

IGP Flexible Algorithm in IP Networks

Table 1: Feature History Table

Feature Name	Release Information	Feature Description
IGP IP Flexible Algorithm for IS-IS Protocol	Release 7.6.1	<p>With IS-IS protocol extensions supporting Interior Gateway Protocol (IGP) Flexible Algorithm (Flex-Algorithm) on the IP data plane, you can now use the Algorithm to calculate IGP paths in an IP network without running Segment Routing. The IGP Flex-Algorithm allows for user-defined algorithms where the IGP computes paths based on a user-defined combination of metric type and constraints.</p> <p>Earlier, you could calculate IGP only using the Shortest Path First (SPF), which meant that you didn't have any choice except to use the default IGP path calculated based on a native IGP metric.</p> <p>The following command is introduced:</p> <ul style="list-style-type: none">• data-plane ip <p>The following commands are modified:</p> <ul style="list-style-type: none">• ipv4 address• ipv6 address• show isis topology

Flexible Algorithm allows operators to customize IGP shortest path computation according to their own needs. The Flexible Algorithm allows Link State IGP (OSPF, ISIS) to compute paths using various constraints. Each Flexible Algorithm represents the triplet (Calculation-Type, Metric-Type, Constraints) which all routers in the area consistently elect using the defined selection algorithm.

In IP networks, the router uses IGP Flexible Algorithm by computing the paths to the IPv4 address [RFC0791] and IPv6 address [RFC8200].

Each interface may be associated with one or more IP addresses, and each IP address may be associated with one Flexible Algorithm.

- Packets sent to an address that is associated with a Flexible Algorithm follow the constraint-based path as calculated by the Flexible Algorithm.
- Packet sent to an address, that is *not* associated with a Flexible Algorithm, follow the IGP least-cost path to the egress node.

IGP IP Flexible Algorithm allows forwarding of the voice traffic and data traffic over different paths in the IP network. It can, for example, provide a low latency path for the voice traffic.

This document describes the IS-IS protocol extensions to support IGP Flexible Algorithm in IP networks.

Prerequisites for IP Flexible Algorithm

Configure the **data-plane ip** command under IGP flex-algo sub-mode to enable participation of the router with the IP Flexible Algorithm.

Flexible Algorithm Definition

The set consisting of (a) calculation-type, (b) metric-type and (c) a set of constraints is referred to as a Flexible-Algorithm Definition.

Flexible-Algorithm is a numeric identifier in the range 128-255 that is associated via provisioning with the Flexible-Algorithm Definition.

To guarantee the loop free forwarding for paths computed for a particular Flex-Algorithm, all routers that are configured to participate in a particular Flex-Algorithm, and in the same Flex-Algorithm definition advertisement scope must agree on the definition of the Flex-Algorithm as in [ietf-lsr-flex-algo](#).

Flexible Algorithm Definition Advertisement

To guarantee the loop free forwarding for paths computed for a particular Flexible Algorithm, all routers in the network must share the same definition of the Flexible Algorithm. This is achieved by dedicated router(s) advertising the definition of each Flexible Algorithm. Such advertisement is associated with the priority to make sure that all routers agree on a single and consistent definition for each Flexible Algorithm.

Definition of Flexible Algorithm includes:

- Metric type
- Affinity constraints
- Exclude SRLG constraints

To enable the router to advertise the definition for the particular Flexible Algorithm, **advertise-definition** command is used. At least one router in the area, preferably two for redundancy, must advertise the Flexible Algorithm definition. Without the valid definition being advertised, the Flexible Algorithm are not be functional.

IP Flexible Algorithm Prefix Advertisement

The IPv4 and IPv6 Algorithm Prefix Reachability TLVs defined in [draft-ietf-lsr-ip-flexalgo](#) are used to advertise prefix reachability associated with a Flexible Algorithm.

IP Flexible Algorithm Participation

Each application using the Flexible Algorithm must use its own participation signaling. IP Flexible Algorithm uses ISIS IP Algorithm Sub-TLV as specified in [draft-ietf-lsr-ip-flexalgo](#).

Computing IP Flexible Algorithm Paths

Each Flexible Algorithm maintains a separate set of paths—One set per each data-plane.

The IP Flexible Algorithm computation uses only the IP Flex-Algorithm prefixes that are advertised in IPv4 and IPv6 Algorithm Prefix Reachability TLV.

Note The performance impact is proportional to the number of IP Flexible Algorithms in the participating router. Routers using the algorithm may use additional CPU cycles to:

- Process new TLVs.
 - Calculate the primary and backup paths for the IP Flex-Algorithm prefixes.
 - Advertise the IPv4 or IPv6 Algorithm Prefix Reachability TLVs.
-

IP Flexible Algorithm Forwarding

IP Flexible Algorithm uses the base IPv4 and IPv6 packets for forwarding.

IP Flexible Algorithm prefixes are advertised in IGP. The forwarding plane installs the IP Flex-Algorithm prefixes advertised by the receiving routers participating in the associated topology and algorithm.

The IP Flex-Algorithm prefixes can be protected by local LFA. When the prefix is associated with an algorithm, the LFA paths to such a prefix are calculated using the Flexible Algorithm in the associated topology. Thus, ensuring that the algorithm follows the same constraints as the calculation of the primary paths.

