CHAPTER 1

Multichassis LACP

In Carrier Ethernet networks, various redundancy mechanisms provide resilient interconnection of nodes and networks. The choice of redundancy mechanisms depends on various factors such as transport technology, topology, single node versus entire network multihoming, capability of devices, autonomous system (AS) boundaries or service provider operations model, and service provider preferences.

Carrier Ethernet network high-availability can be achieved by employing both intra- and interchassis redundancy mechanisms. Cisco’s Multichassis EtherChannel (MCEC) solution addresses the need for interchassis redundancy mechanisms, where a carrier wants to “dual home” a device to two upstream points of attachment (PoAs) for redundancy. Some carriers either cannot or will not run loop prevention control protocols in their access networks, making an alternative redundancy scheme necessary. MCEC addresses this issue with enhancements to the 802.3ad Link Aggregation Control Protocol (LACP) implementation. These enhancements are provided in the Multichassis LACP (mLACP) feature described in this document.

- Prerequisites for mLACP, on page 1
- Restrictions for mLACP, on page 2
- Information About mLACP, on page 3
- How to Configure mLACP, on page 15
- Configuration Examples for mLACP, on page 34

Prerequisites for mLACP

- The command `lacp max-bundle` must be used on all PoAs in order to operate in PoA control and shared control modes.
  - The maximum number of links configured cannot be less than the total number of interfaces in the link aggregation group (LAG) that is connected to the PoA.
  - Each PoA may be connected to a dual-homed device (DHD) with a different number of links for the LAG (configured with a different number of maximum links).

- Each PoA must be configured using the `lacp min-bundle` command with the desired minimum number of links to maintain the LAG in the active state.

- For DHD control there must be an equal number of links going to each PoA.

- The max-bundle value must equal the number of active links connected locally to the PoA (no local intra-PoA active or standby protection).

- LACP fast switchover must be configured on all devices to speed convergence.
Restrictions for mLACP

- mLACP does not support Fast Ethernet.
- mLACP does not support half-duplex links.
- mLACP does not support multiple neighbors.
- Converting a port channel to mLACP can cause a service disruption.
- The maximum number of member links per LAG per PoA is restricted by the maximum number of ports per port channel, as limited by the platform.
- System priority on a DHD must be a lesser priority than on PoAs in POA and shared mode.
- MAC Tunneling Protocol (MTP) supports only one member link in a port channel. This is not applicable for Cisco ASR 903 RSP3 Module.
- A port-channel or its member links may flap while LACP stabilizes.
- DHD-based control does not function when min-links is not configured.
- DHD-controlled revertive behavior with min-links is not supported.
- Brute force failover mode is not supported on Cisco ASR 903 RSP3 Module.
- Brute-force failover always causes min-link failures.
- Any failure with brute-force failover behaves revertively.
- Pseudo-mLACP and ICCP-SM are not supported on Cisco ASR 903 RSP3 Module.

The following restrictions are applicable on the Cisco Aggregation Services Routers 900 Series:

- The `lacp max-bundle max-links` command must be used on all the PoAs in order to operate in PoA control and shared control modes.
  - The value of the max-links variable must be greater than the total number of interfaces in the LAG, which are connected to the PoA.
  - Each PoA may be connected to the dual-homed device (DHD) with a different number of links for the LAG (and, hence configured with a different value for the max-links value) variable.

- The `lacp min-bundle min-links` command has local scope only. Each PoA needs to be configured with the required minimum number of links to maintain the LAG in active state.

- mLACP and Pseudo-mLACP (P-mLACP) feature interoperability between the Cisco 7600 Series Routers and the Cisco ASR 903 is not supported when the former is used as one PoA and the Cisco ASR 903 as another PoA in the same redundancy group.

- mLACP for Layer 2 Virtual Private Network (L2VPN) is supported only with the new protocol-based CLIs.

- MAC Tunneling Protocol (MTP) is not supported.

- The following commands are not supported:
  - `ethernet mac-flush notification mirp`
Information About mLACP

Overview of Multichassis EtherChannel

In Multichassis EtherChannel (MCEC), the DHD is dual-homed to two upstream PoAs. The DHD is incapable of running any loop prevention control protocol such as Multiple Spanning Tree (MST). Therefore, another mechanism is required to prevent forwarding loops over the redundant setup. One method is to place the DHD’s uplinks in a LAG, commonly referred to as EtherChannel. This method assumes that the DHD is capable of running only IEEE 802.3ad LACP for establishing and maintaining the LAG.

LACP, as defined in IEEE 802.3ad, is a link-level control protocol that allows the dynamic negotiation and establishment of LAGs. An extension of the LACP implementation to PoAs is required to convey to a DHD that it is connected to a single virtual LACP peer and not to two disjointed devices. This extension is called Multichassis LACP or mLACP. The figure below shows this setup.

The PoAs forming a virtual LACP peer, from the perspective of the DHD, are defined as members of a redundancy group. For the PoAs in a redundancy group to appear as a single device to the DHD, the states between them must be synchronized through the Interchassis Communication Protocol (ICCP), which provides a control-only interchassis communication channel (ICC).

In Cisco IOS Release 12.2(33)SRE, the system functions in active/standby redundancy mode. In this mode DHD uplinks that connect to only a single PoA can be active at any time. The DHD recognizes one PoA as active and the other as standby but does not preclude a given PoA from being active for one DHD and standby for another. This capability allows two PoAs to perform load sharing for different services.

Interactions with the MPLS Pseudowire Redundancy Mechanism

The network setup shown in the figure above can be used to provide provider edge (PE) node redundancy for Virtual Private LAN Service (VPLS) and Virtual Private Wire Service (VPWS) deployments over Multiprotocol Label Switching (MPLS). In these deployments, the uplinks of the PoAs host the MPLS pseudowires that

- show ethernet service instance id mac-tunnel
- errdisable recovery cause mlacp
provide redundant connectivity over the core to remote PE nodes. Proper operation of the network requires
interaction between the redundancy mechanisms employed on the attachment circuits (for example, mLACP)
and those employed on the MPLS pseudowires. This interaction ensures the state (active or standby) is
synchronized between the attachment circuits and pseudowires for a given PoA.

RFC 4447 introduced a mechanism to signal pseudowire status via the Link Distribution Protocol (LDP) and
defined a set of status codes to report attachment circuit as well as pseudowire fault information. The Preferential
Forwarding Status bit (draft-ietf-pwe3-redundancy-bit) definition proposes to extend these codes to include
two bits for pseudowire redundancy applications:

- Preferential forwarding status: active or standby
- Request pseudowire switchover

The draft also proposes two modes of operation:

- Independent mode--The local PE decides on its pseudowire status independent of the remote PE.
- Primary and secondary modes--One of the PEs determines the state of the remote side through a handshake
  mechanism.

For the mLACP feature, operation is based on the independent mode. By running ICC between the PoAs,
only the preferential forwarding status bit is required; the request pseudowire switchover bit is not used.

The local pseudowire status (active or standby) is determined independently by the PoAs in a redundancy
group and then relayed to the remote PEs in the form of a notification. Similarly, the remote PEs perform
their own selection of their pseudowire status and notify the PoAs on the other side of the core.

After this exchange of local states, the pseudowires used for traffic forwarding are those selected to be active
independently on both local and remote ends.

The attachment circuit redundancy mechanism determines and controls the pseudowire redundancy mechanism.
mLACP determines the status of the attachment circuit on a given PoA according to the configured LACP
system and port priorities, and then the status of the pseudowires on a given PoA is synchronized with that
of the local attachment circuits. This synchronization guarantees that the PoA with the active attachment
circuits has its pseudowires active. Similarly, the PoA with the standby attachment circuits has its pseudowires
in standby mode. By ensuring that the forwarding status of the attachment circuits is synchronized with that
of the pseudowires, the need to forward data between PoA nodes within a redundancy group can be avoided.
This synchronization saves platform bandwidth that would otherwise be wasted on inter-PoA data forwarding
in case of failures.

**Redundancy Mechanism Processes**

The Carrier Ethernet redundancy solution should include the following processes (and how they apply to the
mLACP solution):

- Attachment circuit active or standby status selection--This selection can be performed by the access node
  or network, the aggregation node, or combination of the two. For mLACP, the attachment circuit status
  selection is determined through collaboration between the DHD and the PoAs.

- Pseudowire forwarding status notification--This notification is mandatory for mLACP operation in VPWS
  and VPLS deployments; that is, when the PoA uplinks employ pseudowire technology. When the PoAs
decide on either an active or standby role, they need to signal the status of the associated pseudowires
to the PEs on the far end of the network. For MPLS pseudowires, this is done using LDP.
• MAC flushing indication--This indication is mandatory for any redundancy mechanism in order to speed
convergence time and eliminate potential traffic blackholing. The mLACP redundancy mechanism should
be integrated with relevant 802.1Q/802.1ad/802.1ah MAC flushing mechanisms as well as MAC flushing
mechanisms for VPLS.

Blackholing occurs when incoming traffic is dropped without informing the source that the data did not reach
its intended recipient. A black hole can be detected only when lost traffic is monitored.

• Active VLAN notification--For mLACP, this notification is not required as long as the PoAs follow the
active/standby redundancy model.

The figure below shows redundancy mechanisms in Carrier Ethernet networks.

**Dual-Homed Topology Using mLACP**

The mLACP feature allows the LACP state machine and protocol to operate in a dual-homed topology. The
mLACP feature decouples the existing LACP implementation from the multichassis specific requirements,
allowing LACP to maintain its adherence to the IEEE 802.3ad standard. The mLACP feature exposes a single
virtual instance of IEEE 802.3ad to the DHD for each redundancy group. The virtual LACP instance
interoperates with the DHD according to the IEEE 802.3ad standard to form LAGs spanning two or more
chassis.

**LACP and 802.3ad Parameter Exchange**

In IEEE 802.3ad, the concatenation of the LACP system MAC address and system priority form an LACP
system ID (8 bytes). The system ID is formed by taking the two-byte system priority value as the most
significant two octets of the system ID. The system MAC address makes up the remainder of the system ID (octets 3 to 8). System ID priority comparisons are based on the lower numerically valued ID.

To provide the highest LACP priority, the mLACP module communicates the system MAC address and priority values for the given redundancy group to its redundancy group peer(s) and vice versa. The mLACP then chooses the lowest system ID value among the PoAs in the given redundancy group to use as the system ID of the virtual LACP instance of the redundancy group.

Cisco IOS Release 12.2(33)SRE introduces two LACP configuration commands to specify the system MAC address and system priority used for a given redundancy group: `mlacp system-mac mac-address` and `mlacp system-priority priority-value`. These commands provide better settings to determine which side of the attachment circuit will control the selection logic of the LAG. The default value for the system MAC address is the chassis backplane default MAC address. The default value for the priority is 32768.

**Port Identifier**

IEEE 802.3ad uses a 4-byte port identifier to uniquely identify a port within a system. The port identifier is the concatenation of the port priority and port number (unique per system) and identifies each port in the system. Numerical comparisons between port IDs are performed by unsigned integer comparisons where the 2-byte Port Priority field is placed in the most significant two octets of the port ID. The 2-byte port number makes up the third and fourth octets. The mLACP feature coordinates the port IDs for a given redundancy group to ensure uniqueness.

