

Configuring Modular QoS Congestion Management

This chapter covers the following topics:

- Congestion Management Overview, on page 1
- Class-based Weighted Fair Queueing, on page 1
- Low-Latency Queuing with Strict Priority Queuing, on page 4
- Overhead Accounting, on page 8
- Traffic Shaping, on page 10
- Traffic Policing, on page 13
- Shared Policer, on page 24
- Prioritize Traffic during Oversubscription, on page 28
- References for Modular QoS Congestion Management, on page 31

Congestion Management Overview

Congestion management features allow you to control congestion by determining the order in which a traffic flow (or packets) is sent out an interface based on priorities assigned to packets. Congestion management entails the creation of queues, assignment of packets to those queues based on the classification of the packet, and scheduling of the packets in a queue for transmission.

The types of traffic regulation mechanisms supported are:

- Class-based Weighted Fair Queueing, on page 1
- · Low-Latency Queuing with Strict Priority Queuing, on page 4
- Traffic Shaping, on page 10
- Traffic Policing, on page 13

Class-based Weighted Fair Queueing

Class-based Weighted Fair Queueing (CBWFQ) allows definition of traffic classes based on customer match criteria. With CBWFQ you can define traffic classes and assign guaranteed amount of minimum bandwidth to them. CBWFQ also allows for a strict priority queue for delay-sensitive traffic.

Bandwidth Remaining

The CBWFQ algorithm derives the weight for each class from the bandwidth remaining value allocated to the class. The **bandwidth remaining** option specifies a weight for the class to the CBWFQ. After the priority-queue is serviced, the leftover bandwidth is distributed as per bandwidth remaining ratio (BWRR) or percentage. If you do not configure this command for any class, the default value of the BWRR is considered as 1 (one). In the case of **bandwidth remaining percent**, the remaining bandwidth is equally distributed among other classes, to make it 100 percentage (100%).

Restrictions

• The bandwidth remaining command is supported only for egress policies.

Configuring Bandwidth Remaining

Supported Platforms: Cisco NCS 540 Series Routers.

This procedure configures the minimum bandwidth and bandwidth remaining on the router

```
Note
```

The **bandwidth**, **bandwidth remaining**, **shaping**, **queue-limit** and wred commands may be configured together in the same class. But, **priority** cannot be configured along with **bandwidth**, **bandwidth remaining** and wred commands.

You can configure shape average command along with priority command.

Configuration Example

You have to accomplish the following to complete the bandwidth remaining configuration:

- 1. Creating or modifying a policy-map that can be attached to one or more interfaces
- 2. Specifying the traffic class whose policy has to be created or changed
- **3.** Allocating the leftover bandwidth for the class
- 4. Attaching the policy-map to an output interface

```
Router# configure
Router(config)#class-map qos-6
Router(config-cmap)#match traffic-class 4
Router(config-cmap)#exit
Router(config)#class-map qos-5
Router(config-cmap)#match traffic-class 5
Router(config-cmap)#commit
Router(config)# policy-map test-bw-bw-rem
Router(config-pmap)# class qos-6
Router(config-pmap-c)# bandwidth percent 60
Router(config-pmap-c)# bandwidth remaining percent 60
Router(config-pmap-c)#bandwidth percent 20
```

```
Router(config-pmap-c)#bandwidth remaining percent 40
Router(config-pmap-c# exit
Router(config-pmap)# exit
Router(config)# interface HundredGigE 0/6/0/18
Router(config-if)# service-policy output test-bw-bw-rem
Router(config-if)# commit
```

Running Configuration

```
policy-map test-bw-bw-rem
class qos-6
bandwidth percent 60
bandwidth remaining percent 60
!
class qos-5

Low-Latency Queuing with Strict Priority Queuing

The Low-Latency Queuing (LLQ) feature brings strict priority queuing (PQ) to the CBWFQ scheduling mechanism. Priority queuing (PQ) in strict priority mode ensures that one type of traffic is sent, possibly at the expense of all others. For PQ, a low-priority queue can be detrimentally affected, and, in the worst case, never allowed to send its packets if a limited amount of bandwidth is available or the transmission rate of critical traffic is high.

Configuring Low Latency Queuing with Strict Priority queuing

Configuring low latency queuing (LLQ) with strict priority queuing (PQ) allows delay-sensitive data such as voice to be de-queued and sent before the packets in other queues are de-queued.

Guidelines

- Only priority level 1 to 7 is supported, with 1 being the highest priority and 7 being the lowest. However, the default CoSQ 0 has the lowest priority among all.
- Priority level 1 to 7 is supported for non-H-QoS profiles, with 1 being the highest priority and 7 being the lowest. For H-QoS profiles, priority level 1 to 4 is supported. For all profiles, however, the class default is CoSQ 0 and has the lowest priority among all.
- Egress policing is not supported. Hence, in the case of strict priority queuing, there are chances that the other queues do not get serviced.
- You can configure shape average and queue-limit commands along with priority.
- You can configure shape average, random-detect, and queue-limit commands along with priority.

Configuration Example

You have to accomplish the following to complete the LLQ with strict priority queuing:

- 1. Creating or modifying a policy-map that can be attached to one or more interfaces
- 2. Specifying the traffic class whose policy has to be created or changed.

- 3. Specifying priority to the traffic class
- 4. (Optional) Shaping the traffic to a specific bit rate
- 5. Attaching the policy-map to an output interface

