios(config-sr-te-policy-perf-meas)# reverse-path label 16001
```

Running Config

```
segment-routing
traffic-eng
policy BAA
performance-measurement
liveness-detection
logging
session-state-change
!
liveness-profile name sample-profile
invalidation-action down
!
reverse-path
label 16001
!
!
!
!
end
```

Configure Segment Lists to Activate Candidate Paths in SRv6 for PM Liveness

Table 125: Feature History Table

Feature Name	Release Information	Feature Description
Configure Segment Lists to Activate Candidate Paths in SRv6 for PM Liveness	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards).</p> <p>You can now enable a candidate path to be up by configuring the minimum number of active segment lists associated with the candidate path. The head-end router determines that a candidate path is up based on the minimum number of active segment lists configured.</p> <p>In earlier releases, the head-end router identified a candidate path as up only when all the segment lists associated with the path were active.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> The validation-cp minimum-active segment-lists option is introduced in the performance-measurement liveness-detection command. <p>YANG Data Models:</p> <ul style="list-style-type: none"> Cisco-IOS-XR-infra-xtc-agent-cfg.yang <p>See (GitHub, Yang Data Models Navigator)</p>

The state of the segment lists in a candidate path determines whether a candidate path is up or down. You can now configure the minimum number of active segment lists associated with a candidate path. The head-end router identifies a candidate path as up when one or more segment lists are active.

Note

If the configured minimum number of active segment lists is greater than the number of available segment lists in a candidate path, the head-end router determines the candidate path as up only when all the segment lists are active.

In earlier releases, the router identified a candidate path as up only when all the segment lists associated with the path were active.

Configuration Example

Configure the minimum number of segment lists in SRv6

Perform this task to activate three segment lists to have the PM liveness session up:

```
Router(config)#segment-routing
Router(config-sr)#traffic-eng
Router(config-sr-te)#policy po-103
Router(config-sr-te-policy)#performance-measurement
Router(config-sr-te-policy-perf-meas)#liveness-detection
Router(config-sr-te-policy-live-detect)#validation-cp minimum-active segment-lists 3
```

Show Running Configuration

```
segment-routing
traffic-eng
policy po-103
performance-measurement
liveness-detection
validation-cp minimum-active segment-lists 3
!
!
!
!
```

Verification

The following example shows three active segment-lists to have the PM liveness session up:

```
Router#show performance-measurement sr-policy liveness color 103 detail verbose private
Mon Oct 30 15:10:51.863 EDT
```

```

Configure Flow Labels in SRv6 Header for PM Liveness

Table 126: Feature History Table

Feature Name	Release Information	Feature Description
Configure Flow Labels in SRv6 Header for PM Liveness	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards).</p> <p>You can now monitor the activeness of multiple paths for a given segment list using flow labels in the SRv6 header.</p> <p>In earlier releases, the SRv6 header didn't include flow labels.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> The flow-label keyword is introduced in the performance-measurement liveness-profile command. <p>YANG Data Models:</p> <ul style="list-style-type: none"> Cisco-IOS-XR-performance-measurement-cfg.yang Cisco-IOS-XR-perf-meas-oper.yang <p>See (GitHub, Yang Data Models Navigator)</p>

To monitor the activeness of multiple paths for a given a segment list, you can configure the SRv6 header to include flow labels as the packet travels in the network. When there are multiple paths, different traffic flows may use different paths. A flow label is a flow identifier and you can use different flow labels to monitor different ECMP paths. It's only used for IPv6 probe packets. Flow labels are 20-bit fields in the SRv6 header.

Configure flow labels in the SRv6 header

Perform the following task in the global configuration mode to configure flow labels in the SRv6 header:

```
Router#configure
Router(config)#performance-measurement
Router(config-perf-meas)#liveness-profile name name1
Router(config-pm-ls-profile)#probe flow-label from 0 to 1000000 increment 10
```

Running Configuration

```
performance-measurement
  liveness-profile name name1
  probe
```

```

    flow-label from 0 to 1000000 increment 10
  !
!
!

```

Verification

The following example shows an SR-policy configured with flow labels:

```
Router#show performance-measurement sr-policy liveness color 1001 detail verbose private
```

```
Mon Oct 30 15:25:55.241 EDT
```

```
0/1/CPU0

Hardware offload of SR policy liveness monitoring

Table 127: Feature History Table

Feature Name	Release	Description
Hardware Offload of MPLS Liveness Monitoring	Release 7.10.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards)</p> <p>You can now offload MPLS liveness monitoring for performance measurement to the router's hardware, which is the Network Processing Unit (NPU). This hardware-based approach improves efficiency and scalability, helping you meet delay-sensitive Service Level Agreements (SLAs). Previously, this monitoring was handled in software.</p> <p>The feature introduces a new keyword npu-offload under the performance-measurement liveness-profile name<i>liveness profile</i> command.</p> <p>Note This feature is not supported on NC57 series of LC cards and routers.</p>

Performance Measurement (PM) hardware offload feature allows the offload of PM liveness monitoring session to the Network Processing Unit (NPU) on the platform, which considerably improves scale and reduces the overall network convergence detection time.

This improvement is done by sending rapid failure detection probes (messages) and detecting policy or path failures quickly and help routing protocols in recalculating the routing table.

This feature is required in order to quickly react on delay-bound Service Level Agreement (SLAs), for example 5G low-latency, where SRTE policy can quickly re-optimize once the SLA is violated.

Advantages of the PM Hardware Offloading feature are as listed:

- Probes are sent every 3.3 milliseconds
- Complete liveness of the endpoint is now reduced to 10ms from 50ms when the operator configures the multiplier to be 3 (10ms = 3.3ms * 3).
- Currently, the hardware offload supports only liveness monitoring .

Note The hardware offload does not support delay and loss measurement yet.

Usage Guidelines and Limitations

The following usage guidelines and limitations apply:

- The NPU offload generates PM probes (Packets Per Second) with a maximum limit. PPS is directly proportional with the number of sessions and transmit interval. If the PPS exceeds the limit supported by the offload engine, the stretch algorithm activates. This algorithm doubles the transmit interval until the PPS is within the supported limit. Use 'show performance-measurement pps' command to verify the maximum probes per second (PPS) supported by offload engine and total pps currently in use.

Configuration Example

Note

The **hw-module profile offload 4** command is a prerequisite for LC CPU sessions to work.

Once you use the **hw-module profile offload 4** command, the Bidirectional Forwarding Detection for IPv6 (BFDv6) at the router will not work even if the Performance Measurement sessions are hosted only on LC CPU and not offloaded to the offload processor.

Use the 4th option **4 PM-HW-Offload and Bsync** in **hw-module profile offload** command to configure the Hardware Profile Offloading.

```
Router(config)#hw-module profile offload ?
1 BFDv6 and Bsync
2 BFDv6 and Route download
3 Route download and Bsync
4 PM-HW-Offload and Bsync
```

Reload the router to apply the hardware offload profile. After reloading, the Performance Measurement application loads on the offload engine.

Note

For SRv6 Liveness Monitoring - Hardware Offloading configuration, SRv6 uSID must be enabled. Use the following configuration to enable SRv6 uSID must be enabled

```
Router(config)# hw-module profile segment-routing srv6 mode micro-segment format f3216
```

The following example allows you to enable Performance Measurement Liveness Hardware (NPU) offload in the SR environment.

Note

The configuration also applies to the default liveness profile and the configuration applies to the router.

```
Router(config)#performance-measurement
Router(config-perf-meas)#liveness-profile name hwo_profile
Router(config-pm-ld-profile)#npu-offload
Router(config-pm-ld-profile-npu-offload)#commit
```

Running Configuration

The running configuration for this feature is as shown for both SRv6 and MPLS:

```

performance-measurement
  liveness-profile name hwo_profile
    npu-offload
  !
!
!

```

Verification

Use the show command to verify the running configuration as shown for both MPLS and SRv6 Liveness Monitoring - Hardware Offloading :

• Example for MPLS

```

Router# show performance-measurement sessions detail

Delay Measurement

Delay measurement is a mechanism used to measure the latency or delay experienced by data packets when they traverse a network.

The PM for delay measurement uses the IP/UDP packet format defined in RFC 5357 (TWAMP-Light) for probes. Two-Way Active Measurement Protocol (TWAMP) adds two-way or round-trip measurement capabilities. TWAMP employs time stamps applied at the echo destination (reflector) to enable greater accuracy. In the case of TWAMP Light, the Session-Reflector doesn't necessarily know about the session state. The Session-Reflector simply copies the Sequence Number of the received packet to the Sequence Number field of the reflected packet. The controller receives the reflected test packets and collects two-way metrics. This architecture allows for collection of two-way metrics.

Benefits

- **Network Troubleshooting:** You can quickly and easily identify areas in your network with high delay and resolve network problems using delay measurement.
- **Network Planning and Optimization:** You can easily understand the performance of your network under various conditions and design a network that can handle expected traffic loads.
- **Quality of Service (QoS):** You can ensure quality of service standards are being met by continuously monitoring the delay in your network.

Supported Delay Measurement Methods

You can measure delay using the following methods:

- [Link Delay Measurement, on page 715](#) Use to monitor delay experienced by data packets in a single link or path between two nodes in a network.
- [IP endpoint delay measurement:](#) Use to monitor the amount of time it takes for a data packet to travel from a source device to a specific IP endpoint within a network.
- [SR Policy End-to-End Delay Measurement , on page 746:](#) Use to monitor the end-to-end delay experienced by the traffic sent over an SR policy.

Measurement Modes

The following table compares the different hardware and timing requirements for the measurement modes that are supported in SR PM.

Table 128: Measurement Mode Requirements

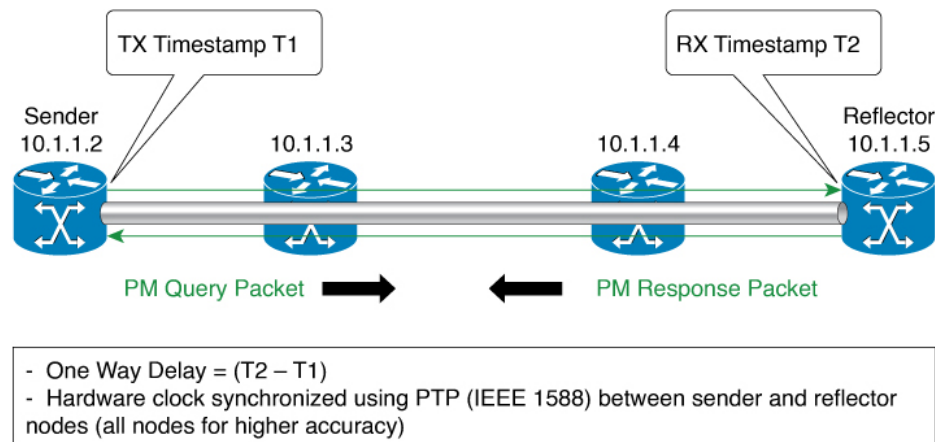

Measurement Mode	Sender: PTP-Capable HW and HW Timestamping	Reflector: PTP-Capable HW and HW Timestamping	PTP Clock Synchronization between Sender and Reflector
One-way	Required	Required	Required
Two-way	Required	Required	Not Required
Loopback	Required	Not Required	Not Required

One-Way Measurement Mode

One-way measurement mode provides the most precise form of one-way delay measurement. PTP-capable hardware and hardware timestamping are required on both Sender and Reflector, with PTP Clock Synchronization between Sender and Reflector.

Delay measurement in one-way mode is calculated as $(T2 - T1)$.

Figure 41: One-Way

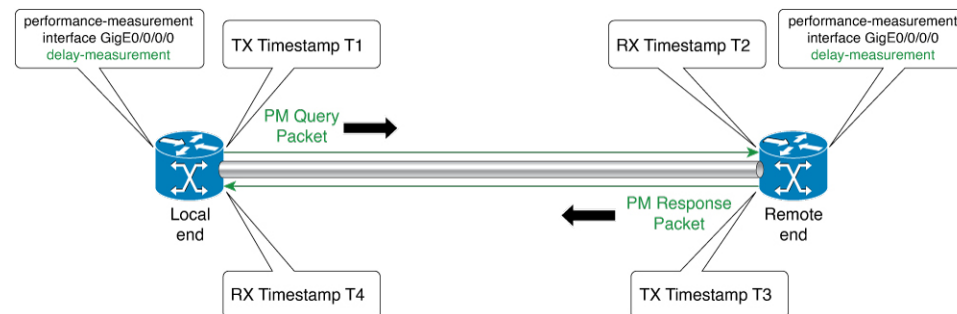

The PM query and response for one-way delay measurement can be described in the following steps:

1. The local-end router sends PM query packets periodically to the remote side once the egress line card on the router applies timestamps on packets.
2. The ingress line card on the remote-end router applies time-stamps on packets as soon as they are received.
3. The remote-end router sends the PM packets containing time-stamps back to the local-end router.
4. One-way delay is measured using the time-stamp values in the PM packet.

Far-end delay metrics in one-way measurement mode

Table 129: Feature History Table

Feature Name	Release Information	Description
Far-end delay metrics in one-way measurement mode	Release 24.4.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Native])</p> <p>Segment Routing Performance Monitoring (SR PM) now enables network operators to compute both far-end ($T4 - T3$) and near-end ($T2 - T1$) delay metrics, offering a comprehensive view of end-to-end delay across the data path. Measuring far-end delay, from the responder to the querier node, enhances visibility and allows operators to precisely monitor and assess network performance.</p> <p>Previously, you could measure the near-end delay metrics for a given data path.</p>

The far-end delay metric measures the round-trip time a packet takes to travel from the source to the destination across the Segment Routing network. It calculates the time it takes for the packet to reach the far end of a segment and return to the source.

Starting from Cisco IOS XR Release 24.4.1, the PM session automatically calculates both near-end ($T2 - T1$) and far-end ($T4 - T3$) metrics. The far-end delay is the delay from the responder to the querier node. This metric is automatically included in the CLI and telemetry outputs.

The far-end metrics provide network operators a complete view of delay across the entire data path, and not just the near-end. The feature enables network operators to understand the full path latency and ensures accurate network monitoring.

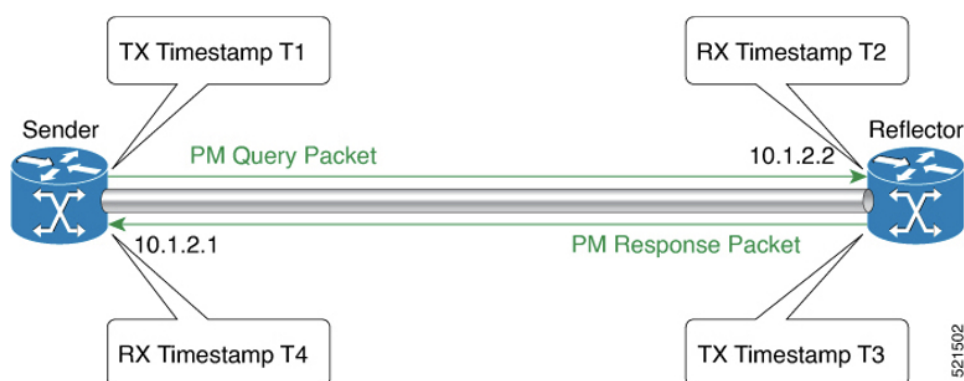

Note If the measurement mode is not set to one-way or is set to loopback, SR PM skips the far-end delay metric computation.

Two-Way Measurement Mode

Two-way measurement mode provides two-way measurements. PTP-capable hardware and hardware timestamping are required on both Sender and Reflector, but PTP clock synchronization between Sender and Reflector is not required.

Delay measurement in two-way mode is calculated as $((T4 - T1) - (T3 - T2))/2$

Figure 42: Two-Way

The PM query and response for two-way delay measurement can be described in the following steps:

1. The local-end router sends PM query packets periodically to the remote side once the egress line card on the router applies timestamps on packets.
2. Ingress line card on the remote-end router applies time-stamps on packets as soon as they are received.
3. The remote-end router sends the PM packets containing time-stamps back to the local-end router. The remote-end router time-stamps the packet just before sending it for two-way measurement.
4. The local-end router time-stamps the packet as soon as the packet is received for two-way measurement.
5. Delay is measured using the time-stamp values in the PM packet.

Loopback Measurement Mode

Loopback measurement mode provides two-way and one-way measurements. PTP-capable hardware and hardware timestamping are required on the Sender, but are not required on the Reflector.

Delay measurements in Loopback mode are calculated as follows:

- Round-Trip Delay = $(T4 - T1)$
- One-Way Delay = Round-Trip Delay/2

Figure 43: Loopback

The PM query and response for Loopback delay measurement can be described in the following steps:

1. The local-end router sends PM probe packets periodically on the SR Policy.
2. The probe packets are loopback on the endpoint node (not punted), with no timestamping on endpoint node.
3. Round-trip Delay = $T_4 - T_1$.

Link Delay Measurement

Note From Cisco IOS XR Release 7.6.1 onwards, Cisco Network Convergence System 5700 Series routers and routers with the Cisco NC57 line cards operating in native mode support the following features:

- Link Delay Measurement
- Named Profiles
- Static Delay Value on an Interface

Table 130: Feature History Table

Feature Name	Release Information	Feature Description
Delay Measurement on NCS-57C3-MOD Fixed Port Routers	Release 24.1.1	Introduced in the release on: NCS 5700 fixed port routers. The NCS-57C3-MOD fixed port routers now support the Two-Way Active Measurement Protocol (TWAMP) Light, which allows them to measure network delay metrics for links, IP Endpoints, and SR policy. These routers optimize forwarding capacity of up to 2.4 Terabits and are energy-efficient, enhancing network performance and reliability. By utilizing TWAMP Light, you can obtain detailed data for more precise and timely diagnosis of potential network issues, improving network performance and reliability.
Link Delay Measurement with IPv6 Link Local Address	Release 7.3.1	The performance measurement for link delay determines the source and destination IP addresses used in the OAM packet based on the IP address of the interface, where the delay measurement operation is enabled. This feature enables using the IPv6 link-local address as the OAM packet source IP address, when no IPv4 or IPv6 address is configured in the interface.

The PM for link delay uses the IP/UDP packet format defined in RFC 5357 (TWAMP-Light) for probes. Two-Way Active Measurement Protocol (TWAMP) adds two-way or round-trip measurement capabilities. TWAMP employs time stamps applied at the echo destination (reflector) to enable greater accuracy. In the case of TWAMP Light, the Session-Reflector doesn't necessarily know about the session state. The Session-Reflector simply copies the Sequence Number of the received packet to the Sequence Number field of the reflected packet. The controller receives the reflected test packets and collects two-way metrics. This architecture allows for collection of two-way metrics.

Usage Guidelines and Restrictions for PM for Link Delay

The following restrictions and guidelines apply for the PM for link delay feature for different links.

- For broadcast links, only point-to-point (P2P) links are supported. P2P configuration on IGP is required for flooding the value.
- For link bundles, the hashing function may select a member link for forwarding but the reply may come from the remote line card on a different member link of the bundle.

- For one-way delay measurement, clocks should be synchronized on two end-point nodes of the link using PTP.
- Link delay measurement is supported on IPv4 unnumbered interfaces. An IPv4 unnumbered interface is identified by a node ID (a loopback address) and the local SNMP index assigned to the interface. Note that the reply messages could be received on any interface, since the packets are routed at the responder based on the loopback address used to identify the link.

Configuration Example: PM for Link Delay

This example shows how to configure performance-measurement functionalities for link delay as a global default profile. The default values for the different parameters in the PM for link delay is given as follows:

- **probe measurement mode:** The default measurement mode for probe is two-way delay measurement. If you are configuring one-way delay measurement, hardware clocks must be synchronized between the local-end and remote-end routers using precision time protocol (PTP). See [Measurement Modes, on page 711](#) for more information.
- **protocol:** Interface delay measurement using RFC 5357 with IP/UDP encapsulation (TWAMP-Light).
- **tx-interval:** Interval for sending probe packet. The default value is 3000000 microseconds and the range is from 30000 to 15000000 microseconds.
- **computation interval:** Interval for metric computation. Default is 30 seconds; range is 1 to 3600 seconds.
- **periodic advertisement:** Periodic advertisement is enabled by default.
- **periodic-advertisement interval:** The default value is 120 seconds and the interval range is from 30 to 3600 seconds.
- **periodic-advertisement threshold:** Checks the minimum-delay metric change for threshold crossing for periodic advertisement. The default value is 10 percent and the range is from 0 to 100 percent.
- **periodic-advertisement minimum change:** The default value is 1000 microseconds (usec) and the range is from 0 to 100000 microseconds.
- **accelerated advertisement:** Accelerated advertisement is disabled by default.
- **accelerated-advertisement threshold:** Checks the minimum-delay metric change for threshold crossing for accelerated advertisement. The default value is 20 percent and the range is from 0 to 100 percent.
- **accelerated-advertisement minimum change:** The default value is 500 microseconds and the range is from 0 to 100000 microseconds.

```
RP/0/0/CPU0:router(config)# performance-measurement delay-profile interfaces default
RP/0/0/CPU0:router(config-pm-dm-intf)# probe
RP/0/0/CPU0:router(config-pm-dm-intf-probe)# measurement-mode one-way
RP/0/0/CPU0:router(config-pm-dm-intf-probe)# tx-interval 30000
RP/0/0/CPU0:router(config-pm-dm-intf-probe)# computation-interval 60
RP/0/0/CPU0:router(config-pm-dm-intf-probe)# exit

RP/0/0/CPU0:router(config-pm-dm-intf)# advertisement periodic
RP/0/0/CPU0:router(config-pm-dm-intf-adv-per)# interval 120
RP/0/0/CPU0:router(config-pm-dm-intf-adv-per)# threshold 20
RP/0/0/CPU0:router(config-pm-dm-intf-adv-per)# minimum-change 1000
RP/0/0/CPU0:router(config-pm-dm-intf-adv-per)# exit

RP/0/0/CPU0:router(config-pm-dm-intf)# advertisement accelerated
```

```
RP/0/0/CPU0:router(config-pm-dm-intf-adv-acc)# threshold 30
RP/0/0/CPU0:router(config-pm-dm-intf-adv-acc)# minimum-change 1000
RP/0/0/CPU0:router(config-pm-dm-intf-adv-per)# exit
```

Configure the UDP Destination Port

Configuring the UDP port for TWAMP-Light protocol is optional. By default, PM uses port 862 as the TWAMP-reserved UDP destination port for delay.

The UDP port is configured for each PM measurement probe type (delay, loss, protocol, authentication mode, etc.) on querier and responder nodes. If you configure a different UDP port, the UDP port for each PM measurement probe type must match on the querier and the responder nodes.

Note The same UDP destination port is used for delay measurement for links and SR Policy.

This example shows how to configure the UDP destination port for delay.

```
Router(config)# performance-measurement
Router(config-perf-meas)# protocol twamp-light
Router(config-pm-protocol)# measurement delay unauthenticated
Router(config-pm-proto-mode)# querier-dst-port 12000
```

Enable PM for Link Delay Over an Interface

This example shows how to enable PM for link delay over an interface.

```
RP/0/0/CPU0:router(config)# performance-measurement
RP/0/0/CPU0:router(config-perf-meas)# interface TenGigE0/0/0/0
RP/0/0/CPU0:router(config-pm-intf)# next-hop ipv4 10.10.10.2 // Optional IPv4 or IPv6
next-hop address
RP/0/0/CPU0:router(config-pm-intf)# delay-measurement
RP/0/0/CPU0:router(config-pm-intf-dm)# exit
```

The source and destination IP addresses used in the OAM packet are determined by the IP address present on the interface where the delay-measurement operation is enabled and the setting of the optional **next-hop** address.

