About This Guide

The following topics explain how to use this guide.

- Document Objectives, on page xix
- Related Documentation, on page xix
- Document Conventions, on page xix
- Communications, Services, and Additional Information, on page xxi

Document Objectives

The purpose of this guide is to help you configure VPN on the Adaptive Security Appliance (ASA) using the command-line interface. This guide does not cover every feature, but describes only the most common configuration scenarios.

You can also configure and monitor the ASA by using Adaptive Security Device Manager (ASDM), a web-based GUI application. ASDM includes configuration wizards to guide you through some common configuration scenarios, and online help for less common scenarios.

This guide applies to the Cisco ASA series. Throughout this guide, the term “ASA” applies generically to supported models, unless specified otherwise.

Related Documentation

About Tunneling, IPsec, and ISAKMP

This topic describes the Internet Protocol Security (IPsec) and the Internet Security Association and Key Management Protocol (ISAKMP) standards used to build Virtual Private Networks (VPNs).

Tunneling makes it possible to use a public TCP/IP network, such as the Internet, to create secure connections between remote users and a private corporate network. Each secure connection is called a tunnel.

The ASA uses the ISAKMP and IPsec tunneling standards to build and manage tunnels. ISAKMP and IPsec accomplish the following:

• Negotiate tunnel parameters
• Establish tunnels
• Authenticate users and data
• Manage security keys
• Encrypt and decrypt data
• Manage data transfer across the tunnel
• Manage data transfer inbound and outbound as a tunnel endpoint or router

The ASA functions as a bidirectional tunnel endpoint. It can receive plain packets from the private network, encapsulate them, create a tunnel, and send them to the other end of the tunnel where they are unencapsulated and sent to their final destination. It can also receive encapsulated packets from the public network, unencapsulate them, and send them to their final destination on the private network.
IPsec Overview

The ASA uses IPsec for LAN-to-LAN VPN connections and provides the option of using IPsec for client-to-LAN VPN connections. In IPsec terminology, a peer is a remote-access client or another secure gateway. For both connection types, the ASA supports only Cisco peers. Because we adhere to VPN industry standards, ASAs can work with other vendors’ peers; however, we do not support them.

During tunnel establishment, the two peers negotiate security associations that govern authentication, encryption, encapsulation, and key management. These negotiations involve two phases: first, to establish the tunnel (the IKE SA) and second, to govern traffic within the tunnel (the IPsec SA).

A LAN-to-LAN VPN connects networks in different geographic locations. In IPsec LAN-to-LAN connections, the ASA can function as initiator or responder. In IPsec client-to-LAN connections, the ASA functions only as responder. Initiators propose SAs; responders accept, reject, or make counter-proposals—all in accordance with configured SA parameters. To establish a connection, both entities must agree on the SAs.

Understanding IPsec Tunnels

IPsec tunnels are sets of SAs that the ASA establishes between peers. The SAs specify the protocols and algorithms to apply to sensitive data and also specify the keying material that the peers use. IPsec SAs control the actual transmission of user traffic. SAs are unidirectional, but are generally established in pairs (inbound and outbound).

The peers negotiate the settings to use for each SA. Each SA consists of the following:

- IKEv1 transform sets or IKEv2 proposals
- Crypto maps
- ACLs
- Tunnel groups
- Prefragmentation policies

ISAKMP and IKE Overview

ISAKMP is the negotiation protocol that lets two hosts agree on how to build an IPsec security association (SA). It provides a common framework for agreeing on the format of SA attributes. This security association includes negotiating with the peer about the SA and modifying or deleting the SA. ISAKMP separates negotiation into two phases: Phase 1 and Phase 2. Phase 1 creates the first tunnel, which protects later ISAKMP negotiation messages. Phase 2 creates the tunnel that protects data.

IKE uses ISAKMP to set up the SA for IPsec to use. IKE creates the cryptographic keys used to authenticate peers.

The ASA supports IKEv1 for connections from the legacy Cisco VPN client, and IKEv2 for the AnyConnect VPN client.

To set the terms of the ISAKMP negotiations, you create an IKE policy, which includes the following:

- The authentication type required of the IKEv1 peer, either RSA signature using certificates or preshared key (PSK).
- An encryption method to protect the data and ensure privacy.
• A Hashed Message Authentication Codes (HMAC) method to ensure the identity of the sender, and to ensure that the message has not been modified in transit.

• A Diffie-Hellman group to determine the strength of the encryption-key-determination algorithm. The ASA uses this algorithm to derive the encryption and hash keys.

• For IKEv2, a separate pseudo-random function (PRF) used as the algorithm to derive keying material and hashing operations required for the IKEv2 tunnel encryption and so on.

• A limit to the time the ASA uses an encryption key before replacing it.

With IKEv1 policies, you set one value for each parameter. For IKEv2, you can configure multiple encryption and authentication types, and multiple integrity algorithms for a single policy. The ASA orders the settings from the most secure to the least secure and negotiates with the peer using that order. This ordering allows you to potentially send a single proposal to convey all the allowed transforms instead of sending each allowed combination as with IKEv1.

The ASA does not support IKEv2 multiple security associations (SAs). The ASA currently accepts inbound IPsec traffic only on the first SA that is found. If IPsec traffic is received on any other SA, it is dropped with reason `vpn-overlap-conflict`. Multiple IPsec SAs can come about from duplicate tunnels between two peers, or from asymmetric tunneling.

Understanding IKEv1 Transform Sets and IKEv2 Proposals

An IKEv1 transform set or an IKEv2 proposal is a combination of security protocols and algorithms that define how the ASA protects data. During IPsec SA negotiations, the peers must identify a transform set or proposal that is the same at both peers. The ASA then applies the matching transform set or proposal to create an SA that protects data flows in the ACL for that crypto map.

With IKEv1 transform sets, you set one value for each parameter. For IKEv2 proposals, you can configure multiple encryption and authentication types and multiple integrity algorithms for a single proposal. The ASA orders the settings from the most secure to the least secure and negotiates with the peer using that order. This allows you to potentially send a single proposal to convey all the allowed combinations instead of the need to send each allowed combination individually as with IKEv1.

The ASA tears down the tunnel if you change the definition of the transform set or proposal used to create its SA. See the Clear Security Associations, on page 42” for further information.

---

**Note**

If you clear or delete the only element in a transform set or proposal, the ASA automatically removes the crypto map references to it.

About IKEv2 Multi-Peer Crypto Map

Beginning with the 9.14(1) release, ASA IKEv2 supports multi-peer crypto map—when a peer in a tunnel goes down, IKEv2 attempts to establish the tunnel with the next peer in the list. You can configure crypto map with a maximum of 10 peer addresses. This multiple peer support on IKEv2 is useful, especially, when you are migrating from IKEv1 with multi-peer crypto maps.

IKEv2 supports only bi-directional crypto maps. Hence, the multiple peers are also configured on bi-directional crypto maps, and the same is used to accept the request from peers initiating the tunnel.
IKEv2 Initiator Behavior

IKEv2 initiates session with a peer, say Peer1. If Peer1 is unreachable for 5 SA_INIT retransmits, a final retransmit is sent. This activity takes about 2 minutes.

When Peer1 fails, the SA_INIT message is sent to Peer2. If Peer2 is also unreachable, session establishment is initiated with Peer3 after 2 minutes.

After all the peers are exhausted in the peer list of the crypto map, IKEv2 intiaites the session again from Peer1 until a SA is established with any of the peers. The following figure depicts this behavior.

Figure 1: Initiator Process Flow

Continuous traffic is required to initiate IKE SA so that each failure attempt would move to the next peer and finally some reachable peer establishes the SA. In cases of disrupted traffic, a manual trigger is needed to initiate the IKE SA with the next peer.

IKEv2 Responder Behavior

If the responder device of IKE SA is configured with multiple peers in the crypto map, whenever an IKE SA is attempted, the address of the initiator IKE SA is validated with that of the current active peer in the crypto map.

For example, if the current active peer in the crypto map (being used as Responder) is the first peer, then the IKE SA is initiated from Peer1 IP address. Similarly, if the current active peer in the crypto map (being used as Responder) is the second peer, then IKE SA is initiated from Peer2 IP address.

Peer Index Reset Upon Crypto Map Changes

Any change to the crypto map resets the peer index to zero, and the tunnel initiation starts from first peer in the list. Following table provides multiple peer index transition under specific conditions:

Table 1: Multi-Peer Index Transition before SA

<table>
<thead>
<tr>
<th>Conditions prior to SA</th>
<th>Peer Index Moved</th>
</tr>
</thead>
<tbody>
<tr>
<td>Peer not reachable</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Guidelines for IKEv2 Multi-Peer

#### IKEv1 and IKEv2 Protocols

If a crypto map is configured with both the IKE versions and multiple peers, SA attempt is made on each peer with both versions before moving to next peer.

For example, if a crypto map is configured with two peers, say P1 and P2, then the tunnel is initiated to P1 with IKEv2, P1 with IKEv1, P2 with IKEv2, and so on.

#### High Availability

A crypto map with multiple peers initiates tunnels to the Responder device that is in HA. It moves to the next Responder device when the first device isn’t reachable.

An initiator device initiates tunnels to the Responder device. If the active device goes down, the standby device attempts to establish the tunnel from the Peer1 IP address, irrespective of the crypto map moving to the Peer2 IP address on the active device.
Centralized Cluster

A crypto map with multiple peers can initiate tunnels to the Responder device that is in a Centralized cluster deployment. If the first device is unreachable, it attempts to move to the next Responder device.

An initiator device initiates tunnels to the Responder device. Every node in the cluster moves to the next Peer2, if Peer1 isn’t reachable.

Distributed Cluster

Distributed clustering isn’t supported when an IKEv2 multi-peer crypto map is configured.

Multiple Context Modes

In multiple context modes, multi-peer behavior is specific to each context.

Debug Command

If the tunnel establishment fails, enable these commands to further analyse the issue.

- `debug crypto ikev2 platform 255`
- `debug crypto ikev2 protocol 255`
- `debug crypto ike-common 255`

The following example is that of a debug log that is specific to IKEv2 multi-peer, which displays the transition of peers.

```
Sep 13 10:08:58 [IKE COMMON DEBUG] Failed to initiate ikev2 SA with peer 192.168.2.2, initiate to next peer 192.168.2.3 configured in the multiple peer list of the crypto map.
```

Licensing for IPsec VPNs

Note

This feature is not available on No Payload Encryption models.

IPsec remote access VPN using IKEv2 requires an AnyConnect Plus or Apex license, available separately. IPsec remote access VPN using IKEv1 and IPsec site-to-site VPN using IKEv1 or IKEv2 uses the Other VPN license that comes with the base license. See Cisco ASA Series Feature Licenses for maximum values per model.

Guidelines for IPsec VPNs

Context Mode Guidelines

Supported in single or multiple context mode. AnyConnect Apex license is required for remote-access VPN in multi-context mode. Although ASA does not specifically recognize an AnyConnect Apex license, it enforces licenses characteristics of an Apex license such as AnyConnect Premium licensed to the platform limit, AnyConnect for mobile, AnyConnect for Cisco VPN phone, and advanced endpoint assessment.
Firewall Mode Guidelines
Supported in routed firewall mode only. Does not support transparent firewall mode.

Failover Guidelines
IPsec VPN sessions are replicated in Active/Standby failover configurations only.

Configure ISAKMP

Configure IKEv1 and IKEv2 Policies
IKEv1 and IKEv2 each support a maximum of 20 IKE policies, each with a different set of values. Assign a unique priority to each policy that you create. The lower the priority number, the higher the priority.
When IKE negotiations begin, the peer that initiates the negotiation sends all of its policies to the remote peer, and the remote peer tries to find a match. The remote peer checks all of the peer's policies against each of its configured policies in priority order (highest priority first) until it discovers a match.
A match exists when both policies from the two peers contain the same encryption, hash, authentication, and Diffie-Hellman parameter values. For IKEv1, the remote peer policy must also specify a lifetime less than or equal to the lifetime in the policy the initiator sent. If the lifetimes are not identical, the ASA uses the shorter lifetime. For IKEv2 the lifetime is not negotiated but managed locally between each peer, making it possible to configure lifetime independently on each peer. If no acceptable match exists, IKE refuses negotiation and the SA is not established.
There is an implicit trade-off between security and performance when you choose a specific value for each parameter. The level of security the default values provide is adequate for the security requirements of most organizations. If you are interoperating with a peer that supports only one of the values for a parameter, your choice is limited to that value.
You must include the priority in each of the ISAKMP commands. The priority number uniquely identifies the policy and determines the priority of the policy in IKE negotiations.

Procedure

Step 1
To create an IKE policy, enter the `crypto ikev1 | ikev2` policy command from global configuration mode in either single or multiple context mode. The prompt displays IKE policy configuration mode.

Example:

```
hostname(config)# crypto ikev1 policy 1
```

Note
New ASA configurations do not have a default IKEv1 or IKEv2 policy.

Step 2
Specify the encryption algorithm. The default is AES-128.

```
encryption[aes| aes-192| aes-256]
```

Example:
Configure IKEv1 and IKEv2 Policies

```
hostname(config-ikev1-policy)#
encryption aes
```

**Step 3** Specify the hash algorithm. The default is SHA-1.

```
hash[sha]
```

**Example:**

```
hostname(config-ikev1-policy)#
hash sha
```

**Step 4** Specify the authentication method. The default is preshared keys.

```
authentication[pre-shared]rsa-sig
```

**Example:**

```
hostname(config-ikev1-policy)# authentication rsa-sig
```

**Step 5** Specify the Diffie-Hellman group identifier. The default is Group 14.

```
group [14]
```

**Example:**

```
hostname(config-ikev1-policy)#
group 14
```

**Step 6** Specify the SA lifetime. The default is 86400 seconds (24 hours).

```
lifetime seconds
```

**Example:**

This example sets a lifetime of 4 hours (14400 seconds):

```
hostname(config-ikev1-policy)# lifetime 14400
```

**Step 7** Specify additional settings using the IKEv1 and IKEv2 policy keywords and their values provided in IKE Policy Keywords and Values, on page 9. If you do not specify a value for a given policy parameter, the default value applies.
## IKE Policy Keywords and Values

<table>
<thead>
<tr>
<th>Authentication</th>
<th>rsa-sig</th>
<th>A digital certificate with keys generated by the RSA signatures algorithm</th>
<th>Specifies the authentication method the ASA uses to establish the identity of each IPsec peer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>pre-share (default)</td>
<td>Preshared keys</td>
<td>Preshared keys do not scale well with a growing network but are easier to set up in a small network.</td>
<td></td>
</tr>
<tr>
<td>Encryption</td>
<td>aes (default)</td>
<td>AES with a 128-bit key</td>
<td>Specifies the symmetric encryption algorithm that protects data transmitted between two IPsec peers. The default is 128-bit key.</td>
</tr>
<tr>
<td>Keyword</td>
<td>Meaning</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td>---------</td>
<td>-------------</td>
<td></td>
</tr>
<tr>
<td>hash</td>
<td>sha (default)</td>
<td>SHA-1 (HMAC variant)</td>
<td>Specifies the hash algorithm used to ensure data integrity. It ensures that a packet comes from where it says it comes from and that it has not been modified in transit.</td>
</tr>
<tr>
<td>group</td>
<td>1</td>
<td>Group 1 (768-bit)</td>
<td>Specifies the Diffie-Hellman group identifier, which the two IPsec peers use to derive a shared secret without transmitting it to each other. The lower the Diffie-Hellman group number, the less CPU time it requires to execute. The higher the Diffie-Hellman group number, the greater the security. The default group is DH Group 14.</td>
</tr>
<tr>
<td>lifetime</td>
<td>integer value (86400 = default)</td>
<td>120 to 2147483647 seconds</td>
<td>Specifies the SA lifetime. The default is 86,400 seconds or 24 hours. As a general rule, a shorter lifetime provides more secure ISAKMP negotiations (up to a point). However, with shorter lifetimes, the ASA sets up future IPsec SAs more quickly.</td>
</tr>
</tbody>
</table>

<tr>
<td>aes aes-192 aes-256</td>
<td></td>
<td>The Advanced Encryption Standard supports key lengths of 128, 192, 256 bits.</td>
</tr>
<tr>
<td>policy_index</td>
<td></td>
<td>Accesses the IKEv2 policy sub-mode.</td>
</tr>
<tr>
<td>prf</td>
<td>sha (default)</td>
<td>SHA-1 (HMAC variant)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Specifies the pseudo random function (PRF)—the algorithm used to generate keying material.</td>
</tr>
<tr>
<td>sha256</td>
<td>SHA 2, 256-bit digest</td>
<td>Specifies the Secure Hash Algorithm SHA 2 with the 256-bit digest.</td>
</tr>
</tbody>
</table>
Enable IKE on the Outside Interface

You must enable IKE on the interface that terminates the VPN tunnel. Typically this is the outside, or public interface. To enable IKEv1 or IKEv2, use the `crypto [ikev1 | ikev2] enable interface-name` command from global configuration mode in either single or multiple context mode.

For example:

```
hostname(config)# crypto ikev1 enable outside
```
Disable IKEv1 Aggressive Mode

Phase 1 IKEv1 negotiations can use either main mode or aggressive mode. Both provide the same services, but aggressive mode requires only two exchanges between the peers totaling three messages, rather than three exchanges totaling six messages. Aggressive mode is faster, but does not provide identity protection for the communicating parties. Therefore, the peers must exchange identification information before establishing a secure SA. Aggressive mode is enabled by default.

Note
Disabling aggressive mode prevents Cisco VPN clients from using preshared key authentication to establish tunnels to the ASA. However, they may use certificate-based authentication (that is, ASA or RSA) to establish tunnels.

To disable aggressive mode, enter the following command in either single or multiple context mode:

```bash
hostname(config)# crypto ikev1 am-disable
```

If you have disabled aggressive mode, and want to revert back to it, use the no form of the command. For example:

```bash
hostname(config)# no crypto ikev1 am-disable
```

Configure an ID Method for IKEv1 and IKEv2 ISAKMP Peers

During IKEv1 or IKEv2 ISAKMP Phase 1 negotiations, the peers must identify themselves to each other. You can choose the identification method from the following options.

<table>
<thead>
<tr>
<th>Address</th>
<th>Uses the IP addresses of the hosts exchanging ISAKMP identity information.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatic (default)</td>
<td>Determines ISAKMP negotiation by connection type:</td>
</tr>
<tr>
<td></td>
<td>• IP address for preshared key.</td>
</tr>
<tr>
<td></td>
<td>• Cert Distinguished Name for certificate authentication.</td>
</tr>
<tr>
<td>Hostname</td>
<td>Uses the fully qualified domain name of the hosts exchanging ISAKMP identity information (default). This name comprises the hostname and the domain name.</td>
</tr>
<tr>
<td>Key ID key_id_string</td>
<td>Specifies the string used by the remote peer to look up the preshared key.</td>
</tr>
</tbody>
</table>

The ASA uses the Phase 1 ID to send to the peer. This is true for all VPN scenarios except LAN-to-LAN IKEv1 connections in main mode that authenticate with preshared keys.

To change the peer identification method, enter the following command in either single or multiple context mode:
crypto isakmp identity \{address | hostname | key-id | id-string | auto\}

For example, the following command sets the peer identification method to hostname:

`hostname(config)# crypto isakmp identity hostname`

### INVALID_SELECTORS Notification

If an IPsec system receives an inbound packet on an SA and the packet's header fields are not consistent with the selectors for the SA, it MUST discard the packet. The audit log entry for this event includes the current date/time, SPI, IPsec protocol(s), source and destination of the packet, any other vector values of the packet that are available, and the selector values from the relevant SA entry. The system generates and sends an IKE notification of INVALID_SELECTORS to the sender (IPsec peer), indicating that the received packet was discarded because of failure to pass selector checks.

The ASA already implements the logging of this event in CTM using the existing syslog shown below:

```
%ASA-4-751027: IKEv2 Received INVALID_SELECTORS Notification from peer: <peer IP>. Peer received a packet (SPI=<spi>) from <local_IP>. The decapsulated inner packet didn't match the negotiated policy in the SA. Packet destination <pkt_daddr>, port <pkt_dest_port>, source <pkt_saddr>, port <pkt_src_port>, protocol <pkt_prot>
```

An administrator can now enable or disable sending an IKEv2 notification to the peer when an inbound packet is received on an SA that does not match the traffic selectors for that SA. If enabled, the IKEv2 notification messages are rate limited to one notification message per SA every five seconds. The IKEv2 notification is sent in an IKEv2 informational exchange to the peer.

### Configure IKEv2 Pre-shared Key in Hex

You can configure the IKEv2 pre-shared keys in Hex by adding the keyword `hex` to both the local and remote pre-shared key commands.

```
ikev2 local-authentication pre-shared-key \{ 0 | 8 | hex \} <string>
ikev2 remote-authentication pre-shared-key \{ 0 | 8 | hex \} <string>
```

### Enable or Disable Sending of IKE Notification

An administrator can enable or disable sending an IKE notification to the peer when an inbound packet is received on an IKEv2 IPsec VPN connection that does not match the traffic selectors for that connection. Sending this notification is disabled by default. Sending IKE INVALID_SELECTORS Notifications when Authorization of a username from ASDM certificate is enabled or disabled using the following CLI:

```
[no] crypto ikev2 notify invalid Selectors
```

When certificate authentication is performed, the CN from the certificate is the username, and authorization is performed against the LOCAL server. If “service-type” attribute is retrieved, it is processed as described earlier.
**Configure IKEv2 Fragmentation Options**

On the ASA, IKEv2 fragmentation can be enabled or disabled, the MTU (Maximum Transmission Unit) used when fragmenting IKEv2 packets can be specified, and a preferred fragmentation method can be configured by the administrator using the following command:

```
[no] crypto ikev2 fragmentation [mtu <mtu-size>] [preferred-method [ietf | cisco]]
```

By default, all methods of IKEv2 fragmentation are enabled, the MTU is 576 for IPv4, or 1280 for IPv6, and the preferred method is the IETF standard RFC-7383.

Specify the `mtu <mtu-size>` with the following considerations:

- The MTU value used should include the IP(IPv4/IPv6) header + UDP header size.
- If not specified by the administrator the default MTU is 576 for IPv4, or 1280 for IPv6.
- Once specified, the same MTU will be used for both IPv4 and IPv6.
- Valid range is 68-1500.

One of the following supported fragmentation methods can be configured as the preferred fragmentation method for IKEv2 `preferred-method [ietf | cisco]`:

- IETF RFC-7383 standard based IKEv2 fragmentation.
  - This method will be used when both peers specify support and preference during negotiation.
  - Using this method, encryption is done after fragmentation providing individual protection for each IKEv2 Fragment message.
- Cisco proprietary fragmentation.
  - This method will be used if it is the only method provided by a peer, such as the AnyConnect client, or if both peers specify support and preference during negotiation.
  - Using this method fragmentation is done after encryption. The receiving peer cannot decrypt or authenticate the message until all fragments are received.
  - This method does not interoperate with non-Cisco peers.

The command `show running-config crypto ikev2` will display the current configuration, and `show crypto ikev2 sa detail` displays the MTU enforced if fragmentation was used for the SA.

**Before you begin**

- Path MTU Discovery is not supported, the MTU needs to be manually configured to match the needs of the network.
- This configuration is global and will affect future SAs established after the configuration has been applied. Older SAs will not be affected. Same behavior holds true when fragmentation is disabled.
- A maximum of a 100 fragments can be received.

**Examples**

- To disable IKEv2 fragmentation:
AAA Authentication With Authorization

aaa authentication http console LOCAL
aaa authorization http console radius

AAA authentication is performed against the LOCAL server using the username/password typed in by the user. Additional authorization is performed against the radius server using the same username. service-type attribute, if retrieved, is processed as described earlier.

Enable IPsec over NAT-T

NAT-T lets IPsec peers establish a connection through a NAT device. It does this by encapsulating IPsec traffic in UDP datagrams, using port 4500, which provides NAT devices with port information. NAT-T auto-detects any NAT devices and only encapsulates IPsec traffic when necessary.

Note

Due to a limitation of the AnyConnect client, you must enable NAT-T for the AnyConnect client to successfully connect using IKEv2. This requirement applies even if the client is not behind a NAT-T device.

The ASA can simultaneously support standard IPsec, IPsec over TCP, NAT-T, and IPsec over UDP, depending on the client with which it is exchanging data.

The following breakdown shows the connections with each option enabled.

no crypto ikev2 fragmentation

• To reinstate the default operation:
  crypto ikev2 fragmentation
  or
  crypto ikev2 fragmentation mtu 576
  preferred-method ietf

• To change the MTU value to 600:
  crypto ikev2 fragmentation mtu 600

• To restore the default MTU value:
  no crypto ikev2 fragmentation mtu 576

• To change the preferred method of fragmentation to Cisco:
  crypto ikev2 fragmentation preferred-method cisco

• To restore the preferred fragmentation method to IETF:
  no crypto ikev2 fragmentation preferred-method cisco
  or
  crypto ikev2 fragmentation preferred-method ietf
<table>
<thead>
<tr>
<th>Options</th>
<th>Enabled Feature</th>
<th>Client Position</th>
<th>Feature Used</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option 1</td>
<td>If NAT-T is enabled</td>
<td>and client is behind NAT, then</td>
<td>NAT-T is used</td>
</tr>
<tr>
<td></td>
<td></td>
<td>and no NAT exists, then</td>
<td>Native IPsec (ESP) is used</td>
</tr>
<tr>
<td>Option 2</td>

<td>NAT-T is used</td>
</tr>
<tr>
<td></td>
<td></td>
<td>and no NAT exists, then</td>
<td>IPsec over UDP is used</td>
</tr>
</tbody>
</table>

When IPsec over TCP is enabled, it takes precedence over all other connection methods.

When you enable NAT-T, the ASA automatically opens port 4500 on all IPsec-enabled interfaces.

The ASA supports multiple IPsec peers behind a single NAT/PAT device operating in LAN-to-LAN or remote access networks, but not both. In a mixed environment, the remote access tunnels fail the negotiation because all peers appear to be coming from the same public IP address, address of the NAT device. Also, remote access tunnels fail in a mixed environment because they often use the same name as the LAN-to-LAN tunnel group (that is, the IP address of the NAT device). This match can cause negotiation failures among multiple peers in a mixed LAN-to-LAN and remote access network of peers behind the NAT device.

To use NAT-T, perform the following site-to-site steps in either single or multiple context mode:

**Procedure**

**Step 1**

Enter the following command to enable IPsec over NAT-T globally on the ASA:

```bash
crypto isakmp nat-traversal natkeepalive
```

The range for the natkeepalive argument is 10 to 3600 seconds. The default is 20 seconds.

**Example:**

Enter the following command to enable NAT-T and set the keepalive value to one hour:

```bash
hostname(config)# crypto isakmp nat-traversal 3600
```

**Step 2**

Select the before-encryption option for the IPsec fragmentation policy by entering this command:

```bash
hostname(config)# crypto ipsec fragmentation before-encryption
```
This option lets traffic travel across NAT devices that do not support IP fragmentation. It does not impede the operation of NAT devices that do support IP fragmentation.

Enable IPsec with IKEv1 over TCP

IPsec over TCP encapsulates both the IKEv1 and IPsec protocols within a TCP-like packet and enables secure tunneling through both NAT and PAT devices and firewalls. This feature is disabled by default. IPsec/IKEv1 over TCP enables a Cisco VPN client to operate in an environment in which standard ESP or IKEv1 cannot function or can function only with modification to existing firewall rules.

Note
This feature does not work with proxy-based firewalls.

IPsec over TCP works with remote access clients. You enable IPsec over TCP on both the ASA and the client to which it connects. On the ASA, it is enabled globally, working on all IKEv1-enabled interfaces. It does not work for LAN-to-LAN connections.

The ASA can simultaneously support standard IPsec, IPsec over TCP, NAT-Traversal, and IPsec over UDP, depending on the client with which it is exchanging data. IPsec over TCP, if enabled, takes precedence over all other connection methods.

You can enable IPsec over TCP for up to 10 ports that you specify. If you enter a well-known port, for example port 80 (HTTP) or port 443 (HTTPS), the system displays a warning that the protocol associated with that port no longer works on the public interface. The consequence is that you can no longer use a browser to manage the ASA through the public interface. To solve this problem, reconfigure the HTTP/HTTPS management to different ports.

The default port is 10000.

You must configure TCP port(s) on the client as well as on the ASA. The client configuration must include at least one of the ports you set for the ASA.

To enable IPsec over TCP for IKEv1 globally on the ASA, perform the following command in either single or multiple context mode:

```
crypto ikev1 ipsec-over-tcp [port port 1...port0]
```

This example enables IPsec over TCP on port 45:

```
hostname(config)# crypto ikev1 ipsec-over-tcp port 45
```

Configure Certificate Group Matching for IKEv1

Tunnel groups define user connection terms and permissions. Certificate group matching lets you match a user to a tunnel group using either the Subject DN or Issuer DN of the user certificate.

Note
Certificate group matching applies to IKEv1 and IKEv2 LAN-to-LAN connections only. IKEv2 remote access connections support the pull-down group selection configured in the webvpn-attributes of the tunnel-group and webvpn configuration mode for certificate-group-map, and so on.
To match users to tunnel groups based on these fields of the certificate, you must first create rules that define a matching criteria, and then associate each rule with the desired tunnel group.

To create a certificate map, use the `crypto ca certificate map` command. To define a tunnel group, use the `tunnel-group` command.

You must also configure a certificate group matching policy, specifying to match the group from the rules, or from the organizational unit (OU) field, or to use a default group for all certificate users. You can use any or all of these methods.

**Procedure**

**Step 1**
To configure the policy and rules by which certificate-based ISAKMP sessions map to tunnel groups, and to associate the certificate map entries with tunnel groups, enter the tunnel-group-map command in either single or multiple context mode.

```
tunnel-group-map enable {rules | ou | ike-id | peer ip}
```

```
tunnel-group-map [rule-index] enable policy
```

<table>
<thead>
<tr>
<th>Policy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ike-id</code></td>
<td>Indicates that if a tunnel group is not determined based on a rule lookup or taken from the OU, then the certificate-based ISAKMP sessions are mapped to a tunnel group based on the content of the phase1 ISAKMP ID.</td>
</tr>
<tr>
<td><code>ou</code></td>
<td>Indicates that if a tunnel-group is not determined based on a rule lookup, then use the value of the OU in the subject distinguished name (DN).</td>
</tr>
<tr>
<td><code>peer-ip</code></td>
<td>Indicates that if a tunnel group is not determined based on a rule lookup or taken from the OU or ike-id methods, then use the peer IP address.</td>
</tr>
<tr>
<td><code>rules</code></td>
<td>Indicates that the certificate-based ISAKMP sessions are mapped to a tunnel group based on the certificate map associations configured by this command.</td>
</tr>
</tbody>
</table>

Be aware of the following:

- You can invoke this command multiple times as long as each invocation is unique and you do not reference a map index more than once.
- Rules cannot be longer than 255 characters.
Configure IPsec

This section describes the procedures required to configure the ASA when using IPsec to implement a VPN.

Define Crypto Maps

Crypto maps define the IPsec policy to be negotiated in the IPsec SA. They include the following:

- ACL to identify the packets that the IPsec connection permits and protects.
• Peer identification.
• Local address for the IPsec traffic. (See Apply Crypto Maps to Interfaces, on page 30 for more details.)
• Up to 11 IKEv1 transform sets or IKEv2 proposals, with which to attempt to match the peer security settings.

A crypto map set consists of one or more crypto maps that have the same map name. You create a crypto map set when you create its first crypto map. The following site-to-site task creates or adds to a crypto map in either single or multiple context mode:

```
crypto map map-name seq-num match address access-list-name
```

Use the access-list-name to specify the ACL ID, as a string or integer up to 241 characters in length.

Tip
Use all capital letters to more easily identify the ACL ID in your configuration.

You can continue to enter this command to add crypto maps to the crypto map set. In the following example, `mymap` is the name of the crypto map set to which you might want to add crypto maps:

```
crypto map mymap 10 match address 101
```

The sequence number (seq-num) shown in the syntax above distinguishes one crypto map from another one with the same name. The sequence number assigned to a crypto map also determines its priority among the other crypto maps within a crypto map set. The lower the sequence number, the higher the priority. After you assign a crypto map set to an interface, the ASA evaluates all IP traffic passing through the interface against the crypto maps in the set, beginning with the crypto map with the lowest sequence number.

```
[no] crypto map map-name map_index set pfs [group14 | group15 | group16 | group19 | group20 | group21]
```

Specifies the ECDH group used for Perfect Forward Secrecy (PFS) for the cryptography map. Prevents you from configuring group14 and group24 options for a cryptography map (when using an IKEv1 policy).

```
[no] crypto map map-name seq-num set reverse-route [dynamic]
```

Enables Reverse Route Injection (RRI) for any connection based on this crypto map entry. If dynamic is not specified, RRI is done upon configuration and is considered static, remaining in place until the configuration changes or is removed. The ASA automatically adds static routes to the routing table and announces these routes to its private network or border routers using OSPF.

If dynamic is specified, routes are created upon the successful establishment of IPsec security associations (SA's) and deleted after the IPsec SA's are deleted.

You cannot configure a dynamic crypto map with the same name as a static crypto map and vice versa, even if one of the crypto maps is not actually in use.

Note
Dynamic RRI applies to IKEv2 based static crypto maps only.

```
[no] crypto map name priority set validate-icmp-errors
OR
[no]crypto dynamic-map name priority set validate-icmp-errors
```

Site-to-Site and Client VPN
Define Crypto Maps
Specifies whether incoming ICMP error messages are validated for the cryptography or dynamic cryptography map.

[no] crypto map <name> <priority> set df-bit [clear-df | copy-df | set-df]

OR

[no] crypto map dynamic-map <name> <priority> set df-bit [clear-df | copy-df | set-df]

Configures the existing do not fragment (DF) policy (at a security association level) for the cryptography or dynamic cryptography map.

- clear-df—Ignores the DF bit.
- copy-df—Maintains the DF bit.
- set-df—Sets and uses the DF bit.

[no] crypto map <name> <priority> set tfc-packets [burst <length | auto] [payload-size <bytes | auto] [timeout <seconds | auto]

OR

[no] crypto dynamic-map <name> <priority> set tfc-packets [burst <length | auto] [payload-size <bytes | auto] [timeout <seconds | auto]

An administrator can enable dummy Traffic Flow Confidentiality (TFC) packets at random lengths and intervals on an IPsec security association. You must have an IKEv2 IPsec proposal set before enabling TFC.

The ACL assigned to a crypto map consists of all of the ACEs that have the same ACL name, as shown in the following command syntax:

`access-list access-list-name {deny | permit} ip source source-netmask destination destination-netmask`

You create an ACL when you create its first ACE. The following command syntax creates or adds to an ACL:

`access-list access-list-name {deny | permit} ip source source-netmask destination destination-netmask`

In the following example, the ASA applies the IPsec protections assigned to the crypto map to all traffic flowing from the 10.0.0.0 subnet to the 10.1.1.0 subnet:

`access-list 101 permit ip 10.0.0.0 255.255.255.0 10.1.1.0 255.255.255.0`

The crypto map that matches the packet determines the security settings used in the SA negotiations. If the local ASA initiates the negotiation, it uses the policy specified in the static crypto map to create the offer to send to the specified peer. If the peer initiates the negotiation, the ASA attempts to match the policy to a static crypto map, and if that fails, then it attempts to match any dynamic crypto maps in the crypto map set, to decide whether to accept or reject the peer offer.

For two peers to succeed in establishing an SA, they must have at least one compatible crypto map. To be compatible, a crypto map must meet the following criteria:

- The crypto map must contain compatible crypto ACLs (for example, mirror image ACLs). If the responding peer uses dynamic crypto maps, so the ASA also must contain compatible crypto ACLs as a requirement to apply IPsec.
- Each crypto map identifies the other peer (unless the responding peer uses dynamic crypto maps).
- The crypto maps have at least one transform set or proposal in common.
You can apply only one crypto map set to a single interface. Create more than one crypto map for a particular interface on the ASA if any of the following conditions exist:

- You want specific peers to handle different data flows.
- You want different IPsec security to apply to different types of traffic.

For example, create a crypto map and assign an ACL to identify traffic between two subnets and assign one IKEv1 transform set or IKEv2 proposal. Create another crypto map with a different ACL to identify traffic between another two subnets and apply a transform set or proposal with different VPN parameters.

If you create more than one crypto map for an interface, specify a sequence number (seq-num) for each map entry to determine its priority within the crypto map set.

Each ACE contains a permit or deny statement. The following table explains the special meanings of permit and deny ACEs in ACLs applied to crypto maps.

<table>
<thead>
<tr>
<th>Result of Crypto Map Evaluation</th>
<th>Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Match criterion in an ACE containing a permit statement</td>
<td>Halt further evaluation of the packet against the remaining ACEs in the crypto map set, and evaluate the packet security settings against those in the IKEv1 transform sets or IKEv2 proposals assigned to the crypto map. After matching the security settings to those in a transform set or proposal, the ASA applies the associated IPsec settings. Typically for outbound traffic, this means that it decrypts, authenticates, and routes the packet.</td>
</tr>
<tr>
<td>Match criterion in an ACE containing a deny statement</td>
<td>Interrupt further evaluation of the packet against the remaining ACEs in the crypto map under evaluation, and resume evaluation against the ACEs in the next crypto map, as determined by the next seq-num assigned to it.</td>
</tr>
<tr>
<td>Fail to match all tested permit ACEs in the crypto map set</td>
<td>Route the packet without encrypting it.</td>
</tr>
</tbody>
</table>

ACEs containing deny statements filter out outbound traffic that does not require IPsec protection (for example, routing protocol traffic). Therefore, insert initial deny statements to filter outbound traffic that should not be evaluated against permit statements in a crypto ACL.

For an inbound, encrypted packet, the security appliance uses the source address and ESP SPI to determine the decryption parameters. After the security appliance decrypts the packet, it compares the inner header of the decrypted packet to the permit ACEs in the ACL associated with the packet SA. If the inner header fails to match the proxy, the security appliance drops the packet. If the inner header matches the proxy, the security appliance routes the packet.

When comparing the inner header of an inbound packet that was not encrypted, the security appliance ignores all deny rules because they would prevent the establishment of a Phase 2 SA.

**Note**

To route inbound, unencrypted traffic as clear text, insert deny ACEs before permit ACEs. ASA cannot push more than 28 ACE in split-tunnel access-list.
The objective in configuring Security Appliances A, B, and C in this example LAN-to-LAN network is to permit tunneling of all traffic originating from one of the hosts and destined for one of the other hosts. However, because traffic from Host A.3 contains sensitive data from the Human Resources department, it requires strong encryption and more frequent rekeying than the other traffic. So you will want to assign a special transform set for traffic from Host A.3.

The simple address notation shown in this figure and used in the following explanation is an abstraction. An example with real IP addresses follows the explanation.

To configure Security Appliance A for outbound traffic, you create two crypto maps, one for traffic from Host A.3 and the other for traffic from the other hosts in Network A, as shown in the following example:

```plaintext
Crypto Map Seq_No_1
 deny packets from A.3 to B
 deny packets from A.3 to C
 permit packets from A to B
 permit packets from A to C

Crypto Map Seq_No_2
 permit packets from A.3 to B
 permit packets from A.3 to C
```

After creating the ACLs, you assign a transform set to each crypto map to apply the required IPsec to each matching packet.

Cascading ACLs involves the insertion of deny ACEs to bypass evaluation against an ACL and resume evaluation against a subsequent ACL in the crypto map set. Because you can associate each crypto map with different IPsec settings, you can use deny ACEs to exclude special traffic from further evaluation in the corresponding crypto map, and match the special traffic to permit statements in another crypto map to provide...
or require different security. The sequence number assigned to the crypto ACL determines its position in the evaluation sequence within the crypto map set.

The following illustration shows the cascading ACLs created from the conceptual ACEs in this example. The meaning of each symbol is defined as follows:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/ \</td>
<td>Crypto map within a crypto map set.</td>
</tr>
<tr>
<td>\</td>
<td>(Gap in a straight line) Exit from a crypto map when a packet matches an ACE.</td>
</tr>
<tr>
<td>🍊</td>
<td>Packet that fits the description of one ACE. Each size ball represents a different packet matching the respective ACE in the figure. The differences in size merely represent differences in the source and destination of each packet.</td>
</tr>
<tr>
<td>/</td>
<td>Redirection to the next crypto map in the crypto map set.</td>
</tr>
<tr>
<td></td>
<td>Response when a packet either matches an ACE or fails to match all of the permit ACEs in a crypto map set.</td>
</tr>
</tbody>
</table>
Security Appliance A evaluates a packet originating from Host A.3 until it matches a permit ACE and attempts to assign the IPsec security associated with the crypto map. Whenever the packet matches a deny ACE, the ASA ignores the remaining ACEs in the crypto map and resumes evaluation against the next crypto map, as determined by the sequence number assigned to it. So in the example, if Security Appliance A receives a packet from Host A.3, it matches the packet to a deny ACE in the first crypto map and resumes evaluation of the packet against the next crypto map. When it matches the packet to the permit ACE in that crypto map, it applies the associated IPsec security (strong encryption and frequent rekeying).

To complete the ASA configuration in the example network, we assign mirror crypto maps to ASAs B and C. However, because ASAs ignore deny ACEs when evaluating inbound, encrypted traffic, we can omit the mirror equivalents of the deny A.3 B and deny A.3 C ACEs, and therefore omit the mirror equivalents of Crypto Map 2. So the configuration of cascading ACLs in ASAs B and C is unnecessary.
The following table shows the ACLs assigned to the crypto maps configured for all three ASAs, A, B and C:

<table>
<thead>
<tr>
<th>Security Appliance A</th>
<th>Security Appliance B</th>
<th>Security Appliance C</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Crypto Map Sequence No.</strong></td>
<td><strong>ACE Pattern</strong></td>
<td><strong>Crypto Map Sequence No.</strong></td>
</tr>
<tr>
<td>1</td>
<td>deny A.3 B</td>
<td></td>
</tr>
<tr>
<td></td>
<td>deny A.3 C</td>
<td></td>
</tr>
<tr>
<td></td>
<td>permit A B</td>
<td></td>
</tr>
<tr>
<td></td>
<td>permit A C</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>permit A.3 B</td>
<td></td>
</tr>
<tr>
<td></td>
<td>permit A.3 C</td>
<td></td>
</tr>
</tbody>
</table>

The following illustration maps the conceptual addresses shown previously to real IP addresses.

The real ACEs shown in the following table ensure that all IPsec packets under evaluation within this network receive the proper IPsec settings.
### Example of LAN-to-LAN Crypto Maps

<table>
<thead>
<tr>
<th>Security Appliance</th>
<th>Crypto Map Sequence No.</th>
<th>ACE Pattern</th>
<th>Real ACEs</th>
</tr>
</thead>
</table>
| A                  | 1                       | deny A.3 B  | deny 192.168.3.3  
                               |             |             | 255.255.255.192  
                               |             |             | 192.168.12.0  
                               |             |             | 255.255.255.248  |
|                    |                         | deny A.3 C  | deny 192.168.3.3  
                               |             |             | 255.255.255.192

                               |             |             | 255.255.255.224  |
|                    |                         | permit A B  | permit 192.168.3.0  
                               |             |             | 255.255.255.192  
                               |             |             | 192.168.12.0  
                               |             |             | 255.255.255.248  |
|                    |                         | permit A C  | permit 192.168.3.0  
                               |             |             | 255.255.255.192  
                               |             |             | 192.168.201.0  
                               |             |             | 255.255.255.224  |
|                    | 2                       | permit A.3 B | permit 192.168.3.3  
                               |             |             | 255.255.255.192  
                               |             |             | 192.168.12.0  
                               |             |             | 255.255.255.248  |
|                    |                         | permit A.3 C | permit 192.168.3.3  
                               |             |             | 255.255.255.192  
                               |             |             | 192.168.201.0  
                               |             |             | 255.255.255.224  |
| B                  | None needed              | permit B A  | permit 192.168.12.0  
                               |             |             | 255.255.255.248  
                               |             |             | 192.168.3.0  
                               |             |             | 255.255.255.192  |
|                    |                         | permit B C  | permit 192.168.12.0  
                               |             |             | 255.255.255.248  
                               |             |             | 192.168.201.0  
                               |             |             | 255.255.255.224  |
You can apply the same reasoning shown in the example network to use cascading ACLs to assign different security settings to different hosts or subnets protected by a ASA.

**Note**
By default, the ASA does not support IPsec traffic destined for the same interface from which it enters. Names for this type of traffic include U-turn, hub-and-spoke, and hairpinning. However, you can configure IPsec to support U-turn traffic by inserting an ACE to permit traffic to and from the network. For example, to support U-turn traffic on Security Appliance B, add a conceptual “permit B B” ACE to ACL1. The actual ACE would be as follows: `permit 192.168.12.0 255.255.255.248 192.168.12.0 255.255.255.248`

---

**Set Public Key Infrastructure (PKI) Keys**

You must set public key infrastructure (PKI) in order for an administrator to choose the Suite B ECDSA algorithms when generating or zeroing a keypair:

**Before you begin**

If you are configuring a cryptography map to use an RSA or ECDSA trustpoint for authentication, you must first generate the key set. You can then create the trustpoint and reference it in the tunnel group configuration.

**Procedure**

**Step 1**
Choose the Suite B ECDSA algorithm when generating a keypair:

```
```

**Step 2**
Choose the Suite B ECDSA algorithm when zeroizing a keypair:

```
crypto key zeroize [rsa | ecdsa] [default | label <name>] | noconfirm]
```
Apply Crypto Maps to Interfaces

You must assign a crypto map set to each interface through which IPsec traffic flows. The ASA supports IPsec on all interfaces. Assigning the crypto map set to an interface instructs the ASA to evaluate all the traffic against the crypto map set and to use the specified policy during connection or SA negotiation.

Assigning a crypto map to an interface also initializes run-time data structures, such as the SA database and the security policy database. Reassigning a modified crypto map to the interface resynchronizes the run-time data structures with the crypto map configuration. Also, adding new peers through the use of new sequence numbers and reassigning the crypto map does not tear down existing connections.

Use Interface ACLs

By default, the ASA lets IPsec packets bypass interface ACLs. If you want to apply interface ACLs to IPsec traffic, use the `no` form of the `sysopt connection permit-vpn` command.

The crypto map ACL bound to the outgoing interface either permits or denies IPsec packets through the VPN tunnel. IPsec authenticates and deciphers packets that arrive from an IPsec tunnel, and subjects them to evaluation against the ACL associated with the tunnel.

ACLs define which IP traffic to protect. For example, you can create ACLs to protect all IP traffic between two subnets or two hosts. (These ACLs are similar to ACLs used with the `access-group` command. However, with the `access-group` command, the ACL determines which traffic to forward or block at an interface.)

Before the assignment to crypto maps, the ACLs are not specific to IPsec. Each crypto map references the ACLs and determines the IPsec properties to apply to a packet if it matches a permit in one of the ACLs.

ACLs assigned to IPsec crypto maps have four primary functions:

- Select outbound traffic to be protected by IPsec (permit = protect).
- Trigger an ISAKMP negotiation for data traveling without an established SA.
- Process inbound traffic to filter out and discard traffic that should have been protected by IPsec.
- Determine whether to accept requests for IPsec SAs when processing IKE negotiation from the peer. (Negotiation applies only to `ipsec-isakmp crypto map` entries.) The peer must permit a data flow associated with an `ipsec-isakmp crypto map` command entry to ensure acceptance during negotiation.

---

If you delete the only element in an ACL, the ASA also removes the associated crypto map.

If you modify an ACL currently referenced by one or more crypto maps, use the `crypto map interface` command to reinitialize the run-time SA database. See the `crypto map` command for more information.

We recommend that for every crypto ACL specified for a static crypto map that you define at the local peer, you define a “mirror image” crypto ACL at the remote peer. The crypto maps should also support common transforms and refer to the other system as a peer. This ensures correct processing of IPsec by both peers.
Every static crypto map must define an ACL and an IPsec peer. If either is missing, the crypto map is incomplete and the ASA drops any traffic that it has not already matched to an earlier, complete crypto map. Use the show conf command to ensure that every crypto map is complete. To fix an incomplete crypto map, remove the crypto map, add the missing entries, and reapply it.

We discourage the use of the *any* keyword to specify source or destination addresses in crypto ACLs because they cause problems. We strongly discourage the *permit any any* command statement because it does the following:

- Protects all outbound traffic, including all protected traffic sent to the peer specified in the corresponding crypto map.
- Requires protection for all inbound traffic.

In this scenario, the ASA silently drops all inbound packets that lack IPsec protection.

Be sure that you define which packets to protect. If you use the *any* keyword in a *permit* statement, preface it with a series of *deny* statements to filter out traffic that would otherwise fall within that *permit* statement that you do not want to protect.

Decrypted through traffic is permitted from the client despite having an access group on the outside interface, which calls a deny ip any any access-list, while *no sysopt connection permit-vpn* is configured.

Users who want to control access to the protected network via site-to-site or remote access VPN using the *no sysopt permit* command in conjunction with an access control list (ACL) on the outside interface are not successful.

In this situation, when management-access inside is enabled, the ACL is not applied, and users can still connect using SSH to the security appliance. Traffic to hosts on the inside network are blocked correctly by the ACL, but cannot block decrypted through traffic to the inside interface.

The *ssh* and *http* commands are of a higher priority than the ACLs. In other words, to deny SSH, Telnet, or ICMP traffic to the device from the VPN session, use *ssh*, *telnet* and *icmp* commands, which deny the IP local pool should be added.

Regardless of whether the traffic is inbound or outbound, the ASA evaluates traffic against the ACLs assigned to an interface. Follow these steps to assign IPsec to an interface:

**Procedure**

1. **Step 1** Create the ACLs to be used for IPsec.
2. **Step 2** Map the lists to one or more crypto maps, using the same crypto map name.
3. **Step 3** Map the IKEv1 transform sets or IKEv2 proposals to the crypto maps to apply IPsec to the data flows.
4. **Step 4** Apply the crypto maps collectively as a crypto map set by assigning the crypto map name they share to the interface.
Example

In this example, IPsec protection applies to traffic between Host 10.0.0.1 and Host 10.2.2.2 as the data exits the outside interface on ASA A toward Host 10.2.2.2.

ASA A evaluates traffic from Host 10.0.0.1 to Host 10.2.2.2, as follows:
- source = host 10.0.0.1
- dest = host 10.2.2.2

ASA A also evaluates traffic from Host 10.2.2.2 to Host 10.0.0.1, as follows:
- source = host 10.2.2.2
- dest = host 10.0.0.1

The first permit statement that matches the packet under evaluation determines the scope of the IPsec SA.

Change IPsec SA Lifetimes

You can change the global lifetime values that the ASA uses when negotiating new IPsec SAs. You can override these global lifetime values for a particular crypto map.

IPsec SAs use a derived, shared, secret key. The key is an integral part of the SA; the keys time out together to require the key to refresh. Each SA has two lifetimes: timed and traffic-volume. An SA expires after the respective lifetime and negotiations begin for a new one. The default lifetimes are 28,800 seconds (eight hours) and 4,608,000 kilobytes (10 megabytes per second for one hour).

If you change a global lifetime, the ASA drops the tunnel. It uses the new value in the negotiation of subsequently established SAs.

When a crypto map does not have configured lifetime values and the ASA requests a new SA, it inserts the global lifetime values used in the existing SA into the request sent to the peer. When a peer receives a negotiation request, it uses the smaller of either the lifetime value the peer proposes or the locally configured lifetime value as the lifetime of the new SA.
The peers negotiate a new SA before crossing the lifetime threshold of the existing SA to ensure that a new SA is ready when the existing one expires. The peers negotiate a new SA when about 5 to 15 percent of the lifetime of the existing SA remains.

**Change VPN Routing**

By default, per-packet adjacency lookups are done for the outer ESP packets, lookups are not done for packets sent through the IPsec tunnel.

In some network topologies, when a routing update has altered the inner packet’s path, but the local IPsec tunnel is still up, packets through the tunnel may not be routed correctly and fail to reach their destination.

To prevent this, enable per-packet routing lookups for the IPsec inner packets.

**Before you begin**

To avoid any performance impact from these lookups, this feature is disabled by default. Enable it only when necessary.

**Procedure**

Enable per-packet routing lookups for the IPsec inner packets.

```
[no] [crypto] ipsec inner-routing-lookup
```

**Note** This command, when configured, is only applicable for non-VTI based tunnels.

**Example**

```
ciscoasa(config)# crypto ipsec inner-routing-lookup
ciscoasa(config)# show run crypto ipsec
crypto ipsec ikev2 ipsec-proposal GCM
protocol esp encryption aes-gcm
protocol esp integrity null
crypto ipsec inner-routing-lookup
```

**Create Static Crypto Maps**

To create a basic IPsec configuration using a static crypto map, perform the following steps:

**Procedure**

**Step 1** To create an ACL to define the traffic to protect, enter the following command:

```
access-list access-list-name {deny | permit} ip source source-netmask destination destination-netmask
```
The `access-list-name` specifies the ACL ID, as a string or integer up to 241 characters in length. The `destination-netmask` and `source-netmask` specifies an IPv4 network address and subnet mask. In this example, the `permit` keyword causes all traffic that matches the specified conditions to be protected by crypto.

**Example:**

```
hostname(config)# access-list 101 permit ip 10.0.0.0 255.255.255.0 10.1.1.0 255.255.255.0
```

**Step 2**

To configure an IKEv1 transform set that defines how to protect the traffic, enter the following command:

```
crypto ipsec ikev1 transform-set transform-set-name encryption [authentication]
```

*Encryption* specifies which encryption method protects IPsec data flows:

- `esp-aes`—Uses AES with a 128-bit key.
- `esp-aes-192`—Uses AES with a 192-bit key.
- `esp-aes-256`—Uses AES with a 256-bit key.
- `esp-null`—No encryption.

*Authentication* specifies which encryption method to protect IPsec data flows:

- `esp-sha-hmac`—Uses the SHA/HMAC-160 as the hash algorithm.
- `esp-none`—No HMAC authentication.

**Example:**

In this example, `myset1` and `myset2` and `aes_set` are the names of the transform sets.

```
hostname(config)# crypto ipsec ikev1 transform-set myset1 esp-aes esp-sha-hmac
hostname(config)# crypto ipsec ikev1 transform-set aes_set esp-md5-hmac esp-aes-256
```

**Step 3**

To configure an IKEv2 proposal that also defines how to protect the traffic, enter the following command:

```
crypto ipsec ikev2 ipsec-proposal [proposal tag]
```

*proposal tag* is the name of the IKEv2 IPsec proposal, a string from 1 to 64 characters.

Create the proposal and enter the ipsec proposal configuration mode where you can specify multiple encryption and integrity types for the proposal.

**Example:**

```
hostname(config)# crypto ipsec ikev2 ipsec-proposal secure
```

In this example, `secure` is the name of the proposal. Enter a protocol and encryption types:

```
hostname(config-ipsec-proposal)# protocol esp encryption aes
```

**Example:**

This command chooses which AES-GCM or AES-GMAC algorithm to use:

```
protocol esp encryption [ aes| aes-192 | aes-256 | aes-gcm| aes-gcm-192 | aes-gcm-256| null]
```

If SHA-2 or null is chosen, you must choose which algorithm to use as an IPsec integrity algorithm. You must choose the null integrity algorithm if AES-GCM/GMAC is configured as the encryption algorithm:
[no] protocol esp integrity [sha-1 | sha-256 | sha-384 | sha-512 | null]

**Note** You must choose the null integrity algorithm if AES-GCM/GMAC has been configured as the encryption algorithm. SHA-256 can be used for integrity and PRF to establish IKEv2 tunnels, but it can also be used for ESP integrity protection.

**Step 4** (Optional) An administrator can enable path maximum transfer unit (PMTU) aging and set the interval at which the PMTU value is reset to its original value.

[no] crypto ipsec security-association pmtu-aging reset-interval

**Step 5** To create a crypto map, perform the following site-to-site steps using either single or multiple context mode:

a) Assign an ACL to a crypto map:

```
crypto map map-name seq-num match address access-list-name
```

A crypto map set is a collection of crypto map entries, each with a different sequence number (seq-num) but the same map name. Use the access-list-name to specify the ACL ID, as a string or integer up to 241 characters in length. In the following example, mymap is the name of the crypto map set. The map set sequence number 10, which is used to rank multiple entries within one crypto map set. The lower the sequence number, the higher the priority.

**Example:**

In this example, the ACL named 101 is assigned to crypto map mymap.

```
crypto map mymap 10 match address 101
```

b) Specify the peer to which the IPsec-protected traffic can be forwarded:

```
crypto map map-name sequence numberset peer ip_address1 [ip_address2] [...]
```

**Example:**

```
crypto map mymap 10 set peer 192.168.1.100
```

The ASA sets up an SA with the peer assigned the IP address 192.168.1.100.

**Note** Beginning with 9.14(1), ASA supports multiple peers in IKEv2 crypto map. You can add a maximum of 10 peers to the list.

c) Specify which IKEv1 transform sets or IKEv2 proposals are allowed for this crypto map. List multiple transform sets or proposals in order of priority (highest priority first). You can specify up to 11 transform sets or proposals in a crypto map using either of these two commands:

```
crypto map map-name seq-num set ikev1 transform-set transform-set-name1 [transform-set-name2, …transform-set-name11]
```

OR

```
crypto map map-name seq-num set ikev2 ipsec-proposal proposal-name1 [proposal-name2, … proposal-name11]
```

*Proposal-name1 and proposal-name11 specifies one or more names of the IPsec proposals for IKEv2. Each crypto map entry supports up to 11 proposals.*

**Example:**

```
In this example for IKEv1, when traffic matches ACL 101, the SA can use either myset1 (first priority) or myset2 (second priority) depending on which transform set matches the transform set of the peer.

```
crypto map mymap 10 set ikev1 transform-set myset1 myset2
```

d) (Optional) For IKEv2, specify the mode for applying ESP encryption and authentication to the tunnel. This determines what part of the original IP packet has ESP applied.

```
crypto map map-name seq-num set ikev2 mode [transport | tunnel | transport-require]
```

- **Tunnel mode**—(default) Encapsulation mode will be tunnel mode. Tunnel mode applies ESP encryption and authentication to the entire original IP packet (IP header and data), thus hiding the ultimate source and destination addresses. The entire original IP datagram is encrypted, and it becomes the payload in a new IP packet.

  This mode allows a network device, such as a router, to act as an IPsec proxy. That is, the router performs encryption on behalf of the hosts. The source router encrypts packets and forwards them along the IPsec tunnel. The destination router decrypts the original IP datagram and forwards it on to the destination system.

  The major advantage of tunnel mode is that the end systems do not need to be modified to receive the benefits of IPsec. Tunnel mode also protects against traffic analysis; with tunnel mode, an attacker can only determine the tunnel endpoints and not the true source and destination of the tunneled packets, even if they are the same as the tunnel endpoints.

- **Transport mode**—Encapsulation mode will be transport mode with option to fallback on tunnel mode, if peer does not support it. In Transport mode only the IP payload is encrypted, and the original IP headers are left intact.

  This mode has the advantages of adding only a few bytes to each packet and allowing devices on the public network to see the final source and destination of the packet. With transport mode, you can enable special processing (for example, QoS) on the intermediate network based on the information in the IP header. However, the Layer 4 header is encrypted, which limits examination of the packet.

- **Transport Required**—Encapsulation mode will be transport mode only, falling back to tunnel mode is not allowed.

Where **tunnel** encapsulation mode is the default, **transport** encapsulation mode is transport mode with the option to fallback to tunnel mode if the peer does not support it, and **transport-require** encapsulation mode enforces transport mode only.

**Note** Transport mode is not recommended for Remote Access VPNs.

Examples of negotiation of the encapsulation mode is as follows:

- If the initiator proposes transport mode, and the responder responds with tunnel mode, the initiator will fallback to Tunnel mode.

- If the initiator proposes tunnel mode, and responder responds with transport mode, the responder will fallback to Tunnel mode.

- If the initiator proposes tunnel mode and responder has transport-require mode, then NO PROPOSAL CHOSEN will be sent by the responder.

- Similarly if initiator has transport-require, and responder has tunnel mode, NO PROPOSAL CHOSEN will be sent by the responder.
e) (Optional) Specify an SA lifetime for the crypto map if you want to override the global lifetime.

```
crypto map map-name seq-num set security-association lifetime {seconds number | kilobytes {number | unlimited}}
```

*Map-name* specifies the name of the crypto map set. *Seq-num* specifies the number you assign to the crypto map entry. You can set both lifetimes based on time or on data transmitted. However, the data transmitted lifetime applies to site-to-site VPN only, it does not apply to remote access VPN.

**Example:**
This example shortens the timed lifetime for the crypto map mymap 10 to 2700 seconds (45 minutes). The traffic volume lifetime is not changed.

```
crypto map mymap 10 set security-association lifetime seconds 2700
```

f) (Optional) Specify that IPsec require perfect forward secrecy when requesting new SA for this crypto map, or require PFS in requests received from the peer:

```
crypto map map_name seq-num set pfs [group14 | group15 | group16 | group19 | group20 | group21]
```

**Example:**
This example requires PFS when negotiating a new SA for the crypto map mymap 10. The ASA uses the 2048-bit Diffie-Hellman prime modulus group in the new SA.

```
crypto map mymap 10 set pfs group14
```

g) (Optional) Enable Reverse Route Injection (RRI) for any connection based on this crypto map entry.

```
crypto map map_name seq-num set reverse-route [dynamic]
```

If dynamic is not specified, RRI is done upon configuration and is considered static, remaining in place until the configuration changes or is removed. The ASA automatically adds static routes to the routing table and announces these routes to its private network or border routers using OSPF.

If dynamic is specified, routes are created upon the successful establishment of IPsec security associations (SA's) and deleted after the IPsec SA's are deleted.

**Note** Dynamic RRI applies to IKEv2 based static crypto maps only.

**Example:**
```
crypto map mymap 10 set reverse-route dynamic
```

**Step 6** Apply a crypto map set to an interface for evaluating IPsec traffic:

```
crypto map map-name interface interface-name
```

*Map-name* specifies the name of the crypto map set. *Interface-name* specifies the name of the interface on which to enable or disable ISAKMP IKEv1 negotiation.

**Example:**
In this example, the ASA evaluates the traffic going through the outside interface against the crypto map mymap to determine whether it needs to be protected.
Create Dynamic Crypto Maps

A dynamic crypto map is a crypto map without all of the parameters configured. It acts as a policy template where the missing parameters are later dynamically learned, as the result of an IPsec negotiation, to match the peer requirements. The ASA applies a dynamic crypto map to let a peer negotiate a tunnel if its IP address is not already identified in a static crypto map. This occurs with the following types of peers:

- Peers with dynamically assigned public IP addresses.
  Both LAN-to-LAN and remote access peers can use DHCP to obtain a public IP address. The ASA uses this address only to initiate the tunnel.
- Peers with dynamically assigned private IP addresses.
  Peers requesting remote access tunnels typically have private IP addresses assigned by the headend. Generally, LAN-to-LAN tunnels have a predetermined set of private networks that are used to configure static maps and therefore used to establish IPsec SAs.

As an administrator configuring static crypto maps, you might not know the IP addresses that are dynamically assigned (via DHCP or some other method), and you might not know the private IP addresses of other clients, regardless of how they were assigned. VPN clients typically do not have static IP addresses; they require a dynamic crypto map to allow IPsec negotiation to occur. For example, the headend assigns the IP address to a Cisco VPN client during IKE negotiation, which the client then uses to negotiate IPsec SAs.

**Note**
A dynamic crypto map requires only the `transform-set` parameter.

Dynamic crypto maps can ease IPsec configuration, and we recommend them for use in networks where the peers are not always predetermined. Use dynamic crypto maps for Cisco VPN clients (such as mobile users) and routers that obtain dynamically assigned IP addresses.

**Tip**
Use care when using the `any` keyword in `permit` entries in dynamic crypto maps. If the traffic covered by such a `permit` entry could include multicast or broadcast traffic, insert `deny` entries for the appropriate address range into the ACL. Remember to insert `deny` entries for network and subnet broadcast traffic, and for any other traffic that IPsec should not protect.

Dynamic crypto maps work only to negotiate SAs with remote peers that initiate the connection. The ASA cannot use dynamic crypto maps to initiate connections to a remote peer. With a dynamic crypto map, if outbound traffic matches a permit entry in an ACL and the corresponding SA does not yet exist, the ASA drops the traffic.

A crypto map set may include a dynamic crypto map. Dynamic crypto map sets should be the lowest priority crypto maps in the crypto map set (that is, they should have the highest sequence numbers) so that the ASA evaluates other crypto maps first. It examines the dynamic crypto map set only when the other (static) map entries do not match.
Similar to static crypto map sets, a dynamic crypto map set consists of all of the dynamic crypto maps with the same dynamic-map-name. The dynamic-seq-num differentiates the dynamic crypto maps in a set. If you configure a dynamic crypto map, insert a permit ACL to identify the data flow of the IPsec peer for the crypto ACL. Otherwise the ASA accepts any data flow identity the peer proposes.

⚠️ Caution

Do not assign module default routes for traffic to be tunneled to a ASA interface configured with a dynamic crypto map set. To identify the traffic that should be tunneled, add the ACLs to the dynamic crypto map. Use care to identify the proper address pools when configuring the ACLs associated with remote access tunnels. Use Reverse Route Injection to install routes only after the tunnel is up.

Create a crypto dynamic map entry using either single or multiple context mode. You can combine static and dynamic map entries within a single crypto map set.

Procedure

**Step 1** (Optional) Assign an ACL to a dynamic crypto map:

```
crypto dynamic-map dynamic-map-name dynamic-seq-num match address access-list-name
```

This determines which traffic should be protected and not protected. *Dynamic-map-name* specifies the name of the crypto map entry that refers to a pre-existing dynamic crypto map. *Dynamic-seq-num* specifies the sequence number that corresponds to the dynamic crypto map entry.

**Example:**

In this example, ACL 101 is assigned to dynamic crypto map dyn1. The map sequence number is 10.

```
crypto dynamic-map dyn1 10 match address 101
```

**Step 2** Specify which IKEv1 transform sets or IKEv2 proposals are allowed for this dynamic crypto map. List multiple transform sets or proposals in order of priority (highest priority first) using the command for IKEv1 transform sets or IKEv2 proposals:

```
crypto dynamic-map dynamic-map-name dynamic-seq-num set ikev1 transform-set transform-set-name1, 
(transform-set-name2, ..., transform-set-name9)
```

```
crypto dynamic-map dynamic-map-name dynamic-seq-num set ikev2 ipsec-proposal proposal-name1
(proposal-name2, ..., proposal-name11)
```

*Dynamic-map-name* specifies the name of the crypto map entry that refers to a pre-existing dynamic crypto map. *Dynamic-seq-num* specifies the sequence number that corresponds to the dynamic crypto map entry. The *transform-set-name* is the name of the transform-set being created or modified. The *proposal-name* specifies one or more names of the IPSec proposals for IKEv2.

**Example:**

In this example for IKEv1, when traffic matches ACL 101, the SA can use either myset1 (first priority) or myset2 (second priority), depending on which transform set matches the transform sets of the peer.

```
crypto dynamic-map dyn 10 set ikev1 transform-set myset1 myset2
```

**Step 3** (Optional) Specify the SA lifetime for the crypto dynamic map entry if you want to override the global lifetime value:
crypto dynamic-map dynamic-map-name dynamic-seq-num set security-association lifetime {seconds number | kilobytes {number | unlimited}}

`Dynamic-map-name` specifies the name of the crypto map entry that refers to a pre-existing dynamic crypto map. `Dynamic-seq-num` specifies the sequence number that corresponds to the dynamic crypto map entry. You can set both lifetimes based on time or on data transmitted. However, the data transmitted lifetime applies to site-to-site VPN only, it does not apply to remote access VPN.

**Example:**
This example shortens the timed lifetime for dynamic crypto map `dyn1` 10 to 2700 seconds (45 minutes). The time volume lifetime is not changed.

```plaintext
crypto dynamic-map dyn1 10 set security-association lifetime seconds 2700
```

**Step 4** (Optional) Specify that IPsec ask for PFS when requesting new SAs for this dynamic crypto map, or should demand PFS in requests received from the peer:

```plaintext
crypto dynamic-map dynamic-map-name dynamic-seq-num set pfs |group14|group15|group16|group19|group20|group21
```

`Dynamic-map-name` specifies the name of the crypto map entry that refers to a pre-existing dynamic crypto map. `Dynamic-seq-num` specifies the sequence number that corresponds to the dynamic crypto map entry.

**Example:**

```plaintext
crypto dynamic-map dyn1 10 set pfs group14
```

**Step 5** Add the dynamic crypto map set into a static crypto map set.

Be sure to set the crypto maps referencing dynamic maps to be the lowest priority entries (highest sequence numbers) in a crypto map set.

```plaintext
crypto map map-name seq-num ipsec-isakmp dynamic dynamic-map-name
```

`Map-name` specifies the name of the crypto map set. `Dynamic-map-name` specifies the name of the crypto map entry that refers to a pre-existing dynamic crypto map.

**Example:**

```plaintext
crypto map mymap 200 ipsec-isakmp dynamic dyn1
```

---

**Provide Site-to-Site Redundancy**

You can define multiple IKEv1 peers by using crypto maps to provide redundancy. This configuration is useful for site-to-site VPNs. This feature is not supported with IKEv2.

If one peer fails, the ASA establishes a tunnel to the next peer associated with the crypto map. It sends data to the peer that it has successfully negotiated with, and that peer becomes the active peer. The active peer is the peer that the ASA keeps trying first for follow-on negotiations until a negotiation fails. At that point the ASA goes on to the next peer. The ASA cycles back to the first peer when all peers associated with the crypto map have failed.
Managing IPsec VPNs

Viewing an IPsec Configuration

These are the commands that you can enter in either single or multiple context mode to view information about your IPsec configuration.

Table 3: Commands to View IPsec Configuration Information

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show running-configuration crypto</code></td>
<td>Displays the entire crypto configuration, including IPsec, crypto maps, dynamic crypto maps, and ISAKMP.</td>
</tr>
<tr>
<td><code>show running-config crypto ipsec</code></td>
<td>Displays the complete IPsec configuration.</td>
</tr>
<tr>
<td><code>show running-config crypto isakmp</code></td>
<td>Displays the complete ISAKMP configuration.</td>
</tr>
<tr>
<td><code>show running-config crypto map</code></td>
<td>Displays the complete crypto map configuration.</td>
</tr>
<tr>
<td><code>show running-config crypto dynamic-map</code></td>
<td>Displays the dynamic crypto map configuration.</td>
</tr>
<tr>
<td><code>show all crypto map</code></td>
<td>Displays all of the configuration parameters, including those with default values.</td>
</tr>
<tr>
<td><code>show crypto ikev2 sa detail</code></td>
<td>Shows the Suite B algorithm support in the Encryption statistics.</td>
</tr>
<tr>
<td><code>show crypto ipsec sa</code></td>
<td>Shows the Suite B algorithm support and the ESPv3 IPsec output in either single or multiple context mode.</td>
</tr>
<tr>
<td><code>show ipsec stats</code></td>
<td>Shows information about the IPsec subsystem in either single or multiple context mode. ESPv3 statistics are shown in TFC packets and valid and invalid ICMP errors received.</td>
</tr>
</tbody>
</table>

Wait for Active Sessions to Terminate Before Rebooting

You can schedule an ASA reboot to occur only when all active sessions have terminated voluntarily. This feature is disabled by default.

Use the `reload` command to reboot the ASA. If you set the `reload-wait` command, you can use the `reload quick` command to override the `reload-wait` setting. The `reload` and `reload-wait` commands are available in privileged EXEC mode; neither includes the `isakmp` prefix.

Procedure

To enable waiting for all active sessions to voluntarily terminate before the ASA reboots, perform the following site-to-site task in either single or multiple context mode:
crypto isakmp reload-wait

Example:

hostname(config)# crypto isakmp reload-wait

Alert Peers Before Disconnecting

Remote access or LAN-to-LAN sessions can drop for several reasons, such as an ASA shutdown or reboot, session idle timeout, maximum connection time exceeded, or administrator cut-off.

The ASA can notify qualified peers (in LAN-to-LAN configurations or VPN clients) of sessions that are about to be disconnected. The peer or client receiving the alert decodes the reason and displays it in the event log or in a pop-up pane. This feature is disabled by default.

Qualified clients and peers include the following:

- Security appliances with Alerts enabled
- Cisco VPN clients running Version 4.0 or later software (no configuration required)

To enable disconnect notification to IPsec peers, enter the `crypto isakmp disconnect-notify` command in either single or multiple context mode.

Clear Security Associations

Certain configuration changes take effect only during the negotiation of subsequent SAs. If you want the new settings to take effect immediately, clear the existing SAs to reestablish them with the changed configuration. If the ASA is actively processing IPsec traffic, clear only the portion of the SA database that the configuration changes affect. Reserve clearing the full SA database for large-scale changes, or when the ASA is processing a small amount of IPsec traffic.

The following table lists commands you can enter to clear and reinitialize IPsec SAs in either single or multiple context mode.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>clear configure crypto</code></td>
<td>Removes an entire crypto configuration, including IPsec, crypto maps, dynamic crypto maps, and ISAKMP.</td>
</tr>
<tr>
<td><code>clear configure crypto ca trustpoint</code></td>
<td>Removes all trustpoints.</td>
</tr>
<tr>
<td><code>clear configure crypto dynamic-map</code></td>
<td>Removes all dynamic crypto maps. Includes keywords that let you remove specific dynamic crypto maps.</td>
</tr>
<tr>
<td><code>clear configure crypto map</code></td>
<td>Removes all crypto maps. Includes keywords that let you remove specific crypto maps.</td>
</tr>
<tr>
<td><code>clear configure crypto isakmp</code></td>
<td>Removes the entire ISAKMP configuration.</td>
</tr>
<tr>
<td><code>clear configure crypto isakmp policy</code></td>
<td>Removes all ISAKMP policies or a specific policy.</td>
</tr>
</tbody>
</table>
Clear Crypto Map Configurations

The `clear configure crypto` command includes arguments that let you remove elements of the crypto configuration, including IPsec, crypto maps, dynamic crypto maps, CA trustpoints, all certificates, certificate map configurations, and ISAKMP.

Be aware that if you enter the `clear configure crypto` command without arguments, you remove the entire crypto configuration, including all certificates.

For more information, see the `clear configure crypto` command in the *Cisco ASA Series Command Reference*. 

<table>
<thead>
<tr>
<th>clear crypto isakmp sa</th>
<th>Removes the entire ISAKMP SA database.</th>

L2TP over IPsec

This chapter describes how to configure L2TP over IPsec/IKEv1 on the ASA.

- About L2TP over IPsec/IKEv1 VPN, on page 45
- Licensing Requirements for L2TP over IPsec, on page 47
- Prerequisites for Configuring L2TP over IPsec, on page 47
- Guidelines and Limitations, on page 47
- Configuring L2TP over Eclipse with CLI, on page 49
- Feature History for L2TP over IPsec, on page 54

About L2TP over IPsec/IKEv1 VPN

Layer 2 Tunneling Protocol (L2TP) is a VPN tunneling protocol that allows remote clients to use the public IP network to securely communicate with private corporate network servers. L2TP uses PPP over UDP (port 1701) to tunnel the data.

L2TP protocol is based on the client/server model. The function is divided between the L2TP Network Server (LNS), and the L2TP Access Concentrator (LAC). The LNS typically runs on a network gateway such as a router, while the LAC can be a dial-up Network Access Server (NAS) or an endpoint device with a bundled L2TP client such as Microsoft Windows, Apple iPhone, or Android.

The primary benefit of configuring L2TP with IPsec/IKEv1 in a remote access scenario is that remote users can access a VPN over a public IP network without a gateway or a dedicated line, which enables remote access from virtually anyplace with POTS. An additional benefit is that no additional client software, such as Cisco VPN client software, is required.

---

**Note**

L2TP over IPsec supports only IKEv1. IKEv2 is not supported.

The configuration of L2TP with IPsec/IKEv1 supports certificates using the preshared keys or RSA signature methods, and the use of dynamic (as opposed to static) crypto maps. This summary of tasks assumes completion of IKEv1, as well as pre-shared keys or RSA signature configuration. See Chapter 41, “Digital Certificates,” in the general operations configuration guide for the steps to configure preshared keys, RSA, and dynamic crypto maps.
L2TP with IPsec on the ASA allows the LNS to interoperate with native VPN clients integrated in such operating systems as Windows, MAC OS X, Android, and Cisco IOS. Only L2TP with IPsec is supported, native L2TP itself is not supported on ASA. The minimum IPsec security association lifetime supported by the Windows client is 300 seconds. If the lifetime on the ASA is set to less than 300 seconds, the Windows client ignores it and replaces it with a 300 second lifetime.

**IPsec Transport and Tunnel Modes**

By default, the ASA uses IPsec tunnel mode—the entire original IP datagram is encrypted, and it becomes the payload in a new IP packet. This mode allows a network device, such as a router, to act as an IPsec proxy. That is, the router performs encryption on behalf of the hosts. The source router encrypts packets and forwards them along the IPsec tunnel. The destination router decrypts the original IP datagram and forwards it on to the destination system. The major advantage of tunnel mode is that the end systems do not need to be modified to receive the benefits of IPsec. Tunnel mode also protects against traffic analysis; with tunnel mode, an attacker can only determine the tunnel endpoints and not the true source and destination of the tunneled packets, even if they are the same as the tunnel endpoints.

However, the Windows L2TP/IPsec client uses IPsec transport mode—only the IP payload is encrypted, and the original IP headers are left intact. This mode has the advantages of adding only a few bytes to each packet and allowing devices on the public network to see the final source and destination of the packet. The following figure illustrates the differences between IPsec tunnel and transport modes.

*Figure 3: IPsec in Tunnel and Transport Modes*

In order for Windows L2TP and IPsec clients to connect to the ASA, you must configure IPsec transport mode for a transform set using the `crypto ipsec transform-set trans_name mode transport` command. This command is used in the configuration procedure.

**Note**

ASA cannot push more than 28 ACE in split-tunnel access-list.
With this transport capability, you can enable special processing (for example, QoS) on the intermediate network based on the information in the IP header. However, the Layer 4 header is encrypted, which limits the examination of the packet. Unfortunately, if the IP header is transmitted in clear text, transport mode allows an attacker to perform some traffic analysis.

### Licensing Requirements for L2TP over IPsec

This feature is not available on No Payload Encryption models.

IPsec remote access VPN using IKEv2 requires an AnyConnect Plus or Apex license, available separately. IPsec remote access VPN using IKEv1 and IPsec site-to-site VPN using IKEv1 or IKEv2 uses the Other VPN license that comes with the base license. See Cisco ASA Series Feature Licenses for maximum values per model.

### Prerequisites for Configuring L2TP over IPsec

Configuring L2TP over IPsec has the following prerequisites:

- **Group Policy** - You can configure the default group policy (DfltGrpPolicy) or a user-defined group policy for L2TP/IPsec connections. In either case, the group policy must be configured to use the L2TP/IPsec tunneling protocol. If the L2TP/IPsec tunneling protocol is not configured for your user-defined group policy, configure the DfltGrpPolicy for the L2TP/IPsec tunneling protocol and allow your user-defined group policy to inherit this attribute.

- **Connection Profile** - You need to configure the default connection profile (tunnel group), DefaultRAGroup, if you are performing “pre-shared key” authentication. If you are performing certificate-based authentication, you can use a user-defined connection profile that can be chosen based on certificate identifiers.

- **IP connectivity needs to be established between the peers.** To test connectivity, try to ping the IP address of the ASA from your endpoint and try to ping the IP address of your endpoint from the ASA.

- **Make sure that UDP port 1701 is not blocked anywhere along the path of the connection.**

- **If a Windows 7 endpoint device authenticates using a certificate that specifies a SHA signature type, the signature type must match that of the ASA, either SHA1 or SHA2.**

### Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

**Context Mode Guidelines**

Supported in single context mode.
Firewall Mode Guidelines
Supported only in routed firewall mode. Transparent mode is not supported.

Failover Guidelines
L2TP over IPsec sessions are not supported by stateful failover.

IPv6 Guidelines
There is no native IPv6 tunnel setup support for L2TP over IPsec.

Software Limitation on All Platforms
We currently only support 4096 L2TP over IPsec tunnels.

Authentication Guidelines
The ASA only supports the PPP authentications PAP and Microsoft CHAP, Versions 1 and 2, on the local database. EAP and CHAP are performed by proxy authentication servers. Therefore, if a remote user belongs to a tunnel group configured with the `authentication eap-proxy` or `authentication chap` commands, and the ASA is configured to use the local database, that user will not be able to connect.

Supported PPP Authentication Types
L2TP over IPsec connections on the ASA support only the PPP authentication types as shown:

<table>
<thead>
<tr>
<th>AAA Server Type</th>
<th>Supported PPP Authentication Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOCAL</td>
<td>PAP, MSCHAPv1, MSCHAPv2</td>
</tr>
<tr>
<td>RADIUS</td>
<td>PAP, CHAP, MSCHAPv1, MSCHAPv2, EAP-Proxy</td>
</tr>
<tr>
<td>TACACS+</td>
<td>PAP, CHAP, MSCHAPv1</td>
</tr>
<tr>
<td>LDAP</td>
<td>PAP</td>
</tr>
<tr>
<td>NT</td>
<td>PAP</td>
</tr>
<tr>

<td>In response to the server challenge, the client returns the encrypted [challenge plus password] with a cleartext username. This protocol is more secure than the PAP, but it does not encrypt data.</td>
</tr>
</tbody>
</table>
Configuring L2TP over Eclipse with CLI

You must configure IKEv1 (ISAKMP) policy settings to allow native VPN clients to make a VPN connection to the ASA using the L2TP over Eclipse protocol.

- IKEv1 phase 1 — AES encryption with SHA1 hash method.
- Eclipse phase 2 — AES encryption with SHA hash method.
- PPP Authentication — PAP, MS-CHAPv1, or MSCHAPv2 (preferred).
- Pre-shared key (only for iPhone).

Procedure

Step 1
Create a transform set with a specific ESP encryption type and authentication type.

```
crypto ipsec ike_version transform-set transform_name ESP_Encryption_Type ESP_Authentication_Type
```

Example:
```
crypto ipsec ikev1 transform-set my-transform-set-ikev1 esp-aes esp-sha-hmac
```

Step 2
Instruct Eclipse to use transport mode rather than tunnel mode.

```
crypto ipsec ike_version transform-set trans_name mode transport
```

Example:
```
crypto ipsec ikev1 transform-set my-transform-set-ikev1 mode transport
```

Step 3
Specify L2TP/Eclipse as the vpn tunneling protocol.
vpn-tunnel-protocol tunneling_protocol

Example:
hostname(config)# group-policy DfltGrpPolicy attributes
hostname(config-group-policy)# vpn-tunnel-protocol l2tp-ipsec

Step 4 (Optional) Instruct the adaptive security appliance to send DNS server IP addresses to the client for the group policy.
dns value [none | IP_Primary | IP_Secondary]

Example:
hostname(config)# group-policy DfltGrpPolicy attributes
hostname(config-group-policy)# dns value 209.165.201.1 209.165.201.2

Step 5 (Optional) Instruct the adaptive security appliance to send WINS server IP addresses to the client for the group policy.
wins-server value [none | IP_primary [IP_secondary]]

Example:
hostname(config)# group-policy DfltGrpPolicy attributes
hostname(config-group-policy)# wins-server value 209.165.201.3 209.165.201.4

Step 6 (Optional) Create an IP address pool.
ip local pool pool_name starting_address-ending_address mask subnet_mask

Example:
hostname(config)# ip local pool sales_addresses 10.4.5.10-10.4.5.20 mask 255.255.255.0

Step 7 (Optional) Associate the pool of IP addresses with the connection profile (tunnel group).
address-pool pool_name

Example:
hostname(config)# tunnel-group DefaultRAGroup general-attributes
hostname(config-tunnel-general)# address-pool sales_addresses

Step 8 Link the name of a group policy to the connection profile (tunnel group).
default-group-policy name

Example:
hostname(config)# tunnel-group DefaultRAGroup general-attributes
hostname(config-tunnel-general)# default-group-policy DfltGrpPolicy

Step 9 Specify an authentication server to verify users attempting L2TP over the IPsec connections. If you want the authentication to fallback to local authentication when the server is not available, add LOCAL to the end of the command.
authentication-server-group server_group [local]

Example:
hostname(config)# tunnel-group DefaultRAGroup general-attributes
hostname(config-tunnel-general)# authentication-server-group sales_server LOCAL
Step 10 Specify a method to authenticate users attempting L2TP over Eclipse connections, for the connection profile (tunnel group). If you are not using the ASA to perform local authentication, and you want to fallback to local authentication, add LOCAL to the end of the command.

```
authentication auth_type
```

**Example:**
```
hostname(config)# tunnel-group DefaultRAGroup ppp-attributes
hostname(config-ppp)# authentication ms-chap-v1
```

Step 11 Set the pre-shared key for your connection profile (tunnel group).

```
tunnel-group tunnel group name ipsec-attributes
```

**Example:**
```
hostname(config)# tunnel-group DefaultRAGroup ipsec-attributes
hostname(config-tunnel-ipsec)# ikev1 pre-shared-key cisco123
```

Step 12 (Optional) Generate a AAA accounting start and stop record for an L2TP session for the connection profile (tunnel group).

```
accounting-server-group aaa_server_group
```

**Example:**
```
hostname(config)# tunnel-group DefaultRAGroup general-attributes
hostname(config-tunnel-general)# accounting-server-group sales_aaa_server
```

Step 13 Configure the interval (in seconds) between hello messages. The range is 10 through 300 seconds. The default interval is 60 seconds.

```
l2tp tunnel hello seconds
```

**Example:**
```
hostname(config)# l2tp tunnel hello 100
```

Step 14 (Optional) Enable NAT traversal so that ESP packets can pass through one or more NAT devices.

If you expect multiple L2TP clients behind a NAT device to attempt L2TP over Eclipse connections to the adaptive security appliance, you must enable NAT traversal.

```
crypto isakmp nat-traversal seconds
```

To enable NAT traversal globally, check that ISAKMP is enabled (you can enable it with the `crypto isakmp enable` command) in global configuration mode, and then use the `crypto isakmp nat-traversal` command.

**Example:**
```
hostname(config)# crypto ikev1 enable
hostname(config)# crypto isakmp nat-traversal 1500
```

Step 15 (Optional) Configure tunnel group switching. The goal of tunnel group switching is to give users a better chance at establishing a VPN connection when they authenticate using a proxy authentication server. Tunnel group is synonymous with connection profile.

```
strip-group
strip-realm
```

**Example:**
Creating IKE Policies to Respond to Windows 7 Proposals

Windows 7 L2TP/IPsec clients send several IKE policy proposals to establish a VPN connection with the ASA. Define one of the following IKE policies to facilitate connections from Windows 7 VPN native clients.

Follow the procedure Configuring L2TP over IPsec for ASA. Add the additional steps in this task to configure the IKE policy for Windows 7 native VPN clients.

Procedure

**Step 1**
Display the attributes and the number of any existing IKE policies.

Example:

```
hostname(config)# show run crypto ikev1
```

**Step 2**
Configure an IKE policy. The number argument specifies the number of the IKE policy you are configuring. This number was listed in the output of the `show run crypto ikev1` command.

