Implementing Layer-3 Multicast Routing on Cisco IOS XR Software

This module describes how to implement Layer 3 multicast routing on Cisco ASR 9000 Series Routers running Cisco IOS XR Software.

Multicast routing is a bandwidth-conserving technology that reduces traffic by simultaneously delivering a single stream of information to potentially thousands of corporate recipients and homes. Applications that take advantage of multicast routing include video conferencing, corporate communications, distance learning, and distribution of software, stock quotes, and news.

This document assumes that you are familiar with IPv4 and IPv6 multicast routing configuration tasks and concepts for Cisco IOS XR Software.

Multicast routing allows a host to send packets to a subset of all hosts as a group transmission rather than to a single host, as in unicast transmission, or to all hosts, as in broadcast transmission. The subset of hosts is known as group members and are identified by a single multicast group address that falls under the IP Class D address range from 224.0.0.0 through 239.255.255.255.

For detailed conceptual information about multicast routing and complete descriptions of the multicast routing commands listed in this module, you can refer to the Related Documents, on page 185.

Prerequisites for Implementing Multicast Routing

- You must install and activate the multicast pie.
- For detailed information about optional PIE installation, see *Cisco ASR 9000 Series Aggregation Services Router Getting Started Guide*
- For MLDP, an MPLS PIE has to be installed.
- You must be in a user group associated with a task group that includes the proper task IDs. The command reference guides include the task IDs required for each command. If you suspect user group assignment is preventing you from using a command, contact your AAA administrator for assistance.
- You must be familiar with IPv4 and IPv6 multicast routing configuration tasks and concepts.
- Unicast routing must be operational.
- To enable multicast VPN, you must configure a VPN routing and forwarding (VRF) instance.

### Multicast Routing Functional Overview

Traditional IP communication allows a host to send packets to a single host (*unicast transmission*) or to all hosts (*broadcast transmission*). Multicast provides a third scheme, allowing a host to send a single data stream to a subset of all hosts (*group transmission*) at about the same time. IP hosts are known as group members.

Packets delivered to group members are identified by a single multicast group address. Multicast packets are delivered to a group using best-effort reliability, just like IP unicast packets.

The multicast environment consists of senders and receivers. Any host, regardless of whether it is a member of a group, can send to a group. However, only the members of a group receive the message.

A multicast address is chosen for the receivers in a multicast group. Senders use that group address as the destination address of a datagram to reach all members of the group.

Membership in a multicast group is dynamic; hosts can join and leave at any time. There is no restriction on the location or number of members in a multicast group. A host can be a member of more than one multicast group at a time.

How active a multicast group is and what members it has can vary from group to group and from time to time. A multicast group can be active for a long time, or it may be very short-lived. Membership in a group can change constantly. A group that has members may have no activity.

Routers use the Internet Group Management Protocol (IGMP) (IPv4) and Multicast Listener Discovery (MLD) (IPv6) to learn whether members of a group are present on their directly attached subnets. Hosts join multicast groups by sending IGMP or MLD report messages.

Many multimedia applications involve multiple participants. Multicast is naturally suitable for this communication paradigm.

Multicast Routing Implementation

Cisco IOS XR Software supports the following protocols to implement multicast routing:

- IGMP is used between hosts on a LAN and the routers on that LAN to track the multicast groups of which hosts are members.
- Protocol Independent Multicast in sparse mode (PIM-SM) is used between routers so that they can track which multicast packets to forward to each other and to their directly connected LANs.
- Protocol Independent Multicast in Source-Specific Multicast (PIM-SSM) is similar to PIM-SM with the additional ability to report interest in receiving packets from specific source addresses (or from all but the specific source addresses), to an IP multicast address.
- PIM-SSM is made possible by IGMPv3 and MLDv2. Hosts can now indicate interest in specific sources using IGMPv3 and MLDv2. SSM does not require a rendezvous point (RP) to operate.
- PIM Bidirectional is a variant of the Protocol Independent Multicast suit of routing protocols for IP multicast. PIM-BIDIR is designed to be used for many-to-many applications within individual PIM domains.

This image shows IGMP and PIM-SM operating in a multicast environment.

Figure 1: Multicast Routing Protocols
PIM-SM, PIM-SSM, and PIM-BIDIR

Protocol Independent Multicast (PIM) is a multicast routing protocol used to create multicast distribution trees, which are used to forward multicast data packets. PIM is an efficient IP routing protocol that is “independent” of a routing table, unlike other multicast protocols such as Multicast Open Shortest Path First (MOSPF) or Distance Vector Multicast Routing Protocol (DVMRP).

Cisco IOS XR Software supports Protocol Independent Multicast in sparse mode (PIM-SM), Protocol Independent Multicast in Source-Specific Multicast (PIM-SSM), and Protocol Independent Multicast in Bi-directional mode (BIDIR) permitting these modes to operate on your router at the same time.

PIM-SM and PIM-SSM supports one-to-many applications by greatly simplifying the protocol mechanics for deployment ease. Bidir PIM helps deploy emerging communication and financial applications that rely on a many-to-many applications model. BIDIR PIM enables these applications by allowing them to easily scale to a very large number of groups and sources by eliminating the maintenance of source state.

PIM-SM Operations

PIM in sparse mode operation is used in a multicast network when relatively few routers are involved in each multicast and these routers do not forward multicast packets for a group, unless there is an explicit request for the traffic.

For more information about PIM-SM, see the PIM-Sparse Mode, on page 9.

PIM-SSM Operations

PIM in Source-Specific Multicast operation uses information found on source addresses for a multicast group provided by receivers and performs source filtering on traffic.

- By default, PIM-SSM operates in the 232.0.0.0/8 multicast group range for IPv4 and ff3x::/32 (where x is any valid scope) in IPv6. To configure these values, use the ssm range command.
- If SSM is deployed in a network already configured for PIM-SM, only the last-hop routers must be upgraded with Cisco IOS XR Software that supports the SSM feature.
- No MSDP SA messages within the SSM range are accepted, generated, or forwarded.

PIM-Bidirectional Operations

PIM Bidirectional (BIDIR) has one shared tree from sources to RP and from RP to receivers. This is unlike the PIM-SM, which is unidirectional by nature with multiple source trees - one per (S,G) or a shared tree from receiver to RP and multiple SG trees from RP to sources.

Benefits of PIM BIDIR are as follows:

- As many sources for the same group use one and only state (*, G), only minimal states are required in each router.
- No data triggered events.
- Rendezvous Point (RP) router not required. The RP address only needs to be a routable address and need not exist on a physical device.
Restrictions for PIM-SM and PIM-SSM, and PIM BIDIR

Interoperability with SSM

PIM-SM operations within the SSM range of addresses change to PIM-SSM. In this mode, only PIM (S,G) join and prune messages are generated by the router, and no (S,G) RP shared tree or (*,G) shared tree messages are generated.

IGMP Version

To report multicast memberships to neighboring multicast routers, hosts use IGMP, and all routers on the subnet must be configured with the same version of IGMP.

A router running Cisco IOS XR Software does not automatically detect Version 1 systems. You must use the version command in router IGMP configuration submode to configure the IGMP version.

PIM-Bidir Restrictions

PIM-Bidir is not supported on MVPN.

Internet Group Management Protocol

Cisco IOS XR Software provides support for Internet Group Management Protocol (IGMP) over IPv4.

IGMP provides means for hosts to indicate which multicast traffic they are interested in and for routers to control and limit the flow of multicast traffic throughout the network. Routers build state by means of IGMP and MLD messages; that is, router queries and host reports.

A set of queries and hosts that receive multicast data streams from the same source is called a multicast group. Hosts use IGMP and MLD messages to join and leave multicast groups.

Note

IGMP messages use group addresses, which are Class D IP addresses. The high-order four bits of a Class D address are 1110. Host group addresses can be in the range 224.0.0.0 to 239.255.255.255. The address 224.0.0.0 is guaranteed not to be assigned to any group. The address 224.0.0.1 is assigned to all systems on a subnet. The address 224.0.0.2 is assigned to all routers on a subnet.

IGMP Versions

The following points describe IGMP versions 1, 2, and 3:

- IGMP Version 1 provides for the basic query-response mechanism that allows the multicast router to determine which multicast groups are active and for other processes that enable hosts to join and leave a multicast group.

- IGMP Version 2 extends IGMP allowing such features as the IGMP query timeout and the maximum query-response time. See RFC 2236.

- IGMP Version 3 permits joins and leaves for certain source and group pairs instead of requesting traffic from all sources in the multicast group.
IGMP Routing Example

Figure 2: IGMPv3 Signaling, on page 8 illustrates two sources, 10.0.0.1 and 10.0.1.1, that are multicasting to group 239.1.1.1. The receiver wants to receive traffic addressed to group 239.1.1.1 from source 10.0.0.1 but not from source 10.0.1.1. The host must send an IGMPv3 message containing a list of sources and groups (S, G) that it wants to join and a list of sources and groups (S, G) that it wants to leave. Router C can now use this information to prune traffic from Source 10.0.1.1 so that only Source 10.0.0.1 traffic is being delivered to Router C.

Figure 2: IGMPv3 Signaling

![Diagram of IGMPv3 Signaling]

Note
When configuring IGMP, ensure that all systems on the subnet support the same IGMP version. The router does not automatically detect Version 1 systems. Configure the router for Version 2 if your hosts do not support Version 3.

Protocol Independent Multicast

Protocol Independent Multicast (PIM) is a routing protocol designed to send and receive multicast routing updates. Proper operation of multicast depends on knowing the unicast paths towards a source or an RP. PIM relies on unicast routing protocols to derive this reverse-path forwarding (RPF) information. As the name PIM implies, it functions independently of the unicast protocols being used. PIM relies on the Routing Information Base (RIB) for RPF information.
If the multicast subsequent address family identifier (SAFI) is configured for Border Gateway Protocol (BGP), or if multicast intact is configured, a separate multicast unicast RIB is created and populated with the BGP multicast SAFI routes, the intact information, and any IGP information in the unicast RIB. Otherwise, PIM gets information directly from the unicast SAFI RIB. Both multicast unicast and unicast databases are outside of the scope of PIM.

Note
Cisco IOS XR Software supports PIM-SM, PIM-SSM, and PIM Version 2 only. PIM Version 1 hello messages that arrive from neighbors are rejected.

PIM-Sparse Mode

Typically, PIM in sparse mode (PIM-SM) operation is used in a multicast network when relatively few routers are involved in each multicast. Routers do not forward multicast packets for a group, unless there is an explicit request for traffic. Requests are accomplished using PIM join messages, which are sent hop by hop toward the root node of the tree. The root node of a tree in PIM-SM is the rendezvous point (RP) in the case of a shared tree or the first-hop router that is directly connected to the multicast source in the case of a shortest path tree (SPT). The RP keeps track of multicast groups, and the sources that send multicast packets are registered with the RP by the first-hop router of the source.

As a PIM join travels up the tree, routers along the path set up the multicast forwarding state so that the requested multicast traffic is forwarded back down the tree. When multicast traffic is no longer needed, a router sends a PIM prune message up the tree toward the root node to prune (or remove) the unnecessary traffic. As this PIM prune travels hop by hop up the tree, each router updates its forwarding state appropriately. Ultimately, the forwarding state associated with a multicast group or source is removed. Additionally, if prunes are not explicitly sent, the PIM state will timeout and be removed in the absence of any further join messages. PIM-SM is the best choice for multicast networks that have potential members at the end of WAN links.

PIM-Source Specific Multicast

In many multicast deployments where the source is known, protocol-independent multicast-source-specific multicast (PIM-SSM) mapping is the obvious multicast routing protocol choice to use because of its simplicity. Typical multicast deployments that benefit from PIM-SSM consist of entertainment-type solutions like the ETTH space, or financial deployments that completely rely on static forwarding.

PIM-SSM is derived from PIM-SM. However, whereas PIM-SM allows for the data transmission of all sources sending to a particular group in response to PIM join messages, the SSM feature forwards traffic to receivers only from those sources that the receivers have explicitly joined. Because PIM joins and prunes are sent directly towards the source sending traffic, an RP and shared trees are unnecessary and are disallowed. SSM is used to optimize bandwidth utilization and deny unwanted Internet broadcast traffic. The source is provided by interested receivers through IGMPv3 membership reports.

In SSM, delivery of datagrams is based on (S,G) channels. Traffic for one (S,G) channel consists of datagrams with an IP unicast source address S and the multicast group address G as the IP destination address. Systems receive traffic by becoming members of the (S,G) channel. Signaling is not required, but receivers must subscribe or unsubscribe to (S,G) channels to receive or not receive traffic from specific sources. Channel
subscription signaling uses IGMP to include mode membership reports, which are supported only in Version 3 of IGMP (IGMPv3).

To run SSM with IGMPv3, SSM must be supported on the multicast router, the host where the application is running, and the application itself. Cisco IOS XR Software allows SSM configuration for an arbitrary subset of the IP multicast address range 224.0.0.0 through 239.255.255.255. When an SSM range is defined, existing IP multicast receiver applications do not receive any traffic when they try to use addresses in the SSM range, unless the application is modified to use explicit (S,G) channel subscription.

**PIM-Bidirectional Mode**

PIM BIDIR is a variant of the Protocol Independent Multicast (PIM) suite of routing protocols for IP multicast. In PIM, packet traffic for a multicast group is routed according to the rules of the mode configured for that multicast group. In bidirectional mode, traffic is only routed along a bidirectional shared tree that is rooted at the rendezvous point (RP) for the group. In PIM-BIDIR, the IP address of the RP acts as the key to having all routers establish a loop-free spanning tree topology rooted in that IP address. This IP address does not need to be a router, but can be any unassigned IP address on a network that is reachable throughout the PIM domain. Using this technique is the preferred configuration for establishing a redundant RP configuration for PIM-BIDIR.

In Cisco IOS XR Release 4.2.1, Anycast RP is not supported on PIM Bidirectional mode.

PIM-BIDIR is designed to be used for many-to-many applications within individual PIM domains. Multicast groups in bidirectional mode can scale to an arbitrary number of sources without incurring overhead due to the number of sources. PIM-BIDIR is derived from the mechanisms of PIM-sparse mode (PIM-SM) and shares many SPT operations. PIM-BIDIR also has unconditional forwarding of source traffic toward the RP upstream on the shared tree, but no registering process for sources as in PIM-SM. These modifications are necessary and sufficient to allow forwarding of traffic in all routers solely based on the (*, G) multicast routing entries. This feature eliminates any source-specific state and allows scaling capability to an arbitrary number of sources.

The traditional PIM protocols (dense-mode and sparse-mode) provided two models for forwarding multicast packets, source trees and shared trees. Source trees are rooted at the source of the traffic while shared trees are rooted at the rendezvous point. Source trees achieve the optimum path between each receiver and the source at the expense of additional routing information: an (S,G) routing entry per source in the multicast routing table. The shared tree provides a single distribution tree for all of the active sources. This means that traffic from different sources traverse the same distribution tree to reach the interested receivers, therefore reducing the amount of routing state in the network. This shared tree needs to be rooted somewhere, and the location of this root is the rendezvous point. PIM BIDIR uses shared trees as their main forwarding mechanism.

The algorithm to elect the designated forwarder is straightforward, all the PIM neighbors in a subnet advertise their unicast route to the rendezvous point and the router with the best route is elected. This effectively builds a shortest path between every subnet and the rendezvous point without consuming any multicast routing state (no (S,G) entries are generated). The designated forwarder election mechanism expects all of the PIM neighbors to be BIDIR enabled. In the case where one of more of the neighbors is not a BIDIR capable router, the election fails and BIDIR is disabled in that subnet.
PIM Shared Tree and Source Tree (Shortest Path Tree)

In PIM-SM, the rendezvous point (RP) is used to bridge sources sending data to a particular group with receivers sending joins for that group. In the initial setup of state, interested receivers receive data from senders to the group across a single data distribution tree rooted at the RP. This type of distribution tree is called a shared tree or rendezvous point tree (RPT) as illustrated in Figure 3: Shared Tree and Source Tree (Shortest Path Tree), on page 11. Data from senders is delivered to the RP for distribution to group members joined to the shared tree.

![Figure 3: Shared Tree and Source Tree (Shortest Path Tree)](image)

Unless the `spt-threshold infinity` command is configured, this initial state gives way as soon as traffic is received on the leaf routers (designated router closest to the host receivers). When the leaf router receives traffic from the RP on the RPT, the router initiates a switch to a data distribution tree rooted at the source sending traffic. This type of distribution tree is called a shortest path tree or source tree. By default, the Cisco IOS XR Software switches to a source tree when it receives the first data packet from a source.

The following process describes the move from shared tree to source tree in more detail:

1. Receiver joins a group; leaf Router C sends a join message toward RP.
2. RP puts link to Router C in its outgoing interface list.
3. Source sends data; Router A encapsulates data in Register and sends it to RP.
4. RP forwards data down the shared tree to Router C and sends a join message toward Source. At this point, data may arrive twice at the RP, once encapsulated and once natively.
5. When data arrives natively (unencapsulated) at RP, RP sends a register-stop message to Router A.
6. By default, receipt of the first data packet prompts Router C to send a join message toward Source.

7. When Router C receives data on (S,G), it sends a prune message for Source up the shared tree.

8. RP deletes the link to Router C from outgoing interface of (S,G). RP triggers a prune message toward Source.

Join and prune messages are sent for sources and RPs. They are sent hop by hop and are processed by each PIM router along the path to the source or RP. Register and register-stop messages are not sent hop by hop. They are exchanged using direct unicast communication between the designated router that is directly connected to a source and the RP for the group.

Tip

The `spt-threshold infinity` command lets you configure the router so that it never switches to the shortest path tree (SPT).

Multicast-Intact

The multicast-intact feature provides the ability to run multicast routing (PIM) when Interior Gateway Protocol (IGP) shortcuts are configured and active on the router. Both Open Shortest Path First, version 2 (OSPFv2), and Intermediate System-to-Intermediate System (IS-IS) support the multicast-intact feature. Multiprotocol Label Switching Traffic Engineering (MPLS-TE) and IP multicast coexistence is supported in Cisco IOS XR Software by using the `mpls traffic-eng multicast-intact` IS-IS or OSPF router command. See Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide for information on configuring multicast intact using IS-IS and OSPF commands.

