Digital Certificates

This chapter describes how to configure digital certificates.

- About Digital Certificates, on page 1
- Guidelines for Digital Certificates, on page 9
- Configure Digital Certificates, on page 12
- How to Set Up Specific Certificate Types, on page 34
- Set a Certificate Expiration Alert (for Identity or CA Certificates), on page 49
- Monitoring Digital Certificates, on page 49
- History for Certificate Management, on page 52

About Digital Certificates

Digital certificates provide digital identification for authentication. A digital certificate includes information that identifies a device or user, such as the name, serial number, company, department, or IP address. CAs are trusted authorities that “sign” certificates to verify their authenticity, thereby guaranteeing the identity of the device or user. CAs issue digital certificates in the context of a PKI, which uses public-key or private-key encryption to ensure security.

For authentication using digital certificates, at least one identity certificate and its issuing CA certificate must exist on an ASA. This configuration allows multiple identities, roots, and certificate hierarchies. The ASA evaluates third-party certificates against CRLs, also called authority revocation lists, all the way from the identity certificate up the chain of subordinate certificate authorities.

Descriptions of several different types of available digital certificates follow:

- A CA certificate is used to sign other certificates. It is self-signed and called a root certificate. A certificate that is issued by another CA certificate is called a subordinate certificate.

- CAs also issue identity certificates, which are certificates for specific systems or hosts.

- Code-signer certificates are special certificates that are used to create digital signatures to sign code, with the signed code itself revealing the certificate origin.

The local CA integrates an independent certificate authority feature on the ASA, deploys certificates, and provides secure revocation checking of issued certificates. The local CA provides a secure, configurable, in-house authority for certificate authentication with user enrollment through a website login page.
CA certificates and identity certificates apply to both site-to-site VPN connections and remote access VPN connections. Procedures in this document refer to remote access VPN use in the ASDM GUI.

Digital certificates provide digital identification for authentication. A digital certificate includes information that identifies a device or user, such as the name, serial number, company, department, or IP address. CAs are trusted authorities that “sign” certificates to verify their authenticity, thereby guaranteeing the identity of the device or user. CAs issue digital certificates in the context of a PKI, which uses public-key or private-key encryption to ensure security.

For authentication using digital certificates, at least one identity certificate and its issuing CA certificate must exist on an ASA. This configuration allows multiple identities, roots, and certificate hierarchies. Descriptions of several different types of available digital certificates follow:

- A CA certificate is used to sign other certificates. It is self-signed and called a root certificate.
- A certificate that is issued by another CA certificate is called a subordinate certificate.

CAs are responsible for managing certificate requests and issuing digital certificates. A digital certificate includes information that identifies a user or device, such as a name, serial number, company, department, or IP address. A digital certificate also includes a copy of the public key for the user or device. A CA can be a trusted third party, such as VeriSign, or a private (in-house) CA that you establish within your organization.

For an example of a scenario that includes certificate configuration and load balancing, see the following URL: https://supportforums.cisco.com/docs/DOC-5964.

### Public Key Cryptography

Digital signatures, enabled by public key cryptography, provide a way to authenticate devices and users. In public key cryptography, such as the RSA encryption system, each user has a key pair containing both a public and a private key. The keys act as complements, and anything encrypted with one of the keys can be decrypted with the other.

In simple terms, a signature is formed when data is encrypted with a private key. The signature is attached to the data and sent to the receiver. The receiver applies the public key of the sender to the data. If the signature sent with the data matches the result of applying the public key to the data, the validity of the message is established.

This process relies on the receiver having a copy of the public key of the sender and a high degree of certainty that this key belongs to the sender, not to someone pretending to be the sender.

Obtaining the public key of a sender is normally handled externally or through an operation performed at installation. For example, most web browsers are configured with the root certificates of several CAs by default. For VPN, the IKE protocol, a component of IPsec, can use digital signatures to authenticate peer devices before setting up security associations.
Certificate Scalability

Without digital certificates, you must manually configure each IPsec peer for each peer with which it communicates; as a result, each new peer that you add to a network would require a configuration change on each peer with which it needs to communicate securely.

When you use digital certificates, each peer is enrolled with a CA. When two peers try to communicate, they exchange certificates and digitally sign data to authenticate each other. When a new peer is added to the network, you enroll that peer with a CA and none of the other peers need modification. When the new peer attempts an IPsec connection, certificates are automatically exchanged and the peer can be authenticated.

With a CA, a peer authenticates itself to the remote peer by sending a certificate to the remote peer and performing some public key cryptography. Each peer sends its unique certificate, which was issued by the CA. This process works because each certificate encapsulates the public key for the associated peer, each certificate is authenticated by the CA, and all participating peers recognize the CA as an authenticating authority. The process is called IKE with an RSA signature.

The peer can continue sending its certificate for multiple IPsec sessions, and to multiple IPsec peers, until the certificate expires. When its certificate expires, the peer administrator must obtain a new one from the CA.

CAs can also revoke certificates for peers that no longer participate in IPsec. Revoked certificates are not recognized as valid by other peers. Revoked certificates are listed in a CRL, which each peer may check before accepting a certificate from another peer.

Some CAs have an RA as part of their implementation. An RA is a server that acts as a proxy for the CA, so that CA functions can continue when the CA is unavailable.

Key Pairs

Key pairs are RSA or Elliptic Curve Signature Algorithm (ECDSA) keys, which have the following characteristics:

- RSA keys can be used for SSH or SSL.
- SCEP enrollment supports the certification of RSA keys.
- The maximum RSA key size is 4096, and the default is 2048.
- The maximum ECDSA key length is 521, and the default is 384.
- You can generate a general purpose RSA key pair, used for both signing and encryption, or you can generate separate RSA key pairs for each purpose. Separate signing and encryption keys help to reduce exposure of the keys, because SSL uses a key for encryption but not signing. However, IKE uses a key for signing but not encryption. By using separate keys for each, exposure of the keys is minimized.

Trustpoints

Trustpoints let you manage and track CAs and certificates. A trustpoint is a representation of a CA or identity pair. A trustpoint includes the identity of the CA, CA-specific configuration parameters, and an association with one, enrolled identity certificate.

After you have defined a trustpoint, you can reference it by name in commands requiring that you specify a CA. You can configure many trustpoints.
If the Cisco ASA has multiple trustpoints that share the same CA, only one of these trustpoints sharing the CA can be used to validate user certificates. To control which trustpoint sharing a CA is used for validation of user certificates issued by that CA, use the `support-user-cert-validation` command.

For automatic enrollment, a trustpoint must be configured with an enrollment URL, and the CA that the trustpoint represents must be available on the network and must support SCEP.

You can export and import the keypair and issued certificates associated with a trustpoint in PKCS12 format. This format is useful to manually duplicate a trustpoint configuration on a different ASA.

**Certificate Enrollment**

The ASA needs a CA certificate for each trustpoint and one or two certificates for itself, depending upon the configuration of the keys used by the trustpoint. If the trustpoint uses separate RSA keys for signing and encryption, the ASA needs two certificates, one for each purpose. In other key configurations, only one certificate is needed.

The ASA supports automatic enrollment with SCEP and with manual enrollment, which lets you paste a base-64-encoded certificate directly into the terminal. For site-to-site VPNs, you must enroll each ASA. For remote access VPNs, you must enroll each ASA and each remote access VPN client.

**Proxy for SCEP Requests**

The ASA can proxy SCEP requests between AnyConnect and a third-party CA. The CA only needs to be accessible to the ASA if it is acting as the proxy. For the ASA to provide this service, the user must authenticate using any of the methods supported by AAA before the ASA sends an enrollment request. You can also use host scan and dynamic access policies to enforce rules of eligibility to enroll.

The ASA supports this feature only with an AnyConnect SSL or IKEv2 VPN session. It supports all SCEP-compliant CAs, including Cisco IOS CS, Windows Server 2003 CA, and Windows Server 2008 CA.

Clientless (browser-based) access does not support SCEP proxy, although WebLaunch—clientless-initiated AnyConnect—does support it.

The ASA does not support polling for certificates.

The ASA supports load balancing for this feature.

**Revocation Checking**

When a certificate is issued, it is valid for a fixed period of time. Sometimes a CA revokes a certificate before this time period expires; for example, because of security concerns or a change of name or association. CAs periodically issue a signed list of revoked certificates. Enabling revocation checking forces the ASA to check that the CA has not revoked a certificate each time that it uses the certificate for authentication.

When you enable revocation checking, the ASA checks certificate revocation status during the PKI certificate validation process, which can use either CRL checking, OCSP, or both. OCSP is only used when the first method returns an error (for example, indicating that the server is unavailable).

With CRL checking, the ASA retrieves, parses, and caches CRLs, which provide a complete list of revoked (and unrevoked) certificates with their certificate serial numbers. The ASA evaluates certificates according to CRLs, also called authority revocation lists, from the identity certificate up the chain of subordinate certificate authorities.
OCSP offers a more scalable method of checking revocation status in that it localizes certificate status through a validation authority, which it queries for status of a specific certificate.

**Supported CA Servers**

The ASA supports the following CA servers:

Cisco IOS CS, ASA Local CA, and third-party X.509 compliant CA vendors including, but not limited to:

- Baltimore Technologies
- Entrust
- Digicert
- Geotrust
- GoDaddy
- iPlanet/Netscape
- Microsoft Certificate Services
- RSA Keon
- Thawte
- VeriSign

**CRLs**

CRLs provide the ASA with one way of determining whether a certificate that is within its valid time range has been revoked by the issuing CA. CRL configuration is part of configuration of a trustpoint.

You can configure the ASA to make CRL checks mandatory when authenticating a certificate by using the `revocation-check crl` command. You can also make the CRL check optional by using the `revocation-check crl none` command, which allows the certificate authentication to succeed when the CA is unavailable to provide updated CRL data.

The ASA can retrieve CRLs from CAs using HTTP, SCEP, or LDAP. CRLs retrieved for each trustpoint are cached for a configurable amount of time for each trustpoint.

When the ASA has cached a CRL for longer than the amount of time it is configured to cache CRLs, the ASA considers the CRL too old to be reliable, or “stale.” The ASA tries to retrieve a newer version of the CRL the next time that a certificate authentication requires a check of the stale CRL.

You could receive a *revocation check* failure for a user connection/certificate if you exceed the CRL entry limit. The syslog returns a message that it has too many entries to process, if the maximum number of entries per CRL is more than 65534.