**Port Number**

A port number serves as a unique identifier for a port within a device. The LACP port number for a port is equal to the port’s ifIndex value (or is based on the slot and subslot identifiers on the Cisco 7600 router). LACP relies on port numbers to detect rewiring. For multichassis operation, you must enter the `mlacp node-id node-id` command to coordinate port numbers between the two PoAs in order to prevent overlap.

**Dual-Homed Topology Using mLACP**

The mLACP feature allows the LACP state machine and protocol to operate in a dual-homed topology. The mLACP feature decouples the existing LACP implementation from the multichassis specific requirements, allowing LACP to maintain its adherence to the IEEE 802.3ad standard. The mLACP feature exposes a single virtual instance of IEEE 802.3ad to the DHD for each redundancy group. The virtual LACP instance interoperates with the DHD according to the IEEE 802.3ad standard to form LAGs spanning two or more chassis.

**Multichassis Considerations**

Because LACP is a link layer protocol, all messages exchanged over a link contain information that is specific and local to that link. The exchanged information includes:

- System attributes--priority and MAC address
- Link attributes--port key, priority, port number, and state

When extending LACP to operate over a multichassis setup, synchronization of the protocol attributes and states between the two chassis is required.
System MAC Address

LACP relies on the system MAC address to determine the identity of the remote device connected over a particular link. Therefore, to mask the DHD from its connection to two disjointed devices, coordination of the system MAC address between the two PoAs is essential. In Cisco IOS software, the LACP system MAC address defaults to the ROM backplane base MAC address and cannot be changed by configuration. For multichassis operation the following two conditions are required:

- System MAC address for each PoA should be communicated to its peer--For example, the PoAs elect the MAC address with the lower numeric value to be the system MAC address. The arbitration scheme must resolve to the same value. Choosing the lower numeric MAC address has the advantage of providing higher system priority.

- System MAC address is configurable--The system priority depends, in part, on the MAC address, and a service provider would want to guarantee that the PoAs have higher priority than the DHD (for example, if both DHD and PoA are configured with the same system priority and the service provider has no control over DHD). A higher priority guarantees that the PoA port priorities take precedence over the DHD’s port priority configuration. If you configure the system MAC address, you must ensure that the addresses are uniform on both PoAs; otherwise, the system will automatically arbitrate the discrepancy, as when a default MAC address is selected.

System Priority

LACP requires that a system priority be associated with every device to determine which peer’s port priorities should be used by the selection logic when establishing a LAG. In Cisco IOS software, this parameter is configurable through the CLI. For multichassis operation, this parameter is coordinated by the PoAs so that the same value is advertised to the DHD.

Port Key

The port key indicates which links can form a LAG on a given system. The key is locally significant to an LACP system and need not match the key on an LACP peer. Two links are candidates to join the same LAG if they have the same key on the DHD and the same key on the PoAs; however, the key on the DHD is not required to be the same as the key on the PoAs. Given that the key is configured according to the need to aggregate ports, there are no special considerations for this parameter for multichassis operation.

Failure Protection Scenarios

The mLACP feature provides network resiliency by protecting against port, link, and node failures. These failures can be categorized into five types. The figure below shows the failure points in a network, denoted by the letters A through E.

- A--Failure of the uplink port on the DHD
- B--Failure of the Ethernet link
- C--Failure of the downlink port on the active PoA
- D--Failure of the active PoA node
- E--Failure of the active PoA uplinks
When any of these faults occur, the system reacts by triggering a switchover from the active PoA to the standby PoA. The switchover involves failing over the PoA’s uplinks and downlinks simultaneously.

Failure points A and C are port failures. Failure point B is an Ethernet link failure and failure point D is a node failure. Failure point E can represent one of four different types of uplink failures when the PoAs connect to an MPLS network:

- **Pseudowire failure**—Monitoring individual pseudowires (for example, using VCCV-BFD) and, upon a pseudowire failure, declare uplink failure for the associated service instances.
- **Remote PE IP path failure**—Monitoring the IP reachability to the remote PE (for example, using IP Route-Watch) and, upon route failure, declare uplink failure for all associated service instances.
- **LSP failure**—Monitoring the LSP to a given remote PE (for example, using automated LSP-Ping) and, upon LSP failure, declare uplink failure for all associated service instances.
- **PE isolation**—Monitoring the physical core-facing interfaces of the PE. When all of these interfaces go down, the PE effectively becomes isolated from the core network, and the uplink failure is declared for all affected service instances.

As long as the IP/MPLS network employs native redundancy and resiliency mechanisms such as MPLS fast reroute (FRR), the mLACP solution is sufficient for providing protection against PE isolation. Pseudowire, LSP, and IP path failures are managed by the native IP/MPLS protection procedures. That is, interchassis failover via mLACP is triggered only when a PE is completely isolated from the core network, because native IP/MPLS protection mechanisms are rendered useless. Therefore, failure point E is used to denote PE isolation from the core network.

The set of core-facing interfaces that should be monitored are identified by explicit configuration. The set of core-facing interfaces must be defined independently per redundancy group. Failure point E (unlike failure point A, B, or C) affects and triggers failover for all the multichassis LAGs configured on a given PoA.

### Operational Variants

LACP provides a mechanism by which a set of one or more links within a LAG are placed in standby mode to provide link redundancy between the devices. This redundancy is normally achieved by configuring more ports with the same key than the number of links a device can aggregate in a given LAG (due to hardware or...
software restrictions, or due to configuration). For example, for active/standby redundancy, two ports are configured with the same port key, and the maximum number of allowed links in a LAG is configured to be 1. If the DHD and PoAs are all capable of restricting the number of links per LAG by configuration, three operational variants are possible.

**DHD-based Control**

The value of PoAs must be greater than the value of DHD. In DHD-based control, maximum number of links per bundle should be one. The PoAs must be configured to limit the maximum number of links per bundle to be greater than one. Thus, the selection of the active/standby link is the responsibility of the DHD. Which link is designated active and which is marked standby depends on the relative port priority, as configured on the system with the higher system priority. A PoA configured with a higher system priority can still determine the selection outcome. The DHD makes the selection and places the link with lower port priority in standby mode.

To accommodate DHD-controlled failover, the DHD must be configured with the max-bundle value equal to a number of links (L), where L is the fewest number of links connecting the DHD to a PoA. The max-bundle value restricts the DHD from bundling links to both PoAs at the same time (active/active). Although the DHD controls the selection of active/standby links, the PoA can still dictate the individual member link priorities by configuring the PoA’s virtual LACP instance with a lower system priority value than the DHD’s system priority.

The DHD control variant must be used with a PoA minimum link threshold failure policy where the threshold is set to L (same value for L as described above). A minimum link threshold must be configured on each of the PoAs because an A, B, or C link failure that does not trigger a failover (minimum link threshold is still satisfied) causes the DHD to add one of the standby links going to the standby PoA to the bundle. This added link results in the unsupported active/active scenario.

**Note**

DHD control does not use the mLACP hot-standby state on the standby PoA, which results in higher failover times than the other variants.

DHD control eliminates the split brain problem on the attachment circuit side by limiting the DHD’s attempts to bundle all the links.

**PoA Control**

In PoA control, the PoA is configured to limit the maximum number of links per bundle to be equal to the number of links (L) going to the PoA. The DHD is configured with that parameter set to some value greater than L. Thus, the selection of the active/standby links becomes the responsibility of the PoA.

**Shared Control (PoA and DHD)**

In shared control, both the DHD and the PoA are configured to limit the maximum number of links per bundle to L—the number of links going to the PoA. In this configuration, each device independently selects the active/standby link. Shared control is advantageous in that it limits the split-brain problem in the same manner as DHD control, and shared control is not susceptible to the active/active tendencies that are prevalent in DHD control. A disadvantage of shared control is that the failover time is determined by both the DHD and the PoA, each changing the standby links to SELECTED and waiting for each of the WAIT_WHILE_TIMERs to expire before moving the links to IN_SYNC. The independent determination of failover time and change of link states means that both the DHD and PoAs need to support the LACP fast-switchover feature in order to provide a failover time of less than one second.
mLACP Failover

The mLACP forces a PoA failover to the standby PoA when one of the following failures occurs:

- Failure of the DHD uplink port, Ethernet link, or downlink port on the active PoA—A policy failover is triggered via a configured failover policy and is considered a forced failover. When the number of active and SELECTED links to the active PoA goes below the configured minimum threshold, mLACP forces a failover to the standby PoA’s member links. This minimum threshold is configured using the `lacp min-links` command in interface configuration mode. The PoAs determine the failover independent of the operational control variant in use.

- Failure of the active PoA—This failure is detected by the standby PoA. mLACP automatically fails over to standby because mLACP on the standby PoA is notified of failure via ICRM and brings up its local member links. In the DHD-controlled variant, this failure looks the same as a total member link failure, and the DHD activates the standby links.

- Failure of the active PoA uplinks—mLACP is notified by ICRM of PE isolation and relinquishes its active member links. This failure is a “forced failover” and is determined by the PoAs independent of the operational control variant in use.

Dynamic Port Priority

The default failover mechanism uses dynamic port priority changes on the local member links to force the LACP selection logic to move the required standby link(s) to the SELECTED and Collecting_Distributing state. This state change occurs when the LACP actor port priority values for all affected member links on the currently active PoA are changed to a higher numeric value than the standby PoA’s port priority (which gives the standby PoA ports a higher claim to bundle links). Changing the actor port priority triggers the transmission of an mLACP Port Config Type-Length-Value (TLV) message to all peers in the redundancy group. These messages also serve as notification to the standby PoA(s) that the currently active PoA is attempting to relinquish its role. The LACP then transitions the standby link(s) to the SELECTED state and moves all the currently active links to STANDBY.

Dynamic port priority changes are not automatically written back to the running configuration or to the NVRAM configuration. If you want the current priorities to be used when the system reloads, the `mlacp lag-priority` command must be used and the configuration must be saved.

Revertive and Nonrevertive Modes

Dynamic port priority functionality is used by the mLACP feature to provide both revertive mode and nonrevertive mode. The default operation is revertive, which is the default behavior in single chassis LACP. Nonrevertive mode can be enabled on a per port-channel basis by using the `lacp failover non-revertive` command in interface configuration mode. In Cisco IOS Release 12.2(33)SRE this command is supported only for mLACP.

Nonrevertive mode is used to limit failover and, therefore, possible traffic loss. Dynamic port priority changes are utilized to ensure that the newly activated PoA remains active after the failed PoA recovers.

Revertive mode operation forces the configured primary PoA to return to active state after it recovers from a failure. Dynamic port priority changes are utilized when necessary to allow the recovering PoA to resume its active role.
**Brute Force Shutdown**

**Note**
This feature is not applicable for Cisco ASR 903 RSP3 Module.

A brute-force shutdown is a forced failover mechanism to bring down the active physical member link interface(s) for the given LAG on the PoA that is surrendering its active status. The port-channel and any remaining active member link goes to an “err-disabled” state. This mechanism does not depend on the DHD’s ability to manage dynamic port priority changes and compensates for deficiencies in the DHD’s LACP implementation.

