Revision History

Table 2: Revision History

Revision Details	Release
Enhancement introduced to session accounting and failure management with AAA profiles.	2025.01.0
Introduced support to balance transaction load on the RADIUS server based on least outstanding transactions.	2024.03.0

Revision Details	Release
Introduced Asynchronous mode for sending RADIUS Accounting messages.	2024.03.0
Introduced support for different interim intervals for service and session accounting.	2024.02.0
Introduced a conditional approach to Change of Authorization (CoA) retries based on the Error-Cause AVPs.	2024.02.0
Support is added for IPv6 transport between cnBNG and RADIUS AAA server, and also between cnBNG endpoint and CoA client.	2024.01.0
The RADIUS Automated Testing feature is introduced.	2024.01.0
The user-plane-ip keyword is added to the nas-ip attribute under radius accounting , and radius attribute configurations.	2023.04.0
First introduced.	2021.01.0

Feature Description

Note: All references to BNG in this chapter refer to the Cloud-Native Broadband Network Gateway (cnBNG).

This chapter provides information about configuring authentication, authorization, and accounting (AAA) functions on the BNG. BNG interacts with the RADIUS server to perform AAA functions. A group of RADIUS servers form a server group that is assigned specific AAA tasks. A method list defined on a server or server group lists methods by which authorization is performed. Some of the RADIUS features include creating specific AAA attribute formats, load balancing of RADIUS servers, throttling of RADIUS records, Change of Authorization (CoA), Session Accounting, and Service Accounting for QoS.

AAA Overview

AAA acts as a framework for effective network management and security. It helps in managing network resources, enforcing policies, auditing network usage, and providing bill-related information. BNG connects to an external RADIUS server that provides the AAA functions.

The RADIUS server performs the three independent security functions (authentication, authorization, and accounting) to secure networks against unauthorized access. The RADIUS server runs the Remote Authentication Dial-In User Service (RADIUS) protocol. (For details about RADIUS protocol, refer to RFC 2865). The RADIUS server manages the AAA process by interacting with BNG, and databases and directories containing user information.

The RADIUS protocol runs on a distributed client-server system. The RADIUS client runs on BNG (Cisco ASR 9000 Series Router) that sends authentication requests to a central RADIUS server. The RADIUS server contains all user authentication and network service access information.

The AAA processes, the role of RADIUS server during these processes, and some BNG restrictions, are explained in these sections:

Authentication

The authentication process identifies a subscriber on the network, before granting access to the network and network services. The process of authentication works on a unique set of criteria that each subscriber has for gaining access to the network. Typically, the RADIUS server performs authentication by matching the credentials (user name and password) the subscriber enters with those present in the database for that subscriber. If the credentials match, the subscriber is granted access to the network. Otherwise, the authentication process fails, and network access is denied.

Authorization

After the authentication process, the subscriber is authorized for performing certain activity. Authorization is the process that determines what type of activities, resources, or services a subscriber is permitted to use. For example, after logging into the network, the subscriber may try to access a database, or a restricted website. The authorization process determines whether the subscriber has the authority to access these network resources.

AAA authorization works by assembling a set of attributes based on the authentication credentials provided by the subscriber. The RADIUS server compares these attributes, for a given username, with information contained in a database. The result is returned to BNG to determine the actual capabilities and restrictions that are to be applied for that subscriber.

Accounting

The accounting keeps track of resources used by the subscriber during network access. Accounting is used for billing, trend analysis, tracking resource utilization, and capacity planning activities. During the accounting process, a log is maintained for network usage statistics. The information monitored include, but are not limited to - subscriber identities, applied configurations on the subscriber, the start and stop times of network connections, and the number of packets and bytes transferred to, and from, the network.

BNG reports subscriber activity to the RADIUS server in the form of accounting records. Each accounting record comprises of an accounting attribute value. This value is analyzed and used by the RADIUS server for network management, client billing, auditing, etc.

The accounting records of the subscriber sessions may timeout if the BNG does not receive acknowledgments from the RADIUS server. This timeout can be due to RADIUS server being unreachable or due to network connectivity issues leading to slow performance of the RADIUS server. It is therefore recommended that a RADIUS server **deadtime** be configured on the BNG, to avoid loss of sessions. Once this value is configured, and if a particular session is not receiving an accounting response even after retries, then that particular RADIUS server is considered to be non-working and further requests are not sent to that server.

Restrictions

- On BNG, local authentication and local authorization are not supported. It must be done by the RADIUS server.
- On session disconnect, transmission of the Accounting-Stop request to RADIUS may be delayed for a few seconds while the system waits for the "final" session statistics to be collected from the hardware. The Event-Timestamp attribute in that Accounting-Stop request should, however, reflect the time the client disconnects, and not the transmission time.
- RADIUS over IPv6 is not supported.

Using RADIUS Server Group

A RADIUS server group is a named group of one or more RADIUS servers. Each server group is used for a particular service. For example, in an AAA network configuration having two RADIUS server groups, the first server group can be assigned the authentication and authorization task, while the second group can be assigned the accounting task.

Server groups can include multiple host entries for the same server. Each entry, however, must have a unique identifier. This unique identifier is created by combining an IP address and a UDP port number. Different ports of the server, therefore, can be separately defined as individual RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on the same server. Further, if two different host entries on the same RADIUS server are configured for the same service (like the authentication process), then the second host entry acts as a fail-over backup for the first one. That is, if the first host entry fails to provide authentication services, BNG tries with the second host entry. (The RADIUS host entries are tried in the order in which they are created.)

For assigning specific actions to the server group, see [Configuring RADIUS Server Group, on page 33](#).

Specifying Method Order

Method order for AAA defines the methods using which authorization is performed, and the sequence in which these methods are executed. Before any defined authentication method is performed, the method order must be applied to the configuration mechanism responsible for validating user-access credentials.

On BNG, you have to specify the method order and the server group that will be used for AAA services. For specifying method order, see [Configuring Method Order for AAA, on page 25](#).

Defining AAA Attributes

The AAA attribute is an element of RADIUS packet. A RADIUS packet transfers data between a RADIUS server and a RADIUS client. The AAA attribute parameter, and its value - form a Attribute Value Pair (AVP). The AVP carries data for both requests and responses for the AAA transaction.

The AAA attributes either can be predefined as in Internet Engineering Task Force (IETF) attributes or vendor defined as in vendor-specific attributes (VSAs). For more information about the list of BNG supported attributes, see [RADIUS Attributes](#).

The RADIUS server provides configuration updates to BNG in the form of attributes in RADIUS messages. The configuration updates can be applied on a subscriber during session setup through two typical methods—per-user attributes, which applies configuration on a subscriber as part of the subscriber's authentication Access Accept, or through explicit domain, port, or service authorization Access Accepts. This is all controlled by the Policy Rule Engine's configuration on the subscriber.

When BNG sends an authentication or an authorization request to an external RADIUS server as an Access Request, the server sends back configuration updates to BNG as part of the Access Accept. In addition to RADIUS configuring a subscriber during setup, the server can send a change of authorization (CoA) message autonomously to the BNG during the subscriber's active session life cycle, even when the BNG did not send a request. These RADIUS CoA updates act as dynamic updates, referencing configured elements in the BNG and instructing the BNG to update a particular control policy or service policy.

BNG supports the concept of a "service", which is a group of configured features acting together to represent that service. Services can be represented as either features configured on dynamic-templates through CLI, or as features configured as RADIUS attributes inside Radius Servers. Services are activated either directly from

CLI or RADIUS through configured "activate" actions on the Policy Rule Engine, or through CoA "activate-service" requests. Services can also be deactivated directly (removing all the involved features within the named service) through configured "deactivate" action on the Policy Rule Engine or through CoA "deactivate-service" requests.

