

Configuring High Availability

This chapter contains the following sections:

- High Availability Overview, on page 1
- How High Availability Works, on page 1
- Deploying ESC High Availability, on page 2
- Configuring the Northbound Interface Access, on page 5
- Important Notes, on page 7
- Troubleshooting High Availability, on page 8

High Availability Overview

ESC supports High Availability (HA) in the form of a Primary and Standby model. Two ESC instances are deployed in the network to prevent ESC failure and provide ESC service with minimum service interruption. If the primary ESC instance fails, the standby instance automatically takes over the ESC services. ESC HA resolves the following single point failures:

- Network failures
- Power failures
- · Dead VM instance
- · Scheduled downtime
- Hardware issues
- Internal application failures

How High Availability Works

ESC HA network can be either set up as a single installation of a ESC HA pair or deployed as two standalone ESC nodes that are converted into HA pair after re-configuring these nodes post deployment. A HA deployment consists of two ESC instances: a primary and a standby. Under normal circumstances, the primary ESC instance provides the service. The corresponding standby instance is passive. The standby instance is in constant communication with the primary instance and monitors the primary instances' status. If the primary ESC instance fails, the standby instance automatically takes over the ESC services to provide ESC service with minimum interruption.

The standby also has a complete copy of the database of the primary, but it does not actively manage the network until the primary instance fails. The KeepAliveD service monitors both primary and standby instances activity status. When the primary instance fails, the standby takes over automatically. The standby instance takes over primary instance to manage the services while primary instance restoration is taking place.

When the failed instance is restored, if required you can manually initiate a switch-over and resume network management via the primary instance.

Both primary and standby ESC instances are connected to the northbound orchestration system through an IPv4 or IPv6 network. For the northbound system, a unique virtual IP address is assigned to access the current primary ESC High Availability instance. The deployed VNFs are connected to both ESC primary and standby instances through another IPv6 network.

ESC HA nodes are managed by KeepAliveD and DRBD (Replication tool to keep the ESC database synchronized) sync network services. While the KeepAliveD service monitors both primary and standby instances status, the DRBD service monitors primary instance DB and sync the changes to the standby instance DB. These two services can be co-located on same VIP network or in two separate networks. VM handshake between ESC instances occurs through the KeepAliveD over the IPv4 or IPv6 network.

Deploying ESC High Availability

To deploy Cisco Elastic Services Controller (ESC) High Availability (HA), ESC standalone instances can be installed on two separate nodes - Primary and Standby. For more information see, How High Availability Works, on page 1. You can connect the Primary and Standby instances to either a Cinder volume or Replication based volume (DRBD).

The following deployment mechanisms can be used to deploy ESC HA:

Internal Storage—When ESC HA is configured with Internal storage, the Primary and the Standby
instances have individual databases which are always synchronized. In this solution, ESC HA is designed
with database replication and DRBD is used as the tool for disk-level replication. The database in the
Primary instance simultaneously propagates the data to the database in the Standby instance thus requiring
no external storage. In the event of a Primary instance failing, the Standby instance get assigned the role
of the Primary instance along with its own synchronized database.

ESC HA is deployed using Internal storage, the ESC instances reply on the virtual IP address (that is kad_vip argument), and the interface of vrrp instance (that is kad_vif argument) to select the Primary ESC instance. To establish a reliable heartbeat network, it is recommended that the Primary and Standby ESC instances are on different physical hosts. The reliability of the physical links between the ESC instances (such as, network interface bonding) can also be taken into consideration.

 Replicate External-Storages — In this type of architecture, ESC HA is configured with DRBD and both Primary and Standby instance store their data in two external storages (OpenStack Cinder volumes).
 Each ESC node is attached by a Cinder volume and ESC data files are stored in the cinder volume. The data in two ESC node are synchronized through the database replication mechanism provided by DRBD.