```
crypto ikev1 policy number
```

**Step 3**
Set the authentication method the ASA uses to establish the identity of each IPsec peer to use preshared keys.

Example:

```
hostname(config-ikev1-policy)# authentication pre-share
```
Step 4  Choose a symmetric encryption method that protects data transmitted between two IPsec peers. For Windows 7, choose `aes` for 128-bit AES, or `aes-256`.

```
encryption {aes|aes-256}
```

Step 5  Choose the hash algorithm that ensures data integrity. For Windows 7, specify `sha` for the SHA-1 algorithm.

```
Example:
hostname(config-ikev1-policy)# hash sha
```

Step 6  Choose the Diffie-Hellman group identifier. You can specify 14 for aes,aes-256 encryption types.

```
Example:
hostname(config-ikev1-policy)# group 14
```

Step 7  Specify the SA lifetime in seconds. For Windows 7, specify 86400 seconds to represent 24 hours.

```
Example:
hostname(config-ikev1-policy)# lifetime 86400
```

Configuration Example for L2TP over IPsec

The following example shows configuration file commands that ensure ASA compatibility with a native VPN client on any operating system:

```
group-policy sales_policy internal
group-policy sales_policy attributes
wins-server value 209.165.201.3 209.165.201.4
dns-server value 209.165.201.1 209.165.201.2
vpn-tunnel-protocol l2tp-ipsec
tunnel-group DefaultRAGroup general-attributes
default-group-policy sales_policy
address-pool sales_addresses
tunnel-group DefaultRAGroup ipsec-attributes
pre-shared-key *
tunnel-group DefaultRAGroup ppp-attributes
no authentication pap
authentication chap
authentication ms-chap-v1
authentication ms-chap-v2
crypto ipsec ikev1 transform-set trans esp-aes esp-sha-hmac
crypto ipsec ikev1 transform-set trans mode transport
crypto dynamic-map dyno 10 set ikev1 transform-set trans
crypto map vpn 20 ipsec-isakmp dynamic dyno
crypto map vpn interface outside
crypto ikev1 enable outside
crypto ikev1 policy 10
authentication pre-share

encryption aes
hash sha
```

High Availability Options

• High Availability Options, on page 57
• Load Balancing, on page 58

High Availability Options

Distributed VPN Clustering, Load balancing and Failover are high-availability features that function differently and have different requirements. In some circumstances you may use multiple capabilities in your deployment. The following sections describe these features. Refer to the appropriate release of the ASA General Operations CLI Configuration Guide for details on Distributed VPN and Failover. Load Balancing details are included here.

VPN and Clustering on the FXOS Chassis

An ASA FXOS Cluster supports one of two mutually exclusive modes for S2S VPN, centralized or distributed:

• Centralized VPN Mode. The default mode. In centralized mode, VPN connections are established with the master of the cluster only.

VPN functionality is limited to the master unit and does not take advantage of the cluster high availability capabilities. If the master unit fails, all existing VPN connections are lost, and VPN connected users see a disruption in service. When a new master is elected, you must reestablish the VPN connections.

When you connect a VPN tunnel to a Spanned interface address, connections are automatically forwarded to the master unit. VPN-related keys and certificates are replicated to all units.

• Distributed VPN Mode. In this mode, S2S IPsec IKEv2 VPN connections are distributed across members of an ASA cluster providing scalability. Distributing VPN connections across the members of a cluster allows both the capacity and throughput of the cluster to be fully utilized, significantly scaling VPN support beyond Centralized VPN capabilities.
Centralized VPN clustering mode supports S2S IKEv1 and S2S IKEv2.

Distributed VPN clustering mode supports S2S IKEv2 only.

Distributed VPN clustering mode is supported on the Firepower 9300 only.

Remote access VPN is not supported in centralized or distributed VPN clustering mode.

Load Balancing

Load balancing is a mechanism for equitably distributing remote-access VPN traffic among the devices in a virtual cluster. It is based on simple distribution of traffic without taking into account throughput or other factors. A load-balancing cluster consists of two or more devices, one is the virtual master, and the other devices are the backup. These devices do not need to be of the exact same type, or have identical software versions or configurations.

All active devices in a virtual cluster carry session loads. Load balancing directs traffic to the least-loaded device in the cluster, distributing the load among all devices. It makes efficient use of system resources and provides increased performance and high availability.

Failover

A failover configuration requires two identical ASAs connected to each other through a dedicated failover link and, optionally, a stateful failover link. The health of the active interfaces and units is monitored to determine when specific failover conditions are met. If those conditions occur, failover occurs. Failover supports both VPN and firewall configurations.

The ASA supports two failover configurations: Active/Active failover and Active/Standby failover.

With Active/Active failover, both units can pass network traffic. This is not true load balancing, although it might appear to have the same effect. When failover occurs, the remaining active unit takes over passing the combined traffic, based on the configured parameters. Therefore, when configuring Active/Active failover, you must make sure that the combined traffic for both units is within the capacity of each unit.

With Active/Standby failover, only one unit passes traffic, while the other unit waits in a standby state and does not pass traffic. Active/Standby failover lets you use a second ASA to take over the functions of a failed unit. When the active unit fails, it changes to the standby state, while the standby unit changes to the active state. The unit that becomes active assumes the IP addresses (or, for transparent firewall, the management IP address) and MAC addresses of the failed unit and begins passing traffic. The unit that is now in standby state takes over the standby IP addresses of the active unit. If an active unit fails, the standby takes over without any interruption to the client VPN tunnel.

Load Balancing

About Load Balancing

If you have a remote-client configuration in which you are using two or more ASAs connected to the same network to handle remote sessions, you can configure these devices to share their session load. This feature
is called load balancing. Load balancing directs session traffic to the least loaded device, thus distributing the load among all devices. It makes efficient use of system resources and provides increased performance an availability.

To implement load balancing, you group together logically two or more devices on the same private LAN-to-LAN network into a virtual cluster.

All devices in the virtual cluster carry session loads. One device in the virtual cluster, the virtual cluster master, directs incoming connection requests to the other devices, called backup devices. The virtual cluster master monitors all devices in the cluster, keeps track of how busy each is, and distributes the session load accordingly. The role of virtual cluster master is not tied to a physical device; it can shift among devices. For example, if the current virtual cluster master fails, one of the backup devices in the cluster takes over that role and immediately becomes the new virtual cluster master.

The virtual cluster appears to outside clients as a single virtual cluster IP address. This IP address is not tied to a specific physical device. It belongs to the current virtual cluster master; hence, it is virtual. A VPN client attempting to establish a connection connects first to this virtual cluster IP address. The virtual cluster master then sends back to the client the public IP address of the least-loaded available host in the cluster. In a second transaction (transparent to the user) the client connects directly to that host. In this way, the virtual cluster master directs traffic evenly and efficiently across resources.

If a machine in the cluster fails, the terminated sessions can immediately reconnect to the virtual cluster IP address. The virtual cluster master then directs these connections to another active device in the cluster. Should the virtual cluster master itself fail, a backup device in the cluster immediately and automatically takes over as the new virtual session master. Even if several devices in the cluster fail, users can continue to connect to the cluster as long as any one device in the cluster is up and available.

**VPN Load-Balancing Algorithm**

The master device maintains a sorted list of backup cluster members in ascending IP address order. The load of each backup cluster member is computed as an integer percentage (the number of active sessions). AnyConnect inactive sessions do not count towards the SSL VPN load for load balancing. The master device redirects the IPsec and SSL VPN tunnel to the device with the lowest load until it is 1 percent higher than the rest. When all backup cluster members are 1% higher than the master, the master device redirects to itself.

For example, if you have one master and two backup cluster members, the following cycle applies:

---

**Note**

All nodes start with 0%, and all percentages are rounded half-up.

1. The master device takes the connection if all members have a load at 1% higher than the master.
2. If the master does not take the connection, the session is taken by whichever backup device has the least load percentage.
3. If all members have the same percentage load, the backup device with the least number of sessions gets the session.
4. If all members have the same percentage load and the same number of sessions, the device with the least IP addresses gets the session.
VPN Load-Balancing Cluster Configurations

A load-balancing cluster can consist of ASAs of the same release or of mixed releases subject to the following restrictions:

- Load-balancing clusters that consist of both same release ASAs can run load balancing for a mixture of IPsec, AnyConnect, and clientless SSL VPN client and clientless sessions.
- Load-balancing clusters that include mixed release ASAs or same release ASAs can support only IPsec sessions. In such a configuration, however, the ASAs might not reach their full IPsec capacity.

Since Release 7.1(1), IPsec and SSL VPN sessions count or weigh equally in determining the load that each device in the cluster carries. This represents a departure from the load balancing calculation for the ASA Release 7.0(x) software in that this platform use a weighting algorithm that, on some hardware platforms, calculates SSL VPN session load differently from IPsec session load.

The virtual master of the cluster assigns session requests to the members of the cluster. The ASA regards all sessions, SSL VPN or IPsec, as equal and assigns them accordingly. You can configure the number of IPsec and SSL VPN sessions to allow, up to the maximum allowed by your configuration and license.

We have tested up to ten nodes in a load-balancing cluster. Larger clusters might work, but we do not officially support such topologies.

Examples of Typical Mixed Cluster Scenarios

If you have a mixed configuration—that is, if your load-balancing cluster includes devices running a mixture of ASA software releases—the difference in weighting algorithms becomes an issue if the initial cluster master fails and another device takes over as master.

The following scenarios illustrate the use of VPN load balancing in clusters consisting of a mixture of ASAs running ASA Release 7.1(1) and ASA Release 7.0(x) software.

Scenario 1: Mixed Cluster with No SSL VPN Connections

In this scenario, the cluster consists of a mixture of ASAs. Some of the ASA cluster peers are running ASA Release 7.0(x), and some are running Release 7.1(1). The pre-7.1(1) peers do not have any SSL VPN connections, and the 7.1(1) cluster peers have only the base SSL VPN license, which allows two SSL VPN sessions, but there are no SSL VPN connections. In this case, all the connections are IPsec, and load balancing works fine.

Scenario 2: Mixed Cluster Handling SSL VPN Connections

Suppose, for example, an ASA running ASA Release 7.1(1) software is the initial cluster master and then that device fails. Another device in the cluster takes over automatically as master and applies its own load-balancing algorithm to determine processor loads within the cluster. A cluster master running ASA Release 7.1(1) software cannot weight session loads in any way other than what that software provides. Therefore, it cannot assign a combination of IPsec and SSL VPN session loads properly to ASA devices running earlier versions. The following scenario illustrates this dilemma.

This scenario is similar to the previous one, in that the cluster consists of a mixture of ASAs. Some of the ASA cluster peers are running ASA Release 7.0,(x) and some are running Release 7.1(1). In this case, however, the cluster is handling SSL VPN connections as well as IPsec connections.

If a device that is running software earlier than ASA Release 7.1(1) is the cluster master, the master applies the protocol and logic in effect prior to Release 7.1(1). That is, sessions might be directed to load-balancing peers that have exceeded their session limit. In that case, the user is denied access.
If the cluster master is a device running ASA Release 7.0(x) software, the old session-weighting algorithm applies only to the pre-7.1(1) peers in the cluster. No one should be denied access in this case. Because the pre-7.1(1) peers use the session-weighting algorithm, they are more lightly loaded.

An issue arises, however, because you cannot guarantee that the 7.1(1) peer is always the cluster master. If the cluster master fails, another peer assumes the role of master. The new master might be any of the eligible peers. Because of the unpredictability of the results, we recommend that you avoid configuring this type of cluster.

**Frequently Asked Questions About Load Balancing**

- Multi-Context Mode
- IP Address Pool Exhaustion
- Unique IP Address Pools
- Using Load Balancing and Failover on the Same Device
- Load Balancing on Multiple Interfaces
- Maximum Simultaneous Sessions for Load Balancing Clusters
Multi-Context Mode
Q. Is load balancing supported in multi-context mode?
A. Neither load balancing or stateful failover is supported in multi-context mode.

IP Address Pool Exhaustion
Q. Does the ASA consider IP address pool exhaustion as part of its VPN load-balancing method?
A. No. If the remote access VPN session is directed to a device that has exhausted its IP address pools, the session does not establish. The load-balancing algorithm is based on load, and is computed as an integer percentage (number of active and maximum sessions) that each backup cluster member supplies.

Unique IP Address Pools
Q. To implement VPN load balancing, must the IP address pools for AnyConnect clients or IPsec clients on different ASAs be unique?
A. Yes. IP address pools must be unique for each device.

Using Load Balancing and Failover on the Same Device
Q. Can a single device use both load balancing and failover?
A. Yes. In this configuration, the client connects to the IP address of the cluster and is redirected to the least-loaded ASA in the cluster. If that device fails, the standby unit takes over immediately, and there is no impact to the VPN tunnel.

Load Balancing on Multiple Interfaces
Q. If we enable SSL VPN on multiple interfaces, is it possible to implement load balancing for both of the interfaces?
A. You can define only one interface to participate in the cluster as the public interface. The idea is to balance the CPU loads. Multiple interfaces converge on the same CPU, so the concept of load balancing on multiple interfaces has no meaning.

Maximum Simultaneous Sessions for Load Balancing Clusters
Q. Consider a deployment of two ASA 5525-Xs, each with a 100-user SSL VPN license. In a load-balancing cluster, does the maximum total number of users allow 200 simultaneous sessions, or only 100? If we add a third device later with a 100-user license, can we now support 300 simultaneous sessions?
A. With VPN load balancing, all devices are active, so the maximum number of sessions that your cluster can support is the total of the number of sessions for each of the devices in the cluster, in this case 300.

Licensing for Load Balancing
VPN load balancing requires an active 3DES/AES license. The security appliance checks for the existence of this crypto license before enabling load balancing. If it does not detect an active 3DES or AES license, the security appliance prevents the enabling of load balancing and also prevents internal configuration of 3DES by the load balancing system unless the license permits this usage.
Guidelines and Limitations for VPN Load Balancing

Eligible Clients
Load balancing is effective only on remote sessions initiated with the following clients:

- Cisco AnyConnect Secure Mobility Client (Release 3.0 and later)
- Cisco ASA 5505 Security Appliance (when acting as an Easy VPN client)
- IOS EZVPN Client devices supporting IKE-redirect (IOS 831/871)
- Clientless SSL VPN (not a client)

Client Considerations
Load balancing works with IPsec clients and SSL VPN client and clientless sessions. All other VPN connection types (L2TP, PPTP, L2TP/IPsec), including LAN-to-LAN, can connect to an ASA on which load balancing is enabled, but they cannot participate in load balancing.

When multiple ASA nodes are clustered for load balancing, and using Group URLs is desired for AnyConnect client connections, the individual ASA nodes must:

- Configure each remote access connection profile with a Group URL for each load balancing virtual cluster address (IPv4 and IPv6).
- Configure a Group URL for this node's VPN Load Balancing public address.

Context Mode
VPN load balancing is not supported in multiple context mode.

Certificate Verification
When performing certificate verification for load balancing with AnyConnect, and the connection is redirected by an IP address, the client does all of its name checking through this IP address. Make sure the redirection IP address is listed in the certificates common name or the subject alt name. If the IP address is not present in these fields, then the certificate will be deemed untrusted.

Following the guidelines defined in RFC 2818, if a subject alt name is included in the certificate, we only use the subject alt name for name checks, and we ignore the common name. Make sure that the IP address of the server presenting the certificate is defined in the subject alt name of the certificate.

For a standalone ASA, the IP address is the IP of that ASA. In a clustering situation, it depends on the certificate configuration. If the cluster uses one certificate, then the certificate should have SAN extensions for the cluster IP address and cluster FQDN and should contain Subject Alternative Name extensions that have each ASA's IP and FQDN. If the cluster uses multiple certificates, then the certificate for each ASA should have SAN extensions for the cluster IP, cluster FQDN, and the individual ASA's IP address and FQDN.

Geographical Load Balancing
In a load balancing environment where the DNS resolutions are being changed at regular intervals, you must carefully consider how to set the time to live (TTL) value. For the DNS load balance configuration to work successfully with AnyConnect, the ASA name to address mapping must remain the same from the time the ASA is selected until the tunnel is fully established. If too much time passes before the credentials are entered,
the lookup restarts and a different IP address may become the resolved address. If the DNS mapping changes
to a different ASA before the credentials are entered, the VPN tunnel fails.

Geographical load balancing for VPN often uses a Cisco Global Site Selector (GSS). The GSS uses DNS for
the load balancing, and the time to live (TTL) value for DNS resolution is defaulted to 20 seconds. You can
significantly decrease the likelihood of connection failures if you increase the TTL value on the GSS. Increasing
to a much higher value allows ample time for the authentication phase when the user is entering credentials
and establishing the tunnel.

To increase the time for entering credentials, you may also consider disabling Connect on Start Up.

Configuring Load Balancing

If you have a remote-client configuration in which you are using two or more ASAs connected to the same
network to handle remote sessions, you can configure these devices to share their session load. This feature
is called load balancing, which directs session traffic to the least loaded device, thereby distributing the load
among all devices. Load balancing makes efficient use of system resources and provides increased performance
and system availability.

To use load balancing, do the following on each device in the cluster:

• Configure the load-balancing cluster by establishing common VPN load-balancing cluster attributes.
  This includes a virtual cluster IP address, UDP port (if necessary), and IPsec shared secret for the cluster.
  All participants in the cluster must have an identical cluster configuration, except for the device priority
  within the cluster.

• Configure the participating device by enabling load balancing on the device and defining device-specific
  properties, such as its public and private addresses. These values vary from device to device.

Prerequisites for Load Balancing

Also refer to the Guidelines and Limitations for VPN Load Balancing, on page 63.

• Load balancing is disabled by default. You must explicitly enable load balancing.

• You must have first configured the public (outside) and private (inside) interfaces. Subsequent references
  in this section use the names outside and inside.

  You can use the interface and nameif commands to configure different names for these interfaces.

• You must have previously configured the interface to which the virtual cluster IP address refers. Establish
  a common virtual cluster IP address, UDP port (if necessary), and IPsec shared secret for the cluster.

• All devices that participate in a cluster must share the same cluster-specific values: IP address, encryption
  settings, encryption key, and port.

• If you are using encryption, you must configure the load balancing inside interface. If that interface is
  not enabled on the load balancing inside interface, an error message appears when you try to configure
  cluster encryption.

• The Local CA feature is not supported if you use Active/Active stateful failover or VPN load-balancing.
  The Local CA cannot be subordinate to another CA; it can act only as the Root CA.
Configure the Public and Private Interfaces for Load Balancing

To configure the public (outside) and private (inside) interfaces for the load-balancing cluster devices, do the following steps:

**Procedure**

**Step 1**
Configure the public interface on the ASA by entering the `interface` command with the `lbpublic` keyword in `vpn-load-balancing` configuration mode. This command specifies the name or IP address of the public interface for load balancing for this device:

*Example:*

```
hostname(config)# vpn load-balancing
hostname(config-load-balancing)# interface lbpublic outside
hostname(config-load-balancing)#
```

**Step 2**
Configure the private interface on the ASA by entering the `interface` command with the `lbprivate` keyword in `vpn-load-balancing` configuration mode. This command specifies the name or IP address of the private interface for load balancing for this device:

*Example:*

```
hostname(config-load-balancing)# interface lbprivate inside
hostname(config-load-balancing)#
```

**Step 3**
Set the priority to assign to this device within the cluster. The range is from 1 to 10. The priority indicates the likelihood of this device becoming the virtual cluster master, either at startup or when an existing master fails. The higher you set the priority (for example, 10), the more likely it is that this device becomes the virtual cluster master.

*Example:*

For example, to assign this device a priority of 6 within the cluster, enter the following command:

```
hostname(config-load-balancing)# priority 6
hostname(config-load-balancing)#
```

**Step 4**
If you want to apply network address translation for this device, enter the `nat` command with the NAT assigned address for the device. You can define an IPv4 and an IPv6 address or specify the device’s hostname.

*Example:*

For example, to assign this device a NAT address of 192.168.30.3 and 2001:DB8::1, enter the following command:

```
hostname(config-load-balancing)# nat 192.168.30.3 2001:DB8::1
hostname(config-load-balancing)#
```

Configure the Load Balancing Cluster Attributes

To configure the load-balancing cluster attributes for each device in the cluster, do the following steps:
Configure the Load Balancing Cluster Attributes

Procedure

**Step 1** Set up VPN load balancing by entering the **vpn load-balancing** command in global configuration mode:

**Example:**

```
hostname(config)# vpn load-balancing
hostname(config-load-balancing)#
```

This enters vpn-load-balancing configuration mode, in which you can configure the remaining load-balancing attributes.

**Step 2** Configure the IP address or the fully qualified domain name of the cluster to which this device belongs. This command specifies the single IP address or FQDN that represents the entire virtual cluster. Choose an IP address that is within the public subnet address range shared by all the ASAs in the virtual cluster. You can specify an IPv4 or IPv6 address.

**Example:**

For example, to set the cluster IP address to IPv6 address, 2001:DB8::1, enter the following command:

```
hostname(config-load-balancing)# cluster ip address 2001:DB8::1
hostname(config-load-balancing)#
```

**Step 3** Configure the cluster port. This command specifies the UDP port for the virtual cluster in which this device is participating. The default value is 9023. If another application is using this port, enter the UDP destination port number that you want to use for load balancing.

**Example:**

For example, to set the cluster port to 4444, enter the following command:

```
hostname(config-load-balancing)# cluster port 4444
hostname(config-load-balancing)#
```

**Step 4** (Optional) Enable IPsec encryption for the cluster.

The default is no encryption. This command enables or disables IPsec encryption. If you configure this check attribute, you must first specify and verify a shared secret. The ASAs in the virtual cluster communicate via LAN-to-LAN tunnels using IPsec. To ensure that all load-balancing information communicated between the devices is encrypted, enable this attribute.

**Note** When using encryption, you must have previously configured the load-balancing inside interface.

If that interface is not enabled on the load-balancing inside interface, you get an error message when you try to configure cluster encryption.

If the load-balancing inside interface was enabled when you configured cluster encryption, but was disabled before you configured the participation of the device in the virtual cluster, you get an error message when you enter the `participate` command (or, in ASDM, check the Participate in Load Balancing Cluster check box), and encryption is not enabled for the cluster.

To use cluster encryption, use the `crypto ikev1 enable` command with the inside interface specified.

**Example:**

```
```
Hostname(config-load-balancing)# cluster encryption
Hostname(config-load-balancing)#

**Step 5**  
If you enable cluster encryption, you must also specify the IPsec shared secret by entering the `cluster key` command. This command specifies the shared secret between IPsec peers when you have enabled IPsec encryption. The value you enter in the box appears as consecutive asterisk characters.

*Example:*  
For example, to set the shared secret to 123456789, enter the following command:

Hostname(config-load-balancing)# cluster key 123456789
Hostname(config-load-balancing)#

**Step 6**  
Enable this device’s participation in the cluster by entering the participate command:

*Example:*  

Hostname(config-load-balancing)# participate
Hostname(config-load-balancing)#

---

**What to do next**  
When multiple ASA nodes are clustered for load balancing, and using Group URLs is desired for AnyConnect client connections, on the individual ASA nodes you must:

- Configure each remote access connection profile with a Group URL for each load balancing virtual cluster address (IPv4 and IPv6).
- Configure a Group URL for this node's VPN Load Balancing public address.

Use the `tunnel-group, general-attributes, group-url` command to configure these Group URLs.

**Enable Redirection Using a Fully Qualified Domain Name**

By default, the ASA sends only IP addresses in load-balancing redirection to a client. If certificates are in use that are based on DNS names, the certificates will be invalid when redirected to a backup device.

As a VPN cluster master, this ASA can send a fully qualified domain name (FQDN), using reverse DNS lookup, of a cluster device (another ASA in the cluster) instead of its outside IP address when redirecting VPN client connections to that cluster device.

To enable or disable redirection using a fully qualified domain name in vpn load-balancing mode, use the `redirect-fqdn enable` command in global configuration mode. This behavior is disabled by default.

**Before you begin**  
All of the outside and inside network interfaces on the load-balancing devices in a cluster must be on the same IP network.
Procedure

Step 1  
Enable the use of FQDNs for load balancing with the `redirect-fqdn enable` command:

```bash
[no] redirect-fqdn {enable | disable}
```

Example:

```bash
hostname(config)# vpn load-balancing
hostname(config-load-balancing)# redirect-fqdn enable
hostname(config-load-balancing)#
```

Step 2  
Add an entry for each of your ASA outside interfaces into your DNS server if such entries are not already present. Each ASA outside IP address should have a DNS entry associated with it for lookups. These DNS entries must also be enabled for reverse lookup.

Step 3  
Enable DNS lookups on your ASA with the `dns domain-lookup inside` command or whichever interface has a route to your DNS server.

Step 4  
Define your DNS server IP address on the ASA. For example: `dns name-server 10.2.3.4` (IP address of your DNS server).

Configuration Examples for VPN Load Balancing

Basic VPN Load Balancing CLI Configuration

The following is an example of a VPN load balancing command sequence that includes an interface command that enables redirection for a fully qualified domain name, specifies the public interface of the cluster as `test` and the private interface of the cluster as `foo`:

```bash
hostname(config)# interface GigabitEthernet 0/1
hostname(config-if)# ip address 209.165.202.159 255.255.255.0
hostname(config)# nameif test
hostname(config)# interface GigabitEthernet 0/2
hostname(config-if)# ip address 209.165.201.30 255.255.255.0
hostname(config)# nameif foo
hostname(config)# vpn load-balancing
hostname(config-load-balancing)# nat 192.168.10.10
hostname(config-load-balancing)# priority 9
hostname(config-load-balancing)# interface lbpublic test
hostname(config-load-balancing)# interface lbprivate foo
hostname(config-load-balancing)# cluster ip address 209.165.202.224
hostname(config-load-balancing)# cluster key 123456789
hostname(config-load-balancing)# cluster encryption
hostname(config-load-balancing)# cluster port 9023
hostname(config-load-balancing)# redirect-fqdn enable
hostname(config-load-balancing)# participate
```

Viewing Load Balancing

The load-balancing cluster master receives a periodic message from each ASA in the cluster with the number of active AnyConnect and clientless sessions, as well as the maximum allowed sessions based on the configured
or license limits. If an ASA in the cluster shows 100 percent full capacity, the cluster master cannot redirect more connections to it. Although the ASA may show as full, some users may be in inactive/wait-to-resume state, wasting the licenses. As a workaround, each ASA provides the total number of sessions minus the sessions in inactive state, instead of the total number of sessions. Refer to the `sessiondb summary` command in the command reference. In other words, the inactive sessions are not reported to the cluster master. Even if the ASA is full (with some inactive sessions), the cluster master still redirects connections to it if necessary. When the ASA receives the new connection, the session that has been inactive the longest is logged off, allowing new connections to take its license.

The following example shows 100 SSL sessions (active only) and a 2 percent SSL load. These numbers do not include the inactive sessions. In other words, inactive sessions do not count towards the load for load balancing.

```
hostname# show vpn load-balancing
Status : enabled
Role : Master
Failover : Active
Encryption : enabled
Cluster IP : 192.168.1.100
Peers : 1

Load %
Sessions
Public IP  Role  Pri Model  IPsec SSL IPsec SSL
192.168.1.9 Master 7  ASA-5540 4 2 216 100
192.168.1.19 Backup 9  ASA-5520 0 0 0 0
```
CHAPTER 4

General VPN Parameters

The ASA implementation of virtual private networking includes useful features that do not fit neatly into categories. This chapter describes some of these features.

- Guidelines and Limitations, on page 71
- Configure IPsec to Bypass ACLs, on page 72
- Permitting Intra-Interface Traffic (Hairpinning), on page 72
- Setting Maximum Active IPsec or SSL VPN Sessions, on page 74
- Use Client Update to Ensure Acceptable IPsec Client Revision Levels, on page 74
- Implement NAT-Assigned IP to Public IP Connection, on page 76
- Configure VPN Session Limits, on page 78
- Using an Identify Certificate When Negotiating, on page 79
- Configure the Pool of Cryptographic Cores, on page 80
- Configure Dynamic Split Tunneling, on page 81
- Configure the Management VPN Tunnel, on page 82
- Viewing Active VPN Sessions, on page 82
- About ISE Policy Enforcement, on page 84
- Configure Advanced SSL Settings, on page 89
- Persistent IPsec Tunneled Flows, on page 94

Guidelines and Limitations

This section includes the guidelines and limitations for this feature.

Context Mode Guidelines

Supported in single and multiple context mode. In the appropriate release of the ASA General Operations CLI Configuration Guide, refer to Guidelines for Multiple Context Mode for the list of what is not supported in multiple context mode, and New Features which gives the breakdown of what was added throughout the releases.

Firewall Mode Guidelines

Supported only in routed firewall mode. Transparent mode is not supported.
Configure IPsec to Bypass ACLs

To permit any packets that come from an IPsec tunnel without checking ACLs for the source and destination interfaces, enter the `sysopt connection permit-vpn` command in global configuration mode.

You might want to bypass interface ACLs for IPsec traffic if you use a separate VPN concentrator behind the ASA and want to maximize the ASA performance. Typically, you create an ACL that permits IPsec packets by using the `access-list` command and apply it to the source interface. Using an ACL allows you to specify the exact traffic you want to allow through the ASA.

The following example enables IPsec traffic through the ASA without checking ACLs:

```
hostname(config)# sysopt connection permit-vpn
```

Note

Decrypted through-traffic is permitted from the client despite having an access group on the outside interface, which calls a `deny ip any any` ACL, while `no sysopt connection permit-vpn` is configured.

Trying to control access to the protected network via site-to-site or remote access VPN using the `no sysopt permit-vpn` command in conjunction with an access control list (ACL) on the outside interface are not successful.

`sysopt connection permit-vpn` will bypass ACLs (both in and out) on interface where crypto map for that interesting traffic is enabled, along with egress (out) ACLs of all other interfaces, but not the ingress (in) ACLs.

In this situation, when management-access inside is enabled, the ACL is not applied, and users can still connect to the ASA using SSH. Traffic to hosts on the inside network is blocked correctly by the ACL, but decrypted through-traffic to the inside interface is not blocked.

The `ssh` and `http` commands are of a higher priority than the ACLs. To deny SSH, Telnet, or ICMP traffic to the box from the VPN session, use `ssh`, `telnet` and `icmp` commands.

Permitting Intra-Interface Traffic (Hairpinning)

The ASA includes a feature that lets a VPN client send IPsec-protected traffic to another VPN user by allowing that traffic in and out of the same interface. This is also called “hairpinning”, which can be thought of as VPN spokes (clients) connecting through a VPN hub (the ASA).

Hairpinning can also redirect incoming VPN traffic back out through the same interface as unencrypted traffic. This can be useful, for example, to a VPN client that does not have split tunneling, but needs to both access a VPN and browse the web.

The figure below shows VPN Client 1 sending secure IPsec traffic to VPN Client 2 while also sending unencrypted traffic to a public web server.
To configure this feature, use the `same-security-traffic` command in global configuration mode with its intra-interface argument.

The command syntax is `same-security-traffic permit {inter-interface | intra-interface}`.

The following example shows how to enable intra-interface traffic:

```
hostname(config)# same-security-traffic permit intra-interface
```

**Note**

Use the `same-security-traffic` command with the `inter-interface` argument to permit communication between interfaces with the same security level. This feature is not specific to IPsec connections. For more information, see the “Configuring Interface Parameters” chapter of this guide.

To use hairpinning, you must apply the proper NAT rules to the ASA interface, as described in NAT Considerations for Intra-Interface Traffic.

**NAT Considerations for Intra-Interface Traffic**

For the ASA to send unencrypted traffic back out through the interface, you must enable NAT for the interface so that publicly routable addresses replace your private IP addresses (unless you already use public IP addresses in your local IP address pool). The following example applies an interface PAT rule to traffic sourced from the client IP pool:

```
hostname(config)# ip local pool clientpool 192.168.0.10-192.168.0.100
hostname(config)# object network vpn_nat
hostname(config-network-object)# subnet 192.168.0.0 255.255.255.0
hostname(config-network-object)# nat (outside,outside) interface
```

When the ASA sends encrypted VPN traffic back out this same interface, however, NAT is optional. The VPN-to-VPN hairpinning works with or without NAT. To apply NAT to all outgoing traffic, implement only
the commands above. To exempt the VPN-to-VPN traffic from NAT, add commands (to the example above) that implement NAT exemption for VPN-to-VPN traffic, such as:

```
hostname(config)# nat (outside,outside) source static vpn_nat vpn_nat destination static vpn_nat vpn_nat
```

For more information on NAT rules, see the “Applying NAT” chapter of this guide.

**Setting Maximum Active IPsec or SSL VPN Sessions**

To limit VPN sessions to a lower value than the ASA allows, enter the `vpn-sessiondb` command in global configuration mode:

```
vpn-sessiondb {max-anyconnect-premium-or-essentials-limit <number> | max-other-vpn-limit <number>}
```

The `max-anyconnect-premium-or-essentials-limit` keyword specifies the maximum number of AnyConnect sessions, from 1 to the maximum sessions allowed by the license.

**Note**

The `max-other-vpn-limit` keyword specifies the maximum number of VPN sessions other than AnyConnect client sessions, from 1 to the maximum sessions allowed by the license. This includes the Cisco VPN client (IPsec IKEv1) and Lan-to-Lan VPN sessions.

This limit affects the calculated load percentage for VPN Load Balancing.

The following example shows how to set a maximum Anyconnect VPN session limit of 450:

```
hostname(config)# vpn-sessiondb max-anyconnect-premium-or-essentials-limit 450
```

**Use Client Update to Ensure Acceptable IPsec Client Revision Levels**

**Note**
The information in this section applies to IPsec connections only.

The client update feature lets administrators at a central location automatically notify VPN client users that it is time to update the VPN client software.

Remote users might be using outdated VPN software or hardware client versions. You can use the `client-update` command at any time to enable updating client revisions; specify the types and revision numbers of clients to which the update applies; provide a URL or IP address from which to get the update; and, in the case of Windows clients, optionally notify users that they should update their VPN client version. For Windows
clients, you can provide a mechanism for users to accomplish that update. This command applies only to the
IPsec remote-access tunnel-group type.

To perform a client update, enter the `client-update` command in either general configuration mode or
tunnel-group ipsec-attributes configuration mode. If the client is already running a software version on the
list of revision numbers, it does not need to update its software. If the client is not running a software version
on the list, it should update. The following procedure explains how to perform a client update:

**Procedure**

**Step 1**
In global configuration mode, enable client update by entering this command:

```
hostname(config)# client-update enable
hostname(config)#
```

**Step 2**
In global configuration mode, specify the parameters for the client update that you want to apply to all clients
of a particular type. That is, specify the type of client, the URL or IP address from which to get the updated
image, and the acceptable revision number or numbers for that client. You can specify up to four revision
numbers, separated by commas.

If the user’s client revision number matches one of the specified revision numbers, there is no need to update
the client. This command specifies the client update values for all clients of the specified type across the entire
ASA.

Use this syntax:

```
hostname(config)# client-update type type url url-string rev-nums rev-numbers
hostname(config)#
```

The available client types are `win9X` (includes Windows 95, Windows 98 and Windows ME platforms),
`winnt` (includes Windows NT 4.0, Windows 2000 and Windows XP platforms), `windows` (includes all
Windows based platforms).

If the client is already running a software version on the list of revision numbers, it does not need to update
its software. If the client is not running a software version on the list, it should update. You can specify up to
three of these client update entries. The keyword `windows` covers all of the allowable Windows platforms.
If you specify `windows`, do not specify the individual Windows client types.

**Note**
For all Windows clients, you must use the protocol http:// or https:// as the prefix for the URL.

The following example configures client update parameters for the remote access tunnel group. It
designates the revision number 4.6.1 and the URL for retrieving the update, which is
https://support/updates.

```
hostname(config)# client-update type windows url https://support/updates/ rev-nums 4.6.1
hostname(config)#
```

Alternatively, you can configure client update just for individual tunnel groups, rather than for all clients of
a particular type. (See Step 3.)

**Note**
You can have the browser automatically start an application by including the application name at
the end of the URL; for example: `https://support/updates/vpnclient.exe`. 
Step 3 Define a set of client-update parameters for a particular ipsec-ra tunnel group.

In tunnel-group ipsec-attributes mode, specify the tunnel group name and its type, the URL or IP address from which to get the updated image, and a revision number. If the user’s client’s revision number matches one of the specified revision numbers, there is no need to update the client, for example, for a Windows client enter this command:

```
hostname(config)# tunnel-group remotegrp type ipsec-ra
hostname(config)# tunnel-group remotegrp ipsec-attributes
hostname(config-tunnel-ipsec)# client-update type windows url https://support/updates/rev_nums 4.6.1
hostname(config-tunnel-ipsec)#
```

Step 4 (Optional) Send a notice to active users with outdated Windows clients that their client needs updating. For these users, a pop-up window appears, offering them the opportunity to launch a browser and download the updated software from the site that you specified in the URL. The only part of this message that you can configure is the URL. (See Step 2 or 3.) Users who are not active get a notification message the next time they log on. You can send this notice to all active clients on all tunnel groups, or you can send it to clients on a particular tunnel group. For example, to notify all active clients on all tunnel groups, enter the following command in privileged EXEC mode:

```
hostname# client-update all
hostname#
```

If the user’s client’s revision number matches one of the specified revision numbers, there is no need to update the client, and no notification message is sent to the user.

What to do next

Note If you specify the client-update type as windows (specifying all Windows-based platforms) and later want to enter a client-update type of win9x or winnt for the same entity, you must first remove the windows client type with the no form of the command, then use new client-update commands to specify the new client types.

Implement NAT-Assigned IP to Public IP Connection

In rare situations, you might want to use a VPN peer’s real IP address on the inside network instead of an assigned local IP address. Normally with VPN, the peer is given an assigned local IP address to access the inside network. However, you might want to translate the local IP address back to the peer-s real public address if, for example, your inside servers and network security is based on the peer’s real IP address.

Cisco ASA 55xx introduced a way to translate the VPN client’s assigned IP address on the internal/protected network to its public (source) IP address. This feature supports the scenario where the target servers/services on the internal network and network security policy require communication with the VPN client’s public/source IP instead of the assigned IP on the internal corporate network.

You can enable this feature on one interface per tunnel group. Object NAT rules are dynamically added and deleted when the VPN session is established or disconnected.
Because of routing issues, we do not recommend using this feature unless you know you need it.

- Only supports legacy (IKEv1) and AnyConnect clients.
- Return traffic to the public IP addresses must be routed back to the ASA so the NAT policy and VPN policy can be applied.
- Only supports IPv4 assigned and public addresses.
- Multiple peers behind a NAT/PAT device are not supported.
- Does not support load balancing (because of routing issue).
- Does not support roaming.

**Procedure**

**Step 1**
In global configuration mode, enter `tunnel general`.

**Step 2**
Use this syntax to enable the address translation:

```
hostname(config-tunnel-general)# nat-assigned-to-public-ip interface
```

This command dynamically installs NAT policies of the assigned IP address to the public IP address of the source. The `interface` determines where to apply NAT.

**Step 3**
Use this syntax to disable the address translation:

```
hostname(config-tunnel-general)# no nat-assigned-to-public-ip
```

**Displaying VPN NAT Policies**

Address translation uses the underlying object NAT mechanisms; therefore, the VPN NAT policy displays just like manually configured object NAT policies. This example uses 95.1.226.4 as the assigned IP and 75.1.224.21 as the peer’s public IP:

```
hostname# show nat
Auto NAT Policies (Section 2)
1 (outside) to (inside) source static _vpn_nat_95.1.226.4 75.1.224.21
  translate_hits = 315, untranslate_hits = 315

prompt# show nat detail
Auto NAT Policies (Section 2)
1 (outside) to (inside) source static _vpn_nat_95.1.226.4 75.1.224.21
  translate_hits = 315, untranslate_hits = 315
  Source = Origin: 95.1.226.4/32, Translated: 75.1.224.21/32
```

*Outside* is the interface to which the AnyConnect client connects and *inside* is the interface specific to the new tunnel group.
Since VPN NAT policies are dynamic and not added to the configuration, the VPN NAT object and NAT policy are hidden from the show run object and show run nat reports.

Configure VPN Session Limits

You can run as many IPsec and SSL VPN sessions as your platform and ASA license supports. To view the licensing information including maximum sessions for your ASA, enter the `show version` command in global configuration mode and look for the licensing section. The following example shows the command and the licensing information from the output of this command; the other output is redacted for clarity.

```
hostname(config)# show version
...
Licensed features for this platform:
Maximum Physical Interfaces : Unlimited perpetual
Maximum VLANs : 500 perpetual
Inside Hosts : Unlimited perpetual
Failover : Active/Active perpetual
Encryption-DES : Enabled perpetual
Encryption-3DES-AES : Enabled perpetual
Security Contexts : 100 perpetual
Carrier : Enabled perpetual
AnyConnect Premium Peers : 5000 perpetual
AnyConnect Essentials : 5000 perpetual
Other VPN Peers : 5000 perpetual
Total VPN Peers : 5000 perpetual
AnyConnect for Mobile : Enabled perpetual
AnyConnect for Cisco VPN Phone : Enabled perpetual
Advanced Endpoint Assessment : Enabled perpetual
Shared License : Disabled perpetual
Total TLS Proxy Sessions : 3000 perpetual
Botnet Traffic Filter : Disabled perpetual
IPS Module : Disabled perpetual
Cluster : Enabled perpetual
Cluster Members : 2 perpetual

This platform has an ASA5555 VPN Premium license.
```

Show License Resource Allocation

Use the following command to show the resource allocation:

```
asa2(config)# sh resource allocation
Resource          Total    % of Avail
Conns[rate]       100(U)   0.00%
Inspects[rate]    unlimited
Syslogs[rate]     unlimited
Conns             unlimited
Hosts             unlimited
IPsec             unlimited
Mac-addresses     unlimited
ASDM              10       5.00%
SSH               10       10.00%
Telnet            10       10.0%
Xlates            unlimited
```
Show License Resource Usage

Use the following command to show resource usage:

```
 ASA(config-ca-trustpoint)# sh resource usage
```

You can also use the `sh resource usage system controller all 0` command to show system level usage with the limit as the platform limit.

<table>
<thead>
<tr>

Limit VPN Sessions

To limit AnyConnect VPN sessions (either IPsec/IKEv2 or SSL) to a lower value than the ASA allows, use the `vpn-sessiondb max-anyconnect-premium-or-essentials-limit` command in global configuration mode. To remove the session limit, use the `no` version of this command.

If the ASA license allows 500 SSL VPN sessions, and you want to limit the number of AnyConnect VPN sessions to 250, enter the following command:

```
hostname(config)# vpn-sessiondb max-anyconnect-premium-or-essentials-limit 250
```

To remove the session limit, use the `no` version of this command:

```
hostname(config)# no vpn-sessiondb max-anyconnect-premium-or-essentials-limit 250
```

Using an Identify Certificate When Negotiating

The ASA needs to use an identity certificate when negotiating the IKEv2 tunnel with AnyConnect clients. For ikev2 remote access trustpoint configuration, use the following commands

```
crypto ikev2 remote-access trustpoint <name> [line<number>]
```

Using this command allows the AnyConnect client to support group selection for the end user. You can configure two trustpoints at the same time: two RSA, two ECDSA, or one of each. The ASA scans the configured trustpoint list and chooses the first one that the client supports. If ECDSA is preferred, you should configure that trustpoint before the RSA trustpoint.
The line number option specifies where in the line number you want the trustpoint inserted. Typically, this option is used to insert a trustpoint at the top without removing and re-adding the other line. If a line is not specified, the ASA adds the trustpoint at the end of the list.

If you try to add a trustpoint that already exists, you receive an error. If you use the `no crypto ikev2 remote-access trustpoint` command without specifying which trustpoint name to remove, all trustpoint configuration is removed.

## Configure the Pool of Cryptographic Cores

You can change the allocation of cryptographic cores on Symmetric Multi-Processing (SMP) platforms to increase the throughput of AnyConnect TLS/DTLS traffic. These changes can accelerate the SSL VPN datapath and provide customer-visible performance gains in AnyConnect, smart tunnels, and port forwarding. These steps describe configuring the pool of cryptographic cores in either single or multiple context mode.

Cryptographic core re-balancing is available on the following platforms:

- 5545-X
- 5555-X

### Procedure

Specify how to allocate crypto accelerator processors:

`crypto engine accelerator-bias`

- **balanced** — Equally distributes cryptography hardware resources (Admin/SSL and IPsec cores).
- **ipsec** — Allocates cryptography hardware resources to favor IPsec (includes SRTP encrypted voice traffic).
- **ssl** — Allocates cryptography hardware resources to favor Admin/SSL.

### Example:

```
hostname(config)# crypto engine ?

configure mode commands/options:
accelerator-bias

hostname(config)# crypto engine accelerator-bias ?

configure mode commands/options
balanced - Equally distribute crypto hardware resources
ipsec - Allocate crypto hardware resources to favor IPsec/Encrypted Voice (SRTP)
ssl - Allocate crypto hardware resources to favor SSL

hostname(config)# crypto engine accelerator-bias ssl
```
# Configure Dynamic Split Tunneling

With dynamic split tunneling, you can dynamically provision split exclude tunneling after tunnel establishment based on the host DNS domain name. Dynamic split tunneling is configured by creating a custom attribute and adding it to a group policy.

## Before you begin

To use this feature, you must have AnyConnect release 4.5 (or later). Refer to [About Dynamic Split Tunneling](#) for further explanation.

## Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
</table>
| Step 1 | Define the custom attribute type in the WebVPN context with the following command: `anyconnect-custom-attr
dynamic-split-exclude-domains
description dynamic split exclude domains` | Purpose | |
| Step 2 | Define the custom attribute names for each cloud/web service that needs access by the client outside the VPN tunnel. For example, add Google_domains to represent a list of DNS domain names pertaining to Google web services. The attribute value contains the list of domain names to exclude from the VPN tunnel and must be comma-separated-values (CSV) format as the following:  

`anyconnect-custom-data
dynamic-split-exclude-domains webex.com,
webexconnect.com, tags.tiqcdn.com` | | |
| Step 3 | Attach the previously defined custom attribute to a certain policy group with the following command, executed in the group-policy attributes context: `anyconnect-custom
dynamic-split-exclude-domains value webex_service_domains` | | |

## What to do next

If split include tunneling is configured, a dynamic split exclusion is enforced only if at least one of the DNS response IP addresses is part of the split-include network. If there is no overlap between any of the DNS response IP addresses and any of the split-include networks, enforcing dynamic split exclusion is not necessary since traffic matching all DNS response IP addresses is already excluded from tunneling.
Configure the Management VPN Tunnel

A management VPN tunnel ensures connectivity to the corporate network whenever the client system is powered up, not just when a VPN connection is established by the end user. You can perform patch management on out-of-the-office endpoints, especially devices that are infrequently connected by the user, via VPN, to the office network. Endpoint OS login scripts which require corporate network connectivity will also benefit from this feature.

The management VPN tunnel is meant to be transparent to the end user; therefore, network traffic initiated by user applications is not impacted, by default, but instead directed outside the management VPN tunnel.

If a user complains of slow logins, it may be an indication that the management tunnel was not configured appropriately. Refer to the Cisco AnyConnect Secure Mobility Client Administration Guide for additional requirements, incompatibilities, limitations, and troubleshooting of management VPN tunnel.

Before you begin
Requires AnyConnect release 4.7 (or later)

Procedure

Step 1
Add the uploaded profile (*profileMgmt*) to the group policy (*MgmtTunGrpPolicy*) mapped to the tunnel group used by the management tunnel connection:

```plaintext
group-policy MgmtTunGrpPolicy attributes
webvpn
no anyconnect profiles value profileMgmt type user
anyconnect profiles value profileMgmt type vpn-mgmt
```

Step 2
To deploy the management VPN profile through user tunnel connection, add the uploaded profile (*profileMgmt*) to the group policy (*DfltGrpPolicy*) mapped to the tunnel group used by the user tunnel connection:

```plaintext
group-policy DfltGrpPolicy attributes
webvpn
no anyconnect profiles value profileMgmt type user
anyconnect profiles value profileMgmt type vpn-mgmt
```

Viewing Active VPN Sessions

The following topics explain how to view VPN session information.
Viewing Active AnyConnect Sessions by IP Address Type

To view active AnyConnect sessions using the command line interface, enter the `show vpn-sessiondb anyconnect filter p-ipversion` or `show vpn-sessiondb anyconnect filter a-ipversion` command in privileged EXEC mode.

- Display the active AnyConnect sessions which are filtered by the endpoint’s public IPv4 or IPv6 address. The public address is the address assigned to the endpoint by the enterprise.

  `show vpn-sessiondb anyconnect filter p-ipversion {v4 | v6}`

- Display the active AnyConnect sessions which are filtered by the endpoint’s assigned IPv4 or IPv6 address. The assigned address is the address assigned to the AnyConnect Secure Mobility Client by the ASA.

  `show vpn-sessiondb anyconnect filter a-ipversion {v4 | v6}`

Example Output from `show vpn-sessiondb anyconnect filter p-ipversion [v4 | v6]` command

```
hostname(config)# show vpn-sessiondb anyconnect filter p-ipversion v4

Session Type: AnyConnect
Username : user1  Index : 40
Assigned IP : 192.168.17.10  Public IP : 198.51.100.1
Protocol : AnyConnect-Parent SSL-Tunnel
License : AnyConnect Premium
Encryption : AnyConnect-Parent: (1)none SSL-Tunnel: (1)RC4
Hashing : AnyConnect-Parent: (1)none SSL-Tunnel: (1)SHA1
Bytes Tx : 10570  Bytes Rx : 8085
Group Policy : GroupPolicy_SSLACCLIENT
Tunnel Group : SSLACCLIENT
Login Time : 15:17:12 UTC Mon Oct 22 2012
Duration : 0h:00m:09s
Inactivity : 0h:00m:00s
NAC Result : Unknown
VLAN Mapping : N/A  VLAN : none
```

Output from `show vpn-sessiondb anyconnect filter a-ipversion [v4 | v6]` command

```
hostname(config)# show vpn-sessiondb anyconnect filter a-ipversion v6

Session Type: AnyConnect
Username : user1  Index : 45
Assigned IP : 192.168.17.10
Assigned IPv6: 2001:DB8:9:1::24
Protocol : AnyConnect-Parent SSL-Tunnel
License : AnyConnect Premium
Encryption : AnyConnect-Parent: (1)none SSL-Tunnel: (1)RC4
Hashing : AnyConnect-Parent: (1)none SSL-Tunnel: (1)SHA1
Bytes Tx : 10662  Bytes Rx : 17248
Group Policy : GroupPolicy_SSL_IPv6 Tunnel Group : SSL_IPv6
Login Time : 17:42:42 UTC Mon Oct 22 2012
```
Viewing Active Clientless SSL VPN Sessions by IP Address Type

To view active clientless SSL VPN sessions using the command line interface, enter the `show vpn-sessiondb webvpn filter ipversion` command in privileged EXEC mode.

The public address is the address assigned to the endpoint by the enterprise.

```
show vpn-sessiondb webvpn filter ipversion {v4 | v6}
```

**Examples**

```
hostname# sh vpn-sessiondb webvpn filter ipversion v4
```

**Viewing Active LAN to LAN VPN Sessions by IP Address Type**

To view active clientless SSL VPN sessions using the command line interface, enter the `show vpn-sessiondb l2l filter ipversion` command in privileged EXEC mode.

This command shows active LAN to LAN VPN sessions filtered by the connection’s public IPv4 or IPv6 address.

The public address is the address assigned to the endpoint by the enterprise.

```
show vpn-sessiondb l2l filter ipversion {v4 | v6}
```

**About ISE Policy Enforcement**

The Cisco Identity Services Engine (ISE) is a security policy management and control platform. It automates and simplifies access control and security compliance for wired, wireless, and VPN connectivity. Cisco ISE is primarily used to provide secure access and guest access, support bring your own device (BYOD) initiatives, and enforce usage policies in conjunction with Cisco TrustSec.
The ISE Change of Authorization (CoA) feature provides a mechanism to change the attributes of an authentication, authorization, and accounting (AAA) session after it is established. When a policy changes for a user or user group in AAA, CoA packets can be sent directly to the ASA from the ISE to reinitialize authentication and apply the new policy. An Inline Posture Enforcement Point (IPEP) is not required to apply access control lists (ACLs) for each VPN session established with the ASA.

ISE policy enforcement is supported on the following VPN clients:

- IPSec
- AnyConnect
- L2TP/IPSec

Some policy elements such as Dynamic ACL (dACL) and Security Group Tag (SGT) are supported, whereas policy elements such as VLAN assignment and IP address assignment are not supported.

The system flow is as follows:

1. An end user requests a VPN connection.
2. The ASA authenticates the user to the ISE and receives a user ACL that provides limited access to the network.
3. An accounting start message is sent to the ISE to register the session.
4. Posture assessment occurs directly between the NAC agent and the ISE. This process is transparent to the ASA.
5. The ISE sends a policy update to the ASA via a CoA “policy push.” This identifies a new user ACL that provides increased network access privileges.

Additional policy evaluations may occur during the lifetime of the connection, transparent to the ASA, via subsequent CoA updates.

### Configure RADIUS Server Groups for ISE Policy Enforcement

To enable ISE policy assessment and enforcement, configure a RADIUS AAA server group for the ISE servers and add the servers to the group. When you configure the tunnel group for the VPN, you specify this server group for AAA services in the group.

#### Procedure

**Step 1** Create the RADIUS AAA server group.

```
aaa-server group_name protocol radius
```

```bash
hostname(config)# aaa-server servergroup1 protocol radius
```
Configure RADIUS Server Groups for ISE Policy Enforcement

Step 2
Enable the RADIUS dynamic authorization (CoA) services for the AAA server group.

```
dynamic-authorization [port number]
```

Specifying a port is optional. The default is 1700, the range is 1024 to 65535.

When you use the server group in a VPN tunnel, the RADIUS server group will be registered for CoA notification and the ASA will listen to the port for the CoA policy updates from ISE.

```
dynamic-authorization
```

Step 3
If you do not want to use ISE for authentication, enable authorize-only mode for the RADIUS server group.

```
authorize-only
```

This indicates that when this server group is used for authorization, the RADIUS Access Request message will be built as an “Authorize Only” request as opposed to the configured password methods defined for the AAA server. If you do configure a common password using `radius-common-pw` command for the RADIUS server, it will be ignored.

For example, you would use authorize-only mode if you want to use certificates for authentication rather than this server group. You would still use this server group for authorization and accounting in the VPN tunnel.

```
authorize-only
```

Step 4
Enable the periodic generation of RADIUS interim-accounting-update messages.

```
interim-accounting-update [periodic [hours]]
```

ISE maintains a directory of active sessions based on the accounting records that it receives from NAS devices like the ASA. However, if ISE does not receive any indication that the session is still active (accounting message or posture transactions) for a period of 5 days, it will remove the session record from its database. To ensure that long-lived VPN connections are not removed, configure the group to send periodic interim-accounting-update messages to ISE for all active sessions.

- `periodic [hours]` enables the periodic generation and transmission of accounting records for every VPN session that is configured to send accounting records to the server group in question. You can optionally include the interval, in hours, for sending these updates. The default is 24 hours, the range is 1 to 120.

- (No parameters.) If you use this command without the `periodic` keyword, the ASA sends interim-accounting-update messages only when a VPN tunnel connection is added to a clientless VPN session. When this happens the accounting update is generated in order to inform the RADIUS server of the newly assigned IP address.

```
interim-accounting-update periodic 12
```

Step 5
(Optional.) Merge a downloadable ACL with the ACL received in the Cisco AV pair from a RADIUS packet.

```
merge-dacl {before-avpair | after-avpair}
```

This option applies only to VPN connections. For VPN users, ACLs can be in the form of Cisco AV pair ACLs, downloadable ACLs, and an ACL that is configured on the ASA. This option determines whether or not to merge these ACLs.
not the downloadable ACL and the AV pair ACL are merged, and does not apply to any ACLs configured on the ASA.

The default setting is **no merge dacl**, which specifies that downloadable ACLs will not be merged with Cisco AV pair ACLs. If both an AV pair and a downloadable ACL are received, the AV pair has priority and is used.

The **before-avpair** option specifies that the downloadable ACL entries should be placed before the Cisco AV pair entries.

The **after-avpair** option specifies that the downloadable ACL entries should be placed after the Cisco AV pair entries.

```
hostname(config)# aaa-server servergroup1 protocol radius
hostname(config-aaa-server-group)# merge-dacl before-avpair
```

**Step 6** (Optional.) Specify the maximum number of requests sent to a RADIUS server in the group before trying the next server.

```
max-failed-attempts number
```

The range is from 1 and 5. The default is 3.

If you configured a fallback method using the local database (for management access only), and all the servers in the group fail to respond, then the group is considered to be unresponsive, and the fallback method is tried. The server group remains marked as unresponsive for a period of 10 minutes (by default), so that additional AAA requests within that period do not attempt to contact the server group, and the fallback method is used immediately. To change the unresponsive period from the default, see the **reactivation-mode** command in the next step.

If you do not have a fallback method, the ASA continues to retry the servers in the group.

```
hostname(config-aaa-server-group)# max-failed-attempts 2
```

**Step 7** (Optional.) Specify the method (reactivation policy) by which failed servers in a group are reactivated.

```
reactivation-mode {depletion [deadtime minutes] | timed}
```

Where:

- **depletion [deadtime minutes]** reactivates failed servers only after all of the servers in the group are inactive. This is the default reactivation mode. You can specify the amount of time, between 0 and 1440 minutes, that elapses between the disabling of the last server in the group and the subsequent reenabling of all servers. The default is 10 minutes.

- **timed** reactivates failed servers after 30 seconds of down time.

```
hostname(config-aaa-server-group)# reactivation-mode deadtime 20
```

**Step 8** (Optional.) Send accounting messages to all servers in the group.

```
accounting-mode simultaneous
```

To restore the default of sending messages only to the active server, enter the **accounting-mode single** command.
Step 9  Add the ISE RADIUS servers to the group.

```bash
aaa-server group_name [(interface_name)] host {server_ip | name} [key]
```

Where:

- `group_name` is the name of the RADIUS server group.
- `(interface_name)` is the name of the interface through which the server is reached. The default is (inside). The parentheses are required.
- `host {server_ip | name}` is the IP address or the hostname of the ISE RADIUS server.
- `key` is the optional key for encrypting the connection. You can more easily enter this key on the `key` command after entering the `aaa-server-host` mode. If you do not configure a key, the connection is not encrypted (plaintext). The key is a case-sensitive, alphanumeric string of up to 127 characters that is the same value as the key on the RADIUS server.

You can add more than one server to the group.

```bash
hostname(config)# aaa-server servergroup1 (inside) host 10.1.1.3
hostname(config-aaa-server-host)# key sharedsecret
hostname(config-aaa-server-host)# exit
```

### Example Configurations for ISE Policy Enforcement

#### Configure VPN Tunnel for ISE Dynamic Authentication with Passwords

The following example shows how to configure an ISE server group for dynamic authorization (CoA) updates and hourly periodic accounting. Included is the tunnel group configuration that configures password authentication with ISE.

```bash
ciscoasa(config)# aaa-server ise protocol radius
ciscoasa(config-aaa-server-group)# interim-accounting-update periodic 1
ciscoasa(config-aaa-server-group)# dynamic-authorization
ciscoasa(config-aaa-server-group)# exit
ciscoasa(config)# aaa-server ise (inside) host 10.1.1.3
ciscoasa(config-aaa-server-host)# key sharedsecret
ciscoasa(config-aaa-server-host)# exit
ciscoasa(config)# tunnel-group aaa-coa general-attributes
ciscoasa(config-tunnel-general)# address-pool vpn
ciscoasa(config-tunnel-general)# authentication-server-group ise
ciscoasa(config-tunnel-general)# accounting-server-group ise
ciscoasa(config-tunnel-general)# exit
```
Configure VPN Tunnel for ISE Authorization-Only

The following example shows how to configure a tunnel group for local certificate validation and authorization with ISE. Include the `authorize-only` command in the server group configuration, because the server group will not be used for authentication.

ciscoasa(config)# aaa-server ise protocol radius
ciscoasa(config-aaa-server-group)# authorize-only
ciscoasa(config-aaa-server-group)# interim-accounting-update periodic 1
ciscoasa(config-aaa-server-group)# dynamic-authorization
ciscoasa(config-aaa-server-group)# exit
ciscoasa(config)# aaa-server ise (inside) host 10.1.1.3
  ciscoasa(config-aaa-server-host)# key sharedsecret
  ciscoasa(config-aaa-server-host)# exit
  ciscoasa(config)# tunnel-group aaa-coa general-attributes
    ciscoasa(config-tunnel-general)# address-pool vpn
    ciscoasa(config-tunnel-general)# authentication certificate
    ciscoasa(config-tunnel-general)# authorization-server-group ise
    ciscoasa(config-tunnel-general)# accounting-server-group ise
    ciscoasa(config-tunnel-general)# exit

Troubleshooting Policy Enforcement

The following commands can be used for debugging.
To trace CoA activity:

```
diag radius dynamic-authorization
```

To trace redirect URL functionality:

```
diag aaa url-redirect
```

To view NP classification rules corresponding to URL redirect functionality:

```
show asp table classify domain url-redirect
```

Configure Advanced SSL Settings

The ASA uses the Secure Sockets Layer (SSL) protocol and the Transport Layer Security (TLS) to support secure message transmission for ASDM, Clientless SSL VPN, VPN, and browser-based sessions. The ASA supports the SSLv3, TLSv1, TLSv1.1, and TLSv1.2 protocols for SSL-based VPN and management connections. In addition, DTLS is used for AnyConnect VPN client connections.

The following ciphers are supported as noted:

<table>
<thead>
<tr>
<th>Cipher</th>
<th>TLSv1.1 / DTLS V1</th>
<th>TLSV1.2 / DTLSV 1.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>AES128-GCM-SHA256</td>
<td>no</td>
<td>yes</td>
</tr>
<tr>
<td>AES128-SHA</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>AES128-SHA256</td>
<td>no</td>
<td>yes</td>
</tr>
</tbody>
</table>
### Configure Advanced SSL Settings

<table>
<thead>
<tr>

<td>no</td>
</tr>
</tbody>
</table>

**Note**

For Release 9.4(1), all SSLv3 keywords have been removed from the ASA configuration, and SSLv3 support has been removed from the ASA. If you have SSLv3 enabled, a boot-time error will appear from the command with the SSLv3 option. The ASA will then revert to the default use of TLSv1.

To specify the minimum protocol version for which the ASA will negotiate SSL/TLS and DTLS connections, perform the following steps:
Procedure

Step 1
Set the minimum protocol version for which the ASA will negotiate a connection.

```
ssl server-version [tlsv1 | tlsv1.1 | tlsv1.2] [dtlsv1 | dtlsv1.2]
```

Where:

- **tlsv1** — Enter this keyword to accept SSLv2 Client Hellos and negotiate TLSv1 (or greater)
- **tlsv1.1** — Enter this keyword to accept SSLv2 Client Hellos and negotiate TLSv1.1 (or greater)
- **tlsv1.2** — Enter this keyword to accept SSLv2 Client Hellos and negotiate TLSv1.2 (or greater)
- **dtlsv1** — Enter this keyword to accept DTLSv1 Client Hellos and negotiate DTLSv1 (or greater)
- **dtlsv1.2** — Enter this keyword to accept DTLSv1.2 Client Hellos and negotiate DTLSv1.2 (or greater)

**Note**  The configuration and use of DTLS applies to Cisco AnyConnect remote access connections only.

Ensure the TLS session is as secure, or more secure than the DTLS session by using an equal or higher version of TLS than DTLS. Given this, tlsv1.2 is the only acceptable TLS version when choosing dtls1.2; and any TLS version can be used with dtls1 since they are all equal to or greater than DTLS 1.0.

**Example:**

```
hostname(config)# ssl server-version tlsv1.1
hostname(config)# ssl server-version tlsv1.2 dtls1.2
```

Step 2
Specify the SSL/TLS protocol version that the ASA uses when acting as a client.

```
ssl client-version [tlsv1 | tlsv1.1 | tlsv1.2]
```

```
hostname(config)# ssl client-version tlsv1
```

The tlsv1 keyword specifies that the ASA transmit TLSv1 client hellos and negotiate TLSv1 (or greater). The tlsv1.1 keyword specifies that the ASA transmit TLSv1.1 client hellos and negotiate TLSv1.1 (or greater). The tlsv1.2 keyword specifies that the ASA transmit TLSv1.2 client hellos and negotiate TLSv1.2 (or greater). (DTLS not available for SSL client role).

Step 3
Specify the encryption algorithms for the SSL, DTLS, and TLS protocols.

```
ssl cipher version [ level | custom string]
```

Where:

- The **version** argument specifies the SSL, DTLS, or TLS protocol version. Supported versions include:
  - **default** — The set of ciphers for outbound connections.
  - **dtlsv1** — The ciphers for DTLSv1 inbound connections.
  - **dtlsv1.2** — The ciphers for DTLSv1.2 inbound connections.
Configure Advanced SSL Settings

- `tlsv1`—The ciphers for TLSv1 inbound connections.
- `tlsv1.1`—The ciphers for TLSv1.1 inbound connections.
- `tlsv1.2`—The ciphers for TLSv1.2 inbound connections.

- The **level** argument specifies the strength of the ciphers and indicates the minimum level of ciphers that are configured. Valid values in increasing order of strength are:
  - `all`—Includes all ciphers.
  - `low`—Includes all ciphers except NULL-SHA.
  - `medium` (this is the default for all protocol versions)—Includes all ciphers (except NULL-SHA, DES-CBC-SHA, RC4-MD5, RC4-SHA, and DES-CBC3-SHA).
  - `fips`—Includes all FIPS-compliant ciphers (except NULL-SHA, DES-CBC-SHA, RC4-MD5, RC4-SHA, and DES-CBC3-SHA).
  - `high` (applies only to TLSv1.2)—Includes only AES-256 with SHA-2 ciphers.

- Specifying the **custom string** option allows you to have full control of the cipher suite using OpenSSL cipher definition strings. For more information, see [https://www.openssl.org/docs/apps/ciphers.html](https://www.openssl.org/docs/apps/ciphers.html).

The recommended setting is **medium**. Using **high** may limit connectivity. Using custom may limit functionality if there are only a few ciphers configured. Restricting the default custom value limits outbound connectivity, including clustering.

The ASA specifies the order of priority for supported ciphers. See the command reference for more information. This command replaces the `ssl encryption` command, which has been deprecated starting with Version 9.3(2).

**Step 4**

Allow multiple trustpoints on a single interface.

```
ssl trust-point name [ interface vpnlb-ip ] domain domain-name
```

hostname(config)# ssl trust-point www-cert domain www.example.com

The **name** argument specifies the name of the trustpoint. The **interface** argument specifies the name of the interface on which a trustpoint is configured. The `vpnlb-ip` keyword applies only to interfaces and associates this trustpoint with the VPN load-balancing cluster IP address on this interface. The **domain/domain-name** keyword-argument pair specifies a trustpoint that is associated with a particular domain name that is used to access the interface.

You may configure a maximum of 16 trustpoints per interface.

If you do not specify an interface or domain, this command creates the fallback trustpoint for all interfaces that do not have a trustpoint configured.

If you enter the `ssl trustpoint ?` command, the available configured trustpoints appear. If you enter the `ssl trust-point name ?` command (for example, `ssl trust-point mysslcert ?`), the available configured interfaces for the trustpoint-SSL certificate association appear.

Observe these guidelines when using this command:

- The value for trustpoint must be the name of the CA trustpoint as configured in the `crypto ca trustpoint name` command.
- The value for interface must be the name of a previously configured interface.
Removing a trustpoint also removes any `ssl trust-point` entries that reference that trustpoint.

You can have one `ssl trust-point` entry for each interface and one that specifies no interfaces.

You can reuse the same trustpoint for multiple entries.

A trustpoint configured with the domain keyword may apply to multiple interfaces (depending on how you connect).

You may only have one `ssl trust-point` per `domain-name` value.

If the following error appears after you enter this command:

```
error:0B080074:x509 certificate routines:X509_check_private_key:key values mismatch@x509_cmp.c:339
```

It means that a user has configured a new certificate to replace a previously configured certificate. No action is required.

The certificates are chosen in the following order:

- If a connection matches the value of the `domain` keyword, that certificate is chosen first. (`ssl trust-point namedomain domain-name` command)
- If a connection is made to the load-balancing address, the vpnlb-ip certificate is chosen. (`ssl trust-point name interface vpnlb-ip` command)
- The certificate configured for the interface. (`ssl trust-point name` interface command)
- The default certificate not associated with an interface. (`ssl trust-point name`)
- The ASA's self-signed, self-generated certificate.

**Step 5** Specify the DH group to be used with DHE-RSA ciphers that are used by TLS.

```
ssl dh-group [group14 | group15 | group16 | group 19 | group 20 | group21]
```

```
hostname(config)# ssl dh-group group14
```

The group14, 15, 16, 19, 20, and 21 keyword configures DH group 14 (2048-bit modulus, 224-bit prime order subgroup).

Group 14 is not compatible with Java 7. All groups are compatible with Java 8. Groups 14 is FIPS-compliant. The default value is `ssl dh-group group14`.

**Step 6** Specify the group to be used with ECDHE-ECDSA ciphers that are used by TLS.

```
ssl ecdh-group [group19 | group20 | group21]
```

```
hostname(config)# ssl ecdh-group group20
```

The group19 keyword configures group 19 (256-bit EC). The group20 keyword configures group 20 (384-bit EC). The group21 keyword configures group 21 (521-bit EC).

The default value is `ssl ecdh-group group19`. 

Note  ECDSA and DHE ciphers are the highest priority.

Example

Persistent IPsec Tunneled Flows

In networks running a version of ASA software prior to Release 8.0.4, existing IPsec LAN-to-LAN or Remote-Access TCP traffic flows going through an IPSec tunnel are dropped when the tunnel drops. The flows are recreated as needed when and if the tunnel comes back up. This policy works well from the resource-management and security standpoints. However, there are cases in which such behavior introduces issues for users, particularly for those migrating from PIX to ASA-only environments and for legacy TCP applications that do not restart easily or in networks that include gateways that tend to drop tunnels frequently. (See CSCsj40681 and CSCsi47630 for details.)

The persistent IPsec tunneled flows feature addresses this issue. With this feature enabled, the ASA preserves and resumes stateful (TCP) tunneled flows. All other flows are dropped when the tunnel drops and must reestablish when a new tunnel comes up.

Note  This feature supports IPsec LAN-to-LAN tunnels and IPsec Remote-Access tunnels running in Network-Extension Mode. It does not support IPsec or AnyConnect/SSL VPN remote access tunnels.

The following example shows how the persistent IPsec tunneled flows feature works.

Figure 5: Network Scenario

In this example the BXB and RTP networks are connected through a secure LAN-to-LAN tunnel by a pair of security appliances. A PC in the BXB network is executing an FTP transfer from a server in the RTP network through the secure tunnel. In this scenario, assume that for some reason the tunnel drops after the PC has logged into the server and started the transfer. Although the tunnel is be reestablished since the data is still attempting to flow, the FTP transfer will not complete. The user must terminate the transfer and start over by logging back into the server. However, if persistent IPsec tunnel flows is enabled, as long as the tunnel is recreated within the timeout interval, the data continues to flow successfully through the new tunnel because the security appliances retain the history (state information) for this flow.
Scenario

The following sections describe the data flow situations for a dropped and recovered tunnel, first with the persistent IPsec tunneled flows feature disabled, then with the feature enabled. In both of these cases, see the preceding figure for an illustration of the network. In this illustration:

- Flow B-C defines the tunnel and carries the encrypted ESP data.
- Flow A-D is the TCP connection for the FTP transfer and traverses the tunnel defined by flow B-C. This flow also contains state information used by the firewall to inspect the TCP/FTP flow. The state information is vital and is constantly updated by the firewall as the transfer progresses.

**Note**

The reverse flows in each direction are omitted for simplicity.

Disabled Persistent IPsec Tunneled Flows

When the LAN-2-LAN tunnel drops, both flow A-D and flow B-C and any state information belonging to them are deleted. Subsequently, the tunnel is reestablished, and flow B-C is recreated and is able to resume carrying tunneled data. But the TCP/FTP flow A-D runs into trouble. Because the state information describing the flow up to this point in the FTP transfer has been deleted, the stateful firewall blocks the in-flight FTP data and rejects the flow A-D creation. Having lost the history of this flow ever existing, the firewall treats the FTP transfer as stray TCP packets and drops them. This is the default behavior.

Enabled Persistent IPsec Tunneled Flows

With the persistent IPsec tunneled flows feature enabled, as long as the tunnel is recreated within the timeout window, data continues flowing successfully because the ASA still has access to the state information in flow A-D.

With this feature enabled, the ASA treats the flows independently. This means that flow A-D is not deleted when the tunnel defined by flow B-C is dropped. The ASA preserves and resumes stateful (TCP) tunneled flows. All other flows are dropped and must reestablish on the new tunnel. This does not weaken the security policy for tunneled flows, because the ASA drops any packets arriving on flow A-D while the tunnel is down.

Tunneled TCP flows are not dropped, so they rely on the TCP timeout for cleanup. However, if the timeout is disabled for a particular tunneled flow, that flow remains in the system until being cleared manually or by other means (for example, by a TCP RST from the peer).

Configure Persistent IPsec Tunneled Flows Using CLI

Configuration Example

Troubleshooting Persistent IPsec Tunneled Flows

Both the `show asp table` and the `show conn` commands can be useful in troubleshooting issues with persistent IPsec tunneled flows.
Is the Persistent IPsec Tunneled Flows Feature Enabled?

To see whether a particular tunnel has this feature enabled, look at the VPN context associated with the tunnel using the `show asp table` command. The `show asp table vpn-context` command displays a “+PRESERVE” flag for each context that maintains stateful flows after the tunnel drops, as shown in the following example (bolding added for legibility):

```
hostname(config)# show asp table vpn-context
VPN CTX=0x0005FF54, Ptr=0x6DE62DA0, DECR+ESP+PRESERVE, UP, pk=0000000000, rk=0000000000, gc=0
VPN CTX=0x0005B234, Ptr=0x6DE635E0, ENCR+ESP+PRESERVE, UP, pk=0000000000, rk=0000000000, gc=0
```

```
hostname(config)# show asp table vpn-context detail
VPN CTX = 0x0005FF54
Peer IP = ASA_Private
Pointer = 0x6DE62DA0
State = UP
Flags = DECR+ESP+PRESERVE
SA = 0x001659BF
SPI = 0xB326496C
Group = 0
Pkts = 0
Bad Pkts = 0
Bad SPI = 0
Spoof = 0
Bad Crypto = 0
Rekey Pkt = 0
Rekey Call = 0
VPN CTX = 0x0005B234
Peer IP = ASA_Private
Pointer = 0x6DE635E0
State = UP
Flags = ENCR+ESP+PRESERVE
SA = 0x0017988D
SPI = 0x9AA50F43
Group = 0
Pkts = 0
Bad Pkts = 0
Bad SPI = 0
Spoof = 0
Bad Crypto = 0
Rekey Pkt = 0
Rekey Call = 0
```

Locating Orphaned Flows

If a LAN-to-LAN/Network-Extension-Mode tunnel drops and does not recover before the timeout, there might be a number of orphaned tunnel flows. These flows are not torn down as a result of the tunnel going down, but all the data attempting to flow through them is dropped. To see these flows, use the `show conn` command, as in the following examples (bolding added for emphasis and to show user input):
asa2(config)# show conn detail
9 in use, 14 most used
Flags: A - awaiting inside ACK to SYN, a - awaiting outside ACK to SYN,
B - initial SYN from outside, C - CTIQBE media, D = DNS, d = dump,
E - outside back connection, F - outside FIN, f - inside FIN,
G - group, g - MGCP, H - H.323, h - H.225.0, I - inbound data,
i - incomplete, J - GTP, j - GTP data, K = GTP t3-response
k - Skinny media, M - SMTP data, m - SIP media, n = GUP
O - outbound data, P - inside back connection, p - Phone-proxy TFTP connection,
q = SQL*Net data, R - outside acknowledged FIN,
r - inside acknowledged FIN, S - awaiting inside SYN,
s - awaiting outside SYN, T - SIP, t - SIP transient, U - up,
V = VPN orphan, W = WAAS,
X - inspected by service module

The following example shows sample output from the show conn command when an orphan flow exists, as
indicated by the V flag:

hostname# show conn
16 in use, 19 most used
TCP out 192.168.110.251:7393 in 192.168.150.252:21 idle 0:00:00 bytes 1048 flags UOVB
TCP out 192.168.110.251:21137 in 192.168.150.252:21 idle bytes 1048 flags UIOB

To limit the report to those connections that have orphan flows, add the vpn_orphan option to the show conn
state command, as in the following example:

hostname# show conn state vpn_orphan
14 in use, 19 most used
TCP out 192.168.110.251:7393 in 192.168.150.252:21 idle 0:00:00 bytes 2841019 flags UOVB
Connection Profiles, Group Policies, and Users

This chapter describes how to configure VPN connection profiles (formerly called “tunnel groups”), group policies, and users. This chapter includes the following sections.

• Overview of Connection Profiles, Group Policies, and Users, on page 99
• Connection Profiles, on page 100
• Configure Connection Profiles, on page 104
• Group Policies, on page 140
• Use of a Zone Labs Integrity Server, on page 178
• Configure User Attributes, on page 185

Overview of Connection Profiles, Group Policies, and Users

Groups and users are core concepts in managing the security of virtual private networks (VPNs) and in configuring the ASA. They specify attributes that determine user access to and use of the VPN. A group is a collection of users treated as a single entity. Users get their attributes from group policies. A connection profile identifies the group policy for a specific connection. If you do not assign a particular group policy to a user, the default group policy for the connection applies.

In summary, you first configure connection profiles to set the values for the connection. Then you configure group policies. These set values for users in the aggregate. Then you configure users, which can inherit values from groups and configure certain values on an individual user basis. This chapter describes how and why to configure these entities.

You configure connection profiles using tunnel-group commands. In this chapter, the terms “connection profile” and “tunnel group” are often used interchangeably.

Connection profiles and group policies simplify system management. To streamline the configuration task, the ASA provides a default LAN-to-LAN connection profile (DefaultL2Lgroup), a default remote access connection profile for IKEv2 VPN (DefaultRAgroup), a default connection profile for Clientless SSL and AnyConnect SSL connections (DefaultWEBVPGROUP), and a default group policy (DfltGrpPolicy). The default connection profiles and group policy provide settings are likely to be common for many users. As you add users, you can specify that they “inherit” parameters from a group policy. Thus you can quickly configure VPN access for large numbers of users.
If you decide to grant identical rights to all VPN users, then you do not need to configure specific connection profiles or group policies, but VPNs seldom work that way. For example, you might allow a finance group to access one part of a private network, a customer support group to access another part, and an MIS group to access other parts. In addition, you might allow specific users within MIS to access systems that other MIS users cannot access. Connection profiles and group policies provide the flexibility to do so securely.

The ASA also includes the concept of object groups, which are a superset of network lists. Object groups let you define VPN access to ports as well as networks. Object groups relate to ACLs rather than to group policies and connection profiles. For more information about using object groups, see Chapter 20, "Objects" in the general operations configuration guide.

The security appliance can apply attribute values from a variety of sources. It applies them according to the following hierarchy:

1. Dynamic Access Policy (DAP) record
2. Username
3. Group policy
4. Group policy for the connection profile
5. Default group policy

Therefore, DAP values for an attribute have a higher priority than those configured for a user, group policy, or connection profile.

When you enable or disable an attribute for a DAP record, the ASA applies that value and enforces it. For example, when you disable HTTP proxy in dap webvpn configuration mode, the ASA looks no further for a value. When you instead use the no value for the http-proxy command, the attribute is not present in the DAP record, so the security appliance moves down to the AAA attribute in the username, and if necessary, to the group policy and finds a value to apply. The ASA clientless SSL VPN configuration supports only one http-proxy and one https-proxy command each. We recommend that you use ASDM to configure DAP.

Connection Profiles

A connection profile consists of a set of records that determines tunnel connection policies. These records identify the servers to which the tunnel user is authenticated, as well as the accounting servers, if any, to which connection information is sent. They also identify a default group policy for the connection, and they contain protocol-specific connection parameters. Connection profiles include a small number of attributes that pertain to creating the tunnel itself. Connection profiles include a pointer to a group policy that defines user-oriented attributes.

The ASA provides the following default connection profiles: DefaultL2Lgroup for LAN-to-LAN connections, DefaultRAgroup for IPSEC remote access connections, and DefaultWEBVPNGroup for SSL VPN (browser-based and AnyConnect Client based) connections. You can modify these default connection profiles, but you cannot delete them. You can also create one or more connection profiles specific to your environment. Connection profiles are local to the ASA and are not configurable on external servers.
Some profiles (such as IKEv1 in phase 1) may be unable to determine whether an endpoint is remote access or LAN-to-LAN. If it cannot determine the tunnel group, it defaults to:

```
tunnel-group-map default-group <tunnel-group-name>
```

(default is DefaultRAGroup).

### General Connection Profile Connection Parameters

General parameters are common to all VPN connections. The general parameters include the following:

- **Connection profile name**—You specify a connection-profile name when you add or edit a connection profile. The following considerations apply:
  - For clients that use preshared keys to authenticate, the connection profile name is the same as the group name that a client passes to the ASA.
  - Clients that use certificates to authenticate pass this name as part of the certificate, and the ASA extracts the name from the certificate.

- **Connection type**—Connection types include IKEv1 remote-access, IPsec LAN-to-LAN, and AnyConnect (SSL/IKEv2). A connection profile can have only one connection type.

- **Authentication, Authorization, and Accounting servers**—These parameters identify the server groups or lists that the ASA uses for the following purposes:
  - Authenticating users
  - Obtaining information about services users are authorized to access
  - Storing accounting records

A server group can consist of one or more servers.

- **Default group policy for the connection**—A group policy is a set of user-oriented attributes. The default group policy is the group policy whose attributes the ASA uses as defaults when authenticating or authorizing a tunnel user.

- **Client address assignment method**—This method includes values for one or more DHCP servers or address pools that the ASA assigns to clients.

- **Password management**—This parameter lets you warn a user that the current password is due to expire in a specified number of days (the default is 14 days), then offer the user the opportunity to change the password.

- **Strip group and strip realm**—These parameters direct the way the ASA processes the usernames it receives. They apply only to usernames received in the form user@realm.

A realm is an administrative domain appended to a username with the @ delimiter (user@abc). If you strip the realm, the ASA uses the username and the group (if present) for authentication. If you strip the group, the ASA uses the username and the realm (if present) for authentication.

Enter the strip-realm command to remove the realm qualifier, and enter the strip-group command to remove the group qualifier from the username during authentication. If you remove both qualifiers,
authentication is based on the username alone. Otherwise, authentication is based on the full
username@realm or username<delimiter> group string. You must specify strip-realm if your server is
unable to parse delimiters.

In addition, for L2TP/IPsec clients only, when you specify the strip-group command the ASA selects
the connection profile (tunnel group) for user connections by obtaining the group name from the username
presented by the VPN client.

• Authorization required—This parameter lets you require authorization before a user can connect, or turn
off that requirement.

• Authorization DN attributes—This parameter specifies which Distinguished Name attributes to use when
performing authorization.

IPsec Tunnel-Group Connection Parameters

IPsec parameters include the following:

• A client authentication method: preshared keys, certificates, or both.
  • For IKE connections based on preshared keys, this is the alphanumeric key itself (up to 128 characters
    long), associated with the connection policy.
  • Peer-ID validation requirement—This parameter specifies whether to require validating the identity
    of the peer using the peer’s certificate.
  • If you specify certificates or both for the authentication method, the end user must provide a valid
    certificate in order to authenticate.

• An extended hybrid authentication method: XAUTH and hybrid XAUTH.
  You use isakmp ikev1-user-authentication command to implement hybrid XAUTH authentication
  when you need to use digital certificates for ASA authentication and a different, legacy method for remote
  VPN user authentication, such as RADIUS, TACACS+ or SecurID.

• ISAKMP (IKE) keepalives settings. This feature lets the ASA monitor the continued presence of a remote
  peer and report its own presence to that peer. If the peer becomes unresponsive, the ASA removes the
  connection. Enabling IKE keepalives prevents hung connections when the IKE peer loses connectivity.

There are various forms of IKE keepalives. For this feature to work, both the ASA and its remote peer
must support a common form. This feature works with the following peers:

  • Cisco AnyConnect VPN Client
  • Cisco IOS software
  • Cisco Secure PIX Firewall

  Non-Cisco VPN clients do not support IKE keepalives.

If you are configuring a group of mixed peers, and some of those peers support IKE keepalives and
others do not, enable IKE keepalives for the entire group. The feature does not affect the peers that
do not support it.
If you disable IKE keepalives, connections with unresponsive peers remain active until they time out, so we recommend that you keep your idle timeout short. To change your idle timeout, see Configure Group Policies, on page 143.

Note

To reduce connectivity costs, disable IKE keepalives if this group includes any clients connecting via ISDN lines. ISDN connections normally disconnect if idle, but the IKE keepalive mechanism prevents connections from idling and therefore from disconnecting.

If you do disable IKE keepalives, the client disconnects only when either its IKE or IPsec keys expire. Failed traffic does not disconnect the tunnel with the Peer Timeout Profile values as it does when IKE keepalives are enabled.

If you have a LAN-to-LAN configuration using IKE main mode, make sure that the two peers have the same IKE keepalive configuration. Both peers must have IKE keepalives enabled or both peers must have it disabled.

• If you configure authentication using digital certificates, you can specify whether to send the entire certificate chain (which sends the peer the identity certificate and all issuing certificates) or just the issuing certificates (including the root certificate and any subordinate CA certificates).

• You can notify users who are using outdated versions of Windows client software that they need to update their client, and you can provide a mechanism for them to get the updated client version. You can configure and change the client-update, either for all connection profiles or for particular connection profiles.

• If you configure authentication using digital certificates, you can specify the name of the trustpoint that identifies the certificate to send to the IKE peer.

Connection Profile Connection Parameters for SSL VPN Sessions

The table below provides a list of connection profile attributes that are specific to SSL VPN (AnyConnect client and clientless) connections. In addition to these attributes, you configure general connection profile attributes common to all VPN connections. For step-by-step information about configuring connection profiles, see Configure Connection Profiles for Clientless SSL VPN Sessions, on page 121.

Note

In earlier releases, “connection profiles” were known as “tunnel groups.” You configure a connection profile with tunnel-group commands. This chapter often uses these terms interchangeably.

## Configure Connection Profiles

This section describes the contents and configuration of connection profiles in both single-context mode or multiple-context mode.
Multiple-context mode applies only to IKEv2 and IKEv1 site to site and does not apply to AnyConnect, Clientless SSL VPN, legacy Cisco VPN client, the Apple native VPN client, the Microsoft native VPN client, or cTCP for IKEv1 IPsec.

You can modify the default connection profiles, and you can configure a new connection profile as any of the three tunnel-group types. If you do not explicitly configure an attribute in a connection profile, that attribute gets its value from the default connection profile. The default connection-profile type is remote access. The subsequent parameters depend upon your choice of tunnel type. To see the current configured and default configuration of all your connection profiles, including the default connection profile, enter the `show running-config all tunnel-group` command.

**Maximum Connection Profiles**

The maximum number of connection profiles (tunnel groups) that an ASA can support is a function of the maximum number of concurrent VPN sessions for the platform + 5. Attempting to add an additional tunnel group beyond the limit results in the following message: “ERROR: The limit of 30 configured tunnel groups has been reached.”

**Default IPsec Remote Access Connection Profile Configuration**

The contents of the default remote-access connection profile are as follows:

```
tunnel-group DefaultRAGroup type remote-access
tunnel-group DefaultRAGroup general-attributes
    no address-pool
    no ipv6-address-pool
    authentication-server-group LOCAL
    accounting-server-group RADIUS
    default-group-policy DfltGrpPolicy
    no dhcp-server
    no strip-realm
    no override-account-disable
    no strip-group
    no authorization-required
    authorization-dn-attributes CN OU
    tunnel-group DefaultRAGroup webvpn-attributes
    hic-fail-group-policy DfltGrpPolicy
    customization DfltCustomization
    authentication aaa
    no override-svc-download
    no radius-reject-message
    dns-group DefaultDNS
    tunnel-group DefaultRAGroup ipsec-attributes
        no pre-shared-key
        peer-id-validate req
        no chain
        no trust-point
        isakmp keepalive threshold 1500 retry 2
        no radius-sdi-xauth
        isakmp ikev1-user-authentication xauth
    tunnel-group DefaultRAGroup ppp-attributes
        no authentication pap
        authentication chap
```
IPsec Tunnel-Group General Attributes

The general attributes are common across more than one tunnel-group type. IPsec remote access and clientless SSL VPN tunnels share most of the same general attributes. IPsec LAN-to-LAN tunnels use a subset. Refer to the Cisco ASA Series Command Reference for complete descriptions of all commands. This section describes, in order, how to configure remote-access and LAN-to-LAN connection profiles.

Configure Remote-Access Connection Profiles

Use a remote-access connection profile when setting up a connection between the following remote clients and a central-site ASA:

- AnyConnect Secure Mobility Client (connecting with SSL or IPsec/IKEv2)
- Clientless SSL VPN (browser-based connecting with SSL)
- Cisco ASA 5500 Easy VPN hardware client (connecting with IPsec/IKEv1)

We also provide a default group policy named DfltGrpPolicy.
To configure a remote-access connection profile, first configure the tunnel-group general attributes, then the remote-access attributes. See the following sections:

- Specify a Name and Type for the Remote Access Connection Profile, on page 107.
- Configure Remote-Access Connection Profile General Attributes, on page 107.
- Configure Double Authentication, on page 111
- Configure Remote-Access Connection Profile IPsec IKEv1 Attributes, on page 113.
- Configure IPsec Remote-Access Connection Profile PPP Attributes, on page 115

Specify a Name and Type for the Remote Access Connection Profile

Procedure

Create the connection profile, specifying its name and type, by entering the **tunnel-group** command.

For a remote-access tunnel, the type is **remote-access**.