```
Router# configure
Router(config)#class-map qos-1
Router(config-cmap)#match traffic-class 1
Router(config-cmap)#commit
Router(config)#class-map qos-2
Router(config-cmap)#match traffic-class 2
Router (config-cmap) #commit
Router(config) # policy-map test-priority-1

Configuring Low Latency Queuing for Specific QoS Flows

Table 1: Feature History Table

Feature Name	Release Information	Feature Description
Low Latency Queuing for Specific QoS Flows	Release 7.3.2	This feature allows you to configure low latency or priority for specific QoS flows at the class-level within a policy map. It enables delay-sensitive data to be prioritized and transmitted before other packets in other queues.

This feature allows you to configure low latency or priority for specific QoS flows at the class-level within a policy map. It enables delay-sensitive data to be prioritized and transmitted before other packets in other queues.

Low Latency Queuing (LLQ) is achieved by enabling low delay IPS profile for the designated Virtual Output Queuing (VOQ).

```

Limitations

- No support on logical interfaces and sub-interfaces.
- Device on which low latency is enabled, throughput may be degraded.
- We recommend that you enable only one high priority traffic class (TC) per port for low latency. Enabling multiple TC with low latency may result in burst.

Note Configurations are restricted on any TCs, but it is recommended that you enable LLQ on only one TC.

Overhead Accounting

Traffic shapers and policers use packet traffic descriptors to ensure adherence to the service level agreement in QoS. However, when traffic flows from one hop to another in a network, headers added or removed at interim hops affect the packet bytes being accounted for by QoS at each hop. When your end-user network measures the packet bytes to ensure they receive the payload as agreed, these additional header bytes cause a discrepancy.

QoS overhead accounting provides the flexibility to operators to decide which header bytes can be excluded by the traffic shaper and policer and which can be included, depending on the end user's requirements and device capabilities, to meet the committed payload in units of bytes. For example, if the QoS commitment includes the additional header bytes, the overhead accounting feature allows your router to account for this overhead and reduces the traffic policing and shaping rates accordingly. This is also called a **positive accounting overhead**.

If however, the committed rate doesn't include the additional bytes, overhead accounting allows your router to adjust the core stream traffic such that the traffic policing and shaping rates are increased. This is also called a **negative accounting overhead**.

To summarize, QoS overhead accounting enables the router to account for packet overhead when shaping and policing traffic to a specific rate. This accounting ensures that the router runs QoS features on the actual bandwidth that the subscriber traffic consumes.

Any interface that supports QoS policies supports overhead accounting.

You can enable user overhead accounting using the optional configuration of **accounting user-defined** *<overhead size in bytes>* while attaching the service policy on the egress interface.

Guidelines and Restrictions

- Overhead accounting for ingress shaping is not supported.
- You can't program more than one compensation value per NPU or router, even if they're on different egress ports.
- You can configure the same egress compensation for different egress ports.

Configuring for Overhead Accounting

To configure overhead accounting, you must:

- 1. Create a policy map and configure QoS actions for that map.
- 2. Configure overhead accounting and attach the map to an interface.

```
/* create QoS policy */
Router#configure terminal
Router(config)#policy-map policer
Router(config-pmap)#class class-default
Router(config-pmap-c)#police rate percent 10
Router(config-pmap-c-police)#commit
/* configure account overhead value while attaching the QoS policy to interface */
Router(config)#int hundredGigE 0/0/0/2
Router(config-if)#service-policy input policer account user-defined 12
Router(config-if)#commit
Router(config-if)#root
Router(config)#end
```

Running Configuration

```
Router#sh run int hundredGigE 0/0/0/2
interface HundredGigE0/0/0/2
service-policy input policer account user-defined 12
!
```

The following example shows how to configure a negative overhead accounting value:

```
Router#conf
Router(config)#int hundredGigE 0/0/0/2
```

Router(config-if)#service-policy input policer account user-defined -12
Router(config-if)#commit

To modify an overhead accounting value, you must:

- 1. Remove the existing QoS policy and re-add it.
- 2. Configure the new overhead accounting value.