You can enable multicast-intact in the IGP when multicast routing protocols (PIM) are configured and IGP shortcuts are configured on the router. IGP shortcuts are MPLS tunnels that are exposed to IGP. The IGPs route the IP traffic over these tunnels to destinations that are downstream from the egress router of the tunnel (from an SPF perspective). PIM cannot use IGP shortcuts for propagating PIM joins because reverse path forwarding (RPF) cannot work across a unidirectional tunnel.

When you enable multicast-intact on an IGP, the IGP publishes a parallel or alternate set of equal-cost next-hops for use by PIM. These next-hops are called `mcast-intact next-hops`. The mcast-intact next-hops have the following attributes:

- They are guaranteed not to contain any IGP shortcuts.
- They are not used for unicast routing but are used only by PIM to look up an IPv4 next hop to a PIM source.
- They are not published to the Forwarding Information Base (FIB).
- When multicast-intact is enabled on an IGP, all IPv4 destinations that were learned through link-state advertisements are published with a set equal-cost mcast-intact next-hops to the RIB. This attribute applies even when the native next-hops have no IGP shortcuts.
- In IS-IS, the max-paths limit is applied by counting both the native and mcast-intact next-hops together. (In OSPFv2, the behavior is slightly different.)
Designated Routers

Cisco routers use PIM-SM to forward multicast traffic and follow an election process to select a designated router (DR) when there is more than one router on a LAN segment.

The designated router is responsible for sending PIM register and PIM join and prune messages toward the RP to inform it about host group membership.

If there are multiple PIM-SM routers on a LAN, a designated router must be elected to avoid duplicating multicast traffic for connected hosts. The PIM router with the highest IP address becomes the DR for the LAN unless you choose to force the DR election by use of the `dr-priority` command. The DR priority option allows you to specify the DR priority of each router on the LAN segment (default priority = 1) so that the router with the highest priority is elected as the DR. If all routers on the LAN segment have the same priority, the highest IP address is again used as the tiebreaker.

Figure 4: Designated Router Election on a Multiaccess Segment, on page 14 illustrates what happens on a multiaccess segment. Router A (10.0.0.253) and Router B (10.0.0.251) are connected to a common multiaccess Ethernet segment with Host A (10.0.0.1) as an active receiver for Group A. As the Explicit Join model is used, only Router A, operating as the DR, sends joins to the RP to construct the shared tree for Group A. If Router B were also permitted to send (*, G) joins to the RP, parallel paths would be created and Host A would receive duplicate multicast traffic. When Host A begins to source multicast traffic to the group, the DR’s responsibility is to send register messages to the RP. Again, if both routers were assigned the responsibility, the RP would receive duplicate multicast packets.

If the DR fails, the PIM-SM provides a way to detect the failure of Router A and to elect a failover DR. If the DR (Router A) were to become inoperable, Router B would detect this situation when its neighbor adjacency with Router A timed out. Because Router B has been hearing IGMP membership reports from Host A, it already has IGMP state for Group A on this interface and immediately sends a join to the RP when it becomes the new DR. This step reestablishes traffic flow down a new branch of the shared tree using Router B. Additionally, if Host A were sourcing traffic, Router B would initiate a new register process immediately after receiving the next multicast packet from Host A. This action would trigger the RP to join the SPT to Host A, using a new branch through Router B.
Two PIM routers are neighbors if there is a direct connection between them. To display your PIM neighbors, use the `show pim neighbor` command in EXEC mode.

**Tip**

```

**Note**

DR election process is required only on multiaccess LANs. The last-hop router directly connected to the host is the DR.

---

**Rendezvous Points**

When PIM is configured in sparse mode, you must choose one or more routers to operate as a rendezvous point (RP). A rendezvous point is a single common root placed at a chosen point of a shared distribution tree, as illustrated in **Figure 3: Shared Tree and Source Tree (Shortest Path Tree)**, on page 11. A rendezvous point can be either configured statically in each box or learned through a dynamic mechanism.

PIM DRs forward data from directly connected multicast sources to the rendezvous point for distribution down the shared tree. Data is forwarded to the rendezvous point in one of two ways:

- Encapsulated in register packets and unicast directly to the rendezvous point by the first-hop router operating as the DR
- Multicast forwarded by the RPF forwarding algorithm, described in the **Reverse-Path Forwarding**, on page 16, if the rendezvous point has itself joined the source tree.
The rendezvous point address is used by first-hop routers to send PIM register messages on behalf of a host sending a packet to the group. The rendezvous point address is also used by last-hop routers to send PIM join and prune messages to the rendezvous point to inform it about group membership. You must configure the rendezvous point address on all routers (including the rendezvous point router).

A PIM router can be a rendezvous point for more than one group. Only one rendezvous point address can be used at a time within a PIM domain. The conditions specified by the access list determine for which groups the router is a rendezvous point.

You can either manually configure a PIM router to function as a rendezvous point or allow the rendezvous point to learn group-to-RP mappings automatically by configuring Auto-RP or BSR. (For more information, see the Auto-RP, on page 15 section that follows and PIM Bootstrap Router, on page 16.)

### Auto-RP

Automatic route processing (Auto-RP) is a feature that automates the distribution of group-to-RP mappings in a PIM network. This feature has these benefits:

- It is easy to use multiple RPs within a network to serve different group ranges.
- It allows load splitting among different RPs.
- It facilitates the arrangement of RPs according to the location of group participants.
- It avoids inconsistent, manual RP configurations that might cause connectivity problems.

Multiple RPs can be used to serve different group ranges or to serve as hot backups for each other. To ensure that Auto-RP functions, configure routers as candidate RPs so that they can announce their interest in operating as an RP for certain group ranges. Additionally, a router must be designated as an RP-mapping agent that receives the RP-announcement messages from the candidate RPs, and arbitrates conflicts. The RP-mapping agent sends the consistent group-to-RP mappings to all remaining routers. Thus, all routers automatically determine which RP to use for the groups they support.

**Tip**

By default, if a given group address is covered by group-to-RP mappings from both static RP configuration, and is discovered using Auto-RP or PIM BSR, the Auto-RP or PIM BSR range is preferred. To override the default, and use only the RP mapping, use the `rp-address override` keyword.

**Note**

If you configure PIM in sparse mode and do not configure Auto-RP, you must statically configure an RP as described in the Configuring a Static RP and Allowing Backward Compatibility, on page 54. When router interfaces are configured in sparse mode, Auto-RP can still be used if all routers are configured with a static RP address for the Auto-RP groups.

**Note**

Auto-RP is not supported on VRF interfaces. Auto-RP Lite allows you to configure auto-RP on the CE router. It allows the PE router that has the VRF interface to relay auto-RP discovery, and announce messages across the core and eventually to the remote CE. Auto-RP is supported in only the IPv4 address family.
PIM Bootstrap Router

The PIM bootstrap router (BSR) provides a fault-tolerant, automated RP discovery and distribution mechanism that simplifies the Auto-RP process. This feature is enabled by default allowing routers to dynamically learn the group-to-RP mappings.

PIM uses the BSR to discover and announce RP-set information for each group prefix to all the routers in a PIM domain. This is the same function accomplished by Auto-RP, but the BSR is part of the PIM Version 2 specification. The BSR mechanism interoperates with Auto-RP on Cisco routers.

To avoid a single point of failure, you can configure several candidate BSRs in a PIM domain. A BSR is elected among the candidate BSRs automatically. Candidates use bootstrap messages to discover which BSR has the highest priority. The candidate with the highest priority sends an announcement to all PIM routers in the PIM domain that it is the BSR.

Routers that are configured as candidate RPs unicast to the BSR the group range for which they are responsible. The BSR includes this information in its bootstrap messages and disseminates it to all PIM routers in the domain. Based on this information, all routers are able to map multicast groups to specific RPs. As long as a router is receiving the bootstrap message, it has a current RP map.

Reverse-Path Forwarding

Reverse-path forwarding (RPF) is an algorithm used for forwarding multicast datagrams. It functions as follows:

- If a router receives a datagram on an interface it uses to send unicast packets to the source, the packet has arrived on the RPF interface.
- If the packet arrives on the RPF interface, a router forwards the packet out the interfaces present in the outgoing interface list of a multicast routing table entry.
- If the packet does not arrive on the RPF interface, the packet is silently discarded to prevent loops.

PIM uses both source trees and RP-rooted shared trees to forward datagrams; the RPF check is performed differently for each, as follows:

- If a PIM router has an (S,G) entry present in the multicast routing table (a source-tree state), the router performs the RPF check against the IP address of the source for the multicast packet.
- If a PIM router has no explicit source-tree state, this is considered a shared-tree state. The router performs the RPF check on the address of the RP, which is known when members join the group.

Sparse-mode PIM uses the RPF lookup function to determine where it needs to send joins and prunes. (S,G) joins (which are source-tree states) are sent toward the source. (*,G) joins (which are shared-tree states) are sent toward the RP.

Multicast VPN

Multicast VPN (MVPN) provides the ability to dynamically provide multicast support over MPLS networks. MVPN introduces an additional set of protocols and procedures that help enable a provider to support multicast traffic in a VPN.
There are two ways MCAST VPN traffic can be transported over the core network:

- **Rosen GRE (native):** MVPN uses GRE with unique multicast distribution tree (MDT) forwarding to enable scalability of native IP Multicast in the core network. MVPN introduces multicast routing information to the VPN routing and forwarding table (VRF), creating a Multicast VRF. In Rosen GRE, the MCAST customer packets (c-packets) are encapsulated into the provider MCAST packets (p-packets), so that the PIM protocol is enabled in the provider core, and mrrib/mfib is used for forwarding p-packets in the core.

- **MLDP ones (Rosen, partition):** MVPN allows a service provider to configure and support multicast traffic in an MPLS VPN environment. This type supports routing and forwarding of multicast packets for each individual VPN routing and forwarding (VRF) instance, and it also provides a mechanism to transport VPN multicast packets across the service provider backbone. In the MLDP case, the regular label switch path forwarding is used, so core does not need to run PIM protocol. In this scenario, the c-packets are encapsulated in the MPLS labels and forwarding is based on the MPLS Label Switched Paths (LSPs), similar to the unicast case.

In both the above types, the MVPN service allows you to build a Protocol Independent Multicast (PIM) domain that has sources and receivers located in different sites.

To provide Layer 3 multicast services to customers with multiple distributed sites, service providers look for a secure and scalable mechanism to transmit customer multicast traffic across the provider network. Multicast VPN (MVPN) provides such services over a shared service provider backbone, using native multicast technology similar to BGP/MPLS VPN.

In addition to all the ethernet based line cards, Multicast VPN is also supported on the Cisco ASR 9000 Series SPA Interface Processor-700 card from the Cisco IOS XR Software Release 4.0 onwards. Cisco ASR 9000 Series SPA Interface Processor-700 enables the Cisco ASR 9000 Series Routers to support multiple legacy services (such as TDM and ATM) on a router that is primarily designed for Ethernet networks. Cisco ASR 9000 Series SPA Interface Processor-700 is QFP-based and therefore has the flexibility and service scale offered by Cisco ASIC and the reliability of Cisco IOS XR Software.

MVPN emulates MPLS VPN technology in its adoption of the multicast domain (MD) concept, in which provider edge (PE) routers establish virtual PIM neighbor connections with other PE routers that are connected to the same customer VPN. These PE routers thereby form a secure, virtual multicast domain over the provider network. Multicast traffic is then transmitted across the core network from one site to another, as if the traffic were going through a dedicated provider network.

Multi-instance BGP is supported on multicast and MVPN. Multicast-related SAFIs can be configured on multiple BGP instances.

**Multicast VPN Routing and Forwarding**

Dedicated multicast routing and forwarding tables are created for each VPN to separate traffic in one VPN from traffic in another.

The VPN-specific multicast routing and forwarding database is referred to as **MVRF**. On a PE router, an MVRF is created when multicast is enabled for a VRF. Protocol Independent Multicast (PIM), and Internet Group Management Protocol (IGMP) protocols run in the context of MVRF, and all routes created by an MVRF protocol instance are associated with the corresponding MVRF. In addition to VRFs, which hold
VPN-specific protocol states, a PE router always has a global VRF instance, containing all routing and forwarding information for the provider network.

### Multicast Distribution Tree Tunnels

The multicast distribution tree (MDT) can span multiple customer sites through provider networks, allowing traffic to flow from one source to multiple receivers. For MLDP, the MDT tunnel trees are called as Labeled MDT (LMDT).

Secure data transmission of multicast packets sent from the customer edge (CE) router at the ingress PE router is achieved by encapsulating the packets in a provider header and transmitting the packets across the core. At the egress PE router, the encapsulated packets are decapsulated and then sent to the CE receiving routers.

Multicast distribution tree (MDT) tunnels are point-to-multipoint. A MDT tunnel interface is an interface that MVRF uses to access the multicast domain. It can be deemed as a passage that connects an MVRF and the global MVRF. Packets sent to an MDT tunnel interface are received by multiple receiving routers. Packets sent to an MDT tunnel interface are encapsulated, and packets received from a MDT tunnel interface are decapsulated.

**Figure 5: Virtual PIM Peer Connection over an MDT Tunnel Interface**

Encapsulating multicast packets in a provider header allows PE routers to be kept unaware of the packets’ origin—all VPN packets passing through the provider network are viewed as native multicast packets and are routed based on the routing information in the core network. To support MVPN, PE routers only need to support native multicast routing.

MVPN also supports optimized VPN traffic forwarding for high-bandwidth applications that have sparsely distributed receivers. A dedicated multicast group can be used to encapsulate packets from a specific source, and an optimized MDT can be created to send traffic only to PE routers connected to interested receivers. This is referred to as data MDT.

### InterAS Support on Multicast VPN

The Multicast VPN Inter-AS Support feature enables service providers to provide multicast connectivity to VPN sites that span across multiple autonomous systems. This feature was added to MLDP profile that enables Multicast Distribution Trees (MDTs), used for Multicast VPNs (MVPNs), to span multiple autonomous systems.

There are two types of MVPN inter-AS deployment scenarios:
• Single-Provider Inter-AS—A service provider whose internal network consists of multiple autonomous systems.

• Intra-Provider Inter-AS—Multiple service providers that need to coordinate their networks to provide inter-AS support.

To establish a Multicast VPN between two autonomous systems, a MDT-default tunnel must be setup between the two PE routers. The PE routers accomplish this by joining the configured MDT-default group. This MDT-default group is configured on the PE router and is unique for each VPN. The PIM sends the join based on the mode of the groups, which can be PIM SSM, or sparse mode.

Note
PIM-Bidir is not supported on MVPN.

Benefits of MVPN Inter-AS Support
The MVPN Inter-AS Support feature provides these benefits to service providers:

• Increased multicast coverage to customers that require multicast to span multiple services providers in an MPLS Layer 3 VPN service.

• The ability to consolidate an existing MVPN service with another MVPN service, as in the case of a company merger or acquisition.

InterAS Option A
InterAS Option A is the basic Multicast VPN configuration option. In this option, the PE router partially plays the Autonomous System Border Router (ASBR) role in each Autonomous System (AS). Such a PE router in each AS is directly connected through multiple VRF bearing subinterfaces. MPLS label distribution protocol need not run between these InterAS peering PE routers. However, an IGP or BGP protocol can be used for route distribution under the VRF.

The Option A model assumes direct connectivity between PE routers of different autonomous systems. The PE routers are attached by multiple physical or logical interfaces, each of which is associated with a given VPN (through a VRF instance). Each PE router, therefore, treats the adjacent PE router like a customer edge (CE) router. The standard Layer 3 MPLS VPN mechanisms are used for route redistribution with each autonomous system; that is, the PEs use exterior BGP (eBGP) to distribute unlabeled IPv4 addresses to each other.

Note
Option A allows service providers to isolate each autonomous system from the other. This provides better control over routing exchanges and security between the two networks. However, Option A is considered the least scalable of all the inter-AS connectivity options.

InterAS Option B
InterAS Option B is a model that enables VPNv4 route exchanges between the ASBRs. This model also distributes BGP MVPN address family. In this model, the PE routers use internal BGP (iBGP) to redistribute labeled VPNv4 routes either to an ASBR or to route reflector of which an ASBR is a client. These ASBRs use multiprotocol eBGP (MP-eBGP) to advertise VPNv4 routes into the local autonomous systems. The MP-eBGP advertises VPNv4 prefix and label information across the service provider boundaries. The
advertising ASBR router replaces the two-level label stack, which it uses to reach the originating PE router and VPN destination in the local autonomous system, with a locally allocated label before advertising the VPNv4 route. This replacement happens because the next-hop attribute of all routes advertised between the two service providers is reset to the ASBR router's peering address, thus making the ASBR router the termination point of the label-switched path (LSP) for the advertised routes. To preserve the LSP between ingress and egress PE routers, the ASBR router allocates a local label that is used to identify the label stack of the route within the local VPN network. This newly allocated label is set on packets sent towards the prefix from the adjacent service provider.

**Note**
Option B enables service providers to isolate both autonomous systems with the added advantage that it scales to a higher degree than Option A.

In the InterAS Option B model, only BGP-AD profiles are supported:

- MLDP MS-PMSI MP2MP with BGP-AD (profile 4)
- Rosen GRE with or without BGP-AD (profile 9)

**Note** Profile 9 is only supported with leaking root address into IGP.

**Note** MLDP MS-PMSI MP2MP with BGP-AD (profile 5) is not supported.

**InterAS Option C**

InterAS Option C allows exchange of VPNv4 routes between router reflectors (RRs) using multihop eBGP peering sessions. In this model, the MP-eBGP exchange of VPNv4 routes between the RRs of different autonomous systems is combined with the next hops for these routes exchanges between corresponding ASBR routers. This model also distributes BGP MVPN address family along with VPNv4. This model neither allows the VPNv4 routes to be maintained nor distributes by the ASBRs. ASBRs maintains labeled IPv4 routes to the PE routers within its autonomous system and uses eBGP to distribute these routes to other autonomous systems. In any transit autonomous systems, the ASBRs uses eBGP to pass along the labeled IPv4 routes, resulting in the creation of an LSP from the ingress PE router to the egress PE router.

Option C model uses the multihop functionality to allow the establishment for MP-eBGP peering sessions as the RRs of different autonomous systems are not directly connected. The RRs also do not reset the next-hop attribute of the VPNv4 routes when advertising them to adjacent autonomous systems as these do not attract the traffic for the destinations that they advertise, making it mandatory to enable the exchange of next hops. These are just a relay station between the source and receiver PEs. The PE router next-hop addresses for the VPNv4 routes, thus, are exchanged between ASBR routers. The exchange of these addresses between autonomous systems is accomplished by redistributing the PE router /32 addresses between the autonomous systems or by using BGP label distribution.

**Note** Option C normally is deployed only when each autonomous system belongs to the same overall authority, such as a global Layer 3 MPLS VPN service provider with global autonomous systems.

In the InterAS Option C model, these profiles are supported:
- Rosen MLDP without BGP-AD (profile 1)
- MLDP MS-PMSI MP2MP with BGP-AD (profile 4)
- MLDP MS-PMSI MP2MP with BGP-AD (profile 5)
- MLDP VRF in-band signaling (profile 6)
- Rosen GRE with BGP-AD (profile 9)

IPv6 Connectivity over MVPN

On the Cisco ASR 9000 Series Routers, in Cisco IOS XR Software starting Release 4.2.1, IPv6 connectivity is supported between customer sites over an IPv4-only core network with a default VRF. VPN PE routers interoperate between the two address families, with control and forwarding actions between IPv4-encapsulated MDTs and IPv6 customer routes. IPv6 users can configure IPv6-over-IPv4 multicast VPN support through BGP.

In Cisco IOS XR Software, MVPNv6 can have a separate data mdt group configured, which can be different from MVPNv4. But both MVPNv6 and MVPNv4 must have the same default mdt group configured.

The configuration example below shows MVPNv6 data mdt:

```
vrf cisco-sjc1
  address-family ipv4
    mdt data 226.8.3.0/24 threshold 5
    mdt default ipv4 226.8.0.1
  
  address-family ipv6
    mdt data 226.8.4.0/24 threshold 5
    mdt default ipv4 226.8.0.1
```

BGP Requirements

PE routers are the only routers that need to be MVPN-aware and able to signal remote PEs with information regarding the MVPN. It is fundamental that all PE routers have a BGP relationship with each other, either directly or through a route reflector, because the PE routers use the BGP peering address information to derive the RPF PE peer within a given VRF.

PIM-SSM MDT tunnels cannot be set up without a configured BGP MDT address-family, because you establish the tunnels, using the BGP connector attribute.

See the Implementing BGP on Cisco IOS XR Software module of the Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide for information on BGP support for Multicast VPN.

MVPN Static P2MP TE

This feature describes the Multicast VPN (MVPN) support for Multicast over Point-to-Multipoint -Traffic Engineering (P2MP-TE). Currently, Cisco IOS-XR Software supports P2MP-TE only in the Global table and the (S,G) route in the global table can be mapped to P2MP-TE tunnels. However, this feature now enables service providers to use P2MP-TE tunnels to carry VRF multicast traffic. Static mapping is used to map VRF (S, G) traffic to P2MP-TE tunnels, and BGP-AD is used to send P2MP BGP opaque that includes VRF-based P2MP FEC as MDT Selective Provider Multicast Service Interface (S-PMSI).

The advantages of the MVPN support for Multicast over P2MP-TE are:
• Supports traffic engineering such as bandwidth reservation, bandwidth sharing, forwarding replication, explicit routing, and Fast ReRoute (FRR).
• Supports the mapping of multiple multicast streams onto tunnels.

**Figure 6: Multicast VRF**

On PE1 router, multicast S,G (video) traffic is received on a VRF interface. The multicast S,G routes are statically mapped to P2MP-TE tunnels. The head-end then originates an S-PMSI (Type-3) BGP-AD route, for each of the S,Gs, with a PMSI Tunnel Attribute (PTA) specifying the P2MP-TE tunnel as the core-tree. The type of the PTA is set to RSVP-TE P2MP LSP and the format of the PTA Tunnel-identifier <Extended Tunnel ID, Reserved, Tunnel ID, P2MP ID>, as carried in the RSVP-TE P2MP LSP SESSION Object. Multiple S,G A-D routes can have the same PMSI Tunnel Attribute.

The tail-end PEs (PE2, PE3) receive and cache these S-PMSI updates (sent by all head-end PEs). If there is an S,G Join present in the VRF, with the Upstream Multicast Hop (UMH) across the core, then the PE looks for an S-PMSI announcement from the UMH. If an S-PMSI route is found with a P2MP-TE PTA, then the PE associates the tail label(s) of the Tunnel, with that VRF. When a packet arrives on the P2MP-TE tunnel, the tail-end removes the label and does an S,G lookup in the 'associated' VRF. If a match is found, the packet is forwarded as per its outgoing information.

**Multitopology Routing**

Multitopology routing allows you to manipulate network traffic flow when desirable (for example, to broadcast duplicate video streams) to flow over non-overlapping paths.

At the core of multitopology routing technology is router space infrastructure (RSI). RSI manages the global configuration of routing tables. These tables are hierarchically organized into VRF tables under logical routers. By default, RSI creates tables for unicast and multicast for both IPv4 and IPv6 under the default VRF. Using multitopology routing, you can configure named topologies for the default VRF.

PIM uses a routing policy that supports matching on source or group address to select the topology in which to look up the reverse-path forwarding (RPF) path to the source. If you do not configure a policy, the existing behavior (to select a default table) remains in force.

Currently, IS-IS and PIM routing protocols alone support multitopology-enabled network.
Multicast VPN Extranet Routing

Multicast VPN (MVPN) extranet routing lets service providers distribute IP multicast content from one enterprise site to another across a multicast VRF. In other words, this feature provides capability to seamlessly hop VRF boundaries to distribute multicast content end to end.

Unicast extranet can be achieved simply by configuring matching route targets across VRFs. However, multicast extranet requires such configuration to resolve route lookups across VRFs in addition to the following:

- Maintain multicast topology maps across VRFs.
- Maintain multicast distribution trees to forward traffic across VRFs.

Information About Extranets

An extranet can be viewed as part of an enterprise intranet that is extended to users outside the enterprise. A VPN is used as a way to do business with other enterprises and with customers, such as selling products and maintaining strong business partnerships. An extranet is a VPN that connects to one or more corporate sites to external business partners or suppliers to securely share a designated part of the enterprise’s business information or operations.

MVPN extranet routing can be used to solve such business problems as:

- Inefficient content distribution between enterprises.
- Inefficient content distribution from service providers or content providers to their enterprise VPN customers.

MVPN extranet routing provides support for IPv4 and IPv6 address family.

An extranet network requires the PE routers to pass traffic across VRFs (labeled "P" in Figure 7: Components of an Extranet MVPN, on page 24). Extranet networks can run either IPv4 or IPv6, but the core network always runs only IPv4 active multicast.
Extranet Components

Figure 7: Components of an Extranet MVPN

MVRF—Multicast VPN routing and forwarding (VRF) instance. An MVRF is a multicast-enabled VRF. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a provider edge (PE) router.

Source MVRF—An MVRF that can reach the source through a directly connected customer edge (CE) router.

Receiver MVRF—An MVRF to which receivers are connected through one or more CE devices.

Source PE—A PE router that has a multicast source behind a directly connected CE router.

Receiver PE—A PE router that has one or more interested receivers behind a directly connected CE router.

Information About the Extranet MVPN Routing Topology

In unicast routing of peer-to-peer VPNs, BGP routing protocol is used to advertise VPN IPv4 and IPv6 customer routes between provider edge (PE) routers. However, in an MVPN extranet peer-to-peer network, PIM RPF is used to determine whether the RPF next hop is in the same or a different VRF and whether that source VRF is local or remote to the PE.

Source MVRF on a Receiver PE Router

To provide extranet MVPN services to enterprise VPN customers by configuring a source MVRF on a receiver PE router, you would complete the following procedure:

- On a receiver PE router that has one or more interested receivers in an extranet site behind a directly connected CE router, configure an MVRF that has the same default MDT group as the site connected to the multicast source.

- On the receiver PE router, configure the same unicast routing policy to import routes from the source MVRF to the receiver MVRF.
If the originating MVRF of the RPF next hop is local (source MVRF at receiver PE router), the join state of the receiver VRFs propagates over the core by using the default multicast distribution tree (MDT) of the source VRF. Figure 8: Source MVRF at the Receiver PE Router, on page 25 illustrates the flow of multicast traffic in an extranet MVPN topology where the source MVRF is configured on a receiver PE router (source at receiver MVRF topology). An MVRF is configured for VPN-A and VPN-B on PE2, a receiver PE router. A multicast source behind PE1, the source PE router, is sending out a multicast stream to the MVRF for VPN-A, and there are interested receivers behind PE2, the receiver PE router for VPN-B, and also behind PE3, the receiver PE router for VPN-A. After PE1 receives the packets from the source in the MVRF for VPN-A, it replicates and forwards the packets to PE2 and PE3. The packets received at PE2 in VPN-A are decapsulated and replicated to receivers in VPN-B.

**Figure 8: Source MVRF at the Receiver PE Router**

Receiver MVRF on the Source PE Router

To provide extranet MVPN services to enterprise VPN customers by configuring the receiver MVRF on the source PE router, complete the following procedure:

- For each extranet site, you would configure an additional MVRF on the source PE router, which has the same default MDT group as the receiver MVRF, if the MVRF is not already configured on the source PE.
- In the receiver MVRF configuration, you would configure the same unicast routing policy on the source and receiver PE routers to import routes from the source MVRF to the receiver MVRF.

If the originating MVRF of the RPF next-hop is remote (receiver MVRF on the source PE router), then the join state of receiver VRFs propagates over the core through the MDT of each receiver.

**Figure 9: Receiver MVRF at the Source PE Router Receiver**, on page 26 illustrates the flow of multicast traffic in an extranet MVPN topology where a receiver MVRF is configured on the source PE router. An MVRF is configured for VPN-A and VPN-B on PE1, the source PE router. A multicast source behind PE1 is sending out a multicast stream to the MVRF for VPN-A, and there are interested receivers behind PE2 and PE3, the receiver PE routers for VPN-B and VPN-A, respectively. After PE1 receives the packets from the source in the MVRF for VPN-A, it independently replicates and encapsulates the packets in the MVRF for
VPN-A and VPN-B and forwards the packets. After receiving the packets from this source, PE2 and PE3 decapsulate and forward the packets to the respective MVRFs.

**Figure 9: Receiver MVRF at the Source PE Router Receiver**

For more information, see also Configuring MVPN Extranet Routing, on page 110 and Configuring MVPN Extranet Routing: Example, on page 155.

### RPF Policies in an Extranet

RPF policies can be configured in receiver VRFs to bypass RPF lookup in receiver VRFs and statically propagate join states to specified source VRF. Such policies can be configured to pick a source VRF based on either multicast group range, multicast source range, or RP address.

For more information about configuration of RPF policies in extranets, see Configuring RPL Policies in Receiver VRFs to Propagate Joins to a Source VRF: Example, on page 157 and Configuring RPL Policies in Receiver VRFs on Source PE Routers to Propagate Joins to a Source VRF: Example, on page 159.

### Multicast VPN Hub and Spoke Topology

Hub and spoke topology is an interconnection of two categories of sites — Hub sites and Spoke sites. The routes advertised across sites are such that they achieve connectivity in a restricted hub and spoke fashion. A spoke can interact only with its hub because the rest of the network (that is, other hubs and spokes) appears hidden behind the hub.

The hub and spoke topology can be adopted for these reasons:

- Spoke sites of a VPN customer receives all their traffic from a central (or Hub) site hosting services such as server farms.
- Spoke sites of a VPN customer requires all the connectivity between its spoke sites through a central site. This means that the hub site becomes a transit point for interspoke connectivity.
• Spoke sites of a VPN customer do not need any connectivity between spoke sites. Hubs can send and receive traffic from all sites but spoke sites can send or receive traffic only to or from Hub sites.

Realizing the Hub and Spoke Topology

Hub and spoke implementation leverages the infrastructure built for MVPN Extranet. The regular MVPN follows the model in which packets can flow from any site to the other sites. But Hub and Spoke MVPN will restrict traffic flows based on their subscription.

A site can be considered to be a geographic location with a group of CE routers and other devices, such as server farms, connected to PE routers by PE-CE links for VPN access. Either every site can be placed in a separate VRF, or multiple sites can be combined in one VRF on the PE router.

By provisioning every site in a separate VRF, you can simplify the unicast and multichub and spoke implementation. Such a configuration brings natural protection from traffic leakage - from one spoke site to another. Cisco IOS XR Software implementation of hub and spoke follows the one-site-to-one VRF model. Any site can be designated as either a hub or spoke site, based on how the import or export of routes is setup. Multiple hub and spoke sites can be collated on a given PE router.

Unicast Hub and Spoke connectivity is achieved by the spoke sites importing routes from only Hub sites, and Hub sites importing routes from all sites. As the spoke sites do not exchange routes, spoke to spoke traffic cannot flow. If interspoke connectivity is required, hubs can choose to re-inject routes learned from one spoke site into another spoke site.

MVPN Hub and Spoke is achieved by separating core tunnels, for traffic sourced from hub sites, and spoke sites. MDT hub is the tunnel carrying traffic sourced from all Hub sites, and MDT spoke carries traffic sourced from all spoke sites. Such tunnel end-points are configured on all PEs participating in hub and spoke topology. If spoke sites do not host any multicast sources or RPs, provisioning of MDT Spoke can be completely avoided at all such routers.

Once these tunnels are provisioned, multicast traffic path will be policy routed in this manner:

1. Hub sites will send traffic to only MDT Hub.
2. Spoke sites will send traffic to only MDT Spoke.
3. Hub sites will receive traffic from both tunnels.
4. Spoke sites will receive traffic from only MDT Hub.

These rules ensure that hubs and spokes can send and receive traffic to or from each other, but direct spoke to spoke communication does not exist. If required, interspoke multicast can flow by turning around the traffic at Hub sites.

These enhancements are made to the Multicast Hub and Spoke topology in Cisco IOS XR Software Release 4.0:

• Auto-RP and BSR are supported across VRFs that are connected through extranet. It is no longer restricted to using static RP only.
• MP-BGP can publish matching import route-targets while passing prefix next hop information to RIB.
• Route policies can use extended community route targets instead of IP address ranges.
• Support for extranet v4 data mdt was included so that data mdt in hub and spoke can be implemented.
Label Switched Multicast (LSM) Multicast Label Distribution Protocol (mLDP) based Multicast VPN (mVPN) Support

Label Switch Multicast (LSM) is MPLS technology extensions to support multicast using label encapsulation. Next-generation MVPN is based on Multicast Label Distribution Protocol (mLDP), which can be used to build P2MP and MP2MP LSPs through a MPLS network. These LSPs can be used for transporting both IPv4 and IPv6 multicast packets, either in the global table or VPN context.

Benefits of LSM MLDP based MVPN

LSM provides these benefits when compared to GRE core tunnels that are currently used to transport customer traffic in the core:

- It leverages the MPLS infrastructure for transporting IP multicast packets, providing a common data plane for unicast and multicast.
- It applies the benefits of MPLS to IP multicast such as Fast ReRoute (FRR) and
- It eliminates the complexity associated PIM.

Configuring MLDP MVPN

The MLDP MVPN configuration enables IPv4 multicast packet delivery using MPLS. This configuration uses MPLS labels to construct default and data Multicast Distribution Trees (MDTs). The MPLS replication is used as a forwarding mechanism in the core network. For MLDP MVPN configuration to work, ensure that the global MPLS mLDP configuration is enabled. To configure MVPN extranet support, configure the source...
multicast VPN Routing and Forwarding (mVRF) on the receiver Provider Edge (PE) router or configure the receiver mVRF on the source PE. MLDP MVPN is supported for both intranet and extranet.

Figure 10: MLDP based MPLS Network

P2MP and MP2MP Label Switched Paths

mLDP is an application that sets up Multipoint Label Switched Paths (MP LSPs) in MPLS networks without requiring multicast routing protocols in the MPLS core. mLDP constructs the P2MP or MP2MP LSPs without interacting with or relying upon any other multicast tree construction protocol. Using LDP extensions for MP LSPs and Unicast IP routing, mLDP can setup MP LSPs. The two types of MP LSPs that can be setup are Point-to-Multipoint (P2MP) and Multipoint-to-Multipoint (MP2MP) type LSPs.

A P2MP LSP allows traffic from a single root (ingress node) to be delivered to a number of leaves (egress nodes), where each P2MP tree is uniquely identified with a 2-tuple (root node address, P2MP LSP identifier). A P2MP LSP consists of a single root node, zero or more transit nodes, and one or more leaf nodes, where typically root and leaf nodes are PEs and transit nodes are P routers. A P2MP LSP setup is receiver-driven and is signaled using mLDP P2MP FEC, where LSP identifier is represented by the MP Opaque Value element. MP Opaque Value carries information that is known to ingress LSRs and Leaf LSRs, but need not be interpreted by transit LSRs. There can be several MP LSPs rooted at a given ingress node, each with its own identifier.

A MP2MP LSP allows traffic from multiple ingress nodes to be delivered to multiple egress nodes, where a MP2MP tree is uniquely identified with a 2-tuple (root node address, MP2MP LSP identifier). For a MP2MP LSP, all egress nodes, except the sending node, receive a packet sent from an ingress node.

A MP2MP LSP is similar to a P2MP LSP, but each leaf node acts as both an ingress and egress node. To build an MP2MP LSP, you can setup a downstream path and an upstream path so that:

- Downstream path is setup just like a normal P2MP LSP
- Upstream path is setup like a P2P LSP towards the upstream router, but inherits the downstream labels from the downstream P2MP LSP.
Packet Flow in mLDP-based Multicast VPN

For each packet coming in, MPLS creates multiple out-labels. Packets from the source network are replicated along the path to the receiver network. The CE1 router sends out the native IP multicast traffic. The PE1 router imposes a label on the incoming multicast packet and replicates the labeled packet towards the MPLS core network. When the packet reaches the core router (P), the packet is replicated with the appropriate labels for the MP2MP default MDT or the P2MP data MDT and transported to all the egress PEs. Once the packet reaches the egress PE, the label is removed and the IP multicast packet is replicated onto the VRF interface.

Realizing a mLDP-based Multicast VPN

There are different ways a Label Switched Path (LSP) built by mLDP can be used depending on the requirement and nature of application such as:

• P2MP LSPs for global table transit Multicast using in-band signaling.
• P2MP/MP2MP LSPs for MVPN based on MI-PMSI or Multidirectional Inclusive Provider Multicast Service Instance (Rosen Draft).
• P2MP/MP2MP LSPs for MVPN based on MS-PMSI or Multidirectional Selective Provider Multicast Service Instance (Partitioned E-LAN).

The Cisco ASR 9000 Series Router performs the following important functions for the implementation of MLDP:

1 Encapsulating VRF multicast IP packet with GRE/Label and replicating to core interfaces (imposition node).
2 Replicating multicast label packets to different interfaces with different labels (Mid node).
3 Decapsulate and replicate label packets into VRF interfaces (Disposition node).

Characteristics of mLDP Profiles

The characteristics of various mLDP profiles are listed in this section.

Profile 1: Rosen-mLDP (with no BGP-AD)

These are the characteristics of this profile:

• MP2MP mLDP trees are used in the core.
• VPN-ID is used as the VRF distinguisher.
• Configuration based on Default MDTs.
• Same Default-MDT core-tree used for IPv4 and IPv6 traffic.
• Data-MDT announcements sent by PIM (over Default-MDT).
• The multicast traffic can either be SM or SSM.
• Inter-AS Options A, B, and C are supported. Connector Attribute is announced in VPN-IP routes.
Profile 2: MS-PMSI-mLDP-MP2MP (No BGP-AD)
These are the characteristics of this profile:

• MP2MP mLDP trees are used in the core.
• Different MS-PMSI core-trees for IPv4 and IPv6 traffic.
• The multicast traffic can be SM or SSM.
• Extranet, Hub and Spoke are supported.
• Inter-AS Options A, B, and C are supported. Connector Attribute is announced in VPN-IP routes.

Profile 3: Rosen-GRE with BGP-AD
These are the characteristics of this profile:

• PIM-trees are used in the core. The data encapsulation method used is GRE.
• SM or SSM used in the core.
• Configuration is based on Default-MDTs.
• The multicast traffic can be SM or SSM.
• MoFRR in the core is supported.
• Extranet, Hub and Spoke, CsC, Customer-RP-discovery (Embedded-RP, AutoRP and BSR) are supported.
• Inter-AS Options A, B, and C are supported. VRF-Route-Import EC is announced in VPN-IP routes.

Profile 4: MS-PMSI-mLDP-MP2MP with BGP-AD
These are the characteristics of this profile:

• MP2MP mLDP trees are used in the core.
• The multicast traffic can be SM or SSM.
• Extranet, Hub and Spoke, CsC, Customer-RP-discovery (Embedded-RP, AutoRP, and BSR) are supported.
• Inter-AS Options A, B, and C are supported. VRF-Route-Import EC is announced in VPN-IP routes.

Profile 5: MS-PMSI-mLDP-P2MP with BGP-AD
These are the characteristics of this profile:

• P2MP mLDP trees are used in the core.
• The multicast traffic can be SM or SSM.
• Extranet, Hub and Spoke, CsC, Customer-RP-discovery (Embedded-RP, AutoRP, and BSR) are supported.
• Inter-AS Options A, B, and C are supported. VRF-Route-Import EC is announced in VPN-IP routes.

Profile 6: VRF In-band Signaling (No BGP-AD)
These are the characteristics of this profile:

• P2MP mLDP trees are used in the core.
• MoFRR in the core is supported.
• There is one core tree built per VRF-S,G route. There can be no (*,G) routes in VRF, with RPF reachability over the core.
• The multicast traffic can be SM S,G or SSM.

Profile 7: Global Inband Signalling
These are the characteristics of this profile:
• P2MP mLDP inband tree in the core; no C-multicast Routing.
• Customer traffic can be SM S,G or SSM.
• Support for global table S,Gs on PEs.

For more information on mLDP implementation and OAM concepts, see the Cisco IOS XR MPLS Configuration Guide for the Cisco ASR 9000 Series Router

Profile 8: Global P2MP-TE
