Implementing MPLS Traffic Engineering

Multiprotocol Label Switching (MPLS) is a standards-based solution driven by the Internet Engineering Task Force (IETF) that was devised to convert the Internet and IP backbones from best-effort networks into business-class transport mediums.

MPLS, with its label switching capabilities, eliminates the need for an IP route look-up and creates a virtual circuit (VC) switching function, allowing enterprises the same performance on their IP-based network services as with those delivered over traditional networks such as Frame Relay or Asynchronous Transfer Mode (ATM).

MPLS traffic engineering (MPLS-TE) software enables an MPLS backbone to replicate and expand upon the TE capabilities of Layer 2 ATM and Frame Relay networks. MPLS is an integration of Layer 2 and Layer 3 technologies. By making traditional Layer 2 features available to Layer 3, MPLS enables traffic engineering. Thus, you can offer in a one-tier network what now can be achieved only by overlaying a Layer 3 network on a Layer 2 network.

The LMP and GMPLS-NNI features are not supported on PRP hardware.

Prerequisites for Implementing Cisco MPLS Traffic Engineering

These prerequisites are required to implement MPLS TE:

- You must be in a user group associated with a task group that includes the proper task IDs. The command reference guides include the task IDs required for each command. If you suspect user group assignment is preventing you from using a command, contact your AAA administrator for assistance.
- Router that runs Cisco IOS XR software.
- Installed composite mini-image and the MPLS package, or a full composite image.
- IGP activated.
- To configure Point-to-Multipoint (P2MP)-TE, a base set of RSVP and TE configuration parameters on ingress, midpoint, and egress nodes in the MPLS network is required. In addition, Point-to-Point (P2P) parameters are required.

Information About Implementing MPLS Traffic Engineering

To implement MPLS-TE, you should understand these concepts:

Overview of MPLS Traffic Engineering

MPLS-TE software enables an MPLS backbone to replicate and expand upon the traffic engineering capabilities of Layer 2 ATM and Frame Relay networks. MPLS is an integration of Layer 2 and Layer 3 technologies. By making traditional Layer 2 features available to Layer 3, MPLS enables traffic engineering. Thus, you can offer in a one-tier network what now can be achieved only by overlaying a Layer 3 network on a Layer 2 network.

MPLS-TE is essential for service provider and Internet service provider (ISP) backbones. Such backbones must support a high use of transmission capacity, and the networks must be very resilient so that they can withstand link or node failures. MPLS-TE provides an integrated approach to traffic engineering. With MPLS, traffic engineering capabilities are integrated into Layer 3, which optimizes the routing of IP traffic, given the constraints imposed by backbone capacity and topology.

Related Topics

Benefits of MPLS Traffic Engineering

MPLS-TE enables ISPs to route network traffic to offer the best service to their users in terms of throughput and delay. By making the service provider more efficient, traffic engineering reduces the cost of the network.

Currently, some ISPs base their services on an overlay model. In the overlay model, transmission facilities are managed by Layer 2 switching. The routers see only a fully meshed virtual topology, making most destinations appear one hop away. If you use the explicit Layer 2 transit layer, you can precisely control how traffic uses available bandwidth. However, the overlay model has numerous disadvantages. MPLS-TE achieves the TE benefits of the overlay model without running a separate network and without a non-scalable, full mesh of router interconnects.

How MPLS-TE Works

MPLS-TE automatically establishes and maintains label switched paths (LSPs) across the backbone by using RSVP. The path that an LSP uses is determined by the LSP resource requirements and network resources, such as bandwidth. Available resources are flooded by means of extensions to a link-state-based Interior Gateway Protocol (IGP).

MPLS-TE tunnels are calculated at the LSP headend router, based on a fit between the required and available resources (constraint-based routing). The IGP automatically routes the traffic to these LSPs.

Typically, a packet crossing the MPLS-TE backbone travels on a single LSP that connects the ingress point to the egress point. MPLS-TE is built on these mechanisms:

Tunnel interfaces

From a Layer 2 standpoint, an MPLS tunnel interface represents the headend of an LSP. It is configured with a set of resource requirements, such as bandwidth and media requirements, and priority. From a Layer 3 standpoint, an LSP tunnel interface is the headend of a unidirectional virtual link to the tunnel destination.

MPLS-TE path calculation module

This calculation module operates at the LSP headend. The module determines a path to use for an LSP. The path calculation uses a link-state database containing flooded topology and resource information.

RSVP with TE extensions

RSVP operates at each LSP hop and is used to signal and maintain LSPs based on the calculated path.

MPLS-TE link management module

This module operates at each LSP hop, performs link call admission on the RSVP signaling messages, and performs bookkeeping on topology and resource information to be flooded.

Link-state IGP (Intermediate System-to-Intermediate System [IS-IS] or Open Shortest Path First [OSPF]—each with traffic engineering extensions)

These IGPs are used to globally flood topology and resource information from the link management module.

Enhancements to the shortest path first (SPF) calculation used by the link-state IGP (IS-IS or OSPF)

The IGP automatically routes traffic to the appropriate LSP tunnel, based on tunnel destination. Static routes can also be used to direct traffic to LSP tunnels.
Label switching forwarding

This forwarding mechanism provides routers with a Layer 2-like ability to direct traffic across multiple hops of the LSP established by RSVP signaling.

One approach to engineering a backbone is to define a mesh of tunnels from every ingress device to every egress device. The MPLS-TE path calculation and signaling modules determine the path taken by the LSPs for these tunnels, subject to resource availability and the dynamic state of the network.

The IGP (operating at an ingress device) determines which traffic should go to which egress device, and steers that traffic into the tunnel from ingress to egress. A flow from an ingress device to an egress device might be so large that it cannot fit over a single link, so it cannot be carried by a single tunnel. In this case, multiple tunnels between a given ingress and egress can be configured, and the flow is distributed using load sharing among the tunnels.

Note
GRE over MPLS-TE tunnel is not supported. Hence, you cannot carry GRE traffic over an LSP established for MPLS-TE tunnel using RSVP-TE. This restriction also applies to SR-TE tunnels.

MPLS Traffic Engineering

Multiprotocol Label Switching (MPLS) is an Internet Engineering Task Force (IETF)-specified framework that provides efficient designation, routing, forwarding, and switching of traffic flows through the network.

TE is the process of adjusting bandwidth allocations to ensure that enough bandwidth is available for high-priority traffic.

In MPLS TE, the upstream router creates a network tunnel for a particular traffic stream and sets the bandwidth available for that tunnel.

Backup AutoTunnels

The MPLS Traffic Engineering AutoTunnel Backup feature enables a router to dynamically build backup tunnels on the interfaces that are configured with MPLS TE tunnels. This feature enables a router to dynamically build backup tunnels when they are needed. This prevents you from having to build MPLS TE tunnels statically.

The MPLS Traffic Engineering (TE)—AutoTunnel Backup feature has these benefits:

- Backup tunnels are built automatically, eliminating the need for users to preconfigure each backup tunnel and then assign the backup tunnel to the protected interface.
- Protection is expanded—FRR does not protect IP traffic that is not using the TE tunnel or Label Distribution Protocol (LDP) labels that are not using the TE tunnel.

This feature protects against these failures:

- **P2P Tunnel NHOP protection**—Protects against link failure for the associated P2P protected tunnel
- **P2P Tunnel NNHOP protection**—Protects against node failure for the associated P2P protected tunnel
P2MP Tunnel NHOP protection—Protects against link failure for the associated P2MP protected tunnel

- Configure the MPLS-TE Auto-Tunnel Backup: Example, on page 176

**AutoTunnel Attribute-set**

This feature supports auto-tunnels configuration using attribute templates, known as attribute-set. The TE attribute-set template that specifies a set of TE tunnel attributes, is locally configured at the head-end of auto-tunnels. The control plane triggers the automatic provisioning of a corresponding TE tunnel, whose characteristics are specified in the respective attribute-set.

Currently, auto-tunnel backups are created with the default values of all tunnel attributes. To support configurable attributes for auto-tunnel backup, it is required to configure attribute-set and assign it to the backup tunnels. The attribute-set consists of a set of tunnel attributes such as priority, affinity, signaled bandwidth, logging, policy-class, record-route and so on.

The following rules (consistent across all auto-tunnels) apply while configuring the attribute-set:

- If no attribute-set template is defined, the auto-tunnels is created using default attribute values.
- If an attribute-set is defined and the attribute-set template is already configured, the auto-tunnel is created using the attributes specified in the associated attribute-set.
- If an attribute-set is assigned, but it is not defined or configured, auto-tunnel is not created.
- Any number of attribute-sets can be configured with same attribute settings.
- Empty tunnel attribute implies all parameters have default values.
- When specific attribute is not specified in the attribute-set, a default value for that attribute is used.

**Link Protection**

The backup tunnels that bypass only a single link of the LSP path provide link protection. They protect LSPs, if a link along their path fails, by rerouting the LSP traffic to the next hop, thereby bypassing the failed link. These are referred to as NHOP backup tunnels because they terminate at the LSP's next hop beyond the point of failure.

This figure illustrates link protection.
The backup tunnels that bypass next-hop nodes along LSP paths are called NNHOP backup tunnels because they terminate at the node following the next-hop node of the LSPs, thereby bypassing the next-hop node. They protect LSPs by enabling the node upstream of a link or node failure to reroute the LSPs and their traffic around a node failure to the next-hop node. NNHOP backup tunnels also provide protection from link failures because they bypass the failed link and the node.

This figure illustrates node protection.

Backup AutoTunnel Assignment

At the head or mid points of a tunnel, the backup assignment finds an appropriate backup to protect a given primary tunnel for FRR protection.

The backup assignment logic is performed differently based on the type of backup configured on the output interface used by the primary tunnel. Configured backup types are:

- Static Backup
- AutoTunnel Backup
• No Backup (In this case no backup assignment is performed and the tunnels is unprotected.)

Note
Static backup and Backup AutoTunnel cannot exist together on the same interface or link.

Note
Node protection is always preferred over link protection in the Backup AutoTunnel assignment.

In order that the Backup AutoTunnel feature operates successfully, the following configuration must be applied at global configuration level:

ipv4 unnumbered mpls traffic-eng Loopback 0

Note
The Loopback 0 is used as router ID.

Explicit Paths

Explicit paths are used to create backup autotunnels as follows:

For NHOP Backup Autotunnels:

• NHOP excludes the protected link’s local IP address.
• NHOP excludes the protected link’s remote IP address.
• The explicit-path name is _autob_nhhop_tunnelxxx, where xxx matches the dynamically created backup tunnel ID.

For NNHOP Backup Autotunnels:

• NNHOP excludes the protected link’s local IP address.
• NNHOP excludes the protected link’s remote IP address (link address on next hop).
• NNHOP excludes the NHOP router ID of the protected primary tunnel next hop.
• The explicit-path name is _autob_nnhop_tunnelxxx, where xxx matches the dynamically created backup tunnel ID.

Periodic Backup Promotion

The periodic backup promotion attempts to find and assign a better backup for primary tunnels that are already protected.

With AutoTunnel Backup, the only scenario where two backups can protect the same primary tunnel is when both an NHOP and NNHOP AutoTunnel Backups get created. The backup assignment takes place as soon as the NHOP and NNHOP backup tunnels come up. So, there is no need to wait for the periodic promotion.
Although there is no exception for AutoTunnel Backups, periodic backup promotion has no impact on primary tunnels protected by AutoTunnel Backup.

One exception is when a manual promotion is triggered by the user using the `mpls traffic-eng fast-reroute timers promotion` command, where backup assignment or promotion is triggered on all FRR protected primary tunnels—even unprotected ones. This may trigger the immediate creation of some AutoTunnel Backup, if the command is entered within the time window when a required AutoTunnel Backup has not been yet created.

You can configure the periodic promotion timer using the global configuration `mpls traffic-eng fast-reroute timers promotion sec` command. The range is 0 to 604800 seconds.

---

**Note**

A value of 0 for the periodic promotion timer disables the periodic promotion.

---

**Protocol-Based CLI**

Cisco IOS XR software provides a protocol-based command line interface. The CLI provides commands that can be used with the multiple IGP protocols supported by MPLS-TE.

**Differentiated Services Traffic Engineering**

MPLS Differentiated Services (Diff-Serv) Aware Traffic Engineering (DS-TE) is an extension of the regular MPLS-TE feature. Regular traffic engineering does not provide bandwidth guarantees to different traffic classes. A single bandwidth constraint is used in regular TE that is shared by all traffic. To support various classes of service (CoS), users can configure multiple bandwidth constraints. These bandwidth constraints can be treated differently based on the requirement for the traffic class using that constraint.

MPLS DS-TE provides the ability to configure multiple bandwidth constraints on an MPLS-enabled interface. Available bandwidths from all configured bandwidth constraints are advertised using IGP. TE tunnel is configured with bandwidth value and class-type requirements. Path calculation and admission control take the bandwidth and class-type into consideration. RSVP is used to signal the TE tunnel with bandwidth and class-type requirements.

MPLS DS-TE is deployed with either Russian Doll Model (RDM) or Maximum Allocation Model (MAM) for bandwidth calculations.

Cisco IOS XR software supports two DS-TE modes: Prestandard and IETF.

**Related Topics**

- Confirming DiffServ-TE Bandwidth
- Bandwidth Configuration (MAM): Example
- Bandwidth Configuration (RDM): Example

**Prestandard DS-TE Mode**

Prestandard DS-TE uses the Cisco proprietary mechanisms for RSVP signaling and IGP advertisements. This DS-TE mode does not interoperate with third-party vendor equipment. Note that prestandard DS-TE is enabled only after configuring the sub-pool bandwidth values on MPLS-enabled interfaces.

Prestandard Diff-Serve TE mode supports a single bandwidth constraint model a Russian Doll Model (RDM) with two bandwidth pools: global-pool and sub-pool.
TE class map is not used with Prestandard DS-TE mode.

Related Topics
   Configuring a Prestandard DS-TE Tunnel, on page 65
   Configure IETF DS-TE Tunnels: Example, on page 163

IETF DS-TE Mode

IETF DS-TE mode uses IETF-defined extensions for RSVP and IGP. This mode interoperates with third-party vendor equipment.

IETF mode supports multiple bandwidth constraint models, including RDM and MAM, both with two bandwidth pools. In an IETF DS-TE network, identical bandwidth constraint models must be configured on all nodes.

TE class map is used with IETF DS-TE mode and must be configured the same way on all nodes in the network.

Bandwidth Constraint Models

IETF DS-TE mode provides support for the RDM and MAM bandwidth constraints models. Both models support up to two bandwidth pools.

Cisco IOS XR software provides global configuration for the switching between bandwidth constraint models. Both models can be configured on a single interface to preconfigure the bandwidth constraints before swapping to an alternate bandwidth constraint model.

Note

NSF is not guaranteed when you change the bandwidth constraint model or configuration information.

By default, RDM is the default bandwidth constraint model used in both pre-standard and IETF mode.

Maximum Allocation Bandwidth Constraint Model

The MAM constraint model has the following characteristics:
   • Easy to use and intuitive.
   • Isolation across class types.
   • Simultaneously achieves isolation, bandwidth efficiency, and protection against QoS degradation.

Related Topics
   Configuring an IETF DS-TE Tunnel Using MAM, on page 69

Russian Doll Bandwidth Constraint Model

The RDM constraint model has these characteristics:
   • Allows greater sharing of bandwidth among different class types.
   • Ensures bandwidth efficiency simultaneously and protection against QoS degradation of all class types.
   • Specifies that it is used in conjunction with preemption to simultaneously achieve isolation across class-types such that each class-type is guaranteed its share of bandwidth, bandwidth efficiency, and protection against QoS degradation of all class types.
We recommend that RDM not be used in DS-TE environments in which the use of preemption is precluded. Although RDM ensures bandwidth efficiency and protection against QoS degradation of class types, it does not guarantee isolation across class types.

**Related Topics**

*Configuring an IETF DS-TE Tunnel Using RDM*, on page 67

### TE Class Mapping

Each of the eight available bandwidth values advertised in the IGP corresponds to a TE class. Because the IGP advertises only eight bandwidth values, there can be a maximum of only eight TE classes supported in an IETF DS-TE network.

TE class mapping must be exactly the same on all routers in a DS-TE domain. It is the responsibility of the operator to configure these settings properly as there is no way to automatically check or enforce consistency.

The operator must configure TE tunnel class types and priority levels to form a valid TE class. When the TE class map configuration is changed, tunnels already up are brought down. Tunnels in the down state, can be set up if a valid TE class map is found.

The default TE class and attributes are listed. The default mapping includes four class types.

### Flooding

Available bandwidth in all configured bandwidth pools is flooded on the network to calculate accurate constraint paths when a new TE tunnel is configured. Flooding uses IGP protocol extensions and mechanisms to determine when to flood the network with bandwidth.
Flooding Triggers

TE Link Management (TE-Link) notifies IGP for both global pool and sub-pool available bandwidth and maximum bandwidth to flood the network in these events:

- Periodic timer expires (this does not depend on bandwidth pool type).
- Tunnel origination node has out-of-date information for either available global pool or sub-pool bandwidth, causing tunnel admission failure at the midpoint.
- Consumed bandwidth crosses user-configured thresholds. The same threshold is used for both global pool and sub-pool. If one bandwidth crosses the threshold, both bandwidths are flooded.

Flooding Thresholds

Flooding frequently can burden a network because all routers must send out and process these updates. Infrequent flooding causes tunnel heads (tunnel-originating nodes) to have out-of-date information, causing tunnel admission to fail at the midpoints.

You can control the frequency of flooding by configuring a set of thresholds. When locked bandwidth (at one or more priority levels) crosses one of these thresholds, flooding is triggered.

Thresholds apply to a percentage of the maximum available bandwidth (the global pool), which is locked, and the percentage of maximum available guaranteed bandwidth (the sub-pool), which is locked. If, for one or more priority levels, either of these percentages crosses a threshold, flooding is triggered.

Note

Setting up a global pool TE tunnel can cause the locked bandwidth allocated to sub-pool tunnels to be reduced (and hence to cross a threshold). A sub-pool TE tunnel setup can similarly cause the locked bandwidth for global pool TE tunnels to cross a threshold. Thus, sub-pool TE and global pool TE tunnels can affect each other when flooding is triggered by thresholds.

Fast Reroute

Fast Reroute (FRR) provides link protection to LSPs enabling the traffic carried by LSPs that encounter a failed link to be rerouted around the failure. The reroute decision is controlled locally by the router connected to the failed link. The headend router on the tunnel is notified of the link failure through IGP or through RSVP. When it is notified of a link failure, the headend router attempts to establish a new LSP that bypasses the failure. This provides a path to reestablish links that fail, providing protection to data transfer.

FRR (link or node) is supported over sub-pool tunnels the same way as for regular TE tunnels. In particular, when link protection is activated for a given link, TE tunnels eligible for FRR are redirected into the protection LSP, regardless of whether they are sub-pool or global pool tunnels.

Note

The ability to configure FRR on a per-LSP basis makes it possible to provide different levels of fast restoration to tunnels from different bandwidth pools.

You should be aware of these requirements for the backup tunnel path:

- Backup tunnel must not pass through the element it protects.
• Primary tunnel and a backup tunnel should intersect at least at two points (nodes) on the path: point of local repair (PLR) and merge point (MP). PLR is the headend of the backup tunnel, and MP is the tailend of the backup tunnel.

Note
When you configure TE tunnel with multiple protection on its path and merge point is the same node for more than one protection, you must configure record-route for that tunnel.

Related Topics
Protecting MPLS Tunnels with Fast Reroute, on page 58

IS-IS IP Fast Reroute Loop-free Alternative
For bandwidth protection, there must be sufficient backup bandwidth available to carry primary tunnel traffic. Use the `ipfrr lfa` command to compute loop-free alternates for all links or neighbors in the event of a link or node failure. To enable node protection on broadcast links, IPRR and bidirectional forwarding detection (BFD) must be enabled on the interface under IS-IS.

Note
MPLS FRR and IPFRR cannot be configured on the same interface at the same time.

For information about configuring BFD, see Cisco IOS XR Interface and Hardware Configuration Guide for the Cisco CRS-1 Router.

MPLS-TE and Fast Reroute over Link Bundles
MPLS Traffic Engineering (TE) and Fast Reroute (FRR) are supported over bundle interfaces. MPLS-TE/FRR over virtual local area network (VLAN) interfaces is supported. Bidirectional forwarding detection (BFD) over VLAN is used as an FRR trigger to obtain less than 50 milliseconds of switchover time.

These link bundle types are supported for MPLS-TE/FRR:
• Over POS link bundles.
• Over Ethernet link bundles.
• Over VLANs over Ethernet link bundles.
• Number of links are limited to 100 for MPLS-TE and FRR.
• VLANs go over any Ethernet interface (for example, GigabitEthernet, TenGigE, and FastEthernet, so forth).

FRR is supported over bundle interfaces in the following ways:
• Uses minimum links as a threshold to trigger FRR over a bundle interface.
• Uses the minimum total available bandwidth as a threshold to trigger FRR.
Ignore Intermediate System-to-Intermediate System Overload Bit Setting in MPLS-TE

The Ignore Intermediate System-to-Intermediate System (IS-IS) overload bit avoidance feature allows network administrators to prevent RSVP-TE label switched paths (LSPs) from being disabled, when a router in that path has its Intermediate System-to-Intermediate System (IS-IS) overload bit set.

