Implementing DHCP for IPv6

This module describes how to configure Dynamic Host Configuration Protocol (DHCP) for IPv6.

- DHCPv6 Prefix Delegation, on page 1
- How to Implement DHCP for IPv6, on page 6

DHCPv6 Prefix Delegation

The IPv6 Access Services—DHCPv6 Prefix Delegation feature can be used to manage link, subnet, and site addressing changes. Dynamic Host Configuration Protocol for IPv6 (DHCPv6) can be used in environments to deliver stateful and stateless information, which are defined as follows:

- Stateful prefix delegation—Address assignment is centrally managed and clients must obtain configuration information such as address autoconfiguration and neighbor discovery that is not available through protocols.

- Stateless prefix delegation—Stateless configuration parameters do not require a server to maintain any dynamic state for individual clients, such as Domain Name System (DNS) server addresses and domain search list options.

Extensions to DHCPv6 also enable prefix delegation, through which an ISP can automate the process of assigning prefixes to a customer for use within the customer’s network. The prefix delegation occurs between a provider edge (PE) device and customer premises equipment (CPE) using the DHCPv6 prefix delegation option. Once the ISP has delegated prefixes to a customer, the customer may further subnet and assign prefixes to the links in the customer’s network.

Configuring Nodes Without Prefix Delegation

Stateless DHCPv6 allows DHCPv6 to be used for configuring a node with parameters that do not require a server to maintain any dynamic state for the node. The use of stateless DHCP is controlled by router advertisement (RA) messages multicasted by routers. The Cisco IOS XE DHCPv6 client will invoke stateless DHCPv6 when it receives an RA. The Cisco IOS XE DHCPv6 server will respond to a stateless DHCPv6 request with configuration parameters, such as the DNS servers and domain search list options.
Client and Server Identification

Each DHCPv6 client and server is identified by a DHCP unique identifier (DUID). The DUID is carried in client identifier and server identifier options. The DUID is unique across all DHCP clients and servers, and it is stable for any specific client or server. DHCPv6 uses DUIDs based on link-layer addresses for both the client and server identifier. The device uses the MAC address from the lowest-numbered interface to form the DUID. The network interface is assumed to be permanently attached to the device.

When a DHCPv6 client requests two prefixes with the same DUID but with different identity association identifiers (IAIDs) on two different interfaces, these prefixes are considered to be for two different clients, and the interface information is maintained for both.

Rapid Commit

The DHCPv6 client can obtain configuration parameters from a server either through a rapid two-message exchange (solicit, reply) or through a four-message exchange (solicit, advertise, request, and reply). By default, the four-message exchange is used. When the rapid-commit option is enabled by both the client and the server, the two-message exchange is used.

DHCPv6 Client and Relay Functions

The DHCPv6 client and relay functions are mutually exclusive on an interface. When one of these functions is enabled and a user tries to configure a different function on the same interface, one of the following messages is displayed: “Interface is in DHCP client mode” or “Interface is in DHCP relay mode.”

The following sections describe these functions:

Client Function

The DHCPv6 client function can be enabled on individual IPv6-enabled interfaces.

Note

You need APPX license package to enable the DHCPv6 client function on the device.

The DHCPv6 client can request and accept those configuration parameters that do not require a server to maintain any dynamic state for individual clients, such as DNS server addresses and domain search list options.

The DHCPv6 client can also request the delegation of prefixes. The prefixes acquired from a delegating device will be stored in a local IPv6 general prefix pool. The prefixes in the general prefix pool can then be referred to from other applications; for example, the general prefix pool can be used to number device downstream interfaces.

For IPv6, the details of the default gateway are received from router advertisement (RA) and not from the DHCP server. The details of the default gateway obtained from the DHCP server are not added in the client server. Hence, the following IPv6 commands must be configured on the client interface:

- `ipv6 nd autoconfig prefix`
- “ipv6 nd autoconfig default”
**Server Selection**

A DHCPv6 client builds a list of potential servers by sending a solicit message and by collecting advertise message replies from servers. These messages are ranked based on the preference value, and servers may add a preference option to their advertise messages explicitly stating their preference value. If the client needs to acquire prefixes from servers, only servers that have advertised prefixes are considered.

**IAPD and IAID**

An Identity Association for Prefix Delegation (IAPD) is a collection of prefixes assigned to a requesting device. A requesting device may have more than one IAPD; for example, one for each of its interfaces.