These are the characteristics of this profile:
• P2MP-TE tree, with static Destination list, in the core; no C-multicast Routing.
• Static config of (S,G) required on Head-end PE.
• Only C-SSM support on PEs.
• Support for global table S,Gs on PEs.

Profile 9: Rosen-mLDP with BGP-AD
These are the characteristics of this profile:
• Single MP2MP mLDP core-tree as the Default-MDT, with PIM C-multicast Routing.
• All UMH options supported.
• Default and Data MDT supported.
• Customer traffic can be SM or SSM.
• RIB-Extranet, RPL-Extranet, Hub & Spoke supported.
• Customer-RP-discovery (Embedded-RP, AutoRP & BSR) is supported.

Profile 10: VRF Static-P2MP-TE with BGP AD
These are the characteristics of this profile:
• P2MP-TE tree, with static Destination list, in the core; no C-multicast Routing.
• Static config of (S,G) required on Head-end PE.
• Only C-SSM support on PEs.
• Support for IPv4 MVPN S,Gs on PEs. No support for IPv6 MVPN routes.
Profile 11: Rosen-PIM/GRE with BGP C-multicast Routing

These are the characteristics of this profile:

- PIM-trees in the core, data encapsulation is GRE, BGP C-multicast Routing.
- Static config of (S,G) required on Head-end PE.
- For PIM-SSM core-tree and PIM-SM core-tree with no spt-infinity, all UMH options are supported.
- For PIM-SM core-tree with spt-infinity case, only SFS (Highest PE or Hash-of-BGP-paths) is supported. Hash of installed-paths method is not supported.
- Default and Data MDTs supported.
- Customer traffic can be SM or SSM.
- Inter-AS Option A supported. Options B and C not supported.

Profile 12: Rosen-mLDP-P2MP with BGP C-multicast Routing

These are the characteristics of this profile:

- Full mesh of P2MP mLDP core-tree as the Default-MDT, with BGP C-multicast Routing.
- All UMH options supported.
- Default and Data MDT supported.
- Customer traffic can be SM or SSM.
- RPL-Tail-end-Extranet supported.
- Inter-AS Option A, B and C supported.

Profile 13: Rosen-mLDP-MP2MP with BGP C-multicast Routing

These are the characteristics of this profile:

- Single MP2MP mLDP core-tree as the Default-MDT, with BGP C-multicast Routing.
- Only SFS (Highest PE or Hash-of-BGP-paths) is supported. Hash of Installed-paths method is not supported.
- Default and Data MDT supported.
- Customer traffic can be SM or SSM.
- RIB-Tail-end-Extranet, RPL-Tail-end-Extranet supported.
- Customer-RP-discovery (Embedded-RP, AutoRP & BSR) is supported.
- Inter-AS Option A, B and C supported. For Options B and C, Root has to be on a PE or the root-address reachability has to be leaked across all autonomous systems.

Profile 14: MP2MP-mLDP-P2MP with BGP C-multicast Routing

These are the characteristics of this profile:

- Full mesh of P2MP mLDP core-tree as the Default-MDT, with BGP C-multicast Routing.
- All UMH options supported.
Profile 15: MP2MP-mLDP-MP2MP with BGP C-multicast Routing

These are the characteristics of this profile:

- Full mesh of MP2MP mLDP core-tree as the Default-MDT, with BGP C-multicast Routing.
- All UMH options supported.
- Default and Data MDT supported.
- Customer traffic can be SM or SSM.
- RPL-Tail-end-Extranet supported.
- Customer-RP-discovery (Embedded-RP, AutoRP & BSR) is supported.
- Inter-AS Option A, B and C supported.

Profile 16: Rosen-Static-P2MP-TE with BGP C-multicast Routing

These are the characteristics of this profile:

- Full mesh of Static-P2MP-TE core-trees, as the Default-MDT, with BGP C-multicast Routing.
- All UMH options supported.
- Support for Data MDT, Default MDT.
- Customer traffic can be SM, SSM.
- RPL-Tail-end-Extranet supported.
- Customer-RP-discovery (Embedded-RP, AutoRP & BSR) is supported.
- Inter-AS Option A supported. Options B and C not supported.

Note
Whenever multicast stream crosses configured threshold on encap PE(Head PE), S-PMSI is announced. Core tunnel is static P2MP-TE tunnel configured under route-policy for the stream. Static P2MP-TE data mdt is implemented in such a way that it can work with dynamic data mdt, dynamic default mdt and default static P2MP.

Profile 17: Rosen-mLDP-P2MP with BGP AD/PIM C-multicast Routing

These are the characteristics of this profile:

- Full mesh of P2MP mLDP core-tree as the Default-MDT, with PIM C-multicast Routing.
- All UMH options supported.
• Default and Data MDT supported.
• Customer traffic can be SM or SSM.
• RPL-Extranet, Hub & Spoke supported.
• Customer-RP-discovery (Embedded-RP, AutoRP & BSR) is supported.
• Inter-AS Option A, B and C supported.

Profile 18: Rosen-Static-P2MP-TE with BGP AD/PIM C-multicast Routing
These are the characteristics of this profile:
• Full mesh of Static-P2MP-TE core-trees, as the Default-MDT, with PIM C-multicast Routing.
• All UMH options supported.
• Default MDT supported; Data MDT is not supported.
• Customer traffic can be SM, SSM.
• RPL-Extranet, Hub & Spoke supported.
• Customer-RP-discovery (Embedded-RP, AutoRP & BSR) is supported.
• Inter-AS Option A supported. Options B and C not supported.

Profile 20: Rosen-P2MP-TE with BGP AD/PIM C-multicast Routing
These are the characteristics of this profile:
• Dynamic P2MP-TE tunnels setup on demand, with PIM C-multicast Routing.
• All UMH options supported.
• Default and Data MDT supported.
• Customer traffic can be SM, SSM.
• RPL-Extranet, Hub & Spoke supported.
• Customer-RP-discovery (Embedded-RP, AutoRP & BSR) is supported.
• Inter-AS Option A and C supported.

Profile 22: Rosen-P2MP-TE with BGP C-multicast Routing
These are the characteristics of this profile:
• Dynamic P2MP-TE tunnels with BGP C-multicast Routing
• All UMH options supported.
• Default and Data MDT supported.
• Customer traffic can be SM or SSM.
• RIB-Tail-end-Extranet, RPL-Tail-end-Extranet supported.
• Customer-RP-discovery (Embedded-RP, AutoRP & BSR) is supported.
- Inter-AS Option A and C- supported.

**Profile 24: Partitioned-P2MP-TE with BGP AD/PIM C-multicast Routing**

These are the characteristics of this profile:
- Dynamic P2MP-TE tunnels setup on demand, with PIM C-multicast Routing
- All UMH options supported.
- Default and Data MDT supported.
- Customer traffic can be SM or SSM.
- RPL-Extranet, Hub & Spoke supported.
- Customer-RP-discovery (Embedded-RP, AutoRP & BSR) is supported.
- Inter-AS Option A and C- supported.

**Profile 26: Partitioned-P2MP-TE with BGP C-multicast Routing**

These are the characteristics of this profile:
- Dynamic P2MP-TE tunnels with BGP C-multicast Routing
- All UMH options supported.
- Default and Data MDT supported.
- Customer traffic can be SM, SSM.
- RIB-Tail-end-Extranet, RPL-Tail-end-Extranet supported.
- Customer-RP-discovery (Embedded-RP, AutoRP & BSR) is supported.
- Inter-AS Option A and C- supported.

**Configuration rules for profiles**

**Rules for Rosen-mGRE profiles (profiles- 0, 3, 11)**
- All profiles require VPNv4 or v6 unicast reachability.
- By default, encap 1400-byte size c-multicast IP packet is supported. To support decap or encap larger packet size, `mdt mtu` command.
- Loopback configuration is required. Use the `mdt source loopback0` command. Other loopbacks can be used for different VRFs, but this is not recommended.

**Rules for Rosen-mLDP profiles (profiles- 1, 9, 12, 13, 17)**
- mLDP must be globally enabled.
- VPN-id is mandatory for Rosen-mLDP MP2MP profiles.
- Root node must be specified manually. Multiple root nodes can be configured for Root Node Redundancy.
- If only profile 1 is configured, MVPN must be enabled under bgp.
• For BGP-AD profiles, the remote PE address is required.

**Rules for mLDP profiles (profiles- 2, 4, 5, 14, 15)**

• MVPN must be enabled under bgp, if only profile 2 is configured.
• Support only for static RP for customer RP.

**Rules for inband mLDP profiles (profiles- 6, 7)**

• MVPN must be enabled under bgp for vrf-inband profiles.
• Data MDT is not supported.
• Backbone facing interface (BFI) must be enabled on tail PE.
• Source route of SSM must be advertise to tail PE by iBGP.

**MLDP inband signaling**

MLDP Inband signaling allows the core to create (S,G) or (*,G) state without using out-of-band signaling such as BGP or PIM. It is supported in VRF (and in the global context). Both IPv4 and IPv6 multicast groups are supported.

In MLDP Inband signaling, one can configure an ACL range of multicast (S,G). This (S,G) can be transported in MLDP LSP. Each multicast channel (S,G), is 1 to 1 mapped to each tree in the inband tree. The (S,G) join, through IGMP/MLD/PIM, will be registered in MRIB, which is the client of MLDP.

MLDP In-band signalling supports transiting PIM (S,G) or (*,G) trees across a MPLS core without the need for an out-of-band protocol. In-band signaling is only supported for shared-tree-only forwarding (also known as sparse-mode threshold infinity). PIM Sparse-mode behavior is not supported (switching from (*,G) to (S,G)).

The details of the MLDP profiles are discussed in the *Cisco ASR 9000 Series Aggregation Services Router Multicast Configuration Guide*.

**Summary of Supported MVPN Profiles**

This tables summarizes the supported MVPN profiles:

<table>
<thead>
<tr>
<th>Profile Number</th>
<th>Name</th>

### Profile Number | Name | Opaque-value | BGP-AD | Data-MDT
--- | --- | --- | --- | ---
4 | MS- PMSI (Partition) MLDP MP2MP with BGP -AD | Type 1 - Source-PE:Global -ID | • I- PMSI with empty PTA  
• MS- PMSI for partition mdt  
• S- PMSI for data-mdt  
• S- PMSI cust RP-discovery trees | BGP-AD
5 | MS- PMSI (Partition) MLDP P2MP with BGP -AD | Type 1 - Source-PE:Global -ID | • I- PMSI with empty PTA  
• MS- PMSI for partition mdt  
• S- PMSI for data-mdt  
• S- PMSI cust RP-discovery trees | BGP-AD
6 | VRF Inband MLDP | RD:S,G | N/A | N/A
7 | Global Inband | S,G | N/A | N/A
8 | Global P2MP TE | N/A | N/A | N/A
9 | Rosen MLDP with BGP -AD | Type 2 - RootAddresss:VPN -ID:0 -n | • Intra-AS MI- PMSI  
• S- PMSI for Data-MDT | PIM or BGP-AD (knob controlled)

### Configuration Process for MLDP MVPN (Intranet)

These steps provide a broad outline of the different configuration process of MLDP MVPN for intranet:

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>For detailed summary of the various MVPN profiles, see the <a href="#">Summary of Supported MVPN Profiles</a>, on page 37.</td>
</tr>
</tbody>
</table>

- Enabling MPLS MLDP
  - configure
• **mpls ldp mldp**

  - Configuring a VRF entry
    - configure
      - vrf vrf_name
      - address-family ipv4/ipv6 unicast
      - import route-target route-target-ext-community
      - export route-target route-target-ext-community

  - Configuring VPN ID
    - configure
      - vrf vrf_name
      - vpn id vpn_id

  The configuring VPN ID procedure is needed for profiles 1 and 9 (Rosen MLDP).

  - Configuring MVPN Routing and Forwarding instance
    - configure
      - multicast-routing vrf vrf_name
      - address-family ipv4
      - mdt default mldp ipv4 root-node

  For profile 1 (MLDP Rosen), the **mdt default mldp ipv4** command and for profile 4/5 (MS- PMSI with BGP-AD), the **mdt partitioned mldp ipv4 mp2mp/p2mp** command are configured.

  - Configuring the Route Distinguisher
    - configure
      - router bgp AS Number
      - vrf vrf_name
      - rd rd_value

  - Configuring Data MDTs (optional)
    - configure
      - multicast-routing vrf vrf_name
      - address-family ipv4
      - mdt data <1-255>

  - Configuring BGP MDT address family
    - configure
      - router bgp AS Number
- address-family ipv4 mdt

- Configuring BGP vpn4 address family
  - configure
  - router bgp AS Number
  - address-family vpn4 unicast

- Configuring BGP IPv4 VRF address family
  - configure
  - router bgp AS Number
  - vrf vrf_name
  - address-family ipv4 unicast

- Configuring PIM SM/SSM Mode for the VRFs
  - configure
  - router pim
  - vrf vrf_name
  - address-family ipv4
  - rpf topology route-policy rosen_mvpn_mldp

For each profile, a different route-policy is configured.

- Configuring route-policy
  - route-policy rosen_mvpn_mldp
  - set core-tree tree-type
  - pass
  - end-policy

For profile 1 (MLDP Rosen), the mldp-rosen core tree type and for profile 4/5 (MS-PMSI with BGP-AD), the mldp-partitioned-mp2mp/p2mp core tree type are configured.

**Note**

The configuration of the above procedures depends on the profile used for each configuration. For detailed examples of each profile, see Configuring LSM based MLDP: Examples, on page 175.

### MVPN over GRE

A unicast GRE tunnel could be the accepting or forwarding interface for either a mVPN-GRE VRF route or a core route. When multicast packets arrive on the VRF interface with the intent of crossing the core, they are
first encapsulated with a multicast GRE header (S,G) which are applicable to the VRF’s MDT. Then, before the packets are actually forwarded, they are encapsulated in a unicast GRE header. The (S,D) in this packet are the origination and termination addresses for the unicast GRE tunnel.

GRE tunnel stitching is when both the accepting and forwarding interfaces are unicast GRE tunnels. Here, the packet has two GRE encapss. The outer encap is the unicast header for the GRE tunnel. The inner encap is the multicast GRE header for the MDT. This is called as double encap. There is a loss in terms of both bandwidth and throughput efficiency. The bandwidth efficiency loss is because 48 bytes of encap headers are being added to the original (VRF) packet. The throughput efficiency loss is the result of the processing time required to apply two encaps.

For the mVPN-GRE, if the VRF interface is a GRE tunnel, the protocol packets received from LPTS will be accompanied with the receiving unicast GRE tunnel interface and the VRF id of the VRF in which the GRE tunnel is configured. Thus VRF specific processing can be done on the packet.

Restrictions

- MVPN over GRE is supported only on ASR 9000 Enhanced Ethernet LCs.

Native Multicast

GRE tunneling provides a method to transport native multicast traffic across a non-Multicast enabled IP network. Once the multicast traffic in encapsulated with GRE, it appears as an IP packet to the core transport network.

A GRE tunnel can be a forwarding interface when the router is the imposition (or encap) router for that GRE tunnel. The imposition router must prepend a unicast IPv4 header and GRE header to the multicast packet. The source and destination IPv4 addresses for the added header are determined by the user configuration of the tunnel. The newly encapsulated packet is then forwarded as a unicast packet.

When a GRE tunnel is an accepting interface for a multicast route, the router is the disposition (or decap) router for the tunnel. The outer IPv4 header and GRE header must be removed to expose the inner multicast packet. The multicast packet will then be forwarded just as any other multicast packet that arrives on a non-tunnel interface.

Forwarding behavior
Figure depicts a Unicast GRE tunnel between two routers. The imposition router has a multicast (S,G) route which has the GRE tunnel as a forwarding interface. At the disposition router, the GRE tunnel is an accepting interface for the multicast (S,G). As seen, the packet is unicast GRE encapsulated when it traverses the tunnel.

*Figure 11: Unicast GRE tunnel between two routers*

---

**Note**

Starting with IOS XR 5.3.2 release, IPv6 traffic is supported.

---

**GRE Limitations**

Listed below are the limitations for unicast GRE tunnels:

- GRE unicast tunnel supports IPv4 encapsulation only.

  **Note** Starting from the IOS XR 5.3.2 release, GRE unicast tunnels support IPv6 encapsulation.

- Native and mVPN traffic over underlying ECMP links are not supported.

  **Note** Starting with IOS XR 5.3.2 release, native and mVPN traffic over underlying ECMP links, including bundles is supported.

- IPv6 multicast for GRE unicast tunnels is not supported, in releases prior to IOS XR 5.3.2.
• Transport header support is limited to IPv4.
• Path MTU discovery will not be supported over GRE tunnel interfaces. When size of the packet going over GRE tunnel interface exceeds the tunnel MTU, the microcode will punt the packet to the slow path for best effort fragmentation. Since punted packets are policed, this doesn't provide real fragmentation support. This combined with no support for path MTU discovery means that user is responsible for making sure the MTUs configured along the tunnel path are large enough to guarantee the GRE packet will not be fragmented between tunnel source and destination routers.
• No support for optional checksum, key, and sequence number fields.
• No support for nested and concatenated GRE tunnels. If packets with nested GRE header are received they will be dropped.
• No L3 features (like QoS, ACL and netflow) support for GRE tunnel interfaces. Features configured on the underlying physical interface will be applied.
• ASR9000 SIP-700 linecard unicast GRE is NOT supported on VRFs.
• Support for up to 500 GRE tunnels per system for multicast.

**Signaling and RPF on GRE Tunnels**

Signaling will use the same mechanism when a unicast GRE tunnel terminated at an ingress linecard regardless of whether the GRE tunnel interface belongs to a VRF or not. In the case of mVPN-GRE the Master Linecard / Master NP mechanism must still be used for egress punts of decapsulated VRF packets.

RPF selection can be static configured via a route policy configuration. Static RPF is more preferred and expected if the RPF should be the GRE tunnel. RPF may be selected dynamically via RIB updates for the upstream router's unicast reach-ability, although this is not preferred.

**PIM Registration**

PIM registration packets can be forwarded on a unicast GRE tunnel as long as the IPv4 unicast GRE interface is selected by FIB for unicast forwarding of the encapsulated PIM registration packets toward the PIM RP. In this case, the packet is essentially double encapsulated with unicast, ie, the original multicast packet is encapsulated by PIM in a unicast PIM register packet. This is then encapsulated with the unicast GRE tunnel header.

At the PIM RP, outermost unicast header will be removed and the PIM registration packets will be delivered to PIM via LPTS as in the current PIM registration packet processing. It is advisable to avoid any MTU/TTL or ACL/QoS configuration issues that result in the registration packets getting dropped.

**Auto-RP**

Auto-RP lite on PEs, Auto-RP/BSR/static-RP/ Anycast-RP with MSDP peering etc can be supported over GRE tunnels with MFIB netio chain support. It is advisable to avoid any MTU/TTL or ACL/QoS configuration issues that result in the registration packets getting dropped. Auto-RP routes will flood autp-rp packets to every multicast egress interface including IPv4 unicast GRE tunnels.
Multicast Source Discovery Protocol

Multicast Source Discovery Protocol (MSDP) is a mechanism to connect multiple PIM sparse-mode domains. MSDP allows multicast sources for a group to be known to all rendezvous points (RPs) in different domains. Each PIM-SM domain uses its own RPs and need not depend on RPs in other domains.

An RP in a PIM-SM domain has MSDP peering relationships with MSDP-enabled routers in other domains. Each peering relationship occurs over a TCP connection, which is maintained by the underlying routing system.

MSDP speakers exchange messages called Source Active (SA) messages. When an RP learns about a local active source, typically through a PIM register message, the MSDP process encapsulates the register in an SA message and forwards the information to its peers. The message contains the source and group information for the multicast flow, as well as any encapsulated data. If a neighboring RP has local joiners for the multicast group, the RP installs the S, G route, forwards the encapsulated data contained in the SA message, and sends PIM joins back towards the source. This process describes how a multicast path can be built between domains.

Although you should configure BGP or Multiprotocol BGP for optimal MSDP interdomain operation, this is not considered necessary in the Cisco IOS XR Software implementation. For information about how BGP or Multiprotocol BGP may be used with MSDP, see the MSDP RPF rules listed in the Multicast Source Discovery Protocol (MSDP), Internet Engineering Task Force (IETF) Internet draft.

VRF-aware MSDP

VRF (VPN Routing and Forwarding)-aware MSDP enables MSDP to function in the VRF context. This in turn, helps the user to locate the PIM (protocol Independent Multicast) RP on the Provider Edge and use MSDP for anycast-RP.

MSDP needs to be VRF-aware when:

- Anycast-RP is deployed in an MVPN (Multicast MVPN) in such a manner that one or more PIM RPs in the anycast-RP set are located on a PE. In such a deployment, MSDP needs to operate in the VRF context on the PE.
- The PIM RP is deployed in an MVPN in such a manner that it is not on a PE and when the customer multicast routing type for the MVPN is BGP and the PEs have suppress-shared-tree-join option configured. In this scenario, there is no PE-shared tree link, so traffic may stop at the RP and it does not flow to other MVPN sites. An MSDP peering between the PIM RP and one or more PEs resolves the issue.

Multicast Nonstop Forwarding

The Cisco IOS XR Software nonstop forwarding (NSF) feature for multicast enhances high availability (HA) of multicast packet forwarding. NSF prevents hardware or software failures on the control plane from disrupting the forwarding of existing packet flows through the router.

The contents of the Multicast Forwarding Information Base (MFIB) are frozen during a control plane failure. Subsequently, PIM attempts to recover normal protocol processing and state before the neighboring routers time out the PIM hello neighbor adjacency for the problematic router. This behavior prevents the NSF-capable router from being transferred to neighbors that will otherwise detect the failure through the timed-out adjacency.
Routes in MFIB are marked as stale after entering NSF, and traffic continues to be forwarded (based on those routes) until NSF completion. On completion, MRIB notifies MFIB and MFIB performs a mark-and-sweep to synchronize MFIB with the current MRIB route information.

**Multicast Configuration Submodes**

Cisco IOS XR Software moves control plane CLI configurations to protocol-specific submodes to provide mechanisms for enabling, disabling, and configuring multicast features on a large number of interfaces.

Cisco IOS XR Software allows you to issue most commands available under submodes as one single command string from the global or XR config mode.

For example, the `ssm` command could be executed from the multicast-routing configuration submode like this:

```
RP/0/RSP0/CPU0:router(config)# multicast-routing
RP/0/RSP0/CPU0:router(config-mcast-ipv4)# ssm range
```

Alternatively, you could issue the same command from the global or XR config mode like this:

```
RP/0/RSP0/CPU0:router(config)# multicast-routing ssm range
```

The following multicast protocol-specific submodes are available through these configuration submodes:

**Multicast-Routing Configuration Submode**

In Cisco IOS XR software release 3.7.2 and later, basic multicast services start automatically when the multicast PIE (`asr9k-mcast-p.pie`) is installed, without any explicit configuration required. The following multicast services are started automatically:

- MFWD
- MRIB
- PIM
- IGMP

Other multicast services require explicit configuration before they start. For example, to start the MSDP process, you must enter the `router msdp` command and explicitly configure it.

When you issue the `multicast-routing ipv4` or `multicast-routing ipv6` command, all default multicast components (PIM, IGMP, MLD, MFWD, and MRIB) are automatically started, and the CLI prompt changes to "config-mcast-ipv4" or "config-mcast-ipv6", indicating that you have entered multicast-routing configuration submode.

**PIM Configuration Submode**

When you issue the `router pim` command, the CLI prompt changes to "config-pim-ipv4," indicating that you have entered the default pim address-family configuration submode.

To enter pim address-family configuration submode for IPv6, type the `address-family ipv6` keyword together with the `router pim` command before pressing Enter.
IGMP Configuration Submode

When you issue the `router igmp` command, the CLI prompt changes to "config-igmp," indicating that you have entered IGMP configuration submode.

MLD Configuration Submode

When you issue the `router mld` command, the CLI prompt changes to "config-mld," indicating that you have entered MLD configuration submode.

MSDP Configuration Submode

When you issue the `router msdp` command, the CLI prompt changes to “config-msdp,” indicating that you have entered router MSDP configuration submode.

Understanding Interface Configuration Inheritance

Cisco IOS XR Software allows you to configure commands for a large number of interfaces by applying command configuration within a multicast routing submode that could be inherited by all interfaces. To override the inheritance mechanism, you can enter interface configuration submode and explicitly enter a different command parameter.

For example, in the following configuration you could quickly specify (under router PIM configuration mode) that all existing and new PIM interfaces on your router will use the hello interval parameter of 420 seconds. However, Packet-over-SONET/SDH (POS) interface 0/1/0/1 overrides the global interface configuration and uses the hello interval time of 210 seconds.

```
RP/0/RSP0/CPU0:router(config)# router pim
RP/0/RSP0/CPU0:router(config-pim-default-ipv4)# hello-interval 420
RP/0/RSP0/CPU0:router(config-pim-default-ipv4)# interface pos 0/1/0/1
RP/0/RSP0/CPU0:router(config-pim-ipv4-if)# hello-interval 210
```

The following is a listing of commands (specified under the appropriate router submode) that use the inheritance mechanism:

```
router pim
    dr-priority
    hello-interval
    join-prune-interval
multicast-routing
    version
    query-interval
    query-max-response-time
    explicit-tracking
router mld
    interface all disable
    version
    query-interval
    query-max-response-time
    explicit-tracking
router msdp
    connect-source
    sa-filter
```
Understanding Interface Configuration Inheritance Disablement

As stated elsewhere, Cisco IOS XR Software allows you to configure multiple interfaces by applying configurations within a multicast routing submode that can be inherited by all interfaces.

To override the inheritance feature on specific interfaces or on all interfaces, you can enter the address-family IPv4 or IPv6 submode of multicast routing configuration mode, and enter the `interface-inheritance disable` command together with the `interface type interface-path-id` or `interface all` command. This causes PIM or IGMP protocols to disallow multicast routing and to allow only multicast forwarding on those interfaces specified. However, routing can still be explicitly enabled on specified individual interfaces.

The following configuration disables multicast routing interface inheritance under PIM and IGMP generally, although forwarding enablement continues. The example shows interface enablement under IGMP of GigabitEthernet 0/6/0/3:

```
RP/0/RSP0/CPU0:router# multicast-routing
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# interface all enable
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# interface-inheritance disable
```

For related information, see Understanding Enabling and Disabling Interfaces, on page 47

Understanding Enabling and Disabling Interfaces

When the Cisco IOS XR Software multicast routing feature is configured on your router, by default, no interfaces are enabled.

To enable multicast routing and protocols on a single interface or multiple interfaces, you must explicitly enable interfaces using the `interface` command in multicast routing configuration mode.

To set up multicast routing on all interfaces, enter the `interface all` command in multicast routing configuration mode. For any interface to be fully enabled for multicast routing, it must be enabled specifically (or be default) in multicast routing configuration mode, and it must not be disabled in the PIM and IGMP/MLD configuration modes.

For example, in the following configuration, all interfaces are explicitly configured from multicast routing configuration submode:

```
RP/0/RSP0/CPU0:router(config)# multicast-routing
RP/0/RSP0/CPU0:router(config-mcast)# interface all enable
```
To disable an interface that was globally configured from the multicast routing configuration submode, enter interface configuration submode, as illustrated in the following example:

```
RP/0/RSP0/CPU0:router(config-mcast)# interface GigabitEthernet0/0/0
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4-if)# disable
```
Overriding VRFs in IGMP Interfaces

All unicast traffic on the user-to-network interfaces of next-generation aggregation or core networks must be mapped to a specific VRF. They must then be mapped to an MPLS VPN on the network-to-network side. This requires the configuration of a physical interface in this specific VRF.

This feature allows mapping of IGMP packets entering through a user-to-user interface to the multicast routes in the global multicast routing table. This ensures that the interface in a specific VRF can be part of the outgoing list of interfaces in the table for a multicast route.

IGMP packets entering through a non-default VRF interface in the default (global) VRF are processed, with IGMP later distributing the interface-related multicast state (route/interface) to MRIB. This occurs through the default VRF rather than through the VRF to which the interface belongs. MRIB, PIM, MSDP, and MFIB then process the multicast state for this interface through the default VRF.

When an IGMP join for a specific (S,G) is received on the configured interface, IGMP stores this information in its VRF-specific databases. But, when sending an update to MRIB, IGMP sends this route through the default VRF. MRIB then programs this (S,G) along with this interface as an OLIST member in the default multicast routing table.

Similarly, when PIM requests information about IGMP routes from MRIB, MRIB sends this update to PIM in the context of the default VRF.

This feature specifically supports:

- Mapping of IGMP requests on an interface in a non-default VRF to the default VRF multicast routing table.
- Enabling and disabling of VRF override functionality at runtime.
- Routing policy configuration at the global (default) VRF level, because routing policy configuration cannot be done at the granularity of an individual interface.
- Enablement and disablement of an IGMP VRF override on all Layer-3 and Layer-2 interface types, including physical Ethernet, VLAN sub-interface, bundles and VLANs over bundles.
- The same scale of multicast routes and OLIST interfaces currently supported by the platform even when VRF override functionality is operational.

VRF support for MLD

MLD receives MLD joins, membership queries and membership reports under VRF. The MLD process will have LPTS entries per VRF and traffic is redirected based on the matching VRF entry to the correct interface configured under the given VRF. Support for Source-Specific Multicast (SSM) is also provided under VRF.

Support for Satellite nV

Multicast components, which include IGMP, IGMP Snooping, PIM, MRIB/LMRIB, MFIB, L2FIB, are enhanced to recognize the new Satellite-Ether interface type and to also query and maintain the logical or physical type.
How to Implement Multicast Routing

This section contains instructions for both building a basic multicast configuration, as well as optional tasks to help you to optimize, debug, and discover the routers in your multicast network.

Configuring PIM-SM and PIM-SSM

SUMMARY STEPS

1. configure
2. multicast-routing [address-family {ipv4 | ipv6}]
3. interface all enable
4. exit
5. Use router igmp for IPv4 hosts or use router mld for IPv6
6. version {1 | 2 | 3} for IPv4 (IGMP) hosts or version {1 | 2} for IPv6 (MLD) hosts.
7. commit
8. show pim [ipv4 | ipv6] group-map [ip-address-name] [info-source]
9. show pim [vrf vrf-name] [ipv4 | ipv6] topology [source-ip-address [group-ip-address] | entry-flag flag | interface-flag | summary] [route-count]

### Configuring PIM-SSM for Use in a Legacy Multicast Deployment

Deploying PIM-SSM in legacy multicast-enabled networks can be problematic, because it requires changes to the multicast group management protocols used on the various devices attached to the network. Host, routers, and switches must all be upgraded in such cases.

To support legacy hosts and switches in a PIM-SSM deployment, Cisco ASR 9000 Series Routers offer a configurable mapping feature. Legacy group membership reports for groups in the SSM group range are mapped to a set of sources providing service for that set of (S,G) channels.

This configuration consists of two tasks:

#### Restrictions for PIM-SSM Mapping

PIM-SSM mapping does not modify the SSM group range. Instead, the legacy devices must report group membership for desired groups in the SSM group range.

#### Configuring a Set of Access Control Lists for Static SSM Mapping

This task configures a set of access control lists (ACLs) where each ACL describes a set of SSM groups to be mapped to one or more sources.

### SUMMARY STEPS

1. configure
2. ipv4 access-list acl-name
3. [sequence-number] permit source [source-wildcard]
4. Repeat Step 3, on page 53 to add more entries to the ACL.
5. Repeat Step 2, on page 53 through Step 4, on page 53 until you have entered all the ACLs you want to be part of the set.
6. commit

## Configuring a Set of Sources for SSM Mapping

This task consists of configuring a set of sources mapped by SSM groups, as described by access lists (ACLs).

### SUMMARY STEPS

1. configure
2. router igmp [vrf vrf-name]
3. ssm map static source-address access-list
4. Repeat Step 3, on page 54 as many times as you have source addresses to include in the set for SSM mapping.
5. commit
6. show igmp [vrf vrf-name] ssm map [group-address][detail]

### DETAILED STEPS

### Configuring a Static RP and Allowing Backward Compatibility

When PIM is configured in sparse mode, you must choose one or more routers to operate as a rendezvous point (RP) for a multicast group. An RP is a single common root placed at a chosen point of a shared distribution tree. An RP can either be configured statically in each router, or learned through Auto-RP or BSR.

This task configures a static RP. For more information about RPs, see the Rendezvous Points, on page 14. For configuration information for Auto-RP, see the Configuring Auto-RP to Automate Group-to-RP Mappings, on page 56.

### SUMMARY STEPS

1. configure
2. router pim [address-family {ipv4 | ipv6}]
3. rp-address ip-address [group-access-list] [bidir] [override]
4. old-register-checksum
5. exit
6. {ipv4 | ipv6} access-list name
7. [sequence-number] permit source [source-wildcard]
8. commit

```
```
RP/0/RSP0/CPU0:router(config)# commit
```
Configuring Auto-RP to Automate Group-to-RP Mappings

This task configures the Auto-RP mechanism to automate the distribution of group-to-RP mappings in your network. In a network running Auto-RP, at least one router must operate as an RP candidate and another router must operate as an RP mapping agent. The VRF interface on Cisco ASR 9000 Series Routers cannot be an auto-rp candidate-rp.

