

Configure Gigabit Ethernet for Layer 2 VPNs

This chapter introduces you to Layer 2 features and standards, and describes how you can configure L2VPN features.

The distributed Gigabit Ethernet (including 10-Gigabit and 100-Gigabit) architecture and features deliver network scalability and performance, while enabling service providers to offer high-density, high-bandwidth networking solutions designed to interconnect the router with other systems in POPs, including core and edge routers and Layer 2 and Layer 3 switches.

Introduction to Layer 2 Virtual Private Networks

A Layer 2 Virtual Private Network (VPN) emulates a physical sub-network in an IP or MPLS network, by creating private connections between two points. Building a L2VPN network requires coordination between the service provider and customer. The service provider establishes Layer 2 connectivity. The customer builds a network by using the data link resources obtained from the service provider. In a L2VPN service, the service provider does not require information about the customer's network topology and other information. This helps maintain customer privacy, while using the service provider resources to establish the network.

The service provider requires Provider Edge (PE) routers with the following capabilities:

- Encapsulation of L2 protocol data units (PDU) into Layer 3 (L3) packets.
- Interconnection of any-to-any L2 transports.
- Support for MPLS tunneling mechanism.
- Process databases that include all information related to circuits and their connections.

This section introduces Layer 2 Virtual Private Networks (VPNs) and the corresponding Gigabit Ethernet services.

Introduction to Layer 2 VPNs on Gigabit Ethernet Interfaces

A L2VPN network enables service providers (SPs) to provide L2 services to geographically disparate customer sites. Typically, a SP uses an access network to connect the customer to the core network. This access network may use a mixture of L2 technologies, such as Ethernet and Frame Relay. The connection between the customer site and the nearby SP edge router is known as an attachment circuit (AC). Traffic from the customer travels over this link to the edge of the SP core network. The traffic then tunnels through a pseudowire over the SP core network to another edge router. The edge router sends the traffic down another AC to the customer's remote site.

The L2VPN feature enables the connection between different types of L2 attachment circuits and pseudowires, allowing users to implement different types of end-to-end services.

Note BOOTP traffic (dst UDP 68) over any type of pseudowire is unsupported.

Cisco IOS XR software supports a point-to-point end-to-end service, where two Ethernet circuits are connected together. An L2VPN Ethernet port can operate in one of two modes:

- **Port Mode**—In this mode, all packets reaching the port are sent over the pseudowire, regardless of any VLAN tags that are present on the packets. In Port mode, the configuration is performed under the `l2transport` configuration mode.
- **VLAN Mode**—Each VLAN on a CE (customer edge) or access network to PE (provider edge) link can be configured as a separate L2VPN connection (using either VC type 4 or VC type 5). To configure L2VPN on VLANs, see *The Carrier Ethernet Model* chapter in this manual. In VLAN mode, the configuration is performed under the individual sub-interface.

Switching can take place in the following ways:

- **AC-to-PW**—Traffic reaching the PE is tunneled over a PW (pseudowire) (and conversely, traffic arriving over the PW is sent out over the AC). This is the most common scenario.
- **Local switching**—Traffic arriving on one AC is immediately sent out of another AC without passing through a pseudowire.
- **PW stitching**—Traffic arriving on a PW is not sent to an AC, but is sent back into the core over another PW.

**Note**

- If your network requires that packets are transported transparently, you may need to modify the packet's destination MAC (Media Access Control) address at the edge of the Service Provider (SP) network. This prevents the packet from being consumed by the devices in the SP network.
- The **encapsulation dot1ad *vlan-id*** and **encapsulation dot1ad *vlan-id* dot1q any** commands cannot co-exist on the same physical interface or bundle interface. Similarly, the **encapsulation dot1q *vlan-id*** and **encap dot1q *vlan-id* second-dot1q any** commands cannot co-exist on the same physical interface or bundle interface. If there is a need to co-exist, it is recommended to use the exact keyword in the single tag encapsulation. For example, **encap dot1ad *vlan-id* exact** or **encap dot1q *vlan-id* exact**.
- In an interface which already has QinQ configuration, you cannot configure the QinQ Range sub-interface where outer VLAN range of QinQ Range overlaps with outer VLAN of QinQ. Attempting this configuration results in the splitting of the existing QinQ and QinQ Range interfaces. However, the system can be recovered by deleting a recently configured QinQ Range interface.
- In an interface which already has QinQ Range configuration, you cannot configure the QinQ Range sub-interface where outer VLAN range of QinQ Range overlaps with inner VLAN of QinQ Range. Attempting this configuration results in the splitting of the existing QinQ and QinQ Range interfaces. However, the system can be recovered by deleting a recently configured QinQ Range interface.
- The inner VLAN ranges of sub-interfaces configured cannot have overlapping values. In such overlapping inner VLAN range cases, the system can be recovered by reloading the LC on Cisco IOS XR Release 6.5.x.