```
Router#conf
Router(config)#int hundredGigE 0/0/0/2
Router(config-if)#no service-policy input policer
Router(config-if)#service-policy input policer account user-defined -20
Router(config-if)#commit
Router#sh run int hundredGigE 0/0/0/2
interface HundredGigE0/0/0/2
service-policy input policer account user-defined -20
!
```

Positive Accounting Use Case

If QoS commitment includes Preamble, Frame Delimiter & Interframe Gap and has the following configuration:

service-policy input <foo> account user-defined +20

For QoS purposes, your router treats this packet as a packet of size = Actual Packet size + 20. Hence, the effective policing and shaping is *reduced* to match the downstream interface.

Negative Accounting Use Case

If QoS commitment to your router does not include VLAN header information, and has the following configuration:

service-policy input <foo> account user-defined -4

For QoS purposes, your router treats this packet as a packet of size = Actual Packet size -4. Hence, the effective policing and shaping is *increased* to match the downstream interface.

Associated Commands

service-policy (overhead accounting)

Traffic Shaping

Traffic shaping allows you to control the traffic flow exiting an interface to match its transmission to the speed of the remote target interface and ensure that the traffic conforms to policies contracted for it. Traffic adhering to a particular profile can be shaped to meet downstream requirements, hence eliminating bottlenecks in topologies with data-rate mismatches.

Configure VOQ-Level Traffic Shaping

The traffic shaping performed on outgoing interfaces is done at the Layer 1 level and includes the Layer 1 header in the rate calculation.

Guidelines

- It is mandatory to configure all the eight traffic-class classes (including class-default) for the egress
 policies.
- You can configure shape average command along with priority command.

Configuration Example

You have to accomplish the following to complete the traffic shaping configuration:

- 1. Creating or modifying a policy-map that can be attached to one or more interfaces
- 2. Specifying the traffic class whose policy has to be created or changed
- 3. Shaping the traffic to a specific bit rate and set peak burst size
- 4. Attaching the policy-map to an output interface

```
Router# configure
Router(config)#class-map c5
Router(config-cmap)#match traffic-class 5
Router(config-cmap)#commit
Router(config)# policy-map egress_policy1
Router(config-pmap)# class c5
Router(config-pmap-c)# shape average 40 percentpercent 50 1000
Router(config-pmap-c# exit
Router(config-pmap)# exit
Router(config)# interface HundredGigE 0/1/0/0
Router(config-if)# service-policy output egress_policy1
Router(config-if)# commit
```

Running Configuration

```
class-map c5
match traffic-class 5
commit
policy-map egress policy1
class c5
 shape average percent 40
 1
class class-default
 !
 end-policy-map
Т
interface HundredGigE0/6/0/18
service-policy output egress policy1
!
class-map c5
match traffic-class 5
commit
```