Each IAPD is identified by an IAID. The IAID is chosen by the requesting device and is unique among the IAPD IAIDs on the requesting device. IAIDs are made consistent across reboots by using information from the associated network interface, which is assumed to be permanently attached to the device.

**DHCPv6 Relay Agent**

A DHCPv6 relay agent, which may reside on the client’s link, is used to relay messages between the client and the server. The DHCPv6 relay agent operation is transparent to the client. A DHCPv6 client locates a DHCPv6 server using a reserved, link-scoped multicast address. For direct communication between the DHCPv6 client and the DHCPv6 server, both of them must be attached to the same link. However, in some situations where ease of management, economy, or scalability is a concern, it is desirable to allow a DHCPv6 client to send a message to a DHCPv6 server that is not connected to the same link. IPv6 enable is required for IPv6 DHCP relay, although IPv6 address is configured.

**DHCPv6 Relay Agent Notification for Prefix Delegation**

The DHCPv6 relay agent notification for prefix delegation allows the device working as a DHCPv6 relay agent to find prefix delegation options by reviewing the contents of a DHCPv6 RELAY-REPLY packet that is relayed by the relay agent to the client. When a prefix delegation option is found by the relay agent, the relay agent extracts the information about the prefix that is being delegated and inserts an IPv6 static route matching the prefix delegation information onto the relay agent. Future packets destined to that prefix via relay will be forwarded based on the information contained in the prefix delegation. The IPv6 static route is then left in the routing table until the prefix delegation lease time expires or the relay agent receives a release packet from the client releasing the prefix delegation.

No user configuration is required for this feature. Static route management is done automatically by the relay agent.

IPv6 routes are added when the relay agent relays a RELAY-REPLY packet, and IPv6 routes are deleted when the prefix delegation lease time expires or the relay agent receives a release message. An IPv6 static route in the routing table of the relay agent can be updated when the prefix delegation lease time is extended.

The DHCP—DHCPv6 Relay Agent Notification for Prefix Delegation feature leaves a static IPv6 route on the routing table of the relay agent. The registered IPv6 address allows unicast reverse packet forwarding (uRPF) to work by allowing the device doing the reverse lookup to confirm that the IPv6 address on the relay agent is not malformed or spoofed. The static route that remains in the routing table of the relay agent can be redistributed to other routing protocols to advertise the subnets to other nodes. Static routes will be removed when a DHCP_DECLINE message is sent by the client.

**DHCPv6 Relay Options: Remote-ID for Gigabit Ethernet and Fast Ethernet Interfaces**

The DHCPv6 Ethernet Remote ID Option feature adds the remote identification (remote-ID) option to relayed (RELAY-FORWARD) DHCPv6 packets.
The remote-ID option provides information to the DHCPv6 server, which includes port information, the system’s DUID, and the VLAN ID. This information can be used to uniquely identify both the relay and the port on the relay through which the client packet arrived. The DHCPv6 server uses this information to select parameters specific to a particular user, host, or subscriber modem.

The addition of the remote-ID option to the RELAY-FORWARD packet occurs automatically and no user configuration is necessary.

The DHCPv6 server does not need to echo the remote-ID option in the RELAY-REPLY packet. The Internet Assigned Numbers Authority (IANA) has assigned the DHCPv6 option code 37 for the relay agent remote-ID option.

If the remote-ID option is included in the RELAY-REPLY packet, the option is removed from the packet before it is relayed to the client.

**DHCPv6 Relay Options: Reload Persistent Interface ID**

The DHCPv6 Relay—Reload Persistent Interface ID Option feature makes the interface ID option persistent. The interface ID is used by relay agents to decide which interface should be used to forward a RELAY-REPLY packet. A persistent interface-ID option will not change if the device acting as a relay agent goes offline during a reload or a power outage. When the device acting as a relay agent returns online, it is possible that changes to the internal interface index of the relay agent may have occurred in certain scenarios (such as, when the relay agent reboots and the number of interfaces in the interface index changes, or when the relay agents boot up and have more virtual interfaces than it did before the reboot). This feature prevents such scenarios from causing any problems.