The ASA caches CRLs for an amount of time determined by the following two factors:

- The number of minutes specified with the `cache-time` command. The default value is 60 minutes.
- The NextUpdate field in the CRLs retrieved, which may be absent from CRLs. You control whether the ASA requires and uses the NextUpdate field with the `enforcenextupdate` command.

The ASA uses these two factors in the following ways:
• If the NextUpdate field is not required, the ASA marks CRLs as stale after the length of time defined by the cache-time command.

• If the NextUpdate field is required, the ASA marks CRLs as stale at the sooner of the two times specified by the cache-time command and the NextUpdate field. For example, if the cache-time command is set to 100 minutes and the NextUpdate field specifies that the next update is 70 minutes away, the ASA marks CRLs as stale in 70 minutes.

If the ASA has insufficient memory to store all CRLs cached for a given trustpoint, it deletes the least recently used CRL to make room for a newly retrieved CRL.

OCSP provides the ASA with a way of determining whether a certificate that is within its valid time range has been revoked by the issuing CA. OCSP configuration is part of trustpoint configuration.

OCSP localizes certificate status on a validation authority (an OCSP server, also called the responder) which the ASA queries for the status of a specific certificate. This method provides better scalability and more up-to-date revocation status than does CRL checking, and helps organizations with large PKI installations deploy and expand secure networks.

Note

The ASA allows a five-second time skew for OCSP responses.

You can configure the ASA to make OCSP checks mandatory when authenticating a certificate by using the revocation-check ocs command. You can also make the OCSP check optional by using the revocation-check ocs none command, which allows the certificate authentication to succeed when the validation authority is unavailable to provide updated OCSP data.

OCSP provides three ways to define the OCSP server URL. The ASA uses these servers in the following order:

1. The OCSP URL defined in a match certificate override rule by using the match certificate command).
2. The OCSP URL configured by using the ocs url command.
3. The AIA field of the client certificate.
To configure a trustpoint to validate a self-signed OCSP responder certificate, you import the self-signed responder certificate into its own trustpoint as a trusted CA certificate. Then you configure the **match certificate** command in the client certificate validating trustpoint to use the trustpoint that includes the self-signed OCSP responder certificate to validate the responder certificate. Use the same procedure for configuring validating responder certificates external to the validation path of the client certificate.

The OCSP server (responder) certificate usually signs the OCSP response. After receiving the response, the ASA tries to verify the responder certificate. The CA normally sets the lifetime of the OCSP responder certificate to a relatively short period to minimize the chance of being compromised. The CA usually also includes an ocs-no-check extension in the responder certificate, which indicates that this certificate does not need revocation status checking. However, if this extension is not present, the ASA tries to check revocation status using the same method specified in the trustpoint. If the responder certificate is not verifiable, revocation checks fail. To avoid this possibility, use the **revocation-check none** command to configure the responder certificate validating trustpoint, and use the **revocation-check ocs** command to configure the client certificate.

---

### The Local CA

The local CA performs the following tasks:

- Integrates basic certificate authority operation on the ASA.
- Deploys certificates.
- Provides secure revocation checking of issued certificates.
- Provides a certificate authority on the ASA for use with browser-based and client-based SSL VPN connections.
- Provides trusted digital certificates to users, without the need to rely on external certificate authorization.
- Provides a secure, in-house authority for certificate authentication and offers straightforward user enrollment by means of a website login.

### Storage for Local CA Files

The ASA accesses and implements user information, issued certificates, and revocation lists using a local CA database. This database resides in local flash memory by default, or can be configured to reside on an external file system that is mounted and accessible to the ASA.

No limits exist on the number of users that can be stored in the local CA user database; however, if flash memory storage issues arise, syslogs are generated to alert the administrator to take action, and the local CA could be disabled until the storage issues are resolved. Flash memory can store a database with 3500 users or less; however, a database of more than 3500 users requires external storage.

### The Local CA Server

After you configure a local CA server on the ASA, users can enroll for a certificate by logging into a website and entering a username and a one-time password that is provided by the local CA administrator to validate their eligibility for enrollment.

The following figure shows that the local CA server resides on the ASA and handles enrollment requests from website users and CRL inquiries coming from other certificate validating devices and ASAs. Local CA database
and configuration files are maintained either on the ASA flash memory (default storage) or on a separate storage device.

*Figure 1: The Local CA*

Certificates and User Login Credentials

The following section describes the different methods of using certificates and user login credentials (username and password) for authentication and authorization. These methods apply to IPsec, AnyConnect, and Clientless SSL VPN.

In all cases, LDAP authorization does not use the password as a credential. RADIUS authorization uses either a common password for all users or the username as a password.

User Login Credentials

The default method for authentication and authorization uses the user login credentials.

- **Authentication**
  - Enabled by the authentication server group setting in the tunnel group (also called ASDM Connection Profile)
  - Uses the username and password as credentials

- **Authorization**
  - Enabled by the authorization server group setting in the tunnel group (also called ASDM Connection Profile)
  - Uses the username as a credential

Certificates

If user digital certificates are configured, the ASA first validates the certificate. It does not, however, use any of the DNs from certificates as a username for the authentication.

If both authentication and authorization are enabled, the ASA uses the user login credentials for both user authentication and authorization.
• Authentication
  • Enabled by the authentication server group setting
  • Uses the username and password as credentials

• Authorization
  • Enabled by the authorization server group setting
  • Uses the username as a credential

If authentication is disabled and authorization is enabled, the ASA uses the primary DN field for authorization.

• Authentication
  • DISABLED (set to None) by the authentication server group setting
  • No credentials used

• Authorization
  • Enabled by the authorization server group setting
  • Uses the username value of the certificate primary DN field as a credential

Note
If the primary DN field is not present in the certificate, the ASA uses the secondary DN field value as the username for the authorization request.

For example, consider a user certificate that includes the following Subject DN fields and values:

Cn=anyuser,OU=sales;O=XYZCorporation;L=boston;S=mass;C=us;ea=anyuser@example.com

If the Primary DN = EA (E-mail Address) and the Secondary DN = CN (Common Name), then the username used in the authorization request would be anyuser@example.com.

Guidelines for Digital Certificates

This section includes guidelines and limitations that you should check before configuring digital certificates.

Context Mode Guidelines
• Supported in single context mode only for third-party CAs.

Failover Guidelines
• Does not support replicating sessions in Stateful Failover.
• Does not support failover for local CAs.
IPv6 Guidelines

Does not support IPv6.

Local CA Certificates

• Make sure that the ASA is configured correctly to support certificates. An incorrectly configured ASA can cause enrollment to fail or request a certificate that includes inaccurate information.

• Make sure that the hostname and domain name of the ASA are configured correctly. To view the currently configured hostname and domain name, enter the `show running-config` command.

• Make sure that the ASA clock is set accurately before configuring the CA. Certificates have a date and time that they become valid and expire. When the ASA enrolls with a CA and obtains a certificate, the ASA checks that the current time is within the valid range for the certificate. If it is outside that range, enrollment fails.

• Thirty days before the local CA certificate expires, a rollover replacement certificate is generated, and a syslog message informs the administrator that it is time for local CA rollover. The new local CA certificate must be imported onto all necessary devices before the current certificate expires. If the administrator does not respond by installing the rollover certificate as the new local CA certificate, validations may fail.

• The local CA certificate rolls over automatically after expiration using the same keypair. The rollover certificate is available for export in base 64 format.

The following example shows a base 64 encoded local CA certificate:

```
MIIXlwIBAzCCF1EGCSqGSIb3DQEHAaCCF0IEghc+MIIXOjCCFzYYGCSqGSIb3DQEHBqCCFycwghcjcAgEAMIIXHA
YJKoZIhvcNAQcBMgsGCCsGCSqGSIb3DQEEMAMQwDQYjYtgh4b3g6vYtGQgwbh34v4hFy+GGG2dNlB4OLpahUM+IG3S

FrzoGlH8BFqdPaljBhAazuSmElm3j/2dQ3Atro1G9nIsRHgV39fcBgw4fEabH9/G/anb+fj81d5101JjDYY
bP86tvb2y0VZ6aKFIv10h2AfCr6Pbwfc9UBZ/aF3BCyM2aN2xPzrXv94CaYrqyotZdAkSYA5KWScyEcgdoqmu
BeGDK0ncTknfyUXM+fG5rb3qAXy1GklyFIS5Bm9Do6RURoG1DSrQreq/hj...
```

END OF CERTIFICATE

SCEP Proxy Support

• Ensure that the ASA and the Cisco ISE Policy Service Nodes are synchronized using the same NTP server.

• AnyConnect Secure Mobility Client 3.0 or later must be running at the endpoint.

• The authentication method, configured in the connection profile for your group policy, must be set to use both AAA and certificate authentication.

• An SSL port must be open for IKEv2 VPN connections.

• The CA must be in auto-grant mode.
Local CA Certificate Database

To maintain the local CA certificate database, make sure that you save the certificate database file, LOCAL-CA-SERVER.cdb, with the write memory command each time that a change to the database occurs. The local CA certificate database includes the following files:

- The LOCAL-CA-SERVER.p12 file is the archive of the local CA certificate and keypair that is generated when the local CA server is initially enabled.
- The LOCAL-CA-SERVER.crl file is the actual CRL.
- The LOCAL-CA-SERVER.ser file keeps track of the issued certificate serial numbers.

Additional Guidelines

- For ASAs that are configured as CA servers or clients, limit the validity period of the certificate to less than the recommended end date of 03:14:08 UTC, January 19, 2038. This guideline also applies to imported certificates from third-party vendors.

- Beginning with 9.13.1, ASA establishes LDAP/SSL connection only if one of the following certification criteria is satisfied:
  - The LDAP server certificate is trusted (exists in a trustpoint or the ASA trustpool) and is valid.
  - A CA certificate from servers issuing chain is trusted (exists in a trustpoint or the ASA trustpool) and all subordinate CA certificates in the chain are complete and valid.

- You cannot configure the local CA when failover is enabled. You can only configure the local CA server for standalone ASAs without failover. For more information, see CSCty43366.

- When a certificate enrollment is completed, the ASA stores a PKCS12 file containing the user's keypair and certificate chain, which requires about 2 KB of flash memory or disk space per enrollment. The actual amount of disk space depends on the configured RSA key size and certificate fields. Keep this guideline in mind when adding a large number of pending certificate enrollments on an ASA with a limited amount of available flash memory, because these PKCS12 files are stored in flash memory for the duration of the configured enrollment retrieval timeout. We recommend using a key size of at least 2048.