```
tunnel-group tunnel_group_name type remote-access
```

**Example:**

For example, to create a remote-access connection profile named TunnelGroup1, enter the following command:

```
hostname(config)# tunnel-group TunnelGroup1 type remote-access
hostname(config)#
```

Configure Remote-Access Connection Profile General Attributes

To configure or change the connection profile general attributes, specify the parameters in the following steps:

**Procedure**

**Step 1**

To configure the general attributes, enter the **tunnel-group general-attributes** task in either single or multiple context mode, which enters tunnel-group general-attributes configuration mode. The prompt changes to indicate the change in mode.

```
thostname(config)# tunnel-group tunnel_group_name general-attributes
hostname(config-tunnel-general)#
```

**Step 2**

Specify the name of the authentication-server group, if any, to use. If you want to use the LOCAL database for authentication if the specified server group fails, append the keyword **LOCAL**:

```
hostname(config-tunnel-general)# authentication-server-group [(interface_name)] groupname [LOCAL]
hostname(config-tunnel-general)#
```
The name of the authentication server group can be up to 16 characters long.
You can optionally configure interface-specific authentication by including the name of an interface after the group name. The interface name, which specifies where the tunnel terminates, must be enclosed in parentheses. The following command configures interface-specific authentication for the interface named test using the server named servergroup1 for authentication:

```
hostname(config-tunnel-general)# authentication-server-group (test) servergroup1
```

**Step 3**
Specify the name of the authorization-server group, if any, to use. When you configure this value, users must exist in the authorization database to connect:

```
hostname(config-tunnel-general)# authorization-server-group groupname
```

The name of the authorization server group can be up to 16 characters long. For example, the following command specifies the use of the authorization-server group FinGroup:

```
hostname(config-tunnel-general)# authorization-server-group FinGroup
```

**Step 4**
Specify the name of the accounting-server group, if any, to use:

```
hostname(config-tunnel-general)# accounting-server-group groupname
```

The name of the accounting server group can be up to 16 characters long. For example, the following command specifies the use of the accounting-server group named comptroller:

```
hostname(config-tunnel-general)# accounting-server-group comptroller
```

**Step 5**
Specify the name of the default group policy:

```
hostname(config-tunnel-general)# default-group-policy policynname
```

The name of the group policy can be up to 64 characters long. The following example sets DfltGrpPolicy as the name of the default group policy:

```
hostname(config-tunnel-general)# default-group-policy DfltGrpPolicy
```

**Step 6**
Specify the names or IP addresses of the DHCP server (up to 10 servers), and the names of the DHCP address pools (up to 6 pools). The defaults are no DHCP server and no address pool. The dhcp-server command will allow you to configure the ASA to send additional options to the specified DHCP servers when it is trying to get IP addresses for VPN clients. See the dhcp-server command in the Cisco ASA Series Command Reference guide for more information.
If you specify an interface name, you must enclose it within parentheses.

You configure address pools with the `ip local pool` command in global configuration mode.

**Step 7**

Specify the name of the NAC authentication server group, if you are using Network Admission Control, to identify the group of authentication servers to be used for Network Admission Control posture validation. Configure at least one Access Control Server to support NAC. Use the `aaa-server` command to name the ACS group. Then use the `nac-authentication-server-group` command, using the same name for the server group.

The following example identifies `acs-group1` as the authentication server group to be used for NAC posture validation:

```
hostname(config-group-policy)# nac-authentication-server-group acs-group1
hostname(config-group-policy)
```

The following example inherits the authentication server group from the default remote access group:

```
hostname(config-group-policy)# no nac-authentication-server-group
hostname(config-group-policy)
```

**Note** NAC requires a Cisco Trust Agent on the remote host.

**Step 8**

Specify whether to strip the group or the realm from the username before passing it on to the AAA server. The default is not to strip either the group name or the realm:

```
hostname(config-tunnel-general)# strip-group
hostname(config-tunnel-general)# strip-realm
hostname(config-tunnel-general)#
```

A realm is an administrative domain. If you strip the realm, the ASA uses the username and the group (if present) authentication. If you strip the group, the ASA uses the username and the realm (if present) for authentication. Enter the `strip-realm` command to remove the realm qualifier, and use the `strip-group` command to remove the group qualifier from the username during authentication. If you remove both qualifiers, authentication is based on the `username` alone. Otherwise, authentication is based on the full `username@realm` or `username<delimiter>group` string. You must specify `strip-realm` if your server is unable to parse delimiters.

**Step 9**

Optionally, if your server is a RADIUS, RADIUS with NT, or LDAP server, you can enable password management.
If you are using an LDAP directory server for authentication, password management is supported with the Sun Microsystems JAVA System Directory Server (formerly named the Sun ONE Directory Server) and the Microsoft Active Directory.

Sun—The DN configured on the ASA to access a Sun directory server must be able to access the default password policy on that server. We recommend using the directory administrator, or a user with directory administrator privileges, as the DN. Alternatively, you can place an ACI on the default password policy.

Microsoft—You must configure LDAP over SSL to enable password management with Microsoft Active Directory.

This feature, which is disabled by default, warns a user when the current password is about to expire. The default is to begin warning the user 14 days before expiration:

```
hostname(config-tunnel-general)# password-management
hostname(config-tunnel-general)#
```

If the server is an LDAP server, you can specify the number of days (0 through 180) before expiration to begin warning the user about the pending expiration:

```
hostname(config-tunnel-general)# password-management [password-expire in days n]
hostname(config-tunnel-general)#
```

Note The `password-management` command, entered in tunnel-group general-attributes configuration mode replaces the deprecated `radius-with-expiry` command that was formerly entered in tunnel-group `ipsec-attributes` mode.

When you configure the `password-management` command, the ASA notifies the remote user at login that the user’s current password is about to expire or has expired. The ASA then offers the user the opportunity to change the password. If the current password has not yet expired, the user can still log in using that password. The ASA ignores this command if RADIUS or LDAP authentication has not been configured.

Note that this does not change the number of days before the password expires, but rather, the number of days ahead of expiration that the ASA starts warning the user that the password is about to expire.

If you do specify the `password-expire-in-days` keyword, you must also specify the number of days.

Specifying this command with the number of days set to 0 disables this command. The ASA does not notify the user of the pending expiration, but the user can change the password after it expires.

See Configure Microsoft Active Directory Settings for Password Management, on page 136 for more information.

The ASA Version 7.1 and later generally supports password management for the AnyConnect VPN Client, the Cisco IPsec VPN Client, the SSL VPN full-tunneling client, and Clientless connections when authenticating with LDAP or with any RADIUS connection that supports MS-CHAPv2. Password management is not supported for any of these connection types for Kerberos/AD (Windows password) or NT 4.0 Domain.

Some RADIUS servers that support MS-CHAP do not currently support MS-CHAPv2. The `password-management` command requires MS-CHAPv2, so please check with your vendor.
The RADIUS server (for example, Cisco ACS) could proxy the authentication request to another authentication server. However, from the ASA perspective, it is talking only to a RADIUS server.

For LDAP, the method to change a password is proprietary for the different LDAP servers on the market. Currently, the ASA implements the proprietary password management logic only for Microsoft Active Directory and Sun LDAP servers. Native LDAP requires an SSL connection. You must enable LDAP over SSL before attempting to do password management for LDAP. By default, LDAP uses port 636.

**Step 10**

Specify the attribute or attributes to use in deriving a name for an authorization query from a certificate. This attribute specifies what part of the subject DN field to use as the username for authorization:

```
hostname(config-tunnel-general)# authorization-dn-attributes (primary-attribute [secondary-attribute] | use-entire-name)
```

For example, the following command specifies the use of the CN attribute as the username for authorization:

```
hostname(config-tunnel-general)# authorization-dn-attributes CN
```

The authorization-dn-attributes are:
- **C** (Country)
- **CN** (Common Name)
- **DNQ** (DN Qualifier)
- **EA** (E-mail Address)
- **GENQ** (Generational Qualifier)
- **GN** (Given Name)
- **I** (Initials)
- **L** (Locality)
- **N** (Name)
- **O** (Organization)
- **OU** (Organizational Unit)
- **SER** (Serial Number)
- **SN** (Surname)
- **SP** (State/Province)
- **T** (Title)
- **UID** (User ID)
- **UPN** (User Principal Name).

**Step 11**

Step 12

Specify whether to require a successful authorization before allowing a user to connect. The default is not to require authorization.

```
hostname(config-tunnel-general)# authorization-required
```

---

**Configure Double Authentication**

Double authentication is an optional feature that requires a user to enter an additional authentication credential, such as a second username and password, on the login screen. Specify the following commands to configure double authentication.

**Procedure**

**Step 1**

Specify the secondary authentication server group. This command specifies the AAA server group to use as the secondary AAA server.

```
hostname(config-tunnel-general)# secondary-authentication-server-group groupname
```

**Note**

This command applies only to AnyConnect client VPN connections.

The secondary server group cannot specify an SDI server group. By default, no secondary authentication is required.
hostname(config-tunnel-general)# secondary-authentication-server-group [interface_name] {none | LOCAL | groupname [LOCAL]} [use-primary-name]

If you use the none keyword, no secondary authentication is required. The groupname value specifies the AAA server group name. Local specifies the use of the internal server database, and when used with the groupname value, LOCAL specifies fallback.

For example, to set the primary authentication server group to sdigroup and the secondary authentication server group to ldaps_server, enter the following commands:

hostname(config-tunnel-general)# authentication-server-group
hostname(config-tunnel-general)# secondary-authentication-server-group

Note If you use the use-primary-name keyword, then the login dialog requests only one username. In addition, if the usernames are extracted from a digital certificate, only the primary username is used for authentication.

Step 2 If obtaining the secondary username from a certificate, enter secondary-username-from-certificate:

hostname(config-tunnel-general)# secondary-username-from-certificate C | CN | ... | use-script

The values for the DN fields to extract from the certificate for use as a secondary username are the same as for the primary username-from-certificate command. Alternatively, you can specify the use-script keyword, which directs the ASA to use a script file generated by ASDM.

For example, to specify the Common Name as the primary username field and Organizational Unit as the secondary username field, enter the following commands:

hostname(config-tunnel-general)# tunnel-group test1 general-attributes
hostname(config-tunnel-general)# username-from-certificate cn
hostname(config-tunnel-general)# secondary-username-from-certificate ou

Step 3 Use the secondary-pre-fill-username command in tunnel-group webvpng-attributes mode to enable extracting a secondary username from a client certificate for use in authentication. Use the keywords to specify whether this command applies to a clientless connection or an SSL VPN (AnyConnect) client connection and whether you want to hide the extracted username from the end user. This feature is disabled by default. Clientless and SSL-client options can both exist at the same time, but you must configure them in separate commands.

hostname(config-tunnel-general)# secondary-pre-fill-username-from-certificate {clientless | client} [hide]

For example, to specify the use of pre-fill-username for both the primary and secondary authentication for a connection, enter the following commands:

hostname(config-tunnel-general)# tunnel-group test1 general-attributes
hostname(config-tunnel-general)# pre-fill-username client
hostname(config-tunnel-general)# secondary-pre-fill-username client
Step 4 Specify which authentication server to use to obtain the authorization attributes to apply to the connection. The primary authentication server is the default selection. This command is meaningful only for double authentication.

```
hostname(config-tunnel-general)# authentication-attr-from-server {primary | secondary}
```

For example, to specify the use of the secondary authentication server, enter the following commands:

```
hostname(config-tunnel-general)# tunnel-group test1 general-attributes
hostname(config-tunnel-general)# authentication-attr-from-server secondary
```

Step 5 Specify which authentication username, primary or secondary, to associate with the session. The default value is primary. With double authentication enabled, it is possible that two distinct usernames are authenticated for the session. The administrator must designate one of the authenticated usernames as the session username. The session username is the username provided for accounting, session database, syslogs, and debug output.

```
hostname(config-tunnel-general)# authenticated-session-username {primary | secondary}
```

For example, to specify that the authentication username associated with the session must come from the secondary authentication server, enter the following commands:

```
hostname(config-tunnel-general)# tunnel-group test1 general-attributes
hostname(config-tunnel-general)# authenticated-session-username secondary
```

---

**Configure Remote-Access Connection Profile IPsec IKEv1 Attributes**

To configure the IPsec IKEv1 attributes for a remote-access connection profile, perform the following steps. The following description assumes that you have already created the remote-access connection profile. Remote-access connection profiles have more attributes than LAN-to-LAN connection profiles.

**Procedure**

**Step 1** To specify the IPsec attributes of an remote-access tunnel-group, enter tunnel-group ipsec-attributes mode by entering the following command in either single or multiple context mode. The prompt changes to indicate the mode change.

```
hostname(config)# tunnel-group tunnel-group-name ipsec-attributes
```

This command enters tunnel-group ipsec-attributes configuration mode, in which you configure the remote-access tunnel-group IPsec attributes in either single or multiple context mode.

For example, the following command designates that the tunnel-group ipsec-attributes mode commands that follow pertain to the connection profile named TG1. Notice that the prompt changes to indicate that you are now in tunnel-group ipsec-attributes mode:

```
hostname(config)# tunnel-group TG1 type remote-access
```
Configure Remote-Access Connection Profile IPsec IKEv1 Attributes

**Step 2** Specify the preshared key to support IKEv1 connections based on preshared keys. For example, the following command specifies the preshared key xyzx to support IKEv1 connections for an IPsec IKEv1 remote access connection profile:

```
hostname(config-tunnel-ipsec)# ikev1 pre-shared-key xyzx
```

**Step 3** Specify whether to validate the identity of the peer using the peer’s certificate:

```
hostname(config-tunnel-ipsec)# peer-id-validate option
```

The possible `option` values are `req` (required), `cert` (if supported by certificate), and `nocheck` (do not check). The default is `req`.

For example, the following command specifies that peer-id validation is required:

```
hostname(config-tunnel-ipsec)# peer-id-validate req
```

**Step 4** Specify whether to enable sending of a certificate chain. The following command includes the root certificate and any subordinate CA certificates in the transmission:

```
hostname(config-tunnel-ipsec)# chain
```

This attribute applies to all IPsec tunnel-group types.

**Step 5** Specify the name of a trustpoint that identifies the certificate to be sent to the IKE peer:

```
hostname(config-tunnel-ipsec)# ikev1 trust-point trust-point-name
```

The following command specifies mytrustpoint as the name of the certificate to be sent to the IKE peer:

```
hostname(config-ipsec)# ikev1 trust-point mytrustpoint
```

**Step 6** Specify the ISAKMP keepalive threshold and the number of retries allowed:

```
hostname(config-tunnel-ipsec)# isakmp keepalive threshold <number> retry <number>
```

The `threshold` parameter specifies the number of seconds (10 through 3600) that the peer is allowed to idle before beginning keepalive monitoring. The `retry` parameter is the interval (2 through 10 seconds) between retries after a keepalive response has not been received. IKE keepalives are enabled by default. To disable ISAKMP keepalives, enter `isakmp keepalive disable`. 
For example, the following command sets the IKE keepalive threshold value to 15 seconds and sets the retry interval to 10 seconds:

```
hostname(config-tunnel-ipsec)# isakmp keepalive threshold 15 retry 10
hostname(config-tunnel-ipsec)#
```

The default value for the `threshold` parameter is 300 for remote-access and 10 for LAN-to-LAN, and the default value for the `retry` parameter is 2.

To specify that the central site (secure gateway) should never initiate ISAKMP monitoring, enter the following command:

```
hostname(config-tunnel-ipsec)# isakmp keepalive threshold infinite
hostname(config-tunnel-ipsec)#
```

**Step 7** Specify the ISAKMP hybrid authentication method, XAUTH or hybrid XAUTH.

You use the `isakmp ikev1-user-authentication` command to implement hybrid XAUTH authentication when you need to use digital certificates for ASA authentication and a different, legacy method for remote VPN user authentication, such as RADIUS, TACACS+ or SecurID. Hybrid XAUTH breaks phase 1 of IKE down into the following two steps, together called hybrid authentication:

- The ASA authenticates to the remote VPN user with standard public key techniques. This establishes an IKE security association that is unidirectionally authenticated.
- An XAUTH exchange then authenticates the remote VPN user. This extended authentication can use one of the supported legacy authentication methods.

**Note** Before the authentication type can be set to hybrid, you must configure the authentication server, create a preshared key, and configure a trustpoint.

You can use the `isakmp ikev1-user-authentication` command with the optional interface parameter to specify a particular interface. When you omit the interface parameter, the command applies to all the interfaces and serves as a back-up when the per-interface command is not specified. When there are two `isakmp ikev1-user-authentication` commands specified for a connection profile, and one uses the `interface` parameter and one does not, the one specifying the interface takes precedence for that particular interface.

For example, the following commands enable hybrid XAUTH on the inside interface for a connection profile called example-group:

```
hostname(config)# tunnel-group example-group type remote-access
tunnel-group example-group type remote-access
hostname(config)#
hostname(config)# tunnel-group example-group ipsec-attributes
hostname(config-tunnel-ipsec)#
hostname(config-tunnel-ipsec)#
hostname(config-tunnel-ipsec)#
hostname(config-tunnel-ipsec)#
```

---

**Configure IPsec Remote-Access Connection Profile PPP Attributes**

To configure the Point-to-Point Protocol attributes for a remote-access connection profile, perform the following steps. PPP attributes apply only to IPsec remote-access connection profiles. The following description assumes that you have already created the IPsec remote-access connection profile.
Procedure

**Step 1**  
Enter tunnel-group ppp-attributes configuration mode, in which you configure the remote-access tunnel-group PPP attributes, by entering the following command. The prompt changes to indicate the mode change:

```sh
hostname(config)# tunnel-group tunnel-group-name type remote-access
hostname(config)# tunnel-group tunnel-group-name ppp-attributes
hostname(config-tunnel-ppp)#
```

For example, the following command designates that the tunnel-group ppp-attributes mode commands that follow pertain to the connection profile named TG1. Notice that the prompt changes to indicate that you are now in tunnel-group ppp-attributes mode:

```sh
hostname(config)# tunnel-group TG1 type remote-access
hostname(config)# tunnel-group TG1 ppp-attributes
hostname(config-tunnel-ppp)#
```

**Step 2**  
Specify whether to enable authentication using specific protocols for the PPP connection. The protocol value can be any of the following:

- **pap**—Enables the use of Password Authentication Protocol for the PPP connection.
- **chap**—Enables the use of Challenge Handshake Authentication Protocol for the PPP connection.
- **ms-chap-v1 or ms-chap-v2**—Enables the use of Microsoft Challenge Handshake Authentication Protocol, version 1 or version 2 for the PPP connection.
- **eap**—Enables the use of Extensible Authentication protocol for the PPP connection.

CHAP and MSCHAPv1 are enabled by default.

The syntax of this command is:

```sh
hostname(config-tunnel-ppp)# authentication protocol
hostname(config-tunnel-ppp)#
```

To disable authentication for a specific protocol, use the `no` form of the command:

```sh
hostname(config-tunnel-ppp)# no authentication protocol
hostname(config-tunnel-ppp)#
```

For example, the following command enables the use of the PAP protocol for a PPP connection:

```sh
hostname(config-tunnel-ppp)# authentication pap
hostname(config-tunnel-ppp)#
```

The following command enables the use of the MS-CHAP, version 2 protocol for a PPP connection:

```sh
hostname(config-tunnel-ppp)# authentication ms-chap-v2
hostname(config-tunnel-ppp)#
```
The following command enables the use of the EAP-PROXY protocol for a PPP connection:

```
hostname(config-tunnel-ppp)# authentication pap
hostname(config-tunnel-ppp)#
```

The following command disables the use of the MS-CHAP, version 1 protocol for a PPP connection:

```
hostname(config-tunnel-ppp)# no authentication ms-chap-v1
hostname(config-tunnel-ppp)#
```

### Configure LAN-to-LAN Connection Profiles

An IPsec LAN-to-LAN VPN connection profile applies only to LAN-to-LAN IPsec client connections. While many of the parameters that you configure are the same as for IPsec remote-access connection profiles, LAN-to-LAN tunnels have fewer parameters. The following sections show you how to configure a LAN-to-LAN connection profile:

- Specify a Name and Type for a LAN-to-LAN Connection Profile, on page 117
- Configure LAN-to-LAN Connection Profile General Attributes, on page 118
- Configure LAN-to-LAN IPsec IKEv1 Attributes, on page 118

### Default LAN-to-LAN Connection Profile Configuration

The contents of the default LAN-to-LAN connection profile are as follows:

```
tunnel-group DefaultL2LGroup type ipsec-l2l
tunnel-group DefaultL2LGroup general-attributes
default-group-policy DfltGrpPolicy
tunnel-group DefaultL2LGroup ipsec-attributes
   no ikev1 pre-shared-key
   peer-id-validate req
   no chain
   no ikev1 trust-point
   isakmp keepalive threshold 10 retry 2
```

LAN-to-LAN connection profiles have fewer parameters than remote-access connection profiles, and most of these are the same for both groups. For your convenience in configuring the connection, they are listed separately here. Any parameters that you do not explicitly configure inherit their values from the default connection profile.

### Specify a Name and Type for a LAN-to-LAN Connection Profile

To specify a name and a type for a connection profile, enter the `tunnel-group` command, as follows:

```
hostname(config)# tunnel-group tunnel_group_name type tunnel_type
```

For a LAN-to-LAN tunnel, the type is `ipsec-l2l`; for example, to create the LAN-to-LAN connection profile named `docs`, enter the following command:
Configure LAN-to-LAN Connection Profile General Attributes

To configure the connection profile general attributes, perform the following steps:

Procedure

**Step 1**
Enter tunnel-group general-attributes mode by specifying the general-attributes keyword in either single or multiple context mode:

```
tunnel-group tunnel-group-name general-attributes
```

**Example:**
For the connection profile named docs, enter the following command:

```
hostname(config)# tunnel-group docs general-attributes
hostname(config-tunnel-general)#
```

The prompt changes to indicate that you are now in config-general mode, in which you configure the tunnel-group general attributes.

**Step 2**
Specify the name of the default group policy:

```
default-group-policy policymame
```

**Example:**
The following command specifies that the name of the default group policy is MyPolicy:

```
hostname(config-tunnel-general)# default-group-policy MyPolicy
hostname(config-tunnel-general)#
```

Configure LAN-to-LAN IPsec IKEv1 Attributes

To configure the IPsec IKEv1 attributes, perform the following steps:

Procedure

**Step 1**
To configure the tunnel-group IPsec IKEv1 attributes, enter tunnel-group ipsec-attributes configuration mode by entering the tunnel-group command with the IPsec-attributes keyword in either single or multiple context mode.

```
tunnel-group tunnel-group-name ipsec-attributes
```

```
hostname(config)# tunnel-group tunnel-group-name ipsec-attributes
hostname(config-tunnel-ipsec)#
```
For example, the following command enters config-ipsec mode so that you can configure the parameters for the connection profile named TG1:

```
hostname(config)# tunnel-group TG1 ipsec-attributes
hostname(config-tunnel-ipsec)#
```

The prompt changes to indicate that you are now in tunnel-group ipsec-attributes configuration mode.

**Step 2** Specify the preshared key to support IKEv1 connections based on preshared keys.

```
hostname(config-tunnel-ipsec)# ikev1 pre-shared-key key
hostname(config-tunnel-ipsec)#
```

For example, the following command specifies the preshared key XYZX to support IKEv1 connections for an LAN-to-LAN connection profile:

```
hostname(config-tunnel-ipsec)# ikev1 pre-shared-key XYZX
hostname(config-tunnel-general)#
```

**Step 3** Specify whether to validate the identity of the peer using the peer’s certificate:

```
hostname(config-tunnel-ipsec)# peer-id-validate option
hostname(config-tunnel-ipsec)#
```

The available options are `req` (required), `cert` (if supported by certificate), and `nocheck` (do not check). The default is `req`. For example, the following command sets the peer-id-validate option to `nocheck`:

```
hostname(config-tunnel-ipsec)# peer-id-validate nocheck
hostname(config-tunnel-ipsec)#
```

**Step 4** Specify whether to enable sending of a certificate chain. This action includes the root certificate and any subordinate CA certificates in the transmission:

```
hostname(config-tunnel-ipsec)# chain
hostname(config-tunnel-ipsec)#
```

You can apply this attribute to all tunnel-group types.

**Step 5** Specify the name of a trustpoint that identifies the certificate to be sent to the IKE peer:

```
hostname(config-tunnel-ipsec)# trust-point trust-point-name
hostname(config-tunnel-ipsec)#
```

For example, the following command sets the trustpoint name to mytrustpoint:

```
hostname(config-tunnel-ipsec)# trust-point mytrustpoint
hostname(config-tunnel-ipsec)#
```

You can apply this attribute to all tunnel-group types.
Step 6  Specify the ISAKMP (IKE) keepalive threshold and the number of retries allowed. The threshold parameter specifies the number of seconds (10 through 3600) that the peer is allowed to idle before beginning keepalive monitoring. The retry parameter is the interval (2 through 10 seconds) between retries after a keepalive response has not been received. IKE keepalives are enabled by default. To disable IKE keepalives, enter the no form of the isakmp command:

```
hostname(config)# isakmp keepalive threshold <number> retry <number>
hostname(config-tunnel-ipsec)#
```

For example, the following command sets the ISAKMP keepalive threshold to 15 seconds and sets the retry interval to 10 seconds:

```
hostname(config-tunnel-ipsec)# isakmp keepalive threshold 15 retry 10
hostname(config-tunnel-ipsec)#
```

The default value for the threshold parameter for LAN-to-LAN is 10, and the default value for the retry parameter is 2.

To specify that the central site (secure gateway) should never initiate ISAKMP monitoring, enter the following command:

```
hostname(config-tunnel-ipsec)# isakmp keepalive threshold infinite
hostname(config-tunnel-ipsec)#
```

Step 7  Specify the ISAKMP hybrid authentication method, XAUTH or hybrid XAUTH.

You use isakmp ikev1-user-authentication command to implement hybrid XAUTH authentication when you need to use digital certificates for ASA authentication and a different, legacy method for remote VPN user authentication, such as RADIUS, TACACS+ or SecurID. Hybrid XAUTH breaks phase 1 of IKE down into the following two steps, together called hybrid authentication:

a) The ASA authenticates to the remote VPN user with standard public key techniques. This establishes an IKE security association that is unidirectionally authenticated.

b) An XAUTH exchange then authenticates the remote VPN user. This extended authentication can use one of the supported legacy authentication methods.

Note  Before the authentication type can be set to hybrid, you must configure the authentication server, create a preshared key, and configure a trustpoint.

For example, the following commands enable hybrid XAUTH for a connection profile called example-group:

```
hostname(config)# tunnel-group example-group type remote-access
hostname(config)# tunnel-group example-group ipsec-attributes
hostname(config-tunnel-ipsec)# isakmp ikev1-user-authentication hybrid
hostname(config-tunnel-ipsec)#
```
Configure Connection Profiles for Clientless SSL VPN Sessions

The tunnel-group general attributes for clientless SSL VPN connection profiles are the same as those for IPsec remote-access connection profiles, except that the tunnel-group type is webvpn and the **strip-group** and **strip-realm** commands do not apply. You define the attribute specific to clientless SSL VPN separately. The following sections describe how to configure clientless SSL VPN connection profiles:

- Configure General Tunnel-Group Attributes for Clientless SSL VPN Sessions, on page 121
- Configure Tunnel-Group Attributes for Clientless SSL VPN Sessions, on page 124

**Configure General Tunnel-Group Attributes for Clientless SSL VPN Sessions**

To configure or change the connection profile general attributes, specify the parameters in the following steps.

**Procedure**

**Step 1**
To configure the general attributes, enter **tunnel-group general-attributes** command, which enters tunnel-group general-attributes configuration mode in either single or multiple context mode. Note that the prompt changes:

```
hostname(config)# tunnel-group tunnel_group_name general-attributes
hostname(config-tunnel-general)#
```

To configure the general attributes for TunnelGroup3, created in the previous section, enter the following command:

```
hostname(config)# tunnel-group TunnelGroup3 general-attributes
hostname(config-tunnel-general)#
```

**Step 2**
Specify the name of the authentication-server group, if any, to use. If you want to use the LOCAL database for authentication if the specified server group fails, append the keyword LOCAL:

```
hostname(config-tunnel-general)# authentication-server-group groupname [LOCAL]
hostname(config-tunnel-general)#
```

For example, to configure the authentication server group named test, and to provide fallback to the LOCAL server if the authentication server group fails, enter the following command:

```
hostname(config-tunnel-general)# authentication-server-group test LOCAL
hostname(config-tunnel-general)#
```

The authentication-server-group name identifies a previously configured authentication server or group of servers. Use the **aaa-server** command to configure authentication servers. The maximum length of the group tag is 16 characters.

You can also configure interface-specific authentication by including the name of an interface in parentheses before the group name. The following interfaces are available by default:

- inside—Name of interface GigabitEthernet0/1
- outside—Name of interface GigabitEthernet0/0
Configure General Tunnel-Group Attributes for Clientless SSL VPN Sessions

Note The ASA’s outside interface address (for both IPv4/IPv6) cannot overlap with the private side address space.

Other interfaces you have configured (using the `interface` command) are also available. The following command configures interface-specific authentication for the interface named outside using the server servergroup1 for authentication:

```
hostname(config-tunnel-general)# authentication-server-group (outside) servergroup1
```

Step 3 Optionally, specify the name of the authorization-server group, if any, to use. If you are not using authorization, go to Step 6. When you configure this value, users must exist in the authorization database to connect:

```
hostname(config-tunnel-general)# authorization-server-group groupname
```

Use the `aaa-server` command to configure authorization servers. The maximum length of the group tag is 16 characters.

For example, the following command specifies the use of the authorization-server group FinGroup:

```
hostname(config-tunnel-general)# authorization-server-group FinGroup
```

Step 4 Specify whether to require a successful authorization before allowing a user to connect. The default is not to require authorization.

```
hostname(config-tunnel-general)# authorization-required
```

Step 5 Specify the attribute or attributes to use in deriving a name for an authorization query from a certificate. This attribute specifies what part of the subject DN field to use as the username for authorization:

```
hostname(config-tunnel-general)# authorization-dn-attributes {primary-attribute [secondary-attribute] | use-entire-name}
```

For example, the following command specifies the use of the CN attribute as the username for authorization:

```
hostname(config-tunnel-general)# authorization-dn-attributes CN
```

The authorization-dn-attributes are C (Country), CN (Common Name), DNQ (DN qualifier), EA (E-mail Address), GENQ (Generational qualifier), GN (Given Name), I (Initials), L (Locality), N (Name), O (Organization), OU (Organizational Unit), SER (Serial Number), SN (Surname), SP (State/Province), T (Title), UID (User ID), and UPN (User Principal Name).

Step 6 Optionally, specify the name of the accounting-server group, if any, to use. If you are not using accounting, go to Step 7. Use the `aaa-server` command to configure accounting servers. The maximum length of the group tag is 16 characters:

```
hostname(config-tunnel-general)# accounting-server-group groupname
```
For example, the following command specifies the use of the accounting-server group comptroller:

```
hostname(config-tunnel-general)# accounting-server-group comptroller
```

**Step 7**  
Optionally, specify the name of the default group policy. The default value is DfltGrpPolicy:

```
hostname(config-tunnel-general)# default-group-policy policynam
```

The following example sets MyDfltGrpPolicy as the name of the default group policy:

```
hostname(config-tunnel-general)# default-group-policy MyDfltGrpPolicy
```

**Step 8**  
Optionally, specify the name or IP address of the DHCP server (up to 10 servers), and the names of the DHCP address pools (up to 6 pools). Separate the list items with spaces. The defaults are no DHCP server and no address pool.

```
hostname(config-tunnel-general)# dhcp-server server1 [...server10]
hostname(config-tunnel-general)# address-pool [(interface name)] address_pool1 [...address_pool6]
```

**Note**  
The interface name must be enclosed in parentheses.

You configure address pools with the `ip local pool` command in global configuration mode. See IP Addresses for VPNS, on page 195 for information about configuring address pools.

**Step 9**  
Optionally, if your server is a RADIUS, RADIUS with NT, or LDAP server, you can enable password management.

**Note**  
If you are using an LDAP directory server for authentication, password management is supported with the Sun Microsystems JAVA System Directory Server (formerly named the Sun ONE Directory Server) and the Microsoft Active Directory.

- **Sun**—The DN configured on the ASA to access a Sun directory server must be able to access the default password policy on that server. We recommend using the directory administrator, or a user with directory administrator privileges, as the DN. Alternatively, you can place an ACI on the default password policy.

- **Microsoft**—You must configure LDAP over SSL to enable password management with Microsoft Active Directory.

This feature, which is enabled by default, warns a user when the current password is about to expire. The default is to begin warning the user 14 days before expiration:

```
hostname(config-tunnel-general)# password-management
```

```
If the server is an LDAP server, you can specify the number of days (0 through 180) before expiration to begin warning the user about the pending expiration:

```
hostname(config-tunnel-general)# password-management [password-expire in days n]
hostname(config-tunnel-general)#
```

**Note** The `password-management` command, entered in tunnel-group general-attributes configuration mode replaces the deprecated `radius-with-expiry` command that was formerly entered in tunnel-group ipsec-attributes mode.

When you configure this command, the ASA notifies the remote user at login that the user’s current password is about to expire or has expired. The ASA then offers the user the opportunity to change the password. If the current password has not yet expired, the user can still log in using that password. The ASA ignores this command if RADIUS or LDAP authentication has not been configured.

Note that this does not change the number of days before the password expires, but rather, the number of days ahead of expiration that the ASA starts warning the user that the password is about to expire.

If you do specify the `password-expire-in-days` keyword, you must also specify the number of days.

See Configure Microsoft Active Directory Settings for Password Management, on page 136 for more information.

---

**Configure Tunnel-Group Attributes for Clientless SSL VPN Sessions**

To configure the parameters specific to a clientless SSL VPN connection profile, follow the steps in this section. Clientless SSL VPN was formerly known as WebVPN, and you configure these attributes in tunnel-group webvpn-attributes mode.

**Procedure**

**Step 1** To specify the attributes of a clientless SSL VPN tunnel-group, enter tunnel-group webvpn-attributes mode by entering the following command. The prompt changes to indicate the mode change:

```
hostname(config)# tunnel-group tunnel-group-name webvpn-attributes
hostname(config-tunnel-ipsec)#
```

For example, to specify the webvpn-attributes for the clientless SSL VPN tunnel-group named sales, enter the following command:

```
hostname(config)# tunnel-group sales webvpn-attributes
hostname(config-tunnel-webvpn)#
```

**Step 2** To specify the authentication method to use: AAA, digital certificates, or both, enter the `authentication` command. You can specify either aaa or certificate or both, in any order.

```
hostname(config-tunnel-webvpn)# authentication authentication_method
hostname(config-tunnel-webvpn)#
```
For example, The following command allows both AAA and certificate authentication:

```
hostname(config-tunnel-webvpn)# authentication aaa certificate
```

**Step 3**

The ASA queries NetBIOS name servers to map NetBIOS names to IP addresses. Clientless SSL VPN requires NetBIOS to access or share files on remote systems. Clientless SSL VPN uses NetBIOS and the CIFS protocol to access or share files on remote systems. When you attempt a file-sharing connection to a Windows computer by using its computer name, the file server you specify corresponds to a specific NetBIOS name that identifies a resource on the network.

To make the NBNS function operational, you must configure at least one NetBIOS server (host). You can configure up to three NBNS servers for redundancy. The ASA uses the first server on the list for NetBIOS/CIFS name resolution. If the query fails, it uses the next server.

To specify the name of the NBNS (NetBIOS Name Service) server to use for CIFS name resolution, use the `nbns-server` command. You can enter up to three server entries. The first server you configure is the primary server, and the others are backups, for redundancy. You can also specify whether this is a master browser (rather than just a WINS server), the timeout interval, and the number of retries. A WINS server or a master browser is typically on the same network as the ASA, or reachable from that network. You must specify the timeout interval before the number of retries:

```
hostname(config-tunnel-webvpn)# nbns-server {host-name | IP_address} [master] [seconds] [retry number]
```

For example, to configure the server named nbnsprimary as the primary server and the server 192.168.2.2 as the secondary server, each allowing three retries and having a 5-second timeout, enter the following command:

```
hostname(config)# name 192.168.2.1 nbnsprimary
hostname(config-tunnel-webvpn)# nbns-server nbnsprimary master timeout 5 retry 3
hostname(config-tunnel-webvpn)# nbns-server 192.168.2.2 timeout 5 retry 3
```

The timeout interval can range from 1 through 30 seconds (default 2), and the number of retries can be in the range 0 through 10 (default 2).

The `nbns-server` command in tunnel-group webvpn-attributes configuration mode replaces the deprecated `nbns-server` command in webvpn configuration mode.

**Step 4**

To specify alternative names for the group, use the `group-alias` command. Specifying the group alias creates one or more alternate names by which the user can refer to a tunnel-group. The group alias that you specify here appears in the drop-down list on the user’s login page. Each group can have multiple aliases or no alias, each specified in separate commands. This feature is useful when the same group is known by several common names, such as “Devtest” and “QA.”

For each group alias, enter a `group-alias` command. Each alias is enabled by default. You can optionally explicitly enable or disable each alias:

```
hostname(config-tunnel-webvpn)# group-alias alias [enable | disable]
```

For example, to enable the aliases QA and Devtest for a tunnel-group named QA, enter the following commands:
hostname(config-tunnel-webvpn)# group-alias QA enable
hostname(config-tunnel-webvpn)# group-alias Devtest enable

Note: The webvpn tunnel-group-list must be enabled for the (dropdown) group list to appear.

Step 5

Specify incoming URLs or IP addresses for the group.

group-url url [enable | disable]

You can configure multiple URLs or addresses (or none) for a group. For each group URL or address, enter a group-url command. The url specifies a URL or IP address for this tunnel group. You must specify the entire URL or address, including either the http or https protocol. Each URL or address can be enabled (default) or disabled individually.

Specifying a group URL or IP address eliminates the need for the user to select a group at login. When a user logs in, the ASA looks for the user’s incoming URL or address in the tunnel-group-policy table. If it finds the URL or address and if group-url is enabled in the connection profile, then the ASA automatically selects the associated connection profile and presents the user with only the username and password fields in the login window. This simplifies the user interface and has the added advantage of never exposing the list of groups to the user. The login window that the user sees uses the customizations configured for that connection profile.

If the URL or address is disabled and group-alias is configured, then the dropdown list of groups is displayed, and the user must make a selection.

You cannot associate the same URL or address with multiple groups. The ASA verifies the uniqueness of the URL or address before accepting the URL or address for a connection profile.

Example:

To enable the group URLs http://www.example.com and http://192.168.10.10 for the tunnel-group named RadiusServer, enter the following commands:

hostname(config)# tunnel-group RadiusServer type webvpn
hostname(config)# tunnel-group RadiusServer general-attributes
hostname(config-tunnel-general)# authentication server-group RADIUS
hostname(config-tunnel-general)# accounting-server-group RADIUS
hostname(config-tunnel-general)# tunnel-group RadiusServer webvpn-attributes
hostname(config-tunnel-webvpn)# group-alias “Cisco Remote Access” enable
hostname(config-tunnel-webvpn)# group-url http://www.example.com enable
hostname(config-tunnel-webvpn)# group-url http://192.168.10.10 enable

For a more extensive example, see Customize Login Windows for Users of Clientless SSL VPN Sessions, on page 129.

A Load Balancing deployment that uses Group URLs for AnyConnect client connectivity, requires each ASA node in the cluster to configure a Group URL for the virtual cluster address, as well as a Group URL for the node’s Load Balancing public address.

Example:

Configure group-urls appropriately for a load balancing deployment with two ASA nodes in a cluster whose addresses are as follows:

• Virtual IP for Load Balancing = https://vip-vpn.example.com/groupname
The Tunnel-Group configuration on ASA1 must have the following group-url's configured:

```
hostname(config)# tunnel-group LB1 type webvpn
hostname(config)# tunnel-group LB1 general-attributes
hostname(config-tunnel-general)# group-url https://vip-vpn.example.com/groupname
hostname(config-tunnel-general)# group-url https://asa1.example.com/groupname
```

The Tunnel-Group configuration on ASA2 must have the following group-url's configured:

```
hostname(config)# tunnel-group LB2 type webvpn
hostname(config)# tunnel-group LB2 general-attributes
hostname(config-tunnel-general)# group-url https://vip-vpn.example.com/groupname
hostname(config-tunnel-general)# group-url https://asa2.example.com/groupname
```

Step 6 (Optional.) AnyConnect 4.6 introduced an enhanced version of SAML integration with an embedded browser which replaces the native (external) browser integration from previous releases. To allow AnyConnect clients earlier than release 4.6 to authenticate using SAML, enter `saml external browser`:

```
hostname(config)# tunnel-group [tunnel-group-name=webvpn-attributes]
hostname(config-tunnel-webvpn)# saml external browser
```

The default is to disable AnyConnect clients earlier than 4.6 from connecting over SAML. This option will be removed in subsequent releases.

Step 7 (Optional.) To exempt certain users from running the Hostscan application of Cisco Secure Desktop on a per connection profile basis if they enter one of the group URLs, enter the following command:

```
hostname(config-tunnel-webvpn)# without-csd [anyconnect]
hostname(config-tunnel-webvpn)#
```

Entering this command prevents the detection of endpoint conditions for these sessions, so you may need to adjust the dynamic access policy (DAP) configuration.

Include the `anyconnect` keyword if you want to limit the exemption to AnyConnect connections only. If you do not include the keyword, the exemption applies to clientless, Layer 3, and AnyConnect connections.

Step 8 To specify the DNS server group to use for a connection profile for clientless SSL VPN sessions, use the `dns-group` command. The group you specify must be one you already configured in global configuration mode (using the `dns server-group` and `name-server` commands).

By default, the connection profile uses the DNS server group DefaultDNS. However, this group must be configured before the security appliance can resolve DNS requests.

The following example configures a new DNS server group named corp_dns and specifies that server group for the connection profile telecommuters:

```
hostname(config)# dns server-group corp_dns
hostname(config-dns-server-group)# domain-name cisco.com
hostname(config-dns-server-group)# name-server 209.165.200.224
```
Step 9
(Optional) To enable extracting a username from a client certificate for use in authentication and authorization, use the `pre-fill-username` command in tunnel-group webvpn-attributes mode.

```
hostname(config)# pre-fill-username (client | clientless)
```

The `pre-fill-username` command enables the use of a username extracted from the certificate field specified in the `username-from-certificate` command (in tunnel-group general-attributes mode) as the username for username/password authentication and authorization. To use this pre-fill username from certificate feature, you must configure both commands.

**Note** In Version 8.0.4, the username is not pre-filled; instead, any data sent in the username field is ignored.

The following example, entered in global configuration mode, creates an IPsec remote access tunnel group named remotegrp, enables getting the username from a certificate, and specifies that the name for an authentication or authorization query for an SSL VPN client must be derived from a digital certificate:

```
hostname(config)# tunnel-group remotegrp type ipsec_ra
hostname(config)# tunnel-group remotegrp general-attributes
hostname(config-tunnel-general)# username-from-certificate CN OU
hostname(config)# tunnel-group remotegrp webvpn-attributes
hostname(config-tunnel-webvpn)# pre-fill-username client
```

Step 10
To enable extracting a secondary ername from a client certificate for use in authentication and authorization, use the `secondary-pre-fill-username` command in tunnel-group webvpn-attributes mode.

```
hostname(config)# secondary-pre-fill-username (client | clientless)
```

Step 11
(Optional) To specify whether to override the group policy or username attributes configuration for downloading an AnyConnect or SSL VPN client, use the `override-svc-download` command. This feature is disabled by default.

The security appliance allows clientless or AnyConnect client connections for remote users based on whether clientless and/or SSL VPN is enabled in the group policy or username attributes with the `vpn-tunnel-protocol` command. The `anyconnect ask` command further modifies the client user experience by prompting the user to download the client or return to the WebVPN home page.

However, you might want clientless users logging in under specific tunnel groups to not experience delays waiting for the download prompt to expire before being presented with the clientless SSL VPN home page. You can prevent delays for these users at the connection profile level with the `override-svc-download` command. This command causes users logging through a connection profile to be immediately presented with the clientless SSL VPN home page regardless of the `vpn-tunnel-protocol` or `anyconnect ask` command settings.

In the following example, you enter tunnel-group webvpn attributes configuration mode for the connection profile engineering and enable the connection profile to override the group policy and username attribute settings for client download prompts:
Step 12

(Optional) To enable the display of a RADIUS reject message on the login screen when authentication is rejected, use the `radius-eject-message` command.

The following example enables the display of a RADIUS rejection message for the connection profile named engineering:

```
hostname(config)# tunnel-group engineering webvpn-attributes
hostname(config-tunnel-webvpn)# override-svc-download
hostname(config-tunnel-webvpn)# radius-reject-message
```

---

**Customize Login Windows for Users of Clientless SSL VPN Sessions**

Customizations determine the appearance of the windows that the user sees upon login. You configure the customization parameters as part of configuring clientless SSL VPN. To apply a previously defined web-page customization to change the look-and-feel of the web page that the user sees at login, enter the customization command in group-policy webvpn configuration mode:

```
hostname(config-group-webvpn)# customization customization_name
```

For example, to use the customization named blueborder, enter the following command:

```
hostname(config-group-webvpn)# customization blueborder
```

You configure the customization itself by entering the `customization` command in webvpn mode.

The following example shows a command sequence that first establishes a customization named 123 that defines a password prompt. The example then defines a group policy named testpolicy and uses the `customization` command to specify the use of the customization named 123 for clientless SSL VPN sessions:

```
hostname(config)# webvpn
hostname(config-webvpn)# customization 123
hostname(config-webvpn-cust)# password-prompt Enter password
hostname(config-webvpn-cust)# exit
hostname(config)# group-policy testpolicy nopassword
hostname(config)# group-policy testpolicy attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# customization value 123
```

You can set up different login windows for different groups by using a combination of customization profiles and connection profiles. For example, assuming that you had created a customization profile called salesgui, you can create a connection profile for clientless SSL VPN sessions called sales that uses that customization profile, as the following example shows:
Procedure

Step 1  In webvpn mode, define a customization for clientless SSL VPN access, in this case named salesgui and change the default logo to mycompanylogo.gif. You must have previously loaded mycompanylogo.gif onto the flash memory of the ASA and saved the configuration. See Clientless SSL VPN Overview, on page 293 for details.

hostname# webvpn
hostname (config-webvpn)# customization value salesgui
hostname(config-webvpn-custom)# logo file disk0:\mycompanylogo.gif
hostname(config-webvpn-custom)#

Step 2  In global configuration mode, set up a username and associate with it the customization for clientless SSL VPN that you have just defined:

hostname# username seller attributes
hostname(config-username)# webvpn
hostname(config-username-webvpn)# customization value salesgui
hostname(config-username-webvpn)# exit
hostname(config-username)# exit
hostname#

Step 3  In global configuration mode, create a tunnel-group for clientless SSL VPN sessions named sales:

hostname# tunnel-group sales type webvpn
hostname(config-tunnel-webvpn)#

Step 4  Specify that you want to use the salesgui customization for this connection profile:

hostname# tunnel-group sales webvpn-attributes
hostname(config-tunnel-webvpn)# customization salesgui

Step 5  Set the group URL to the address that the user enters into the browser to log in to the ASA; for example, if the ASA has the IP address 192.168.3.3, set the group URL to https://192.168.3.3:

hostname(config-tunnel-webvpn)# group-url https://192.168.3.3.
hostname(config-tunnel-webvpn)#

If a port number is required for a successful login, include the port number, preceded by a colon. The ASA maps this URL to the sales connection profile and applies the salesgui customization profile to the login screen that the user sees upon logging in to https://192.168.3.3.

About Tunnel Groups for Standards-based IKEv2 Clients

A tunnel group is a set of records that contain tunnel connection policies. You configure a tunnel group to identify AAA servers, specify connection parameters, and define a default group policy. The ASA stores tunnel groups internally.
The default tunnel group for IPsec remote access is the DefaultRAGroup. You may modify the default tunnel group, but not delete it.

IKEv2 allows asymmetric authentication methods to be configured (that is, preshared key authentication for the originator but certificate authentication or EAP authentication for the responder) using separate local and remote authentication CLIs. Therefore, with IKEv2 you have asymmetric authentication, in which one side authenticates with one credential and the other side uses another credential (either a preshared key, certificate, or EAP).

The DefaultRAGroup should be configured for EAP authentication because these client connections cannot be mapped to a specific tunnel group unless certificate authentication is used with certificate DN matching.

**Standards-based IKEv2 Attribute Support**

The ASA supports the following IKEv2 attributes:

- **INTERNAL_IP4_ADDRESS/INTERNAL_IP6_ADDRESS**—IPv4 or IPv6 address

**Note**

Dual stack (assignment of both an IPv4 and IPv6 address) is not supported for IKEv2. If both an IPv4 and an IPv6 address are requested and both addresses may be assigned, only an IPv4 address is assigned.

- **INTERNAL_IP4_NETMASK**—IPv4 address network mask
- **INTERNAL_IP4_DNS/INTERNAL_IP6_DNS**—Primary/Secondary DNS address
- **INTERNAL_IP4_NBNS**—Primary/Secondary WINS address
- **INTERNAL_IP4_SUBNET/INTERNAL_IP6_SUBNET**—Split-tunneling lists
- **APPLICATION_VERSION**—Ignored. No response is sent to avoid communicating any version information about the ASA for security reasons. However, the client configuration payload request may include this attribute, and the string appears on the ASA in the `vpn-sessiondb` command output and in the syslog.

**DAP Support**

To allow DAP policy configuration per connection type, a new Client Type, IPsec-IKEv2-Generic-RA, can be used to apply specific policy for this connection type.

**Tunnel Group Selection for Remote Access Clients**

The following table provides a list of remote access clients and their available tunnel group options:

<table>
<thead>
<tr>
<th>Remote Access Client</th>
<th>Tunnel Group List</th>
<th>Group URL</th>
<th>Certificate DN Matching</th>
<th>Default Group (DefaultRAGroup)</th>
<th>Other</th>
</tr>
</thead>
<tbody>
<tr>
<td>AnyConnect VPN Client</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>N/A</td>
</tr>
</tbody>
</table>
### Authentication Support for Standards-based IKEv2 Clients

The following table provides a list of standards-based IKEv2 clients and their supported authentication methods:

<table>
<thead>
<tr>
<th>Client Type/Authentication Method</th>
<th>EAP-TLS</th>
<th>EAP-MSCHAPv2</th>
<th>EAP-MD5</th>
<th>Certificate Only</th>
<th>PSK</th>
</tr>
</thead>
<tbody>
<tr>
<td>StrongSwan on Linux</td>
<td>N/A</td>
<td>• ISE—Yes</td>
<td>• ISE—Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ACS—Yes</td>
<td>• ACS—Yes</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FreeRadius—Yes</td>
<td>FreeRadius—Yes</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• AD via FreeRadius—Yes</td>
<td>FreeRadius—Yes</td>
<td></td>
<td></td>
</tr>
<tr>
<td>StrongSwan on Android</td>
<td>N/A</td>
<td>• ISE—Yes</td>
<td>No</td>
<td>Yes</td>
<td>N/A</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ACS—Yes</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FreeRadius—Yes</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• AD via FreeRadius—Yes</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note**: Authentication method limitations are based on lack of support on the client, not on the ASA. All EAP method authentication is proxied by the ASA between the client and EAP server. EAP method support is based on client and EAP server support for the EAP method.
<table>
<thead>
<tr>
<th>Client Type/Authentication Method</th>
<th>EAP-TLS</th>
<th>EAP-MSCHAPv2</th>
<th>EAP-MD5</th>
<th>Certificate Only</th>
<th>PSK</th>
</tr>
</thead>
</table>

• AD via FreeRadius—Yes | N/A | Yes | Yes |

**Add Multiple Certificate Authentication**

The Aggregate Authentication protocol has been extended to define the protocol exchange for multiple-certificate authentication and utilize this for both session types. After the client makes an SSL
connection and enters into aggregate authentication, another SSL connection is made, and the ASA sees that the client requires certificate authentication and requests the client certificate.

The ASA configures the required authentication for an AnyConnect connection of a remote-access type tunnel group. A tunnel-group mapping is performed with the existing methods such as certificate rule mapping, group-url, and so on, but then the required authentication methods are negotiated with the client.

**Example**

tunnel-group <name> webvpn-attributes
authentication {{aaa {certificate | multiple-certificate}}|saml}

The authentication options are AAA only, certificate only, multiple-certificate only, AAA and certificate, AAA and multiple-certificate, and SAML.

ASA(config)# tunnel-group AnyConnect webvpn-attributes
ASA(config-tunnel-webvpn)# authentication?
tunnel-group-webvpn mode commands/options:
  aaa Use username and password for authentication
  certificate Use certificate for authentication
  multiple-certificate Use multiple certificates for authentication
  saml Use SAML for authentication
ASA(config-tunnel-webvpn)# authentication multiple-certificate?
tunnel-group-webvpn mode commands/options:
  aaa Use username and password for authentication
  <cr>
ASA(config-tunnel-webvpn)# authentication aaa?
tunnel-group-webvpn mode commands/options:
  certificate Use certificate for authentication
  multiple-certificate Use multiple certificates for authentication
  <cr>

**Configure the query-identity Option for Retrieval of EAP Identity**

The Microsoft Windows 7 IKEv2 client sends an IP address as the Internet Key Exchange (IKE) identity that prevents the Cisco ASA server from using it efficiently for tunnel-group lookup. The ASA must be configured with the `query-identity` option for EAP authentication to allow the ASA to retrieve a valid EAP identity from the client.

For certificate-based authentication, the ASA server and Microsoft Windows 7 client certificates must have an Extended Key Usage (EKU) field as follows:

- For the client certificate, EKU field = client authentication certificate.
- For the server certificate, EKU field = server authentication certificate.

You can obtain the certificates from the Microsoft Certificate Server or other CA server.

For EAP authentication, the Microsoft Windows 7 IKEv2 client expects an EAP identity request before any other EAP requests. Make sure that you configure the `query-identity` keyword in the tunnel group profile on the IKEv2 ASA server to send an EAP identity request to the client.
DHCP intercept is supported for IKEv2 to allow Windows to do split-tunneling. This feature only works with IPv4 split-tunneling attributes.

Procedure

Step 1
To set the connection type to IPsec remote access, enter the `tunnel-group` command. The syntax is `tunnel-group name type`, where name is the name you assign to the tunnel group, and type is the type of tunnel:

In the following example, the IKEv2 preshared key is configured as 44kkaol59636jnf:

```
hostname(config-tunnel-ipsec)# ikev2 local-authentication pre-shared-key 44kkaol59636jnf
```

Note You must configure the `ikev2 remote-authentication pre-shared-key` command or `ikev2 remote-authentication certificate` command to complete the authentication.

Step 2
To specify Extensible Authentication Protocol (EAP) as the method that supports user authentication with standards-based, third-party IKEv2 remote access clients, use the `ikev2 remote-authentication eap [query-identity]` command.

Note Before you can enable EAP for remote authentication, you must configure local authentication using a certificate and configure a valid trustpoint using the `ikev2 local-authentication {certificate trustpoint}` command. Otherwise, the EAP authentication request is rejected.

You may configure multiple options that allow the client to use any of the configured options, but not all, for remote authentication.

For IKEv2 connections, the tunnel group mapping must know which authentication methods to allow for remote authentication (PSK, certificate, and EAP) and local authentication (PSK and certificate), and which trust point to use for local authentication. Currently, mapping is performed using the IKE ID, which is taken from the peer or peer certificate field value (using the certificate map). If both options fail, then the in-coming connection is mapped to the default remote access tunnel group, DefaultRAGroup. A certificate map is an applicable option only when the remote peer is authenticated via a certificate. This map allows mapping to different tunnel groups. For certificate authentication only, the tunnel group lookup is performed using rules or using the default setting. For EAP and PSK authentication, the tunnel group lookup is performed using the IKE ID on the client (it matches the tunnel group name) or using the default setting.

For EAP authentication, you must use the DefaultRAGroup tunnel group unless the client allows the IKE ID and username to be configured independently.

The following example shows an EAP request for authentication being denied:

```
ciscoasa(config-tunnel-ipsec)# ikev2 remote-authentication eap query-identity
```

```
ciscoasa(config-tunnel-ipsec)# ikev2 remote-authentication certificate
```

```
ciscoasa(config-tunnel-ipsec)# ikev2 local-authentication pre-shared-key 12345678
ERROR: The local-authentication method is required to be certificate based if remote-authentication allows EAP
```

```
ciscoasa(config-tunnel-ipsec)# ikev2 local-authentication certificate myIDcert
```
Step 3  Save your changes.

hostname(config)# write memory
hostname(config)#

To verify that the tunnel is up and running, use the `show vpn-sessiondb summary` or `show crypto ipsec sa` command.

### Configure Microsoft Active Directory Settings for Password Management

If you are using an LDAP directory server for authentication, password management is supported with the Sun Microsystems JAVA System Directory Server (formerly named the Sun ONE Directory Server) and the Microsoft Active Directory.

- **Sun**—The DN configured on the ASA to access a Sun directory server must be able to access the default password policy on that server. We recommend using the directory administrator, or a user with directory administrator privileges, as the DN. Alternatively, you can place an ACI on the default password policy.

- **Microsoft**—You must configure LDAP over SSL to enable password management with Microsoft Active Directory.

To use password management with Microsoft Active Directory, you must set certain Active Directory parameters as well as configuring password management on the ASA. This section describes the Active Directory settings associated with various password management actions. These descriptions assume that you have also enabled password management on the ASA and configured the corresponding password management attributes. The specific steps in this section refer to Active Directory terminology under Windows 2000. This section assumes that you are using an LDAP directory server for authentication.

#### Use Active Directory to Force the User to Change Password at Next Logon

To force a user to change the user password at the next logon, specify the `password-management` command in tunnel-group general-attributes configuration mode on the ASA and perform the following steps under Active Directory:

**Procedure**

**Step 1** Choose `Start` > `Programs` > `Administrative Tools` > `Active Directory Users and Computers`.

**Step 2** Right-click to choose `Username` > `Properties` > `Account`.

**Step 3** Check the `User must change password at next logon` check box.

The next time this user logs on, the ASA displays the following prompt: “New password required. Password change required. You must enter a new password with a minimum length **n** to continue.” You can set the minimum required password length, **n**, as part of the Active Directory configuration at `Start` > `Programs` > `Administrative Tools` > `Domain Security Policy` > `Windows Settings` > `Security Settings` > `Account Policies` > `Password Policy`. Select `Minimum password length`. 
Use Active Directory to Specify Maximum Password Age

To enhance security, you can specify that passwords expire after a certain number of days. To specify a maximum password age for a user password, specify the `password-management` command in tunnel-group general-attributes configuration mode on the ASA and perform the following steps under Active Directory:

Note

The `radius-with-expiry` command, formerly configured as part of tunnel-group remote-access configuration to perform the password age function, is deprecated. The `password-management` command, entered in tunnel-group general-attributes mode, replaces it.

Procedure

Step 2 Double-click Maximum password age.
Step 3 Check the Define this policy setting check box and specify the maximum password age, in days, that you want to allow.

Use Active Directory to Enforce Minimum Password Length

To enforce a minimum length for passwords, specify the `password-management` command in tunnel-group general-attributes configuration mode on the ASA and perform the following steps under Active Directory:

Procedure

Step 1 Choose Start > Programs > Administrative Tools > Domain Security Policy.
Step 2 Choose Windows Settings > Security Settings > Account Policies > Password Policy.
Step 3 Double-click Minimum Password Length.
Step 4 Check the Define this policy setting check box and specify the minimum number of characters that the password must contain.

Use Active Directory to Enforce Password Complexity

To enforce complex passwords—for example, to require that a password contain upper- and lowercase letters, numbers, and special characters—enter the `password-management` command in tunnel-group general-attributes configuration mode on the ASA and perform the following steps under Active Directory:

Procedure

Step 2
Double-click Password must meet complexity requirements to open the Security Policy Setting dialog box.

Step 3
Check the Define this policy setting check box and select Enable.

Enforcing password complexity takes effect only when the user changes passwords; for example, when you have configured Enforce password change at next login or Password expires in n days. At login, the user receives a prompt to enter a new password, and the system will accept only a complex password.

Configure the Connection Profile for RADIUS/SDI Message Support for the AnyConnect Client

This section describes procedures to ensure that the AnyConnect VPN client using RSA SecureID Software tokens can properly respond to user prompts delivered to the client through a RADIUS server proxying to an SDI server(s).

Note
If you have configured the double-authentication feature, SDI authentication is supported only on the primary authentication server.

When a remote user connects to the ASA with the AnyConnect VPN client and attempts to authenticate using an RSA SecurID token, the ASA communicates with the RADIUS server, which in turn, communicates with the SDI server about the authentication.

During authentication, the RADIUS server presents access challenge messages to the ASA. Within these challenge messages are reply messages containing text from the SDI server. The message text is different when the ASA is communicating directly with an SDI server than when communicating through the RADIUS proxy. Therefore, in order to appear as a native SDI server to the AnyConnect client, the ASA must interpret the messages from the RADIUS server.

Also, because the SDI messages are configurable on the SDI server, the message text on the ASA must match (in whole or in part) the message text on the SDI server. Otherwise, the prompts displayed to the remote client user may not be appropriate for the action required during authentication. The AnyConnect client may fail to respond and authentication may fail.

Configure the Security Appliance to Support RADIUS/SDIMessages, on page 138 describes how to configure the ASA to ensure successful authentication between the client and the SDI server.

Configure the Security Appliance to Support RADIUS/SDI Messages

To configure the ASA to interpret SDI-specific RADIUS reply messages and prompt the AnyConnect user for the appropriate action, perform the following steps:

Procedure

Step 1
Configure a connection profile (tunnel group) to forward RADIUS reply messages in a manner that simulates direct communication with an SDI server using the proxy-auth sdi command from tunnel-group webvpn configuration mode. Users authenticating to the SDI server must connect over this connection profile.

Example:
hostname(config)# tunnel-group sales webvpn attributes
hostname(tunnel-group-webvpn)# proxy-auth sdi

**Step 2**

Configure the RADIUS reply message text on the ASA to match (in whole or in part) the message text sent by the RADIUS server with the **proxy-auth_map sdi** command from tunnel-group webvpn configuration mode.

The default message text used by the ASA is the default message text used by Cisco Secure Access Control Server (ACS). If you are using Cisco Secure ACS, and it is using the default message text, you do not need to configure the message text on the ASA. Otherwise, use the **proxy-auth_map sdi** command to ensure the message text matches.

The table below shows the message code, the default RADIUS reply message text, and the function of each message. Because the security appliance searches for strings in the order that they appear in the table, you must ensure that the string you use for the message text is not a subset of another string.

For example, “new PIN” is a subset of the default message text for both new-pin-sup and next-ccode-and-reauth. If you configure new-pin-sup as “new PIN,” when the security appliance receives “new PIN with the next card code” from the RADIUS server, it will match the text to the new-pin-sup code instead of the next-ccode-and-reauth code.

<table>
<thead>
<tr>
<th>Message Code</th>
<th>Default RADIUS Reply Message Text</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>next-code</td>
<td>Enter Next PASSCODE</td>
<td>Indicates the user must enter the NEXT tokencode without the PIN.</td>
</tr>
<tr>
<td>new-pin-sup</td>
<td>Please remember your new PIN</td>
<td>Indicates the new system PIN has been supplied and displays that PIN for the user.</td>
</tr>
<tr>
<td>new-pin-meth</td>
<td>Do you want to enter your own pin</td>
<td>Requests from the user which new PIN method to use to create a new PIN.</td>
</tr>
<tr>
<td>new-pin-req</td>
<td>Enter your new Alpha-Numerical PIN</td>
<td>Indicates a user-generated PIN and requests that the user enter the PIN.</td>
</tr>
<tr>
<td>new-pin-reenter</td>
<td>Reenter PIN:</td>
<td>Used internally by the ASA for user-supplied PIN confirmation. The client confirms the PIN without prompting the user.</td>
</tr>
<tr>
<td>new-pin-sys-ok</td>
<td>New PIN Accepted</td>
<td>Indicates the user-supplied PIN was accepted.</td>
</tr>
<tr>
<td>next-ccode-and-reauth</td>
<td>new PIN with the next card code</td>
<td>Follows a PIN operation and indicates the user must wait for the next tokencode and to enter both the new PIN and next tokencode to authenticate.</td>
</tr>
<tr>
<td>Message Code</td>
<td>Default RADIUS Reply Message Text</td>
<td>Function</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------</td>
<td>--------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ready-for-sys-pin</td>
<td>ACCEPT A SYSTEM GENERATED PIN</td>
<td>Used internally by the ASA to indicate the user is ready for the system-generated PIN.</td>
</tr>
</tbody>
</table>

The following example enters aaa-server-host mode and changes the text for the RADIUS reply message new-pin-sup:

```
hostname(config)# aaa-server radius_sales host 10.10.10.1
hostname(config-aaa-server-host)# proxy-auth_map sdi new-pin-sup "This is your new PIN"
```

## Group Policies

This section describes group policies and how to configure them.

A group policy is a set of user-oriented attribute/value pairs for IPsec connections that are stored either internally (locally) on the device or externally on a RADIUS server. The connection profile uses a group policy that sets terms for user connections after the tunnel is established. Group policies let you apply whole sets of attributes to a user or a group of users, rather than having to specify each attribute individually for each user.

Enter the `group-policy` commands in global configuration mode to assign a group policy to users or to modify a group policy for specific users.

The ASA includes a default group policy. In addition to the default group policy, which you can modify but not delete, you can create one or more group policies specific to your environment.

You can configure internal and external group policies. Internal groups are configured on the ASA’s internal database. External groups are configured on an external authentication server, such as RADIUS. Group policies include the following attributes:

- Identity
- Server definitions
- Client firewall settings
- Tunneling protocols
- IPsec settings
- Hardware client settings
- Filters
- Client configuration settings
- Connection settings
Modify the Default Group Policy

The ASA supplies a default group policy. You can modify this default group policy, but you cannot delete it. A default group policy, named DfltGrpPolicy, always exists on the ASA, but this default group policy does not take effect unless you configure the ASA to use it. When you configure other group policies, any attribute that you do not explicitly specify inherits its value from the default group policy.

**Note**
AnyConnect profiles, including any or all AnyConnect Profile Types (such as Network Access Manager, Umbrella, and so on), that are configured on (and then assigned to) the DfltGrpPolicy, are not inherited by other group policies, unless the other group policies explicitly are configured to inherit from the DfltGrpPolicy. In other words, AnyConnect profiles that are associated with the DfltGrpPolicy are not inherited when specific AnyConnect profiles are configured on a group policy.

To view the default group policy, enter the following command:

```
hostname(config)# show running-config all group-policy DfltGrpPolicy
```

To configure the default group policy, enter the following command:

```
hostname(config)# group-policy DfltGrpPolicy internal
```

**Note**
The default group policy is always internal. Despite the fact that the command syntax is `hostname(config)# group-policy DfltGrpPolicy {internal | external}`, you cannot change its type to external.

To change any of the attributes of the default group policy, use the `group-policy attributes` command to enter attributes mode, then specify the commands to change whatever attributes that you want to modify:

```
hostname(config)# group-policy DfltGrpPolicy attributes
```

**Note**
The attributes mode applies only to internal group policies.

The default group policy, DfltGrpPolicy, that the ASA provides is as follows:

```
hostname# show run all group-policy DfltGrpPolicy

Configure Group Policies

A group policy can apply to any kind of tunnel. In each case, if you do not explicitly define a parameter, the group takes the value from the default group policy.

You can perform these configuration tasks in both single context mode or multiple-context mode:

Multiple-context mode applies only to IKEv2 and IKEv1 site to site and does not apply to AnyConnect, Clientless SSL VPN, the Apple native VPN client, the Microsoft native VPN client, or cTCP for IKEv1 IPsec.

Configure an External Group Policy

External group policies take their attribute values from the external server that you specify. For an external group policy, you must identify the AAA server group that the ASA can query for attributes and specify the password to use when retrieving attributes from the external AAA server group. If you are using an external authentication server, and if your external group-policy attributes exist in the same RADIUS server as the users that you plan to authenticate, you have to make sure that there is no name duplication between them.
External group names on the ASA refer to user names on the RADIUS server. In other words, if you configure external group X on the ASA, the RADIUS server sees the query as an authentication request for user X. So external groups are really just user accounts on the RADIUS server that have special meaning to the ASA. If your external group attributes exist in the same RADIUS server as the users that you plan to authenticate, there must be no name duplication between them.

The ASA supports user authorization on an external LDAP or RADIUS server. Before you configure the ASA to use an external server, you must configure the server with the correct ASA authorization attributes and, from a subset of these attributes, assign specific permissions to individual users. Follow the instructions in Configure an External AAA Server for VPN, on page 277 to configure your external server.

**Procedure**

To configure an external group policy, perform the following step and specify a name and type for the group policy, along with the server-group name and a password:

```
hostname(config)# group-policy group_policy_name type server-group server_group_name password server_password
hostname(config)#
```

**Note** For an external group policy, RADIUS is the only supported AAA server type.

For example, the following command creates an external group policy named ExtGroup that gets its attributes from an external RADIUS server named ExtRAD and specifies that the password to use when retrieving the attributes is newpassword:

```
hostname(config)# group-policy ExtGroup external server-group ExtRAD password newpassword
hostname(config)#
```

**Note** You can configure several vendor-specific attributes (VSAs), as described in Configure an External AAA Server for VPN, on page 277. If a RADIUS server is configured to return the Class attribute (#25), the ASA uses that attribute to authenticate the Group Name. On the RADIUS server, the attribute must be formatted as: `OU=groupname`; where `groupname` is identical to the Group Name configured on the ASA—for example, `OU=Finance`.

### Create an Internal Group Policy

To configure an internal group policy, enter configuration mode, use the group-policy command, specify a name, and the `internal` type for the group policy:

```
hostname(config)# group-policy group_policy_name internal
hostname(config)#
```

For example, the following command creates the internal group policy named GroupPolicy1:
You cannot change the name of a group policy after you create it.

You can configure the attributes of an internal group policy by copying the values of a preexisting group policy by appending the keyword `from` and specifying the name of the existing policy:

```
hostname(config)# group-policy group_policy_name internal from group_policy_name
hostname(config-group-policy)#
```

For example, the following command creates the internal group policy named GroupPolicy2 by copying the attributes of GroupPolicy1:

```
hostname(config)# group-policy GroupPolicy2 internal from GroupPolicy1
hostname(config-group-policy)#
```

### Configure General Internal Group Policy Attributes

#### Group Policy Name

The group policy name was chosen when the internal group policy was created. You cannot change the name of a group policy once it has been created. See [Create an Internal Group Policy](#) on page 144 for more information.

#### Configure the Group Policy Banner Message

Specify the banner, or welcome message, if any, that you want to display. The default is no banner. The message that you specify is displayed on remote clients when they connect. To specify a banner, enter the `banner` command in group-policy configuration mode. The banner text can be up to 500 characters long. Enter the “n” sequence to insert a carriage return.

The overall banner length, which is displayed during post-login on the VPN remote client, has increased from 510 to 4000 characters in ASA version 9.5.1.

A carriage-return and line-feed included in the banner counts as two characters.

To delete a banner, enter the `no` form of this command. Be aware that using the `no` version of the command deletes all banners for the group policy.

A group policy can inherit this value from another group policy. To prevent inheriting a value, enter the `none` keyword instead of specifying a value for the banner string, as follows:

```
hostname(config-group-policy)# banner [value banner_string | none]
```
The following example shows how to create a banner for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# banner value Welcome to Cisco Systems ASA 9.0.
```

### Specify Address Pools for Remote Access Connections

When remote access clients connect to the ASA, the ASA can assign the client an IPv4 or IPv6 address based on the group-policy specified for the connection.

You can specify a list of up to six local address pools to use for local address allocation. The order in which you specify the pools is significant. The ASA allocates addresses from these pools in the order in which the pools appear in this command.

### Assign an IPv4 Address Pool to an Internal Group Policy

**Before you begin**  
Create the IPv4 address pool.

**Procedure**

**Step 1** Enter group policy configuration mode.

```
group-policy value attributes
```

**Example:**

```
hostname(config)#
```

**Step 2** Assign the address pool named ipv4-pool1, ipv4-pool2, and ipv4pool3 to the FirstGroup group policy. You are allowed to specify up to 6 address pools for group-policy.

```
address-pools value pool-name1 pool-name2 pool-name6
```

**Example:**

```
asa4(config-group-policy)#
```

**Step 3** (Optional) Use the no address-pools value pool-name command to remove the address-pools from the group policy configuration and return the address pool setting to inherit the address pool information from other sources such as the DefltGroupPolicy.

```
no address-pools value pool-name1 pool-name2 pool-name6
```

**Example:**

```
hostname(config-group-policy)#
```
Step 4  (Optional) The `address-pools none` command disables this attribute from being inherited from other sources of policy, such as the DefltGrpPolicy.

```
hostname(config-group-policy)# address-pools none
hostname(config-group-policy)#
```

Step 5  (Optional) The `no address pools none` command removes the `address-pools none` command from the group policy, restoring the default value, which is to allow inheritance.

```
hostname(config-group-policy)# no address-pools none
hostname(config-group-policy)#
```

---

Assign an IPv6 Address Pool to an Internal Group Policy

Before you begin

Create the IPv6 address pool. See IP Addresses for VPNs, on page 195.

Procedure

Step 1  Enter group policy configuration mode.

```
group-policy value attributes
```

Example:

```
hostname> en
hostname# config t
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)#
```

Step 2  Assign the address pool named ipv6-pool1 to the FirstGroup group policy. You can assign up to six ipv6 address pools to a group policy.

Example:

This example shows ipv6-pool1, ipv6-pool2, and ipv6-pool3 being assigned to the FirstGroup group policy.

```
hostname(config-group-policy)# ipv6-address-pools value ipv6-pool1 ipv6-pool2 ipv6-pool3
hostname(config-group-policy)#
```

Step 3  (Optional) Use the `no ipv6-address-pools value pool-name` command to remove the address-pools from the group policy configuration and return the address pool setting to inherit the address pool information from other sources such as the DfltGrpPolicy.

```
no ipv6-address-pools value pool-name1 pool-name2 pool-name6
```

Example:
hostname(config-group-policy)# no ipv6-address-pools value ipv6-pool1 ipv6-pool2 ipv6-pool3
hostname(config-group-policy)#

**Step 4**  
(Optional) Use the `ipv6-address-pools none` command to disable this attribute from being inherited from other sources of policy, such as the DfltGrpPolicy.

hostname(config-group-policy)# ipv6-address-pools none
hostname(config-group-policy)#

**Step 5**  
(Optional) Use the `no ipv6-address pools none` command to remove the `ipv6-address-pools none` command from the group policy, restoring the default value, which is to allow inheritance.

hostname(config-group-policy)# no ipv6-address-pools none
hostname(config-group-policy)#

---

### Specify the Tunneling Protocol for the Group Policy

Specify the VPN tunnel type for this group policy by entering the `vpn-tunnel-protocol {ikev1 | ikev2 | l2tp-ipsec | ssl-client | ssl-clientless}` command from group-policy configuration mode.

The default value is to inherit the attributes of the Default Group Policy. To remove the attribute from the running configuration, enter the `no` form of this command.

The parameter values for this command include:

- **ikev1**—Negotiates an IPsec IKEv1 tunnel between two peers (the Cisco VPN Client or another secure gateway). Creates security associations that govern authentication, encryption, encapsulation, and key management.

- **ikev2**—Negotiates an IPsec IKEv2 tunnel between two peers (the AnyConnect Secure Mobility Client or another secure gateway). Creates security associations that govern authentication, encryption, encapsulation, and key management.

- **l2tp-ipsec**—Negotiates an IPsec tunnel for an L2TP connection.

- **ssl-client**—Negotiates an SSL tunnel using TLS or DTLS with the AnyConnect Secure Mobility Client.

- **ssl-clientless**—Provides VPN services to remote users via an HTTPS-enabled web browser, and does not require a client.

Enter this command to configure one or more tunneling modes. You must configure at least one tunneling mode for users to connect over a VPN tunnel.

The following example shows how to configure the IPsec IKEv1 tunneling mode for the group policy named FirstGroup:

hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-tunnel-protocol ikev1
hostname(config-group-policy)#
Specify a VLAN for Remote Access or Apply a Unified Access Control Rule to the Group Policy

Filters consist of rules that determine whether to allow or reject tunneled data packets coming through the ASA, based on criteria such as source address, destination address, and protocol. You can specify an IPv4 or IPv6 unified access control list for your group policy or allow it to inherit the ACLs specified in the Default Group Policy.

Choose one of the following options to specify an egress VLAN (also called “VLAN mapping”) for remote access or specify an ACL to filter the traffic:

### Note
When doing VLAN mapping with IPv6, the outside (destination) address must be unique for each of the VLANs so that decrypted traffic is routed to inside networks. You cannot have the same destination network with different VLANs and route metrics.

- Enter the following command in group-policy configuration mode to specify the egress VLAN for remote access VPN sessions assigned to this group policy or to a group policy that inherits this group policy:

  ```
  [no] vlan \{vlan_id | none\}
  ```

  - `no vlan` removes the `vlan_id` from the group policy. The group policy inherits the `vlan` value from the default group policy.
  - `none` removes the `vlan_id` from the group policy and disables VLAN mapping for this group policy. The group policy does not inherit the `vlan` value from the default group policy.
  - `vlan_id` is the number of the VLAN, in decimal format, to assign to remote access VPN sessions that use this group policy. The VLAN must be configured on this ASA per the instructions in the “Configuring VLAN Subinterfaces and 802.1Q Trunking” in the general operations configuration guide.

  **Note**
  The egress VLAN feature works for HTTP connections, but not for FTP and CIFS.

- Specify the name of the access control rule (ACL) to apply to VPN session, using the `vpn-filter` command in group policy mode. You can specify an IPv4 or IPv6 ACL using the `vpn-filter` command.

  **Note**
  In previous releases, the deprecated `ipv6-vpn-filter` command could be used to specify an IPv6 ACL if there were no IPv6 entries specified by `vpn-filter`. As of ASA 9.1(4), `ipv6-vpn-filter` has been disabled and IPv6 ACL entries must be specified using the `vpn-filter` command. If `ipv6-vpn-filter` is set, the VPN connection will be terminated.

  **Note**
  You can also configure this attribute in username mode, in which case the value configured under username supersedes the group-policy value.

  ```
  hostname(config-group-policy)# vpn-filter \{value ACL name | none\}
  ```
You configure ACLs to permit or deny various types of traffic for this group policy. You then enter the `vpn-filter` command to apply those ACLs.

To remove the ACL, including a null value created by entering the `vpn-filter none` command, enter the `no` form of this command. The `no` option allows inheritance of a value from another group policy.

A group policy can inherit this value from another group policy. To prevent inheriting a value, enter the `none` keyword instead of specifying an ACL name. The `none` keyword indicates that there is no ACL and sets a null value, thereby disallowing an ACL.

The following example shows how to set a filter that invokes an ACL named acl_vpn for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-filter acl_vpn
```

A `vpn-filter` command is applied to post-decrypted traffic after it exits a tunnel and pre-encrypted traffic before it enters a tunnel. An ACL that is used for a vpn-filter should NOT also be used for an interface access-group. When a `vpn-filter` command is applied to a group policy that governs Remote Access VPN client connections, the ACL should be configured with the client assigned IP addresses in the `src_ip` position of the ACL and the local network in the `dest_ip` position of the ACL.

When a `vpn-filter` command is applied to a group-policy that governs a LAN to LAN VPN connection, the ACL should be configured with the remote network in the `src_ip` position of the ACL and the local network in the `dest_ip` position of the ACL.

Caution should be used when constructing the ACLs for use with the vpn-filter feature. The ACLs are constructed with the post-decrypted traffic in mind. However, ACLs are also applied to the traffic in the opposite direction. For this pre-encrypted traffic that is destined for the tunnel, the ACLs are constructed with the `src_ip` and `dest_ip` positions swapped.

In the following example, the vpn-filter is used with a Remote Access VPN client. This example assumes that the client assigned IP address is 10.10.10.1/24 and the local network is 192.168.1.0/24.

The following ACE allows the Remote Access VPN client to telnet to the local network:

```
hostname(config-group-policy)# access-list vpnfilt-ra permit 10.10.1 255.255.255.255
192.168.1.0 255.255.255.0 eq 23
```

The following ACE allows the local network to telnet to the Remote Access client:

```
hostname(config-group-policy)# access-list vpnfilt-ra permit 10.10.1 255.255.255.255
192.168.1.0 255.255.255.0 eq 23
```

Note: The ACE `access-list vpnfilt-ra permit 10.10.1 255.255.255.255 192.168.1.0
255.255.255.0 eq 23` allows the local network to initiate a connection to the Remote Access client on any TCP port if it uses a source port of 23. The ACE `access-list vpnfilt-ra permit 10.10.1
255.255.255.255 eq 23 192.168.1.0 255.255.255.0` allows the Remote Access client to initiate a connection to the local network on any TCP port if it uses a source port of 23.
In the next example, the vpn-filter is used with a LAN to LAN VPN connection. This example assumes that the remote network is 10.0.0.0/24 and the local network is 192.168.1.0/24. The following ACE allows remote network to telnet to the local network:

```
hostname(config-group-policy)# access-list vpnfilt-l2l permit 10.0.0.0 255.255.255.0
192.168.1.0 255.255.255.0 eq 23
```

The following ACE allows the local network to telnet to the remote network:

```
hostname(config-group-policy)# access-list vpnfilt-l2l permit 10.0.0.0 255.255.255.0 eq 23
192.168.1.0 255.255.255.0
```

The ACE `access-list vpnfilt-l2l permit 10.0.0.0 255.255.255.0 192.168.1.0 255.255.255.0 eq 23` allows the local network to initiate a connection to the remote network on any TCP port if it uses a source port of 23. The ACE `access-list vpnfilt-l2l permit 10.0.0.0 255.255.255.0 eq 23 192.168.1.0 255.255.255.0` allows the remote network to initiate a connection to the local network on any TCP port if it uses a source port of 23.

---

**Specify VPN Access Hours for a Group Policy**

**Before you begin**

Create a time range. See the "Configuring Time Ranges" in the general operations configuration guide.

**Procedure**

**Step 1**

Enter group policy configuration mode.

```
group-policy value attributes
```

**Example:**

```
hostname> en
hostname# config t
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)#
```

**Step 2**

You can set the VPN access hours by associating a configured time-range policy with a group policy using the `vpn-access-hours` command in group-policy configuration mode. This command assigns a VPN access time range named business-hours to the group policy named FirstGroup.

A group policy can inherit a time-range value from a default or specified group policy. To prevent this inheritance, enter the `none` keyword instead of the name of a time-range in this command. This keyword sets VPN access hours to a null value, which allows no time-range policy.

```
vpn-access-hours value {time-range-name | none}
```

**Example:**
Specify Simultaneous VPN Logins for a Group Policy

Specify the number of simultaneous logins allowed for any user, using the `vpn-simultaneous-logins integer` command in group-policy configuration mode.

The default value is 3. The range is an integer in the range 0 through 2147483647. A group policy can inherit this value from another group policy. Enter 0 to disable login and prevent user access. The following example shows how to allow a maximum of 4 simultaneous logins for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-simultaneous-logins 4
```

**Note** While the maximum limit for the number of simultaneous logins is very large, allowing several simultaneous logins could compromise security and affect performance.

Stale AnyConnect, IPsec Client, or Clientless sessions (sessions that are terminated abnormally) might remain in the session database, even though a “new” session has been established with the same username.

If the value of `vpn-simultaneous-logins` is 1, and the same user logs in again after an abnormal termination, then the stale session is removed from the database, and the new session is established. If, however, the existing session is still an active connection and the same user logs in again, perhaps from another PC, the first session is logged off and removed from the database, and the new session is established.

If the number of simultaneous logins is a value greater than 1, then, when you have reached that maximum number and try to log in again, the session with the longest idle time is logged off. If all current sessions have been idle an equally long time, then the oldest session is logged off. This action frees up a session and allows the new login.

Restrict Access to a Specific Connection Profile

Specify whether to restrict remote users to access only through the connection profile, using the `group-lock` command in group-policy configuration mode.

```
hostname(config-group-policy)# group-lock {value tunnel-grp-name | none}
hostname(config-group-policy)# no group-lock
```

The `tunnel-grp-name` variable specifies the name of an existing connection profile that the ASA requires for the user to connect. Group-lock restricts users by checking if the group configured in the VPN client is the same as the connection profile to which the user is assigned. If it is not, the ASA prevents the user from connecting. If you do not configure group-lock, the ASA authenticates users without regard to the assigned group. Group locking is disabled by default.
To remove the `group-lock` attribute from the running configuration, enter the `no` form of this command. This option allows inheritance of a value from another group policy.