The table lists the differences between the HA options :

	Internal Storage Based ESC HA	Replicate External Storage Based ESC HA
Data sharing method	1	Data replication between two external storages (cinder volume)

Installation Method	Post-installation Configuration Bootvm Installation	Bootvm Installation
VIM Support	OpenStack, VMware, KVM	OpenStack only
Dependency	VIM independent	Rely on OpenStack cinder
Advantages	 No dependency on specific VIM components. Flexible to build of HA clusters from commodity hardware, without the requirement for shared-storage. 	 Use database replication mechanism for data synchronization Two cinder volumes are used as external storage and are attached to ESC node.
Limitations	The data consistency may be affected in a double fault condition (occurs when both ESC nodes have problems).	× ×

Deploying ESC in High Availability Mode on Internal Storage

When you boot ESC instances on Primary and Standby instances, you need to specify the following *bootvm.py* command arguments to deploy ESC HA on an internal storage:

• kad_vip

When ESC HA is deployed, the *kad_vip* argument allows end users to access the Primary ESC instance.

- kad_vif
- ha_node_list

These arguments enable the *bootvm.py* command to automatically set up the internal storage on the OpenStack. For more information on using the *bootvm.py* command arguments, see Appendix A: Cisco Elastic Services Controller Installer Arguments.

To deploy ESC HA instances, use the bootvm script on both the nodes with the following arguments:

```
ON HA NODE 1:
```

```
$ ./bootvm.py <ESC_HA_Nodel>\
--user_pass <username>:<password>\
--user_confd_pass <username>:<password>\
--gateway_ip <default gateway IP address>\
--net <network namel>\
--ipaddr <static ip address>
--image <image_name>\
--avail_zone nova:<openstack zone>\
--ha_node_list=<ESC_HA_NODE1_IP> <ESC_HA_NODE2_IP>\
--db volume id <cinder volume id>\
```

```
--kad vip <virtual IP address>\
--kad vif <VRRP_Interface_Instance>\
--ha mode drbd
ON HA NODE 2:
$ ./bootvm.py <ESC HA Node2>\
--user pass <username>:<password>\
--user_confd_pass <username>:<password>\
--gateway ip <default gateway IP address>\
--net <network name1>\
--ipaddr <static ip addresses>\
--image <image name>\
--avail zone nova:<openstack zone>\
--ha node list=<ESC HA NODE1 IP> <ESC HA NODE2 IP>\
--db volume id <cinder volume id>\
--kad_vip <virtual IP address>\
--kad vif <VRRP Interface Instance>\
--ha mode drbd
```

OR

You can also use **escadm** tool to re-configure ESC HA parameters on each of the standalone ESC VMs. Three parameters "--ha_node_list, --kad_vip, --kad_vif" are all required to configure ESC HA. For example:

```
$ sudo bash
$ escadm ha set --ha_node_list='<ESC_HA_NODE1_IP> <ESC_HA_NODE2_IP>' --kad_vip <virtual IP
address> --kad_vif <VRRP_Interface_Instance>
$ sudo escadm restart
```

Deploying ESC in High Availability Mode on Replicate External Storage

Replicate external storage ESC HA requires two cinder volumes for database storage.

Before you begin

- · Networks and IP addresses that both ESC instances will connect to
- Keepalived interface and virtual IP for HA switchover

Step 1 Create two cinder volumes in OpenStack. The configured cinder volume size should be 3GB.

```
$ cinder create --display-name cindervolume_name_a[SIZE]
$ cinder create --display-name cindervolume_name_b[SIZE]
```

Step 2 Check the status of the created cinder volume and find the uuids for deployment.

\$ cinder list

Step 3 Deploy ESC HA instances. Use the bootvm script on both the nodes with the following arguments:

ON HA NODE 1:

```
$ ./bootvm.py <ESC_HA_Node1>\
--user pass <username>:<password>\
```

```
--user confd pass <username>:<password>\
--gateway_ip <default gateway IP address>\
--net <network name1>\
--ipaddr <static ip address>\
--image <image name>\
--avail zone nova:<openstack zone>\
--kad vip <virtual IP address>\
--kad vif <VRRP Interface Instance>\
--ha node list=<ESC HA NODE1 IP> <ESC HA NODE2 IP>\
--db volume id <cinder volume id>\
--ha mode drbd on cinder
ON HA NODE 2:
$ ./bootvm.py <ESC HA Node2>\
--user pass <username>:<password>\
--user confd pass <username>:<password>\
--gateway ip <default gateway IP address>\
--net <network name1>\
--ipaddr <static ip address>\
--image <image_name>\
--avail zone nova:<openstack zone>\
--kad vip <virtual IP address>\
--kad vif <VRRP Interface_Instance>\
--ha node list=<ESC HA NODE1 IP> <ESC HA NODE2 IP>\
--db volume id <cinder volume id>\
--ha mode drbd on cinder
```

Step 4 After both VMs are rebooted; the keepalived state on one of ESC VM should be one of ESC VM should be in MASTER state and the other one should be in BACKUP state. You can check ESC HA state by using following command: *\$ sudo escadm status --v*.

Configuring the Northbound Interface Access

When you configure ESC HA, you can also specify a virtual Anycast IP address to the HA pair. The northbound interface as well as the service portal uses virtual Anycast IP address to access the ESC Primary HA instance. When deploying ESC HA, use the following arguments with the *./bootvm.py* script.

- --ha_node_list
- --kad_vip
- --kad_vif

For more details on these arguments, see section Appendix A: Cisco Elastic Services Controller Installer Arguments.

The following section explains how to configure ESC HA with multiple interfaces and to configure the virtual Anycast IP address.

Configuring ESC HA with Multiple Interfaces

You can configure ESC HA with DRDB synchronization and VRRP heartbeat broadcasting on a network interface for data synchronization and VNF monitoring. You can use an additional network interface to allocate Virtual IP for the northbound access. To configure the multiple interfaces on ESC HA nodes, use --ha_node_list,

--kad_vip, --kad_vif arguments to specify these multiple network interfaces configuration. For details on these arguments, see section Appendix A: Cisco Elastic Services Controller Installer Arguments.

Example configuration steps are shown below:

```
./bootvm.py <esc hal> \
--user pass <username>:<password>
--user confd pass <username>:<password>
--image <image id> \
--net <net-name> \
--gateway ip <default gateway ip address> \
--ipaddr <ip address1> <ip address2> \
--ha node list < IP addresses HA nodes1> < IP addresses for HA nodes2> \
--kad vip <keepaliveD VIP of the HA nodes and the interface for keepaliveD VIP> \ (for
example: --kad vip 192.0.2.254:eth2)
--kad vri <virtual router id of vrrp instance>
--kad vif <virtual IP of the HA nodes or the interface of the keepalived VRRP> \setminus (for
example: --kad vif eth1 )
--ha mode <HA installation mode> \
--route <routing configuration> \
                                    (for example:192.0.2.254/24:192.168.0.1:eth1 )
--avail zone nova:<openstack zone> \
```

Similarly, a three network interface can be configured for ESC HA nodes. An example three interfaces configuration is shown below with the following assumptions :

- Network 1 is an IPv6 network used for northbound connection. ESC VIP is allocated in this network and the Orchestrator send requests to ESC through ESC VIP.
- Network 2 is an IPv4 network used for ESC sync traffic (DRDB synchronization) and VRRP heartbeat. This network is also used for OpenStack connection and VNF monitoring.
- Network 3 is another IPv4 network used for management. The SA, rsyslog, etc. can use this network to manage ESC.

./bootvm.py esc-ha-0 --image ESC-2_2_x_yyy --net esc-v6 esc-net --gateway_ip 192.168.0.1 --ipaddr 2001:cc0:2020::fa 192.168.0.239 192.168.5.239 --ha_node_list 192.168.0.239 192.168.0.243 --kad_vip [2001:cc0:2020::fc/48]:eth0 --kad_vif eth1 --ha_mode drbd --route 10.85.103.0/24:192.168.0.1:eth1 --avail_zone nova: zone name

./bootvm.py esc-ha-1 --image ESC-2_2_x_yyy --net esc-v6 esc-net lab-net-0 --gateway_ip 192.168.0.1 --ipaddr 2001:cc0:2020::fa 192.168.0.239 192.168.5.239 --ha_node_list 192.168.0.239 192.168.0.243 --kad_vip [2001:cc0:2020::fc/48]:eth0 --kad_vif eth1 --ha_mode drbd --route 10.85.103.0/24:192.168.0.1:eth1 --avail_zone nova: zone name

Configuring the ESC HA Virtual IP Address

In this option, the value of kad_vip argument should be a virtual IP, which allows the service portal and the northbound to access the Primary ESC and send requests to ESC HA service through virtual IP (VIP).