This feature changes the DHCPv6 interface-ID option to be expressed as the short form of the interface name. The interface name as the DHCPv6 interface ID helps avoid potential problems that could arise due to physical or logical interfaces changing on the relay agent after a reload.

**DHCPv6 Relay Chaining**

DHCPv6 messages can be relayed through multiple relay agents. This configuration is called *relay chaining*. A relay chaining configuration can be supported only when each relay agent adds information to DHCPv6 messages before relaying them. The information helps in relaying the DHCPv6 reply back to the DHCPv6 client through the same path.

The delegated IPv6 prefix must be routable in order to be useful. The actual DHCPv6 Prefix Delegation (PD) client may not be permitted to inject routes into the delegating network. In service provider (SP) networks, for example, an edge device typically acts as a DHCPv6 relay agent, and this edge device often has the responsibility to maintain routes within the SP network for clients’ PD bindings. In the event that DHCPv6 requests and responses are relayed through a chain of DHCPv6 relays, there may be a need to introduce appropriate routes (particularly with DHCPv6 PD) in the Forwarding Information Base (FIB) so that routing is handled transparently.

**DHCPv6 Relay SSO and ISSU**

In specific Cisco networking devices that support dual route processors (RPs), stateful switchover (SSO) takes advantage of RP redundancy to increase network availability. The feature establishes one of the RPs as the active processor while the other RP is designated as the standby processor, and then synchronizing critical state information between them. Following an initial synchronization between the two processors, SSO dynamically maintains RP state information between them.

The Cisco IOS XE In Service Software Upgrade (ISSU) process allows the Cisco IOS XE software to be updated or otherwise modified while packet forwarding continues. In most networks, planned software upgrades
are a significant cause of downtime. The ISSU allows the Cisco IOS XE software to be modified while packet forwarding continues. This increases network availability and reduces downtime caused by planned software upgrades.

The SSO and the ISSU use redundant hardware, with the active and standby RP each running an instance of the DHCPv6 relay agent. Both instances exchange run-time state data.

For further information about the SSO and the ISSU, see the “Stateful Switchover” and the “Cisco IOS XE In Service Software Upgrade” modules respectively, in the Cisco IOS High Availability Configuration Guide.

**DHCPv6 Relay Options: Remote-ID for Ethernet Interfaces**

This feature adds the remote identification (remote-ID) option to relayed (RELAY-FORWARD) DHCPv6 packets.

The remote-ID option provides information to the DHCPv6 server, including port information, the system’s DUID, and the VLAN ID. Collectively, this information can be used to uniquely identify both the relay and the port on the relay through which the client’s packet arrived. The DHCPv6 server uses this information to select parameters specific to a particular user, host, or subscriber modem. This feature works only for Ethernet interfaces at this time.

This feature introduces no user configuration. Because the addition of the remote-ID option to the RELAY-FORWARD packet occurs automatically, no user configuration is necessary.

The DHCPv6 server does not need to echo the remote-ID option in the RELAY-REPLY packet. Internet Assigned Numbers Authority (IANA) has assigned the DHCPv6 option code 37 for the relay agent remote-ID option.

If the remote-ID option is included in the RELAY-REPLY packet, the option is stripped out of the packet before the packet is relayed to the client.

**DHCPv6 Relay Options: Reload Persistent Interface-ID**

This feature makes the interface-ID option, which is used by relay agents to decide which interface should be used when forwarding a RELAY-REPLY packet, persistent. A persistent interface-ID option will not change if the router acting as a relay agent goes offline (such as during a reload or a power outage). When the router acting as a relay agent returns online, it is possible that changes to the internal interface index of the relay agent may have occurred in certain scenarios (such as cases where the relay agent reboots and has a change in the number of interfaces in the interface index, or the relay agents boots up and has more virtual interfaces than it did before the reboot). This feature prevents this scenario from causing any problems.