When the **next-hop** address is not specified, the following rules apply to determine the source and destination IP addresses used in the OAM packet:

- If an IPv4 address is configured under the interface, then:
 - OAM packet source IP address = Interface's IPv4 address
 - OAM packet destination IP address = 127.0.0.0
- Else, if an IPv6 global address is configured under the interface, then:
 - OAM packet source IP address = Interface's IPv6 global address
 - OAM packet destination IP address = 0::ff:127.0.0.0
- Else, if an IPv6 link-local address is assigned to the interface, then:
 - OAM packet source IP address = Interface's IPv6 link-local address

- OAM packet destination IP address = 0::ff:127.0.0.0

When the **next-hop {ipv4 | ipv6}** address is configured, the following rules apply to determine the source and destination IP addresses used in the OAM packet:

- If a next-hop IPv4 address is configured, then:
 - OAM packet source IP address = Interface's IPv4 address
 - OAM packet destination IP address = Configured next-hop IPv4 address

Note If there is no IPv4 address configured under the interface, then the delay-measurement probe does not send OAM packets.

- If a next-hop IPv6 address is configured, then:
 - OAM packet source IP address = Interface's IPv6 global address
 - OAM packet destination IP address = Configured next-hop IPv6 address

Note If there is no IPv6 global address configured under the interface, then the delay-measurement probe does not send OAM packets.

This example shows how to enable PM for link delay over an interface with IPv4 address configured:

```
interface TenGigE0/0/0/0
  ipv4 address 10.10.10.1 255.255.255.0

performance-measurement
  interface TenGigE0/0/0/0
    delay-measurement
```

This example shows how to enable PM for link delay over an interface IPv6 address configured:

```
interface TenGigE0/0/0/0
  ipv6 address 10:10:10::1/64

performance-measurement
  interface TenGigE0/0/0/0
    delay-measurement
```

This example shows how to enable PM for link delay over an interface with a specified next-hop IPv4 address:

```
interface TenGigE0/0/0/0
  ipv4 address 10.10.10.1 255.255.255.0

performance-measurement
  interface TenGigE0/0/0/0
    next-hop ipv4 10.10.10.2
```

```
delay-measurement
```

This example shows how to enable PM for link delay over an interface with a specified next-hop IPv6 address:

```
interface TenGigE0/0/0/0
  ipv6 address 10:10:10::1/64

performance-measurement
  interface TenGigE0/0/0/0
    next-hop ipv6 10:10:10::2
    delay-measurement
```

This example shows how to enable PM for link delay over an interface with only IPv6 link-local address:

```
interface TenGigE0/0/0/0
  ipv6 enable

performance-measurement
  interface TenGigE0/0/0/0
    delay-measurement
```

You can also use the following commands for verifying the PM for link delay on the local-end router.

Command	Description
show performance-measurement history probe interfaces [<i>interface</i>]	Displays the PM link-delay probe history for interfaces.
show performance-measurement history aggregated interfaces [<i>interface</i>]	Displays the PM link-delay aggregated history for interfaces.
show performance-measurement history advertisement interfaces [<i>interface</i>]	Displays the PM link-delay advertisement history for interfaces.
show performance-measurement counters [<i>interface interface</i>] [<i>location location-name</i>]	Displays the PM link-delay session counters.

You can also use the following commands for verifying the PM for link-delay configuration on the remote-end router.

Command	Description
show performance-measurement responder summary [<i>location location-name</i>]	Displays the PM for link-delay summary on the remote-end router (responder).
show performance-measurement responder interfaces [<i>interface</i>]	Displays PM for link-delay for interfaces on the remote-end router.
show performance-measurement responder counters [<i>interface interface</i>] [<i>location location-name</i>]	Displays the PM link-delay session counters on the remote-end router.

Configure a Static Delay Value on an Interface

You can configure an interface to advertise a static delay value, instead of the measured delay value. When you configure a static delay value, the advertisement is triggered immediately. The average, minimum, and maximum advertised values will use the static delay value, with a variance of 0.

Scheduled probes will continue, and measured delay metrics will be aggregated and stored in history buffer. However, advertisement threshold checks are suppressed so that there are no advertisements of the actual measured delay values. If the configured static delay value is removed, the next scheduled advertisement threshold check will update the advertised measured delay values.

The static delay value can be configured from 1 to 16777215 microseconds (16.7 seconds).

This example shows how to configure a static delay of 1000 microseconds:

```
RP/0/0/CPU0:router(config)# performance-measurement
RP/0/0/CPU0:router(config-perf-meas)# interface TenGigE0/0/0/0
RP/0/0/CPU0:router(config-pm-intf)# delay-measurement
RP/0/0/CPU0:router(config-pm-intf-dm)# advertise-delay 1000
```

Running Configuration

```
performance-measurement

SR Performance Measurement Named Profiles

CLI Changes for Segment Routing Performance Measurement

- Prior to Cisco IOS XR release 7.6.1, performance measurement delay and liveness named profiles can be configured using the **performance-measurement {delay-profile | liveness-profile} {sr-policy | endpoint | interface} name name** command.

Starting with Cisco IOS XR release 7.6.1, performance measurement delay and liveness named profiles can also be configured using the **performance-measurement {delay-profile | liveness-profile} name name** command. The configuration is stored in NVRAM in the same CLI format used to create it. There is no conversion from the old CLI to the new CLI.

Starting with Cisco IOS XR release 7.10.1, the **{sr-policy | endpoint | interface} name name** CLI has been deprecated. Old configurations stored in NVRAM will be rejected at boot-up.

As a result, performance measurement delay and liveness named profiles using the old CLI must be re-configured using the new CLI.

Note The default performance measurement delay and liveness profiles configured using the **performance-measurement {delay-profile | liveness-profile} {sr-policy | endpoint | interface} default** commands are still valid and are not affected.

- Prior to Cisco IOS XR release 7.6.1, performance measurement delay and liveness probes can be configured using the **burst-interval milliseconds** command.

Starting with Cisco IOS XR release 7.6.1, performance measurement delay and liveness probes can also be configured using the **tx-interval microseconds** command.

Starting with Cisco IOS XR release 7.10.1, the **burst-interval milliseconds** CLI has been deprecated. Old configurations stored in NVRAM will be rejected at boot-up.

As a result, performance measurement delay and liveness probes using the old CLI must be re-configured using the new CLI.

- In Cisco IOS XR release 7.10.1 and 7.11.1, the **measurement-mode loopback** CLI for delay profile has been deprecated.

You can create a named performance measurement profile for delay or liveness.

Delay Profile

This example shows how to create a named SR performance measurement delay profile.

```
Router(config)# performance-measurement delay-profile name profile2
Router(config-pm-dm-profile)# probe
Router(config-pm-dm-probe)# tx-interval 60000
Router(config-pm-dm-probe)# computation-interval 60
Router(config-pm-dm-probe)# protocol twamp-light
Router(config-pm-dm-probe)# tos dscp 63
Router(config-pm-dm-probe)# exit
```

```
Router(config-pm-dm-profile)# advertisement
Router(config-pm-dm-adv)# periodic
Router(config-pm-dm-adv-per)# interval 60
Router(config-pm-dm-adv-per)# minimum-change 1000
Router(config-pm-dm-adv-per)# threshold 20
Router(config-pm-dm-adv-per)# commit
```

Apply the delay profile for an SR Policy.

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# policy TEST
Router(config-sr-te-policy)# color 4 end-point ipv4 10.10.10.10
Router(config-sr-te-policy)# performance-measurement
Router(config-sr-te-policy-perf-meas)# delay-measurement delay-profile name profile2

Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 100

Liveness Profile

This example shows how to create a *named* SR performance measurement liveness profile.

```
Router(config)# performance-measurement liveness-profile name profile3
Router(config-pm-ld-profile)# probe
Router(config-pm-ld-probe)# tx-interval 60000
Router(config-pm-ld-profile)# probe
Router(config-pm-ld-probe)# tx-interval 60000
Router(config-pm-ld-probe)# tos dscp 10
Router(config-pm-ld-probe)# exit

Router(config-pm-ld-profile)# liveness-detection
Router(config-pm-ld-profile-ld)# multiplier 5
Router(config-pm-ld-profile-ld)# commit
```

Apply the Liveness Profile for the SR Policy

This example shows how to enable PM for SR policy liveness for a specific policy.

For the same policy, you cannot enable delay-measurement (delay-profile) and liveness-detection (liveness-profile) at the same time. For example, if delay measurement is enabled, use the **no delay-measurement** command to disable it, and then enable the following command for enabling liveness detection.

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# policy TRST2
Router(config-sr-te-policy)# color 40 end-point ipv4 20.20.20.20
Router(config-sr-te-policy)# candidate-paths
Router(config-sr-te-policy-path)# preference 50
Router(config-sr-te-policy-path-pref)# explicit segment-list LIST3
Router(config-sr-te-pp-info)# weight 2

Router(config-sr-te-policy-path-pref)# explicit segment-list LIST4
Router(config-sr-te-pp-info)# weight 3

Router(config-sr-te-policy)# performance-measurement
Router(config-sr-te-policy-perf-meas)# liveness-detection liveness-profile name profile3
```

Running Configuration

```
Router# show run segment-routing traffic-eng policy TRST2

segment-routing
 traffic-eng

Delay Normalization

Table 131: Feature History Table

Feature Name	Release Information	Feature Description
SR-TE Delay Normalization for OSPF	Release 7.3.1	This feature extends the current Delay Normalization feature to support OSPF.

Performance measurement (PM) measures various link characteristics like packet loss and delay. Such characteristics can be used by IS-IS as a metric for Flexible Algorithm computation. Low latency routing using dynamic delay measurement is one of the primary use cases for Flexible Algorithm technology.

Delay is measured in microseconds. If delay values are taken as measured and used as link metrics during the IS-IS topology computation, some valid ECMP paths might be unused because of the negligible difference in the link delay.

The Delay Normalization feature computes a normalized delay value and uses the normalized value instead. This value is advertised and used as a metric during the Flexible Algorithm computation.

The normalization is performed when the delay is received from the delay measurement component. When the next value is received, it is normalized and compared to the previous saved normalized value. If the values are different, then the LSP generation is triggered.

The following formula is used to calculate the normalized value:

- **Dm** – measured Delay
- **Int** – configured normalized Interval
- **Off** – configured normalized Offset (must be less than the normalized interval Int)
- **Dn** – normalized Delay
- **a** = Dm / Int (rounded down)
- **b** = a * Int + Off

If the measured delay (Dm) is less than or equal to **b**, then the normalized delay (Dn) is equal to **b**. Otherwise, Dn is **b + Int**.

Example

The following example shows a low-latency service. The intent is to avoid high-latency links (1-6, 5-2). Links 1-2 and 5-6 are both low-latency links. The measured latency is not equal, but the difference is insignificant.

We can normalize the measured latency before it is advertised and used by IS-IS. Consider a scenario with the following:

- Interval = 10
- Offset = 3

The measured delays will be normalized as follows:

- **Dm** = 29

$$a = 29 / 10 = 2 \text{ (2.9, rounded down to 2)}$$

$$b = 2 * 10 + 3 = 23$$

In this case, **Dm** (29) is greater than **b** (23); so **Dn** is equal to **b+I** (23 + 10) = **33**

- **Dm** = 31

$$a = 31 / 10 = 3 \text{ (3.1, rounded down to 3)}$$

$$b = 3 * 10 + 3 = 33$$

In this case, **Dm** (31) is less than **b** (33); so **Dn** is **b** = **33**

The link delay between 1-2 and 5-6 is normalized to 33.

Configuration

Delay normalization is disabled by default. To enable and configure delay normalization, use the **delay normalize interval interval [offset offset]** command.

- *interval* – The value of the normalize interval in microseconds.
- *offset* – The value of the normalized offset in microseconds. This value must be smaller than the value of normalized interval.

IS-IS Configuration

```
router isis 1
 interface GigEth 0/0/0/0
  delay normalize interval 10 offset 3
  address-family ipv4 unicast
  metric 77
```

OSPF Configuration

```
router ospf 1
 area 0
  interface GigabitEthernet0/0/0/0
   delay normalize interval 10 offset 3
  !
 !
 !
```

Link Anomaly Detection with IGP Penalty

Table 132: Feature History Table

Feature Name	Release Information	Feature Description
Link Anomaly Detection with IGP Penalty	Release 7.4.1	This feature allows you to define thresholds above the measured delay that is considered “anomalous” or unusual. When this threshold is exceeded, an anomaly (A) bit/flag is set along with link delay attribute that is sent to clients.

Customers might experience performance degradation issues, such as increased latency or packet loss on a link. Degraded links might be difficult to troubleshoot and can affect applications, especially in cases where traffic is sent over multiple ECMP paths where one of those paths is degraded.

The Anomaly Detection feature allows you to define a delay anomaly threshold to identify unacceptable link delays. Nodes monitor link performance using link delay monitoring probes. The measured value is compared against the delay anomaly threshold values. When the upper bound threshold is exceeded, the link is declared “abnormal”, and performance measurement sets an anomaly bit (A-bit). When IGP receives the A-bit, IGP can automatically increase the IGP metric of the link by a user-defined amount to make this link undesirable or unusable. When the link recovers (lower bound threshold), PM resets the A-bit.

For information on configuring IGP penalty, see the following:

- [IS-IS Penalty for Link Delay Anomaly](#)
- [OSPF Penalty for Link Delay Anomaly](#)

Usage Guidelines and Limitations

This feature is not active when narrow metrics are configured because the performance measurement advertisement requires the “wide” metric type length values.

Configuration Example

The following example shows how to configure the upper and lower anomaly thresholds. The range for *upper_bound* and *lower_bound* is from 1 to 200,000 microseconds. The *lower_bound* value must be less than the *upper_bound* value.

```
RP/0/0/CPU0:router(config)# performance-measurement delay-profile interfaces default
RP/0/0/CPU0:router(config-pm-dm-intf)# advertisement
RP/0/0/CPU0:router(config-pm-dm-intf-adv)# anomaly-check upper-bound 5000 lower-bound 1000
RP/0/0/CPU0:router(config-pm-dm-intf-adv)# commit
```

Running Configuration

```
performance-measurement
 delay-profile interfaces default
  advertisement
  anomaly-check
  upper-bound 5000 lower-bound 1000
!
```

```

Delay Measurement for IP Endpoint

Table 133: Feature History Table

Feature Name	Release Information	Feature Description
Delay Measurement for IP Endpoint over SRv6 Network on Cisco NCS 5508 and Cisco NCS 5700 Series Routers	Release 24.3.1	<p>Introduced in this release on: NCS 5500 modular routers, NCS 5700 fixed port routers, NCS 5700 line cards [Mode: Native] .</p> <p>Delay Measurement for IP Endpoint over SRv6 Network is now supported on the NCS 5500 modular routers and NCS 5700 line cards in the Native mode.</p>
Delay Measurement for IP Endpoint over SRv6 Network	Release 24.2.1	<p>Introduced in the release on: NCS 5500 fixed port routers.</p> <p>In Segment Routing over an IPv6 network (SRv6), you can measure packet delay from the source to a specific IP endpoint. You can use this information for troubleshooting, network maintenance, and optimizing network performance.</p> <p>Additionally, you can use flow labels to verify the delay of each subsequent hop path towards the IP endpoint of that path. So that, when network traffic is distributed across multiple available paths towards an IP endpoint, delay measurement tracks the delay of each of these paths towards the IP endpoint.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> • The source-address ipv6 keyword is introduced in the performance-measurement endpoint command. • The segment-list name keyword is introduced in the segment-routing traffic-eng explicit command. • The flow-label keyword is introduced in the performance-measurement delay-profile name command. <p>YANG Data Model:</p> <ul style="list-style-type: none"> • <code>Cisco-IOS-XR-um-performance-measurement-cfg</code> • <code>Cisco-IOS-XR-perf-meas-oper.yang</code> <p>(See GitHub, YANG Data Models Navigator)</p>
IP Endpoint Delay Measurement Monitoring	Release 7.4.1	<p>This feature measures the end-to-end delay and monitors liveness of a specified IP endpoint node, including VRF-aware (awareness of multiple customers belonging to different VRFs).</p> <p>This feature is supported on IPv4, IPv6, and MPLS data planes.</p>

Delay for an IP endpoint is the amount of time it takes for a data packet to travel from a source device to a specific IP endpoint within a network.

To measure a delay for a packet, also called a probe, is sent from a source device to the target IP endpoint.

The time from when the packet leaves the source to when it arrives at the endpoint is measured and recorded as the delay.

You can measure one-way delay, Two-way delay, and Roundtrip delay or delay in loop-back mode. For more information on Delay measurement, see Link Delay Measurement and Measurement Modes.

Collecting IP Endpoint Probe Statistics

- Statistics associated with the probe for delay metrics are available via Histogram and Streaming Telemetry.
- Model Driven Telemetry (MDT) is supported for the following data:
 - Summary, endpoint, session, and counter show command bags.
 - History buffers data
- Model Driven Telemetry (MDT) and Event Driven Telemetry (EDT) are supported for the following data:
 - Delay metrics computed in the last probe computation-interval (event: probe-completed)
 - Delay metrics computed in the last aggregation-interval; that is, end of the periodic advertisement-interval (event: advertisement-interval expired)
 - Delay metrics last notified (event: notification-triggered)
- The following xpaths for MDT/EDT is supported:
 - `Cisco-IOS-XR-perf-meas-oper:performance-measurement/nodes/node/endpoints/endpoint-delay/endpoint-last-probes`
 - `Cisco-IOS-XR-perf-meas-oper:performance-measurement/nodes/node/endpoints/endpoint-delay/endpoint-last-aggregations`
 - `Cisco-IOS-XR-perf-meas-oper:performance-measurement/nodes/node/endpoints/endpoint-delay/endpoint-last-advertisements`

Guidelines and Limitations

You can specify a custom labeled path through one or more user-configured segment-lists. User-configured segment-list represents the forwarding path from sender to reflector when the probe is configured in delay-measurement mode.

- Examples of the custom segment-list include:
 - Probe in delay-measurement mode with a segment-list that includes Flex-Algo prefix SID of the endpoint
 - Probe in delay-measurement mode with a segment-list that includes a SID-list with labels to reach the endpoint or the sender (forward direction)
 - Probe in delay-measurement mode with a segment-list that includes BSID associated with SR policy to reach the end point.

- Endpoint segment list configuration is not supported under nondefault VRF.
- SR Performance Measurement endpoint session over BVI interface is not supported.

Supported Features for IP Endpoint Over SRv6 Network

These features are supported for IP Endpoint Delay Measurement over SRv6 Network:

- IPv6 Endpoint Delay in Default VRF over SRv6
- SRv6 Endpoint Delay in Default VRF on NCS 5700 fixed port routers and NCS 5500 modular routers.
Endpoint can be Node SID, Flex-Algo SID, Packed uSID carrier.
- IPv6 Endpoint Delay in VRF (static uDT6)
- IPv6 Endpoint Delay in VRF (dynamic uDT6 encap)
- IPv4 Endpoint Delay in VRF or GRT (static uDT4)
- IPv4 Endpoint Delay in VRF or GRT (dynamic uDT4 encap)

Unsupported Features for IP Endpoint Over SRv6 Network

- SRv6 PM is not supported on routers that use channelized ports
- The IPv6 Endpoint in vrf (dynamic uDT6) is not supported on NCS 5508 because the timestamp is not preserved among different LCs. However, it is supported when using an SRv6 segment list with the uDT case. In this scenario, use a global source address instead of the source address within the VRF.
- The IPv6 or IPv4 Endpoint in VRF is not supported for dynamic uDT on NCS 5508.

However, it is supported when using an SRv6 segment list with the uDT case. In this scenario, use a global source address instead of the source address within the VRF.

For example:

```
performance-measurement
  endpoint ipv4 10.2.2.2 vrf srv6_underlay
    delay-measurement
```

- SRv6 PM IPv6 endpoint delay session over SRv6 does not work on the Route Processor (RP) of NCS 5500 line cards and NCS 5700 line cards in the NCS 5508 Modular Router.

IP Endpoint Delay Measurement over MPLS Network Usecases

The following use-cases show different ways to deploy delay measurement and liveness detection for IP endpoints.

Use-Case 1: Delay Measurement Probe Toward an IP Endpoint Reachable in the Global Routing Table

The following figure illustrates a delay measurement probe toward an IP endpoint reachable in the global routing table. The network interconnecting the sender and the reflector provides plain IP connectivity.

Figure 44: Delay Measurement Probe Toward an IP Endpoint Reachable in the Global Routing Table

Configuration

```
RouterA(config)# performance-measurement
RouterA(config-perf-meas)# endpoint ipv4 10.1.1.5
RouterA(config-pm-ep)# source-address ipv4 10.1.1.1
RouterA(config-pm-ep)# delay-measurement
RouterA(config-pm-ep-dm)# exit
RouterA(config-pm-ep)# exit
RouterA(config-perf-meas)# delay-profile endpoint default
RouterA(config-pm-dm-ep)# probe
RouterA(config-pm-dm-ep-probe)# measurement-mode one-way
```

Running Configuration

```
performance-measurement
 endpoint ipv4 10.1.1.5
   source-address ipv4 10.1.1.1
   delay-measurement
   !
   !
 delay-profile endpoint default
  probe
  measurement-mode one-way
  !
  !
  !
```

Verification

```
RouterA# show performance-measurement endpoint ipv4 10.1.1.5
```

Next burst packet will be sent in 0.207 seconds

Burst packet sent every 3.0 seconds

Use-Case 2: Delay Measurement Probe Toward an IP Endpoint Reachable in a User-Specified VRF

The following figure illustrates a delay measurement probe toward an IP endpoint reachable in a user-specified L3VPN's VRF routing table. The L3VPN ingress PE (Router A) acts as the sender. The reflector is located in a CE device behind the L3VPN egress PE (Router E). The network interconnecting the L3VPN PEs provides MPLS connectivity with Segment Routing.

Use Case 3: Delay Measurement Probe Toward an IP Endpoint Using Custom Labeled Paths

The following figure illustrates a delay measurement probe toward an IP endpoint learned by the IGP. The network interconnecting the sender and reflector provides MPLS connectivity with Segment Routing.

The IP endpoint is advertised with multiple SR algorithms (Algo 0 and Flex Algo 128). The probe is configured with two custom-labeled paths in order to monitor the LSP for each algorithm separately.

Note Starting from Cisco IOS XR Release 24.1.1, use the **segment-routing traffic-eng explicit segment-list name** command to configure the segment list.

Earlier, the **segment-routing traffic-eng segment-list name** command was used to configure the segment list.

Figure 46: Delay Measurement Probe Toward an IP Endpoint Using Custom Labeled Paths

Note The probe response messages are not shown in the above figure.