The attribute values received from RADIUS interact with the subscriber session in this way:

- BNG merges the values received in the RADIUS update with the existing values that were provisioned statically by means of CLI commands, or from prior RADIUS updates.
- In all cases, values received in a RADIUS update take precedence over any corresponding CLI provisioned values or prior RADIUS updates. Even if you reconfigured the CLI provisioned values, the system does not override session attributes or features that were received in a RADIUS update.
- Changes made to CLI provision values on the dynamic template take effect immediately on all sessions using that template, assuming the template features have not already been overridden by RADIUS. Same applies to service updates made through CoA "service-update" requests.

AAA Attribute List

An attribute list is named list that contains a set of attributes. You can configure the RADIUS server to use a particular attribute list to perform the AAA function.

To create an attribute list, see [Configuring RADIUS Attributes, on page 29](#).

AAA Attribute Format

It is possible to define a customized format for some attributes. For the configuration syntax for creating a new format, see [Configuring AAA Attributes, on page 23](#).

Once the format is defined, the FORMAT-NAME can be applied to various AAA attributes such as username, nas-port-ID, calling-station-ID, and called-station-ID. The configurable AAA attributes that use the format capability are explained in the section [Creating Attributes of Specific Format, on page 5](#).

To create a customized nas-port attribute and apply a predefined format to nas-port-ID attribute, see [Configuring RADIUS Attribute Format, on page 30](#).

Specific functions can be defined for an attribute format for specific purposes. For example, if the input username is "text@abc.com", and only the portion after "@" is required as the username, a function can be defined to retain only the portion after "@" as the username. Then, "text" is dropped from the input, and the new username is "abc.com". To apply username truncation function to a named-attribute format, see [Configuring AAA Attributes, on page 23](#).

Creating Attributes of Specific Format

BNG supports the use of configurable AAA attributes. The configurable AAA attributes have specific user-defined formats. The following sections list some of the configurable AAA attributes used by BNG.

Username

BNG has the ability to construct AAA username and other format-supported attributes for subscribers using MAC address, circuit-ID, remote-ID, and DHCP Option-60 (and a larger set of values available in CLI). The DHCP option-60 is one of the newer options that is communicated by the DHCP client to the DHCP server in its requests; it carries Vendor Class Identifier (VCI) of the DHCP client's hardware.

The MAC address attribute is specified in the CLI format in either of these forms:

- mac-address: for example, 0000.4096.3e4a
- mac-address-ietf: for example, 00-00-40-96-3E-4A
- mac-address-raw: for example, 000040963e4a
- mac-address-custom1: for example, 01.23.45.67.89.AB

(This particular MAC address format is available only from Release 6.2.1 and later).

NAS-Port-ID

The NAS-Port-ID is constructed by combining BNG port information and access-node information. The BNG port information consists of a string in this form:

```
"eth phy_slot/phy_subslot/phy_port:XPI.XCI"
```

For 802.1Q tunneling (QinQ), XPI is the outer VLAN tag and XCI is the inner VLAN tag.

If the interface is QinQ, the default format of nas-port-ID includes both the VLAN tags; if the interface is single tag, it includes a single VLAN tag.

In the case of a single VLAN, only the outer VLAN is configured, using this syntax:

```
<slot>/<subslot>/<port>/<outer_vlan>
```

In the case of QinQ, the VLAN is configured using this syntax:

```
<slot>/<subslot>/<port>/<inner_vlan>.<outer_vlan>
```

In the case of a bundle-interface, the phy_slot and the phy_subslot are set to zero (0); whereas the phy_port number is the bundle number. For example, 0/0/10/30 is the NAS-Port-ID for a Bundle-Ether10.41 with an outer VLAN value 30.

The nas-port-ID command is extended to use the 'nas-port-type' option so that the customized format (configured with the command shown above) can be used on a specific interface type (nas-port-type).

If 'type' option is not specified, then the nas-port-ID for all interface types is constructed according to the format name specified in the command.

Calling-Station-ID and Called-Station-ID

BNG supports the use of configurable calling-station-ID and called-station-ID. The calling-station-ID is a RADIUS attribute that uses Automatic Number Identification (ANI), or similar technology. It allows the network access server (NAS) to send to the Access-Request packet, the phone number from which the call came from. The called-station-ID is a RADIUS attribute that uses Dialed Number Identification (DNIS), or similar technology. It allows the NAS to send to the Access-Request packet, the phone number that the user called from.

Making RADIUS Server Settings

In order to make BNG interact with the RADIUS server, certain server specific settings must be made on the BNG router.

For more making RADIUS server settings, see [Configuring RADIUS Server, on page 32](#).

Restriction

The service profile push or asynchronously pushing a profile to the system is not supported. To download a profile from Radius, the profile must be requested initially as part of the subscriber request. Only service-update is supported and can be used to change a service that was previously downloaded.

Balancing Transaction Load on the RADIUS Server

Table 3: Feature History

Feature Name	Release Information	Description
Balancing Transaction Load on the RADIUS Server	2024.03.0	This feature enhances performance by distributing AAA messages across servers, ensuring faster response times. It selects the RADIUS server with the fewest outstanding transactions, rather than using the previous First server or Round Robin methods, which did not account for server load. This results in a more efficient handling of authentication, authorization, and accounting tasks.

The Balancing Transaction Load on the RADIUS Server feature provides a mechanism to share the load of RADIUS access and accounting transactions, across a set of RADIUS servers. Each AAA request processing is considered to be a transaction. cnBNG distributes batches of transactions to servers within a server group.

When the first transaction for a new batch is received, cnBNG determines the server with the lowest number of outstanding transactions in its queue. This server is assigned that batch of transactions. cnBNG keeps repeating this determination process to ensure that the server with the least-outstanding transactions always gets a new batch. This method is known as the least-outstanding method of load balancing.

The size of each batch is configurable. Changes in the batch size may impact the CPU load and network throughput. There is no standard size for batches, but generally, more than 50 transactions is considered large, and fewer than 25 is considered small.

Retransmitted messages go to the same server. The number of outstanding RADIUS messages is tracked per server at the pod level. Load balancing applies to the named RADIUS server groups or a global server group specified in the subscriber profile. In AAA method lists, this group must be referred to as "radius." All servers in the RADIUS group are subject to load balancing.

RADIUS Server Status and Automated Testing

The Balancing Transaction Load on the RADIUS Server feature checks the status of servers before sending transaction batches. Only live servers receive transaction batches.

Transactions are not sent to servers marked as dead. A server remains marked as dead until its timer expires. The server is included again only when the RADIUS automated tester verifies it as alive. Otherwise, the server is excluded from the selection algorithm.

The RADIUS automated tester periodically sends a request to the server. If the server returns an **Access-Reject** message, it is alive. If not, it remains marked as dead until detected as alive.

If a server is unresponsive, it is marked as dead, and transactions fail over to the next available server.

When using the RADIUS automated tester, verify that the authentication, authorization, and accounting (AAA) servers respond to test packets sent by the network access server (NAS). Incorrect configurations may cause packet drops and servers to be erroneously marked as dead.

For configuring the load balancing on the RADIUS server, see [Configuring RADIUS Server Selection Logic, on page 33](#).

RADIUS Change of Authorization Overview

The RADIUS Change of Authorization (CoA) function allows the RADIUS server to change the authorization settings for a subscriber who is already authorized. CoA is an extension to the RADIUS standard that allows sending asynchronous messages from RADIUS servers to a RADIUS client, like BNG.

Note A CoA server can be a different from the RADIUS server.

To identify the subscriber whose configuration needs to be changed, a RADIUS CoA server supports and uses a variety of keys (RADIUS attributes) such as Accounting-Session-ID, Username, IP-Address, and ipv4:vrf-id.

The RADIUS CoA supports:

- account-update — BNG parses and applies the attributes received as part of the CoA profile. Only subscriber-specific attributes are supported and applied on the user profile.
- activate-service — BNG starts a predefined service on a subscriber. The service settings can either be defined locally by a dynamic template, or downloaded from the RADIUS server.
- deactivate-service — BNG stops a previously started service on the subscriber, which is equivalent to deactivating a dynamic-template.