- The lifetime ca-certificate command takes effect when the local CA server certificate is first generated (that is, when you initially configure the local CA server and issue the no shutdown command). When the CA certificate expires, the configured lifetime value is used to generate the new CA certificate. You cannot change the lifetime value for existing CA certificates.

- You should configure the ASA to use an identity certificate to protect ASDM traffic and HTTPS traffic to the management interface. Identity certificates that are automatically generated with SCEP are regenerated after each reboot, so make sure that you manually install your own identity certificates. For an example of this procedure that applies only to SSL, see the following URL:

- The ASA and the AnyConnect clients can only validate certificates in which the X520Serialnumber field (the serial number in the Subject Name) is in PrintableString format. If the serial number format uses encoding such as UTF8, the certificate authorization will fail.

- Use only valid characters and values for certificate parameters when you import them on the ASA.
To use a wildcard (*) symbol, make sure that you use encoding on the CA server that allows this character in the string value. Although RFC 5280 recommends using either a UTF8String or PrintableString, you should use UTF8String because PrintableString does not recognize the wildcard as a valid character. The ASA rejects the imported certificate if an invalid character or value is found during the import. For example:

```
ERROR: Failed to parse or verify imported certificate ciscoasa(config)# Read 162*H÷ytes as CA certificate:0U0= \Ivr"phOV*3é¥p0 CRYPTO_PKI(make trustedCerts list)
CERT-C: E ..cert-c/source/certlist.c(302): Error #711h

CERT-C: E ..cert-c/source/p?contnt.c(169): Error #703h
crypto_certc_pkcs7_extract_certs_and_crls failed (1795):
crypto_certc_pkcs7_extract_certs_and_crls failed
CRYPTO_PKI: status = 1795: failed to verify or insert the cert into storage
```

## Configure Digital Certificates

The following topics explain how to configure digital certificates.

### Configure Key Pairs

To create or remove key pairs, perform the following steps.

**Procedure**

**Step 1**
Generate one default, general-purpose RSA key pair.
```
crypto key generate rsa modulus 2048
```
**Example:**
```
ciscoasa(config)# crypto key generate rsa modulus 2048
```

The default key modulus is 2048, but you should specify the modulus explicitly to ensure you get the size you require. The key is named Default-RSA-Key.

If you also want an Elliptic Curve Signature Algorithm (ECDSA) key, you can generate the Default-ECDSA-Key. The default length is 384, but you can also use 256 or 521.
```
crypto key generate ecdsa elliptic-curve 384
```

**Step 2**
(Optional) Create additional keys with unique names.
```
crypto key generate rsa label key-pair-label modulus size
crypto key generate ecdsa label key-pair-label elliptic-curve size
```
**Example:**
```
ciscoasa(config)# crypto key generate rsa label exchange modulus 2048
```
The label is referenced by the trustpoint that uses the key pair.

For RSA keys, the modulus can be one of the following (in bits): 512, 768, 1024, 2048, 4096.
For ECDSA keys, the elliptic curve can be one of the following (in bits): 256, 384, 521.

**Step 3** Verify key pairs that you have generated.

`show crypto key mypubkey {rsa | ecdsa}`

**Example:**

```
ciscoasa/contexta(config)# show crypto mypubkey key rsa
```

**Step 4** Save the key pair that you have generated.

`write memory`

**Example:**

```
ciscoasa(config)# write memory
```

**Step 5** If necessary, remove existing key pairs so that you can generate new ones.

`crypto key zeroize {rsa | ecdsa}`

**Example:**

```
ciscoasa(config)# crypto key zeroize rsa
```

**Step 6** (Optional) Archive the local CA server certificate and key pair.

`copy`

**Example:**

```
ciscoasa# copy LOCAL-CA-SERVER_0001.pl2 tftp://10.1.1.22/user6/
```

This command copies the local CA server certificate and key pair and all files from the ASA using either FTP or TFTP.

**Note** Make sure that you back up all local CA files as often as possible.

**Example**

The following example shows how to remove key pairs:

```
ciscoasa(config)# crypto key zeroize rsa
WARNING: All RSA keys will be removed.
WARNING: All device certs issued using these keys will also be removed.
Do you really want to remove these keys? [yes/no] y
```
Configure Trustpoints

To configure a trustpoint, perform the following steps:

**Procedure**

**Step 1**
Create a trustpoint that corresponds to the CA from which the ASA needs to receive a certificate.

```plaintext
crypto ca trustpoint trustpoint-name
```

**Example:**

```
ciscoasa/contexta(config)# crypto ca trustpoint Main
```

You enter the crypto ca trustpoint configuration mode, which controls CA-specific trustpoint parameters that you may configure starting in Step 3.

**Step 2**
Choose one of the following options:

- Request automatic enrollment using SCEP with the specified trustpoint and configures the enrollment URL.
  ```plaintext
enrollment protocol scep url
  ```
  **Example:**
  ```
ciscoasa/contexta(config-ca-trustpoint)# enrollment protocol scep url
  http://10.29.67.142:80/certsrv/mscep/mscep.dll
  ```

- Request automatic enrollment using CMP with the specified trustpoint and configures the enrollment URL.
  ```plaintext
enrollment protocol cmp url
  ```
  **Example**
  ```
ciscoasa/contexta(config-ca-trustpoint)# enrollment protocol cmp url
  http://10.29.67.142:80/certsrv/mscep/mscep.dll
  ```

- Request manual enrollment with the specified trustpoint by pasting the certificate received from the CA into the terminal.
  ```plaintext
  enrollment terminal
  ```
  ```
ciscoasa/contexta(config-ca-trustpoint)# enrollment terminal
  ```

- Request self signed certificate.
  ```plaintext
  enrollment self
  ```

**Step 3**
If the trustpoint has been configured to use CMP in the step above, you can optionally enable the functionality that automatically requests certificates. This automation is based on configurable triggers that control if CMPv2 auto update is used, when it is triggered, and if a new keypair is generated. Enter a percentage of the absolute lifetime of the certificate after which auto-enroll will be necessary and specify if you want to generate a new key while renewing the certificate.
[no] auto-enroll [<percent>] [regenerate]

**Step 4** Specify the available CRL configuration options.

revocation-check crl none

**Example:**

```plaintext
ciscoasa/contexta(config-ca-trustpoint)# revocation-check crl none
ciscoasa/contexta(config-ca-trustpoint)# revocation-check crl

ciscoasa/contexta(config-ca-trustpoint)# revocation-check none
```

**Note** To enable either required or optional CRL checking, make sure that you configure the trustpoint for CRL management after obtaining certificates.

**Step 5** Enable or disable the basic constraints extension and CA flag.

[no] ca-check

The basic constraints extension identifies whether the subject of the certificate is a Certificate Authority (CA), in which case the certificate can be used to sign other certificates. The CA flag is part of this extension. The presence of these items in a certificate indicates that the certificate’s public key can be used to validate certificate signatures.

The ca-check command is enabled by default, so you need to enter this command only if you want to disable basic constraints and the CA flag.

**Example:**

```plaintext
ciscoasa/contexta(config-ca-trustpoint)# no ca-check
```

**Step 6** During enrollment, ask the CA to include the specified e-mail address in the Subject Alternative Name extension of the certificate.

email address

**Example:**

```plaintext
ciscoasa/contexta(config-ca-trustpoint)# email example.com
```

**Step 7** (Optional) Specify a retry period in minutes, and applies only to SCEP enrollment.

enrollment retry period

**Example:**

```plaintext
ciscoasa/contexta(config-ca-trustpoint)# enrollment retry period 5
```

**Step 8** (Optional) Specify a maximum number of permitted retries, and applies only to SCEP enrollment.

enrollment retry count

**Example:**

```plaintext
ciscoasa/contexta(config-ca-trustpoint)# enrollment retry period 2
```
Step 9  
During enrollment, ask the CA to include the specified fully qualified domain name in the Subject Alternative Name extension of the certificate.

fqdn  
Example:

ciscoasa/contexta(config-ca-trustpoint)# fqdn example.com

Step 10  
During enrollment, ask the CA to include the IP address of the ASA in the certificate.

ip-address  
Example:

ciscoasa/contexta(config-ca-trustpoint)# ip-address 10.10.100.1

Step 11  
Specify the key pair whose public key is to be certified.

keypair name  
Example:

ciscoasa/contexta(config-ca-trustpoint)# keypair exchange

Step 12  
Only if you have trustpoints configured for CMP, determine if you want to generate EDCSA keys or RSA keys for any CMP manual and automatic enrollments.

no keypair name | [rsa modulus 1024|2048|4096|512|768] | [edcsa elliptic-curve 256|384|521]

Step 13  
Configure OCSP URL overrides and trustpoints to use for validating OCSP responder certificates.

match certificate map-name override ocsp  
Example:

ciscoasa/contexta(config-ca-trustpoint)# match certificate examplemap override ocsp

Step 14  
Disable the nonce extension on an OCSP request. The nonce extension cryptographically binds requests with responses to avoid replay attacks.

ocsp disable-nonc

Example:

ciscoasa/contexta(config-ca-trustpoint)# ocsp disable-nonc

Step 15  
Configure an OCSP server for the ASA to use to check all certificates associated with a trustpoint rather than the server specified in the AIA extension of the client certificate.

ocsp url  
Example:

ciscoasa/contexta(config-ca-trustpoint)# ocsp url
Configure CRLs for a Trustpoint

To use mandatory or optional CRL checking during certificate authentication, you must configure CRLs for each trustpoint. To configure CRLs for a trustpoint, perform the following steps:

Procedure

Step 1
Enter crypto ca trustpoint configuration mode for the trustpoint whose CRL configuration you want to modify.
Configure CRLs for a Trustpoint

crypto ca trustpoint trustpoint-name

Example:
ciscoasa (config)# crypto ca trustpoint Main

Note Make sure that you have enabled CRLs before entering this command. In addition, the CRL must be available for authentication to succeed.

Step 2 Enter crl configuration mode for the current trustpoint.
crl configure

Example:
ciscoasa(config-ca-trustpoint)# crl configure

Tip To set all CRL configuration parameters to default values, use the default command. At any time during CRL configuration, reenter this command to restart the procedure.

Step 3 Choose one of the following to configure retrieval policy:

• CRLs are retrieved only from the CRL distribution points that are specified in authenticated certificates.
  policy cdp

  ciscoasa(config-ca-crl)# policy cdp

  Note SCEP retrieval is not supported by distribution points specified in certificates.