The IS-IS overload bit avoidance feature is activated using this command:

```plaintext
mpls traffic-eng path-selection ignore overload
```

The IS-IS overload bit avoidance feature is deactivated using the `no` form of this command:

```plaintext
no mpls traffic-eng path-selection ignore overload
```

When the IS-IS overload bit avoidance feature is activated, all nodes, including head nodes, mid nodes, and tail nodes, with the overload bit set, are ignored. This means that they are still available for use with RSVP-TE label switched paths (LSPs). This feature enables you to include an overloaded node in CSPF.

**Enhancement Options of IS-IS OLA**

You can restrict configuring IS-IS overload bit avoidance with the following enhancement options:

- **path-selection ignore overload head**
  - The tunnels stay up if `set-overload-bit` is set by IS-IS on the head router. Ignores overload during CSPF for LSPs originating from an overloaded node. In all other cases (mid, tail, or both), the tunnel stays down.

- **path-selection ignore overload mid**
  - The tunnels stay up if `set-overload-bit` is set by IS-IS on the mid router. Ignores overload during CSPF for LSPs transiting from an overloaded node. In all other cases (head, tail, or both), the tunnel stays down.

- **path-selection ignore overload tail**
  - The tunnels stay up if `set-overload-bit` is set by IS-IS on the tail router. Ignores overload during CSPF for LSPs terminating at an overloaded node. In all other cases (head, mid, or both), the tunnel stays down.

- **path-selection ignore overload**
  - The tunnels stay up irrespective of on which router the `set-overload-bit` is set by IS-IS.

**Note**

When you do not select any of the options, including head nodes, mid nodes, and tail nodes, you get a behavior that is applicable to all nodes. This behavior is backward compatible in nature.

For more information related to IS-IS overload avoidance related commands, see *MPLS Command Reference for the Cisco CRS Router*.

**Related Topics**

- Configuring the Ignore Integrated IS-IS Overload Bit Setting in MPLS-TE, on page 73
- Configure the Ignore IS-IS Overload Bit Setting in MPLS-TE: Example, on page 164
**DWDM Transponder Integration**

A GMPLS UNI based solution preserves all the advantages of the integration of the DWDM transponder into the router blade. These advantages include:

- improved CAPEX and OPEX models
- component, space and power savings
- improved IP availability through pro-active protection.

**GMPLS Benefits**

GMPLS bridges the IP and photonic layers, thereby making possible interoperable and scalable parallel growth in the IP and photonic dimensions.

This allows for rapid service deployment and operational efficiencies, as well as for increased revenue opportunities. A smooth transition becomes possible from a traditional segregated transport and service overlay model to a more unified peer model.

By streamlining support for multiplexing and switching in a hierarchical fashion, and by utilizing the flexible intelligence of MPLS-TE, optical switching GMPLS becomes very helpful for service providers wanting to manage large volumes of traffic in a cost-efficient manner.

**GMPLS Support**

GMPLS-TE provides support for:

- Open Shortest Path First (OSPF) for bidirectional TE tunnel
- Frame, lambda, and port (fiber) labels
- Numbered or Unnumbered links
- OSPF extensions–Route computation with optical constraints
- RSVP extensions–Graceful Restart
- Graceful deletion
- LSP hierarchy
- Peer model
- Border model Control plane separation
- Interarea or AS-Verbatim
- BGP4 or MPLS
- Restoration–Dynamic path computation
- Control channel manager
- Link summary
- Protection and restoration
GMPLS Protection and Restoration

GMPLS provides protection against failed channels (or links) between two adjacent nodes (span protection) and end-to-end dedicated protection (path protection). After the route is computed, signaling to establish the backup paths is carried out through RSVP-TE or CR-LDP. For span protection, 1+1 or M:N protection schemes are provided by establishing secondary paths through the network. In addition, you can use signaling messages to switch from the failed primary path to the secondary path.

Note
Only 1:1 end-to-end path protection is supported.

The restoration of a failed path refers to the dynamic establishment of a backup path. This process requires the dynamic allocation of resources and route calculation. The following restoration methods are described:

- Line restoration—Finds an alternate route at an intermediate node.
- Path restoration—Initiates at the source node to route around a failed path within the path for a specific LSP.

Restoration schemes provide more bandwidth usage, because they do not preallocate any resource for an LSP. GMPLS combines MPLS-FRR and other types of protection, such as SONET/SDH and wavelength.

In addition to SONET alarms in POS links, protection and restoration is also triggered by bidirectional forwarding detection (BFD).

1:1 LSP Protection

When one specific protecting LSP or span protects one specific working LSP or span, 1:1 protection scheme occurs. However, normal traffic is transmitted only over one LSP at a time for working or recovery.

1:1 protection with extra traffic refers to the scheme in which extra traffic is carried over a protecting LSP when the protecting LSP is not being used for the recovery of normal traffic. For example, the protecting LSP is in standby mode. When the protecting LSP is required to recover normal traffic from the failed working LSP, the extra traffic is preempted. Extra traffic is not protected, but it can be restored. Extra traffic is transported using the protected LSP resources.

Shared Mesh Restoration and M:N Path Protection

Both shared mesh restoration and M:N (1:N is more practical) path protection offers sharing for protection resources for multiple working LSPs. For 1:N protection, a specific protecting LSP is dedicated to the protection of up to N working LSPs and spans. Shared mesh is defined as preplanned LSP rerouting, which reduces the restoration resource requirements by allowing multiple restoration LSPs to be initiated from distinct ingress nodes to share common resources, such as links and nodes.

End-to-end Recovery

End-to-end recovery refers to an entire LSP from the source for an ingress router endpoint to the destination for an egress router endpoint.
GMPLS Protection Requirements

The GMPLS protection requirements are specific to the protection scheme that is enabled at the data plane. For example, SONET APS or MPLS-FRR are identified as the data level for GMPLS protection.

GMPLS Prerequisites

The following prerequisites are required to implement GMPLS on Cisco IOS XR software:

• You must be in a user group associated with a task group that includes the proper task IDs for GMPLS commands.

• Router that runs Cisco IOS XR software.

• Installation of the Cisco IOS XR software mini-image on the router.

Flexible Name-based Tunnel Constraints

MPLS-TE Flexible Name-based Tunnel Constraints provides a simplified and more flexible means of configuring link attributes and path affinities to compute paths for MPLS-TE tunnels.

In the traditional TE scheme, links are configured with attribute-flags that are flooded with TE link-state parameters using Interior Gateway Protocols (IGPs), such as Open Shortest Path First (OSPF).

MPLS-TE Flexible Name-based Tunnel Constraints lets you assign, or map, up to 32 color names for affinity and attribute-flag attributes instead of 32-bit hexadecimal numbers. After mappings are defined, the attributes can be referred to by the corresponding color name in the command-line interface (CLI). Furthermore, you can define constraints using include, include-strict, exclude, and exclude-all arguments, where each statement can contain up to 10 colors, and define include constraints in both loose and strict sense.

You can configure affinity constraints using attribute flags or the Flexible Name Based Tunnel Constraints scheme; however, when configurations for both schemes exist, only the configuration pertaining to the new scheme is applied.

MPLS Traffic Engineering Interarea Tunneling

These topics describe the following new extensions of MPLS-TE:

• Interarea Support, on page 18

• Multiarea Support, on page 18

• Loose Hop Expansion, on page 19

• Loose Hop Reoptimization, on page 19
Interarea Support

The MPLS-TE interarea tunneling feature allows you to establish P2P and P2MP TE tunnels spanning multiple Interior Gateway Protocol (IGP) areas and levels, thereby eliminating the requirement that headend and tailend routers reside in a single area.

Interarea support allows the configuration of a TE LSP that spans multiple areas, where its headend and tailend label switched routers (LSRs) reside in different IGP areas.

Multiarea and Interarea TE are required by the customers running multiple IGP area backbones (primarily for scalability reasons). This lets you limit the amount of flooded information, reduces the SPF duration, and lessens the impact of a link or node failure within an area, particularly with large WAN backbones split in multiple areas.

Figure 3: Interarea (OSPF) TE Network Diagram

This figure shows a typical interarea TE network.

Multiarea Support

Multiarea support allows an area border router (ABR) LSR to support MPLS-TE in more than one IGP area. A TE LSP is still confined to a single area.

Multiarea and Interarea TE are required when you run multiple IGP area backbones. The Multiarea and Interarea TE allows you to:

- Limit the volume of flooded information.
- Reduce the SPF duration.
- Decrease the impact of a link or node failure within an area.
As shown in the figure, R2, R3, R7, and R4 maintain two databases for routing and TE information. For example, R3 has TE topology information related to R2, flooded through Level-1 IS-IS LSPs plus the TE topology information related to R4, R9, and R7, flooded as Level 2 IS-IS Link State PDUs (LSPs) (plus, its own IS-IS LSP).

**Note**

You can configure multiple areas within an IS-IS Level 1. This is transparent to TE. TE has topology information about the IS-IS level, but not the area ID.

**Loose Hop Expansion**

Loose hop optimization allows the reoptimization of tunnels spanning multiple areas and solves the problem which occurs when an MPLS-TE LSP traverses hops that are not in the LSP’s headend's OSPF area and IS-IS level.

Interarea MPLS-TE allows you to configure an interarea traffic engineering (TE) label switched path (LSP) by specifying a loose source route of ABRs along the path. It is the then the responsibility of the ABR (having a complete view of both areas) to find a path obeying the TE LSP constraints within the next area to reach the next hop ABR (as specified on the headend). The same operation is performed by the last ABR connected to the tailend area to reach the tailend LSR.

For P2MP-TE tunnels, ABRs support loose hop ERO expansion to find path to the next ABR until it reaches to the tail-end LSR, without introducing remerge.

You must be aware of these considerations when using loose hop optimization:

- You must specify the router ID of the ABR node (as opposed to a link address on the ABR).
- When multiarea is deployed in a network that contains subareas, you must enable MPLS-TE in the subarea for TE to find a path when loose hop is specified.
- You must specify the reachable explicit path for the interarea tunnel.

**Loose Hop Reoptimization**

Loose hop reoptimization allows the reoptimization of the tunnels spanning multiple areas and solves the problem which occurs when an MPLS-TE headend does not have visibility into other IGP areas.

Whenever the headend attempts to reoptimize a tunnel, it tries to find a better path to the ABR in the headend area. If a better path is found then the headend initiates the setup of a new LSP. In case a suitable path is not found in the headend area, the headend initiates a querying message. The purpose of this message is to query
the ABRs in the areas other than the headend area to check if there exist any better paths in those areas. The purpose of this message is to query the ABRs in the areas other than the headend area, to check if a better path exists. If a better path does not exist, ABR forwards the query to the next router downstream. Alternatively, if better path is found, ABR responds with a special Path Error to the headend to indicate the existence of a better path outside the headend area. Upon receiving the Path Error that indicates the existence of a better path, the headend router initiates the reoptimization.

**ABR Node Protection**

Because one IGP area does not have visibility into another IGP area, it is not possible to assign backup to protect ABR node. To overcome this problem, node ID sub-object is added into the record route object of the primary tunnel so that at a PLR node, backup destination address can be checked against primary tunnel record-route object and assign a backup tunnel.

**Fast Reroute Node Protection**

If a link failure occurs within an area, the upstream router directly connected to the failed link generates an RSVP path error message to the headend. As a response to the message, the headend sends an RSVP path tear message and the corresponding path option is marked as invalid for a specified period and the next path-option (if any) is evaluated.

To retry the ABR immediately, a second path option (identical to the first one) should be configured. Alternatively, the retry period (path-option hold-down, 2 minutes by default) can be tuned to achieve a faster retry.

**Related Topics**

Protecting MPLS Tunnels with Fast Reroute, on page 58

**Make-Before-Break**

The MPLS TE Make-Before-Break (MBB) explicit path and path option feature allows tunnels whose explicit paths or path options are modified to be reoptimized without losing any data. An explicit path or a path option modification is entirely configuration driven. Any change to an in-use path option or an in-use explicit path of a tunnel triggers the MBB procedure.

MBB lets the LSP hold on to the existing resources until the new path is successfully established and traffic has been directed over to the new LSP before the original LSP is torn down. This ensures that no data packets are lost during the transition to the new LSP.

With this feature the flapping of tunnels whose explicit paths or path options are modified, is avoided. This feature is enabled by default.

**MPLS-TE Forwarding Adjacency**

The MPLS-TE Forwarding Adjacency feature allows a network administrator to handle a traffic engineering, label-switched path (LSP) tunnel as a link in an Interior Gateway Protocol (IGP) network based on the Shortest Path First (SPF) algorithm. A forwarding adjacency can be created between routers regardless of their location in the network.
MPLS-TE Forwarding Adjacency Benefits

TE tunnel interfaces are advertised in the IGP network just like any other links. Routers can then use these advertisements in their IGPs to compute the SPF even if they are not the head end of any TE tunnels.

Related Topics
- Configuring MPLS-TE Forwarding Adjacency, on page 101
- Configure Forwarding Adjacency: Example, on page 170

MPLS-TE Forwarding Adjacency Restrictions

The MPLS-TE Forwarding Adjacency feature has these restrictions:

- Using the MPLS-TE Forwarding Adjacency increases the size of the IGP database by advertising a TE tunnel as a link.
- The MPLS-TE Forwarding Adjacency is supported by Intermediate System-to-Intermediate System (IS-IS).
- When the MPLS-TE Forwarding Adjacency is enabled on a TE tunnel, the link is advertised in the IGP network as a Type-Length-Value (TLV) 22 without any TE sub-TLV.
- MPLS-TE forwarding adjacency tunnels must be configured bidirectionally.
- Multicast intact is not supported with MPLS-TE Forwarding Adjacency.

MPLS-TE Forwarding Adjacency Prerequisites

Your network must support the following features before enabling the MPLS-TE Forwarding Adjacency feature:

- MPLS
- IP Cisco Express Forwarding
- Intermediate System-to-Intermediate System (IS-IS)
- OSPF

Unequal Load Balancing

Unequal load balancing permits the routing of unequal proportions of traffic through tunnels to a common destination. Load shares on tunnels to the same destination are determined by TE from the tunnel configuration and passed through the MPLS Label Switching Database (LSD) to the Forwarding Information Base (FIB).

Note

Load share values are renormalized by the FIB using values suitable for use by the forwarding code. The exact traffic ratios observed may not, therefore, exactly mirror the configured traffic ratios. This effect is more pronounced if there are many parallel tunnels to a destination, or if the load shares assigned to those tunnels are very different. The exact renormalization algorithm used is platform-dependent.

There are two ways to configure load balancing:
Explicit configuration

Using this method, load shares are explicitly configured on each tunnel.

Bandwidth configuration

If a tunnel is not configured with load-sharing parameters, the tunnel bandwidth and load-share values are considered equivalent for load-share calculations between tunnels, and a direct comparison between bandwidth and load-share configuration values is calculated.

Note
Load shares are not dependent on any configuration other than the load share and bandwidth configured on the tunnel and the state of the global configuration switch.

Path Computation Element

Path Computation Element (PCE) solves the specific issue of inter-domain path computation for MPLS-TE label switched path (LSPs), when the head-end router does not possess full network topology information (for example, when the head-end and tail-end routers of an LSP reside in different IGP areas).

PCE uses area border routers (ABRs) to compute a TE LSP spanning multiple IGP areas as well as computation of Inter-AS TE LSP.

PCE is usually used to define an overall architecture, which is made of several components, as follows:

Path Computation Element (PCE)

Represents a software module (which can be a component or application) that enables the router to compute paths applying a set of constraints between any pair of nodes within the router’s TE topology database. PCEs are discovered through IGP.

Path Computation Client (PCC)

Represents a software module running on a router that is capable of sending and receiving path computation requests and responses to and from PCEs. The PCC is typically an LSR (Label Switching Router).

PCC-PCE communication protocol (PCEP)

Specifies that PCEP is a TCP-based protocol defined by the IETF PCE WG, and defines a set of messages and objects used to manage PCEP sessions and to request and send paths for multi-domain TE LSPs. PCEP is used for communication between PCC and PCE (as well as between two PCEs) and employs IGP extensions to dynamically discover PCE.

Figure 5: Path Computation Element Network Diagram

This figure shows a typical PCE implementation.
Path computation elements provides support for the following message types and objects:

- Message types: Open, PCReq, PCRep, PCErr, Close
- Objects: OPEN, CLOSE, RP, END-POINT, LSPA, BANDWIDTH, METRIC, and NO-PATH

**Policy-Based Tunnel Selection**

These topics provide information about policy-based tunnel selection (PBTS):

**Policy-Based Tunnel Selection**

Policy-Based Tunnel Selection (PBTS) provides a mechanism that lets you direct traffic into specific TE tunnels based on different criteria. PBTS will benefit Internet service providers (ISPs) who carry voice and data traffic through their MPLS and MPLS/VPN networks, who want to route this traffic to provide optimized voice service.

PBTS works by selecting tunnels based on the classification criteria of the incoming packets, which are based on the IP precedence, experimental (EXP), or type of service (ToS) field in the packet. When there are no paths with a default class configured, this traffic is forwarded using the paths with the lowest class value. PBTS supports up to seven (exp 1 - 7) EXP values associated with a single TE tunnel.

**Figure 6: Policy-Based Tunnel Selection Implementation**

This figure illustrates a PBTS implementation.
Policy-Based Tunnel Selection Functions

The following PBTS functions are supported:

- IPv4 traffic arrives unlabeled on the VRF interface and the non-VRF interface.
- MPLS traffic is supported on the VRF interface and the non-VRF interface.
- Load balancing across multiple TE tunnels with the same traffic class attribute is supported.
- Selected TE tunnels are used to service the lowest tunnel class as default tunnels.
- LDP over TE tunnel and single-hop TE tunnel are supported.
- Both Interior Gateway Protocol (IGP) and Label Distribution Protocol (LDP) paths are used as the default path for all traffic that belongs to a class that is not configured on the TE tunnels.
- According to the quality-of-service (QoS) policy, tunnel selection is based on the outgoing experimental (EXP) value and the remarked EXP value.
- L2VPN preferred path selection lets traffic be directed to a particular TE tunnel.
- IPv6 traffic for both 6VPE and 6PE scenarios are supported.

Related Topics
Configuring Policy-based Tunnel Selection, on page 108

PBTS Restrictions

When implementing PBTS, the following restrictions are listed:

- When QoS EXP remarking on an interface is enabled, the EXP value is used to determine the egress tunnel interface, not the incoming EXP value.
- Egress-side remarking does not affect PBTS tunnel selection.
- When no default tunnel is available for forwarding, traffic is dropped.
Enabling Forward Class Zero in PBTS

This PBTS feature enhancement allows you to configure forward class zero or the default class as a PBTS forwarding class effective with Cisco IOS-XR release 6.4.1. Earlier, only values from one to seven were configurable as PBTS forwarding classes.

Set DF Bit

The Set DF Bit feature enables to apply 'set df (do not fragment)' policy to an interface. Any packet that matches with the set df policy will either clear the bit or set the bit.

The set df bit policy can be enabled to clear the df bit before forwarding the packet in IPv4 traffic.

For more information on Set DF Bit, see the Implementing MPLS Traffic Engineering chapter in the MPLS Configuration Guide for the Cisco CRS Routers. For more information on Set DF Bit commands, see the MPLS Traffic Engineering Commands chapter in the MPLS Command Reference for the Cisco CRS Router.

Path Protection

Path protection provides an end-to-end failure recovery mechanism (that is, a full path protection) for MPLS-TE tunnels. A secondary Label Switched Path (LSP) is established, in advance, to provide failure protection for the protected LSP that is carrying a tunnel's TE traffic. When there is a failure on the protected LSP, the source router immediately enables the secondary LSP to temporarily carry the tunnel's traffic. If there is a failure on the secondary LSP, the tunnel no longer has path protection until the failure along the secondary path is cleared. Path protection can be used within a single area (OSPF or IS-IS), external BGP [eBGP], and static routes.

The failure detection mechanisms triggers a switchover to a secondary tunnel by:

- Path error or resv-tear from Resource Reservation Protocol (RSVP) signaling
- Notification from the Bidirectional Forwarding Detection (BFD) protocol that a neighbor is lost
- Notification from the Interior Gateway Protocol (IGP) that the adjacency is down
- Local teardown of the protected tunnel's LSP due to preemption in order to signal higher priority LSPs, a Packet over SONET (POS) alarm, online insertion and removal (OIR), and so on

An alternate recovery mechanism is Fast Reroute (FRR), which protects MPLS-TE LSPs only from link and node failures, by locally repairing the LSPs at the point of failure. Co-existence of FRR and path protection is supported; this means FRR and path-protection can be configured on the same tunnel at the same time.

Although not as fast as link or node protection, presignaling a secondary LSP is faster than configuring a secondary primary path option, or allowing the tunnel's source router to dynamically recalculate a path. The actual recovery time is topology-dependent, and affected by delay factors such as propagation delay or switch fabric latency.

Related Topics

Configure Tunnels for Path Protection: Example, on page 172

Pre-requisites for Path Protection

These are the pre-requisites for enabling path protection:

- Ensure that your network supports MPLS-TE, Cisco Express Forwarding, and Intermediate System-to-Intermediate System (IS-IS) or Open Shortest Path First (OSPF).
• Enable MPLS.
• Configure TE on the routers.
• Configure a TE tunnel with a dynamic path option by using the \texttt{path-option} command with the \texttt{dynamic} keyword.