The brute-force shutdown changes the status of each member link to ADMIN_DOWN to force the transition of the standby links to the active state. Note that this process eliminates the ability of the local LACP implementation to monitor the link state.

The brute-force shutdown operates in revertive mode, so dynamic port priorities cannot be used to control active selection. The brute-force approach is configured by the `lacp failover brute-force` command in interface configuration mode. This command is not allowed in conjunction with a nonrevertive configuration.

**Peer Monitoring with Interchassis Redundancy Manager**

There are two ways in which a peer can be monitored with Interchassis Redundancy Manager (ICRM):

- Routewatch (RW)--This method is the default.
- Bidirectional Forwarding Detection (BFD)--You must configure the redundancy group with the `monitor peer bfd` command.

**Note**
In Cisco IOS XE Everest 16.5.1 release, RSP3 Module only supports single-hop BFD, hence only single-hop BFD is applicable for mLACP peer monitoring.

**Note**
For stateful switchover (SSO) deployments (with redundant support in the chassis), BFD monitoring and a static route for the ICCP connection are required to prevent “split brain” after an SSO failover.

For each redundancy group, for each peer (member IP), a monitoring adjacency is created. If there are two peers with the same IP address, the adjacency is shared regardless of the monitoring mode. For example, if redundancy groups 1 and 2 are peered with member IP 10.10.10.10, there is only one adjacency to 10.10.10.10, which is shared in both redundancy groups. Furthermore, redundancy group 1 can use BFD monitoring while redundancy group 2 is using RW.

**Note**
BFD is completely dependent on RW--there must be a route to the peer for ICRM to initiate BFD monitoring. BFD implies RW and sometimes the status of the adjacency may seem misleading but is accurately representing the state. Also, if the route to the peer PoA is not through the directly connected (back-to-back) link between the systems, BFD can give misleading results.

An example of output from the `show redundancy interchassis` command follows:
Device# show redundancy interchassis
Redundancy Group 1 (0x1)
Applications connected: mLACP
Monitor mode: Route-watch
member ip: 201.0.0.1 'mlacp-201', CONNECTED
Route-watch for 201.0.0.1 is UP
mLACP state: CONNECTED
ICRM fast-failure detection neighbor table
IP Address Status Type Next-hop IP Interface
========== ====== ==== =========== =========
201.0.0.1 UP RW

To interpret the adjacency status displayed by the show redundancy interchassis command, refer to the table below.

Table 1: Status Information from the show redundancy interchassis command

<table>
<thead>
<tr>
<th>Adjacency Type</th>
<th>Adjacency Status</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>RW</td>
<td>DOWN</td>
<td>RW or bfd is configured, but there is no route for the given IP address.</td>
</tr>
<tr>
<td>RW</td>
<td>UP</td>
<td>RW or bfd is configured. RW is up, meaning there is a valid route to the peer. If bfd is configured and the adjacency status is UP, bfd is probably not configured on the interface of the route’s adjacency.</td>
</tr>
<tr>
<td>BFD</td>
<td>DOWN</td>
<td>bfd is configured. A route exists and the route’s adjacency is to an interface that has bfd enabled. bfd is started but the peer is down. The DOWN status can be because the peer is not present or bfd is not configured on the peer’s interface.</td>
</tr>
<tr>
<td>BFD</td>
<td>UP</td>
<td>bfd is configured and operational.</td>
</tr>
</tbody>
</table>

Note: If the adjacency type is “bfd,” rw is up regardless of the bfd status.

MAC Flushing Mechanisms

When mLACP is used to provide multichassis redundancy in multipoint bridged services (for example, VPLS), there must be a MAC flushing notification mechanism in order to prevent potential traffic blackholing.

At the failover from a primary PoA to a secondary PoA, a service experiences traffic blackholing when the DHD in question remains inactive and while other remote devices in the network are attempting to send traffic to that DHD. Remote bridges in the network have stale MAC entries pointing to the failed PoA and direct traffic destined to the DHD to the failed PoA, where the traffic is dropped. This blackholing continues until the remote devices age out their stale MAC address table entries (which typically takes five minutes). To prevent this anomaly, the newly active PoA, which has taken control of the service, transmits a MAC flush notification message to the remote devices in the network to flush their stale MAC address entries for the service in question.

The exact format of the MAC flushing message depends on the nature of the network transport: native 802.1Q/802.1ad Ethernet, native 802.1ah Ethernet, VPLS, or provider backbone bridge (PBB) over VPLS. Furthermore, in the context of 802.1ah, it is important to recognize the difference between mechanisms used for customer-MAC (C-MAC) address flushing versus bridge-MAC (B-MAC) address flushing.

The details of the various mechanisms are discussed in the following sections.
Multiple I-SID Registration Protocol (MIRP) is enabled by default on 802.1ah service instances. The use of MIRP in 802.1ah networks is shown in the figure below.

Device DHD1 is dual-homed to two 802.1ah backbone edge bridges (BEB1 and BEB2). Assume that initially the primary path is through BEB1. In this configuration BEB3 learns that the host behind DHD1 (with MAC address CM1) is reachable via the destination B-MAC M1. If the link between DHD1 and BEB1 fails and the host behind DHD1 remains inactive, the MAC cache tables on BEB3 still refer to the BEB1 MAC address even though the new path is now via BEB2 with B-MAC address M2. Any bridged traffic destined from the host behind DHD2 to the host behind DHD1 is wrongfully encapsulated with B-MAC M1 and sent over the MAC tunnel to BEB1, where the traffic blackholes.

To circumvent the traffic blackholing problem when the link between DHD1 and BEB1 fails, BEB2 performs two tasks:

- Flushes its own MAC address table for the service or services in question.
- Transmits an MIRP message on its uplink to signal the far end BEB (BEB3) to flush its MAC address table. Note that the MIRP message is transparent to the backbone core bridges (BCBs). The MIRP message is processed on a BEB because only BCBs learn and forward based on B-MAC addresses and they are transparent to C-MAC addresses.

Note

MIRP triggers C-MAC address flushing for both native 802.1ah and PBB over VPLS. This is not applicable for Cisco ASR 903 RSP3 Module.

The figure below shows the operation of the MIRP.
The MIRP has not been defined in IEEE but is expected to be based on the IEEE 802.1ak Multiple Registration Protocol (MRP). MRP maintains a complex finite state machine (FSM) for generic attribute registration. In the case of MIRP, the attribute is an I-SID. As such, MIRP provides a mechanism for BEBs to build and prune a per I-SID multicast tree. The C-MAC flushing notification capability of MIRP is a special case of attribute registration in which the device indicates that an MIRP declaration is “new,” meaning that this notification is the first time a BEB is declaring interest in a particular I-SID.

**LDP MAC Address Withdraw**

When the mLACP feature is used for PE redundancy in traditional VPLS (that is, not PBB over VPLS), the MAC flushing mechanism is based on the LDP MAC Address Withdraw message as defined in RFC 4762. The required functional behavior is as follows: Upon a failover from the primary PoA to the standby PoA, the standby PoA flushes its local MAC address table for the affected services and generates the LDP MAC Address Withdraw messages to notify the remote PEs to flush their own MAC address tables. One message is generated for each pseudowire in the affected virtual forwarding instances (VFIs).
How to Configure mLACP

Configuring Interchassis Group and Basic mLACP Commands (Global Redundancy Group Configuration)

Perform this task to set up the communication between multiple PoAs and to configure them in the same group.

SUMMARY STEPS

1. enable
2. configure terminal
3. redundancy
4. interchassis group group-id
5. monitor peer bfd
6. member ip ip-address
7. mlacp node-id node-id
8. mlacp system-mac mac-address
9. mlacp system-priority priority-value
10. backbone interface type number
11. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>

### Configuring the mLACP Interchassis Group and Other Port-Channel Commands

Perform this task to set up mLACP attributes specific to a port channel. The `mlacp interchassis group` command links the port-channel interface to the interchassis group that was created in the previous Configuring Interchassis Group and Basic mLACP Commands (Global Redundancy Group Configuration), on page 15.
**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface port-channel *port-channel-number*
4. lacp max-bundle *max-bundles*
5. lacp failover {brute-force|non-revertive}
6. exit
7. redundancy
8. interchassis group *group-id*
9. exit
10. exit
11. errdisable recovery cause mlacp-minlink
12. end

## Configuring Redundancy for VPWS

Perform this task to provide Layer 2 VPN service redundancy for VPWS.

### SUMMARY STEPS

1. enable
2. configure terminal
3. pseudowire-class pw-class-name
4. encapsulation mpls
5. status peer topology dual-homed
6. exit
7. interface port-channel port-channel-number
8. no ip address
9. lacp fast-switchover
10. lacp max-bundle max-bundles
11. exit
12. redundancy
13. interchassis group group-id
14. exit
15. exit
16. interface port-channel port-channel-number
17. service instance id ethernet [evc-name]
18. encapsulation dot1q vlan-id [, vlan-id[- vlan-id]] [native]
19. exit
20. xconnect peer-ip-address vc-id [encapsulation mpls | pw-class pw-class-name] [pw-class pw-class-name] [sequencing {transmit | receive | both}]
21. backup peer peer-router-ip-addr vcid [pw-class pw-class-name] [priority value]
22. end

**Configuring Redundancy for VPLS**

**Coupled and Decoupled Modes for VPLS**

VPLS can be configured in either coupled mode or decoupled mode. Coupled mode is when at least one attachment circuit in VFI changes state to active, all pseudowires in VFI advertise active. When all attachment circuits in VFI change state to standby, all pseudowires in VFI advertise standby mode. See the figure below.

VPLS decoupled mode is when all pseudowires in the VFI are always active and the attachment circuit state is independent of the pseudowire state. This mode provides faster switchover time when a platform does not support pseudowire status functionality, but extra flooding and multicast traffic will be dropped on the PE with standby attachment circuits. However, if the attachment circuit is down, all pseudowires also go down. See the figure below.