• CRLs are retrieved only from URLs that you configure.
  policy static

  ciscoasa(config-ca-crl)# policy static

• CRLs are retrieved from CRL distribution points specified in authenticated certificates and from URLs that you configure.
  policy both

  ciscoasa(config-ca-crl)# policy both

Step 4 If you used the static or both keywords when you configured the CRL policy, you must configure URLs for CRL retrieval. You can enter up to five URLs, ranked 1 through 5. The n argument is the rank assigned to the URL.
url n url

Example:
ciscoasa (config-ca-crl)# url 2 http://www.example.com
To remove a URL, use the `no url n` command.

**Step 5**
Specify HTTP, LDAP, or Scep as the CRL retrieval method.

`protocol http | ldap | scep`

*Example:*

```
ciscoasa(config-ca-crl)# protocol http
```

**Step 6**
Configure how long the ASA caches CRLs for the current trustpoint. The **refresh-time** argument is the number of minutes that the ASA waits before considering a CRL stale.

`cache-time refresh-time`

*Example:*

```
ciscoasa(config-ca-crl)# cache-time 420
```

**Step 7**
Choose one of the following:

- Require the NextUpdate field to be present in CRLs. This is the default setting.

  `enforcenextupdate`

  *Example:*

  ```
ciscoasa(config-ca-crl)# enforcenextupdate
```

- Allow the NextUpdate field to be absent in CRLs.

  `no enforcenextupdate`

  *Example:*

  ```
ciscoasa(config-ca-crl)# no enforcenextupdate
```

**Step 8**
Identify the LDAP server to the ASA if LDAP is specified as the retrieval protocol. You can specify the server by DNS hostname or by IP address. You can also provide a port number if the server listens for LDAP queries on a port other than the default of 389.

`ldap-defaults server`

*Example:*

```
ciscoasa (config-ca-crl)# ldap-defaults ldap1
```

*Note*  If you use a hostname instead of an IP address to specify the LDAP server, make sure that you have configured the ASA to use DNS.

**Step 9**
Allow CRL retrieval if the LDAP server requires credentials.

`ldap-dn admin-DN password`

*Example:*

```
ciscoasa (config-ca-crl)# ldap-dn cn=admin,ou=devtest,o=engineering c00lRunZ
```
Step 10 Retrieve the current CRL from the CA represented by the specified trustpoint and test the CRL configuration for the current trustpoint.

```
crypto ca crl request trustpoint
```

**Example:**

```
ciscoasa (config-ca-crl)# crypto ca crl request Main
```

Step 11 Save the running configuration.

```
write memory
```

**Example:**

```
ciscoasa (config)# write memory
```

---

**Export or Import a Trustpoint Configuration**

To export and import a trustpoint configuration, perform the following steps:

**Procedure**

**Step 1** Export a trustpoint configuration with all associated keys and certificates in PKCS12 format.

```
crypto ca export trustpoint
```

**Example:**

```
ciscoasa(config)# crypto ca export Main
```

The ASA displays the PKCS12 data in the terminal. You can copy the data. The trustpoint data is password protected; however, if you save the trustpoint data in a file, make sure that the file is in a secure location.

**Step 2** Import keypairs and issued certificates that are associated with a trustpoint configuration.

```
crypto ca import trustpoint pkcs12
```

**Example:**

```
ciscoasa(config)# crypto ca import Main pkcs12
```

The ASA prompts you to paste the text into the terminal in base 64 format. The key pair imported with the trustpoint is assigned a label that matches the name of the trustpoint that you create.

**Note** If an ASA has trustpoints that share the same CA, you can use only one of the trustpoints that share the CA to validate user certificates. To control which trustpoint that shares a CA is used for validation of user certificates issued by that CA, use the `support-user-cert-validation` keyword.
Examples
The following example exports PKCS12 data for the trustpoint Main with the passphrase Wh0zits:

ciscoasa(config)# crypto ca export Main pkcs12 Wh0zits
Exported pkcs12 follows:
[ PKCS12 data omitted ]
---End - This line not part of the pkcs12---

The following example manually imports PKCS12 data to the trustpoint Main with the passphrase Wh0zits:
ciscoasa (config)# crypto ca import Main pkcs12 Wh0zits
Enter the base 64 encoded pkcs12.
End with a blank line or the word "quit" on a line by itself:
[ PKCS12 data omitted ]
quit
INFO: Import PKCS12 operation completed successfully

The following example manually imports a certificate for the trustpoint Main:
ciscoasa (config)# crypto ca import Main certificate
% The fully-qualified domain name in the certificate will be: securityappliance.example.com
Enter the base 64 encoded certificate.
End with a blank line or the word “quit” on a line by itself
[ certificate data omitted ]
quit
INFO: Certificate successfully imported

Configure CA Certificate Map Rules
You can configure rules based on the Issuer and Subject fields of a certificate. Using the rules you create, you can map IPsec peer certificates to tunnel groups with the tunnel-group-map command.

To configure a CA certificate map rule, perform the following steps:

Procedure

**Step 1**
Enter CA certificate map configuration mode for the rule you want to configure and specify the rule sequence number.

crypto ca certificate map [map_name]sequence-number

**Example:**
ciscoasa(config)# crypto ca certificate map test-map 10
If you do not specify the map name, the rule is added to the default map: DefaultCertificateMap. For each rule number, you can specify one or more fields to match.

**Step 2**

Specify the issuer name or subject name:

\{{\text{issuer-name}} \mid \text{subject-name}\} \ [\text{attr attribute}] \ \text{operator string}

**Example:**

```plaintext
ciscoasa(config-ca-cert-map)# issuer-name cn=asa.example.com
ciscoasa(config-ca-cert-map)# subject-name attr cn eq mycert
ciscoasa(config-ca-cert-map)# subject-name attr uid eq jcrichton
```

You can match the entire value, or specify the attributes that you want to match. The following are valid attributes:

- c—Country
- cn—Common Name
- dc—Domain Component
- dnq—DN Qualifier
- ea—EmailAddress
- genq—Generational Qualifier
- gn—Given Name
- i—Initials
- ip—IP Address
- l—Locality
- n—Name
- o—Organization Name
- ou—Organizational Unit
- ser—Serial Number
- sn—Surname
- sp—State/Province
- t—Title
- uid—UserID
- uname—Unstructured Name

The following are valid operators:

- eq—The field or attribute must be identical to the value given.
- ne—The field or attribute cannot be identical to the value given.
- co—Part or all of the field or attribute must match the value given.
Step 3  Specify the alternative subject name:

alt-subject-name operator string

Example:

ciscoasa(config-ca-cert-map)# alt-subject-name eq happydays

The following are valid operators:

- eq—The field must be identical to the value given.
- ne—The field cannot be identical to the value given.
- co—Part or all of the field must match the value given.
- nc—No part of the field can match the value given.

Step 4  Specify the extended key usage:

extended-key-usage operator OID_string

Example:

ciscoasa(config-ca-cert-map)# extended-key-usage nc clientauth

The following are valid operators:

- co—Part or all of the field must match the value given.
- nc—No part of the field can match the value given.

The following are valid OID strings:

- string—User-defined string.
- clientauth—Client Authentication (1.3.6.1.5.5.7.3.2)
- codesigning—Code Signing (1.3.6.1.5.5.7.3.3)
- emailprotection—Secure Email Protection (1.3.6.1.5.5.7.3.4)
- ocspsigning—OCSP Signing (1.3.6.1.5.5.7.3.9)
- serverauth—Server Authentication (1.3.6.1.5.5.7.3.1)
- timestamping—Time Stamping (1.3.6.1.5.5.7.3.8)

Configure Reference Identities

When the ASA is acting as a TLS client, it supports rules for verification of an application server's identity as defined in RFC 6125. This RFC specifies procedures for representing the reference identities (configured
on the ASA) and verifying them against the presented identities (sent from the application server). If the presented identity cannot be matched against the configured reference identity, the connection is not established and an error is logged.

The server presents its identity by including one or more identifiers in the server certificate presented to the ASA while establishing the connection. Reference identities are configured on the ASA, to be compared to the identity presented in a server certificate during connection establishment. These identifiers are specific instances of the four identifier types specified in RFC 6125. The four identifier types are:

- **CN_ID**: A Relative Distinguished Name (RDN) in a certificate subject field that contains only one attribute-type-and-value pair of type Common Name (CN), where the value matches the overall form of a domain name. The CN value cannot be free text. A CN-ID reference identifier does not identify an application service.

- **DNS-ID**: A subjectAltName entry of type dNSName. This is a DNS domain name. A DNS-ID reference identifier does not identify an application service.

- **SRV-ID**: A subjectAltName entry of type otherName whose name form is SRVName as defined in RFC 4985. A SRV-ID identifier may contain both a domain name and an application service type. For example, a SRV-ID of “_imaps.example.net” would be split into a DNS domain name portion of “example.net” and an application service type portion of “imaps.”

- **URI-ID**: A subjectAltName entry of type uniformResourceIdentifier whose value includes both (i) a “scheme” and (ii) a “host” component (or its equivalent) that matches the “reg-name” rule specified in RFC 3986. A URI-ID identifier must contain the DNS domain name, not the IP address, and not just the hostname. For example, a URI-ID of “sip:voice.example.edu” would be split into a DNS domain name portion of “voice.example.edu” and an application service type of “sip.”

A reference identity is created when configuring one with a previously unused name. Once a reference identity has been created, the four identifier types and their associated values can be added or deleted from the reference identity. The reference identifiers MAY contain information identifying the application service and MUST contain information identifying the DNS domain name.

**Before you begin**

- Reference identities are used when connecting to the Syslog Server and the Smart Licensing server only. No other ASA SSL client mode connections currently support the configuration or use of reference identities.

- ASA implements all the rules for matching the identifiers described in RFC 6125 except for pinned certificates and fallback for interactive clients.

- Ability to pin certificates is not implemented. Therefore, *No Match Found, Pinned Certificate* will not occur. Also, a user will not be given the opportunity to pin a certificate if a match is not found since our implementation is not an interactive client.

**Procedure**

**Step 1** Enter the `[no] crypto ca reference-identity` command in global configuration mode to place the ASA in ca-reference-identity mode.

`[no] crypto ca reference-identity reference-identity-name`
If a reference identity with this reference-identity-name is not found, a new reference identity is created. If the no form of the command is issued for a reference identity that is still in use, a warning is displayed and the reference identity is not deleted.

**Step 2**

Enter reference-ids while in ca-reference-identity mode. Multiple reference-ids of any type may be added to the reference identity.

- `[no] cn-id value`
- `[no] dns-id value`
- `[no] srv-id value`
- `[no] uri-id value`

To remove a reference identity, use the no form of the command.