\textbf{Related Topics}

Configure Tunnels for Path Protection: Example, on page 172

\section*{Restrictions for Path Protection}

• Only Point-to-Point (P2P) tunnels are supported.
• Point-to-Multipoint (P2MP) TE tunnels are not supported.
• A maximum of one standby LSP is supported.
• There can be only one secondary path for each dynamic path option.
• Explicit path option can be configured for the path protected TE with the secondary path option as dynamic.
• A maximum number of path protected tunnel TE heads is 2000.
• A maximum number of TE tunnel heads is equal to 4000.
• When path protection is enabled for a tunnel, and the primary label switched path (LSP) is not assigned a backup tunnel, but the standby LSP is assigned fast-reroute (FRR), the MPLS TE FRR protected value displayed is different from the Cisco express forwarding (CEF) fast-reroute value.
• Inter-area is not supported for path protection.

\textbf{Related Topics}

Configure Tunnels for Path Protection: Example, on page 172

\section*{Restrictions for Explicit Path Protection}

Explicit paths are used to create backup autotunnels. Explicit path protection provides a recovery mechanism to protect explicit paths for MPLS-TE tunnels. These restrictions are listed to protect an explicit path:

• Only one explicit protecting path is supported per path-option.
• Link or node path diversity is not ensured for explicit protecting paths.
• An explicit protecting path cannot protect a dynamic path option.
• All options such as \texttt{verbatim}, \texttt{lockdown} are supported for the protecting path as long as it's explicit.
• An explicit path cannot be protected by its own path option level.
• An explicit path can be protected by a path option level that references the same explicit path name or identifier, because it is considered another path-option.
• Enhanced path protection is not supported.

\textbf{Related Topics}

Configure Tunnels for Path Protection: Example, on page 172
Co-existence of Path Protection with Fast Reroute

Path protection and FRR can be configured on the same tunnel at the same time. The co-existence of path protection and FRR on the same tunnel provides these benefits:

- Protection is expanded — having an FRR protected tunnel that is also path-protected ensures that failures of non-protected links on the primary path are handled more efficiently by a quick switch-over to the pre-signaled standby LSP.

- Quick and effective re-optimization — having a pre-computed standby LSP allows the system to minimize re-optimization LSP path calculation and signaling, by simply switching over to the pre-signaled standby LSP. Effectively, path protection switch over replaces the post-FRR LSP down event re-optimization.

- Total time on backup is reduced — handling FRR failure using a path protection switch over reduces total time on backup because the traffic is diverted from the backup to the standby, as soon as the head-end receives the FRR LSP down notification, without having to wait for a re-optimization LSP.

MPLS-TE Automatic Bandwidth

The MPLS-TE automatic bandwidth feature measures the traffic in a tunnel and periodically adjusts the signaled bandwidth for the tunnel.

These topics provide information about MPLS-TE automatic bandwidth:

**MPLS-TE Automatic Bandwidth Overview**

MPLS-TE automatic bandwidth is configured on individual Label Switched Paths (LSPs) at every head-end. MPLS-TE monitors the traffic rate on a tunnel interface. Periodically, MPLS-TE resizes the bandwidth on the tunnel interface to align it closely with the traffic in the tunnel. MPLS-TE automatic bandwidth can perform these functions:

- Monitors periodic polling of the tunnel output rate

- Resizes the tunnel bandwidth by adjusting the highest rate observed during a given period

For every traffic-engineered tunnel that is configured for an automatic bandwidth, the average output rate is sampled, based on various configurable parameters. Then, the tunnel bandwidth is readjusted automatically based upon either the largest average output rate that was noticed during a certain interval, or a configured maximum bandwidth value.

This table lists the automatic bandwidth functions.

**Table 2: Automatic Bandwidth Variables**

</tbody>
</table>

The output rate on a tunnel is collected at regular intervals that are configured by using the `application` command in MPLS-TE auto bandwidth interface configuration mode. When the application period timer expires, and when the difference between the measured and the current bandwidth exceeds the adjustment threshold, the tunnel is reoptimized. Then, the bandwidth samples are cleared to record the new largest output rate at the next interval.

When reoptimizing the LSP with the new bandwidth, a new path request is generated. If the new bandwidth is not available, the last good LSP continues to be used. This way, the network experiences no traffic interruptions.

If minimum or maximum bandwidth values are configured for a tunnel, the bandwidth, which the automatic bandwidth signals, stays within these values.

**Note**
When more than 100 tunnels are **auto-bw** enabled, the algorithm will jitter the first application of every tunnel by a maximum of 20% (max 1 hour). The algorithm does this to avoid too many tunnels running auto bandwidth applications at the same time.

If a tunnel is shut down, and is later brought again, the adjusted bandwidth is lost and the tunnel is brought back with the initial configured bandwidth. In addition, the application period is reset when the tunnel is brought back.

**Related Topics**
- Configuring the Collection Frequency, on page 109
- Configuring the Automatic Bandwidth Functions, on page 111
- Configure Automatic Bandwidth: Example, on page 173

**Adjustment Threshold**

Adjustment Threshold is defined as a percentage of the current tunnel bandwidth and an absolute (minimum) bandwidth. Both thresholds must be fulfilled for the automatic bandwidth to resignal the tunnel. The tunnel bandwidth is resized only if the difference between the largest sample output rate and the current tunnel bandwidth is larger than the adjustment thresholds.

For example, assume that the automatic bandwidth is enabled on a tunnel in which the highest observed bandwidth B is 30 Mbps. Also, assume that the tunnel was initially configured for 45 Mbps. Therefore, the difference is 15 mbit/s. Now, assuming the default adjustment thresholds of 10% and 10kbps, the tunnel is
signalled with 30 Mbps when the application timer expires. This is because 10% of 45Mbit/s is 4.5 Mbit/s, which is smaller than 15 Mbit/s. The absolute threshold, which by default is 10kbps, is also crossed.

Overflow Detection

Overflow detection is used if a bandwidth must be resized as soon as an overflow condition is detected, without having to wait for the expiry of an automatic bandwidth application frequency interval.

For overflow detection one configures a limit N, a percentage threshold Y% and optionally, a minimum bandwidth threshold Z. The percentage threshold is defined as the percentage of the actual signalled tunnel bandwidth. When the difference between the measured bandwidth and the actual bandwidth are both larger than Y% and Z threshold, for N consecutive times, then the system triggers an overflow detection.

The bandwidth adjustment by the overflow detection is triggered only by an increase of traffic volume through the tunnel, and not by a decrease in the traffic volume. When you trigger an overflow detection, the automatic bandwidth application interval is reset.

By default, the overflow detection is disabled and needs to be manually configured.

Underflow Detection

Underflow detection is used when the bandwidth on a tunnel drops significantly, which is similar to overflow but in reverse.

Underflow detection applies the highest bandwidth value from the samples which triggered the underflow. For example, if you have an underflow limit of three, and the following samples trigger the underflow for 10 kbps, 20 kbps, and 15 kbps, then, 20 kbps is applied.

Unlike overflow, the underflow count is not reset across an application period. For example, with an underflow limit of three, you can have the first two samples taken at the end of an application period and then the underflow gets triggered by the first sample of the next application period.

Restrictions for MPLS-TE Automatic Bandwidth

When the automatic bandwidth cannot update the tunnel bandwidth, the following restrictions are listed:

- Tunnel is in a fast reroute (FRR) backup, active, or path protect active state. This occurs because of the assumption that protection is a temporary state, and there is no need to reserve the bandwidth on a backup tunnel. You should prevent taking away the bandwidth from other primary or backup tunnels.

- Reoptimization fails to occur during a lockdown. In this case, the automatic bandwidth does not update the bandwidth unless the bandwidth application is manually triggered by using the `mpls traffic-eng auto-bw apply` command in EXEC mode.

Forcing the Current Application Period to Expire Immediately, on page 110

Point-to-Multipoint Traffic-Engineering

Point-to-Multipoint Traffic-Engineering Overview

The Point-to-Multipoint (P2MP) Resource Reservation Protocol-Traffic Engineering (RSVP-TE) solution allows service providers to implement IP multicast applications, such as IPTV and real-time video, broadcast
over the MPLS label switch network. The RSVP-TE protocol is extended to signal point-to-point (P2P) and P2MP label switched paths (LSPs) across the MPLS and GMPLS networks.

By using RSVP-TE extensions as defined in RFC 4875, multiple subLSPs are signaled for a given TE source. The P2MP tunnel is considered as a set of Source-to-Leaf (S2L) subLSPs that connect the TE source to multiple leaf Provider Edge (PE) nodes.

At the TE source, the ingress point of the P2MP-TE tunnel, IP multicast traffic is encapsulated with a unique MPLS label, which is associated with the P2MP-TE tunnel. The traffic continues to be label-switched in the P2MP tree. If needed, the labeled packet is replicated at branch nodes along the P2MP tree. When the labeled packet reaches the egress leaf (PE) node, the MPLS label is removed and forwarded onto the IP multicast tree across the PE-CE link.

To enable end-to-end IP multicast connectivity, RSVP is used in the MPLS-core for P2MP-TE signaling and PIM is used for PE-CE link signaling.

- All edge routers are running PIM-SSM or Source-Specific Multicast (SSM) to exchange multicast routing information with the directly-connected Customer Edge (CE) routers.
- In the MPLS network, RSVP P2MP-TE replaces PIM as the tree building mechanism, RSVP-TE grafts or prunes a given P2MP tree when the end-points are added or removed in the TE source configuration (explicit user operation).

These are the definitions for Point-to-Multipoint (P2MP) tunnels:

**Source**

Configures the node in which Label Switched Path (LSP) signaling is initiated.

**Mid-point**

Specifies the transit node in which LSP signaling is processed (for example, not a source or receiver).

**Receiver, Leaf, and Destination**

Specifies the node in which LSP signaling ends.

**Branch Point**

Specifies the node in which packet replication is performed.

**Source-to-Leaf (S2L) SubLSP**

Specifies the P2MP-TE LSP segment that runs from the source to one leaf.

**Point-to-Multipoint Traffic-Engineering Features**

- P2MP RSVP-TE (RFC 4875) is supported. RFC 4875 is based on nonaggregate signaling; for example, per S2L signaling. Only P2M LSP is supported.

- `interface tunnel-mte` command identifies the P2MP interface type.

- P2MP tunnel setup is supported with label replication.

- Fast-Reroute (FRR) protection is supported with sub-50 msec for traffic loss.

- Explicit routing is supported by using under utilized links.

- Reoptimization is supported by calculating a better set of paths to the destination with no traffic loss.
**Note**

Per-S2L reoptimization is not supported.

- IPv4 and IPv6 payloads are supported.
- IPv4 and IPv6 multicast forwarding are supported on a P2MP tunnel interface through a static IGMP and MLD group configuration.
- Both IP multicast and P2MP Label Switch Multicast (LSM) coexist in the same network; therefore, both use the same forwarding plane (LFIB or MPLS Forwarding Infrastructure [MFI]).
- P2MP label replication supports only Source-Specific Multicast (SSM) traffic. SSM configuration supports the default value, none.
- Static mapping for multicast groups to the P2MP-TE tunnel is required.

**Point-to-Multipoint Traffic-Engineering Benefits**

- Single point of traffic control ensures that signaling and path engineering parameters (for example, protection and diversity) are configured only at the TE source node.
- Ability to configure explicit paths to enable optimized traffic distribution and prevention of single point of failures in the network.
- Link protection of MPLS-labeled traffic traversing branch paths of the P2MP-TE tree.
- Ability to do bandwidth Admission Control (AC) during set up and signaling of P2MP-TE paths in the MPLS network.

**Point-to-Multipoint RSVP-TE**

RSVP-TE signals a P2MP tunnel base that is based on a manual configuration. If all Source-to-Leaf (S2L)s use an explicit path, the P2MP tunnel creates a static tree that follows a predefined path based on a constraint such as a deterministic Label Switched Path (LSP). If the S2L uses a dynamic path, RSVP-TE creates a P2MP tunnel base on the best path in the RSVP-TE topology. RSVP-TE supports bandwidth reservation for constraint-based routing.

When an explicit path option is used, specify both the local and peer IP addresses in the explicit path option, provided the link is a GigabitEthernet or a TenGigE based interface. For point-to-point links like POS or bundle POS, it is sufficient to mention the remote or peer IP address in the explicit path option.
RSVP-TE distributes stream information in which the topology tree does not change often (where the source and receivers are). For example, large scale video distribution between major sites is suitable for a subset of multicast applications. Because multicast traffic is already in the tunnel, the RSVP-TE tree is protected as long as you build a backup path.

Fast-Reroute (FRR) capability is supported for P2MP RSVP-TE by using the unicast link protection. You can choose the type of traffic to go to the backup link.

The P2MP tunnel is applicable for all TE Tunnel destination (IntraArea and InterArea). Inter-AS is not supported.

The P2MP tunnel is signaled by the dynamic and explicit path option in the IGP intra area. Only interArea and interAS, which are used for the P2MP tunnels, are signaled by the verbatim path option.

### Point-to-Multipoint Fast Reroute

MPLS-TE Fast Reroute (FRR) is a mechanism to minimize interruption in traffic delivery to a TE Label Switched Path (LSP) destination as a result of link failures. FRR enables temporarily fast switching of LSP traffic along an alternative backup path around a network failure, until the TE tunnel source signals a new end-to-end LSP.

Both Point-to-Point (P2P) and P2MP-TE support only the Facility FRR method from RFC 4090.

P2P LSPs are used to backup P2MP S2L (source 2 Leaf). Only link and bandwidth protection for P2MP S2Ls are supported. Node protection is not supported.

MPLS-TE link protection relies on the fact that labels for all primary LSPs and subLSPs are using the MPLS global label allocation. For example, one single (global) label space is used for all MPLS-TE enabled physical interfaces on a given MPLS LSP.

### Point-to-Multipoint Label Switch Path

The Point-to-Multipoint Label Switch Path (P2MP LSP) has only a single root, which is the Ingress Label Switch Router (LSR). The P2MP LSP is created based on a receiver that is connected to the Egress LSR. The Egress LSR initiates the creation of the tree (for example, tunnel grafting or pruning is done by performing an individual sub-LSP operation) by creating the Forwarding Equivalency Class (FEC) and Opaque Value.

**Note**

Grafting and pruning operate on a per destination basis.

The Opaque Value contains the stream information that uniquely identifies the tree to the root. To receive label switched multicast packets, the Egress Provider Edge (PE) indicates to the upstream router (the next hop closest to the root) which label it uses for the multicast source by applying the label mapping message.
The upstream router does not need to have any knowledge of the source; it needs only the received FEC to identify the correct P2MP LSP. If the upstream router does not have any FEC state, it creates it and installs the assigned downstream outgoing label into the label forwarding table. If the upstream router is not the root of the tree, it must forward the label mapping message to the next hop upstream. This process is repeated hop-by-hop until the root is reached.

By using downstream allocation, the router that wants to receive the multicast traffic assigns the label for it. The label request, which is sent to the upstream router, is similar to an unsolicited label mapping (that is, the upstream does not request it). The upstream router that receives that label mapping uses the specific label to send multicast packets downstream to the receiver. The advantage is that the router, which allocates the labels, does not get into a situation where it has the same label for two different multicast sources. This is because it manages its own label space allocation locally.

Path Option for Point-to-Multipoint RSVP-TE

P2MP tunnels are signaled by using the dynamic and explicit path-options in an IGP intra area. InterArea cases for P2MP tunnels are signaled by the verbatim path option.

Path options for P2MP tunnels are individually configured for each sub-LSP. Only one path option per sub-LSP (destination) is allowed. You can choose whether the corresponding sub-LSP is dynamically or explicitly routed. For the explicit option, you can configure the verbatim path option to bypass the topology database lookup and verification for the specified destination.

Both dynamic and explicit path options are supported on a per destination basis by using the path-option (P2MP-TE) command. In addition, you can combine both path options.

Explicit Path Option

Configures the intermediate hops that are traversed by a sub-LSP going from the TE source to the egress MPLS node. Although an explicit path configuration enables granular control sub-LSP paths in an MPLS network, multiple explicit paths are configured for specific network topologies with a limited number of (equal cost) links or paths.

Dynamic Path Option

Computes the IGP path of a P2MP tree sub-LSP that is based on the OSPF and ISIS algorithm. The TE source is dynamically calculated based on the IGP topology.

Note

Dynamic path option can only compute fully-diverse standby paths. While, explicit path option supports partially diverse standby paths as well.

Dynamic Path Calculation Requirements

Dynamic path calculation for each sub-LSP uses the same path parameters as those for the path calculation of regular point-to-point TE tunnels. As part of the sub-LSP path calculation, the link resource (bandwidth) is included, which is flooded throughout the MPLS network through the existing RSVP-TE extensions to OSPF and ISIS. Instead of dynamic calculated paths, explicit paths are also configured for one or more sub-LSPs that are associated with the P2MP-TE tunnel.

- OSPF or ISIS are used for each destination.
- TE topology and tunnel constraints are used to input the path calculation.
- Tunnel constraints such as affinity, bandwidth, and priorities are used for all destinations in a tunnel.
• Path calculation yields an explicit route to each destination.

**Static Path Calculation Requirements**

The static path calculation does not require any new extensions to IGP to advertise link availability.

• Explicit path is required for every destination.
• Offline path calculation is used.
• TE topology database is not needed.
• If the topology changes, reoptimization is not required.

**MPLS Traffic Engineering Shared Risk Link Groups**

Shared Risk Link Groups (SRLG) in MPLS traffic engineering refer to situations in which links in a network share a common fiber (or a common physical attribute). These links have a shared risk, and that is when one link fails, other links in the group might fail too.

OSPF and Intermediate System-to-Intermediate System (IS-IS) flood the SRLG value information (including other TE link attributes such as bandwidth availability and affinity) using a sub-type length value (sub-TLV), so that all routers in the network have the SRLG information for each link.

To activate the SRLG feature, configure the SRLG value of each link that has a shared risk with another link. A maximum of 30 SRLGs per interface is allowed. You can configure this feature on multiple interfaces including the bundle interface.

**Figure 7: Shared Risk Link Group** illustrates the MPLS TE SRLG values configured on the bundle interface.
Explicit Path

The Explicit Path configuration allows you to configure the explicit path. An IP explicit path is a list of IP addresses, each representing a node or link in the explicit path.

The MPLS Traffic Engineering (TE)—IP Explicit Address Exclusion feature provides a means to exclude a link or node from the path for an Multiprotocol Label Switching (MPLS) TE label-switched path (LSP).

This feature is enabled through the `explicit-path` command that allows you to create an IP explicit path and enter a configuration submode for specifying the path. The feature adds to the submode commands of the `exclude-address` command for specifying addresses to exclude from the path.

The feature also adds to the submode commands of the `exclude-srlg` command that allows you to specify the IP address to get SRLG values to be excluded from the explicit path.

If the excluded address or excluded srlg for an MPLS TE LSP identifies a flooded link, the constraint-based shortest path first (CSPF) routing algorithm does not consider that link when computing paths for the LSP. If the excluded address specifies a flooded MPLS TE router ID, the CSPF routing algorithm does not allow paths for the LSP to traverse the node identified by the router ID.

Fast ReRoute with SRLG Constraints

Fast ReRoute (FRR) protects MPLS TE Label Switch Paths (LSPs) from link and node failures by locally repairing the LSPs at the point of failure. This protection allows data to continue to flow on LSPs, while their headend routers attempt to establish new end-to-end LSPs to replace them. FRR locally repairs the protected LSPs by rerouting them over backup tunnels that bypass failed links or nodes.

Backup tunnels that bypass only a single link of the LSP's path provide Link Protection. They protect LSPs by specifying the protected link IP addresses to extract SRLG values that are to be excluded from the explicit path, thereby bypassing the failed link. These are referred to as next-hop (NHOP) backup tunnels because they terminate at the LSP's next hop beyond the point of failure. Figure 8: NHOP Backup Tunnel with SRLG constraint illustrates an NHOP backup tunnel.
In the topology shown in the above figure, the backup tunnel path computation can be performed in this manner:

- Get all SRLG values from the exclude-SRLG link (SRLG values 5 and 6)
- Mark all the links with the same SRLG value to be excluded from SPF
- Path computation as CSPF R2->R6->R7->R3

FRR provides Node Protection for LSPs. Backup tunnels that bypass next-hop nodes along LSP paths are called **NNHOP backup tunnels** because they terminate at the node following the next-hop node of the LSP paths, thereby bypassing the next-hop node. They protect LSPs when a node along their path fails, by enabling the node upstream to the point of failure to reroute the LSPs and their traffic, around the failed node to the next-next hop. They also protect LSPs by specifying the protected link IP addresses that are to be excluded from the explicit path, and the SRLG values associated with the IP addresses excluded from the explicit path. NNHOP backup tunnels also provide protection from link failures by bypassing the failed link as well as the node. **Figure 9: NNHOP Backup Tunnel with SRLG constraint** illustrates an NNHOP backup tunnel.
In the topology shown in the above figure, the backup tunnel path computation can be performed in this manner:

- Get all SRLG values from the exclude-SRLG link (SRLG values 5 and 6)
- Mark all links with the same SRLG value to be excluded from SPF
- Verify path with SRLG constraint
- Path computation as CSPF R2->R9->R10->R4

Multiple Backup Tunnels Protecting the Same Interface

- Redundancy—If one backup tunnel is down, other backup tunnels protect LSPs.
- Increased backup capacity—If the protected interface is a high-capacity link and no single backup path exists with an equal capacity, multiple backup tunnels can protect that one high-capacity link. The LSPs using this link fall over to different backup tunnels, allowing all of the LSPs to have adequate bandwidth protection during failure (rerouting). If bandwidth protection is not desired, the router spreads LSPs across all available backup tunnels (that is, there is load balancing across backup tunnels).