Configuration

```

Current computation:
  Started at: Jul 19 2021 16:31:53.827 (15.844 seconds ago)
  Packets sent: 4, received: 0, lost: 4
  Measured delays (uSec): avg: 0, min: 0, max: 0, variance: 0
  Next probe scheduled at: Jul 19 2021 16:32:22.957 (in 13.286 seconds)
  Next burst packet will be sent in 2.940 seconds
  Burst packet sent every 3.0 seconds

```

Use-Case 4: Liveness Detection Probe Toward an IP Endpoint

IP endpoint liveness detection leverages the loopback measurement-mode. The following workflow describes the sequence of events.

1. The sender creates and transmits the PM probe packets.
 The IP destination address (DA) on the probe packets is set to the loopback value of the sender itself.
 The transmit timestamp (T1) is added to the payload.
 The probe packet is encapsulated with the label corresponding to the endpoint.
2. The network delivers the PM probe packets following the LSP toward the endpoint.
3. The end-point receives the PM probe packets.
 Packets are forwarded back to the sender based on the forwarding entry associated with the IP DA of the PM probe packet. If an LSP exists, the probe packet is encapsulated with the label of the sender.
4. The sender node receives the PM probe packets.
 The received timestamp (T4) stored.
 If the sender node doesn't receive the specified number of probe packets (based on the configured multiplier), the sender node declares the PM session as down.

The following figure illustrates a liveness detection probe toward an IP endpoint learned by the IGP. The network interconnecting the sender and reflector provides MPLS connectivity with Segment Routing.

The liveness detection multiplier is set to 5 to specify the number of consecutive missed probe packets before the PM session is declared as down.

Figure 47: IP Endpoint Liveness Detection

Configuration

```
RouterA(config)# performance-measurement
RouterA(config-perf-meas)# endpoint ipv4 10.1.1.5
RouterA(config-pm-ep)# source-address ipv4 10.1.1.1
RouterA(config-pm-ep)# liveness-detection
RouterA(config-pm-ep-ls)# exit
RouterA(config-pm-ep)# exit
RouterA(config-perf-meas)# liveness-profile endpoint default
RouterA(config-pm-ls-ep)# liveness-detection
RouterA(config-pm-ls-ep-ls)# multiplier 5
RouterA(config-pm-ls-ep-ls)# exit
```

Running Configuration

```
performance-measurement
 endpoint ipv4 10.1.1.5
   source-address ipv4 10.1.1.1
   liveness-detection
   !
   !
 liveness-profile endpoint default
   liveness-detection
     multiplier 5
   !
 !
 !
end
```

Verification

```
RouterA# show performance-measurement endpoint ipv4 10.1.1.5
```

Session State: Down
Missed count: 0

```

IP Endpoint Delay Measurement over SRv6 Network Usecase

The following figure illustrates a delay measurement probe toward an IP endpoint over the SRv6 network. The network interconnecting the sender and the reflector provides plain IP connectivity.

523655

```

RP/0/RSP0/CPU0:ios#configure
RP/0/RSP0/CPU0:ios(config)#performance-measurement
RP/0/RSP0/CPU0:ios(config-perf-meas)#endpoint ipv6 FCBB:0:1::
RP/0/RSP0/CPU0:ios(config-pm-ep)#delay-measurement
RP/0/RSP0/CPU0:ios(config-pm-ep-dm)#delay-profile name test
RP/0/RSP0/CPU0:ios(config-pm-ep-dm)#exit
RP/0/RSP0/CPU0:ios(config-pm-ep)#exit
RP/0/RSP0/CPU0:ios(config-perf-meas)#liveness-profile name test
RP/0/RSP0/CPU0:ios(config-pm-ld-profile)#probe
RP/0/RSP0/CPU0:ios(config-pm-ld-probe)#flow-label explicit 100 200 300
RP/0/RSP0/CPU0:ios(config-pm-ld-probe)#

```

The following example shows how to use flow label for delay profile for a default endpoint:

```

RP/0/RSP0/CPU0:ios#configure
RP/0/RSP0/CPU0:ios(config)#performance-measurement
RP/0/RSP0/CPU0:ios(config-perf-meas)#delay-profile endpoint default
RP/0/RSP0/CPU0:ios(config-pm-dm-ep)#probe
RP/0/RSP0/CPU0:ios(config-pm-dm-ep-probe)#flow-label explicit 100 200 300

```

Show Running Configuration

```

performance-measurement
 endpoint ipv6 FCBB:0:1::
  delay-measurement
   delay-profile name test
  !
 !
 liveness-profile name test

```

```

probe
  flow-label explicit 100 200 300
!
!
!

```

Verification

The show output displays the delay information for the endpoint.

```

SR Policy End-to-End Delay Measurement

Note From Cisco IOS XR Release 7.6.1 onwards, this feature is supported on Cisco Network Convergence System 5700 Series routers and routers with the Cisco NC57 line cards operating in native mode.

The PM for SR Policy uses the IP/UDP packet format defined in RFC 5357 (TWAMP-Light) for probes. Two-Way Active Measurement Protocol (TWAMP) adds two-way or round-trip measurement capabilities. TWAMP employs time stamps applied at the echo destination (reflector) to enable greater accuracy. In the case of TWAMP Light, the Session-Reflector doesn't necessarily know about the session state. The Session-Reflector simply copies the Sequence Number of the received packet to the Sequence Number field of the reflected packet. The controller receives the reflected test packets and collects two-way metrics. This architecture allows for collection of two-way metrics.

The extended TE link delay metric (minimum-delay value) can be used to compute paths for SR policies as an optimization metric or as an accumulated delay bound.

There is a need to monitor the end-to-end delay experienced by the traffic sent over an SR policy to ensure that the delay does not exceed the requested "upper-bound" and violate SLAs. You can verify the end-to-end delay values before activating the candidate-path or the segment lists of the SR policy in forwarding table, or to deactivate the active candidate-path or the segment lists of the SR policy in forwarding table.

Note The end-to-end delay value of an SR policy will be different than the path computation result (for example, the sum of TE link delay metrics) due to several factors, such as queuing delay within the routers.

Usage Guidelines and Limitations for PM for SR Policy Delay

The following usage guidelines and limitations apply:

- SR-PM delay measurement over SR Policy is supported on manually configured SR Policies and On-Demand SR Policies (ODN).
- SR-PM delay measurement over SR Policy is not supported on PCE-initiated SR Policies.
- Hardware clocks must be synchronized between the querier and the responder nodes of the link using PTP for one-way delay measurement.
- SR-PM delay measurement over SR Policy is not supported on NCS 5700 series fixed-port routers or NC57 line cards as head-end node when the probe packets contain more than 6 labels.

Configuring Performance Measurement Parameters

This example shows how to configure performance-measurement parameters for SR policy delay as a global default profile. The default values for the different parameters in the PM for SR policy delay is given as follows:

- **probe**: The default mode for probe is one-way delay measurement. Two-way delay and loopback modes are supported. See [Measurement Modes, on page 711](#) for more information.
- **tx-interval**: Interval for sending probe packet. The default value is 3000000 microseconds and the range is from 30000 to 15000000 microseconds.

- **computation interval:** Interval for metric computation. Default is 30 seconds; range is 1 to 3600 seconds.
- **protocol:**
 - **twamp-light:** SR Policy delay measurement using RFC 5357 with IP/UDP encap. This is the default protocol.
- **tos:** Type of Service
 - **dscp value:** The default value is 48 and the range is from 0 to 63.
 - **traffic-class value:** The default value is 6 and the range is from 0 to 7.
- **advertisement threshold-check:** minimum-delay/maximum-delay - The default value of periodic advertisement threshold-check is maximum-delay.
- **periodic advertisement:** Periodic advertisement is enabled by default.
- **periodic-advertisement interval:** The default value is 120 seconds and the interval range is from 30 to 3600 seconds.
- **periodic-advertisement threshold:** Checks the minimum-delay metric change for threshold crossing for periodic advertisement. The default value is 10 percent and the range is from 0 to 100 percent.
- **periodic-advertisement minimum-change:** The default value is 500 microseconds (usec) and the range is from 0 to 100000 microseconds.
- **accelerated advertisement:** Accelerated advertisement is disabled by default.
- **accelerated-advertisement threshold:** Checks the minimum-delay metric change for threshold crossing for accelerated advertisement. The default value is 20 percent and the range is from 0 to 100 percent.
- **accelerated-advertisement minimum:** The default value is 500 microseconds and the range is from 1 to 100000 microseconds.

```

Router(config)# performance-measurement delay-profile sr-policy default
Router(config-pm-dm-srpolicy)# probe
Router(config-pm-dm-srpolicy-probe)# tx-interval 60000
Router(config-pm-dm-srpolicy-probe)# computation-interval 60
Router(config-pm-dm-srpolicy-probe)# protocol twamp-light
Router(config-pm-dm-srpolicy-probe)# tos dscp 63
Router(config-pm-dm-srpolicy-probe)# exit

Router(config-pm-dm-srpolicy)# advertisement
Router(config-pm-dm-srpolicy-adv)# periodic
Router(config-pm-dm-srpolicy-adv-per)# interval 60
Router(config-pm-dm-srpolicy-adv-per)# minimum-change 1000
Router(config-pm-dm-srpolicy-adv-per)# threshold 20
Router(config-pm-dm-srpolicy-adv-per)# exit

Router(config-pm-dm-srpolicy-adv)# accelerated
Router(config-pm-dm-srpolicy-adv-acc)# minimum-change 1000
Router(config-pm-dm-srpolicy-adv-acc)# threshold 10
Router(config-pm-dm-srpolicy-adv-acc)# exit

Router(config-pm-dm-srpolicy-adv)# threshold-check minimum-delay
Router(config-pm-dm-srpolicy-adv)# exit
Router(config-pm-dm-srpolicy)#

```

Configure the UDP Destination Port

Configuring the UDP port for TWAMP-Light protocol is optional. By default, PM uses port 862 as the TWAMP-reserved UDP destination port for delay.

The UDP port is configured for each PM measurement probe type (delay, loss, protocol, authentication mode, etc.) on querier and responder nodes. If you configure a different UDP port, the UDP port for each PM measurement probe type must match on the querier and the responder nodes.

Note The same UDP destination port is used for delay measurement for links and SR Policy.

This example shows how to configure the UDP destination port for delay.

```
Router(config)# performance-measurement
Router(config-perf-meas)# protocol twamp-light
Router(config-pm-protocol)# measurement delay unauthenticated
Router(config-pm-proto-mode)# querier-dst-port 12000
```

Enable Performance Measurement for SR Policy

This example shows how to enable PM for SR policy delay for a specific policy.

```
Router(config)# segment-routing traffic-eng
Router(config-sr-te)# policy foo
Router(config-sr-te-policy)# performance-measurement
Router(config-sr-te-policy-perf-meas)# delay-measurement
```

SR Policy Probe IP/UDP ECMP Hashing Configuration

This example shows how to configure SR Policy ECMP IP-hashing mode.

- The destination IPv4 address 127.x.x.x – 127.y.y.y is used in the Probe messages to take advantages of 3-tuple IP hashing (source-address, destination-address, and local router ID) for ECMP paths of SR-MPLS Policy.

Note The destination IPv4 address must be 127/8 range (loopback), otherwise it will be rejected.

- One PM session is always created for the actual endpoint address of the SR Policy.
- You can specify the number of IP addresses to sweep. The range is from 0 (default, no sweeping) to 128.
- Platforms may have a limitation for large label stack size to not check IP address for hashing.

```
Router(config)# performance-measurement delay-profile sr-policy default
Router(config-pm-dm-srpolicy)# probe
Router(config-pm-dm-srpolicy-probe)# sweep
Router(config-pm-dm-srpolicy-probe-sweep)# destination ipv4 127.0.0.1 range 28
```

Verification

Fallback delay advertisement

Table 134: Feature History Table

Feature Name	Release Information	Feature Description
Fallback delay advertisement	Release 24.4.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Native])</p> <p>You can now advertise fallback delay value, retaining delay information in performance metrics even when delay metrics for interfaces are temporarily unavailable due to hardware, synchronization, or network connectivity issues. The feature ensures optimal routing decisions by maintaining network stability and consistent performance, even when real-time metrics are temporarily unavailable.</p> <p>Previously, the performance metrics did not include delay metrics when they were temporarily inaccessible, resulting in visibility gaps in the network and less effective routing.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <p>The performance-measurement interface command is modified with a new advertise-delay fallback keyword.</p> <p>YANG Data Models:</p> <ul style="list-style-type: none"> • Cisco-IOS-XR-performance-measurement-cfg.yang <p>See (GitHub, Yang Data Models Navigator)</p>

Fallback delay advertisement for interfaces

The feature enables network operators to handle situations where GRE tunnel delay interface delay metric is not available due to hardware, synchronization, or connectivity issues. Instead of removing the interface delay

metrics from the network performance metrics, which might cause network visibility loss and potential suboptimal routing decisions, network operators can configure and advertise the fallback delay value. The network can make routing decisions based on the fallback delay value instead of assuming that the link is entirely unusable.

The feature provides a backup plan for hardware failures or other issues that prevent accurate delay measurement for GRE tunnel interfaces, ensuring operational continuity by avoiding the removal of delay metrics.

Fallback delay mechanisms for seamless routing

With this feature, the network makes informed routing decisions by advertising either a maximum metric value with an anomaly flag or a user-configured fallback value.

- **Maximum Metric with an Anomaly Flag:** When you cannot measure the delay data for an interface due to hardware issues, connectivity problems, by default the performance measurement system advertises the highest possible metric value for that interface. The default fallback value advertised is 16777215 micro seconds. Also, it tags this metric with an anomaly flag, alerting the network that there is an issue with real-time delay data.
- **User-Configured Fallback Value:** When you configure a fallback value, you can advertise this fallback delay value instead of the maximum metric. The option is useful in cases where a predictable, user-defined delay value can help maintain stable routing, avoiding drastic changes in network behavior due to temporary loss of delay data.

Benefits of fallback delay advertisement for interfaces

- **Resilience:** Ensures that the network continues to make optimal routing decisions when delay metrics are not available due to hardware failures or transient session errors.
- **Predictability:** By configuring a fallback value, network administrators can ensure that the network behaves predictably in the absence of real-time delay metrics.
- **Continuity:** Prevents the removal of delay metrics, maintaining continuous visibility and routing capability.

Configure interface fallback delay value

Perform the following steps to configure a specific fallback delay value for interfaces:

Procedure

Step 1 Enable SR-PM.

Example:

```
Router#config
Router(config)#performance-measurement
```

Step 2 Set the advertise-delay fallback value for the interface to ensure that the router advertises this value when the computed delay metric is unavailable.

In the following example, the advertised interface fallback delay value is **1000**.

Example:

```
Router(config-perf-meas)#interface GigabitEthernet 0/2/0/0
Router(config-pm-intf)#delay-measurement
Router(config-pm-intf-dm)#advertise-delay fallback 1000
Router(config-pm-intf-dm)#commit
```

Step 3 Run the **show running-config** command to verify the running configuration.

Example:

```
!
performance-measurement
 interface GigabitEthernet0/2/0/0
   delay-measurement
     advertise-delay fallback 1000
!
!
```

Step 4 Run the **show performance-measurement sessions** command to verify whether the advertised metric is the default maximum metric value with an anomaly flag or the configured fallback delay value.

In the following show output, when the performance measurement session begins, by default the interface advertises the maximum metric value and the delay A flag is set.

Example:

```
Router#show performance-measurement sessions

Path Tracing in SRv6 Network

Operators do not know the actual path that the packets take within their network. This makes operations, such as troubleshooting routing problems, or verifying Equal-Cost Multipath (ECMP), a complex problem. Also, operators want to characterize the network in terms of delay and load on a per-hop basis.

Knowledge of the Path Tracing Midpoint helps the operators to troubleshoot the routing problems faster.

This feature allows the operators to:

- Detect the actual path the packet takes between any two nodes in network (A and Z).
- Measure the end-to-end delay from A to Z.
- Measure the per-hop delay at each node on the path from A to Z.
- Detects the load on each router that forwards the packet from A to Z

Path Tracing (PT) provides a log or record of the packet path as a sequence of interface IDs along with its time-stamp. In addition, it provides a record of end-to-end delay, per-hop delay, and load on each egress interface along the packet delivery path.

In Path Tracing, a node can behave as a source, midpoint, or a sink node.

The source node generates and injects probe packets toward a destination node to trace the time-stamp and interface ID along the path of the probe packet. The Interface ID value of 0 means that Path Tracing (PT) is disabled on the interface.

Path Tracing (PT) Midpoint: It is a transit node that performs IPv6 routing. In addition, it records the PT information (MCD) in the HbH-PT.

Note There is no support for Path Tracing Midpoint on transit nodes that perform SRH operations or SRv6 endpoint operations. Support starts from Cisco IOS XR Release 24.1.1.

- Midpoint Compressed Data (MCD): The PT Midpoint along the packet delivery path from the Source to Sink node, stores its PT information into the HbH-PT header. This PT information is called Midpoint Compressed Data (MCD).
- Hop-by-Hop Path Tracing (HbH-PT): In IPv6 The HbH PT Options header is used to carry optional information that is examined and processed by every node along a packet's delivery path. It contains a stack of MCDs.
- PT-Aware Midpoint: A midpoint node that performs plain IPv6 routing or SR Endpoint processing and in addition stores the Path Tracing information in HbH-PT.
- PT-Unaware Midpoint: A midpoint node that performs plain IPv6 routing or SR Endpoint processing and is not capable of performing Path Tracing.
- PT-Legacy Midpoint: A midpoint node that performs plain IPv6 routing or SR Endpoint processing and is not capable of recording Path Tracing information in the HBH-PT. However, it is capable of exporting Path Tracing information directly to the collector, using the node telemetry system.
- PT Source: A Source node is the one that starts a PT session and generates PT probes. Support starts from Cisco IOS XR Release 24.1.1.

- PT Sink: A node that receives the PT probes sent from the Source node containing the information recorded by every PT Midpoint along the path and forwards them to the collector after recording its Path Tracing information. Support starts from Cisco IOS XR Release 24.1.1.
- RC: Regional collector that receives PT probes, parses, and stores them in Timeseries DB

The destination or sink node that receives the PT probes generated by the PT source node, stores PT related info into PT-TLV and forwards them to a Regional Collector (RC). This Regional Collector (RC) parses and stores them in the TimeSeries Database. It uses the information in the Hop-by-Hop Path Tracing (HbH-PT) to construct the packet delivery path and the timestamps at each node.

Limitations and Guidelines

This section lists the limitations of the path tracing feature.

- PT Source and Sink nodes are not supported.
- The system can still work as PT midpoint for other devices acting as Source or Sink in the PT network path.
- No support for interface load calculation and recording on IPv6 Path Tracing Midpoint Node.

Configure Midpoint, Sink, and Source Nodes

Note These configurations must be done on the Source, Midpoint and Sink routers as shown in the following configuration examples.

- Configuration example of Midpoint node:

Configure the Interface ID under Path-tracing for the Midpoint node and for it to participate in the MCD updates inside the probe packets:

```
Router(config)# performance-measurement
Router(config-pm)# interface FourHundredGigE0/0/0/1
Router(config-pm-interf)# path-tracing
Router(config-pm-interf-interf-id)# interface-id 200
Router(config-pm-interf-time)# exit
```

Running Configuration

- Running configuration example of Midpoint node:

Configure the Interface ID under Path-tracing for the Midpoint node and for it to participate in the MCD updates inside the probe packets:

```
performance-measurement
interface FourHundredGigE0/0/0/1
  path-tracing
    interface-id 200
  exit
```

```

!
!
!
!

```

Verification

It is good to check the target interface configuration and performance-measurement configuration for that interface.

Verify using the show commands listed below to check if the PT configuration is applied to the interface properly.

```

Router# show cef interface fourHundredGigE 0/0/0/1
FourHundredGigE0/0/0/1 is up if_handle 0x0f000208 if_type IFT_FOURHUNDREDGE(0xcd)
  idb info 0x94dfbf88 flags 0x30001 ext 0x0
  Vrf Local Info (0x0)
  Interface last modified, create
  Reference count 1      Next-Hop Count 0
  PT (path tracing) is enabled: id:0xC8 load_in:0x0 load_out:0x0 tts:0x3
  Protocol Reference count 0
  Protocol ipv4 not configured or enabled on this card
  Primary IPV4 local address NOT PRESENT

```

This is an example of Show CLI with Interface ID:

```

Router# show run performance-measurement
performance-measurement
probe-profile name foo
  tx-interval 6000
  flow-label from 100 to 300 increment 10
!
!
Router# sh performance-measurement profile named-profile

Two-Way Active Measurement Protocol Light Source Address Filtering

Table 135: Feature History Table

Feature Name	Release Information	Feature Description
Two-Way Active Measurement Protocol Light Source Address Filtering	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers NCS 5500 modular routers NCS 5700 fixed port routers NCS 5500 line cards NCS 5700 line cards [Mode: Native]</p> <p>You can now restrict unauthorized users from sending packets to the network and prevent compromising the network security and reliability. For a destination UDP port, you can configure the list of IP addresses that can send Two-Way Active Measurement Protocol (TWAMP)-light packets to responder or querier nodes.</p> <p>In earlier releases, the responder or querier node accepted TWAMP-light packets from all IP addresses.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> The querier and responder keywords are introduced in the performance-measurement protocol twamp-light measurement delay command. <p>YANG Data Models:</p> <ul style="list-style-type: none"> Cisco-IOS-XR-performance-measurement-cfg.yang Cisco-IOS-XR-perf-meas-oper.yang <p>See (GitHub, Yang Data Models Navigator)</p>

Earlier, the responder node scanned all IP addresses of a querier on the destination UDP port. In other words, the responder node accepted packets from any IP address. See [Measurement Modes](#) for more information about querier and responder nodes.

Note The responder is also called the reflector, and the querier is also called the sender.

With this configuration, you can specify the source IP addresses on both the responder and querier nodes. The responder or querier nodes accept packets only from the IP addresses configured in the TWAMP-light protocol, and reject the packets from an IP address that isn't included in the configured list.

All the configured addresses are available for use on all interfaces in the Local Packet Transport Services (LPTS). The configured address filter applies to both default and nondefault VRFs. The TWAMP delay measurement sessions use the configured addresses.

Usage Guidelines and Limitations

The following usage guidelines and limitations apply:

- When you configure the prefix entries on the responder or querier nodes, the PM adds the responder or querier node source IP address to the LPTS. For each prefix, a new LPTS entry is added or created.
- For TWAMP liveness sessions, the PM automatically adds the source IP addresses to the LPTS for if you have configured the prefix entries on the responder or querier nodes.
- As the maximum number of LPTS hardware entries are limited, ensure that enough LPTS entries are allocated for the IP addresses on a line card. You can scale the LPTS configuration to maximum LPTS entries for the PM flow-type. For more details on configuring the LPTS entries for PM flow-type, refer to the *IP Addresses and Services Configuration Guide*.

Note The PM UDP port accepts all incoming IPv4 or IPv6 packets when there are no IPv4 or IPv6 prefix entries configured.