This feature changes the DHCPv6 interface-ID option to be expressed as simply the short form of the interface name. This syntax helps avoid potential problems that could arise due to physical or logical interfaces changing on the relay agent after a reload.
How to Implement DHCP for IPv6

Configuring the DHCPv6 Server Function

Configuring the DHCPv6 Configuration Pool

SUMMARY STEPS

1. enable
2. configure terminal
3. ipv6 dhcp pool poolname
4. domain-name domain
5. dns-server ipv6-address
6. prefix-delegation ipv6-prefix / prefix-length client-duid [iaid iauid] [lifetime]
7. prefix-delegation pool poolname [lifetime valid-lifetime preferred-lifetime]
8. exit
9. interface type number
10. ipv6 dhcp server poolname [rapid-commit] [preference value] [allow-hint]
11. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>

Configuring a Binding Database Agent for the Server Function

SUMMARY STEPS

1. enable
2. configure terminal
3. ipv6 dhcp database agent [write-delay seconds] [timeout seconds]
4. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

**Step 3**

- ipv6 dhcp database *agent [write-delay seconds] [timeout seconds]*

**Example:**

```
Device(config)# ipv6 dhcp database
tftp://10.0.0.1/dhcp-binding
```

**Purpose**

Specifies DHCPv6 binding database agent parameters.

- **agent-URL**—flash, NVRAM, FTP, TFTP, or RCP uniform resource locator.
- **write-delay**—specifies how often DHCP sends database updates. By default, DHCPv6 server waits 300 seconds before transmitting database changes. The minimum delay is 60 seconds.
- **timeout**—specifies the time to wait for a database transfer. Infinity is defined as zero seconds. Transfers that exceed the timeout period are aborted. Default value is 300 seconds.

**Step 4**

- `end`

**Example:**

```
Device(config)# end
```

Returns to privileged EXEC mode.

---

## Configuring the DHCPv6 Client Function

General prefixes can be defined dynamically from a prefix received by a DHCPv6 prefix delegation client. The delegated prefix is stored in a general prefix.

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ipv6 dhcp client pd {prefix-name | hint ipv6-prefix} [rapid-commit]`
5. `ipv6 nd autoconfig prefix`
6. `ipv6 nd autoconfig default-router`
7. `end`

### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td><code>Device&gt; enable</code></td>
<td>- Enter your password if prompted.</td>
</tr>
</tbody>
</table>

| **Step 2** configure terminal | Enters global configuration mode. |
| **Example:** | |

### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device# configure terminal</td>
<td>Specifies an interface type and number, and enters interface configuration mode.</td>
</tr>
<tr>
<td><strong>Step 3</strong> interface type number</td>
<td>Enables the DHCPv6 client process and enables a request for prefix delegation through a specified interface. <strong>Note</strong> The <code>ipv6 dhcp client pd hint</code> command should always be used along with the <code>ipv6 dhcp client pd pd-name</code> command.</td>
</tr>
<tr>
<td>Example: Device(config)# interface fastethernet 0/0/0</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> ipv6 dhcp client pd {prefix-name</td>
<td>hint ipv6-prefix} [rapid-commit]</td>
</tr>
<tr>
<td>Example: Device(config-if)# ipv6 dhcp client pd dhcp-prefix</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> ipv6 nd autoconfig prefix</td>
<td>Allows Neighbor Discovery to install a default route to the Neighbor Discovery-derived default router.</td>
</tr>
<tr>
<td>Example: Device(config-if)# ipv6 nd autoconfig prefix</td>
<td></td>
</tr>
<tr>
<td><strong>Step 6</strong> ipv6 nd autoconfig default-router</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config-if)# ipv6 nd autoconfig default-router</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> end</td>
<td></td>
</tr>
<tr>
<td>Example: Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>

*Example*

The following example depicts the usage of `ipv6 dhcp client pd hint` command along with the `ipv6 dhcp client pd pd-name` command.

```
interface GigabitEthernet0/10
no ip address
media-type auto-select
negotiation auto
ipv6 address prefix-from-provider ::1/48
ipv6 enable
ipv6 dhcp client pd hint 2001:DB8:43:/48
ipv6 dhcp client pd prefix-from-provider
```