For a list of supported Vendor-Specific Attributes for account operations, see [Vendor-Specific Attributes for Account Operations](#).

Note In order for BNG to enable interim accounting, it is mandatory for the CoA request to have both accounting method list from the dynamic-template and Acct-Interim-Interval attribute from the user profile. This behavior is applicable for accounting enabled through dynamic-template.

Service Update from CoA

The service update feature allows an existing service-profile to be updated with a new RADIUS attribute list representing the updated service. This impacts any subscriber who is already activated with the service and new subscriber who activate the service in the future. The new CoA **service-update** command is used for activating this feature. The CoA request for the service update should have these attributes:

- "subscriber:command=service-update" Cisco VSA
- "subscriber:service-name=<service name>" Cisco VSA
- Other attributes that are part of the service profile

A service update CoA should have a minimum of these attributes:

- vsa cisco generic 1 string "subscriber:command=service-update"
- vsa cisco generic 1 string "subscriber:service-name=<service name>"

Web Logon with RADIUS Based CoA

To support Web Logon, a set of Policy Rule Events need to be configured in an ordered manner. These events are as follows:

- session-start:
 - On the start of a session, a subscriber is setup to get internet connectivity. The service is activated to redirect HTTP traffic to a Web portal for web-based logon.
 - Start the timer with duration for the maximum waiting period for authentication.
- account-logon—The Web portal collects the user credentials such as username and password and triggers a CoA account-logon command. When this event is triggered, subscriber username and password are authenticated by the RADIUS server. Once the authentication is successful, the HTTP redirect service is deactivated, granting user access to already connected internet setup. Also, the timer established in session-start must be stopped. However, if the authentication fails during account-logon, BNG sends a NAK CoA request, allowing for further authentication attempts to take place.
- timer expiry—When the timer expires, the subscriber session is disconnected based on the configuration.

Enhanced CoA with Conditional Retry Logic

Table 4: Feature History

Feature Name	Release Information	Description
Enhanced CoA with Conditional Retry Logic	2024.02.0	We have introduced a conditional approach to Change of Authorization (CoA) retries based on the Error-Cause AVPs carried in CoA response messages. The CoA client uses the error cause reason and determines whether to initiate a CoA retry. This enhancement can reduce unnecessary traffic and processing overhead, resulting in more efficient network operations and better allocation of resources.

If a CoA request is erroneous, the cnBNG rejects it with a CoA Negative Acknowledgment (NAK) response. The CoA client treats all NAK responses equally, and attempts to send CoA requests automatically. This logic of sending unconditional retries for all error types strains network resources, leading to potential performance degradation for both the policy plane and the cn-BNG.

The Enhanced CoA with Conditional Retry Logic feature enables the CoA client to use the error cause carried in a CoA NAK response message and determine whether to send the CoA request again. For example, if the error cause is “503 Session Context Not found,” indicating that the subscriber session is nonexistent or already terminated, the CoA client would recognize that retrying the request would be futile as the cnBNG does not recognize the session context.

By adopting a conditional approach to CoA retries based on the Error-Cause AVPs, the system can avoid unnecessary traffic and processing overhead, resulting in a more efficient network performance.

User Authentication and Authorization in the Local Network

The user authentication and authorization in the local network feature in BNG provides the option to perform subscriber authorization locally (in a subscriber's network), instead of both remote authentication and authorization that occurs in RADIUS servers. With the User Authentication and Authorization in the Local Network feature, you can run the RADIUS server locally in your network, manage, and configure the RADIUS server locally in your network to the profile that is required for the environment. In the case of a remote RADIUS server, the RADIUS server is maintained by an external regulatory body (not within the subscriber's network) and subscriber will not be able to manage or configure the server.

Figure 1: User Authentication and Authorization in the Local Network

User Authentication and Authorization in the Local Network feature is used in a case when a user wants to perform a two-level authentication or authorization, first, a remote authentication (or authorization) followed by a local authorization (or authentication).

Note All the debug commands applicable to AAA server are applicable on User Authentication and Authorization in the Local Network feature.

Service Accounting

Accounting records for each service enabled on a subscriber can be sent to the configured RADIUS server. These records can include service-start, service-stop, and service-interim records containing the current state of the service and any associated counters. This feature is the Service Accounting feature. Service accounting records are consolidated accounting records that represent the collection of features that make up a service as part of a subscriber session.

Service accounting starts when a subscriber session comes up with a service enabled on it. This can happen through a dynamic template applied through a control policy, through access-accept (AA) messages when the session is authorized, or through a change of authorization (CoA), when a new service is applied on a subscriber session. Service accounting stops either when the session is terminated, or a service is removed from the session through CoA, or some other event that deactivates the service. Start records have no counters; interim and stop records with QoS counters are generated when service accounting is enabled for QoS. Interim

accounting records can be generated, in between start and stop accounting, as an option with a pre-defined periodic interval. When the interim period is zero, interim accounting records are not created. Different interim intervals are based on every service for each session. Service accounting is enabled on each template, based on the configuration.

From Release 2024.02.0 onwards, different interim intervals for service and session accounting is supported. We recommend that you set the session interim accounting interval as a multiple of the service interim interval. For example, if the service accounting interim is set to 5 minutes, the session interim accounting interval must be set to a multiple of 5 minutes (such as 5, 10, 15 minutes, and so on).

For more information on service accounting for QoS, refer to [Authentication, Authorization, and Accounting Functions, on page 1](#). For more information on commands to configure service accounting, refer to the [Configuring Service Accounting](#).

For service accounting, statistics for ingress and egress QoS policies, which are applied under each service for a given subscriber, may need to be reported as part of the accounting interim and stop records. For each service, these QoS counters can be reported as part of the accounting records:

- BytesIn — Aggregate of bytes matching all classes of the ingress QoS policy for the service minus the policer drops.
- PacketsIn — Aggregate of packets matching all classes of the ingress QoS policy for the service minus the policer drops.
- BytesOut — Aggregate of bytes matching all classes of the egress QoS policy for the service minus the queuing drops.
- PacketsOut — Aggregate of packets matching all classes of the egress QoS policy for the service minus the queuing drops.

Dynamic template features that support accounting statistic collection and require that their statistics be reported in the AAA service accounting records can enable accounting statistics on their features using the newly-introduced optional **acct-stats** configuration option. This option is not available for the features that do not support statistic collection. By default, QoS accounting statistics are disabled to optimize performance.

Note The QoS counters for each direction is reported only if a QoS policy is applied for that service in the given direction. For example, if a service does not have an ingress policy applied, BytesIn and PacketsIn counters are reported as being 0.

Pre-requisites

- Subscriber accounting, the parent accounting record for service accounting, must be configured to enable the service accounting feature to work.
- The keyword **acct-stats** must be configured in service-policy configuration to enable the service accounting feature to report feature counter information as part of the records.

Restriction

- Service accounting is supported on bundle subscriber interfaces but not on line card subscriber interfaces.
- IPv4 and IPv6 subscriber sessions has a single set of service accounting records. They are merged into one set of bytes_in, bytes_out, packets_in, packets_out counters.

Utilizing Session accounting AAA profiles for Service Accounting and Accounting Send-Stop Setup-Failure

Table 5: Feature History

Feature Name	Release Information	Description
Utilizing Session accounting AAA profiles for Service Accounting and Accounting Send-Stop Setup-Failure	2025.01.0	This feature enhances session accounting by allowing the use of a single AAA profile for both session and service accounting, reducing the need for multiple feature templates. This simplifies the configuration process when connecting to multiple RADIUS servers. Accounting Send-Stop Setup-Failure improves session management by sending an accounting stop record in case of session setup failures, ensuring that the RADIUS server clears stale session entries.

Utilizing Session accounting AAA profiles for Service Accounting

This feature allows you to efficiently manage Authentication, Authorization, and Accounting (AAA) profiles when a Control Plane (CP) is connected to multiple RADIUS servers. Normally, setting up multiple AAA profiles for authorization, session, and service accounting requires an increase in feature templates, which can complicate configuration and management. This feature aims to streamline the process by allowing the use of session accounting AAA profiles for service accounting, thereby reducing the number of necessary feature templates.