```
class c5
  shape average percent 50 1000
!
  class class-default
!
  end-policy-map
!
interface HundredGigE0/6/0/18
  service-policy output egress_policy1
!
```

Traffic Policing

Traffic policing allows you to control the maximum rate of traffic sent or received on an interface and to partition a network into multiple priority levels or class of service (CoS). Traffic policing manages the maximum rate of traffic through a token bucket algorithm. The token bucket algorithm uses user-configured values to determine the maximum rate of traffic allowed on an interface at a given moment in time. The token bucket algorithm is affected by all traffic entering or leaving the interface (depending on where the traffic policy with traffic policing is configured) and is useful in managing network bandwidth in cases where several large packets are sent in the same traffic stream. By default, the configured bandwidth value takes into account the Layer 2 encapsulation that is applied to traffic leaving the interface.

Traffic policing also provides a certain amount of bandwidth management by allowing you to set the burst size (Bc) for the committed information rate (CIR). See, Committed Bursts and Excess Bursts, on page 14.

The router supports the following traffic policing mode(s):

- Single-Rate Two-Color (SR2C) in color-blind mode. See Single-Rate Policer, on page 14.
- Single-Rate Three-Color (SR3C) in color-blind mode.
- Two-Rate Three-Color (2R3C) in color-blind mode. See Two-Rate Policer, on page 18.

Restrictions

- Traffic policing is supported only in ingress direction, and only color-blind mode is supported.
- The policing rate accuracy may vary up to +/-2% from the configured policer value.
- Ensure that you don't configure a policer and match criteria for **discard-class** in the same class. Even though the configuration is allowed, the policer doesn't work and allows all traffic without dropping packets.
- · Policer marking is not supported.
- Policers are configured in the interface at the core level and "show qos int <>" value is displayed at the NPU level.

For policers configured in a bundle interface where bundle members are from the same NPU but different cores (NPU cores), each member sends the traffic up to the core level policer configuration, but "show qos int \sim " displays the NPU level policer output.

• Example:

For bundle interface with two 10GE members (same NPU, but one interface from core0, one interface from core1) 2R3C policer applied on bundle interface (1G confirm rate, 1G exceed rate – total 2G policer rate) will be shown on the "show qos int \sim " output):

Interface in core0 - 500 Mbps confirm rate, 500 Mbps exceed rate

Interface in core1 – 500 Mbps confirm rate, 500 Mbps exceed rate

For traffic in one out of two interfaces, the policed rate will be 1Gbps. For traffic on two interfaces, policed rate will be 2Gbps.

Committed Bursts and Excess Bursts

Unlike a traffic shaper, a traffic policer does not buffer excess packets and transmit them later. Instead, the policer executes a "send or do not send" policy without buffering. Policing uses normal or committed burst (bc) values and excess burst values (be) to ensure that the router reaches the configured committed information rate (CIR). Policing decides if a packet conforms or exceeds the CIR based on the burst values you configure. Burst parameters are based on a generic buffering rule for routers, which recommends that you configure buffering to be equal to the round-trip time bit-rate to accommodate the outstanding TCP windows of all connections in times of congestion. During periods of congestion, proper configuration of the excess burst parameter enables the policer to drop packets less aggressively.

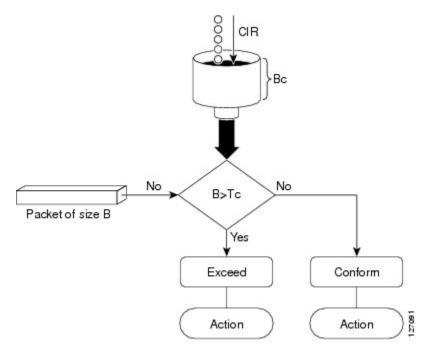

For more details, see Committed Bursts, on page 31 and Excess Bursts, on page 31.

Single-Rate Policer

Single-Rate Two-Color Policer

A single-rate two-color (SR2C) policer provides one token bucket with two actions for each packet: a conform action and an exceed action.

Figure 1: Workflow of Single-Rate Two-Color Policer

Based on the committed information rate (CIR) value, the token bucket is updated at every refresh time interval. The Tc token bucket can contain up to the Bc value, which can be a certain number of bytes or a period of time. If a packet of size B is greater than the Tc token bucket, then the packet exceeds the CIR value and a default action is performed. If a packet of size B is less than the Tc token bucket, then the packet conforms and a different default action is performed.

Single-Rate Three-Color Policer

A single-rate three-color (SR3C) policer provides one token bucket with three actions for each packet: a conform action, an exceed action and a violate action. The packet is marked based on the CIR value and the two associated burst size - committed burst size (CBS) and excess burst size (EBS). If a packet does not exceed the CBS, it is marked as conformed packet. The packet is marked as exceeded if it exceeds CBS, but not the EBS. If it exceeds the EBS as well, it is marked as violate packet.

Configure Traffic Policing (Single-Rate Two-Color)

Traffic policing is often configured on interfaces at the edge of a network to limit the rate of traffic entering or leaving the network. The default conform action for single-rate two color policer is to transmit the packet and the default exceed action is to drop the packet. Users cannot modify these default actions.

Configuration Example

You have to accomplish the following to complete the traffic policing configuration:

- 1. Creating or modifying a policy-map that can be attached to one or more interfaces
- 2. Specifying the traffic class whose policy has to be created or changed
- 3. (Optional) Specifying the marking action
- 4. Specifying the policy rate for the traffic

5. Attaching the policy-map to an input interface

```
Router# configure
Router(config)# policy-map test-police-1
Router(config-pmap)# class ipv6-6
Router(config-pmap-c)# set dscp cs2 (optional)
Router(config-pmap-c)# police rate percent 20 burst 10000 bytes
Router(config-pmap-c-police)# exit
Router(config-pmap-c)# exit
Router(config-pmap)# exit
Router(config)# interface HundredGigE 0/6/0/18
Router(config-if)# service-policy input test-police-1
Router(config-if)# commit
```

Running Configuration

```
class-map match-any ipv6-6
match precedence 3
end-class-map

Configure Traffic Policing (Single-Rate Three-Color)

The default conform action and exceed actions for single-rate three-color policer are to transmit the packet and the default violate action is to drop the packet. User cannot modify these default actions.

Configuration Example

You have to accomplish the following to complete the traffic policing configuration:

- 1. Creating or modifying a policy-map that can be attached to one or more interfaces
- 2. Specifying the traffic class whose policy has to be created or changed
- 3. (Optional) Specifying the marking action
- 4. Configuring the policy rate for the traffic along with the peak-burst values
- 5. Attaching the policy-map to an input interface

```
Router# configure
Router(config)# policy-map test-police-1R3C
Router(config-pmap)# class ipv4-5
Router(config-pmap-c)# set qos-group 2 (optional)
Router(config-pmap-c)# police rate percent 20 burst 100000 bytes peak-burst 190000 bytes
Router(config-pmap-c-police)# exit
Router(config-pmap-c)# exit
Router(config-pmap)# exit
Router(config)# interface HundredGigE 0/6/0/18
Router(config-if)# service-policy input test-police-1R3C
Router(config-if)# commit
```