SRLG Limitations

There are few limitations to the configured SRLG feature:

- The exclude-address and exclude-srlg options are not allowed in the IP explicit path strict-address network.
- Whenever SRLG values are modified after tunnels are signalled, they are verified dynamically in the next path verification cycle.

Soft-Preemption

MPLS-TE preemption consists of freeing the resources of an established LSP, and assigning them to a new LSP. The freeing of resources causes a traffic disruption to the LSP that is being preemted. Soft preemption is an extension to the RSVP-TE protocol to minimize and even eliminate such traffic disruption over the preemted LSP.

The soft-preemption feature attempts to preempt the LSPs in a graceful manner to minimize or eliminate traffic loss. However, the link might be over-subscribed for a period of time.

In a network that implements soft preemption, zero traffic loss is achieved in this manner:

- When signaling a new LSP, the ingress router indicates to all the intermediate nodes that the existing LSP is to be softly preempted, in case its resources are needed and is to be reassigned.
- When a given intermediate node needs to soft-preempt the existing LSP, it sends a new or special path error (preemption pending) to the ingress router. The intermediate node does not dismantle the LSP and maintains its state.
- When the ingress router receives the path error (preemption pending) from the intermediate node, it immediately starts a re-optimization that avoids the link that caused the preemption.
- When the re-optimization is complete, the ingress router tears down the soft-preempted LSP.

Path Option Attributes

The path option attributes are configurable through a template configuration. This template, named attribute-set, is configured globally in the MPLS traffic-engineering mode.

You can apply an attribute-set to a path option on a per-LSP basis. The path option configuration is extended to take a path option attribute name. LSPs computed with a particular path option uses the attributes as specified by the attribute-set under that path option.
These prerequisites are required to implement path option attributes:

- Path option type attribute-set is configured in the MPLS TE mode
- Path option CLI extended to accept an attribute-set name

---

**Note**
The `signalled-bandwidth` and `affinity` attributes are supported under the attribute-set template.

---

**Related Topics**
Configuring Attributes within a Path-Option Attribute, on page 134

---

**Configuration Hierarchy of Path Option Attributes**

You can specify a value for an attribute within a path option attribute-set template. This does not prevent the configuring of the same attribute at a tunnel level. However, it is important to note that only one level is taken into account. So, the configuration at the LSP level is considered more specific than the one at the level of the tunnel, and it is used from this point onwards.

Attributes that are not specified within an attribute-set take their values as usual—configuration at the tunnel level, configuration at the global MPLS level, or default values. Here is an example:

```plaintext
attribute-set path-option MYSET  
  affinity 0xBEEF mask 0xBEEF

interface tunnel-te 10  
  affinity 0xCAFE mask 0xCAFE  
  signalled-bandwidth 1000  
  path-option 1 dynamic attribute-set name MYSET  
  path-option 2 dynamic
```

In this example, the attribute-set named `MYSET` is specifying affinity as 0xBEEF. The signalled bandwidth has not been configured in this `MYSET`. The tunnel 10, meanwhile, has affinity 0xCAFE configured. LSPs computed from path-option 1 uses the affinity 0xBEEF/0xBEEF, while LSPs computed from path-option 2 uses the affinity 0xCAFE/0xCAFE. All LSPs computed using any of these path-options use `signalled-bandwidth` as 1000, as this is the only value that is specified only at the tunnel level.

---

**Note**
The attributes configured in a path option attribute-set template takes precedence over the same attribute configured under a tunnel. An attribute configured under a tunnel is used only if the equivalent attribute is not specified by the in-use path option attribute-set template.

---

**Related Topics**
Configuring Attributes within a Path-Option Attribute, on page 134

---

**Traffic Engineering Bandwidth and Bandwidth Pools**

MPLS traffic engineering allows constraint-based routing (CBR) of IP traffic. One of the constraints satisfied by CBR is the availability of required bandwidth over a selected path. Regular TE tunnel bandwidth is called the **global pool**. The **subpool bandwidth** is a portion of the global pool. If it is not in use, the subpool bandwidth is not reserved from the global pool. Therefore, subpool tunnels require a priority higher than that of non-subpool tunnels.
You can configure the signalled-bandwidth path option attribute to use either the global pool (default) or the subpool bandwidth. The signalled-bandwidth value for the path option may be any valid value and the pool does not have to be the same as that which is configured on the tunnel.

**Note**

When you configure signalled-bandwidth for path options with the `signalled-bandwidth bandwidth [sub-pool | global] kbps` command, use either all subpool bandwidths or all global-pool bandwidth values.

**Related Topics**

- Configuring Attributes within a Path-Option Attribute, on page 134

### Path Option Switchover

Reoptimization to a particular path option is not possible if the in-use path option and the new path option do not share the same bandwidth class. The path option switchover operation would fail in such a scenario. Use this command at the EXEC configuration mode to switchover to a newer path option:

```
mpls traffic-eng switchover tunnel-xx ID path-option index
```

The switchover to a newer path option is achieved, in these instances:

- when a lower index path option is available
- when any signalling message or topology update causes the primary LSP to go down
- when a local interface fails on the primary LSP or a path error is received on the primary LSP

**Note**

Path option switchover between various path options with different bandwidth classes is not allowed.

**Related Topics**

- Configuring Attributes within a Path-Option Attribute, on page 134

### Path Option and Path Protection

When path-protection is enabled, a standby LSP is established to protect traffic going over the tunnel. The standby LSP may be established using either the same path option as the primary LSP, or a different one.

The standby LSP is computed to be diverse from the primary LSP, so bandwidth class differences does not matter. This is true in all cases of diversity except node-diversity. With node diversity, it is possible for the standby LSP to share up to two links with the primary LSP, the link exiting the head node, and the link entering the tail node.

If you want to switchover from one path option to another path option and these path options have different classes, the path option switchover is rejected. However, the path option switchover can not be blocked in the path-protection feature. When the standby LSP becomes active using another path option of a different class type, the path option switchover cannot be rejected at the head end. It might get rejected by the downstream node.

Node-diversity is only possible under limited conditions. The conditions that must be met are:
• there is no second path that is both node and link diverse
• the current LSP uses a shared-media link at the head egress or tail ingress
• the shared-media link used by the current LSP permits computation of a node-diverse path

In Cisco IOS XR, reoptimization between different class types would actually be rejected by the next hop. This rejection will occur by an admission failure.

**Auto-Tunnel Mesh**

The MPLS traffic engineering auto-tunnel mesh (Auto-mesh) feature allows you to set up full mesh of TE P2P tunnels automatically with a minimal set of MPLS traffic engineering configurations. You may configure one or more mesh-groups. Each mesh-group requires a destination-list (IPv4 prefix-list) listing destinations, which are used as destinations for creating tunnels for that mesh-group.

You may configure MPLS TE auto-mesh type attribute-sets (templates) and associate them to mesh-groups. LSR creates tunnels using the tunnel properties defined in the attribute-set.

Auto-Tunnel mesh provides benefits:

• Minimizes the initial configuration of the network.
  
  You may configure tunnel properties template and mesh-groups or destination-lists on each TE LSRs that further creates full mesh of TE tunnels between those LSRs.

• Minimizes future configurations resulting due to network growth.
  
  It eliminates the need to reconfigure each existing TE LSR in order to establish a full mesh of TE tunnels whenever a new TE LSR is added in the network.

---

**Destination List (Prefix-List)**

Auto-mesh tunnels can be automatically created using prefix-list. Each TE enabled router in the network learns about the TE router IDs through a existing IGP extension.

You can view the router IDs on the router using this command:

```
show mpls traffic-eng topology | include TE Id
IGP Id: 0001.0000.0010.00, MPLS TE Id:100.1.1.1 Router Node (ISIS 1 level-2)
IGP Id: 0001.0000.0011.00, MPLS TE Id:100.2.2.2 Router Node (ISIS 1 level-2)
IGP Id: 0001.0000.0012.00, MPLS TE Id:100.3.3.3 Router Node (ISIS 1 level-2)
```
A prefix-list may be configured on each TE router to match a desired set of router IDs (MPLS TE ID as shown in the above output). For example, if a prefix-list is configured to match addresses of 100.0.0.0 with wildcard 0.255.255.255, then all 100.x.x.x router IDs are included in the auto-mesh group.

When a new TE router is added in the network and its router ID is also in the block of addresses described by the prefix-list, for example, 100.x.x.x, then it is added in the auto-mesh group on each existing TE router without having to explicitly modify the prefix-list or perform any additional configuration.

Auto-mesh does not create tunnels to its own (local) TE router IDs.

---

**Note**

When prefix-list configurations on all routers are not identical, it can result in non-symmetrical mesh of tunnels between those routers.

**P2MP-TE Auto-tunnels**

The MPLS point-to-multi point traffic-engineering auto-tunnels (P2MP-TE Auto-tunnels) feature enables dynamic creation and management of P2MP auto-tunnels for the transport of VPLS traffic on Cisco IOS XR Software. The P2MP-TE auto-tunnel configuration is disabled by default. Use the `auto-tunnel p2mp-te tunnel-id` configuration to enable P2MP-TE Auto-tunnel. This configures the tunnel ID range that can be allocated to P2MP auto-tunnels. This also determines the maximum number of P2MP auto-tunnels that can be created.

For more information on P2MP TE Auto-tunnels, see the Implementing MPLS Traffic Engineering chapter in the MPLS Configuration Guide for the Cisco CRS Routers. For more information on Set DF Bit commands, see the MPLS Traffic Engineering Commands chapter in the MPLS Command Reference for the Cisco CRS Router.

**PWHE over MPLS TE Tunnels**

The Pseudowire Headend (PWHE) over MPLS TE Tunnels feature enables the PWHE traffic to pass through MPLS traffic engineering (TE) tunnels.

The PWHE and the MPLS TE tunnels are configured independently. No specific configuration is required for a TE tunnel to forward PWHE traffic through it. The pseudowire traffic automatically passes through the TE tunnel, after the routing protocol is configured in such a way that the routing algorithm considers the TE tunnel as the route to reach the pseudowire endpoint.
In this figure, S-PE is the PWHE and OSPF manages the routing. A MPLS TE tunnel is configured between A-PE and S-PE. After the MPLS TE tunnel is defined (either by defining a static route or using the autoroute announce command) as the path through which to forward traffic to S-PE, the PWHE traffic passes through that tunnel.

**Workflow - Sending PWHE Traffic over MPLS TE Tunnels**

Complete these configurations on the S-PE to enable PWHE traffic to flow through the MPLS TE tunnel.

VRF Redirection to MPLS TE Tunnels

The VRF redirection to MPLS TE tunnels feature adds automatic route MPLS TE tunnels through autoroute destination configuration. The VRF redirection to MPLS TE tunnels maps VRF prefixes over TE tunnels in the core to reach the same egress provider edge (PE). This enables to load-balance prefix traffic on multiple tunnels based on equal cost multi-path (ECMP). The ECMP is used to load-share the flow(s) on multiple available paths towards the destination PE. The route added by autoroute destination inherits the same IGP computed metric to the tunnel endpoint. Any changes to the IGP route metric to the tunnel endpoint is automatically reflected on the autoroute destination route too.

In a typical VPN deployment over a TE core network, an operator creates a mesh of TE tunnels between PE routers and then configures autoroute announce to these tunnels. This leads to a mix of default VRF and VPNv4 traffic on the same tunnel connecting the PE routers. An operator may want to segregate their VPNv4 traffic on different tunnels. This can be achieved by creating multiple tunnels to the egress PE(s). The limitation of this approach is that the static routes are added with zero metrics. The VRF Redirection to MPLS TE Tunnels feature is a solution to resolve this limitation. Multiple VRFs can be mapped on the same tunnel by adding multiple autoroute destination addresses (BGP next-hops) to the same tunnel.

A-PE has a similar configuration, except for the fact that there is no PWHE defined on it.

In a PWHE-based pseudowire configuration, the TE tunnel cannot be configured as the preferred-path for pseudowire traffic. Therefore, the preferred-path tunnel-te option under the L2VPN XConnect PW-Class is not supported. However, the TE tunnel redundancy and TE fast-reroute mechanisms are supported with PWHE over MPLS TE tunnels.
Routes added by static route are always added with zero cost metric. This results in traffic that is mapped on multiple tunnels to always load-balance due to ECMP. This may be undesirable when some of those tunnels have sub-optimal paths (have higher underlying cost to the endpoint). With autoroute destination, only the tunnel whose IGP cost to its endpoint is lowest will be considered for carrying traffic.

VRF redirection over TE tunnels feature supports:

- Automatic redirection of VRF traffic over TE tunnels.
- Multiple autoroute destinations under one tunnel to aggregate VRF traffic. If two VRFs are to be mapped on same tunnel, then two autoroute destination prefixes (BGP next-hops) will be configured under the tunnel.
- One autoroute destination under multiple tunnels to enable ECMP load-balance of VRF traffic.
- Implicit /32 mask for each route. Only host addresses residing on the tunnel endpoint are supported.
- High availability, RP failover, and non-stop forwarding (NSF) scenarios by proving hitless to traffic mechanisms.

For more information on VRF Redirection to MPLS TE Tunnels, see the Implementing MPLS Traffic Engineering chapter in the MPLS Configuration Guide for the Cisco CRS Routers. For more information on VRF Redirection to MPLS TE Tunnels commands, see the MPLS Traffic Engineering Commands chapter in the MPLS Command Reference for the Cisco CRS Router.

### MPLS TE Extended Admin Groups

The MPLS TE extended admin groups (EAG) configuration assigns EAG/AG name to bit-position and associates affinity-names with TE links. The configuration extends to assign names, up to 256, to TE links over the selected interface and assigns 32 names per attribute-set and index.

For more information on MPLS TE Extended Admin Groups, see the Implementing MPLS Traffic Engineering chapter in the MPLS Configuration Guide for the Cisco CRS Routers. For more information on MPLS TE Extended Admin Groups commands, see the MPLS Traffic Engineering Commands chapter in the MPLS Command Reference for the Cisco CRS Router.

### Stateful Path Computation Element

The stateful path computation element (PCE) describes a set of procedures by which a path computation client (PCC) can report and delegate control of head-end tunnels sourced from the PCC to a PCE peer. The PCE peer can request the PCC to update and modify parameters of label switched paths (LSPs) it controls. The stateful model also enables a PCC to allow the PCE to initiate computations allowing the PCE to perform network-wide orchestration.

For more information on Stateful PCE, see the Implementing MPLS Traffic Engineering chapter in the MPLS Configuration Guide for the Cisco CRS Routers. For more information on Stateful PCE commands, see the MPLS Traffic Engineering Commands chapter in the MPLS Command Reference for the Cisco CRS Router.

### Stateful PCE State Reporting

State reporting refers to the PCC sending information to PCEs about the state of LSPs. This is done as state changes occur and is used to keep PCEs informed of changes to the LSP as they occur. State reporting is also used as part of state synchronization and delegation.

A state report is a message sent by a PCC to a PCE reporting on the state of one or more TE tunnels. This allows the PCE to stay abreast of changes as they occur. Reports are triggered when the PCE needs to be informed of state. These occur when:
Stateful PCE State Synchronization

Synchronization refers to a procedure that occurs after a PCEP session is established between a PCE and a PCC. The purpose of state synchronization is to download the current LSP database of the PCC to a PCE. This is done through a set of state reports which are marked as synchronizations. This is the first communication to occur after the session is brought up. A full re-send of state reports can also be avoided when the PCE already has an up-to-date version of the LSP database as the version number can be indicated by the PCE during PCEP session establishment.

Stateful PCE Delegation

Delegation is the action by which control of a state is granted to a PCE by the PCC. A PCE to which control was delegated can alter attributes of the LSP. Control is only delegated to one PCE at a time.

- Delegation of control can be revoked from a PCE by the PCC.
- Delegation of control can also be returned to the PCC by the PCE.

Stateful PCE State Updating

State updating refers to the PCE sending information to a PCC to alter the attributes of an LSP. A state update is a message sent by a PCE to a PCC to alter the state of one or more TE tunnels. State updating is allowed only if the PCE has previously been delegated control of the LSP. State updating is also used to return delegated control.

Stateful PCE Creation of LSPs

Creation (or instantiation) of an LSP is a procedure by which a PCE instructs a PCC to create an LSP respecting certain attributes. For LSPs created in this manner, the PCE is delegated control automatically. Stateful PCE procedures enable a PCE to instruct a PCC to create a locally sourced tunnel.

Delegation of PCC Initiated Tunnels

The delegation of path computation client (PCC) initiated tunnels feature enables the ability to control PCC initiated tunnels through stateful path computation element (PCE).

When a PCC is connected to multiple PCEs, use the precedence command to select stateful PCEs for delegating LSPs. Precedence can take any value between 0 and 255. The default precedence value is 255. When there are multiple stateful PCEs with active PCEP sessions, PCC selects the PCE with the lowest precedence value. If multiple PCEs have the same precedence, PCC selects a PCE with the lowest IP address. A PCC considers only the PCEs with active PCEP session for delegating LSPs.
When a PCEP session over which tunnels have been delegated is terminated, the PCC waits till the re-delegation timer expires before re-delegating tunnels. If a PCEP session comes back up within re-delegation timer expiration, tunnels will be delegated back to the same PCE.

For information on PCC, see Path Computation Element, on page 22.

**MPLS TE Usability Enhancements**

MPLS traffic engineering command line interface and logging output messages are enhanced as follows:

- The `show mpls traffic engineering` commands display `signaled-name` and supports `signaled-name` filter.
- Ability to allow immediate teardown of all labelled switched paths (LSPs) of the specified tunnel and to create new LSPs.
- Default behavior when affinity check fails at head-end is to reoptimize all LSP types.
- Logging output messages include MPLS TE tunnel signaled name.
- Logging of path change events and available bandwidth on the new for all auto-bandwidth operations.
- Auto-bandwidth logging output includes signaled name.

**MPLS TE IPv6 Autoroute**

The MPLS TE IPv6 Autoroute feature enables the use of IPv4 MPLS TE tunnels for IPv6 routing. The routing protocol IGP (IS-IS) considers the IPv4 MPLS TE tunnel for IPv6 routing path calculation only if the tunnel is advertised to carry IPv6 traffic. To advertise the tunnel, either IPv6 autoroute announce (AA) configuration or IPv6 forwarding adjacency (FA) configuration should be made on the tunnel. Also, the IPv6 has to be enabled on the tunnel so that the tunnel can handle IPv6 traffic.

For more information on MPLS TE IPv6 Autoroute, see the Implementing MPLS Traffic Engineering chapter in the MPLS Configuration Guide for the Cisco CRS Routers. For more information on MPLS TE IPv6 Autoroute commands, see the MPLS Traffic Engineering Commands chapter in the MPLS Command Reference for the Cisco CRS Router.

**MPLS TE IPv6 Autoroute Restrictions**

- IGP support is only for IS-IS.
- IS-IS IPv4 and IPv6 must be configured under the same IS-IS instance.
- Unequal load balancing (UELB) does not apply to IPv6 traffic. While it may still be configured and used for IPv4 traffic, IPv6 traffic does not acknowledge the UELB configuration. However, equal loadsharing works for IPv6.
- Policy-based tunnel selection (PBTS) does not apply for IPv6 traffic. While it may still be configured and used for IPv4 traffic, IPv6 traffic does not acknowledge the PBTS configuration.
- MPLS auto tunnels do not support IPv6 autoroute announce and IPv6 forwarding adjacency configurations.
MPLS TE Path Cost Limit

The MPLS TE path cost limit feature enables graceful migration of TE label switched paths (LSPs) away from a link without affecting the traffic. This is useful when a link is scheduled to be decommissioned or brought down for maintenance.

In order to take a link out of service and gracefully migrate the LSPs away from it, the cost assigned to the link is to be set higher than the path cost limit (path aggregate admin-weight) assigned at the LSP headend. The cost of the tunnel is equal to the aggregate cost of the links through which the tunnel passes. The headend routers recalculate the total path costs at the time of periodic path verification. At this stage, the headend routers automatically check if the path limit is crossed and reroute the LSPs away from the out-of-service link.

This sample illustration explains the TE path cost limit application:

*Figure 11: MPLS TE path cost limit application*

Here, the path cost limit for the LSP is set at 50. To move the LSP away from the link between F and G, the link cost is increased to 50.

For more information on MPLS TE Path Cost Limit, see the Implementing MPLS Traffic Engineering chapter in the MPLS Configuration Guide for the Cisco CRS Routers. For more information on MPLS TE Path Cost Limit commands, see the MPLS Traffic Engineering Commands chapter in the MPLS Command Reference for the Cisco CRS Router.

Soft-preemption over FRR Backup Tunnels

The soft-preemption over FRR backup tunnels feature enables to move LSP traffic over the backup tunnels when the LSP is soft-preempted. MPLS TE tunnel soft-preemption allows removal of extra TE traffic in a graceful manner, by giving the preempted LSP a grace period to move away from the link. Though this mechanism saves the traffic of the preempted LSP from being dropped, this might cause traffic drops due to congestion as more bandwidth is reserved on the link than what is available. When the soft-preemption over FRR backup tunnel is enabled, the traffic of the preempted LSP is moved onto the FRR backup, if it is available and ready. This way, the capacity of the backup tunnel is used to remove the potential congestion that might be caused by soft-preemption.

