

# Policy Based Routing

This chapter describes how to configure the Cisco ASA to support policy based routing (PBR). The following sections describe policy based routing, guidelines for PBR, and configuration for PBR.

- [About Policy Based Routing, on page 1](#)
- [Guidelines for Policy Based Routing, on page 3](#)
- [Configure Policy Based Routing, on page 4](#)
- [History for Policy Based Routing, on page 6](#)

## About Policy Based Routing

Traditional routing is destination-based, meaning packets are routed based on destination IP address. However, it is difficult to change the routing of specific traffic in a destination-based routing system. With Policy Based Routing (PBR), you can define routing based on criteria other than destination network—PBR lets you route traffic based on source address, source port, destination address, destination port, protocol, or a combination of these.

Policy Based Routing:

- Lets you provide Quality of Service (QoS) to differentiated traffic.
- Lets you distribute interactive and batch traffic across low-bandwidth, low-cost permanent paths and high-bandwidth, high-cost switched paths.
- Allows Internet service providers and other organizations to route traffic originating from various sets of users through well-defined Internet connections.

Policy Based Routing can implement QoS by classifying and marking traffic at the network edge, and then using PBR throughout the network to route marked traffic along a specific path. This permits routing of packets originating from different sources to different networks, even when the destinations are the same, and it can be useful when interconnecting several private networks.

## Why Use Policy Based Routing?

Consider a company that has two links between locations: one a high-bandwidth, low-delay expensive link, and the other a low-bandwidth, higher-delay, less-expensive link. While using traditional routing protocols, the higher-bandwidth link would get most, if not all, of the traffic sent across it based on the metric savings obtained by the bandwidth and/or delay (using EIGRP or OSPF) characteristics of the link. PBR allows you

to route higher priority traffic over the high-bandwidth/low-delay link, while sending all other traffic over the low-bandwidth/high-delay link.

Some applications of policy based routing are:

## Equal-Access and Source-Sensitive Routing

In this topology, traffic from HR network & Mgmt network can be configured to go through ISP1 and traffic from Eng network can be configured to go through ISP2. Thus, policy based routing enables the network administrators to provide equal-access and source-sensitive routing, as shown here.

## Quality of Service

By tagging packets with policy based routing, network administrators can classify the network traffic at the perimeter of the network for various classes of service and then implementing those classes of service in the core of the network using priority, custom or weighted fair queuing (as shown in the figure below). This setup improves network performance by eliminating the need to classify the traffic explicitly at each WAN interface in the core of backbone network.

## Cost Saving

An organization can direct the bulk traffic associated with a specific activity to use a higher-bandwidth high-cost link for a short time and continues basic connectivity over a lower-bandwidth low-cost link for interactive traffic by defining the topology, as show here.

## Load Sharing

In addition to the dynamic load-sharing capabilities offered by ECMP load balancing, network administrators can now implement policies to distribute traffic among multiple paths based on the traffic characteristics.

As an example, in the topology depicted in the Equal-Access Source Sensitive Routing scenario, an administrator can configure policy based routing to load share the traffic from HR network through ISP1 and traffic from Eng network through ISP2.

## Implementation of PBR

The ASA uses ACLs to match traffic and then perform routing actions on the traffic. Specifically, you configure a route map that specifies an ACL for matching, and then you specify one or more actions for that traffic. Finally, you associate the route map with an interface where you want to apply PBR on all incoming traffic

## Guidelines for Policy Based Routing

### Firewall Mode

Supported only in routed firewall mode. Transparent firewall mode is not supported.

### Per-flow Routing

Since the ASA performs routing on a per-flow basis, policy routing is applied on the first packet and the resulting routing decision is stored in the flow created for the packet. All subsequent packets belonging to the same connection simply match this flow and are routed appropriately.

### PBR Policies Not Applied for Output Route Look-up

Policy Based Routing is an ingress-only feature; that is, it is applied only to the first packet of a new incoming connection, at which time the egress interface for the forward leg of the connection is selected. Note that PBR will not be triggered if the incoming packet belongs to an existing connection, or if NAT is applied.