Running Configuration

```
class-map match-any ipv4-5
match precedence 3
end-class-map
!
```

policy-map test-police-1R3C

```

police rate

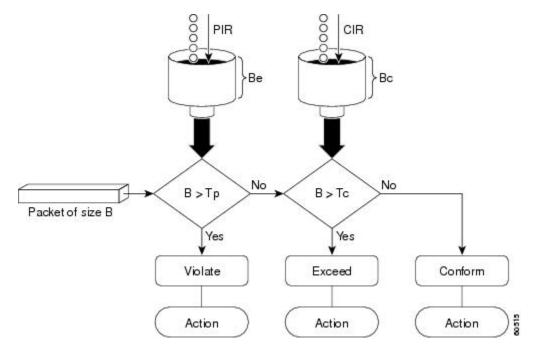

Two-Rate Policer

The two-rate policer manages the maximum rate of traffic by using two token buckets: the committed token bucket and the peak token bucket. The dual-token bucket algorithm uses user-configured values to determine the maximum rate of traffic allowed on a queue at a given moment. In this way, the two-rate policer can meter traffic at two independent rates: the committed information rate (CIR) and the peak information rate (PIR).

The dual-token bucket algorithm provides users with three actions for each packet—a conform action, an exceed action, and an optional violate action. Traffic entering a queue with the two-rate policer configured is placed into one of these categories. The actions are pre-determined for each category. The default conform and exceed actions are to transmit the packet, and the default violate action is to drop the packet.

This figure shows how the two-rate policer marks a packet and assigns a corresponding action to the packet.

Figure 2: Marking Packets and Assigning Actions—Two-Rate Policer

Also, see Two-Rate Policer Details, on page 32.

The router supports Two-Rate Three-Color (2R3C) policer.

Configure Traffic Policing (Two-Rate Three-Color)

The default conform and exceed actions for two-rate three-color (2R3C) policer are to transmit the packet and the default violate action is to drop the packet. Users cannot modify these default actions.

Configuration Example

You have to accomplish the following to complete the two-rate three-color traffic policing configuration:

- 1. Creating or modifying a policy-map that can be attached to one or more interfaces
- 2. Specifying the traffic class whose policy has to be created or changed
- 3. Specifying the packet marking
- 4. Configuring two rate traffic policing
- 5. Attaching the policy-map to an input interface

```
Router# configure
Router(config)# policy-map policy1
```

```
Router(config-pmap)# class ipv4-7
Router(config-pmap-c)# set qos-group 4
Router(config-pmap-c)# police rate percent 20 burst 100000 bytes peak-rate percent 50
peak-burst 200000 bytes
Router(config-pmap-c-police)# exit
Router(config-pmap-c)# exit
Router(config-pmap)# exit
Router(config)# interface HundredGigE 0/6/0/18
Router(config-if)# service-policy input policy1
Router(config-if)# commit
```

Running Configuration

```
policy-map policy1
class ipv4-7
set qos-group 4
police rate percent 20 burst 100000 bytes peak-rate percent 50 peak-burst 200000 bytes
!
!
interface HundredGigE 0/6/0/18