To disable group-lock, enter the `group-lock` command with the `none` keyword. The `none` keyword sets group-lock to a null value, thereby allowing no group-lock restriction. It also prevents inheriting a group-lock value from a default or specified group policy.

### Specify the Maximum VPN Connection Time in a Group Policy

#### Procedure

**Step 1** (Optional) Configure a maximum amount of time for VPN connections, using the `vpn-session-timeout` command in group-policy configuration mode or in username configuration mode.

The minimum time is 1 minute, and the maximum time is 35791394 minutes. There is no default value. At the end of this period of time, the ASA terminates the connection.

The following example shows how to set a VPN session timeout of 180 minutes for the group policy named `FirstGroup`:

```plaintext
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-session-timeout 180
hostname(config-group-policy)#
```

The following example shows how to set a VPN session timeout of 180 minutes for the user named `anyuser`:

```plaintext
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-session-timeout 180
hostname(config-username)#
```

Other actions using the `[no] vpn-session-timeout {minutes | none}` command:

- To remove the attribute from this policy and allow inheritance, enter the `no vpn-session-timeout` form of this command.
- To allow an unlimited timeout period, and thus prevent inheriting a timeout value, enter `vpn-session-timeout none`.

**Step 2** Configure the time at which a session timeout alert message is displayed to the user using the `vpn-session-timeout alert-interval {minutes | none}` command.

This alert message tells users how many minutes left until their VPN session is automatically disconnected. The following example shows how to specify that users will be notified 20 minutes before their VPN session is disconnected. You can specify a range of 1-30 minutes.

```plaintext
hostname(config-webvpn)# vpn-session-timeout alert-interval 20
```

Other actions using the `[no] vpn-session-timeout alert-interval {minutes | none}` command:

- Use the `no` form of the command to indicate that the VPN session timeout alert-interval attribute will be inherited from the Default Group Policy:
  ```plaintext
  hostname(config-webvpn)# no vpn-session-timeout alert-interval
  ```
Specify a VPN Session Idle Timeout for a Group Policy

Procedure

Step 1  (Optional) To configure a VPN idle timeout period use the `vpn-idle-timeout minutes` command in group-policy configuration mode or in username configuration mode.

If there is no communication activity on the connection in this period, the ASA terminates the connection. The minimum time is 1 minute, the maximum time is 35791394 minutes, and the default is 30 minutes.

The following example shows how to set a VPN idle timeout of 15 minutes for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-idle-timeout 15
```

Other actions using the `[no] vpn-idle-timeout {minutes | none}` command:

- Enter `vpn-idle-timeout none` to disable VPN idle timeout and prevent inheriting a timeout value.

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-idle-timeout none
```

This results in AnyConnect (both SSL and IPsec/IKEv2) and Clientless VPN using the global webvpn `default-idle-timeout seconds` value. This command is entered in webvpn-config mode, for example:

```
hostname(config-webvpn)# default-idle-timeout 300
```

The default is 1800 seconds (30 min), the range is 60-86400 seconds.

For all webvpn connections, the `default-idle-timeout` value is enforced only if `vpn-idle-timeout none` is set in the group policy/username attribute. A non-zero idle timeout value is required by ASA for all AnyConnect connections.

For Site-to-Site (IKEv1, IKEv2) and IKEv1 remote-access VPNs, we recommend you Disable timeout and allow for an unlimited idle period.

- To disable the idle timeout for this group policy or user policy, enter `no vpn-idle-timeout`. The value will be inherited.

- If you do not set `vpn-idle-timeout` at all, in anyway, the value is inherited, which defaults to 30 minutes.

Step 2  (Optional) You can optionally configure the time at which an idle timeout alert message is displayed to the user using the `vpn-idle-timeout alert-interval {minutes}` command.

This alert message tells users how many minutes they have left until their VPN session is disconnected due to inactivity. The default alert interval is one minute.

The following example shows how to set a VPN idle timeout alert interval of 3 minutes for the user named anyuser:

```
```
Other actions using the `[no] vpn-idle-timeout alert-interval {minutes | none}` command:

- The `none` parameter indicates that users will not receive an alert.

```plaintext
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-idle-timeout none
hostname(config-username)#
```

- To remove the alert interval for this group or user policy enter `no vpn-idle-timeout alert-interval`. The value will be inherited.
- If you do not set this parameter at all, the default alert interval is one minute.

---

## Configure WINS and DNS Servers for a Group Policy

You can specify primary and secondary WINS servers and DNS servers. The default value in each case is none. To specify these servers, perform the following steps:

### Procedure

**Step 1** Specify the primary and secondary WINS servers:

```plaintext
hostname(config-group-policy)# wins-server value {ip_address [ip_address] | none}
hostname(config-group-policy)#
```

The first IP address specified is that of the primary WINS server. The second (optional) IP address is that of the secondary WINS server. Specifying the `none` keyword instead of an IP address sets WINS servers to a null value, which allows no WINS servers and prevents inheriting a value from a default or specified group policy.

Every time that you enter the `wins-server` command, you overwrite the existing setting. For example, if you configure WINS server x.x.x.x and then configure WINS server y.y.y.y, the second command overwrites the first, and y.y.y.y becomes the sole WINS server. The same is true for multiple servers. To add a WINS server rather than overwrite previously configured servers, include the IP addresses of all WINS servers when you enter this command.

The following examples show how to configure WINS servers with the IP addresses 10.10.10.15 and 10.10.10.30 for the group policy named FirstGroup:

```plaintext
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# wins-server value 10.10.10.15 10.10.10.30
hostname(config-group-policy)#
```

**Step 2** Specify the primary and secondary DNS servers:

```plaintext
hostname(config-group-policy)# dns-server value {ip_address [ip_address] | none}
```
hostname(config-group-policy)#

The first IP address specified is that of the primary DNS server. The second (optional) IP address is that of the secondary DNS server. Specifying the **none** keyword instead of an IP address sets DNS servers to a null value, which allows no DNS servers and prevents inheriting a value from a default or specified group policy. You can specify up to four DNS server addresses: up to two IPv4 addresses and two IPv6 addresses.

Every time that you enter the **dns-server** command, you overwrite the existing setting. For example, if you configure DNS server x.x.x.x and then configure DNS server y.y.y.y, the second command overwrites the first, and y.y.y.y becomes the sole DNS server. The same is true for multiple servers. To add a DNS server rather than overwrite previously configured servers, include the IP addresses of all DNS servers when you enter this command.

The following example shows how to configure DNS servers with the IP addresses 10.10.10.15, 10.10.10.30, 2001:DB8::1, and 2001:DB8::2 for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
dns-server value 10.10.10.15 10.10.10.30 2001:DB8::1 2001:DB8::2
hostname(config-group-policy)#
```

**Step 3** If there is no default domain name specified in the **DefaultDNS DNS server group**, you must specify a default domain. Use the domain name and top level domain for example, **example.com**.

```
asa4(config)# group-policy FirstGroup attributes
default-domain value example.com
asa4(config-group-policy)#
```

**Step 4** Configure the DHCP network scope:

```
hostname(config-group-policy)# dhcp-network-scope {ip_address | none}
hostname(config-group-policy)#
```

DHCP scope specifies the range of IP addresses (that is, a subnetwork) that the ASA DHCP server should use to assign addresses to users of this group policy.

The following example shows how to set an IP subnetwork of 10.10.85.0 (specifying the address range of 10.10.85.0 through 10.10.85.255) for the group policy named First Group:

```
hostname(config)# group-policy FirstGroup attributes
dhcp-network-scope 10.10.85.0
```

---

### Set the Split-Tunneling Policy

Set the rules for tunneling traffic by specifying the split-tunneling policy for IPv4 traffic:

```
split-tunnel-policy {tunnelall | tunnelspecified | excludespecified}
no split-tunnel-policy
```
Set the rules for tunneling traffic by specifying the split-tunneling policy for IPv6 traffic:

```
ipv6-split-tunnel-policy {tunnelall | tunnlespecified | excludespecified}
```

```
no ipv6-split-tunnel-policy
```

The policies options are:

- **tunnlespecified** — Tunnels all traffic to or from the networks specified in the Network List through the tunnel. Data to all other addresses travels in the clear and is routed by the remote user’s Internet service provider.

  For versions of ASA 9.1.4 and higher, when you specify an include list, you can also specify an exclude list for a subnet inside the include range. Addresses in the excluded subnet will not be tunneled, and the rest of the include list will be. The networks in the exclusion list will not be sent over the tunnel. The exclusion list is specified using deny entries, and the inclusion list is specified using permit entries.

- **excludespecified** — Does not tunnel traffic to or from the networks specified in the Network List. Traffic from or to all other addresses is tunneled. The VPN client profile that is active on the client must have Local LAN Access enabled.

  Network in the exclusion list that are not a subset of the include list are ignored by the client.

- **tunnelall** — Specifies that all traffic goes through the tunnel. This policy disables split tunneling. Remote users have access to the corporate network, but they do not have access to local networks. This is the default option.

**Note**

Split tunneling is a traffic management feature, not a security feature. For optimum security, we recommend that you not enable split tunneling.

**Example**

The following examples shows how to set a split tunneling policy of tunneling only specified networks for the group policy named FirstGroup for IPv4 and IPv6:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# split-tunnel-policy tunnlespecified

hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# ipv6-split-tunnel-policy tunnlespecified
```

**Specify a Network List for Split-Tunneling**

In split tunneling, network lists determine what network traffic travels across the tunnel. AnyConnect makes split tunneling decisions on the basis of a network list, which is an ACL.

```
hostname(config-group-policy)# split-tunnel-network-list {value access-list_name | none}
```
hostname(config-group-policy)# no split-tunnel-network-list value [access-list_name]

• **value** access-list name — identifies an ACL that enumerates the networks to tunnel or not tunnel. The ACL can be a unified ACL with ACEs that specify both IPv4 and IPv6 addresses.

• **none** — indicates that there is no network list for split tunneling; the ASA tunnels all traffic. Specifying the **none** keyword sets a split tunneling network list with a null value, thereby disallowing split tunneling. It also prevents inheriting a default split tunneling network list from a default or specified group policy.

To delete a network list, enter the **no** form of this command. To delete all split tunneling network lists, enter the **no split-tunnel-network-list** command without arguments. This command deletes all configured network lists, including a null list if you created one by entering the **none** keyword.

When there are no split tunneling network lists, users inherit any network lists that exist in the default or specified group policy. To prevent users from inheriting such network lists, enter the **split-tunnel-network-list none** command.

**Example**

The following example shows how to create a network list named FirstList, and add it to the group policy named FirstGroup. FistList is an exclusion list and an inclusion list that is a subnet of the exclusion list:

```
hostname(config)# split-tunnel-policy tunnelspecified
hostname(config)# access-list FirstList deny ip 10.10.10.0 255.255.255.0 any
hostname(config)# access-list FirstList permit ip 10.0.0.0 255.0.0.0 any
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# split-tunnel-network-list value FirstList
```

The following example shows how to create a network list named v6, and add the v6 split tunnel policy to the group policy named GroupPolicy_ipv6-ikev2. v6 is an exclusion list and an inclusion list that is a subnet of the exclusion list:

```
hostname(config)# access-list v6 extended permit ip fd90:5000::/32 any6
hostname(config)# access-list v6 extended deny ip fd90:5000:3000:2880::/64 any6
hostname(config)# group-policy GroupPolicy_ipv6-ikev2 internal
hostname(config)# group-policy GroupPolicy_ipv6-ikev2 attributes
hostname(config-group-policy)# vpn-tunnel-protocol ikev2 ssl-client
hostname(config-group-policy)# ipv6-split-tunnel-policy tunnelspecified
hostname(config-group-policy)# split-tunnel-network-list value v6
```

**Verify the Split Tunnel Configuration**

Run the **show runn group-policy attributes** command to verify your configuration. This example shows that the administrator has set both an IPv4 and IPv6 network policy and used the network list (unified ACL), FirstList for both policies.

```
hostname(config-group-policy)# show runn group-policy FirstGroup attributes
group-policy FirstGroup attributes
split-tunnel-policy tunnelspecified
ipv6-split-tunnel-policy tunnelspecified
split-tunnel-network-list value FirstList
```
Configure Domain Attributes for Split Tunneling

You can specify a default domain name or a list of domains to be resolved through the split tunnel, which we refer to as split DNS.

AnyConnect 3.1 supports true split DNS functionality for Windows and Mac OS X platforms. If the group policy on the security appliance enables split-include tunneling, and if it specifies the DNS names to be tunneled, AnyConnect tunnels any DNS queries that match those names to the private DNS server. True split DNS allows tunnel access to only DNS requests that match the domains pushed to the client by the ASA. These requests are not sent in the clear. On the other hand, if the DNS requests do not match the domains pushed down by the ASA, AnyConnect lets the DNS resolver on the client operating system submit the host name in the clear for DNS resolution.

Split DNS supports standard and update queries (including A, AAAA, NS, TXT, MX, SOA, ANY, SRV, PTR, and CNAME). PTR queries matching any of the tunneled networks are allowed through the tunnel.

For Mac OS X, AnyConnect can use true split-DNS for a certain IP protocol only if one of the following conditions is met:

- Split-DNS is configured for one IP protocol (such as IPv4), and Client Bypass Protocol is configured for the other IP protocol (such as IPv6) in the group policy (with no address pool configured for the latter IP protocol).
- Split-DNS is configured for both IP protocols.

Define a Default Domain Name

The ASA passes the default domain name to the AnyConnect client. The client appends the domain name to DNS queries that omit the domain field. This domain name applies only to tunneled packets. When there are no default domain names, users inherit the default domain name in the default group policy.

To specify the default domain name for users of the group policy, enter the `default-domain` command in group-policy configuration mode. To delete a domain name, enter the `no` form of this command.

```
hostname(config-group-policy)# default-domain {value domain-name | none}
hostname(config-group-policy)# no default-domain [domain-name]
```

The `value` domain-name parameter identifies the default domain name for the group. To specify that there is no default domain name, enter the `none` keyword. This command sets a default domain name with a null value, which disallows a default domain name and prevents inheriting a default domain name from a default or specified group policy.

To delete all default domain names, enter the `no default-domain` command without arguments. This command deletes all configured default domain names, including a null list if you created one by entering the `default-domain` command with the `none` keyword. The `no` form allows inheriting a domain name.

The following example shows how to set a default domain name of FirstDomain for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# default-domain value FirstDomain
```
Define a List of Domains for Split Tunneling

Enter a list of domains to be resolved through the split tunnel, in addition to the default domain. Enter the `split-dns` command in group-policy configuration mode. To delete a list, enter the `no` form of this command.

When there are no split tunneling domain lists, users inherit any that exist in the default group policy. To prevent users from inheriting such split tunneling domain lists, enter the `split-dns` command with the `none` keyword.

To delete all split tunneling domain lists, enter the `no split-dns` command without arguments. This deletes all configured split tunneling domain lists, including a null list created by issuing the `split-dns` command with the `none` keyword.

The parameter `value` domain-name provides a domain name that the ASA resolves through the split tunnel. The `none` keyword indicates that there is no split DNS list. It also sets a split DNS list with a null value, thereby disallowing a split DNS list, and prevents inheriting a split DNS list from a default or specified group policy. The syntax of the command is as follows:

```
hostname(config-group-policy)# split-dns {value domain-name1 [domain-name2... domain-nameN] | none}
```

Enter a single space to separate each entry in the list of domains. There is no limit on the number of entries, but the entire string can be no longer than 255 characters. You can use only alphanumeric characters, hyphens (-), and periods (.). If the default domain name is to be resolved through the tunnel, you must explicitly include that name in this list.

The following example shows how to configure the domains Domain1, Domain2, Domain3, and Domain4 to be resolved through split tunneling for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# split-dns value Domain1 Domain2 Domain3 Domain4
```

**Note**

When configuring split DNS, ensure the private DNS servers specified do not overlap with the DNS servers configured for the client platform. If they do, name resolution does not function properly and queries may be dropped.

Configure DHCP Intercept for Windows XP and Split Tunneling

A Microsoft XP anomaly results in the corruption of domain names if split tunnel options exceed 255 bytes. To avoid this problem, the ASA limits the number of routes it sends to 27 to 40 routes, with the number of routes dependent on the classes of the routes.

DHCP Intercept lets Microsoft Windows XP clients use split-tunneling with the ASA. The ASA replies directly to the Microsoft Windows XP client DHCP Inform message, providing that client with the subnet mask, domain name, and classless static routes for the tunnel IP address. For Windows clients prior to Windows XP, DHCP Intercept provides the domain name and subnet mask. This is useful in environments in which using a DHCP server is not advantageous.

The `intercept-dhcp` command enables or disables DHCP intercept.

```
hostname(config-group-policy)# intercept-dhcp netmask {enable | disable}
```
hostname(config-group-policy)#

The *netmask* variable provides the subnet mask for the tunnel IP address. The **no** form of this command removes the DHCP intercept from the configuration:

```bash
[no] intercept-dhcp
```

The following example shows how to set DHCP Intercepts for the group policy named FirstGroup:

```bash
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# intercept-dhcp enable
```

### Configure Browser Proxy Settings for use with Remote Access Clients

Follow these steps to configure the proxy server parameters for a client.

**Procedure**

**Step 1** Configure a browser proxy server and port for a client device by entering the **msie-proxy server** command in group-policy configuration mode:

```bash
hostname(config-group-policy)# msie-proxy server {value server[:port] | none}
hostname(config-group-policy)#
```

The default value is **none**, which is not specifying any proxy server settings on the browser of the client device. To remove the attribute from the configuration, use the **no** form of the command.

```bash
hostname(config-group-policy)# no msie-proxy server
hostname(config-group-policy)#
```

The line containing the proxy server IP address or hostname and the port number must be less than 100 characters long.

The following example shows how to configure the IP address 192.168.10.1 as a browser proxy server, using port 880, for the group policy named FirstGroup:

```bash
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# msie-proxy server value 192.168.21.1:880
hostname(config-group-policy)#
```

**Step 2** Configure the browser proxy actions (“methods”) for a client device by entering the **msie-proxy method** command in group-policy configuration mode.

```bash
hostname(config-group-policy)# msie-proxy method [auto-detect | no-modify | no-proxy | use-server]
hostname(config-group-policy)#
```
The default value is no-modify. To remove the attribute from the configuration, use the no form of the command.

```
hostname(config-group-policy)# no msie-proxy method [auto-detect | no-modify | no-proxy | use-server]
```

The available methods are as follows:

- **auto-detect**—Enables the use of automatic proxy server detection in the browser for the client device.
- **no-modify**—Leaves the HTTP browser proxy server setting in the browser unchanged for this client device.
- **no-proxy**—Disables the HTTP proxy setting in the browser for the client device.
- **use-server**—Sets the HTTP proxy server setting in the browser to use the value configured in the msie-proxy server command.

The line containing the proxy server IP address or hostname and the port number must be less than 100 characters long.

The following example shows how to configure auto-detect as the browser proxy setting for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# msie-proxy method auto-detect
```

The following example configures the browser proxy setting for the group policy named FirstGroup to use the server QAserver, port 1001 as the server for the client device:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# msie-proxy server QAserver:port 1001
hostname(config-group-policy)# msie-proxy method use-server
```

**Step 3** Configure browser proxy exception list settings for a local bypass on the client device by entering the msie-proxy except-list command in group-policy configuration mode. These addresses are not accessed by a proxy server. This list corresponds to the Exceptions box in the Proxy Settings dialog box.

```
hostname(config-group-policy)# msie-proxy except-list {value server[::port] | none}
```

To remove the attribute from the configuration, use the no form of the command:

```
hostname(config-group-policy)# no msie-proxy except-list
```

- **value server:host**—Specifies the IP address or name of an MSIE server and port that is applied for this client device. The port number is optional.
• **none**—Indicates that there is no IP address/hostname or port and prevents inheriting an exception list.

By default, msie-proxy except-list is disabled.

The line containing the proxy server IP address or hostname and the port number must be less than 100 characters long.

The following example shows how to set a browser proxy exception list, consisting of the server at IP address 192.168.20.1, using port 880, for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# msie-proxy except-list value 192.168.20.1:880
```

**Step 4** Enable or disable browser proxy local-bypass settings for a client device by entering the `msie-proxy local-bypass` command in group-policy configuration mode.

```
hostname(config-group-policy)# msie-proxy local-bypass {enable | disable}
```

To remove the attribute from the configuration, use the `no` form of the command.

```
hostname(config-group-policy)# no msie-proxy local-bypass {enable | disable}
```

By default, msie-proxy local-bypass is disabled.

The following example shows how to enable browser proxy local-bypass for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# msie-proxy local-bypass enable
```

---

**Configure Security Attributes for IPsec (IKEv1) Clients**

To specify the security settings for a group, perform these steps.

**Procedure**

**Step 1** Specify whether to let users store their login passwords on the client system, using the `password-storage` command with the `enable` keyword in group-policy configuration mode. To disable password storage, use the `password-storage` command with the `disable` keyword.

```
hostname(config-group-policy)# password-storage {enable | disable}
```

Configure Security Attributes for IPsec (IKEv1) Clients

For security reasons, password storage is disabled by default. Enable password storage only on systems that you know to be in secure sites.

To remove the password-storage attribute from the running configuration, enter the no form of this command:

```
hostname(config-group-policy)# no password-storage
```

Specifying the no form enables inheritance of a value for password-storage from another group policy.

This command does not apply to interactive hardware client authentication or individual user authentication for hardware clients.

The following example shows how to enable password storage for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# password-storage enable
```

**Step 2** Specify whether to enable IP compression, which is disabled by default.

**Note** IP compression is not supported for IPsec IKEv2 connections.

```
hostname(config-group-policy)# ip-comp {enable | disable}
```

To enable LZS IP compression, enter the ip-comp command with the enable keyword in group-policy configuration mode. To disable IP compression, enter the ip-comp command with the disable keyword.

To remove the ip-comp attribute from the running configuration, enter the no form of this command. This enables inheritance of a value from another group policy.

```
hostname(config-group-policy)# no ip-comp
```

Enabling data compression might speed up data transmission rates for remote dial-in users connecting with modems.

**Tip** Data compression increases the memory requirement and CPU usage for each user session and consequently decreases the overall throughput of the ASA. For this reason, we recommend that you enable data compression only for remote users connecting with a modem. Design a group policy specific to modem users, and enable compression only for them.

**Step 3** Specify whether to require that users reauthenticate on IKE re-key by using the re-xauth command with the enable keyword in group-policy configuration mode.
IKE re-key is not supported for IKEv2 connections.

If you enable reauthentication on IKE re-key, the ASA prompts the user to enter a username and password during initial Phase 1 IKE negotiation and also prompts for user authentication whenever an IKE re-key occurs. Reauthentication provides additional security.

If the configured re-key interval is very short, users might find the repeated authorization requests inconvenient. To avoid repeated authorization requests, disable reauthentication. To check the configured re-key interval, in monitoring mode, enter the `show crypto ipsec sa` command to view the security association lifetime in seconds and lifetime in kilobytes of data. To disable user reauthentication on IKE re-key, enter the `disable` keyword. Reauthentication on IKE re-key is disabled by default.

```
hostname(config-group-policy)# re-xauth {enable | disable}
```

To enable inheritance of a value for reauthentication on IKE re-key from another group policy, remove the re-xauth attribute from the running configuration by entering the `no` form of this command:

```
hostname(config-group-policy)# no re-xauth
```

**Note**  
Reauthentication fails if there is no user at the other end of the connection.

**Step 4**  
Specify whether to enable perfect forward secrecy. In IPsec negotiations, perfect forward secrecy ensures that each new cryptographic key is unrelated to any previous key. A group policy can inherit a value for perfect forward secrecy from another group policy. Perfect forward secrecy is disabled by default. To enable perfect forward secrecy, use the `pfs` command with the `enable` keyword in group-policy configuration mode.

```
hostname(config-group-policy)# pfs {enable | disable}
```

To disable perfect forward secrecy, enter the `pfs` command with the `disable` keyword.

To remove the perfect forward secrecy attribute from the running configuration and prevent inheriting a value, enter the `no` form of this command.

```
hostname(config-group-policy)# no pfs
```

---

### Configure IPsec-UDP Attributes for IKEv1 Clients

IPsec over UDP, sometimes called IPsec through NAT, lets a hardware client connect via UDP to a ASA that is running NAT. It is disabled by default. IPsec over UDP is proprietary; it applies only to remote-access connections, and it requires mode configuration. The ASA exchanges configuration parameters with the client while negotiating SAs. Using IPsec over UDP may slightly degrade system performance.
To enable IPsec over UDP, configure the `ipsec-udp` command with the `enable` keyword in group-policy configuration mode, as follows:

```
hostname(config-group-policy)# ipsec-udp {enable | disable}
hostname(config-group-policy)# no ipsec-udp
```

To use IPsec over UDP, you must also configure the `ipsec-udp-port` command, as described in this section. To disable IPsec over UDP, enter the `disable` keyword. To remove the IPsec over UDP attribute from the running configuration, enter the `no` form of this command. This enables inheritance of a value for IPsec over UDP from another group policy.

The following example shows how to set IPsec over UDP for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# ipsec-udp enable
```

If you enabled IPsec over UDP, you must also configure the `ipsec-udp-port` command in group-policy configuration mode. This command sets a UDP port number for IPsec over UDP. In IPsec negotiations, the ASA listens on the configured port and forwards UDP traffic for that port even if other filter rules drop UDP traffic. The port numbers can range from 4001 through 49151. The default port value is 10000.

To disable the UDP port, enter the `no` form of this command. This enables inheritance of a value for the IPsec over UDP port from another group policy.

```
hostname(config-group-policy)# ipsec-udp-port port
```

The following example shows how to set an IPsec UDP port to port 4025 for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# ipsec-udp-port 4025
```

### Configure Attributes for VPN Hardware Clients

**Procedure**

1. **Step 1** *(Optional)* Configure Network Extension Mode with the following command:

   `[no] nem [enable | disable]`

   Network extension mode lets hardware clients present a single, routable network to the remote private network over the VPN tunnel. PAT does not apply. Therefore, devices behind the Easy VPN Server have direct access to devices on the private network behind the Easy VPN Remote over the tunnel, and only over the tunnel, and vice versa. The hardware client must initiate the tunnel, but after the tunnel is up, either side can initiate data exchange.

   **Example:**

   The following example shows how to set NEM for the group policy named FirstGroup:
Step 2  (Optional) Configure Secure Unit Authentication with the following command:

\[ \text{[no] secure-unit-authentication [enable | disable]} \]

Secure unit authentication provides additional security by requiring VPN hardware clients to authenticate with a username and password each time that the client initiates a tunnel. With this feature enabled, the hardware client does not use the saved username and password if configured. Secure unit authentication is disabled by default.

Secure unit authentication requires that you have an authentication server group configured for the connection profile the hardware client(s) uses. If you require secure unit authentication on the primary ASA, be sure to configure it on any backup servers as well.

Note: With this feature enabled, to bring up a VPN tunnel, a user must be present to enter the username and password.

Example:

The following example shows how to enable secure unit authentication for the group policy named FirstGroup:

\[
\begin{align*}
\text{hostname(config)} \# & \text{ group-policy FirstGroup attributes} \\
\text{hostname(config-group-policy)} \# & \text{ secure-unit-authentication enable}
\end{align*}
\]

To disable secure unit authentication, enter the disable keyword. To remove the secure unit authentication attribute from the running configuration, enter the no form of this command. This option allows inheritance of a value from another group policy.

Step 3  (Optional) Configure User Authentication with the following command:

\[ \text{[no] user-authentication [enable | disable]} \]

When enabled, user authentication requires that individual users behind a hardware client authenticate to gain access to the network across the tunnel. Individual users authenticate according to the order of authentication servers that you configure. User authentication is disabled by default.

If you require user authentication on the primary ASA, be sure to configure it on any backup servers as well.

Example:

The following example shows how to enable user authentication for the group policy named FirstGroup:

\[
\begin{align*}
\text{hostname(config)} \# & \text{ group-policy FirstGroup attributes} \\
\text{hostname(config-group-policy)} \# & \text{ user-authentication enable}
\end{align*}
\]

To disable user authentication, enter the disable keyword. To remove the user authentication attribute from the running configuration, enter the no form of this command. This option allows inheritance of a value for user authentication from another group policy.

Step 4 Set an idle timeout for individual users that have authenticated with the following command:

\[ \text{[no] user-authentication-idle-timeout minutes | none} \]
The *minutes* parameter specifies the number of minutes in the idle timeout period. The minimum is 1 minute, the default is 30 minutes, and the maximum is 35791394 minutes.

If there is no communication activity by a user behind a hardware client in the idle timeout period, the ASA terminates the client’s access. This timer terminates only the client’s access through the VPN tunnel, not the VPN tunnel itself.

**Example:**
The following example shows how to set an idle timeout value of 45 minutes for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# user-authentication enable
hostname(config-group-policy)# user-authentication-idle-timeout 45
```

To delete the idle timeout value, enter the `no` form of this command. This option allows inheritance of an idle timeout value from another group policy. To prevent inheriting an idle timeout value, enter the `user-authentication-idle-timeout` command with the `none` keyword. This command sets the idle timeout with a null value, which disallows an idle timeout and prevents inheriting a user authentication idle timeout value from a default or specified group policy.

**Note**  
The idle timeout indicated in response to the `show uauth` command is always the idle timeout value of the user who authenticated the tunnel on the Cisco Easy VPN remote device.

**Step 5**  
Configure IP Phone Bypass with the following command:

```
ip-phone-bypass enable
```

IP Phone Bypass lets IP phones behind hardware clients connect without undergoing user authentication processes. IP Phone Bypass is disabled by default. This only applies when IUA is enabled.

**Note**  
You must also configure MAC address exemption on the client to exempt these clients from authentication.

To disable IP Phone Bypass, enter the `disable` keyword. To remove the IP phone Bypass attribute from the running configuration, enter the `no` form of this command. This option allows inheritance of a value for IP Phone Bypass from another group policy.

**Step 6**  
Configure LEAP Bypass with the following command:

```
leap-bypass enable
```

LEAP Bypass only applies when `user-authentication` is enabled. This command lets LEAP packets from Cisco wireless access point devices establish LEAP authentication and then authenticate again per user authentication. LEAP Bypass is disabled by default.

LEAP users behind a hardware client have a circular dilemma: they cannot negotiate LEAP authentication because they cannot send their credentials to the RADIUS server behind the central site device over the tunnel. The reason they cannot send their credentials over the tunnel is that they have not authenticated on the wireless network. To solve this problem, LEAP Bypass lets LEAP packets, and only LEAP packets, traverse the tunnel to authenticate the wireless connection to a RADIUS server before individual users authenticate. Then the users proceed with individual user authentication.

LEAP Bypass operates correctly under the following conditions:

- `secure-unit-authentication` must be disabled. If interactive unit authentication is enabled, a non-LEAP (wired) device must authenticate the hardware client before LEAP devices can connect using that tunnel.
• **user-authentication** is enabled. Otherwise, LEAP Bypass does not apply.

• Access points in the wireless environment must be Cisco Aironet Access Points running Cisco Discovery Protocol (CDP). The wireless NIC cards for PCs can be other brands.

**Example:**
The following example shows how to set LEAP Bypass for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# user-authentication enable
hostname(config-group-policy)# leap-bypass enable
```

To disable LEAP Bypass, enter the `disable` keyword. To remove the LEAP Bypass attribute from the running configuration, enter the `no` form of this command. This option allows inheritance of a value for LEAP Bypass from another group policy:

---

**Configure Group Policy Attributes for AnyConnect Secure Mobility Client Connections**

After enabling AnyConnect client connections as described in *AnyConnect VPN Client Connections, on page 231*, you can enable or require AnyConnect features for a group policy. Follow these steps in group-policy **webvpn** configuration mode:

**Procedure**

**Step 1**
Enter group policy **webvpn** configuration mode. For example:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
```

**Step 2**
To disable the permanent installation of the AnyConnect client on the endpoint computer, use the `anyconnect keep-installer` command with the `none` keyword. For example:

```
hostname(config-group-webvpn)# anyconnect keep-installer none
hostname(config-group-webvpn)#
```

The default is that permanent installation of the client is enabled. The client remains installed on the endpoint at the end of the AnyConnect session.

**Step 3**
To enable compression of HTTP data over an AnyConnect SSL connection for the group policy, enter the `anyconnect ssl compression` command. By default, compression is set to `none` (disabled). To enable compression, use the `deflate` keyword. For example:

```
hostname(config-group-webvpn)# anyconnect compression deflate
hostname(config-group-webvpn)#
```
Step 4 Configure Dead Peer Detection, on page 246

Step 5 You can ensure that an AnyConnect connection through a proxy, firewall, or NAT device remains open, even if the device limits the time that the connection can be idle by adjusting the frequency of keepalive messages using the `anyconnect ssl keepalive` command:

```
anyconnect ssl keepalive {none | seconds}
```

Adjusting keepalives also ensures the AnyConnect client does not disconnect and reconnect when the remote user is not actively running a socket-based application, such as Microsoft Outlook or Microsoft Internet Explorer.

The following example configures the security appliance to enable the AnyConnect client to send keepalive messages, with a frequency of 300 seconds (5 minutes):

```
hostname(config-group-webvpn)# anyconnect ssl keepalive 300
hostname(config-group-webvpn)#
```

Step 6 To enable the AnyConnect client to perform a re-key on an SSL session, use the `anyconnect ssl rekey` command:

```
anyconnect ssl rekey {method {ssl | new-tunnel} | time minutes | none}
```

By default, re-key is disabled.

Specifying the method as `new-tunnel` specifies that the AnyConnect client establishes a new tunnel during SSL re-key. Specifying the method as `none` disables re-key. Specifying the method as `ssl` specifies that SSL renegotiation takes place during re-key. Instead of specifying the method, you can specify the time; that is, the number of minutes from the start of the session until the re-key takes place, from 1 through 10080 (1 week).

The following example configures the AnyConnect client to renegotiate with SSL during re-key and configures the re-key to occur 30 minutes after the session begins:

```
hostname(config-group-webvpn)# anyconnect ssl rekey method ssl
hostname(config-group-webvpn)# anyconnect ssl rekey time 30
hostname(config-group-webvpn)#
```

Step 7 The Client Protocol Bypass feature allows you to configure how the AnyConnect client manages IPv4 traffic when ASA is expecting only IPv6 traffic or how it manages IPv6 traffic when it is expecting only IPv4 traffic.

When the AnyConnect client makes a VPN connection to the ASA, the ASA could assign it an IPv4, IPv6, or both an IPv4 and IPv6 address. If the ASA assigns the AnyConnect connection only an IPv4 address or only an IPv6 address, you can now configure the Client Bypass Protocol to drop network traffic for which the ASA did not assign an IP address, or allow that traffic to bypass the ASA and be sent from the client unencrypted or “in the clear.”

For example, assume that the ASA assigns only an IPv4 address to an AnyConnect connection and the endpoint is dual stacked. When the endpoint attempts to reach an IPv6 address, if Client Bypass Protocol is disabled, the IPv6 traffic is dropped; however, if Client Bypass Protocol is enabled, the IPv6 traffic is sent from the client in the clear.

If establishing an IPsec tunnel (as opposed to an SSL connection), the ASA is not notified whether or not IPv6 is enabled on the client, so ASA always pushes down the client bypass protocol setting.

Use the `client-bypass-protocol` command to enable or disable the client bypass protocol feature. This is the command syntax:
**client-bypass-protocol {enable | disable}**

The following example enables client bypass protocol:

```
hostname(config-group-policy)# client-bypass-protocol enable
hostname(config-group-policy)#
```

The following example disables client bypass protocol:

```
hostname(config-group-policy)# client-bypass-protocol disable
hostname(config-group-policy)#
```

The following example removes an enabled or disabled client bypass protocol setting:

```
hostname(config-group-policy)# no client-bypass-protocol enable
hostname(config-group-policy)#
```

**Step 8**

If you have configured Load Balancing between your ASAs, specify the FQDN of the ASA in order to resolve the ASA IP address used for re-establishing the VPN session. This setting is critical to support client roaming between networks of different IP protocols (such as IPv4 to IPv6).

You cannot use the ASA FQDN present in the AnyConnect profile to derive the ASA IP address after roaming. The addresses may not match the correct device (the one the tunnel was established to) in the load balancing scenario.

If the device FQDN is not pushed to the client, the client will try to reconnect to whatever IP address the tunnel had previously established. In order to support roaming between networks of different IP protocols (from IPv4 to IPv6), AnyConnect must perform name resolution of the device FQDN after roaming, so that it can determine which ASA address to use for re-establishing the tunnel. The client uses the ASA FQDN present in its profile during the initial connection. During subsequent session reconnects, it always uses the device FQDN pushed by ASA (and configured by the administrator in the group policy), when available. If the FQDN is not configured, the ASA derives the device FQDN (and sends it to the client) from whatever is set under Device Setup > Device Name/Password and Domain Name.

If the device FQDN is not pushed by the ASA, the client cannot re-establish the VPN session after roaming between networks of different IP protocols.

Use the `gateway-fqdn` command to configure the FQDN of the ASA. This is the command syntax:

```
gateway-fqdn { value FQDN_Name | none } or no gateway-fqdn
```

The following example defines the FQDN of the ASA as ASAName.example.cisco.com

```
hostname(config-group-policy)# gateway-fqdn value ASAName.example.cisco.com
hostname(config-group-policy)#
```

The following example removes the FQDN of the ASA from the group policy. The group policy then inherits this value from the Default Group Policy.

```
hostname(config-group-policy)# no gateway-fqdn
hostname(config-group-policy)#
```
The following example defines the FQDN as an empty value. The global FQDN configured using hostname and domain-name commands will be used if available.

```
hostname(config-group-policy)# gateway-fqdn none
hostname(config-group-policy)#
```

### Configure Backup Server Attributes

Configure backup servers if you plan on using them. IPsec backup servers let a VPN client connect to the central site when the primary ASA is unavailable. When you configure backup servers, the ASA pushes the server list to the client as the IPsec tunnel is established. Backup servers do not exist until you configure them, either on the client or on the primary ASA.

Configure backup servers either on the client or on the primary ASA. If you configure backup servers on the ASA, it pushes the backup server policy to the clients in the group, replacing the backup server list on the client if one is configured.

**Note**

If you are using hostnames, it is wise to have backup DNS and WINS servers on a separate network from that of the primary DNS and WINS servers. Otherwise, if clients behind a hardware client obtain DNS and WINS information from the hardware client via DHCP, and the connection to the primary server is lost, and the backup servers have different DNS and WINS information, clients cannot be updated until the DHCP lease expires. In addition, if you use hostnames and the DNS server is unavailable, significant delays can occur.

To configure backup servers, enter the `backup-servers` command in group-policy configuration mode:

```
hostname(config-group-policy)# backup-servers {server1 server2... server10 | clear-client-config | keep-client-config}
```

To remove a backup server, enter the `no` form of this command with the backup server specified. To remove the backup-servers attribute from the running configuration and enable inheritance of a value for backup-servers from another group policy, enter the `no` form of this command without arguments.

```
hostname(config-group-policy)# no backup-servers {server1 server2... server10 | clear-client-config | keep-client-config}
```

The **clear-client-config** keyword specifies that the client uses no backup servers. The ASA pushes a null server list.

The **keep-client-config** keyword specifies that the ASA sends no backup server information to the client. The client uses its own backup server list, if configured. This is the default.

The `server1 server2... server10` parameter list is a space-delimited, priority-ordered list of servers for the VPN client to use when the primary ASA is unavailable. This list identifies servers by IP address or hostname. The list can be 500 characters long, and it can contain up to 10 entries.

The following example shows how to configure backup servers with IP addresses 10.10.10.1 and 192.168.10.14, for the group policy named FirstGroup:
Configure Network Admission Control Parameters

The group-policy NAC commands in this section all have default values. Unless you have a good reason for changing them, accept the default values for these parameters.

The ASA uses Extensible Authentication Protocol (EAP) over UDP (EAPoUDP) messaging to validate the posture of remote hosts. Posture validation involves the checking of a remote host for compliance with safety requirements before the assignment of a network access policy. An Access Control Server must be configured for Network Admission Control before you configure NAC on the security appliance.

The Access Control Server downloads the posture token, an informational text string configurable on the ACS, to the security appliance to aid in system monitoring, reporting, debugging, and logging. A typical posture token is Healthy, Checkup, Quarantine, Infected, or Unknown. Following posture validation or clientless authentication, the ACS downloads the access policy for the session to the security appliance.

To configure Network Admission Control settings for the default group policy or an alternative group policy, perform the following steps.

Procedure

**Step 1**
(Optional) Configure the status query timer period. The security appliance starts the status query timer after each successful posture validation and status query response. The expiration of this timer triggers a query for changes in the host posture, referred to as a status query. Enter the number of seconds in the range 30 through 1800. The default setting is 300.

To specify the interval between each successful posture validation in a Network Admission Control session and the next query for changes in the host posture, use the `nac-sq-period` command in group-policy configuration mode:

```
hostname(config-group-policy)# nac-sq-period seconds
hostname(config-group-policy)#
```

To inherit the value of the status query timer from the default group policy, access the alternative group policy from which to inherit it, then use the `no` form of this command:

```
hostname(config-group-policy)# no nac-sq-period [seconds]
hostname(config-group-policy)
```

The following example changes the value of the status query timer to 1800 seconds:

```
hostname(config-group-policy)# nac-sq-period 1800
hostname(config-group-policy)#
```

The following example inherits the value of the status query timer from the default group policy:

```
hostname(config-group-policy)# no nac-sq-period
hostname(config-group-policy)#
```
Step 2  (Optional) Configure the NAC revalidation period. The security appliance starts the revalidation timer after each successful posture validation. The expiration of this timer triggers the next unconditional posture validation. The security appliance maintains posture validation during revalidation. The default group policy becomes effective if the Access Control Server is unavailable during posture validation or revalidation. Enter the interval in seconds between each successful posture validation. The range is 300 through 86400. The default setting is 36000.

To specify the interval between each successful posture validation in a Network Admission Control session, use the `nac-reval-period` command in group-policy configuration mode:

```
hostname(config-group-policy)# nac-reval-period seconds
hostname(config-group-policy)#
```

To inherit the value of the Revalidation Timer from the default group policy, access the alternative group policy from which to inherit it, then use the `no` form of this command:

```
hostname(config-group-policy)# no nac-reval-period [seconds]
hostname(config-group-policy)#
```

The following example changes the revalidation timer to 86400 seconds:

```
hostname(config-group-policy)# nac-reval-period 86400
hostname(config-group-policy)
```

The following example inherits the value of the revalidation timer from the default group policy:

```
hostname(config-group-policy)# no nac-reval-period
hostname(config-group-policy)#
```

Step 3  (Optional) Configure the default ACL for NAC. The security appliance applies the security policy associated with the selected ACL if posture validation fails. Specify `none` or an extended ACL. The default setting is `none`. If the setting is `none` and posture validation fails, the security appliance applies the default group policy.

To specify the ACL to be used as the default ACL for Network Admission Control sessions that fail posture validation, use the `nac-default-acl` command in group-policy configuration mode:

```
hostname(config-group-policy)# nac-default-acl {acl-name | none}
hostname(config-group-policy)#
```

To inherit the ACL from the default group policy, access the alternative group policy from which to inherit it, then use the `no` form of this command:

```
hostname(config-group-policy)# no nac-default-acl [acl-name | none]
hostname(config-group-policy)#
```

The elements of this command are as follows:

- `acl-name`—Specifies the name of the posture validation server group, as configured on the ASA using the `aaa-server host` command. The name must match the server-tag variable specified in that command.
none—Disables inheritance of the ACL from the default group policy and does not apply an ACL to NAC sessions that fail posture validation.

Because NAC is disabled by default, VPN traffic traversing the ASA is not subject to the NAC Default ACL until NAC is enabled.

The following example identifies acl-1 as the ACL to be applied when posture validation fails:

```
 hostname(config-group-policy)# nac-default-acl acl-1
 hostname(config-group-policy)#
```

The following example inherits the ACL from the default group policy:

```
 hostname(config-group-policy)# no nac-default-acl
 hostname(config-group-policy)#
```

The following example disables inheritance of the ACL from the default group policy and does not apply an ACL to NAC sessions that fail posture validation:

```
 hostname(config-group-policy)# nac-default-acl none
 hostname(config-group-policy)#
```

**Step 4** Configure NAC exemptions for VPN. By default, the exemption list is empty. The default value of the filter attribute is none. Enter the `vpn-nac-exempt` command once for each operating system (and ACL) to be matched to exempt remote hosts from posture validation.

To add an entry to the list of remote computer types that are exempt from posture validation, use the `vpn-nac-exempt` command in group-policy configuration mode:

```
 hostname(config-group-policy)# vpn-nac-exempt os "os name" [filter acl-name | none] {disable}
 hostname(config-group-policy)#
```

To disable inheritance and specify that all hosts are subject to posture validation, use the `none` keyword immediately following `vpn-nac-exempt`:

```
 hostname(config-group-policy)# vpn-nac-exempt none
 hostname(config-group-policy)#
```

To remove an entry from the exemption list, use the `no` form of this command and name the operating system (and ACL) in the entry to be removed:

```
 hostname(config-group-policy)# no vpn-nac-exempt os "os name"[filter acl-name | none] [disable]
 hostname(config-group-policy)#
```

To remove all entries from the exemption list associated with this group policy and inherit the list from the default group policy, use the `no` form of this command without specifying additional keywords:

```
 hostname(config-group-policy)# no vpn-nac-exempt
 hostname(config-group-policy)#
```
The syntax elements for these commands are as follows:

- **acl-name**—Name of the ACL present in the ASA configuration.
- **disable**—Disables the entry in the exemption list without removing it from the list.
- **filter**—(Optional) Apply an ACL to filter the traffic if the computer matches the OS name.
- **none**—When entered immediately after **vpn-nac-exempt**, this keyword disables inheritance and specifies that all hosts are subject to posture validation. When entered immediately after **filter**, this keyword indicates that the entry does not specify an ACL.
- **OS**—Exempts an operating system from posture validation.
- **os name**—Operating system name. Quotation marks are required only if the name includes a space (for example, “Windows XP”).

The following example disables inheritance and specifies that all hosts will be subject to posture validation:

```
hostname(config-group-policy)# no vpn-nac-exempt none
hostname(config-group-policy)
```

The following example removes all entries from the exemption list:

```
hostname(config-group-policy)# no vpn-nac-exempt
hostname(config-group-policy)
```

**Step 5**  
Enable or disable Network Admission Control by entering the following command:

```
hostname(config-group-policy)# nac {enable | disable}
hostname(config-group-policy)#
```

To inherit the NAC setting from the default group policy, access the alternative group policy from which to inherit it, then use the **no** form of this command:

```
hostname(config-group-policy)# no nac [enable | disable]
hostname(config-group-policy)#
```

By default, NAC is disabled. Enabling NAC requires posture validation for remote access. If the remote computer passes the validation checks, the ACS server downloads the access policy for the ASA to enforce. NAC is disabled by default.

An Access Control Server must be present on the network.

The following example enables NAC for the group policy:

```
hostname(config-group-policy)# nac enable
hostname(config-group-policy)#
```
Configure VPN Client Firewall Policies

A firewall isolates and protects a computer from the Internet by inspecting each inbound and outbound packet of data to determine whether to allow it through the firewall or to drop it. Firewalls provide extra security if remote users in a group have split tunneling configured. In this case, the firewall protects the user’s computer, and thereby the corporate network, from intrusions by way of the Internet or the user’s local LAN. Remote users connecting to the ASA with the VPN client can choose the appropriate firewall option.

Set personal firewall policies that the ASA pushes to the VPN client during IKE tunnel negotiation by using the `client-firewall` command in group-policy configuration mode. To delete a firewall policy, enter the `no` form of this command.

To delete all firewall policies, enter the `no client-firewall` command without arguments. This command deletes all configured firewall policies, including a null policy if you created one by entering the `client-firewall` command with the `none` keyword.

When there are no firewall policies, users inherit any that exist in the default or other group policy. To prevent users from inheriting such firewall policies, enter the `client-firewall` command with the `none` keyword.

The Add or Edit Group Policy dialog box on the Client Firewall tab lets you configure firewall settings for VPN clients for the group policy being added or modified.

---

**Note**

Only VPN clients running Microsoft Windows can use these firewall features. They are currently not available to hardware clients or other (non-Windows) software clients.

In the first scenario, a remote user has a personal firewall installed on the PC. The VPN client enforces firewall policy defined on the local firewall, and it monitors that firewall to make sure it is running. If the firewall stops running, the VPN client drops the connection to the ASA. (This firewall enforcement mechanism is called Are You There (AYT), because the VPN client monitors the firewall by sending it periodic “are you there?” messages; if no reply comes, the VPN client knows the firewall is down and terminates its connection to the ASA.) The network administrator might configure these PC firewalls originally, but with this approach, each user can customize his or her own configuration.

In the second scenario, you might prefer to enforce a centralized firewall policy for personal firewalls on VPN client PCs. A common example would be to block Internet traffic to remote PCs in a group using split tunneling. This approach protects the PCs, and therefore the central site, from intrusions from the Internet while tunnels are established. This firewall scenario is called push policy or Central Protection Policy (CPP). On the ASA, you create a set of traffic management rules to enforce on the VPN client, associate those rules with a filter, and designate that filter as the firewall policy. The ASA pushes this policy down to the VPN client. The VPN client then in turn passes the policy to the local firewall, which enforces it.

Configure AnyConnect Client Firewall Policies

Firewall rules for the AnyConnect client can specify IPv4 and IPv6 addresses.

**Before you begin**

You have created Unified Access Rules with IPv6 addresses specified.
Procedure

**Step 1** Enter webvpn group policy configuration mode.

```bash
webvpn
```

**Example:**

```
hostname(config)# group-policy ac-client-group attributes
hostname(config-group-policy)# webvpn
```

**Step 2** Specify an access control rule for the private or public network rule. The private network rule is the rule applied to the VPN virtual adapter interface on the client.

```bash
anyconnect firewall-rule client-interface {private | public} value [RuleName]
```

**Example:**

```
hostname(config-group-webvpn)# anyconnect firewall-rule client-interface private value ClientFWRule
```

**Step 3** Display the group policy attributes as well as the webvpn policy attribute for the group policy.

```bash
show runn group-policy [value]
```

**Example:**

```
hostname(config-group-webvpn)# show run group-policy FirstGroup
group-policy FirstGroup internal
group-policy FirstGroup attributes
webvpn
  anyconnect firewall-rule client-interface private value ClientFWRule
```

**Step 4** Remove the client firewall rule from the private network rule.

```bash
no anyconnect firewall-rule client-interface private value [RuleName]
```

**Example:**

```
hostname(config-group-webvpn)# no anyconnect firewall-rule client-interface private value
hostname(config-group-webvpn)#
```

---

**Use of a Zone Labs Integrity Server**

This section introduces the Zone Labs Integrity server, also called the Check Point Integrity server, and presents an example procedure for configuring the ASA to support the Zone Labs Integrity server. The Integrity server is a central management station for configuring and enforcing security policies on remote PCs. If a remote PC does not conform to the security policy dictated by the Integrity server, it is not granted access to the private network protected by the Integrity server and ASA.

The VPN client software and the Integrity client software are co-resident on a remote PC. The following steps summarize the actions of the remote PC, ASA, and Integrity server in the establishment of a session between the PC and the enterprise private network:
1. The VPN client software (residing on the same remote PC as the Integrity client software) connects to the ASA and tells the ASA what type of firewall client it is.

2. After the ASA approves the client firewall type, the ASA passes Integrity server address information back to the Integrity client.

3. With the ASA acting as a proxy, the Integrity client establishes a restricted connection with the Integrity server. A restricted connection is only between the Integrity client and the Integrity server.

4. The Integrity server determines if the Integrity client is in compliance with the mandated security policies. If the Integrity client is in compliance with security policies, the Integrity server instructs the ASA to open the connection and provide the Integrity client with connection details.

5. On the remote PC, the VPN client passes connection details to the Integrity client and signals that policy enforcement should begin immediately and the Integrity client can enter the private network.

6. After the VPN connection is established, the Integrity server continues to monitor the state of the Integrity client using client heartbeat messages.

Note
The current release of the ASA supports one Integrity server at a time, even though the user interfaces support the configuration of up to five Integrity servers. If the active Integrity server fails, configure another one on the ASA and then reestablish the VPN client session.

To configure the Integrity server, perform the following steps:

Procedure

Step 1 Configure an Integrity server using the IP address 10.0.0.5.

\texttt{zonelabs-\textit{Integrity server-address} \{hostname1 | ip-address1\}}

\textbf{Example:}

\begin{verbatim}
hostname(config)# zonelabs-\textit{Integrity server-address} 10.0.0.5
\end{verbatim}

Step 2 Specify port 300 (the default port is 5054).

\texttt{zonelabs-\textit{integrity port} port-number}

\textbf{Example:}

\begin{verbatim}
hostname(config)# zonelabs-\textit{integrity port} 300
\end{verbatim}

Step 3 Specify the inside interface for communications with the Integrity server.

\texttt{zonelabs-\textit{integrity interface} interface}

\textbf{Example:}

\begin{verbatim}
hostname(config)# zonelabs-\textit{integrity interface} inside
\end{verbatim}

Step 4 Ensure that the ASA waits 12 seconds for a response from either the active or standby Integrity servers before declaring the Integrity server as failed and closing the VPN client connections.
Set the Firewall Client Type to Zone Labs

Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>To set the firewall client type to the Zone Labs Integrity type, enter the following command: client-firewall {opt</td>
<td>req} zonelabs-integrity</td>
</tr>
</tbody>
</table>

Note: If the connection between the ASA and the Integrity server fails, the VPN client connections remain open by default so that the enterprise VPN is not disrupted by the failure of an Integrity server. However, you may want to close the VPN connections if the Zone Labs Integrity server fails.

```
zonelabs-integrity fail-timeout timeout
Example:
hostname(config)# zonelabs-integrity fail-timeout 12
```

**Step 5**: Configure the ASA so that connections to VPN clients close when the connection between the ASA and the Zone Labs Integrity server fails.

```
zonelabs-integrity fail-close
Example:
hostname(config)# zonelabs-integrity fail-close
```

**Step 6**: Return the configured VPN client connection fail state to the default and ensure that the client connections remain open.

```
zonelabs-integrity fail-open
Example:
hostname(config)# zonelabs-integrity fail-open
```

**Step 7**: Specify that the Integrity server connects to port 300 (the default is port 80) on the ASA to request the server SSL certificate.

```
zonelabs-integrity ssl-certificate-port cert-port-number
Example:
hostname(config)# zonelabs-integrity ssl-certificate-port 300
```

**Step 8**: While the server SSL certificate is always authenticated, specify that the client SSL certificate of the Integrity server be authenticated.

```
zonelabs-integrity ssl-client-authentication {enable | disable}
Example:
hostname(config)# zonelabs-integrity ssl-client-authentication enable
```
Set the Client Firewall Parameters

Enter the following commands to set the appropriate client firewall parameters. You can configure only one instance of each command. For more information, see Configure VPN Client Firewall Policies, on page 177.

- **Cisco Integrated Firewall**

  hostname(config-group-policy)# client-firewall (opt | req) cisco-integrated acl-in ACL acl-out ACL

- **Cisco Security Agent**

  hostname(config-group-policy)# client-firewall (opt | req) cisco-security-agent

- **No Firewall**

  hostname(config-group-policy)# client-firewall none

- **Custom Firewall**

  hostname(config-group-policy)# client-firewall (opt | req) custom vendor-id num product-id num policy (AYT | CPP acl-in ACL acl-out ACL) [description string]

- **Zone Labs Firewalls**

  hostname(config-group-policy)# client-firewall (opt | req) zonelabs-integrity

  hostname(config-group-policy)# client-firewall (opt | req) zonelabs-zonealarm policy (AYT | CPP acl-in ACL acl-out ACL)

  hostname(config-group-policy)# client-firewall (opt | req) zonelabs-zonealarmorpro policy (AYT | CPP acl-in ACL acl-out ACL)

  hostname(config-group-policy)# client-firewall (opt | req) zonelabs-zonealarmpro policy (AYT | CPP acl-in ACL acl-out ACL)

  When the firewall type is **zonelabs-integrity**, do not include arguments. The Zone Labs Integrity Server determines these policies.
Set the Client Firewall Parameters

- Sygate Personal Firewalls
  
  hostname(config-group-policy)# client-firewall {opt | req} sygate-personal

  hostname(config-group-policy)# client-firewall {opt | req} sygate-personal-pro

  hostname(config-group-policy)# client-firewall {opt | req} sygate-security-agent

- Network Ice, Black Ice Firewall

  hostname(config-group-policy)# client-firewall {opt | req} networkice-blackice

Table 8: client-firewall Command Keywords and Variables

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acl-in ACL</td>
<td>Provides the policy the client uses for inbound traffic.</td>
</tr>
<tr>
<td>acl-out ACL</td>
<td>Provides the policy the client uses for outbound traffic.</td>
</tr>
<tr>
<td>AYT</td>
<td>Specifies that the client PC firewall application controls the firewall policy. The ASA checks to make sure that the firewall is running. It asks, “Are You There?” If there is no response, the ASA tears down the tunnel.</td>
</tr>

<tr>
<td>zonelabs-zonealarmpro policy</td>
<td>Specifies Zone Labs Zone Alarm Pro firewall type.</td>
</tr>
</tbody>
</table>

The following example shows how to set a client firewall policy that requires Cisco Intrusion Prevention Security Agent for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# client-firewall req cisco-security-agent
```

### Configure Client Access Rules

Configure rules that limit the remote access client types and versions that can connect via IPsec through the ASA by using the `client-access-rule` command in group-policy configuration mode. Construct rules according to these guidelines:

- If you do not define any rules, the ASA permits all connection types.
- When a client matches none of the rules, the ASA denies the connection. If you define a deny rule, you must also define at least one permit rule; otherwise, the ASA denies all connections.
- For both software and hardware clients, type and version must exactly match their appearance in the `show vpn-sessiondb remote` display.
- The * character is a wildcard, which you can enter multiple times in each rule. For example, `client-access rule 3 deny type * version 3.*` creates a priority 3 client access rule that denies all client types running versions 3.x software.
- You can construct a maximum of 25 rules per group policy.
- There is a limit of 255 characters for an entire set of rules.
- You can enter n/a for clients that do not send client type and/or version.

To delete a rule, enter the `no` form of this command. This command is equivalent to the following command:

```
hostname(config-group-policy)# client-access-rule 1 deny type "Cisco VPN Client" version 4.0
```

To delete all rules, enter the `no client-access-rule command` without arguments. This deletes all configured rules, including a null rule if you created one by issuing the `client-access-rule` command with the `none` keyword.

By default, there are no access rules. When there are no client access rules, users inherit any rules that exist in the default group policy.
To prevent users from inheriting client access rules, enter the `client-access-rule` command with the `none` keyword. The result of this command is that all client types and versions can connect.

```
hostname(config-group-policy)# client-access rule priority {permit | deny} type version {version | none}
```

```
hostname(config-group-policy)# no client-access rule [priority {permit | deny} type version]
```

The table below explains the meaning of the keywords and parameters in these commands.

**Table 9: client-access rule Command Keywords and Variables**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deny</td>
<td>Denies connections for devices of a particular type and/or version.</td>
</tr>
<tr>
<td>none</td>
<td>Allows no client access rules. Sets client-access-rule to a null value, thereby allowing no restriction. Prevents inheriting a value from a default or specified group policy.</td>
</tr>
<tr>
<td>permit</td>
<td>Permits connections for devices of a particular type and/or version.</td>
</tr>
<tr>
<td>priority</td>
<td>Determines the priority of the rule. The rule with the lowest integer has the highest priority. Therefore, the rule with the lowest integer that matches a client type and/or version is the rule that applies. If a lower priority rule contradicts, the ASA ignores it.</td>
</tr>
<tr>
<td>type</td>
<td>Identifies device types via free-form strings. The string must match exactly its appearance in the <code>show vpn-sessiondb remote</code> display, except that you can enter the * character as a wildcard.</td>
</tr>
<tr>
<td>version</td>
<td>Identifies the device version via free-form strings, for example 7.0. A string must match exactly its appearance in the <code>show vpn-sessiondb remote</code> display, except that you can enter the * character as a wildcard.</td>
</tr>
</tbody>
</table>

The following example shows how to create client access rules for the group policy named FirstGroup. These rules permit Cisco VPN clients running software version 4.x, while denying all Windows NT clients:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# client-access-rule 1 deny type WinNT version *
hostname(config-group-policy)# client-access-rule 2 permit "Cisco VPN Client" version 4.*
```
The "type" field is a free-form string that allows any value, but that value must match the fixed value that the client sends to the ASA at connect time.

**Configure User Attributes**

This section describes user attributes and how to configure them.

By default, users inherit all user attributes from the assigned group policy. The ASA also lets you assign individual attributes at the user level, overriding values in the group policy that applies to that user. For example, you can specify a group policy giving all users access during business hours, but give a specific user 24-hour access.

**View the Username Configuration**

To display the configuration for all usernames, including default values inherited from the group policy, enter the **all** keyword with the `show running-config username` command, as follows:

```plaintext
hostname# show running-config all username
hostname#
```

This displays the encrypted password and the privilege level, for all users, or, if you supply a username, for that specific user. If you omit the **all** keyword, only explicitly configured values appear in this list. The following example displays the output of this command for the user named testuser:

```plaintext
hostname# show running-config all username testuser
username testuser password 12RsxXnpbyr/I9Z encrypted privilege 15
```

**Configure Attributes for Individual Users**

To configure specific users, you assign a password (or no password) and attributes to a user using the `username` command, which enters username mode. Any attributes that you do not specify are inherited from the group policy.

The internal user authentication database consists of the users entered with the `username` command. The `login` command uses this database for authentication. To add a user to the ASA database, enter the `username` command in global configuration mode. To remove a user, use the `no` version of this command with the username you want to remove. To remove all usernames, use the `clear configure username` command without appending a username.

**Set a User Password and Privilege Level**

Enter the `username` command to assign a password and a privilege level for a user. You can enter the `nopassword` keyword to specify that this user does not require a password. If you do specify a password, you can specify whether that password is stored in an encrypted form.
The optional `privilege` keyword lets you set a privilege level for this user. Privilege levels range from 0 (the lowest) through 15. System administrators generally have the highest privilege level. The default level is 2.

```
hostname(config)# username name {nopassword | password password [encrypted]}
(privilege priv_level)}
```

```
hostname(config)# no username [name]
```

The table below describes the meaning of the keywords and variables used in this command.

<table>
<thead>
<tr>
<th>Keyword/Variable</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>encrypted</td>
<td>Indicates that the password is encrypted.</td>
</tr>
<tr>
<td>name</td>
<td>Provides the name of the user.</td>
</tr>
<tr>
<td>nopassword</td>
<td>Indicates that this user needs no password.</td>
</tr>
<tr>
<td>password password</td>
<td>Indicates that this user has a password, and provides the password.</td>
</tr>
<tr>
<td>privilege priv_level</td>
<td>Sets a privilege level for this user. The range is from 0 to 15, with lower numbers having less ability to use commands and administer the ASA. The default privilege level is 2. The typical privilege level for a system administrator is 15.</td>
</tr>
</tbody>
</table>

By default, VPN users that you add with this command have no attributes or group policy association. You must explicitly configure all values.

The following example shows how to configure a user named anyuser with an encrypted password of pw_12345678 and a privilege level of 12:

```
hostname(config)# username anyuser password pw_12345678 encrypted privilege 12
```

```
hostname(config)#
```

### Configure User Attributes

After configuring the user’s password (if any) and privilege level, you set the other attributes. These can be in any order. To remove any attribute-value pair, enter the `no` form of the command.

Enter `username` mode by entering the `username` command with the `attributes` keyword:

```
hostname(config)# username name attributes
hostname(config-username)#
```

The prompt changes to indicate the new mode. You can now configure the attributes.
Configure VPN User Attributes

The VPN user attributes set values specific to VPN connections, as described in the following sections.

Configure Inheritance

You can let users inherit from the group policy the values of attributes that you have not configured at the username level. To specify the name of the group policy from which this user inherits attributes, enter the `vpn-group-policy` command. By default, VPN users have no group-policy association:

```
hostname(config-username)# vpn-group-policy group-policy-name
hostname(config-username)# no vpn-group-policy group-policy-name
```

For an attribute that is available in username mode, you can override the value of an attribute in a group policy for a particular user by configuring it in username mode.

The following example shows how to configure a user named anyuser to use attributes from the group policy named FirstGroup:

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-group-policy FirstGroup
hostname(config-username)#
```

Configure Access Hours

Associate the hours that this user is allowed to access the system by specifying the name of a configured time-range policy:

To remove the attribute from the running configuration, enter the `no` form of this command. This option allows inheritance of a time-range value from another group policy. To prevent inheriting a value, enter the `vpn-access-hours none` command. The default is unrestricted access.

```
hostname(config-username)# vpn-access-hours value {time-range | none}
hostname(config-username)# vpn-access-hours value none
hostname(config)#
```

The following example shows how to associate the user named anyuser with a time-range policy called 824:

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-access-hours 824
hostname(config-username)#
```

Configure Maximum Simultaneous Logins

Specify the maximum number of simultaneous logins allowed for this user. The range is 0 through 2147483647. The default is 3 simultaneous logins. To remove the attribute from the running configuration, enter the `no` form of this command. Enter 0 to disable login and prevent user access.

```
hostname(config-username)# vpn-simultaneous-logins integer
hostname(config-username)# no vpn-simultaneous-logins
hostname(config-username)# vpn-session-timeout alert-interval none
```
While the maximum limit for the number of simultaneous logins is very large, allowing several could compromise security and affect performance.

The following example shows how to allow a maximum of 4 simultaneous logins for the user named anyuser:

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-simultaneous-logins 4
```

### Configure the Idle Timeout

**Procedure**

**Step 1** (Optional) To configure a VPN idle timeout period use the `vpn-idle-timeout minutes` command in group-policy configuration mode or in username configuration mode.

If there is no communication activity on the connection in this period, the ASA terminates the connection. The minimum time is 1 minute, the maximum time is 35791394 minutes, and the default is 30 minutes.

The following example shows how to set a VPN idle timeout of 15 minutes for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-idle-timeout 15
```

Other actions using the `[no] vpn-idle-timeout {minutes | none}` command:

- Enter `vpn-idle-timeout none` to disable VPN idle timeout and prevent inheriting a timeout value.

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-idle-timeout none
```

This results in AnyConnect (both SSL and IPsec/IKEv2) and Clientless VPN using the global `webvpn default-idle-timeout seconds` value. This command is entered in `webvpn-config` mode, for example:

```
hostname(config-webvpn)# default-idle-timeout 300. The default is 1800 seconds (30 min), the range is 60-86400 seconds.
```

For all webvpn connections, the `default-idle-timeout` value is enforced only if `vpn-idle-timeout none` is set in the group policy/username attribute. A non-zero idle timeout value is required by ASA for all AnyConnect connections.

For Site-to-Site (IKEv1, IKEv2) and IKEv1 remote-access VPNs, we recommend you Disable timeout and allow for an unlimited idle period.

- To disable the idle timeout for this group policy or user policy, enter `no vpn-idle-timeout`. The value will be inherited.

- If you do not set `vpn-idle-timeout` at all, in anyway, the value is inherited, which defaults to 30 minutes.

**Step 2** (Optional) You can optionally configure the time at which an idle timeout alert message is displayed to the user using the `vpn-idle-timeout alert-interval {minutes}` command.
This alert message tells users how many minutes they have left until their VPN session is disconnected due to inactivity. The default alert interval is one minute.

The following example shows how to set a VPN idle timeout alert interval of 3 minutes for the user named anyuser:

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-idle-timeout alert-interval 3
```

Other actions using the `[no] vpn-idle-timeout alert-interval {minutes | none}` command:

- The `none` parameter indicates that users will not receive an alert.
  
```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-idle-timeout none
```

- To remove the alert interval for this group or user policy enter `no vpn-idle-timeout alert-interval`. The value will be inherited.
- If you do not set this parameter at all, the default alert interval is one minute.

### Configure the Maximum Connect Time

#### Procedure

**Step 1** (Optional) Configure a maximum amount of time for VPN connections, using the `vpn-session-timeout {minutes}` command in group-policy configuration mode or in username configuration mode.

The minimum time is 1 minute, and the maximum time is 35791394 minutes. There is no default value. At the end of this period of time, the ASA terminates the connection.

The following example shows how to set a VPN session timeout of 180 minutes for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# vpn-session-timeout 180
```

The following example shows how to set a VPN session timeout of 180 minutes for the user named anyuser:

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-session-timeout 180
```

Other actions using the `[no] vpn-session-timeout {minutes | none}` command:

- To remove the attribute from this policy and allow inheritance, enter the `no vpn-session-timeout` form of this command.
- To allow an unlimited timeout period, and thus prevent inheriting a timeout value, enter `vpn-session-timeout none`.

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-session-timeout none
```
Step 2

Configure the time at which a session timeout alert message is displayed to the user using the `vpn-session-timeout alert-interval {minutes | none}` command.

This alert message tells users how many minutes left until their VPN session is automatically disconnected. The following example shows how to specify that users will be notified 20 minutes before their VPN session is disconnected. You can specify a range of 1-30 minutes.

```
hostname(config-webvpn)# vpn-session-timeout alert-interval 20
```

Other actions using the `[no] vpn-session-timeout alert-interval {minutes | none}` command:

- Use the no form of the command to indicate that the VPN session timeout alert-interval attribute will be inherited from the Default Group Policy:

  ```
  hostname(config-webvpn)# no vpn-session-timeout alert-interval
  ```

- The `vpn-session-timeout alert-interval none` indicates that users will not receive an alert.

---

Apply an ACL Filter

Specify the name of a previously-configured, user-specific ACL to use as a filter for VPN connections. To disallow an ACL and prevent inheriting an ACL from the group policy, enter the `vpn-filter` command with the none keyword. To remove the ACL, including a null value created by issuing the `vpn-filter none` command, enter the `no` form of this command. The `no` option allows inheritance of a value from the group policy. There are no default behaviors or values for this command.

You configure ACLs to permit or deny various types of traffic for this user. You then use the `vpn-filter` command to apply those ACLs.

```
hostname(config-username)# vpn-filter {value ACL_name | none}
hostname(config-username)# no vpn-filter
hostname(config-username)#
```

Note

Clientless SSL VPN does not use ACLs defined in the `vpn-filter` command.

The following example shows how to set a filter that invokes an ACL named acl_vpn for the user named anyuser:

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-filter value acl_vpn
hostname(config-username)#
```

Specify the IPv4 Address and Netmask

Specify the IP address and netmask to assign to a particular user. To remove the IP address, enter the `no` form of this command.

```
hostname(config-username)# vpn-framed-ip-address {ip_address}
hostname(config-username)# no vpn-framed-ip-address
```
The following example shows how to set an IP address of 10.92.166.7 for a user named anyuser:

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-framed-ip-address 10.92.166.7
hostname(config-username)
```

Specify the network mask to use with the IP address specified in the previous step. If you used the `no vpn-framed-ip-address` command, do not specify a network mask. To remove the subnet mask, enter the `no` form of this command. There is no default behavior or value.

```
hostname(config-username)# vpn-framed-ip-netmask {netmask}
hostname(config-username)# no vpn-framed-ip-netmask
hostname(config-username)
```

The following example shows how to set a subnet mask of 255.255.255.254 for a user named anyuser:

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-framed-ip-netmask 255.255.255.254
hostname(config-username)
```

### Specify the IPv6 Address and Netmask

Specify the IPv6 address and netmask to assign to a particular user. To remove the IP address, enter the `no` form of this command.

```
hostname(config-username)# vpn-framed-ipv6-address {ip_address}
hostname(config-username)# no vpn-framed-ipv6-address
hostname(config-username)
```

The following example shows how to set an IP address and netmask of 2001::3000:1000::2000:1/64 for a user named anyuser. This address indicates a prefix value of 2001:0000:0000:0000 and an interface ID of 3000:1000:2000:1.

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-framed-ipv6-address 2001::3000:1000:2000:1/64
hostname(config-username)
```

### Specify the Tunnel Protocol

Specify the VPN tunnel types (IPsec or clientless SSL VPN) that this user can use. The default is taken from the default group policy, the default for which is IPsec. To remove the attribute from the running configuration, enter the `no` form of this command.

```
hostname(config-username)# vpn-tunnel-protocol [webvpn | IPsec]
hostname(config-username)# no vpn-tunnel-protocol [webvpn | IPsec]
hostname(config-username)
```
The parameter values for this command are as follows:

- **IPsec**—Negotiates an IPsec tunnel between two peers (a remote access client or another secure gateway). Creates security associations that govern authentication, encryption, encapsulation, and key management.

- **webvpn**—Provides clientless SSL VPN access to remote users via an HTTPS-enabled web browser, and does not require a client.

Enter this command to configure one or more tunneling modes. You must configure at least one tunneling mode for users to connect over a VPN tunnel.

The following example shows how to configure clientless SSL VPN and IPsec tunneling modes for the user named anyuser:

```
hostname(config)# username anyuser attributes
hostname(config-username)# vpn-tunnel-protocol webvpn
hostname(config-username)# vpn-tunnel-protocol IPsec
```

**Restrict Remote User Access**

Configure the `group-lock` attribute with the `value` keyword to restrict remote users to access only through the specified, preexisting connection profile. Group-lock restricts users by checking whether the group configured in the VPN client is the same as the connection profile to which the user is assigned. If it is not, the ASA prevents the user from connecting. If you do not configure group-lock, the ASA authenticates users without regard to the assigned group.

To remove the `group-lock` attribute from the running configuration, enter the `no` form of this command. This option allows inheritance of a value from the group policy. To disable group-lock, and to prevent inheriting a group-lock value from a default or specified group policy, enter the `group-lock` command with the `none` keyword.

```
hostname(config-username)# group-lock {value tunnel-grp-name | none}
hostname(config-username)# no group-lock
```

The following example shows how to set group lock for the user named anyuser:

```
hostname(config)# username anyuser attributes
hostname(config-username)# group-lock value tunnel-group-name
```

**Enable Password Storage for Software Client Users**

Specify whether to let users store their login passwords on the client system. Password storage is disabled by default. Enable password storage only on systems that you know to be in secure sites. To disable password storage, enter the `password-storage` command with the `disable` keyword. To remove the password-storage attribute from the running configuration, enter the `no` form of this command. This enables inheritance of a value for password-storage from the group policy.

```
hostname(config-username)# password-storage {enable | disable}
hostname(config-username)# no password-storage
```
This command has no bearing on interactive hardware client authentication or individual user authentication for hardware clients.

The following example shows how to enable password storage for the user named anyuser:

```
hostname(config) username anyuser attributes
hostname(config-username) password-storage enable
hostname(config-username)
```
Enable Password Storage for Software Client Users
CHAPTER 6

IP Addresses for VPNs

- Configure an IP Address Assignment Policy, on page 195
- Configure Local IP Address Pools, on page 197
- Configure AAA Addressing, on page 199
- Configure DHCP Addressing, on page 200

Configure an IP Address Assignment Policy

The ASA can use one or more of the following methods for assigning IP addresses to remote access clients. If you configure more than one address assignment method, the ASA searches each of the options until it finds an IP address. By default, all methods are enabled.

- **aaa** Retrieves addresses from an external authentication, authorization, and accounting server on a per-user basis. If you are using an authentication server that has IP addresses configured, we recommend using this method. This method is available for IPv4 and IPv6 assignment policies.

- **dhcp** Obtains IP addresses from a DHCP server. If you want to use DHCP, you must configure a DHCP server. You must also define the range of IP addresses that the DHCP server can use. This method is available for IPv4 assignment policies.

- **local** Internally configured address pools are the easiest method of address pool assignment to configure. If you choose local, you must also use the `ip-local-pool` command to define the range of IP addresses to use. This method is available for IPv4 and IPv6 assignment policies.

  - Allow the reuse of an IP address so many minutes after it is released—Delays the reuse of an IP address after its return to the address pool. Adding a delay helps to prevent problems firewalls can experience when an IP address is reassigned quickly. By default the ASA does not impose a delay. This configurable element is available for IPv4 assignment policies.

Use one of the following methods to specify a way to assign IP addresses to remote access clients.
Configure IPv4 Address Assignments

Procedure

Enable an address assignment method for the ASA to use when assigning IPv4 address to VPN connections. The available methods to obtain an IP address are from a AAA server, DHCP server, or a local address pool. All of these methods are enabled by default.

```
vpn-addr-assign {aaa | dhcp | local [reuse-delay minutes]}
```

Example:

For example, you can configure the reuse of an IP address for between 0 and 480 minutes after the IP address has been released.

```
hostname(config)# vpn-addr-assign aaa
hostname(config)# vpn-addr-assign local reuse-delay 180
```

This example uses the no form of the command to disable an address assignment method.

```
hostname(config)# no vpn-addr-assign dhcp
```

Configure IPv6 Address Assignments

Procedure

Enable an address assignment method for the ASA to use when assigning IPv6 address to VPN connections. The available methods to obtain an IP address are from a AAA server or a local address pool. Both of these methods are enabled by default.

```
ipv6-vpn-addr-assign {aaa | local}
```

Example:

```
hostname(config)# ipv6-vpn-addr-assign aaa
```

This example uses the no form of the command to disable an address assignment method.

```
hostname(config)# no ipv6-vpn-addr-assign local
```

View Address Assignment Methods

Procedure

Use one of these methods to view the address assignment method configured on the ASA:
• View IPv4 Address Assignments
  Show the configured address assignment method. The configured address method could be aaa, dhcp, or local.

  ```
  show running-config all vpn-addr-assign
  vpn-addr-assign aaa
  vpn-addr-assign dhcp
  vpn-addr-assign local
  ```

• View IPv6 Address Assignments
  Show the configured address assignment method. Configured address methods could be aaa or local.

  ```
  show running-config all ipv6-vpn-addr-assign
  ipv6-vpn-addr-assign aaa
  ipv6-vpn-addr-assign local reuse-delay 0
  ```

---

**Configure Local IP Address Pools**

To configure IPv4 address pools to use for VPN remote access tunnels, enter the `ip local pool` command in global configuration mode. To delete address pools, enter the `no` form of this command.

To configure IPv6 address pools to use for VPN remote access tunnels, enter the `ipv6 local pool` command in global configuration mode. To delete address pools, enter the `no` form of this command.

The ASA uses address pools based on the connection profile or group policy for the connection. The order in which you specify the pools is important. If you configure more than one address pool for a connection profile or group policy, the ASA uses them in the order in which you added them to the ASA.

If you assign addresses from a non-local subnet, we suggest that you add pools that fall on subnet boundaries to make adding routes for these networks easier.

---

**Note**

When you modify existing address pools currently in use within an active tunnel-group (that is, open to end users for connections), you must perform the change in a change window and ensure the following:

• The connected users are logged off.

• The address pools are removed from the tunnel-group and modified as required.

• The modified address pools are then added back under the tunnel-group.

If an address pool is not modified in this manner, it may cause inconsistencies in the ASA's behaviour.
Configure Local IPv4 Address Pools

Procedure

Step 1  Configure IP address pools as the address assignment method. Enter the `vpn-addr-assign` command with the `local` argument.

Example:

```
hostname(config)# vpn-addr-assign local
```

Step 2  Configure an address pool. The command names the pool, specifies a range of IPv4 addresses and the subnet mask.

```
ip local pool poolname first_address-last_address mask
```

Example:

This example configures an IP address pool named `firstpool`. The starting address is 10.20.30.40 and the ending address is 10.20.30.50. The network mask is 255.255.255.0.

```
hostname(config)# ip local pool firstpool 10.20.30.40-10.20.30.50 mask 255.255.255.0
```

This example deletes the IP address pool named `firstpool`.

```
hostname(config)# no ip local pool firstpool
```

Configure Local IPv6 Address Pools

Procedure

Step 1  Configures IP address pools as the address assignment method, enter the `ipv6-vpn-addr-assign` command with the `local` argument.

Example:

```
hostname(config)# ipv6-vpn-addr-assign local
```

Step 2  Configures an address pool. The command names the pool, identifies the starting IPv6 address, the prefix length in bits, and the number of addresses to use in the range.

```
ipv6 local pool pool_name starting_address prefix_length number_of_addresses
```

Example:

This example configures an IP address pool named `ipv6pool`. The starting address is 2001:DB8::1, the prefix length is 32 bits, and the number of addresses to use in the pool is 100.

```
hostname(config)# ipv6 local pool ipv6pool 2001:DB8::1/32 100
```

This example deletes the IP address pool named `ipv6pool`.

```
hostname(config)# no ipv6 local pool ipv6pool
```
Configure AAA Addressing

To use a AAA server to assign addresses for VPN remote access clients, you must first configure a AAA server or server group. See the `aaa-server protocol` command in the command reference.

In addition, the user must match a connection profile configured for RADIUS authentication.

The following examples illustrate how to define a AAA server group called RAD2 for the tunnel group named firstgroup. It includes one more step than is necessary, in that previously you might have named the tunnel group and defined the tunnel group type. This step appears in the following example as a reminder that you have no access to subsequent tunnel-group commands until you set these values.

An overview of the configuration that these examples create follows:

```
hostname(config)# vpn-addr-assign aaa
hostname(config)# tunnel-group firstgroup type ipsec-ra
hostname(config)# tunnel-group firstgroup general-attributes
hostname(config)# authentication-server-group RAD2
```

To configure AAA for IP addressing, perform the following steps:

**Procedure**

**Step 1**
To configure AAA as the address assignment method, enter the `vpn-addr-assign` command with the `aaa` argument:

```
hostname(config)# vpn-addr-assign aaa
hostname(config)#
```

**Step 2**
To establish the tunnel group called firstgroup as a remote access or LAN-to-LAN tunnel group, enter the `tunnel-group` command with the `type` keyword. The following example configures a remote access tunnel group.

```
hostname(config)# tunnel-group firstgroup type ipsec-ra
hostname(config)#
```

**Step 3**
To enter general-attributes configuration mode, which lets you define a AAA server group for the tunnel group called firstgroup, enter the `tunnel-group` command with the `general-attributes` argument.

```
hostname(config)# tunnel-group firstgroup general-attributes
hostname(config)#
```

**Step 4**
To specify the AAA server group to use for authentication, enter the `authentication-server-group` command.
Configure DHCP Addressing

To use DHCP to assign addresses for VPN clients, you must first configure a DHCP server and the range of IP addresses that the DHCP server can use. Then you define the DHCP server on a connection profile basis. Optionally, you can also define a DHCP network scope in the group policy associated with a connection profile or username. This is either an IP network number or IP Address that identifies to the DHCP server which pool of IP addresses to use.

The following examples define the DHCP server at IP address 172.33.44.19 for the connection profile named firstgroup. They also define a DHCP network scope of 192.86.0.0 for the group policy called remotegroup. (The group policy called remotegroup is associated with the connection profile called firstgroup). If you do not define a network scope, the DHCP server assigns IP addresses in the order of the address pools configured. It goes through the pools until it identifies an unassigned address.

The following configuration includes more steps than are necessary, in that previously you might have named and defined the connection profile type as remote access, and named and identified the group policy as internal or external. These steps appear in the following examples as a reminder that you have no access to subsequent tunnel-group and group-policy commands until you set these values.

Guidelines and Limitations

You can only use an IPv4 address to identify a DHCP server to assign client addresses.

Configure DHCP Addressing

Procedure

Step 1 Configure IP address pools as the address assignment method.

vpn-addr-assign dhcp

Step 2 Establish the connection profile called firstgroup as a remote access connection profile.

tunnel-group firstgroup type remote-access

Step 3 Enter the general-attributes configuration mode for the connection profile so that you can configure a DHCP server.

tunnel-group firstgroup general-attributes

Step 4 Define the DHCP server by IPv4 address. You can not define a DHCP server by an IPv6 address. You can specify more than one DHCP server address for a connection profile. Enter the dhcp-server command. This
command allows you to configure the ASA to send additional options to the specified DHCP servers when it is trying to get IP addresses for VPN clients.

```
dhcp-server IPv4_address_of_DHCP_server
```

**Example:**
The example configures a DHCP server at IP address 172.33.44.19.

```
hostname(config-general)# dhcp-server 172.33.44.19
```

**Step 5** Exit the tunnel-group mode.

```
hostname(config-general)# exit
```

**Step 6** Create an internal group policy called remotegroup.

```
hostname(config)# group-policy remotegroup internal
```

**Example:**
The example enters group policy attributes configuration mode for remotegroup group-policy.

```
hostname(config)# group-policy remotegroup attributes
```

**Step 7** (Optional) Enter the group-policy attributes configuration mode, which lets you configure a subnetwork of IP addresses for the DHCP server to use. Enter the `group-policy` command with the `attributes` keyword.

**Example:**

```
hostname(config)# group-policy remotegroup attributes
```

**Step 8** (Optional) To specify the range of IP addresses the DHCP server should use to assign addresses to users of the group policy called remotegroup, enter the `dhcp-network-scope` command.

The example configures a network scope of 192.86.0.0.