You can use the **show interfaces** command to display AC and pseudowire information.

Configure Link Loss Forwarding for Layer 2 Transport

Link Loss Forwarding (LLF) is supported on Cisco router. The LLF is used to avoid any packet loss and trigger the network convergence through alternate links.

LLF sends signals across the PW to the neighbouring device to bring the PW and far-end AC down if the local AC goes down. The LLF feature supports the **l2transport propagate remote-status** command used to propagate Layer 2 transport events.

LLF is supported for TenGigE and GigE interfaces and not supported on the Bundle interfaces.

Running Configuration

```
/* Configuring propagation remote-status */
interface TenGigE 0/0/0/5
  l2transport
    propagate remote-status
  !
!
```

Ethernet Data Plane Loopback

The Ethernet Data Plane Loopback function allows you to run loopback tests to test the connectivity and quality of connections through a Layer 2 cloud. You can run this test on:

- Main interface or sub-interfaces
- Bundle or its sub-interfaces
- Multiple hops through the underlying network

You can use this feature to test the throughput of an Ethernet port remotely. You can verify the maximum rate of frame transmission with no frame loss.

This feature allows for bidirectional or unidirectional throughput measurement, and on-demand or out-of-service (intrusive) operation during service turn-up.

Two types of Ethernet loopback are supported:

- External loopback - Traffic loopback occurs at the Ingress interface. Traffic does not flow into the router for loopback.
- Internal loopback - Traffic loopback occurs at the Egress interface. Traffic loopback occurs after the traffic flows into the router to the other interface.

Ethernet data traffic can be looped back on per port basis. This feature supports a maximum of 100 concurrent Ethernet data plane loopback sessions per system. Filters based on frame header can be used for initiating the loopback session. This ensures that only a subset of traffic that is received on an interface is looped back. You can use Source MAC, Destination MAC, and VLAN Priority (COS bits) as filters.

Ethernet Data Plane Loopback Configuration Restrictions

These configuration restrictions are applicable for Ethernet Data Plane Loopback:

- Ethernet data plane loopback is not supported on L3 interfaces or L3 sub-interfaces.
- The following filters are not supported:
 - Outer VLAN or range of outer VLAN
 - Inner VLAN or range of inner VLAN
 - Ether type
- Only the following combinations of filters are supported for external loopback:
 - Source MAC
 - Source MAC and Destination MAC
 - Source MAC, Destination MAC, and VLAN priority
 - Destination MAC
 - Destination MAC and VLAN priority

- The rewrite modification on the loopback traffic is not supported.

Note Ensure that no rewrite should be configured on subinterface.

- Ethernet data plane loopback is not supported on packets with destination address as the broadcast MAC address.
- Ethernet data plane loopback is not supported on BVI interface.
- Ethernet data plane loopback is not supported on bridge-domain interfaces in Cisco IOS XR Release 6.3.2.
Layer2 VPN bridge-domains internal loopback is not supported.
- Only one Ethernet loopback session, either internal or external, can be active on the same interface at any given instance.
- This feature supports a maximum throughput of 10Gbps for internal loopback over all the sessions. For external loopback, there is no throughput limit.
- Dropping of packets that are received in the non-loopback direction is not supported.
- Ethernet data plane loopback is not supported on packets having destination as multicast and broadcast MAC address.
- External and internal Ethernet data plane loopback is not supported over bridge domain.
- The Cisco NCS 560 Series Routers do not support Ethernet loopback (external and internal) on Layer2 VPN bridge-domain.

Configure Ethernet Data Plane Loopback

This section describes how you can configure Ethernet Data Plane Loopback on physical interface and sub-interface. Configuring Ethernet Data Plane Loopback involves these steps:

- Configuring Ethernet Data Plane External Loopback
- Starting an Ethernet Data Plane Loopback Session