---

**Example**

Configure a reference identity for RFC 6125 server certificate validation for a syslog server:

```bash
Ciscoasa(config)# crypto ca reference-identity syslogServer
Ciscoasa(config-ca-ref-identity)# dns-id syslog1-bxb.cisco.com
Ciscoasa(config-ca-ref-identity)# cn-id syslog1-bxb.cisco.com
```

**What to do next**

Use the reference identity when configuring the Syslog and the Smart Call Home server connections.

---

**Obtain Certificates Manually**

To obtain certificates manually, perform the following steps:

**Before you begin**

You must have already obtained a base-64 encoded CA certificate from the CA represented by the trustpoint.

**Procedure**

**Step 1**

Import the CA certificate for the configured trustpoint.

```bash
ciscoasa(config)# crypto ca authenticate trustpoint
```

**Example:**

```bash
Ciscoasa(config)# crypto ca authenticate Main
Enter the base 64 encoded CA certificate. End with a blank line or the word "quit" on a line by itself.
MIIDRTCCAu+gAwIBAgIQKVcqP/KW74VP0Z2L+J8RTABqFkhEg9w0BAQYDVQF
[ certificate data omitted ]
quit
```
INFO: Certificate has the following attributes:
Fingerprint: 24b81433 409b3fd5 e5431699 8d490d34
Do you accept this certificate? [yes/no]: y
Trustpoint CA certificate accepted.

% Certificate successfully imported

Whether a trustpoint requires that you manually obtain certificates is determined by the use of the enrollment terminal command when you configure the trustpoint.

**Step 2**

Enroll the ASA with the trustpoint.

`crypto ca enroll` **trustpoint**

**Example:**

ciscoasa(config)# crypto ca enroll Main
% Start certificate enrollment ..
% The fully-qualified domain name in the certificate will be: securityappliance.example.com
% Include the device serial number in the subject name? [yes/no]: n

Display Certificate Request to terminal? [yes/no]: y
Certificate Request follows:

MIIBDCAQkCAQAwIzEhMB8GCSqGSIb3DQEJAhYSRmVyYWxXxZgUuturesVY28uY29t
[ certificate request data omitted ]
	
---End - This line not part of the certificate request---

Redisplay enrollment request? [yes/no]: n

This command generates a certificate for signing data and depending on the type of keys that you have configured, for encrypting data. If you use separate RSA keys for signing and encryption, the `crypto ca enroll` command displays two certificate requests, one for each key. If you use general-purpose RSA keys for both signing and encryption, the `crypto ca enroll` command displays one certificate request.

To complete enrollment, obtain a certificate for all certificate requests generated by the `crypto ca enroll` command from the CA represented by the applicable trustpoint. Make sure that the certificate is in base-64 format.

**Step 3**

When a trustpoint is configured for CMP, either a shared secret value (ir) or the name of the trustpoint that contains the certificate that will sign the request (cr) can be specified, but not both. Provide either an out-of-band value by the CA that is used to confirm the authenticity and integrity of messages exchanged with ASA or provide the name of the trustpoint with a previously-issued device certificate used for signing the CMP enrollment request. The shared-secret or signing-certificate keywords are only available when the trustpoint enrollment protocol is set to CMP.

crypto ca enroll trustpoint [regenerate] [shared-secret <value> | signing-certificate <value>]

**Step 4**

Determine whether or not a new keypair should be generated prior to building the enrollment request.

crypto ca enroll trustpoint [regenerate] [shared-secret <value> | signing-certificate <value>]

**Step 5**

Import each certificate you receive from the CA and make sure that you paste the certificate to the terminal in base-64 format.
crypto ca import trustpoint certificate

Example:

ciscoasa (config)# crypto ca import Main certificate
% The fully-qualified domain name in the certificate will be: securityappliance.example.com

Enter the base 64 encoded certificate. End with a blank line or the word “quit” on a line by itself

[ certificate data omitted ]
quit
INFO: Certificate successfully imported

Step 6 Verify that the enrollment process was successful by displaying certificate details issued for the ASA and the CA certificate for the trustpoint.

show crypto ca certificate

Example:

ciscoasa(config)# show crypto ca certificate Main

Step 7 Save the running configuration.

write memory

Example:

ciscoasa(config)# write memory

Step 8 Repeat these steps for each trustpoint that you configure for manual enrollment.

Obtain Certificates Automatically with SCEP

This section describes how to obtain certificates automatically using SCEP.

Before you begin
You must have already obtained a base-64 encoded CA certificate from the CA represented by the trustpoint.

Procedure

Step 1 Obtain the CA certificate for the configured trustpoint.

crypto ca authenticate trustpoint

Example:

ciscoasa/contexta(config)# crypto ca authenticate Main
When you configure the trustpoint, use of the enrollment url command determines whether or not you must obtain certificates automatically via SCEP.

Step 2
Enroll the ASA with the trustpoint. This command retrieves a certificate for signing data and depending on the type of keys that you have configured, for encrypting data. Before entering this command, contact the CA administrator, who may need to authenticate the enrollment request manually before the CA grants certificates.

crypto ca enroll trustpoint

Example:

ciscoasa/contexta(config)# crypto ca enroll Main

If the ASA does not receive a certificate from the CA within one minute (the default) of sending a certificate request, it resends the certificate request. The ASA continues sending a certificate request each minute until a certificate is received.

If the fully qualified domain name configured for the trustpoint is not identical to the fully qualified domain name of the ASA, including the case of the characters, a warning appears. To resolve this issue, exit the enrollment process, make any necessary corrections, and reenter the crypto ca enroll command.

Note If the ASA reboots after you have issued the crypto ca enroll command but before you have received the certificate, reenter the crypto ca enroll command and notify the CA administrator.

Step 3
Verify that the enrollment process was successful by displaying certificate details issued for the ASA and the CA certificate for the trustpoint.

show crypto ca certificate

Example:

ciscoasa/contexta(config)# show crypto ca certificate Main

Step 4
Save the running configuration.

write memory

Example:

ciscoasa/contexta(config)# write memory

Configure Proxy Support for SCEP Requests

To configure the ASA to authenticate remote access endpoints using third-party CAs, perform the following steps:

Procedure

Step 1
Enter tunnel-group ipsec-attributes configuration mode.
**tunnel-group name ipsec-attributes**

Example:

```
ciscoasa(config)# tunnel-group remotegrp ipsec-attributes
```

**Step 2**

Enable client services.

```
crypto ikev2 enable outside client-services port portnumber
```

Example:

```
ciscoasa(config-tunnel-ipsec)# crypto ikev2 enable outside client-services
```

The default port number is 443.

**Note** This command is needed only if you support IKEv2.

**Step 3**

Enter tunnel-group general-attributes configuration mode.

```
tunnel-group name general-attributes
```

Example:

```
ciscoasa(config)# tunnel-group 209.165.200.225 general-attributes
```

**Step 4**

Enable SCEP enrollment for the tunnel group.

```
scep-enrollment enable
```

Example:

```
ciscoasa(config-tunnel-general)# scep-enrollment enable
INFO: 'authentication aaa certificate' must be configured to complete setup of this option.
```

**Step 5**

Enter group-policy attributes configuration mode.

```
group-policy name attributes
```

Example:

```
ciscoasa(config)# group-policy FirstGroup attributes
```

**Step 6**

Enroll the SCEP CA for the group policy. Enter this command once per group policy to support a third-party digital certificate.

```
scep-forwarding-url value URL
```

Example:

```
ciscoasa(config-group-policy)# scep-forwarding-url value http://ca.example.com:80/
```

**URL** is the SCEP URL on the CA.
Step 7  Supply a common, secondary password when a certificate is unavailable for WebLaunch support of the SCEP proxy.

secondary-pre-fill-username clientless hide use-common-password password

Example:

ciscoasa(config)# tunnel-group remotegrp webvpn-attributes
ciscoasa(config-tunnel-webvpn)# secondary-pre-fill-username clientless hide
use-common-password secret

You must use the hide keyword to support the SCEP proxy.
For example, a certificate is not available to an endpoint requesting one. Once the endpoint has the certificate, AnyConnect disconnects, then reconnects to the ASA to qualify for a DAP policy that provides access to internal network resources.

Step 8  Hide the secondary prefill username for AnyConnect VPN sessions.

secondary-pre-fill-username ssl-client hide use-common-password password

Example:

ciscoasa(config-tunnel-webvpn)# secondary-pre-fill-username ssl-client hide
use-common-password secret

Despite the ssl-client keyword inherited from earlier releases, use this command to support AnyConnect sessions that use either IKEv2 or SSL.
You must use the hide keyword to support the SCEP proxy.

Step 9  Supply the username when a certificate is unavailable.

secondary-username-from-certificate {use-entire-name | use-script | {primary_attr [secondary-attr]}}
[no-certificate-fallback cisco-secure-desktop machine-unique-id]

Example:

ciscoasa(config-tunnel-webvpn)# secondary-username-from-certificate CN no-certificate-fallback
cisco-secure-desktop machine-unique-id

Configure the CA Certificate Lifetime

To configure the local CA server certificate lifetime, perform the following steps:

Procedure

Step 1  Enter local ca server configuration mode.
crypto ca server

Example:
ciscoasa(config)# crypto ca server

Step 2  Determine the expiration date to be included in the certificate. The default lifetime of a local CA certificate is 15 years.

lifetime ca-certificate time

Example:

ciscoasa(config-ca-server)# lifetime ca-certificate 365

Make sure that you set the validity period of the certificate between 5 to 30 years.

Step 3  (Optional) Reset the local CA certificate lifetime to the default value of 15 years.

no lifetime ca-certificate

Example:

ciscoasa(config-ca-server)# no lifetime ca-certificate

The local CA server automatically generates a replacement CA certificate 30 days before it expires, which allows the replacement certificate to be exported and imported onto any other devices for certificate validation of user certificates that have been issued by the local CA certificate after the current local CA certificate has expired. The following pre-expiration syslog message is generated:

%ASA-1-717049: Local CA Server certificate is due to expire in days days and a replacement certificate is available for export.

Note  When notified of this automatic rollover, the administrator must make sure that the new local CA certificate is imported onto all required devices before it expires.