```
hostname(config-group-policy)# dhcp-network-scope 192.86.0.0
```

**Note** The dhcp-network-scope must be a routable IP address and not the subset of the DHCP pool. The DHCP server determines which subnet this IP address belongs to and assigns an IP address from that pool. You can use any IP address as the dhcp-network-scope, but it may require that static routes be added to the network.

**Example**
A summary of the configuration that these examples create follows:

```
hostname(config)# vpn-addr-assign dhcp
hostname(config)# tunnel-group firstgroup type remote-access
tunnel-group firstgroup general-attributes
```

---

hostname(config-general)#\ dhcp-server 172.33.44.19
hostname(config-general)#\ exit
hostname(config)#\ group-policy remotegroup internal
hostname(config)#\ group-policy remotegroup attributes
hostname(config-group-policy)#\ dhcp-network-scope 192.86.0.0

What to do next

See the dhcp-server command in the Cisco Security Appliance Command Reference guide for more information.
Remote Access IPsec VPNs

Remote access VPNs allow users to connect to a central site through a secure connection over a TCP/IP network. The Internet Security Association and Key Management Protocol, also called IKE, is the negotiation protocol that lets the IPsec client on the remote PC and the ASA agree on how to build an IPsec Security Association. Each ISAKMP negotiation is divided into two sections called Phase1 and Phase2.

Phase 1 creates the first tunnel to protect later ISAKMP negotiation messages. Phase 2 creates the tunnel that protects data travelling across the secure connection.

To set the terms of the ISAKMP negotiations, you create an ISAKMP policy. It includes the following:

- An authentication method, to ensure the identity of the peers.
- An encryption method, to protect the data and ensure privacy.
- A Hashed Message Authentication Codes (HMAC) method to ensure the identity of the sender and to ensure that the message has not been modified in transit.
- A Diffie-Hellman group to set the size of the encryption key.
- A time limit for how long the ASA uses an encryption key before replacing it.

A transform set combines an encryption method and an authentication method. During the IPsec security association negotiation with ISAKMP, the peers agree to use a particular transform set to protect a particular data flow. The transform set must be the same for both peers.

About Remote Access IPsec VPNs
A transform set protects the data flows for the ACL specified in the associated crypto map entry. You can create transform sets in the ASA configuration, and then specify a maximum of 11 of them in a crypto map or dynamic crypto map entry. For more overview information, including a table that lists valid encryption and authentication methods, see Create an IKEv1 Transform Set or IKEv2 Proposal, on page 208.

You can configure the ASA to assign an IPv4 address, an IPv6 address, or both an IPv4 and an IPv6 address to an AnyConnect client by creating internal pools of addresses on the ASA or by assigning a dedicated address to a local user on the ASA.

The endpoint must have the dual-stack protocol implemented in its operating system to be assigned both types of addresses. In both scenarios, when no IPv6 address pools are left but IPv4 addresses are available or when no IPv4 address pools are left but IPv6 addresses are available, connection still occurs. The client is not notified; however, so the administrator must look through the ASA logs for the details.

Assigning an IPv6 address to the client is supported for the SSL protocol.

### About Mobike and Remote Access VPNs

Mobile IKEv2 (mobike) extends ASA RA VPNs to support mobile device roaming. This support means the end-point IP address for a mobile device’s IKE/IPSEC security association (SA) can be updated rather than deleted when the device moves from its current connection point to another.

Mobike is available by default on ASAs since version 9.8(1), meaning Mobike is “always on.” Mobike is enabled for each SA only when the client proposes it and the ASA accepts it. This negotiation occurs as part of the IKE_AUTH exchange.

After the SA is established with mobike support as enabled, client can change its address anytime and notify the ASA using the INFORMATIONAL exchange with UPDATE_SA_ADDRESS payload indicating the new address. The ASA will process this message and update the SA with the new client IP address.

You can use the `show crypto ikev2 sa detail` command to determine whether mobike is enabled for all current SAs.

The current Mobike implementation supports the following:

- IPv4 addresses only
- Changes in NAT mappings
- Path connectivity and outage detection, by means of optional Return Routability checking
- Active/standby failover
- VPN load balancing

If the Return Routability Check (RRC) feature is enabled, an RRC message is sent to the mobile client to confirm the new IP address before the SA is updated.
Licensing Requirements for Remote Access IPsec VPNs for 3.1

Note

This feature is not available on No Payload Encryption models.

IPsec remote access VPN using IKEv2 requires an AnyConnect Plus or Apex license, available separately. IPsec remote access VPN using IKEv1 and IPsec site-to-site VPN using IKEv1 or IKEv2 uses the Other VPN license that comes with the base license. See Cisco ASA Series Feature Licenses for maximum values per model.

Restrictions for IPsec VPN

• Firewall Mode Guidelines—Supported only in routed firewall mode. Transparent mode is not supported.

• Failover Guidelines IPsec—VPNs sessions are replicated in Active/Standby failover configurations only. Active/Active failover configurations are not supported.

Configure Remote Access IPsec VPNs

This section describes how to configure remote access VPNs.

Configure Interfaces

An ASA has at least two interfaces, referred to here as outside and inside. Typically, the outside interface is connected to the public Internet, while the inside interface is connected to a private network and is protected from public access.

To begin, configure and enable two interfaces on the ASA. Then assign a name, IP address and subnet mask. Optionally, configure its security level, speed and duplex operation on the security appliance.

Procedure

Step 1

Enter interface configuration mode from global configuration mode.

```
interface {interface}
```

Example:

```
hostname(config)# interface ethernet0
hostname(config-if)#
```

Step 2

Set the IP address and subnet mask for the interface.

```
ip address ip_address [mask] [standby ip_address]
```

Example:
Configure ISAKMP Policy and Enabling ISAKMP on the Outside Interface

**Procedure**

**Step 1**
Specify the authentication method and the set of parameters to use during IKEv1 negotiation. Priority uniquely identifies the Internet Key Exchange (IKE) policy and assigns a priority to the policy. Use an integer from 1 to 65,534, with 1 being the highest priority and 65,534 the lowest.

In the steps that follow, we set the priority to 1.

**Step 2**
Specify the encryption method to use within an IKE policy.

```
crypto ikev1 policy priority encryption {aes-192 | aes-256 | } 
```

**Example:**

```
hostname(config)# crypto ikev1 policy 1 encryption aes-192
hostname(config)#
```

**Step 3**
Specify the hash algorithm for an IKE policy (also called the HMAC variant).

```
crypto ikev1 policy priority hash { | sha}
```

**Example:**

```
hostname(config)# crypto ikev1 policy 1 hash sha
hostname(config)#
```

**Step 4**
Specify the Diffie-Hellman group for the IKE policy—the crypto protocol that allows the IPsec client and the ASA to establish a shared secret key.

```
crypto ikev1 policy priority group {14 | 19 | 20 | 21}
```

**Example:**

```
hostname(config)# crypto ikev1 policy 1 group 14
hostname(config)#
```
Step 5 Specify the encryption key lifetime—the number of seconds each security association should exist before expiring.

```
crypto ikev1 policy priority lifetime {seconds}
```

The range for a finite lifetime is 120 to 2147483647 seconds. Use 0 seconds for an infinite lifetime.

Example:
```
hostname(config)# crypto ikev1 policy 1 lifetime 43200
hostname(config)#
```

Step 6 Enable ISAKMP on the interface named outside.

```
crypto ikev1 enable interface-name
```

Example:
```
hostname(config)# crypto ikev1 enable outside
hostname(config)#
```

Step 7 Save the changes to the configuration.

```
write memory
```

---

**Configure an Address Pool**

The ASA requires a method for assigning IP addresses to users. This section uses address pools as an example.

### Procedure

Create an address pool with a range of IP addresses, from which the ASA assigns addresses to the clients.

```
ip local pool poolname first-address—last-address [mask mask]
```

The address mask is optional. However, You must supply the mask value when the IP addresses assigned to VPN clients belong to a non-standard network and the data could be routed incorrectly if you use the default mask. A typical example is when the IP local pool contains 10.10.10.0/255.255.255.0 addresses, since this is a Class A network by default. This could cause routing issues when the VPN client needs to access different subnets within the 10 network over different interfaces.

Example:
```
hostname(config)# ip local pool testpool 192.168.0.10—192.168.0.15
hostname(config)#
Add a User

Procedure

Create a user, password, and privilege level.

```
username name {nopassword | password password [mschap | encrypted | nt-encrypted]} [privilege priv_level]
```

Example:
```
Hostname(config)# username testuser password 12345678
```

Create an IKEv1 Transform Set or IKEv2 Proposal

This section shows how to configure a transform set (IKEv1) or proposal (IKEv2), which combines an encryption method and an authentication method.

The following steps show how to create both an IKEv1 and an IKEv2 proposal.

Procedure

Step 1
Configure an IKEv1 transform set that specifies the IPsec IKEv1 encryption and hash algorithms to be used to ensure data integrity.

```
crypto ipsec ikev1 transform-set transform-set-name encryption-method [authentication]
```

Use one of the following values for encryption:
- esp-aes to use AES with a 128-bit key.
- esp-aes-192 to use AES with a 192-bit key.
- esp-aes-256 to use AES with a 256-bit key.
- esp-null to not use encryption.

Use one of the following values for authentication:
- esp-md5-hmac to use the MD5/HMAC-128 as the hash algorithm.
- esp-sha-hmac to use the SHA/HMAC-160 as the hash algorithm.
- esp-none to not use HMAC authentication.

Example:
```
To Configure an IKEv1 transform set using AES:

hostname(config)# crypto ipsec transform set FirstSet esp-aes esp-sha-hmac
```

Step 2
Configure an IKEv2 proposal set that specifies the IPsec IKEv2 protocol, encryption, and integrity algorithms to be used.
esp specifies the Encapsulating Security Payload (ESP) IPsec protocol (currently the only supported protocol for IPsec).

crypto ipsec ikev2 ipsec-proposal proposal_name

protocol {esp} {encryption {||aes|aes-192|aes-256}||integrity {sha-1}}

Use one of the following values for encryption:

- aes to use AES (default) with a 128-bit key encryption for ESP.
- aes-192 to use AES with a 192-bit key encryption for ESP.
- aes-256 to use AES with a 256-bit key encryption for ESP.

Use one of the following values for integrity:

- sha-1 (default) specifies the Secure Hash Algorithm (SHA) SHA-1, defined in the U.S. Federal Information Processing Standard (FIPS), for ESP integrity protection.

To configure an IKEv2 proposal:

hostname(config)# crypto ipsec ikev2 ipsec-proposal secure_proposal

hostname(config-ipsec-proposal)# protocol esp encryption aes integrity sha-1

---

Define a Tunnel Group

A tunnel group is a collection of tunnel connection policies. You configure a tunnel group to identify AAA servers, specify connection parameters, and define a default group policy. The ASA stores tunnel groups internally.

There are two default tunnel groups in the ASA system: DefaultRAGroup, which is the default remote-access tunnel group, and DefaultL2LGroup, which is the default LAN-to-LAN tunnel group. You can change these groups, but do not delete them. The ASA uses these groups to configure default tunnel parameters for remote access and LAN-to-LAN tunnel groups when there is no specific tunnel group identified during tunnel negotiation.

Procedure

Step 1
Create an IPsec remote access tunnel-group (also called connection profile).

tunnel-group name type

Example:

hostname(config)# tunnel-group testgroup type ipsec-ra
hostname(config)#

Step 2
Enter tunnel group general attributes mode where you can enter an authentication method.

tunnel-group name general-attributes
Example:

```
hostname(config)# tunnel-group testgroup general-attributes
hostname(config-tunnel-general)#
```

Step 3  Specify an address pool to use for the tunnel group.

```
address-pool [interface name] address_pool1 [...address_pool6]
```

Example:

```
hostname(config-general)# address-pool testpool
```

Step 4  Enter tunnel group ipsec attributes mode where you can enter IPsec-specific attributes for IKEv1 connections.

```
tunnel-group name ipsec-attributes
```

Example:

```
hostname(config)# tunnel-group testgroup ipsec-attributes
hostname(config-tunnel-ipsec)#
```

Step 5  (Optional) Configure a pre-shared key (IKEv1 only). The key can be an alphanumeric string from 1-128 characters.

The keys for the adaptive security appliance and the client must be identical. If a Cisco VPN Client with a different preshared key size tries to connect, the client logs an error message indicating it failed to authenticate the peer.

```
ikev1 pre-shared-key key
```

Example:

```
hostname(config-tunnel-ipsec)# pre-shared-key 44kkaol59636jnfx
```

Create a Dynamic Crypto Map

Dynamic crypto maps define policy templates in which not all the parameters are configured. This lets the ASA receive connections from peers that have unknown IP addresses, such as remote access clients.

Dynamic crypto map entries identify the transform set for the connection. You can also enable reverse routing, which lets the ASA learn routing information for connected clients, and advertise it via RIP or OSPF.

Perform the following task:

**Procedure**

Step 1  Create a dynamic crypto map and specifies an IKEv1 transform set or IKEv2 proposal for the map.

- For IKEv1, use this command:
  
  ```
  crypto dynamic-map dynamic-map-name seq-num set ikev1 transform-set transform-set-name
  ```

- For IKEv2, use this command:
  
  ```
  crypto dynamic-map dynamic-map-name seq-num set ikev2 ipsec-proposal proposal-name
  ```
Create a Crypto Map Entry to Use the Dynamic Crypto Map

Create a crypto map entry that lets the ASA use the dynamic crypto map to set the parameters of IPsec security associations.

In the following examples for this command, the name of the crypto map is mymap, the sequence number is 1, and the name of the dynamic crypto map is dyn1, which you created in the previous section.

Procedure

**Step 1**
Create a crypto map entry that uses a dynamic crypto map.

```bash
crypto map map-name seq-num ipsec-isakmp dynamic dynamic-map-name
```

**Example:**
```
hostname(config)# crypto map mymap 1 ipsec-isakmp dynamic dyn1
```

**Step 2**
Apply the crypto map to the outside interface.

```bash
crypto map map-name interface interface-name
```

**Example:**
```
hostname(config)# crypto map mymap interface outside
```

**Step 3**
Saves the changes to the configuration.

```
write memory
```

Configuring IPSec IKEv2 Remote Access VPN in Multi-Context Mode

For more information about configuring Remote Access IPsec VPNs, see the following sections:

- Configure Interfaces, on page 205
Configuration Examples for Remote Access IPsec VPNs

The following example shows how to configure a remote access IPsec/IKEv1 VPN:

```plaintext
hostname(config)# crypto ikev1 policy 10
hostname(config-ikev1-policy)# authentication pre-share
hostname(config-ikev1-policy)# encryption aes-256
hostname(config-ikev1-policy)# hash sha
hostname(config-ikev1-policy)# group 2
hostname(config)# crypto ikev1 enable outside
hostname(config)# ip local pool POOL 192.168.0.10-192.168.0.15
hostname(config)# username testuser password 12345678
hostname(config)# crypto ipsec ikev1 transform set AES256-SHA
esp-aes-256 esp-sha-hmac
hostname(config)# tunnel-group RAVPN type remote-access
hostname(config)# tunnel-group RAVPN general-attributes
hostname(config)# address-pool POOL
hostname(config)# tunnel-group RAVPN ipsec-attributes
hostname(config)# ikev1 pre-shared-key ravpnkey
hostname(config)# crypto dynamic-map DYNMAP 1 set ikev1
transform-set AES256-SHA
hostname(config)# crypto dynamic-map DYNMAP 1 set reverse-route
hostname(config)# crypto map CMAP 1 ipsec-isakmp dynamic DYNMAP
hostname(config)# crypto map CMAP interface outside
```

The following example shows how to configure a remote access IPsec/IKEv2 VPN:

```plaintext
hostname(config)# crypto ikev2 policy 1
hostname(config-ikev2-policy)# group 2
hostname(config-ikev2-policy)# integrity sha512
hostname(config-ikev2-policy)# prf sha512
hostname(config)# crypto ikev2 enable outside
hostname(config)# ip local pool POOL 192.168.0.10-192.168.0.15
hostname(config)# username testuser password 12345678
hostname(config)# crypto ipsec ikev2 ipsec-proposal AES256-SHA512
hostname(config-ipsec-proposal)# protocol esp encryption aes-256
hostname(config-ipsec-proposal)# protocol esp integrity sha-512
hostname(config)# tunnel-group RAVPN type remote-access
hostname(config)# tunnel-group RAVPN general-attributes
hostname(config)# address-pool POOL
hostname(config)# tunnel-group RAVPN ipsec-attributes
hostname(config)# tunnel-group RAVPN local-authentication
pre-shared-key localravpnkey
hostname(config)# ikev2 local-authentication
pre-shared-key localravpnkey
hostname(config)# ikev2 remote-authentication
pre-shared-key remoterravpnkey
```
Configuration Examples for Standards-Based IPSec IKEv2 Remote Access VPN in Multiple-Context Mode

The following examples show how to configure ASA for Standards-based remote access IPSec/IKEv2 VPN in multi-context mode. The examples provide information for the System Context and User Context configurations respectively.

For the System Context configuration:

```
class default
    limit-resource All 0
    limit-resource Mac-addresses 65536
    limit-resource ASDM 5
    limit-resource SSH 5
    limit-resource Telnet 5
    limit-resource VPN AnyConnect 4.0%
```

hostname(config)# context CTX2
hostname(config-ctx)# member default ===============> License allotment for contexts using class
hostname(config-ctx)# allocate-interface Ethernet1/1.200
hostname(config-ctx)# allocate-interface Ethernet1/3.100
hostname(config-ctx)# config-url disk0:/CTX2.cfg

For the User Context configuration:

```
hostname/CTX2(config)# ip local pool CTX2-pool 1.1.2.1-1.1.2.250 mask 255.255.255.0
hostname/CTX2(config)# aaa-server ISE protocol radius
hostname/CTX2(config)# aaa-server ISE (inside) host 10.10.190.100
hostname/CTX2(config-aaa-server-host)# key *****
hostname/CTX2(config-aaa-server-host)# exit
hostname/CTX2(config)#
```

```
hostname/CTX2(config)# group-policy GroupPolicy_CTX2-IKEv2 internal
hostname/CTX2(config)# group-policy GroupPolicy_CTX2-IKEv2 attributes
hostname/CTX2(config)# group-policy ikev2
hostname/CTX2(config)# exit
hostname/CTX2(config)#
```

```
hostname/CTX2(config)# crypto dynamic-map SYSTEM_DEFAULT_CRYPTO_MAP 65535 set ikev2
ipsec-proposal AES256 AES192 AES 3DES DES
hostname/CTX2(config)# crypto map outside_map 65535 ipsec-isakmp dynamic
SYSTEM_DEFAULT_CRYPTO_MAP
hostname/CTX2(config)# crypto map outside_map interface outside
```
IPSec/IKEv2 Remote Access Connections from Standard-based Clients by default fall on tunnel group "DefaultRAGroup".

```plaintext
hostname/CTX2(config)#tunnel-group DefaultRAGroup type remote-access
hostname/CTX2(config)#tunnel-group DefaultRAGroup general-attributes
hostname/CTX2(config-tunnel-general)#default-group-policy GroupPolicy_CTX2-IKEv2
hostname/CTX2(config-tunnel-general)#address-pool CTX2-pool
hostname/CTX2(config-tunnel-general)#authentication-server-group ISE
hostname/CTX2(config-tunnel-general)#exit
 hostname/CTX2(config)#
hostname/CTX2(config)#tunnel-group DefaultRAGroup ipsec-attributes
hostname/CTX2(config-tunnel-ipsec)#ikev2 remote-authentication eap query-identity
hostname/CTX2(config-tunnel-ipsec)#ikev2 local-authentication certificate ASDM_TrustPoint0
hostname/CTX2(config-tunnel-ipsec)#exit
hostname/CTX2(config)#
```

### Configuration Examples for AnyConnect IPSec IKEv2 Remote Access VPN in Multiple-Context Mode

The following examples show how to configure ASA for AnyConnect remote access IPSec/IKEv2 VPN in multi-context mode. The examples provide information for the System Context and User Context configurations respectively.

For the System Context configuration:

```plaintext
class default
  limit-resource All 0
  limit-resource Mac-addresses 65536
  limit-resource ASDM 5
  limit-resource SSH 5
  limit-resource Telnet 5
  limit-resource VPN AnyConnect 4.0%

hostname(config)#context CTX3
hostname(config-ctx)#member default ===============> License allotment for contexts using class
hostname(config-ctx)#allocate-interface Ethernet1/1.200
hostname(config-ctx)#allocate-interface Ethernet1/3.100
hostname(config-ctx)#config-url disk0:/CTX3.cfg

Virtual File System creation for each context can have Cisco AnyConnect files like Image and profile.

hostname(config-ctx)#storage-url shared disk0:/shared disk0
```

For the User Context configuration:

```plaintext
hostname/CTX3(config)#ip local pool ctx3-pool 1.1.3.1-1.1.3.250 mask 255.255.255.0
hostname/CTX3(config)#webvpn
hostname/CTX3(config-webvpn)#enable outside
hostname/CTX3(config-webvpn)# anyconnect image disk0:/anyconnect-win-4.6.00010-webdeploy-k9.pkg 1
hostname/CTX3(config-webvpn)# anyconnect profiles IKEv2-ctx1 disk0:/ikev2-ctx1.xml
hostname/CTX3(config-webvpn)# anyconnect enable
hostname/CTX3(config-webvpn)#tunnel-group-list enable
```
hostname/CTX3(config)#username cisco password *****
hostname/CTX3(config)#ssl trust-point ASDM_TrustPoint0 outside
hostname/CTX3(config)#group-policy GroupPolicy_CTX3-IKEv2 internal
hostname/CTX3(config)#group-policy GroupPolicy_CTX3-IKEv2 attributes

hostname/CTX3(config-group-policy)#vpn-tunnel-protocol ikev2 ssl-client
hostname/CTX3(config-group-policy)#dns-server value 10.3.5.6
hostname/CTX3(config-group-policy)#wins-server none
hostname/CTX3(config-group-policy)#default-domain none
hostname/CTX3(config-group-policy)#webvpn
hostname/CTX3(config-group-webvpn)#anyconnect profiles value IKEv2-ctx1 type user

hostname/CTX3(config)#crypto ikev2 enable outside client-services port 443
hostname/CTX3(config)#crypto ikev2 remote-access trustpoint ASDM_TrustPoint0
hostname/CTX3(config)#crypto dynamic-map SYSTEM_DEFAULT_CRYPTO_MAP 65535 set ikev2
ipsec-proposal AES256 AES192 AES 3DES DES
hostname/CTX3(config)#crypto map outside_map 65535 ipsec-isakmp dynamic
SYSTEM_DEFAULT_CRYPTO_MAP
hostname/CTX3(config)#crypto map outside_map interface outside

hostname/CTX3(config)#tunnel-group CTX3-IKEv2 type remote-access
tunnel-group CTX3-IKEv2 general-attributes
tunnel-group CTX3-IKEv2 webvpn-attributes
tunnel-group CTX3-IKEv2 address-pool ctx3-pool
tunnel-group CTX3-IKEv2 webvpn-attributes
hostname/CTX3(config)#group-alias CTX3-IKEv2 enable

LAN-to-LAN IPsec VPNs

A LAN-to-LAN VPN connects networks in different geographic locations.

You can create LAN-to-LAN IPsec connections with Cisco peers and with third-party peers that comply with all relevant standards. These peers can have any mix of inside and outside addresses using IPv4 and IPv6 addressing.

This chapter describes how to build a LAN-to-LAN VPN connection.

- Summary of the Configuration, on page 217
- Configure Site-to-Site VPN in Multi-Context Mode, on page 218
- Configure Interfaces, on page 219
- Configure ISAKMP Policy and Enable ISAKMP on the Outside Interface, on page 220
- Create an IKEv1 Transform Set, on page 222
- Create an IKEv2 Proposal, on page 223
- Configure an ACL, on page 224
- Define a Tunnel Group, on page 225
- Create a Crypto Map and Applying It To an Interface, on page 226

Summary of the Configuration

This section provides a summary of the example LAN-to-LAN configuration this chapter describes. Later sections provide step-by-step instructions.

```
hostname(config)# interface ethernet0/0
hostname(config-if)# ip address 10.10.4.100 255.255.0.0
hostname(config-if)# nameif outside
hostname(config-if)# no shutdown
hostname(config)# crypto ikev1 policy 1
hostname(config-ikev1-policy)# authentication pre-share
hostname(config-ikev1-policy)# encryption aes
hostname(config-ikev1-policy)# hash sha
hostname(config-ikev1-policy)# group 2
hostname(config-ikev1-policy)# lifetime 43200
hostname(config)# crypto ikev1 enable outside
hostname(config)# crypto ikev2 policy 1
hostname(config)# crypto ikev2 enable outside
hostname(config)# crypto ikev2-policy# encryption aes
hostname(config-ikev2-policy)# group 2
hostname(config-ikev2-policy)# prf sha
hostname(config-ikev2-policy)# lifetime 43200
```
Configure Site-to-Site VPN in Multi-Context Mode

Follow these steps to allow site-to-site support in multi-mode. By performing these steps, you can see how resource allocation breaks down.

**Procedure**

**Step 1**
To configure the VPN in multi-mode, configure a resource class and choose VPN licenses as part of the allowed resource. The "Configuring a Class for Resource Management" provides these configuration steps. The following is an example configuration:

```
class ctx1
  limit-resource VPN Burst Other 100
  limit-resource VPN Other 1000
```

**Step 2**
Configure a context and make it a member of the configured class that allows VPN licenses. The following is an example configuration:

```
context context1
  member ctx1
  allocate-interface GigabitEthernet3/0.2
  allocate-interface GigabitEthernet3/1.2
  allocate-interface Management0/0
  config-url disk0:/sm_s2s_ik1_ip4_no_webvpn.txt
  join-failover-group 1
```

**Step 3**
Configure connection profiles, policies, crypto maps, and so on, just as you would with single context VPN configuration of site-to-site VPN.

Configure Interfaces

An ASA has at least two interfaces, referred to here as outside and inside. Typically, the outside interface is connected to the public Internet, while the inside interface is connected to a private network and is protected from public access.

To begin, configure and enable two interfaces on the ASA. Then, assign a name, IP address and subnet mask. Optionally, configure its security level, speed, and duplex operation on the security appliance.

Note

The ASA’s outside interface address (for both IPv4/IPv6) cannot overlap with the private side address space.

Procedure

Step 1
To enter Interface configuration mode, in global configuration mode enter the `interface` command with the default name of the interface to configure. In the following example the interface is ethernet0.

```
hostname(config)＃interface ethernet0/0
hostname(config-if)＃
```

Step 2
To set the IP address and subnet mask for the interface, enter the `ip address` command. In the following example the IP address is 10.10.4.100 and the subnet mask is 255.255.0.0.

```
hostname(config-if)＃ip address 10.10.4.100 255.255.0.0
hostname(config-if)＃
```

Step 3
To name the interface, enter the `nameif` command, maximum of 48 characters. You cannot change this name after you set it. In the following example the name of the ethernet0 interface is outside.

```
hostname(config-if)＃nameif outside
hostname(config-if)＃
```

Step 4
To enable the interface, enter the no version of the `shutdown` command. By default, interfaces are disabled.

```
hostname(config-if)＃no shutdown
hostname(config-if)＃
```

Step 5
To save your changes, enter the `write memory` command:

```
hostname(config-if)＃write memory
hostname(config-if)＃
```

Step 6
To configure a second interface, use the same procedure.
Configure ISAKMP Policy and Enable ISAKMP on the Outside Interface

ISAKMP is the negotiation protocol that lets two hosts agree on how to build an IPsec security association (SA). It provides a common framework for agreeing on the format of SA attributes. This includes negotiating with the peer about the SA, and modifying or deleting the SA. ISAKMP separates negotiation into two phases: Phase 1 and Phase 2. Phase 1 creates the first tunnel, which protects later ISAKMP negotiation messages. Phase 2 creates the tunnel that protects data.

IKE uses ISAKMP to setup the SA for IPsec to use. IKE creates the cryptographic keys used to authenticate peers.

The ASA supports IKEv1 for connections from the legacy Cisco VPN client, and IKEv2 for the AnyConnect VPN client.

To set the terms of the ISAKMP negotiations, you create an IKE policy, which includes the following:

- The authentication type required of the IKEv1 peer, either RSA signature using certificates or preshared key (PSK).
- An encryption method, to protect the data and ensure privacy.
- A Hashed Message Authentication Codes (HMAC) method to ensure the identity of the sender, and to ensure that the message has not been modified in transit.
- A Diffie-Hellman group to determine the strength of the encryption-key-determination algorithm. The ASA uses this algorithm to derive the encryption and hash keys.
- For IKEv2, a separate pseudo-random function (PRF) used as the algorithm to derive keying material and hashing operations required for the IKEv2 tunnel encryption.
- A limit to the time the ASA uses an encryption key before replacing it.

With IKEv1 policies, for each parameter, you set one value. For IKEv2, you can configure multiple encryption and authentication types, and multiple integrity algorithms for a single policy. The ASA orders the settings from the most secure to the least secure and negotiates with the peer using that order. This allows you to potentially send a single proposal to convey all the allowed transforms instead of the need to send each allowed combination as with IKEv1.

The following sections provide procedures for creating IKEv1 and IKEv2 policies and enabling them on an interface:

- Configure ISAKMP Policies for IKEv1 Connections, on page 220
- Configure ISAKMP Policies for IKEv2 Connections, on page 222

Configure ISAKMP Policies for IKEv1 Connections

To configure ISAKMP policies for IKEv1 connections, use the `crypto ikev1 policy` priority command to enter IKEv1 policy configuration mode where you can configure the IKEv1 parameters.
Procedure

Step 1  Enter IPsec IKEv1 policy configuration mode. For example:

```bash
hostname(config)# crypto ikev1 policy 1
hostname(config-ikev1-policy)#
```

Step 2  Set the authentication method. The following example configures a preshared key:

```bash
hostname(config-ikev1-policy)# authentication pre-share
hostname(config-ikev1-policy)#
```

Step 3  Set the encryption method. The following example configures:

```bash
hostname(config-ikev1-policy)# encryption aes
hostname(config-ikev1-policy)#
```

Step 4  Set the HMAC method. The following example configures SHA-1:

```bash
hostname(config-ikev1-policy)# hash sha
hostname(config-ikev1-policy)#
```

Step 5  Set the Diffie-Hellman group. The following example configures Group 14:

```bash
hostname(config-ikev1-policy)# group 14
hostname(config-ikev1-policy)#
```

Step 6  Set the encryption key lifetime. The following example configures 43,200 seconds (12 hours):

```bash
hostname(config-ikev1-policy)# lifetime 43200
hostname(config-ikev1-policy)#
```

Step 7  Enable IKEv1 on the interface named outside in either single or multiple context mode:

```bash
hostname(config)# crypto ikev1 enable outside
hostname(config)#
```

Step 8  To save your changes, enter the `write memory` command:

```bash
hostname(config)# write memory
hostname(config)#
```
Configure ISAKMP Policies for IKEv2 Connections

To configure ISAKMP policies for IKEv2 connections, use the `crypto ikev2 policy` priority command to enter IKEv2 policy configuration mode where you can configure the IKEv2 parameters.

Procedure

**Step 1** Enter IPsec IKEv2 policy configuration mode. For example:

```
hostname(config)# crypto ikev2 policy 1
hostname(config-ikev2-policy)#
```

**Step 2** Set the encryption method. The following example configures AES:

```
hostname(config-ikev2-policy)# encryption aes
hostname(config-ikev2-policy)#
```

**Step 3** Set the Diffie-Hellman group. The following example configures Group 15:

```
hostname(config-ikev2-policy)# group 15
hostname(config-ikev2-policy)#
```

**Step 4** Set the pseudo-random function (PRF) used as the algorithm to derive keying material and hashing operations required for the IKEv2 tunnel encryption. The following example configures SHA-1 (an HMAC variant):

```
hostname(config-ikev2-policy)# prf sha
hostname(config-ikev2-policy)#
```

**Step 5** Set the encryption key lifetime. The following example configures 43,200 seconds (12 hours):

```
hostname(config-ikev2-policy)# lifetime seconds 43200
hostname(config-ikev2-policy)#
```

**Step 6** Enable IKEv2 on the interface named outside:

```
hostname(config)# crypto ikev2 enable outside
hostname(config)#
```

**Step 7** To save your changes, enter the `write memory` command:

```
hostname(config)# write memory
hostname(config)#
```

Create an IKEv1 Transform Set

An IKEv1 transform set combines an encryption method and an authentication method. During the IPsec security association negotiation with ISAKMP, the peers agree to use a particular transform set to protect a particular data flow. The transform set must be the same for both peers.
A transform set protects the data flows for the ACL specified in the associated crypto map entry. You can create transform sets in the ASA configuration, and then specify a maximum of 11 of them in a crypto map or dynamic crypto map entry.

The table below lists valid encryption and authentication methods.

**Table 10: Valid Encryption and Authentication Methods**

<table>
<thead>
<tr>
<th>Valid Encryption Methods</th>
<th>Valid Authentication Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>esp-null</td>
<td>esp-sha-hmac (default)</td>
</tr>
<tr>
<td>esp-null-128</td>
<td></td>
</tr>
<tr>
<td>esp-null-192</td>
<td></td>
</tr>
<tr>
<td>esp-null-256</td>
<td></td>
</tr>
</tbody>
</table>

Tunnel Mode is the usual way to implement IPsec between two ASAs that are connected over an untrusted network, such as the public Internet. Tunnel mode is the default and requires no configuration.

To configure a transform set, perform the following site-to-site tasks in either single or multiple context mode:

**Procedure**

**Step 1**

In global configuration mode enter the `crypto ipsec ikev1 transform-set` command. The following example configures a transform set with the name FirstSet, esp-aes encryption, and esp-sha-hmac authentication. The syntax is as follows:

```
hostname(config)# crypto ipsec ikev1 transform-set
```

```
hostname(config)# crypto ipsec ikev1 transform-set FirstSet esp-aes esp-sha-hmac
```

**Step 2**

Save your changes.

```
hostname(config)# write memory
```

---

**Create an IKEv2 Proposal**

For IKEv2, you can configure multiple encryption and authentication types, and multiple integrity algorithms for a single policy. The ASA orders the settings from the most secure to the least secure and negotiates with the peer using that order. This allows you to potentially send a single proposal to convey all the allowed transforms instead of the need to send each allowed combination as with IKEv1.
The table below lists valid IKEv2 encryption and authentication methods.

**Table 11: Valid IKEv2 Encryption and Integrity Methods**

<table>
<thead>
<tr>
<th>Valid Encryption Methods</th>
<th>Valid Integrity Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>aes (default) - AES with a 128-bit key.</td>
<td>sha (default)</td>
</tr>
<tr>
<td>aes-192</td>
<td></td>
</tr>
<tr>
<td>aes-256</td>
<td></td>
</tr>
</tbody>
</table>

To configure an IKEv2 proposal, perform the following tasks in either single or multiple context mode:

**Procedure**

---

**Step 1**
In global configuration mode, use the `crypto ipsec ikev2 ipsec-proposal` command to enter ipsec proposal configuration mode where you can specify multiple encryption and integrity types for the proposal. In this example, `secure` is the name of the proposal:

```
hostname(config)# crypto ipsec ikev2 ipsec-proposal secure
hostname(config-ipsec-proposal)#
```

**Step 2**
Then enter a protocol and encryption types. ESP is the only supported protocol. For example:

```
hostname(config-ipsec-proposal)# protocol esp encryption aes
hostname(config-ipsec-proposal)#
```

**Step 3**
Enter an integrity type. For example:

```
hostname(config-ipsec-proposal)# protocol esp integrity sha-1
hostname(config-ipsec-proposal)#
```

**Step 4**
Save your changes.

---

**Configure an ACL**

The ASA uses access control lists to control network access. By default, the adaptive security appliance denies all traffic. You need to configure an ACL that permits traffic. For more information, see "Information About Access Control Lists" in the general operations configuration guide.

The ACLs that you configure for this LAN-to-LAN VPN control connections are based on the source and translated destination IP addresses. Configure ACLs that mirror each other on both sides of the connection. An ACL for VPN traffic uses the translated address.
Note

For more information on configuring an ACL with a VPN filter, see the Specify a VLAN for Remote Access or Apply a Unified Access Control Rule to the Group Policy, on page 149.

Procedure

Step 1
Enter the **access-list extended** command. The following example configures an ACL named l2l_list that lets traffic from IP addresses in the 192.168.0.0 network travel to the 150.150.0.0 network. The syntax is **access-list** listname **extended permit ip** source-ipaddress source-netmask destination-ipaddress destination-netmask.

```
hostname(config)# access-list l2l_list extended permit ip 192.168.0.0 255.255.0.0 150.150.0.0 255.255.0.0
hostname(config)#
```

Step 2
Configure an ACL for the ASA on the other side of the connection that mirrors the ACL. Subnets that are defined in two different crypto ACLs and are attached to the same crypto map should not overlap. In the following example, the prompt for the peer is hostname2.

```
hostname2(config)# access-list l2l_list extended permit ip 150.150.0.0 255.255.0.0 192.168.0.0 255.255.0.0
hostname2(config)#
```

Define a Tunnel Group

A tunnel group is a set of records that contain tunnel connection policies. You configure a tunnel group to identify AAA servers, specify connection parameters, and define a default group policy. The ASA stores tunnel groups internally.

There are two default tunnel groups in the ASA: DefaultRAGroup, which is the default IPsec remote-access tunnel group, and DefaultL2Lgroup, which is the default IPsec LAN-to-LAN tunnel group. You can modify them, but not delete them.

The main difference between IKE versions 1 and 2 lies in terms of the authentication method they allow. IKEv1 allows only one type of authentication at both VPN ends (that is, either preshared key or certificate). However, IKEv2 allows asymmetric authentication methods to be configured (that is, preshared key authentication for the originator but certificate authentication for the responder) using separate local and remote authentication CLIs. Therefore, with IKEv2 you have asymmetric authentication, in which one side authenticates with one credential and the other side uses another credential (either a preshared key or certificate).

You can also create one or more new tunnel groups to suit your environment. The ASA uses these groups to configure default tunnel parameters for remote access and LAN-to-LAN tunnel groups when there is no specific tunnel group identified during tunnel negotiation.

To establish a basic LAN-to-LAN connection, you must set two attributes for a tunnel group:

- Set the connection type to IPsec LAN-to-LAN.
- Configure an authentication method for the IP address (that is, a preshared key for IKEv1 and IKEv2).
**Procedure**

**Step 1**
To set the connection type to IPsec LAN-to-LAN, enter the `tunnel-group` command.

The syntax is `tunnel-group name type`, where name is the name you assign to the tunnel group, and type is the type of tunnel. The tunnel types as you enter them in the CLI are:

- **remote-access** (IPsec, SSL, and clientless SSL remote access)
- **ipsec-l2l** (IPsec LAN-to-LAN)

In the following example, the name of the tunnel group is the IP address of the LAN-to-LAN peer, 10.10.4.108.

```
hostname(config)# tunnel-group 10.10.4.108 type ipsec-l2l
```

**Note**
LAN-to-LAN tunnel groups that have names that are not IP addresses can be used only if the tunnel authentication method is Digital Certificates and/or the peer is configured to use Aggressive Mode.

**a.**

**Step 2**
To set the authentication method to use a preshared key, enter the `ipsec-attributes` mode and then enter the `ikev1-pre-shared-key` command to create the preshared key. You need to use the same preshared key on both ASAs for this LAN-to-LAN connection.

The key is an alphanumeric string of 1-128 characters.

In the following example, the IKEv1 preshared key is 44kkaol59636jnfx:

```
hostname(config)# tunnel-group 10.10.4.108 ipsec-attributes
hostname(config-tunnel-ipsec)# ikev1-pre-shared-key 44kkaol59636jnfx
```

**Step 3**
Save your changes.

```
hostname(config)# write memory
```

To verify that the tunnel is up and running, use the `show vpn-sessiondb summary`, `show vpn-sessiondb detail l2l`, or `show crypto ipsec sa` command.

---

**Create a Crypto Map and Applying It To an Interface**

Crypto map entries pull together the various elements of IPsec security associations, including the following:

- Which traffic IPsec should protect, which you define in an ACL.
- Where to send IPsec-protected traffic, by identifying the peer.
- What IPsec security applies to this traffic, which a transform set specifies.
- The local address for IPsec traffic, which you identify by applying the crypto map to an interface.
For IPsec to succeed, both peers must have crypto map entries with compatible configurations. For two crypto map entries to be compatible, they must, at a minimum, meet the following criteria:

- The crypto map entries must contain compatible crypto ACLs (for example, mirror image ACLs). If the responding peer uses dynamic crypto maps, the entries in the ASA crypto ACL must be “permitted” by the peer’s crypto ACL.
- The crypto map entries each must identify the other peer (unless the responding peer is using a dynamic crypto map).
- The crypto map entries must have at least one transform set in common.

If you create more than one crypto map entry for a given interface, use the sequence number (seq-num) of each entry to rank it: the lower the seq-num, the higher the priority. At the interface that has the crypto map set, the ASA evaluates traffic against the entries of higher priority maps first.

If Reverse Route Injection (RRI) is applied to a crypto map, that map must be unique to one interface on the ASA. In other words, the same crypto map cannot be applied to multiple interfaces. If more than one crypto map is applied to multiple interfaces, routes may not be cleaned up correctly. If multiple interfaces require a crypto map, each route must use a uniquely defined map.

Create multiple crypto map entries for a given interface if either of the following conditions exist:

- Different peers handle different data flows.
- You want to apply different IPsec security to different types of traffic (to the same or separate peers), for example, if you want traffic between one set of subnets to be authenticated, and traffic between another set of subnets to be both authenticated and encrypted. In this case, define the different types of traffic in two separate ACLs, and create a separate crypto map entry for each crypto ACL.

**Note**

To create a crypto map and apply it to the outside interface in global configuration mode, perform the following steps in either single or multiple context mode:

**Procedure**

**Step 1**

To assign an ACL to a crypto map entry, enter the `crypto map match address` command.

The syntax is `crypto map map-name seq-num match address aclname`. In the following example the map name is `abcmap`, the sequence number is 1, and the ACL name is `l2l_list`.

```
hostname(config)# crypto map abcmap 1 match address l2l_list
```

**Step 2**

To identify the peer(s) for the IPsec connection, enter the `crypto map set peer` command.

The syntax is `crypto map map-name seq-num set peer {ip_address1 | hostname1} [... ip_address10 | hostname10]`. In the following example the peer name is `10.10.4.108`.

```
hostname(config)# crypto map abcmap 1 set peer 10.10.4.108
```
Apply Crypto Maps to Interfaces

You must apply a crypto map set to each interface through which IPsec traffic travels. The ASA supports IPsec on all interfaces. Applying the crypto map set to an interface instructs the ASA to evaluate all interface traffic against the crypto map set and to use the specified policy during connection or security association negotiations.

Binding a crypto map to an interface also initializes the runtime data structures, such as the security association database and the security policy database. When you later modify a crypto map in any way, the ASA automatically applies the changes to the running configuration. It drops any existing connections and reestablishes them after applying the new crypto map.

To apply the configured crypto map to the outside interface, perform the following steps:

**Procedure**

**Step 1** Enter the `crypto map interface` command. The syntax is `crypto map map-name interface` interface-name.

```
hostname(config)# crypto map abcmap interface outside
hostname(config)#
```

**Step 2** Save your changes.
hostname(config)# write memory
hostname(config)#
About the AnyConnect VPN Client

The Cisco AnyConnect Secure Mobility Client provides secure SSL and IPSec/IKEv2 connections to the ASA for remote users. Without a previously-installed client, remote users enter the IP address in their browser of an interface configured to accept SSL or IPSec/IKEv2 VPN connections. Unless the ASA is configured to redirect http:// requests to https://, users must enter the URL in the form https://<address>.

After entering the URL, the browser connects to that interface and displays the login screen. If the user satisfies the login and authentication, and the ASA identifies the user as requiring the client, it downloads the client that matches the operating system of the remote computer. After downloading, the client installs and configures itself, establishes a secure SSL or IPSec/IKEv2 connection and either remains or uninstalls itself (depending on the configuration) when the connection terminates.

In the case of a previously installed client, when the user authenticates, the ASA examines the revision of the client, and upgrades the client as necessary.

When the client negotiates an SSL VPN connection with the ASA, it connects using Transport Layer Security (TLS), and optionally, Datagram Transport Layer Security (DTLS). DTLS avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

The AnyConnect client can be downloaded from the ASA, or it can be installed manually on the remote PC by the system administrator. For more information about installing the client manually, see the appropriate release of the Cisco AnyConnect Secure Mobility Configuration Guide.

The ASA downloads the client based on the group policy or username attributes of the user establishing the connection. You can configure the ASA to automatically download the client, or you can configure it to prompt the remote user about whether to download the client. In the latter case, if the user does not respond, you can configure the ASA to either download the client after a timeout period or present the login page.
Requirements for AnyConnect

For the requirements of endpoint computers running the AnyConnect Secure Mobility Client, see the appropriate release of the Cisco AnyConnect Secure Mobility Release Notes.

Guidelines and Limitations for AnyConnect

- The ASA does not verify remote HTTPS certificates.
- Supported in single or multiple context mode. AnyConnect Apex license is required for remote-access VPN in multi-context mode. Although ASA does not specifically recognize an AnyConnect Apex license, it enforces licenses characteristics of an Apex license such as AnyConnect Premium licensed to the platform limit, AnyConnect for mobile, AnyConnect for Cisco VPN phone, and advanced endpoint assessment. Shared licensing, AnyConnect Essentials, failover license aggregation, and flex/time-based licenses are not supported.

Licensing Requirements for AnyConnect

This feature is not available on No Payload Encryption models.

VPN Licenses require an AnyConnect Plus or Apex license, available separately. See Cisco ASA Series Feature Licenses for maximum values per model.

If you start a clientless SSL VPN session and then start an AnyConnect client session from the portal, 1 session is used in total. However, if you start the AnyConnect client first (from a standalone client, for example) and then log into the clientless SSL VPN portal, then 2 sessions are used.

Configure AnyConnect Connections

This section describes prerequisites, restrictions, and detailed tasks to configure the ASA to accept AnyConnect VPN client connections.

Configure the ASA to Web-Deploy the Client

The section describes the steps to configure the ASA to web-deploy the AnyConnect client.

Before you begin

Copy the client image package to the ASA using TFTP or another method.

Procedure

Step 1

Identify a file on flash as an AnyConnect client package file.

The ASA expands the file in cache memory for downloading to remote PCs. If you have multiple clients, assign an order to the client images with the order argument.
The ASA downloads portions of each client in the order you specify until it matches the operating system of the remote PC. Therefore, assign the lowest number to the image used by the most commonly-encountered operating system.

**anyconnect image filename order**

Example:

```
hostname(config-webvpn)# anyconnect image
anyconnect-win-2.3.0254-k9.pkg 1
hostname(config-webvpn)# anyconnect image
anyconnect-macosx-i386-2.3.0254-k9.pkg 2
hostname(config-webvpn)# anyconnect image
anyconnect-linux-2.3.0254-k9.pkg 3
```

**Note** You must issue the **anyconnect enable** command after configuring the AnyConnect images with the **anyconnect image** command. If you do not enable AnyConnect, it will not operate as expected, and **show webvpn anyconnect** considers the SSL VPN client as not enabled rather than listing the installed AnyConnect packages.

**Step 2** Enable SSL on an interface for clientless or AnyConnect SSL connections.

**enable interface**

Example:

```
hostname(config)# webvpn
hostname(config-webvpn)# enable outside
```

**Step 3** Without issuing this command, AnyConnect does not function as expected, and a **show webvpn anyconnect** command returns that the “SSL VPN is not enabled,” instead of listing the installed AnyConnect packages.

**anyconnect enable**

**Step 4** (Optional) Create an address pool. You can use another method of address assignment, such as DHCP and/or user-assigned addressing.

**ip local pool poolname startaddr-endaddr mask mask**

Example:

```
hostname(config)# ip local pool vpn_users 209.165.200.225-209.165.200.254
mask 255.255.255.224
```

**Step 5** Assign an address pool to a tunnel group.

**address-pool poolname**

Example:

```
hostname(config)# tunnel-group telecommuters general-attributes
hostname(config-tunnel-general)# address-pool vpn_users
```

**Step 6** Assign a default group policy to the tunnel group.

**default-group-policy name**

Example:

```
hostname(config-tunnel-general)# default-group-policy sales
```
Step 7 Enable the display of the tunnel-group list on the clientless portal and AnyConnect GUI login page. The list of aliases is defined by the `group-alias name enable` command.

`group-alias name enable`  
**Example:**

```
hostname(config)# tunnel-group telecommuters webvpn-attributes
hostname(config-tunnel-webvpn)# group-alias sales_department enable
```

Step 8 Specify the AnyConnect clients as a permitted VPN tunneling protocol for the group or user.

`tunnel-group-list enable`  
**Example:**

```
hostname(config)# webvpn
hostname(config-webvpn)# tunnel-group-list enable
```

Step 9 Specify SSL as a permitted VPN tunneling protocol for the group or user. You can also specify additional protocols. For more information, see the `vpn-tunnel-protocol` command in the command reference.

`vpn-tunnel-protocol`  
**Example:**

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# vpn-tunnel-protocol
```

---

**What to do next**

For more information about assigning users to group policies, see Chapter 6, Configuring Connection Profiles, Group Policies, and Users.

---

**Enable Permanent Client Installation**

Enabling permanent client installation disables the automatic uninstalling feature of the client. The client remains installed on the remote computer for subsequent connections, reducing the connection time for the remote user.

To enable permanent client installation for a specific group or user, use the `anyconnect keep-installer` command from group-policy or username webvpn modes.

The default is that permanent installation of the client is enabled. The client remains on the remote computer at the end of the session. The following example configures the existing group-policy `sales` to remove the client on the remote computer at the end of the session:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-policy)# anyconnect keep-installer installed none
```
Configure DTLS

Datagram Transport Layer Security (DTLS) allows the AnyConnect client establishing an SSL VPN connection to use two simultaneous tunnels—an SSL tunnel and a DTLS tunnel. Using DTLS avoids latency and bandwidth problems associated with SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

Before you begin

See, Configure Advanced SSL Settings, on page 89 to configure DTLS on this headend, and which version of DTLS is used.

In order for DTLS to fall back to a TLS connection, Dead Peer Detection (DPD) must be enabled. If you do not enable DPD, and the DTLS connection experiences a problem, the connection terminates instead of falling back to TLS. For more information on DPD, see Configure Dead Peer Detection, on page 246.

Procedure

**Step 1** Specify DTLS options for AnyConnect VPN connections:

a) Enable SSL and DTLS on the interface in webvpn mode.

   By default, DTLS is enabled when SSL VPN access is enabled on an interface.

   ```
   hostname(config)# webvpn
   hostname(config-webvpn)# enable outside
   ```

   Disable DTLS for all AnyConnect client users with the `enable interface tls-only` command in webvpn configuration mode.

   ```
   hostname(config)# webvpn
   hostname(config-webvpn)# enable outside tls-only
   ```

b) Configure the ports for SSL and DTLS using the `port` and `dtls port` commands.

   ```
   hostname(config)# webvpn
   hostname(config-webvpn)# enable outside
   hostname(config-webvpn)# port 555
   hostname(config-webvpn)# dtls port 556
   ```

**Step 2** Specify DTLS options for specific group policies.

a) Enable DTLS for specific groups or users with the `anyconnect ssl dtls` command in group policy webvpn or username webvpn configuration mode.

   ```
   hostname(config)# group-policy sales attributes
   hostname(config-group-policy)# webvpn
   hostname(config-group-webvpn)# anyconnect ssl dtls enable
   ```

b) If desired, enable DTLS compression using the anyconnect dtls compression command.
Prompt Remote Users

Procedure

You can enable the ASA to prompt remote SSL VPN client users to download the client with the `anyconnect ask` command from group policy webvpn or username webvpn configuration modes:

```
[no] anyconnect ask {none | enable [default {webvpn | } timeout value]}
```

- `anyconnect enable` prompts the remote user to download the client or go to the clientless portal page and waits indefinitely for user response.
- `anyconnect ask enable default` immediately downloads the client.
- `anyconnect ask enable default webvpn` immediately goes to the portal page.
- `anyconnect ask enable default timeout value` prompts the remote user to download the client or go to the clientless portal page and waits the duration of `value` before taking the default action—downloading the client.
- `anyconnect ask enable default clientless timeout value` prompts the remote user to download the client or go to the clientless portal page, and waits the duration of `value` before taking the default action—displaying the clientless portal page.

The figure below shows the prompt displayed to remote users when either `default anyconnect timeout value` or `default webvpn timeout value` is configured:

*Figure 6: Prompt Displayed to Remote Users for SSL VPN Client Download*

```
AnyConnect will start in 112 seconds.

- Start now
- Cancel
```

Example

The following example configures the ASA to prompt the user to download the client or go to the clientless portal page and wait *10 seconds for a response* before downloading the client:

```
hostname(config-group-webvpn)# anyconnect ask enable default anyconnect timeout 10
```
Enable AnyConnect Client Profile Downloads

You enable Cisco AnyConnect Secure Mobility client features in the AnyConnect profiles—XML files that contain configuration settings for the core client with its VPN functionality and for the optional client modules. The ASA deploys the profiles during AnyConnect installation and updates. Users cannot manage or modify profiles.

You can configure a profile using the AnyConnect profile editor, a convenient GUI-based configuration tool launched from ASDM or ISE. The AnyConnect software package for Windows includes the editor, which activates when you load the AnyConnect package on the chosen headend device and specify it as an AnyConnect client image.

We also provide a standalone version of the profile editor for Windows that you can use as an alternative to the profile editor integrated with ASDM or ISE. If you are predeploying the client, you can use the standalone profile editor to create profiles for the VPN service and other modules that you deploy to computers using your software management system.

For more information on the AnyConnect client and its Profile Editor, see the appropriate release of the Cisco AnyConnect Secure Mobility Configuration Guide.

The AnyConnect client protocol defaults to SSL. To enable IPsec IKEv2, you must configure the IKEv2 settings on the ASA and also configure IKEv2 as the primary protocol in the client profile. The IKEv2 enabled profile must be deployed to the endpoint computer; otherwise the client attempts to connect using SSL.

Procedure

Step 1
Use the profile editor from ASDM/ISE or the standalone profile editor to create a profile.

Step 2
Load the profile file into flash memory on the ASA using tftp or another method.

Step 3
Use the anyconnect profiles command from webvpn configuration mode to identify the file as a client profile to load into cache memory.

Example:
The following example specifies the files sales_hosts.xml and engineering_hosts.xml as profiles:

```
asa1(config-webvpn)# anyconnect profiles sales
disk0:/sales_hosts.xml
asa1(config-webvpn)# anyconnect profiles engineering
disk0:/engineering_hosts.xml
```

The profiles are now available to group policies.

View the profiles loaded in cache memory using the `dir cache:/stc/profiles` command:

```
hostname(config-webvpn)# dir cache:/stc/profiles

Directory of cache:/stc/profiles/

  0   ---- 774       11:54:41 Nov 22 2006  engineering.xml
  0   ---- 774       11:54:29 Nov 22 2006  sales.xml

2428928 bytes total (18219008 bytes free)
```
Step 4 Enter group policy webvpn configuration mode and specify a client profile for a group policy with the `anyconnect profiles` command:

**Example:**
You can enter the `anyconnect profiles value` command followed by a question mark (?) to view the available profiles. For example:

```
asa1(config-group-webvpn)# anyconnect profiles value ?
```

```
config-group-webvpn mode commands/options:
Available configured profile packages: engineering sales
```

The next example configures the group policy to use the profile `sales` with the client profile type `vpn`:

```
asa1(config-group-webvpn)# anyconnect profiles value sales type vpn
asa1(config-group-webvpn)#
```

---

**Enable AnyConnect Client Deferred Upgrade**

Deferred Upgrade allows the AnyConnect user to delay download of a client upgrade. When a client update is available, AnyConnect opens a dialog asking the user if they would like to update, or to defer the upgrade. This upgrade dialog will not appear unless you have AutoUpdate set to `Enabled` in the AnyConnect profile setting.

Deferred Upgrade is enabled by adding custom attribute types and named values to the ASA; then referencing and configuring those attributes in a group policy.

The following custom attributes support Deferred Upgrade:

<table>
<thead>
<tr>
<th>Custom Attribute Type</th>
<th>Valid Values</th>
<th>Default Value</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>DeferredUpdateAllowed</td>
<td>true, false</td>
<td>false</td>
<td>True enables deferred update. If deferred update is disabled (false), the settings below are ignored.</td>
</tr>
<tr>
<td>DeferredUpdateMinimumVersion</td>
<td>x.y.z</td>
<td>0.0.0</td>
<td>Minimum version of AnyConnect that must be installed for updates to be deferable. The minimum version check applies to all modules enabled on the headend. If any enabled module (including VPN) is not installed or does not meet the minimum version, the connection is not eligible for deferred update. If this attribute is not specified, then a deferral prompt is displayed (or auto-dismissed) regardless of the version installed on the endpoint.</td>
</tr>
</tbody>
</table>
### Custom Attribute Type

<table>
<thead>
<tr>
<th>Attribute Type</th>
<th>Valid Values</th>
<th>Default Value</th>
<th>Notes</th>
</tr>
</thead>
</table>
| DeferredUpdateDismissTimeout   | 0-300 (seconds)    | none (disabled) | Number of seconds that the deferred upgrade prompt is displayed before being dismissed automatically. This attribute only applies when a deferred update prompt is to be displayed (the minimum version attribute is evaluated first). If this attribute is missing, then the auto-dismiss feature is disabled, and a dialog is displayed (if required) until the user responds. Setting this attribute to zero allows automatic deferral or upgrade to be forced based on:  
  - The installed version and the value of DeferredUpdateMinimumVersion.  
  - The value of DeferredUpdateDismissResponse. |
| DeferredUpdateDismissResponse  | defer update       | update          | Action to take when DeferredUpdateDismissTimeout occurs.                                                                                           |
Step 3

Add or remove the custom attribute named values to a group policy using the `anyconnect-custom` command:

- `anyconnect-custom attr-type value attr-name`
- `anyconnect-custom attr-type none`
- `no anyconnect-custom attr-type`

Example:

The following example shows how to enable Deferred Update for the group policy named sales and set the timeout to 150 seconds:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# anyconnect-custom DeferredUpdateAllowed value def-allowed
hostname(config-group-policy)# anyconnect-custom DeferredUpdateDismissTimeout value def-timeout
```

Enable DSCP Preservation

By setting another custom attribute, you can control Differentiated Services Code Point (DSCP) on Windows or OS X platforms for DTLS connections only. Enabling DSCP preservation allows devices to prioritize latency sensitive traffic; the router takes into account whether this is set and marks prioritized traffic to improve outbound connection quality.

Procedure

Step 1

Create the custom attribute types with the `anyconnect-custom-attr` command in `webvpn` configuration mode:

```
[no] anyconnect-custom-attr DSCPPreservationAllowed description Set to control Differentiated Services Code Point (DSCP) on Windows or OS X platforms for DTLS connections only.
```

Step 2

Add named values for custom attributes with the `anyconnect-custom-data` command in global configuration mode:

```
[no] anyconnect-custom-data DSCPPreservationAllowed true
```

Note: By default, AnyConnect performs DSCP preservation (true). To disable it, set the custom attributes to false on the headend and reinitiate the connection.

Enable Additional AnyConnect Client Features

To minimize download time, the client only requests downloads (from the ASA or ISE) of the core modules that it needs. As additional features become available for the AnyConnect client, you need to update the remote clients in order for them to use the features.
To enable new features, you must specify the new module names using the `anyconnect modules` command from group policy webvpn or username webvpn configuration mode:

```
[no]anyconnect modules {none | value string}
```

Separate multiple strings with commas.

## Enable Start Before Logon

Start Before Logon (SBL) allows login scripts, password caching, drive mapping, and more, for the AnyConnect client installed on a Windows PC. For SBL, you must enable the ASA to download the module which enables graphical identification and authentication (GINA) for the AnyConnect client. The following procedure shows how to enable SBL:

### Procedure

**Step 1**
Enable the ASA to download the GINA module for VPN connection to specific groups or users using the `anyconnect modules vpngina` command from group policy webvpn or username webvpn configuration modes.

**Example:**
In the following example, the user enters group-policy attributes mode for the group policy `telecommuters`, enters webvpn configuration mode for the group policy, and specifies the string `vpngina`:

```
hostname(config)# group-policy telecommuters attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anyconnect modules value vpngina
```

**Step 2**
Retrieve a copy of the client profiles file (AnyConnectProfile.tmpl).

**Step 3**
Edit the profiles file to specify that SBL is enabled. The example below shows the relevant portion of the profiles file (AnyConnectProfile.tmpl) for Windows:

```xml
<Configuration>
  <ClientInitialization>
    <UseStartBeforeLogon>false</UseStartBeforeLogon>
  </ClientInitialization>
</Configuration>
```

The `<UseStartBeforeLogon>` tag determines whether the client uses SBL. To turn SBL on, replace `false` with `true`. The example below shows the tag with SBL turned on:

```xml
<Configuration>
  <ClientInitialization>
    <UseStartBeforeLogon>true</UseStartBeforeLogon>
  </ClientInitialization>
</Configuration>
```

**Step 4**
Save the changes to AnyConnectProfile.tmpl and update the profile file for the group or user on the ASA using the `profile` command from webvpn configuration mode. For example:

```
asa1(config-webvpn)# anyconnect profiles sales disk0:/sales_hosts.xml
```
Translating Languages for AnyConnect User Messages

The ASA provides language translation for the portal and screens displayed to users that initiate browser-based, Clientless SSL VPN connections, as well as the interface displayed to Cisco AnyConnect VPN Client users. This section describes how to configure the ASA to translate these user messages.

Understand Language Translation

Functional areas and their messages that are visible to remote users are organized into translation domains. All messages displayed on the user interface of the Cisco AnyConnect VPN Client are located in the AnyConnect domain.

The software image package for the ASA includes a translation table template for the AnyConnect domain. You can export the template, which creates an XML file of the template at the URL you provide. The message fields in this file are empty. You can edit the messages and import the template to create a new translation table object that resides in flash memory.

You can also export an existing translation table. The XML file created displays the messages you edited previously. Reimporting this XML file with the same language name creates a new version of the translation table object, overwriting previous messages. Changes to the translation table for the AnyConnect domain are immediately visible to AnyConnect client users.

Create Translation Tables

The following procedure describes how to create translation tables for the AnyConnect domain:

Procedure

Step 1

Export a translation table template to a computer with the export webvpn translation-table command from privileged EXEC mode.

In the following example, the show import webvpn translation-table command shows available translation table templates and tables.

```
hostname# show import webvpn translation-table
Translation Tables' Templates:
  customization
  AnyConnect
  PortForwarder
  url-list
  webvpn
  Citrix-plugin
  RPC-plugin
  Telnet-SSH-plugin
  VNC-plugin
Translation Tables:
```

Then the user exports the translation table for the AnyConnect translation domain. The filename of the XML file created is named client and contains empty message fields:

```
hostname# export webvpn translation-table AnyConnect
```
In the next example, the user exports a translation table named `zh`, which was previously imported from a template. `zh` is the abbreviation by Microsoft Internet Explorer for the Chinese language.

```
hostname# export webvpn translation-table customization language zh tftp://209.165.200.225/chinese_client
```

**Step 2** Edit the Translation Table XML file. The following example shows a portion of the AnyConnect template. The end of this output includes a message ID field (`msgid`) and a message string field (`msgstr`) for the message `Connected`, which is displayed on the AnyConnect client GUI when the client establishes a VPN connection. The complete template contains many pairs of message fields:

```
#: SOME DESCRIPTIVE TITLE.
#: Copyright (C) YEAR THE PACKAGE'S COPYRIGHT HOLDER
#: This file is distributed under the same license as the PACKAGE package.
#: FIRST AUTHOR <EMAIL@ADDRESS>, YEAR.
#:,
#: fuzzy
msgid ""
msgstr ""
"Project-Id-Version: PACKAGE VERSION\n"
"Report-Msgid-Bugs-To: \n"
"PO-Revision-Date: YEAR-MO-DA HO:MI+ZONE\n"
"Last-Translator: FULL NAME <EMAIL@ADDRESS>\n"
"Language-Team: LANGUAGE <LL@li.org>\n"
"MIME-Version: 1.0\n"
"Content-Type: text/plain; charset=CHARSET\n"
"Content-Transfer-Encoding: 8bit\n"
#: C:\cygwin\home\<user>\cvc\main\Api\AgentIfc.cpp:23
#: C:\cygwin\home\<user>\cvc\main\Api\check\AgentIfc.cpp:22
#: C:\cygwin\home\<user>\cvc\main\Api\save\AgentIfc.cpp:23
#: C:\cygwin\home\<user>\cvc\main\Api\save\older\AgentIfc.cpp:22
msgid "Connected"
msgstr "Connected"
```

The `msgid` contains the default translation. The `msgstr` that follows `msgid` provides the translation. To create a translation, enter the translated text between the quotes of the `msgstr` string. For example, to translate the message “Connected” with a Spanish translation, insert the Spanish text between the quotes:

```
msgid "Connected"
msgstr "Conectado"
```

Be sure to save the file.

**Step 3** Import the translation table using the `import webvpn translation-table` command from privileged EXEC mode. Be sure to specify the name of the new translation table with the abbreviation for the language that is compatible with the browser.

In the following example, the XML file is imported `es-us`—the abbreviation used by Microsoft Internet Explorer for Spanish spoken in the United States.
Remove Translation Tables

If you no longer need a translation table, you can remove it.

**Procedure**

**Step 1** List the existing translation tables.

In the following example, the `show import webvpn translation-table` command shows available translation table templates and tables. Various tables are available for French (fr), Japanese (ja), and Russian (ru).

```
hostname# show import webvpn translation-table
Translation Tables' Templates:
  AnyConnect
  PortForwarder
  banners
  csd
  customization
  url-list
  webvpn
Translation Tables:
  fr AnyConnect
  fr PortForwarder
  fr customization
  fr webvpn
  ja AnyConnect
  ja PortForwarder
  ja customization
  ja webvpn
  ru AnyConnect
  ru PortForwarder
  ru customization
  ru webvpn
```

**Step 2** Remove the unwanted translation table.
revert webvpn translation-table translationdomain language language
Where translationdomain is the domain listed on the right in the Translation Tables listing shown above, and language is the 2-character language name.

You must remove each table individually. You cannot remove all of the tables for a given language with one command.

For example, to remove the French translation table for AnyConnect:

```
ciscoasa# revert webvpn translation-table anyconnect language fr
ciscoasa#
```

---

**Configuring Advanced AnyConnect SSL Features**

The following section describes advanced features that fine-tune AnyConnect SSL VPN connections.

### Enable Rekey

When the ASA and the AnyConnect client perform a rekey on an SSL VPN connection, they renegotiate the crypto keys and initialization vectors, increasing the security of the connection.

To enable the client to perform a rekey on an SSL VPN connection for a specific group or user, use the `anyconnect ssl rekey` command from group-policy or username webvpn modes.

```
[no]anyconnect ssl rekey {method {new-tunnel | none | ssl} | time minutes}
```

- `method new-tunnel` specifies that the client establishes a new tunnel during rekey.
- `method ssl` specifies that the client establishes a new tunnel during rekey.
- `method none` disables rekey.
- `time minutes` specifies the number of minutes from the start of the session, or from the last rekey, until the rekey takes place, from 1 to 10080 (1 week).

---

**Note**

Configuring the rekey method as `ssl` or `new-tunnel` specifies that the client establishes a new tunnel during rekey instead of the SSL renegotiation taking place during the rekey. See the command reference for a history of the `anyconnect ssl rekey` command.

In the following example, the client is configured to renegotiate with SSL during rekey, which takes place 30 minutes after the session begins, for the existing group-policy `sales`:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anyconnect ssl rekey method ssl
hostname(config-group-webvpn)# anyconnect ssl rekey time 30
```
Configure Dead Peer Detection

Dead Peer Detection (DPD) ensures that the ASA (gateway) or the client can quickly detect a condition where the peer is not responding, and the connection has failed. To enable dead peer detection (DPD) and set the frequency with which either the AnyConnect client or the ASA gateway performs DPD, do the following:

**Before you begin**

- This feature applies to connectivity between the ASA gateway and the AnyConnect SSL VPN Client only. It does not work with IPsec since DPD is based on the standards implementation that does not allow padding, and Clientless SSL VPN is not supported.
- If you enable DTLS, enable Dead Peer Detection (DPD) also. DPD enables a failed DTLS connection to fallback to TLS. Otherwise, the connection terminates.
- When DPD is enabled on the ASA, you can use the Optimal MTU (OMTU) function to find the largest endpoint MTU at which the client can successfully pass DTLS packets. Implement OMTU by sending a padded DPD packet to the maximum MTU. If a correct echo of the payload is received from the head end, the MTU size is accepted. Otherwise, the MTU is reduced, and the probe is sent again until the minimum MTU allowed for the protocol is reached.

**Procedure**

**Step 1**
Go to the desired group policy.
Enter group policy or username webvpn mode:
```
hostname(config)# group-policy group-policy-name attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)#
```

Or,
```
hostname# username username attributes
hostname(config-username)# webvpn
hostname (config-username-webvpn #
```

**Step 2**
Set Gateway Side Detection.
Use the `[no] anyconnect dpd-interval {[gateway {seconds | none}]}` command.
The gateway refers to the ASA. You enable DPD and specify the interval with which the ASA waits for any packet from the client as a range of from 30 (default) to 3600 seconds (1 hour). A value of 300 is recommended. If no packets are received within that interval, the ASA performs the DPD test with three attempts at the same interval. If the ASA does not receive a response from the client, it tears down the TLS/DTLS tunnel.

**Note** Specifying `none` disables the DPD testing that the ASA performs. Use `no anyconnect dpd-interval` to remove this command from the configuration.

Specifying `none` disables the DPD testing that the ASA performs. Use `no anyconnect dpd-interval` to remove this command from the configuration.

**Step 3**
Set Client Side Detection.
Use the `[no] anyconnect dpd-interval {[client {seconds | none}]}` command.
The client refers to the AnyConnect client. You enable DPD and specify the frequency with which the client performs the DPD test as a range of from 30 (default) to 3600 seconds (1 hour). A value of 300 is recommended. Specifying client none disables DPD performed by the client. Use no anyconnect dpd-interval to remove this command from the configuration.

Example

The following example sets the frequency of DPD performed by the ASA to 30 seconds, and the frequency of DPD performed by the client set to 10 seconds for the existing group-policy sales:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anyconnect dpd-interval gateway 30
hostname(config-group-webvpn)# anyconnect dpd-interval client 10
```

Enable Keepalive

You can adjust the frequency of keepalive messages to ensure that an SSL VPN connection through a proxy, firewall, or NAT device remains open, even if the device limits the time that the connection can be idle. Adjusting the frequency also ensures that the client does not disconnect and reconnect when the remote user is not actively running a socket-based application, such as Microsoft Outlook or Microsoft Internet Explorer.

Keepalives are enabled by default. If you disable keepalives, in the event of a failover, SSL VPN client sessions are not carried over to the standby device.

To set the frequency of keepalive messages, use the keepalive command from group-policy webvpn or username webvpn configuration mode: Use the no form of the command to remove the command from the configuration and cause the value to be inherited:

```
[no] anyconnect ssl keepalive {none | seconds}
```

- **none** disables client keepalive messages.
- **seconds** enables the client to send keepalive messages, and specifies the frequency of the messages in the range of 15 to 600 seconds.

In the following example, the ASA is configured to enable the client to send keepalive messages with a frequency of 300 seconds (5 minutes), for the existing group-policy sales:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anyconnect ssl keepalive 300
```

Use Compression

Compression increases the communications performance between the ASA and the client by reducing the size of the packets being transferred for low-bandwidth connections. By default, compression for all SSL VPN connections is enabled on the ASA, both at the global level and for specific groups or users.
When implementing compression on broadband connections, you must carefully consider the fact that compression relies on loss-less connectivity. This is the main reason that it is not enabled by default on broadband connections.

Compression must be turned-on globally using the `compression` command from global configuration mode, and then it can be set for specific groups or users with the `anyconnect ssl compression` command in group-policy and username webvpn modes.

Changing Compression Globally

To change the global compression settings, use the `anyconnect ssl compression` command from global configuration mode. To remove the command from the configuration, use the `no` form of the command.

In the following example, compression is disabled for all SSL VPN connections globally:

```
hostname(config)# no compression
```

Changing Compression for Groups and Users

To change compression for a specific group or user, use the `anyconnect ssl compression` command in the group-policy and username webvpn modes:

```
[no] anyconnect ssl compression {deflate | none}
```

By default, for groups and users, SSL compression is set to `deflate` (enabled).

To remove the `anyconnect ssl compression` command from the configuration and cause the value to be inherited from the global setting, use the `no` form of the command:

In the following example, compression is disabled for the group-policy sales:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# no anyconnect ssl compression none
```

Adjust MTU Size

You can adjust the MTU size (from 576 to 1406 bytes) for SSL VPN connections established by the client with the `anyconnect mtu` command from group policy webvpn or username webvpn configuration mode:

```
[no] anyconnect mtu size
```

This command affects only the AnyConnect client. The legacy Cisco SSL VPN Client () is not capable of adjusting to different MTU sizes. Also, client connections established in SSL and those established in SSL with DTLS are impacted by this command.

The default for this command in the default group policy is `no anyconnect mtu`. The MTU size is adjusted automatically based on the MTU of the interface that the connection uses, minus the IP/UDP/DTLS overhead.

You may receive an "MTU configuration sent from the secure gateway is too small" message, for example, when running the ISE Posture AnyConnect module. If you enter `anyconnect mtu 1200` along with `anyconnect ssl df-bit-ignore disable`, you can avoid these system scan errors.
**Example**

The following example configures the MTU size to 1200 bytes for the group policy telecommuters:

```
hostname(config)# group-policy telecommuters attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# anyconnect mtu 1200
```

**Update AnyConnect Client Images**

You can update the client images on the ASA at any time using the following procedure:

**Procedure**

**Step 1**
Copy the new client images to the ASA using the `copy` command from privileged EXEC mode, or using another method.

**Step 2**
If the new client image files have the same filenames as the files already loaded, reenter the `anyconnect image` command that is in the configuration. If the new filenames are different, uninstall the old files using the `[no]anyconnect image`image command. Then use the `anyconnect image` command to assign an order to the images and cause the ASA to load the new images.

**Enable IPv6 VPN Access**

If you want to configure IPv6 access, you must use the command-line interface. Release 9.0(x) of the ASA adds support for IPv6 VPN connections to its outside interface using SSL and IKEv2/Ipsec protocols.

You enable IPv6 access using the `ipv6 enable` command as part of enabling SSL VPN connections. The following is an example for an IPv6 connection that enables IPv6 on the outside interface:

```
hostname(config)# interface GigabitEthernet0/0
hostname(config-if)# ipv6 enable
```

To enable IPv6 SSL VPN, do the following general actions:

1. Enable IPv6 on the outside interface.
2. Enable IPv6 and an IPv6 address on the inside interface.
3. Configure an IPv6 address local pool for client assigned IP Addresses.
4. Configure an IPv6 tunnel default gateway.

**Procedure**

**Step 1**
Configure Interfaces:

```
interface GigabitEthernet0/0
  nameif outside
```
Monitor AnyConnect Connections

To view information about active sessions, use the `show vpn-sessiondb` command:

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>show vpn-sessiondb</code></td>
<td>Displays information about active sessions.</td>
</tr>
<tr>
<td><code>vpn-sessiondb logoff</code></td>
<td>Logs off VPN sessions.</td>
</tr>
<tr>
<td><code>show vpn-sessiondb anyconnect</code></td>
<td>Enhances the VPN session summary to show OSPFv3 session information.</td>
</tr>
<tr>
<td><code>show vpn-sessiondb ratio encryption</code></td>
<td>Shows the number of tunnels and percentages for the Suite B algorithms (such as AES-GCM-128, AES-GCM-192, AES-GCM-256, AES-GMAC-128, and so on).</td>
</tr>
</tbody>
</table>
Log Off AnyConnect VPN Sessions

To log off all VPN sessions, use the vpn-sessiondb logoff command in global configuration mode:

```
hostname# vpn-sessiondb logoff
INFO: Number of sessions of type "" logged off : 1
```

You can log off individual sessions using either the name argument or the index argument:

```
vpn-sessiondb logoff name name
vpn-sessiondb logoff index index
```

The sessions that have been inactive the longest time are marked as idle (and are automatically logged off) so that license capacity is not reached and new users can log in. If the session resumes at a later time, it is removed from the inactive list.

You can find both the username and the index number (established by the order of the client images) in the output of the show vpn-sessiondb anyconnect command. The following examples shows the username lee and index number 1.

```
hostname# show vpn-sessiondb anyconnect
Session Type: AnyConnect
```

Example

The Inactivity field shows the elapsed time since an AnyConnect session lost connectivity. If the session is active, 00:00m:00s appears in this field.

```
hostname# show vpn-sessiondb
Session Type: SSL VPN Client
Username : lee
Index : 1 IP Addr : 209.165.200.232
Protocol : SSL VPN Client Encryption : 3DES
Hashing : SHA1 Auth Mode : userPassword
TCP Dst Port : 443 TCP Src Port : 54230
Bytes Tx : 20178 Bytes Rx : 8662
Pkts Tx : 27 Pkts Rx : 19
Client Ver : Cisco STC 1.1.0.117
Client Type : Internet Explorer
Group : DfltGrpPolicy
Login Time : 14:32:03 UTC Wed Mar 20 2007
Duration : 0h:00m:04s
Inactivity : 0h:00m:04s
Filter Name :
```

```
hostname# vpn-sessiondb logoff
INFO: Number of sessions of type "" logged off : 1
```

```
hostname# vpn-sessiondb logoff name tester
Do you want to logoff the VPN session(s)? [confirm]
INFO: Number of sessions with name "tester" logged off : 1
```
Username : lee  Index : 1
Assigned IP : 192.168.246.1  Public IP : 10.139.1.2
Protocol : AnyConnect-Parent SSL-Tunnel DTLS-Tunnel
License : AnyConnect Premium
Encryption : RC4 AES128  Hashing : SHA1
Bytes Tx : 11079  Bytes Rx : 4942
Group Policy : EngPolicy  Tunnel Group : EngGroup
Login Time : 15:25:13 EST Fri Jan 28 2011
Duration : 0h:00m:15s
Inactivity : 0h:00m:00s
NAC Result : Unknown
VLAN Mapping : N/A  VLAN : none

The following example terminates the session using the name option of the `vpn-session-db logoff` command:

```
hostname# vpn-sessiondb logoff name lee
Do you want to logoff the VPN session(s)? [confirm]
INFO: Number of sessions with name “lee” logged off : 1
hostname#
```

### Feature History for AnyConnect Connections

The following table lists the release history for this feature.

#### Table 13: Feature History for AnyConnect Connections

AnyConnect HostScan

The AnyConnect Posture Module provides the AnyConnect Secure Mobility Client the ability to identify the operating system, anti-malware and firewall software installed on the host. The HostScan application gathers this information. Posture assessment requires HostScan to be installed on the host.

- Prerequisites for HostScan, on page 253
- Licensing for HostScan, on page 254
- HostScan Packaging, on page 254
- Install or Upgrade HostScan, on page 254
- Enable or Disable HostScan, on page 255
- View the HostScan Version Enabled on the ASA, on page 256
- Uninstall HostScan, on page 256
- Assign AnyConnect Feature Modules to Group Policies, on page 257
- HostScan Related Documentation, on page 258

Prerequisites for HostScan

The AnyConnect Secure Mobility Client with the posture module requires these minimum ASA components:

- ASA 8.4
- ASDM 6.4

These AnyConnect features require that you install the posture module.

- SCEP authentication
- AnyConnect Telemetry Module

The posture module can be installed on any of these platforms:

- Windows 7, 8, 8.1, 10, 10 RS1, RS2, & RS3 (x86 (32-bit) and x64 (64-bit)
- macOS 10.11, 10.12, and 10.13
- Linux Red Hat 6, 7 & Ubuntu 14.04 (LTS) and 16.04 (LTS) (64-bit only)
Licensing for HostScan

These are the AnyConnect licensing requirements for the HostScan:

- AnyConnect Apex
- AnyConnect VPN Only

HostScan Packaging

You can load the HostScan package on to the ASA as a standalone package: `hostscan-version.pkg`. This file contains the HostScan software as well as the HostScan library and support charts.

Install or Upgrade HostScan

Use this procedure to install or upgrade the HostScan package and enable it using the command line interface for the ASA.

Before you begin

Note

If you are attempting to upgrade to HostScan version 4.6.x or later from a 4.3.x version or earlier, you will receive an error message due to the fact that all existing AV/AS/FW DAP policies and LUA script(s) that you have previously established are incompatible with HostScan 4.6.x or greater.

There is a one time migration procedure that must be done to adapt your configuration. This procedure involves leaving this dialog box to migrate your configuration to be compatible with HostScan 4.4.x before saving this configuration. Abort this procedure and refer to the AnyConnect HostScan 4.3.x to 4.6.x Migration Guide for detailed instructions. Briefly, migration involves navigating to the ASDM DAP policy page to review and manually deleting the incompatible AV/AS/FW attributes, and then reviewing and rewriting LUA scripts.

- Log on to the ASA and enter global configuration mode. In global configuration mode, the ASA displays this prompt: `hostname(config)#`
- Upload the `hostscan_version-k9.pkg` file to the ASA.

Procedure

Step 1
Enter webvpn configuration mode.

Example:

`hostname(config)# webvpn`

Step 2
Specify the path to the package you want to designate as the HostScan image. You can specify a standalone HostScan package or an AnyConnect Secure Mobility Client package as the HostScan package.
Enable or Disable HostScan

These commands enable or disable an installed HostScan image using the command line interface of the ASA.

**Before you begin**

Log on to the ASA and enter global configuration mode. In global configuration mode, the ASA displays this prompt: hostname(config)#

**Procedure**

**Step 1**
Enter webvpn configuration mode.

**Example:**

webvpn

**Step 2**
Enable the standalone HostScan image if it has not been uninstalled from your ASA.

**Step 3**
Disable HostScan for all installed HostScan packages.

**Note**

Before you uninstall the enabled HostScan image, you must first disable HostScan using this command.

no hostscan enable
View the HostScan Version Enabled on the ASA

Use this procedure to determine the enabled HostScan version using ASA’s command line interface.

Before you begin

Log on to the ASA and enter privileged exec mode. In privileged exec mode, the ASA displays this prompt:
hostname#

Procedure

Show the version of HostScan enabled on the ASA.
show webvpn hostscan

Uninstall HostScan

Uninstalling HostScan package removes it from view on the ASDM interface and prevents the ASA from deploying it even if HostScan is enabled. Uninstalling HostScan does not delete the HostScan package from the flash drive.

Before you begin

Log on to the ASA and enter global configuration mode. In global configuration mode, the ASA displays this prompt: hostname(config)#.

Procedure

Step 1 Enter webvpn configuration mode.
webvpn

Step 2 Disable the HostScan image you want to uninstall.
no hostscanenable

Step 3 Specify the path to the HostScan image you want to uninstall. A standalone HostScan package may have been designated as the HostScan package.
no hostscan image path

Example:
hostname(webvpn)#no hostscan image disk0:/hostscan-3.6.0-k9.pkg

Step 4 Save the running configuration to flash. After successfully saving the new configuration to flash memory, you receive the message [OK].
write memory

Assign AnyConnect Feature Modules to Group Policies

This procedure associates AnyConnect feature modules with a group policy. When VPN users connect to the ASA, the ASA downloads and installs these AnyConnect feature modules to their endpoint computer.

Before you begin

Log on to the ASA and enter global configuration mode. In global configuration mode, the ASA displays this prompt: hostname(config)#

Procedure

Step 1 Adds an internal group policy for Network Client Access

```
group-policy name internal
```

Example:

```
hostname(config)# group-policy PostureModuleGroup internal
```

Step 2 Edit the new group policy. After entering the command, you receive the prompt for group policy configuration mode, hostname(config-group-policy)#.

```
group-policy name attributes
```

Example:

```
hostname(config)# group-policy PostureModuleGroup attributes
```

Step 3 Enter group policy webvpn configuration mode. After you enter the command, the ASA returns this prompt: hostname(config-group-webvpn)#

```
webvpn
```

Step 4 Configure the group policy to download AnyConnect feature modules for all users in the group.