Accounting Send-Stop Setup-Failure

The RADIUS server creates a session context when authorization and authentication are successful. If the session fails to establish, a stale session context may remain on the RADIUS server. To clear this, the cnBNG Control Plane sends an accounting stop record in the event of a session setup failure. This stop record is sent if the subscriber profile is configured with the **send-stop** option.

Configure Session Accounting AAA Profiles for Service Accounting

Procedure

Step 1 Configure AAA profiles to be used for service accounting.

Example:

```
config
  profile aaa aaa_name
    authentication
      method-order custom_server_group
    exit
  authorization
    password password
    type subscriber method-order custom_server_group
```

```

    username value value
    password password
    exit
  accounting
    method-order custom_server_group
    exit
  exit

```

Here is a sample configuration for creating AAA profiles named **east-aaaprofile** and **west-aaaprofile**.

```

profile aaa east-aaaprofile
  authentication
    method-order server-group1
  exit
  authorization
    type subscriber method-order server-group1
    username value cnbng
    password cisco
  exit
  accounting
    method-order server-group1
  exit
exit

profile aaa west-aaaprofile
  authentication
    method-order server-group2
  exit
  authorization
    type subscriber method-order server-group2
    username value cnbng
    password cisco
  exit
  accounting
    method-order server-group2
  exit
exit

```

Step 2 Configure session accounting AAA profiles in feature templates.

Example:

Config

```

profile feature-template basetemplate1
  session-accounting
    enable
    aaa-profile east-aaaprofile
    periodic-interval 2000
  exit

profile feature-template basetemplate2
  session-accounting
    enable
    aaa-profile west-aaaprofile
    periodic-interval 2000
  exit

profile feature-template plan-100Mbps
  qos

```

```

    in-policy inpolicy
    out-policy outpolicy
exit
service-accounting
    enable
    aaa-profile use-session-aaaprofile
    periodic-interval 2000
exit
exit

```

According to this sample configuration, subscribers using **basetemplate1** with the **plan-100Mbps** feature template will use **east-aaaprofile** for service accounting. Conversely, subscribers using **basetemplate2** with the **plan-100Mbps** feature template will use **west-aaaprofile** for service accounting.

Configure Accounting Send-Stop Setup-Failure

Procedure

Configure the subscriber profile to enable the sending of accounting stop records upon session bring-up failures.

Example:

```

configure
  profile subscriber subprofile1
    accounting send-stop setup-failure aaa-profile aaa_profile_name
  exit

```

If the AAA_Profile_Name is	then
use-author-profile	the AAA profile configured for authorization is used for sending the accounting stop record in case of session bringup failure. This configuration is used for IPoE sessions.
use-authen-profile	the AAA profile configured for authentication is used for sending the accounting stop record in case of session bringup failure. This configuration is used for PPPoE, LAC or LNS sessions.

This configuration is crucial for managing IPoE sessions, as well as PPPoE, LAC, or LNS sessions, ensuring that session contexts are appropriately cleared from the RADIUS server.

RADIUS Accounting Message Handling

Table 6: Feature History

Feature Name	Release Information	Description
RADIUS Accounting Message Handling	2024.03.0	We have enhanced the system performance by preventing packet identifier (PID) exhaustion with the new Asynchronous mode for sending RADIUS Accounting messages. The cnBNG now releases PIDs after dispatching messages, rather than waiting for a long time to receive server responses. This change allows for PID reuse, mitigating scale issues and improving KPIs.

The cnBNG currently sends RADIUS Accounting messages to servers in synchronous mode. It reserves a packet identifier (PID) for each message. The PID is only released when a response arrives from the server. If the server fails to respond promptly, the cnBNG attempts to resend the message. The PID remains reserved until all timeouts and retransmissions are complete. During periods of high traffic, this can lead to PID exhaustion. As a result, cnBNG may drop new incoming RADIUS messages due to the lack of available PIDs, leading to a decrease in Key Performance Indicators (KPIs).

Asynchronous RADIUS Accounting Messages

To improve performance, cnBNG can switch to asynchronous mode for sending RADIUS Accounting messages. In this mode, cnBNG does not wait for a server response. After sending a message, the cnBNG waits for a timeout of one second, and then releases the PID. This allows the PID to be reused for subsequent messages. However, a brief delay is implemented before reusing a PID. This change can prevent PID exhaustion during high traffic and enhance KPIs. Note that the asynchronous mode applies only to RADIUS Accounting messages.

Configure Asynchronous RADIUS Accounting

Configure Asynchronous mode for Session Accounting

Use this configuration to enable asynchronous mode for session accounting.

```
config
  profile aaa aaa_name
    accounting
      session { acct-interim-async true/false | acct-start-async true/false |
acct-stop-async true/false }
    commit
```

Configure Asynchronous mode for Service Accounting

Use this configuration to enable asynchronous mode for service accounting.

```
config
  profile aaa aaa_name
    accounting
      service { acct-interim-async true/false | acct-start-async true/false |
acct-stop-async true/false }
    commit
```

Note If asynchronous RADIUS accounting is configured, message retransmission functionality will be unavailable. Lost messages due to network issues or server errors will not be retried by the Control Plane.

NOTES:

- **profile aaa aaa_name**: Specifies the AAA profile name and enters the AAA configuration mode.
- **accounting**: Enters the accounting sub-mode.
- **session [service] acct-interim-async true/false**: Specifies the option to enable or disable the asynchronous mode when interim updates are sent.
- **session [service] acct-start-async true/false**: Specifies the option to enable or disable the asynchronous mode when an Accounting-Start request is sent to AAA.
- **session [service] acct-stop-async true/false**: Specifies the option to enable or disable the asynchronous mode when an Accounting-Stop request is sent.

Standard Compliance

The AAA features are aligned with the following standards:

- RFC 2865 - Remote Authentication Dial In User Service (RADIUS)
- RFC 2866 - RADIUS Accounting
- RFC 5176 - Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)

RADIUS Automated Testing

For subscriber authentication and accounting, the cnBNG-CP chooses a RADIUS server from the list of configured servers, and sends RADIUS messages. If the RADIUS server is unreachable, it is considered dead, and is excluded from the selection algorithm until a 'dead-timer' expires. After this timer expires, the dead server is re-included in the selection list without checking if it is now reachable. This causes the cnBNG-CP to retransmit messages to the still-unreachable server, causing retransmissions and delays, which negatively impact Key Performance Indicators (KPIs).

The RADIUS Automated Testing feature allows the cnBNG-CP to periodically check the status of the RADIUS server until the server is considered dead or the dead-timer expires. With this feature, if the dead-timer expires, the cnBNG-CP attempts to send authentication and accounting TEST messages to the RADIUS server that is currently unreachable. If the server does not respond to these messages, it is marked as dead, and this process continues until the server is reachable. If the RADIUS server responds within the set number of retransmissions and timeouts, it is marked as available, and is then included in the selection algorithm list that is used to choose RADIUS servers.

There are two configuration scenarios:

- The following happens when RADIUS Automated Testing is enabled without the Idle-timer functionality:
When the dead-detection criteria is met, the dead-timer starts with the value configured for **deadtime** CLI. Whenever the dead-timer expires, TEST messages are sent to the RADIUS server to check if the

server is reachable. If the RADIUS server responds, the dead-timer stops, and the RADIUS server is marked UP. If the RADIUS server doesn't respond, the dead-timer is restarted.