### Configuring the DHCPv6 Relay Agent

**SUMMARY STEPS**

1. enable
2. `configure terminal`
3. `interface type number`
4. `ipv6 enable`
5. `ipv6 dhcp relay destination ipv6-address [interface-type interface-number]`
6. `end`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | `enable` | Enables privileged EXEC mode.  
| | **Example:** |  
| | Device> enable | • Enter your password if prompted. |
| **Step 2** | `configure terminal` | Enters global configuration mode. |
| | **Example:** |  
| | Device# configure terminal | |
| **Step 3** | `interface type number` | Specifies an interface type and number, and enters interface configuration mode. |
| | **Example:** |  
| | Device(config)# interface gigabitethernet 4/2/0 | |
| **Step 4** | `ipv6 enable` | Enables IPv6 processing on an interface. |
| | **Example:** |  
| | Device(config-if)# ipv6 enable | |
| **Step 5** | `ipv6 dhcp relay destination ipv6-address [interface-type interface-number]` | Specifies a destination address to which client packets are forwarded and enables the DHCPv6 relay service on the interface. |
| | **Example:** |  
| | Device(config-if) ipv6 dhcp relay destination FE80::250:A2FF:FEBF:A056 gigabitethernet 4/3/0 | |
| **Step 6** | `end` | Returns to privileged EXEC mode. |
| | **Example:** |  
| | Device(config-if)# end | |

**Configuring Route Addition for Relay and Server**

To enable route addition by DHCPv6 relay and server for the delegated prefix, use the `ipv6 dhcp iapd-route-add` command in global configuration mode.
DHCPv6 relay inserts a route for the delegated prefix without additional configuration (i.e., the default is `ipv6 dhcp iapd-route-add`), which of course isn’t NVGEN’ed. If you want to disable this insertion, you must configure `no ipv6 dhcp iapd-route-add`.

The relay tracks valid and preferred lifetimes for the delegated prefix. When the prefix reaches the end of the valid lifetime, the route is automatically removed from the routing table.

To add routes for individually assigned IPv6 addresses on the relay or server, use the `ipv6 dhcp iana-route-add` command in global configuration mode.

### Defining a General Prefix with the DHCPv6 Prefix Delegation Client Function

Perform this task to configure the DHCPv6 client function on an interface and enable prefix delegation on an interface. The delegated prefix is stored in a general prefix.

#### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `ipv6 dhcp client pd {prefix-name | hint ipv6-prefix} [rapid-commit]`

### Purpose

Command or Action | Purpose
--- | ---
Device# debug ipv6 dhcp relay | Enables DHCPv6 redundancy debugging.

#### Step 5

**debug ipv6 dhcp redundancy [detail]**

**Example:**
Device# debug ipv6 dhcp redundancy

### Verifying the DHCPv6 Configuration

#### SUMMARY STEPS
1. **enable**
2. **show ipv6 dhcp**
3. **show ipv6 dhcp binding [ipv6-address]**
4. **show ipv6 dhcp database [agent-URL]**
5. **show ipv6 dhcp interface [type number]**
6. **show ipv6 dhcp pool [poolname]**
7. **show running-config**

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 1** | enable  
**Example:**  
Device# enable |
| Enables privileged EXEC mode.  
* Enter your password if prompted. |
| **Step 2** | show ipv6 dhcp  
**Example:**  
Device# show ipv6 dhcp |
| Displays the DUID on a specified device. |
| **Step 3** | show ipv6 dhcp binding [ipv6-address]  
**Example:**  
Device# show ipv6 dhcp binding |
| Displays automatic client bindings from the DHCPv6 database. |
| **Step 4** | show ipv6 dhcp database [agent-URL]  
**Example:**  
Device# show ipv6 dhcp database |
| Displays the DHCPv6 binding database agent information. |
| **Step 5** | show ipv6 dhcp interface [type number]  
**Example:**  
Device# show ipv6 dhcp interface |
| Displays DHCPv6 interface information. |
| **Step 6** | show ipv6 dhcp pool [poolname]  
**Example:**  
Device# show ipv6 dhcp pool |
| Displays DHCPv6 configuration pool information. |
### Example Verifying the DHCPv6 Configuration

#### Sample Output from the show ipv6 dhcp Command

The following sample output from the `show ipv6 dhcp` command displays the DUID of the device:

```
Device# show ipv6 dhcp
This device's DHCPv6 unique identifier (DUID): 000300010002FCA5DC1C
```

