

Troubleshooting Connections and Resources

This chapter describes how to troubleshoot the ASA and includes the following sections:

- Testing Your Configuration, page 20-1
- Monitoring Per-Process CPU Usage, page 20-7

Testing Your Configuration

ſ

This section describes how to test connectivity for the single mode ASA or for each security context, how to ping the ASA interfaces, and how to allow hosts on one interface to ping through to hosts on another interface.

We recommend that you only enable pinging and debugging messages during troubleshooting. When you are done testing the ASA, follow the steps in the Disabling the Test Configuration, page 20-6.

This section includes the following topics:

- Enabling ICMP Debugging Messages and Syslog Messages, page 20-2
- Pinging ASA Interfaces, page 20-3
- Passing Traffic Through the ASA, page 20-5
- Disabling the Test Configuration, page 20-6
- Determining Packet Routing with Traceroute, page 20-7
- Tracing Packets with Packet Tracer, page 20-7

Enabling ICMP Debugging Messages and Syslog Messages

Debugging messages and syslog messages can help you troubleshoot why your pings are not successful. The ASA only shows ICMP debugging messages for pings to the ASA interfaces, and not for pings through the ASA to other hosts.

To enable debugging and syslog messages, perform the following steps:

	Command	Purpose Shows ICMP packet information for pings to the ASA interfaces.	
Step 1	debug icmp trace		
	Example: hostname(config)# debug icmp trace		
Step 2	logging monitor debug	Sets syslog messages to be sent to Telnet or SSH sessions.	
	Example: hostname(config)# logging monitor debug	NoteYou can alternately use the logging buffer debug command to send log messages to a buffer, and then view them later using the show logging command.	
Step 3	terminal monitor	Sends the syslog messages to a Telnet or SSH session.	
	Example: hostname(config)# terminal monitor		
Step 4	logging on	Enables syslog message generation.	
	Example: hostname(config)# logging on		

Examples

The following example shows a successful ping from an external host (209.165.201.2) to the ASA outside interface (209.165.201.1):

```
hostname(config)# debug icmp trace
Inbound ICMP echo reply (len 32 id 1 seq 256) 209.165.201.1 > 209.165.201.2
Outbound ICMP echo request (len 32 id 1 seq 512) 209.165.201.2 > 209.165.201.1
Inbound ICMP echo reply (len 32 id 1 seq 512) 209.165.201.1 > 209.165.201.2
Outbound ICMP echo request (len 32 id 1 seq 768) 209.165.201.2 > 209.165.201.1
Inbound ICMP echo reply (len 32 id 1 seq 768) 209.165.201.1 > 209.165.201.2
Outbound ICMP echo reply (len 32 id 1 seq 768) 209.165.201.1 > 209.165.201.2
Outbound ICMP echo request (len 32 id 1 seq 1024) 209.165.201.2 > 209.165.201.1
Inbound ICMP echo reply (len 32 id 1 seq 1024) 209.165.201.2 > 209.165.201.2
```

The output shows the ICMP packet length (32 bytes), the ICMP packet identifier (1), and the ICMP sequence number (the ICMP sequence number starts at 0, and is incremented each time that a request is sent).

I

Pinging ASA Interfaces

To test whether the ASA interfaces are up and running and that the ASA and connected routers are operating correctly, you can ping the ASA interfaces.

To ping the ASA interfaces, perform the following steps:

Step 1

Host

10.1.1.56

Draw a diagram of your single-mode ASA or security context that shows the interface names, security levels, and IP addresses.

Although this procedure uses IP addresses, the **ping** command also supports DNS names and names that are assigned to a local IP address with the **name** command.

Host

209.165.201.24

The diagram should also include any directly connected routers and a host on the other side of the router from which you will ping the ASA. You will use this information in this procedure and in the procedure in the Passing Traffic Through the ASA, page 20-5. (See Figure 20-1.)

Figure 20-1 Network Diagram with Interfaces, Routers, and Hosts

209.265.200.230

Host

Host

10.1.3.6

Step 2 Ping each ASA interface from the directly connected routers. For transparent mode, ping the management IP address. This test ensures that the ASA interfaces are active and that the interface configuration is correct.

A ping might fail if the ASA interface is not active, the interface configuration is incorrect, or if a switch between the ASA and a router is down (see Figure 20-2). In this case, no debugging messages or syslog messages appear, because the packet never reaches the ASA.

I

If the ping reaches the ASA, and it responds, debugging messages similar to the following appear:

ICMP echo reply (len 32 id 1 seq 256) 209.165.201.1 > 209.165.201.2 ICMP echo request (len 32 id 1 seq 512) 209.165.201.2 > 209.165.201.1

If the ping reply does not return to the router, then a switch loop or redundant IP addresses may exist (see Figure 20-3).

Figure 20-3 Ping Failure Because of IP Addressing Problems

Step 3 Ping each ASA interface from a remote host. For transparent mode, ping the management IP address. This test checks whether the directly connected router can route the packet between the host and the ASA, and whether the ASA can correctly route the packet back to the host.

A ping might fail if the ASA does not have a return route to the host through the intermediate router (see Figure 20-4). In this case, the debugging messages show that the ping was successful, but syslog message 110001 appears, indicating a routing failure has occurred.