**Steps for Configuring Redundancy for VPLS**

Perform the following task to configure redundancy for VPLS.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `l2 vfi name manual`
4. `vpn id vpn-id`
5. `status decoupled`
6. `neighbor neighbor ip-address vc-id {encapsulation mpls | pw-class pw-class-name}`
7. `exit`
8. `interface port-channel port-channel-number`
9. `no ip address`
10. `lACP fast-switchover`
11. `lACP max-bundle max-bundles`
12. **exit**
13. **redundancy**
14. **interchassis group** *group-id*
15. **exit**
16. **exit**
17. **interface port-channel** *port-channel-number*
18. **service instance** *id* *ethernet* [*evc-name*]
19. **encapsulation dot1q** *vlan-id* [*vlan-id*-*vlan-id*] [*native*]
20. **bridge-domain** *bridge-id* [*split-horizon* [*group* *group-id*]]
21. **exit**
22. **interface vlan** *vlanid*
23. **no ip address**
24. **xconnect vfi** *vfi-name*
25. **end**

<tr>
<td>Router(config-vfi)# neighbor 10.1.1.1 50 encapsulation mpls</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong></td>
<td>exit</td>
<td>Exits VFI configuration mode and returns to global configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config-vfi)# exit</td>
<td></td>
</tr>
<tr>
<td><strong>Step 8</strong></td>
<td>interface port-channel <em>port-channel-number</em></td>
<td>Configures the port channel and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config)# interface port-channel1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 9</strong></td>
<td>no ip address</td>
<td>Specifies that the VLAN interface does not have an IP address assigned to it.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config-if)# no ip address</td>
<td></td>
</tr>
<tr>
<td><strong>Step 10</strong></td>
<td>lacp fast-switchover</td>
<td>Enables LACP 1-to-1 link redundancy.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config-if)# lacp fast-switchover</td>
<td></td>
</tr>
<tr>
<td><strong>Step 11</strong></td>
<td>lacp max-bundle <em>max-bundles</em></td>
<td>Configures the max-bundle links that are connected to the PoA. The value of the <em>max-bundles</em> argument should not be less than the total number of links in the LAG that are connected to the PoA.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config-if)# lacp max-bundle 2</td>
<td></td>
</tr>
<tr>
<td>* • Determines whether the redundancy group is under DHD control, PoA control, or both.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>* • Range is 1 to 8. Default value is 8.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 12</strong></td>
<td>exit</td>
<td>Exits interface configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config-if)# exit</td>
<td></td>
</tr>
<tr>
<td><strong>Step 13</strong></td>
<td>redundancy</td>
<td>• Enters redundancy configuration mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config)# redundancy</td>
<td></td>
</tr>
<tr>
<td><strong>Step 14</strong></td>
<td>interchassis group <em>group-id</em></td>
<td>Specifies that the port channel is an mLACP port-channel.</td>
</tr>
<tr>
<td>Example:</td>
<td>Router(config-red)# interchassis group 230</td>
<td></td>
</tr>
<tr>
<td>* • The <em>group-id</em> should match the configured redundancy group.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td><strong>Step 15</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>exit</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router(config-r-ic)# exit</td>
<td>Exits interchassis redundancy mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 16</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>exit</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router(config-red)# exit</td>
<td>Exits redundancy configuration mode.</td>
<td></td>
</tr>
<tr>

<td>Configures the port channel and enters interface configuration mode.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router(config)# interface port-channel1</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 18</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>service instance  id  ethernet [evc-name]</td>
<td>Configures an Ethernet service instance and enters Ethernet service configuration mode.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router(config-if)# service instance 1 ethernet</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 19</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>encapsulation     dot1q vlan-id [vlan-id[vlan-id]]{native}</td>
<td>Enables IEEE 802.1Q encapsulation of traffic on a specified subinterface in a VLAN.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router(config-if-srv)# encapsulation dot1q 100</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 20</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>bridge-domain     bridge-id [split-horizon [group group-id]]</td>
<td>Configures the bridge domain. Binds the service instance to a bridge domain instance where domain-number is the identifier for the bridge domain instance.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router(config-if-srv)# bridge-domain 200</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 21</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>exit</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router(config-if-srv)# exit</td>
<td>Exits service instance configuration mode.</td>
<td></td>
</tr>
<tr>
<td><strong>Step 22</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>interface vlan    vlanid</td>
<td>Creates a dynamic switch virtual interface (SVI).</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router(config-if)# interface vlan 200</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Step 23</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>no ip address</td>
<td>Specifies that the VLAN interface does not have an IP address assigned to it.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Router(config-if)# no ip address</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Command or Action</td>
<td>Purpose</td>
<td></td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td>Step 24 xconnect vfi vfi-name</td>
<td>Specifies the Layer 2 VFI that you are binding to the VLAN port.</td>
<td></td>
</tr>
<tr>
<td>Example: Router(config-if)# xconnect vfi vfi-16</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Step 25 end</td>
<td>Returns the CLI to privileged EXEC mode.</td>
<td></td>
</tr>
<tr>
<td>Example: Router(config-if)# end</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Configuring Hierarchical VPLS**

Perform this task to configure Hierarchical VPLS (H-VPLS).

**SUMMARY STEPS**

1. enable
2. configure terminal
3. pseudowire-class pw-class-name
4. encapsulation mpls
5. status peer topology dual-homed
6. status decoupled
7. exit
8. interface port-channel port-channel-number
9. no ip address
10. lacp fast-switchover
11. lacp max-bundle max-bundles
12. exit
13. redundancy
14. interchassis group group-id
15. exit
16. exit
17. interface port-channel port-channel-number
18. service instance id ethernet [evc-name]
19. encapsulation dot1q vlan-id [, vlan-id[- vlan-id]] [native]
20. exit
21. xconnect peer-ip-address vc-id [encapsulation mpls | pw-class pw-class-name] [pw-class pw-class-name] [sequencing {transmit | receive | both}]
22. backup peer peer-router-ip-add vcid [pw-class pw-class-name] [priority value]
23. end
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><strong>Enter your password if prompted.</strong></td>
</tr>
<tr>
<td><code>enable</code></td>
<td><strong>router&gt; enable</strong></td>
</tr>
</tbody>
</table>

| **Step 2** | Enters global configuration mode. |
| **Example:** | **Router# configure terminal** |
| `configure terminal` | |

| **Step 3** | Specifies the name of a Layer 2 pseudowire class and enters pseudowire class configuration mode. |
| **Example:** | **Router(config)# pseudowire-class ether-pw** |
| `pseudowire-class pw-class-name` | |

| **Step 4** | Specifies that MPLS is used as the data encapsulation method for tunneling Layer 2 traffic over the pseudowire. |
| **Example:** | **Router(config-pw-class)# encapsulation mpls** |
| `encapsulation mpls` | |

| **Step 5** | Enables the reflection of the attachment circuit status onto both the primary and secondary pseudowires. This configuration is necessary if the peer PEs are connected to a dual-homed device. |
| **Example:** | **Router(config-pw-class)# status peer topology dual-homed** |
| `status peer topology dual-homed` | |

| **Step 6** | (Optional) Enables decoupled mode. The state of the attachment circuits on the uPE is decoupled from the state of the pseudowires. The mLACP controls the state of the attachment circuits. |
| **Example:** | **Router(config-pw-class)# status decoupled** |
| `status decoupled` | |

| **Step 7** | Exits pseudowire class configuration mode and returns to global configuration mode. |
| **Example:** | **Router(config-pw-class)# exit** |
| `exit` | |

| **Step 8** | Configures the port channel and enters interface configuration mode. |
| **Example:** | **Router(config)# interface port-channel1** |
| `interface port-channel port-channel-number` | |

<p>| <strong>Step 9</strong> | Specifies that the VLAN interface does not have an IP address assigned to it. |
| <strong>Example:</strong> | <strong>Router(config-if)# no ip address</strong> |
| <code>no ip address</code> | |</p>
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| **Step 10** lACP fast-switchover  
Example:  
Router(config-if)# lACP fast-switchover | Enables LACP 1-to-1 link redundancy. |
| **Step 11** lACP max-bundle *max-bundles*  
Example:  
Router(config-if)# lACP max-bundle 4 | Configures the max-bundle links that are connected to the PoA. The value of the *max-bundles* argument should not be less than the total number of links in the LAG that are connected to the PoA.  
- Determines whether the redundancy group is under DHD control, PoA control, or both.  
- Range is 1 to 8. Default value is 8. |
| **Step 12** exit  
Example:  
Router(config-if)# exit | Exits interface configuration mode. |
| **Step 13** redundancy  
Example:  
Router(config)# redundancy | Enters redundancy configuration mode. |
| **Step 14** interchassis group *group-id*  
Example:  
Router(config-red)# interchassis group 230 | Specifies that the port channel is an mLACP port channel.  
- The *group-id* should match the configured redundancy group. |
| **Step 15** exit  
Example:  
Router(config-r-ic)# exit | Exits interchassis redundancy mode. |
| **Step 16** exit  
Example:  
Router(config-red)# exit | Exits redundancy configuration mode. |
| **Step 17** interface port-channel *port-channel-number*  
Example:  
Router(config)# interface port-channel | Configures the port channel and enters interface configuration mode. |
| **Step 18** service instance *id ethernet* *evc-name*  
Example: | Configures an Ethernet service instance and enters Ethernet service configuration mode. |
<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Router(config-if)# service instance 1 ethernet</code></td>
<td>Enables IEEE 802.1Q encapsulation of traffic on a specified subinterface in a VLAN.</td>
</tr>
</tbody>
</table>

**Step 19**

**encapsulation dot1q** `vlan-id [, vlan-id[-vlan-id]]` [native]

**Example:**

`Router(config-if-srv)# encapsulation dot1q 100`

**Step 20**

**exit**

**Example:**

`Router(config-if-srv)# exit`

**Step 21**

**xconnect peer-ip-address vc-id {encapsulation mpls | pw-class pw-class-name} [pw-class pw-class-name] [sequencing {transmit | receive | both}]**

**Example:**

`Router(config-if)# xconnect 10.0.3.201 123 pw-class vlan-xconnect`

**Step 22**

**backup peer peer-router-ip-addr vcid [pw-class pw-class-name] [priority value]**

**Example:**

`Router(config-if)# backup peer 10.1.1.1 123 pw-class ether-pw`

**Step 23**

**end**

**Example:**

`Router(config-if)# end`

**Troubleshooting mLACP**

**Debugging mLACP**

Use these `debug` commands for general mLACP troubleshooting.

**SUMMARY STEPS**

1. `enable`
2. `debug redundancy interchassis {all | application | error | event | monitor}`
3. `debug mpls ldp iccp`
4. `debug lacp [all | event | fsm | misc | multi-chassis {all | database | lacp-mgr | redundancy-group | user-interface}] | packet]`
## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><strong>enable</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Router&gt; enable</td>
<td>Enables privileged EXEC mode.&lt;br&gt;• Enter your password if prompted.</td>

</tr>
<tr>
<td>Step 5</td>
<td><strong>debug lacp etherchannel</strong>&lt;br&gt;<strong>Example:</strong>&lt;br&gt;Router# debug lacp etherchannel</td>
<td>Enables debugging for etherchannel component.</td>
</tr>
</tbody>
</table>

## Debugging mLACP on an Attachment Circuit or EVC

Use these **debug** commands for troubleshooting mLACP on an attachment circuit or on an EVC.

## SUMMARY STEPS

1. **enable**
2. **debug acircuit** {checkpoint | error | event}
3. **debug ethernet service** {all | api | error | evc [evc-id] | ha | instance [id | interface type number | qos] | interface type number | microblock | oam-mgr}

## DETAILED STEPS

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td><strong>enable</strong>&lt;br&gt;<strong>Example:</strong></td>
<td>Enables privileged EXEC mode.&lt;br&gt;• Enter your password if prompted.</td>
</tr>
</tbody>
</table>
### Command or Action

**Step 1**

**Purpose**

*Enables privileged EXEC mode.*

**Example:**

```
Router> enable
```

**Step 2**

**Command or Action**

```
debug acircuit {checkpoint | error | event}
```

**Example:**

```
Router# debug acircuit event
```

**Purpose**

*Displays checkpoints, errors, and events that occur on the attachment circuits between the PE and CE routers.*

**Step 3**

**Command or Action**

```
debugethernet service {all | api | error | evc [evc-id] | ha | instance [id id] interface type number | qos} | interface type number | microblock | oam-mgr}
```

**Example:**

```
Router# debug ethernet service all
```

**Purpose**

*Enables debugging of Ethernet customer service instances.*

### Debugging mLACP on ATOM Pseudowires

Use the `debug mpls l2transport vc` command for troubleshooting mLACP on ATOM pseudowires.