For more information on Soft-Preemption over FRR Backup, see the Implementing MPLS Traffic Engineering chapter in the MPLS Configuration Guide for the Cisco CRS Routers. For more information on Soft-Preemption over FRR Backup commands, see the MPLS Traffic Engineering Commands chapter in the MPLS Command Reference for the Cisco CRS Router.
MPLS TE Auto-tunnel Mesh One-hop

The MPLS TE Auto-tunnel primary one-hop feature allows automatic creation of tunnels over TE enabled interfaces to next hop neighbors. The Auto-tunnel primary one-hop is configurable under the MPLS TE Auto-tunnel mesh group mode and for each mesh group. The Auto-tunnel primary one-hop configuration automatically creates one-hop tunnels to next hop neighbors. A router that becomes a next hop neighbor will have a set of one-hop tunnels created automatically.

For more information on MPLS TE Auto-tunnel Primary One-hop, see the Implementing MPLS Traffic Engineering chapter in the MPLS Configuration Guide for the Cisco CRS Routers. For more information on MPLS TE Auto-tunnel Primary One-hop commands, see the MPLS Traffic Engineering Commands chapter in the MPLS Command Reference for the Cisco CRS Router.

Inter-area Traffic Engineering with Dynamic ABR Discovery

The inter-area traffic engineering with dynamic ABR discovery feature adds support for inter-area point-to-point (P2P) and point-to-multi-point (P2MP) traffic engineering with dynamic ABR discovery. With this feature, there is no need to specify transit ABR addresses in the explicit paths to allow for dynamic/best path computation for inter-area tunnels.

For more information on Inter-area Traffic Engineering with Dynamic ABR Discovery, see the Implementing MPLS Traffic Engineering chapter in the MPLS Configuration Guide for the Cisco CRS Routers.

Named Tunnel

The Named Tunnel feature provides a simplified and flexible means of naming MPLS-TE tunnels.

In the traditional TE tunnel naming scheme, the tunnels are configured with IDs, where an ID is a 16-bit number. With increased TE tunnel scale in the network, and with the 64K limit, there is scarcity of unique tunnel IDs.

The Named Tunnel feature lets you name the TE tunnels in the network with unique tunnel IDs, which lets you manage the network more efficiently. This feature allows you to provision TE tunnels using STRING names.

For example: TUNNEL-NY-TO-LA

Named Path Option

For a given tunnel, you can configure one or more path options - each identified by a unique name. The path option expresses the preference for the path; lower numbers have a higher preference, with 1 having the highest preference. You can also configure the computation method for the path.

How to Implement Traffic Engineering

Traffic engineering requires coordination among several global neighbor routers, creating traffic engineering tunnels, setting up forwarding across traffic engineering tunnels, setting up FRR, and creating differential service.

These procedures are used to implement MPLS-TE:
Building MPLS-TE Topology

Perform this task to configure MPLS-TE topology (required for traffic engineering tunnel operations).

Before you begin

Before you start to build the MPLS-TE topology, you must have enabled:

- IGP such as OSPF or IS-IS for MPLS-TE.
- MPLS Label Distribution Protocol (LDP).
- RSVP on the port interface.
- Stable router ID is required at either end of the link to ensure that the link is successful. If you do not assign a router ID, the system defaults to the global router ID. Default router IDs are subject to change, which can result in an unstable link.
- If you are going to use nondefault holdtime or intervals, you must decide the values to which they are set.

**Implementing MPLS Traffic Engineering**  

**Building MPLS-TE Topology**
## Creating an MPLS-TE Tunnel

Creating an MPLS-TE tunnel is a process of customizing the traffic engineering to fit your network topology. Perform this task to create an MPLS-TE tunnel after you have built the traffic engineering topology.

### Before you begin

The following prerequisites are required to create an MPLS-TE tunnel:

- You must have a router ID for the neighboring router.
- Stable router ID is required at either end of the link to ensure that the link is successful. If you do not assign a router ID to the routers, the system defaults to the global router ID. Default router IDs are subject to change, which can result in an unstable link.
- If you are going to use nondefault holdtime or intervals, you must decide the values to which they are set.

### SUMMARY STEPS

1. configure
2. interface tunnel-te tunnel-id
3. destination ip-address
4. ipv4 unnumbered type interface-path-id
5. path-option preference - priority dynamic
6. signalled- bandwidth {bandwidth [class-type ct ] | sub-pool bandwidth}
7. commit
8. (Optional) show mpls traffic-eng tunnels
9. (Optional) show ipv4 interface brief
### DETAILED STEPS

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
### Configuring Forwarding over the MPLS-TE Tunnel

Perform this task to configure forwarding over the MPLS-TE tunnel created in the previous task. This task allows MPLS packets to be forwarded on the link between network neighbors.

#### Before you begin

The following prerequisites are required to configure forwarding over the MPLS-TE tunnel:

- You must have a router ID for the neighboring router.
- Stable router ID is required at either end of the link to ensure that the link is successful. If you do not assign a router ID to the routers, the system defaults to the global router ID. Default router IDs are subject to change, which can result in an unstable link.

#### SUMMARY STEPS

1. configure
2. interface tunnel-te tunnel-id
3. ipv4 unnumbered type interface-path-id
4. autoroute announce
5. exit
6. router static address-family ipv4 unicast prefix mask ip-address interface type
7. commit
8. (Optional) ping {ip-address | hostname}
9. (Optional) show mpls traffic-eng autoroute

**Protecting MPLS Tunnels with Fast Reroute**

Perform this task to protect MPLS-TE tunnels, as created in the previous task.

**Note**
Although this task is similar to the previous task, its importance makes it necessary to present as part of the tasks required for traffic engineering on Cisco IOS XR software.

**Before you begin**

The following prerequisites are required to protect MPLS-TE tunnels:

- You must have a router ID for the neighboring router.
- Stable router ID is required at either end of the link to ensure that the link is successful. If you do not assign a router ID to the routers, the system defaults to the global router ID. Default router IDs are subject to change, which can result in an unstable link.
- You must first configure a primary tunnel.

**SUMMARY STEPS**

1. configure
2. interface tunnel-te tunnel-id
3. fast-reroute
4. exit
5. mpls traffic-eng
6. interface type interface-path-id
7. backup-path tunnel-te tunnel-number
8. exit
9. exit
10. interface tunnel-te tunnel-id
11. backup-bw {backup bandwidth | sub-pool {bandwidth | unlimited} | global-pool {bandwidth | unlimited} }
12. ipv4 unnumbered type interface-path-id
13. path-option preference-priority {explicit name explicit-path-name}
14. destination ip-address
15. commit
16. (Optional) `show mpls traffic-eng tunnels backup`
17. (Optional) `show mpls traffic-eng tunnels protection frr`
18. (Optional) `show mpls traffic-eng fast-reroute database`

<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td>Step 15</td>
<td>commit</td>
<td></td>
</tr>
</tbody>
</table>

### Step 15
commit

#### Note
When you configure TE tunnel with multiple protection on its path and merge point is the same node for more than one protection, you must configure record-route for that tunnel.

### Step 16
(Optional) **show mpls traffic-eng tunnels backup**

**Example:**

```
RP/0/RP0/CPU0:router# show mpls traffic-eng tunnels backup
```

Displays the backup tunnel information.

### Step 17
(Optional) **show mpls traffic-eng tunnels protection frr**

**Example:**

```
RP/0/RP0/CPU0:router# show mpls traffic-eng tunnels protection frr
```

Displays the tunnel protection information for Fast-Reroute (FRR).

### Step 18
(Optional) **show mpls traffic-eng fast-reroute database**

**Example:**

```
RP/0/RP0/CPU0:router# show mpls traffic-eng fast-reroute database
```

Displays the protected tunnel state (for example, the tunnel’s current ready or active state).

**Configuring a Prestandard DS-TE Tunnel**

Perform this task to configure a Prestandard DS-TE tunnel.

**Before you begin**

The following prerequisites are required to configure a Prestandard DS-TE tunnel:

- You must have a router ID for the neighboring router.
• Stable router ID is required at either end of the link to ensure that the link is successful. If you do not assign a router ID to the routers, the system defaults to the global router ID. Default router IDs are subject to change, which can result in an unstable link.

SUMMARY STEPS

1. configure
2. rsvp interface type interface-path-id
3. bandwidth [total reservable bandwidth] [bc0 bandwidth] [global-pool bandwidth] [sub-pool reservation-bw]
4. exit
5. exit
6. interface tunnel-te tunnel-id
7. signalled-bandwidth {bandwidth [class-type ct] | sub-pool bandwidth}
8. commit

```
RP/0/RP0/CPU0:router(config)# mpls traffic-eng
```

**Step 7**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ds-te mode ietf</td>
<td>Enables IETF DS-TE mode and default TE class map. IETF DS-TE mode is configured on all network nodes.</td>
</tr>
</tbody>
</table>

**Example:**

```
RP/0/RP0/CPU0:router(config-mpls-te)# ds-te mode ietf
```
### Purpose

**Command or Action**

<table>
<thead>
<tr>
<th>Step 8</th>
<th>exit</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>RP/0/RP0/CPU0:router(config-mpls-te)# exit</td>
</tr>
</tbody>
</table>

Exits the current configuration mode.

<table>
<thead>
<tr>
<th>Step 9</th>
<th>interface tunnel-te tunnel-id</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Example:</strong></td>
<td>RP/0/RP0/CPU0:router(config)# interface tunnel-te 4 RP/0/RP0/CPU0:router(config-if)#</td>
</tr>
</tbody>
</table>

Configures an MPLS-TE tunnel interface.

| Step 10 | signalled-bandwidth {bandwidth [class-type ct] | sub-pool bandwidth} |
|---------|-----------------------|
| **Example:** | RP/0/RP0/CPU0:router(config-if)# signalled-bandwidth 10 class-type 1 |

Configures the bandwidth required for an MPLS TE tunnel. Because the default tunnel priority is 7, tunnels use the default TE class map (namely, class-type 1, priority 7).

### Configuring MPLS -TE and Fast-Reroute on OSPF

Perform this task to configure MPLS-TE and Fast Reroute (FRR) on OSPF.
Before you begin

Note

Only point-to-point (P2P) interfaces are supported for OSPF multiple adjacencies. These may be either native P2P interfaces or broadcast interfaces on which the **OSPF P2P configuration** command is applied to force them to behave as P2P interfaces as far as OSPF is concerned. This restriction does not apply to IS-IS.

The tunnel-te interface is not supported under IS-IS.

### SUMMARY STEPS

1. **configure**
2. **interface tunnel-te tunnel-id**
3. **path-option [protecting] preference-priority {dynamic [pce [address ipv4 address] | explicit {name path-name | identifier path-number} | [isis instance name {level level} | [ospf instance name {area area ID} | ] | [verbatim] | [lockdown]}}**
4. Repeat Step 3 as many times as needed.
5. **commit**
6. **show mpls traffic-eng tunnels [tunnel-number]**

### Configuring the Ignore Integrated IS-IS Overload Bit Setting in MPLS-TE

Perform this task to configure an overload node avoidance in MPLS-TE. When the overload bit is enabled, tunnels are brought down when the overload node is found in the tunnel path.

**SUMMARY STEPS**

1. `configure`
2. `mpls traffic-eng`
3. `path-selection ignore overload {head | mid | tail}`
4. `commit`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><code>configure</code></td>
<td>Enters MPLS-TE configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td><code>mpls traffic-eng</code></td>
<td>Enters MPLS-TE configuration mode.</td>
</tr>
</tbody>
</table>

**Example:**

```
RP/0/RP0/CPU0:router(config-mpls-te)#
```

| Step 3 | `path-selection ignore overload {head | mid | tail}` | Ignores the Intermediate System-to-Intermediate System (IS-IS) overload bit setting for MPLS-TE. |

**Example:**

```
RP/0/RP0/CPU0:router(config-mpls-te)#
path-selection ignore overload head
```

| Step 4 | `commit` | |

**Related Topics**

Configuring GMPLS

To fully configure GMPLS, you must complete these high-level tasks in order:

- Configuring IPCC Control Channel Information, on page 74
- Configuring Local and Remote TE Links, on page 77
- Configuring Numbered and Unnumbered Optical TE Tunnels, on page 87
- Configuring LSP Hierarchy, on page 91
- Configuring Border Control Model, on page 91
- Configuring Path Protection, on page 92

Note: These high-level tasks are broken down into, in some cases, several subtasks.

Configuring IPCC Control Channel Information

To configure IPCC control channel information, complete these subtasks:

- Configuring Router IDs, on page 74
- Configuring OSPF over IPCC, on page 76

Note: You must configure each subtask on both the headend and tailend router.

Configuring Router IDs

Perform this task to configure the router ID for the headend and tailend routers.

SUMMARY STEPS

1. configure
2. interface type interface-path-id
3. ipv4 address ipv4-address mask
4. exit
5. router ospf process-name
6. mpls traffic-eng router-id type interface-path-id
7. commit

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

**Command or Action**

| Step 2 | interface type interface-path-id  
| Example: |  
| | RP/0/RP0/CPU0:router(config)# interface POS0/6/0/0 |

Enters MPLS-TE interface configuration mode and enables traffic engineering on a particular interface on the originating node.

### Step 3

**Command or Action**

| ipv4 address ipv4-address mask  
| Example: |  
| | RP/0/RP0/CPU0:router(config-if)# ipv4 address 192.168.1.27 255.0.0.0 |

Specify a primary or secondary IPv4 address for an interface.

- Network mask can be a four-part dotted decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means that the corresponding address bit belongs to the network address.
- Network mask can be indicated as a slash (/) and a number (prefix length). The prefix length is a decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash must precede the decimal value, and there is no space between the IP address and the slash.

### Step 4

**Command or Action**

| exit  
| Example: |  
| | RP/0/RP0/CPU0:router(config-if)# exit  
| | RP/0/RP0/CPU0:router(config)# |

Exits the current configuration mode.

### Step 5

**Command or Action**

| router ospf process-name  
| Example: |  
| | RP/0/RP0/CPU0:router(config)# router ospf 1  
| | RP/0/RP0/CPU0:router(config-ospf)# |

Configures an Open Shortest Path First (OSPF) routing process. The process name is any alphanumeric string no longer than 40 characters without spaces.

### Step 6

**Command or Action**

| mpls traffic-eng router-id type interface-path-id  
| Example: |  
| | RP/0/RP0/CPU0:router(config-ospf)# mpls traffic-eng router id Loopback0 |

Specifies that the TE router identifier for the node is the IP address that is associated with a given interface. The router ID is specified with an interface name or an IP address. By default, MPLS uses the global router ID.

### Step 7

### Configuring Local and Remote TE Links

These subtasks describe how to configure local and remote MPLS-TE link parameters for numbered and unnumbered TE links on both headend and tailend routers.

- Configuring Numbered and Unnumbered Links, on page 77
- Configuring Local Reservable Bandwidth, on page 79
- Configuring Local Switching Capability Descriptors, on page 79
- Configuring Persistent Interface Index, on page 80
- Enabling LMP Message Exchange, on page 81
- Disabling LMP Message Exchange, on page 82
- Configuring Remote TE Link Adjacency Information for Numbered Links, on page 83
- Configuring Remote TE Link Adjacency Information for Unnumbered Links, on page 85

### Configuring Numbered and Unnumbered Links

Perform this task to configure numbered and unnumbered links.
Unnumbered TE links use the IP address of the associated interface.

**SUMMARY STEPS**

1. configure
2. interface type interface-path-id
3. Do one of the following:
   - `ipv4 address ipv4-address mask`
   - `ipv4 unnumbered interface type interface-path-id`
4. commit

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure</td>
<td>Enters MPLS-TE interface configuration mode and enables traffic engineering on a particular interface on the originating node.</td>
</tr>
</tbody>
</table>

**Step 2**

interface type interface-path-id

Example:

```plaintext
RP/0/RP0/CPU0:router(config)# interface POS0/6/0/0
```

**Step 3**

Do one of the following:

- `ipv4 address ipv4-address mask`
- `ipv4 unnumbered interface type interface-path-id`

Example:

```plaintext
RP/0/RP0/CPU0:router(config-if)# ipv4 address 192.168.1.27 255.0.0.0
```

Specifies a primary or secondary IPv4 address for an interface.

- Network mask is a four-part dotted decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means that the corresponding address bit belongs to the network address.
- Network mask is indicated as a slash (/) and a number (prefix length). The prefix length is a decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash must precede the decimal value, and there is no space between the IP address and the slash.

or

- Enables IPv4 processing on a point-to-point interface without assigning an explicit IPv4 address to that interface.
Configuring Local Reservable Bandwidth

Perform this task to configure the local reservable bandwidth for the data bearer channels.

**SUMMARY STEPS**

1. configure
2. rsdp interface type interface-path-id
3. bandwidth [total reservable bandwidth] [bc0 bandwidth] [global-pool bandwidth] [sub-pool reservable-bw]
4. commit

**DETAILED STEPS**

<table>

Configuring Numbered and Unnumbered Optical TE Tunnels

These subtasks are included:

- Configuring an Optical TE Tunnel Using Dynamic Path Option, on page 87
- Configuring an Optical TE Tunnel Using Explicit Path Option, on page 89

Note
Before you can successfully bring optical TE tunnels “up,” you must complete the procedures in the preceding sections.

The following characteristics can apply to the headend (or, signaling) router:

- Tunnels can be numbered or unnumbered.
- Tunnels can be dynamic or explicit.

The following characteristics can apply to the tailend (or, passive) router:

- Tunnels can be numbered or unnumbered.
- Tunnels must use the explicit path-option.

Configuring an Optical TE Tunnel Using Dynamic Path Option

Perform this task to configure a numbered or unnumbered optical tunnel on a router; in this example, the dynamic path option on the headend router. The dynamic option does not require that you specify the different hops to be taken along the way. The hops are calculated automatically.

Note
The examples describe how to configure optical tunnels. It does not include procedures for every option available on the headend and tailend routers.

SUMMARY STEPS

1. configure
2. interface tunnel-gte tunnel-id
3. ipv4 address ip-address/prefix or ipv4 unnumbered type interface-path-id
4. switching transit switching type encoding encoding type
5. priority setup-priority hold-priority
6. signalled-bandwidth {bandwidth [class-type ct] | sub-pool bandwidth}
7. destination ip-address
8. path-option path-id dynamic
9. direction [bidirectional]
10. commit

| Step 3 | ipv4 address ip-address/prefix or ipv4 unnumbered type interface-path-id  
Example:  
RP/0/RP0/CPU0:router(config-if)# ipv4 address 192.168.1.27 255.0.0.0 | Specifies a primary or secondary IPv4 address for an interface.  
- Network mask can be a four-part dotted decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means that the corresponding address bit belongs to the network address.  
- Network mask can be indicated as a slash (/) and a number (prefix length). The prefix length is a decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash must precede the decimal value, and there is no space between the IP address and the slash.  
or  
- Enables IPv4 processing on a point-to-point interface without assigning an explicit IPv4 address to that interface. |
| Step 4 | switching transit switching type encoding encoding type  
Example:  
RP/0/RP0/CPU0:router(config-if)# switching transit lsc encoding sonetadh | Specifies the switching capability and encoding types for all transit TE links used to signal the optical tunnel. |
| Step 5 | priority setup-priority hold-priority  
Example:  
RP/0/RP0/CPU0:router(config-if)# priority 1 1 | Configures setup and reservation priorities for MPLS-TE tunnels. |
| Step 6 | signalled-bandwidth \{bandwidth [class-type ct] | sub-pool bandwidth\}  
Example:  
RP/0/RP0/CPU0:router(config-if)# | Sets the CT0 bandwidth required on this interface. Because the default tunnel priority is 7, tunnels use the default TE class map (namely, class-type 1, priority 7). |
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>signalled-bandwidth 10 class-type 1</td>
<td></td>
</tr>
</tbody>
</table>

### Step 7

**destination ip-address**

**Example:**

```
RP/0/RP0/CPU0:router(config-if)# destination 192.168.92.125
```

Assigns a destination address on the new tunnel.

- Destination address is the remote node’s MPLS-TE router ID.
- Destination address is the merge point between backup and protected tunnels.

### Step 8

**path-option path-id dynamic**

**Example:**

```
RP/0/RP0/CPU0:router(config-if)# path-option 1 dynamic
```

Configures the dynamic path option and path ID.

### Step 9

**direction [bidirectional]**

**Example:**

```
RP/0/RP0/CPU0:router(config-if)# direction bidirection
```

Configures a bidirectional optical tunnel for GMPLS.

### Step 10

**commit**

---

**SUMMARY STEPS**

1. configure
2. interface tunnel-gte tunnel-id
3. ipv4 address ipv4-address mask or ipv4 unnumbered type interface-path-id
4. passive
5. match identifier tunnel number
6. destination ip-address
7. commit

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure</td>
<td></td>
</tr>
</tbody>
</table>
### Command or Action

**Step 2**  
`interface tunnel-gte tunnel-id`  
**Example:**  
```
RP/0/RP0/CPU0:router(config)# interface tunnel-gte 1
RP/0/RP0/CPU0:router(config-if)#
```

**Purpose**  
Configures an MPLS-TE tunnel interface for GMPLS interfaces.

**Step 3**  
`ipv4 address ipv4-address mask`  
or  
`ipv4 unnumbered type interface-path-id`  
**Example:**  
```
RP/0/RP0/CPU0:router(config-if)# ipv4 address 127.0.0.1 255.0.0.0
```

**Purpose**  
Specifies a primary or secondary IPv4 address for an interface.

- Network mask can be a four-part dotted decimal address. For example, 255.0.0.0 indicates that each bit equal to 1 means that the corresponding address bit belongs to the network address.