Figure 20-4 Ping Failure Because the ASA Has No Return Route

20-5

Passing Traffic Through the ASA

After you successfully ping the ASA interfaces, make sure that traffic can pass successfully through the ASA. By default, you can ping from a high security interface to a low security interface. You just need to enable ICMP inspection to allow returning traffic through. If you want to ping from high to low, then you need to apply an ACL to allow traffic. If you use NAT, this test shows that NAT is operating correctly.

Ping from the host or router through the source interface to another host or router on another interface. Repeat this step for as many interface pairs as you want to check.

If the ping succeeds, a syslog message appears to confirm the address translation for routed mode (305009 or 305011) and that an ICMP connection was established (302020). You can also enter either the **show xlate** or **show conns** command to view this information.

The ping might fail because NAT is not configured correctly. In this case, a syslog message appears, showing that the NAT failed (305005 or 305006). If the ping is from an outside host to an inside host, and you do not have a static translation, the following syslog message appears:

%ASA-3-106010: deny inbound icmp.

The ASA only shows ICMP debugging messages for pings to the ASA interfaces, and not for pings through the ASA to other hosts.

Figure 20-5 Ping Failure Because the ASA is Not Translating Addresses

Detailed Steps

	Command	Purpose
Step 1	policy-map global_policy	Edits the default global policy and enters policy-map configuration mode.
Step 2	class inspection_default	Edits the default class map, which matches application traffic for standard protocols and ports. For ICMP, this class matches all ICMP traffic.
Step 3	inspect icmp	Enables the ICMP inspection engine and ensures that ICMP responses can return to the source host.

Step 4	(Optional, for low security interfaces)	Adds	an ACL to allow ICMP traffic from any source host.
	access-list ICMPACL extended permit icmp any any		
Step 5	access-group ICMPACL in interface outside	Assigns the ACL to the outside interface. Replace "outside" with your interface name if it is different. Repeat the command for each interface that you want to allow ICMP traffic from high to low.	
		Note	After you apply this ACL to an interface that is not the lowest security interface, only ICMP traffic is allowed; the implicit permit from high to low is removed. For example, to allow a DMZ interface (level 50) to ping the inside interface (level 100), you need to apply this ACL. However, now traffic from DMZ to outside (level 0) is limited to ICMP traffic only, as opposed to all traffic that the implicit permit allowed before. After testing ping, be sure to remove this ACL from your interfaces, especially interfaces to which you want to restore the implicit permit (no access-list ICMPACL).

Disabling the Test Configuration

After you complete your testing, disable the test configuration that allows ICMP to and through the ASA and that prints debugging messages. If you leave this configuration in place, it can pose a serious security risk. Debugging messages also slow ASA performance.

To disable the test configuration, perform the following steps:

	Command	Purpose
Step 1	no debug icmp trace	Disables ICMP debugging messages.
Step 2	no logging on	Disables logging.
Step 3	no access-list ICMPACL	Removes the ICMPACL ACL, and deletes the related access-group commands.
Step 4	policy-map global_policy class inspection_default no inspect icmp	(Optional) Disables the ICMP inspection engine.

Determining Packet Routing with Traceroute

You can trace the route of a packet using the traceroute feature, which is accessed with the **traceroute** command. A traceroute works by sending UDP packets to a destination on an invalid port. Because the port is not valid, the routers along the way to the destination respond with an ICMP Time Exceeded Message, and report that error to the ASA.

Tracing Packets with Packet Tracer

The packet tracer tool provides packet tracing for packet sniffing and network fault isolation, as well as detailed information about the packets and how they are processed by the ASA. If a configuration command did not cause the packet to drop, the packet tracer tool can provide information about the cause in an easily readable format.

In addition, you can trace the lifespan of a packet through the ASA to see whether the packet is operating correctly with the packet tracer tool. This tool enables you to do the following:

- Debug all packet drops in a production network.
- Verify the configuration is working as intended.
- Show all rules applicable to a packet, along with the CLI commands that caused the rule addition.
- Show a time line of packet changes in a data path.
- Inject tracer packets into the data path.
- Search for an IPv4 or IPv6 address based on the user identity and the FQDN.

To trace packets, enter the following command:

Command	Purpose
<pre>packet-tracer input [ifc_name] [icmp [sip user username fqdn fqdn-string] type code ident [dip fqdn fqdn-string]] [tcp [sip user username fqdn fqdn-string] sport [dip fqdn fqdn-string] dport] [udp [sip user username fqdn fqdn- string] sport [dip fqdn fqdn-string] dport] [rawip [sip user username fqdn fqdn-string] [dip fqdn fqdn-string]] [detailed] [xml]</pre>	Provides detailed information about the packets and how they are processed by the ASA. The example shows how to enable packet tracing from inside host 10.2.25.3 to external host 209.165.202.158, including detailed information.
Example: hostname# packet-tracer input inside tcp 10.2.25.3 www 209.165.202.158 aol detailed	

Monitoring Per-Process CPU Usage

You can monitor the processes that run on the CPU. You can obtain information about the percentage of CPU that is used by a certain process. CPU usage statistics are sorted in descending order to display the highest consumer at the top. Also included is information about the load on the CPU per process, at 5 seconds, 1 minute, and 5 minutes before the log time. This information is updated automatically every 5 seconds to provide real-time statistics.

You can use the **show process cpu-usage sorted** command to find a breakdown of the process-related load-to-CPU that is consumed by any configured contexts.