Configure IP address on querier and responder nodes

- The length of the IPv4 and IPv6 prefixes must be less than 32 and 128 respectively.
- The length or mask of the source IP address must be:
 - For IPv4: 0–31
 - For IPv6: 0–127

Configure the IP address on a responder

Perform this task to configure the IP address of a querier on a responder node for delay measurement.

```
Router#configure
Router(config)#performance-measurement
Router(config-perf-meas)#protocol twamp-light
```

```

Router(config-pm-protocol)#measurement delay
Router(config-pm-proto-meas)#responder
Router(config-pm-proto-responder)#allow-querier
Router(config-pm-allowed-querier)#address ipv4 10.10.10.1

```

Running Configuration

```

performance-measurement
 protocol twamp-light
   measurement delay
   responder
   allow-querier
   address ipv4 10.10.10.1
!
!
!
!
End

```

Verification

The following example shows output from the IP address of a querier, which is configured on a responder node for delay measurement.

```

Router#show performance-measurement allowed-querier summary
Wed Oct 11 10:41:43.268 UTC

```

Configure the source IP address on a querier

Perform this task to configure the IP address of a responder on a querier node for delay measurement.

```

Router#configure
Router(config)#performance-measurement
Router(config-perf-meas)#protocol twamp-light
Router(config-pm-protocol)#measurement delay
Router(config-pm-proto-meas)#querier
Router(config-pm-proto-querier)#allow-responder
Router(config-pm-allowed-responder)#address ipv4 10.10.10.1

```

Running Configuration

```

performance-measurement
 protocol twamp-light
   measurement delay
   querier
   allow-responder
   address ipv4 10.10.10.1

```

```

!
!
!
!
End

```

Verification

The following example shows output from the IP address of a responder, which is configured on a querier node for delay measurement.

```

Router#show performance-measurement allowed-responder summary
Wed Mar 29 19:38:06.381 UTC

```

```

0/RP1/CPU0

```

```

Allowed-responder IPv4 prefix                : 2
  10.10.10.1/32 [Auto]
  3.3.3.3/32

Synthetic Loss Measurement

Table 136: Feature History Table

Feature Name	Release	Description
Synthetic Loss Measurement	Release 24.1.1	<p>Introduced in this release on: NCS 5500 fixed port routers NCS 5500 modular routers NCS 5700 fixed port routers NCS 5500 line cards NCS 5700 line cards [Mode: Native]</p> <p>You can now proactively monitor and address potential network issues before they impact users by measuring key parameters everywhere, packet loss, and jitter. Using this information, you can plan network capacity optimally and ensure quality of service. Such proactive action is possible because this feature reports synthetic Two-Way Active Measurement Protocol (TWAMP) test packets deployed in delay-profile or delay measurement sessions.</p> <p>It also enables you to set the upper and lower limits and notifies when the synthetic packet loss metric is out of the set limit.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> The optional anomaly-loss and anomaly-check keywords are introduced in the performance-measurement delay-profile command. show performance-measurement history <p>YANG Data Model</p> <ul style="list-style-type: none"> New XPaths for <code>Cisco-IOS-XR-um-performance-measurement-cfg</code> New operations for <code>Cisco-IOS-XR-perf-meas-oper.yang</code> (see GitHub, YANG Data Models Navigator)

Synthetic packets are data packets that are artificially generated for the purpose of testing or managing a network, as opposed to being generated by normal network data traffic. These packets are unrelated to regular user activities or data. Instead, they are intentionally designed to serve monitoring, testing, and diagnostic purposes.

Synthetic TWAMP test packets deployed in delay profile are used to simulate network traffic, test network performance, and evaluate network infrastructure. They are particularly useful for assessing the quality of service (QoS) of a network, identifying network vulnerabilities, and troubleshooting network issues. These packets enable network administrators to identify potential problems before they impact the overall network performance and reliability. *For more information on TWAMP, refer to the IP Service Level Agreements chapter in the System Monitoring Configuration Guide for Cisco NCS 5500 Series Routers.*

Overall, synthetic packets play a critical role in network management, providing network engineers with a powerful tool for optimizing network performance, identifying and resolving issues.

Note This is an inbuilt feature of delay measurement. To get the synthetic packet loss information for delay-measurement sessions, you must only configure the delay sessions. No additional configuration is required for Synthetic Loss Measurement. However, an optional **anomaly-loss** command is introduced.

Synthetic packets simulate various types of traffic that can be sent with the normal traffic to measure loss or latency, throughput or packet loss. This is often done in network performance monitoring and testing, where the goal is to understand how the network or a specific network device performs under typical conditions.

This feature enables you to measure and monitor the Synthetic packets lost and help make informed decisions on the following:

- **Network Performance Monitoring:** Synthetic packets can be used to simulate different types of network traffic in order to measure and test the performance of network devices or the network itself.
- **Troubleshooting:** They can be used to diagnose problems in a network by sending them through different parts of the system to see where they may fail or be slowed down.
- **Security:** They can also be used in security applications, such as penetration testing, where synthetic packets are sent to a system to find vulnerabilities.

Configure Synthetic Loss measurement

The following example enables Synthetic Loss Measurement for an SR Policy.

Note A delay-measurement session is good enough to get the synthetic packet loss automatically, without any extra configuration. The configure shown here is for anomaly loss, which is optional.

```
Router(config)#performance-measurement
Router(config-perf-meas)#delay-profile sr-policy default
Router(config-pm-dm-srpolicy)#advertisement
Router(config-pm-dm-srpolicy-adv)#anomaly-loss
Router(config-pm-dm-srpolicy-adv-anom-loss)#upper-bound 30 lower-bound 20
Router(config-pm-dm-srpolicy-adv-anom-loss)#commit
```

Note Similarly, you can configure Synthetic Loss Measurement for **endpoint default**, **interface default** or **name** (named profile).

Running Configuration

The running configuration for this feature is as shown:

```
performance-measurement
  delay-profile sr-policy default
  advertisement
    anomaly-loss
      upper-bound 30 lower-bound 20
    !
  !
!
!
!
```

Verification

Use the show commands to verify the running configuration as shown:

```
Router# show performance-measurement interfaces delay detail
Interface Name: GigabitEthernet0/2/0/0 (ifh: 0x1000020)
```

```
...
  Last advertisement:
  ...
  Packets sent: 40, received: 40, lost: 0
  ...
  Next advertisement:
  ...
  Packets sent: 10, received: 10, lost: 0
  ...
  Current computation:
  ...
  Packets sent: 4, received: 4, lost: 0
```

```
Router# show performance-measurement history probe-computation interfaces
```

```
Interface Name: GigabitEthernet0/2/0/0 (ifh: 0x1000020)
```

```
Delay-Measurement history (uSec):
```

Probe	Start	Timestamp	Pkt (TX/RX)	Average	Min	Max
Aug 01 2023	08:04:15.230		10/10	704	651	779

Endpoint

Use these show commands to verify the Endpoint configuration. The example include endpoint delay details and advertisement history. You can also verify the aggregation history.

```
Router# show performance-measurement endpoint delay detail
```

```
Endpoint name: IPv4-192.168.0.4-vrf-default
```

```
...
  Last advertisement:
  ...
  Packets sent: 40, received: 40, lost: 0
  ...
  Next advertisement:
  ...
  Packets sent: 30, received: 30, lost: 0
  ...
  Current computation:
  ...
```

```
Packets sent: 6, received: 6, lost: 0
...
```

```
Router# show performance-measurement history advertisement endpoint
Endpoint name: IPv4-192.168.0.4-vrf-default
```

```
...
Delay-Measurement history (uSec):
  Advertisement Timestamp  Pkt (TX/RX)  Average      Min      Max      Reason
  Aug 01 2023 08:31:18.835    40/40      3948      3127    15503    PER-MAX
```

RSVP-TE

Use these show commands to verify the RSVP-TE configuration. The example include rsvp-te delay details and the aggregation history. You can also verify the advertisement history.

```
Router# show performance-measurement rsvp-te detail
Tunnel name: tunnel-te1 (ifh: 0xd0)
```

```
...
Last advertisement:
...
Packets sent: 40, received: 40, lost: 0
...
Next advertisement:
...
Packets sent: 10, received: 10, lost: 0
...
Last computation:
...
Packets sent: 10, received: 10, lost: 0
...
Current computation:

```

=====

In this scenario, the router was running normally and then advertised a packet loss anomaly, the flag is set; later the router resumed to normal, the flag is unset, and it advertised a packet loss anomaly again.

Delay and synthetic loss measurement for GRE tunnel interfaces

Table 137: Feature History Table

Feature Name	Release Information	Feature Description
Delay and synthetic loss measurement for GRE tunnel interfaces	Release 24.4.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Native])</p> <p>You can now measure the latency or delay experienced by data packets when they traverse a network, and also proactively monitor and address potential network issues before they impact users by measuring key parameters such as packet loss, and jitter for GRE tunnel interfaces.</p> <p>This feature enables you to report synthetic Two-Way Active Measurement Protocol (TWAMP) test packets that are deployed in delay-profile or delay measurement sessions, and enables delay measurement for GRE tunnel interfaces.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <p>The performance-measurement interface command supports the tunnel-ip keyword.</p>

Delay and synthetic loss measurement for GRE tunnel interfaces

With this feature, you can configure a GRE interface with delay measurement under PM. You can now run sessions over a GRE tunnel as an interface session, and the PM advertises these measurement metrics to the Interface Manager (IM).

The PM for delay measurement uses the IP/UDP packet format that is defined in RFC 5357 (TWAMP-Light) for probes.

Synthetic packets are data packets that are artificially generated for testing or managing a network, as opposed to being generated by normal network data traffic. These packets are unrelated to regular user activities or data. Instead, they are intentionally designed to serve monitoring, testing, and diagnostic purposes. With

synthetic loss measurement, you can set the upper and lower limits and notify when the synthetic packet loss metric is out of the set limit.

For more information about delay and synthetic loss measurement, see the [Delay Measurement, on page 711](#) and [Synthetic Loss Measurement, on page 765](#) sections.

Measurement modes for GRE tunnel interfaces

GRE tunnel interfaces support these modes to measure delay and synthetic loss:

- One-way
- Two-way

Both one-way and two-way measurement modes support round-trip synthetic loss measurement.

Usage guidelines and limitations for delay and synthetic loss measurement for GRE tunnels

Limitations

These limitations apply:

- Loopback delay measurement mode does not support GRE interfaces.
- Liveness measurement does not support GRE interfaces.
- GRE over SRv6 or SR-MPLS underlay is not supported for performance measurement.
- IP-in-IP tunnel mode (without the GRE header) is not supported.
- Interface delay measurement is not supported in nondefault VRF.
- The NCS 5700 series routers do not support IPv6 over GRE tunnels on the responder node, while the querier node uses software timestamps.

Usage guidelines

These guidelines apply:

- You can measure only one path for GRE tunnels with ECMP paths.
- GRE encapsulation mode for IP tunnel is supported.
- The NCS 5500 series routers support IPv4 over GRE tunnel mode with bidirectional data flow.
- GRE interface tunnels over an IGP network are supported.
- The Cisco NCS 55A1 2nd generation fixed chassis supports SR-PM over GRE tunnels.

Configure delay and synthetic loss measurement for GRE tunnel interfaces

Procedure

Step 1 Run the **interface tunnel-ip** command to configure the tunnel mode, source, and destination for the interface.

Note

You must configure the responder node to decapsulate the GRE tunnel and establish a proper return path to the querier node.

In the following example, the tunnel uses GRE in IPv4 mode, encapsulating or decapsulating IP packets for transport across the tunnel. The source IP address of the tunnel is set to 209.165.201.2, indicating the origin of the IP packets. The destination IP address is set to 209.165.201.3, indicating where the encapsulated packets are sent.

Example:

```
Router#config
Router(config)#interface tunnel-ip 23
Router(config-if)#ipv4 address 209.165.201.1/27
Router(config-if)#ipv6 address 2001:DB8::/32
Router(config-if)#tunnel mode gre ipv4 encap
Router(config-if)#tunnel mode gre ipv4 decap
Router(config-if)#tunnel source 209.165.201.2
Router(config-if)#tunnel destination 209.165.201.3
Router(config-pm-intf-dm)#commit
```

Step 2 Enable delay measurement on the configured GRE tunnel interface.

Example:

```
Router(config)#performance-measurement
Router(config-perf-meas)#interface tunnel-ip 23
Router(config-pm-intf)#delay-measurement
Router(config-pm-intf-dm)#commit
```

Step 3 Run the **show running-config** command to verify the running configuration.

Example:

```
!
interface tunnel-ip23
  ipv4 address 209.165.201.1 255.255.255.224
  ipv6 address 2001:db8::/32
  tunnel mode gre ipv4 decap
  tunnel source 209.165.201.2
  tunnel destination 209.165.201.3
!
performance-measurement
  interface tunnel-ip23
    delay-measurement
  !
!
```

Step 4 Run the **performance-measurement delay-profile** command to configure synthetic loss measurement for the GRE tunnel interface.

For more information about configuring synthetic loss measurement, see the [Configure Synthetic Loss measurement, on page 766](#) section.

Step 5 Run the **show performance-measurement interfaces delay** command to verify the delay and synthetic loss measurement that is enabled for the GRE tunnel interface.

Example:

```
Router#show performance-measurement interfaces delay detail
Mon Nov  4 12:44:56.849 UTC
```

```
0/RP0/CPU0
```

```
Interface Name: tunnel-ip23 (ifh: 0x78000014)

Delay Measurement Using Software Timestamp

Table 138: Feature History Table

Feature Name	Release Information	Feature Description
Delay Measurement Using Software Timestamp	Release 24.3.1	<p>Introduced in this release on: NCS 5500 modular routers; NCS 5500 fixed port routers.</p> <p>You can now identify performance issues caused by the network, disk I/O, processing, or other factors using software timestamping on your router by measuring the delay and loss of each network path, even if the existing hardware lacks timestamp support.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none">• The timestamp-format NTP keyword is introduced in the performance-measurement delay-profile command.

Timestamps for Delay Measurement

The Performance Measurement (PM) is a crucial mechanism that measures the delay and loss on network paths. It measures the delay and loss by sending and receiving timestamped probe packets at the ingress and egress nodes.

PM uses probe packets to carry specific Type-Length-Value (TLVs) to encode the measurement information for delay measurement. One of the TLVs used for delay measurement is the Timestamp TLV that contains the time when a node sends or receives the probe packet.

The Timestamp TLV can have different formats, such as Precision Time Protocol (PTP) or Network Time Protocol (NTP).

You need to insert the Timestamp TLV close to the physical interface where the packet is transmitted or received to accurately measure the delay.

You can measure delay and loss using hardware timestamp. If the hardware does not support the timestamp capability and the corresponding format and offset, software timestamp is an option that you need to consider.

Before Release 24.3.1, only hardware timestamping was supported.

Software Timestamps for Delay Measurement

A software timestamp is a method that uses software for the insertion of Type-Length-Value (TLVs) into probe packets..

In instances where the hardware device does not support timestamping, we enable the router to set the timestamp in software, which helps insert the Type-Length-Value (TLVs) into the probe packets. The default timestamp format is PTP. You can configure to use the NTP format using the **timestamp-format NTP** command.

Measurement Modes for Software Timestamp

The software timestamp supports these three modes:

- One-way measurement mode
- Two-way measurement mode
- Loopback measurement mode

For more information, see [Measurement Modes, on page 711](#).

Supported Features for Software Timestamp

The software timestamp supports these performance measurement features:

- Link delay measurement
- SR Policy
- IP Endpoint with both MPLS and SRv6
- RSVP-TE LSPs

Key Concepts

- **Delay Measurement** : Delay measurement is a mechanism used to measure the latency or delay experienced by data packets when they traverse a network. For more information, see [Delay Measurement](#).
- **NTP** : Network Time Protocol (NTP) provides time synchronization to all devices on a network. The primary NTP servers are synchronized to a reference clock, such as GPS receivers and telephone modem services.

For more information, see *System Management Configuration Guide for Cisco NCS 5500 Series Routers*

- **PTP**: Precision Time Protocol (PTP) defines a method for distributing time across a network with its foundation based on the IEEE 1588-2008 standard.

For more information, see *System Management Configuration Guide for Cisco NCS 5500 Series Routers*

Benefits of Software Timestamp

Software Timestamp helps you

- provide a software-based timestamping fallback option when the hardware lacks support for the necessary timestamping capability, format, or offset.
- insert the timestamp to probe packets when a hardware device cannot support the required format or offset.

- enable the packet loss measurement automatically since the software can also insert the Counter TLV, which contains the sequence number of the probe packet.

How Delay is Measured Using Software Timestamp?

Here is how you measure a delay using software timestamp:

1. **Event Initiation:** When a client sends a packet, the current time is recorded as a timestamp using PTP or NTP.
2. **Event Completion:** When the client receives an acknowledgment from the server, another timestamp is recorded.
3. **Delay Calculation:** The delay is calculated by subtracting the first event's timestamp from the second event's timestamp. This calculation provides the round-trip time (RTT) or one-way delay, depending on the specific context.
4. **Accuracy and Precision:** The accuracy of software timestamps relies on the resolution of the system clock and any potential delays introduced by the software layers handling the timestamping.

Guidelines and Limitations for Software Timestamp

Here are some of the guidelines and limitations that you need to keep in mind before you configure software timestamp:

- For devices that support hardware timestamping, the hardware timestamp has priority over the software timestamp.
- One-way delay measurement is not supported when there is a mix of hardware and software timestamp ping.
- Delay Measurement using Software Timestamp is not supported on the Compatibility mode of NCS 5500 modular routers using NCS 5500 line cards and NCS 5700 line cards.

Configure Software Timestamp for Delay Measurement

The default software timestamp format is PTP. You can enable the router to use the NTP format using the **timestamp-format NTP** command.

You can configure software timestamp for

- Link delay
- SR Policy
- IP Endpoint with both MPLS and SRv6, and
- RSVP-TE LSPs.

Procedure

Step 1 Use the **timestamp-format NTP** command to configure software timestamp with NTP format on a router.

- This example shows how to configure a software timestamp for IP Endpoint.

```
Router#configure
Router(config)# performance-measurement
Router(config-perf-meas)#delay-profile endpoint default
Router(config-pm-dm-ep)#probe
Router(config-pm-dm-ep-probe)#timestamp-format NTP
Router(config-pm-dm-ep-probe)#
```

- This example shows how to configure software timestamp for SR policy.

```
Router#configure
Router(config)# performance-measurement
Router(config-perf-meas)#delay-profile sr-policy default
Router(config-pm-dm-srpoli)#probe
Router(config-pm-dm-srpoli-probe)#timestamp-format NTP
```

- This example shows how to configure software timestamp for delay profile name.

```
Router#configure
Router(config)# performance-measurement
Router(config-perf-meas)#delay-profile name blue
Router(config-pm-dm-profile)#probe
Router(config-pm-dm-profile-probe)#timestamp-format NTP
Router(config-pm-dm-profile-probe)#
```

- This example shows how to configure software timestamp for interface delay profile.

```
Router#configure
Router(config)# performance-measurement
Router(config-perf-meas)#delay-profile interfaces default
Router(config-pm-dm-intf)#probe
Router(config-pm-dm-intf-probe)#timestamp-format NTP
Router(config-pm-dm-intf-probe)#
```

- This example shows how to configure software timestamp for RSVP-TE LSPs.

```
Router#configure
Router(config)# performance-measurement
Router(config-perf-meas)#delay-profile rsvp-te default
Router(config-pm-dm-rsvpte)#probe
Router(config-pm-dm-rsvpte-probe)#timestamp-format NTP
Router(config-pm-dm-rsvpte-probe)#
```

Step 2 Execute the **show performance-measurement sessions** command to verify the timestamp format.