---

**Configure the User Certificate Lifetime**

To configure the user certificate lifetime, perform the following steps:

**Procedure**

Step 1  Enter local ca server configuration mode.

crypto ca server

Example:

ciscoasa(config)# crypto ca server

Step 2  Set the length of time that you want user certificates to remain valid. The valid time range is one day to four years. The default lifetime value is two years.
**Configure the CRL Lifetime**

To configure the CRL lifetime, perform the following steps:

**Procedure**

**Step 1**
Enter local ca server configuration mode.

```
crypto ca server
```

**Example:**

```
ciscoasa(config)# crypto ca server
```

**Step 2**
Set the length of time that you want the CRL to remain valid.

```
lifetime crl time
```

**Example:**

```
ciscoasa(config-ca-server)# lifetime crl 10
```

The local CA updates and reissues the CRL each time that a user certificate is revoked or unrevoked, but if no revocation changes occur, the CRL is reissued automatically once each CRL lifetime. If you do not specify a CRL lifetime, the default time period is six hours.

**Step 3**
Force the issuance of a CRL at any time, which immediately updates and regenerates a current CRL to overwrite the existing CRL.

```
crypto ca server crl issue
```

**Example:**

```
ciscoasa(config-ca-server)# crypto ca server crl issue
```

A new CRL has been issued.
Do not use this command unless the CRL file has been removed in error or has been corrupted and must be regenerated.

## Configure the Server Keysize

To configure the server keysize, perform the following steps:

### Procedure

**Step 1** Enter local ca server configuration mode.

```
crypto ca server
```

**Example:**

```
ciscoasa(config)# crypto ca server
```

**Step 2** Specify the size of the public and private keys generated at user-certificate enrollment.

```
keysize server
```

**Example:**

```
ciscoasa(config-ca-server)# keysize server 2048
```

The key pair size options are 512, 768, 1024, 2048, 4096 bits, and the default value is 1024 bits.

**Note** After you have enabled the local CA, you cannot change the local CA keysize, because all issued certificates would be invalidated. To change the local CA keysize, you must delete the current local CA and reconfigure a new one.

### Example

The following is sample output that shows two user certificates in the database.

```
Username: user1
Renewal allowed until: Not Allowed
Number of times user notified: 0
PKCS12 file stored until: 12:45:52 UTC Fri Jan 4 2017
Certificates Issued:
  serial: 0x71
  issued: 12:45:52 UTC Thu Jan 3 2008
  expired: 12:17:37 UTC Sun Dec 31 2017
  status: Not Revoked
Username: user2
Renewal allowed until: Not Allowed
Number of times user notified: 0
PKCS12 file stored until: 12:27:59 UTC Fri Jan 4 2008
```
How to Set Up Specific Certificate Types

After you have established trusted certificates, you can begin other fundamental tasks such as establishing identity certificates or more advanced configurations such as establishing local CA or code signing certificates.

Before you begin

Read about digital certificate information and establish trusted certificates. CA certificates with no private key are used by all VPN protocols and webvpn, and are configured in trustpoints to validate incoming client certificates. Similarly, a trustpool is a list of trusted certificates used by webvpn features to validate proxied connections to https servers and to validate the smart-call-home certificate.

Procedure

A local CA allows VPN clients to enroll for certificates directly from the ASA. This advanced configuration converts the ASA into a CA. To configure CAs, refer to CA Certificates, on page 34.

What to do next

Set up a certificate expiration alert or monitor digital certificates and certificate management history.

CA Certificates

This page is where you manage CA certificates. The following topics explain what you can do.

Configure the Local CA Server

To configure the local CA server, perform the following steps:

Procedure

Step 1
Enter local ca server configuration mode.

crypto ca server

Example:

ciscoasa(config)# crypto ca server
Step 2 Specify the SMTP from-address, a valid e-mail address that the local CA uses as a from address when sending e-mail messages that deliver one-time passwords (OTPs) for an enrollment invitation to users.

**smtp from-address e-mail_address**

**Example:**

ciscoasa(config-ca-server) # smtp from-address SecurityAdmin@example.com

Step 3 (Optional) Specify the subject-name DN that is appended to each username on issued certificates.

**subject-name-default dn**

**Example:**

ciscoasa(config-ca-server)# subject-name-default cn=engineer, o=asc systems, c=US

The subject-name DN and the username combine to form the DN in all user certificates that are issued by the local CA server. If you do not specify a subject-name DN, you must specify the exact subject name DN to be included in a user certificate each time that you add a user to the user database.

**Note** Make sure that you review all optional parameters carefully before you enable the configured local CA, because you cannot change issuer-name and keysizes server values after you enable the local CA for the first time.

Step 4 Create the self-signed certificate and associate it with the local CA on the ASA.

**no shutdown**

**Example:**

ciscoasa(config-ca-server)# no shutdown

The self-signed certificate key usage extension has key encryption, key signature, CRL signing, and certificate signing capabilities.

**Note** After the self-signed local CA certificate has been generated, to change any characteristics, you must delete the existing local CA server and completely recreate it.

The local CA server keeps track of user certificates, so the administrator can revoke or restore privileges as needed.

**Example**

The following example shows how to configure the local CA server using the predefined default values for all required parameters:

ciscoasa(config)# crypto ca server
ciscoasa(config-ca-server)# smtp from-address SecurityAdmin@example.com
ciscoasa(config-ca-server)# subject-name-default cn=engineer, o=asc Systems, c=US
ciscoasa(config-ca-server)# no shutdown
CA Server Management

Delete the Local CA Server

To delete an existing local CA server (either enabled or disabled), perform the following steps:

Procedure

Enter one of the following commands to remove an existing local CA server (either enabled or disabled):

- **no crypto ca server**
  
  Example
  ```
  ciscoasa(config)# no crypto ca server
  ```

- **clear configure crypto ca server**
  
  Example
  ```
  ciscoasa(config)# clear config crypto ca server
  ```

**Note**  
Deleting the local CA server removes the configuration from the ASA. After the configuration has been deleted, it is unrecoverable.

Make sure that you also delete the associated local CA server database and configuration files (that is, all files with the wildcard name, LOCAL-CA-SERVER.*).

Manage User Certificates

To change the certificate status, perform the following steps:

Procedure

1. **Step 1** Select specific certificates by username or by certificate serial number in the Manage User Certificates pane.
2. **Step 2** Choose one of the following options:
   - Click **Revoke** to remove user access if the user certificate lifetime period runs out. The local CA also marks the certificate as revoked in the certificate database, automatically updates the information, and reissues the CRL.
   - Select a revoked certificate and click **Unrevoke** to restore access. The local CA also marks the certificate as unrevoked in the certificate database, automatically updates the certificate information, and reissues an updated CRL.
3. **Step 3** Click **Apply** when you are done to save your changes.
Enable the Local CA Server

To enable the local CA server, perform the following steps.

Before you begin

Before enabling the local CA server, you must first create a passphrase of at least seven characters to encode and archive a PKCS12 file that includes the local CA certificate and keypair to be generated. The passphrase unlocks the PKCS12 archive if the CA certificate or keypair is lost.

Procedure

Step 1  Enter local ca server configuration mode.

crypto ca server

Example:

ciscoasa(config)# crypto ca server

Step 2  Enable the local CA server.

no shutdown

Example:

ciscoasa(config-ca-server)# no shutdown

This command generates the local CA server certificate, keypair and necessary database files, and archives the local CA server certificate and keypair in a PKCS12 file. You must enter an 8-65 alphanumeric password. After initial startup, you can disable the local CA without being prompted for the password.

Step 3  Save the configuration to make sure that the local CA certificate and keypair are not lost after a reboot occurs.

write memory

Example:

ciscoasa(config)# write memory

Examples

The following example enables the local CA server:

ciscoasa(config)# crypto ca server

ciscoasa(config-ca-server)# no shutdown

% Some server settings cannot be changed after CA certificate generation.
% Please enter a passphrase to protect the private key
% or type Return to exit
Password: caserver
Re-enter password: caserver
Keypair generation process begin. Please wait...

The following is sample output that shows local CA server configuration and status:

Certificate Server LOCAL-CA-SERVER:
  Status: enabled
  State: enabled
  Server's configuration is locked (enter "shutdown" to unlock it)
  Issuer name: CN=wz5520-1-16
  CA certificate fingerprint/thumbprint: (MD5)
    76dd1439 ac94fdbc 74a0a89f cb815acc
  CA certificate fingerprint/thumbprint: (SHA1)
    58754ffd 9f19f9fd b13b4b02 15b3e4be b70b5a83
  Last certificate issued serial number: 0x6
  CA certificate expiration timer: 14:25:11 UTC Jan 16 2008
  CRL NextUpdate timer: 16:09:55 UTC Jan 24 2007
  Current primary storage dir: flash:

**Configure Auto Import of Trustpool Certificates**

Smart licensing uses the Smart Call Home infrastructure. When the ASA configures Smart Call Home anonymous reporting in the background, the ASA automatically creates a trustpoint containing the certificate of the CA that issued the Call Home server certificate. The ASA now supports validation of the certificate if the issuing hierarchy of the server certificate changes, without the need for customer involvement to adjust certificate hierarchy changes. You can automate the update of the trustpool bundle at periodic intervals so that Smart Call Home can remain active if the self-signed certificate of the CA server changes. This feature is not supported under multi-context deployments.

Automatic import of trustpool certificate bundles requires you to specify the URL that ASA uses to download and import the bundle. Use the following command so the import happens daily at a regular interval with the default Cisco URL and default time of 22 hours:

ciscoasa(config-ca-trustpool)# auto-import-url Default

You can also enable auto import with a custom URL with the following command:

ciscoasa(config-ca-trustpool)# auto-import url http://www.thawte.com

To give you more flexibility to set downloads during off peak hours or other convenient times, enter the following command which enables the import with a custom time:

ciscoasa(config-ca-trustpool)# auto-import time 23:23:23

Setting the automatic import with both a custom URL and custom time requires the following command:

**Show the State of the Trustpool Policy**

Use the following command to see the current state of the trustpool policy:

show crypto ca trustpool policy

This command returns information like the following:

0 trustpool certificates installed
Trustpool auto renewal statistics:
State: Not in progress
Last import result: Not attempted N/A
Current Jitter: 0

Trustpool auto import statistics:
Last import result: N/A
Next schedule import at 22:00:00 Tues Jul 21 2015

Trustpool Policy

- Trustpool revocation checking is disabled.
- CRL cache time: 60 seconds
- CRL next update field: required and enforced
- Auto import of trustpool is enabled
- Download time: 22:00:00

Policy Overrides:
None configured

---

**Clear CA Trustpool**

To reset the trustpool policy to its default state, use the following command:

clear configure crypto ca trustpool

Since the automatic import of trustpoint certificates is turned off by default, using this command disables the feature.