- The following happens when the **idle-timer** CLI along with **auto-test enable** is configured:

When the RADIUS server is UP, the status of the server is checked periodically by sending TEST RADIUS messages to the selected RADIUS server as per the configured idle-timer value. If the RADIUS server doesn't respond to the TEST messages, then the RADIUS server is marked as dead. The dead-timer starts as per the value configured in the **deadtime** CLI, and the periodic TEST message is stopped. Once the dead-timer expires, TEST RADIUS messages are sent to the RADIUS server, and the dead-timer is restarted. If the server responds to the TEST messages, the server is marked as UP, the dead-timer is stopped, and periodic TEST messages are restarted. If the server does not respond to TEST messages, on every dead-timer expiry, TEST RADIUS messages are sent to check reachability.

Restrictions

- RADIUS server availability based on VRF is not supported.
- **Show peers** command is not instance-aware.
- Round-trip time (RTT) is based on the server level, not the instance level.
- Server status is maintained per instance. All other statuses are maintained at a global level.
- Presently, only two VIPs are supported.

Software Upgrades

When you upgrade your current software (release version prior to cnBNG 2024.01) to cnBNG 2024.01 and later releases, perform the following steps:

- Fetch the keys of the RADIUS server from ETCD using the following command:

```
kubectl exec -it -n bng <etcd pod name> -- etcdctl get --prefix "" --keys-only | grep serv
```

- Delete the key from ETCD using the following command:

```
kubectl exec -it -n bng <etcd pod name> -- etcdctl del key "serverkey"
```

Note Rolling upgrade is not supported for this software upgrade scenario.

Configure RADIUS Automated Testing

This section describes how to enable RADIUS Automated Testing feature for accounting and authorization.

```
config
  profile radius
    server ipv4_address port_number
    type { acct | auth }
    auto-test enable
    auto-test enable idle-timer number
  commit
```

To disable the RADIUS Automated Testing feature, use the **no auto-test enable** command, and to disable the idle-timer functionality, use the **no auto-test idle-timer** command.

Note When the RADIUS Automated Testing feature is disabled, the status of the RADIUS server is reset to UP (reachable).

NOTES:

- **profile radius**: Enters the RADIUS configuration mode.
- **server ipv4_address port_number**: Specifies the IPv4 address and port of the RADIUS server.
- **type { acct | auth }**: Specifies the type of the RADIUS server. It can be one of the following:
 - **acct**: RADIUS server used for the accounting requests
 - **auth**: RADIUS server used for the authentication requests
- **auto-test enable**: Enables RADIUS automated testing.
- **auto-test enable idle-timer minutes**: Enables the idle-timer functionality. *minutes* value ranges from 1 through 30.
- **commit**: Commits the configuration.

Verifying RADIUS Automated Testing

Use the following **show** commands to verify the RADIUS Automated Testing feature.

```
bng# show radius auth-server 10.1.45.112:1812
Mon Nov  6 11:01:25.394 UTC+00:00
-----
Server: 10.1.45.112, port: 1812, status: instance 1: up , port-type: Auth
75 requests, 0 pending, 0 retransmits
0 accepts, 75 rejects, 0 timeouts
0 bad responses, 0 bad authenticators
0 unknown types, 0 dropped, 1004 ms latest rtt
Auto Test Stats:
instance 1:
Requests:74 Pending:0 Retransmits:0
Rejects:74 Timeouts:0 Responses:0
BadAuth:0 Dropped:0 BadResp:0
-----

bng# show radius acct-server 10.1.45.112:1813
Mon Nov  6 11:22:58.330 UTC+00:00
-----
Server: 10.1.45.112, port: 1813, status: instance 1: up , port-type: Acct
338 requests, 0 pending, 0 retransmits
338 responses, 0 timeouts
0 bad responses, 0 bad authenticators
0 unknown types, 0 dropped, 3 ms latest rtt
Auto Test Stats:
instance 1:
Requests:337 Pending:0 Retransmits:0
Rejects:0 Timeouts:0 Responses:337
BadAuth:0 Dropped:0 BadResp:0
```

RADIUS Attributes Filtering

Table 7: Feature History

Feature Name	Release Information	Description
RADIUS Attributes Filtering	2025.01.0	You can now customize RADIUS messages by including or excluding specific attributes to meet your server's requirements. This feature enhances your control over shared data between RADIUS clients and servers and optimizes message performance by filtering unnecessary attributes, thus reducing server load.

The RADIUS Attributes Filtering feature allows you to manage which RADIUS attributes are included or excluded from RADIUS messages. This is achieved through CLI commands that specify which IETF and vendor-specific attributes should be filtered. This feature applies only to RADIUS Authentication and Accounting Request and Reply message types, and does not affect CoA and Disconnect messages originated by the AAA Client.

This feature does not control the behavior of the AAA server. Instead, it manages how attributes are included or excluded in outbound messages based on specific actions:

- **Request Processing:** During the **Request** phase, the system processes Accept or Reject actions to determine the inclusion or exclusion of specific attributes in outbound Access-Request and Accounting-Request messages (such as START, INTERIM, or STOP messages) as necessary.
- **Reply Processing:** In the **Reply** phase, even if the AAA Server sends specific attributes, the cnBNG Control Plane (CP) uses its predefined configurations to determine whether to accept or reject these attributes. These configurations guide the cnBNG CP in deciding whether to apply or ignore the attribute values for sessions. This process ensures that attributes are correctly applied without modifying the original messages from the AAA Server.

Restrictions and Guidelines for RADIUS Attributes Filtering

These restrictions apply to the RADIUS Attributes Filtering feature:

- This feature is not supported for CoA and Disconnect messages originated by the AAA Client.
- This feature is only applicable to Authentication and Accounting Request and Reply message types.
- Attribute filtering is not supported for global RADIUS configurations.
- Multiple attribute lists can be configured, but only one attribute list per request and reply can be attached. Configuring multiple lists per request or reply for authentication and accounting is not possible.
- If there is a mismatch between the server-group list name attached to request/reply and the one configured in RADIUS server attribute configuration, the list is considered invalid, and attribute filtering will function as PASS. Similarly, if the list is not present, the feature will work as PASS.
- There is no automatic validation for the number of attributes or the names of Vendor Specific Attributes (VSAs). You must ensure that the IETF or numbered attributes are configured correctly and VSA names are spelled accurately. The Ops Center does not check the attribute list values for correctness.
- No change is introduced by this feature in how monitor protocol and monitor subscriber work.

- No change is introduced by this feature in other profile radius CLIs.

Configure RADIUS Attributes Filtering

Procedure

Step 1 Define the IETF and vendor-specific attributes in lists using the **profile radius** configuration.

Example:

```
configure
  profile radius
    radius-server
      attribute attr-list list_name
      ietf-attributes ietf_attributes
      vendor-attribute vendor-id vendor_id vendor-type vendor_type_value name [ addrv6
client-mac-address ]
    exit
```

The following is a sample configuration:

```
profile radius
  radius-server
    attribute attr-list list1
    ietf-attributes [ 88 100 30 2 ]
    vendor-attribute vendor-id 9 vendor-type 1 name [ addrv6 client-mac-address ]
    vendor-attribute vendor-id 9 vendor-type 56
    vendor-attribute vendor-id 9 vendor-type 60
    vendor-attribute vendor-id 3561 vendor-type 1
  exit
  attribute attr-list list2
  ietf-attributes [ 40 42 47 61 88 100 ]
  vendor-attribute vendor-id 9 vendor-type 56
  vendor-attribute vendor-id 3561 vendor-type 1
  exit
exit
```

NOTES:

- **profile radius**: Enters the RADIUS configuration mode.
- **radius-server attribute attr-list list_name**: Specifies the RADIUS server attributes list.
- **ietf-attributes ietf_attributes**: Configures the list of Internet Engineering Task Force (IETF) attributes. For example, **ietf-attributes [88 8 30 2]** indicates that IETF attributes such as Framed-IP-Pool (88), Framed-IP-Address (8), Called-Station-Id(30), User-Password(2) are configured.
- **vendor-attribute vendor-id vendor_id**: Configures RADIUS attribute filtering for Vendor Specific Attributes (VSAs) by specifying vendor information such as the vendor-id in the RADIUS attribute list.
- **vendor-type value**: Configures the vendor specific information such as the vendor-type in the RADIUS attribute list.