Configuration Example

```
/* Configuring Ethernet Data Plane External Loopback */

/* On physical interface */

RP/0/RSP0/CPU0:router# configure
RP/0/RSP0/CPU0:router(config)# interface tenGigE 0/0/0/0 l2transport
RP/0/RSP0/CPU0:router((config-if-12)# ethernet loopback permit external

/* Starting an Ethernet Data Plane Loopback Session */

RP/0/RSP0/CPU0:router# ethernet loopback start local interface tenGigE 0/0/0/0 external
source mac-address 0000.0000.0001 destination mac-address 0000.0000.0002 cos 5 timeout none
```

```

/* On physical sub-interface */

RP/0/RSP0/CPU0:router# configure
RP/0/RSP0/CPU0:router(config)# interface tenGigE 0/2/0/0/0.1 l2transport
RP/0/RSP0/CPU0:router(config-subif)# encapsulation dot1q 100
RP/0/RSP0/CPU0:router((config-if-12)# ethernet loopback permit external

/* Starting an Ethernet Data Plane Loopback Session */

RP/0/RSP0/CPU0:router# ethernet loopback start local interface tenGigE 0/2/0/0/0.1 external
source mac-address 0000.0000.0001 destination mac-address 0000.0000.0002 cos 5 timeout
none

/* Configuring Ethernet Data Plane Internal Loopback */

/* On physical interface

RP/0/RSP0/CPU0:router# configure
RP/0/RSP0/CPU0:router(config)# interface tenGigE 0/0/0/1 l2transport
RP/0/RSP0/CPU0:router((config-if-12)# ethernet loopback permit internal

/* Starting an Ethernet Data Plane Loopback Session */

RP/0/RSP0/CPU0:router# ethernet loopback start local interface tenGigE 0/0/0/1 internal
source mac-address 0000.0000.0002 destination mac-address 0000.0000.0003 cos 5 timeout none

/* On physical sub-interface */

RP/0/RSP0/CPU0:router# configure
RP/0/RSP0/CPU0:router(config)# interface tenGigE 0/2/0/0/0.1 l2transport
RP/0/RSP0/CPU0:router(config-subif)# encapsulation dot1q 100
RP/0/RSP0/CPU0:router(config-if-12)# ethernet loopback permit internal

/* Starting an Ethernet Data Plane Loopback Session */

RP/0/RSP0/CPU0:router# ethernet loopback start local interface tenGigE 0/2/0/0/0.1 internal
source mac-address 0000.0000.0002 destination mac-address 0000.0000.0003 cos 5 timeout
none

/* Stopping an Ethernet Data Plane Loopback Session */

RP/0/RSP0/CPU0:router# ethernet loopback stop local interface tenGigE 0/0/0/0 id 1
RP/0/RSP0/CPU0:router# ethernet loopback stop local interface tenGigE 0/0/0/1 id 2
RP/0/RSP0/CPU0:router# ethernet loopback stop local interface tenGigE 0/2/0/0/0.1 id 1

```

Similarly, you can configure the Ethernet Data Plane Loopback session for bundle interface and bundle sub-interface.

Ethernet loopback works even after SSO.

Running Configuration

This section shows Ethernet Data Plane Loopback running configuration.

```

/* External Loopback */

/* On physical interface */

```

```

configure
interface interface tenGigE 0/0/0/0 l2transport
  ethernet loopback permit external
!

/* On physical sub-interface */

configure
interface interface tenGigE 0/2/0/0/0.1 l2transport
  encapsulation dot1q 100
  ethernet loopback permit external
!

/* Internal Loopback */

/* On physical interface */

configure
interface interface tenGigE 0/0/0/1 l2transport
  ethernet loopback permit internal
!

/* On physical sub-interface */

configure
interface interface tenGigE 0/2/0/0/0.1 l2transport
  encapsulation dot1q 100
  ethernet loopback permit internal
!

```

Verification

The following example displays the loopback capabilities per interface. The output shows internal loopback has been permitted on Ten Gigabit Ethernet 0/0/0/1 interface and external loopback has been permitted on Ten Gigabit Ethernet 0/0/0/0 interface.

```
RP/0/RSP0/CPU0:router# show ethernet loopback permitted
```

```

-----
Interface                               Dot1q(s)                               Direction
-----
tenGigE 0/0/0/1.1                       100                                     Internal
tenGigE 0/0/0/0.1                       100                                     External
-----