**Customize the Local CA Server**

To configure a customized local CA server, perform the following steps:

**Procedure**

1. **Step 1** Enter local ca server configuration mode.
   
   ```
   crypto ca server
   ```

   **Example:**
   
   ```
   ciscoasa(config)# crypto ca server
   ```

2. **Step 2** Specify parameters that do not have default values.
   
   ```
   issuer-name DN-string
   ```

   **Example:**
   
   ```
   ciscoasa(config-ca-server)# issuer-name cn=xx5520,cn=30.132.0.25,ou=DevTest,ou=QA,o=ASC Systems
   ```

3. **Step 3** Customize the FQDN for the enrollment URL sent from the local CA server to the user.
   
   ```
   smtp fqdn hostname.domain name
   ```

   **Example:**
Customize the Local CA Server

```
ciscoasa(config-ca-server)# smtp subject Priority E-Mail: Enclosed Confidential Information is Required for Enrollment
```

If you do not specify the FQDN, ASA will use its FQDN for the enrollment url.

**Step 4**
Specify the e-mail address that is to be used as the From: field of all e-mail messages that are generated by the local CA server.

```
smtp from-address e-mail_address
```

**Example:**
```
ciscoasa(config-ca-server)# smtp from-address SecurityAdmin@example.com
```

**Step 5**
Customize the text that appears in the subject field of all e-mail messages sent from the local CA server.

```
smtp subject subject-line
```

**Example:**
```
ciscoasa(config-ca-server)# smtp subject Priority E-Mail: Enclosed Confidential Information is Required for Enrollment
```

**Step 6**
Specify an optional subject-name DN to be appended to a username on issued certificates.

```
subject-name-default dn
```

**Example:**
```
ciscoasa(config-ca-server)# subject-name default cn=engineer, o=ASC Systems, c=US
```

The default subject-name DN becomes part of the username in all user certificates issued by the local CA server.

The allowed DN attribute keywords are as follows:

- C = Country
- CN = Common Name
- EA = E-mail Address
- L = Locality
- O = Organization Name
- OU = Organization Unit
- ST = State/Province
- SN = Surname
- ST = State/Province
Note If you do not specify a subject-name-default to serve as a standard subject-name default, you must specify a DN each time that you add a user.

---

Disable the Local CA Server

To disable the local CA server, perform the following steps:

**Procedure**

**Step 1** Enter local ca server configuration mode.

```
crypto ca server
```

*Example:*

```
ciscoasa(config)# crypto ca server
```

**Step 2** Disable the local CA server.

```
shutdown
```

*Example:*

```
ciscoasa(config-ca-server)# shutdown
INFO: Local CA Server has been shutdown.
```

This command disables website enrollment, allows you to modify the local CA server configuration, and stores the current configuration and associated files. After initial startup, you can reenable the local CA without being prompted for the password.

---

Set Up External Local CA File Storage

To configure external local CA file storage, perform the following steps:

**Procedure**

**Step 1** Access configuration mode for the specific file system type.

```
mount name type
```

*Example:*

```
ciscoasa(config)# mount mydata type cifs
```

**Step 2** Mount a CIFS file system.

```
mount name type cifs
```
Example:

ciscoasa(config-mount-cifs)# mount mydata type cifs
server 10.1.1.10 share myshare
domain example.com
username user6
password ********
status enable

Note Only the user who mounts a file system can unmount it with the no mount command.

Step 3 Enter local ca server configuration mode.
crypto ca server

Example:

ciscoasa(config)# crypto ca server

Step 4 Specify the location of mydata, the premounted CIFS file system to be used for the local CA server database.
database path mount-name directory-path

Example:

ciscoasa(config-ca-server)# database path mydata:newuser

This command establishes a path to the server and then specifies the local CA file or folder name to use for storage and retrieval. To return local CA file storage to the ASA flash memory, use the no database path command.

Note To secure stored local CA files on an external server requires a premounted file system of file type CIFS or FTP that is username-protected and password-protected.

Step 5 Save the running configuration.
write memory

Example:

ciscoasa(config)# write memory

For external local CA file storage, each time that you save the ASA configuration, user information is saved from the ASA to the premounted file system and file location, mydata:newuser.

For flash memory storage, user information is saved automatically to the default location for the start-up configuration.

Example

The following example shows the list of local CA files that appear in flash memory or in external storage:
Download and Store CRLs

To download and store CRLs, perform the following steps:

Procedure

Step 1
Enter local ca server configuration mode.

crypto ca server

Example:

cursora(config)# crypto ca server

Step 2
Open a port on an interface to make the CRL accessible from that interface. The specified interface and port are used to listen for incoming requests for the CRL.

publish-crl interface interface port portnumber

Example:

cursora(config-ca-server)# publish-crl outside 70

The interface and optional port selections are as follows:

- inside—Name of interface/GigabitEthernet0/1
- management—Name of interface/ Management0/0
- outside—Name of interface/GigabitEthernet0/0
- Port numbers can range from 1-65535. TCP port 80 is the HTTP default port number.

Note
If you do not specify this command, the CRL is not accessible from the CDP location, because this command is required to open an interface to download the CRL file.

The CDP URL can be configured to use the IP address of an interface, and the path of the CDP URL and the filename can also be configured (for example, http://10.10.100/user8/my_crl_file).

In this case, only the interface with that IP address configured listens for CRL requests, and when a request comes in, the ASA matches the path, /user8/my_crl_file to the configured CDP URL. When the path matches, the ASA returns the stored CRL file.
The protocol must be HTTP, so the prefix displayed is http://.

**Step 3**

Specify the CDP to be included in all issued certificates. If you do not configure a specific location for the CDP, the default URL location is http://hostname.domain/+CSCOCA+/asa_ca.crl.

```plaintext
cdp-url url
```

**Example:**

```
ciscoasa(config-ca-server)# cdp-url http://172.16.1.1/pathname/myca.crl
```

The local CA updates and reissues the CRL each time a user certificate is revoked or unrevoked. If no revocation changes occur, the CRL is reissued once each CRL lifetime.

If this command is set to serve the CRL directly from the local CA ASA, see Download and Store CRLs for instructions about opening a port on an interface to make the CRL accessible from that interface.

The CRL exists for other devices to validate the revocation of certificates issued by the local CA. In addition, the local CA tracks all issued certificates and status within its own certificate database. Revocation checking is performed when a validating party needs to validate a user certificate by retrieving the revocation status from an external server, which might be the CA that issued the certificate or a server designated by the CA.

---

**Enrollment and User Management**

**Set Up Enrollment Parameters**

To set up enrollment parameters, perform the following steps:

**Procedure**

**Step 1**
Enter local ca server configuration mode.

```plaintext
crypto ca server
```

**Example:**

```
ciscoasa(config)# crypto ca server
```

**Step 2**
Specify the number of hours that an issued OTP for the local CA enrollment page is valid. The default expiration time is 72 hours.

```plaintext
op expiration timeout
```

**Example:**

```
ciscoasa(config-ca-server)# otp expiration 24
```

**Note**

The user OTP to enroll for a certificate on the enrollment website is also used as the password to unlock the PKCS12 file that includes the issued certificate and keypair for the specified user.

**Step 3**
Specify the number of hours an already-enrolled user can retrieve a PKCS12 enrollment file.
enrollment-retrieval timeout

Example:

ciscoasa(config-ca-server)# enrollment-retrieval 120

This time period begins when the user is successfully enrolled. The default retrieval period is 24 hours. Valid values for the retrieval period range from 1 to 720 hours. The enrollment retrieval period is independent of the OTP expiration period.

After the enrollment retrieval time expires, the user certificate and keypair are no longer available. The only way a user may receive a certificate is for the administrator to reinitialize certificate enrollment and allow a user to log in again.

Add and Enroll Users

To add a user who is eligible for enrollment in the local CA database, perform the following steps:

Procedure

Step 1  Add a new user to the local CA database.

```
crypto ca server user-db add username [dn dn] [email emailaddress]
```

Example:

```
ciscoasa(config-ca-server)# crypto ca server user-db add user1 dn user1@example.com,Engineer, Example Company, US, email user1@example.com
```

The username argument is a string of 4-64 characters, which is the simple username for the user being added. The username can be an e-mail address, which then is used to contact the user as necessary for enrollment invitations.

The dn argument is the distinguished name, a global, authoritative name of an entry in the OSI Directory (X.500) (for example, cn=user1@example.com, cn=Engineer, o=Example Company, c=US).

The email-address argument is the e-mail address of the new user to which OTPs and notices are to be sent.

Step 2  Provide user privileges to a newly added user.

```
crypto ca server user-db allow user
```

Example:

```
ciscoasa(config-ca-server)# crypto ca server user-db allow user
```

Step 3  Notify a user in the local CA database to enroll and download a user certificate, which automatically e-mails the OTP to that user.

```
crypto ca server user-db email-otp username
```

Example:
ciscoasa(config-ca-server)# crypto ca server user-db email-otp exampleuser1

**Note**  When an administrator wants to notify a user through e-mail, the administrator must specify the e-mail address in the username field or in the e-mail field when adding that user.

**Step 4**  Show the issued OTP.

**crypto ca server user-db show-otp**

**Example:**

ciscoasa(config-ca-server)# crypto ca server user-db show-otp

**Step 5**  Set the enrollment time limit in hours. The default expiration time is 72 hours.

**otp expiration timeout**

**Example:**

ciscoasa(config-ca-server)# otp expiration 24

This command defines the amount of time that the OTP is valid for user enrollment. This time period begins when the user is allowed to enroll.

After a user enrolls successfully within the time limit and with the correct OTP, the local CA server creates a PKCS12 file, which includes a keypair for the user and a user certificate that is based on the public key from the keypair generated and the subject-name DN specified when the user is added. The PKCS12 file contents are protected by a passphrase, the OTP. The OTP can be handled manually, or the local CA can e-mail this file to the user to download after the administrator allows enrollment.

The PKCS12 file is saved to temporary storage with the name, `username.p12`. With the PKCS12 file in storage, the user can return within the enrollment-retrieval time period to download the PKCS12 file as many times as needed. When the time period expires, the PKCS12 file is removed from storage automatically and is no longer available to download.

**Note**  If the enrollment period expires before the user retrieves the PKCS12 file that includes the user certificate, enrollment is not permitted.