**SUMMARY STEPS**

1. configure
2. router pim [address-family ipv4]
3. auto-rp candidate-rp type instance scope ttl-value [group-list access-list-name] [interval seconds] bidir
4. auto-rp mapping-agent type number scope ttl-value [interval seconds]
5. exit
6. ipv4 access-list name
7. [sequence-number] permit source [source-wildcard]
8. commit

</table>
### Configuring the Bootstrap Router

This task configures one or more candidate bootstrap routers (BSRs) and a BSR mapping agent. This task also connects and locates the candidate BSRs in the backbone portion of the network.

For more information about BSR, see the PIM Bootstrap Router, on page 16.
### SUMMARY STEPS

1. `configure`
2. `router pim [address-family {ipv4 | ipv6}]`
3. `bsr candidate-bsr ip-address [hash-mask-len length] [priority value]`
4. `bsr candidate-rp ip-address [group-list access-list interval seconds] [priority value] bidir`
5. `interface type interface-path-id`
6. `bsr-border`
7. `exit`
8. `exit`
9. `{ipv4 | ipv6} access-list name`
10. Do one of the following:
    - `[sequence-number] permit source [source-wildcard]`
    - `[sequence-number] permit source-prefix dest-prefix`
11. `commit`
12. `clear pim [vrf vrf-name] [ipv4 | ipv6] bsr`
13. `show pim [vrf vrf-name] [ipv4 | ipv6] bsr candidate-rp`
14. `show pim [vrf vrf-name] [ipv4 | ipv6] bsr election`
15. `show pim [vrf vrf-name][ipv4 | ipv6] bsr rp-cache`
16. `show pim [vrf vrf-name][ipv4 | ipv6] group-map [ip-address-name] [info-source]`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure</code></td>
<td>Enters PIM configuration mode, or address-family configuration submode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>`router pim [address-family {ipv4</td>
<td>ipv6}]`</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> RP/0/RSP0/CPU0:router(config)# router pim</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td><code>bsr candidate-bsr ip-address [hash-mask-len length] [priority value]</code></td>
<td>Configures the router to advertise itself as a PIM Version 2 candidate RP to the BSR.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> RP/0/RSP0/CPU0:router(config-pim-default-ipv4)# bsr candidate-bsr 10.0.0.1 hash-mask-len 30</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td><code>bsr candidate-rp ip-address [group-list access-list interval seconds] [priority value] bidir</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> RP/0/RSP0/CPU0:router(config-pim-default-ipv4)# bsr candidate-rp 10.0.0.1 group-list access-list 10.0.0.1 interval 120</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

- **Example:**
  
  ```
  RP/0/RSP0/CPU0:router(config-pim-default-ipv4)>
  bsr candidate-rp 172.16.0.0 group-list 4 bidir
  ```

### Purpose

- **See Step 9, on page 59 for group list 4 configuration.**

### Step 5

- **interface type interface-path-id**

- **Example:**
  
  ```
  RP/0/RSP0/CPU0:router(config-pim-default-ipv4)>
  interface GigE 0/1/0/0
  ```

- **(Optional) Enters interface configuration mode for the PIM protocol.**

### Step 6

- **bsr-border**

- **Example:**
  
  ```
  RP/0/RSP0/CPU0:router(config-pim-ipv4-if)>
  bsr-border
  ```

- **(Optional) Stops the forwarding of bootstrap router (BSR) messages on a Protocol Independent Multicast (PIM) router interface.**

### Step 7

- **exit**

- **Example:**
  
  ```
  RP/0/RSP0/CPU0:router(config-pim-ipv4-if)>
  exit
  ```

- **(Optional) Exits PIM interface configuration mode, and returns the router to PIM configuration mode.**

### Step 8

- **exit**

- **Example:**
  
  ```
  RP/0/RSP0/CPU0:router(config-pim-default-ipv4)>
  exit
  ```

- **Exits PIM configuration mode.**

### Step 9

- **{ipv4 | ipv6} access-list name**

- **Example:**
  
  ```
  RP/0/RSP0/CPU0:router(config)>
  ipv4 access-list 4
  ```

- **(Optional) Defines the candidate group list to the BSR.**

  - Access list number 4 specifies the group prefix associated with the candidate RP address 172.16.0.0. (See Step 4, on page 58).
  - This RP is responsible for the groups with the prefix 239.

### Step 10

- **Do one of the following:**
  
  - `[sequence-number] permit source [source-wildcard]`
  
  - `[sequence-number] permit source-prefix dest-prefix`

- **Example:**
  
  ```
  RP/0/RSP0/CPU0:router(config-ipv4-acl)>
  permit
  ```

- **(Optional) Permits multicast group 239.1.1.1 for the candidate group list.**

**Tip**  
The commands in Step 6, on page 59 and Step 7, on page 59 can be combined in one command string and entered from global configuration mode like this: ipv4 access-list rp-access permit 239.1.1.1 0.255.255.255

### Calculating Rates per Route

This procedure enables multicast hardware forward-rate counters on a per-VRF-family basis.
SUMMARY STEPS

1. **configure**
2. **multicast-routing [vrf vrf-name] [address-family {ipv4 | ipv6}]**
3. **rate-per-route**
4. **interface {type interface-path-id | all} enable**
5. Do one of the following:
   - accounting per-prefix
   - accounting per-prefix forward-only

6. **commit**
7. **show mfib [vrf vrf-name] [ipv4 | ipv6] route [rate | statistics] [* | source-address] [group-address [/prefix-length] [detail | old-output] | summary] [location node-id]"
Configuring Multicast Nonstop Forwarding

This task configures the nonstop forwarding (NSF) feature for multicast packet forwarding for the purpose of alleviating network failures, or software upgrades and downgrades.

Although we strongly recommend that you use the NSF lifetime default values, the optional Step 3, on page 63 through Step 6, on page 64 allow you to modify the NSF timeout values for Protocol Independent Multicast (PIM) and Internet Group Management Protocol (IGMP) or Multicast Listener Discovery (MLD). Use these commands when PIM and IGMP (or MLD) are configured with nondefault interval or query intervals for join and prune operations.

Generally, configure the IGMP NSF and PIM NSF lifetime values to equal or exceed the query or join query interval. For example, if you set the IGMP query interval to 120 seconds, set the IGMP NSF lifetime to 120 seconds (or greater).

If the Cisco IOS XR Software control plane does not converge and reconnect after NSF is enabled on your router, multicast packet forwarding continues for up to 15 minutes, then packet forwarding stops.
Before You Begin

For NSF to operate in your multicast network, you must also enable NSF for the unicast protocols (such as IS-IS, OSPF, and BGP) that PIM relies on for Reverse Path Forwarding (RPF) information. See the appropriate configuration modules to learn how to configure NSF for unicast protocols.

SUMMARY STEPS

1. configure
2. router pim [address-family {ipv4 | ipv6}]
3. nsf lifetime seconds
4. exit
5. router {igmp | mld}
6. nsf lifetime seconds
7. commit
8. show {igmp nsf
9. show mfib [ipv4 | ipv6] nsf [location node-id]
10. show mrrib [ipv4 | ipv6] nsf
11. show pim [ipv4 | ipv6] nsf

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>router pim [address-family {ipv4</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>RP/0/RSP0/CPU0:router(config)# router pim address-family ipv4</td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>nsf lifetime seconds</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>RP/0/RSP0/CPU0:router(config-pim-default-ipv4)# nsf lifetime 30</td>
</tr>

### Configuring Multicast VPN

- **Enabling a VPN for Multicast Routing,** on page 66 (required)
- **"Configuring BGP to Advertise VRF Routes for Multicast VPN from PE to PE"** (required)

See the module "Implementing BGP on Cisco IOS XR Software in *Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide*."
• Configuring an MDT Address Family Session in BGP as a PE-to-PE Protocol (optional for PIM-SM MDT groups; required for PIM-SSM MDT groups)
   See the "Configuring an MDT Address Family Session in BGP" section in Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide.

• Configuring a provider-edge-to-customer-edge protocol (optional)

• Specifying the PIM VRF Instance, on page 68 (optional)

Prerequisites for Multicast VPN

• PIM and multicast forwarding must be configured on all interfaces used by multicast traffic. In an MVPN, you must enable PIM and multicast forwarding for the following interfaces:
  ◦ Physical interface on a provider edge (PE) router that is connected to the backbone.
  ◦ Interface used for BGP peering source address.
  ◦ Any interfaces configured as PIM rendezvous points.

  Note: PIM and multicast forwarding are enabled in multicast routing configuration mode. No additional configuration is required in router pim mode to enable the PIM protocol.

• Interfaces in the VPN intended for use in forwarding multicast traffic must be enabled for PIM and multicast forwarding.

• BGP should already be configured and operational on all routers that are sending or receiving multicast traffic.

• To enable MVPN, you must include a VPN IPv4 address-family (AFI) in your BGP configuration. See Restrictions for Multicast VPN for Multicast Routing, on page 65. (See also the "Enabling BGP Routing" section in Cisco IOS XR Routing Configuration Guide.)

• All PE routers in the multicast domain must be running a Cisco IOS XR Software image that supports MVPN.

• Multicast forwarding must be configured for the global IPv4 address family.

• Each multicast SM VRF domain must have an associated PIM rendezvous point (RP) definition. Using Auto-RP and the bootstrap router (BSR), you may configure RP services in the MVPN on the customer-edge (CE) device because the MVPN learns about the RP dynamically. The VRF interface can be used as a listener on the PE device.

To enable static RP services, you must configure every device in the domain for this purpose.

Restrictions for Multicast VPN for Multicast Routing

• Configuration of the MDT source on a per-VRF basis is only supported on IPv4.
The MDT group address should be the same for both the address families in the same VRF.

**Enabling a VPN for Multicast Routing**

This task enables multicast VPN routing for IPv4.

The MDT group address is used by provider edge (PE) routers to form a virtual PIM "neighborship" for the MDT. This enables the PEs to communicate with other PEs in the VRF as if they shared a LAN.

When sending customer VRF traffic, PEs encapsulate the traffic in their own (S,G) state, where the G is the MDT group address, and the S is the MDT source for the PE. By joining the (S,G) MDT of its PE neighbors, a PE router is able to receive the encapsulated multicast traffic for that VRF.

Although the VRF itself may have many multicast sources sending to many groups, the provider network needs only to install state for one group per VRF, in other words, the MDT group.

**SUMMARY STEPS**

1. configure
2. multicast-routing
3. address-family ipv4
4. nsf
5. mdt source type interface-path-id

<td></td>
</tr>
<tr>
<td>address-family ipv4</td>
<td>Specifies that nonstop forwarding (NSF) maintains the forwarding state in case of a disruption to a multicast process.</td>
<td></td>
</tr>
</tbody>
</table>

**Step 4**  
nsf  
**Example:**  
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# nsf  

**Step 5**  
mdt source type interface-path-id  
**Example:**  
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# mdt source GigE 0/1/0/0  

**Step 6**  
interface all enable  
**Example:**  
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# interface all enable  

**Step 7**  
vrf vrf-name  
**Example:**  
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# vrf vrf_A  

**Step 8**  
address-family {ipv4}]  

**Step 9**  
mdt default mdt-group-address  
**Example:**  
RP/0/RSP0/CPU0:router(config-mcast-vrf_A-ipv4)# mdt default 239.23.2.1  

**Step 10**  
mdt data mdt-group-address/prefix-length threshold acl-name  
**Example:**  
RP/0/RSP0/CPU0:router(config-mcast-vrf_A-ipv4)# mdt data 239.23.3.0/24 threshold 1200 acl-A  

The MDT source interface name should be the same as the one used for BGP.

Caution To avoid any possibility of a reverse-path forwarding (RPF) failure, you should proactively enable any interfaces that might possibly carry multicast traffic.

This group range should not overlap the MDT default group.

This is an optional command. The default threshold below which traffic is sent using a data MDT group is 1 kbps. However, you may configure a higher threshold, if desired. You may also, optionally, configure an access list to limit the number of groups to be tunneled through a data MDT.
### Purpose

Traffic from groups not on the access-list continues to be tunneled using the default MDT group. This is an optional step.

### Command or Action

- **mdt mtu size**

**Example:**
```
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# mdt mtu 1550
```

### Step 11

- **interface all enable**

**Example:**
```
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# interface all enable
```

### Step 12

- **commit**

### Step 13

#### Specifying the PIM VRF Instance

If you are configuring Protocol Independent Multicast in sparse mode (PIM-SM) in the MVPN, you may also need to configure a rendezvous point (RP). This task specifies the optional PIM VPN instance.

### SUMMARY STEPS

1. configure
2. `router pim vrf vrf-name address-family {ipv4 | ipv6}
3. rp-address ip-address [group-access-list-name] [bidir] [override]
4. commit

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure</td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>`router pim vrf vrf-name address-family {ipv4</td>
</tr>
</tbody>
</table>

**Example:**
```
RP/0/RSP0/CPU0:router(config)# router pim vrf vrf_A address-family ipv4
```

**Note**
The default MTU for PIM/GRE MDT is 1376 and the default value for mLDP/P2MP-TE MDT is 9000 for Multicast VPN.

| 4    | commit            |         |
Configuring the MDT Source per VRF

This optional feature lets you change the default routing mechanism in a multicast VPN network topology, which routes all unicast traffic through a BGP peering loopback configured on a default VRF. Instead, you may configure a loopback that allows you to specify the MDT source using a specific VRF, as opposed to the default VRF. This overrides the current behavior and updates BGP as part of a MDT group. BGP then modifies the source and connector attributes in the MDT SAFI and VPN IPv4 updates.

For VRFs on which the MDT source is not configured, the MDT source for the default VRF is applied. Also, when the MDT source on a VRF is unconfigured, the configuration of the MDT source default VRF takes effect.

In the configuration below, the default VRF does not require explicit reference in Step 5.

SUMMARY STEPS

1. configure  
2. multicast-routing  
3. address-family [ ipv4 | ipv6 ]  
4. mdt source loopback 0  
5. exit  
6. vrf 101  
7. address-family ipv4  
8. mdt source loopback 1  
9. Repeat the steps 6 to 8, as many times as needed to create other VRFs.  
10. commit  
11. show pim vrf all mdt interface  

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure</td>
<td>Enables IP multicast routing and forwarding.</td>
</tr>
<tr>
<td><strong>Step 2</strong> multicast-routing</td>
<td></td>
</tr>
</tbody>
</table>
| Example: RP/0/RSP0/CPU0:router(config)# multicast-routing  
RP/0/RSP0/CPU0:router(config-mcast)# |  |
| **Step 3** address-family [ ipv4 | ipv6 ] |  |
| Example: RP/0/RSP0/CPU0:router(config-mcast)# address-family ipv4 | Enters ipv4 (or ipv6) address-family submode. |
### Purpose
Configure the interface used to set the MDT source address for MVPN, using the default VRF.

**Step 4**
**mdt source loopback 0**

**Example:**
```
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# mdt source loopback 0
```

**Purpose:** Configures the interface used to set the MDT source address for MVPN, using the default VRF.

**Step 5**
**exit**

**Example:**
```
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# exit
```

**Purpose:** Exits from the current mode.

**Step 6**
**vrf 101**

**Example:**
```
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# vrf 101
```

**Step 7**
**address-family ipv4**

**Example:**
```
RP/0/RSP0/CPU0:router(config-mcast-101)# address-family ipv4
```

**Purpose:** Enters the IPv4 address-family mode.

**Step 8**
**mdt source loopback 1**

**Example:**
```
RP/0/RSP0/CPU0:router(config-mcast-101-ipv4)# mdt source loopback 1
```

**Purpose:** Configures the interface used to set the MDT source address for MVPN.

**Step 9**
Repeat the steps 6 to 8, as many times as needed to create other VRFs.

**Example:**
```
RP/0/RSP0/CPU0:router(config-mcast-102)# vrf 102 mdt source loopback 2
```

**Step 10**
**commit**

**Step 11**
**show pim vrf all mdt interface**

**Example:**
```
RP/0/RSP0/CPU0:router# show pim vrf all mdt interface

<table>
<thead>
<tr>
<th>GroupAddress</th>
<th>Interface</th>
<th>Source</th>
<th>Vrf</th>
</tr>
</thead>
<tbody>
<tr>
<td>239.0.0.239</td>
<td>mdtVRF_NAME</td>
<td>Loopback1</td>
<td></td>
</tr>
</tbody>
</table>
```

**Purpose:** To verify the MDT source per VRF configuration, use the `show pim vrf all mdt interface` command.
Configuring Label Switched Multicast

Deployment of an LSM MLDP-based MVPN involves configuring a default MDT and one or more data MDTs. A static default MDT is established for each multicast domain. The default MDT defines the path used by PE routers to send multicast data and control messages to other PE routers in the multicast domain. A default MDT is created in the core network using a single MP2MP LSP.