Note

For **vendor-type 1** and **vendor-type 9**, attribute values are specified in the name list.

For example, **vendor-attribute vendor-id 9 vendor-type 56** configures Cisco vendor attributes `cisco-vsa-sub-qos-pol-out`, and `cisco-vsa-sub-activate-service` with vendor-id 9 and vendor-type 56.

vendor-attribute vendor-id 3561 vendor-type 56 configures the non-Cisco vendor attribute `Agent-Circuit-Id` with vendor-id 3561 and vendor type 1.

- **name:** [Optional] Specifies the attribute name for a Cisco generic Vendor Specific Attribute (VSA).

The **name** option is only available for vendor-id 9 and vendor-type 1.

Note

For vendor-type 1, if names are not configured, the accept or reject action applies to all vendor-type attributes of the configured vendor ID.

- **addrv6 client-mac-address:** [Optional] Specifies the client MAC address in AABB.CCDD.EEFF format.

Step 2 Configure the accept attributes list for both request and reply messages in RADIUS authentication and accounting.

Example:

```
config
profile radius
server-group server_group_name
accounting
request accept list_1_name
reply accept list_1_name
exit
authentication
request accept list_2_name
reply accept list_2_name
exit
server auth ip_address port_number
exit
server acct ip_address port_number
commit
```

Step 3 Configure the reject attributes list for both request and reply messages in RADIUS authentication and accounting.

Example:

```
config
profile radius
server-group server_group_name
accounting
request reject list_1_name
reply reject list_1_name
exit
authentication
request reject list_2_name
reply reject list_2_name
exit
server auth ip_address port_number
exit
```

```
server acct ip_address port_number
commit
```

NOTES:

- **server-group** *server_group_name*: Specifies the profile server group name to enter the Profile Server Group configuration mode.
- **accounting**: Enters the accounting sub-mode.
 - **request accept** *list_1_name*: Configures the accept attributes list for request messages in RADIUS accounting.
 - **reply accept** *list_1_name*: Configures the accept attributes list for reply messages in RADIUS accounting.
 - **request reject** *list_1_name*: Configures the reject attributes list for request messages in RADIUS accounting.
 - **reply reject** *list_1_name*: Configures the reject attributes list for reply messages in RADIUS accounting.
- **authentication**: Enters the authentication sub-mode.
 - **request accept** *list_1_name*: Configures the accept attributes list for request messages in RADIUS authentication.
 - **reply accept** *list_1_name*: Configures the accept attributes list for reply messages in RADIUS authentication.
 - **request reject** *list_1_name*: Configures the reject attributes list for request messages in RADIUS authentication.
 - **reply reject** *list_1_name*: Configures the reject attributes list for reply messages in RADIUS authentication.
- **server auth** *ip_address port_number*: Configures the authentication server.
- **server acct** *ip_address port_number*: Configures the accounting server.

Step 4 Use the **monitor protocol interface radius pcap yes** command to display and capture data packets from RADIUS interface messages.

NOTES:

- **pcap yes**: Enables PCAP file generation. By default, it is set to **no**.

Step 5 Use the **monitor subscriber supi supi_id capture-duration duration internal-messages yes** command to enable subscriber monitoring based on subscriber identity (SUPI).

NOTES:

- **supi** *supi_id*: Specifies the subscriber identity. For example, **aa11.0000.0001**, where *aa11.0000.0001* is the mac-id.
- **capture-duration** *duration*: [Optional] Specifies the duration, in seconds, for which the monitor subscriber is enabled. The default duration is 300 seconds.
- **internal-messages yes**: Enables internal messages, which are disabled by default.

Configuring AAA Functions

This section describes how to configure the following Authentication, Authorization, and Accounting (AAA) functions on the Control Plane (CP).

The configuration of the AAA functions involves the following procedures:

- Configuring AAA Attributes
- Configuring the CoA-NAS Interface
- Configuring Method Order for AAA
- Configuring RADIUS Accounting Options
- Configuring RADIUS Accounting Server Group
- Configuring RADIUS Attributes
- Configuring RADIUS-Dead Time
- Configuring RADIUS-Detect Dead Server
- Configuring RADIUS Pod
- Configuring RADIUS Maximum Retry
- Configuring RADIUS NAS-IP
- Configuring RADIUS Server
- Configuring RADIUS Server Group
- Configuring RADIUS Server Selection Logic
- Configuring RADIUS Timeout

Configuring AAA Attributes

Use the following commands to configure a function for the AAA attribute format.

NOTES:

- **profile attribute-format** *attribute_format_name*: Specifies the AAA attributes and enters the Attribute Format Configuration mode.
- **authorization**: Enters the Authorization sub-mode.
- **format-order** *attribute_format* | **identifier** { *addr* | *circuit-id-tag* | *client-mac-address* | *client-mac-address-custom1* | *client-mac-address-custom2* | *client-mac-address-ietf* | *client-mac-address-raw* | *dhcp-client-id* | *dhcp-client-id-spl* | *dhcp-user-class* | *dhcp-vendor-class* | *dhcpv4-client-id-spl* | *dhcpv4-vendor-class* | *dhcpv6-client-id-ent-ident* | *dhcpv6-interface-id* | *dhcpv6-vendor-class-string* | *inner-vlan-id* | *outer-vlan-id* | *physical-adapter* | *physical-chassis* | *physical-port* | *physical-slot* | *physical-subslot* | *port-type* | *pppoe-session-id* | *remote-id-tag* | *service-name* | *username* } | **value** *value* }: Specifies the AAA attribute format order as follows:
 - **addr**: Specifies the IPv4 address of the subscriber.

- **circuit-id-tag**: Specifies the circuit identifier tag.
- **client-mac-address**: Specifies the client MAC address in AABB.CCDD.EEFF format.
- **client-mac-address-custom1**: Specifies the first custom client MAC address in AABB.CCDD.EEFF format.
- **client-mac-address-custom2**: Specifies the second custom client MAC address in AABB.CCDD.EEFF format.
- **client-mac-address-ietf**: Specifies the client MAC address in Internet Engineering Task Force (IETF) format. That is, AA-BB-CC-DD-EE-FF format.
- **client-mac-address-raw**: Specifies the client MAC address in raw (AABBCCDDEEFF) format.
- **dhcp-client-id**: Specifies the DHCP client identifier.
- **dhcp-client-id-spl**: Specifies the DHCP client identifier special string.
- **dhcp-user-class**: Specifies the DHCP user class.
- **dhcp-vendor-class**: Specifies the DHCP vendor class.
- **dhcpv4-client-id-spl**: Specifies the DHCPv4 client identifier special string.
- **dhcpv4-vendor-class**: Specifies the DHCPv4 vendor class.
- **dhcpv6-client-id-ent-ident**: Specifies the DHCPv6 client and enterprise identifiers.
- **dhcpv6-interface-id**: Specifies the DHCPv6 interface identifier.
- **dhcpv6-vendor-class-string**: Specifies the DHCPv6 vendor class string.
- **inner-vlan-id**: Specifies the inner VLAN identifier.
- **outer-vlan-id**: Specifies the outer VLAN identifier.
- **physical-adapter**: Specifies the physical adapter.
- **physical-chassis**: Specifies the physical chassis.
- **physical-port**: Specifies the physical port.
- **physical-slot**: Specifies the physical slot.
- **physical-subslot**: Specifies the physical subslot.
- **port-type**: Specifies the interface or port type.
- **pppoe-session-id**: Specifies the PPPoE physical identifier.
- **remote-id-tag**: Specifies the remote identifier tag.
- **service-name**: Specifies the service name.
- **username**: Specifies the username.