- This example shows how to verify the timestamp format for the IP endpoint:

```
Router# show performance-measurement endpoint detail
Endpoint name: IPv4-192.168.0.4-vrf-default
Source address      : 192.168.0.2

CHAPTER 16

Configure Topology-Independent Loop-Free Alternate (TI-LFA)

Table 139: Feature History Table

Feature Name	Release Information	Feature Description
mLDP LSP protection with optimal TI-LFA backup paths	Release 24.4.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>You can now enhance the protection and convergence for Multicast Label Distribution Protocol Label Switched Paths (mLDP LSP) using Topology Independent Loop-Free Alternate (TI-LFA) backup paths. TI-LFA calculates an optimal, loop-free post-convergence path, and you can encode it as a list of segments.</p> <p>With this change, the TI-LFA supports zero-segment and single-segment backup paths, enabling native Point-to-Multipoint (P2MP) over SR code with a Tree Segment Identifier (Tree-SID) profile.</p>

Feature Name	Release Information	Feature Description
SR-TILFA	Release 7.3.1	This feature is now supported on routers that have the Cisco NC57 line cards installed and operate in native mode. To enable the native mode, use the hw-module profile npu native-mode-enable command in the configuration mode. Ensure that you reload the router after configuring the native mode.

Topology-Independent Loop-Free Alternate (TI-LFA) uses segment routing to provide link, node, and Shared Risk Link Groups (SRLG) protection in topologies where other fast reroute techniques cannot provide protection.

- Classic Loop-Free Alternate (LFA) is topology dependent, and therefore cannot protect all destinations in all networks. A limitation of LFA is that, even if one or more LFAs exist, the optimal LFA may not always be provided.
- Remote LFA (RLFA) extends the coverage to 90-95% of the destinations, but it also does not always provide the most desired repair path. RLFA also adds more operational complexity by requiring a targeted LDP session to the RLFAs to protect LDP traffic.

TI-LFA provides a solution to these limitations while maintaining the simplicity of the IPFRR solution.

The goal of TI-LFA is to reduce the packet loss that results while routers converge after a topology change due to a link or node failure. Rapid failure repair (< 50 msec) is achieved through the use of pre-calculated backup paths that are loop-free and safe to use until the distributed network convergence process is completed.

The optimal repair path is the path that the traffic will eventually follow after the IGP has converged. This is called the post-convergence path. This path is preferred for the following reasons:

- Optimal for capacity planning — During the capacity-planning phase of the network, the capacity of a link is provisioned while taking into consideration that such link will be used when other links fail.
- Simple to operate — There is no need to perform a case-by-case adjustments to select the best LFA among multiple candidate LFAs.
- Fewer traffic transitions — Since the repair path is equal to the post-convergence path, the traffic switches paths only once.

The following topology illustrates the optimal and automatic selection of the TI-LFA repair path.

Figure 1: A network diagram illustrating the convergence of TI-LFA. The network consists of 8 nodes (1-8) and a PE4 node. Node 1 is the Source, and nodes 5 and 8 are Dest1 and Dest2 respectively. A red star indicates a link failure between nodes 2 and 3. The diagram shows four types of paths: Initial (solid blue), Classic LFA FRR (dashed blue), TI-LFA (dash-dot blue), and Post-convergence (solid dark blue). Metrics are shown on links: 100 for links (1,2), (2,4), and (3,4); 10 for other links. The text "Default metric: 10" is at the bottom.

- Initial
- Classic LFA FRR
- TI-LFA
- Post-convergence

With classic LFA, traffic would be steered to Node 4 after a failure of the protected link. This path is not optimal, since traffic is routed over edge node Node 4 that is connected to lower capacity links.

In this example, if the protected link fails, the shortest path from Node2 to Node5 would be:

Node7 is the PQ-node for destination Node5. TI-LFA encodes a single segment (prefix SID of Node7) in the header of the packets on the repair path.

Starting Cisco IOS XR Release 24.4.1, you can enhance protection and convergence for Multicast Label Distribution Protocol Label Switched Paths (mLDP LSP) using TI-LFA backup paths. TI-LFA calculates an optimal, loop-free post-convergence path. It enforces this path by encoding it as a list of segments. This enhancement enables native Point-to-Multipoint (P2MP) over SR code with a Tree Segment Identifier (Tree-SID) profile. TI-LFA supports link protection in topologies.

TI-LFA supports the following protection:

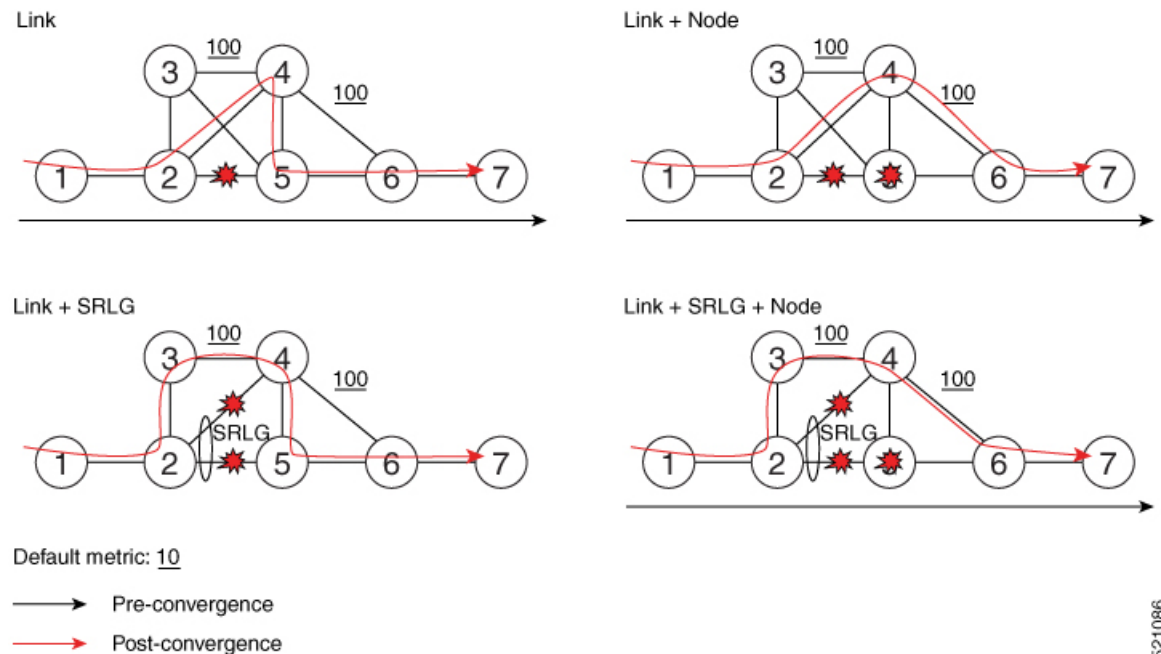

- Link protection — The link is excluded during the post-convergence backup path calculation.
- Node protection — The neighbor node is excluded during the post convergence backup path calculation.

- Shared Risk Link Groups (SRLG) protection — SRLG refer to situations in which links in a network share a common fiber (or a common physical attribute). These links have a shared risk: when one link fails, other links in the group might also fail. TI-LFA SRLG protection attempts to find the post-convergence backup path that excludes the SRLG of the protected link. All local links that share any SRLG with the protecting link are excluded.

When you enable link protection, you can also enable node protection, SRLG protection, or both, and specify a tiebreaker priority in case there are multiple LFAs.

The following example illustrates the link, node, and SRLG protection types. In this topology, Node2 applies different protection models to protect traffic to Node7.

Figure 49: TI-LFA Protection Types

521086

- [Usage guidelines and limitations for TI-LFA, on page 786](#)

- [SR-MPLS over GRE as TI-LFA Backup Path, on page 795](#)
- [Unlabeled IPv6 Traffic Protection, on page 806](#)

Usage guidelines and limitations for TI-LFA

Guidelines

- IGP directly programs a TI-LFA backup path requiring 3 or fewer labels, including the label of the protected destination prefix.

Limitations

- The platform does not support programming of TI-LFA backup paths requiring more than 3 labels.

These limitations apply to TI-LFA starting Cisco IOS XR Release 24.4.1:

- TI-LFA includes zero-segment and single-segment backup paths but does not include double-segment backup path.
- TI-LFA bundles with multiple members may experience convergence time exceeding 50 milliseconds during Fast Reroute (FRR) switchovers.

TI-LFA Functionality	IS-IS ¹	OSPFv2
<i>Protected Traffic Types</i>		
Protection for SR labeled traffic	Supported	Supported
Protection of IPv4 unlabeled traffic	Supported (IS-ISv4)	Supported
Protection of IPv6 unlabeled traffic	Supported (IS-ISv6)	N/A
<i>Protection Types</i>		
Link Protection	Supported	Supported
Node Protection	Supported	Supported
Local SRLG Protection	Supported	Supported
Weighted Remote SRLG Protection	Supported	Supported
Line Card Disjoint Protection	Supported	Unsupported
<i>Interface Types</i>		
Ethernet Interfaces	Supported	Supported
TI-LFA with L3VPN	Supported	Supported
Ethernet Bundle Interfaces	Supported	Supported
TI-LFA over GRE Tunnel as Protecting Interface	Supported	Supported
<i>Additional Functionality</i>		
Maximum number of labels that can be pushed on the backup path (including the label of the protected prefix)	3	3
BFD-triggered	Supported	Supported
BFDv6-triggered	Supported	N/A
Prefer backup path with lowest total metric	Supported	Supported
Prefer backup path from ECMP set	Supported	Supported
Prefer backup path from non-ECMP set	Supported	Supported
Load share prefixes across multiple backups paths	Supported	Supported

TI-LFA Functionality	IS-IS ¹	OSPFv2
Limit backup computation up to the prefix priority	Supported	Supported

¹ Unless specified, IS-IS support is IS-ISv4 and IS-ISv6

Configuring TI-LFA for IS-IS

This task describes how to enable per-prefix Topology Independent Loop-Free Alternate (TI-LFA) computation to converge traffic flows around link, node, and SRLG failures.

Before you begin

Ensure that the following topology requirements are met:

- Routers are configured with IS-IS.
- Segment routing for IS-IS is configured. See [Enabling Segment Routing for IS-IS Protocol, on page 283](#).

SUMMARY STEPS

1. **configure**
2. **router isis** *instance-id*
3. **interface** *type interface-path-id*
4. **address-family ipv4** [**unicast**]
5. **fast-reroute per-prefix**
6. **fast-reroute per-prefix ti-lfa**
7. **fast-reroute per-prefix tiebreaker** { **node-protecting** | **srlg-disjoint** } **index** *priority*

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.
Step 2	router isis <i>instance-id</i> Example: RP/0/RP0/CPU0:router(config)# router isis 1	Enables IS-IS routing for the specified routing instance, and places the router in router configuration mode. Note You can change the level of routing to be performed by a particular routing instance by using the is-type router configuration command.
Step 3	interface <i>type interface-path-id</i> Example:	Enters interface configuration mode.

	Command or Action	Purpose
	RP/0/RP0/CPU0:router(config-isis)# interface GigabitEthernet0/0/2/1	
Step 4	address-family ipv4 [unicast] Example: RP/0/RP0/CPU0:router(config-isis-if)# address-family ipv4 unicast	Specifies the IPv4 address family, and enters router address family configuration mode.
Step 5	fast-reroute per-prefix Example: RP/0/RP0/CPU0:router(config-isis-if-af)# fast-reroute per-prefix	Enables per-prefix fast reroute.
Step 6	fast-reroute per-prefix ti-lfa Example: RP/0/RP0/CPU0:router(config-isis-if-af)# fast-reroute per-prefix ti-lfa	Enables per-prefix TI-LFA fast reroute link protection.
Step 7	fast-reroute per-prefix tiebreaker {node-protecting srlg-disjoint} index priority Example: RP/0/RP0/CPU0:router(config-isis-if-af)# fast-reroute per-prefix tie-breaker srlg-disjoint index 100	Enables TI-LFA node or SRLG protection and specifies the tiebreaker priority. Valid <i>priority</i> values are from 1 to 255. The lower the <i>priority</i> value, the higher the priority of the rule. Link protection always has a lower priority than node or SRLG protection. Note The same attribute cannot be configured more than once on an interface. Note For IS-IS, TI-LFA node protection and SRLG protection can be configured on the interface or the instance.

TI-LFA has been successfully configured for segment routing.

Configuring TI-LFA for OSPF

This task describes how to enable per-prefix Topology Independent Loop-Free Alternate (TI-LFA) computation to converge traffic flows around link, node, and SRLG failures.

Note TI-LFA can be configured on the instance, area, or interface. When configured on the instance or area, all interfaces in the instance or area inherit the configuration.

Before you begin

Ensure that the following topology requirements are met:

- Routers are configured with OSPF.
- Segment routing for OSPF is configured. See [Enabling Segment Routing for OSPF Protocol, on page 314](#).

SUMMARY STEPS

1. **configure**
2. **router ospf** *process-name*
3. **area** *area-id*
4. **interface** *type interface-path-id*
5. **fast-reroute per-prefix**
6. **fast-reroute per-prefix ti-lfa**
7. **fast-reroute per-prefix tiebreaker** { **node-protecting** | **srlg-disjoint** } **index** *priority*

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.
Step 2	router ospf <i>process-name</i> Example: RP/0/RP0/CPU0:router(config)# router ospf 1	Enables OSPF routing for the specified routing process, and places the router in router configuration mode.
Step 3	area <i>area-id</i> Example: RP/0/RP0/CPU0:router(config-ospf)# area 1	Enters area configuration mode.
Step 4	interface <i>type interface-path-id</i> Example:	Enters interface configuration mode.

	Command or Action	Purpose
	RP/0/RP0/CPU0:router(config-ospf-ar)# interface GigabitEthernet0/0/2/1	
Step 5	fast-reroute per-prefix Example: RP/0/RP0/CPU0:router(config-ospf-ar-if)# fast-reroute per-prefix	Enables per-prefix fast reroute.
Step 6	fast-reroute per-prefix ti-lfa Example: RP/0/RP0/CPU0:router(config-ospf-ar-if)# fast-reroute per-prefix ti-lfa	Enables per-prefix TI-LFA fast reroute link protection.
Step 7	fast-reroute per-prefix tiebreaker {node-protecting srlg-disjoint} index priority Example: RP/0/RP0/CPU0:router(config-ospf-ar-if)# fast-reroute per-prefix tie-breaker srlg-disjoint index 100	Enables TI-LFA node or SRLG protection and specifies the tiebreaker priority. Valid <i>priority</i> values are from 1 to 255. The higher the <i>priority</i> value, the higher the priority of the rule. Link protection always has a lower priority than node or SRLG protection. Note The same attribute cannot be configured more than once on an interface.

TI-LFA has been successfully configured for segment routing.

TI-LFA Node and SRLG Protection: Examples

The following examples show the configuration of the tiebreaker priority for TI-LFA node and SRLG protection, and the behavior of post-convergence backup-path. These examples use OSPF, but the same configuration and behavior applies to IS-IS.

Example: Enable link-protecting and node-protecting TI-LFA

```
router ospf 1
 area 1
   interface GigabitEthernet0/0/2/1
     fast-reroute per-prefix
     fast-reroute per-prefix ti-lfa
     fast-reroute per-prefix tiebreaker node-protecting index 100
```

Both link-protecting and node-protecting TI-LFA backup paths will be computed. If the priority associated with the node-protecting tiebreaker is higher than any other tiebreakers, then node-protecting post-convergence backup paths will be selected, if it is available.

Example: Enable link-protecting and SRLG-protecting TI-LFA

```
router ospf 1
 area 1
   interface GigabitEthernet0/0/2/1
     fast-reroute per-prefix
     fast-reroute per-prefix ti-lfa
     fast-reroute per-prefix tiebreaker srlg-disjoint index 100
```

Both link-protecting and SRLG-protecting TI-LFA backup paths will be computed. If the priority associated with the SRLG-protecting tiebreaker is higher than any other tiebreakers, then SRLG-protecting post-convergence backup paths will be selected, if it is available.

Example: Enable link-protecting, node-protecting and SRLG-protecting TI-LFA

```
router ospf 1
 area 1
   interface GigabitEthernet0/0/2/1
     fast-reroute per-prefix
     fast-reroute per-prefix ti-lfa
     fast-reroute per-prefix tiebreaker node-protecting index 200
     fast-reroute per-prefix tiebreaker srlg-disjoint index 100
```

Link-protecting, node-protecting, and SRLG-protecting TI-LFA backup paths will be computed. If the priority associated with the node-protecting tiebreaker is highest from all tiebreakers, then node-protecting post-convergence backup paths will be selected, if it is available. If the node-protecting backup path is not available, SRLG-protecting post-convergence backup path will be used, if it is available.

Configuring Global Weighted SRLG Protection

A shared risk link group (SRLG) is a set of links sharing a common resource and thus shares the same risk of failure. The existing loop-free alternate (LFA) implementations in interior gateway protocols (IGPs) support SRLG protection. However, the existing implementation considers only the directly connected links while computing the backup path. Hence, SRLG protection may fail if a link that is not directly connected but shares the same SRLG is included while computing the backup path. Global weighted SRLG protection feature provides better path selection for the SRLG by associating a weight with the SRLG value and using the weights of the SRLG values while computing the backup path.

To support global weighted SRLG protection, you need information about SRLGs on all links in the area topology. For IS-IS, you can flood SRLGs for remote links or manually configuring SRLGs on remote links. For OSPF, the SRLG values are advertised in the Extended Link LSA when SRLG is configured for that interface and Segment Routing is enabled.

The administrative weight (cost) of the SRLG can be configured using the **admin-weight** command. This command can be applied for all SRLG (global), or for a specific (named) SRLG. The default (global) admin-weight value is 1 for IS-IS, and 1000 for OSPF.

Configuration Examples: Global Weighted SRLG Protection for IS-IS

There are three types of configurations that are supported for the global weighted SRLG protection feature for IS-IS:

- Local SRLG with global weighted SRLG protection

- Remote SRLG flooding
- Remote SRLG static provisioning

This example shows how to configure the local SRLG with global weighted SRLG protection feature.

```
RP/0/RP0/CPU0:router(config)# srlg
RP/0/RP0/CPU0:router(config-srlg)# interface TenGigE0/0/0/0
RP/0/RP0/CPU0:router(config-srlg-if)# name group1
RP/0/RP0/CPU0:router(config-srlg-if)# exit
RP/0/RP0/CPU0:router(config-srlg)# interface TenGigE0/0/0/1
RP/0/RP0/CPU0:router(config-srlg-if)# name group1

RP/0/RP0/CPU0:router(config-isis-if)# exit
RP/0/RP0/CPU0:router(config-isis)# srlg
RP/0/RP0/CPU0:router(config-isis-srlg)# name group1
RP/0/RP0/CPU0:router(config-isis-srlg-name)# admin-weight 5000
```

This example shows how to configure the global weighted SRLG protection feature with remote SRLG flooding. The configuration includes local and remote router configuration. On the local router, the global weighted SRLG protection is enabled by using the **fast-reroute per-prefix srlg-protection weighted-global** command. In the remote router configuration, you can control the SRLG value flooding by using the **advertise application lfa link-attributes srlg** command. You should also globally configure SRLG on the remote router.

The local router configuration for global weighted SRLG protection with remote SRLG flooding is as follows:

```
RP/0/RP0/CPU0:router(config)# router isis 1
RP/0/RP0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/RP0/CPU0:router(config-isis-af)# fast-reroute per-prefix srlg-protection weighted-global
RP/0/RP0/CPU0:router(config-isis-af)# fast-reroute per-prefix tiebreaker srlg-disjoint index
1
RP/0/RP0/CPU0:router(config-isis-af)# exit
RP/0/RP0/CPU0:router(config-isis)# interface TenGigE0/0/0/0
RP/0/RP0/CPU0:router(config-isis-if)# point-to-point
RP/0/RP0/CPU0:router(config-isis-if)# address-family ipv4 unicast
RP/0/RP0/CPU0:router(config-isis-if-af)# fast-reroute per-prefix
RP/0/RP0/CPU0:router(config-isis-if-af)# fast-reroute per-prefix ti-lfa
RP/0/RP0/CPU0:router(config-isis-if-af)# exit
RP/0/RP0/CPU0:router(config-isis-if)# exit
RP/0/RP0/CPU0:router(config-isis)# srlg
RP/0/RP0/CPU0:router(config-isis-srlg)# name group1
RP/0/RP0/CPU0:router(config-isis-srlg-name)# admin-weight 5000
```

The remote router configuration for global weighted SRLG protection with remote SRLG flooding is as follows:

```

RP/0/RP0/CPU0:router(config)# srlg
RP/0/RP0/CPU0:router(config-srlg)# interface TenGigE0/0/0/0
RP/0/RP0/CPU0:router(config-srlg-if)# name group1
RP/0/RP0/CPU0:router(config-srlg-if)# exit
RP/0/RP0/CPU0:router(config-srlg)# interface TenGigE0/0/0/1
RP/0/RP0/CPU0:router(config-srlg-if)# name group1
RP/0/RP0/CPU0:router(config-srlg-if)# exit
RP/0/RP0/CPU0:router(config-srlg)# name group1 value 100
RP/0/RP0/CPU0:router(config-srlg)# exit
RP/0/RP0/CPU0:router(config)# router isis 1
RP/0/RP0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/RP0/CPU0:router(config-isis-af)# advertise application lfa link-attributes srlg

```

This example shows configuring the global weighted SRLG protection feature with static provisioning of SRLG values for remote links. You should perform these configurations on the local router.

```

RP/0/RP0/CPU0:router(config)# srlg
RP/0/RP0/CPU0:router(config-srlg)# interface TenGigE0/0/0/0
RP/0/RP0/CPU0:router(config-srlg-if)# name group1
RP/0/RP0/CPU0:router(config-srlg-if)# exit
RP/0/RP0/CPU0:router(config-srlg)# interface TenGigE0/0/0/1
RP/0/RP0/CPU0:router(config-srlg-if)# name group1
RP/0/RP0/CPU0:router(config-srlg-if)# exit
RP/0/RP0/CPU0:router(config-srlg)# name group1 value 100
RP/0/RP0/CPU0:router(config-srlg)# exit
RP/0/RP0/CPU0:router(config)# router isis 1
RP/0/RP0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/RP0/CPU0:router(config-isis-af)# fast-reroute per-prefix srlg-protection weighted-global
RP/0/RP0/CPU0:router(config-isis-af)# fast-reroute per-prefix tiebreaker srlg-disjoint index
1
RP/0/RP0/CPU0:router(config-isis-af)# exit
RP/0/RP0/CPU0:router(config-isis)# interface TenGigE0/0/0/0
RP/0/RP0/CPU0:router(config-isis-if)# point-to-point
RP/0/RP0/CPU0:router(config-isis-if)# address-family ipv4 unicast
RP/0/RP0/CPU0:router(config-isis-if-af)# fast-reroute per-prefix
RP/0/RP0/CPU0:router(config-isis-if-af)# fast-reroute per-prefix ti-lfa
RP/0/RP0/CPU0:router(config-isis-if-af)# exit
RP/0/RP0/CPU0:router(config-isis-if)# exit
RP/0/RP0/CPU0:router(config-isis)# srlg
RP/0/RP0/CPU0:router(config-isis-srlg)# name group1
RP/0/RP0/CPU0:router(config-isis-srlg-name)# admin-weight 5000
RP/0/RP0/CPU0:router(config-isis-srlg-name)# static ipv4 address 10.0.4.1 next-hop ipv4
address 10.0.4.2
RP/0/RP0/CPU0:router(config-isis-srlg-name)# static ipv4 address 10.0.4.2 next-hop ipv4
address 10.0.4.1

```

Configuration Examples: Global Weighted SRLG Protection for OSPF

There are two types of configurations that are supported for the global weighted SRLG protection feature for OSPF:

- Local SRLG with global weighted SRLG protection
- Remote SRLG static provisioning

Note There is no specific configuration to enable SRLG flooding in OSPF. The SRLG values are advertised in the Extended Link LSA if SRLG is configured for that interface and Segment Routing is enabled.

This example shows how to configure the local SRLG with global weighted SRLG protection feature.

```
Router(config)# srlg
Router(config-srlg)# interface hundredGigE 0/0/0/0
Router(config-srlg-if)# name group1
Router(config-srlg-if)# exit
Router(config-srlg)# interface hundredGigE 0/0/0/1
Router(config-srlg-if)# name group1
Router(config-srlg-if)# exit
Router(config-srlg)# name group1 value 100
Router(config-srlg)# exit
Router(config)# router ospf 1
Router(config-ospf)# fast-reroute per-prefix srlg-protection weighted-global
Router(config-ospf)# fast-reroute per-prefix tiebreaker srlg-disjoint index 1
Router(config-ospf-ar)# interface hundredGigE 0/0/0/0
Router(config-ospf-ar-if)# fast-reroute per-prefix
Router(config-ospf-ar-if)# fast-reroute per-prefix ti-lfa
Router(config-ospf-ar-if)# exit
Router(config-ospf-ar)# exit
Router(config-ospf)# srlg
Router(config-ospf-srlg)# admin-weight 3000
Router(config-ospf-srlg)# name group1
Router(config-ospf-srlg-name)# admin-weight 5000
```

This example shows configuring the global weighted SRLG protection feature with static provisioning of SRLG values for remote links. You should perform these configurations on the remote router.