**SUMMARY STEPS**

1. enable
2. debug mpls l2transport vc {event | fsm | ldp | sss | status {event | fsm}}

### Detailed Steps

**Step 1**

**Command or Action**

```
enable
```

**Example:**

```
Router> enable
```

**Purpose**

*Enables privileged EXEC mode.*

- Enter your password if prompted.

**Step 2**

**Command or Action**

```
debugethernet service {all | api | error | evc [evc-id] | ha | instance [id id] interface type number | qos} | interface type number | microblock | oam-mgr}
```

**Example:**

```
Router# debug mpls l2transport status event
```

**Purpose**

*Displays information about the status of ATOM virtual circuits (VCs).*

### Debugging Cross-Connect Redundancy Manager and Session Setup

Use the following `debug` commands to troubleshoot cross-connect, redundancy manager, and session setup.

**SUMMARY STEPS**

1. enable
2. debug sss error
3. debug sss events
4. `debug xconnect {error | event}`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Displays diagnostic information about errors that may occur during a subscriber service switch (SSS) call setup.</td>
</tr>
<tr>
<td><code>debug sss error</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong></td>
<td>Displays diagnostic information about SSS call setup events.</td>
</tr>
<tr>
<td><code>debug sss events</code></td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong></td>
<td>Displays errors or events related to a cross-connect configuration.</td>
</tr>
<tr>
<td>`debug xconnect {error</td>
<td>event}`</td>
</tr>
</tbody>
</table>

**Debugging VFI**

Use the `debug vfi` command for troubleshooting a VFI.

**SUMMARY STEPS**

1. `enable`
2. `debug vfi {checkpoint | error | event | fsm {error | event}}`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td><code>enable</code></td>
<td>- Enter your password if prompted.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td>Displays checkpoint information about a VFI.</td>
</tr>
<tr>
<td>`debug vfi {checkpoint</td>
<td>error</td>
</tr>
</tbody>
</table>
**Debugging the Segment Switching Manager (Switching Setup)**

Use the `debug ssm` command for troubleshooting a segment switching manager (SSM).

**SUMMARY STEPS**

1. enable
2. `debug ssm {cm errors | cm events | fhm errors | fhm events | sm errors | sm events | sm counters | xdr}

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td>`debug ssm {cm errors</td>
<td>cm events</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# <code>debug ssm cm events</code></td>
<td></td>
</tr>
</tbody>
</table>

**Debugging High Availability Features in mLACP**

Use the following `debug` commands for troubleshooting High Availability features in mLACP.

**SUMMARY STEPS**

1. enable
2. `debug mpls l2transport checkpoint`
3. `debug acircuit checkpoint`
4. `debug vfi checkpoint`

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td></td>
</tr>
<tr>
<td>enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example:</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td>Router&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong></td>
<td></td>
</tr>
<tr>
<td><code>debug mpls l2transport checkpoint</code></td>
<td>Enables the display of AToM events when AToM is configured for nonstop forwarding/stateful switchover (NSF/SSO) and Graceful Restart.</td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>Router# <code>debug mpls l2transport checkpoint</code></td>
<td></td>
</tr>
</tbody>
</table>
### Configuration Examples for mLACP

#### Example Configuring VPWS

Two sample configurations for VPWS follow: one example for an active PoA and the other for a standby PoA.

The figure below shows a sample topology for a VPWS configuration.

![VPWS Topology Diagram]

#### Active PoA for VPWS

The following VPWS sample configuration is for an active PoA:

```conf
mpls ldp router-id Loopback0 force
mpls ldp graceful-restart
mpls label protocol ldp
  bfd-template single-hop BFD_IPv4
  interval min-tx 50 min-rx 50 multiplier 3
  redundancy
  mode sso
```
interchassis group 100
monitor peer bfd
member ip 2.2.2.2
backbone interface GigabitEthernet0/1/4
backbone interface GigabitEthernet0/5/0
mlacp system-priority 1000
mlacp node-id 1
! pseudowire-class mlacp
encapsulation mpls
status peer topology dual-homed
! interface Loopback0
ip address 1.1.1.1 255.255.255.255
! interface Port-channel1
no ip address
load-interval 30
negotiation auto
lacp failover non-revertive
lacp fast-switchover
lacp max-bundle 4
lacp min-bundle 2
mlacp lag-priority 2
mlacp interchassis group 100
service instance 2 ethernet
  encapsulation dot1q 2
  rewrite ingress tag pop 1 symmetric
  xconnect 3.3.3.3 2 encapsulation mpls pw-class mlacp
  backup peer 4.4.4.4 2 pw-class mlacp
service instance 3999 ethernet
  encapsulation untagged
  l2protocol peer lacp
  bridge-domain 3999
!
interface GigabitEthernet0/1/0
no ip address
load-interval 30
carrier-delay msec 25
no negotiation auto
lacp rate fast
channel-group 1 mode active
end
!
interface TenGigabitEthernet0/2/0
ip address 11.11.1.2 255.255.255.0
load-interval 30
mpls ip
mpls label protocol ldp
bfd template BFD_IPv4
end

Standby PoA for VPWS

The following VPWS sample configuration is for a standby PoA:

mpls ldp router-id Loopback0 forc
mpls ldp graceful-restart
mpls label protocol ldp
!
bfd-template single-hop BFD_IPv4
interval min-tx 50 min-rx 50 multiplier 3
Example Configuring VPLS

Two sample configurations for VPLS follow: one example for an active PoA and the other for a standby PoA.

The figure below shows a sample topology for a VPLS configuration.
Active PoA for VPLS

The following VPLS sample configuration is for an active PoA:

```conf
mpls ldp router-id Loopback0 force
mpls ldp graceful-restart
mpls label protocol ldp
!
  bfd-template single-hop BFD_IPv4
  interval min-tx 50 min-rx 50 multiplier 3
!
redundancy
mode sso
interchassis group 100
  monitor peer bfd
  member ip 2.2.2.2

Multichassis LACP

Standby PoA for H-VPLS
Example Verifying VPWS on an Active PoA

The following `show` commands can be used to display statistics and configuration parameters to verify the operation of the mLACP feature on an active PoA:

**show lacp multichassis group**

Use the `show lacp multichassis group` command to display the interchassis redundancy group value and the operational LACP parameters.

```
Router# show lacp multichassis group 100
Interchassis Redundancy Group 100

Operational LACP Parameters:
  RG State: Synchronized
  System-Id: 1000.7426.acf6.c000
  ICCP Version: 0
  Backbone Uplink Status: Connected
Local Configuration:
  Node-id: 3
  System-Id: 1000.7426.acf6.c000

Peer Information:
  State: Up
  Node-id: 4
  System-Id: 2000.f078.166e.7a00
  ICCP Version: 0

State Flags: Active - A
  Standby - S
  Down - D
  AdminDown - AD
  Standby Reverting - SR
  Unknown - U

mLACP Channel-groups
  Channel State Priority Active Links Inactive Links
  Group Local/Peer Local/Peer Local/Peer
  1 A/S 32773/32774 4/4 0/0
```

**show lacp multichassis port-channel**

Use the `show lacp multichassis port-channel` command to display the interface port-channel value channel group, LAG state, priority, inactive links peer configuration, and standby links.

```
Router# show lacp multichassis port-channel1
Interface Port-channel1
Local Configuration:
  Address: 7426.acf6.c0cb
  Channel Group: 1
  State: Active
  LAG State: Up
  Priority: 32773
  Inactive Links: 0
  Total Active Links: 4
  Bundled: 4
  Selected: 4
  Standby: 0
  Unselected: 0
```
Peer Configuration:
Interface: Port-channel1
Address: f078.166e.7a41
Channel Group: 1
State: Standby
LAG State: Up
Priority: 32774
Inactive Links: 0
Total Active Links: 4
Bundled: 0
Selected: 0
Standby: 4
Unselected: 0

**show mpls ldp iccp**

Use the **show mpls ldp iccp** command to display the LDP session and ICCP state information.

```plaintext
Router# show mpls ldp iccp

ICPM RGID Table
iccp:
rg_id: 100, peer addr: 2.2.2.2
ldp_session 0x2, client_id 0
iccp state: ICPM_ICCP_CONNECTED
app type: MLACP
app state: ICPM_APP_CONNECTED, ptcl ver: 0
ICPM RGID Table total ICCP sessions: 1
ICPM LDP Session Table
iccp:
rg_id: 100, peer addr: 2.2.2.2
ldp_session 0x2, client_id 0
iccp state: ICPM_ICCP_CONNECTED
app type: MLACP
app state: ICPM_APP_CONNECTED, ptcl ver: 0
ICPM LDP Session Table total ICCP sessions: 1

ICPM peer table:
peer:
peer addr: 2.2.2.2, ldp session: 0x2
Discovery handle: 0x450595EC
Num ICCP Sessions: 1
ATS event occurred: TRUE
```

**show mpls l2transport**

Use the **show mpls l2transport** command to display the local interface and session details, destination address, and status.

```plaintext
Router# show mpls l2transport vc 2

<table>
<thead>
<tr>
<th>Local intf</th>
<th>Local circuit</th>
<th>Dest address</th>
<th>VC ID</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Po1</td>
<td>Eth VLAN 2</td>
<td>172.2.2.2</td>

    State: Standby
    LAG State: Up
    Priority: 32768
    Inactive Links: 0
    Total Active Links: 4

show mpls ldp iccp

Use the show mpls ldp iccp command to display the LDP session and ICCP state information.