Policer conform burst
```

Important Notes

- From Cisco IOS XR Release 6.6.25 onwards:
 - a committed information rate of 0 kbps is supported, which is the only exception to the minimum rate of 22 kbps for both commit and excess rates.
 - a policer on a bundle interface also allows absolute rates apart from the already supported units of percent, per-thousand and per-million.
- A policer is programmed per NPU core on a bundle interface. So, all members on a bundle interface from the same core share the policer.

Packets-Per-Second-Based Policer

Table 2: Feature History Table

Feature Name	Release Information	Feature Description
Packets-Per-Second-Based Policer	Release 7.4.1	 Prior to this functionality, when configuring policers, the only available option for policer rates was bit-rate measured in units of bits per second (bps). With this release, you can configure policer rates in units of packets per second (pps) as well. pps-based policer is critical in fending off malicious attacks—when attackers target your specific resources with a vast amount of traffic that contain higher number of packets, but move at a slower packet rate. Protection from such attacks is possible because pps-based policers ensure that regardless of the packet size and rate, the policer only accepts a fixed number of packets per second. This functionality modifies the police rate command.

• Policer rates so far—You used the police rate command to configure policers based on two parameters:

• bit-rates (default unit: bits per second or bps)

- Burst size (default unit: bytes)
- packets-per-second (pps)-based policer—With this additional functionality, you can use the police
 rate command to configure policers in units of packets per second (pps). The pps configuration option
 is available as police rate <pps-value> pps. When you configure the pps option, ensure that you configure
 burst size in packets. (See Restrictions and guidelines.) Thus, the parameters for pps-based policer are:
 - packets per second (pps)
 - burst size (packets)
- Why pps-based-policer—Networks face newer types of attacks, and these days malicious operators don't necessarily employ aggressive tactics that involve overwhelming your bandwidth with large amount of traffic to cause distributed denial of service (DDoS). Now, some attackers go the 'softer' route, where they send smaller packet sizes at slower traffic rates. During such malicious network activity, a bandwidth-based policer can still aggregate up to many packets to be processed if the packet size is small. Attackers tend to use this behavior to bypass bandwidth-based policers to exploit vulnerabilities or try to hit performance limitations by increasing the packet rates.

Packets-per-second-based policers ensure that regardless of the packet size and traffic rate, the policer only accepts a fixed number of packets per second.

pps-based-policer support cheat-sheet—Here's a quick look at some key support areas and their details for pps-based policer.

Support	Details
Classification and marking support	Same as that for bps-based-policer
Units	Equivalent kbps values display for QoS programming and statistics.
H-QoS	Support for parent and child policers
Bursts	Support for confirm burst (bc) and exceed burst (be) values in units of packets. The default value is in multiple of 128 bytes equivalent to 10 milliseconds.
Minimum pps value	For better granularity, recommended minimum value is 100 pps.

Restriction and guidelines

- This functionality is applicable only for ingress.
- When using a pps-based policer, ensure that you configure the burst-size value in number of packets as well. This is because a policer burst rate determines whether a specific number of packets out of contract would be subject to the next action (that is, exceed or violate).
- Within a QoS policy, configure the parent and child policies policers to either bps or pps. Else, the configuration displays an error when you try attaching the policy to an interface.
- For single-level policy maps: under the same policy map, you can configure one class map with bps-based policer and the other class map with a pps-based policer.

• For two-level hierarchical policy maps:

- The parent and child-level policy maps must use the same unit-based policer. That is, both must have either pps-based or bps-based policers.
- If you configure the child-level policy map with pps-based policer, ensure that the parent
 policy-map class default has a pps-based policer.
- Configure pps-based policer—To configure pps-based policer, you must:
 - **1.** Configure a class map.
 - 2. Create a service policy for the map and configure the pps values.
 - 3. Attach the service policy to an interface.

police rate

Shared Policer

The classification of the incoming packet occurs only once. However, based on the different classification criteria, the shared policer feature allows sharing of the policer bucket amongst two or more classes in a QoS policy map. That is, the same token bucket is used for a traffic flow matching against any of the classes sharing the policer.

For example, let us say a policer of 10 Mbps is shared among two classes C1 and C2. This feature ensures that both C1 and C2 get traffic flow assigned on First Come First Serve (FCFS) basis. Also that, if C2 does not have any traffic, C1 uses all of the 10 Mbps for transmission.

This feature includes two components:

- · Policer Bucket Shared
- Policer Bucket Referred

Policer Bucket Shared

The policer bucket shared feature defines and shares a policer bucket instance among multiple classes.

Here is a sample configuration that defines and shares policer bucket instance sp1:

```
policy-map parent
class long-distance
police bucket shared sp1 rate 1 mbps
```

In this configuration, a policy-map for class long-distance traffic type is created to police at 1Mbps rate and the policer bucket is shared.

Policer Bucket Referred

The policer bucket referred feature refers a defined policer bucket instance. Shared policer is not supported across policy levels. This means for example, that parent and child policy cannot share a common bucket.

Here is a sample configuration that refers shared policer bucket instance sp1 :

policy-map voip-child class long-distance-voip police bucket referred spl

In this configuration, a policy-map for class long-distance-voip traffic type is created and the shared policer bucket sp1 is referred.

Shared Policer Statistics

Currently, individual class statistics are not available as a default option for shared policer. You can access statistics in the following modes.

Aggregate Mode

In this mode the policer bucket is shared among two or more classes. However, statistics are not available for every individual class. You can view the aggregate statistics that combine the numbers for all the classes sharing the policer bucket.

Per-Class Mode

In this mode the policer bucket is shared among two or more classes, and you can also view individual class statistics. However, when this mode is active, the Policy-Based Tunnel Selection (PBTS) mechanism is disabled. To enable the per-class mode, you must configure the **hw-module profile qos** shared-policer-per-class-stats command.

Restrictions and Guidelines

The following restrictions and guidelines apply while configuring the shared policer feature.

- When shared policer is enabled in per-class mode, Policy-Based Tunnel Selection (PBTS) mechanism
 is disabled. In other words, shared policer-per-class-mode and PBTS are mutually exclusive features.
- Shared policer is not supported across policy levels. This means, for example, that parent and child policies cannot share a common policer bucket.
- Shared policer is not supported in ingress peering mode.
- Shared policer is supported within classes of the same policy. However, cross-policy bucket sharing is not supported.
- There are no limitations on the number of classes that can share policer.
- There are no changes in policer scale numbers in the aggregate and per-class modes.
- All the existing policer types (1R2C, 1R3C and 2R3C) are supported.
- You must reload the affected line card to enable the per-class-stats mode.

Configuring Shared Policer

To configure shared policer, you must:

- 1. Create a class map to be used for matching packets to the specified class.
- 2. Create a policy map to be used for matching packets to the specified class.
- **3.** Specify a class name.
- 4. Define and share a policer bucket.
- 5. Specify a class name.
- 6. Refer a shared policer bucket.

Prioritize Traffic during Oversubscription

Feature Name	Release Information	Feature Description
Prioritize Traffic during Oversubscription	Release 7.7.1	If the ASIC packet processing capacity is overloaded with continuous flow of packets, it's called oversubscription and it results in packet drops at the interface level. By enabling prioritization of packets during oversubscription, you can protect the high priority traffic. This feature introduces the hw-module oversubscription command.

Table 3: Feature History Table

An application-specific integrated circuit (ASIC) processes the traffic in the router. When the ingress packet enters the network interface in the ASIC, there's a small buffer to converge and process the packets. Independent of the traffic size, there's only one processing point in the ASIC to process the packets called Packet Processing Unit (PPU).

This PPU capacity is about the number of packets being processed per second by the ASIC, based on its packet processing power. The packet processing capacity is independent of the packet size, either it's 100 bytes or 5000 bytes, it processes only the header part, which is a fixed size, independent of the packet size.

Oversubscription occurs when the packet processing capacity is affected, and unable to process packets due to overloading of packets at PPU. But there's still some buffer available, which accommodates the logic of allowing traffic, based on their priority.

The network interface or ports in ASIC are grouped as port groups or quads. Depending upon the ASIC, supported port types include 1G, 10G, 25G, 40G, 50G, 100G, 200G, and 400G. The priority of packets are based on Class of Service (CoS) values.

The CoS value range is 0-7, where 6 and 7 are high priority by default. You can configure priority between 0-5. For example, consider interface X, with priority of 5, and if interface X belongs to a particular quad, then all the other interfaces belonging to that quad is also defined with the same priority of 5. So, if the CoS value is defined on an interface with high priority, then all the interface belonging to that quad becomes prioritized.

For untagged packets (without any VLAN tags) the interface priority is based on the interface name and it is considered with default CoS values as 6 and 7. Control plane packets always go through the highest priority.

Configuring Traffic Priorities on Tagged Interface

Perform this task to configure the traffic priorities using CoS values on tagged interface.

- 1. Creating egress policy-map that can be attached to one or more interfaces
- 2. Specifying the traffic class whose policy has to be created
- 3. Specifying priority to the traffic class
- 4. Creating H-QoS profile with ingress Layer 2 Access Control List (L2 ACL)
- 5. Specifying priority to the interface using oversubscription

Configuration Example