```
anyconnect modules value AnyConnect Module Name
```

The value of the anyconnect module command can contain one or more of the following values. When specifying more than one module, separate the values with a comma:

<table>
<thead>
<tr>
<th>value</th>
<th>AnyConnect Modul/Feature Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>dart</td>
<td>AnyConnect DART (Diagnostics and Reporting Tool)</td>
</tr>
<tr>
<td>vpngina</td>
<td>AnyConnect SBL (Start Before Logon)</td>
</tr>
<tr>
<td>websecurity</td>
<td>AnyConnect Web Security Module</td>
</tr>
<tr>
<td>telemetry</td>
<td>AnyConnect Telemetry Module</td>
</tr>
<tr>
<td>value</td>
<td>AnyConnect Module/Feature Name</td>
</tr>
<tr>
<td>-----------</td>
<td>---------------------------------------------------------------------</td>
</tr>
<tr>
<td>posture</td>
<td>AnyConnect Posture Module</td>
</tr>
<tr>
<td>nam</td>
<td>AnyConnect Network Access Manager</td>
</tr>
<tr>
<td>none</td>
<td>Used by itself to remove all AnyConnect modules from the group policy.</td>
</tr>
<tr>
<td>profileMgmt</td>
<td>AnyConnect Management Tunnel VPN</td>
</tr>
</tbody>
</table>

**Example:**

hostname(config-group-webvpn)# anyconnect modules value websecurity,telemetry,posture

To remove one of the modules, re-send the command specifying only the module values you want to keep. For example, this command removes the websecurity module:

hostname(config-group-webvpn)# anyconnect modules value telemetry,posture

**Step 5**

Save the running configuration to flash.

After successfully saving the new configuration to flash memory, you receive the message [OK] and the ASA returns you to this prompt hostname(config-group-webvpn)#

write memory

---

**HostScan Related Documentation**

Once HostScan gathers the posture credentials from the endpoint computer, you will need to understand subjects like configuring dynamic access policies and using LUA expressions to make use of the information.

These topics are covered in detail in these documents:

- Cisco Secure Desktop Configuration Guides
- Cisco Adaptive Security Device Manager Configuration Guides

See also the Cisco *AnyConnect Secure Mobility Client Administrator Guide* for more information about how HostScan works with AnyConnect clients.
CHAPTER 11

Easy VPN

This chapter describes how to configure any ASA as an Easy VPN Server, and the Cisco ASA with FirePOWER- 5506-X, 5506W-X, 5506H-X, and 5508-X models as an Easy VPN Remote hardware client.

- About Easy VPN, on page 259
- Configure Easy VPN Remote, on page 262
- Configure Easy VPN Server, on page 265
- Feature History for Easy VPN, on page 266

About Easy VPN

Cisco EzVPN greatly simplifies configuration and deployment of VPN for remote offices and mobile workers. Cisco Easy VPN offers flexibility, scalability, and ease of use for site-to-site and remote-access VPNs. It implements the Cisco Unity Client protocol, allowing administrators to define most VPN parameters on the Easy VPN Server, simplifying the Easy VPN Remote configuration.

The Cisco ASA with FirePOWER models 5506-X, 5506W-X, 5506H-X, and 5508-X support Easy VPN Remote as a hardware client that initiates the VPN tunnel to an Easy VPN Server. The Easy VPN server can be another ASA (any model), or a Cisco IOS-based router. An ASA cannot function as both an Easy VPN Remote and an Easy VPN Server simultaneously.

Note

The Cisco ASA 5506-X, 5506W-X, 5506H-X and 5508-X models support L3 switching not L2 switching. Use an external switch when using Easy VPN Remote with multiple hosts or devices on the inside network. A switch is not required if a single host is on the inside network of the ASA.

The following sections describe Easy VPN options and settings.

Easy VPN Interfaces

Upon system startup, the Easy VPN external and internal interfaces are determined by their security level. The physical interface with the lowest security level is used for the external connection to an Easy VPN server. The physical or virtual interface with the highest security level is used for the internal connection to secure resources. If Easy VPN determines that there are two or more interfaces with the same highest security level, Easy VPN is disabled.
You can change the internal secure interface using the `vpnclient secure interface` command if desired, to or from, a physical or virtual interface. You cannot change the external interface from the automatically selected default, physical interface.

For example, on an ASA5506 platform, the factory configuration has a BVI with the highest security level interface set to 100 (with its member interfaces also at level 100), and an external interface with security level zero. By default, Easy VPN selects these interfaces.

When a virtual interface (a Bridged Virtual Interface or BVI) is selected upon startup or assigned by the administrator as the internal secure interface, the following applies:

- All BVI member interfaces are considered Internal Secured interfaces irrespective of their own security levels.

- ACL and NAT rules need to be added on all the member interfaces. AAA rules are added on the BVI interface alone.

**Easy VPN Connections**

Easy VPN uses IPsec IKEv1 tunnels. The Easy VPN Remote hardware client's configuration must be compatible with the VPN configuration on the Easy VPN Server headend. If using secondary servers, their configuration must be identical to the primary server.

The ASA Easy VPN Remote configures the IP address of the primary Easy VPN Server and optionally, up to 10 secondary (backup) servers. Use the `vpnclient server` command in global configuration mode to configure these servers. If unable to set up the tunnel to the primary server, the client tries the connection to the first secondary VPN server, and then sequentially down the list of VPN servers at 8 second intervals. If the setup tunnel to the first secondary server fails, and the primary server comes online during this time, the client will proceed to set up the tunnel to the second secondary VPN server.

By default, the Easy VPN hardware client and server encapsulate IPsec in User Datagram Protocol (UDP) packets. Some environments, such as those with certain firewall rules, or NAT and PAT devices, prohibit UDP. To use standard Encapsulating Security Protocol (ESP, Protocol 50) or Internet Key Exchange (IKE, UDP 500) in such environments, you must configure the client and the server to encapsulate IPsec within TCP packets to enable secure tunneling. Use the `vpnclient ipsec-over-tcp` command to configure this. If your environment allows UDP, however, configuring IPsec over TCP adds unnecessary overhead.

**Easy VPN Tunnel Groups**

Upon tunnel establishment, the Easy VPN Remote specifies the tunnel group, configured on the Easy VPN Server, that will be used for the connection. The Easy VPN Server pushes group policy or user attributes to the Easy VPN Remote hardware client determining tunnel behavior. To change certain attributes, you must modify them on the ASAs configured as primary or secondary Easy VPN Servers.

The Easy VPN Remote client specifies the group policy using the `vpnclient vpn-group` command to configure its name and pre-shared key, or the `vpnclient trustpoint` command to identify a pre-configured trustpoint.

**Easy VPN Mode of Operation**

The mode determines whether the hosts behind the Easy VPN Remote are accessible or not from the enterprise network over the tunnel:

- Client mode, also called Port Address Translation (PAT) mode, isolates all devices on the Easy VPN Remote private network from those on the enterprise network. The Easy VPN Remote performs Port Address Translation (PAT) for all VPN traffic for its inside hosts. The network and addresses on the
The private side of the Easy VPN Remote are hidden, and cannot be accessed directly. IP address management is not required for the Easy VPN Client inside interface or the inside hosts.

- Network Extension Mode (NEM) makes the inside interface and all inside hosts route-able across the enterprise network over the tunnel. Hosts on the inside network obtain their IP addresses from an accessible subnet (statically or via DHCP) pre-configured with static IP addresses. PAT does not apply to VPN traffic in NEM. This mode does not require a VPN configuration or tunnel for each host on the inside network, the Easy VPN Remote provides tunneling for all of the hosts.

The Easy VPN Server defaults to Client mode. To configure NEM mode use the `nem enable` command in group policy configuration mode. Specifying one of the modes of operation on the Easy VPN Remote is mandatory before establishing a tunnel because it does not have a default mode. On the Easy VPN Remote use the `vpnclient mode` command to configure PAT or NEM.

**Note**
The Easy VPN Remote ASA configured for NEM mode supports automatic tunnel initiation. Automatic initiation requires the configuration and storage of credentials used to set up the tunnel. Automatic tunnel initiation is disabled if secure unit authentication is enabled.

An Easy VPN Remote in Network Extension Mode with multiple interfaces configured builds a tunnel for locally encrypted traffic only from the interface with the highest security level.

### Easy VPN User Authentication

The ASA Easy VPN Remote can store the username and password for automatic login using the `vpnclient username` command.

For additional security, the Easy VPN Server can require:

- Secure unit authentication (SUA)—ignores the configured username and password requiring a user to manually authenticate. By default, SUA is disabled, enable SUA on the Easy VPN Server using the `secure-unit-authentication enable` command.

- Individual user authentication (IUA)—requires users behind the Easy VPN Remote to authenticate before receiving access to the enterprise VPN network. By default, IUA is disabled, enable IUA on the Easy VPN Server using the `user-authentication enable` command.

When using IUA, specific devices, such as Cisco IP Phones or printers, behind the hardware client will need to bypass individual user authentication. To configure this, specify IP phone bypass, using the `ip-phone-bypass` command, on the Easy VPN Server and MAC address exemption, using the `mac-exempt` command, on the Easy VPN Remote.

Additionally, the Easy VPN Server can set or remove the idle timeout period after which the Easy VPN Server terminates the client’s access using the `user-authentication-idle-timeout` command on the Easy VPN Server.

The Cisco Easy VPN server intercepts HTTP traffic and redirects the user to a login page if the user name and password is not configured, or SUA is disabled, or IUA is enabled. HTTP redirection is automatic and does not require configuration on the Easy VPN Server.

### Remote Management

The ASA operating as an Easy VPN Remote hardware client supports management access using SSH or HTTPS, with or without additional IPsec encryption.
By default, management tunnels use IPsec encryption within SSH or HTTPS encryption. You can clear the IPsec encryption layer allowing management access outside of the VPN tunnel using the `vpngroup command. Clearing tunnel management merely removes the IPsec encryption level and does not affect any other encryption, such as SSH or HTTPS, that exists on the connection.

For additional security, the Easy VPN Remote can require the IPsec encryption and limit administrative access to specific hosts or networks on the corporate side using the `vpngroup management tunnel command in global configuration mode.

Use `no vpngroup management` to return to default remote management operation.

---

**Note**

Do not configure a management tunnel on a ASA Easy VPN Remote if a NAT device is operating between it and the Internet. In that configuration, clear remote management using the `vpngroup management clear command.

Regardless of your configuration, DHCP requests (including renew messages) should not flow over IPsec tunnels. Even with a vpngroup management tunnel, DHCP traffic is prohibited.

---

### Configure Easy VPN Remote

**Before you begin**

Gather the following information to configure the Easy VPN Remote:

- The address of the primary Easy VPN Server, and secondary servers if available.
- The addressing mode, Client or NEM, the Easy VPN Remote should operate in.
- The Easy VPN Server group policy name and password (pre-shared key), or a pre-configured trust point that will select and authenticate the desired group policy.
- The user(s) configured on the Easy VPN Server that are authorized to use the VPN tunnel.
- If a BVI interface is being used for a remote management interface, `management-access` must be configured on that interface.

**Procedure**

**Step 1**

Configure the Easy VPN Server addresses.

```
vpngroup server ip-primary [ip-secondary-1... ip-secondary-n]
```

- `ip-primary-address`—the IP address or DNS name of the primary Easy VPN server.
- `ip-secondary-n` (Optional)—a list of the IP addresses or DNS names of up to ten backup Easy VPN servers. Use a space to separate the items in the list.

**Example:**

```
asa(config)#vpngroup server 10.10.10.15 10.10.10.30 192.168.10.10
```
Step 2  (Optional) Reassign the internal secure interface if the automatically chosen default one is not desired.

Upon startup, the physical interface or BVI with the highest security level is used for the internal connection to secure resources. If you prefer a different interface, use the `vpnclient secure interface interface-name` command. A physical or virtual interface can be assigned.

Step 3  Specify the mode of operation.

```
vpnclient mode {client-mode | network-extension-mode}
```

- **client-mode**—Uses Port Address Translation (PAT) mode to isolate the addresses of the inside hosts, relative to the client, from the enterprise network.
- **network-extension-mode**—Addresses of the inside hosts are accessible from the enterprise network.

**Example:**

```
asa(config)# vpnclient mode network-extension-mode
```

Step 4  (Optional) If desired, configure the Easy VPN hardware client to use TCP-encapsulated IPsec.

```
vpnclient ipsec-over-tcp [port tcp_port]
```

The Easy VPN hardware client uses port 10000 if not specified.

If you configure an Easy VPN Remote to use TCP-encapsulated IPsec, enter the `crypto ipsec df-bit clear-df outside` command to clear the Don't Fragment (DF) bit from the encapsulated header. A DF bit is a bit within the IP header that determines whether the packet can be fragmented. This command lets the Easy VPN hardware client send packets that are larger than the MTU size.

**Example:**

Configure the Easy VPN hardware client to use TCP-encapsulated IPsec, using the port 10501, and let it send large packets over the outside interface:

```
hostname(config)# vpnclient ipsec-over-tcp port 10501
hostname(config)# crypto ipsec df-bit clear-df outside
```

Step 5  Identify the tunnel group, configured on the Easy VPN Server, using one of the following methods:

- Specify the Easy VPN Server group policy name and password (pre-shared key).

```
vpnclient vpngroup group_name password preshared_key
```

  - **group_name**—name of the VPN tunnel group configured on the Easy VPN server. You must configure this tunnel group on the server before establishing a connection.

  - **preshared_key**—the IKE pre-shared key used for authentication on the Easy VPN Server.

For example, enter the following command to identify the VPN tunnel group named TestGroup1 and the IKE pre-shared key my_key123.

```
hostname(config)# vpnclient vpngroup TestGroup1 password my_key123
```

- Specify a per-configured trust point to select and authenticate the group policy.

```
vpnclient trustpoint trustpoint_name [chain]
```

  - **trustpoint_name**—names the trustpoint identifying the RSA certificate to use for authentication.
• chain (Optional)—sends the entire certificate chain.

For example, enter the following command to specify the identity certificate named central and send the entire certificate chain:

hostname(config)# crypto ca trustpoint central
hostname(config)# vpnclient trustpoint central chain

Step 6
If NEM and split-tunneling are configured in the group policy, configure the VPN tunnel to autoconnect.

vpnclient nem-st-autoconnect

Step 7
(Optional) If Individual User Authentication (IAU) and IP Phone Bypass is configured in the group policy on the Easy VPN Server, exempt devices such as Cisco IP phones, wireless access points, and printers, from authentication since they are incapable of authenticating.

vpnclient mac-exempt mac_addr_1 mac_mask_1 [mac_addr_2 mac_mask_2...mac_addr_n mac_mask_n]

• The list of addresses cannot exceed 15.

• mac_addr—the MAC address, in dotted hexadecimal notation, of the device to bypass individual user authentication.

• mac_mask—the network mask for the corresponding MAC address.

A MAC mask of ffff.ffff.0000 matches all devices made by the same manufacturer. A MAC mask of ffff.ffff.ffff matches a single device.

Only the first six characters of the specific MAC address are required if you use the MAC mask ffff.ffff.0000 to specify all devices by the same manufacturer.

Example:
Cisco IP phones have the Manufacturer ID 00036b, so the following command exempts any Cisco IP phone, including Cisco IP phones, you might add in the future:

hostname(config)# vpnclient mac-exempt 0003.6b00.0000 ffff.ff00.0000

Note
Individual User Authentication and IP Phone Bypass must be configured on the Easy VPN Server group policy as shown:

hostname(config-group-policy)# user-authentication enable
hostname(config-group-policy)# ip-phone-bypass enable

Step 8
Configure automatic Xauth user login credentials.

vpnclient username username password password

Step 9
(Optional) Configure Remote Management of the Easy VPN Remote.

By default, management tunnels use IPsec encryption within SSH or HTTPS encryption. Use one of the following commands to remove the IPsec encryption or retain this encryption and only allow certain hosts to manage the ASA.

• vpnclient management clear

Clears the IPsec encryption layer allowing management access outside of the VPN tunnel.
• `vpnclient management tunnel ip_addr_1 ip_mask_1 [ip_addr_2 ip_mask_2...ip_addr_n ip_mask_n]`

**Example:**
Enter the following command to automate the creation of an IPsec tunnel to provide management access to the host with IP address 192.168.10.10:

```
hostname(config)# vpnclient management tunnel 192.168.10.10 255.255.255.0
```

**Note**  Do not configure a management tunnel on a ASA Easy VPN Remote if a NAT device is operating between it and the Internet. In that configuration, clear remote management using the `vpnclient management clear` command.

**Step 10**  Enable the Easy VPN hardware client on the ASA.

```
vpnclient enable
```

The server address(es), mode, and tunnel group specification must be configured before you can enable Easy VPN Remote.

**Step 11**  (Optional) Manually connect the Easy VPN tunnel if your configuration requires this.

```
vpnclient connect
```

---

## Configure Easy VPN Server

**Before you begin**

Ensure all secondary Easy VPN Servers are configured with the identical options and settings as the primary Easy VPN Server.

**Procedure**

**Step 1**  Configure the Easy VPN Server for IPsec IKEv1 support. See *Connection Profiles, Group Policies, and Users,* on page 99.

**Step 2**  Set the specific Easy VPN Server attributes. See *Configure Attributes for VPN Hardware Clients,* on page 166.
## Feature History for Easy VPN

<table>
<thead>
<tr>
<th>Feature Name</th>
<th>Releases</th>
<th>Feature Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cisco Easy VPN client on the ASA 5506-X, 5506W-X, 5506H-X, and 5508-X</td>
<td>9.5(1)</td>
<td>This release supports Cisco Easy VPN on the ASA 5506-X series and for the ASA 5508-X. The ASA acts as a VPN hardware client when connecting to the VPN headend. Any devices (computers, printers, and so on) behind the ASA on the Easy VPN port can communicate over the VPN; they do not have to run VPN clients individually. Note that only one ASA interface can act as the Easy VPN port; to connect multiple devices to that port, you need to place a Layer 2 switch on the port, and then connect your devices to the switch. We introduced the following commands: <code>vpnclient enable</code>, <code>vpnclient server</code>, <code>vpnclient mode</code>, <code>vpnclient username</code>, <code>vpnclient ipsec-over-tcp</code>, <code>vpnclient management</code>, <code>vpnclient vpngroup</code>, <code>vpnclient trustpoint</code>, <code>vpnclient nem-st-autoconnect</code>, <code>vpnclient mac-exempt</code></td>
</tr>
<tr>
<td>Feature Name</td>
<td>Releases</td>
<td>Feature Information</td>
</tr>
<tr>
<td>--------------</td>
<td>----------</td>
<td>---------------------</td>
</tr>
<tr>
<td>Easy VPN Enhancements for BVI Support</td>
<td>9.9(2)</td>
<td>Easy VPN has been enhanced to support a Bridged Virtual Interface as its internal secure interface, and administrators are now allowed to directly configure the internal secure interface using the new <code>vpnclient secure interface [interface-name]</code> command. A physical interface, or a Bridged Virtual Interface can be assigned as the internal secure interface. If this is not set by the administrator, Easy VPN will choose its internal secure interface using security levels as before, whether it is an independent physical interface or a BVI. Also, management services, such as <code>telnet</code>, <code>http</code>, and <code>ssh</code>, can now be configured on a BVI if management access has been enabled on that BVI. New or Modified commands: <code>vpnclient secure interface [interface-name]</code>, <code>https</code>, <code>telnet</code>, <code>ssh</code>, <code>management-access</code></td>
</tr>
</tbody>
</table>
Virtual Tunnel Interface

This chapter describes how to configure a VTI tunnel.

• About Virtual Tunnel Interfaces, on page 269
• Guidelines for Virtual Tunnel Interfaces, on page 269
• Create a VTI Tunnel, on page 270

About Virtual Tunnel Interfaces

The ASA supports a logical interface called Virtual Tunnel Interface (VTI). As an alternative to policy based VPN, a VPN tunnel can be created between peers with Virtual Tunnel Interfaces configured. This supports route based VPN with IPsec profiles attached to the end of each tunnel. This allows dynamic or static routes to be used. Egressing traffic from the VTI is encrypted and sent to the peer, and the associated SA decrypts the ingress traffic to the VTI.

Using VTI does away with the requirement of configuring static crypto map access lists and mapping them to interfaces. You no longer have to track all remote subnets and include them in the crypto map access list. Deployments become easier, and having static VTI which supports route based VPN with dynamic routing protocol also satisfies many requirements of a virtual private cloud.

Guidelines for Virtual Tunnel Interfaces

IPv6

• IPv6 is not supported.

General Configuration Guidelines

• VTIs are only configurable in IPsec mode. To terminate GRE tunnels on an ASA is unsupported.

• You can use dynamic or static routes for traffic using the tunnel interface.

• The MTU for VTIs is automatically set, according to the underlying physical interface.

• If Network Address Translation has to be applied, the IKE and ESP packets will be encapsulated in the UDP header.
• IKE and IPsec security associations will be re-keyed continuously regardless of data traffic in the tunnel. This ensures that VTI tunnels are always up.
• Tunnel group name must match what the peer will send as its IKEv1 or IKEv2 identity.
• For IKEv1 in LAN-to-LAN tunnel groups, you can use names which are not IP addresses, if the tunnel authentication method is digital certificates and/or the peer is configured to use aggressive mode.
• VTI and crypto map configurations can co-exist on the same physical interface, provided the peer address configured in the crypto map and the tunnel destination for the VTI are different.
• By default, all traffic through VTI is encrypted.
• There are no security level configurations for VTI interfaces.
• Access list can be applied on a VTI interface to control traffic through VTI.
• Only BGP is supported over VTI.
• If ASA is terminating IOS IKEv2 VTI clients, disable the config-exchange request on IOS, because ASA cannot retrieve the mode-CFG attributes for this L2L session initiated by an IOS VTI client.

Context Mode
Supported in single mode only.

Firewall Mode
Supported in routed mode only.

Create a VTI Tunnel

To configure a VTI tunnel, create an IPsec proposal (transform set). You will need to create an IPsec profile that references the IPsec proposal, followed by a VTI interface with the IPsec profile. Configure the remote peer with identical IPsec proposal and IPsec profile parameters. SA negotiation will start when all tunnel parameters are configured.

For the ASA which is a part of both the VPN VTI domains, and has BGP adjacency on the physical interface:
When a state change is triggered due to the interface health check, the routes in the physical interface will be deleted until BGP adjacency is re-established with the new active peer. This behavior does not apply to logical VTI interfaces.

Procedure

Step 1 Add an IPsec Proposal (Transform Sets).
Step 2 Add an IPsec Profile.
Step 3 Add a VTI Tunnel.
Add an IPsec Proposal (Transform Sets)

A transform set is required to secure traffic in a VTI tunnel. Used as a part of the IPsec profile, it is a set of security protocols and algorithms that protects the traffic in the VPN.

**Before you begin**

- You can use either pre-shared key or certificates for authenticating the IKE session associated with a VTI. IKEv2 allows asymmetric authentication methods and keys. For both IKEv1 and IKEv2, you must configure the pre-shared key under the tunnel group used for the VTI.
- For certificate based authentication using IKEv1, you must specify the trustpoint to be used at the initiator. For the responder, you must configure the trustpoint in the tunnel-group command. For IKEv2, you must configure the trustpoint to be used for authentication under the tunnel group command for both initiator and responder.

**Procedure**

Add an IKEv1 transform set, or an IKEv2 IPsec proposal to establish the security association.

Add an IKEv1 transform set:

```
crypto ipsec ikev1 transform-set {transform-set-name | encryption | authentication}
```

**Example:**

```
ciscoasa(config)#crypto ipsec ikev1 transform-set SET1 esp-aes esp-sha-hmac
```

*Encryption* specifies which encryption method protects IPsec data flows:

- esp-aes—Uses AES with a 128-bit key.
- esp-aes-192—Uses AES with a 192-bit key.
- esp-aes-256—Uses AES with a 256-bit key.
- esp-null—No encryption.

*Authentication* specifies which encryption method to protect IPsec data flows:

- esp-md5-hmac—Uses the MD5/HMAC-128 as the hash algorithm.
- esp-sha-hmac—Uses the SHA/HMAC-160 as the hash algorithm.
- esp-none—No HMAC authentication.

Add an IKEv2 IPsec proposal.

- Specify a name for the IPsec proposal:

```
crypto ipsec ikev2 ipsec-proposal IPsec proposal name
```

**Example:**
Add an IPsec Profile

An IPsec profile contains the required security protocols and algorithms in the IPsec proposal or transform set that it references. This ensures a secure, logical communication path between two site-to-site VTI VPN peers.

Procedure

**Step 1**
Set a name for the profile:
```
crypto ipsec profile name
```
**Example:**
```
ciscoasa(config)##crypto ipsec profile PROFILE1
```

**Step 2**
Set the IKEv1 or IKEv2 proposal. You can choose either an IKEv1 transform set or an IKEv2 IPsec proposal.

a) Set the IKEv1 transform set.
   - To set the IKEv1 proposal, enter the following command in the crypto ipsec profile command sub-mode:
     ```
     set ikev1 transform set set_name
     ```
     In this example, SET1 is the IKEv1 proposal set created previously.
     ```
ciscoasa(config-ipsec-profile)##set ikev1 transform-set SET1
```

b) Set the IKEv2 proposal.
   - To set the IKEv2 proposal, enter the following command in the crypto ipsec profile command sub-mode:
     ```
     set ikev2 ipsec-proposal IPsec_proposal_name
     ```
     In this example, SET1 is the IKEv2 IPsec proposal created previously.
     ```
ciscoasa(config-ipsec-profile)##set ikev2 ipsec-proposal SET1
```

**Step 3**
(Optional) Specify the duration of the security association:
```
set security-association lifetime {seconds number | kilobytes {number | unlimited}}
```
**Example:**
```
ciscoasa(config-ipsec-profile)##set ikev2 ipsec-proposal SET1
```
Step 4  (Optional) Configure the end of the VTI tunnel to act only as a responder:

**responder-only**

- You can configure one end of the VTI tunnel to perform only as a responder. The responder-only end will not initiate the tunnel or rekeying.

- If you are using IKEv2, set the duration of the security association lifetime, greater than the lifetime value in the IPsec profile in the initiator end. This is to facilitate successful rekeying by the initiator end and ensure that the tunnels remain up.

- If you are using IKEv1, IOS should always be in responder-only mode since IOS doesn't support continuous channel mode. The ASA becomes the initiator and session and rekeys.

- If the rekey configuration in the initiator end is unknown, remove the responder-only mode to make the SA establishment bi-directional, or configure an infinite IPsec lifetime value in the responder-only end to prevent expiry.

Step 5  (Optional) Specify the PFS group. Perfect Forward Secrecy (PFS) generates a unique session key for each encrypted exchange. This unique session key protects the exchange from subsequent decryption. To configure PFS, you have to select the Diffie-Hellman key derivation algorithm to use when generating the PFS session key. The key derivation algorithms generate IPsec security association (SA) keys. Each group has a different size modulus. A larger modulus provides higher security, but requires more processing time. You must have matching Diffie-Hellman groups on both peers.

```
set pfs { group14 }
```

**Example:**

```
ciscoasa(config-ipsec-profile)# set pfs group14
```

Step 6  (Optional) Specify a trustpoint that defines the certificate to be used while initiating a VTI tunnel connection.

```
set trustpoint name
```

**Example:**

```
ciscoasa(config-ipsec-profile)#set trustpoint TPVTI
```

---

### Add a VTI Interface

To create a new VTI interface and establish a VTI tunnel, perform the following steps:

**Note**
Implement IP SLA to ensure that the tunnel remains up when a router in the active tunnel is unavailable. See Configure Static Route Tracking in the ASA General Operations Configuration Guide in [http://www.cisco.com/go/asa-config](http://www.cisco.com/go/asa-config).
**Procedure**

**Step 1**  
Create a new tunnel interface:

```bash  
interface tunnel tunnel_interface_number  
```

**Example:**

```
ciscoasa(config)#interface tunnel 100  
```

Specify a tunnel ID, from a range of 0 to 100. Up to 100 VTI interfaces are supported.

**Note**  
If you will be migrating configurations from other devices to ASA 5506 devices, use the tunnel ID range of 1 - 100. This is to ensure compatibility of the tunnel range of 1 - 100 available in ASA 5506 devices.

**Step 2**  
Enter the name of the VTI interface.

Enter the following command in the `interface tunnel` command submode:

```bash  
nameif interface name  
```

**Example:**

```
ciscoasa(config-if)#nameif vti  
```

**Step 3**  
Enter the IP address of the VTI interface.

```bash  
ip address IP address mask  
```

**Example:**

```
ciscoasa(config-if)#ip address 192.168.1.10 255.255.255.254  
```

**Step 4**  
Specify the tunnel source interface.

```bash  
tunnel source interface interface name  
```

**Example:**

```
ciscoasa(config-if)#tunnel source interface outside  
```

**Step 5**  
Specify the tunnel destination IP address.

```bash  
tunnel destination IP address  
```

**Example:**

```
ciscoasa(config-if)#tunnel destination 10.1.1.1  
```

**Step 6**  
Configure the tunnel with tunnel mode IPsec IPv4.

```bash  
tunnel mode ipsec ipv4  
```

**Example:**

```
ciscoasa(config-if)#tunnel mode ipsec ipv4  
```

**Step 7**  
Assign the IPsec profile to tunnel.

```bash  
tunnel protection ipsec IPsec profile  
```

**Example:**

```
ciscoasa(config-if)#tunnel protection ipsec Profile1  
```
This new VTI can be used to create an IPsec site-to-site VPN.
Add a VTI Interface
CHAPTER 13

Configure an External AAA Server for VPN

About External AAA Servers

This ASA can be configured to use an external LDAP, RADIUS, or TACACS+ server to support Authentication, Authorization, and Accounting (AAA) for the ASA. The external AAA server enforces configured permissions and attributes. Before you configure the ASA to use an external server, you must configure the external AAA server with the correct ASA authorization attributes and, from a subset of these attributes, assign specific permissions to individual users.

Understanding Policy Enforcement of Authorization Attributes

The ASA supports several methods of applying user authorization attributes (also called user entitlements or permissions) to VPN connections. You can configure the ASA to obtain user attributes from any combination of:

- a Dynamic Access Policy (DAP) on the ASA
- an external RADIUS or LDAP authentication and/or authorization server
- a group policy on the ASA

If the ASA receives attributes from all sources, the attributes are evaluated, merged, and applied to the user policy. If there are conflicts between attributes, the DAP attributes take precedence.

The ASA applies attributes in the following order:

1. DAP attributes on the ASA—Introduced in Version 8.0(2), these attributes take precedence over all others. If you set a bookmark or URL list in DAP, it overrides a bookmark or URL list set in the group policy.

2. User attributes on the AAA server—The server returns these attributes after successful user authentication and/or authorization. Do not confuse these with attributes that are set for individual users in the local AAA database on the ASA (User Accounts in ASDM).
3. Group policy configured on the ASA—If a RADIUS server returns the value of the RADIUS CLASS attribute IETF-Class-25 (OU=group-policy) for the user, the ASA places the user in the group policy of the same name and enforces any attributes in the group policy that are not returned by the server.

   For LDAP servers, any attribute name can be used to set the group policy for the session. The LDAP attribute map that you configure on the ASA maps the LDAP attribute to the Cisco attribute IETF-Radius-Class.

4. Group policy assigned by the Connection Profile (called tunnel-group in the CLI)—The Connection Profile has the preliminary settings for the connection, and includes a default group policy applied to the user before authentication. All users connecting to the ASA initially belong to this group, which provides any attributes that are missing from the DAP, user attributes returned by the server, or the group policy assigned to the user.

5. Default group policy assigned by the ASA (DfltGrpPolicy)—System default attributes provide any values that are missing from the DAP, user attributes, group policy, or connection profile.

Guidelines For Using External AAA Servers

The ASA enforces the LDAP attributes based on attribute name, not numeric ID. RADIUS attributes, are enforced by numeric ID, not by name.

For ASDM Version 7.0, LDAP attributes include the cVPN3000 prefix. For ASDM Versions 7.1 and later, this prefix was removed.

LDAP attributes are a subset of the Radius attributes, which are listed in the Radius chapter.

Configure Multiple Certificate Authentication

You can now validate multiple certificates per session with AnyConnect SSL and IKEv2 client protocols. For example, you can make sure that the issuer name of the machine certificate matches a particular CA and therefore that the device is a corporate-issued device.

The multiple certificates option allows certificate authentication of both the machine and user via certificates. Without this option, you could only do certificate authentication of one or the other, but not both.

The pre-fill username field allows a field from the second (user) certificate to be parsed and used for subsequent AAA authentication in a AAA and certificate authenticated connection. The username for both primary and secondary prefill is always retrieved from the second (user) certificate received from the client.

Beginning with 9.14(1), ASA allows you to specify which certificate the primary and secondary username should come from when configuring multiple certificate authentication and using the pre-fill username option for Authentication or Authorization. For information, see Configure Multiple Certificate Username, on page 279

With multiple certificate authentication, two certificates are authenticated: the second (user) certificate received from the client is the one that the pre-fill and username-from-certificate primary and secondary usernames are parsed from.

The existing authentication webvpn attributes is modified to include an option for multiple-certificate authentication:

tunnel-group <name> webvpn-attributes
authentication { [aaa] [certificate | multiple-certificate] | saml }
With multiple-certificate authentication, you can make policy decisions based on the fields of a certificate used to authenticate that connection attempt. The user and machine certificate received from the client during multiple-certificate authentication is loaded into DAP to allow policies to be configured based on the field of the certificate. To add multiple certificate authentication using Dynamic Access Policies (DAP) so that you can set up rules to allow or disallow connection attempts, refer to Add Multiple Certificate Authentication to DAP in the appropriate release of the ASA VPN ASDM Configuration Guide.

**Configure Multiple Certificate Username**

A new command was introduced in ASA 9.14(1) to configure the certificate that ASA must use as the primary and secondary username for authentication or authorization. You can specify whether to use the machine certificate sent in SSL or IKE (first certificate) or the user certificate from client (second certificate) to get the authentication and authorization parameters. This option is available and can be configured for any tunnel groups irrespective of the authentication type (aaa, certificate, or multiple-certificate). However, the configuration takes effect only for Multiple Certificate Authentication (multiple-certificate or aaa multiple-certificate). When the option is not used for Multiple Certificate Authentication, the second certificate is used by default for authentication or authorization.

**Procedure**

**Step 1** Specify whether to use the primary username from the first or second certificate:

```
username-from-certificate-choice {first-certificate | second-certificate}
```

**Step 2** Specify whether to use the secondary username from the first or second certificate:

```
secondary-username-from-certificate-choice {first-certificate | second-certificate}
```

**Example:**

```
tunnel-group tgl webvpn-attributes
authentication aaa multiple-certificate
pre-fill-username client
secondary-pre-fill-username client
tunnel-group tgl type remote-access
tunnel-group tgl general-attributes
secondary-authentication-server-group LOCAL
username-from-certificate-choice first-certificate
secondary-username-from-certificate-choice first-certificate
```

**Configure LDAP Authorization for VPN**

After LDAP authentication for VPN access has succeeded, the ASA queries the LDAP server, which returns LDAP attributes. These attributes generally include authorization data that applies to the VPN session.

You may require authorization from an LDAP directory server that is separate and distinct from the authentication mechanism. For example, if you use an SDI or certificate server for authentication, no authorization information is passed back. For user authorizations in this case, you can query an LDAP directory after successful authentication, accomplishing authentication and authorization in two steps.
To set up VPN user authorization using LDAP, perform the following steps.

**Procedure**

**Step 1** Create a AAA server group.

```bash
aaa-server server_group protocol {kerberos | ldap | nt | radius | sdi | tacacs+}
```

*Example:*

```bash
hostname(config)# aaa-server servergroup1 protocol ldap
hostname(config-aaa-server-group)
```

**Step 2** Create an IPsec remote access tunnel group named remotegrp.

```bash
tunnel-group groupname
```

*Example:*

```bash
hostname(config)# tunnel-group remotegrp
```

**Step 3** Associate the server group and the tunnel group.

```bash
tunnel-group groupname general-attributes
```

*Example:*

```bash
hostname(config)# tunnel-group remotegrp general-attributes
```

**Step 4** Assigns a new tunnel group to a previously created AAA server group for authorization.

```bash
authorization-server-group group-tag
```

*Example:*

```bash
hostname(config-general)# authorization-server-group ldap_dir_1
```

**Example**

The following example shows commands for enabling user authorization with LDAP. The example then creates an IPsec remote access tunnel group named RAVPN and assigns that new tunnel group to the previously created LDAP AAA server group for authorization:

```bash
hostname(config)# tunnel-group RAVPN type remote-access
hostname(config)# tunnel-group RAVPN general-attributes
hostname(config-general)# authorization-server-group (inside) LDAP
 hostname(config-general)#
```
After you complete this configuration work, you can then configure additional LDAP authorization parameters such as a directory password, a starting point for searching a directory, and the scope of a directory search by entering the following commands:

```
hostname(config)# aaa-server LDAP protocol ldap
hostname(config-aaa-server-group)# aaa-server LDAP (inside) host 10.0.2.128
hostname(config-aaa-server-host)# ldap-base-dn DC=AD,DC=LAB,DC=COM
hostname(config-aaa-server-host)# ldap-group-base-dn DC=AD,DC=LAB,DC=COM
hostname(config-aaa-server-host)# ldap-scope subtree
hostname(config-aaa-server-host)# ldap-login-dn AD\cisco
hostname(config-aaa-server-host)# ldap-login-password cisco123
hostname(config-aaa-server-host)# ldap-over-ssl enable
hostname(config-aaa-server-host)# server-type microsoft
```

**Active Directory/LDAP VPN Remote Access Authorization Examples**

This section presents example procedures for configuring authentication and authorization on the ASA using the Microsoft Active Directory server. It includes the following topics:

- **Policy Enforcement of User-Based Attributes**, on page 281
- **Place LDAP Users in a Specific Group Policy**, on page 283
- **Enforce Static IP Address Assignment for AnyConnect Tunnels**, on page 284
- **Enforce Dial-in Allow or Deny Access**, on page 286
- **Enforce Logon Hours and Time-of-Day Rules**, on page 288

Other configuration examples available on Cisco.com include the following TechNotes.

- **ASA/PIX: Mapping VPN Clients to VPN Group Policies Through LDAP Configuration Example**
- **PIX/ASA 8.0: Use LDAP Authentication to Assign a Group Policy at Login**

**Policy Enforcement of User-Based Attributes**

This example displays a simple banner to the user, showing how you can map any standard LDAP attribute to a well-known Vendor-Specific Attribute (VSA), and you can map one or more LDAP attribute(s) to one or more Cisco LDAP attributes. It applies to any connection type, including the IPsec VPN client, AnyConnect SSL VPN client, or clientless SSL VPN.

To enforce a simple banner for a user who is configured on an AD LDAP server use the Office field in the General tab to enter the banner text. This field uses the attribute named physicalDeliveryOfficeName. On the ASA, create an attribute map that maps physicalDeliveryOfficeName to the Cisco attribute Banner1.

During authentication, the ASA retrieves the value of physicalDeliveryOfficeName from the server, maps the value to the Cisco attribute Banner1, and displays the banner to the user.
Procedure

**Step 1**  
Right-click the username, open the Properties dialog box then the **General** tab and enter banner text in the Office field, which uses the AD/LDAP attribute physicalDeliveryOfficeName.

**Step 2**  
Create an LDAP attribute map on the ASA.  
Create the map Banner and map the AD/LDAP attribute physicalDeliveryOfficeName to the Cisco attribute Banner1:

```plaintext
hostname(config)# ldap attribute-map Banner  
hostname(config-ldap-attribute-map)# map-name physicalDeliveryOfficeName Banner1
```

**Step 3**  
Associate the LDAP attribute map to the AAA server.  
Enter the aaa server host configuration mode for the host 10.1.1.2 in the AAA server group MS_LDAP, and associate the attribute map Banner that you previously created:

```plaintext
hostname(config)# aaa-server MS_LDAP host 10.1.1.2  
hostname(config-aaa-server-host)# ldap-attribute-map Banner
```

**Step 4**  
Test the banner enforcement.
Place LDAP Users in a Specific Group Policy

This example applies to any connection type, including the IPSec VPN client, AnyConnect SSL VPN client, or clientless SSL VPN. In this example, User1 is connecting through a clientless SSL VPN connection.

To place an LDAP user into a specific group policy use the Department field of the Organization tab to enter the name of the group policy. Then create an attribute map, and map Department to the Cisco attribute IETF-Radius-Class.

During authentication, the ASA retrieves the value of Department from the server, maps the value to the IETF-Radius-Class, and places User1 in the group policy.

Procedure

Step 1
Right-click the username, open the Properties dialog box then the Organization tab and enter Group-Policy-1 in the Department field.

Step 2
Define an attribute map for the LDAP configuration.
Map the AD attribute Department to the Cisco attribute IETF-Radius-Class:

```
hostname(config)# ldap attribute-map group_policy
hostname(config-ldap-attribute-map)# map-name Department IETF-Radius-Class
```

Step 3
Associate the LDAP attribute map to the AAA server.
Enter the aaa server host configuration mode for the host 10.1.1.2 in the AAA server group MS_LDAP, and associate the attribute map group_policy that you previously created:

hostname(config)# aaa-server MS_LDAP host 10.1.1.2
hostname(config-aaa-server-host)# ldap-attribute-map group_policy

**Step 4** Add the group-policy, Group-policy-1 as entered in the Department field on the server, on the ASA and configure the required policy attributes that will be assigned to the user:

hostname(config)# group-policy Group-policy-1 external server-group LDAP_demo
hostname(config-aaa-server-group)#

**Step 5** Establish the VPN connection as the user would, and verify that the session inherits the attributes from Group-Policy1 (and any other applicable attributes from the default group-policy).

**Step 6** Monitor the communication between the ASA and the server by enabling the `debug ldap 255` command from privileged EXEC mode. The following is sample output from this command, which has been edited to provide the key messages:

```
[29] Authentication successful for user1 to 10.1.1.2
[29] Retrieving user attributes from server 10.1.1.2
[29] Retrieved Attributes:
[29] department: value = Group-Policy-1
[29] mapped to IETF-Radius-Class: value = Group-Policy-1
```

---

**Enforce Static IP Address Assignment for AnyConnect Tunnels**

This example applies to full-tunnel clients, such as the IPsec client and the SSL VPN clients.

To enforce static AnyConnect static IP assignments configure the AnyConnect client user Web1 to receive a static IP address, enter the address in the Assign Static IP Address field of the Dialin tab on the AD LDAP server (this field uses the msRADIUSFramedIPAddress attribute), and create an attribute map that maps this attribute to the Cisco attribute IETF-Radius-Framed-IP-Address.

During authentication, the ASA retrieves the value of msRADIUSFramedIPAddress from the server, maps the value to the Cisco attribute IETF-Radius-Framed-IP-Address, and provides the static address to User1.

**Procedure**

**Step 1** Right-click the username, open the Properties dialog box then the **Dial-in** tab, check the **Assign Static IP Address** check box, and enter an IP address of 10.1.1.2.
Step 2  Create an attribute map for the LDAP configuration shown. Map the AD attribute msRADIUSFramedIPAddress used by the Static Address field to the Cisco attribute IETF-Radius-Framed-IP-Address:

    hostname(config)# ldap attribute-map static_address
    hostname(config-ldap-attribute-map)# map-name msRADIUSFramedIPAddress
        IETF-Radius-Framed-IP-Address

Step 3  Associate the LDAP attribute map to the AAA server.
Enter the aaa server host configuration mode for the host 10.1.1.2 in the AAA server group MS_LDAP, and associates the attribute map static_address that you previously created in:

    hostname(config)# aaa-server MS_LDAP host 10.1.1.2
    hostname(config-aaa-server-host)# ldap-attribute-map static_address

Step 4  Verify that the vpn-address-assignment command is configured to specify AAA by viewing this part of the configuration:

    hostname(config)# show run all vpn-addr-assign
    vpn-addr-assign aaa  << Make sure this is configured >>
no vpn-addr-assign dhcp
vpn-addr-assign local
hostname(config)#

**Step 5** Establish a connection to the ASA with the AnyConnect client. Observe that the user receives the IP address configured on the server and mapped to the ASA.

**Step 6** Use the `show vpn-sessiondb svc` command to view the session details and verify the address assigned:

```
hostname# show vpn-sessiondb svc
```

```
Session Type: SVC
Username : web1 Index : 31
Assigned IP : 10.1.1.2 Public IP : 10.86.181.70
Protocol : Clientless SSL-Tunnel DTLS-Tunnel
Encryption : RC4 AES128 Hashing : SHA1
Bytes Tx : 304140 Bytes Rx : 470506
Group Policy : VPN_User_Group Tunnel Group : Group1_TunnelGroup
Login Time : 11:13:05 UTC Tue Aug 28 2007
Duration : 0h:01m:48s
NAC Result : Unknown
VLAN Mapping : N/A VLAN : none
```

---

**Enforce Dial-in Allow or Deny Access**

This example creates an LDAP attribute map that specifies the tunneling protocols allowed by the user. You map the allow access and deny access settings on the Dialin tab to the Cisco attribute Tunneling-Protocol, which supports the following bitmap values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Tunneling Protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>PPTP</td>
</tr>
<tr>
<td>2</td>
<td>L2TP</td>
</tr>
<tr>
<td>4</td>
<td>IPsec (IKEv1)</td>
</tr>
<tr>
<td>8</td>
<td>L2TP/IPsec</td>
</tr>
<tr>
<td>16</td>
<td>Clientless SSL</td>
</tr>
<tr>
<td>32</td>
<td>SSL client—AnyConnect or SSL VPN client</td>
</tr>
<tr>
<td>64</td>
<td>IPsec (IKEv2)</td>
</tr>
</tbody>
</table>

1. (1) IPsec and L2TP over IPsec are not supported simultaneously. Therefore, the values 4 and 8 are mutually exclusive.
2. (2) See note 1.

Use this attribute to create an Allow Access (TRUE) or a Deny Access (FALSE) condition for the protocols, and enforce the method for which the user is allowed access.

See Tech Note ASA/PIX: Mapping VPN Clients to VPN Group Policies Through LDAP Configuration Example for another example of enforcing dial-in allow access or deny access.
Procedure

Step 1  Right-click the username, open the Properties dialog box then the **Dial-in** tab, and click the Allow Access radio button.

![User Properties Dialog Box](image)

**Note**  If you choose the Control access through the Remote Access Policy option, then a value is not returned from the server, and the permissions that are enforced are based on the internal group policy settings of the ASA.

Step 2  Create an attribute map to allow both an IPsec and AnyConnect connection, but deny a clientless SSL connection.

   a) Create the map `tunneling_protocols`:

   ```
   hostname(config)# ldap attribute-map tunneling_protocols
   ```

   b) Map the AD attribute `msNPAllowDialin` used by the Allow Access setting to the Cisco attribute `Tunneling-Protocols`:

   ```
   hostname(config-ldap-attribute-map)# map-name msNPAllowDialin Tunneling-Protocols
   ```
c) Add map values:

    hostname(config-ldap-attribute-map)# map-value msNPAllowDialin FALSE 48
    hostname(config-ldap-attribute-map)# map-value msNPAllowDialin TRUE 4

**Step 3** Associate the LDAP attribute map to the AAA server.

a) Enter the aaa server host configuration mode for the host 10.1.1.2 in the AAA server group MS_LDAP:

    hostname(config)# aaa-server MS_LDAP host 10.1.1.2

b) Associates the attribute map tunneling_protocols that you created:

    hostname(config-aaa-server-host)# ldap-attribute-map tunneling_protocols

**Step 4** Verify that the attribute map works as configured.

Try connections using clientless SSL, the user should be informed that an unauthorized connection mechanism was the reason for the failed connection. The IPsec client should connect because IPsec is an allowed tunneling protocol according to the attribute map.

---

**Enforce Logon Hours and Time-of-Day Rules**

The following example shows how to configure and enforce the hours that a clientless SSL user (such as a business partner) is allowed to access the network.

On the AD server, use the Office field to enter the name of the partner, which uses the physicalDeliveryOfficeName attribute. Then we create an attribute map on the ASA to map that attribute to the Cisco attribute Access-Hours. During authentication, the ASA retrieves the value of physicalDeliveryOfficeName and maps it to Access-Hours.

**Procedure**

**Step 1** Select the user, right-click **Properties**, and open the **General** tab:
Step 2
Create an attribute map.

Create the attribute map `access_hours` and map the AD attribute `physicalDeliveryOfficeName` used by the `Office` field to the Cisco attribute `Access-Hours`.

```
hostname(config)# ldap attribute-map access_hours
hostname(config-ldap-attribute-map)# map-name physicalDeliveryOfficeName Access-Hours
```

Step 3
Associate the LDAP attribute map to the AAA server.

Enter the `aaa server host` configuration mode for `host 10.1.1.2` in the AAA server group `MS_LDAP` and associate the attribute map `access_hours` that you created.

```
hostname(config)# aaa-server MS_LDAP host 10.1.1.2
hostname(config-aaa-server-host)# ldap-attribute-map access_hours
```

Step 4
Configure time ranges for each value allowed on the server.

Configure Partner access hours from 9am to 5pm Monday through Friday:

```
hostname(config)# time-range Partner
hostname(config-time-range)# periodic weekdays 09:00 to 17:00
```
Enforce Logon Hours and Time-of-Day Rules
PART II

Clientless SSL VPN

• Clientless SSL VPN Overview, on page 293
• Basic Clientless SSL VPN Configuration, on page 297
• Advanced Clientless SSL VPN Configuration, on page 327
• Policy Groups, on page 341
• Clientless SSL VPN Remote Users, on page 375
• Clientless SSL VPN Users, on page 385
• Clientless SSL VPN with Mobile Devices, on page 411
• Customizing Clientless SSL VPN, on page 413
• Clientless SSL VPN Troubleshooting, on page 433
Introduction to Clientless SSL VPN

Clientless SSL VPN enables end users to securely access resources on the corporate network from anywhere using an SSL-enabled Web browser. The user first authenticates with a Clientless SSL VPN gateway, which then allows the user to access pre-configured network resources.

Security contexts (also called firewall multimode) and Active/Active stateful failover are not supported when Clientless SSL VPN is enabled.

Clientless SSL VPN creates a secure, remote-access VPN tunnel to an ASA using a web browser without requiring a software or hardware client. It provides secure and easy access to a broad range of web resources and both web-enabled and legacy applications from almost any device that can connect to the Internet via HTTP. They include:

- Internal websites.
- Web-enabled applications.
- NT/Active Directory file shares.
- Microsoft Web App to Exchange Server 2010 in 8.4(2) and later.
- Application Access (smart tunnel or port forwarding access to other TCP-based applications).

Clientless SSL VPN uses Secure Sockets Layer Protocol and its successor, Transport Layer Security (SSL/TLS) to provide the secure connection between remote users and specific, supported internal resources that you configure as an internal server. The ASA recognizes connections that must be proxied, and the HTTP server interacts with the authentication subsystem to authenticate users.
The network administrator provides access to resources by users of Clientless SSL VPN sessions on a group basis. Users have no direct access to resources on the internal network.

**Prerequisites for Clientless SSL VPN**

See the Supported VPN Platforms, Cisco ASA 5500 Series for the platforms and browsers supported by Clientless SSL VPN on the ASA.

**Guidelines and Limitations for Clientless SSL VPN**

- ActiveX pages require that you enable ActiveX Relay or enter `activex-relay` on the associated group policy. If you do so or assign a smart tunnel list to the policy, and the browser proxy exception list on the endpoint specifies a proxy, the user must add a "shutdown.webvpn.relay." entry to that list.

- The ASA does not support clientless access to Windows Shares (CIFS) Web Folders from Mozilla Firefox, MS Edge, Google Chrome, macOS, or Linux.

- The ASA does not support clientless access to Windows Shares (CIFS) Web Folders from Windows 7, Vista, Internet Explorer 8 to 10, Mac OS X, or Linux.

- Certificate authentication, including the DoD Common Access Card and SmartCard, works with the Safari keychain only.

- Even if you install a trusted certificate for clientless connections, clients might see an untrusted certificate warning.

- The ASA does not support DSA certificates for Clientless SSL VPN connections. RSA certificates are supported.

- Some domain-based security products have requirements beyond those requests that originate from the ASA.

- Configuration control inspection and other inspection features under the Modular Policy Framework are not supported.

- The `vpn-filter` command under group policy is for client-based access and is not supported. `Filter` under Clientless SSL VPN mode in group policy is for clientless-based access only.

- Neither NAT or PAT is applicable to the client.

- The ASA does not support the use of the QoS rate-limiting commands, such as `police` or `priority-queue`.

- The ASA does not support the use of connection limits, checking via the static or the Modular Policy Framework `set connection` command.

- Because AnyConnect works on lower network layers without a dependency to web content, we recommend that you configure AnyConnect on ASA to access web applications that seem unsupported with clientless WebVPN.

• When a clientless VPN session is initiated, RADIUS accounting start messaging is generated. The start message will not contain a Framed-IP-Address because addresses are not assigned to clientless VPN sessions. If a Layer3 VPN connection is subsequently initiated from the clientless portal page, an address is assigned and is reported to the RADIUS server in an interim-update accounting message. You can expect similar RADIUS behavior when a Layer3 VPN tunnel is established using the weblaunch feature. In this case, the accounting start message is sent without a framed IP address after a user is authenticated but before the Layer3 tunnel is established. This start message is followed by an interim update message once the Layer3 tunnel is established.

When you have several group policies configured for the clientless portal, they are displayed in a drop-down on the logon page. When the first group policy in the list requires a certificate, then the user must have a matching certificate. If some of your group policies do not use certificates, you must configure the list to display a non-certificate policy first. Alternatively, you may want to create a dummy group policy with the name “0-Select-a-group.”

Tip
You can control which policy is displayed first by naming your group polices alphabetically, or prefix them with numbers. For example, 1-AAA, 2-Certificate.

Licenseing for Clientless SSL VPN

Use of the AnyConnect Secure Mobility Client requires that you purchase either an AnyConnect Plus and Apex license. The license(s) required depends on the AnyConnect VPN Client and Secure Mobility features that you plan to use, and the number of sessions that you want to support. These user-based licences include access to support and software updates to align with general BYOD trends.

AnyConnect 4.4 licenses are used with ASA (and also ISR, CSR, and ASR), as well as other non-VPN headends such as Identity Services Engine (ISE), Cloud Web Security (CWS), and Web Security Appliance (WSA). A consistent model is used regardless of the headend, so there is no impact when headend migrations occur.

Rewrite Each URL

By default, the ASA allows all portal traffic to all Web resources (for example HTTPS, CIFS, RDP, and plug-ins). Clientless SSL VPN rewrites each URL to one that is meaningful only to the ASA. The user cannot use this URL to confirm that they are connected to the website they requested. To avoid placing users at risk from phishing websites, assign a Web ACL to the policies configured for clientless access—group policies, dynamic access policies, or both—to control traffic flows from the portal. We recommend switching off URL Entry on these policies to prevent user confusion over what is accessible.

Figure 7: Example URL Entered by User

Figure 8: Same URL Rewritten by Security Appliance and Displayed in Browser Window
Switch Off URL Entry on the Portal Page

The portal page opens when the user establishes a browser-based connection.

Before you begin

Configure a group policy for all users who require Clientless SSL VPN access, and enable Clientless SSL VPN only for that group policy.

Procedure

Step 1
Switch to group policy clientless ssl vpn configuration mode.
webvpn

Step 2
Control the ability of the user to enter any HTTP/HTTPS URL.
url-entry

Step 3
(Optional) Switch off URL Entry.
url-entry disable

Trusted Certificate Pools

The ASA groups trusted certificates into trustpools. Trustpools can be thought of as a special case of Trustpoint representing multiple known CA certificates. The ASA includes a default bundle of certificates, similar to the bundle of certificates provided with web browsers. Those certificates are inactive until activated by the administrator by issuing the crypto ca import default command.

When connecting to a remote server with a web browser using the HTTPS protocol, the server provides a digital certificate signed by a certificate authority (CA) to identify itself. Web browsers include a collection of CA certificates which are used to verify the validity of the server certificate.

When connecting to a remote SSL-enabled server through Clientless SSL VPN, it is important to know that you can trust the remote server, and that you are connecting to the correct remote server. ASA 9.0 introduced support for SSL server certificate verification against a list of trusted certificate authority (CA) certificates for Clientless SSL VPN.

On Configuration > Remote Access VPN > Certificate Management > Trusted Certificate Pool, you can enable certificate verification for SSL connections to https sites. You can also manage the certificates in the trusted certificate pool.

Note

ASA trustpools are similar to but not identical to Cisco IOS trustpools.
Configure Auto Import of Trustpool Certificates

Smart licensing uses the Smart Call Home infrastructure. When the ASA configures Smart Call Home anonymous reporting in the background, the ASA automatically creates a trustpoint containing the certificate of the CA that issued the Call Home server certificate. The ASA now supports validation of the certificate if the issuing hierarchy of the server certificate changes, without the need for customer involvement to adjust certificate hierarchy changes. You can automate the update of the trustpool bundle at periodic intervals so that Smart Call Home can remain active if the self-signed certificate of the CA server changes. This feature is not supported under multi-context deployments.

Automatic import of trustpool certificate bundles requires you to specify the URL that ASA uses to download and import the bundle. Use the following command so the import happens daily at a regular interval with the default Cisco URL and default time of 22 hours:

```bash
ciscoasa(config-ca-trustpool)# auto-import-url Default
```

You can also enable auto import with a custom URL with the following command:

```bash
ciscoasa(config-ca-trustpool)# auto-import url http://www.thawte.com
```

To give you more flexibility to set downloads during off peak hours or other convenient times, enter the following command which enables the import with a custom time:

```bash
ciscoasa(config-ca-trustpool)# auto-import time 23:23:23
```

Setting the automatic import with both a custom URL and custom time requires the following command:

```bash
```

Show the State of the Trustpool Policy

Use the following command to see the current state of the trustpool policy:

```bash
show crypto ca trustpool policy
```

This command returns information like the following:

```
0 trustpool certificates installed
Trustpool auto renewal statistics:
  State: Not in progress
  Last import result: Not attempted N/A
  Current Jitter: 0

Trustpool auto import statistics:
  Last import result: N/A
  Next schedule import at 22:00:00 Tues Jul 21 2015

Trustpool Policy
  Trustpool revocation checking is disabled.
  CRL cache time: 60 seconds
  CRL next update field: required and enforced
  Auto import of trustpool is enabled
  Automatic import URL: http://www.cisco.com/security/pki/trs/ios_core.p7b
  Download time: 22:00:00

Policy Overrides:
  None configured
```

Clear CA Trustpool

To reset the trustpool policy to its default state, use the following command:
clear configure crypto ca trustpool

Since the automatic import of trustpoint certificates is turned off by default, using this command disables the feature.

## Edit the Policy of the Trusted Certificate Pool

### Procedure

| Step 1 | Revocation Check—Configure whether to check the certificates in the pool for revocation, and then choose whether to use CLR or OCSP and whether to make the certificate invalid if checking for revocation fails. |
| Step 2 | Certificate Matching Rules—Select certificate maps to exempt from revocation or expiration checks. A certificate map links certificates to AnyConnect or clientless SSL connection profiles (also known as tunnel groups). |
| Step 3 | CRL Options—Decide how often to refresh the CRL cache, between 1 and 1440 minutes (1140 minutes is 24 hours). |
| Step 4 | Automatic Import—Cisco periodically updates the "default" list of trusted CAs. If you check Enable Automatic Import, and keep the default settings, the ASA checks for an updated list of trusted CAs on the Cisco site every 24 hours. If the list has changed, the ASA downloads and imports the new default trusted CA list. |

## Configure Browser Access to Plug-ins

A browser plug-in is a separate program that a Web browser invokes to perform a dedicated function, such as connect a client to a server within the browser window. The ASA lets you import plug-ins for download to remote browsers in Clientless SSL VPN sessions. Of course, Cisco tests the plug-ins it redistributes, and in some cases, tests the connectivity of plug-ins we cannot redistribute. However, we do not recommend importing plug-ins that support streaming media at this time.

The ASA does the following when you install a plug-in onto the flash device:

- (Cisco-distributed plug-ins only) Unpacks the jar file specified in the URL.
- Writes the file to the ASA file system.
- Populates the drop-down list next to the URL attributes in ASDM.
- Enables the plug-in for all future Clientless SSL VPN sessions, and adds a main menu option and an option to the drop-down list next to the Address field of the portal page.

The following shows the changes to the main menu and Address field of the portal page when you add the plug-ins described in the following sections.

### Table 14: Effects of Plug-ins on the Clientless SSL VPN Portal Page

<td>Virtual Network Computing services</td>
<td>vnc://</td>
</tr>
</tbody>
</table>

* Not a recommended plug-in.

When the user in a Clientless SSL VPN session clicks the associated menu option on the portal page, the portal page displays a window to the interface and displays a help pane. The user can choose the protocol displayed in the drop-down list and enter the URL in the Address field to establish a connection.

The plug-ins support single sign-on (SSO).

**Prerequisites with Plug-Ins**

- Clientless SSL VPN must be enabled on the ASA to provide remote access to the plug-ins.

- To configure SSO support for a plug-in, you install the plug-in, add a bookmark entry to display a link to the server, and specify SSO support when adding the bookmark.

- The minimum access rights required for remote use belong to the guest privilege mode.

- Plug-ins require ActiveX or Oracle Java Runtime Environment (JRE). See the Supported VPN Platforms, Cisco ASA 5500 Series compatibility matrices for version requirements.

**Restrictions with Plug-Ins**

**Note**

The remote desktop protocol plug-in does not support load balancing with a session broker. Because of the way the protocol handles the redirect from the session broker, the connection fails. If a session broker is not used, the plug-in works.

- The plug-ins support single sign-on (SSO). They use the *same* credentials entered to open the Clientless SSL VPN session. Because the plug-ins do not support macro substitution, you do not have the options to perform SSO on different fields such as the internal domain password or on an attribute on a RADIUS or LDAP server.

- A stateful failover does not retain sessions established using plug-ins. Users must reconnect following a failover.
If you use stateless failover instead of stateful failover, clientless features such as bookmarks, customization, and dynamic access-policies are not synchronized between the failover ASA pairs. In the event of a failover, these features do not work.

Prepare the Security Appliance for a Plug-in

Before you begin

Ensure that Clientless SSL VPN is enabled on an ASA interface.

Do not specify an IP address as the common name (CN) for the SSL certificate. The remote user attempts to use the FQDN to communicate with the ASA. The remote PC must be able to use DNS or an entry in the System32\drivers\etc\hosts file to resolve the FQDN.

Procedure

Step 1  Show whether Clientless SSL VPN is enabled on the ASA.
show running-config

Step 2  Install an SSL certificate onto the ASA interface and provide a fully-qualified domain name (FQDN) for remote user connection.

Install Plug-ins Redistributed by Cisco

Cisco redistributes the following open-source, Java-based components to be accessed as plug-ins for Web browsers in Clientless SSL VPN sessions.

Before you begin

Ensure Clientless SSL VPN is enabled on an interface on the ASA. To do so, enter the show running-config command.
### Table 15: Plug-ins Redistributed by Cisco

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Description</th>
<th>Source of Redistributed Plug-in</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDP</td>
<td>Accesses Microsoft Terminal Services hosted by Windows Vista and Windows 2003 R2. Supports Remote Desktop ActiveX Control. We recommend using this plug-in that supports both RDP and RDP2. Only versions up to 5.1 of the RDP and RDP2 protocols are supported. Version 5.2 and later are not supported.</td>
<td><a href="http://properjavardp.sourceforge.net/">http://properjavardp.sourceforge.net/</a></td>
</tr>
<tr>
<td>RDP2</td>
<td>Accesses Microsoft Terminal Services hosted by Windows Vista and Windows 2003 R2. Supports Remote Desktop ActiveX Control. This legacy plug-in supports only RDP2. We do not recommend using this plug-in; instead, use the RDP plug-in above.</td>
<td></td>
</tr>
<tr>
<td>SSH</td>
<td>The Secure Shell-Telnet plug-in lets the remote user establish a Secure Shell (v1 or v2) or Telnet connection to a remote computer. Because keyboard-interactive authentication is not supported by JavaSSH, it cannot be supported with SSH plugin (used to implement different authentication mechanisms).</td>
<td><a href="http://javashh.org/">http://javashh.org/</a></td>
</tr>
<tr>
<td>VNC</td>
<td>The Virtual Network Computing plug-in lets the remote user use a monitor, keyboard, and mouse to view and control a computer with remote desktop sharing (also known as VNC server or service) turned on. This version changes the default color of the text and contains updated French and Japanese help files.</td>
<td><a href="http://www.tightvnc.com/">http://www.tightvnc.com/</a></td>
</tr>
</tbody>
</table>

* Consult the plug-in documentation for information on deployment configuration and restrictions.
These plug-ins are available on the Cisco Adaptive Security Appliance Software Download site.

**Note**

The ASA does not retain the `import webvpn plug-in protocol` command in the configuration. Instead, it loads the contents of the `cisco-config/97/plugin` directory automatically. A secondary ASA obtains the plug-ins from the primary ASA.

---

**Procedure**

**Step 1**  
Install the plug-in onto the flash device of the ASA.

```plaintext
import webvpn plug-in protocol [ rdp | rdp2 | [ ssh | telnet ] | vnc ] URL
```

**Note**  
Do not enter this command once for SSH and once for Telnet. When typing `ssh, telnet`, do not insert a space. This provides plug-in access to both Secure Shell and Telnet services.

**Example:**

The following example shows entering the hostname or address of the TFTP or FTP server and the path to the plug-in, where URL is the remote path to the plug-in .jar file.

```plaintext
hostname# import webvpn plug-in protocol ssh,telnet
tftp://local_tftp_server/plugins/ssh-plugin.jar
Accessing
tftp://local_tftp_server/plugins/ssh-plugin.jar...!!!!!!!!!
Writing file disk0:/cisco_config/97/plugin/ssh...!
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
238510 bytes copied in 3.650 secs (79503 bytes/sec)
```

**Step 2**  
(Optional) Switch off and remove Clientless SSL VPN support for a plug-in, as well as removing it from the flash drive of the ASA.

```plaintext
revert webvpn plug-in protocol protocol
```

**Example:**

```plaintext
hostname# revert webvpn plug-in protocol rdp
```

---

**Provide Access to a Citrix XenApp Server**

As an example of how to provide Clientless SSL VPN browser access to third-party plug-ins, this section describes how to add Clientless SSL VPN support for the Citrix XenApp Server Client.

With a Citrix plug-in installed on the ASA, Clientless SSL VPN users can use a connection to the ASA to access Citrix XenApp services.

A stateful failover does not retain sessions established using the Citrix plug-in. Citrix users must reauthenticate after failover.
Create and Install the Citrix Plug-in

Before you begin
You must prepare the security application for a plug-in.
You must configure the Citrix Web Interface software to operate in a mode that does not use the (Citrix) “secure gateway.” Otherwise, the Citrix client cannot connect to the Citrix XenApp Server.

Procedure

Step 1
Download the ica-plugin.zip file from the Cisco Software Download website. This file contains files that Cisco customized for use with the Citrix plug-in.

Step 2
Download the Citrix Java client from the Citrix site.
In the download area of the Citrix website, choose Citrix Receiver, and Receiver for Other Platforms, and click Find. Click the Receiver for Java hyperlink and download the archive.

Step 3
Extract the following files from the archive, and then add them to the ica-plugin.zip file:
• JICA-configN.jar
• JICAEngN.jar

Step 4
Ensure the EULA included with the Citrix Java client grants you the rights and permissions to deploy the client on your Web servers.

Step 5
Install the plug-in by using ASDM, or entering the following CLI command in privileged EXEC mode:
import webvpn plug-in protocol ica URL
URL is the hostname or IP address and path to the ica-plugin.zip file.

Note Adding a bookmark is required to provide SSO support for Citrix sessions. We recommend that you use URL parameters in the bookmark to provide convenient viewing, for example:
ica://10.56.1.114/?DesiredColor=4&DesiredHRes=1024&DesiredVRes=768

Step 6
Establish an SSL VPN clientless session and click the bookmark or enter the URL for the Citrix server. Use the Client for Java Administrator’s Guide as needed.

View the Plug-ins Installed on the Security Appliance

Procedure

Step 1
List the Java-based client applications available to users of Clientless SSL VPN.

Example:
hostname# show import webvpn plug
ssh
rdp
vnc
ica

Step 2  Include hash and date of the plug-in.

Example:

hostname show import webvpn plug detail
post GXN2BIGGGAo0kEMibDQEaMu2GWZ3Q= Tues, 29 Apr 2008 19:57:03 GMT
rdp fHeyReI0UwDCgAL9HdTs PnjdBoo= Tues, 15 Sep 2009 23:23:56 GMT

Configure Port Forwarding

Port forwarding lets users access TCP-based applications over a Clientless SSL VPN connection. Such applications include the following:

• Lotus Notes
• Microsoft Outlook
• Microsoft Outlook Express
• Perforce
• Sametime
• Secure FTP (FTP over SSH)
• SSH
• Telnet
• Windows Terminal Service
• XDDTS

Other TCP-based applications may also work, but we have not tested them. Protocols that use UDP do not work.

Port forwarding is the legacy technology for supporting TCP-based applications over a Clientless SSL VPN connection. You may choose to use port forwarding because you have built earlier configurations that support this technology.

Consider the following alternatives to port forwarding:

• Smart tunnel access offers the following advantages to users:
  • Smart tunnel offers better performance than plug-ins.
  • Unlike port forwarding, smart tunnel simplifies the user experience by not requiring the user connection of the local application to the local port.
  • Unlike port forwarding, smart tunnel does not require users to have administrator privileges.
Unlike port forwarding and smart tunnel access, a plug-in does not require the client application to be installed on the remote computer.

When configuring port forwarding on the ASA, you specify the port the application uses. When configuring smart tunnel access, you specify the name of the executable file or its path.

**Prerequisites for Port Forwarding**

- Ensure Oracle Java Runtime Environment (JRE) 8u131 b11, 7u141 b11, 6u151 b10, or later is installed on the remote computers to support port forwarding (application access) and digital certificates.

- Browser-based users of Safari on macOS 10.12 must identify a client certificate for use with the URL of the ASA, once with the trailing slash and once without it, because of the way Safari interprets URLs. For example,
  - https://example.com/
  - https://example.com

- Users of Microsoft Windows 7 SP1 or later who use port forwarding or smart tunnels must add the URL of the ASA to the Trusted Site zone. To access the Trusted Site zone, they must start Internet Explorer and choose the **Tools > Internet Options > Security** tab. Windows 7 SP1 (or later) users can also switch off Protected Mode to facilitate smart tunnel access; however, we recommend against this method because it increases the computer’s vulnerability to attack.

**Restrictions for Port Forwarding**

- Port forwarding supports only TCP applications that use static TCP ports. Applications that use dynamic ports or multiple TCP ports are not supported. For example, SecureFTP, which uses port 22, works over Clientless SSL VPN port forwarding, but standard FTP, which uses ports 20 and 21, does not.

- Port forwarding does not support protocols that use UDP.

- Port forwarding does not support Microsoft Outlook Exchange (MAPI) proxy. However, you can configure smart tunnel support for Microsoft Office Outlook in conjunction with Microsoft Outlook Exchange Server.

- A stateful failover does not retain sessions established using Application Access (either port forwarding or smart tunnel access). Users must reconnect following a failover.

- Port forwarding does not support connections to personal digital assistants.

- Because port forwarding requires downloading the Java applet and configuring the local client, and because doing so requires administrator permissions on the local system, it is unlikely that users will be able to use applications when they connect from public remote systems.

  The Java applet displays in its own window on the end user HTML interface. It shows the contents of the list of forwarded ports available to the user, as well as which ports are active, and amount of traffic in bytes sent and received.

  The port forwarding applet displays the local port and the remote port as the same when the local IP address 127.0.0.1 is being used and cannot be updated by the Clientless SSL VPN connection from the ASA. As a result, the ASA creates new IP addresses 127.0.0.2, 127.0.0.3, and so on for local proxy IDs.
Because you can modify the hosts file and use different loopbacks, the remote port is used as the local port in the applet. To connect, you can use Telnet with the hostname, without specifying the port. The correct local IP addresses are available in the local hosts file.

**Configure DNS for Port Forwarding**

Port forwarding forwards the domain name of the remote server or its IP address to the ASA for resolution and connection. In other words, the port forwarding applet accepts a request from the application and forwards it to the ASA. The ASA makes the appropriate DNS queries and establishes the connection on behalf of the port forwarding applet. The port forwarding applet only makes DNS queries to the ASA. It updates the host file so that when a port forwarding application attempts a DNS query, the query redirects to a loopback address. Configure the ASA to accept the DNS requests from the port forwarding applet as follows:

**Procedure**

**Step 1** Enter the dns server-group mode and configure a DNS server group named example.com.

**Example:**

```
hostname(config)# dns server-group example.com
```

**Step 2** Specify the domain name. The default domain-name setting is DefaultDNS.

**Example:**

```
hostname(config-dns-server-group)# domain-name example.com
```

**Step 3** Resolve the domain name to an IP address.

**Example:**

```
hostname(config-dns-server-group)# name-server 192.168.10.10
```

**Step 4** Switch to Clientless SSL VPN configuration mode.

```
webvpn
```

**Step 5** Switch to tunnel-group Clientless SSL VPN configuration mode.

```
tunnel-group webvpn
```

**Step 6** Specify the domain name that the tunnel groups will use. By default, the security appliance assigns the default Clientless SSL VPN group as the default tunnel group for clientless connections. Follow this instruction if the ASA uses that tunnel group to assign settings to the clientless connections. Otherwise, follow this step for each tunnel configured for clientless connections.

**Example:**

```
asa2(config-dns-server-group)# exit
asa2(config)# tunnel-group DefaultWEBVPNGroup webvpn-attributes
asa2(config-tunnel-webvpn)# dns-group example.com
```
Make Applications Eligible for Port Forwarding

The Clientless SSL VPN configuration of each ASA supports port forwarding lists, each of which specifies local and remote ports used by the applications for which to provide access. Because each group policy or username supports only one port forwarding list, you must group each set of applications supported into a list.

Procedure

Step 1
Display the port forwarding list entries already present in the ASA configuration.
```
show run webvpn port-forward
```

Step 2
Switch to Clientless SSL VPN configuration mode.
```
webvpn
```

Following the configuration of a port forwarding list, assign the list to group policies or usernames, as described in the next section.

Assign a Port Forwarding List

You can add or edit a named list of TCP applications to associate with users or group policies for access over Clientless SSL VPN connections. For each group policy and username, you can configure Clientless SSL VPN to do one of the following:

Note

These options are mutually exclusive for each group policy and username. Use only one.

- Start port forwarding access automatically upon user login.

Before you begin

Before initiating the `port-forward enable list name` command, the user is required to start port forwarding manually, using Application Access > Start Applications on the Clientless SSL VPN portal page.

These commands are available to each group policy and username. The configuration of each group policy and username supports only one of these commands at a time, so when you enter one, the ASA replaces the one present in the configuration of the group policy or username in question with the new one, or in the case of the last command, simply removes the `port-forward` command from the group policy or username configuration.

Procedure

Step 1
Start port forwarding automatically upon user login.
```
port-forward auto-start <list name>
```

Step 2
Enable or prevent port forwarding upon user login.
**Automate Port Forwarding**

To start port forwarding automatically upon user login, enter the following commands:

**Procedure**

**Step 1** Switch to Clientless SSL VPN configuration mode.
```
webvpn
```

**Step 2** Switch to group-policy or username Clientless SSL VPN configuration mode.
```
group-policy webvpn or username webvpn
```

**Step 3** Start port forwarding automatically upon user login.
```
port-forward auto-start list_name
```

`list_name` names the port forwarding list already present in the ASA Clientless SSL VPN configuration. You cannot assign more than one port forwarding list to a group policy or username.

**Example:**
The following example assigns the port forwarding list named apps1 to the group policy.
```
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# port-forward auto-start apps1
```

**Step 4** Display the port forwarding list entries present in the ASA configuration.
```
show run webvpn port-forward
```

**Step 5** (Optional) Remove the port-forward command from the group policy or username and reverts to the default.
```
no port-forward
```

---

**Enable and Switch off Port Forwarding**

By default, port forwarding is switched off.
**Configure File Access**

Clientless SSL VPN serves remote users with HTTPS portal pages that interface with proxy CIFS and/or FTP clients running on the ASA. Using either CIFS or FTP, Clientless SSL VPN provides users with network access to the files on the network, to the extent that the users meet user authentication requirements and the file properties do not restrict access. The CIFS and FTP clients are transparent; the portal pages delivered by Clientless SSL VPN provide the appearance of direct access to the file systems.

When a user requests a list of files, Clientless SSL VPN queries the server designated as the master browser for the IP address of the server containing the list. The ASA gets the list and delivers it to the remote user on a portal page.

Clientless SSL VPN lets the user invoke the following CIFS and FTP functions, depending on user authentication requirements and file properties:

- Navigate and list domains and workgroups, servers within a domain or workgroup, shares within a server, and files within a share or directory.
- Create directories.
- Download, upload, rename, move, and delete files.
The ASA uses a master browser, WINS server, or DNS server, typically on the same network as the ASA or reachable from that network, to query the network for a list of servers when the remote user clicks Browse Networks in the menu of the portal page or on the toolbar displayed during the Clientless SSL VPN session.

The master browser or DNS server provides the CIFS/FTP client on the ASA with a list of the resources on the network, which Clientless SSL VPN serves to the remote user.

---

**Note**

Before configuring file access, you must configure the shares on the servers for user access.

---

### CIFS File Access Requirement and Limitation

To access `\server\share\subfolder\personal` folder, the user must have a minimum of read permission for all parent folders, including the share itself.

Use Download or Upload to copy and paste files to and from CIFS directories and the local desktop. The Copy and Paste buttons are intended for remote to remote actions only, not local to remote, or remote to local.

If you drag and drop a file from a web folder to a folder on your workstation, you might get what appears to be a temporary file. Refresh the folder on your workstation to update the view and show the transferred file.

The CIFS browse server feature does not support double-byte character share names (share names exceeding 13 characters in length). This only affects the list of folders displayed, and does not affect user access to the folder. As a workaround, you can pre-configure the bookmark(s) for the CIFS folder(s) that use double-byte share names, or the user can enter the URL or bookmark of the folder in the format `cifs://server/<long-folder-name>`. For example:

```
cifs://server/Do you remember?
cifs://server/Do%20you%20remember%3F
```

### Add Support for File Access

---

**Note**

The procedure describes how to specify the master browser and WINS servers. As an alternative, you can use ASDM to configure URL lists and entries that provide access to file shares.

Adding a share in ASDM does not require a master browser or a WINS server. However, it does not provide support for the Browse Networks link. You can use a hostname or an IP address to refer to ServerA when entering the nbns-server command. If you use a hostname, the ASA requires a DNS server to resolve it to an IP address.

---

**Procedure**

**Step 1**

Switch to Clientless SSL VPN configuration mode.

```
webvpn
```

**Step 2**

Switch to tunnel-group Clientless SSL VPN configuration mode.

```
tunnel-group webvpn
```
Step 3  Browse a network or domain for each NetBIOS Name Server (NBNS).

```
nbns-server {IPaddress | hostname} [master] [timeout timeout] [retry retries]
```

- `master` is the computer designated as the master browser. The master browser maintains the list of computers and shared resources. Any NBNS server you identify with this command without entering the master portion of the command must be a Windows Internet Naming Server (WINS). Specify the master browser first, then specify the WINS servers. You can specify up to three servers, including the master browser, for a connection profile.

- `timeout` is the number of seconds the ASA waits before sending the query again, to the same server if it is the only one, or another server if there are more than one. The default timeout is 2 seconds; the range is 1 to 30 seconds.

- `retries` is the number of times to retry queries to the NBNS server. The ASA recycles through the list of servers this number of times before sending an error message. The default value is 2; the range is 1 through 10.

**Example:**

```
hostname(config-tunnel-webvpn)# nbns-server 192.168.1.20 master
hostname(config-tunnel-webvpn)# nbns-server 192.168.1.41
hostname(config-tunnel-webvpn)# nbns-server 192.168.1.47
```

Step 4  Display the NBNS servers already present in the connection profile configuration.

```
show tunnel-group webvpn-attributes
```

Step 5  (Optional) Specify the character set to encode in Clientless SSL VPN portal pages delivered to remote users. By default, the encoding type set on the remote browser determines the character set for Clientless SSL VPN portal pages, so you need to set the character encoding only if it is necessary to ensure proper encoding on the browser.

```
character-encoding charset
```

`charset` is a string consisting of up to 40 characters, and is equal to one of the valid character sets identified in [http://www.iana.org/assignments/character-sets](http://www.iana.org/assignments/character-sets). You can use either the name or the alias of a character set listed on that page. Examples include iso-8859-1, shift_jis, and ibm850.

**Note**  The character-encoding and file-encoding values do not exclude the font family to be used by the browser. You need to complement the setting of one of these values with the `page style` command in webvpn customization command mode to replace the font family if you are using Japanese Shift_JIS character encoding, as shown in the following example, or enter the `no page style` command in webvpn customization command mode to remove the font family.

**Example:**

The following example sets the character-encoding attribute to support Japanese Shift_JIS characters, removes the font family, and retains the default background color.

```
hostname(config)# webvpn
hostname(config-webvpn)# character-encoding shift_jis
hostname(config-webvpn)# customization DfltCustomization
hostname(config-webvpn-custom)# page style background-color:white
```

Step 6  (Optional) Specify the encoding for Clientless SSL VPN portal pages from specific CIFS servers. Thus, you can use different file-encoding values for CIFS servers that require different character encodings.
file-encoding {server-name | server-ip-address} charset

Example:
The following example sets the file-encoding attribute of the CIFS server 10.86.5.174 to support IBM860 (alias “CP860”) characters.

hostname(config-webvpn)# file-encoding 10.86.5.174 cp860

Ensure Clock Accuracy for SharePoint Access

The Clientless SSL VPN server on the ASA uses cookies to interact with applications such as Microsoft Word on the endpoint. The cookie expiration time set by the ASA can cause Word to malfunction when accessing documents on a SharePoint server if the time on the ASA is incorrect. To prevent this malfunction, set the ASA clock properly. We recommend configuring the ASA to dynamically synchronize the time with an NTP server. For instructions, see the section on setting the date and time in the general operations configuration guide.

Virtual Desktop Infrastructure (VDI)

The ASA supports connections to Citrix and VMWare VDI servers.

• For Citrix, the ASA allows access through clientless portal to user's running Citrix Receiver.
• VMWare is configured as a (smart tunnel) application.

VDI servers can also be accessed through bookmarks on the Clientless Portal, like other server applications.

Limitations to VDI

• Authentication using certificates or Smart Cards is not supported for auto sign-on, since these forms of authentication do not allow the ASA in the middle.
• The XML service must be installed and configured on the XenApp and XenDesktop servers.
• Client certificate verifications, double Auth, internal passwords and CSD (all of CSD, not just Vault) are not supported when standalone mobile clients are used.

Citrix Mobile Support

A mobile user running the Citrix Receiver can connect to the Citrix server by:

• Connecting to the ASA with AnyConnect, and then connecting to the Citrix server.
• Connecting to the Citrix server through the ASA, without using the AnyConnect client. Logon credentials can include:
  • A connection profile alias (also referred to as a tunnel-group alias) in the Citrix logon screen. A VDI server can have several group policies, each with different authorization and connection settings.
• An RSA SecureID token value, when the RSA server is configured. RSA support includes next token for an invalid entry, and also for entering a new PIN for an initial or expired PIN.

Limitations of Citrix

Certificate Limitations
• Certificate/Smart Card authentication is not supported as means of auto sign-on.
• Client certificate verifications and CSD are not supported
• Md5 signature in the certificates are not working because of security issue, which is a known problem on iOS: http://support.citrix.com/article/CTX132798
• SHA2 signature is not supported except for Windows, as described on the Citrix website: http://www.citrix.com/
• A key size >1024 is not supported

Other Limitations
• HTTP redirect is not supported; the Citrix Receiver application does not work with redirects.
• XML service must be installed and configured on the XenApp and XenDesktop servers.

About Citrix Mobile Receiver User Logon
The logon for mobile users connecting to the Citrix server depends on whether the ASA has configured the Citrix server as a VDI server or a VDI proxy server.
When the Citrix server is configured as a VDI server:
1. Using the AnyConnect Secure Mobility Client, connect to ASA with VPN credentials.
2. Using Citrix Mobile Receiver, connect to Citrix server with Citrix server credentials (if single-signon is configured, the Citrix credentials are not required).

When the ASA is configured as a to a VDI proxy server:
1. Using Citrix Mobile Receiver, connect to the ASA entering credentials for both the VPN and Citrix server. After the first connection, if properly configured, subsequent connections only require VPN credentials.

Configure the ASA to Proxy a Citrix Server
You can configure the ASA to act as a proxy for the Citrix servers, so that connections to the ASA appear to the user like connections to the Citrix servers. The AnyConnect client is not required when you enable VDI proxy in ASDM. The following high-level steps show how the end user connects to Citrix.

Procedure

Step 1 A mobile user opens Citrix Receiver and connects to ASA's URL.
Step 2
The user provides credentials for the XenApp server and the VPN credentials on the Citrix logon screen.

Step 3
For each subsequent connection to the Citrix server, the user only needs to enter the VPN credentials.

Using the ASA as a proxy for XenApp and XenDesktop removes the requirement for a Citrix Access Gateway. XenApp server info is logged on the ASA, and displays in ASDM.

Configure the Citrix server's address and logon credentials, and assign that VDI server to a Group Policy or username. If both username and group-policy are configured, username settings override group-policy settings.

What to do next
http://www.youtube.com/watch?v=JMM2RzppaG8 - This video describes the advantages of using the ASA as a Citrix proxy.

Assign a VDI Server to a Group Policy

VDI servers are configured and assigned to Group Policies by:

- Adding the VDI server on the VDI Access pane, and assigning a group policy to the server.

- Adding a VDI server to the group policy.

If both username and group policy are configured, username settings take precedence over group policy. Enter the following:

```
configure terminal
group-policy DfltGrpPolicy attributes
  webvpn
    vdi type <citrix> url <url> domain <domain> username <username> password <password>
configure terminal
username <username> attributes
  webvpn
    vdi type <citrix> url <url> domain <domain> username <username> password <password>
```

The syntax options are defined as follows:

- **type**—Type of VDI. For a Citrix Receiver type, this value must be *citrix*.

- **url**—Full URL of the XenApp or XenDesktop server including http or https, hostname, and port number, as well as the path to the XML service.

- **username**—Username for logging into the virtualization infrastructure server. This value can be a clientless macro.

- **password**—Password for logging into the virtualization infrastructure server. This value can be a clientless macro.

- **domain**—Domain for logging into the virtualization infrastructure server. This value can be a clientless macro.
Use SSL to Access Internal Servers

**Procedure**

**Step 1**
Switch to group policy Clientless SSL VPN configuration mode.
webvpn

**Step 2**
Switch off URL entry.
url-entry disable

Clientless SSL VPN uses SSL and its successor, TLS1 to provide a secure connection between remote users and specific, supported internal resources at an internal server.

---

Configure Clientless SSL VPN and ASDM Ports

From version 8.0(2), the ASA supports both Clientless SSL VPN sessions and ASDM administrative sessions simultaneously on port 443 of the outside interface. You can configure these applications on different interfaces.

**Procedure**

**Step 1**
Switch to Clientless SSL VPN configuration mode.
webvpn

**Step 2**
Change the SSL listening port for Clientless SSL VPN.
port port_number

**Example:**
This example enables Clientless SSL VPN on port 444 of the outside interface. With this configuration, remote users initiating Clientless SSL VPN sessions enter https://<outside_ip>:444 in the browser.