Router# show mpls ldp iccp
ICPM RGID Table
  iccp:
    rg_id: 100, peer addr: 172.3.3.3
    ldp_session 0x3, client_id 0
show mpls l2transport

Use the `show mpls l2transport` command to display the local interface and session details, destination address, and the status.

```
Router# show mpls l2transport vc 4000
Local intf Local circuit Dest address VC ID Status
-------------- -------------------------- --------------- ---------- ----------
VFI VPLS VFI 172.2.2.2 4000 UP
VFI VPLS VFI 172.4.4.4 4000 UP
```

show etherchannel summary

Use the `show etherchannel summary` command to display the status and identity of the mLACP member links.

```
Router# show etherchannel summary
Flags: D - down P/bndl - bundled in port-channel
       I - stand-alone s/susp - suspended
       H - Hot-standby (LACP only)
       R - Layer3 S - Layer2
       U - in use f - failed to allocate aggregator

M - not in use, minimum links not met
w - unsuitable for bundling
s - waiting to be aggregated
d - default port

Number of channel-groups in use: 1
Number of aggregators: 1

Group Port-channel Protocol Ports
-----------------------------------------------
1 Po1(RU) LACP Gi0/0/1(bndl-act) Gi0/0/2(bndl-act) Gi0/0/3(bndl-act) Gi0/0/4(bndl-act)

RU - L3 port-channel UP State
SU - L2 port-channel UP state
P/bndl - Bundled
S/susp - Suspended
```

show lacp internal

Use the `show lacp internal` command to display the device, port, and member-link information.
Example Verifying VPLS on a Standby PoA

The show commands in this section can be used to display statistics and configuration parameters to verify the operation of the mLACP feature:

show lacp multichassis group

Use the show lacp multichassis group interchassis group number command to display the LACP parameters, local configuration, status of the backbone uplink, peer information, node ID, channel, state, priority, active, and inactive links.
show lacp multichassis portchannel

Use the `show lacp multichassis portchannel` command to display the interface port-channel value channel group, LAG state, priority, inactive links peer configuration, and standby links.

```
Router# show lacp multichassis port-channel1
Interface Port-channel1
Local Configuration:
  Address: 0014.6a8b.c680
  Channel Group: 1
  State: Standby
  LAG State: Up
  Priority: 32768
  Inactive Links: 0
  Total Active Links: 4
  Bundled: 0
  Selected: 0
  Standby: 4
  Unselected: 0
Peer Configuration:
  Interface: Port-channel1
  Address: 000a.f331.2680
  Channel Group: 1
  State: Active
  LAG State: Up
  Priority: 28000
  Inactive Links: 0
  Total Active Links: 4
  Bundled: 4
  Selected: 4
  Standby: 0
  Unselected: 0
```

show mpls ldp iccp

Use the `show mpls ldp iccp` command to display the LDP session and ICCP state information.

```
Router# show mpls ldp iccp
ICPM RGID Table
  iccp:
    rg_id: 100, peer addr: 172.1.1.1
    ldp_session 0x2, client_id 0
    iccp state: ICPM_ICCP_CONNECTED
    app type: MLACP
      app state: ICPM_APP_CONNECTED, ptcl ver: 0
ICPM RGID Table total ICCP sessions: 1
ICPM LDP Session Table
  iccp:
    rg_id: 100, peer addr: 172.1.1.1
    ldp_session 0x2, client_id 0
    iccp state: ICPM_ICCP_CONNECTED
    app type: MLACP
      app state: ICPM_APP_CONNECTED, ptcl ver: 0
ICPM LDP Session Table total ICCP sessions: 1
```

show mpls l2transport

Use the `show mpls l2transport` command to display the local interface and session details, destination address, and status.
show etherchannel summary

Use the `show etherchannel summary` command to display the status and identity of the mLACP member links.

Router# show etherchannel summary

Flags:  D - down       P/bndl - bundled in port-channel
        I - stand-alone  s/susp - suspended
        H - Hot-standby (LACP only)
        R - Layer3      S - Layer2
        U - in use       f - failed to allocate aggregator
        M - not in use, minimum links not met
        u - unsuitable for bundling
        w - waiting to be aggregated
        d - default port

Number of channel-groups in use: 1
Number of aggregators: 1

CHAPTER 2

Configuring IEEE 802.3ad Link Bundling

This document describes how the IEEE 802.3ad Link Bundling feature leverages the EtherChannel infrastructure within Cisco IOS XE software to manage the bundling of Ethernet links. The supported Ethernet link types for link bundling are Gigabit Ethernet and Ten Gigabit Ethernet.

- Prerequisites for Configuring IEEE 802.3ad Link Bundling, on page 55
- Restrictions for Configuring IEEE 802.3ad Link Bundling, on page 55
- Information About Configuring IEEE 802.3ad Link Bundling, on page 56
- How to Configure IEEE 802.3ad Link Bundling, on page 61
- Configuration Examples for IEEE 802.3ad Link Bundling, on page 75

Prerequisites for Configuring IEEE 802.3ad Link Bundling

- Knowledge of how EtherChannels and Link Aggregation Control Protocol (LACP) function in a network
- Verification that both ends of the LACP link have the same baseline software version

Restrictions for Configuring IEEE 802.3ad Link Bundling

- The maximum number of Ethernet links per bundle that can be supported varies by platform. Some platforms support 4 while other platforms support a maximum 8.
- All links must operate at the same link speed and in full-duplex mode (LACP does not support half-duplex mode).
- EVCs must be with configured untagged encapsulation along with L2PT peer, to activate the LACP neighbor configuration.
- All links must be configured as either EtherChannel links or LACP links.
- Only physical interfaces can form aggregations. Aggregations of VLAN interfaces are not possible nor is an aggregation of aggregations.
- If a router is connected to a switch, the bundle terminates on the switch.
- An EtherChannel will not form if one of the LAN ports is a Switched Port Analyzer (SPAN) destination port.
• All ports in an EtherChannel must use the same EtherChannel protocol.

• Maximum of four bundled ports per Ethernet port channel are supported.

• The maximum number of bundled ports per Ethernet port channel that can be supported varies by platform. Some platforms support 4, 8, and 14 while other platforms support a maximum of 16.

• Maximum of 64 Ethernet port channels in a chassis are supported.

• For RSP3, a maximum of 48 Ether channel and a maximum of 8 member-link per Ether channel are supported prior to the Cisco IOS XE 16.10.x release. Starting from the Cisco IOS XE 16.10.x release, 16 member-link per port channel is supported. The restrictions for 8 member-link port channel are also applicable for 16 member-link port channel.

• Quality of service (QoS) is supported on individual bundled ports and not on Ethernet port channels.

• Generic Routing Encapsulation (GRE) is not supported.

• Media type should be uniform across 1G and 10G links.

• 16 member links per port channel is supported only for 1G and 10G port-channel bundles.

• For load balancing across 16 member links per port channel, a wide range of addresses (such as Source MAC, Destination MAC, Source IP, Destination IP, and VC) should be used to have the traffic flowing across all the 16 member links.

• Maximum of 64 Ethernet port channels in a chassis are supported.

• Quality of service (QoS) is supported on individual bundled ports and not on Ethernet port channels.

• Generic Routing Encapsulation (GRE) is not supported.

• Media type should be uniform across 1G and 10G links.

• 16 member links per port channel is supported only for 1G and 10G port-channel bundles.

• For load balancing across 16 member links per port channel, a wide range of addresses (such as Source MAC, Destination MAC, Source IP, Destination IP, and VC) should be used to have the traffic flowing across all the 16 member links.

• LACP neighbor comes up on dot1q tagged EFP. This is a known behavior.

Information AboutConfiguringIEEE802.3adLinkBundling

GigabitEtherChannel

GigabitEtherChannel (GEC) is high-performance Ethernet technology that provides Gigabit per second (Gb/s) transmission rates. A Gigabit EtherChannel bundles individual Ethernet links (Gigabit Ethernet or Ten Gigabit Ethernet) into a single logical link that provides the aggregate bandwidth of up to eight physical links. All LAN ports in each EtherChannel must be the same speed and all must be configured as either Layer 2 or Layer 3 LAN ports. Inbound broadcast and multicast packets on one link in an EtherChannel are blocked from returning on any other link in the EtherChannel.
When a link within an EtherChannel fails, traffic previously carried over the failed link switches to the remaining links within that EtherChannel. Also when a failure occurs, a trap is sent that identifies the device, the EtherChannel, and the failed link.

**Port-Channel and LACP-Enabled Interfaces**

Each EtherChannel has a numbered port-channel interface that must be manually created before interfaces can be added to the channel group. The configuration of a port-channel interface affects all LAN ports assigned to that port-channel interface.

To change the parameters of all ports in an EtherChannel, change the configuration of the port-channel interface; for example, if you want to configure Spanning Tree Protocol or configure a Layer 2 EtherChannel as a trunk. Any configuration or attribute changes you make to the port-channel interface are propagated to all interfaces within the same channel group as the port-channel; that is, configuration changes are propagated to the physical interfaces that are not part of the port-channel but are part of the channel group.

The configuration of a LAN port affects only that LAN port.

**IEEE 802.3ad Link Bundling**

The IEEE 802.3ad Link Bundling feature provides a method for aggregating multiple Ethernet links into a single logical channel based on the IEEE 802.3ad standard. This feature helps improve the cost effectiveness of a device by increasing cumulative bandwidth without necessarily requiring hardware upgrades. In addition, IEEE 802.3ad Link Bundling provides a capability to dynamically provision, manage, and monitor various aggregated links and enables interoperability between various Cisco devices and devices of third-party vendors.

LACP supports the automatic creation of EtherChannels by exchanging LACP packets between LAN ports. LACP packets are exchanged only between ports in passive and active modes. The protocol “learns” the capabilities of LAN port groups dynamically and informs the other LAN ports. After LACP identifies correctly matched Ethernet links, it facilitates grouping the links into an EtherChannel. Then the EtherChannel is added to the spanning tree as a single bridge port.

Both the passive and active modes allow LACP to negotiate between LAN ports to determine if they can form an EtherChannel, based on criteria such as port speed and trunking state. (Layer 2 EtherChannels also use VLAN numbers.) LAN ports can form an EtherChannel when they are in compatible LACP modes, as in the following examples:

- A LAN port in active mode can form an EtherChannel with another LAN port that is in active mode.
- A LAN port in active mode can form an EtherChannel with another LAN port in passive mode.
- A LAN port in passive mode cannot form an EtherChannel with another LAN port that is also in passive mode because neither port will initiate negotiation.

LACP uses the following parameters:

- **LACP system priority**—You must configure an LACP system priority on each device running LACP. The system priority can be configured automatically or through the command-line interface (CLI). LACP uses the system priority with the device MAC address to form the system ID and also during negotiation with other systems.

- **LACP port priority**—You must configure an LACP port priority on each port configured to use LACP. The port priority can be configured automatically or through the CLI. LACP uses the port priority to decide which ports should be put in standby mode when there is a hardware limitation that prevents all
compatible ports from aggregating. LACP also uses the port priority with the port number to form the
port identifier.

- LACP administrative key—LACP automatically configures an administrative key value on each port
configured to use LACP. The administrative key defines the ability of a port to aggregate with other
ports. A port’s ability to aggregate with other ports is determined by the following:
  - Port physical characteristics such as data rate, duplex capability, and point-to-point or shared medium
  - Configuration restrictions that you establish

On ports configured to use LACP, it tries to configure the maximum number of compatible ports in an
EtherChannel, up to the maximum allowed by the hardware. To use the hot standby feature in the event a
channel port fails, both ends of the LACP bundle must support the `lacp max-bundle` command.

As a control protocol, LACP uses the Slow Protocol Multicast address of 01-80-C2-00-00-02 to transmit
LACP protocol data units (PDUs). Aside from LACP, the Slow Protocol linktype is to be utilized by operations,
administration, and maintenance (OAM) packets, too. Subsequently, a subtype field is defined per the IEEE
802.3ad standard \[1\] (Annex 43B, section 4) differentiating LACP PDUs from OAM PDUs.

---

**Note**

LACP and Port Aggregation Control Protocol (PAgP) are not compatible. Ports configured for PAgP cannot
form port channels on ports configured for LACP, and ports configured for LACP cannot form port channels
on ports configured for PAgP.