---

**Renew Users**

To specify the timing of renewal notices, perform the following steps:

**Procedure**

**Step 1**  Enter local ca server configuration mode.

**crypto ca server**

**Example:**
Step 2  Specifies the number of days (1-90) before the local CA certificate expires that an initial reminder to re-enroll is sent to certificate owners.

renewal-reminder time

Example:

ciscoasa(config-ca-server)# renewal-reminder 7

If a certificate expires, it becomes invalid. Renewal notices and the times they are e-mailed to users are variable, and can be configured by the administrator during local CA server configuration.

Three reminders are sent. An e-mail is automatically sent to the certificate owner for each of the three reminders, provided an e-mail address is specified in the user database. If no e-mail address exists for the user, a syslog message alerts you of the renewal requirement.

The ASA automatically grants certificate renewal privileges to any user who holds a valid certificate that is about to expire, as long as the user still exists in the user database. Therefore, if an administrator does not want to allow a user to renew automatically, the administrator must remove the user from the database before the renewal time period.

---

**Restore Users**

To restore a user and a previously revoked certificate that was issued by the local CA server, perform the following steps:

**Procedure**

**Step 1**  Enter local ca server configuration mode.

crypto ca server

Example:

ciscoasa(config)# crypto ca server

**Step 2**  Restore a user and unrevoke a previously revoked certificate that was issued by the local CA server.

crypto ca server unrevoke cert-serial-no

Example:

ciscoasa(config-ca-server)# crypto ca server unrevoke 782ea09f

The local CA maintains a current CRL with serial numbers of all revoked user certificates. This list is available to external devices and can be retrieved directly from the local CA if it is configured to do so with the cdp-url
command and the \texttt{publish-crl} command. When you revoke (or unrevoke) any current certificate by certificate serial number, the CRL automatically reflects these changes.

---

**Remove Users**

To delete a user from the user database by username, perform the following steps:

**Procedure**

**Step 1**
Enter local ca server configuration mode.

\texttt{crypto ca server}

\texttt{Example:}

\texttt{ciscoasa(config)# crypto ca server}

**Step 2**
Remove a user from the user database and allow revocation of any valid certificates that were issued to that user.

\texttt{crypto ca server user-db remove \textit{username}}

\texttt{Example:}

\texttt{ciscoasa(config-ca-server)# crypto ca server user-db remove user1}

---

**Revoke Certificates**

To revoke a user certificate, perform the following steps:

**Procedure**

**Step 1**
Enter local ca server configuration mode.

\texttt{crypto ca server}

\texttt{Example:}

\texttt{ciscoasa(config)# crypto ca server}

**Step 2**
Enter the certificate serial number in hexadecimal format.

\texttt{crypto ca server revoke \textit{cert-serial-no}}

\texttt{Example:}

\texttt{ciscoasa(config-ca-server)# crypto ca server revoke 782ea09f}
This command marks the certificate as revoked in the certificate database on the local CA server and in the CRL, which is automatically reissued.

**Note** The password is also required if the certificate for the ASA needs to be revoked, so make sure that you record it and store it in a safe place.

---

## Set a Certificate Expiration Alert (for Identity or CA Certificates)

ASA checks all the CA and ID certificates in the trust points for expiration once every 24 hours. If a certificate is nearing expiration, a syslog will be issued as an alert.

A CLI is provided to configure the reminder and recurrence intervals. By default, reminders start at 60 days prior to expiration and recur every 7 days. You can configure the interval at which reminders are sent and the number of days before the expiration at which the first alert is sent by using the following command:

```
[no] crypto ca alerts expiration [begin <days before expiration>] [repeat <days>]
```

Irrespective of the alerts configuration, a reminder is sent every day during the last week of expiration. The following `show` and `clear` commands have also been added:

```
clear conf crypto ca alerts
show run crypto ca alerts
```

In addition to the renewal reminder, if an already expired certificate is found in the configuration, a syslog is generated once every day to rectify the configuration by either renewing the certificate or removing the expired certificate.

For example, assume that the expiration alerts are configured to begin at 60 days and repeat every 6 days after that. If the ASA is rebooted at 40 days, an alert is sent on that day, and the next alert is sent on the 36th day.

---

**Note** Expiration checking is not done on trust pool certificates. The Local CA trust point is treated as a regular trustpoint for expiration checking too.

---

## Monitoring Digital Certificates

See the following commands for monitoring digital certificate status:

- `show crypto ca server`
  
  This command shows local CA configuration and status.

- `show crypto ca server cert-db`
  
  This command shows user certificates issued by the local CA.

- `show crypto ca server certificate`
This command shows local CA certificates on the console in base 64 format and the rollover certificate when available, including the rollover certificate thumb print for verification of the new certificate during import onto other devices.

- **show crypto ca server crl**
  This command shows CRLs.

- **show crypto ca server user-db**
  This command shows users and their status, which can be used with the following qualifiers to reduce the number of displayed records:
    - **allowed.** Shows only users currently allowed to enroll.
    - **enrolled.** Shows only users that are enrolled and hold a valid certificate
    - **expired.** Shows only users holding expired certificates.
    - **on-hold.** Lists only users without a certificate and not currently allowed to enroll.

- **show crypto ca server user-db allowed**
  This command shows users who are eligible to enroll.

- **show crypto ca server user-db enrolled**
  This command shows enrolled users with valid certificates.

- **show crypto ca server user-db expired**
  This command shows users with expired certificates.

- **show crypto ca server user-db on-hold**
  This command shows users without certificates who are not allowed to enroll.

- **show crypto key name of key**
  This command shows key pairs that you have generated.

- **show running-config**
  This command shows local CA certificate map rules.

**Examples**

The following example shows an RSA general-purpose key:

```
ciscoasa/contexta(config)# show crypto key mypubkey rsa
Key pair was generated at: 16:39:47 central Feb 10 2010
Key name: <Default-RSA-Key>
Usage: General Purpose Key
Modulus Size (bits): 2048
Storage: config
Key Data:
  30820122 300d0609 2a864886 f70d0101 01050003 82010f00 3082010a 02820101
  00ea2c38 df9c606e ddb7b08a e8b0a1a8 65592d85 0711cac5 fceddee1 fa494297
  525fffc0 90da8a4c e696e44e 0646c661 48b3602a 960d7a3a 52dae14a 5f983603
  elf33e40 a6ce04f5 9a812894 b0fe0403 f8d7e05e aea79603 2dcd56cc 01261b3e
```
Digital Certificates

Monitoring Digital Certificates

The following examples show the local CA CRL:

ciscoasa(config)# show crypto ca server crl
Certificate Revocation List:
  Issuer: cn=xx5520-1-3-2007-1
  This Update: 13:32:53 UTC Jan 4 2010
  Next Update: 13:32:53 UTC Feb 3 2010
  Number of CRL entries: 2
  CRL size: 270 bytes
Revoked Certificates:
  Serial Number: 0x6f
  Revocation Date: 12:30:01 UTC Jan 4 2010
  Serial Number: 0x47
  Revocation Date: 13:32:48 UTC Jan 4 2010

The following example shows one user on-hold:

ciscoasa(config)# show crypto ca server user-db on-hold
username: wilma101
e-mail: <None>
dn: <None>
allowed: <not allowed>
notified: 0
ciscoasa(config)#

The following example shows output of the show running-config command, in which local CA certificate map rules appear:

crypto ca certificate map 1
  issuer-name co asc
  subject-name attr ou eq Engineering
## History for Certificate Management

**Table 1: History for Certificate Management**

<table>
<thead>
<tr>
<th>Feature Name</th>
<th>Platform Releases</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificate management</td>
<td>7.0(1)</td>
<td>Digital certificates (including CA certificates, identity certificates, and code signer certificates) provide digital identification for authentication. A digital certificate includes information that identifies a device or user, such as the name, serial number, company, department, or IP address. CAs are trusted authorities that “sign” certificates to verify their authenticity, thereby guaranteeing the identity of the device or user. CAs issue digital certificates in the context of a PKI, which uses public-key or private-key encryption to ensure security.</td>
</tr>
<tr>
<td>Certificate management</td>
<td>7.2(1)</td>
<td>We introduced the following commands: <code>issuer-name DN-string</code>, <code>revocation-check crl none</code>, <code>revocation-check crl</code>, <code>revocation-check none</code>. We deprecated the following commands: `crl {required</td>
</tr>
</tbody>

### Feature Name | Platform Releases | Description
--- | --- | ---
Certificate management | 8.0(2) | We introduced the following commands: `cdp-url`, `crypto ca server`, `crypto ca server crl issue`, `crypto ca server revoke cert-serial-no`, `crypto ca server unrevoke cert-serial-no`, `crypto ca server user-db add user [dn dn] [email e-mail-address]`, `crypto ca server user-db allow {username | all-unenrolled | all-certholders} [display-otp] [email-otp] [replace-otp]`, `crypto ca server user-db email-otp {username | all-unenrolled | all-certholders}`, `crypto ca server user-db remove username`, `crypto ca server user-db show-otp {username | all-certholders | all-unenrolled}`, `crypto ca server user-db write {no} database path mount-name directory-path`, `debug crypto ca server [level], lifetime, [ca-certificate | certificate | crl] time, no shutdown, otp expiration timeout, renewal-reminder time, show crypto ca server, show crypto ca server cert-db [user username | allowed | enrolled | expired | on-hold] [serial certificate-serial-number]`, `show crypto ca server certificate`, `show crypto ca server crl`, `show crypto ca server user-db [expired | allowed | on-hold | enrolled]`, `show crypto key name of key`, `show running-config`, `shutdown`.

SCEP proxy | 8.4(1) | We introduced this feature, which provides secure deployment of device certificates from third-party CAs.

We introduced the following commands:
<table>
<thead>
<tr>

<tbody>
<tr>
<td>Reference Identities</td>
<td>9.6(2)</td>
<td>TLS client processing now supports rules for verification of a server identity defined in RFC 6125, Section 6. Identity verification will be done during PKI validation for TLS connections to the Syslog Server and the Smart Licensing server only. If the presented identity cannot be matched against the configured reference identity, the connection is not established. We added or modified the following commands: <code>crypto ca reference-identity</code>, <code>logging host</code>, <code>call home profile destination address</code></td>
</tr>
<tr>
<td>Local CA Server</td>
<td>9.12(1)</td>
<td>To make the FQDN of the enrollment URL configurable instead of using the ASA's configured FQDN, a new CLI option is introduced. This new option is added to the smtp mode of crypto ca server. We deprecated Local CA Server and will be removing in a later release—When ASA is configured as local CA server, it is enabled to issue digital certificates, publish Certificate Revocation Lists (CRLs), and securely revoke issued certificates. This feature has become obsolete and hence the crypto ca server command is deprecated.</td>