Configuring the CoA-NAS Interface

Use the following configuration to define Change of Authorization (CoA) NAS interface in the RADIUS endpoint.

```
config
  endpoint radius
    interface coa-nas
      vip-ip ipv4_address vip-port port_number
      vip-ipv6 ipv6_address vip-ipv6-port port_number
    end
```

NOTES:

- **endpoint radius:** Enters the RADIUS endpoint configuration mode.
- **interface coa-nas:** This keyword defines a new interface "coa-nas", and allows to enter the CoA NAS interface configuration mode.
- **vip-ip *ipv4_address* vip-port *port_number*:** Configures the IPv4 address of the host. *ipv4_address* must be in standard IPv4 dotted decimal notation.

You can configure a list of VIP-IPs to listen to the inbound CoA or DM requests.

vip-port *port_number*: Specify the port number of the UDP proxy. By default, the port number is 3799. This default value is used only when the VIP-IP is specified.

Important

This configuration allows only port to be specified per IP.

The BNG (udp-pxy) listens to the inbound CoA or DM request messages on these ports and ACK or NAK messages sent with the respective source IP and port.

- **vip-ipv6 *ipv6_address* vip-ipv6-port *port_number*:** Configures the IPv6 address of the host.
- **vip-ipv6-port *port_number*:** Specify the port number of the UDP proxy.

Configuring Method Order for AAA

Use the following commands to assign the method order for the server group to use for subscriber authentication, authorization, and accounting.

Authentication

```
config
  profile aaa aaa_name
    authentication
      method-order custom_server_group
    commit
```

NOTES:

- **profile aaa *aaa_name*:** Specifies the AAA profile name and enters the AAA Configuration mode.
- **authentication:** Enters the Authentication sub-mode.

- **method-order** *custom_server_group*: Specifies the method-order to be applied by default for subscriber authentication.

custom_server_group specifies the name of the server group where the method-order is applied.

Authorization

```
config
  profile aaa aaa_name
    authorization
      password password
      type subscriber method-order custom_server_group
      username { format attribute_format | identifier { addr | circuit-id-tag
| client-mac-address | client-mac-address-custom1 |
client-mac-address-custom2 | client-mac-address-ietf |
client-mac-address-raw | dhcp-client-id | dhcp-client-id-spl |
dhcp-user-class | dhcp-vendor-class | dhcpv4-client-id-spl |
dhcpv4-vendor-class | dhcpv6-client-id-ent-ident | dhcpv6-interface-id |
dhcpv6-vendor-class-string | inner-vlan-id | outer-vlan-id |
physical-adapter | physical-chassis | physical-port | physical-slot |
physical-subslot | port-type | pppoe-session-id | remote-id-tag |
service-name | username } | value value }
      commit
```

NOTES:

- **profile aaa** *aaa_name*: Specifies the AAA profile name and enters the AAA Configuration mode.
- **authorization**: Enters the Authorization sub-mode.
- **password** *password*: Specifies the password for subscriber authentication.
- **type subscriber method-order** *custom_server_group*: Specifies the method-order to be applied by default for subscriber authorization.
custom_server_group specifies the name of the server group where the method-order is applied.
- **username { format** *attribute_format* | **identifier {** *addr* | *circuit-id-tag* | *client-mac-address* | *client-mac-address-custom1* | *client-mac-address-custom2* | *client-mac-address-ietf* | *client-mac-address-raw* | *dhcp-client-id* | *dhcp-client-id-spl* | *dhcp-user-class* | *dhcp-vendor-class* | *dhcpv4-client-id-spl* | *dhcpv4-vendor-class* | *dhcpv6-client-id-ent-ident* | *dhcpv6-interface-id* | *dhcpv6-vendor-class-string* | *inner-vlan-id* | *outer-vlan-id* | *physical-adapter* | *physical-chassis* | *physical-port* | *physical-slot* | *physical-subslot* | *port-type* | *pppoe-session-id* | *remote-id-tag* | *service-name* | *username* } | **value** *value* }: Specifies the username format, identifier, or value.
 - **format** *attribute_format*: Specifies the username attribute format.
 - **identifier {** *addr* | *circuit-id-tag* | *client-mac-address* | *client-mac-address-custom1* | *client-mac-address-custom2* | *client-mac-address-ietf* | *client-mac-address-raw* | *dhcp-client-id* | *dhcp-client-id-spl* | *dhcp-user-class* | *dhcp-vendor-class* | *dhcpv4-client-id-spl* | *dhcpv4-vendor-class* | *dhcpv6-client-id-ent-ident* | *dhcpv6-interface-id* | *dhcpv6-vendor-class-string* | *inner-vlan-id* | *outer-vlan-id* | *physical-adapter* | *physical-chassis* | *physical-port* | *physical-slot* | *physical-subslot* | *port-type* | *pppoe-session-id* | *remote-id-tag* | *service-name* | *username* }: Specifies the username identifiers as follows:
 - **addr**: Specifies the IPv4 address of the subscriber.

- **circuit-id-tag**: Specifies the circuit identifier tag.
- **client-mac-address**: Specifies the client MAC address in AABB.CCDD.EEFF format.
- **client-mac-address-custom1**: Specifies the first custom client MAC address in AABB.CCDD.EEFF format.
- **client-mac-address-custom2**: Specifies the second custom client MAC address in AABB.CCDD.EEFF format.
- **client-mac-address-ietf**: Specifies the client MAC address in Internet Engineering Task Force (IETF) format. That is, AA-BB-CC-DD-EE-FF format.
- **client-mac-address-raw**: Specifies the client MAC address in raw (AABBCCDDEEFF) format.
- **dhcp-client-id**: Specifies the DHCP client identifier.
- **dhcp-client-id-spl**: Specifies the DHCP client identifier special string.
- **dhcp-user-class**: Specifies the DHCP user class.
- **dhcp-vendor-class**: Specifies the DHCP vendor class.
- **dhcpv4-client-id-spl**: Specifies the DHCPv4 client identifier special string.
- **dhcpv4-vendor-class**: Specifies the DHCPv4 vendor class.
- **dhcpv6-client-id-ent-ident**: Specifies the DHCPv6 client and enterprise identifiers.
- **dhcpv6-interface-id**: Specifies the DHCPv6 interface identifier.
- **dhcpv6-vendor-class-string**: Specifies the DHCPv6 vendor class string.
- **inner-vlan-id**: Specifies the inner VLAN identifier.
- **outer-vlan-id**: Specifies the outer VLAN identifier.
- **physical-adapter**: Specifies the physical adapter.
- **physical-chassis**: Specifies the physical chassis.
- **physical-port**: Specifies the physical port.
- **physical-slot**: Specifies the physical slot.
- **physical-subslot**: Specifies the physical subslot.
- **port-type**: Specifies the interface or port type.
- **pppoe-session-id**: Specifies the PPPoE physical identifier.
- **remote-id-tag**: Specifies the remote identifier tag.
- **service-name**: Specifies the service name.
- **username**: Specifies the username.

Accounting

```

config
  profile aaa aaa_name
    accounting
      method-order custom_server_group
    commit

```

NOTES:

- **profile aaa *aaa_name***: Specifies the AAA profile name and enters the AAA Configuration mode.
- **accounting**: Enters the Accounting sub-mode.
- **method-order *custom_server_group***: Specifies the method-order to be applied by default for subscriber accounting.
custom_server_group specifies the name of the server group where the method-order is applied.

Configuring RADIUS Accounting Options

This section describes how to configure the RADIUS accounting options.

NOTES:

- **profile radius accounting**: Enters the RADIUS accounting configuration mode.
- **algorithm { first-server | round-robin }**: Defines the algorithm for selecting the RADIUS server.
 - **first-server**: Sets the selection logic as highest priority first. This is the default behavior.
 - **round-robin**: Sets the selection logic as round-robin order of servers.
- **deadtime value**: Sets the time to elapse between RADIUS server marked unreachable and when we can re-attempt to connect.
value must be an integer from 0 through 65535. Default: 10 minutes.
- **detect-dead-server response-timeout value**: Sets the timeout value that marks a server as "dead" when a packet is not received for the specified number of seconds.
value must be an integer from 1 through 65535. Default: 10 seconds.
- **max-retry value**: Sets the maximum number of times that the system will attempt retry with the RADIUS server.
value must be an integer from 0 through 65535. Default: 2
- **timeout value**: Sets the time to wait for response from the RADIUS server before retransmitting.
value must be an integer from 1 through 65535. Default: 2 seconds.
- **commit**: Commits the configuration.
- All the keyword options under the RADIUS accounting configuration mode are also available within the RADIUS configuration mode.