```
Router(config)# srlg
Router(config-srlg)# interface hundredGigE 0/0/0/0
Router(config-srlg-if)# name group1
Router(config-srlg-if)# exit
Router(config-srlg)# interface hundredGigE 0/0/0/1
Router(config-srlg-if)# name group1
Router(config-srlg-if)# exit
Router(config-srlg)# name group1 value 100
Router(config-srlg)# exit
Router(config)# router ospf 1
Router(config-ospf)# area 1
Router(config-ospf-ar)# interface hundredGigE 0/0/0/0
Router(config-ospf-ar-if)# exit
Router(config-ospf-ar)# exit
```

SR-MPLS over GRE as TI-LFA Backup Path

This feature allows the router (as ABR) to program a Generic Routing Encapsulation (GRE) tunnel as an outgoing interface for TI-LFA backup paths computed by the IGP in a Segment Routing network. Single-segment TI-LFA scenario is supported. In this scenario, the router pushes one extra label when programming the backup path.

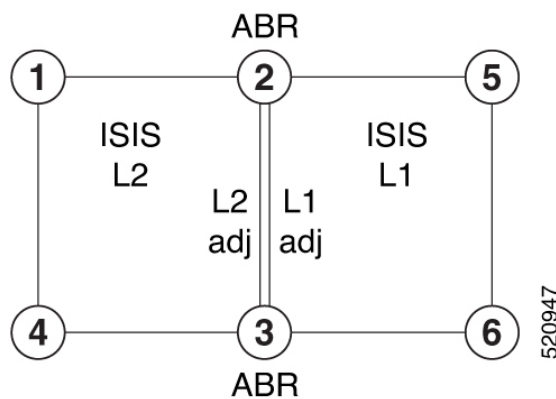

Note GRE is a tunneling protocol that provides a simple generic approach to transport packets of one protocol over another protocol by means of encapsulation. See the [Configuring GRE Tunnels](#) chapter in the *Interface and Hardware Component Configuration Guide for Cisco NCS 5500 Series Routers*.

Multi-Level Network Topology

The following example shows a multi-level network topology with interconnecting links between ABRs.

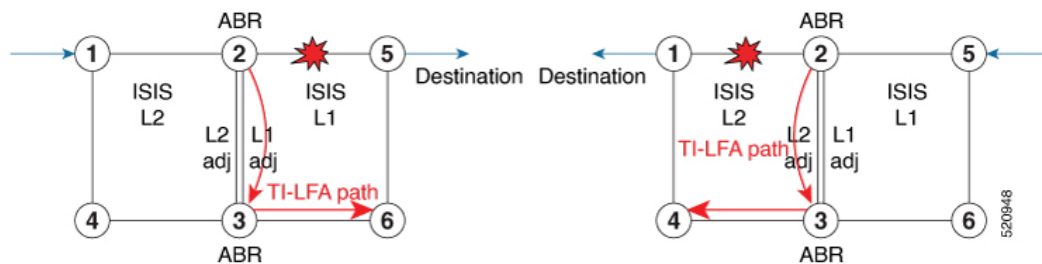

Note This could also be a multi-instance network topology.

Two links between ABR 2 and ABR 3 are required, one in each IS-IS level. These links provide protection in each direction and ensure that there is always an alternate path inside the IGP domain.

Note Alternatively, a single link with two logical sub-interfaces could be used between the ABRs.

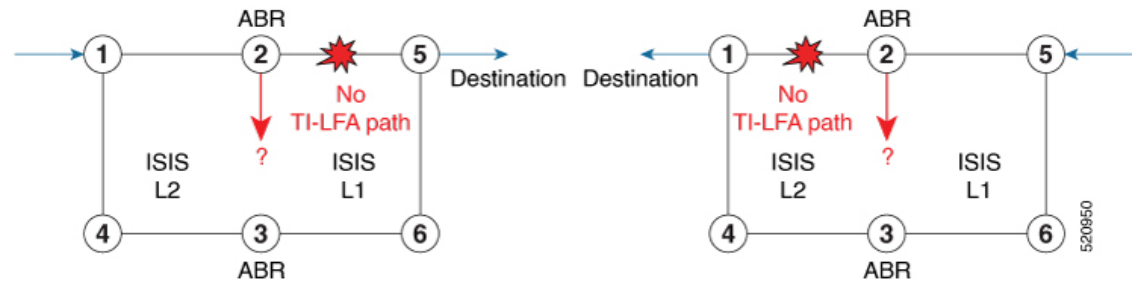

TI-LFA performs the backup path calculation inside the domain (process, level, or area) of the failed link.

For example, if the link between nodes 2 and 5 failed, the link between ABR 2 and 3 would create a TI-LFA path in L1 IS-IS level. If the link between nodes 1 and 2 failed, the link between ABR 2 and 3 would create a TI-LFA path in L2 IS-IS level.

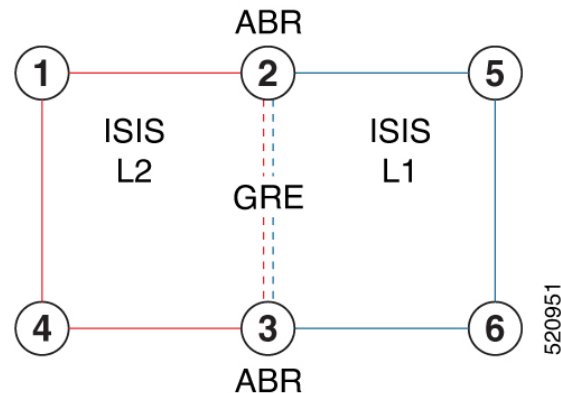

However, if the interconnecting link between ABRs are in the same Shared Risk Link Groups (SRLG) as other links inside the domain (for example, the link between Nodes 2 and 3 are in the same SRLG as link between Nodes 2 and 5), TI-LFA with local SRLG protection would not find an alternate path.

In cases where it is not feasible to provide interconnecting links between ABRs (for example, the ABR nodes might be in different locations with no connectivity options), TI-LFA will not be able to compute backup paths for all of the prefixes.

To address these issues, you can create a GRE tunnel in each domain, between the ABRs, which can be used as TI-LFA backup paths.

Now, if a link failure occurs in either IS-IS level (for example, between nodes 1 and 2 or between nodes 2 and 5), the path is protected by the GRE tunnel.

Backup Path for Link Failure Between Nodes 2 and 5

Traffic from node 1 is rerouted over the GRE tunnel TI-LFA backup path between ABR nodes 2 and 3.

Traffic flowing in the opposite direction, from node 5 to node 1, is simply routed over nodes 6-3-4 to node 1.

Limitations

The following behaviors and limitations apply to the router when a GRE tunnel is programmed as backup interface for TI-LFA:

- The MPLS label of a protected prefix must be the same in the primary and backup paths (SWAP scenario)

- Single-segment TI-LFA is supported. In this scenario, the router pushes one extra label when programming the backup path. The total label stack is 2, including the primary label and backup label.
- Double-segment (or more) TI-LFA is not supported. In this scenario, the router pushes two or more extra labels when programming the backup path.
- GRE tunnel as a primary or backup path for an SR policy with TI-LFA protection is not supported.

Example: SR-MPLS over GRE as TI-LFA Backup Path

The examples in this section use the following network topology:

Configurations Without Interconnecting ABR Links

The following sample configurations show OSPF configurations for nodes 2, 3 and 5. Nodes 2 and 3 are ABRs between Area 0 and Area 100. There is no connection between the ABRs.

Configuration on ABR 2 for Area 0 and Area 100

```
router ospf 100
router-id 2.2.2.2
segment-routing mpls
segment-routing forwarding mpls
fast-reroute per-prefix
fast-reroute per-prefix ti-lfa enable
segment-routing sr-prefer
area 0
interface Loopback0
prefix-sid index 2
!
interface TenGigE0/0/1/10
network point-to-point
!
area 100
interface TenGigE0/0/1/11

```

GRE Tunnel Configuration

The following examples show how to configure GRE tunnels between the ABRs in each area to provide TI-LFA backup paths for the Segment Routing network.

GRE BLU is configured in Area 0 using Loopback50 (on ABR2) and Loopback 60 (on ABR3). These loopbacks are advertised in Area 100:

Figure 50: GRE BLU

GRE RED is configured in Area 100 using Loopback55 (on ABR2) and Loopback 66 (on ABR3). These loopbacks are advertised in Area 0:

Figure 51: GRE RED

Configuration on ABR 2

```
interface Loopback0
  ipv4 address 2.2.2.2 255.255.255.255
!
interface Loopback50
  description Lo for GRE BLU
  ipv4 address 50.0.0.50 255.255.255.0
!
interface Loopback55
```

```

description Lo for GRE RED
ipv4 address 55.55.55.55 255.255.255.255
!
interface tunnel-ip5060
description GRE virtual link for Area 0 BLU
ipv4 address 66.3.2.2 255.255.255.0
tunnel source Loopback50
tunnel destination 60.0.0.60
!
interface tunnel-ip5566
description GRE virtual link for Area 100 RED
ipv4 address 100.3.2.2 255.255.255.0
tunnel source Loopback55
tunnel destination 66.66.66.66

router ospf 100
router-id 2.2.2.2
segment-routing mpls
segment-routing forwarding mpls
fast-reroute per-prefix
fast-reroute per-prefix ti-lfa enable
segment-routing sr-prefer
area 0
interface Loopback0
prefix-sid index 2
!
interface Loopback55
passive enable
!
interface tunnel-ip5060
cost 1000
!
interface TenGigE0/0/1/10
network point-to-point
!
!
area 100
interface Loopback50
passive enable
!
interface tunnel-ip5566
cost 1000
!
interface TenGigE0/0/1/11
network point-to-point

```

Note In the above configuration, GRE tunnel-ip5060 belongs to area 0, but its source and destination addresses are advertised in area 100. This ensures disjointness between the GRE tunnel and the links in area 0 that it protects. The same applies to GRE tunnel-ip5566 which belongs to area 100 and its source and destination addresses are advertised in area 0.

A high cost is applied to the GRE tunnel interfaces so that they are used only as a backup path.

Configuration on ABR 3

```

interface Loopback0
ipv4 address 3.3.3.3 255.255.255.255
!
interface Loopback60
description Lo for GRE BLU

```

```

    ipv4 address 60.0.0.60 255.255.255.0
    !
interface Loopback66
  description Lo for GRE RED
  ipv4 address 66.66.66.66 255.255.255.255
  !
interface tunnel-ip5060
  description GRE virtual link for Area 0 BLU
  ipv4 address 66.3.2.3 255.255.255.0
  tunnel source Loopback60
  tunnel destination 50.0.0.50
  !
interface tunnel-ip5566
  description GRE virtual link for Area 100 RED
  ipv4 address 100.3.2.3 255.255.255.0
  tunnel source Loopback66
  tunnel destination 55.55.55.55

router ospf 100
  router-id 3.3.3.3
  segment-routing mpls
  segment-routing forwarding mpls
  fast-reroute per-prefix
  fast-reroute per-prefix ti-lfa enable
  segment-routing sr-prefer
  area 0
    interface Loopback0
    prefix-sid index 3
    !
    interface TenGigE0/0/0/9
    network point-to-point
    !
    interface Loopback66
    passive enable
    !
    interface tunnel-ip5060
    cost 1000
    !
  area 100
    interface TenGigE0/0/0/3
    network point-to-point
    !
    interface Loopback60
    passive enable
    !
    interface tunnel-ip5566
    cost 1000

```

Note In the above configuration, GRE tunnel-ip5060 belongs to area 0, but its source and destination addresses are advertised in area 100. This ensures disjointness between the GRE tunnel and the links in area 0 that it protects. The same applies to GRE tunnel-ip5566 which belongs to area 100 and its source and destination addresses are advertised in area 0.

A high cost is applied to the GRE tunnel interfaces so that they are used only as a backup path.

TI-LFA Fast Reroute Coverage on Node 5 After GRE Tunnel Configuration

The following output shows that this configuration provides 100% TI-LFA fast reroute coverage on Node 5:

```
RP/0/RSP0/CPU0:Node5# show ip ospf fast-reroute prefix-summary
Load for five secs: 5%/1%; one minute: 4%; five minutes: 4%
Time source is NTP, 11:20:31.743 UTC Fri Jul 19 2019
      OSPF Router with ID (5.5.5.5) (Process ID 100)
      Base Topology (MTID 0)

Area 100:
Interface      Protected   Primary paths   Protected paths   Percent protected
                Yes        All  High  Low   All  High  Low   All  High  Low

Te0/0/27        Yes         9    6    3     9    6    3    100% 100% 100%
Te0/0/26        Yes        11    6    5    11    6    5    100% 100% 100%

Area total:                20    12    8    20    12    8    100% 100% 100%

Process total:              20    12    8    20    12    8    100% 100% 100%
```

Traffic Flow with GRE Tunnel as TI-LFA Backup

With a link failure between Node 1 and ABR 2, traffic flowing from Node 1 to Node 5 is simply routed through Nodes 4-3-6 to Node 5.

With GRE tunnel as TI-LFA backup, traffic flowing from Node 5 to Node 1 will be encapsulated at ABR2 and routing over the GRE tunnel.

With a link failure between Node 5 and ABR 2, traffic flowing from Node 5 to Node 1 is simply routed through Nodes 6-3-4 to Node 1.

With GRE tunnel as TI-LFA backup, traffic flowing from Node 1 to Node 5 will be encapsulated at ABR2 and routing over the GRE tunnel.

Unlabeled IPv6 Traffic Protection

Table 140: Feature History Table

Feature Name	Release Information	Feature Description
IPv6 Unlabeled Traffic protection with TI-LFA	Release 7.3.1	<p>TI-LFA provides protection for SR-labeled traffic (IPv4 and IPv6 prefixes associated with a prefix SID) and for other unlabeled IPv4 prefixes.</p> <p>This feature introduces support for protecting unlabeled IPv6 prefixes.</p>

This feature introduces support for protecting unlabeled IPv6 prefixes. IS-IS can calculate and install TI-LFA backup paths for unlabeled IPv6 prefixes.

By default, all IPv6 prefixes without a prefix SID are eligible to have a dynamic local label assigned to them. This behavior provides the greatest degree of protection, but in some deployments, it may consume too many MPLS labels. This feature provides the ability to disable local label allocation or to restrict local label allocation to a subset of prefixes based on a prefix list or route policy.

Use the following commands in IS-IS IPv6 address family configuration mode to specify the local label allocation behavior:

- **segment-routing mpls unlabeled protection disable**—Disable local label allocation.
- **segment-routing mpls unlabeled protection prefix-list *sample_prefix_list***—Restricts local label allocation to the prefixes based on a prefix list.
- **segment-routing mpls unlabeled protection route-policy *sample_rpl***—Restricts local label allocation to the prefixes based a route policy.

Configuration

The following example shows how to disable local label allocation:

```
Router(config)# router isis 1
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# segment-routing mpls unlabeled protection disable
Router(config-isis-af)#
```

The following example shows how to enable local label allocation for prefixes in a prefix list:

```
Router(config)# ipv6 prefix-list sample_prefix_list
Router(config-ipv6-pfx)# 10 permit 333::333:0:0/96 ge 112
Router(config-ipv6-pfx)# 20 permit 666::666:0:0/96 ge 112
Router(config-ipv6-pfx)# exit
Router(config)#

Router(config)# router isis 1
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# segment-routing mpls unlabeled protection prefix-list
sample_prefix_list
Router(config-isis-af)# commit
```

The following example shows how to enable local label allocation for prefixes in a route policy:

```
Router(config)# prefix-set sample_prefix_set
Router(config-pfx)# 333::333:1:0/112
Router(config-pfx)# end-set
Router(config)# route-policy sample_rpl
Router(config-rpl)# if destination in sample_prefix_set then
Router(config-rpl-if)# pass
Router(config-rpl-if)# else drop endif
Router(config-rpl)# end-policy
Router(config)#

Router(config)# router isis 1
Router(config-isis)# address-family ipv6 unicast
Router(config-isis-af)# segment-routing mpls unlabeled protection route-policy sample_rpl
Router(config-isis-af)# commit
```

Verification

In the following **show** command output, 24103 is the local label used to program the prefix with a TI-LFA backup.

```

Router# show isis ipv6 unicast route 333::333:1:0/112 detail

CHAPTER 17

Configure Segment Routing Microloop Avoidance

The Segment Routing Microloop Avoidance feature enables link-state routing protocols, such as IS-IS and OSPF, to prevent or avoid microloops during network convergence after a topology change.

- [About Segment Routing Microloop Avoidance, on page 809](#)
- [Usage Guidelines and Limitations, on page 812](#)
- [Configure Segment Routing Microloop Avoidance for IS-IS, on page 812](#)
- [Configure Segment Routing Microloop Avoidance for OSPF, on page 818](#)

About Segment Routing Microloop Avoidance

IP hop-by-hop routing may induce microloops (uLoops) at any topology transition. Microloops are a day-one IP challenge. Microloops are brief packet loops that occur in the network following a topology change:

- Link down or up (remote or local)
- Metric increase or decrease (remote or local)
- OSPFv2 only — Single-node cost-out: This occurs when a Router LSA (Link State Advertisement) is received with all non-stub links set to the maximum metric (link cost of 65535). It indicates that the node is being taken out of the routing path by setting the links to an unreachable state.
- OSPFv2 only — Single-node cost-in: This occurs when a Router LSA is received that brings the node back into the routing path by changing at least one non-stub link from the maximum metric mode.

Microloops are caused by the non-simultaneous convergence of different nodes in the network. If a node converges and sends traffic to a neighbor node that has not converged yet, traffic may be looped between these two nodes, resulting in packet loss, jitter, and out-of-order packets.

Segment Routing can be used to resolve the microloop problem. A router with the Segment Routing Microloop Avoidance feature detects if microloops are possible for a destination on the post-convergence path following a topology change associated with a remote link event.

If a node determines that a microloop could occur on the new topology, the IGP computes a microloop-avoidant path by updating the forwarding table and temporarily (based on a RIB update delay timer) installing the SID-list imposition entries associated with the microloop-avoidant path for the destination. Traffic is steered to that destination loop-free.

After the RIB update delay timer expires, IGP updates the forwarding table and removes the microloop-avoidant SID list. Traffic now natively follows the post-convergence path.

SR microloop avoidance is a local behavior and therefore not all nodes need to implement it to get the benefits.

In the topology below, microloops can occur after the failure of the link between Node6 and Node7, or if Node6 costs out.

At steady state, Node1 sends traffic to node 6 (16006) via Node7. Node 7 is configured with TI-LFA to protect traffic to Node6.

TI-LFA on Node7 pre-computes a backup path for traffic to Node6 (prefix SID 16006) that will be activated if the link between Node7 and Node6 goes down. In this network, the backup path would steer traffic toward Node5 (prefix SID 16005) and then via link between Node5 and Node6 (adj-SID 24056). All nodes are notified of the topology change due to the link failure.

However, if nodes along the path do not converge at the same time, microloops can be introduced. For example, if Node2 converged before Node3, Node3 would send traffic back to Node2 as the shortest IGP path to Node6. The traffic between Node2 and Node3 creates a microloop.

Node1 updates the forwarding table and installs the SID-list imposition entries for those destinations with possible microloops, such as Node6. All nodes converge and update their forwarding tables, using SID lists where needed.

Segment Routing Configuration Guide for Cisco NCS 5500 Series Routers, IOS XR Release 24.1.x, 24.2.x, 24.3.x, 24.4.x

Usage Guidelines and Limitations

IGP directly programs a microloop-avoidant path requiring 3 or fewer labels, including the label of the destination prefix.

The platform does not support programming of microloop-avoidant paths requiring more than 3 labels.

Note

Starting with Cisco IOS XR Release 24.4.1, the maximum label stack supported with uloop is 8. Before this release, the maximum was 3.

Configure Segment Routing Microloop Avoidance for IS-IS

This task describes how to enable Segment Routing Microloop Avoidance and set the Routing Information Base (RIB) update delay value for IS-IS.

Before you begin

Ensure that the following topology requirements are met:

- Routers are configured with IS-IS.
- Segment routing for IS-IS is configured. See [Enabling Segment Routing for IS-IS Protocol](#), on page 283.

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.

	Command or Action	Purpose
Step 2	router isis <i>instance-id</i> Example: RP/0/RP0/CPU0:router(config)# router isis 1	Enables IS-IS routing for the specified routing instance, and places the router in router configuration mode. You can change the level of routing to be performed by a particular routing instance by using the is-type router configuration command.
Step 3	address-family ipv4 [unicast] Example: RP/0/RP0/CPU0:router(config-isis)# address-family ipv4 unicast	Specifies the IPv4 address family and enters router address family configuration mode.
Step 4	microloop avoidance segment-routing Example: RP/0/RP0/CPU0:router(config-isis-af)# microloop avoidance segment-routing	Enables Segment Routing Microloop Avoidance.
Step 5	microloop avoidance rib-update-delay <i>delay-time</i> Example: RP/0/RP0/CPU0:router(config-isis-af)# microloop avoidance rib-update-delay 3000	Specifies the amount of time the node uses the microloop avoidance policy before updating its forwarding table. The <i>delay-time</i> is in milliseconds. The range is from 1-60000. The default value is 5000.

Microloop Avoidance for IS-IS with Per-Prefix Filtering

Table 141: Feature History Table

Feature Name	Release Information	Feature Description
Microloop Avoidance for IS-IS with Per-Prefix Filtering	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>Currently, when SR Microloop Avoidance for IS-IS is enabled, it applies to all prefixes.</p> <p>This feature allows you to selectively allow or deny specific IPv4 or IPv6 prefixes or routes that may cause microloops, which allows for efficient use of hardware resources and ensures overall network stability.</p> <p>This feature introduces these changes:</p> <p>CLI:</p> <ul style="list-style-type: none"> The microloop avoidance segment-routing command is modified with the new route-policy name option for IS-IS. <p>YANG Data Model:</p> <ul style="list-style-type: none"> This feature extends the native <code>Cisco-IOS-XR-um-router-isis-cfg.yang</code> model (see GitHub, YANG Data Models Navigator)

Per-prefix filtering is an enhancement to the existing IOS XR IS-IS SR microloop avoidance feature. Per-prefix filtering allows network administrators to specify a subset of IP prefixes (v4 and v6) to which micro loop avoidance mechanisms can be applied.

Note Per-prefix filtering is available only for SR microloop avoidance and is not supported for local microloop avoidance.

When SR microloop avoidance is enabled, it applies to all prefixes. However, it might be important to preserve hardware resources for certain prefixes. In such a cases, it is beneficial to use SR microloop avoidance per-prefix filtering to allow only those prefixes without such limitations to be subjected to SR microloop avoidance. Per-prefix filtering provides a level of granularity that allows you to apply microloop avoidance only for the prefixes that require it, and to avoid consumption of resources that might otherwise be exhausted.

SR Microloop avoidance per-prefix filtering is configured under the IPv4 or IPv6 address family (AF). It will only be used for filtering in that specific AF. Filtering is applied to prefixes from all algorithms (Algo 0, Flexible Algorithms 128 to 255).

- For SR MLPS – If a prefix has multiple Flexible Algorithm paths and the filtering configuration permits SR microloop avoidance for that prefix, then SR microloop avoidance is allowed for "all" Flexible Algorithm paths associated with that prefix. On the other hand, if a prefix has multiple Flexible Algorithm

paths and the filtering configuration prohibits SR microloop avoidance for that prefix, then microloop avoidance is disabled for all Flexible Algorithm paths associated with that prefix.

- For SRv6 – Regardless of the association of the prefix to the algorithm, filtering is applied solely on a per-prefix basis.

SR microloop avoidance per-prefix filtering uses route policies to identify the prefixes subjected to microloop avoidance. When SR microloop avoidance per-prefix filtering is enabled, the prefixes are verified against the route policy as follows:

- If the route policy permits the prefixes (pass), SR microloop avoidance computes the explicit path for the prefixes.
- If the route policy prevents the prefixes from being considered for SR microloop avoidance (drop), it is treated as if there is no explicit path defined for that prefix. The network will rely on the standard routing mechanisms to determine the path for those prefixes after convergence.