---

### Benefits of IEEE 802.3ad Link Bundling

- Increased network capacity without changing physical connections or upgrading hardware
- Cost savings from the use of existing hardware and software for additional functions
- A standard solution that enables interoperability of network devices
- Port redundancy without user intervention when an operational port fails

### LACP Enhancements

The following LACP enhancements are supported:

- Four member links per LACP bundle.
- Cisco nonstop forwarding (NSF), and nonstop routing (NSR) on Gigabit EtherChannel bundles.
- Link failover time of 250 milliseconds or less and a maximum link failover time of 2 seconds; port
  channels remain in the LINK_UP state to eliminate reconvergence by the Spanning-Tree Protocol.
- Shutting down a port channel when the number of active links falls below the minimum threshold. In
  the port channel interface, a configurable option is provided to bring down the port channel interface
  when the number of active links falls below the minimum threshold. For the port-channel state to be
  symmetric on both sides of the channel, the peer must also be running LACP and have the same `lacp
  min-bundle` command setting.
- The IEEE Link Aggregation Group (LAG) MIB.
LACP for Gigabit Interfaces

The LACP (802.3ad) for Gigabit Interfaces feature bundles individual Ethernet links (Gigabit Ethernet or Ten Gigabit Ethernet) into a single logical link that provides the aggregate bandwidth of up to four physical links.

All LAN ports on a port channel must be the same speed and must all be configured as either Layer 2 or Layer 3 LAN ports. If a segment within a port channel fails, traffic previously carried over the failed link switches to the remaining segments within the port channel. Inbound broadcast and multicast packets on one segment in a port channel are blocked from returning on any other segment of the port channel.

Note

The network device may impose its own limits on the number of bundled ports per port channel.

Features Supported on Gigabit EtherChannel Bundles

The table below lists the features that are supported on Gigabit EtherChannel (GEC) bundles.

Table 2: Gigabit EtherChannel Bundle Features

<table>
<thead>
<tr>
<th>Cisco IOS XE Release</th>

</table>
### Guidelines for LACP for Gigabit Interfaces Configuration

Port channel interfaces that are configured improperly with LACP are disabled automatically to avoid network loops and other problems. To avoid configuration problems, observe these guidelines and restrictions:

- Every port added to a port channel must be configured identically. No individual differences in configuration are allowed.
- Bundled ports can be configured on different line cards in a chassis.
- Maximum transmission units (MTUs) must be configured on only port channel interfaces; MTUs are propagated to the bundled ports.
- QoS and committed access rate (CAR) are applied at the port level. Access control lists (ACLs) are applied on port channels.
- MAC configuration is allowed only on port channels.
- MPLS IP should be enabled on bundled ports using the `mpls ip` command.
- Unicast Reverse Path Forwarding (uRPF) should be applied on the port channel interface using the `ip verify unicast reverse-path` command in interface configuration mode.
- Cisco Discovery Protocol should be enabled on the port channel interface using the `cdp enable` command in interface configuration mode.
- All LAN ports in a port channel should be enabled. If you shut down a LAN port in a port channel, the shutdown is treated as a link failure and the traffic is transferred to one of the remaining ports in the port channel.
- Create a port channel interface using the `interface port-channel` command in global configuration mode.

</table>
• When an Ethernet interface has an IP address assigned, disable that IP address before adding the interface to the port channel. To disable an existing IP address, use the no ip address command in interface configuration mode.

• The hold queue in command is valid only on port channel interfaces. The hold queue out command is valid only on bundled ports.

Five-Tuple Hash Load Balancing

Cisco ASR 900 supports different load balancing hash algorithms with combinations of MAC (L2) or IP (L3) headers on the RSP3 platform to find the hash key. Five-Tuple hash algorithm on RSP3 includes protocol field and L4 port numbers while calculating the hash key. Hash key is calculated based on the following parameters:

- Source IP address
- Destination IP address
- Source port
- Destination port
- Protocol ID (only TCP/UDP is supported for layer 4 protocols)

How to Configure IEEE 802.3ad Link Bundling

Enabling LACP

SUMMARY STEPS

1. enable
2. configure terminal
3. interface port-channel channel-number
4. channel-group channel-group-number mode {active | passive}
5. end

DETAILED STEPS

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
</tbody>
</table>
You must manually create a port channel logical interface. Perform this task to configure a port channel.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. interface port-channel *channel-number*
4. lacp max-bundle *max-bundles*
5. ip address *ip-address* *mask*
6. end
7. show running-config interface port-channel *group-number*

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td></td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> interface port-channel <em>channel-number</em></td>
<td>Identifies the interface port channel and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# interface port-channel 10</td>
<td></td>
</tr>
</tbody>
</table>
### Configuring LACP (802.3ad) for Gigabit Interfaces

Perform this task to create a port channel with two bundled ports. You can configure a maximum of four bundled ports per port channel.

**SUMMARY STEPS**

1. `enable`
2. `configure terminal`
3. `interface port-channel number`
4. `ip address ip-address mask`
5. `interface type slot/subslot/port`
6. `no ip address`

---

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 4</td>
<td><strong>lACP max-bundle</strong> <em>max-bundles</em></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Configures three active links on the port channel. The remaining links are in standby mode. Traffic is load-balanced among the active links.</td>
</tr>
<tr>
<td></td>
<td><code>Device(config-if)# lACP max-bundle 3</code></td>
</tr>
<tr>
<td>Step 5</td>
<td><strong>ip address</strong> <em>ip-address mask</em></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Assigns an IP address and subnet mask to the EtherChannel.</td>
</tr>
<tr>
<td></td>
<td><code>Device(config-if)# ip address 172.31.52.10 255.255.255.0</code></td>
</tr>
<tr>
<td>Step 6</td>
<td><code>end</code></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td></td>
<td><code>Device(config-if)# end</code></td>
</tr>
<tr>
<td>Step 7</td>
<td><strong>show running-config interface port-channel</strong></td>
</tr>
<tr>
<td><strong>group-number</strong></td>
<td>Displays the port channel configuration.</td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td><code>Device# show running-config interface port-channel 10</code></td>
</tr>
</tbody>
</table>

---

**Example**

This example shows how to verify the configuration:

```
Device# show running-config interface port-channel 10

Building configuration...
Current configuration: : 110 bytes
!
interface Port-channel10
 ip address 172.31.52.10 255.255.255.0
 no negotiation auto
 lACP max-bundle 3
 end
```
```
channel-group channel-group-number mode {active | passive}
exit
interface type slot/subslot/port
no ip address
channel-group channel-group-number mode {active | passive}
end
```

## DETAILED STEPS

<tr>
<td><strong>Step 12</strong></td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>end</td>
<td></td>
</tr>
<tr>
<td><strong>Example:</strong></td>
<td></td>
</tr>
<tr>
<td>Device(config-if)# end</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

Device> enable
Device# configure terminal
Device(config)# interface port-channel 1
Device(config-if)# ip address 10.1.1.1 255.255.255.0
Device(config-if)# interface gigabitethernet 0/0/2
Device(config-if)# no ip address
Device(config-if)# channel-group 1 mode active
Device(config-if)# exit
Device(config)# interface gigabitethernet 0/0/4
Device(config-if)# no ip address
Device(config-if)# channel-group 1 mode active
Device(config-if)# end
Setting LACP System Priority and Port Priority

Perform this task to set the LACP system priority and port priority. The system ID is the combination of the LACP system priority and the MAC address of a device. The port identifier is the combination of the port priority and port number.

**SUMMARY STEPS**

1. enable
2. configure terminal
3. lACP system-priority *priority*
4. interface *slot/subslot/port*
5. lACP port-priority *priority*
6. end
7. show lACP sys-id

**DETAILED STEPS**

<table>
<thead>
<tr>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong> enable</td>
<td>Enables privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device&gt; enable</td>
<td>• Enter your password if prompted.</td>
</tr>
<tr>
<td><strong>Step 2</strong> configure terminal</td>
<td>Enters global configuration mode.</td>
</tr>
<tr>
<td>Example: Device# configure terminal</td>
<td></td>
</tr>
<tr>
<td><strong>Step 3</strong> lACP system-priority <em>priority</em></td>
<td>Sets the system priority.</td>
</tr>
<tr>
<td>Example: Device(config)# lACP system-priority 200</td>
<td></td>
</tr>
<tr>
<td><strong>Step 4</strong> interface <em>slot/subslot/port</em></td>
<td>Specifies the bundled port on which to set the LACP port priority and enters interface configuration mode.</td>
</tr>
<tr>
<td>Example: Device(config)# interface gigabitethernet 0/1/1</td>
<td></td>
</tr>
<tr>
<td><strong>Step 5</strong> lACP port-priority <em>priority</em></td>
<td>Specifies the priority for the physical interface.</td>
</tr>
<tr>
<td>Example: Device(config-if)# lACP port-priority 500</td>
<td>• <em>priority</em> — Valid range is from 1 to 65535. The higher the number, the lower the priority.</td>
</tr>
<tr>
<td><strong>Step 6</strong> end</td>
<td>Returns to privileged EXEC mode.</td>
</tr>
<tr>
<td>Example: Device(config-if)# end</td>
<td></td>
</tr>
<tr>
<td><strong>Step 7</strong> show lACP sys-id</td>
<td>Displays the system ID (a combination of the system priority and the MAC address of the device).</td>
</tr>
<tr>
<td>Example: Device# show lACP sys-id</td>
<td></td>
</tr>
</tbody>
</table>
Examples

Device> enable
Device# configure terminal
Device(config)# lacp system-priority 200
Device(config)# interface gigabitethernet 0/1/1
Device(config-if)# lacp port-priority 500
Device(config-if)# end

This example shows how to verify the LACP configuration:

Device# show lacp sys-id
200.abdc.abcd.abcd

Adding and Removing Interfaces from a Link Bundle

SUMMARY STEPS

1. enable
2. configure terminal
3. interface type slot/subslot/port
4. channel-group channel-group-number mode {active | passive}
5. no channel-group channel-group-number mode {active | passive}
6. end

DETAILED STEPS

Troubleshooting Tips

To verify and isolate a fault, start at the highest level maintenance domain and do the following:

1. Check the device error status.
2. When a error exists, perform a loopback test to confirm the error.
3. Run a traceroute to the destination to isolate the fault.
4. If the fault is identified, correct the fault.
5. If the fault is not identified, go to the next lower maintenance domain and repeat steps 1 through 4 at that maintenance domain level.
6. Repeat the first four steps, as needed, to identify and correct the fault.