```
hostname(config)# http server enable
hostname(config)# http 192.168.3.0 255.255.255.0 outside
hostname(config)# webvpn
hostname(config)# port 444
hostname(config-webvpn)# enable outside
```

**Step 3**
(Privileged mode) Change the listening port for ASDM.
http server enable

**Example:**
This example specifies that HTTPS ASDM sessions use port 444 on the outside interface. Clientless SSL VPN is also enabled on the outside interface and uses the default port (443). With this configuration, remote users initiate ASDM sessions by entering https://<outside_ip>:444.
Use HTTPS for Clientless SSL VPN Sessions

In addition to configuring HTTPS, enable HTTP Strict-Transport-Security (HSTS), a web security policy mechanism which helps to protect websites against protocol downgrade attacks and cookie hijacking. HSTS redirects the UA/Browser to HTTPS websites to connect to the web servers securely until the specified timeout expires by sending the following directive:

```
http-headers: hsts-server; enable; max-age="31536000"; include-sub-domains; no preload
```

Where:

- **http-headers**—configures different HTTP headers sent from the ASA to browsers. Set the submode or reset all the http-headers settings:
  - **hsts-client**—starts handling HSTS header from HTTP servers to act as HSTS clients
    - **enable**—allows you to enable or disable HSTS policy. When enabled, the HSTS policy is enforced for known HSTS hosts and HSTS headers.
  - **hsts-server**—Configures the HSTS header to be sent from the ASA to browsers. The header lets ASA tell browsers to only allow access using HTTPS instead of HTTP.
    - **enable**—allows you to enable or disable HSTS policy. When enabled, the HSTS policy is enforced for known HSTS hosts and HSTS headers.
    - **include-sub-domains**—allows domain owners to submit what domains should be included in the HSTS preload list for web browsers.

**Note** To set an additional redirect from your HTTPS site, you must still have the HSTS header in the redirect (rather than the page it redirects to).

- **max-age**—(which is configurable) specifies the time in seconds that the web server must be regarded as an HSTS host and must be accessed securely using HTTPS only. Default is 3153600 seconds (one year). Range is 0-2147483647 seconds.
- **preload**—tells the browser to load the list of domains that are already registered with UA/Browser; that now must be treated as HSTS hosts. The preloaded lists implementation is UA/browser dependent and each UA/browser can specify further restrictions on what the other directives can be. For example, Chrome’s preload list specifies that the HSTS max-age be at least 18 weeks (10,886,400 seconds).
  - **x-content-type-options**—enables sending "X-Content-Type-Options: nosniff" response header
  - **x-xss-protection**—enables sending "X-XSS-Protection: 1[; mode=block]" response header
• content-security-policy—Allows you to enable or disable sending a "Content-Security-Policy" header for WebVPN connections from ASA to browsers and to configure the following directives:
  • default-src—Sets a default source list for the other CSP directives, where <sources> is a URL (or list of URLs) or keyword-source (such as self or none).
  • frame-ancestors—Indicates whether the user agent should allow the embedding of resources using a frame, iframe, object, embed or applet element, or equivalent functionality in non-HTML resources, where <sources> is a URL (or list of URLs) or keyword-source (such as self or none).

Procedure

Step 1  Switch to clientless SSL VPN configuration mode.
Enter webvpn.

Step 2  Enable Clientless SSL VPN sessions on the interface called outside.
Enter enable interface-name.

Step 3  Enter the http-headers submodes or reset all the http-header settings by entering http-headers. This command configures different HTTP headers sent from the ASA to browsers.

Step 4  Enter hsts-client or hsts-server and then enable.

Step 5  Enter include-sub-domains.

Step 6  Enter preload.

Step 7  Configure the amount of time in seconds that HSTS remains in effect.
Enter hsts max-age max-age-in-seconds.
The value ranges from <0-31536000> seconds. Default is 10,886,400 (18 weeks). Once this limit is reached, HSTS is no longer in effect.

Example
hostname(config-webvpn)# http-headers
hostname(config-webvpn-http-headers)# hsts-server or hsts-client
hostname(config-webvpn-http-headers-hsts-srv)# enable
hostname(config-webvpn-http-headers-hsts-srv)# include-sub-domains
hostname(config-webvpn-http-headers-hsts-srv)# preload
hostname(config-webvpn-http-headers-hsts-srv)# max-age 31536000
hostname(config-webvpn-http-headers-hsts-srv)# content-security-policy enable

What to do next
To see the current configuration, use the show running-config webvpn [hsts].
To clear the current configuration, use the clear configure webvpn.
Configure Support for Proxy Servers

The ASA can terminate HTTPS connections and forward HTTP and HTTPS requests to proxy servers. These servers act as intermediaries between users and the public or private network. Requiring network access via a proxy server that the organization controls provides another opportunity for filtering, to assure secure network access and administrative control.

When configuring support for HTTP and HTTPS proxy services, you can assign preset credentials to send with each request for basic authentication. You can also specify URLs to exclude from HTTP and HTTPS requests.

Before you begin

You can specify a proxy autoconfiguration (PAC) file to download from an HTTP proxy server, however, you may not use proxy authentication when specifying the PAC file.

Procedure

Step 1
Switch to Clientless SSL VPN configuration mode.
webvpn

Step 2
Configure the ASA to use an external proxy server to handle HTTP and HTTPS requests.
http-proxy and https-proxy

Note Proxy NTLM authentication is not supported in http-proxy. Only proxy without authentication and basic authentication are supported.

Step 3
Configure HTTP proxy.
http-proxy host [port] [exclude url] [username username {password password}]

Step 4
Configure HTTPS proxy.
https-proxy host [port] [exclude url] [username username {password password}]

Step 5
Set the PAC file URL.
http-proxy pac url

Step 6
(Optional) Exclude URLs from those that can be sent to the proxy server.
exclude

Step 7
Provide the hostname or IP address for the external proxy server.
host

Step 8
Download the proxy autoconfiguration file to the ASA using a JavaScript function which identifies a proxy for each URL.
pac

Step 9
(Optional) (Only available if you specify a username) Accompanies each proxy request with a password to provide basic, proxy authentication.
password

**Step 10**
Send the password to the proxy server with each HTTP or HTTPS request.

password

**Step 11**
(Optional) Provide the port number used by the proxy server. The default HTTP port is 80. The default HTTPS port is 443. The ASA uses each of these ports if you do not specify an alternative value. The range is 1-65535.

port

**Step 12**
If you entered `exclude`, enter a URL or a comma-delimited list of several URLs to exclude from those that can be sent to the proxy server. The string does not have a character limit, but the entire command cannot exceed 512 characters. You can specify literal URLs or use the following wildcards:

- `*` to match any string, including slashes (/) and periods (.). You must accompany this wildcard with an alphanumeric string.
- `?` to match any single character, including slashes and periods.
- `[x-y]` to match any single character in the range of x and y, where x represents one character and y represents another character in the ANSI character set.
- `![x-y]` to match any single character that is not in the range.

**Step 13**
If you entered `http-proxy pac`, follow it with `http://` and type the URL of the proxy autoconfiguration file. (If you omit the `http://` portion, the CLI ignores the command.)

**Step 14**
(Optional) Accompany each HTTP proxy request with a username for basic, proxy authentication. Only the `http-proxy host` command supports this keyword.

username

**Step 15**
Send the username to the proxy server with each HTTP or HTTPS request.

username

**Step 16**
Show how to configure use of an HTTP proxy server with an IP address of 209.165.201.1 using the default port, sending a username and password with each HTTP request.

**Example:**
```
hostname(config-webvpn)# http-proxy 209.165.201.1 user jsmith password mysecretdonttell
```

**Step 17**
Show the same command, except when the ASA receives the specific URL www.example.com in an HTTP request, it resolves the request instead of passing it on to the proxy server.

**Example:**
```
hostname(config-webvpn)# http-proxy 209.165.201.1 exclude www.example.com username jsmith password mysecretdonttell
```

**Step 18**
Show how to specify a URL to serve a proxy autoconfiguration file to the browser.

**Example:**
```
hostname(config-webvpn)# http-proxy pac http://www.example.com/pac
```
The ASA Clientless SSL VPN configuration supports only one http-proxy and one https-proxy command each. For example, if one instance of the http-proxy command is already present in the running configuration and you enter another, the CLI overwrites the previous instance.

**Note** Proxy NTLM authentication is not supported in http-proxy. Only proxy without authentication and basic authentication is supported.

---

### Configure SSL/TLS Encryption Protocols

Port forwarding requires the Oracle Java Runtime Environment (JRE). Port forwarding does not work when a user of Clientless SSL VPN connects with some SSL versions. Refer to the Supported VPN Platforms, Cisco ASA 5500 Series for supported JRE versions.

### Authenticate with Digital Certificates

SSL uses digital certificates for authentication. The ASA creates a self-signed SSL server certificate when it boots; or you can install in the ASA an SSL certificate that has been issued in a PKI context. For HTTPS, this certificate must then be installed on the client.

#### Restrictions of Digital Certificates Authentication

Email clients such as MS Outlook, MS Outlook Express, and Eudora lack the ability to access the certificate store.

For more information on authentication and authorization using digital certificates, see the section on using certificates and user login credentials in the general operations configuration guide.

### Configure Browser Access to Client-Server Plug-ins

The Client-Server Plug-in table displays the plug-ins the ASA makes available to browsers in Clientless SSL VPN sessions.

To add, change, or remove a plug-in, do one of the following:

- To add a plug-in, click **Import**. The Import Plug-ins dialog box opens.
- To remove a plug-in, choose it and click **Delete**.

### About Installing Browser Plug-ins

A browser plug-in is a separate program that a Web browser invokes to perform a dedicated function, such as connect a client to a server within the browser window. The ASA lets you import plug-ins for download to remote browsers in Clientless SSL VPN sessions. Of course, Cisco tests the plug-ins it redistributes, and in some cases, tests the connectivity of plug-ins we cannot redistribute. However, we do not recommend importing plug-ins that support streaming media at this time.

The ASA does the following when you install a plug-in onto the flash device:

- (Cisco-distributed plug-ins only) Unpacks the jar file specified in the URL.
• Writes the file to the csco-config/97/plugin directory on the ASA file system.

• Populates the drop-down list next to the URL attributes in ASDM.

• Enables the plug-in for all future Clientless SSL VPN sessions, and adds a main menu option and an option to the drop-down list next to the Address field of the portal page.

The following table shows the changes to the main menu and address field of the portal page when you add the plug-ins described in the following sections.

Table 16: Effects of Plug-ins on the Clientless SSL VPN Portal Page

<table>
<thead>
<tr>
<th>Plug-in</th>
<th>Main Menu Option Added to Portal Page</th>
<th>Address Field Option Added to Portal Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>ica</td>
<td>Citrix Client</td>
<td>citrix://</td>
</tr>
<tr>
<td>rdp</td>
<td>Terminal Servers</td>
<td>rdp://</td>
</tr>
<tr>
<td>rdp2</td>
<td>Terminal Servers Vista</td>
<td>rdp2://</td>
</tr>
<tr>
<td>ssh,telnet</td>
<td>SSH</td>
<td>ssh://</td>
</tr>
<tr>
<td></td>
<td>Telnet</td>
<td>telnet://</td>
</tr>
<tr>
<td>vnc</td>
<td>VNC Client</td>
<td>vnc://</td>
</tr>
</tbody>
</table>

A secondary ASA obtains the plug-ins from the primary ASA.

When the user in a Clientless SSL VPN session clicks the associated menu option on the portal page, the portal page displays a window to the interface and displays a help pane. The user can choose the protocol displayed in the drop-down list and enter the URL in the Address field to establish a connection.

Some Java plug-ins may report a status of connected or online even when a session to the destination service is not set up. The open-source plug-in reports the status, not the ASA.

Prerequisites for Installing Browser Plug-ins

• The plug-ins do not work if the security appliance configures the clientless session to use a proxy server.

   Note  The remote desktop protocol plug-in does not support load balancing with a session broker. Because of the way the protocol handles the redirect from the session broker, the connection fails. If a session broker is not used, the plug-in works.

• The plug-ins support single sign-on (SSO). They use the same credentials entered to open the Clientless SSL VPN session. Because the plug-ins do not support macro substitution, you do not have the options
to perform SSO on different fields such as the internal domain password or on an attribute on a RADIUS or LDAP server.

• To configure SSO support for a plug-in, you install the plug-in, add a bookmark entry to display a link to the server, and specify SSO support when adding the bookmark.

• The minimum access rights required for remote use belong to the guest privilege mode.

Requirements for Installing Browser Plug-ins

• Per the GNU General Public License (GPL), Cisco redistributes plug-ins without having made any changes to them. Per the GPL, Cisco cannot directly enhance these plug-ins.

• Clientless SSL VPN must be enabled on the ASA to provide remote access to the plug-ins.

• A stateful failover does not retain sessions established using plug-ins. Users must reconnect following a failover.

• Plug-ins require that ActiveX or Oracle Java Runtime Environment (JRE) is enabled on the browser. There is no ActiveX version of the RDP plug-in for 64-bit browsers.

Set Up RDP Plug-in

To set up and use an RDP plug-in, you must add a new environment variable.

Procedure

Step 1 Right-click My Computer to access the System Properties, and choose the Advanced tab.

Step 2 On the Advanced tab, choose the environment variables button.

Step 3 In the new user variable dialog box, enter the RF_DEBUG variable.

Step 4 Verify the new Environment Variable in the user variables section.

Step 5 If you used the client computer with versions of Clientless SSL VPN before version 8.3, you must remove the old Cisco Portforwarder Control. Go to the C:/WINDOWS/Downloaded Program Files directory, right-click portforwarder control, and choose Remove.

Step 6 Clear all of the Internet Explorer browser cache.

Step 7 Launch your Clientless SSL VPN session and establish an RDP session with the RDP ActiveX Plug-in.

You can now observe events in the Windows Application Event viewer.

Prepare the Security Appliance for a Plug-in

Procedure

Step 1 Ensure that Clientless SSL VPN is enabled on an ASA interface.

Step 2 Install an SSL certificate onto the ASA interface to which remote users use a fully-qualified domain name (FQDN) to connect.
Do not specify an IP address as the common name (CN) for the SSL certificate. The remote user attempts to use the FQDN to communicate with the ASA. The remote PC must be able to use DNS or an entry in the System32\drivers\etc\hosts file to resolve the FQDN.

Configure the ASA to Use the New HTML File

Procedure

Step 1  Import the file and images as Web Content.

```bash
import webvpn webcontent <file> <url>
```

Example:

```
hostname# import webvpn webcontent /+CSCOU+/login.inc tftp://209.165.200.225/login.inc
!!!!!!!!* Web resource `+CSCOU+/login.inc' was successfully initialized
hostname#
```

Step 2  Export a customization template.

```
export webvpn customization <file> <URL>
```

Example:

```
hostname# export webvpn customization template tftp://209.165.200.225/sales_vpn_login
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
%INFO: Customization object 'Template' was exported to tftp://10.21.50.120/sales_vpn_login
```

Step 3  Change the full customization mode tag in the file to enable.

Example:

```
Example:
This example supplies the URL of the login file stored in the ASA memory.

<full-customization>
  <mode>enable</mode>
  <url>/+CSCOU+/login.inc</url>
</full-customization>
```

Step 4  Import the file as a new customization object.

Example:

```
hostname# import webvpn customization sales_vpn_login tftp://10.21.50.120/sales_vpn_login
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
%INFO: customization object 'sales_vpn_login' was successfully imported
```

Step 5  Apply the customization object to a Connection Profile (tunnel group).

Example:

```
hostname(config)# tunnel-group Sales webvpn-attributes
hostname(config-tunnel-webvpn)# customization sales_vpn_login
```
Configure the ASA to Use the New HTML File
Microsoft Kerberos Constrained Delegation Solution

Many organizations want to authenticate their Clientless VPN users and extend their authentication credentials seamlessly to web-based resources using authentication methods beyond what the ASA SSO feature can offer today. With the growing demand to authenticate remote access users with smart cards and One-time Passwords (OTPs), the SSO feature falls short in meeting that demand, because it forwards only conventional user credentials, such as static username and password, to clientless web-based resources when authentication is required.

For example, neither certificate- nor OTP-based authentication methods encompass a conventional username and password necessary for the ASA to seamlessly perform SSO access to web-based resources. When authenticating with a certificate, a username and password are not required for the ASA to extend to web-based resources, making it an unsupported authentication method for SSO. On the other hand, OTP does include a static username; however, the password is dynamic and will subsequently change throughout the VPN session. In general, Web-based resources are configured to accept static usernames and passwords, thus also making OTP an unsupported authentication method for SSO.

Microsoft’s Kerberos Constrained Delegation (KCD), a new feature introduced in software release 8.4 of the ASA, provides access to Kerberos-protected Web applications in the private network. With this benefit, you can seamlessly extend certificate- and OTP-based authentication methods to Web applications. Thus, with SSO and KCD working together although independently, many organizations can now authenticate their clientless VPN users and extend their authentication credentials seamlessly to Web applications using all authentication methods supported by the ASA.

How KCD Works

Kerberos relies on a trusted third party to validate the digital identity of entities in a network. These entities (such as users, host machines, and services running on hosts) are called principals and must be present in the same domain. Instead of secret keys, Kerberos uses tickets to authenticate a client to a server. The ticket is derived from the secret key and consists of the client’s identity, an encrypted session key, and flags. Each ticket is issued by the key distribution center and has a set lifetime.
The Kerberos security system is a network authentication protocol used to authenticate entities (users, computers, or applications) and protect network transmissions by scrambling the data so that only the device that the information was intended for can decrypt it. You can configure KCD to provide Clientless SSL VPN users with SSO access to any Web services protected by Kerberos. Examples of such Web services or applications include Outlook Web Access (OWA), Sharepoint, and Internet Information Server (IIS).

Two extensions to the Kerberos protocol were implemented: protocol transition and constrained delegation. These extensions allow the Clientless SSL VPN remote access users to access Kerberos-authenticated applications in the private network.

Protocol transition provides you with increased flexibility and security by supporting different authentication mechanisms at the user authentication level and by switching to the Kerberos protocol for security features (such as mutual authentication and constrained delegation) in subsequent application layers. Constrained delegation provides a way for domain administrators to specify and enforce application trust boundaries by limiting where application services can act on a user’s behalf. This flexibility improves application security designs by reducing the chance of compromise by an untrusted service.

For more information on constrained delegation, see RFC 1510 via the IETF website (http://www.ietf.org).

Authentication Flow with KCD

The following figure depicts the packet and process flow a user experiences directly and indirectly when accessing resources trusted for delegation via the clientless portal. This process assumes that the following tasks have been completed:

- Configured KCD on ASA
- Joined the Windows Active Directory and ensured services are trusted for delegation
- Delegated ASA as a member of the Windows Active Directory domain
A clientless user session is authenticated by the ASA using the authentication mechanism configured for the user. (In the case of smartcard credentials, ASA performs LDAP authorization with the userPrincipalName from the digital certificate against the Windows Active Directory).

1. After successful authentication, the user logs in to the ASA clientless portal page. The user accesses a Web service by entering a URL in the portal page or by clicking on the bookmark. If the Web service requires authentication, the server challenges ASA for credentials and sends a list of authentication methods supported by the server.

KCD for Clientless SSL VPN is supported for all authentication methods (RADIUS, RSA/SDI, LDAP, digital certificates, and so on). Refer to the AAA Support table at http://www.cisco.com/en/US/docs/security/asa/asa84/configuration/guide/access_aaa.html#wp1069492.

2. Based on the HTTP headers in the challenge, ASA determines whether the server requires Kerberos authentication. (This is part of the SPNEGO mechanism.) If connecting to a backend server requires Kerberos authentication, the ASA requests a service ticket for itself on behalf of the user from the key distribution center.

3. The key distribution center returns the requested tickets to the ASA. Even though these tickets are passed to the ASA, they contain the user’s authorization data. ASA requests a service ticket from the KCD for the specific service that the user wants to access.
Steps 1 to 3 comprise protocol transition. After these steps, any user who authenticates to ASA using a non-Kerberos authentication protocol is transparently authenticated to the key distribution center using Kerberos.

4. ASA requests a service ticket from the key distribution center for the specific service that the user wants to access.
5. The key distribution center returns a service ticket for the specific service to the ASA.
6. ASA uses the service ticket to request access to the Web service.
7. The Web server authenticates the Kerberos service ticket and grants access to the service. The appropriate error message is displayed and requires acknowledgment if there is an authentication failure. If the Kerberos authentication fails, the expected behavior is to fall back to basic authentication.

Configure the ASA for Cross-Realm Authentication

To configure the ASA for cross-realm authentication, you must use the following commands.

Procedure

| Step 1 | Join the Active Directory domain. A 10.1.1.10 domain controller (which is reachable inside the interface).

    ntp hostname

    Example:

    hostname(config)# configure terminal
    #Create an alias for the Domain Controller
    hostname(config)# name 10.1.1.10 DC
    #Configure the Name server

| Step 2 | Perform a lookup.

dns domain-lookup

dns server-group

Example:

This example shows a domain name of private.net and a service account on the domain controller using dcuser as the username and dcuser123! as the password.

hostname(config)# ntp server DC
    #Enable a DNS lookup by configuring the DNS server and Domain name
hostname(config)# dns domain-lookup inside
hostname(config)# dns server-group DefaultDNS
hostname(config-dns-server-group)# name-server DC
hostname(config-dns-server-group)# domain-name private.net

    #Configure the AAA server group with Server and Realm
Configure KCD

To have the ASA join a Windows Active Directory domain and return a success or failure status, perform these steps.

**Procedure**

**Step 1**  
Switch to Clientless SSL VPN configuration mode.  
`webvpn`

**Step 2**  
Configure the KCD.  
`kcd-server`

**Step 3**  
Specify the domain controller name and realm. The AAA server group must be a Kerberos type.  
`kcd-server aaa-server-group`  
**Example:**

```
ASA(config)# aaa-server KG protocol kerberos  
ASA(config)# aaa-server KG (inside) host DC  
ASA(config-aaa-server-host)# kerberos-realm test.edu  
ASA(webvpn-config)# kcd-server KG username user1 password abc123  
ASA(webvpn-config)# no kcd-server
```

**Step 4**  
(Optional) Remove the specified behavior for the ASA.  
`no kcd-server`

**Step 5**  
(Optional) Reset to the internal state.  
`kcd-server reset`

**Step 6**  
Check for the presence of a KCD server and start the domain join process. The Active Directory username and password are used only in EXEC mode and are not saved in the configuration.  
**Note**  
Administrative privileges are required for initial join. A user with service-level privileges on the domain controller will not get access.

```
kcd domain-join username <user> password <pass>
```
user—Does not correspond to a specific administrative user but simply a user with service-level privileges to add a device on the Windows domain controller.

pass—The password does not correspond to a specific password but simply a user with service-level password privileges to add a device on the Windows domain controller

**Step 7** Verify whether the KCD server command has a valid domain join status and then initiate a domain leave.

```
kcd domain-leave
```

## Show KCD Status Information

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Command or Action</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Step 1</strong></td>
<td>With release 9.5.2, the following command requests domain membership through ADI. At a minimum, it returns the domain join status (either joined or not joined) and the failure reason (unknown, server unreachable, or invalid permissions), if applicable.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>show webvpn kcd</code></td>
<td><code>show webvpn kcd</code></td>
</tr>
</tbody>
</table>

**Example:**

```
ASA# show webvpn kcd
KCD-Server Name : DC
User : user1
Password : ****
KCD State : Joined
Failure Reason : Unknown
```

### Debug KCD

The following command is used to control the output of the KCD specific debug messages, rather than to control the level at which ADI emits syslogs, as was the case prior to version 9.5.2:

```
debug webvpn kcd
```

### Show Cached Kerberos Tickets

To display all Kerberos tickets cached on the ASA, enter the following command:

```
show aaa kerberos[username user | host ip | hostname]
```

**Example**

```
ASA# show aaa kerberos
Default Principal Valid Starting Expires Service Principal
asa@example.COM 06/29/10 18:33:00 06/30/10 18:33:00
krbtgt/example.COM@example.COM
```
Clear Cached Kerberos Tickets

To clear all Kerberos ticket information on the ASA, enter the following command:

```
clear aaa kerberos [ username user | host ip | hostname ]
```

- `user`—Used to clear the Kerberos tickets of a specific user
- `hostname`—Used to clear the Kerberos tickets of a specific host

Requirements for Microsoft Kerberos

In order for the `kcd-server` command to function, the ASA must establish a trust relationship between the `source` domain (the domain where the ASA resides) and the `target or resource` domain (the domain where the Web services reside). The ASA, using its unique format, crosses the certification path from the source to the destination domain and acquires the necessary tickets on behalf of the remote access user to access the services.

This crossing of the certificate path is called cross-realm authentication. During each phase of cross-realm authentication, the ASA relies on the credentials at a particular domain and the trust relationship with the subsequent domain.

Configure Application Profile Customization Framework

Clientless SSL VPN includes an Application Profile Customization Framework (APCF) option that lets the ASA handle non-standard applications and Web resources so they display correctly over a Clientless SSL VPN connection. An APCF profile contains a script that specifies when (pre, post), where (header, body, request, response), and what (data) to transform for a particular application. The script is in XML and uses `sed` (stream editor) syntax to transform strings/text.

You can configure and run multiple APCF profiles in parallel on an ASA. Within an APCF profile script, multiple APCF rules can apply. The ASA processes the oldest rule first, based on configuration history, the next oldest rule next.

You can store APCF profiles on the ASA flash memory, or on an HTTP, HTTPS, or TFTP server.
We recommend that you configure an APCF profile only with the assistance of Cisco personnel.

## Manage APCF Packets

### Procedure

**Step 1** Switch to Clientless SSL VPN configuration mode.

```
webvpn
```

**Step 2** Identify and locate an APCF profile to load on the ASA.

```
apcf
```

**Example:**

This example shows how to enable an APCF profile named apcf1.xml, located in flash memory and how to enable an APCF profile named apcf2.xml, located on an HTTPS server called myserver, port 1440, with the path being /apcf.

```
hostname(config)# webvpn
hostname(config-webvpn)# apcf flash:/apcf/apcf1.xml

hostname(config)# webvpn
hostname(config-webvpn)# apcf https://myserver:1440/apcf/apcf2.xml
```

## APCF Syntax

APCF profiles use XML format, and sed script syntax, with the XML tags in the following table.

### Guidelines for APCF

Misuse of an APCF profile can result in reduced performance and undesired rendering of content. In most cases, Cisco Engineering supplies APCF profiles to solve specific application rendering issues.

### Table 17: APCF XML Tags

<table>
<thead>
<tr>
<th>Tag</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;APCF&gt;...&lt;/APCF&gt;</code></td>
<td>The mandatory root element that opens any APCF XML file.</td>
</tr>
<tr>
<td><code>&lt;version&gt;1.0&lt;/version&gt;</code></td>
<td>The mandatory tag that specifies the APCF implementation version. Currently the only version is 1.0.</td>
</tr>
<tr>
<td><code>&lt;application&gt;...&lt;/application&gt;</code></td>
<td>The mandatory tag that wraps the body of the XML description.</td>
</tr>
<tr>
<td><code>&lt;id&gt; text &lt;/id&gt;</code></td>
<td>The mandatory tag that describes this particular APCF functionality.</td>
</tr>
<tr>
<td>Tag</td>
<td>Use</td>
</tr>
<tr>
<td>-----</td>
<td>-----</td>
</tr>
<tr>
<td><code>&lt;apcf-entities&gt;...&lt;/apcf-entities&gt;</code></td>
<td>The mandatory tag that wraps a single or multiple APCF entities.</td>
</tr>
<tr>
<td><code>&lt;js-object&gt;...&lt;/js-object&gt;</code></td>
<td>One of these tags specifies type of content or the stage at which the APCF processing should take place.</td>
</tr>
<tr>
<td><code>&lt;html-object&gt;...&lt;/html-object&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;process-request-header&gt;...&lt;/process-request-header&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;process-response-header&gt;...&lt;/process-response-header&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;preprocess-response-body&gt;...&lt;/preprocess-response-body&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;postprocess-response-body&gt;...&lt;/postprocess-response-body&gt;</code></td>
<td></td>
</tr>
<tr>
<td><code>&lt;conditions&gt;...&lt;/conditions&gt;</code></td>
<td>A child element of the pre/post-process tags that specifies criteria for processing such as:</td>
</tr>
<tr>
<td></td>
<td>• http-version (such as 1.1, 1.0, 0.9)</td>
</tr>
<tr>
<td></td>
<td>• http-method (get, put, post, webdav)</td>
</tr>
<tr>
<td></td>
<td>• http-scheme (“http”, “https”, other)</td>
</tr>
<tr>
<td></td>
<td>• server-regexp regular expression containing `(&quot;a&quot;..&quot;z&quot;</td>
</tr>
<tr>
<td></td>
<td>• server-fnmatch (regular expression containing `(&quot;a&quot;..&quot;z&quot;</td>
</tr>
<tr>
<td></td>
<td>• user-agent-regexp</td>
</tr>
<tr>
<td></td>
<td>• user-agent-fnmatch</td>
</tr>
<tr>
<td></td>
<td>• request-uri-regexp</td>
</tr>
<tr>
<td></td>
<td>• request-uri-fnmatch</td>
</tr>
<tr>
<td></td>
<td>• If more than one of condition tags is present, the ASA performs a logical AND for all tags.</td>
</tr>
<tr>
<td><code>&lt;action&gt; ... &lt;/action&gt;</code></td>
<td>Wraps one or more actions to perform on the content under specified conditions; you can use the following tags to define these actions (shown below):</td>
</tr>
<tr>
<td></td>
<td>• <code>&lt;do&gt;</code></td>
</tr>
<tr>
<td></td>
<td>• <code>&lt;sed-script&gt;</code></td>
</tr>
<tr>
<td></td>
<td>• <code>&lt;rewrite-header&gt;</code></td>
</tr>
<tr>
<td></td>
<td>• <code>&lt;add-header&gt;</code></td>
</tr>
<tr>
<td></td>
<td>• <code>&lt;delete-header&gt;</code></td>
</tr>
<tr>
<td>Tag</td>
<td>Use</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>&lt;do&gt;…&lt;/do&gt;</td>
<td>Child element of the action tag used to define one of the following actions:</td>
</tr>
<tr>
<td></td>
<td>• &lt;no-rewrite/&gt;—Do not mangle the content received from the remote server.</td>
</tr>
<tr>
<td></td>
<td>• &lt;no-toolbar/&gt;—Do not insert the toolbar.</td>
</tr>
<tr>
<td></td>
<td>• &lt;no-gzip/&gt;—Do not compress the content.</td>
</tr>
<tr>
<td></td>
<td>• &lt;force-cache/&gt;—Preserve the original caching instructions.</td>
</tr>
<tr>
<td></td>
<td>• &lt;force-no-cache/&gt;—Make object non-cacheable.</td>
</tr>
<tr>
<td></td>
<td>• &lt;downgrade-http-version-on-backend&gt;—Use HTTP/1.0 when sending the request to remote server.</td>
</tr>
<tr>
<td>&lt;sed-script&gt; TEXT &lt;sed-script&gt;</td>
<td>Child element of the action tag used to change the content of text-based objects. The Text must be a valid Sed script. The &lt;sed-script&gt; applies to the &lt;conditions&gt; tag defined before it.</td>
</tr>
<tr>
<td>&lt;rewrite-header&gt;&lt;/rewrite-header&gt;</td>
<td>Child element of the action tag. Changes the value of the HTTP header specified in the child element &lt;header&gt; tag shown below.</td>
</tr>
<tr>
<td>&lt;add-header&gt;&lt;/add-header&gt;</td>
<td>Child element of the action tag used to add a new HTTP header specified in the child element &lt;header&gt; tag shown below.</td>
</tr>
<tr>
<td>&lt;delete-header&gt;&lt;/delete-header&gt;</td>
<td>Child element of the action tag used to delete the specified HTTP header specified by the child element &lt;header&gt; tag shown below.</td>
</tr>
<tr>
<td>&lt;header&gt;&lt;/header&gt;</td>
<td>Specifies the name HTTP header to be rewritten, added, or deleted. For example, the following tag changes the value of the HTTP header named Connection:</td>
</tr>
<tr>
<td></td>
<td>&lt;rewrite-header&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;header&gt;Connection&lt;/header&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;value&gt;close&lt;/value&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;/rewrite-header&gt;</td>
</tr>
</tbody>
</table>

**Configuration Examples for APCF**

```xml
<APCF>
<version>1.0</version>
<application>
  <id>Do not compress content from example.com</id>
  <apcf-entities>
```

336
<process-request-header>
  <conditions>
    <server-fnmatch>*.example.com</server-fnmatch>
  </conditions>
  <action>
    <do><no-gzip/></do>
  </action>
</process-request-header>

<apcf-entities>
  <application>
    <id>Change MIME type for all .xyz objects</id>
    <apcf-entities>
      <process-response-header>
        <conditions>
          <request-uri-fnmatch>*.xyz</request-uri-fnmatch>
        </conditions>
        <action>
          <rewrite-header>
            <header>Content-Type</header>
            <value>text/html</value>
          </rewrite-header>
        </action>
      </process-response-header>
    </apcf-entities>
  </application>
</APCF>

<APCF>
  <version>1.0</version>
  <application>
    <id>Change MIME type for all .xyz objects</id>
    <apcf-entities>
      <process-response-header>
        <conditions>
          <request-uri-fnmatch>*.xyz</request-uri-fnmatch>
        </conditions>
        <action>
          <rewrite-header>
            <header>Content-Type</header>
            <value>text/html</value>
          </rewrite-header>
        </action>
      </process-response-header>
    </apcf-entities>
  </application>
</APCF>

Encoding

Character encoding, also called “character coding” and “a character set,” is the pairing of raw data (such as 0s and 1s) with characters to represent the data. The language determines the character encoding method to use. Some languages use a single method, while others do not. Usually, the geographic region determines the default encoding method used by the browser, but the remote user can change it. The browser can also detect the encoding specified on the page, and render the document accordingly.

The encoding attribute lets you specify the value of the character-encoding method used on the portal page to ensure that the browser renders it properly, regardless of the region in which the user is using the browser, and regardless of any changes made to the browser.

By default, the ASA applies the “Global Encoding Type” to pages from Common Internet File System servers. The mapping of CIFS servers to their appropriate character encoding, globally with the “Global Encoding Type” attribute, and individually with the file-encoding exceptions displayed in the table, provides for the accurate handling and display of CIFS pages when the proper rendering of filenames or directory paths, as well as pages, is an issue.

View or Specify Character Encoding

With encoding, you can view or specify the character encoding for Clientless SSL VPN portal pages.
Procedure

**Step 1** Global Encoding Type determines the character encoding that all Clientless SSL VPN portal pages inherit except for those from the CIFS servers listed in the table. You can type the string or choose one of the options from the drop-down list, which contains the most common values, as follows:

- big5
- gb2312
- ibm-850
- iso-8859-1
- shift_jis

**Note** If you are using Japanese Shift_jis Character encoding, click *Do Not Specify* in the Font Family area of the associated Select Page Font pane to remove the font family.

- unicode
- windows-1252
- none

**Note** If you click *none* or specify a value that the browser on the Clientless SSL VPN session does not support, it uses its own default encoding.

You can type a string consisting of up to 40 characters, and equal to one of the valid character sets identified in http://www.iana.org/assignments/character-sets. You can use either the name or the alias of a character set listed on that page. The string is case-insensitive. The command interpreter converts upper-case to lower-case when you save the ASA configuration.

**Step 2** Enter the name or IP address of a CIFS server for which the encoding requirement differs from the “Global Encoding Type” attribute setting. The ASA retains the case you specify, although it ignores the case when matching the name to a server.

**Step 3** Choose the character encoding that the CIFS server should provide for Clientless SSL VPN portal pages. You can type the string, or choose one from the drop-down list, which contains only the most common values, as follows:

- big5
- gb2312
- ibm-850
- iso-8859-1
- shift_jis

**Note** If you are using Japanese Shift_jis Character encoding, click *Do Not Specify* in the Font Family area of the associated Select Page Font pane to remove the font family.

- unicode
- windows-1252
If you click none or specify a value that the browser on the Clientless SSL VPN session does not support, it uses its own default encoding.

You can type a string consisting of up to 40 characters, and equal to one of the valid character sets identified in http://www.iana.org/assignments/character-sets. You can use either the name or the alias of a character set listed on that page. The string is case-insensitive. The command interpreter converts upper-case to lower-case when you save the ASA configuration.

---

### Use Email over Clientless SSL VPN

#### Configure Web email: MS Outlook Web App

**Procedure**

- **Step 1**: Enter the URL of the email service into the address field or click an associated bookmark in the Clientless SSL VPN session.
- **Step 2**: When prompted, enter the email server username in the format domain\username.
- **Step 3**: Enter the email password.
Configure Web email: MS Outlook Web App
Create and Apply Clientless SSL VPN Policies for Accessing Resources

Creating and applying policies for Clientless SSL VPN that govern access to resources at an internal server requires you to assign group policies.

Assigning users to group policies simplifies the configuration by letting you apply policies to many users. You can use an internal authentication server on the ASA or an external RADIUS or LDAP server to assign users to group policies. See Chapter 4, “Connection Profiles, Group Policies, and Users” for a thorough explanation of ways to simplify configuration with group policies.

Connection Profile Attributes for Clientless SSL VPN

The following table provides a list of connection profile attributes that are specific to Clientless SSL VPN. In addition to these attributes, you configure general connection profile attributes common to all VPN connections. For step-by-step information on configuring connection profiles, see Chapter 4, “Connection Profiles, Group Policies, and Users”.

Note

In earlier releases, “connection profiles” were known as “tunnel groups.” You configure a connection profile with tunnel-group commands. This chapter often uses these terms interchangeably.
### Table 18: Connection Profile Attributes for Clientless SSL VPN

<table>
<thead>
<tr>
<th>Command</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>Sets the authentication method.</td>
</tr>
<tr>
<td>customization</td>
<td>Identifies the name of a previously defined customization to apply.</td>
</tr>
<tr>
<td>exit</td>
<td>Exits from tunnel-group Clientless SSL VPN attribute configuration mode.</td>
</tr>
<tr>
<td>nbns-server</td>
<td>Identifies the name of the NetBIOS Name Service server (nbns-server) to use for CIFS name resolution.</td>
</tr>
<tr>
<td>group-alias</td>
<td>Specifies the alternate names by which the server can refer to a connection profile.</td>
</tr>
<tr>
<td>group-url</td>
<td>Identifies one or more group URLs. If you establish URLs with this attribute, this group is selected automatically for users when they access using these URLs.</td>
</tr>
<tr>
<td>dns-group</td>
<td>Identifies the DNS server group that specifies the DNS server name, domain name, name server, number of retries, and timeout values.</td>
</tr>
<tr>
<td>help</td>
<td>Provides help for tunnel group configuration commands.</td>
</tr>
<tr>
<td>hic-fail-group-policy</td>
<td>Specifies a VPN feature policy if you use the Cisco Secure Desktop Manager to set the Group-Based Policy attribute to “Use Failure Group-Policy” or “Use Success Group-Policy, if criteria match.”</td>
</tr>
<tr>
<td>no</td>
<td>Removes an attribute value pair.</td>
</tr>
<tr>
<td>override-svc-download</td>
<td>Overrides downloading the group-policy or username attributes configured for downloading the AnyConnect VPN client to the remote user.</td>
</tr>
<tr>
<td>pre-fill-username</td>
<td>Configures username-to-certificate binding on this tunnel group.</td>
</tr>
<tr>
<td>proxy-auth</td>
<td>Identifies this tunnel-group as a specific proxy authentication tunnel group.</td>
</tr>
<tr>
<td>radius-reject-message</td>
<td>Enables the display of the RADIUS reject message on the login screen when authentication is rejected.</td>
</tr>
<tr>
<td>secondary-pre-fill-username</td>
<td>Configures the secondary username-to-certificate binding on this tunnel group.</td>
</tr>
<tr>
<td>without-csd</td>
<td>Switched off CSD for a tunnel group.</td>
</tr>
</tbody>
</table>

**Group Policy and User Attributes for Clientless SSL VPN**

The following table provides a list of group policy and user attributes for Clientless SSL VPN that. For step-by-step instructions on configuring group policy and user attributes, see Configure Group Policy Attributes for Clientless SSL VPN Sessions, on page 344 or Configure Clientless SSL VPN Access for Specific Users, on page 351.
<table>
<thead>
<tr>
<th>Command</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>activex-relay</td>
<td>Lets a user who has established a Clientless SSL VPN session use the browser to launch Microsoft Office applications. The applications use the session to download and upload ActiveX. The ActiveX relay remains in force until the Clientless SSL VPN session closes.</td>
</tr>
<tr>
<td>auto-sign-on</td>
<td>Sets values for auto sign-on, which requires that the user enter username and password credentials only once for a Clientless SSL VPN connection.</td>
</tr>
<tr>
<td>customization</td>
<td>Assigns a customization object to a group policy or user.</td>
</tr>
<tr>
<td>deny-message</td>
<td>Specifies the message delivered to a remote user who logs into Clientless SSL VPN successfully, but has no VPN privileges.</td>
</tr>
<tr>
<td>file-browsing</td>
<td>Enables CIFS file browsing for file servers and shares. Browsing requires NBNS (Master Browser or WINS).</td>
</tr>
<tr>
<td>file-entry</td>
<td>Allows users to enter file server names to access.</td>
</tr>
<tr>
<td>filter</td>
<td>Sets the name of the webtype access list.</td>
</tr>
<tr>
<td>hidden-shares</td>
<td>Controls the visibility of hidden shares for CIFS files.</td>
</tr>
<tr>
<td>homepage</td>
<td>Sets the URL of the Web page that displays upon login.</td>
</tr>
<tr>
<td>html-content-filter</td>
<td>Configures the content and objects to filter from the HTML for this group policy.</td>
</tr>
<tr>
<td>http-comp</td>
<td>Configures compression.</td>
</tr>
</tbody>
</table>
| http-proxy        | Configures the ASA to use an external proxy server to handle HTTP requests.  
  **Note** Proxy NTLM authentication is not supported in `http-proxy`. Only proxy without authentication and basic authentication are supported. |
| keep-alive-ignore | Sets the maximum object size to ignore for updating the session timer. |
| port-forward      | Applies a list of Clientless SSL VPN TCP ports to forward. The user interface displays the applications in this list. |
| post-max-size     | Sets the maximum object size to post.                                   |
| smart-tunnel      | Configures a list of programs and several smart tunnel parameters to use smart tunnel. |
| storage-objects   | Configures storage objects for the data stored between sessions.        |
| svc               | Configures SSL VPN Client attributes.                                   |
| unix-auth-gid     | Sets the UNIX group ID.                                                 |
| unix-auth-uid     | Sets the UNIX user ID.                                                  |
| url-entry         | Controls the ability of the user to enter any HTTP/HTTPS URL.           |
| url-list          | Applies a list of servers and URLs that Clientless SSL VPN portal page displays for end-user access. |
Configure Group Policy Attributes for Clientless SSL VPN Sessions

Clientless SSL VPN lets users establish a secure, remote-access VPN tunnel to the ASA using a web browser. There is no need for either a software or hardware client. Clientless SSL VPN provides easy access to a broad range of web resources and web-enabled applications from almost any computer that can reach HTTPS Internet sites. Clientless SSL VPN uses SSL and its successor, TLS1, to provide a secure connection between remote users and specific, supported internal resources that you configure at a central site. The ASA recognizes connections that need to be proxied, and the HTTP server interacts with the authentication subsystem to authenticate users. By default, clientless SSL VPN is disabled.

You can customize a configuration of clientless SSL VPN for specific internal group policies.

Note

The webvpn mode that you enter from global configuration mode lets you configure global settings for clientless SSL VPN sessions. The webvpn mode described in this section, which you enter from group-policy configuration mode, lets you customize a configuration of group policies specifically for clientless SSL VPN sessions.

In group-policy webvpn configuration mode, you can specify whether to inherit or customize the following parameters, each of which is described in the subsequent sections:

- customizations
- html-content-filter
- homepage
- filter
- url-list
- port-forward
- port-forward-name
- auto-signon
- deny message
- AnyConnect Secure Mobility Client
- keep-alive ignore
- HTTP compression

In many instances, you define the webvpn attributes as part of configuring clientless SSL VPN, then you apply those definitions to specific groups when you configure the group-policy webvpn attributes. Enter group-policy webvpn configuration mode by using the `webvpn` command in group-policy configuration mode. Webvpn commands for group policies define access to files, URLs and TCP applications over clientless SSL VPN sessions. They also identify ACLs and types of traffic to filter. Clientless SSL VPN is disabled by default.

<table>
<thead>
<tr>
<th>Command</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>user-storage</td>
<td>Configures a location for storing user data between sessions.</td>
</tr>
</tbody>
</table>
To remove all commands entered in group-policy webvpn configuration mode, enter the `no` form of this command. These webvpn commands apply to the username or group policy from which you configure them.

```mermaid
webvpn
no webvpn
```

The following example shows how to enter group-policy webvpn configuration mode for the group policy named FirstGroup:

```mermaid
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)#
```

### Specify a Deny Message

You can specify the message delivered to a remote user who logs into a clientless SSL VPN session successfully, but has no VPN privileges, by entering the `deny-message` command in group-policy webvpn configuration mode:

```mermaid
hostname(config-group-webvpn)# deny-message value "message"
hostname(config-group-webvpn)# no deny-message value "message"
hostname(config-group-webvpn)# deny-message none
```

The `no deny-message value` command removes the message string, so that the remote user does not receive a message.

The `no deny-message none` command removes the attribute from the connection profile policy configuration. The policy inherits the attribute value.

The message can be up to 491 alphanumeric characters long, including special characters, spaces, and punctuation, but not counting the enclosing quotation marks. The text appears on the remote user’s browser upon login. When typing the string in the `deny-message value` command, continue typing even if the command wraps.

The default deny message is: “Login was successful, but because certain criteria have not been met or due to some specific group policy, you do not have permission to use any of the VPN features. Contact your IT administrator for more information.”

The first command in the following example creates an internal group policy named group2. The subsequent commands modify the attributes, including the webvpn deny message associated with that policy.

```mermaid
hostname(config)# group-policy group2 internal
hostname(config)# group-policy group2 attributes
hostname(config-group)# webvpn
hostname(config-group-webvpn)# deny-message value "Your login credentials are OK. However, you have not been granted rights to use the VPN features. Contact your administrator for more information."
```

### Configure Group Policy Filter Attributes for Clientless SSL VPN Sessions

Specify whether to filter Java, ActiveX, images, scripts, and cookies from clientless SSL VPN sessions for this group policy by using the `html-content-filter` command in webvpn mode. HTML filtering is disabled by default.
To remove a content filter, enter the no form of this command. To remove all content filters, including a null value created by issuing the `html-content-filter` command with the `none` keyword, enter the no form of this command without arguments. The no option allows inheritance of a value from another group policy. To prevent inheriting an html content filter, enter the `html-content-filter` command with the `none` keyword.

Using the command a second time overrides the previous setting.

```
hostname(config-group-webvpn)# html-content-filter { java | images | scripts | cookies | none }
hostname(config-group-webvpn)# no html-content-filter { java | images | scripts | cookies | none }
```

The table below describes the meaning of the keywords used in this command.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>cookies</td>
<td>Removes cookies from images, providing limited ad filtering and privacy.</td>
</tr>
<tr>
<td>images</td>
<td>Removes references to images (removes <code>&lt;IMG&gt;</code> tags).</td>
</tr>
<tr>
<td>java</td>
<td>Removes references to Java and ActiveX (removes <code>&lt;EMBED&gt;</code>, <code>&lt;APPLET&gt;</code>, and <code>&lt;OBJECT&gt;</code> tags).</td>
</tr>
<tr>
<td>none</td>
<td>Indicates that there is no filtering. Sets a null value, thereby disallowing filtering. Prevents inheriting filtering values.</td>
</tr>
<tr>
<td>scripts</td>
<td>Removes references to scripting (removes <code>&lt;SCRIPT&gt;</code> tags).</td>
</tr>
</tbody>
</table>

The following example shows how to set filtering of JAVA and ActiveX, cookies, and images for the group policy named FirstGroup:

```
hostname(config)# group-policy FirstGroup attributes
chostname(config-group-policy)# webvpn
chostname(config-group-webvpn)# html-content-filter java cookies images
chostname(config-group-webvpn)#
```

### Specify the User Home Page

Specify a URL for the web page that displays when a user in this group logs in by using the `homepage` command in group-policy webvpn configuration mode. There is no default home page.

To remove a configured home page, including a null value created by issuing the `homepage none` command, enter the no form of this command. The no option allows inheritance of a value from another group policy. To prevent inheriting a home page, enter the `homepage none` command.

The `none` keyword indicates that there is no home page for clientless SSL VPN sessions. It sets a null value, thereby disallowing a home page and prevents inheriting an home page.
Configure Auto-Signon

The auto-signon command is a single sign-on method for users of clientless SSL VPN sessions. It passes the login credentials (username and password) to internal servers for authentication using NTLM authentication, basic authentication, or both. Multiple auto-signon commands can be entered and are processed according to the input order (early commands take precedence).

You can use the auto-signon feature in three modes: webvpn configuration, webvpn group configuration, or webvpn username configuration mode. The typical precedence behavior applies where username supersedes group, and group supersedes global. The mode you choose depends upon the desired scope of authentication.

To disable auto-signon for a particular user to a particular server, use the no form of the command with the original specification of IP block or URI. To disable authentication to all servers, use the no form without arguments. The no option allows inheritance of a value from the group policy.

The following example, entered in group-policy webvpn configuration mode, configures auto-signon for the user named anyuser, using basic authentication, to servers with IP addresses ranging from 10.1.1.0 to 10.1.1.255:

```
hostname(config) # group-policy ExamplePolicy attributes
hostname(config-group-policy) # webvpn
hostname(config-group-webvpn) # auto-signon allow ip 10.1.1.0 255.255.255.0
auth-type all
```

The following example commands configure auto-signon for users of clientless SSL VPN sessions, using either basic or NTLM authentication, to servers defined by the URI mask https://*.example.com/*:

```
hostname(config) # group-policy ExamplePolicy attributes
hostname(config-group-policy) # webvpn
hostname(config-group-webvpn) # auto-signon allow uri https://*.example.com/*
auth-type all
```

Specify the ACL for Clientless SSL VPN Sessions

Specify the name of the ACL to use for clientless SSL VPN sessions for this group policy or username by using the filter command in webvpn mode. Clientless SSL VPN ACLs do not apply until you enter the filter command to specify them.

To remove the ACL, including a null value created by issuing the filter none command, enter the no form of this command. The no option allows inheritance of a value from another group policy. To prevent inheriting filter values, enter the filter value none command.
ACLs for clientless SSL VPN sessions do not apply until you enter the `filter` command to specify them.

You configure ACLs to permit or deny various types of traffic for this group policy. You then enter the `filter` command to apply those ACLs for clientless SSL VPN traffic.

```bash
hostname(config-group-webvpn)# filter {value ACLname | none}
hostname(config-group-webvpn)# no filter
```

The `none` keyword indicates that there is no `webvpn` ACL. It sets a null value, thereby disallowing an ACL and prevents inheriting an ACL from another group policy.

The `ACLname` string following the keyword `value` provides the name of the previously configured ACL.

---

**Note**

Clientless SSL VPN sessions do not use ACLs defined in the `vpn-filter` command.

The following example shows how to set a filter that invokes an ACL named `acl_in` for the group policy named `FirstGroup`:

```bash
hostname(config)# group-policy FirstGroup attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# filter acl_in
hostname(config-group-webvpn)#
```

### Apply a URL List

You can specify a list of URLs to appear on the clientless SSL VPN home page for a group policy. First, you must create one or more named lists by entering the `url-list` command in global configuration mode. To apply a list of servers and URLs for clientless SSL VPN sessions to a particular group policy, allowing access to the URLs in a list for a specific group policy, use the name of the list or lists you create there with the `url-list` command in group-policy `webvpn` configuration mode. There is no default URL list.

To remove a list, including a null value created by using the `url-list none` command, use the `no` form of this command. The `no` option allows inheritance of a value from another group policy. To prevent inheriting a URL list, use the `url-list none` command. Using the command a second time overrides the previous setting:

```bash
hostname(config-group-webvpn)# url-list {value name | none} [index]
hostname(config-group-webvpn)# no url-list
```

The table below shows the `url-list` command parameters and their meanings.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>index</code></td>
<td>Indicates the display priority on the home page.</td>
</tr>
<tr>
<td><code>none</code></td>
<td>Sets a null value for <code>url-list</code>. Prevents inheriting a list from a default or specified group policy.</td>
</tr>
</tbody>
</table>
### Enable ActiveX Relay for a Group Policy

ActiveX Relay lets a user who has established a Clientless SSL VPN session use the browser to launch Microsoft Office applications. The applications use the session to download and upload Microsoft Office documents. The ActiveX relay remains in force until the Clientless SSL VPN session closes.

To enable or disable ActiveX controls on Clientless SSL VPN sessions, enter the following command in group-policy webvpn configuration mode:

```
activex-relay {enable | disable}
```

To inherit the `activex-relay` command from the default group policy, enter the following command:

```
no activex-relay
```

The following commands enable ActiveX controls on clientless SSL VPN sessions associated with a given group policy:

```
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# activex-relay enable
```

### Enable Application Access on Clientless SSL VPN Sessions for a Group Policy

To enable application access for this group policy, enter the `port-forward` command in group-policy webvpn configuration mode. Port forwarding is disabled by default.

Before you can enter the `port-forward` command in group-policy webvpn configuration mode to enable application access, you must define a list of applications that you want users to be able to use in a clientless SSL VPN session. Enter the `port-forward` command in global configuration mode to define this list.

To remove the port forwarding attribute from the group-policy configuration, including a null value created by issuing the `port-forward none` command, enter the `no` form of this command. The `no` option allows inheritance of a list from another group policy. To prevent inheriting a port forwarding list, enter the `port-forward` command with the `none` keyword. The `none` keyword indicates that there is no filtering. It sets a null value, thereby disallowing a filtering, and prevents inheriting filtering values.

The syntax of the command is as follows:

```
hostname(config-group-webvpn)# port-forward {value listname | none}
```
hostname(config-group-webvpn)# no port-forward

The listname string following the keyword value identifies the list of applications users of clientless SSL VPN sessions can access. Enter the port-forward command in webvpn configuration mode to define the list. Using the command a second time overrides the previous setting.

The following example shows how to set a port-forwarding list called ports1 for the internal group policy named FirstGroup:

hostname(config)# group-policy FirstGroup internal attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# port-forward value ports1
hostname(config-group-webvpn)#

**Configure the Port-Forwarding Display Name**

Configure the display name that identifies TCP port forwarding to end users for a particular user or group policy by using the port-forward-name command in group-policy webvpn configuration mode. To delete the display name, including a null value created by using the port-forward-name none command, enter the no form of the command. The no option restores the default name, Application Access. To prevent a display name, enter the port-forward none command. The syntax of the command is as follows:

hostname(config-group-webvpn)# port-forward-name {value name | none}
hostname(config-group-webvpn)# no port-forward-name

The following example shows how to set the name, Remote Access TCP Applications, for the internal group policy named FirstGroup:

hostname(config)# group-policy FirstGroup internal attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# port-forward-name value Remote Access TCP Applications
hostname(config-group-webvpn)#

**Configure the Maximum Object Size to Ignore for Updating the Session Timer**

Network devices exchange short keepalive messages to ensure that the virtual circuit between them is still active. The length of these messages can vary. The keep-alive-ignore command lets you tell the ASA to consider all messages that are less than or equal to the specified size as keepalive messages and not as traffic when updating the session timer. The range is 0 through 900 KB. The default is 4 KB.

To specify the upper limit of the HTTP/HTTPS traffic, per transaction, to ignore, use the keep-alive-ignore command in group-policy attributes webvpn configuration mode:

hostname(config-group-webvpn)# keep-alive-ignore size
hostname(config-group-webvpn)#

The no form of the command removes this specification from the configuration:

hostname(config-group-webvpn)# no keep-alive-ignore
The following example sets the maximum size of objects to ignore as 5 KB:

```
hostname(config-group-webvpn)#
hostname(config-group-webvpn)# keep-alive-ignore 5
```

### Specify HTTP Compression

Enable compression of http data over a clientless SSL VPN session for a specific group or user by entering the `http-comp` command in the group policy `webvpn` mode.

```
hostname(config-group-webvpn)# http-comp {gzip | none}
```

To remove the command from the configuration and cause the value to be inherited, use the `no` form of the command:

```
hostname(config-group-webvpn)# no http-comp {gzip | none}
```

The syntax of this command is as follows:

- `gzip`—Specifies compression is enabled for the group or user. This is the default value.
- `none`—Specifies compression is disabled for the group or user.

For clientless SSL VPN sessions, the `compression` command configured from global configuration mode overrides the `http-comp` command configured in group policy and username `webvpn` modes.

In the following example, compression is disabled for the group-policy sales:

```
hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# http-comp none
```

### Configure Clientless SSL VPN Access for Specific Users

The following sections describe how to customize a configuration for specific users of clientless SSL VPN sessions. Enter username `webvpn` configuration mode by using the `webvpn` command in username configuration mode. Clientless SSL VPN lets users establish a secure, remote-access VPN tunnel to the ASA using a web browser. There is no need for either a software or hardware client. Clientless SSL VPN provides easy access to a broad range of web resources and web-enabled applications from almost any computer that can reach HTTPS Internet sites. Clientless SSL VPN uses SSL and its successor, TLS1, to provide a secure connection between remote users and specific, supported internal resources that you configure at a central site. The ASA recognizes connections that need to be proxied, and the HTTP server interacts with the authentication subsystem to authenticate users.

The username `webvpn` configuration mode commands define access to files, URLs and TCP applications over clientless SSL VPN sessions. They also identify ACLs and types of traffic to filter. Clientless SSL VPN is
disabled by default. These `webvpn` commands apply only to the username from which you configure them. Notice that the prompt changes, indicating that you are now in username webvpn configuration mode.

```
hostname(config-username)# webvpn
hostname(config-username-webvpn)#
```

To remove all commands entered in username webvpn configuration mode, use the `no` form of this command:

```
hostname(config-username)# no webvpn
hostname(config-username)#
```

You do not need to configure clientless SSL VPN to use e-mail proxies.

---

**Note**

The webvpn mode that you enter from global configuration mode lets you configure global settings for clientless SSL VPN sessions. The username webvpn configuration mode described in this section, which you enter from username mode, lets you customize the configuration of specific users specifically for clientless SSL VPN sessions.

In username webvpn configuration mode, you can customize the following parameters, each of which is described in the subsequent steps:

- customizations
- deny message
- html-content-filter
- homepage
- filter
- url-list
- port-forward
- port-forward-name
- auto-signon
- AnyConnect Secure Mobility Client
- keep-alive ignore
- HTTP compression

The following example shows how to enter username webvpn configuration mode for the username anyuser attributes:

```
hostname(config)# username anyuser attributes
hostname(config-username)# webvpn
hostname(config-username-webvpn)#
```
Specify the Content/Objects to Filter from the HTML

To filter Java, ActiveX, images, scripts, and cookies for clientless SSL VPN sessions for this user, enter the `html-content-filter` command in username webvpn configuration mode. To remove a content filter, enter the `no` form of this command. To remove all content filters, including a null value created by issuing the `html-content-filter none` command, enter the `no` form of this command without arguments. The `no` option allows inheritance of a value from the group policy. To prevent inheriting an HTML content filter, enter the `html-content-filter none` command. HTML filtering is disabled by default.

Using the command a second time overrides the previous setting.

```
hostname(config-username-webvpn) # html-content-filter { java | images | scripts | cookies | none }
hostname(config-username-webvpn) # no html-content-filter { java | images | scripts | cookies | none }
```

The keywords used in this command are as follows:

- **cookies**—Removes cookies from images, providing limited ad filtering and privacy.
- **images**—Removes references to images (removes `<IMG>` tags).
- **java**—Removes references to Java and ActiveX (removes `<EMBED>`, `<APPLET>`, and `<OBJECT>` tags).
- **none**—Indicates that there is no filtering. Sets a null value, thereby disallowing filtering. Prevents inheriting filtering values.
- **scripts**—Removes references to scripting (removes `<SCRIPT>` tags).

The following example shows how to set filtering of JAVA and ActiveX, cookies, and images for the user named anyuser:

```
hostname(config)# username anyuser attributes
hostname(config-username)# webvpn
hostname(config-username-webvpn)# html-content-filter java cookies images
```

Specify the User Home Page

To specify a URL for the web page that displays when this user logs into clientless SSL VPN session, enter the `homepage` command in username webvpn configuration mode. To remove a configured home page, including a null value created by issuing the `homepage none` command, enter the `no` form of this command. The `no` option allows inheritance of a value from the group policy. To prevent inheriting a home page, enter the `homepage none` command.

The `none` keyword indicates that there is no clientless SSL VPN home page. It sets a null value, thereby disallowing a home page and prevents inheriting a home page.

The `url-string` variable following the keyword `value` provides a URL for the home page. The string must begin with either `http://` or `https://`.

There is no default home page.

```
hostname(config-username-webvpn)# homepage {value url-string | none}
```
hostname(config-username-webvpn)# no homepage
hostname(config-username-webvpn)#

The following example shows how to specify www.example.com as the home page for the user named anyuser:

hostname(config)# username anyuser attributes
hostname(config-username)# webvpn
hostname(config-username-webvpn)# homepage value www.example.com
hostname(config-username-webvpn)#

Specify a Deny Message

You can specify the message delivered to a remote user who logs into clientless SSL VPN session successfully, but has no VPN privileges by entering the `deny-message` command in username webvpn configuration mode:

hostname(config-username-webvpn)# deny-message value "message"
hostname(config-username-webvpn)# no deny-message value "message"
hostname(config-username-webvpn)# deny-message none

The `no deny-message value` command removes the message string, so that the remote user does not receive a message.

The `no deny-message none` command removes the attribute from the connection profile policy configuration. The policy inherits the attribute value.

The message can be up to 491 alphanumeric characters long, including special characters, spaces, and punctuation, but not counting the enclosing quotation marks. The text appears on the remote user’s browser upon login. When typing the string in the `deny-message value` command, continue typing even if the command wraps.

The default deny message is: “Login was successful, but because certain criteria have not been met or due to some specific group policy, you do not have permission to use any of the VPN features. Contact your IT administrator for more information.”

The first command in the following example enters username mode and configures the attributes for the user named anyuser. The subsequent commands enter username webvpn configuration mode and modify the deny message associated with that user.

hostname(config)# username anyuser attributes
hostname(config-username)# webvpn
hostname(config-username-webvpn)# deny-message value "Your login credentials are OK. However, you have not been granted rights to use the VPN features. Contact your administrator for more information."
hostname(config-username-webvpn)

Apply a URL List

You can specify a list of URLs to appear on the home page for a user who has established a clientless SSL VPN session. First, you must create one or more named lists by entering the `url-list` command in global configuration mode. To apply a list of servers and URLs to a particular user of clientless SSL VPN, enter the `url-list` command in username webvpn configuration mode.
To remove a list, including a null value created by using the `url-list none` command, enter the `no` form of this command. The `no` option allows inheritance of a value from the group policy. To prevent inheriting a url list, enter the `url-list none` command.

```
hostname(config-username-webvpn)# url-list {listname displayname url | none}
hostname(config-username-webvpn)# no url-list
```

The keywords and variables used in this command are as follows:

- **displayname**—Specifies a name for the URL. This name appears on the portal page in the clientless SSL VPN session.
- **listname**—Identifies a name by which to group URLs.
- **none**—Indicates that there is no list of URLs. Sets a null value, thereby disallowing a URL list. Prevents inheriting URL list values.
- **url**—Specifies a URL that users of clientless SSL VPN can access.

There is no default URL list.

Using the command a second time overrides the previous setting.

The following example shows how to set a URL list called AnyuserURLs for the user named anyuser:

```
hostname(config)# username anyuser attributes
hostname(config-username)# webvpn
hostname(config-username-webvpn)# url-list value AnyuserURLs
```

### Enable ActiveX Relay for a User

ActiveX Relay lets a user who has established a Clientless SSL VPN session use the browser to launch Microsoft Office applications. The applications use the session to download and upload Microsoft Office documents. The ActiveX relay remains in force until the Clientless SSL VPN session closes.

To enable or disable ActiveX controls on Clientless SSL VPN sessions, enter the following command in username webvpn configuration mode:

```
activex-relay {enable | disable}
```

To inherit the `activex-relay` command from the group policy, enter the following command:

```
no activex-relay
```

The following commands enable ActiveX controls on Clientless SSL VPN sessions associated with a given username:

```
hostname(config-username-policy)# webvpn
hostname(config-username-webvpn)# activex-relay enable
```

### Enable Application Access for Clientless SSL VPN Sessions

To enable application access for this user, enter the `port-forward` command in username webvpn configuration mode. Port forwarding is disabled by default.
To remove the port forwarding attribute from the configuration, including a null value created by issuing the `port-forward none` command, enter the `no` form of this command. The `no` option allows inheritance of a list from the group policy. To disallow filtering and prevent inheriting a port forwarding list, enter the `port-forward` command with the `none` keyword.

```
hostname(config-username-webvpn)# port-forward {value listname | none}
hostname(config-username-webvpn)# no port-forward
```

The `listname` string following the keyword `value` identifies the list of applications users of clientless SSL VPN can access. Enter the `port-forward` command in configuration mode to define the list.

Using the command a second time overrides the previous setting.

Before you can enter the `port-forward` command in `username webvpn` configuration mode to enable application access, you must define a list of applications that you want users to be able to use in a clientless SSL VPN session. Enter the `port-forward` command in global configuration mode to define this list.

The following example shows how to configure a portforwarding list called `ports1`:

```
hostname(config-group-policy)# webvpn
hostname(config-username-webvpn)# port-forward value ports1
hostname(config-username-webvpn)#
```

**Configure the Port-Forwarding Display Name**

Configure the display name that identifies TCP port forwarding to end users for a particular user by using the `port-forward-name` command in `username webvpn` configuration mode. To delete the display name, including a null value created by using the `port-forward-name none` command, enter the `no` form of the command. The `no` option restores the default name, Application Access. To prevent a display name, enter the `port-forward none` command.

```
hostname(config-username-webvpn)# port-forward-name {value name | none}
hostname(config-username-webvpn)# no port-forward-name
```

The following example shows how to configure the port-forward name test:

```
hostname(config-group-policy)# webvpn
hostname(config-username-webvpn)# port-forward-name value test
hostname(config-username-webvpn)#
```

**Configure the Maximum Object Size to Ignore for Updating the Session Timer**

Network devices exchange short keepalive messages to ensure that the virtual circuit between them is still active. The length of these messages can vary. The `keep-alive-ignore` command lets you tell the ASA to consider all messages that are less than or equal to the specified size as keepalive messages and not as traffic when updating the session timer. The range is 0 through 900 KB. The default is 4 KB.

To specify the upper limit of the HTTP/HTTPS traffic, per transaction, to ignore, use the `keep-alive-ignore` command in `group-policy attributes webvpn` configuration mode:

```
hostname(config-group-webvpn)# keep-alive-ignore size
```
hostname(config-group-webvpn)#

The no form of the command removes this specification from the configuration:

hostname(config-group-webvpn)# no keep-alive-ignore
hostname(config-group-webvpn)#

The following example sets the maximum size of objects to ignore as 5 KB:

hostname(config-group-webvpn)# keep-alive-ignore 5
hostname(config-group-webvpn)#

Configure Auto-Signon

To automatically submit the login credentials of a particular user of clientless SSL VPN to internal servers using NTLM, basic HTTP authentication, or both, use the auto-signon command in username webvpn configuration mode.

The auto-signon command is a single sign-on method for users of clientless SSL VPN sessions. It passes the login credentials (username and password) to internal servers for authentication using NTLM authentication, basic authentication, or both. Multiple auto-signon commands can be entered and are processed according to the input order (early commands take precedence).

You can use the auto-signon feature in three modes: webvpn configuration, webvpn group configuration, or webvpn username configuration mode. The typical precedence behavior applies where username supersedes group, and group supersedes global. The mode you choose depends upon the desired scope of authentication.

To disable auto-signon for a particular user to a particular server, use the no form of the command with the original specification of IP block or URI. To disable authentication to all servers, use the no form without arguments. The no option allows inheritance of a value from the group policy.

The following example commands configure auto-signon for a user of clientless SSL VPN named anyuser, using either basic or NTLM authentication, to servers defined by the URI mask https://*.example.com/*:

hostname(config)# username anyuser attributes
hostname(config-username)# webvpn
hostname(config-username-webvpn)# auto-signon allow uri https://*.example.com/*
   auth-type all

The following example commands configure auto-signon for a user of clientless SSL VPN named anyuser, using either basic or NTLM authentication, to the server with the IP address 10.1.1.0, using subnet mask 255.255.255.0:

hostname(config)# username anyuser attributes
hostname(config-username)# webvpn
hostname(config-username-webvpn)# auto-signon allow ip 10.1.1.0 255.255.255.0
   auth-type all
hostname(config-username-webvpn)#

Specify HTTP Compression

Enable compression of http data over a clientless SSL VPN session for a specific user by entering the http-comp command in the username webvpn configuration mode.
To remove the command from the configuration and cause the value to be inherited, use the `no` form of the command:

```
hostname(config-username-webvpn)# no http-comp {gzip | none}
hostname(config-username-webvpn)#
```

The syntax of this command is as follows:

- `gzip`—Specifies compression is enabled for the group or user. This is the default value.
- `none`—Specifies compression is disabled for the group or user.

For clientless SSL VPN session, the `compression` command configured from global configuration mode overrides the `http-comp` command configured in group policy and username webvpn modes.

In the following example, compression is disabled for the username testuser:

```
hostname(config)# username testuser internal
hostname(config)# username testuser attributes
hostname(config-username)# webvpn
hostname(config-username-webvpn)# http-comp none
hostname(config-username-webvpn)#
```

### Smart Tunnel Access

The following sections describe how to enable smart tunnel access with Clientless SSL VPN sessions, specify the applications to be provided with such access, and provide notes on using it.

To configure smart tunnel access, you create a smart tunnel list containing one or more applications eligible for smart tunnel access, and the endpoint operating system associated with the list. Because each group policy or local user policy supports one smart tunnel list, you must group the non-browser-based applications to be supported into a smart tunnel list. After creating a list, you assign it to one or more group policies or local user policies.

The following sections describe smart tunnels and how to configure them:

- About Smart Tunnels, on page 359
- Prerequisites for Smart Tunnels, on page 359
- Guidelines for Smart Tunnels, on page 360
- Add Applications to Be Eligible for Smart Tunnel Access, on page 361
- About Smart Tunnel Lists, on page 361
- Configure and Apply Smart Tunnel Policy, on page 362
- Configure and Apply a Smart Tunnel Tunnel-Policy, on page 363
- Create a Smart Tunnel Auto Sign-On Server List, on page 364
- Add Servers to a Smart Tunnel Auto Sign-On Server List, on page 365
About Smart Tunnels

A smart tunnel is a connection between a TCP-based application and a private site, using a clientless (browser-based) SSL VPN session with the security appliance as the pathway, and the ASA as a proxy server. You can identify applications for which to grant smart tunnel access, and specify the local path to each application. For applications running on Microsoft Windows, you can also require a match of the SHA-1 hash of the checksum as a condition for granting smart tunnel access.

Lotus SameTime and Microsoft Outlook are examples of applications to which you may want to grant smart tunnel access.

Configuring smart tunnels requires one of the following procedures, depending on whether the application is a client or is a web-enabled application:

- Create one or more smart tunnel lists of the client applications, then assign the list to the group policies or local user policies for whom smart tunnel access is required.
- Create one or more bookmark list entries that specify the URLs of the web-enabled applications eligible for smart tunnel access, then assign the list to the group policies or local user policies for whom smart tunnel access is required.

You can also list web-enabled applications for which to automate the submission of login credentials in smart tunnel connections over Clientless SSL VPN sessions.

Benefits of Smart Tunnels

Smart tunnel access lets a client TCP-based application use a browser-based VPN connection to access a service. It offers the following advantages to users, compared to plug-ins and the legacy technology, port forwarding:

- Smart tunnel offers better performance than plug-ins.
- Unlike port forwarding, smart tunnel simplifies the user experience by not requiring the user connection of the local application to the local port.
- Unlike port forwarding, smart tunnel does not require users to have administrator privileges.

The advantage of a plug-in is that it does not require the client application to be installed on the remote computer.

Prerequisites for Smart Tunnels

See the Supported VPN Platforms, Cisco ASA 5500 Series, for the platforms and browsers supported by smart tunnels.

The following requirements and limitations apply to smart tunnel access on Windows:

- ActiveX or Oracle Java Runtime Environment (JRE 6 or later recommended) on Windows must be enabled on the browser.
ActiveX pages require that you enter the `activex-relay` command on the associated group policy. If you do so or assign a smart tunnel list to the policy, and the browser proxy exception list on the endpoint specifies a proxy, the user must add a “shutdown.webvpn.relay.” entry to this list.

- Only Winsock2, TCP-based applications are eligible for smart tunnel access.
- For Mac OS X only, Java Web Start must be enabled on the browser.
- Smart tunnel is incompatible with IE's Enhanced Protected Mode.

**Guidelines for Smart Tunnels**

- Smart tunnel supports only proxies placed between computers running Microsoft Windows and the security appliance. Smart Tunnel uses the Internet Explorer configuration, which sets system-wide parameters in Windows. That configuration may include proxy information:
  - If a Windows computer requires a proxy to access the ASA, then there must be a static proxy entry in the client's browser, and the host to connect to must be in the client's list of proxy exceptions.
  - If a Windows computer does not require a proxy to access the ASA, but does require a proxy to access a host application, then the ASA must be in the client's list of proxy exceptions.

Proxy systems can be defined the client’s configuration of static proxy entry or automatic configuration, or by a PAC file. Only static proxy configurations are currently supported by Smart Tunnels.

- Kerberos constrained delegation (KCD) is not supported for smart tunnels.

- With Windows, to add smart tunnel access to an application started from the command prompt, you must specify “cmd.exe” in the Process Name of one entry in the smart tunnel list, and specify the path to the application itself in another entry, because “cmd.exe” is the parent of the application.

- With HTTP-based remote access, some subnets may block user access to the VPN gateway. To fix this, place a proxy in front of the ASA to route traffic between the Web and the end user. That proxy must support the CONNECT method. For proxies that require authentication, Smart Tunnel supports only the basic digest authentication type.

- When smart tunnel starts, the ASA by default passes all browser traffic through the VPN session if the browser process is the same. The ASA only also does this if a tunnel-all policy (the default) applies. If the user starts another instance of the browser process, it passes all traffic through the VPN session. If the browser process is the same and the security appliance does not provide access to a URL, the user cannot open it. As a workaround, assign a tunnel policy that is not tunnel-all.

- A stateful failover does not retain smart tunnel connections. Users must reconnect following a failover.

- The Mac version of smart tunnel does not support POST bookmarks, form-based auto sign-on, or POST macro substitution.

- For macOS users, only those applications started from the portal page can establish smart tunnel connections. This requirement includes smart tunnel support for Firefox. Using Firefox to start another instance of Firefox during the first use of a smart tunnel requires the user profile named cisco_st. If this user profile is not present, the session prompts the user to create one.

- In macOS, applications using TCP that are dynamically linked to the SSL library can work over a smart tunnel.
• Smart tunnel does not support the following on macOS:
    • Sandboxed applications (verify in Activity Monitor using View > Columns). For that reason, macOS 10.14 and 10.15 do not support smart tunneling.
    • Proxy services.
    • Auto sign-on.
    • Applications that use two-level name spaces.
    • Console-based applications, such as Telnet, SSH, and cURL.
    • Applications using dlopen or dltsym to locate libsocket calls.
    • Statically linked applications to locate libsocket calls.

• macOS requires the full path to the process and is case-sensitive. To avoid specifying a path for each username, insert a tilde (~) before the partial path (e.g., ~/bin/vnc).

• A new method for smart-tunnel support in the Chrome browser on Mac and Windows devices is now in place. A Chrome Smart Tunnel Extension has replaced the Netscape Plugin Application Program Interfaces (NPAPIs) that are no longer supported on Chrome.

If you click on the smart tunnel enabled bookmark in Chrome without the extension already being installed, you are redirected to the Chrome Web Store to obtain the extension. New Chrome installations will direct the user to the Chrome Web Store to download the extension. The extension downloads the binaries from ASA that are required to run smart tunnel.

Chrome's default download location needs to point to the current user's Downloads folder. Or, if Chrome's download setup is 'Ask every time' the user should choose the Downloads folder when asked.

Your usual bookmark and application configuration while using smart tunnel is unchanged other than the process of installing the new extension and specifying the download location.

Add Applications to Be Eligible for Smart Tunnel Access

The Clientless SSL VPN configuration of each ASA supports smart tunnel lists, each of which identifies one or more applications eligible for smart tunnel access. Because each group policy or username supports only one smart tunnel list, you must group each set of applications to be supported into a smart tunnel list.

About Smart Tunnel Lists

For each group policy and username, you can configure Clientless SSL VPN to do one of the following:
• Start smart tunnel access automatically upon user login.
• Enable smart tunnel access upon user login, but require the user to start it manually, using the Application Access > Start Smart Tunnels button on the Clientless SSL VPN Portal Page.

Note The smart tunnel logon options are mutually exclusive for each group policy and username. Use only one.
The following smart tunnel commands are available to each group policy and username. The configuration of each group policy and username supports only one of these commands at a time, so when you enter one, the ASA replaces the one present in the configuration of the group policy or username in question with the new one, or in the case of the last command, simply removes the smart-tunnel command already present in the group policy or username.

- **smart-tunnel auto-start** *list*
  Start smart tunnel access automatically upon user login.

- **smart-tunnel enable** *list*
  Enable smart tunnel access upon user login, but requires the user to start smart tunnel access manually, using the Application Access > Start Smart Tunnels button on the Clientless SSL VPN portal page.

- **smart-tunnel disable**
  Prevent smart tunnel access.

- **no smart-tunnel [auto-start list | enable list | disable]**
  Remove a smart-tunnel command from the group policy or username configuration which then inherits the [no] smart-tunnel command from the default group-policy. The keywords following the no smart-tunnel command are optional, however, they restrict the removal to the named smart-tunnel command.

---

### Configure and Apply Smart Tunnel Policy

The smart tunnel policy requires a per group policy/username configuration. Each group policy/username references a globally configured list of networks. When the smart tunnel is turned on, you can allow traffic outside of the tunnel with the use of 2 CLIs: one configures the network (a set of hosts), and the other uses the specified smart-tunnel network to enforce a policy on a user. The following commands create a list of hosts to use for configuring smart tunnel policies.

**Procedure**

1. **Step 1**
   Switch to Clientless SSL VPN configuration mode:
   ```
   webvpn
   ```

2. **Step 2**
   Create a list of hosts to use for configuring smart tunnel policies:
   ```
   [no] smart-tunnel network network name ip ip netmask
   ```
   - **network name** is the name to apply to the tunnel policy.
   - **ip** is the IP address of the network.
   - **netmask** is the netmask of the network.

3. **Step 3**
   Establish the hostname mask, such as *.cisco.com:
   ```
   [no] smart-tunnel network network name host host mask
   ```

4. **Step 4**
   Apply smart tunnel policies to a particular group or user policy:
[no] smart-tunnel tunnel-policy [{excludespecified | tunnelspecified} network name | tunnelall]

- *network name* is a list of networks to be tunneled.
- *tunnelall* makes everything tunneled (encrypted).
- *tunnelspecified* tunnels only networks specified by network name.
- *excludespecified* tunnels only networks that are outside of the networks specified by network name.

## Configure and Apply a Smart Tunnel Tunnel-Policy

Like the split tunnel configuration in the SSL VPN client, the smart tunnel policy is a per group-policy/username configuration. Each group policy/username references a globally configured list of networks:

### Procedure

**Step 1** Reference a globally configured list of networks:

[no] smart-tunnel tunnel-policy [{excludespecified | tunnelspecified} network name | tunnelall]

- *network name* is a list of networks to be tunneled.
- *tunnelall* makes everything tunneled (encrypted).
- *tunnelspecified* tunnels only networks specified by network name.
- *excludespecified* tunnels only networks that are outside of the networks specified by network name.

**Step 2** Apply a tunnel policy to a group-policy/user policy:

[no] smart-tunnel network *network name* *ip* *ip netmask*

or

[no] smart-tunnel network *network name* *host* *host mask*

One command specifies host and the other specifies network IPs. Use only one.

- *network name* specifies the name of network to apply to tunnel policy
- *ip* specifies the IP address of a network
- *netmask* specifies the netmask of a network
- *host mask* specifies the hostname mask, such as *.cisco.com

### Example:

Example:

Create a tunnel policy that contains only one host (assuming the inventory pages are hosted at www.example.com (10.5.2.2), and you want to configure both IP address and name for the hosts).

```
ciscoasa(config-webvpn)# smart-tunnel network inventory ip 10.5.2.2
```
Create a Smart Tunnel Auto Sign-On Server List

Procedure

Step 1
Switch to Clientless SSL VPN configuration mode:

webvpn

Step 2
Use for each server to add to the server list:

smart-tunnel auto-sign-on list [use-domain] [realm realm-string] [port port-num] [ip ip-address [netmask] [host hostname-mask]

- list—names the list of remote servers. Use quotation marks around the name if it includes a space. The string can be up to 64 characters. The ASA creates the list if it is not already present in the configuration. Otherwise, it adds the entry to the list. Assign a name that will help you to distinguish.

- use-domain (optional)—Add the Windows domain to the username if authentication requires it. If you enter this keyword, ensure you specify the domain name when assigning the smart tunnel list to one or more group policies, or usernames.

- realm—Configures a realm for the authentication. Realm is associated with the protected area of the website and is passed back to the browser either in the authentication prompt or in the HTTP headers during authentication. Once auto-sign is configured and a realm string is specified, users can configure the realm string on a Web application (such as Outlook Web Access) and access Web applications without signing on.
- **port**—Specifies which port performs auto sign-on. For Firefox, if no port number is specified, auto sign is performed on HTTP and HTTPS, accessed by the default port numbers 80 and 443 respectively.

- **ip**—Specifies the server by its IP address and netmask.

- **ip-address[netmask]**—Identifies the sub-network of hosts to auto-authenticate to.

- **host**—Specifies the server by its hostname or wildcard mask. Using this option protects the configuration from dynamic changes to IP addresses.

- **hostname-mask**—Specifies which hostname or wildcard mask to auto-authenticate to.

### Step 3
(Optional) Remove an entry from the list of servers, specifying both the list and IP address or hostname as it appears in the ASA configuration:

```
nosmart-tunnel autosign-on list [use-domain] [realm realm-string] [port port-num] [ip ip-address [netmask] | host hostname-mask]
```

### Step 4
Display the smart tunnel auto sign-on list entries:

```
show running-config webvpn smart-tunnel
```

### Step 5
Switch to config-webvpn configuration mode:

```
config-webvpn
```

### Step 6
Add all hosts in the subnet and adds the Windows domain to the username if authentication requires it:

```
smart-tunnel autosign-on HR use-domain ip 93.184.216.119 255.255.255.0
```

### Step 7
(Optional) Remove that entry from the list and the list named HR if the entry removed is the only entry in the list:

```
nosmart-tunnel autosign-on HR use-domain ip 93.184.216.119 255.255.255.0
```

### Step 8
Remove the entire list from the ASA configuration:

```
nosmart-tunnel autosign-on HR
```

### Step 9
Add all hosts in the domain to the smart tunnel auto sign-on list named intranet:

```
smart-tunnel autosign-on intranet host *.example.com
```

### Step 10
Remove that entry from the list:

```
nosmart-tunnel autosign-on intranet host *.example.com
```

**Note**
After configuring of the smart tunnel auto sign-on server list, you must assign it to a group policy or a local user policy for it to become active. For more information, see, *Add Servers to a Smart Tunnel Auto Sign-On Server List*, on page 365

---

## Add Servers to a Smart Tunnel Auto Sign-On Server List

The following steps describe how to add servers to the list of servers for which to provide auto sign-on in smart tunnel connections, and assign that list to a group policies or a local user.
Before you begin

- Use the `smart-tunnel auto-sign-on` list command to create a list of servers first. You can assign only one list to a group policy or username.

**Note**
The smart-tunnel auto sign-on feature supports only applications communicating HTTP and HTTPS using Internet Explorer and Firefox.

- If you are using Firefox, make sure that you specify hosts using an exact hostname or IP address (instead of a host mask with wildcards, a subnet using IP addresses, or a netmask). For example, within Firefox, you cannot enter *.cisco.com and expect auto-sign-on to host email.cisco.com.

Procedure

**Step 1**
Switch to Clientless SSL VPN configuration mode:
```
webvpn
```

**Step 2**
Switch to group-policy Clientless SSL VPN configuration mode:
```
group-policy webvpn
```

**Step 3**
Switch to username Clientless SSL VPN configuration mode.
```
username webvpn
```

**Step 4**
Enable smart tunnel auto sign-on Clientless SSL VPN sessions:
```
smart-tunnel auto-sign-on enable
```

**Step 5**
(Optional) Switch off smart tunnel auto sign-on Clientless SSL VPN session, remove it from the group policy or username, and use the default:
```
[no] smart-tunnel auto-sign-on enable list [domain domain]
```
- `list`—The name of a smart tunnel auto sign-on list already present in the ASA Clientless SSL VPN configuration.
- `domain (optional)`—The name of the domain to be added to the username during authentication. If you enter a domain, enter the `use-domain` keyword in the list entries.

**Step 6**
View the smart tunnel auto sign-on list entries in the SSL VPN configuration:
```
show running-config webvpn smart-tunnel
```

**Step 7**
Enable the smart tunnel auto sign-on list named HR:
```
smart-tunnel auto-sign-on enable HR
```

**Step 8**
Enable the smart tunnel auto sign-on list named HR and adds the domain named CISCO to the username during authentication:
```
smart-tunnel auto-sign-on enable HR domain CISCO
```
Step 9 (Optional) Remove the smart tunnel auto sign-on list named HR from the group policy and inherits the smart tunnel auto sign-on list command from the default group policy:

```
no smart-tunnel auto-sign-on enable HR
```

Automate Smart Tunnel Access

To start smart tunnel access automatically upon user login, perform the following steps:

**Before you begin**

For Mac OS X, click the link for the application in the portal’s Application Access panel, with or without auto-start configured.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Switch to Clientless SSL VPN configuration mode: webvpn</td>
</tr>
<tr>
<td>Step 2</td>
<td>Switch to group-policy Clientless SSL VPN configuration mode: group-policy webvpn</td>
</tr>
<tr>
<td>Step 3</td>
<td>Switch to username Clientless SSL VPN configuration mode: username webvpn</td>
</tr>
</tbody>
</table>
| Step 4 | Start smart tunnel access automatically upon user login: smart-tunnel auto-start list  

*list* is the name of the smart tunnel list already present.  

**Example:**

```
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# smart-tunnel auto-start apps1
```

This assigns the smart tunnel list named apps1 to the group policy.

| Step 5 | Display the smart tunnel list entries in the SSL VPN configuration: show running-config webvpn smart-tunnel |
| Step 6 | Remove the smart-tunnel command from the group policy or username and reverts to the default: no smart-tunnel |
Enable and Switch Off Smart Tunnel Access

By default, smart tunnels are switched off.

Procedure

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
</table>
| Step 1 | Switch to Clientless SSL VPN configuration mode:  
  `webvpn` |
| Step 2 | Switch to group-policy Clientless SSL VPN configuration mode:  
  `group-policy webvpn` |
| Step 3 | Switch to username Clientless SSL VPN configuration mode:  
  `username webvpn` |
| Step 4 | Enable smart tunnel access:  
  `smart-tunnel [enable list | disable]`  
  *list* is the name of the smart tunnel list already present. You do not have to start smart tunnel access manually if you entered `smart-tunnel auto-start list` from the previous table. |
| Example: | hostname(config-group-policy)# `webvpn`  
  hostname(config-group-webvpn)# `smart-tunnel enable apps1`  
  This example assigns the smart tunnel list named apps1 to the group policy. |
| Step 5 | Display the smart tunnel list entries in the SSL VPN configuration:  
  `show running-config webvpn smart-tunnel` |
| Step 6 | Remove the smart-tunnel command from the group policy or local user policy and reverts to the default group policy:  
  `no smart-tunnel` |
| Step 7 | Switch off smart tunnel access:  
  `smart-tunnel disable` |

Configure Smart Tunnel Log Off

This section describes how to ensure that the smart tunnel is properly logged off. Smart tunnel can be logged off when all browser windows have been closed, or you can right click the notification icon and confirm log out.
We strongly recommend the use of the logout button on the portal. This method pertains to Clientless SSL VPNs and logs off regardless of whether smart tunnel is used or not. The notification icon should be used only when using standalone applications without the browser.

Configure Smart Tunnel Log Off when Its Parent Process Terminates

This practice requires the closing of all browsers to signify log off. The smart tunnel lifetime is now tied to the starting process lifetime. For example, if you started a smart tunnel from Internet Explorer, the smart tunnel is turned off when no iexplore.exe is running. Smart tunnel can determine that the VPN session has ended even if the user closed all browsers without logging out.

In some cases, a lingering browser process is unintentional and is strictly a result of an error. Also, when a Secure Desktop is used, the browser process can run in another desktop even if the user closed all browsers within the secure desktop. Therefore, smart tunnel declares all browser instances gone when no more visible windows exist in the current desktop.

Note

Procedure

Step 1
Allow administrators to turn on the notification icon on a global basis:

```
[no] smart-tunnel notification-icon
```

This command configures log out properties and controls whether the user is presented with a logout icon for logging out, as opposed to having logout triggered by closing browser windows.

This command also controls logging off when a parent process terminates, which is automatically turned on or off when the notification icon is turned on or off. The `notification-icon` is the keyword that specifies when to use the icon for logout.

The `no` version of this command is the default, in which case, closing all browser windows logs off the SSL VPN session.

Portal logout still takes effect and is not impacted.

Step 2
When using a proxy and adding to the proxy list exception, ensure that smart tunnel is properly closed when you log off, regardless of icon usage or not.