```
Router#configure

Router(config)#policy-map egress

Router(config-pmap)#class qosl

Router(config-pmap-c)#priority level 1

Router(config-pmap-c)#class class-default

Router(config-pmap-c)#end-policy-map

Router(config)#commit

Router(config)#end

Router(config)#end

Router#configure

Router(config)#hw-module profile qos hqos-enable

Router(config)#hw-module oversubscription

Router(config-oversubscription)#prioritize cos 1 interface tenGigE 0/0/0/0

Router(config-oversubscription)#commit

Wed Jul 6 11:07:45.608 UTC
```

NOTE: This CLI Config affects all interfaces in Quad Check 'show oversubscription'for quad details

Running Configuration

```
policy-map egress
class qos-1
  priority level 1
  low-latency-profile
!
  class class-default
!
  end-policy-map
!
hw-module profile qos hqos-enable
hw-module oversubscription
  prioritize cos 1 interface tenGigE 0/0/0/0
Wed_Jul_ 6 11:07:45.608 UTC
```

```
NOTE: This CLI Config affects all interfaces in Quad Check 'show oversubscription'for quad details
```

Verification

Verify the traffic priority configuration for both tagged interfaces, using the **show oversubscription** command.

```
Router#show oversubscription
Wed Jul 6 11:09:03.255 UTC
Interface
                Quad
                               Prioritization
TenGigE0/0/0/0
                      4
                                 cos [ 1 6 7]
TenGigE0/0/0/3
TenGigE0/0/0/2
TenGigE0/0/0/1
                       4
                                  cos [ 1 6 7]
                      4
                                 cos [ 1 6 7]
TenGigE0/0/0/1
                       4
                                 cos [ 1 6 7]
```

Configuring Traffic Priorities on Untagged Interface

Perform this task to configure the traffic priorities using CoS values on tagged interface.

- 1. Creating H-QoS profile with ingress Layer 2 Access Control List (L2 ACL)
- 2. Specifying priority to the interface using oversubscription

Configuration Example

```
Router#configure
Router(config)#hw-module profile qos hqos-enable
Router(config)#hw-module oversubscription
Router(config-oversubscription)#prioritize untagged interface tenGigE 0/0/0/10
Router(config-oversubscription)#commit
Wed Jul 6 11:07:45.608 UTC
```

NOTE: This CLI Config affects all interfaces in Quad Check 'show oversubscription'for quad details

Running Configuration

```
hw-module oversubscription
hw-module profile qos hqos-enable
  prioritize untagged interface tenGigE 0/0/0/10
Wed Jul 6 11:07:45.608 UTC
```

NOTE: This CLI Config affects all interfaces in Quad Check 'show oversubscription'for quad details

Verification

Verify the traffic priority configuration for untagged interfaces, using the show oversubscription command.