Usage Guidelines and Limitations

- SR microloop avoidance per-prefix filtering is supported only for IS-IS.
- A route policy must be defined before it can be attached to the SR microloop avoidance configuration.
- Inline modification of a route policy is not supported. Once a route policy is defined and attached to the SR microloop avoidance configuration, it cannot be modified or removed until the route policy is removed from the SR microloop avoidance configuration.
- The following match types are supported for route policies used for SR microloop avoidance per-prefix filtering:
 - Destination-based match ([prefix](#) or [prefix set](#))
 - [Tag-based match](#)

Example: Configuration

1. Identify the prefixes to be filtered by defining a prefix set or applying a tags to prefixes.

- Prefix Set

```
prefix-set pset-sample-ipv4
 2.3.3.3/32,
 2.4.4.4/32
 2.5.5.5/32
end-set

prefix-set pset-sample-ipv6
 2001:0:0:1::/64,
 2001:0:0:2::/64,
 2001:0:0:2::/64,
 2001:0:0:2::/64
end-set
```

- Tag

```
router isis 1
 interface Loopback1
  address-family ipv4 unicast
```

```

tag 7
prefix-sid index 7

```

2. Create a route policy for the destinations (prefix set) or tagged prefixes.

• Destination

```

route-policy BAR
  if destination in pset-sample-ipv4 then
    pass
  else
    drop
  endif
end-policy

route-policy BAR2
  if destination in (2.3.3.3/32, 2.4.4.4/32) then
    pass
  else
    drop
  endif
end-policy

route-policy BAR3
  if destination in pset-sample-ipv6 then
    drop
  else
    pass
  endif
end-policy

```

• Tag

```

route-policy FOO
  if tag eq 7 then
    drop
  endif
  pass
end-policy

route-policy FOO2
  if tag eq 7 then
    pass
  else
    drop
  endif
end-policy

```

3. Use the **microloop avoidance segment-routing route-policy** *name* command to attach the route policy to the SR Microloop Avoidance configuration.

```

router isis 1
address-family ipv4 unicast
  microloop avoidance segment-routing route-policy FOO2
!
!
address-family ipv6 unicast
  microloop avoidance segment-routing route-policy BAR3

```

Verify

Use the **show isis** command to verify that SR microloop avoidance is enabled under the AF and the route policy is applied for per-prefix filtering.

Router# **show isis**

```

    GigabitEthernet0/2/0/6 is running actively (active in configuration)
    GigabitEthernet0/2/0/7 is running actively (active in configuration)
```

Configure Segment Routing Microloop Avoidance for OSPF

Table 142: Feature History Table

Feature Name	Release Information	Feature Description
Microloop Avoidance for OSPFv2 Single-Node Cost-in and Single-Node Cost-out Events	Release 7.11.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5700 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>Microloops disrupt network connectivity and cause suboptimal routing decisions. This feature avoids microloops by implementing the Greedy walk algorithm, which is similar to TI-LFA computation.</p> <p>This feature extends the microloop avoidance support for additional scenarios in OSPFv2, such as cost-in and cost-out events.</p> <p>This feature introduces these changes:</p> <p>YANG Data Model:</p> <ul style="list-style-type: none">• <code>Cisco-IOS-XR-ipv4-ospf-oper.yang</code> <p>(see GitHub, YANG Data Models Navigator)</p>

This task describes how to enable Segment Routing Microloop Avoidance and set the Routing Information Base (RIB) update delay value for OSPF.

Before you begin

Ensure that the following topology requirements are met:

- Routers are configured with OSPF.
- Segment routing for OSPF is configured. See [Enabling Segment Routing for OSPF Protocol](#), on page 314.

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.
Step 2	router ospf <i>process-name</i> Example: RP/0/RP0/CPU0:router(config)# router ospf 1	Enables OSPF routing for the specified routing process, and places the router in router configuration mode.
Step 3	microloop avoidance segment-routing Example: RP/0/RP0/CPU0:router(config-ospf)# microloop avoidance segment-routing	Enables Segment Routing Microloop Avoidance.
Step 4	microloop avoidance rib-update-delay <i>delay-time</i> Example: RP/0/RP0/CPU0:router(config-ospf)# microloop avoidance rib-update-delay 3000	Specifies the amount of time the node uses the microloop avoidance path before updating its forwarding table. The <i>delay-time</i> is in milliseconds. The range is from 1-60000. The default value is 5000.

CHAPTER 18

Configure Segment Routing Mapping Server

The mapping server is a key component of the interworking between LDP and segment routing. It enables SR-capable nodes to interwork with LDP nodes. The mapping server advertises Prefix-to-SID mappings in IGP on behalf of other non-SR-capable nodes.

- [Segment Routing Mapping Server, on page 821](#)
- [Segment Routing and LDP Interoperability, on page 823](#)
- [Configuring Mapping Server, on page 826](#)
- [Enable Mapping Advertisement, on page 828](#)
- [Enable Mapping Client, on page 830](#)

Segment Routing Mapping Server

The mapping server functionality in Cisco IOS XR segment routing centrally assigns prefix-SIDs for some or all of the known prefixes. A router must be able to act as a mapping server, a mapping client, or both.

- A router that acts as a mapping server allows the user to configure SID mapping entries to specify the prefix-SIDs for some or all prefixes. This creates the local SID-mapping policy. The local SID-mapping policy contains non-overlapping SID-mapping entries. The mapping server advertises the local SID-mapping policy to the mapping clients.
- A router that acts as a mapping client receives and parses remotely received SIDs from the mapping server to create remote SID-mapping entries.
- A router that acts as a mapping server and mapping client uses the remotely learnt and locally configured mapping entries to construct the non-overlapping consistent active mapping policy. IGP instance uses the active mapping policy to calculate the prefix-SIDs of some or all prefixes.

The mapping server automatically manages the insertions and deletions of mapping entries to always yield an active mapping policy that contains non-overlapping consistent SID-mapping entries.

- Locally configured mapping entries must not overlap each other.
- The mapping server takes the locally configured mapping policy, as well as remotely learned mapping entries from a particular IGP instance, as input, and selects a single mapping entry among overlapping mapping entries according to the preference rules for that IGP instance. The result is an active mapping policy that consists of non-overlapping consistent mapping entries.
- At steady state, all routers, at least in the same area or level, must have identical active mapping policies.

Usage Guidelines and Restrictions

Table 143: Feature History Table

Feature Name	Release Information	Feature Description
Advertisement of SID-Mapping Entries Between IS-IS Levels	Release 7.3.1	<p>The Segment Routing Mapping Server (SRMS) is a key component of the interworking between LDP and segment routing, enabling SR-capable nodes to interwork with LDP nodes.</p> <p>This release introduces support for SRMS SID-mapping entries to be advertised between IS-IS levels (for example, from Level 1 to Level 2-only and from Level 2 to Level 1), where previously, the mappings were advertised only within the same IS-IS level, but not between IS-IS levels. This feature simplifies and centralizes the deployment of SRMS by removing the requirement of having a mapping server for each IS-IS area.</p>

- The position of the mapping server in the network is not important. However, since the mapping advertisements are distributed in IGP using the regular IGP advertisement mechanism, the mapping server needs an IGP adjacency to the network.
- The role of the mapping server is crucial. For redundancy purposes, you should configure multiple mapping servers in the networks.
- The mapping server functionality supports the advertisement of SID-mapping entries between IS-IS levels (for example, from L1 to L2-only and from L2 to L1). A mapping server is not required for each IS-IS area.

For example, mapping entries learned from IS-IS Type Level-1 (intra-area) routers can be used to calculate prefix-SIDs for prefixes learned or advertised by IS-IS Type Level-2-only (backbone) routers.

Use the **domain-wide** option to advertise the prefix-SID mappings between Level 1 and Level 2 IS-IS routers.

- The mapping server functionality does not support a scenario where SID-mapping entries learned through one IS-IS instance are used by another IS-IS instance to determine the prefix-SID of a prefix. For example, mapping entries learnt from remote routers by 'router isis 1' cannot be used to calculate prefix-SIDs for prefixes learnt, advertised, or downloaded to FIB by 'router isis 2'. A mapping server is required for each IS-IS instance.
- Segment Routing Mapping Server does not support Virtual Routing and Forwarding (VRF) currently.

Segment Routing and LDP Interoperability

IGP provides mechanisms through which segment routing (SR) interoperate with label distribution protocol (LDP). The control plane of segment routing co-exists with LDP.

The Segment Routing Mapping Server (SRMS) functionality in SR is used to advertise SIDs for destinations, in the LDP part of the network, that do not support SR. SRMS maintains and advertises segment identifier (SID) mapping entries for such destinations. IGP propagates the SRMS mapping entries and interacts with SRMS to determine the SID value when programming the forwarding plane. IGP installs prefixes and corresponding labels, into routing information base (RIB), that are used to program the forwarding information base (FIB).

Example: Segment Routing LDP Interoperability

Consider a network with a mix of segment routing (SR) and label distribution protocol (LDP). A continuous multiprotocol label switching (MPLS) LSP (Labeled Switched Path) can be established by facilitating interoperability. One or more nodes in the SR domain act as segment routing mapping server (SRMS). SRMS advertises SID mappings on behalf of non-SR capable nodes. Each SR-capable node learns about SID assigned to non-SR capable nodes without explicitly configuring individual nodes.

Consider a network as shown in the following figure. This network is a mix of both LDP and SR-capable nodes.

In this mixed network:

- Nodes PE1, P2, P3, and P4 are SR-capable
- Nodes P4, P5, P6, and PE7 are LDP-capable
- Nodes PE1, P2, P3, and P4 are configured with segment routing global block (SRGB) range of 16000 to 23999
- Nodes PE1, P2, P3, and P4 are configured with node segments of 16001, 16002, 16003, and 16004 respectively

A service flow must be established from PE1 to PE3 over a continuous MPLS tunnel. This requires SR and LDP to interoperate.

LDP-to-SR Traffic Direction

The traffic flow in the LDP-to-SR direction involves the following:

1. PE7 learns a service route with service label 40001 and BGP nhop PE1.
2. PE7 has an LDP label binding (24010) from the nhop P6 for the FEC PE1. PE7 forwards the packet to P6.
3. P6 has an LDP label binding (24003) from its nhop P5 for the FEC PE1. P6 forwards the packet to P5.
4. P5 has an LDP label binding (24008) from its nhop P4 for the FEC PE1. P5 forwards the packet to P4.
5. P4 does not have an LDP binding from its nhop P3 for the FEC PE1. But P4 has an SR node segment to the IGP route PE1. P4 forwards the packet to P3 and swaps its local LDP label (24008) for FEC PE1 by the equivalent node segment 16001. This process is called label merging.
6. P3 pops 16001, assuming PE1 has advertised its node segment 16001 with the penultimate-pop flag set and forwards to PE1.
7. PE1 receives the packet and processes the service label.

The end-to-end MPLS LSP is established from an LDP LSP from PE7 to P4 and the related node segment from P4 to PE1.

SR-to-LDP Traffic Direction

Suppose that the operator configures P2 as a Segment Routing Mapping Server (SRMS) and advertises the mappings (1.1.1.7, 16007 for PE7). Because PE7 is non-SR capable, the operator configures that mapping policy at the SRMS; the SRMS advertises the mapping on behalf of the non-SR capable nodes. Multiple SRMS servers can be provisioned in a network for redundancy. The mapping server advertisements are only understood by the SR-capable nodes. The SR-capable routers install the related node segments in the MPLS data plane in exactly the same manner as if node segments were advertised by the nodes themselves.

The traffic flow in the SR to LDP direction involves the following:

1. PE1 learns a service route with service label 50010 and BGP nhop PE7.
2. PE1 has an SR label binding (16007) learned from the SRMS (P2) for PE7.
3. PE1 installs the node segment 16007 following the IGP shortest-path with nhop P3.
4. P3 swaps 16007 for 16007 and forwards to P4.
5. The nhop for P4 for the IGP route PE7 is non-SR capable, since P5 does not advertise the SR capability. However, P4 has an LDP label binding from that nhop for the same FEC (for example, LDP label 24009). P4 would then swap 16007 for 24009 and forward to P5. We refer to this process as label merging.
6. P5 swaps this label with the LDP label received from P6 (for example, LDP label 24006) and forwards to P6.
7. P6 pops the LDP label and forwards to PE7.
8. PE7 receives the packet and processes the service label.

The end-to-end MPLS LSP is established from an SR node segment from PE1 to P4 and an LDP LSP from P4 to PE7.

Observe that the capabilities provided by the SRMS are only required in the SR-to-LDP direction.

Configuring Mapping Server

Perform these tasks to configure the mapping server and to add prefix-SID mapping entries in the active local mapping policy.

SUMMARY STEPS

1. **configure**
2. **segment-routing**
3. **mapping-server**
4. **prefix-sid-map**
5. **address-family ipv4 | ipv6**
6. *ip-address/prefix-length first-SID-value range range*
7. Use the **commit** or **end** command.

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	configure Example: RP/0/RP0/CPU0:router# configure	Enters global configuration mode.
Step 2	segment-routing Example: RP/0/RP0/CPU0:router(config)# segment-routing	Enables segment routing.
Step 3	mapping-server Example: RP/0/RP0/CPU0:router(config-sr)# mapping-server	Enables mapping server configuration mode.
Step 4	prefix-sid-map Example: RP/0/RP0/CPU0:router(config-sr-ms)# prefix-sid-map	Enables prefix-SID mapping configuration mode. Note Two-way prefix SID can be enabled directly under IS-IS or through a mapping server.
Step 5	address-family ipv4 ipv6 Example: This example shows the address-family for ipv4:	Configures address-family for IS-IS.

	Command or Action	Purpose
	<pre>RP/0/RP0/CPU0:router(config-sr-ms-map) # address-family ipv4</pre> <p>This example shows the address-family for ipv6:</p> <pre>RP/0/RP0/CPU0:router(config-sr-ms-map) # address-family ipv6</pre>	
Step 6	<p><i>ip-address/prefix-length first-SID-value range range</i></p> <p>Example:</p> <pre>RP/0/RP0/CPU0:router(config-sr-ms-map-af) # 10.1.1.1/32 10 range 200 RP/0/RP0/CPU0:router(config-sr-ms-map-af) # 20.1.0.0/16 400 range 300</pre>	<p>Adds SID-mapping entries in the active local mapping policy. In the configured example:</p> <ul style="list-style-type: none"> Prefix 10.1.1.1/32 is assigned prefix-SID 10, prefix 10.1.1.2/32 is assigned prefix-SID 11,..., prefix 10.1.1.199/32 is assigned prefix-SID 200 Prefix 20.1.0.0/16 is assigned prefix-SID 400, prefix 20.2.0.0/16 is assigned prefix-SID 401,..., and so on.
Step 7	Use the commit or end command.	<p>commit —Saves the configuration changes and remains within the configuration session.</p> <p>end —Prompts user to take one of these actions:</p> <ul style="list-style-type: none"> Yes — Saves configuration changes and exits the configuration session. No —Exits the configuration session without committing the configuration changes. Cancel —Remains in the configuration session, without committing the configuration changes.

Verify information about the locally configured prefix-to-SID mappings.

Note Specify the address family for IS-IS.

```
RP/0/RP0/CPU0:router# show segment-routing mapping-server prefix-sid-map ipv4
Prefix          SID Index  Range  Flags
20.1.1.0/24      400        300
10.1.1.1/32      10         200
```

Number of mapping entries: 2

```
RP/0/RP0/CPU0:router# show segment-routing mapping-server prefix-sid-map ipv4 detail
Prefix
20.1.1.0/24
  SID Index:      400
  Range:          300
  Last Prefix:    20.2.44.0/24
  Last SID Index: 699
  Flags:
10.1.1.1/32
```

```

SID Index:      10
Range:          200
Last Prefix:    10.1.1.200/32
Last SID Index: 209
Flags:

```

Number of mapping entries: 2

What to do next

Enable the advertisement of the local SID-mapping policy in the IGP.

Enable Mapping Advertisement

In addition to configuring the static mapping policy, you must enable the advertisement of the mappings in the IGP.

Perform these steps to enable the IGP to advertise the locally configured prefix-SID mapping.

Configure Mapping Advertisement for IS-IS

SUMMARY STEPS

1. **router isis** *instance-id*
2. **address-family** { **ipv4** | **ipv6** } [**unicast**]
3. **segment-routing prefix-sid-map advertise-local** [**domain-wide**]
4. Use the **commit** or **end** command.

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	router isis <i>instance-id</i> Example: RP/0/RP0/CPU0:router(config) # router isis 1	Enables IS-IS routing for the specified routing instance, and places the router in router configuration mode. <ul style="list-style-type: none"> You can change the level of routing to be performed by a particular routing instance by using the is-type router configuration command.
Step 2	address-family { ipv4 ipv6 } [unicast] Example: The following is an example for ipv4 address family: RP/0/RP0/CPU0:router(config-isis) # address-family ipv4 unicast	Specifies the IPv4 or IPv6 address family, and enters router address family configuration mode.

	Command or Action	Purpose
Step 3	segment-routing prefix-sid-map advertise-local [domain-wide] Example: <pre>RP/0/RP0/CPU0:router(config-isis-af)# segment-routing prefix-sid-map advertise-local RP/0/RP0/CPU0:router(config-isis-af)# segment-routing prefix-sid-map advertise-local domain-wide</pre>	Configures IS-IS to advertise locally configured prefix-SID mappings. Use the domain-wide option to advertise the prefix-SID mappings between IS-IS Level 1 and Level 2 routers.
Step 4	Use the commit or end command.	commit —Saves the configuration changes and remains within the configuration session. end —Prompts user to take one of these actions: <ul style="list-style-type: none"> • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • Cancel —Remains in the configuration session, without committing the configuration changes.

Verify IS-IS prefix-SID mapping advertisement and TLV.

```
RP/0/RP0/CPU0:router# show isis database verbose

<...removed...>

```

Configure Mapping Advertisement for OSPF

SUMMARY STEPS

1. **router ospf** *process-name*
2. **segment-routing prefix-sid-map advertise-local**
3. Use the **commit** or **end** command.

DETAILED STEPS

Procedure

	Command or Action	Purpose
Step 1	router ospf <i>process-name</i> Example: RP/0/RP0/CPU0:router(config)# router ospf 1	Enables OSPF routing for the specified routing instance, and places the router in router configuration mode.
Step 2	segment-routing prefix-sid-map advertise-local Example: RP/0/RP0/CPU0:router(config-ospf)# segment-routing prefix-sid-map advertise-local	Configures OSPF to advertise locally configured prefix-SID mappings.
Step 3	Use the commit or end command.	commit —Saves the configuration changes and remains within the configuration session. end —Prompts user to take one of these actions: <ul style="list-style-type: none"> • Yes — Saves configuration changes and exits the configuration session. • No —Exits the configuration session without committing the configuration changes. • Cancel —Remains in the configuration session, without committing the configuration changes.

Verify OSP prefix-SID mapping advertisement and TLV.

```
RP/0/RP0/CPU0:router# show ospf database opaque-area
```

```
<...removed...>
```

```
Extended Prefix Range TLV: Length: 24

Prefix  : 10.1.1.1/32
Range Size: 200
Flags   : 0x0
```

```
SID sub-TLV: Length: 8
```

```
Flags    : 0x60
MTID     : 0
Algo     : 0
SID Index : 10
```

Enable Mapping Client

By default, mapping client functionality is enabled.

You can disable the mapping client functionality by using the **segment-routing prefix-sid-map receive disable** command.

You can re-enable the mapping client functionality by using the **segment-routing prefix-sid-map receive** command.

The following example shows how to enable the mapping client for IS-IS:

```
RP/0/RP0/CPU0:router(config)# router isis 1
RP/0/RP0/CPU0:router(config-isis)# address-family ipv4 unicast
RP/0/RP0/CPU0:router(config-isis-af)# segment-routing prefix-sid-map receive
```

The following example shows how to enable the mapping client for OSPF:

```
RP/0/RP0/CPU0:router(config)# router ospf 1
RP/0/RP0/CPU0:router(config-ospf)# segment-routing prefix-sid-map receive
```

CHAPTER 19

Using Segment Routing OAM

Segment Routing Operations, Administration, and Maintenance (OAM) helps service providers to monitor label-switched paths (LSPs) and quickly isolate forwarding problems to assist with fault detection and troubleshooting in the network. The Segment Routing OAM feature provides support for BGP prefix SIDs, IGP prefix and Flexible Algorithm SIDs, and Nil-FEC (forwarding equivalence classes) LSP Ping and Traceroute functionality.

- [MPLS Ping and Traceroute for BGP and IGP Prefix-SID, on page 833](#)
- [Examples: MPLS Ping, Traceroute, and Tree Trace for Prefix-SID, on page 834](#)
- [MPLS LSP Ping and Traceroute Nil FEC Target, on page 836](#)
- [Examples: LSP Ping and Traceroute for Nil_FEC Target , on page 837](#)

MPLS Ping and Traceroute for BGP and IGP Prefix-SID

Table 144: Feature History Table

Feature Name	Release	Description
MPLS Ping and Traceroute for BGP and IGP Prefix-SID	Release 7.6.1	<p>This feature is supported on Cisco Network Convergence System 5700 Series routers and routers with the Cisco NC57 line cards operating in native mode.</p> <p>The MPLS LSP Ping feature is used to check the connectivity between ingress Label Switch Routers (LSRs) and egress LSRs along an LSP.</p>

MPLS Ping and Traceroute operations for Prefix SID are supported for various BGP and IGP scenarios, for example:

- Within an IS-IS level or OSPF area
- Across IS-IS levels or OSPF areas
- Route redistribution from IS-IS to OSPF and from OSPF to IS-IS
- Anycast Prefix SID
- Combinations of BGP and LDP signaled LSPs

The MPLS LSP Ping feature is used to check the connectivity between ingress Label Switch Routers (LSRs) and egress LSRs along an LSP. MPLS LSP ping uses MPLS echo request and reply messages, similar to Internet Control Message Protocol (ICMP) echo request and reply messages, to validate an LSP. The destination IP address of the MPLS echo request packet is different from the address used to select the label stack. The destination IP address is defined as a 127.x.y.z/8 address and it prevents the IP packet from being IP switched to its destination, if the LSP is broken.

The MPLS LSP Traceroute feature is used to isolate the failure point of an LSP. It is used for hop-by-hop fault localization and path tracing. The MPLS LSP Traceroute feature relies on the expiration of the Time to Live (TTL) value of the packet that carries the echo request. When the MPLS echo request message hits a transit node, it checks the TTL value and if it is expired, the packet is passed to the control plane, else the message is forwarded. If the echo message is passed to the control plane, a reply message is generated based on the contents of the request message.

The MPLS LSP Tree Trace (traceroute multipath) operation is also supported for BGP and IGP Prefix SID. MPLS LSP Tree Trace provides the means to discover all possible equal-cost multipath (ECMP) routing paths of an LSP to reach a destination Prefix SID. It uses multipath data encoded in echo request packets to query for the load-balancing information that may allow the originator to exercise each ECMP. When the packet TTL expires at the responding node, the node returns the list of downstream paths, as well as the multipath information that can lead the operator to exercise each path in the MPLS echo reply. This operation is performed repeatedly for each hop of each path with increasing TTL values until all ECMP are discovered and validated.

MPLS echo request packets carry Target FEC Stack sub-TLVs. The Target FEC sub-TLVs are used by the responder for FEC validation. The BGP and IGP IPv4 prefix sub-TLV has been added to the Target FEC Stack sub-TLV. The IGP IPv4 prefix sub-TLV contains the prefix SID, the prefix length, and the protocol (IS-IS or OSPF). The BGP IPv4 prefix sub-TLV contains the prefix SID and the prefix length.