```
*.webvpn.
```

Configure Smart Tunnel Log Off with a Notification Icon

You may also choose to switch off logging off when a parent process terminates so that a session survives if you close a browser. For this practice, you use a notification icon in the system tray to log out. The icon remains until the user clicks the icon to logout. If the session has expired before the user has logged out, the icon remains until the next connection is tried. You may have to wait for the session status to update in the system tray.
Clientless SSL VPN Capture Tool

The Clientless SSL VPN CLI includes a capture tool that lets you log information about websites that do not display properly over a WebVPN connection. The data this tool records can help your Cisco customer support representative troubleshoot problems.

The output of the Clientless SSL VPN capture tool consists of two files:

- mangled.1, 2,3, 4... and so on, depending on the Web page activity. The mangle files record the html actions of the VPN Concentrator transferring these pages on a Clientless SSL VPN connection.

- original.1,2,3,4... and so on, depending on the Web page activity. The original files are the files the URL sent to the VPN Concentrator.

To open and view the files output by the capture tool, go to Administration | File Management. Zip the output files and send them to your Cisco support representative.

Note

Using the Clientless SSL VPN capture tool does impact VPN Concentrator performance. Ensure you switch off the capture tool after you have generated the output files.

Configure Portal Access Rules

This enhancement allows customers to configure a global Clientless SSL VPN access policy to permit or deny Clientless SSL VPN sessions based on the data present in the HTTP header. If the ASA denies a Clientless SSL VPN session, it returns an error code to the endpoint immediately.

The ASA evaluates this access policy before the endpoint authenticates to the ASA. As a result, in the case of a denial, fewer ASA processing resources are consumed by additional connection attempts from the endpoint.

Before you begin

Log on to the ASA and enter global configuration mode. In global configuration mode, the ASA displays hostname(config) #.

Procedure

Step 1

Enter Clientless SSL VPN configuration mode:

webvpn

Step 2

Permit or deny the creation of a Clientless SSL VPN session based on an HTTP header code or a string in the HTTP header:
portal-access-rule priority [{permit | deny [code code]}] {any | user-agent match string}

Example:

hostname(config-webvpn) # portal-access-rule 1 deny code 403 user-agent match *Thunderbird*
hostname(config-webvpn) # portal-access-rule 1 deny code 403 user-agent match ""my agent"

The second example shows the proper syntax for specifying a string with a space. Surround the string with wildcards (*) and then quotes (" ").

---

**Optimize Clientless SSL VPN Performance**

The ASA provides several ways to optimize Clientless SSL VPN performance and functionality. Performance improvements include caching and compressing Web objects. Functionality tuning includes setting limits on content transformation and proxy-bypass. APCF provides an additional method of tuning content transformation.

**Configure Caching**

Caching enhances Clientless SSL VPN performance. It stores frequently reused objects in the system cache, which reduces the need to perform repeated rewriting and compressing of content. It reduces traffic between Clientless SSL VPN and the remote servers, with the result that many applications run much more efficiently.

By default, caching is enabled. You can customize the way caching works for your environment by using the caching commands in cache mode.

**Configure Content Transformation**

By default, the ASA processes all Clientless SSL VPN traffic through a content transformation/rewriting engine that includes advanced elements such as JavaScript and Java to proxy HTTP traffic that may have different semantics and access control rules depending on whether the user is accessing an application within or independently of an SSL VPN device.

Some Web resources require highly individualized treatment. The following sections describe functionality that provides such treatment. Subject to the requirements of your organization and the Web content involved, you may use one of these features.

**Configure a Certificate for Signing Rewritten Java Content**

Java objects that have been transformed by Clientless SSL VPN can subsequently be signed using a PKCS12 digital certificate associated with a trustpoint.

**Procedure**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step 1</td>
<td>Import a certificate:</td>
</tr>
<tr>
<td></td>
<td>crypto ca import</td>
</tr>
<tr>
<td>Step 2</td>
<td>Employ a certificate:</td>
</tr>
</tbody>
</table>
Switch Off Content Rewrite

You may not want some applications and Web resources, for example, public websites, to go through the ASA. The ASA therefore lets you create rewrite rules that let users browse certain sites and applications without going through the ASA. This is similar to split-tunneling in an IPsec VPN connection.

**Procedure**

**Step 1**
Switch to Clientless SSL VPN configuration mode:

```bash
webvpn
```

**Step 2**
Specify applications and resources to access outside a clientless SSLN VPN tunnel:

```bash
rewrite
```
You can use this command multiple times.

**Step 3**
Use in combination with the rewrite command:

```bash
disable
```

The rule order number is important because the security appliance searches rewrite rules by order number, starting with the lowest, and applies the first rule that matches.

**Use Proxy Bypass**

You can configure the ASA to use proxy bypass when applications and Web resources work better with the special content rewriting this feature provides. Proxy bypass is an alternative method of content rewriting that makes minimal changes to the original content. It is often useful with custom Web applications.

You can use the proxy-bypass command multiple times. The order in which you configure entries is unimportant. The interface and path mask or interface and port uniquely identify a proxy bypass rule.

If you configure proxy bypass using ports rather than path masks, depending on your network configuration, you may need to change your firewall configuration to allow these ports access to the ASA. Use path masks...
to avoid this restriction. Be aware, however, that path masks can change, so you may need to use multiple
pathmask statements to exhaust the possibilities.

A path is everything in a URL after the .com or .org or other types of domain name. For example, in the URL
www.example.com/hrbenefits, hrbenefits is the path. Similarly, for the URL www.example.com/hrinsurance,
hrinsurance is the path. To use proxy bypass for all hr sites, you can avoid using the command multiple times
by using the * wildcard as follows: /hr*.

Procedure

CHAPTER 18

Clientless SSL VPN Remote Users

This chapter summarizes configuration requirements and tasks for the user remote system. It also helps users get started with Clientless SSL VPN. It includes the following sections:

Note

- Make sure that the ASA has been configured for Clientless SSL VPN.

Clientless SSL VPN Remote Users

This chapter summarizes configuration requirements and tasks for the user remote system. It also helps users get started with Clientless SSL VPN. It includes the following sections:

Note

- Make sure that the ASA has been configured for Clientless SSL VPN.

Usernames and Passwords

Depending on your network, during a remote session users may have to log on to any or all of the following: the computer itself, an Internet service provider, Clientless SSL VPN, mail or file servers, or corporate applications. Users may have to authenticate in many different contexts, requiring different information, such as a unique username, password, or PIN. Ensure users have the required access.

The following table lists the type of usernames and passwords that Clientless SSL VPN users may need to know.

Table 21: Usernames and Passwords to Give to Clientless SSL VPN Users

<table>
<thead>

</tr>
</tbody>
</table>
Communicate Security Tips

Communicate the following security tips:

• Always log out from a Clientless SSL VPN session, click the logout icon on the Clientless SSL VPN toolbar or close the browser.

• Using Clientless SSL VPN does not ensure that communication with every site is secure. Clientless SSL VPN ensures the security of data transmission between the remote computer or workstation and the ASA on the corporate network. If a user then accesses a non-HTTPS Web resource (located on the Internet or on the internal network), the communication from the corporate ASA to the destination Web server is not secure.

Configure Remote Systems to Use Clientless SSL VPN Features

The following table includes the tasks involved in setting up remote systems to use Clientless SSL VPN, requirements/prerequisites for the task and recommended usage:

You may have configured user accounts differently, and different features may be available to each Clientless SSL VPN user. This table also organizes information by user activity.
Table 22: Clientless SSL VPN Remote System Configuration and End User Requirements

</table>
| **Web Browsing**            | Usernames and passwords for protected websites | Using Clientless SSL VPN does not ensure that communication with every site is secure. See “Communicate Security Tips, on page 376.” The look and feel of Web browsing with Clientless SSL VPN may be different from what users are accustomed to. For example:  
• The Clientless SSL VPN title bar appears above each Web page.  
• You access websites by:  
  • Entering the URL in the Enter Web Address field on the Clientless SSL VPN Home page.  
  • Clicking on a preconfigured website link on the Clientless SSL VPN Home page.  
  • Clicking a link on a webpage accessed via one of the previous two methods.  
    Also, depending on how you configured a particular account, it may be that:  
    • Some websites are blocked.  
    • Only the websites that appear as links on the Clientless SSL VPN Home page are available. |
| **Network Browsing and File Management** | File permissions configured for shared remote access | Only shared folders and files are accessible via Clientless SSL VPN.  
Server name and passwords for protected file servers  
Domain, workgroup, and server names where folders and files reside  
Users may not be familiar with how to locate their files through your organization network.  
Do not interrupt the **Copy File to Server** command or navigate to a different screen while the copying is in progress. Interrupting the operation can cause an incomplete file to be saved on the server. |

</table>

**Other supported products:**

- Outlook Web Access
- Lotus Notes
- Internet Explorer 8.x or Firefox 8.x

**Recommended configurations:**

- Use OWA on Internet Explorer 8.x or Firefox 8.x for best results.
- Use Lotus Notes for web-based email products.

**Notes:**

- If the Remote Server contains the server hostname, you do not need to configure the client application.
- If the Remote Server field contains an IP address, you must configure the client application.

**Using email via Application Access:**

- Fulfill requirements for Application Access (See Using Applications)
- To use mail, start Application Access from the Clientless SSL VPN Home page. The mail client is then available for use.

**Using email via Web Access:**

- Web-based email product installed
- Supported products include:
  - Outlook Web Access
  - Lotus Notes
- Other web-based email products should also work, but we have not verified them.

### Capture Clientless SSL VPN Data

The CLI capture command lets you log information about websites that do not display correctly over a Clientless SSL VPN connection. This data can help your Cisco customer support engineer troubleshoot problems. The following sections describe how to use the capture command:

- Create a Capture File, on page 382
- Use a Browser to Display Capture Data, on page 383

**Note**

Enabling Clientless SSL VPN capture affects the performance of the ASA. Ensure that you switch off the capture after you generate the capture files needed for troubleshooting.

### Create a Capture File

**Procedure**

**Step 1**

Start the Clientless SSL VPN capture utility, to capture packets

```
capture capture-name type webvpn user csslvpn-username
```

- `capture-name` is a name you assign to the capture, which is also prefixed to the name of the capture files.
- `csslvpn-username` is the username to match for capture.

**Example:**

```
hostname# capture hr type webvpn user user2
```

**Step 2**

Stop the capture by using the `no` version of the command:

```
no capture capture-name
```

**Example:**
The capture utility creates a capture-name.zip file, which is encrypted with the password koleso.

**Step 3** Send the .zip file to Cisco, or attach it to a Cisco TAC service request.

**Step 4** To look at the contents of the .zip file, unzip it using the password koleso.

---

### Use a Browser to Display Capture Data

**Procedure**

**Step 1** Start the Clientless SSL VPN capture utility:

```
capture capture-name type webvpn user csslvpn-username
```

- `capture-name` is a name you assign to the capture, which is also prefixed to the name of the capture files.
- `csslvpn-username` is the username to match for capture.

**Example:**

```
hostname# capture hr type webvpn user user2
```

**Step 2** Open a browser and in the address box enter:

```
https://IP address or hostname of the ASA/webvpn_capture.html
```

The captured content displays in a sniffer format.

**Step 3** Stop the capture by using the no version of the command:

```
no capture capture-name
```

**Example:**

```
hostname# no capture hr
```
Use a Browser to Display Capture Data
Clientless SSL VPN Users

- Manage Passwords, on page 385
- Use Single Sign-On with Clientless SSL VPN, on page 387
- Username and Password Requirements, on page 403
- Communicate Security Tips, on page 404
- Configure Remote Systems to Use Clientless SSL VPN Features, on page 404

Manage Passwords

Optionally, you can configure the ASA to warn end users when their passwords are about to expire.

The ASA supports password management for the RADIUS and LDAP protocols. It supports the “password-expire-in-days” option for LDAP only.

You can configure password management for IPsec remote access and SSL VPN tunnel-groups.

When you configure password management, the ASA notifies the remote user at login that the user’s current password is about to expire or has expired. The ASA then offers the user the opportunity to change the password. If the current password has not yet expired, the user can still log in using that password.

This command is valid for AAA servers that support such notification.

The ASA, releases 7.1 and later, generally supports password management for the following connection types when authenticating with LDAP or with any RADIUS configuration that supports MS-CHAPv2:

- AnyConnect VPN Client
- IPsec VPN Client
- Clientless SSL VPN

The RADIUS server (for example, Cisco ACS) could proxy the authentication request to another authentication server. However, from the ASA perspective, it is talking only to a RADIUS server.

Before you begin

- Native LDAP requires an SSL connection. You must enable LDAP over SSL before attempting to do password management for LDAP. By default, LDAP uses port 636.
• If you are using an LDAP directory server for authentication, password management is supported with the Sun Java System Directory Server (formerly named the Sun ONE Directory Server) and the Microsoft Active Directory.

  • Sun—The DN configured on the ASA to access a Sun directory server must be able to access the default password policy on that server. We recommend using the directory administrator, or a user with directory administrator privileges, as the DN. Alternatively, you can place an ACI on the default password policy.

  • Microsoft—You must configure LDAP over SSL to enable password management with Microsoft Active Directory.

• Some RADIUS servers that support MSCHAP currently do not support MSCHAPv2. This command requires MSCHAPv2 so check with your vendor.

• Password management is not supported for any of these connection types for Kerberos/Active Directory (Windows password) or NT 4.0 Domain.

• For LDAP, the method to change a password is proprietary for the different LDAP servers on the market. Currently, the ASA implements the proprietary password management logic only for Microsoft Active Directory and Sun LDAP servers.

• The ASA ignores this command if RADIUS or LDAP authentication has not been configured.

• The password-management command does not change the number of days before the password expires, but rather, the number of days ahead of expiration that the ASA starts warning the user that the password is about to expire.

**Procedure**

**Step 1**
Switch to general-attributes mode:

```bash
tunnel-group general-attributes
```

**Step 2**
Notify remote users that their password is about to expire:

```bash
password-management password-expire-in-days days
```

**Example:**

```bash
hostname(config-general)# password-management password-expire-in-days 90
```

• If you specify the password-expire-in-days keyword, you must also specify the number of days.

• If you set the number of days to 0, this command is switched off.

In this example, the ASA starts warning the user of the password expiration, 90 days before the expiration date.

**Note**
If the password-expire-in-days keyword is not set, the ASA does not notify the user of the pending expiration, but the user can change the password after it expires.
Use Single Sign-On with Clientless SSL VPN

SSO Using SAML 2.0

About SSO and SAML 2.0

The ASA supports SAML 2.0 so that Clientless VPN end users will be able to input their credentials only one time when they switch between Clientless VPN and other SAAS applications outside of the private network.

For instance, an enterprise customer has enabled PingIdentity as their SAML Identity Provider (IdP) and has accounts on Rally, Salesforce, Oracle OEM, Microsoft ADFS, onelogin, or Dropbox which have been SAML 2.0 SSO enabled. When you configure the ASA to support SAML 2.0 SSO as a Service Provider (SP), end users are able to sign in once and have access to all these services including Clientless VPN.

In addition, AnyConnect SAML support was added to allow an AnyConnect 4.4 client to access SAAS-based applications using SAML 2.0. AnyConnect 4.6 introduces an enhanced version of SAML integration with an embedded browser which replaces the native (external) browser integration from previous releases. The new enhanced version with embedded browser requires you to upgrade to AnyConnect 4.6 (or later) and ASA 9.7.1.24 (or later), 9.8.2.28 (or later), or 9.9.2.1 (or later).

The ASA is SP enabled when SAML is configured as the authentication method for a tunnel group, the default tunnel group or any other. The Clientless VPN end user initiates Single sign-on by accessing an enabled ASA or the SAML IdP. Each of these scenarios is described below.

SAML SP-initiated SSO

When the end user initiates login by accessing the ASA using Clientless VPN, sign-on behavior proceeds as follows:

1. When the Clientless VPN end user accesses or chooses a SAML enabled tunnel group, the end user will be redirected to the SAML IdP for Authentication. The user will be prompted unless the user access the group-url directly, in which case the redirect is silent.
   The ASA generates a SAML Authentication Request which the browser redirects to the SAML IdP.

2. The IdP challenges the end user for credential and the end user logs in. The entered credentials must satisfy the IdP authentication configuration.

3. The IdP Response is sent back to the browser and posted to the ASA's sign-in URL. The ASA verifies the response to complete the login.

SAML IdP-initiated SSL

When the user initiates login by accessing the IdP, sign-on behavior proceeds as follows:

1. An end user accesses the IdP. The IdP challenges the end user for credentials according to the IdP's authentication configuration. The end user submits credentials and logs in to the IdP.

2. In general, the end user gets a list of SAML enabled services that have been configured with the IdP. The end user chooses the ASA.

3. A SAML response is sent back to the browser, and posted to the ASA sign-in URL. The ASA verifies the response to complete the login.
Circle of Trust

The trust relationship between the ASA and the SAML Identity Provider is established through configured certificates (ASA trustpoints).

The trust relationship between the end user and SAML Identity Provider is established through the authentication configured on IdP.

SAML Timeouts

In SAML assertion, there are NotBefore and NotOnOrAfter as follows:

```xml
<saml:Conditions
NotBefore="2015-03-10T19:47:41Z" NotOnOrAfter="2015-03-10T20:47:41Z">
```

A SAML timeout configured on the ASA will override NotOnOrAfter if the sum of NotBefore and timeout is earlier than NotOnOrAfter. If NotBefore + timeout is later than NotOnOrAfter, then NotOnOrAfter will take effect.

The timeout should be very short to prevent the assertion from being re-used after the timeout. You must synchronize your ASA's Network Time Protocol (NTP) server with the IdP NTP server in order to use the SAML feature.

Support in Private Network

SAML 2.0-based service provider IdP is supported in a private network. When the SAML IdP is deployed in the private cloud, ASA and other SAML-enabled services are in peer positions, and all in the private network. With the ASA as a gateway between the user and services, authentication on IdP is handled with a restricted anonymous webvpn session, and all traffic between IdP and the user is translated. When the user logs in, the ASA modifies the session with the corresponding attributes and stores the IdP sessions. Then you can use service provider on the private network without entering credentials again.

The SAML IdP NameID attribute determines the user's username and is used for authorization, accounting, and VPN session database.

Note

You cannot exchange authentication information between private and public networks. If you use the same IdP for both internal and external service providers, you must authenticate separately. Internal-only IdP cannot be used with external services; external-only IdP cannot be used with service providers in the private network.

Guidelines and Limitations for SAML 2.0

- SAML 2.0 SSO support is a Clientless VPN feature, so it has the same limitation and allowances as Clientless VPN such as:
  - Multi-context mode and load balancing are not supported.
  - Active/Standby failover is supported, not Active/Active failover.
  - IPv4 and IPv6 sessions are supported.

- ASA supports SAML 2.0 Redirect-POST binding, which is supported by all SAML IdPs.

- The ASA functions as a SAML SP only. It cannot act as an Identity Provider in gateway mode or peer mode.
• This SAML SSO SP feature is a mutual exclusion authentication method. It cannot be used with AAA and certificate together.

• Features that are based on username/password authentication, certificate authentication, and KCD are not supported. For instance, username/password pre-filling feature, form-based Auto sign-on, Macro Substitution based Auto sign-on, KCD SSO, and so on.

• Having SAML authentication attributes available in DAP evaluation (similar to RADIUS attributes sent in RADIUS auth response from AAA server) is not supported.

• Existing Clientless VPN timeout settings still apply to SAML sessions.

• ASA administrators need to ensure clock synchronization between the ASA and the SAML IdP for proper handling of authentication assertions and proper timeout behavior.

• ASA administrators have the responsibility to maintain a valid signing certificate on both ASA and IdP considering the following:
  • The IdP signing certificate is mandatory when configuring an IdP on the ASA.
  • The ASA does not do a revocation check on the signing certificate received from the IdP.

• In SAML assertions, there are NotBefore and NotOnOrAfter conditions. The ASA SAML configured timeout interacts with these conditions as follows:
  • Timeout overrides NotOnOrAfter if the sum of NotBefore and timeout is earlier than NotOnOrAfter.
  • If NotBefore + timeout is later than NotOnOrAfter, then NotOnOrAfter takes effect.
  • If the NotBefore attribute is absent, the ASA denies the login request. If the NotOnOrAfter attribute is absent and SAML timeout is not set, ASA denies the login request.

• When using SAML with AnyConnect, follow these additional guidelines
  • Untrusted server certificates are not allowed in the embedded browser.
  • The embedded browser SAML integration is not supported in CLI or SBL modes.
  • SAML authentication established in a web browser is not shared with AnyConnect and vice versa.
  • Depending on the configuration, various methods are used when connecting to the headend with the embedded browser. For example, while AnyConnect might prefer an IPv4 connection over an IPv6 connection, the embedded browser might prefer IPv6, or vice versa. Similarly, AnyConnect may fall back to no proxy after trying proxy and getting a failure, while the embedded browser may stop navigation after trying proxy and getting a failure.
  • You must synchronize your ASA's Network Time Protocol (NTP) server with the IdP NTP server in order to use the SAML feature.
  • The VPN Wizard on ASDM does not currently support SAML configurations.
  • You cannot access internal servers with SSO after logging in using an internal IdP.
  • The SAML IdP NameID attribute determines the user's username and is used for authorization, accounting, and VPN session database.
Configure a SAML 2.0 Identity Provider (IdP)

Before you begin
Get the Sign-in and Sign-out URLs for your SAML (IdP) provider. You can get the URLs from the provider’s website, or they may provide that information in a metadata file.

Procedure

Step 1
Create a SAML identity provider in webvpn config mode and enter saml-idp sub-mode under webvpn.

```
[ no ] saml idp idp-entityID
```

`idp-entityID`—The SAML IdP entityID must contain 4 to 256 characters.

To remove a SAML IdP, use the `no` form of this command.

Step 2
Configure the IdP URLs.

```
url [ sign-in | sign-out ] value
```

`value`—This is the URL for signing into the IdP or the URL for redirecting to when signing out of the IdP. The `sign-in` URL is required, the `sign-out` URL is optional. The url value must contain 4 to 500 characters.

Step 3
(Optional) Configure the Clientless VPN base URL.

```
base-url URL
```

This URL is provided to third-party IdPs to redirect end users back to the ASA.

When base-url is configured, we use it as the base URL of the AssertionConsumerService and SingleLogoutService attribute in `show saml metadata`.

When base-url is not configured, the URL is determined by the ASA’s hostname and domain-name. For example, we use `https://ssl-vpn.cisco.com` when hostname is `ssl-vpn` and domain-name is `cisco.com`.

An error occurs if neither base-url nor the hostname/domain-name are configured when entering `show saml metadata`.

Step 4
Configure trustpoints between the IdP and SP (ASA).

```
trustpoint [ idp | sp ] trustpoint-name
```

`idp`—Specifies the trustpoint that contains the IdP certificate for the ASA to verify SAML assertions.

`sp`—Specifies the trustpoint that contains the ASA (SP)’s certificate for the IdP to verify ASA’s signature or encrypted SAML assertion.

`trustpoint-name`—Must be a previously configured trustpoint.

Step 5
(Optional) Configure SAML timeout.

```
timeout assertion timeout-in-seconds
```

If specified, this configuration overrides NotOnOrAfter if the sum of NotBefore and timeout-in-seconds is earlier than NotOnOrAfter.

If not specified, NotBefore and NotOnOrAfter in the assertion is used to determine the validity.
For a tunnel group with existing SAML IdP configured, any changes to the saml idp CLI under webvpn are only applied to the tunnel group when SAML is re-enabled for that particular tunnel group. After you configure the timeout, the updated timeout takes effect only after re-issuing the saml identity-provider CLI in the tunnel group webvpn-attributes.

**Note**
For a tunnel group with existing SAML IdP configured, any changes to the saml idp CLI under webvpn are only applied to the tunnel group when SAML is re-enabled for that particular tunnel group. After you configure the timeout, the updated timeout takes effect only after re-issuing the saml identity-provider CLI in the tunnel group webvpn-attributes.

**Step 6**
(Optional) Enable or disable (default setting) the signature in SAML request.

```
signature <value>
```

**Note**
With the upgrade to SSO 2.5.1, the default signing method changes from SHA1 to SHA256, and you can configure which signing method option you prefer by entering the `value` rsa-sha1, rsa-sha256, rsa-sha384, or rsa-sha512.

**Step 7**
(Optional) To set the flag determining that the IdP is an internal network, use the `internal` command. The ASA will then work in a gateway mode.

**Step 8**
Use `show webvpn saml idp` to view the configuration.

**Step 9**
Use `force re-authentication` to cause the identity provider to authenticate directly rather than rely on a previous security context when a SAML authentication request occurs. This setting is the default; therefore, to disable, use `no force re-authentication`.

---

**Example**
The following example configures an IdP named salesforce_idp and uses preconfigured trustpoints:

```
ciscoasa(config)# webvpn
ciscoasa(config-webvpn)#saml idp salesforce_idp

ciscoasa(config-webvpn-saml-idp)#url sign-in
https://asa-dev-ed.my.salesforce.com/idp/endpoint/HttpRedirect
ciscoasa(config-webvpn-saml-idp)#url sign-out
https://asa-dev-ed.my.salesforce.com/idp/endpoint/HttpRedirect

ciscoasa(config-webvpn-saml-idp)#trustpoint idp salesforce_trustpoint
ciscoasa(config-webvpn-saml-idp)#trustpoint sp asa_trustpoint

ciscoasa(config)#show webvpn saml idp
saml idp salesforce_idp
url sign-out https://asa-dev-ed.my.salesforce.com/idp/endpoint/HttpRedirect
trustpoint idp salesforce_trustpoint
trustpoint sp asa_trustpoint
```

The following web page shows an example of how to get URLs for OneLogin,

https://onelogin.zendesk.com/hc/en-us/articles/202767260-Configuring-SAML-for-Clarizen

The following web page is an example of how to use metadata to find the URLs from OneLogin.

**What to do next**
Apply SAML authentication to connection profiles, as described in Configure ASA as a SAML 2.0 Service Provider (SP), on page 392.
Configure ASA as a SAML 2.0 Service Provider (SP)

Follow this procedure to configure a particular tunnel group as a SAML SP.

Note
If you are using SAML authentication with AnyConnect 4.4 or 4.5 and you deploy ASA version 9.7.1.24 (or later), 9.8.2.28 (or later), or 9.9.2.1 (or later) (Release Date: 18-APR-2018), the defaulted SAML behavior is the embedded browser, which is not supported on AnyConnect 4.4 and 4.5. Therefore, you must enable the saml external-browser command in tunnel group configuration in order for AnyConnect 4.4 and 4.5 clients to authenticate with SAML using the external (native) browser.

The saml external-browser command is for migration purposes for those upgrading to AnyConnect 4.6 or later. Because of security limitations, use this solution only as part of a temporary migration while upgrading AnyConnect software. The command itself will be deprecated in the future.

Before you begin
The IdP must have been previously configured. See Configure a SAML 2.0 Identity Provider (IdP), on page 390.

Procedure

Step 1
In tunnel-group webvpn sub-mode, use the saml identify-provider command to assign an IdP.

[no] saml identify-provider idp-entityID

idp-entityID—Must be one of the existing IdPs previously configured.

To disable SAML SP, use the no form of this command.

Step 2
Enable SAML SP feature for the current tunnel group.

authentication saml

SAML authentication method is mutually exclusive.

Example

Example SAML 2.0 and Onelogin

Follow this example using your third party SAML 2.0 IdP in place of the Onelogin information and naming.

1. Set time synchronization between the IdP and the ASA(SP).
Obtain the IdP's SAML metadata from the IdP following procedures provided by your third party IdP.

Import the IdP's signing certificate into a trustpoint.

```
ciscoasa(config)# ntp server 209.244.0.4
```

```
ciscoasa(config)# crypto ca trustpoint onelogin
```
```
ciscoasa(config-ca-trustpoint)# enrollment terminal
```
```
ciscoasa(config-ca-trustpoint)# no ca-check
```
```
ciscoasa(config-ca-trustpoint)# crypto ca authenticate onelogin
```
```
Enter the base 64 encoded CA certificate.
End with the word "quit" on a line by itself
```
```
quit
```
```
INFO: Certificate has the following attributes:
Fingerprint: 85de3781 07388f5b d92d9d14 1e22a549
Do you accept this certificate? [yes/no]: yes
Trustpoint CA certificate accepted.
% Certificate successfully imported
```

Import the SP (ASA) signing PKCS12 into a trustpoint

```
ciscoasa(config)# crypto ca import asa_saml_sp pkcs12 password
```
```
Enter the base 64 encoded pkcs12.
End with the word "quit" on a line by itself:
```
```
quit
```
```
INFO: Import PKCS12 operation completed successfully
```

Add a SAML IdP:

```
ciscoasa(config-webvpn)# saml idp https://app.onelogin.com/saml/metadata/462950
```

Configure attributes under saml-idp sub-mode:

```
Configure the IdP sign-in URL and sign-out URL:
```
```
ciscoasa(config-webvpn-saml-idp)# url sign-in
```
```
ciscoasa(config-webvpn-saml-idp)# url sign-out
```
```
Configure the IdP trustpoint and the SP trustpoint
```
```
ciscoasa(config-webvpn-saml-idp)# trustpoint idp onelogin
```
```
ciscoasa(config-webvpn-saml-idp)# trustpoint sp asa_saml_sp
```
```
Configure the Clientless VPN base URL, SAML request signature and SAML assertion timeout:
```
```
ciscoasa(config-webvpn-saml-idp)# base-url https://172.23.34.222
```
```
ciscoasa(config-webvpn-saml-idp)# signature
```
```
ciscoasa(config-webvpn-saml-idp)# timeout assertion 7200
```

Configure an IdP for a tunnel group and enable SAML authentication.

```
ciscoasa(config)# webvpn
```
```
ciscoasa(config-webvpn)# tunnel-group-list enable
```
```
ciscoasa(config)# tunnel-group cloud_idp_onelogin type remote-access
```
```
ciscoasa(config)# tunnel-group cloud_idp_onelogin webvpn-attributes
```
```
ciscoasa(config-tunnel-webvpn)# group-alias cloud_idp enable
```
```
ciscoasa(config-tunnel-webvpn)# saml identity-provider
```
```
https://app.onelogin.com/saml/metadata/462950
```

Show the ASA's SAML SP metadata:

```
You can get the ASA's SAML SP metadata from
https://172.23.34.222/saml/sp/metadata/cloud_idp_onelogin.
In the URL, cloud_idp_onelogin is the tunnel group name.
```

9. Configure a SAML SP on your third party IdP following procedures provided by your third party IdP.

**Troubleshooting SAML 2.0**

Use `debug webvpn saml value` to debug SAML 2.0 behavior. The following SAML messages will be displayed depending on the `value`:

- 8 — errors
- 16 — warnings and errors
- 128 or 255 — debug, warnings, and errors

**Configure SSO with HTTP Basic or NTLM Authentication**

This section describes single sign-on with HTTP Basic or NTLM authentication. You can configure the ASA to implement SSO using either or both of these methods. The `auto-sign-on` command configures the ASA to automatically pass Clientless SSL VPN user login credentials (username and password) on to internal servers. You can enter multiple `auto-sign-on` commands. The ASA processes them according to the input order (early commands take precedence). You specify the servers to receive the login credentials using either IP address and IP mask, or URI mask.

Use the `auto-sign-on` command in any of three modes: Clientless SSL VPN configuration, Clientless SSL VPN group-policy mode, or Clientless SSL VPN username mode. Username supersedes group, and group supersedes global. Choose the mode with the required scope of authentication:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>webvpn configuration</td>
<td>All Clientless SSL VPN users globally.</td>
</tr>
<tr>
<td>webvpn group-policy configuration</td>
<td>A subset of Clientless SSL VPN users defined by a group policy.</td>
</tr>
<tr>
<td>webvpn username configuration</td>
<td>An individual user of Clientless SSL VPN.</td>
</tr>
</tbody>
</table>

**Examples**

- Configure auto-sign-on for all users of Clientless SSL VPN to servers with IP addresses ranging from 10.1.1.0 to 10.1.1.255 using NTLM authentication:

  `hostname(config-webvpn)# auto-sign-on allow ip 10.1.1.1 255.255.255.0 auth-type ntlm`

- Configure auto-sign-on for all users of Clientless SSL VPN, using basic HTTP authentication, to servers defined by the URI mask `https://*.example.com/*`:

  `hostname(config-webvpn)# auto-sign-on allow uri https://*.example.com/* auth-type`

- Configure auto-sign-on for Clientless SSL VPN sessions associated with the ExamplePolicy group policy, using either basic or NTLM authentication, to servers defined by the URI mask:

  `hostname(config)# group-policy ExamplePolicy attributes
  hostname(config-group-policy)# webvpn
  hostname(config-group-webvpn)# auto-sign-on allow uri https://*.example.com/* auth-type`
Configure SSO with the HTTP Form Protocol

This section describes using the HTTP Form protocol for SSO. HTTP Form protocol is an approach to SSO authentication that can also qualify as a AAA method. It provides a secure method for exchanging authentication information between users of Clientless SSL VPN and authenticating Web servers. You can use it in conjunction with other AAA servers such as RADIUS or LDAP servers.

The ASA again serves as a proxy for users of Clientless SSL VPN to an authenticating Web server but, in this case, it uses HTTP Form protocol and the POST method for requests. You must configure the ASA to send and receive form data.

To configure SSO with the HTTP protocol correctly, you must have a thorough working knowledge of authentication and HTTP protocol exchanges.

As a common protocol, it is applicable only when the following conditions are met for the Web server application used for authentication:

- The authentication cookie must be set for successful request and not set for unauthorized logons. In this case, ASA cannot distinguish successful from failed authentication.

The following figure illustrates the SSO authentication steps, described below:

*Figure 10: SSO Authentication Using HTTP Forms*
1. A user of Clientless SSL VPN first enters a username and password to log on to the Clientless SSL VPN server on the ASA.

2. The Clientless SSL VPN server acts as a proxy for the user and forwards the form data (username and password) to an authenticating Web server using a POST authentication request.

3. If the authenticating Web server approves the user data, it returns an authentication cookie to the Clientless SSL VPN server where it is stored on behalf of the user.

4. The Clientless SSL VPN server establishes a tunnel to the user.

5. The user can now access other websites within the protected SSO environment without re-entering a username and password.

While you would expect to configure form parameters that let the ASA include POST data such as the username and password, you initially may not be aware of additional hidden parameters that the Web server requires. Some authentication applications expect hidden data which is neither visible to nor entered by the user. You can, however, discover hidden parameters the authenticating Web server expects by making a direct authentication request to the Web server from your browser without the ASA in the middle acting as a proxy. Analyzing the Web server response using an HTTP header analyzer reveals hidden parameters in a format similar to the following:

\[
\text{<param name>=<URL encoded value>&<param name>=<URL encoded>}
\]

Some hidden parameters are mandatory and some are optional. If the Web server requires data for a hidden parameter, it rejects any authentication POST request that omits that data. Because a header analyzer does not tell you if a hidden parameter is mandatory or not, we recommend that you include all hidden parameters until you determine which are mandatory.

To configure SSO with the HTTP Form protocol, you must perform the following:

- Configure the uniform resource identifier on the authenticating Web server to receive and process the form data (action-uri).
- Configure the username parameter (user-parameter).
- Configure the user password parameter (password-parameter).

You may also need to do the following tasks depending upon the requirements of authenticating Web server:

- Configure a starting URL if the authenticating Web server requires a pre-login cookie exchange (start-url).
- Configure any hidden authentication parameters required by the authenticating Web server (hidden-parameter).
- Configure the name of an authentication cookie set by the authenticating Web server (auth-cookie-name).

Procedure

**Step 1**
Switch to the aaa-server-host configuration mode:

\[\text{aaa-server-host}\]

**Step 2**
If the authenticating Web server requires it, specify the URL from which to retrieve a pre-login cookie from the authenticating Web server:

\[\text{start-url}\]
Example:

```
hostname(config)# aaa-server testgrp1 protocol http-form
hostname(config)# aaa-server testgrp1 host 10.0.0.2
hostname(config-aaa-server-host)# start-url http://example.com/east/Area.do?Page-Grp1
```

This example specifies the authenticating Web server URL http://example.com/east/Area.do?Page-Grp1 in the testgrp1 server group with an IP address of 10.0.0.2.

**Step 3** Specify a URI for an authentication program on the authenticating Web server:

**action-uri**

**Example:**

```
&REALMOID=06-000a1311-a828-1185-ab41-8333b16a0008&GUID=&SMAUTHREASON=0&METHOD=GET&SMAGENTNA
ME=$SM$5Fzmjnk3DRNwNjk2KcqVCFbIrNT9%2bJ0H0KpshFtg6rBlU2PkkHqLw%3d%3dTARGET=https%3A%2F%2F
auth.example.com
```

To specify this action URI, enter the following commands:

```
hostname(config-aaa-server-host)# action-uri http://www.example.com/auth/index.htm
hostname(config-aaa-server-host)# action-uri l/appdir/authc/forms/MCOlogin.fcc?TYP
hostname(config-aaa-server-host)# action-uri 554433&REALMOID=06-000a1311-a828-1185
hostname(config-aaa-server-host)# action-uri =ab41-8333b16a0008&GUID=&SMAUTHREASON
hostname(config-aaa-server-host)# action-uri =0&METHOD=GET&SMAGENTNAME=$SM$zFzmjnk
hostname(config-aaa-server-host)# action-uri 3DRNwNjk2KcqVCFbIrNT9%2bJ0H0KpshFtg6r
hostname(config-aaa-server-host)# action-uri B1U2PkkHqLw%3d%3dTARGET=https%3A%2F
hostname(config-aaa-server-host)# action-uri %2Fauth.example.com
```

A URI can be entered on multiple, sequential lines. The maximum number of characters per line is 255. The maximum number of characters for a complete URI is 2048.

You must include the hostname and protocol in the action URI. In this example, these appear at the start of the URI in http://www.example.com.

**Step 4** Configure the userid username parameter for the HTTP POST request:

**user-parameter**

**Example:**

```
hostname(config-aaa-server-host)# user-parameter userid
```

**Step 5** Configure the user_password userpassword parameter for the HTTP POST request:

**password-parameter**

**Example:**

```
hostname(config-aaa-server-host)# password-parameter user_password
```

**Step 6** Specify hidden parameters for exchange with the authenticating Web server:

**hidden-parameter**
Example:

hostname(config)# aaa-server testgrp1 host example.com

This example shows an example hidden parameter excerpted from a POST request. This hidden parameter includes four form entries and their values, separated by &. The entries and their values are:

- SMENC with a value of ISO-8859-1.
- SMLOCALE with a value of US-EN.
- %3FEMCOPageCode%3DENG.
- smauthreason with a value of 0.

**Step 7** Specify the name for the authentication cookie:

```plain
auth-cookie-name cookie-name
```

**Example:**

hostname(config-aaa-server-host)# auth-cookie-name SsoAuthCookie

This example specifies an authentication cookie name of SsoAuthCookie.

**Step 8** Switch to tunnel-group general-attributes configuration mode:

```plain
tunnel-group general-attributes
```

**Step 9** Configure a tunnel-group to use the SSO server configured in the previous steps:

```plain
authentication-server-group
testgrp1
```

**Example:**

hostname(config)# tunnel-group testgroup general-attributes
hostname(config-tunnel-general)#authentication-server-group testgrp1

This example configures the tunnel-group named /testgroup/ to use the SSO server(s) named /testgrp1/”.

**Step 10** Switch to AAA server host configuration mode:

```plain
aaa-server-host
```

**Step 11** Specify the name for the authentication cookie:

```plain
auth-cookie-name cookie-name
```

**Example:**

hostname(config-aaa-server-host)# auth-cookie-name SsoAuthCookie
This example specifies an authentication cookie name of SsoAuthCookie.

**Step 12**
Switch to tunnel-group general-attributes mode:
```
tunnel-group general-attributes
```

**Step 13**
Configure a tunnel-group to use the SSO server configured in the previous steps:
```
authentication-server-group group
```

**Example:**
```
hostname(config)# tunnel-group testgroup general-attributes
hostname(config-tunnel-general)# authentication-server-group testgrp1
```

This example configures a tunnel-group named /testgroup/ to use the SSO server(s) named /testgrp1/”.

---

### Gather HTTP Form Data

This section presents the steps for discovering and gathering necessary HTTP Form data. If you do not know what parameters the authenticating Web server requires, you can gather parameter data by analyzing an authentication exchange.

**Before you begin**

These steps require a browser and an HTTP header analyzer.

**Procedure**

**Step 1**
Start your browser and HTTP header analyzer, and connect directly to the Web server login page without going through the ASA.

**Step 2**
After the Web server login page has loaded in your browser, examine the login sequence to determine if a cookie is being set during the exchange. If the Web server has loaded a cookie with the login page, configure this login page URL as the **start-URL**.

**Step 3**
Enter the username and password to log on to the Web server, and press Enter. This action generates the authentication POST request that you examine using the HTTP header analyzer.

An example POST request—with host HTTP header and body—follows:

```
POST /emco/myemco/authc/forms/MCologin.fcc?TYPE=33554433&REALMOID=06-000430e1-7443-125c-ac05-83846dc90034&GUID=&SMAUTHREASON=0&METHOD=GET&SMAGENTNAME=SSM$5FZjnk3DRNwNjk2KcqVCfbIrNT9%2bJ0H0KphFtg6rBIUv2PxxHqLw%3d3d&TARGET=https%3A%2F%2Fwww.example.com%2Femco%2Fmyemco%2FHTTP/1.1
Host: www.example.com
(BODY)
```

---

399
Step 4  Examine the POST request and copy the protocol, host, and the complete URL to configure the action-uri parameter.

Step 5  Examine the POST request body and copy the following:

a) Username parameter. In the preceding example, this parameter is \textit{USERID}, not the value \textit{anyuser}.

b) Password parameter. In the preceding example, this parameter is \textit{USER_PASSWORD}.

c) Hidden parameter.

This parameter is everything in the POST body except the username and password parameters. In the preceding example, the hidden parameter is:

\texttt{SMENC=ISO-8859-1\&SMLOCALE=US-EN\&target=https\%3A\%2F\%2F\%2Fwww.example.com\%2Femco\%2Fmyemco\%2F\&smauthreason=0}

The following figure highlights the action URI, hidden, username and password parameters within sample output from an HTTP analyzer. This is only an example; output varies widely across different websites.

\textit{Figure 11: Action-uri, hidden, username and password parameters}

<table>
<thead>
<tr>
<th></th>
<th>Action URI parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Hidden parameters</td>
</tr>
<tr>
<td>2</td>
<td>Username and password parameters</td>
</tr>
</tbody>
</table>

Step 6  If you successfully log on to the Web server, examine the server response with the HTTP header analyzer to locate the name of the session cookie set by the server in your browser. This is the \texttt{auth-cookie-name} parameter.
In the following server response header, the name of the session cookie is SMSESSION. You just need the name, not the value.

```
Set-Cookie: SMSESSION=yN4Yp5hHVNDgs4FT8dn7+Rwev41haE49XlKc1ltwie0ggnjibhTkUnR8XWP3hrDH6FZ
```

The following figure shows an example of authorization cookies in HTTP analyzer output. This is only an example; output varies widely across different websites.

**Figure 12: Authorization Cookies in Sample HTTP Analyzer Output**

In some cases, the server may set the same cookie regardless of whether the authentication was successful or not, and such a cookie is unacceptable for SSO purposes. To confirm that the cookies are different, repeat Step 1 through Step 6 using invalid login credentials and then compare the “failure” cookie with the “success” cookie. You now have the necessary parameter data to configure the ASA for SSO with HTTP Form protocol.

**Configure SSO for Plug-ins**

Plug-ins support single sign-on (SSO). They use the same credentials (username and password) entered to authenticate the Clientless SSL VPN session. Because the plug-ins do not support macro substitution, you do
not have the option to perform SSO on different fields, such as the internal domain password or the attribute on a RADIUS or LDAP server.

To configure SSO support for a plug-in, you install the plug-in and add a bookmark entry to display a link to the server, specifying SSO support using the cisco_sso=1 parameter. The following examples show plug-in bookmarks enabled for SSO:

```
ssh://ssh-server/?cisco_sso=1
rdp://rdp-server/?Parameter1=value&Parameter2=value&cisco_sso=1
```

### Configure SSO with Macro Substitution

This section describes using macro substitution for SSO. Configuring SSO with macro substitution allows for you to inject certain variables into bookmarks to substitute for dynamic values.

**Note**

Smart tunnel bookmarks support auto-sign-on but not variable substitution. For example, a SharePoint bookmark configured for smart tunnel uses the same username and password credentials to log on to the application as the credentials used to log on to Clientless SSL VPN. (This SSO functionality applies only to clientless VPN and not to AnyConnect.) You can use variable substitutions and auto sign-on simultaneously or separately.

You can now use bookmarks with macro substitutions for auto sign-on on some Web pages. The former POST plug-in approach was created so that administrators could specify a POST bookmark with sign-on macros and receive a kick-off page to load prior to posting the POST request. This POST plug-in approach eliminated those requests that required the presence of cookies or other header items. Now an an administrator determines the pre-load page and URL, which specifies where the post login request is sent. A pre-load page enables an endpoint browser to fetch certain information that is sent along to the webserver or Web application rather than just using a POST request with credentials.

The following variables (or macros) allow for substitutions in bookmarks and forms-based HTTP POST operations:

- `CSCO_WEBVPN_USERNAME`—User login ID
- `CSCO_WEBVPN_PASSWORD`—User login password
- `CSCO_WEBVPN_INTERNAL_PASSWORD`—User internal (or domain) password. This cached credential is not authenticated against a AAA server. When you enter this value, the security appliance uses it as the password for auto sign-on, instead of the password/primary password value.

**Note**

You cannot use any of these three variables in GET-based http(s) bookmarks. Only POST-based http(s) and cifs bookmarks can use these variables.

- `CSCO_WEBVPN_CONNECTION_PROFILE`—User login group drop-down (connection profile alias)
- `CSCO_WEBVPN_MACRO1`—Set with the RADIUS-LDAP Vendor Specific Attribute (VSA). If you are mapping from LDAP with an ldap-attribute-map command, use the WebVPN-Macro-Substitution-Value1 Cisco attribute for this macro. See the Active Directory ldap-attribute-mapping examples at http://www.cisco.com/en/US/docs/security/asa/asa83/configuration/guide/ref_extserver.html#wp1572118.
The CSCO_WEBVPN_MACRO1 macro substitution with RADIUS is performed by VSA#223.

<table>
<thead>
<tr>
<th>WebVPN-Macro-Value1</th>
<th>223</th>
<th>String</th>
<th>Single</th>
<th>Unbounded</th>
</tr>
</thead>
<tbody>
<tr>
<td>WebVPN-Macro-Value2</td>
<td>224</td>
<td>String</td>
<td>Single</td>
<td>Unbounded</td>
</tr>
</tbody>
</table>

A value such as www.cisco.com/email dynamically populates a bookmark on the Clientless SSL VPN portal, such as https://CSCO_WEBVPN_MACRO1 or https://CSCO_WEBVPN_MACRO2 for the particular DAP or group policy.

- CSCO_WEBVPN_MACRO2—set with RADIUS-LDAP Vendor Specific Attribute (VSA). If you are mapping from LDAP with an ldap-attribute-map command, use the WebVPN-Macro-Substitution-Value2 Cisco attribute for this macro. See the Active Directory ldap-attribute-mapping examples at http://www.cisco.com/en/US/docs/security/asa/asa83/configuration/guide/ref_extserver.html#wp1572118.

The CSCO_WEBVPN_MACRO2 macro substitution with RADIUS is performed by VSA#224.

Each time Clientless SSL VPN recognizes one of these six strings in an end-user request (in the form of a bookmark or Post Form), it replaces the string with the user-specified value and then passes the request to a remote server.

If the lookup of the username and password fails on the ASA, an empty string is substituted, and the behavior converts back as if no auto sign-in is available.

## Username and Password Requirements

Depending on your network, during a remote session users may have to log on to any or all of the following: the computer itself, an Internet service provider, Clientless SSL VPN, mail or file servers, or corporate applications. Users may have to authenticate in many different contexts, requiring different information, such as a unique username, password, or PIN. The following table lists the type of usernames and passwords that Clientless SSL VPN users may need to know:

<table>
<thead>
<tr>
<th>Login Username/Password Type</th>
<th>Entered When</th>
</tr>
</thead>
<tbody>
<tr>
<td>Computer</td>
<td>Access the computer</td>
</tr>
<tr>
<td>Internet Service Provider</td>
<td>Access the Internet</td>
</tr>
<tr>
<td>Clientless SSL VPN</td>
<td>Access remote network</td>
</tr>
<tr>
<td>File Server</td>
<td>Access remote file server</td>
</tr>
<tr>
<td>Corporate Application Login</td>
<td>Access firewall-protected internal server</td>
</tr>
<tr>
<td>Mail Server</td>
<td>Access remote mail server via Clientless SSL VPN</td>
</tr>
</tbody>
</table>
Communicate Security Tips

Advise users to always click the logout icon on the toolbar to close the Clientless SSL VPN session. (Closing the browser window does not close the session.)

Clientless SSL VPN ensures the security of data transmission between the remote PC or workstation and the ASA on the corporate network. Advise users that using Clientless SSL VPN does not ensure that communication with every site is secure. If a user then accesses a non-HTTPS Web resource (located on the Internet or on the internal network), the communication from the corporate ASA to the destination Web server is not private because it is not encrypted.

Configure Remote Systems to Use Clientless SSL VPN Features

This section describes how to set up remote systems to use Clientless SSL VPN.

- About Clientless SSL VPN, on page 404
- Prerequisites for Clientless SSL VPN, on page 405
- Use the Clientless SSL VPN Floating Toolbar, on page 405
- Browse the Web, on page 405
- Browse the Network (File Management), on page 406
- Use Port Forwarding, on page 407
- Use email Via Port Forwarding, on page 408
- Use email Via Web Access, on page 409
- Use email Via email Proxy, on page 409
- Use Smart Tunnel, on page 409

You may configure user accounts differently and different Clientless SSL VPN features can be available to each user.

About Clientless SSL VPN

You can connect to the internet using any supported connection including:

- Home DSL, cable, or dial-ups.
- Public kiosks.
- Hotel hotspots.
- Airport wireless nodes.
- Internet cafes.
Prerequisites for Clientless SSL VPN

- Cookies must be enabled on the browser in order to access applications via port forwarding.
- You must have a URL for Clientless SSL VPN. The URL must be an https address in the following form: https://address, where address is the IP address or DNS hostname of an interface of the ASA (or load balancing cluster) on which SSL VPN is enabled. For example, https://cisco.example.com.
- You must have a Clientless SSL VPN username and password.

Note

Clientless SSL VPN supports local printing, but it does not support printing through the VPN to a printer on the corporate network.

Use the Clientless SSL VPN Floating Toolbar

A floating toolbar is available to simplify the use of Clientless SSL VPN. The toolbar lets you enter URLs, browse file locations, and choose preconfigured Web connections without interfering with the main browser window.

The floating toolbar represents the current Clientless SSL VPN session. If you click the Close button, the ASA prompts you to close the Clientless SSL VPN session.

Tip

To paste text into a text field, use Ctrl-V. (Right-clicking is switched off on the toolbar displayed during the Clientless SSL VPN session.)

Note

If you configure your browser to block popups, the floating toolbar cannot display.

Browse the Web

Using Clientless SSL VPN does not ensure that communication with every site is secure. See Communicate Security Tips, on page 404.

The look and feel of Web browsing with Clientless SSL VPN may be different from what users are accustomed to. For example:
- The title bar for Clientless SSL VPN appears above each Web page.
- You access websites by:
• Entering the URL in the **Enter Web Address** field on the Clientless SSL VPN Home page
• Clicking on a preconfigured website link on the Clientless SSL VPN Home page
• Clicking a link on a webpage accessed via one of the previous two methods
• You need the username and password for protected websites

Depending on how you configured a particular account, it may be that:
• Some websites are blocked
• Only the websites that appear as links on the Clientless SSL VPN Home page are available

Also, depending on how you configured a particular account, it may be that:
• Some websites are blocked
• Only the websites that appear as links on the Clientless SSL VPN Home page are available

**Browse the Network (File Management)**

Users may not be familiar with how to locate their files through your organization network.

---

**Note**

Do not interrupt the **Copy File to Server** command or navigate to a different screen while the copying is in progress. Interrupting the operation can cause an incomplete file to be saved on the server.

It is important to remember that
• You must configure file permissions for shared remote access.
• You must have the server names and passwords for protected file servers.
• You must have the domain, workgroup, and server names where folders and files reside.

---

**Note**

Only shared folders and files are accessible via Clientless SSL VPN.

**Use the Remote File Explorer**

The Remote File Explorer provides the user with a way to browse the corporate network from their Web browser. When the users clicks the Remote File System icon on the Cisco SSL VPN portal page, an applet is launched on the user’s system displaying the remote file system in a tree and folder view.

---

**Note**

This functionality requires that the Oracle Java Runtime Environment (JRE) is installed on the user’s machine and that Java is enabled in the Web browser. Launching remote files requires JRE 8u131 b11, 7u141 b11, 6u151 b10, or later.
The browser enables the user to:

- Browse the remote file system.
- Rename files.
- Move or copy files within the remote file system and between the remote and local file systems.
- Perform bulk uploads and downloads of files.

You can download a file by clicking it in the browser, selecting Operations > Download, and providing a location and name to save the file in the Save dialog.

You can upload a file by clicking the destination folder, selecting Operations > Upload, and providing the location and name of the file in the Open dialog.

This functionality has the following restrictions:

- The user cannot view sub-folders for which they are not permitted access.
- Files that the user is not permitted to access cannot be moved or copied, even though they are displayed in the browser.
- The maximum depth of nested folders is 32.
- The tree view does not support drag and drop copying.
- When moving files between multiple instances of the Remote File Explorer, all instances must be exploring the same server (root share).
- The Remote File Explorer can display a maximum of 1500 files and folders in a single folder. If a folder exceeds this limit the folder cannot be displayed.

**Use Port Forwarding**

To use port forwarding, you must configure the client application, using the server’s locally mapped IP address and port number.

- Users should always close the Application Access window when they finish using applications by clicking the **Close** icon. Failure to quit the window properly can cause Application Access or the applications themselves to be switched off.

**Before you begin**

- On macOS, only Safari 11 or older browsers supports this feature.
- You must have client applications installed.
- You must have Cookies enabled on the browser.
- You must have administrator access on the PC if you use DNS names to specify servers, because modifying the hosts file requires it.
- You must have Oracle Java Runtime Environment (JRE) installed.

If JRE is not installed, a pop-up window displays, directing users to a site where it is available. On rare occasions, the port forwarding applet fails with Java exception errors. If this happens, do the following:
1. Clear the browser cache and close the browser.
2. Verify that no Java icons are in the computer task bar.
3. Close all instances of Java.
4. Establish a Clientless SSL VPN session and launch the port forwarding Java applet.

• You must have JavaScript enabled on the browser. By default, it is enabled.
• If necessary, you must configure client applications.

---

**Note**
The Microsoft Outlook client does not require this configuration step. All non-Windows client applications require configuration. To determine if configuration is necessary for a Windows application, check the value of the Remote Server field. If the Remote Server field contains the server hostname, you do not need to configure the client application. If the Remote Server field contains an IP address, you must configure the client application.

---

**Procedure**

**Step 1**
Start a Clientless SSL VPN session and click the Application Access link on the Home page. The Application Access window appears.

**Step 2**
In the Name column, find the name of the server to use, then identify its corresponding client IP address and port number (in the Local column).

**Step 3**
Use this IP address and port number to configure the client application. Configuration steps vary for each client application.

**Note**
Clicking a URL (such as one in an -email message) in an application running over a Clientless SSL VPN session does not open the site over that session. To open a site over the session, paste the URL into the Enter Clientless SSL VPN (URL) Address field.

---

**Use email Via Port Forwarding**

To use email, start Application Access from the Clientless SSL VPN home page. The mail client is then available for use.

---

**Note**
If you are using an IMAP client and you lose your mail server connection or are unable to make a new connection, close the IMAP application and restart Clientless SSL VPN.

You must fulfill requirements for application access and other mail clients.
Use email Via Web Access

The following email applications are supported:

• Microsoft Outlook Web App to Exchange Server 2010.
  OWA requires Internet Explorer 11 (or later) or the latest Firefox.
• Microsoft Outlook Web Access to Exchange Server 2013.
  For best results, use OWA on Internet Explorer 11 (or later) or the latest Firefox.
• Lotus iNotes

Note: You must have the web-based email product installed and other web-based email applications should also work, but we have not verified them.

Use email Via email Proxy

See the instructions and examples for your mail application in Use Email over Clientless SSL VPN, on page 339.

Before You Begin

You must have the SSL-enabled mail application installed.

Do not set the ASA SSL version to TLSv1 Only. Outlook and Outlook Express do not support TLS.

You must have your mail application properly configured.

Other SSL-enabled clients should also work, but we have not verified them.

Use Smart Tunnel

Administration privileges are not required to use Smart Tunnel.

Note: Java is not automatically downloaded for you as it is in port forwarder.

• Smart tunnel requires either ActiveX or JRE on Windows and Java Web Start on Mac OS X.
• You must ensure cookies enabled on the browser.
• You must ensure JavaScript is enabled on the browser.
• Mac OS X does not support a front-side proxy.
• Use only supported operating systems and browsers.
• Only TCP socket-based applications are supported.
Use Smart Tunnel
Clientless SSL VPN with Mobile Devices

Use Clientless SSL VPN with Mobile Devices

You can access Clientless SSL VPN from your Pocket PC or other certified mobile device. Neither the ASA administrator nor the Clientless SSL VPN user need do anything special to use Clientless SSL VPN with a certified mobile device.

Some differences in the mobile device version of Clientless SSL VPN exist:

- A banner Web page replaces the popup Clientless SSL VPN window.
- An icon bar replaces the standard Clientless SSL VPN floating toolbar. This bar displays the Go, Home and Logout buttons.
- The Show Toolbar icon is not included on the main Clientless SSL VPN portal page.
- Upon Clientless SSL VPN logout, a warning message provides instructions for closing the PIE browser properly. If you do not follow these instructions and you close the browser window in the common way, PIE does not disconnect from Clientless SSL VPN or any secure website that uses HTTPS.

Restrictions of Clientless SSL VPN with Mobile

- Clientless SSL VPN supports OWA 2010 Basic Authentication. If Basic Authentication is not configured on an OWA server and a Clientless SSL VPN user attempts to access that server, access is denied.
- Unsupported Clientless SSL VPN features:
  - Application Access and other Java-dependent features.
  - HTTP proxy.
  - The Citrix Metaframe feature (if the PDA does not have the corresponding Citrix ICA client software).
Restrictions of Clientless SSL VPN with Mobile
Customizing Clientless SSL VPN

- Clientless SSL VPN End User Setup, on page 413
- Customize Bookmark Help, on page 426

Clientless SSL VPN End User Setup

This section is for the system administrator who sets up Clientless SSL VPN for end users. It describes how to customize the end-user interface and summarizes configuration requirements and tasks for a remote system. It specifies information to communicate to users to get them started using Clientless SSL VPN.

Define the End User Interface

The Clientless SSL VPN end user interface consists of a series of HTML panels. A user logs on to Clientless SSL VPN by entering the IP address of an ASA interface in the format https://address. The first panel that displays is the login screen.

View the Clientless SSL VPN Home Page

After the user logs in, the portal page opens.

The home page displays all of the Clientless SSL VPN features you have configured, and its appearance reflects the logo, text, and colors you have selected. This sample home page includes all available Clientless SSL VPN features with the exception of identifying specific file shares. It lets users browse the network, enter URLs, access specific websites, and use Application Access (port forwarding and smart tunnels) to access TCP applications.

View the Clientless SSL VPN Application Access Panel

To start port forwarding or smart tunnels, a user clicks the Go button in the Application Access box. The Application Access window opens and displays the TCP applications configured for this Clientless SSL VPN connection. To use an application with this panel open, the user starts the application in the normal way.

Note

A stateful failover does not retain sessions established using Application Access. Users must reconnect following a failover.
View the Floating Toolbar

The floating toolbar shown in the following figure represents the current Clientless SSL VPN session.

*Figure 13: Clientless SSL VPN Floating Toolbar*

Moves the toolbar to the other side of the browser
Logs the user out
Displays the portal home page
Launches a dialog box for URL entry

Be aware of the following characteristics of the floating toolbar:

- The toolbar lets you enter URLs, browse file locations, and choose preconfigured Web connections without interfering with the main browser window.
- If you configure your browser to block popups, the floating toolbar cannot display.
- If you close the toolbar, the ASA prompts you to end the Clientless SSL VPN session.

Customize Clientless SSL VPN Pages

You can change the appearance of the portal pages displayed to Clientless SSL VPN users. This includes the Login page displayed to users when they connect to the security appliance, the Home page displayed to users after the security appliance authenticates them, the Application Access window displayed when users launch an application, and the Logout page displayed when users log out of Clientless SSL VPN sessions.

After you customize the portal pages, you can save your customization and apply it to a specific connection profile, group policy, or user. The changes do not take effect until you reload the ASA, or you switch off and then enable clientless SSL.

You can create and save many customization objects, enabling the security appliance to change the appearance of portal pages for individual users or groups of users.

Information About Customization

The ASA uses customization objects to define the appearance of user screens. A customization object is compiled from an XML file which contains XML tags for all the customizable screen items displayed to remote users. The ASA software contains a customization template that you can export to a remote PC. You can edit this template and import the template back into the ASA as a new customization object.
When you export a customization object, an XML file containing XML tags is created at the URL you specify. The XML file created by the customization object named Template contains empty XML tags and provides the basis for creating new customization objects. This object cannot be changed or deleted from cache memory but can be exported, edited, and imported back into the ASA as a new customization object.

**Customization Objects, Connection Profiles, and Group Policies**

Initially, when a user first connects, the default customization object (named DfltCustomization) identified in the connection profile (tunnel group) determines how the logon screen appears. If the connection profile list is enabled, and the user selects a different group which has its own customization, the screen changes to reflect the customization object for that new group.

After the remote user is authenticated, the screen appearance is determined by whether a customization object has been assigned to the group policy.

### Export a Customization Template

When you export a customization object, an XML file is created at the URL you specify. The customization template (named Template) contains empty XML tags and provides the basis for creating new customization objects. This object cannot be changed or deleted from cache memory but can be exported, edited, and imported back into the ASA as a new customization object.

#### Procedure

**Step 1**
Export a customization object and make changes to the XML tags:
```
export webvpn customization
```

**Step 2**
Import the file as a new object:
```
import webvpn customization
```

**Example:**
The following example exports the default customization object (DfltCustomization) and creates the XML file named dflt_custom.

```
hostname# export webvpn customization DfltCustomization tftp://209.165.200.225/dflt_custom
!!!!!!!!!!!!!!INFO: Customization object 'DfltCustomization' was exported to tftp://10.86.240.197/dflt_custom
hostname#
```

### Edit the Customization Template

This section shows the contents of the customization template and has convenient figures to help you quickly choose the correct XML tag and make changes that affect the screens.

You can use a text editor or an XML editor to edit the XML file. The following example shows the XML tags of the customization template. Some redundant tags have been removed for easier viewing:

```
<custom>
```
Edit the Customization Template

Clientless SSL VPN

For your own security, please:

<li>Clear the browser’s cache</li>
<li>Delete any downloaded files</li>
<li>Close the browser's window</li>

</pane>
<url-lists>
<mode>group</mode>
</url-lists>
<home-page>
<mode>standard</mode>
</url>
</home-page>
</portal>
</custom>
```

The following figure shows the Language Selector drop-down list that is available on the Logon page, and the XML tags for customizing this feature. All these tags are nested within the higher-level `<auth-page>` tag.

**Figure 15: Language Selector on Logon Screen and Associated XML Tags**

The following figure shows the Information Panel that is available on the Logon page, and the XML tags for customizing this feature. This information can appear to the left or right of the login box. These tags are nested within the higher-level `<auth-page>` tag.
The following figure shows the Portal page and the XML tags for customizing this feature. These tags are nested within the higher-level `<auth-page>` tag.

**Figure 17: Portal Page and Associated XML Tags**

After you edit and save the XML file, import it into the cache memory of the ASA. When you import the customization object, the ASA checks the XML code for validity. If the code is valid, the ASA stores the object in a hidden location in cache memory.

```bash
import webvpn customization
```

The following example shows importing the customization object `General.xml` from the URL `209.165.201.22/customization` and naming it `custom1`:
hostname# import webvpn customization custom1
tftp://209.165.201.22/customization/General.xml
Accessing tftp://209.165.201.22/customization/General.xml...
Writing file disk0:/csco_config/97/custom1...
329994 bytes copied in 5.350 secs (65998 bytes/sec)

Apply Customizations to Connection Profiles, Group Policies, and Users

After you create a customization, you can apply the customization to a connection profile (tunnel group), a group, or a user, with the customization command. The options displayed with this command are different depending on the mode you are in.

Procedure

Step 1 Switch to Clientless SSL VPN configuration mode:
webvpn

Step 2 Switch to either tunnel-group, group-policy, or username Clientless SSL VPN configuration:
tunnel-group webvpn OR group-policy webvpn OR username webvpn

Step 3 Apply a customization to a connection profile with name as the name of a customization to apply to the connection profile:
customization name

Or apply a customization to a group or user. The following options are included:

- **none** disables the customization for the group or user, prevents the value from being inherited, and displays the default Clientless SSL VPN pages.
- **value** name is the name of a customization for a group or user.

Example:

This example enters tunnel-group Clientless SSL VPN configuration mode and enables the customization cisco for the connection profile cisco_telecommutes:

```
hostname(config)# tunnel-group cisco_telecommutes webvpn-attributes
hostname(tunnel-group-webvpn)# customization cisco
```

This example enters group policy Clientless SSL VPN configuration mode, queries the security appliance for a list of customizations, and enables the customization cisco for the group policy cisco_sales:

```
hostname(config)# group-policy cisco_sales attributes
hostname(config-group-policy)# webvpn
```
hostname(config-username-webvpn)# customization value?
config-username-webvpn mode commands/options:
Available configured customization profiles:
   DfltCustomization
cisco
hostname(config-group-webvpn)# customization value cisco

This example enters username Clientless SSL VPN configuration mode and enables the customization cisco for the user cisco_employee:
hostname(config)# username cisco_employee attributes
hostname(config-username)# webvpn
hostname(config-username-webvpn)# customization value cisco

Step 4  (Optional) Remove the command from the configuration and remove a customization from the connection profile:
   [ no] customization name

Step 5  (Optional) Remove the command from the configuration and revert to the default:
   [no] customization {none | value name}

Step 6  Show a list of existing customizations:
   customization ?

---

Login Screen Advanced Customization

If you prefer to use your own, custom login screen, rather than changing specific screen elements of the login screen we provide, you can perform this advanced customization using the Full Customization feature.

With Full Customization, you provide the HTML for your own login screen, and you insert Cisco HTML code that calls functions on the ASA that create the Login form and the Language Selector drop-down list.

This section describes the modifications you need to make to your HTML code and the tasks required to configure the ASA to use your code.

The following figure shows the standard Cisco login screen that displays to Clientless SSL VPN users. The Login form is displayed by a function called by the HTML code.
The following figure shows the Language Selector drop-down list. This feature is an option for Clientless SSL VPN users and is also called by a function in the HTML code of the login screen.

The following figure shows a simple example of a custom login screen enabled by the Full Customization feature.
The following HTML code is used as an example and is the code that displays:

```
<head>
<meta http-equiv="Content-Type" content="text/html; charset=windows-1252">
<title>New Page 3</title>
<base target="_self">
</head>

<p align="center">
<img border="0" src="/+CSCOU+/cisco_logo.jpg" width="188" height="48"><font face="Snap ITC" size="6" color="#FF00FF">
</font><font face="Sylfaen" color="#FF0000" size="7">SSL VPN Service by the Cisco ASA5500</font></p>

<body onload="csco_ShowLoginForm('lform');csco_ShowLanguageSelector('selector')">
<table>
<tr><td colspan=3 height=20 align=right><div id="selector" style="width:300px"></div></td></tr>
<tr><td></td><td></td><td></td></tr>
<tr><td height="379"></td>
<td height="379"></td>
<td align=middle valign=middle><div id=lform >
<p>&nbsp;</p></div></td></tr>
</table>
```

Figure 20: Example of Full Customization of Login Screens
The indented code injects the Login form and the Language Selector on the screen. The function 
`csco_ShowLoginForm('lform')` injects the logon form. `csco_ShowLanguageSelector('selector')` injects the Language Selector.

**Modify Your HTML File**

**Procedure**

**Step 1** Name your file logon.inc. When you import the file, the ASA recognizes this filename as the logon screen.

**Step 2** Modify the paths of images used by the file to include `/+CSCOU+/`.

Files that are displayed to remote users before authentication must reside in a specific area of the ASA cache memory represented by the path `/+CSCOU+/`. Therefore, the source for each image in the file must include this path.

For example:

```
src="/+CSCOU+/asa5520.gif"
```

**Step 3** Insert the special HTML code below. This code contains the Cisco functions, described earlier, that inject the login form and language selector onto the screen.

```
<body onload="csco_ShowLoginForm('lform');csco_ShowLanguageSelector('selector')">
<table>
<tr><td colspan=3 height=20 align=right><div id="selector" style="width:300px"></div></td></tr>
<tr><td></td><td></td><td></td></tr>
<tr>
<td height="379"></td>
<td height="379"></td>
<td align=middle valign=middle>
<div id=lform>
<p>&nbsp;</p>
<p>&nbsp;</p>
<p>Loading...</p>
</div>
</td>
</tr>
<tr>
</tr>
</table>
```

The ASA displays help content on the application panels for each selected bookmark. You can customize those help files or create help files in other languages. You then import them to flash memory for display during subsequent sessions. You can also retrieve previously imported help content files, modify them, and reimport them to flash memory.

Each application panel displays its own help file content using a predetermined filename. The prospective location of each is in the `/+CSCOE+/help/language/` URL within flash memory of the ASA. The following table shows the details about each of the help files you can maintain for VPN sessions.

Table 24: VPN Application Help Files

</table>

`language` is the abbreviation of the language rendered by the browser. This field is not used for file translation; it indicates the language used in the file. To specify a particular language code, copy the language abbreviation from the list of languages rendered by your browser. For example, a dialog window displays the languages and associated language codes when you use one of the following procedures:

- Open Internet Explorer and choose Tools > Internet Options > Languages > Add.
- Open Mozilla Firefox and choose Tools > Options > Advanced > General, click Choose next to Languages, and click Select a language to add.
Import a Help file to Flash Memory

Procedure

Import a help content file to flash memory for display in Clientless SSL VPN sessions.

import webvpn webcontent destination_url source_url

- destination_url is the string in the URL of Help File in Flash Memory of the Security Appliance column.
- source_url is the URL of the file to import. Valid prefixes are ftp://, http://, and tftp://.

Example

This example copies the help file app-access-help.inc to flash memory from the TFTP server at 209.165.200.225. The URL includes the abbreviation en for the English language:

hostname# import webvpn webcontent /+CSCOE+/help/en/app-access-hlp.inc
tftp://209.165.200.225/app-access-hlp.inc

Export a Previously Imported Help File from Flash Memory

Procedure

Retrieve a previously imported help content file for subsequent edits.

export webvpn webcontent source_url destination_url

- source_url is the string in “URL of Help File in Flash Memory of the Security Appliance.”
- destination_url is the target URL. Valid prefixes are ftp:// and tftp://. The maximum number of characters is 255.

Example

This example copies the English language help file file-access-hlp.inc displayed on the Browser Networks panel to TFTP Server 209.165.200.225.

hostname# export webvpn webcontent /+CSCOE+/help/en/file-access-hlp.inc
tftp://209.165.200.225/file-access-hlp.inc
Understand Language Translation

The ASA provides language translation for the entire Clientless SSL VPN session. This includes login, logout banners, and portal pages displayed after authentication such as plugins and AnyConnect. Functional areas and their messages that are visible to remote users are organized into translation domains. The following table shows the translation domains and the functional areas translated.

Language Translation Domain Options

<table>
<thead>
<tr>
<th>Translation Domain</th>
<th>Functional Areas Translated</th>
</tr>
</thead>
<tbody>
<tr>
<td>AnyConnect</td>
<td>Messages displayed on the user interface of the Cisco AnyConnect VPN client.</td>
</tr>
<tr>
<td>banners</td>
<td>Message displayed when VPN access is denied for a clientless connection.</td>
</tr>
<tr>
<td>CSD</td>
<td>Messages for the Cisco Secure Desktop (CSD).</td>
</tr>
<tr>
<td>customization</td>
<td>Messages on the logon and logout pages, portal page, and all the messages customizable by the user.</td>
</tr>
<tr>
<td>plugin-ica</td>
<td>Messages for the Citrix plug-in.</td>
</tr>
<tr>
<td>plugin-telnet,ssh</td>
<td>Messages for the Telnet and SSH plug-in.</td>
</tr>
<tr>
<td>plugin-vnc</td>
<td>Messages for the VNC plug-in.</td>
</tr>
<tr>
<td>PortForwarder</td>
<td>Messages displayed to Port Forwarding users.</td>
</tr>
<tr>
<td>url-list</td>
<td>Text that user specifies for URL bookmarks on the portal page.</td>
</tr>
<tr>
<td>webvpn</td>
<td>All the layer 7, AAA and portal messages that are not customizable.</td>
</tr>
</tbody>
</table>

The ASA includes a translation table template for each domain that is part of standard functionality. The templates for plug-ins are included with the plug-ins and define their own translation domains.

You can export the template for a translation domain, which creates an XML file of the template at the URL you provide. The message fields in this file are empty. You can edit the messages and import the template to create a new translation table object that resides in flash memory.

You can also export an existing translation table. The XML file created displays the messages you edited previously. Reimporting this XML file with the same language name creates a new version of the translation table object, overwriting previous messages.

Some templates are static, but some change based on the configuration of the ASA. Because you can customize the logon and logout pages, portal page, and URL bookmarks for clientless users, the ASA generates the customization and url-list translation domain templates dynamically, and the template automatically reflects your changes to these functional areas.
After creating translation tables, they are available to customization objects that you create and apply to group policies or user attributes. With the exception of the AnyConnect translation domain, a translation table has no affect, and messages are not translated on user screens until you create a customization object, identify a translation table to use in that object, and specify that customization for the group policy or user. Changes to the translation table for the AnyConnect domain are immediately visible to AnyConnect client users.

Create Translation Tables

You can create translation tables in both single context mode and multi-context mode:

Procedure

Step 1

Export a translation table template to a computer.

```
export webvpn translation-table
```

**Example:**

This example shows available translation table templates and exports them for the customization domain, which affects messages displayed for users in Clientless SSL VPN sessions. The filename of the XML file created is `portal` (user-specified) and contains empty message fields.

```
hostname# show import webvpn translation-table
Translation Tables' Templates:
customization
AnyConnect
PortForwarder
url-list
webvpn
Citrix-plugin
RPC-plugin
Telnet-SSH-plugin
VNC-plugin
Translation Tables:

hostname# export webvpn translation-table customization template
tftp://209.165.200.225/portal
```

Step 2

Edit the translation table XML file.

**Example:**

This example shows a portion of the template that was exported as `portal`. The end of this output includes a message ID field (msgid) and a message string field (msgstr) for the message which is displayed on the portal page when a user establishes a Clientless SSL VPN session. The complete template contains many pairs of message fields.

```
# Copyright (C) 2006 by Cisco Systems, Inc.
#
#: fuzzy
msgid ""
msgstr ""
"Project-Id-Version: ASA\n"
```
Step 3 Import the translation table.

**import webvpn translation-table**

**Example:**

This example imports the XML file. *es-us* is the abbreviation for Spanish spoken in the United States.

```
hostname# import webvpn translation-table customization language es-us tftp://209.165.200.225/portal
hostname# !!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
hostname# show import webvpn translation-table
Translation Tables' Templates:
AnyConnect
PortForwarder
customization
keepout
url-list
webvpn
Citrix-plugin
RPC-plugin
Telnet-SSH-plugin
VNC-plugin
Translation Tables:
es-us customization
```

If you import a translation table for the AnyConnect domain, your changes are effective immediately. If you import a translation table for any other domain, you must create a customization object, identify the translation table to use in that object, and specify that customization object for the group policy or user.

---

**Reference the Language in a Customization Object**

This section describes how to export the customization template, edit it, and import it as a customization object so that you can refer to it.

**Before you begin**

For the customization object to call these translation tables correctly, the tables must have been previously imported using the same names. These names must be compatible with language options of the browser.
Procedure

Step 1
Export a customization template to a URL where you can edit it.

```
export webvpn customization template
```

This example exports the template and creates the copy sales at the URL specified.

```
hostname# export webvpn customization template tftp://209.165.200.225/sales
```

Step 2
Two areas of XML code in the customization template pertain to translation tables. Edit the customization template and reference the previously-imported translation table.

This example specifies the translation table to use.

- The `<languages>` tag in the XML code is followed by the names of the translation tables. In this example, they are en, ja, zh, ru, and ua.

- The `<default-language>` tag specifies the language that the remote user first encounters when connecting to the ASA. In the example code above, the language is English.

```
<localization>
    <languages>en,ja,zh,ru,ua</languages>
    <default-language>en</default-language>
</localization>
```

This example affects the display of the Language Selector and includes the `<language-selector>` tag and the associated `<language>` tags that enable and customize the Language Selector:

- The `<language-selector>` group of tags includes the `<mode>` tag that enables and disables the displaying of the Language Selector and the `<title>` tag that specifies the title of the drop-down box listing the languages.

- The `<language>` group of tags includes the `<code>` and `<text>` tags that map the language name displayed in the Language Selector drop-down box to a specific translation table.

```
<auth-page>
    ....
    <language-selector>
        <mode>enable</mode>
        <title l10n="yes">Language:</title>
        <language>
            <code>en</code>
            <text>English</text>
        </language>
        <language>
            <code>es-us</code>
            <text>Spanish</text>
        </language>
    </language-selector>
</auth-page>
```

Step 3
Save the file after making your changes.

Step 4
Import the customization template as a new object.
import webvpn customization
Example:

Step 5
Show the new customization object sales.

show import webvpn customization
Example:

hostname# import webvpn customization sales tftp://209.165.200.225/sales
hostname# !!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!

Change a Group Policy or User Attributes to Use the Customization Object

This section describes how to activate your changes for specific groups or users.

Procedure

Step 1
Switch to Clientless SSL VPN configuration mode.
webvpn

Step 2
Switch to group-policy Clientless SSL VPN configuration mode.
group-policy webvpn

Step 3
Enable the customization object.
customization

Example

This example shows the customization object sales enabled in the group policy sales.

hostname(config)# group-policy sales attributes
hostname(config-group-policy)# webvpn
hostname(config-group-webvpn)# customization value sales
Clientless SSL VPN Troubleshooting

- Recover from Hosts File Errors When Using Application Access, on page 433
- WebVPN Conditional Debugging, on page 436
- Capture Data, on page 437
- Protect Clientless SSL VPN Session Cookies, on page 438

Recover from Hosts File Errors When Using Application Access

To prevent hosts file errors that can interfere with Application Access, close the Application Access window properly when you finish using Application Access. To do so, click the close icon.

When Application Access terminates abnormally, the hosts file remains in a Clientless SSL VPN-customized state. Clientless SSL VPN checks the state the next time you start Application Access by searching for a hosts.webvpn file. If it finds one, a Backup HOSTS File Found error message appears, and Application Access is temporarily switched off.

If Application Access is stopped improperly, you leave the remote access client/server applications in limbo. If you try to start these applications without using Clientless SSL VPN, they may malfunction. You may find that hosts that you normally connect to are unavailable. This situation could commonly occur if you run applications remotely from home, fail to quit the Application Access window before shutting down the computer, then try to run the applications later from the office.

The following errors can occur if you do not close the Application Access window properly:

- The next time you try to start Application Access, it may be switched off; you receive a Backup HOSTS File Found error message.
- The applications themselves may be switched off or malfunction, even when you are running them locally.

These errors can result from terminating the Application Access window in any improper way. For example:

- Your browser crashes while you are using Application Access.
- A power outage or system shutdown occurs while you are using Application Access.
- You minimize the Application Access window while you are working, then shut down your computer with the window active (but minimized).
Understanding the Hosts File

The hosts file on your local system maps IP addresses to hostnames. When you start Application Access, Clientless SSL VPN modifies the hosts file, adding Clientless SSL VPN-specific entries. Stopping Application Access by properly closing the Application Access window returns the file to its original state.

<table>
<thead>
<tr>
<th>Before invoking Application Access...</th>
<th>hosts file is in original state.</th>
</tr>
</thead>
<tbody>
<tr>
<td>When Application Access starts....</td>
<td>• Clientless SSL VPN copies the hosts file to hosts.webvpn, thus creating a backup.</td>
</tr>
<tr>
<td></td>
<td>• Clientless SSL VPN then edits the hosts file, inserting Clientless SSL VPN-specific information.</td>
</tr>
<tr>
<td>When Application Access stops...</td>
<td>• Clientless SSL VPN copies the backup file to the hosts file, thus restoring the hosts file to its original state.</td>
</tr>
<tr>
<td></td>
<td>• Clientless SSL VPN deletes hosts.webvpn.</td>
</tr>
<tr>
<td>After finishing Application Access...</td>
<td>hosts file is in original state.</td>
</tr>
</tbody>
</table>

**Note**

Microsoft anti-spyware software blocks changes that the port forwarding Java applet makes to the hosts file. See [www.microsoft.com](http://www.microsoft.com) for information on how to allow hosts file changes when using anti-spyware software.

Reconfigure a Host’s File Automatically Using Clientless SSL VPN

If you are able to connect to your remote access server, follow these steps to reconfigure the host’s file and re-enable both Application Access and the applications.

**Procedure**

**Step 1**  
Start Clientless SSL VPN and log in.  
Click the **Applications Access** link.
Step 2

Choose one of the following options:

- **Restore from backup**—Clientless SSL VPN forces a proper shutdown. It copies the hosts.webvpn backup file to the hosts file, restoring it to its original state, then deletes hosts.webvpn. You then have to restart Application Access.

- **Do nothing**—Application Access does not start. The remote access home page reappears.

- **Delete backup**—Clientless SSL VPN deletes the hosts.webvpn file, leaving the hosts file in its Clientless SSL VPN-customized state. The original hosts file settings are lost. Application Access then starts, using the Clientless SSL VPN-customized hosts file as the new original. Choose this option only if you are unconcerned about losing hosts file settings. If you or a program you use may have edited the hosts file after Application Access has shut down improperly, choose one of the other options, or edit the hosts file manually.

---

**Reconfigure Hosts File Manually**

If you are not able to connect to your remote access server from your current location, or if you have customized the hosts file and do not want to lose your edits, follow these steps to reconfigure the hosts file and reenable both Application Access and the applications.

**Procedure**

**Step 1**

Locate and edit your hosts file. The most common location is c:\windows\sysem32\drivers\etc\hosts.

**Step 2**

Check to see if any lines contain the string: `# added by WebVpnPortForward` If any lines contain this string, your hosts file is Clientless SSL VPN-customized. If your hosts file is Clientless SSL VPN-customized, it looks similar to the following example:

```
server1 # added by WebVpnPortForward
server1.example.com invalid.cisco.com # added by WebVpnPortForward
server2 # added by WebVpnPortForward
server2.example.com invalid.cisco.com # added by WebVpnPortForward
```
server3 # added by WebVpnPortForward
server3.example.com invalid.cisco.com # added by WebVpnPortForward

# Copyright (c) 1993-1999 Microsoft Corp.
#
# This is a sample HOSTS file used by Microsoft TCP/IP for Windows.
#
# This file contains the mappings of IP addresses to hostnames. Each
# entry should be kept on an individual line. The IP address should
# be placed in the first column followed by the corresponding hostname.
# The IP address and the hostname should be separated by at least one
# space.
#
# Additionally, comments (such as these) may be inserted on individual
# lines or following the machine name denoted by a '#' symbol.
#
# For example:
#
# 102.54.94.97 cisco.example.com # source server
# 38.25.63.10 x.example.com # x client host

123.0.0.1 localhost

Step 3 Delete the lines that contain the string: # added by WebVpnPortForward
Step 4 Save and close the file.
Step 5 Start Clientless SSL VPN and log in.
Step 6 Click the Application Access link.

WebVPN Conditional Debugging

With multiple sessions running on a remote access VPN, troubleshooting can be difficult given the size of
the logs. You can use the debug webvpn condition command to set up filters to target your debug process
more precisely.

d debug webvpn condition {group name | p-ipaddress ip_address [{subnet subnet_mask | prefix length}] | reset | user name}

Where:

• group name filters on a group policy (not a tunnel group or connection profile).

• p-ipaddress ip_address [{subnet subnet_mask | prefix length}] filters on the public IP address of the
  client. The subnet mask (for IPv4) or prefix (for IPv6) is optional.

• reset resets all filters. You can use the no debug webvpn condition command to turn off a specific filter.

• user name filters by username.

If you configure more than one condition, the conditions are conjoined (ANDed), so that debugs are shown
only if all conditions are met.

After setting up the condition filter, use the base debug webvpn command to turn on the debug. Simply setting
the conditions does not enable the debug. Use the show debug and show webvpn debug-condition commands
to view the current state of debugging.
Troubleshooting a single user session becomes cumbersome when multiple sessions are running on ASA VPN. Conditional debugging enables verifying the logs of specific sessions based on the filter conditions set. SAML, WebVPN request/response, Anyconnect are the modules which supports conditional debugging.

---

**Note**

Support for "any, any" for IPv4 and IPv6 subnets is provided.

The following shows an example of enabling a conditional debug on the user jdoe.

```plaintext
asa3(config)# debug webvpn condition user jdoe
asa3(config)# show webvpn debug-condition
INFO: Webvpn conditional debug is turned ON
INFO: User name filters:
INFO: jdoe
asa3(config)# debug webvpn
INFO: debug webvpn enabled at level 1.
asa3(config)# show debug
debug webvpn enabled at level 1
INFO: Webvpn conditional debug is turned ON
INFO: User name filters:
INFO: jdoe
```

---

**Capture Data**

The CLI `capture` command lets you log information about websites that do not display properly over a Clientless SSL VPN session. This data can help your Cisco customer support engineer troubleshoot problems.

**Prerequisites**

Enabling Clientless SSL VPN capture affects the performance of the security appliance. Ensure you switch off the capture after you generate the capture files needed for troubleshooting.

**Create a Capture File**

**Procedure**

**Step 1**

Start the capture utility for Clientless SSL VPN and create a capture named hr, which captures traffic for user2 to a file.

```
capture capture_name type webvpn user webvpn_username
```

`capture_name` is a name you assign to the capture, which is also prepended to the name of the capture files. `webvpn_user` is the username to match for capture.

**Example:**
hostname# capture hr type webvpn user user2
WebVPN capture started.
    capture name    hr
    user name   user2
hostname# no capture hr

Step 2  (Optional) Stop the capture utility from capturing packets after a user has logged in and began a Clientless SSL VPN session. The capture utility creates a `capture_name.zip` file, which is encrypted with the password koleso.

```
no capture capture_name
```

Step 3  Send the `.zip` file to Cisco Systems or attach it to a Cisco TAC service request.

Step 4  Unzip the contents of the file using the `koleso` password.

---

## Use a Browser to Display Capture Data

**Procedure**

**Step 1**  Start the capture utility for Clientless SSL VPN.

```
capture capture_name type webvpn user webvpn_username
```

- `capture_name` is a name you assign to the capture, which is also prepended to the name of the capture files.
- `webvpn_user` is the username to match for capture.

**Step 2**  (Optional) Stop the capture utility from capturing packets after a user has logged in and began a Clientless SSL VPN session.

```
no capture capture_name
```

**Step 3**  Open a browser and display the capture named hr in a sniffer format:

```
https://asdm_enabled_interface_of_the_security_appliance:port/admin/capture/capture_name/pcap
```

**Example:**

```
https://192.0.2.1:60000/admin/capture/hr/pcap
```

---

## Protect Clientless SSL VPN Session Cookies

Embedded objects such as Flash applications and Java applets, as well as external applications, usually rely on an existing session cookie to work with the server. They get it from a browser using some Javascript on initialization. Adding the `httponly` flag to the Clientless SSL VPN session cookie makes the session cookie only visible to the browser, not the client-side scripts, and it makes session sharing impossible.
Before you begin

- Change the VPN session cookie setting only when there are no active Clientless SSL VPN sessions.
- Use the `show vpn-sessiondb webvpn` command to check the status of Clientless SSL VPN sessions.
- Use the `vpn-sessiondb logoff webvpn` command to log out of all Clientless SSL VPN sessions.
- The following Clientless SSL VPN features will not work when the `http-only-cookie` command is enabled:
  - Java plug-ins
  - Java rewriter
  - Port forwarding
  - File browser
  - Sharepoint features that require desktop applications (for example, MS Office applications)
  - AnyConnect Web launch
  - Citrix Receiver, XenDesktop, and Xenon
  - Other non-browser-based and browser plugin-based applications

To prevent a Clientless SSL VPN session cookie from being accessed by a third party through a client-side script such as Javascript, perform the following steps:

Procedure

Enable the `http-only` flag for a Clientless SSL VPN session cookie. This is enabled by default.

**http-only-cookie**

**Example:**

```
hostname(config)# webvpn
hostname(config-webvpn)# http-only-cookie
```

**Note**

Use this command only if Cisco TAC advises you to do so. Enabling this command presents a security risk because the Clientless SSL VPN features listed under the Guidelines section will not work without any warning.
Protect Clientless SSL VPN Session Cookies