An LSP MLDP-based MVPN also supports dynamic creation of the data MDTs for high-bandwidth transmission. For high-rate data sources, a data MDT is created using the P2MP LSPs to off-load the traffic from the default MDT to avoid unnecessary waste of bandwidth to PEs that are not part of the stream. You can configure MLDP MVPN for both the intranet or extranet. This configuration section covers the rosen based MLDP profile. For configuration examples of other MLDP profiles, see Configuring LSM based MLDP: Examples, on page 175.

Before configuring MLDP based MVPN, ensure that the MPLS is enabled on the core facing interface. For information in MPLS configuration, see Cisco IOS XR MPLS Configuration Guide. Also, ensure that BGP and any interior gateway protocol (OSPF or ISIS) is enabled on the core router. For more information on BGP and route-policy configuration, see Cisco IOS XR Routing Configuration Guide.

Perform this task to configure label switched multicast:

**Verification of LSM mLDP based MVPN Configuration**

Use these commands to verify the LSM mLDP based MVPN intranet configuration:

- To check the mLDP neighbors, use the `show mpls mldp neighbors` command:

```
Router# show mpls mldp neighbors
mLDP neighbor database
MLDP peer ID    : 1.0.0.1:0, uptime 15:36:30 Up,
Capabilities    : GR, Typed Wildcard FEC, P2MP, MP2MP, MBB
Target Adj      : No
Upstream count  : 0
Branch count    : 0
LDP GR          : Enabled
```
To check the PIM neighbors, use the `show pim vrf vrf-name neighbor` command:

```
Router# show pim vrf A1_MIPMSI neighbor
PIM neighbors in VRF A1_MIPMSI
Neighbor Address  Interface  Uptime  Expires  DR pri  s
101.2.2.101*  Loopback2  15:54:43  00:00:02  1 (DR)  BP
```
To check the multicast routes for a given VRF, use `show mrib vrf vrf_name route` command:

Router# show mrib vrf A1_MIPMSI route

IP Multicast Routing Information Base
Entry flags: L - Domain-Local Source, E - External Source to the Domain,

Configuring MVPN Static P2MP-TE

Perform these steps to configure the multicast VPN for static point-to-multipoint (P2MP) traffic engineering (TE).

**Configuring MVPN P2MP on Ingress PE**

Perform this task to configure MVPN P2MP on Ingress PE.

**SUMMARY STEPS**

1. configure
2. multicast-routing
3. address-family \{ipv4|ipv6\}
4. mdt source type interface-path-id
5. interface all enable
6. vrf vrf-name
7. address-family \{ipv4 | ipv6\}
8. bgp auto-discovery rsvpte
9. mdt static p2mp-te tunnel-mte value
10. interface all enable
11. router igmp
12. vrf name
13. interface type interface-path-id
14. static-group ip_group_address source-address
15. commit
### DETAILED STEPS

<table>

<td></td>
</tr>
<tr>
<td><strong>Example:</strong>&lt;br&gt;RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)#&lt;br&gt;interface all enable</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 33</strong></td>
<td><strong>vrf vpn1</strong>&lt;br&gt;Configures the vrf and enters the vrf configuration mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong>&lt;br&gt;RP/0/RSP0/CPU0:router(config-mcast)#&lt;br&gt;vrf vpn1</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 34</strong></td>
<td><strong>address-family ipv4</strong>&lt;br&gt;Configures the ipv4 address-family and enters the ipv4 address-family submode.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong>&lt;br&gt;RP/0/RSP0/CPU0:router(config-mcast-vpn1)#&lt;br&gt;address-family ipv4</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 35</strong></td>
<td><strong>bgp auto-discovery mldp inter-as</strong>&lt;br&gt;Enables BGP MVPN auto-discovery.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong>&lt;br&gt;RP/0/RSP0/CPU0:router(config-mcast-vpn1-ipv4)#&lt;br&gt;bgp auto-discovery mldp inter-as</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 36</strong></td>
<td><strong>mdt partitioned mldp ipv4 mp2mp</strong>&lt;br&gt;Enables MLDP MP2MP signaled partitioned distribution tree for ipv4 core.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong>&lt;br&gt;RP/0/RSP0/CPU0:router(config-mcast-vpn1-ipv4)#</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td>mdt partitioned mldp ipv4 mp2mp</td>
<td><strong>Note</strong> This configuration varies depending on what core tree option is being used. For example, the above step enables MLDP MP2MP core tree. Instead, if you select, P2MP core tree, the configuration enables MLDP P2MP core tree.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 37</strong> interface all enable</td>
<td>Enables multicast routing and forwarding on all new and existing interfaces. You can also enable individual interfaces.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RP/0/RSP0/CPU0:router(config-mcast-vpn1-ipv4)# interface all enable</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 38</strong> router pim</td>
<td>Configures the router pim and enters the pim configuration mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RP/0/RSP0/CPU0:router(config)# router pim</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 39</strong> vrf vrf1</td>
<td>Configures the vrf and enters the vrf configuration mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RP/0/RSP0/CPU0:router(config-pim)# vrf vrf1</td>
<td></td>
<td></td>

### Configuring ASBR Router for MVPN InterAS Option B or C

Perform this step to configure ASBR router for MVPN InterAS Option B or C:

**Before You Begin**

Perform these steps prior to starting the Configuring ASBR Router for MVPN InterAS Option B or C:

```
prefix-set IGP_leaks
  10.10.10.1/32,
  10.10.10.2/32,
  10.10.10.3/32
end-set

route-policy IGP_INTER_AS_C_OUT
  if destination in IGP_leaks then
    pass
  else
    drop
  endif
end-policy
```

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure</td>
<td></td>
</tr>
</tbody>
</table>
| Step 2 | router static | Enables a static routing process.  
**Example:**  
RP/0/RSP0/CPU0:router(config)# router static |
| Step 3 | address-family ipv4 unicast destination prefix interface-type interface-path-id | Configures the ipv4 address-family for the unicast topology with a destination prefix.  
**Example:**  
RP/0/RSP0/CPU0:router(config-static)# address-family ipv4 unicast 3.3.3.3/32 GigabitEthernet 0/1/0/1 |
| Step 4 | router bgp 2-byte AS number | Configures the router bgp and enters the router bgp configuration mode.  
**Example:**  
RP/0/RSP0/CPU0:router(config)# router bgp 100 |
| Step 5 | bgp router-id ipv4 address | Configures the bgp router id with the ipv4 address.  
**Note**  
Steps 1 to 5 are common for both Option B and C.  
**Example:**  
RP/0/RSP0/CPU0:router(config-bgp)# bgp router-id 10.10.10.1 |
| Step 6 | address-family vpnv4 unicast | Configures the vpnv4 address-family with the unicast topology.  
**Example:**  
RP/0/RSP0/CPU0:router(config-bgp)# address-family vpnv4 unicast |
| Step 7 | retain route-target all | Accepts or retains the received updates containing at least one route target.  
**Example:**  
RP/0/RSP0/CPU0:router(config-bgp-af)# retain route-target all |
| Step 8 | address-family ipv4 mvpn | Configures the ipv4 address-family with the mvpn.  
**Example:**  
RP/0/RSP0/CPU0:router(config-bgp)# address-family
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipv4 mvpn</td>
<td></td>
</tr>
</tbody>
</table>

**Step 9**

<table>
<thead>
<tr>
<th>retain route-target all</th>
<th>Accepts or retains the received updates containing at least one route target.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>RP/0/RSP0/CPU0:router(config-bgp-af)# retain route-target all</td>
</tr>
</tbody>
</table>

**Note**  
Steps 6 to 9 are only for Option B Configuration.

**Step 10**

<table>
<thead>
<tr>
<th>address-family ipv4 unicast</th>
<th>Configures the ipv4 address-family for a unicast topology and enters the ipv4 address-family submode.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>RP/0/RSP0/CPU0:router(config-bgp)# address-family ipv4 unicast</td>
</tr>
</tbody>
</table>

**Step 11**

<table>
<thead>
<tr>
<th>redistribute ospf router_tag</th>
<th>Redistributes information from another routing protocol.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>RP/0/RSP0/CPU0:router(config-bgp-af)# redistribute ospf 100</td>
</tr>
</tbody>
</table>

**Step 12**

<table>
<thead>
<tr>
<th>route-policy policy_name</th>
<th>Configures the route-policy to select RPF topology.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>RP/0/RSP0/CPU0:router(config)# route-policy IGP_INTER_AS_C_OUT</td>
</tr>
</tbody>
</table>

**Step 13**

<table>
<thead>
<tr>
<th>allocate-label all</th>
<th>Allocates label for all prefixes.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>RP/0/RSP0/CPU0:router(config-bgp)# allocate-label all</td>
</tr>
</tbody>
</table>

**Note**  
Steps 10 and 13 are part of the Option C configuration.

**Step 14**

<table>
<thead>
<tr>
<th>neighbor neighbor_address</th>
<th>Specifies and configures a neighbor router with the neighbor address.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>RP/0/RSP0/CPU0:router(config-bgp)# neighbor 10.10.10.02</td>
</tr>
</tbody>
</table>

**Step 15**

<table>
<thead>
<tr>
<th>remote-as 2-byte AS number</th>
<th>Sets remote AS with the mentioned 2-byte AS number.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>RP/0/RSP0/CPU0:router(config-bgp-nbr)# remote-as 100</td>
</tr>
</tbody>
</table>

**Note**  
Steps 14 and 15 are common to both Option B and C.

</tbody>
</table>
### Purpose

**Command or Action**

**Step 24**  
*update-source Loopback 0-65535*  
**Example:**  
RP/0/RSP0/CPU0:router(config-bgp-nbr)# update-source Loopback 0  
Specifies the source of routing updates using the Loopback interface.

**Step 25**  
*address-family vpnv4 unicast*  
**Example:**  
RP/0/RSP0/CPU0:router(config-bgp-nbr)# address-family ipv4 labeled-unicast  
Configures the vpnv4 address-family with the unicast topology.

**Step 26**  
*route-policy policy_name in*  
**Example:**  
RP/0/RSP0/CPU0:router(config-bgp-nbr-af)# route-policy pass-all in  
Applies route-policy to inbound routes.

**Step 27**  
*route-policy policy_name out*  
**Example:**  
RP/0/RSP0/CPU0:router(config-bgp-nbr-af)# route-policy pass-all out  
Applies route-policy to outbound routes.

**Step 28**  
*next-hop-unchanged*  
**Example:**  
RP/0/RSP0/CPU0:router(config-bgp-nbr-af)# next-hop-unchanged  
Indicates that the next hop should be kept as is and not overwritten, before advertising to eBGP peers.

**Step 29**  
*commit*

---

### Configuring Multitopology Routing

This set of procedures configures multitopology routing, which is used by PIM for reverse-path forwarding (RPF) path selection.

- "Configuring a Global Topology and Associating It with an Interface" (required)  
  For information, see *Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide*.

- "Enabling an IS-IS Topology" (required)  
  For information, see *Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide*.
• "Placing an Interface in a Topology in IS-IS" (required)
  For information, see *Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide*.

• "Configuring a Routing Policy" (required)
  For information, see *Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide*.

**Restrictions for Configuring Multitopology Routing**

- Only the default VRF is currently supported in a multitopology solution.
- Only protocol-independent multicast (PIM) and intermediate system-intermediate system (IS-IS) routing protocols are currently supported.
- Topology selection is restricted solely to (S, G) route sources for both SM and SSM. Static and IS-IS are the only interior gateway protocols (IGPs) that support multitopology deployment.

For non-(S, G) route sources like a rendezvous point or bootstrap router (BSR), or when a route policy is not configured, the current policy default remains in effect. In other words, either a unicast-default or multicast-default table is selected for all sources based on any of the following configurations:

- Open Shortest Path First (OSPF)
- Intermediate System-to-Intermediate System (IS-IS)
- Multiprotocol Border Gateway Protocol (MBGP)

**Note**

Although both *multicast* and *unicast* keywords are available when using the `address-family {ipv4 | ipv6}` command in routing policy language (RPL), only topologies under multicast SAFI can be configured globally.

**Information About Multitopology Routing**

Configuring multitopology networks requires the following tasks:

- "Configuring a Global Topology and Associating It with an Interface" (required)
  For information, see *Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide*.
- "Enabling an IS-IS Topology" (required)
  For information, see *Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide*.
- "Placing an Interface in a Topology in IS-IS" (required)
  For information, see *Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide*.
- "Configuring a Routing Policy" (required)
  For information, see *Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide*.
Configuring an RPF Topology in PIM

SUMMARY STEPS

1. configure
2. router pim address-family {ipv4 | ipv6}
3. rpf topology route-policy policy-name
4. exit
5. multicast-routing address-family {ipv4 | ipv6}
6. interface all enable
7. commit
8. show pim [vrf vrf-name] [ipv4 | ipv6] [{unicast | multicast | safi-all} topology {table-name | all}] rpf [ip-address | hash | summary | route-policy]

<tr>
<td></td>
<td>RP/0/RSP0/CPU0:router(config)# multicast-routing address-family ipv4</td>
<td>Enables PIM for the interface.</td>
</tr>
</tbody>
</table>
**Command or Action** | **Purpose**
--- | ---
Step 6 | interface all enable
   Example: RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# interface all enable
   Enables multicast routing and forwarding on all new and existing interfaces.
Step 7 | commit
Step 8 | show pim [vrf vrf-name] [ipv4 | ipv6] {unicast | multicast | safi-all} topology {table-name | all} rpf [ip-address | hash | summary | route-policy]
   Example: RP/0/RSP0/CPU0:router# show pim vrf mtt rpf ipv4 multicast topology all rpf
   Shows PIM RPF entries for one or more tables.

---

### Configuring MVPN Extranet Routing

To be able to import unicast routes from source VRFs to receiver VRFs, the import route targets of receiver VRFs must match the export route targets of a source VRF. Also, all VRFs on the PEs where the extranet source-receiver switchover takes place should be added to the BGP router configuration on those PEs.

Configuring MVPN extranet routing consists of these mandatory and optional tasks, which should be performed in the sequence shown:

- “Configuring a Routing Policy” (required only if performing the following task)
  For information, see *Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide*.

For examples of an end-to-end configuration of each of the two available MVPN extranet topology solutions, see *Configuring MVPN Extranet Routing: Example*, on page 155.

### Prerequisites for MVPN Extranet Routing

- PIM-SM and PIM-SSM are supported. You must configure the multicast group range in the source and receiver VRFs with a matching PIM mode.
- Because only static RP configuration is currently supported for a given multicast group range, both source and receiver MVPFs must be configured with the same RP.
- In the IPv6 Connectivity over MVPN topology model, the data MDT encapsulation range should be large enough to accommodate extranet streams without any aggregation. This prevents extranet traffic, flowing to multiple VRFs, from being carried into only one data MDT.
- Data MDT configuration is required on only the Source VRF and Source PE Router.
Restrictions for MVPN Extranet Routing

- PIM-DM and PIM-BIDIR are not supported.
- Cisco IOS XR Software software supports only IPv4 extranet multicast routing over IPv4 core multicast routing.
- Any PE can be configured as an RP except a PE in the "Receiver VRF on the Source PE Router" model where the extranet switchover occurs, and where the source VRF has no interfaces. This is because the source VRF must have some physical interface to signal the data packets being received from the first hop.
- Cisco IOS XR Software currently supports only one encapsulation of VRF traffic on an extranet. This means that only one encapsulation interface (or MDT) is allowed in the outgoing forwarding interface list of the multicast route. If, for a given stream, there are multiple receiver VRFs joining the same source VRF, only the first receiver VRF receives traffic; other receiver VRF joins are discarded.

Note: This limitation applies only to IPv6 Connectivity over MVPN topology model.

Configuring VPN Route Targets

This procedure demonstrates how to configure a VPN route target for each topology.

Note: Route targets should be configured so that the receiver VRF has unicast reachability to prefixes in the source VRF. These configuration steps can be skipped if prefixes in the source VRF are already imported to the receiver VRF.

SUMMARY STEPS

1. configure
2. vrf source-vrf
3. address-family [ipv4 | ipv6] unicast
4. import route-target [xx.yy:nn | as-number:nn | ip-address:nn]
5. export route-target [xx.yy:nn | as-number:nn | ip-address:nn]
6. commit
7. configure
8. vrf receiver-vrf
9. Repeat Step 3 through Step 6.

</table>
Interconnecting PIM-SM Domains with MSDP

To set up an MSDP peering relationship with MSDP-enabled routers in another domain, you configure an MSDP peer to the local router.

If you do not want to have or cannot have a BGP peer in your domain, you could define a default MSDP peer from which to accept all Source-Active (SA) messages.

Finally, you can change the Originator ID when you configure a logical RP on multiple routers in an MSDP mesh group.

**Before You Begin**

You must configure MSDP default peering, if the addresses of all MSDP peers are not known in BGP or multiprotocol BGP.