```
Router#show oversubscription
```

Wed Jul 6 11:09:0	3.255 UTC	
Interface	Quad	Prioritization
TenGigE0/0/0/10	6	cos [untagged 6 7]
TenGigE0/0/0/11	6	cos [untagged 6 7]
TenGigE0/0/0/9	6	cos [untagged 6 7]
TenGigE0/0/0/8	6	cos [untagged 6 7]

Limitations

- Only up to 20% of the high priority traffic is allowed per quad.
- Oversubscription configuration is supported only on ports with bandwidth greater than 10G.
- · Oversubscription is supported only for packets with VLAN header and control frames.
- You can enable oversubscription only at quad levels, based on the port speed in each quad.

References for Modular QoS Congestion Management

Committed Bursts

The committed burst (bc) parameter of the police command implements the first, conforming (green) token bucket that the router uses to meter traffic. The bc parameter sets the size of this token bucket. Initially, the token bucket is full and the token count is equal to the committed burst size (CBS). Thereafter, the meter updates the token counts the number of times per second indicated by the committed information rate (CIR).

The following describes how the meter uses the conforming token bucket to send packets:

- If sufficient tokens are in the conforming token bucket when a packet arrives, the meter marks the packet green and decrements the conforming token count by the number of bytes of the packet.
- If there are insufficient tokens available in the conforming token bucket, the meter allows the traffic flow to borrow the tokens needed to send the packet. The meter checks the exceeding token bucket for the number of bytes of the packet. If the exceeding token bucket has a sufficient number of tokens available, the meter marks the packet.

Green and decrements the conforming token count down to the minimum value of 0.

Yellow, borrows the remaining tokens needed from the exceeding token bucket, and decrements the exceeding token count by the number of tokens borrowed down to the minimum value of 0.

• If an insufficient number of tokens is available, the meter marks the packet red and does not decrement either of the conforming or exceeding token counts.

Note When the meter marks a packet with a specific color, there must be a sufficient number of tokens of that color to accommodate the entire packet. Therefore, the volume of green packets is never smaller than the committed information rate (CIR) and committed burst size (CBS). Tokens of a given color are always used on packets of that color.

Excess Bursts

The excess burst (be) parameter of the police command implements the second, exceeding (yellow) token bucket that the router uses to meter traffic. The exceeding token bucket is initially full and the token count is equal to the excess burst size (EBS). Thereafter, the meter updates the token counts the number of times per second indicated by the committed information rate (CIR).

The following describes how the meter uses the exceeding token bucket to send packets:

- When the first token bucket (the conforming bucket) meets the committed burst size (CBS), the meter allows the traffic flow to borrow the tokens needed from the exceeding token bucket. The meter marks the packet yellow and then decrements the exceeding token bucket by the number of bytes of the packet.
- If the exceeding token bucket does not have the required tokens to borrow, the meter marks the packet red and does not decrement the conforming or the exceeding token bucket. Instead, the meter performs the exceed-action configured in the police command (for example, the policer drops the packets).

Two-Rate Policer Details

The committed token bucket can hold bytes up to the size of the committed burst (bc) before overflowing. This token bucket holds the tokens that determine whether a packet conforms to or exceeds the CIR as the following describes:

- A traffic stream is conforming when the average number of bytes over time does not cause the committed token bucket to overflow. When this occurs, the token bucket algorithm marks the traffic stream green.
- A traffic stream is exceeding when it causes the committed token bucket to overflow into the peak token bucket. When this occurs, the token bucket algorithm marks the traffic stream yellow. The peak token bucket is filled as long as the traffic exceeds the police rate.

The peak token bucket can hold bytes up to the size of the peak burst (be) before overflowing. This token bucket holds the tokens that determine whether a packet violates the PIR. A traffic stream is violating when it causes the peak token bucket to overflow. When this occurs, the token bucket algorithm marks the traffic stream red.

For example, if a data stream with a rate of 250 kbps arrives at the two-rate policer, and the CIR is 100 kbps and the PIR is 200 kbps, the policer marks the packet in the following way:

- 100 kbps conforms to the rate
- 100 kbps exceeds the rate
- 50 kbps violates the rate

The router updates the tokens for both the committed and peak token buckets in the following way:

- The router updates the committed token bucket at the CIR value each time a packet arrives at the interface. The committed token bucket can contain up to the committed burst (bc) value.
- The router updates the peak token bucket at the PIR value each time a packet arrives at the interface. The peak token bucket can contain up to the peak burst (be) value.
- When an arriving packet conforms to the CIR, the router takes the conform action on the packet and decrements both the committed and peak token buckets by the number of bytes of the packet.
- When an arriving packet exceeds the CIR, the router takes the exceed action on the packet, decrements the committed token bucket by the number of bytes of the packet, and decrements the peak token bucket by the number of overflow bytes of the packet.

• When an arriving packet exceeds the PIR, the router takes the violate action on the packet, but does not decrement the peak token bucket.

See Two-Rate Policer, on page 18.