The IP Flex-Algorithm prefixes can be protected by TI-LFA. For more information on protecting the IP Flex-Algorithm prefixes, see [Protecting Flexible Algorithm IP Prefixes, on page 9](#).

Flexible Algorithm Configuration

The following workflow enables IP Flexible Algorithm:

1. Configure the IP data-plane to participate in the Flexible Algorithm. See [Enabling the Flexible Algorithm Participation, on page 4](#).
2. Define the parameters for FAD. See [Flexible Algorithm Definitions, on page 4](#).
3. Advertise the definition. See [Flexible Algorithm Advertisement, on page 5](#).
4. Define the admin groups. See [Configuring Affinity, on page 5](#).
5. Verify the Flexible Algorithm configuration.
6. Associate the IP address of the interface to the Flexible Algorithm. See [Associating the IP Address to Flexible Algorithm, on page 5](#).

Enabling the Flexible Algorithm Participation

The following command in IS-IS flex-algo submode configuration enables Flexible Algorithm participation on the native IP data plane:

```
router isis instance
flex-algo algo
data-plane ip
```

Note Segment Routing is the default data-plane. To use the IP data-plane, you must enable the **data-plane ip** command.

Flexible Algorithm Definitions

The following commands configure the Flexible Algorithm definition under the flex-algo submode configuration:

- `router isis instance`
`flex-algo algo`
`metric-type {delay | te}`
- `affinity {include-any | include-all | exclude-any} name1, name2, ...`
`name`—Name of the affinity map.
- `priority priority value`
`priority value`—Priority used during the Flexible Algorithm definition election.

Flexible Algorithm Advertisement

The following command enables advertisement of the Flexible Algorithm definition in IS-IS:

```
router isis instance
flex-algo algo
advertise-definition
```

Configuring Affinity

The following command defines the affinity-map. Affinity-map associates the name with the particular Bit positions in the Extended Admin Group bitmask.

```
router isis instance
affinity-map name bit-position bit number
```

- *Name*—Name of the affinity-map.
- *bit number*—Bit position in the Extended Admin Group bitmask.

The following command associates the Flexible Algorithm-specific affinities with an interface:

```
router isis instance
interface type interface-path-id
affinity flex-algo name 1, name 2, ...
```

name—Name of the affinity-map.

Associating the IP Address to Flexible Algorithm

To associate the Flexible Algorithm with the interface global IPv4 or IPv6 address, use the following commands:

- **ipv4 address** *prefix-length* [**secondary** | **algorithm** *algo-no*]
- **ipv6 address** *prefix-length* **algorithm** *algo-no*]

Note If you do not associate an algorithm, the default algorithm value (0) is associated.

The following example shows how to associate IPv4 address with a Flexible Algorithm for loopback interface 1:

```
Router(config)# interface loopback 1
Router(config-if)# ipv4 address 1.1.1.1/32
Router(config-if) #ipv4 address 1.1.1.1/32 algorithm 128 -----> adds the algo value
128
Router(config-if) #commit
```

The following example associates the IPv6 address with a Flexible Algorithm for loopback interface 0:

```
Router(config)# interface loopback 0
Router(config-if)# ipv6 address 1::1/64 -----> add ipv6 add without algo
Router(config-if)# ipv6 address 1::1/64 algorithm 128 -----> add algo value 128
Router(config-if) #commit
```

Example: Configuring IS-IS IP Flexible Algorithm

The following figure is a six-node topology from R1 to R6 with configuration.

- Node R2 defines the FAD.
- IP Flexible Algorithm on node R2 ► R4 ► R3 ► R1.

This example shows the Flexible Algorithm 151 associated to IPv4 address at Loopback interface 51.

```
RP/0/RSP0/CPU0:Router# show run router isis
router isis 1
  is-type level-2-only
  net 49.0000.0000.0000.0012.00

Protecting Flexible Algorithm IP Prefixes

Topology-Independent Loop-Free Alternate (TI-LFA) and Microloop avoidance features provide protection to link, node, and Shared Risk Link Groups (SRLG) using Segment Routing.

The IP Flexible Algorithm does not support TI-LFA and Microloop avoidance on its own. However, you can protect the IP Algorithm prefixes in the IP network by enabling Segment Routing in the network. With Segment Routing Flexible Algorithm, you can also protect the IP Flexible Algorithm traffic on its backup path.

Following conditions are required for TI-LFA protection and/or Microloop avoidance of the IP Flexible Algorithm traffic:

- Both Segment Routing and IP Flexible Algorithms data-planes must be enabled for a particular Flexible Algorithm X in an IS-IS area.
- The exact same set of reachable routers in the IS-IS area is participating in the Segment Routing and IP data-planes for Flexible Algorithm X.

Example: Enabling Flexible Algorithm Protection

The following figure is a six-node topology from R1 to R6 with configurations.

- Node R2 is winning the FAD.
- IP Flexible Algorithm with Flexible Algorithm 151 on nodes R2 ► R4 ► R3 ► R1.
- Segment Routing Flexible Algorithm with Flexible Algorithm 131 on nodes R2 ► R6 ► R5 ► R1 ► R3 ► R4.
- Both Segment Routing and IP Algorithm with Flexible Algorithm 131 on node R1 ► R3 ► R4 ► R2.

Example: Enabling Flexible Algorithm Protection

This example shows the Flexible Algorithm 131 and 151 configuration on R2.