#### Sample Output from the show ipv6 dhcp binding Command

In the following sample output, the `show ipv6 dhcp binding` command displays information about two clients, including their DUIDs, IAPDs, prefixes, and preferred and valid lifetimes:

```
Device# show ipv6 dhcp binding
Client: FE80::202:FCFF:FEA5:DC39 (GigabitEthernet2/1/0)
  DUID: 000300010002FCA5DC1C
  IA PD: IA ID 0x00040001, T1 0, T2 0
  Prefix: 3FFE:C00:C18:1::/68
  preferred lifetime 180, valid lifetime 12345
  expires at Nov 08 2002 02:24 PM (12320 seconds)
Client: FE80::202:FCFF:FEA5:CO39 (GigabitEthernet2/1/0)
  DUID: 000300010002FCA5CO1C
  IA PD: IA ID 0x00040001, T1 0, T2 0
  Prefix: 3FFE:C00:C18:1::/72
  preferred lifetime 180, valid lifetime 12345
  expires at Nov 08 2002 02:24 AM (12320 seconds)
```

#### Sample Output from the show ipv6 dhcp database Command

The following sample output from the `show ipv6 dhcp database` command shows information on the binding database agents TFTP, NVRAM, and flash:

```
Device# show ipv6 dhcp database
Database agent tftp://172.19.216.133/db.tftp:
  write delay: 69 seconds, transfer timeout: 300 seconds
  last written at Jan 09 2003 01:54 PM,
  write timer expires in 56 seconds
  last read at Jan 06 2003 05:41 PM
  successful read times 1
  failed read times 0
  successful write times 3172
  failed write times 2
Database agent nvram:/dhcpv6-binding:
  write delay: 60 seconds, transfer timeout: 300 seconds
```
Sample Output from the show ipv6 dhcp interface Command

The following is sample output from the `show ipv6 dhcp interface` command. In the first example, the command is used on a device that has an interface acting as a DHCPv6 server. In the second example, the command is used on a router that has an interface acting as a DHCPv6 client:

Device# show ipv6 dhcp interface
GigabitEthernet2/1/0 is in server mode
Using pool: svr-p1
Preference value: 20
Rapid-Commit is disabled
Router2# show ipv6 dhcp interface
GigabitEthernet2/1/0 is in client mode
State is OPEN (1)
List of known servers:
Address: FE80::202:FCFF:FEA1:7439, DUID 000300010002FCA17400
Preference: 20
IA PD: IA ID 0x00040001, T1 120, T2 192
Prefix: 3FFE:C00:C18:1::/72
preferred lifetime 240, valid lifetime 54321
expires at Nov 08 2002 09:10 AM (54319 seconds)
Prefix: 3FFE:C00:C18:2::/72
preferred lifetime 300, valid lifetime 54333
expires at Nov 08 2002 09:11 AM (54331 seconds)
Prefix: 3FFE:C00:C18:3::/72
preferred lifetime 280, valid lifetime 51111
expires at Nov 08 2002 08:17 AM (51109 seconds)
DNS server: 2001:DB8:1001::1
DNS server: 2001:DB8:1001::2
Domain name: example1.net
Domain name: example2.net
Domain name: example3.net
Prefix name is cli-p1
Rapid-Commit is enabled

Sample Output from the show ipv6 dhcp pool Command

In the following sample output, the `show ipv6 dhcp pool` command displays information about the configuration pool named svr-p1, including static bindings, prefix information, the DNS server, and the domain names found in the svr-p1 pool:

Device# show ipv6 dhcp pool
DHCPv6 pool: svr-p1
Static bindings:
Configuration Examples for Implementing DHCPv6

Example: Configuring the DHCPv6 Client Function

In the following example, this Dynamic Host Configuration Protocol for IPv6 (DHCPv6) client has three interfaces. Ethernet interface 0/0 is the upstream link to a service provider, which has a DHCPv6 server function enabled. The Fast Ethernet interfaces 0/0 and 0/1 are links to local networks.

The upstream interface, Ethernet interface 0/0, has the DHCPv6 client function enabled. Prefixes delegated by the provider are stored in the general prefix called prefix-from-provider.

The local networks, Fast Ethernet interfaces 0/0 and 0/1, both assign interface addresses based on the general prefix called prefix-from-provider. The bits on the left of the addresses come from the general prefix, and the bits on the right of the addresses are specified statically.

```plaintext
interface Ethernet 0/0
description uplink to provider DHCP IPv6 server
ipv6 dhcp client pd prefix-from-provider
!
interface FastEthernet 0/0
description local network 0
ipv6 address prefix-from-provider ::5:0:0:0:100/64
!
interface FastEthernet 0/1
```
Example: Configuring the DHCPv6 Client Function

description local network 1
ipv6 address prefix-from-provider ::6:0:0:0:100/64