Examples: MPLS Ping, Traceroute, and Tree Trace for Prefix-SID

These examples use the following topology:

MPLS Ping for Prefix-SID

```
RP/0/RP0/CPU0:router-arizona# ping mpls ipv4 10.1.1.4/32
Thu Dec 17 01:01:42.301 PST

Sending 5, 100-byte MPLS Echos to 10.1.1.4,
      timeout is 2 seconds, send interval is 0 msec:

MPLS LSP Ping and Traceroute Nil FEC Target

Table 145: Feature History Table

Feature Name	Release	Description
MPLS LSP Ping and Traceroute Nil FEC Target	Release 7.6.1	<p>This feature is supported on Cisco Network Convergence System 5700 Series routers and routers with the Cisco NC57 line cards operating in native mode.</p> <p>This feature allows operators to provide the ability to freely test any label stack by allowing them to specify the following:</p> <ul style="list-style-type: none"> • label stack • outgoing interface • nexthop address

The Nil-FEC LSP ping and traceroute operations are extensions of regular MPLS ping and traceroute.

Nil-FEC LSP Ping/Traceroute functionality supports segment routing and MPLS Static. It also acts as an additional diagnostic tool for all other LSP types. This feature allows operators to provide the ability to freely test any label stack by allowing them to specify the following:

- label stack
- outgoing interface
- nexthop address

In the case of segment routing, each segment nodal label and adjacency label along the routing path is put into the label stack of an echo request message from the initiator Label Switch Router (LSR); MPLS data plane forwards this packet to the label stack target, and the label stack target sends the echo message back.

The following table shows the syntax for the ping and traceroute commands.

Table 146: LSP Ping and Traceroute Nil FEC Commands

Command Syntax
ping mpls nil-fec labels {label[,label]} [output {interface tx-interface} [nexthop nexthop-ip-addr]]
traceroute mpls nil-fec labels {label[,label]} [output {interface tx-interface} [nexthop nexthop-ip-addr]]

Examples: LSP Ping and Traceroute for Nil_FEC Target

These examples use the following topology:

```

Node loopback IP address: 172.18.1.3   172.18.1.4   172.18.1.5   172.18.1.7

Segment Routing Ping and Traceroute

Table 147: Feature History Table

Feature Name	Release Information	Feature Description
Segment Routing Ping and Traceroute	Release 7.6.1	This feature is supported on Cisco Network Convergence System 5700 Series routers and routers with the Cisco NC57 line cards operating in native mode. Segment routing ping and traceroute features extendsthe MPLS LSP ping and traceroute functionality to perform the connectivity verification on the segment routing control plane.

Feature Name	Release Information	Feature Description
SR OAM for SR Policy (Policy Name / Binding SID / Custom label stack)	Release 7.3.1	This feature extends SR OAM ping and traceroute function for an SR policy (or binding SID)-LSP end-point combination. This addresses the limitations of the Nil-FEC LSP Ping and Traceroute function which cannot perform a ping operation to a segment list that is not associated with an installed SR policy. Also, it cannot validate egress device-specific SR policies.

Segment Routing Ping

The MPLS LSP ping feature is used to check the connectivity between ingress and egress of LSP. MPLS LSP ping uses MPLS echo request and reply messages, similar to Internet Control Message Protocol (ICMP) echo request and reply messages, to validate an LSP. Segment routing ping is an extension of the MPLS LSP ping to perform the connectivity verification on the segment routing control plane.

Note Segment routing ping can only be used when the originating device is running segment routing.

You can initiate the segment routing ping operation only when Segment Routing control plane is available at the originator, even if it is not preferred. This allows you to validate the SR path before directing traffic over the path. Segment Routing ping can use either generic FEC type or SR control-plane FEC type (SR-OSPF, SR-ISIS). In mixed networks, where some devices are running MPLS control plane (for example, LDP) or do not understand SR FEC, generic FEC type allows the device to successfully process and respond to the echo request. By default, generic FEC type is used in the target FEC stack of segment routing ping echo request. Generic FEC is not coupled to a particular control plane; it allows path verification when the advertising protocol is unknown or might change during the path of the echo request. If you need to specify the target FEC, you can select the FEC type as OSPF, IS-IS, or BGP. This ensures that only devices that are running segment routing control plane, and can therefore understand the segment routing IGP FEC, respond to the echo request.

Configuration Examples

These examples show how to use segment routing ping to test the connectivity of a segment routing control plane. In the first example, FEC type is not specified. You can also specify the FEC type as shown in the other examples.

```
RP/0/RP0/CPU0:router# ping sr-mpls 10.1.1.2/32

Sending 5, 100-byte MPLS Echos to 10.1.1.2/32,
      timeout is 2 seconds, send interval is 0 msec:

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
        'L' - labeled output interface, 'B' - unlabeled output interface,

Ping for SR Policy

You can perform the ping operation for an SR policy (or binding SID), and LSP end-point combination. Use the **ping** command's **policy name lsp-end-point** and **policy binding-sid lsp-end-point** options to perform this task. You can instantiate the policy through the CLI, Netconf, PCEP or BGP-TE process.

IPv6 policies are not supported for SR OAM function.

Note As a prerequisite, you must enable the MPLS OAM function.

```
Router(config)# mpls oam
Router(config)# commit
```

```
Router# ping sr-mpls policy name srte_c_4_ep_10.0.0.1 lsp-end-point 209.165.201.1
Router# ping sr-mpls policy binding-sid 1000 lsp-end-point 209.165.201.1
```

Segment Routing Traceroute

The MPLS LSP traceroute is used to isolate the failure point of an LSP. It is used for hop-by-hop fault localization and path tracing. The MPLS LSP traceroute feature relies on the expiration of the Time to Live (TTL) value of the packet that carries the echo request. When the MPLS echo request message hits a transit node, it checks the TTL value and if it is expired, the packet is passed to the control plane, else the message is forwarded. If the echo message is passed to the control plane, a reply message is generated based on the contents of the request message. Segment routing traceroute feature extends the MPLS LSP traceroute functionality to segment routing networks.

Similar to segment routing ping, you can initiate the segment routing traceroute operation only when Segment Routing control plane is available at the originator, even if it is not preferred. Segment Routing traceroute can use either generic FEC type or SR control-plane FEC type (SR-OSPF, SR-ISIS). By default, generic FEC type is used in the target FEC stack of segment routing traceroute echo request. If you need to specify the target FEC, you can select the FEC type as OSPF, IS-IS, or BGP. This ensures that only devices that are running segment routing control plane, and can therefore understand the segment routing IGP FEC, respond to the echo request.

The existence of load balancing at routers in an MPLS network provides alternate paths for carrying MPLS traffic to a target router. The multipath segment routing traceroute feature provides a means to discover all possible paths of an LSP between the ingress and egress routers.

Configuration Examples

These examples show how to use segment routing traceroute to trace the LSP for a specified IPv4 prefix SID address. In the first example, FEC type is not specified. You can also specify the FEC type as shown in the other examples.

```
RP/0/RP0/CPU0:router# traceroute sr-mpls 10.1.1.2/32

Traceroute for SR Policy

You can perform the traceroute operation for an SR policy (or binding SID), and LSP end-point combination. Use the **traceroute** command's **policy name lsp-end-point** and **policy binding-sid lsp-end-point** options to perform this task. You can instantiate the policy through the CLI, Netconf, PCEP or BGP-TE process.

IPv6 policies are not supported for SR OAM function.

Note As a prerequisite, you must enable the MPLS OAM function.

```
Router(config)# mpls oam
Router(config)# commit
```

```
Router# traceroute sr-mpls policy name srte_c_4_ep_10.0.0.1 lsp-end-point 209.165.201.1
Router# traceroute sr-mpls policy binding-sid 1000 lsp-end-point 209.165.201.1
```

Segment Routing TreeTrace Enhancements

Table 148: Feature History Table

Feature Name	Release	Description
Segment Routing TreeTrace Enhancements	Release 7.3.2	<p>The OAM TreeTrace operation provides enhanced traceroute functionality to validate ECMP paths between two endpoints.</p> <p>This feature augments the TreeTrace operation to support SR policies, SR NIL FEC, SR Flex Algo, or a custom list of labels.</p>

The SR-OAM TreeTrace (multipath traceroute) operation provides enhanced traceroute functionality to validate ECMP paths between two endpoints.

The Segment Routing TreeTrace enhancements augment the TreeTrace operation to support SR policies, Flex Algo labels, or a custom list of labels.

- Use the **traceroute sr-mpls multipath policy** EXEC command to specify the target SR policy.
- Use the **traceroute sr-mpls multipath labels** EXEC command to specify the target custom list of labels:
 - The custom list can have 1 to 12 prefix-SID labels.
 - A label can be Algo 0 or Flex Algo prefix-SID label.
- Use the **traceroute sr-mpls multipath nil-fec** EXEC command to specify the target custom list of labels and outgoing information or the target SR policy, to be verified using Nil FEC.

Note As a prerequisite, you must enable the MPLS OAM function.

```
Router(config)# mpls oam
Router(config-oam)# commit
```

Example 1: TreeTrace Operation for an SR Policy

```
Router# traceroute sr-mpls multipath policy name srte_c_10_ep_192.168.0.3 lsp-endpoint

Segment Routing Ping and Traceroute for Flexible Algorithm

Table 149: Feature History Table

Feature Name	Release Information	Feature Description
Segment Routing Ping and Traceroute for Flexible Algorithm	Release 7.6.1	<p>This feature is supported on Cisco Network Convergence System 5700 Series routers and routers with the Cisco NC57 line cards operating in native mode.</p> <p>Flexible Algorithm validation method is based on segment identifier (SID) label and label switched path (LSP) destination, instead of being based on IP address.</p>

Flexible Algorithm validation method is based on segment identifier (SID) label and label switched path (LSP) destination, instead of being based on IP address. The assigner is validated against the topology prefix information provided by SR-PCE database. If the assigner is valid, then the label given is also validated against the SR-PCE database. On the egress side, the destination label is contained in a new SR Label sub-TLV. This label is verified against a SID list provided by SR-PCE.

Note Observe the following guidelines and restrictions:

- All routers within an area must share the same Flexible Algorithm definition for a Flexible Algorithm to be valid.
- All routers within the domain must be configured with the same SRGB range of values.
- BGP-LS must be enabled.
- Only prefix SIDs and Flexible Algorithm SIDs are supported.
- Only single label stack is supported.

Segment Routing Ping for Flexible Algorithm

```

Segment Routing over IPv6 OAM

Segment Routing over IPv6 data plane (SRv6) implementation adds a new type of routing extension header. Hence, the existing ICMPv6 mechanisms including ping and traceroute can be used in the SRv6 network. There is no change in the way ping and traceroute operations work for IPv6- or SRv6-capable nodes in an SRv6 network.

Restrictions and Usage Guidelines

The following restriction applies for SRv6 OAM:

- Ping to an SRv6 SID is not supported.

Examples: SRv6 OAM

The following example shows using ping in an SRv6 network.

```
RP/0/RP0/CPU0:Router# ping ipv6 2001::33:33:33:33
Mon Sep 17 20:04:10.068 UTC
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 2001::33:33:33:33, timeout is 2 seconds:
!!!!
```

Success rate is 100 percent (5/5), round-trip min/avg/max = 1/3/4 ms

The following example shows using traceroute in an SRv6 network.

```
RP/0/RP0/CPU0:Router# traceroute ipv6 2001::33:33:33:33 probe 1 timeout 0 srv6
Fri Sep 14 15:59:25.170 UTC
Type escape sequence to abort.
Tracing the route to 2001::33:33:33:33
 1 2001::22:22:22:22[IP tunnel: DA=cafe:0:0:a4:1::: SRH =(2001::33:33:33:33 ,SL=1)] 2
msec
 2 2001::2:2:2:2[IP tunnel: DA=cafe:0:0:a4:1::: SRH =(2001::33:33:33:33 ,SL=1)] 2 msec
 3 2001::44:44:44:44 2 msec
 4 2001::33:33:33:33 3 msec
```

The following example shows using traceroute in an SRv6 network without an SRH.

```
RP/0/RSP1/CPU0:Router# traceroute ipv6 2001::44:44:44:44 srv6
Wed Jan 16 14:35:27.511 UTC
Type escape sequence to abort.
Tracing the route to 2001::44:44:44:44
 1 2001::2:2:2:2 3 msec 2 msec 2 msec
 2 2001::44:44:44:44 3 msec 3 msec 3 msec
```

The following example shows using ping for a specified IP address in the VRF.

```
RP/0/RP0/CPU0:Router# ping 10.15.15.1 vrf red
Mon Sep 17 20:07:10.085 UTC
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.15.15.1, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/4 ms
```

The following example shows using traceroute for a specified IP address in the VRF.

```
RP/0/RP0/CPU0:Router# traceroute 10.15.15.1 vrf red
Mon Sep 17 20:07:18.478 UTC

Type escape sequence to abort.
Tracing the route to 10.15.15.1
 1 10.15.15.1 3 msec 2 msec 2 msec
```

The following example shows using traceroute for CE1 (4.4.4.5) to CE2 (5.5.5.5) in the VRF:

```
RP/0/RP0/CPU0:Router# traceroute 5.5.5.5 vrf a
Wed Jan 16 15:08:46.264 UTC

Type escape sequence to abort.
Tracing the route to 5.5.5.5
 1 14.14.14.1 5 msec 1 msec 1 msec
 2 15.15.15.1 3 msec 2 msec 2 msec
 3 15.15.15.2 2 msec * 3 msec
```

Data Plane Validation Support for SR-MPLS IPv6-based LSPs

Table 150: Feature History Table

Feature Name	Release Information	Feature Description
Data Plane Validation for SR-MPLS IPv6-based Controller Instantiated LSPs on NCS 5700 Fixed Port Routers	Release 24.2.11	<p>Introduced in this release on: NCS 5700 fixed port routers</p> <p>The feature support is now extended to NCS 5700 fixed port routers.</p>
Data Plane Validation for SR-MPLS IPv6-based Controller Instantiated LSPs	Release 24.2.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native]).</p> <p>You can now verify the network configuration and paths and policies set up, without interrupting or potentially disrupting live network traffic, for SR-MPLS (Segment Routing over Multiprotocol Label Switching) IPv6-based Label Switched Paths (LSPs). With this feature, you can validate controller instantiated LSPs programmed directly into the forwarding hardware.</p> <p>Previously, SR data plane validation was possible over IPv4-based LSPs.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <p>The dataplane-only keyword is introduced in the traceroute sr-mpls and ping sr-mpls commands.</p> <p>YANG Data Models:</p> <ul style="list-style-type: none"> • <code>Cisco-IOS-XR-mpls-traceroute-act.yang</code> • <code>Cisco-IOS-XR-mpls-ping-act.yang</code> <p>See (GitHub, Yang Data Models Navigator)</p>

With this configuration, you can validate the SR-MPLS (Segment Routing over Multiprotocol Label Switching) IPv6-based LSPs and policies without disrupting the live network traffic. You can also validate Service-layer Application Programming Interface (SL-API) initiated LSPs such as controller instantiated LSPs. For more information about SL-API, refer *Use Service Layer API to Bring your Controller on Cisco IOS XR Router* chapter in *Programmability Configuration Guide*.

In the earlier releases, you could perform SR-MPLS data plane validation over IPv4-based LSPs. For more information, refer [Segment Routing Traceroute, on page 841](#) and [Segment Routing Ping, on page 839](#) sections.

Examples: SR-MPLS Data Plane Validation over IPv6-based LSPs

The following example shows how to use segment routing ping to validate SR-MPLS over IPv6-based LSPs:

```
Router#ping sr-mpls dataplane-only 2001:DB8::1/32
Tue Jan 16 15:05:19.120 EST

Sending 5, 100-byte MPLS Echos with Nil FEC to 2001:DB8::1/32,
      timeout is 2 seconds, send interval is 0 msec:

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
        'L' - labeled output interface, 'B' - unlabeled output interface,
        'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
        'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
        'P' - no rx intf label prot, 'p' - premature termination of LSP,
        'R' - transit router, 'I' - unknown upstream index,
        'X' - unknown return code, 'x' - return code 0

Type escape sequence to abort.

!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/8 ms
```

The following example shows how to use segment routing traceroute to validate SR-MPLS over IPv6-based LSPs:

```
Router#traceroute sr-mpls dataplane-only 2001:DB8::1/32
Tue Jan 16 15:08:54.681 EST

Tracing MPLS Label Switched Path with Nil FEC to 2001:DB8::1/32, timeout is 2 seconds

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
        'L' - labeled output interface, 'B' - unlabeled output interface,
        'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
        'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
        'P' - no rx intf label prot, 'p' - premature termination of LSP,
        'R' - transit router, 'I' - unknown upstream index,
        'X' - unknown return code, 'x' - return code 0

Type escape sequence to abort.

  0 11:11:11::1 MRU 1500 [Labels: 18004/explicit-null Exp: 0/0]
L 1 11:11:11::2 MRU 1500 [Labels: implicit-null/explicit-null Exp: 0/0] 3 ms
! 2 15:15:15::4 3 ms
```

The following example shows how to trace the SR-MPLS LSPs with Nil-FEC that includes labels:

```
Router#traceroute sr-mpls nil-fec labels 18004 output interface GigabitEthernet 0/0/0/0
nexthop 10:10:10::2
Tue Jan 16 15:28:03.162 EST

Tracing MPLS Label Switched Path with Nil FEC with labels [18004], timeout is 2 seconds
```

```

Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
       'L' - labeled output interface, 'B' - unlabeled output interface,
       'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
       'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
       'P' - no rx intf label prot, 'p' - premature termination of LSP,
       'R' - transit router, 'I' - unknown upstream index,
       'X' - unknown return code, 'x' - return code 0

Type escape sequence to abort.

  0 10:10:10::1 MRU 1500 [Labels: 18004/explicit-null Exp: 0/0]
L 1 10:10:10::2 MRU 1500 [Labels: implicit-null/explicit-null Exp: 0/0] 2 ms
! 2 15:15:15::4 2 ms

```

MPLS OAM support for SR-TE Policies using MPLS IPv6-based LSPs

Table 151: Feature History Table

Feature Name	Release Information	Feature Description
MPLS OAM support for SR-TE Policies using MPLS IPv6-based LSPs on NCS 5700 Fixed Port Routers	Release 24.2.11	Introduced in this release on: NCS 5700 fixed port routers The feature support is now extended to NCS 5700 fixed port routers.

Feature Name	Release Information	Feature Description
MPLS OAM support for SR-TE Policies using MPLS IPv6-based LSPs	Release 24.2.1	<p>Introduced in this release on: NCS 5500 fixed port routers; NCS 5500 modular routers (NCS 5500 line cards; NCS 5700 line cards [Mode: Compatibility; Native])</p> <p>You can now verify the network configuration and paths and SR-TE policies set up, without interrupting or potentially disrupting live network traffic, for SR-MPLS (Segment Routing over Multiprotocol Label Switching) IPv6-based Label Switched Paths (LSPs).</p> <p>Previously, MPLS OAM support was only for IPv4-based LSPs.</p> <p>The feature introduces these changes:</p> <p>CLI:</p> <p>The traceroute sr-mpls and ping sr-mpls commands are extended to support IPv6 nexthop addresses.</p> <p>YANG Data Models:</p> <ul style="list-style-type: none"> • Cisco-IOS-XR-mpls-traceroute-act.yang • Cisco-IOS-XR-mpls-ping-act.yang <p>See (GitHub, Yang Data Models Navigator)</p>

With this feature, you can now verify the SR-MPLS (Segment Routing over Multiprotocol Label Switching) IPv6-based LSPs and Segment routing for traffic engineering (SR-TE) policies without disrupting the live network traffic.

In the earlier releases, SR-MPLS support was limited to IPv4-based LSPs. For more information, refer [Segment Routing Ping](#) and [Segment Routing Traceroute](#) sections.

Usage Guidelines and Limitations

The following usage guidelines and limitations apply:

- Provide a valid LSP endpoint for non-Null-FEC ping and traceroute operations for SR-TE policies.
- When a path is fully used with traffic, MPLS OAM might incorrectly report packet drops and failures.

Examples: MPLS OAM support for SR-TE Policies with IPv6-based LSPs

The following example shows how to use segment routing traceroute for SR-TE policies with IPv6-based LSPs:

```
Router#traceroute sr-mpls nil-fec policy name srte_c_40_ep_2001:DB8::1
Tue Feb  6 12:07:38.295 EST
```

```
Tracing MPLS Label Switched Path with Nil FEC for SR-TE Policy srte_c_40_ep_2001:DB8::1,
timeout is 2 seconds
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'I' - unknown upstream index,
'X' - unknown return code, 'x' - return code 0
```

Type escape sequence to abort.

```
  0 12:12:12::1 MRU 1500 [Labels: 26134/explicit-null Exp: 0/0]
L 1 12:12:12::3 MRU 1500 [Labels: implicit-null/explicit-null Exp: 0/0] 16 ms
! 2 16:16:16::4 16 ms
```

The following example shows how to use segment routing ping for SR-TE policies with IPv6-based LSPs:

```
Router#ping sr-mpls nil-fec policy name srte_c_40_ep_2001:DB8::1
Tue Feb  6 12:08:28.277 EST
```

```
Sending 5, 100-byte MPLS Echos with Nil FEC for SR-TE Policy srte_c_40_ep_2001:DB8::1,
timeout is 2 seconds, send interval is 0 msec:
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'I' - unknown upstream index,
'X' - unknown return code, 'x' - return code 0
```

Type escape sequence to abort.

```
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/2/3 ms
```

For more information about configuring SR-TE policies, refer [SR-TE Policy Overview, on page 367](#) section.

The following example shows how to use segment routing traceroute with labels using IPv6 LSPs:

```
Router#traceroute sr-mpls labels 18004 lsp-end-point 2001:DB8::1
Tue Feb  6 12:10:41.928 EST
```

```
Tracing MPLS Label Switched Path to NIL FEC with lsp end point 2001:DB8::1, SID Label(s)
[18004], timeout is 2 seconds
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
'L' - labeled output interface, 'B' - unlabeled output interface,
'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
'P' - no rx intf label prot, 'p' - premature termination of LSP,
'R' - transit router, 'I' - unknown upstream index,
'X' - unknown return code, 'x' - return code 0
```

Type escape sequence to abort.

```
0 11:11:11::1 MRU 1500 [Labels: 18004/explicit-null Exp: 0/0]
L 1 11:11:11::2 MRU 1500 [Labels: implicit-null/explicit-null Exp: 0/0] 7 ms
! 2 15:15:15::4 3 ms
```

The following example shows how to use segment routing ping with labels using IPv6 LSPs:

```
Router#ping sr-mpls labels 18004 lsp-end-point 2001:DB8::1
Tue Feb  6 12:11:05.349 EST
```

```
Sending 5, 100-byte MPLS Echos with NIL FEC with lsp end point 2001:DB8::1, SID Label(s)
[18004],
      timeout is 2 seconds, send interval is 0 msec:
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
        'L' - labeled output interface, 'B' - unlabeled output interface,
        'D' - DS Map mismatch, 'F' - no FEC mapping, 'f' - FEC mismatch,
        'M' - malformed request, 'm' - unsupported tlvs, 'N' - no rx label,
        'P' - no rx intf label prot, 'p' - premature termination of LSP,
        'R' - transit router, 'I' - unknown upstream index,
        'X' - unknown return code, 'x' - return code 0
```

Type escape sequence to abort.

```
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/2/4 ms
```