- Network mask can be indicated as a slash (/) and a number (prefix length). The prefix length is a decimal value that indicates how many of the high-order contiguous bits of the address compose the prefix (the network portion of the address). A slash must precede the decimal value, and there is no space between the IP address and the slash.

- Enables IPv4 processing on a point-to-point interface without assigning an explicit IPv4 address to that interface.

**Step 4**  
`passive`  
**Example:**  
```
RP/0/RP0/CPU0:router(config-if)# passive
```

**Purpose**  
Configures a passive interface.

**Note**  
The tailend (passive) router does not signal the tunnel, it simply accepts a connection from the headend router. The tailend router supports the same configuration as the headend router.

**Step 5**  
`match identifier tunnel number`  
**Example:**  
```
RP/0/RP0/CPU0:router(config-if)# match identifier gmpls1_t1
```

**Purpose**  
Configures the match identifier. You must enter the hostname for the head router then underscore `_`, and the tunnel number for the head router. If tunnel-te1 is configured on the head router with a hostname of gmpls1, CLI is match identifier gmpls1_t1.

**Note**  
The match identifier must correspond to the tunnel-gte number configured on the headend router. Together with the address specified using the `destination` command, this identifier uniquely identifies acceptable incoming tunnel requests.

**Step 6**  
`destination ip-address`  

**Purpose**  
Assigns a destination address on the new tunnel.
Configuring LSP Hierarchy

These tasks describe the high-level steps that are required to configure LSP hierarchy. LSP hierarchy allows standard MPLS-TE tunnels to be established over GMPLS-TE tunnels.

Consider the following information when configuring LSP hierarchy:

- LSP hierarchy supports numbered optical TE tunnels with IPv4 addresses only.
- LSP hierarchy supports numbered optical TE tunnels using numbered or unnumbered TE links.

Before you can successfully configure LSP hierarchy, you must first establish a numbered optical tunnel between the headend and tailend routers.

To configure LSP hierarchy, you must perform a series of tasks that have been previously described in this GMPLS configuration section. The tasks, which must be completed in the order presented, are as follows:

1. Establish an optical TE tunnel.
2. Configure an optical TE tunnel under IGP.
3. Configure the bandwidth on the optical TE tunnel.
4. Configure the optical TE tunnel as a TE link.
5. Configure an MPLS-TE tunnel.

Related Topics

Configuring Numbered and Unnumbered Optical TE Tunnels, on page 87

Configuring Border Control Model

Border control model lets you specify the optical core tunnels to be advertised to edge packet topologies. Using this model, the entire topology is stored in a separate packet instance, allowing packet networks where these optical tunnels are advertised to use LSP hierarchy to signal an MPLS tunnel over the optical tunnel.

Consider the following information when configuring protection and restoration:

- GMPLS optical TE tunnel must be numbered and have a valid IPv4 address.
- Router ID, which is used for the IGP area and interface ID, must be consistent in all areas.
- OSPF interface ID may be a numeric or alphanumeric.
Border control model functionality is provided for multiple IGP instances in one area or in multiple IGP areas.

To configure border control model functionality, you will perform a series of tasks that have been previously described in this GMPLS configuration section. The tasks, which must be completed in the order presented, are as follows:

1. Configure two optical tunnels on different interfaces.

When configuring IGP, you must keep the optical and packet topology information in separate routing tables.

2. Configure OSPF adjacency on each tunnel.
3. Configure bandwidth on each tunnel.

**Configuring Path Protection**

These tasks describe how to configure path protection:

- Configuring an LSP, on page 92
- Forcing Reversion of the LSP, on page 95

**Configuring an LSP**

Perform this task to configure an LSP for an explicit path. Path protection is enabled on a tunnel by adding an additional path option configuration at the active end. The path can be configured either explicitly or dynamically.

When the dynamic option is used for both working and protecting LSPs, CSPF extensions are used to determine paths with different degrees of diversity. When the paths are computed, they are used over the lifetime of the LSPs. The nodes on the path of the LSP determine if the PSR is or is not for a given LSP. This determination is based on information that is obtained at signaling.

**SUMMARY STEPS**

1. `configure`
2. `interface tunnel-gte number`
3. `ipv4 address ipv4-address mask or ipv4 unnumbered type interface-path-id`
4. `signalled-name name`
5. `switching transit capability-switching-type encoding encoding-type`
6. `switching endpoint capability-switching-type encoding encoding-type`
7. `priority setup-priority hold-priority`
8. `signalled-bandwidth {bandwidth [class-type ct] | sub-pool bandwidth}`
9. **destination** *ip-address*

10. **path-option** *path-id* explicit \{ *name* *pathname* | *path-number* \}

11. **path-option** *protecting* *path-id* explicit \{ *name* *pathname* | *path-number* \}

12. **commit**

Configuring Flexible Name-based Tunnel Constraints

To fully configure MPLS-TE flexible name-based tunnel constraints, you must complete these high-level tasks in order:

1. Assigning Color Names to Numeric Values, on page 95
2. Associating Affinity-Names with TE Links, on page 96
3. Associating Affinity Constraints for TE Tunnels, on page 97

Assigning Color Names to Numeric Values

The first task in enabling the new coloring scheme is to assign a numerical value (in hexadecimal) to each value (color).

An affinity color name cannot exceed 64 characters. An affinity value cannot exceed a single digit. For example, magenta1.

**SUMMARY STEPS**

1. configure
2. mpls traffic-eng
3. affinity-map affinity name {affinity value | bit-position value}
4. commit
Associating Affinity-Names with TE Links

The next step in the configuration of MPLS-TE Flexible Name-based Tunnel Constraints is to assign affinity names and values to TE links. You can assign up to a maximum of 32 colors. Before you assign a color to a link, you must define the name-to-value mapping for each color.

SUMMARY STEPS

1. configure
2. mpls traffic-eng
3. interface type interface-path-id
4. attribute-names attribute name
5. commit

**Associating Affinity Constraints for TE Tunnels**

The final step in the configuration of MPLS-TE Flexible Name-based Tunnel Constraints requires that you associate a tunnel with affinity constraints.

Using this model, there are no masks. Instead, there is support for four types of affinity constraints:

- include
- include-strict
- exclude
- exclude-all

**Note**

For the affinity constraints above, all but the exclude-all constraint may be associated with up to 10 colors.

**SUMMARY STEPS**

1. configure
2. interface tunnel-te tunnel-id
3. affinity {affinity-value | exclude name | exclude -all | include name | include-strict name}
4. commit

<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure</td>
</tr>
</tbody>
</table>
| **Step 2** | `interface tunnel-te tunnel-id`  
Example:  
```
RP/0/RP0/CPU0:router(config)# interface tunnel-te 6
```
| | Enters MPLS-TE interface configuration mode and enables traffic engineering on a particular interface on the originating node. |
| **Step 3** | `path-option preference-priority dynamic pce`  
Example:  
```
RP/0/RP0/CPU0:router(config-if)# path-option 1
```
| | Configures a TE tunnel as a PCC. |
### Purpose

Configuring PCE Parameters

Perform this task to configure PCE parameters, including a static PCE peer, periodic reoptimization timer values, and request timeout values.

**SUMMARY STEPS**

1. configure
2. mpls traffic-eng
3. pce address ipv4 address
4. pce peer ipv4 address
5. pce keepalive interval
6. pce deadtimer value
7. pce reoptimize value
8. pce request-timeout value
9. pce tolerance keepalive value
10. commit
11. show mpls traffic-eng pce peer [address | all]
12. show mpls traffic-eng pce tunnels

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>configure</td>
<td>Enters MPLS-TE configuration mode.</td>
</tr>
<tr>
<td>Step 2</td>
<td>mpls traffic-eng</td>
<td>Configures a PCE IPv4 address.</td>
</tr>
<tr>
<td>Example:</td>
<td>RP/0/RP0/CPU0:router(config)# mpls traffic-eng</td>
<td></td>
</tr>
<tr>
<td>Step 3</td>
<td>pce address ipv4 address</td>
<td>Configures a PCE peer address. PCE peers are also discovered dynamically through OSPF or ISIS.</td>
</tr>
<tr>
<td>Example:</td>
<td>RP/0/RP0/CPU0:router(config-mpls-te)# pce address ipv4 10.1.1.1</td>
<td></td>
</tr>
<tr>
<td>Step 4</td>
<td>pce peer ipv4 address</td>
<td>Configures a static PCE peer address. PCE peers are also discovered dynamically through OSPF or ISIS.</td>
</tr>
<tr>
<td>Example:</td>
<td>RP/0/RP0/CPU0:router(config-mpls-te)# pce peer address ipv4 10.1.1.1</td>
<td></td>
</tr>
<tr>
<td>Step 5</td>
<td>pce keepalive interval</td>
<td>Configures a PCEP keepalive interval. The range is from 0 to 255 seconds. When the keepalive interval is 0, the LSR does not send keepalive messages.</td>
</tr>
<tr>
<td>Example:</td>
<td>RP/0/RP0/CPU0:router(config-mpls-te)# pce</td>
<td></td>
</tr>
</tbody>
</table>
### Purpose

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>keepalive 10</td>
<td></td>
</tr>
</tbody>
</table>

**Step 6**  
`pce deadtimer value`  
**Example:**  
```
RP/O/RP0/CPU0:router(config-mpls-te)# pce deadtimer 50
```

Configures a PCE deadtimer value. The range is from 0 to 255 seconds. When the dead interval is 0, the LSR does not timeout a PCEP session to a remote peer.

**Step 7**  
`pce reoptimize value`  
**Example:**  
```
RP/O/RP0/CPU0:router(config-mpls-te)# pce reoptimize 200
```

Configures a periodic reoptimization timer value. The range is from 60 to 604800 seconds. When the dead interval is 0, the LSR does not timeout a PCEP session to a remote peer.

**Step 8**  
`pce request-timeout value`  
**Example:**  
```
RP/O/RP0/CPU0:router(config-mpls-te)# pce request-timeout 10
```

Configures a PCE request-timeout. Range is from 5 to 100 seconds. PCC or PCE keeps a pending path request only for the request-timeout period.

**Step 9**  
`pce tolerance keepalive value`  
**Example:**  
```
RP/O/RP0/CPU0:router(config-mpls-te)# pce tolerance keepalive 10
```

Configures a PCE tolerance keepalive value (which is the minimum acceptable peer proposed keepalive).

**Step 10**  
`commit`  

**Step 11**  
`show mpls traffic-eng pce peer [address | all]`  
**Example:**  
```
RP/O/RP0/CPU0:router# show mpls traffic-eng pce peer
```

Displays the PCE peer address and state.

**Step 12**  
`show mpls traffic-eng pce tunnels`  
**Example:**  
```
RP/O/RP0/CPU0:router# show mpls traffic-eng pce tunnels
```

Displays the status of the PCE tunnels.

---

Configuring Policy-based Tunnel Selection

Perform this task to configure policy-based tunnel selection (PBTS).

SUMMARY STEPS

1. `configure`
2. `interface tunnel-te tunnel-id`
3. `ipv4 unnumbered type interface-path-id`
4. `signalled-bandwidth [bandwidth [class-type ct] | sub-pool bandwidth]`
5. `autoroute announce`
6. `destination ip-address`
7. `policy-class {1 - 7} | {default}`
8. `path-option preference-priority {explicit name explicit-path-name}`
9. `commit`

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure</td>
</tr>
</tbody>
</table>
| **Step 2** | interface tunnel-te tunnel-id  
Example:  
RP/0/RP0/CPU0:router(config)# interface tunnel-te 6 | Configures an MPLS-TE tunnel interface and enables traffic engineering on a particular interface on the originating node. |
| **Step 3** | ipv4 unnumbered type interface-path-id  
Example:  
RP/0/RP0/CPU0:router(config-if)# ipv4 unnumbered Loopback0 | Assigns a source address so that forwarding can be performed on the new tunnel. |
| **Step 4** | signalled-bandwidth [bandwidth [class-type ct] | sub-pool bandwidth]  
Example:  
RP/0/RP0/CPU0:router(config-if)# signalled-bandwidth 10 class-type 1 | Configures the bandwidth required for an MPLS TE tunnel. Because the default tunnel priority is 7, tunnels use the default TE class map (namely, class-type 1, priority 7). |
| **Step 5** | autoroute announce  
Example:  
RP/0/RP0/CPU0:router(config-if)# autoroute announce | Enables messages that notify the neighbor nodes about the routes that are forwarding. |
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 6    | destination *ip-address* | Assigns a destination address on the new tunnel.  
|      | Example: RP/0/RP0/CPU0:router(config-if)# destination 10.1.1.1 |  
|      | • Destination address is the remote node’s MPLS-TE router ID.  
|      | • Destination address is the merge point between backup and protected tunnels. |
| 7    | policy-class \{1 - 7\} | Configures PBTS to direct traffic into specific TE tunnels or default class.  
|      | Example: RP/0/RP0/CPU0:router(config-if)# policy-class 1 | Multiple EXP values can be specified as part of a policy-class, separated by spaces. The EXP values configured to a TE tunnel effectively form a monolithic policy-class, which should not overlap with other policy-classes. Once an EXP value is used in a policy-class configuration, it can only be reused if the subsequent policy-class configurations containing that EXP value are identical. For example, if the configuration policy-class 1 2 3 is applied to one or more tunnels, configurations such as policy-class 1, policy-class 2 3, or policy-class 3 4 5 become invalid. |
| 8    | path-option preference-priority {explicit name explicit-path-name} | Sets the path option to explicit with a given name (previously configured) and assigns the path ID.  
|      | Example: RP/0/RP0/CPU0:router(config-if)# path-option 1 explicit name backup-path |  
| 9    | commit | |

### Configuring the Automatic Bandwidth Functions

Perform this task to configure the following automatic bandwidth functions:

- **Application frequency**
  
  Configures the application frequency in which a tunnel bandwidth is updated by the automatic bandwidth.

- **Bandwidth collection**
  
  Configures only the bandwidth collection.

- **Bandwidth parameters**
  
  Configures the minimum and maximum automatic bandwidth to set on a tunnel.

- **Adjustment threshold**
  
  Configures the adjustment threshold for each tunnel.

- **Overflow detection**
  
  Configures the overflow detection for each tunnel.

### SUMMARY STEPS

1. configure
2. `interface tunnel-te tunnel-id`
3. auto-bw
4. application `minutes`
5. `bw-limit {min bandwidth} {max bandwidth}`
6. `adjustment-threshold percentage [min minimum-bandwidth]`
7. `overflow threshold percentage [min bandwidth] limit limit`
8. `commit`
9. `show mpls traffic-eng tunnels [auto-bw]`

</tbody>
</table>
**Example:**  |  |
RP/0/RP0/CPU0:router(config)# explicit-path name backup-srlg  |  |
| **Step 3**  | index 1 exclude-address 192.168.92.1 |
**Example:**  |  |
RP/0/RP0/CPU0:router router(config-expl-path)# index 1 exclude-address 192.168.92.1  |  |
| **Step 4**  | index 2 exclude-srlg 192.168.92.2 |
**Example:**  |  |
RP/0/RP0/CPU0:router router(config-expl-path)# index 2 exclude-srlg 192.168.92.2  |  |
Using Explicit Path With Exclude SRLG

Perform this task to use an explicit path with the exclude SRLG option on the static backup tunnel.

**SUMMARY STEPS**

1. configure
2. mpls traffic-eng
3. interface type interface-path-id
4. backup-path tunnel-te tunnel-number
5. exit
6. exit
7. interface tunnel-te tunnel-id
8. ipv4 unnumbered type interface-path-id
9. path-option preference-priority{ dynamic | explicit {identifier | name explicit-path-name}}
10. destination ip-address
11. exit
12. commit
13. show run explicit-path name name
14. show mpls traffic-eng topology path destination name explicit-path name

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>configure</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>mpls traffic-eng</td>
<td>Enters MPLS-TE configuration mode.</td>
</tr>
</tbody>
</table>

Example:

```
RP/0/RP0/CPU0:router(config)# mpls traffic-eng
```
<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| 3    | **interface** type interface-path-id  
**Example:**  
RP/0/RP0/CPU0:router(config-mpls-te)# interface POS 0/6/0/0 | Enables traffic engineering on a specific interface on the originating node. |
| 4    | **backup-path** tunnel-te tunnel-number  
**Example:**  
RP/0/RP0/CPU0:router(config-mpls-te)# backup-path tunnel-te 2 | Configures an MPLS TE backup path for a specific interface. |
| 5    | **exit**  
**Example:**  
RP/0/RP0/CPU0:router(config-mpls-te-if)# exit | Exits the current configuration mode. |
| 6    | **exit**  
**Example:**  
RP/0/RP0/CPU0:router(config-mpls-te)# exit | Exits the current configuration mode. |
| 7    | **interface** tunnel-te tunnel-id  
**Example:**  
RP/0/RP0/CPU0:router(config)# interface tunnel-te 2 | Configures an MPLS-TE tunnel interface. |
| 8    | **ipv4 unnumbered** type interface-path-id  
**Example:**  
RP/0/RP0/CPU0:router(config-if)# ipv4 unnumbered Loopback0 | Assigns a source address to set up forwarding on the new tunnel. |
| 9    | **path-option** preference-priority| dynamic | explicit  
{identifier | name explicit-path-name}  
**Example:**  
RP/0/RP0/CPU0:router(config-if)# path-option l explicit name backup-srlg | Sets the path option to explicit with a given name (previously configured) and assigns the path ID.  
**Note** You can use the dynamic option to dynamically assign a path. |
| 10   | **destination** ip-address  
**Example:**  
RP/0/RP0/CPU0:router(config-if)# destination 192.168.92.125 | Assigns a destination address on the new tunnel.  
* Destination address is the remote node’s MPLS-TE router ID.  
* Destination address is the merge point between backup and protected tunnels.  
**Note** When you configure TE tunnel with multiple protection on its path and merge point is the same node for more than one protection, you must configure record-route for that tunnel. |

### Configuring Point-to-Multipoint TE

You must enable multicast routing on the edge router before performing Point-to-Multipoint (P2MP) TE configurations. To configure Point-to-Multipoint TE, perform these procedures:

### Enabling Multicast Routing on the Router

Perform this task to enable multicast routing on the router to configure P2MP tunnels.

**Before you begin**

- To configure Point-to-Multipoint (P2MP) tunnels, you must enable multicast routing on the router.  
- The customer-facing interface must enable multicast.

**SUMMARY STEPS**

1. configure  
2. multicast-routing  
3. address-family {ipv4 | ipv6}  
4. interface tunnel-mte tunnel-id  
5. enable
### Enabling Multicast Routing on the Router

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure</td>
<td>Enters multicast routing configuration mode.</td>
</tr>
<tr>
<td><strong>Step 2</strong> multicast-routing</td>
<td></td>
</tr>
</tbody>
</table>
| Example: | RP/0/RP0/CPU0:router(config)# multicast-routing  
RP/0/RP0/CPU0:router(config-mcast)# |
| **Step 3** address-family {ipv4 | ipv6} | Configures the available IPv4 or IPv6 address prefixes to enable multicast routing and forwarding on all router interfaces. |
| Example: | RP/0/RP0/CPU0:router(config-mcast)# address-family ipv6  
RP/0/RP0/CPU0:router(config-mcast-default-ipv6)# |
| **Step 4** interface tunnel-mte tunnel-id | Configures an MPLS-TE P2MP tunnel interface. |
| Example: | RP/0/RP0/CPU0:router(config-mcast-default-ipv6)# interface tunnel-mte 1  
RP/0/RP0/CPU0:router(config-mcast-default-ipv6-if)# |
| **Step 5** enable | Enables multicast routing on the tunnel-mte interface. |
| Example: | RP/0/RP0/CPU0:router(config-mcast-default-ipv6-if)# enable |
| **Step 6** exit | Exits the current configuration mode. |
| Example: | RP/0/RP0/CPU0:router(config-mcast-default-ipv6-if)# exit  
RP/0/RP0/CPU0:router(config-mcast-default-ipv6)# |
Purpose

Command or Action | Purpose
--- | ---
**Step 7** | **interface type interface-path-id**
**Example:**
RP/0/RP0/CPU0:router(config-mcast-default-ipv6)#
interface GigabitEthernet0/2/0/3
RP/0/RP0/CPU0:router(config-mcast-default-ipv6-if)#
Configures multicast routing on the GigabitEthernet interface.

**Step 8** | **enable**
**Example:**
RP/0/RP0/CPU0:router(config-mcast-default-ipv6-if)#
enable
Enables multicast routing on the GigabitEthernet interface.

**Step 9** | **commit**

**Step 10** | **show pim ipv6 interface type interface-path-id**
**Example:**
RP/0/RP0/CPU0:router# show pim ipv6 interface tunnel-mte 1
Displays the output for the P2MP-TE tunnel interface that has IPv6 multicast enabled.

**Configuring Destinations for the Tunnel Interface**

Perform this task to configure three destinations for the tunnel interface for Point-to-Multipoint (P2MP).
These variations are listed to ensure that the destination and path option configurations are separate from the tunnel interface.

- Different path option is used for different destinations. This task shows three destinations.
- Explicit path option is based on an ID or a name.
- Default path option is similar to the Point-to-Point (P2P) LSP.

Before you begin
These prerequisites are required to configure destinations for the tunnel interface.

- Multicast routing must be enabled on both the tunnel-mte interface and customer-facing interface from the source.
- Static-group must be configured on the tunnel-mte interface to forward specified multicast traffic over P2MP LSP.