Displaying Gigabit EtherChannel Information

To display Gigabit Ethernet port channel information, use the `show interfaces port-channel` command in user EXEC mode or privileged EXEC mode. The following example shows information about port channels configured on ports 0/2 and 0/3. The default MTU is set to 1500 bytes.

```
Device# show interfaces port-channel 1
Port-channel1 is up, line protocol is up
Hardware is GEChannel, address is 0013.19b3.7748 (bia 0000.0000.0000)
MTU 1500 bytes, BW 2000000 Kbit, DLY 10 usec, reliability 255/255, txload 1/255, rxload 1/255
Encapsulation ARPA, loopback not set
Keepalive set (10 sec)
ARP type: ARPA, ARP Timeout 04:00:00
No. of active members in this channel: 2
```
Member 0 : GigabitEthernet0/0/3, Full-duplex, 1000Mb/s
Member 1 : GigabitEthernet0/1/7, Full-duplex, 1000Mb/s

Last input 00:00:05, output never, output hang never
Last clearing of "show interface" counters 00:04:40
Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
Interface Port-channel1 queueing strategy: PXF First-In-First-Out
Output queue 0/8192, 0 drops; input queue 0/75, 0 drops
5 minute input rate 0 bits/sec, 0 packets/sec
5 minute output rate 0 bits/sec, 0 packets/sec
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts (0 IP multicasts)
0 runts, 0 giants, 0 throttles
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
3 packets output, 180 bytes, 0 underruns
0 output errors, 0 collisions, 0 interface resets
0 babbles, 0 late collision, 0 deferred
0 lost carrier, 0 no carrier, 0 PAUSE output
0 output buffer failures, 0 output buffers swapped out

The table below describes the significant fields shown in the display.

Table 3: show interfaces port-channel Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port-channel is up, line protocol is up</td>
<td>Indicates the bundle interface is currently active and can transmit and receive or it has been taken down by an administrator.</td>
</tr>
<tr>
<td>Hardware is</td>
<td>Hardware type (Gigabit EtherChannel).</td>
</tr>
<tr>
<td>address is</td>
<td>Address being used by the interface.</td>
</tr>
<tr>
<td>MTU</td>
<td>Maximum transmission unit of the interface.</td>
</tr>
<tr>
<td>BW</td>
<td>Bandwidth of the interface, in kilobits per second.</td>
</tr>
<tr>
<td>DLY</td>
<td>Delay of the interface, in microseconds.</td>
</tr>
<tr>
<td>reliability</td>
<td>Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.</td>
</tr>
<tr>
<td>tx load rxload</td>
<td>Transmit and receive load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes. The calculation uses the value from the <strong>bandwidth</strong> interface configuration command.</td>
</tr>
<tr>
<td>Encapsulation</td>
<td>Encapsulation type assigned to the interface.</td>
</tr>
<tr>
<td>loopback</td>
<td>Indicates if loopbacks are set.</td>
</tr>
<tr>
<td>keepalive</td>
<td>Indicates if keepalives are set.</td>
</tr>
<tr>
<td>ARP type</td>
<td>Address Resolution Protocol (ARP) type on the interface.</td>
</tr>
<tr>
<td>ARP Timeout</td>
<td>Number of hours, minutes, and seconds an ARP cache entry stays in the cache.</td>
</tr>
<tr>
<td>No. of active members in this channel</td>
<td>Number of bundled ports (members) currently active and part of the port channel group.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Member &lt;no.&gt; Gigabit Ethernet: &lt;no./no./no.&gt;</td>
<td>Number of the bundled port and associated Gigabit Ethernet port channel interface.</td>
</tr>
<tr>
<td>Last input</td>
<td>Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the Device. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.</td>
</tr>
<tr>
<td>output</td>
<td>Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.</td>
</tr>
<tr>
<td>output hang</td>
<td>Number of hours, minutes, and seconds since the interface was last reset because of a transmission that took too long. When the number of hours in any of the “last” fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.</td>
</tr>
</tbody>
</table>
| last clearing                             | Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared.  
*** indicates that the elapsed time is too long to be displayed. 
0:00:00 indicates that the counters were cleared more than 231 ms and less than 232 ms ago. |
<p>| Input queue                               | Number of packets in the input queue and the maximum size of the queue.                                                                      |
| Queueing strategy                         | First-in, first-out queueing strategy (other queueing strategies you might see are priority-list, custom-list, and weighted fair).             |
| Output queue                              | Number of packets in the output queue and the maximum size of the queue.                                                                      |
| 5 minute input rate 5 minute output rate   | Average number of bits and packets received or transmitted per second in the last 5 minutes.                                                 |
| packets input                             | Total number of error-free packets received by the system.                                                                                   |
| bytes (input)                             | Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.                               |
| no buffer                                 | Number of received packets discarded because there was no buffer space in the main system. Broadcast storms on Ethernet lines and bursts of noise on serial lines are often responsible for no input buffer events. |
| broadcasts                                | Total number of broadcast or multicast packets received by the interface.                                                                     |
| runts                                     | Number of packets that are discarded because they are smaller than the minimum packet size for the medium.                                   |
| giants                                    | Number of packets that are discarded because they exceed the maximum packet size for the medium.                                               |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input errors</td>
<td>Total number of no buffer, runts, giants, cyclic redundancy checks (CRCs), frame, overrun, ignored, and abort counts. Other input-related errors can also increment the count, so that this sum might not balance with the other counts.</td>
</tr>
<tr>
<td>CRC</td>
<td>CRC generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus. A high number of CRCs is usually the result of collisions or a station transmitting bad data. On a serial link, CRCs usually indicate noise, gain hits or other transmission problems on the data link.</td>
</tr>
<tr>
<td>frame</td>
<td>Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a serial line, this is usually the result of noise or other transmission problems.</td>
</tr>
<tr>
<td>overrun</td>
<td>Number of times the serial receiver hardware was unable to pass received data to a hardware buffer because the input rate exceeded the receiver’s capacity for handling the data.</td>
</tr>
<tr>
<td>ignored</td>
<td>Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be incremented.</td>
</tr>
<tr>
<td>watchdog</td>
<td>Number of times the watchdog receive timer expired.</td>
</tr>
<tr>
<td>multicast</td>
<td>Number of multicast packets received.</td>
</tr>
<tr>
<td>packets output</td>
<td>Total number of messages transmitted by the system.</td>
</tr>
<tr>
<td>bytes (output)</td>
<td>Total number of bytes, including data and MAC encapsulation, transmitted by the system.</td>
</tr>
<tr>
<td>underruns</td>
<td>Number of times that the far-end transmitter has been running faster than the near-end Device’s receiver can handle.</td>
</tr>
<tr>
<td>output errors</td>
<td>Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this might not balance with the sum of the enumerated output errors, as some datagrams can have more than one error, and others can have errors that do not fall into any of the specifically tabulated categories.</td>
</tr>
<tr>
<td>collisions</td>
<td>Number of messages retransmitted because of an Ethernet collision. A packet that collides is counted only once in output packets.</td>
</tr>
<tr>
<td>interface resets</td>
<td>Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within a certain interval. If the system notices that the carrier detect line of an interface is up but the line protocol is down, the system periodically resets the interface in an effort to restart that interface. Interface resets can also occur when an unrecoverable interface processor error occurred, or when an interface is looped back or shut down.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>babbles</td>
<td>The transmit jabber timer expired.</td>
</tr>
<tr>
<td>late collision</td>
<td>Number of late collisions. Late collision happens when a collision occurs after transmitting the preamble. The most common cause of late collisions is that your Ethernet cable segments are too long for the speed at which you are transmitting.</td>
</tr>
<tr>
<td>deferred</td>
<td>Indicates that the chip had to defer while ready to transmit a frame because the carrier was asserted.</td>
</tr>
<tr>
<td>lost carrier</td>
<td>Number of times the carrier was lost during transmission.</td>
</tr>
<tr>
<td>no carrier</td>
<td>Number of times the carrier was not present during the transmission.</td>
</tr>
<tr>
<td>PAUSE output</td>
<td>Not supported.</td>
</tr>
<tr>
<td>output buffer failures</td>
<td>Number of times that a packet was not output from the output hold queue because of a shortage of shared memory.</td>
</tr>
<tr>
<td>output buffers swapped out</td>
<td>Number of packets stored in main memory when the output queue is full; swapping buffers to main memory prevents packets from being dropped when output is congested. The number is high when traffic is bursty.</td>
</tr>
</tbody>
</table>

**Configuring Five-Tupple Hash Load Balancing**

**Note**

EoMPLS FAT PW and VPLS FAT PW are not supported because FAT PW uses MAC based hashing algorithm whereas five-tupple hash load balancing feature uses IP Protocol and L4 Port based hashing.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **port-channel load-balance-hash-algo src-dst-mixed-ip-port**
4. **end**

### Example: Configuring LACP for Gigabit Interfaces

The following example shows how to configure Gigabit Ethernet ports 0/0/2 and 0/0/4 into port channel 1 with LACP parameters.

```
Device> enable
Device# configure terminal
Device(config)# lacp system-priority 65535
Device(config)# interface port-channel 1
Device(config-if)# lacp max-bundle 1
Device(config-if)# ip address 10.1.1.1 255.255.255.0
Device(config-if)# exit
Device(config)# interface gigabitethernet 0/0/2
Device(config-if)# no ip address
Device(config-if)# lacp port-priority 100
Device(config-if)# channel-group 1 mode passive
Device(config-if)# exit
Device(config)# interface gigabitethernet 0/0/4
Device(config-if)# no ip address
Device(config-if)# lacp port-priority 200
Device(config-if)# channel-group 1 mode passive
Device(config-if)# end
```

### Example Associating a Channel Group with a Port Channel

This example shows how to configure channel group number 5 and include it in the channel group.

```
```
Device1# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device1(config)# interface port 5
Device1(config-if)#
*Aug 20 17:06:14.417: %LINEPROTO-5-UPDOWN: Line protocol on Interface Port-channel5, changed state to down

Example Monitoring LACP Status

The following example shows LACP activity that you can monitor by using the `show lacp` command.

```
Device1# show lacp internal
Flags: S - Device is requesting Slow LACPDUs
       F - Device is requesting Fast LACPDUs
       A - Device is in Active mode
       P - Device is in Passive mode
Channel group 5

Example: Displaying Port-Channel Interface Information

The following example shows how to display the configuration of port-channel interface 1.

Device# show interface port-channel 1
Port-channel1 is up, line protocol is up
Hardware is GEChannel, address is 0013.19b3.7748 (bia 0000.0000.0000)
MTU 1500 bytes, BW 2000000 Kbit, DLY 10 usec,
reliability 255/255, txload 1/255, rxload 1/255
Encapsulation ARPA, loopback not set
Keepalive set (10 sec)
ARP type: ARPA, ARP Timeout 04:00:00
No. of active members in this channel: 2
Member 0 : GigabitEthernet0/0/3 , Full-duplex, 1000Mb/s Member 1 : GigabitEthernet0/0/7 ,
Full-duplex, 1000Mb/s
Last input 00:00:05, output never, output hang never
Last clearing of "show interface" counters 00:04:40
Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
Interface Port-channel1 queueing strategy: PXF First-In-First-Out
Output queue 0/192, 0 drops; input queue 0/75, 0 drops
5 minute input rate 0 bits/sec, 0 packets/sec
5 minute output rate 0 bits/sec, 0 packets/sec
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts (0 IP multicasts)
0 runts, 0 giants, 0 throttles
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
0 watchdog, 0 multicast, 0 pause input
3 packets output, 180 bytes, 0 underruns
0 output errors, 0 collisions, 0 interface resets
0 babbles, 0 late collision, 0 deferred
0 lost carrier, 0 no carrier, 0 PAUSE output
0 output buffer failures, 0 output buffers swapped out