**SUMMARY STEPS**

1. configure
2. interface type interface-path-id
3. ipv4 address address mask
4. exit
5. router msdp
6. default-peer ip-address [prefix-list list]
7. originator-id type interface-path-id
8. peer peer-address
9. connect-source type interface-path-id
10. mesh-group name
11. remote-as as-number
12. commit
13. show msdp [ipv4] globals
14. show msdp [ipv4] peer [peer-address]
15. show msdp [ipv4] rpf rpf-address

**DETAILED STEPS**

<tbody>
<tr>
<td><strong>Step 1</strong> configure</td>
<td>(Optional) Enters interface configuration mode to define the IPv4 address for the interface.</td>
</tr>
<tr>
<td><strong>Step 2</strong> interface type interface-path-id</td>
<td>(Optional) Enters interface configuration mode to define the IPv4 address for the interface.</td>
</tr>
<tr>
<td>Example:</td>
<td>Note: This step is required if you specify an interface type and number whose primary address becomes the source IP address for the TCP connection.</td>
</tr>
<tr>
<td>RP/0/RSP0/CPU0:router(config)# interface loopback 0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> ipv4 address address mask</td>
<td>(Optional) Defines the IPv4 address for the interface.</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>Example:</strong> RP/0/RSP0/CPU0:router(config-if)# ipv4 address 10.0.1.3 255.255.255.0</td>
<td><strong>Note</strong> This step is required only if you specify an interface type and number whose primary address becomes the source IP address for the TCP connection. See optional for information about configuring the connect-source command.</td>
</tr>
<tr>
<td><strong>Step 4</strong> exit</td>
<td>Exits interface configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> RP/0/RSP0/CPU0:router(config-if)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> router msdp</td>
<td>Enters MSDP protocol configuration mode.</td>
</tr>
<tr>
<td><strong>Example:</strong> RP/0/RSP0/CPU0:router(config)# router msdp</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> default-peer ip-address [prefix-list list]</td>
<td>(Optional) Defines a default peer from which to accept all MSDP SA messages.</td>
</tr>
<tr>
<td><strong>Example:</strong> RP/0/RSP0/CPU0:router(config-msdp)# default-peer 172.23.16.0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> originator-id type interface-path-id</td>
<td>(Optional) Allows an MSDP speaker that originates a (Source-Active) SA message to use the IP address of the interface as the RP address in the SA message.</td>
</tr>
<tr>
<td><strong>Example:</strong> RP/0/RSP0/CPU0:router(config-msdp)# originator-id GigabitEthernet0/1/1/0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong> peer peer-address</td>
<td>Enters MSDP peer configuration mode and configures an MSDP peer.</td>
</tr>
<tr>
<td><strong>Example:</strong> RP/0/RSP0/CPU0:router(config-msdp)# peer 172.31.1.2</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Configure the router as a BGP neighbor.</td>
</tr>
<tr>
<td></td>
<td>• If you are also BGP peering with this MSDP peer, use the same IP address for MSDP and BGP. You are not required to run BGP or multiprotocol BGP with the MSDP peer, as long as there is a BGP or multiprotocol BGP path between the MSDP peers.</td>

**Controlling Source Information on MSDP Peer Routers**

Your MSDP peer router can be customized to control source information that is originated, forwarded, received, cached, and encapsulated.

When originating Source-Active (SA) messages, you can control to whom you will originate source information, based on the source that is requesting information.

When forwarding SA messages you can do the following:

- Filter all source/group pairs
- Specify an extended access list to pass only certain source/group pairs
Filter based on match criteria in a route map

When receiving SA messages you can do the following:

- Filter all incoming SA messages from an MSDP peer
- Specify an extended access list to pass certain source/group pairs
- Filter based on match criteria in a route map

In addition, you can use time to live (TTL) to control what data is encapsulated in the first SA message for every source. For example, you could limit internal traffic to a TTL of eight hops. If you want other groups to go to external locations, you send those packets with a TTL greater than eight hops.

By default, MSDP automatically sends SA messages to peers when a new member joins a group and wants to receive multicast traffic. You are no longer required to configure an SA request to a specified MSDP peer.

**SUMMARY STEPS**

1. `configure`
2. `router msdp`
3. `sa-filter {in | out} {ip-address | peer-name} [list access-list-name] [rp-list access-list-name]`
4. `cache-sa-state [list access-list-name] [rp-list access-list-name]`
5. `ttl-threshold ttl-value`
6. `exit`
7. `ipv4 access-list name [sequence-number] permit source [source-wildcard]`
8. `commit`

**Multicast only fast reroute (MoFRR)**

MoFRR allows fast reroute for multicast traffic on a multicast router. MoFRR minimizes packet loss in a network when node or link failures occur (at the topology merge point). It works by making simple enhancements to multicast routing protocols.

MoFRR involves transmitting a multicast join message from a receiver towards a source on a primary path and transmitting a secondary multicast join message from the receiver towards the source on a backup path. Data packets are received from the primary and secondary paths. The redundant packets are discarded at topology merge points with the help of Reverse Path Forwarding (RPF) checks. When a failure is detected on the primary path, the repair occurs locally by changing the interface on which packets are accepted to the
secondary interface, thus improving the convergence times in the event of a node or link failure on the primary path.

MoFRR supports ECMP (Equal Cost Multipath) and non-ECMP topologies as well. TI (Topology Independent) MoFRR is a multicast feature that performs fast convergence (Fast ReRoute) for specified routes/flows when failure is detected on one of the paths between the router and the source.

**Operating Modes of MoFRR**

- Flow-based MoFRR—exposes the primary and secondary RPF interfaces to the forwarding plane, with switchover occurring entirely at the hardware level.

Faster convergence is obtainable in Flow-based MoFRR by monitoring the packet counts of the primary stream. If no activity is detected for 30 ms, the switch over is triggered to the backup stream and the traffic loss is within 50 ms.

**Restrictions**

These limitations apply to MoFRR deployments when the Cisco ASR 9000 Series SPA Interface Processor-700 linecard is used in the Cisco ASR 9000 Series Router chassis.

1. Cisco ASR 9000 Series SPA Interface Processor-700 cannot be used on ingress interface as either the primary or backup (ECMP paths) path back to the multicast source.

2. The egress interfaces on Cisco ASR 9000 Series SPA Interface Processor-700 may lead to duplicate multicast streams for short periods of time (the time between the switch from Trident primary to Trident backup paths on ingress).

Point to Multipoint Traffic Engineering Label-Switched Multicast

IP multicast was traditionally used for IPTV broadcasting and content delivery services. MPLS-TE (traffic engineering) is fast replacing the IP multicast technique because of the various advantages of MPLS-TE, such as:

- Fast re-routing and restoration in case of link/ node failure
- Bandwidth guarantee
- Explicit path setting along with off-line computation

MPLS supports point-to-point path. However, in order to use MPLS for multicast service, MPLS has to be extended to handle point-to-multipoint paths. A reliable solution to signal Point-to-Multipoint (P2MP) label switched paths(LSP) is the Point-to-Multipoint TE LSP. This solution uses the Resource Reservation Protocol-Traffic Engineering (RSVP-TE) extension as the signaling protocol for establishing P2MP TE LSPs.

Point to Multipoint LSP(P2MP)

P2MP LSP is unidirectional. In case of native IP multicast, the multicast forwarding always has to perform an acceptance check. This check ensures all multicast packets undergo a RPF check to ensure that the packets have arrived on the correct interface in the direction of the source. However, the acceptance check with MPLS forwarding may be different in case of a unicast or upstream label.

Depending on the multicast signaling protocol, the labeled packet may require an additional L3 lookup at the P and PE routers in order to forward the multicast packet to the physical interfaces according to multicast routing. In this case, the incoming P2MP LSP as the incoming interface for the received multicast packet must
also be available to the multicast forwarding plane during the L3 lookup. For more details on RSVP-TE and P2MP LSP, refer the `Cisco ASR 9000 Series Aggregation Services Router MPLS Configuration Guide`

## Multicast Routing Protocol support for P2MP

All multicast routing protocols support P2MP TE LSP. At ingress node, a multicast protocol must make a mapping between the multicast traffic and the P2MP TE LSP with the configuration of static-join. At egress node, the multicast protocol must conduct a special RPF check for the multicast packet which is received from MPLS core and forward it to the customer facing interface. The RPF check is based on the configuration of static-rpf. These multicast groups which are forwarded over the P2MP TE LSPs can be specified with the static-rpf configuration in case of PIM-SSM.

### Enabling Multicast Forwarding Over Tunnel Interface (at Ingress Node)

This configuration is used for allowing the forwarding of the multicast packet over the specified interface.

## SUMMARY STEPS

Configuration Examples for Implementing Multicast Routing on Software

This section provides the following configuration examples:

Calculating Rates per Route: Example

The following example illustrates output from hardware counters based on rate per route for a specific source and group address location:

```
RP/0/RSP0/CPU0:router# configure
RP/0/RSP0/CPU0:router(config)# multicast-routing vrf vpn12 address-family ipv4
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# rate-per-route
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# interface all enable
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# accounting per-prefix
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# commit
RP/0/RSP0/CPU0:router(config-mcast-default-ipv4)# exit
```
RP/0/RSP0/CPU0:router(config-mcast)# exit
RP/0/RSP0/CPU0:router(config)# exit
RP/0/RSP0/CPU0:router# show mfib route rate

Preventing Auto-RP Messages from Being Forwarded on Software: Example

This example shows that Auto-RP messages are prevented from being sent out of the GigabitEthernet interface 0/3/0/0. It also shows that access list 111 is used by the Auto-RP candidate and access list 222 is used by the boundary command to contain traffic on GigabitEthernet interface 0/3/0/0.

```
ipv4 access-list 111
  10 permit 224.1.0.0 0.0.255.255 any
  20 permit 224.2.0.0 0.0.255.255 any
!
!Access list 111 is used by the Auto-RP candidate.
!
ipv4 access-list 222
  10 deny any host 224.0.1.39
  20 deny any host 224.0.1.40
!
!Access list 222 is used by the boundary command to contain traffic (on
```
Inheritance in MSDP on Software: Example

The following MSDP commands can be inherited by all MSDP peers when configured under router MSDP configuration mode. In addition, commands can be configured under the peer configuration mode for specific peers to override the inheritance feature.

- connect-source
- sa-filter
- ttl-threshold

If a command is configured in both the router msdp and peer configuration modes, the peer configuration takes precedence.

In the following example, MSDP on Router A filters Source-Active (SA) announcements on all peer groups in the address range 226/8 (except IP address 172.16.0.2); and filters SAs sourced by the originator RP 172.16.0.3 to 172.16.0.2.

MSDP peers (172.16.0.1, 172.16.0.2, and 172.17.0.1) use the loopback 0 address of Router A to set up peering. However, peer 192.168.12.2 uses the IPv4 address configured on the GigabitEthernet interface to peer with Router A.

Router A

```
! ipv4 access-list 111
  10 deny ip host 172.16.0.3 any
  20 permit any any
!
ipv4 access-list 112
  10 deny any 226.0.0.0 0.255.255.255
  30 permit any any
!
router msdp
  connect-source loopback 0
  sa-filter in rp-list 111
  sa-filter out rp-list 111
  peer 172.16.0.1
  peer 172.16.0.2
  sa-filter out list 112
  peer 172.17.0.1
  peer 192.168.12.2
  connect-source GigabitEthernet0/3/0/0
```
MSDP-VRF: Example

This is an example where, peer 1.1.1.1 is configured in the VRF context for vrf1.

```config
router msdp
  vrf vrf1
    peer 1.1.1.1
  exit
end!
```

Configuring Route Policy for Static RPF: Example

```config
router static
  address-family ipv4 multicast
    202.93.192.74 /32 202.40.148.11
!
route-policy pim-policy
  set rpf-topology ipv4 multicast topology default
end-policy
!
router pim
  address-family ipv4
    rpf topology route-policy pim-policy
```

Configuring IPv4 Multicast VPN: Example

Cisco ASR 9000 Series Routers support only IPv4 addressing.

This end-to-end configuration example shows how to establish a multicast VPN topology (Figure 12: Topology in CE4PE1PE2 CE3MVPN Configuration, on page 135), using two different routing protocols (OSPF or BGP) to broadcasting traffic between customer-edge(CE) routers and provider-edge (PE) routers:

Figure 12: Topology in CE4PE1PE2 CE3MVPN Configuration

```
CE4----------------PE1-------------------------------------------------PE2--------------CE3
```

For more configuration information, see the Configuring Multicast VPN, on page 64 of this module and also related configuration information in Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide.

    address-family ipv4 unicast
    redistribute connected
Configuring RPL Policies in Receiver VRFs to Propagate Joins to a Source VRF: Example

In addition to configuring route targets, Routing Policy Language (RPL) policies can be configured in receiver VRFs on receiver PE routers to propagate joins to a specified source VRF. However, this configuration is optional.

The following configuration example shows a policy where the receiver VRF can pick either “provider_vrf_1” or “provider_vrf_2” to propagate PIM joins.

In this example, provider_vrf_1 is used for multicast streams in the range of from 227.0.0.0 to 227.255.255.255, while provider_vrf_2 is being used for streams in the range of from 228.0.0.0 to 228.255.255.255.

```conf
route-policy extranet_streams_from_provider_vrf
if destination in (227.0.0.0/32 ge 8 le 32) then
    set rpf-topology vrf provider_vrf_1
elseif destination in (228.0.0.0/32 ge 8 le 32) then
    set rpf-topology vrf provider_vrf_2
else
    pass
endif
end-policy
!
router pim vrf receiver_vrf address-family ipv4
rpf topology route-policy extranet_streams_from_provider_vrf
```

Configuring the Receiver MVRF on the Source PE Router: Example

The following examples show how to configure MVPN extranet routing by specifying the receiver MVRF on the source PE router.

**Note**

You must configure both the source PE router and the receiver PE router.

Configure the Source PE Router Using Route Targets

```conf
interface Loopback5
    ipv4 address 202.5.5.202 255.255.255.255
!
interface GigabitEthernet0/3/0/2
    vrf provider-vrf
    ipv4 address 20.20.20.1 255.255.0.0
!
    vrf provider-vrf
    address-family ipv4 unicast
    import route-target 1100:1
!
    export route-target 1100:1
!
!
    vrf receiver-vrf
    address-family ipv4 unicast
    import route-target 1100:1
```
1101:1
!
export route-target
1101:1
!

router bgp 1
regular BGP MVPN config
vrf provider-vrf
 rd 1100:1
 address-family ipv4 unicast
 redistribute connected
!
 vrf receiver-vrf
 rd 1101:1
 address-family ipv4 unicast
 redistribute connected
!

 vrf receiver_vrf
 address-family ipv4 unicast
 import route-target
 1100:1
 1101:1
!
Configuring RPL Policies in Receiver VRFs on Source PE Routers to Propagate Joins to a Source VRF: Example

In addition to configuring route targets, RPL policies can be configured in receiver VRFs on a source PE router to propagate joins to a specified source VRF. However, this configuration is optional.

The configuration below shows a policy in which the receiver VRF can select either "provider_vrf_1" or "provider_vrf_2" to propagate PIM joins. Provider_vrf_1 will be selected if the rendezvous point (RP) for a multicast stream is 201.22.22.201, while provider_vrf_2 will be selected if the RP for a multicast stream is 202.22.22.201.

As an alternative, you can configure a multicast group-based policy as shown in the Configuring RPL Policies in Receiver VRFs to Propagate Joins to a Source VRF: Example, on page 157.

```
route-policy extranet_streams_from_provider_rp
  if source in (201.22.22.201) then
    set rpf-topology vrf provider_vrf_1
  else if source in (202.22.22.201) then
    set rpf-topology vrf provider_vrf_2
  else
    pass
  endif
end-policy

Cisco ASR 9000 Series Aggregation Services Router Multicast Configuration Guide, Release 4.2.x
Configuring Multicast Hub and Spoke Topology: Example

These examples describe two ways to configure Multicast Hub and Spoke:

*Figure 13: Example for CE1 PE1 PE3 CE3 Multicast Hub and Spoke Topology*

CE1------------------ PE1 ------------------------------------------------ PE3 ------------------ CE3

CE1, PE1, and PE3 are all on Cisco IOS XR Software, CE3 has Cisco IOS Software in order to configure autorp on VRF interface. For information about configuring the CE router, using Cisco IOS software, see the appropriate Cisco IOS software documentation.

Hub and Spoke Non-Turnaround Configuration: Example

A1-Spoke-3

*No turnaround case with bsr and autorp relay*

```

**Hub and Spoke with Turnaround: Example**

Multicast turnaround mandates a 2-interface connection to the hub site

To configure a CE as a turnaround router, it is connected to its respective PE through two interfaces and each interface is placed in a separate hub site vrf called **hub-x-in vrf** and **hub-x-out vrf**. Hub-x-in vrf carries joins that come from the receiver spoke site through the Hub Tunnel and hub-x-out vrf will carry the same joins.
towards the source spoke site through the Spoke Tunnel without violating the four basic rules below. The source spoke sends traffic to the spoke tunnel to hub-x-out which is turned around to the hub-tunnel on the hub-x-in interface.

1. Hub sites sends traffic only to MDTHub.
2. Spoke sites sends traffic only to MDTspoke.
3. Hub sites receives traffic from both tunnels.
4. Spoke sites receives traffic only from MDTHub.

A2-Spoke-1  A2-Hub-2
A2-Spoke-2  A2-Hub-3in
A2-Hub-2out
A2-Spoke-3 (spoke has auto-rp)

**Figure 14: Example for CE1PE1PE2 CE2 Multicast Hub and Spoke Topology with Turnaround**

CE1------------------ PE1 ------------------------------------------------ PE2 ------------------ CE2

Routes exported by hub sites are imported by hub sites and spoke sites. Routes exported by spoke sites are imported by both hub-x-out and hub-x-in and hub site exports spoke routes back into the core by hub VRF route targets. This causes routes originated from one spoke site to be learned by all other spoke sites but with the nexthop of hub-x-out. For example, Spoke2 will see the RPF for Spoke1 reachable with nexthop of A2-Hub-3in. This is the fundamental difference in leaking of routes which helps in achieving turnaround of multicast traffic.

end-policy

Any CE-PE protocol can be used. In this example, A2-Hub-3out exports all the hub and spoke routes to CE2 through EIGRP.

A2-Hub-3in uses route policy A2-Spoke-family to re-import selected spoke routes into PE2 through BGP.