SUMMARY STEPS

1. configure
2. interface tunnel-mte tunnel-id
3. destination ip-address
4. path-option preference-priority explicit identifier path-number
5. path-option preference-priority dynamic
6. exit
7. destination ip-address
8. path-option preference-priority explicit name pathname
9. path-option preference-priority dynamic
10. exit
11. destination ip-address
12. path-option preference-priority explicit name pathname [verbatim]
13. commit
14. show mpls traffic-eng tunnels [brief] [p2mp tunnel-number]

<td>ipv4 unnumbered loopback0</td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
| **Step 4** | **destination ip-address**  
Example:  
RP/0/RP0/CPU0:router(config-if)# destination  
100.0.0.3  
RP/0/RP0/CPU0:router(config-if-p2mp-dest)# | Sets the destination address for tunnel-mte from 1000 to 100.0.0.3. |
| **Step 5** | **logging events lsp-status state**  
Example:  
RP/0/RP0/CPU0:router(config-if-p2mp-dest)# logging events lsp-status state | Sends out the log message when the tunnel LSP goes up or down when the software is enabled. |
| **Step 6** | **logging events lsp-status reroute**  
Example:  
RP/0/RP0/CPU0:router(config-if-p2mp-dest)# logging events lsp-status reroute | Sends out the log message when the tunnel LSP is rerouted due to an FRR event when the software is enabled. |
| **Step 7** | **path-option preference-priority explicit name pathname**  
Example:  
RP/0/RP0/CPU0:router(config-if-p2mp-dest)# path-option 1 explicit name path123 | Specifies the path name of the IP explicit path. Destination 100.0.0.3 uses the explicit path that is identified by the explicit path name "path123." |
| **Step 8** | **exit**  
Example:  
RP/0/RP0/CPU0:router(config-if-p2mp-dest)# exit  
RP/0/RP0/CPU0:router(config-if)# | Exits the current configuration mode. |
| **Step 9** | **fast-reroute**  
Example:  
RP/0/RP0/CPU0:router(config-if)# fast-reroute | Enables fast-reroute (FRR) protection for a P2MP TE tunnel. |
| **Step 10** | **commit**  
Example: |  |
| **Step 11** | **show mpls traffic-eng tunnels [p2mp]**  
Example:  
RP/0/RP0/CPU0:router# show mpls traffic-eng tunnels p2mp | Displays the information for all P2MP tunnels. |
Enabling Soft-Preemption on a Node

Perform this task to enable the soft-preemption feature in the MPLS TE configuration mode. By default, this feature is disabled. You can configure the soft-preemption feature for each node. It has to be explicitly enabled for each node.

SUMMARY STEPS

1. configure
2. mpls traffic-eng
3. soft-preemption
4. timeout seconds
5. commit

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>

<tbody>
<tr>
<td>Step 1</td>
<td>configure</td>
<td></td>
</tr>
</tbody>
</table>
| Step 2 | mpls traffic-eng  
Example:  
RP/0/RP0/CPU0:router(config)# mpls traffic-eng | Enters MPLS-TE configuration mode. |
| Step 3 | auto-tunnel mesh  
Example:  
RP/0/RP0/CPU0:router(config-mpls-te)# auto-tunnel mesh | Enables auto-tunnel mesh groups globally. |
| Step 4 | timer removal unused timeout  
Example:  
RP/0/RP0/CPU0:router(config-mpls-te-auto-mesh)# timers removal unused 10 | Specifies a timer, in minutes, after which a down auto-tunnel mesh gets deleted whose destination was not in TE topology. The default value for this timer is 60.  
The timer gets started when these conditions are met:  
• Tunnel destination node is removed from the topology  
• Tunnel is in down state  
Note  
The unused timer runs per tunnel because the same destination in different mesh-groups may have different tunnels created. |

8. path-option preference-priority dynamic
9. commit
10. (Optional) show mpls traffic-eng autoroute
11. (Optional) show mpls traffic-eng forwarding-adjacency
### Configuring Path-selection Cost Limit

Apply the path-selection cost-limit configuration to set the upper limit on the path aggregate admin-weight when computing paths for MPLS-TE LSPs. Once the path-selection cost is configured, the periodic path verification will check if the cost-limit is crossed. Path-selection cost limit can be configured at global MPLS TE, per interface tunnel, and per path-option attribute set. The path-selection cost limit per path-option attribute set takes the highest priority, followed by per interface and MPLS TE global path-selection cost limit values.

#### Configuring Global Path-selection Cost Limit on MPLS TE Tunnels

Perform these steps to configure path-selection cost limit globally for MPLS TE tunnels:

**SUMMARY STEPS**

1. configure
2. mpls traffic-eng
3. path-selection cost-limit *cost-limit*
4. commit
## DETAILED STEPS

<table>

### Enabling Soft-preemption over FRR Backup Tunnels

Perform these tasks to enable LSP traffic to be moved over the backup tunnel when the LSP is soft-preempted. With this configuration, when there is a soft-preemption, the MPLS TE process triggers a rewrite to move the traffic on the backup tunnel, if the backup tunnel is ready. The rest of the soft-preemption process remains unchanged.

#### Before you begin

Ensure that the following configurations are enabled before enabling soft-preemption over FRR backup:

- Soft-preemption enabled.
- Fast-reroute (FRR) backup tunnel is activated.

### SUMMARY STEPS

1. configure
2. mpls traffic-eng
3. soft-preemption frr-rewrite
4. commit
### DETAILED STEPS

### Implementing Associated Bidirectional Label Switched Paths

Associated Bidirectional Label Switched Paths are LSP instances where the forward and the reverse direction paths are setup, monitored and protected independently and associated together during signaling. You use a RSVP Association object to bind the two forward and reverse LSPs together to form either a co-routed or non co-routed associated bidirectional TE tunnel.

You can associate a protecting MPLS-TE tunnel with either a working MPLS-TE LSP, protecting MPLS-TE LSP, or both. The working LSP is the primary LSP backed up by the protecting LSP. When a working LSP goes down, the protecting LSP is automatically activated. You can configure a MPLS-TE tunnel to operate without protection as well.

For more information on Associated Bidirectional Co-routed LSPs, see the *Cisco ASR 9000 Series Aggregation Services Router MPLS Configuration Guide, Release 5.2.x*. For information on the commands used for Associated Bidirectional Co-routed LSPs, see the *Cisco ASR 9000 Series Aggregation Services Router MPLS Command Reference, Release 5.2.x*.

### Signaling Methods and Object Association for Bidirectional LSPs

This section provides an overview of the association signaling methods for the bidirectional LSPs. Two unidirectional LSPs can be bound to form an associated bidirectional LSP in the following scenarios:

- No unidirectional LSP exists, and both must be established.
- Both unidirectional LSPs exist, but the association must be established.
• One unidirectional LSP exists, but the reverse associated LSP must be established.

Configuration information regarding the LSPs can be provided at one or both endpoints of the associated bidirectional LSP. Depending on the method chosen, there are two models of creating an associated bidirectional LSP: single-sided provisioning, and double-sided provisioning.

• **Single-sided Provisioning:** For the single-sided provisioning, the TE tunnel is configured only on one side. An LSP for this tunnel is initiated by the initiating endpoint with the Association Object inserted in the Path message. The other endpoint then creates the corresponding reverse TE tunnel and signals the reverse LSP in response to this. Currently, there is no support available for configuring single-sided provisioning.

• **Double-sided Provisioning:** For the double-sided provisioning, two unidirectional TE tunnels are configured independently on both sides. The LSPs for the tunnels are signaled with Association Objects inserted in the Path message by both sides to indicate that the two LSPs are to be associated to form a bidirectional LSP.

Consider this topology (an example of associated bidirectional LSP):

Here, LSP1 from A to B, takes the path A,D,B and LSP2 from B to A takes the path B,D,C,A. These two LSPs, once established and associated, form an associated bidirectional LSP between node A and node B. For the double sided provisioning model, both LSP1 and LSP2 are signaled independently with (Extended) Association Object inserted in the Path message, in which the Association Type indicating double-sided provisioning. In this case, the two unidirectional LSPs are bound together to form an associated bidirectional LSP based on identical Association Objects in the two LSPs' Path messages.

**Association Object:** An Association Object is used to bind unidirectional LSPs originating from both endpoints. The Association Object takes the following values:

- **Association Type:** In order to bind two reverse unidirectional LSPs to be an associated bidirectional LSP, the Association Type must be set to indicate either single sided or double sided LSPs.
- **Association ID:** For both single sided and double sided provisioning, Association ID must be set to a value assigned by the node that originates the association for the bidirectional LSP. This is set to the Tunnel ID of the bound LSP or the Tunnel ID of the binding LSP.
- **Association Source:** For double sided provisioning, Association Source must be set to an address selected by the node that originates the association for the bidirectional LSP. For single sided provisioning, Association Source must be set to an address assigned to the node that originates the LSP.
- **Global ID:** This is the global ID for the association global source. This must be set to the global ID of the node that originates the association for the bidirectional LSP.

**Note**

You must provide identical values for the content of the Association Object on either end of the participating LSPs to ensure successful binding of the LSPs.

*Configure Associated Bidirectional Co-routed LSPs, on page 153* describes the procedure to create associated bidirectional co-routed LSPs.
Associated Bidirectional Non Co-routed and Co-routed LSPs

This section provides an overview of associated bidirectional non co-routed and co-routed LSPs. Establishment of MPLS TE-LSP involves computation of a path between a head-end node to a tail-end node, signaling along the path, and modification of intermediate nodes along the path. The signaling process ensures bandwidth reservation (if signaled bandwidth is lesser than 0 and programming of forwarding entries.

Path computation is performed by the head-end nodes of both the participating LSPs using Constrained Shortest Path First (CSPF). CSPF is the 'shortest path (measured in terms of cost) that satisfies all relevant LSP TE constraints or attributes, such as required bandwidth, priority and so on.

**Associated Bidirectional Non Co-routed LSPs:** A non co-routed bidirectional TE LSP follows two different paths, that is, the forward direction LSP path is different than the reverse direction LSP path. Here is an illustration.

In the above topology:

- The outer paths (in green) are working LSP pairs.
- The inner paths (in red) are protecting LSP pairs.
- Router 1 sets up working LSP to Router 3 and protecting LSP to Router 3 independently.
- Router 3 sets up working LSP to Router 1 and protecting LSP to Router 1 independently.

Non co-routed bidirectional TE LSP is available by default, and no configuration is required.

**Note**

In case of non co-routed LSPs, the head-end nodes relax the constraint on having identical forward and reverse paths. Hence, depending on network state you can have identical forward and reverse paths, though the bidirectional LSP is co-routed.

**Associated Bidirectional Co-routed LSPs:** A co-routed bidirectional TE LSP denotes a bidirectional tunnel where the forward direction LSP and reverse direction LSP must follow the same path, for example, the same nodes and paths. Here is an illustration.
In the above topology:

- Paths at the top of the figure (in green) indicate working co-routed LSP pairs.
- Paths at the bottom of the figure (in red) indicate protecting co-routed LSP pairs.
- Router 1 sets up working LSP to Router 3 (in red) after performing bidirectional CSPF and sends reverse explicit route object (ERO) to Router 3. Node Router 3 uses the received reverse ERO to set up reverse red working LSP to Router 1.
- Router 3 sets up protecting LSP to Router 1 (in green) after performing bidirectional CSPF and sends reverse ERO to Router 1. Node Router 1 uses the received reverse ERO to set up reverse green protecting LSP to Router 3.

Configure Associated Bidirectional Co-routed LSPs, on page 153 describes the procedure to configure an associated bidirectional co-routed LSP.

Configure Associated Bidirectional Co-routed LSPs

A co-routed bidirectional packet LSP is a combination of two LSPs (one in the forward direction and the other in reverse direction) sharing the same path between a pair of ingress and egress nodes. It is established using the extensions to RSVP-TE. This type of LSP can be used to carry any of the standard types of MPLS-based traffic, including Layer 2 VPNs, Layer 2 circuits, and Layer 3 VPNs. You can configure a single BFD session for the bidirectional LSP (that is, you do not need to configure a BFD session for each LSP in each direction). You can also configure a single standby bidirectional LSP to provide a backup for the primary bidirectional LSP.

Before you begin

- You must have symmetric source and destination TE router IDs in order for bidirectional LSPs to be associated.
- Tunnels attributes must be configured identically on both sides of co-routed bidirectional LSP.

SUMMARY STEPS

1. `configure`
2. `interface tunnel-te tunnel-id`
3. `bidirectional`
4. `association {id <0-65535> | source-address <IP address>} [global-id <0-4294967295>]`
5. `association type co-routed`
6. `commit`
7. `show mpls traffic-eng tunnels bidirectional-associated co-routed`
**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure</td>
<td></td>
</tr>
</tbody>
</table>
| **Step 2** interface tunnel-te *tunnel-id*  
Example:  
RP/0/RSP0/CPU0:router# interface tunnel-te 1 | Configures an MPLS-TE tunnel interface.                                 |
| **Step 3** bidirectional          | Configure the ingress router for the LSP and include the bidirectional statement to specify that the LSP be established as a bidirectional LSP. |
| Example:  
RP/0/0/CPU0:router(config-if)# bidirectional |                                                                          |
| **Step 4** association *id <0-65535>* | Set the association ID that uniquely identifies the association of LSPs, which is the tunnel ID of the bound LSP (master/slave mode) or the tunnel ID of the binding LSP (peer mode). Also, set the source address to the tunnel sender address of the bound LSP (master/slave mode) or the tunnel sender address of the binding LSP (peer mode). Optionally, specify the global ID for association global source. |
Example:  
RP/0/0/CPU0:router(config-if-bidir)# association id 1 source-address 11.0.0.1 |                                                                          |
| **Step 5** association type co-routed | Specify that the LSP be established as a associated co-routed bidirectional LSP. |
Example:  
RP/0/0/CPU0:router(config-if-bidir)#association type co-routed |                                                                          |
| **Step 6** commit                  |                                                                          |
| **Step 7** show mpls traffic-eng tunnels bidirectional-associated co-routed  
Example:  
RP/0/0/CPU0:router#show mpls traffic-eng tunnels bidirectional-associated co-routed | Shows details of an associated co-routed bidirectional LSP. |

**Show output for an associated co-routed bidirectional LSP configuration**

This is a sample of the output for the `show mpls traffic-eng tunnels role head` command.

RP/0/RSP0/CPU0:router# show mpls traffic-eng tunnels role head

Name: tunnel-te1  Destination: 49.49.49.2
Signalled-Name: IMC0_t1
Status:
  Admin: up Oper: up Path: valid Signalling: connected
  path option 1, type dynamic (Basis for Setup, path weight 20 (reverse 20))
  path option 1, type dynamic (Basis for Standby, path weight 20 (reverse 20))
Path Protection

Path protection provides an end-to-end failure recovery mechanism (that is, full path protection) for associated bidirectional MPLS-TE LSPs. Associated bidirectional MPLS-TE LSPs support 1:1 path protection. You can configure the working and protecting LSPs as part of configuring the MPLS-TE tunnel. The working LSP is the primary LSP used to route traffic, while the protecting LSP is a backup for a working LSP. If the working LSP fails, traffic is switched to the protecting LSP until the working LSP is restored, at which time traffic forwarding reverts back to the working LSP.

When FRR is not enabled on a tunnel, and when GAL-BFD and/or Fault OAM is enabled on an associated bidirectional co-routed LSP, path-protection is activated by the FIB running on the line card that hosts the working LSP. The failure on the working LSP can be detected using BFD or Fault OAM.

Configure Path Protection for Associated Bidirectional LSPs, on page 155 provides procedural details.

You can use the `show mpls traffic-eng fast-reroute log` command to confirm whether protection switching has been activated by FIB.

Configure Path Protection for Associated Bidirectional LSPs

**SUMMARY STEPS**

1. configure
2. interface tunnel-te tunnel-id
3. ipv4 unnumbered type interface-path-id
4. bfd {fast-detect | encap-mode}
5. destination ip-address
6. bidirectional
### DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>configure</td>
<td></td>
</tr>
</tbody>
</table>
| **Step 2** | interface tunnel-te <tunnel-id> | Configures an MPLS-TE tunnel interface.  
Example:  
RP/0/RSP0/CPU0:router# interface tunnel-te 1 |
| **Step 3** | ipv4 unnumbered type interface-path-id | Assigns a source address so that forwarding can be performed on the new tunnel. Loopback is commonly used as the interface type.  
Example:  
RP/0/RP0/CPU0:router(config-if)# ipv4 unnumbered Loopback0 |
| **Step 4** | bfd {fast-detect | encap-mode} | Specify if you want BFD enabled for the LSP over a Generic Associated Channel (G-ACh) or over a IP channel. IP channel is the default.  
Example:  
RP/0/RSP0/CPU0:IMC0(config-if)# bfd  
RP/0/RSP0/CPU0:IMC0(config-if-tunte-bfd)#fast-detect  
RP/0/RSP0/CPU0:IMC0(config-if-tunte-bfd)#encap-mode gal |
| **Step 5** | destination <ip-address> | Assigns a destination address on the new tunnel.  
The destination address is the remote node’s MPLS-TE router ID.  
Example:  
RP/0/RP0/CPU0:router(config-if)# destination 49.49.49.2 |
| **Step 6** | bidirectional | Configure the ingress router for the LSP and include the bidirectional statement to specify that the LSP be established as a bidirectional LSP.  
Example:  
Router(config-if)# bidirectional |
| **Step 7** | bidirectional association {id <0-65535>| source-address <IP address>} [global-id <0-4294967295>] | Set the association ID that uniquely identifies the association of LSPs, which is the tunnel ID of the bound LSP (master/slave mode) or the tunnel ID of the binding LSP (peer mode). Also, set the source address to the tunnel sender address of the bound LSP (master/slave mode) or the tunnel sender address of the binding LSP (peer mode). Also, set the ID for associating the global source.  
Example:  
Router(config-if-bidir)# association id 1  
source-address 11.0.0.1  
Note: Association ID, association source and optional global-id must be configured identically on both the endpoints. |

**Example**

Here is a sample configuration with path protection defined for the Associated Bidirectional LSP.

```
RP/0/RSP0/CPU0:IMC0#config
RP/0/RSP0/CPU0:IMC0(config)#interface tunnel-te 1
RP/0/RSP0/CPU0:IMC0(config-if)#ipv4 unnumbered loopback0
RP/0/RSP0/CPU0:IMC0(config-if)#destination 49.49.49.2
RP/0/RSP0/CPU0:IMC0(config-if)#bidirectional
RP/0/RSP0/CPU0:IMC0(config-if-bidir)#association id 100 source-address 49.49.4$
RP/0/RSP0/CPU0:IMC0(config-if-bidir)#association type co-routed
RP/0/RSP0/CPU0:IMC0(config-if-bidir-co-routed)#path-protection
RP/0/RSP0/CPU0:IMC0(config-if)#path-option 1 dynamic
RP/0/RSP0/CPU0:IMC0(config-if)#commit
```

**OAM Support for Associated Bidirectional LSPs**

You can opt to configure operations, administration and management (OAM) support for Associated Bidirectional LSPs in the following areas:

- **Continuity check**: You can configure bidirectional forwarding detection (BFD) over a Generic Associated Channel (G-ACh) with hardware assist. This allows for BFD Hello packets to be generated and processed in hardware making smaller Hello intervals such as 3.3 ms feasible. For more information on BFD and BFD hardware offload see *Implementing BFD* module in the *Cisco ASR 9000 Series Aggregation Services Router Routing Configuration Guide*.

- **Fault notification**: You can run Fault OAM over associated bidirectional co-routed LSPs to convey fault notification from mid-point to end-point of the LSP. The following fault OAM messages are supported:
  - **Link Down Indication (LDI)**: generated when an interface goes down (for example, to fiber-cut) at mid-point.
  - **Lock Report (LKR)**: generated when an interface is shutdown at mid-point.
You can configure fault OAM to generate OAM message at mid-point or enable protection switching due to fault OAM at end-point. Generate Fault OAM Messages at Mid-point, on page 158 and Generate Fault OAM Messages at End-point, on page 158 provides procedural details.

• **Fault diagnostics:** You can use the ping and traceroute features as a means to check connectivity and isolate failure points for both co-routed and non-co-routed bidirectional TE tunnels. *MPLS Network Management with MPLS LSP Ping and MPLS SP Traceroute* provides details.

---

**Generate Fault OAM Messages at Mid-point**

To program all bi-directional LSPs to generate fault OAM message at mid-point use the following steps:

**SUMMARY STEPS**

1. configure
2. mpls traffic-eng
3. fault-oam
4. commit

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> configure</td>
<td></td>
</tr>
</tbody>
</table>
| **Step 2** mpls traffic-eng  
**Example:**  
RP/0/RSP0/CPU0:IMO(config)# mpls traffic-eng | Configures an MPLS-TE tunnel interface. |
| **Step 3** fault-oam  
**Example:**  
RP/0/RSP0/CPU0:IMC0(config-mpls-te)#fault-oam | Enable fault OAM for an associated bidirectional LSP. |
| **Step 4** commit |         |

**Generate Fault OAM Messages at End-point**

In order to enable protection switching due to fault OAM at end-point use the following steps:

**SUMMARY STEPS**

1. configure
2. interface tunnel-te *tunnel-id*
3. bidirectional association type co-routed fault-oam
4. commit

**DETAILED STEPS**

### Pseudowire Call Admission Control

You can use the Pseudowire Call Admission Control (PW CAC) process to check for bandwidth constraints and ensure that once the path is signaled, the links (pseudowires) participating in the bidirectional LSP association have the required bandwidth. Only pseudowires with sufficient bandwidth are admitted in the bidirectional LSP association process. Configure Pseudowire Bandwidth in the Cisco ASR 9000 Series Aggregation Services Router L2VPN and Ethernet Services Configuration Guide provides procedural details.