```

```
/* This example shows all active sessions on the router */
```

```
RP/0/RSP0/CPU0:router# show ethernet loopback active
```

```

Ethernet Local Management Interface (E-LMI)

The Cisco NCS 560 Series Routers supports the Ethernet Local Management Interface (E-LMI) protocol as defined by the *Metro Ethernet Forum, Technical Specification MEF 16, Ethernet Local Management Interface (E-LMI), January 2006* standard.

E-LMI runs on the link between the customer-edge (CE) device and the provider-edge (PE) device, or User Network Interface (UNI), and provides a way for the CE device to auto-configure or monitor the services offered by the PE device (see this figure).

Figure 1: E-LMI Communication on CE-to-PE Link

E-LMI is an asymmetric protocol whose basic operation involves the User-facing PE (uPE) device providing connectivity status and configuration parameters to the CE using STATUS messages in response to STATUS ENQUIRY messages sent by the CE to the uPE.

E-LMI Messaging

The E-LMI protocol as defined by the MEF 16 standard, defines the use of only two message types—STATUS ENQUIRY and STATUS.

These E-LMI messages consist of required and optional fields called information elements, and all information elements are associated with assigned identifiers. All messages contain the Protocol Version, Message Type, and Report Type information elements, followed by optional information elements and sub-information elements.

E-LMI messages are encapsulated in 46- to 1500-byte Ethernet frames, which are based on the IEEE 802.3 untagged MAC-frame format. E-LMI frames consist of the following fields:

- Destination address (6 bytes)—Uses a standard MAC address of 01:80:C2:00:00:07.
- Source address (6 bytes)—MAC address of the sending device or port.
- E-LMI Ethertype (2 bytes)—Uses 88-EE.
- E-LMI PDU (46–1500 bytes)—Data plus 0x00 padding as needed to fulfill minimum 46-byte length.
- CRC (4 bytes)—Cyclic Redundancy Check for error detection.

For more details about E-LMI messages and their supported information elements, refer to the Metro Ethernet Forum, Technical Specification MEF 16, Ethernet Local Management Interface (E-LMI), January 2006.

E-LMI Operation

The basic operation of E-LMI consists of a CE device sending periodic STATUS ENQUIRY messages to the PE device, followed by mandatory STATUS message responses by the PE device that contain the requested information. Sequence numbers are used to correlate STATUS ENQUIRY and STATUS messages between the CE and PE.

The CE sends the following two forms of STATUS ENQUIRY messages called Report Types:

- E-LMI Check—Verifies a Data Instance (DI) number with the PE to confirm that the CE has the latest E-LMI information.
- Full Status—Requests information from the PE about the UNI and all EVCs.

The CE device uses a polling timer to track sending of STATUS ENQUIRY messages, while the PE device can optionally use a Polling Verification Timer (PVT), which specifies the allowable time between transmission of the PE's STATUS message and receipt of a STATUS ENQUIRY from the CE device before recording an error.

In addition to the periodic STATUS ENQUIRY/STATUS message sequence for the exchange of E-LMI information, the PE device also can send asynchronous STATUS messages to the CE device to communicate changes in EVC status as soon as they occur and without any prompt by the CE device to send that information.

Both the CE and PE devices use a status counter (N393) to determine the local operational status of E-LMI by tracking consecutive errors received before declaring a change in E-LMI protocol status.

Configure Ethernet Local Management Interface (E-LMI)

Before you configure E-LMI on the router, be sure that you complete the following requirements:

- Identify the local and remote UNIs in your network where you want to run E-LMI, and define a naming convention for them.
- Enable E-LMI on the corresponding CE interface link on a device that supports E-LMI CE operation.

E-LMI is not supported on physical sub-interfaces and bundle main and sub- interfaces. E-LMI is configurable on Ethernet physical interfaces only.

In order to ensure the correct interaction between the CE and the PE, each device has two configurable parameters. The CE uses a Polling Timer (PT) and a Polling Counter; the PE uses a Polling Verification Timer (PVT) and a Status Counter.

To configure Ethernet LMI, complete the following tasks:

- Configure EVCs for E-LMI (required)
- Configure Ethernet CFM for E-LMI (required)
- Enable E-LMI on the Physical Interface (required)
- Configure the Polling Verification Timer (optional)
- Configure the Status Counter (optional)

```

LMI Link Status Changed 01:59:54 ago  Last Protocol Error   never
Counters Cleared        never

Sub-interface: TenGigE0/3/0/9/1.1
VLANs: 1
EVC Status: Active
EVC Type: Point-to-Point
OAM Protocol: CFM

```

```

CFM Domain: irf_evpn_up (level 3)
CFM Service: up_mep_evpn_1

Remote UNI Count: Configured = 1, Active = 1
Remote UNI Id                                     Status
-----
<Remote UNI Reference Id: 1>                     Up

```

Make sure:

- The protocol (Ether LMI Link Status) is 'Up'.
- The output does not have "local UNI (UNI Id)" and also it is in provisioned state.
- The interface (Line Protocol State) is 'Up'.
- The CE-VLAN/EVC Map Type is as expected and shows the correct number of EVCs.
- The error counters are all 0.
- The LMI Link Status Changed timer shows the time since the protocol started.
- The sub-interface name(s) corresponds to the EFP(s) configured.
- The VLANs on each interface are as configured.
- The EVC Status is 'Active'.
- The CFM Domain and CFM Service match the provisioning.
- The Remote UNI Id is as provisioned.

Verify CFM (UP MEP)

```

RP/0/RSP0/CPU0:router# show ethernet cfm peer meps
Flags:
> - Ok
R - Remote Defect received
L - Loop (our MAC received)
C - Config (our ID received)
X - Cross-connect (wrong MAID)
* - Multiple errors received
I - Wrong interval
V - Wrong level
T - Timed out
M - Missing (cross-check)
U - Unexpected (cross-check)
S - Standby

Domain irf_evpn_up (level 3), Service up_mep_evpn_1
Up MEP on TenGigE0/3/0/9/1.1 MEP-ID 3001