### Clustering

- Clustering is supported.
- In a cluster scenario, without static or dynamic routes, with `ip-verify-reverse` path enabled, asymmetric traffic may get dropped. So disabling `ip-verify-reverse` path is recommended.

### Additional Guidelines

All existing route map related configuration restrictions and limitations will be carried forward.

## Configure Policy Based Routing

A route map is comprised of one or more route-map statements. Each statement has a sequence number, as well as a permit or deny clause. Each route-map statement contains match and set commands. The match command denotes the match criteria to be applied on the packet. The set command denotes the action to be taken on the packet.

- When multiple next-hops or interfaces are configured as a set action, all options are evaluated one after the other until a valid usable option is found. No load balancing will be done among the configured multiple options.
- The verify-availability option is not supported in multiple context mode.

### Procedure

- 
- Step 1** In ASDM, configure one or more standard or extended ACLs to identify traffic on which you want to perform Policy Based Routing. See **Configuration > Firewall > Advanced > ACL Manager**.
- Step 2** Choose **Configuration > Device Setup > Routing > Route Maps**, and click **Add**.  
The **Add Route Map** dialog box appears.
- Step 3** Enter the route map name and sequence number. You will use this same name for optional additional route map statements. The sequence number is the order in which the ASA assesses the route maps.
- Step 4** Click **Deny** or **Permit**.  
The ACL also includes its own permit and deny statements. For Permit/Permit matches between the route map and the ACL, the Policy Based Routing processing continues. For Permit/Deny matches, processing ends for this route map, and other route maps are checked. If the result is still Permit/Deny, then the regular routing table is used. For Deny/Deny matches, the Policy Based Routing processing continues.
- Step 5** Click the **Match Clause** tab to identify the ACLs you created.  
In the **IPv4** section, choose **Access List** from the drop-down menu, and then select one or more standard or extended ACLs from the dialog box.  
If you use a standard ACL, matching is done on the destination address only. If you use an extended ACL, you can match on source, destination, or both.  
IPv6 ACLs are not supported.
- Step 6** Click the **Policy Based Routing** tab to define policy for traffic flows.  
Check one or more of the following set actions to perform for the matching traffic flows:
- **Set PBR next hop address**—For IPv4, you can configure multiple next-hop IP addresses in which case they are evaluated in the specified order until a valid routable next-hop IP address is found. The configured next-hops should be directly connected; otherwise the set action will not be applied.
  - **Set default next-hop IP address**—For IPv4, if the normal route lookup fails for matching traffic, then the ASA forwards the traffic using this specified next-hop IP address.

- **Recursively find and set next-hop IP address**—Both the next-hop address and the default next-hop address require that the next-hop be found on a directly connected subnet. With this option, the next-hop address does not need to be directly connected. Instead a recursive lookup is performed on the next-hop address, and matching traffic is forwarded to the next-hop used by that route entry according to the routing path in use on the router.
- **Configure Next Hop Verifiability**—Verify if the next IPv4 hops of a route map are available. You can configure an SLA monitor tracking object to verify the reachability of the next-hop. Click **Add** to add next-hop IP address entries, and specify the following information.
  - **Sequence Number**—Entries are assessed in order using the sequence number.
  - **IP Address**—Enter the next hop IP address.
  - **Tracking Object ID**—Enter a valid ID.
- **Set interfaces**—This option configures the interface through which the matching traffic is forwarded. You can configure multiple interfaces, in which case they are evaluated in the specified order until a valid interface is found. When you specify **null0**, all traffic matching the route map will be dropped. There must be a route for the destination that can be routed through the specified interface (either static or dynamic).
- **Set null0 interface as the default interface**—If a normal route lookup fails, the ASA forwards the traffic null0, and the traffic will be dropped.
- **Set do-not-fragment bit to either 1 or 0**—Select the appropriate radio button.
- **Set differential service code point (DSCP) value in QoS bits**—Select a value from the IPv4 drop-down list.

**Step 7** Click **OK**, and then click **Apply**.

**Step 8** To remove an existing PBR route map, select it in the Route Maps list and then click **Delete**.