Configuring RADIUS Accounting Server Group

This section describes how to configure the RADIUS server group.

```
configure
  profile radius
    server-group group_name
  commit
```

NOTES:

- **profile radius:** Enters the RADIUS configuration mode.
- **server group group_name:** Specifies the name of server group for use in RADIUS accounting. *group_name* must be an alphanumeric string.
- **commit:** Commits the configuration.

Configuring RADIUS Attributes

This section describes how to configure the RADIUS attributes for authentication and accounting.

```
config
  profile radius
    attribute { nas-identifier value | nas-ip { ipv4_address | user-plane-ip
} | nas-ipv6 ipv6_address }
  commit
```

NOTES:

- **profile radius:** Enters the RADIUS configuration mode.
- **attribute { nas-identifier value | nas-ip ipv4_address } :** Configures the RADIUS identification parameters.
 - **nas-identifier value:** Specifies the attribute name by which the system will be identified in Accounting-Request messages. *value* must be an alphanumeric string.
 - **nas-ip ipv4_address:** Specifies the NAS IPv4 address. *ipv4_address* must be an IPv4 address in dotted decimal notation.
 - **nas-ip user-plane-ip:** Enables the *user-plane-ip-address* AVPair to use the configured User-Plane IP address in Access-Request or Accounting-Request messages.
 - **nas-ipv6 ipv6_address:** Specifies the NAS IPv6 address.
- **commit:** Commits the configuration.

Sample Configuration

The following is a sample configuration.

```
config
  profile radius
    attribute
      nas-identifier CiscoBng
      nas-ip          10.1.32.83
```

```

nas-ip user-plane-ip
exit
exit

```

Configuring RADIUS Attribute Format

Configuring RADIUS Dead Time

This section describes how to configure the RADIUS dead time.

```

config
  profile radius
    deadtime value
  commit

```

NOTES:

- **profile radius**: Enters the RADIUS configuration mode.
- **deadtime *value***: Sets the time to elapse between RADIUS server marked unreachable and when an reattempt to connect can be made.
value must be an integer from 0 through 65535. Default: 10 minutes.
- **commit**: Commits the configuration.

Sample Configuration

The following is a sample configuration.

```

config
  profile radius
    deadtime 15
  exit

```

Configuring RADIUS Detect Dead Server

This section describes how to configure the RADIUS detect dead server.

```

config
  profile radius
    detect-dead-server response-timeout value
  commit

```

NOTES:

- **profile radius**: Enters the RADIUS configuration mode.
- **detect-dead-server response-timeout *value***: Sets the timeout value that marks a server as "dead" when a packet is not received for the specified number of seconds.
value must be an integer from 1 through 65535. Default: 10 seconds.
- **commit**: Commits the configuration.

Sample Configuration

The following is a sample configuration.

```
config
  profile radius
    detect-dead-server response-timeout 100
  exit
```

Configuring RADIUS NAS-IP

This section describes how to configure the RADIUS NAS-IP.

Global RADIUS NAS-IP Configuration

Use the following configuration to configure the NAS-IP address.

```
config
  endpoint radius-dns
  interface radius-client
    vip-ip ipv4_address
  commit
```

NOTES:

- **endpoint radius-dns:** Enters the endpoint radius-ep configuration mode.
- **interface radius-client:** Enters the radius-client interface-type configuration mode.
- **vip-ip *ipv4_address*:** Sets the NAS-IP value, which is also used as the source-IP in UDP requests towards the RADIUS server.
- **commit:** Commits the configuration.

Configuration Example:

```
config
  endpoint radius-dns
    interface radius-client
      vip-ip 209.165.200.228
    exit
  exit
exit
```

Configuring RADIUS Pod

This section describes how to configure the RADIUS pod.

```
config
  endpoint radius
    replicas number_of_replicas
  commit
```

NOTES:

- **endpoint radius:** Enters the RADIUS endpoint configuration mode.
- **replicas *number_of_replicas*:** Sets the number of replicas required.

- **commit**: Commits the configuration.

Sample Configuration

The following is a sample configuration.

```
config
  endpoint radius
    replicas 3
  exit
```

Configuring RADIUS Retries

This section describes how to configure the maximum RADIUS retries.

```
config
  profile radius
    max-retry value
  commit
```

NOTES:

- **profile radius**: Enters the RADIUS configuration mode.
- **max-retry value**: Sets the maximum number of times that the system will attempt retry with the RADIUS server.
value must be an integer from 0 through 65535. Default: 2
- **commit**: Commits the configuration.

Sample Configuration

The following is a sample configuration.

```
config
  profile radius
    max-retry 2
  exit
```

Configuring RADIUS Server

This section describes how to configure the RADIUS server settings.

```
config
  profile radius
    server ipv4/ipv6_address port_number
    secret secret_key
    priority priority_value
    type { acct | auth }
  commit
```

NOTES:

- **profile radius**: Enters the RADIUS configuration mode.
- **server ipv4/ipv6_address port_number**: Specifies the IPv4/IPv6 address and port of the RADIUS server.

- **secret** *secret_key*: Specifies the secret key.
- **priority** *priority_value*: Specifies the server priority.
- **type { acct | auth }**: Specifies the type of the RADIUS server. It can be one of the following:
 - acct: RADIUS server used for the accounting requests
 - auth: RADIUS server used for the authentication requests
- **commit**: Commits the configuration.

Configuring RADIUS Server Group

Use the following commands to configure the RADIUS server group.

```
config
  profile server-group server_group_name
    radius-group radius_server_group_name
  commit
```

NOTES:

- **profile server-group** *server_group_name*: Specifies the profile server group name to enter the Profile Server Group Configuration mode.
- **radius-group** *radius_server_group_name*: Specifies the RADIUS group server name.

Sample Configuration

The following is a sample configuration:

```
server-group automation-server-group
server auth 10.1.36.121 1812
exit
server acct 10.1.36.121 1813
exit
server auth 2001::10:1:36:121 1812
exit
server acct 2001::10:1:36:121 1813
exit
```

Configuring RADIUS Server Selection Logic

This section describes how to configure the RADIUS server selection logic.

```
config
  profile radius
    algorithm { first-server | round-robin | least-outstanding [
  batch-size number ] }
  commit
```

NOTES:

- **profile radius**: Enters the RADIUS configuration mode.

- **algorithm { first-server | round-robin | least-outstanding [batch-size] }**: Defines the algorithm for selecting the RADIUS server.
 - **first-server**: Sets the selection logic as highest priority first. This is the default behavior.
 - **round-robin**: Sets the selection logic as round-robin order of servers.
 - **least-outstanding** : Sets the selection logic based on the server with the lowest number of outstanding transactions in its queue.
 - **batch-size number**: (Optional) Specifies the size of the batch.
If you do not configure the **batch-size** value in the CLI command, the system takes the default batch size.
- **commit**: Commits the configuration.

Sample Configuration

The following is a sample configuration.

```
config
  profile radius
    algorithm least-outstanding batch-size 30
  exit
```

Configuring RADIUS Timeout

This section describes how to configure the RADIUS timeout.

```
config
  profile radius
    timeout value
  commit
```

NOTES:

- **profile radius**: Enters the RADIUS configuration mode.
- **timeout *value_in_seconds***: Sets the time to wait for response from the RADIUS server before retransmitting.
value must be an integer from 1 through 65535. Default: 2 seconds.
- **commit**: Commits the configuration.

Sample Configuration

The following is a sample configuration.

```
config
  profile radius
    timeout 4
  exit
```