If northbound and both ESC HA nodes are located in the same network, you can connect directly through the virtual IP (VIP). If northbound doesn't sit on the same network as ESC HA, assign a floating IP to ESC HA VIP using the procedure below:

1. Create a port with the VIP address (kad_vip) in the same network as ESC's kad_vip connects.

neutron port-create esc-net --name esc_vip --fixed-ip subnet id=esc-subnet,ip address=192.168.0.87

2. Deploy ESC HA . See Configuring High-Availability section in Installing ESC on OpenStack.

Note Make sure the *kad vip* using the same IP address as the port created above.

3. Associate a floating IP with the port created above. The first uuid is the floating ip id and the second one is the port id.

neutron floatingip-associate <floating IP> <port ID>

Access ESC HA through the floating IP and it will connect to the ESC Primary node.

4. For the portal access, make sure the keepalive network is accessible by your browser and the virtual IP is the IP address to access the portal of the Primary node.

For example, if the VIP is 192.0.2.254, access ESC HA portal with https://192.0.2.254:9001/.

Important Notes

• ESC HA

- An HA failover takes about 2 to 5 minutes. The ESC service will not be available during the switchover time.
- When the switchover is triggered during transactions, all incomplete transactions will be dropped. The requests should be re-sent by northbound if it does not receive any response from ESC.

External Storage

• If the Primary ESC instance is suspended by OpenStack command, the switch over will be triggered but the cinder volume won't be attached to the new Primary ESC instance. This is not a valid use case for ESC HA.

Internal Storage

- Two ESC instances have to be deployed to establish the HA solution. The ESC HA will start to
 work when both ESC instances are successfully deployed and are able to connect to each other. If
 you just deploy one ESC instance with HA parameters, the ESC instance keeps Switching-to-Master
 state and will not be able to provide any service until it reaches its peer.
- Split-brain scenario can still happen in this ESC HA solution, although the chance is very low.

• ETSI-specific Notes

ESC supports ETSI MANO northbound API defined by the European Telecommunications Standards Institute (ETSI) for NFV Management and Orchestration. The ETSI MANO API is another programmatic interface based on the REST architecture. For more information, see ETSI MANO Compliant Lifecycle Operations in the *Cisco Elastic Services Controller User Guide*. Consider the following notes while enabling ETSI service on ESC which is in HA mode:

• The server address value in the *etsi-vnfm.properties* file must be set to a Virtual IP (VIP) address. This IP address can be used to communicate back to the ETSI services using API callbacks. If the virtual IP address is not specified, the ETSI service startup may fail. • The ESC health service (*sudo escadm health or health.sh*) will report that the ETSI service is running but not ready. You can ignore this error as the ETSI service will be running and also processing requests.

Troubleshooting High Availability

• Check for network failures. If a network problem occurs, you must check the following details:

- The IP address assigned is correct, and is based on the OpenStack configuration.
- The gateway for each network interface must be pingable.
- Check the logs for troubleshooting:
 - The ESC Admin logs at /var/log/esc/escadm.log
 - The ESC manager log at /var/log/esc/escmanager.log
 - The ESC HA log at /var/log//esc/esc_haagent.log
 - The KeepAliveD log at /var/log/messages by grep keepalived
- Check for DRBD (Replication based ESC HA) for Internal Storage solution:
 - Check the DRBD configuration file at

/etc/drbd.d/esc.res

• Access the DRBD log

/var/log/messages|grep drbd