### Configure Named Tunnel and Named Path Option

Perform this task to uniquely name TE (Traffic Engineering) tunnels in a network and their path options using STRING names.

#### SUMMARY STEPS

#### DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1 configure</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: RP/0/RP0/CPU0:router# configure</td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
</tr>
<tr>
<td>Step 2 mpls traffic-eng</td>
<td>Enters MPLS-TE configuration mode.</td>
</tr>
<tr>
<td>Example: RP/0/RP0/CPU0:router(config)# mpls traffic-eng</td>
<td></td>
</tr>
<tr>
<td>Step 3 named-tunnels</td>
<td>Enters the named tunnels configuration sub-mode.</td>
</tr>
<tr>
<td>Example: RP/0/RP0/CPU0:router(config-mpls-te)# named-tunnels</td>
<td></td>
</tr>
<tr>
<td>Step 4 tunnel-te tunnel-name</td>
<td>Specifies the TE tunnel name using STRING characters. The STRING limit is 59.</td>
</tr>
<tr>
<td>Example: RP/0/RP0/CPU0:router(config-mpls-te-named-tunnels)# tunnel-te FROM-NY-TO-LA</td>
<td></td>
</tr>
<tr>
<td>Step 5 destination address</td>
<td>Assigns a destination address to the new tunnel.</td>
</tr>
<tr>
<td>Example: RP/0/RP0/CPU0:router(config-mpls-te-tunnel-name)# destination 192.168.0.1</td>
<td></td>
</tr>
<tr>
<td>Step 6 path-option path-name</td>
<td>Specifies the path option name.</td>
</tr>
<tr>
<td>Example: RP/0/RP0/CPU0:router(config-mpls-te-tunnel-name)# path-option VIA_DC</td>
<td></td>
</tr>
<tr>
<td>Step 7 preference value</td>
<td>Specifies the path option preference. The range is from 1 to 4294967295. Lower values have a higher preference.</td>
</tr>
<tr>
<td>Example: RP/0/RP0/CPU0:router(config-path-option-name)# preference 10</td>
<td></td>
</tr>
<tr>
<td>Step 8 computation { explicit explicit-name</td>
<td>dynamic }</td>
</tr>
<tr>
<td>Example: RP/0/RP0/CPU0:router(config-path-option-name)# computation explicit MY_EXPLICIT_PATH</td>
<td>Note: You can use the dynamic option as the path computation method, where the path is dynamically calculated.</td>
</tr>
<tr>
<td>Step 9 root</td>
<td></td>

RP/0/RP0/CPU0:router(config)# ipv4 unnumbered mpls traffic-eng loopback 0` |                                                                 |
|        | Step 11                           | commit                                                                  |

**Verify Named Tunnel and Named Path Option Configuration: Example**

Use the `show mpls traffic-eng tunnels name` `tunnel-name` command to verify the named tunnel configuration. The following example shows sample output for this command:

```
show mpls traffic-eng tunnels name FROM-NY-TO-LA

Name: FROM-NY-TO-LA  Destination: 192.168.0.1  Ifhandle:0x580
Tunnel-ID: 32769
Status:
  Admin:  up Oper:  down  Path:  valid  Signalling:  connected
  path option VIA_DC, preference 10,  type explicit MY_EXPLICIT_PATH
G-PID: 0x0800 (derived from egress interface properties)
Bandwidth Requested: 0 kbps  CT0
Creation Time: Fri Jun 10 15:32:00 2016 (00:36:10 ago)
Config Parameters:
  Bandwidth: 0 kbps (CT0)  Priority: 7 7  Affinity: 0x0/0xffffff
  Metric Type: TE (global)
  Path Selection:
    Tiebreaker: Min-fill (default)
  Hop-limit: disabled
  Cost-limit: disabled
  Path-invalidiation timeout: 10000 msec (default), Action: Tear (default)
  AutoRoute: disabled  LockDown: disabled  Policy class: not set
  Forward class: 0 (default)
  Forwarding-Adjacency: disabled
  Autoroute Destinations: 0
  Loadshare: 0 equal loadshares
  Auto-bw: disabled
  Fast Reroute: Disabled, Protection Desired: None
  Path Protection: Not Enabled
  BFD Fast Detection: Disabled
  Reoptimization after affinity failure: Enabled
  Soft Preemption: Disabled
Displayed 1 (of 3) heads, 0 (of 0) midpoints, 0 (of 0) tails
Displayed 0 up, 1 down, 0 recovering, 0 recovered head
```

**Configuration Examples for Cisco MPLS-TE**

These configuration examples are used for MPLS-TE:
Configure Fast Reroute and SONET APS: Example

When SONET Automatic Protection Switching (APS) is configured on a router, it does not offer protection for tunnels; because of this limitation, fast reroute (FRR) still remains the protection mechanism for MPLS-TE.

When APS is configured in a SONET core network, an alarm might be generated toward a router downstream. If this router is configured with FRR, the hold-off timer must be configured at the SONET level to prevent FRR from being triggered while the core network is performing a restoration. Enter the following commands to configure the delay:

```
RP/0/RP0/CPU0:router(config)# controller sonet 0/6/0/0 delay trigger line 250
RP/0/RP0/CPU0:router(config)# controller sonet 0/6/0/0 path delay trigger 300
```

Build MPLS-TE Topology and Tunnels: Example

The following examples show how to build an OSPF and IS-IS topology:

(OSPF)

```
configure
  mpls traffic-eng
  interface pos 0/6/0/0
  router id loopback 0
  router ospf 1
  router-id 192.168.25.66
  area 0
  interface pos 0/6/0/0
  interface loopback 0
  mpls traffic-eng router-id 192.168.70.1
  mpls traffic-eng area 0
  rsvp
  interface pos 0/6/0/0
  bandwidth 100
  commit
show mpls traffic-eng topology
show mpls traffic-eng link-management advertisement
```

(IS-IS)

```
configure
  mpls traffic-eng
  interface pos 0/6/0/0
  router id loopback 0
  router isis lab
  address-family ipv4 unicast
  mpls traffic-eng level 2
  mpls traffic-eng router-id 192.168.70.2
  !
  interface POS0/0/0/0
  address-family ipv4 unicast
  !
```

The following example shows how to configure tunnel interfaces:

```
interface tunnel-te1
  destination 192.168.92.125
  ipv4 unnumbered loopback 0
```
Configure IETF DS-TE Tunnels: Example

The following example shows how to configure DS-TE:

```
rsvp
  interface pos 0/6/0/0
  bandwidth rdm 100 150 bc1 50
  mpls traffic-eng
ds-te mode ietf
  interface tunnel-te 1
  bandwidth 10 class-type 1
  commit

configure
  rsvp interface 0/6/0/0
  bandwidth mam max-reservable-bw 400 bc0 300 bc1 200
  mpls traffic-eng
ds-te mode ietf
ds-te model mam
  interface tunnel-te 1 bandwidth 10 class-type 1
  commit
```
Configure MPLS-TE and Fast-Reroute on OSPF: Example

CSPF areas are configured on a per-path-option basis. The following example shows how to use the traffic-engineering tunnels (tunnel-te) interface and the active path for the MPLS-TE tunnel:

```
configure
interface tunnel-te 0
  path-option 1 explicit id 6 ospf 126 area 0
  path-option 2 explicit name 234 ospf 3 area 7 verbatim
  path-option 3 dynamic isis mtbf level 1 lockdown
commit
```

Configure the Ignore IS-IS Overload Bit Setting in MPLS-TE: Example

This example shows how to configure the IS-IS overload bit setting in MPLS-TE:

This figure illustrates the IS-IS overload bit scenario:
Consider a MPLS TE topology in which usage of nodes that indicated an overload situation was restricted. In this topology, the router R7 exhibits overload situation and hence this node cannot be used during TE CSPF. To overcome this limitation, the IS-IS overload bit avoidance (OLA) feature was introduced. This feature allows network administrators to prevent RSVP-TE label switched paths (LSPs) from being disabled when a router in that path has its Intermediate System-to-Intermediate System (IS-IS) overload bit set.

The IS-IS overload bit avoidance feature is activated at router R1 using this command:

```
mpls traffic-eng path-selection ignore overload
```

```
configure
mpls traffic-eng
path-selection ignore overload
commit
```

```
Configure an Interarea Tunnel: Example

The following configuration example shows how to configure a traffic engineering interarea tunnel. Router R1 is the headend for tunnel1, and router R2 (20.0.0.20) is the tailend. Tunnel1 is configured with a path option that is loosely routed through Ra and Rb.

```configure
interface Tunnel-te1
  ipv4 unnumbered Loopback0
  destination 192.168.20.20
  signalled-bandwidth 300
  path-option 1 explicit name path-tunnel1

explicit-path name path-tunnel1
  index 10 next-address loose ipv4 unicast 192.168.40.40
  index 20 next-address loose ipv4 unicast 192.168.60.60
  index 30 next-address loose ipv4 unicast 192.168.20.20
```

The following configuration example shows how to configure loose-path retry period (range is 30 to 600 seconds) on headend router.

```config
mpls traffic-eng
  timers loose-path retry-period 120
```

The following configuration example shows the global configuration for loose hop expansion affinity or metric on ABR.

```config
mpls traffic-eng path-selection loose-expansion affinity 0xff
mpls traffic-eng path-selection loose-expansion metric te class-type 5
```
Configure Forwarding Adjacency: Example

The following configuration example shows how to configure an MPLS-TE forwarding adjacency on tunnel-te 68 with a holdtime value of 60:

```plaintext
configure
  interface tunnel-te 68
  forwarding-adjacency holdtime 60
  commit
```

```
Configure PCE: Example

The following configuration example illustrates a PCE configuration:

```
configure
mpls traffic-eng
    interface pos 0/6/0/0
    pce address ipv4 192.168.25.66
    router id loopback 0
    router ospf 1
    router-id 192.168.25.66
    area 0
    interface pos 0/6/0/0
    interface loopback 0
    mpls traffic-eng router-id 192.168.70.1
    mpls traffic-eng area 0
    rsvp
    interface pos 0/6/0/0
    bandwidth 100
    commit
```

The following configuration example illustrates PCC configuration:

```
configure
    interface tunnel-te 10
    ipv4 unnumbered loopback 0
    destination 1.2.3.4
    path-option 1 dynamic pce
    mpls traffic-eng
    interface pos 0/6/0/0
    router id loopback 0
    router ospf 1
    router-id 192.168.25.66
```
Configure Policy-based Tunnel Selection: Example

The following configuration example illustrates a PBTS configuration:

```
configure
  interface tunnel-te0
  ipv4 unnumbered Loopback3
  signalled-bandwidth 50000
  autoroute announce
  destination 1.5.177.2
  policy-class 2
  path-option 1 dynamic
```

Configure Tunnels for Path Protection: Example

The path protection feature is configured on only the source router. The dynamic path option is a prerequisite to configure a path protection.

```
interface tunnel-te150
  ipv4 unnumbered Loopback150
  autoroute announce
  destination 151.151.151.151
  affinity 11 mask 11
  path-protection
  path-option 2 explicit name p2mp3-p2mp4-p2mp5_1
  path-option 10 dynamic
```

Configure Tunnels for Explicit Path Protection: Example

The path protection feature is configured on only the source router. The protected-by keyword configures path protection for an explicit path that is protected by another explicit path.

```
interface tunnel-te150
  ipv4 unnumbered Loopback150
  autoroute announce
  destination 151.151.151.151
  affinity 11 mask 11
  path-protection
  path-option 2 explicit name p2mp3-p2mp4-p2mp5_1 protected-by 10
  path-option 10 explicit
```

Configure Tunnels for Co-existence of Path Protection with Fast Reroute: Example

The path protection feature is configured on only the source router. The dynamic path option is a prerequisite to configure a path protection.

```
interface tunnel-te1
  fast-reroute
  ipv4 unnumbered Loopback150
  autoroute announce
  destination 151.151.151.151
  affinity 11 mask 11
  path-protection
  path-option 2 explicit name p2mp3-p2mp4-p2mp5_1
  path-option 10 dynamic
```

Configure Automatic Bandwidth: Example

The following configuration example illustrates an automatic bandwidth configuration:

```
configure
  interface tunnel-te6
    auto-bw
      bw-limit min 10000 max 500000
      overflow threshold 50 min 1000 limit 3
      adjustment-threshold 20 min 1000
      application 180
```

```

The following example shows the NHOP and NNHOP backup tunnels with excluded SRLG values.

```
RP/0/RP0/CPU0:router# show mpls traffic-eng topology path dest 100.0.0.5 exclude-srlg ipaddr
Path Setup to 100.0.0.2:
bw 0 (CT0), min_bw 0, metric: 30
setup_pri 7, hold_pri 7
affinity_bits 0x0, affinity_mask 0xffffffff
Exclude SRLG Intf Addr : 50.4.5.5
SRLGs Excluded : 10, 30, 1500, 10000000, 4294967290, 4294967295
Hop0:50.5.1.5
Hop1:50.5.1.1
Hop2:50.1.3.1
Hop3:50.1.3.3
Hop4:50.2.3.3
Hop5:50.2.3.2
Hop6:100.0.0.2
```

The following example shows an extract of explicit-path set to protect a specific interface.

```
RP/0/RP0/CPU0:router# sh mpls traffic-eng topology path dest 10.0.0.5 explicit-path name
Path Setup to 100.0.0.5:
bw 0 (CT0), min_bw 9999, metric: 2
setup_pri 7, hold_pri 7
affinity_bits 0x0, affinity_mask 0xffffffff
SRLGs Excluded: 10, 30, 77, 88, 1500, 10000000, 4294967290, 4294967295
Hop0:50.3.4.3
Hop1:50.3.4.4
Hop2:50.4.5.4
Hop3:50.4.5.5
```
Configure the MPLS-TE Auto-Tunnel Backup: Example

The following example shows the auto-tunnel backup configuration for core or edge routers.

```
RP/0/RP0/CPU0:router(config)#
mpls traffic-eng
    auto-tunnel backup
        tunnel-id min 60000 max 61000
        interface pos 0/1/0/0
        auto-tunnel backup
            attribute-set ab
```

The following example shows the protection (NNHOP and SRLG) that was set on the auto-tunnel backup.

```
RP/0/RP0/CPU0:router# show mpls traffic-eng tunnels 1

Implementing MPLS Traffic Engineering
Configure Point-to-Multipoint TE: Examples

These configuration examples show how to configure Point-to-Multipoint TE:

Configure Point-to-Multipoint for the Source: Example

At the source, multicast routing must be enabled on both the tunnel-mte interface and customer-facing interface. Then, the static-group must be configured on the tunnel-mte interface to forward specified multicast traffic over P2MP LSP.

```
multicast-routing
address-family ipv6
    interface tunnel-mte 1
        enable
        !
    interface GigabitEthernet0/2/0/3
        enable
        !
    !
    router mld
    vrf default
    interface tunnel-mte 1
        static-group ff35::1 2000::1 3eFF::A
        !
        !
    interface tunnel-mte 1
        ipv4 unnumbered Loopback0
        destination 3.3.3.3
        path-option 1 dynamic
        destination 4.4.4.4
        path-option 1 dynamic
        !
```

Related Topics

- Enabling Multicast Routing on the Router, on page 123

Configure the Point-to-Multipoint Tunnel: Example

There is no difference between logging events at the tunnel level for both P2P and P2MP. The P2MP tunnel reoptimizes only at the per tunnel level.

```
interface tunnel-mte1
  ipv4 unnumbered Loopback0
  destination 60.60.60.60
  logging events lsp-status state
  logging events lsp-status reroute
  path-option 10 explicit name toR6_via_R2andR3
  !
  logging events lsp-status reoptimize
  logging events lsp-status state
  logging events lsp-status reroute
  fast-reroute
  record-route
  !
  explicit-path name PATH7
  index 1 next-address strict ipv4 unicast 192.168.7.2
  index 2 next-address strict ipv4 unicast 192.168.7.1
  index 3 next-address strict ipv4 unicast 192.168.16.1
  index 4 next-address strict ipv4 unicast 192.168.16.2
```

- Logging Per Destinations for Point-to-Multipoint, on page 131
- Point-to-Multipoint Traffic-Engineering Overview, on page 29

Disable a Destination: Example

From the tunnel-mte interface, you can disable the destination.

```
interface tunnel-mte101
  ipv4 unnumbered Loopback0
  destination 150.150.150.150
  disable
  path-option 10 dynamic
  !
  destination 150.150.150.150
  path-option 2 dynamic
  
```

Configure the Point-to-Multipoint Solution: Example

Requirements for MPLS-TE Configuration

Before the Point-to-Multipoint (P2MP) tunnel is defined, these MPLS-TE requirements must be configured:

- Multiprotocol Label Switching traffic engineering (MPLS-TE)
- Resource ReSerVation Protocol (RSVP)
- Open Shortest Path First (OSPF)

This example shows the entire P2MP solution:

- Source is the location where the P2MP-TE tunnel interface is created.
- Tunnel contains multiple destinations. For example, the P2MP-TE tunnel is configured with two leaf node destinations by using the dynamic and explicit path options.
- Fast-Reroute (FRR) is specified on the P2MP tunnel.
- All regular TE tunnel options such as affinity or bandwidth are configured.
- Static mapping of the group address to the P2MP tunnel is done in IGMP.
  - Internet Group Management Protocol (IGMP).
  - The P2MP-TE midpoint configuration requires only TE and Interior Gateway Protocol (IGP) information.
  - The P2MP-TE receiver configuration requires a static group and RPF map.

Configure MPLS TE Path-selection Cost Limit: Example

This example shows how to set the path-selection cost limit for MPLS TE tunnels at global, TE tunnel interface, and path-option attribute-set levels. By default, the cost-limit set at path-option attribute set takes the priority, if all options are configured and per tunnel interface level takes priority over global cost-limit. At per tunnel interface level, the global cost-limit takes the priority.

Configure Entropy Labels for MPLS TE Networks

Most MPLS networks use load balancing techniques for traffic engineering. What causes latency in such widespread networks is the time taken to inspect the label stack at each transit Label Switching Router (LSR) to determine the next hop or path.

The latency can be reduced by inserting a label known as the entropy label on top of the label stack at the ingress LSR. The entropy label contains the keys required by the load balancing function, and thus eliminates the need for deep packet inspection at transit LSRs. The ingress LSR, which has all the information about incoming packets, extracts the load balancing keys from the entropy label and decides the optimum paths for the packets. The transit LSRs use the rest of the label stack to forward the packets along the pre-determined paths.

The advantages of using entropy labels in MPLS networks are:

• Ingress LSRs operate at lower bandwidths than transit LSRs, and are hence the ideal choice for load balancing.

• Transit LSRs do not need to perform deep packet inspection and can effectively load balance the packets as decided by the Ingress LSRs.

• Transit LSRs are spared from the problem of misinterpreting the protocol denoted in the label stack and thereby causing inequitable distribution of traffic across equal cost paths exiting from the LSR.

The following illustration shows the transit of a packet through the MPLS network. The entropy label is attached at the ingress router for load balancing. When the optimum path is determined for the packet, which contains the payload (data) and the label stack, the entropy label is no longer required.

*Figure 13: Transit of an MPLS Packet with an Entropy Label*

Configuration

1. To configure an MPLS entropy label, use the following configuration.

   ```
   RP0/RP0/CPU0:router(config)# mpls ldp
   RP0/RP0/CPU0:router(config-ldp)# entropy-label
   ```
RP/0/RP0/CPU0:router(config-ldp)# commit
RP/0/RP0/CPU0:router(config-ldp)# end

2. Locate the route that needs to use the entropy label for load balancing.
   RP/0/RP0/CPU0:router# show cef exact-route 10.1.6.1 10.1.1.1
   10.1.1.1/32, version 40, internal 0x1000001 0x0 (ptr 0x8d42b4d8) [1], 0x0 (0x8d5c5020), 0xa20 (0x8e1c0098)
   ... Prefix Len 32, traffic index 0, precedence n/a, priority 4
   via Bundle-Ether613
   via 11.1.5.1/32, Bundle-Ether613, 2 dependencies, weight 0, class 0 [flags 0x0]
   path-idx 2 NHID 0x0 [0x8dd02920 0x8dd02810]
   next hop 11.1.5.1/32
   local adjacency
   local label 24002 labels imposed {ImplNull}

3. Use the route to pass the entropy label for load balancing.
   You are prompted for the option of entering the entropy label for multiple source-destination pairs.
   RP/0/RP0/CPU0:router# bundle-hash bundle-Ether 613
   Specify load-balance configuration (L3/3-tuple or L4/7-tuple) (L3,L4): L3
   Single SA/DA pair (IPv4,IPv6) or range (IPv4 only) or Entropy Label (MPLS only): S/R/E [S]: E
   Enter Entropy Label (in network byte order): 14001
   Entropy Label 14001 -- Link hashed to is TenGigE0/1/0/8/8
   Another? [y]:

4. Verify if traffic is getting load balanced with the MPLS entropy label configuration.
   RP/0/RP0/CPU0:router# show mpls forwarding exact-route label 24002 entropy-label 14001
<table>
