CONTENTS

PART I **Cisco Security Cloud Control Management: Cloud-Delivered Firewall Management Center for Government** 95

CHAPTER 1 **Introduction** 1

Introduction to Cloud-Delivered Firewall Management Center 1

Enable Cloud-Delivered Firewall Management Center on Your Security Cloud Control Tenant 3

Hardware and Software Support 3

Security Cloud Control Platform Maintenance Schedule 4

PART II **Onboard Devices to Cloud-Delivered Firewall Management Center** 5

CHAPTER 2 **Onboard a Secure Firewall Threat Defense to the Cloud-Delivered Firewall Management Center** 7

Onboarding Overview 7

Prerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center 8

Onboard a Device with a CLI Registration Key 10

Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning 12

Onboard a Firewall Threat Defense Device to On-Prem Firewall Management Center using Zero-Touch Provisioning 13

Onboard Firewall Threat Defense Devices using Device Templates to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning 15

Deploy a Threat Defense Device with AWS 16

Deploy a Firewall Threat Defense Device in Azure 18

Onboard an Azure VNet Environment 18

Deploy a Firewall Threat Defense Virtual in Azure 20

Deploy a Firewall Threat Defense Device to Google Cloud Platform 21

Create VPC Networks for GCP 21

Deploy a Firewall Threat Defense Device on Google Cloud Platform 22
Onboard a Secure Firewall Threat Defense Cluster 24
Onboard a Chassis 25
Delete Devices from Cloud-Delivered Firewall Management Center 27
Troubleshooting 27
Troubleshoot Cloud-Delivered Firewall Management Center Connectivity with TCP 27
Troubleshoot Firewall Threat Defense Device Connectivity 28
Troubleshoot Device Connectivity Loss After Cloud-delivered Firewall Management Center Update 28
Troubleshoot Onboarding a Device to the Cloud-Delivered Firewall Management Center Using the CLI Registration Key 29
Error: Device Remains in Pending Setup State After Onboarding 29
Troubleshoot Onboarding a Device to Cloud-Delivered Firewall Management Center Using the Serial Number 30
Device is Offline or Unreachable 30
Error: Serial Number Already Claimed 30
Error: Claim Error 32
Error: Failed to Claim 33
Error: Provisional Error 33

CHAPTER 3 **Migrate On-Premises Management Center Managed Secure Firewall Threat Defense to Cloud-delivered Firewall Management Center 35**
About Migrating Firewall Threat Defense to Cloud-delivered Firewall Management Center 35
Supported On-Premises Firewall Management Center and Firewall Threat Defense Software for Migration 36
Licensing 37
Supported Features 37
Unsupported Features 41
Migration Guidelines and Limitations for VPN Configuration 42
Managing Threat Defense Events and Analytics 43
Before You Begin Migration 44
Migrate Firewall Threat Defense to Cloud-Delivered Firewall Management Center 46
View a Firewall Threat Defense Migration Job 49
Proceed Migration Process 50
Commit Migration Changes Manually to Cloud-delivered Firewall Management Center 51

Revert the Firewall Threat Defense Management to On-Premises Firewall Management Center 52
View Migrated Devices 52
Generate a Firewall Threat Defense Migration Report 54
Delete a Migration Job 54
Enable Notification Settings 55
Troubleshoot Firewall Threat Defense Migration to Cloud-Delivered Firewall Management Center 55
Verify Firewall Threat Defense Connectivity with Cloud-delivered Firewall Management Center 63

CHAPTER 4 **Device Management** 65
Log Into the Command-Line Interface on the Device 65
Manage Devices 67
About the Device Management Page 67
Add a Device Group 68
Register With a New Management Center 68
Shut Down or Restart the Device 70
Download the Managed Device List 70
Migrate Firewall Threat Defense Devices 71
Supported Devices for Migration 71
License for Migration 72
Prerequisites for Migration 72
What Configurations Does the Wizard Migrate? 72
Limitations for Migration 74
Best Practices for Threat Defense Device Migration 74
Hot Swap an SSD on the Secure Firewall 3100 Series 75

CHAPTER 5 **Device Settings** 79
Edit General Settings 79
Copy a Configuration to Another Device 81
Export and Import the Device Configuration 82
Edit License Settings 86
View System Information 87
View Device Inventory 88
View the Inspection Engine 88
Edit Health Settings 88

Edit Management Settings 89
Configure a Redundant Manager Access Data Interface 89
Change Manager Access Interface Settings 94
Change the Device IP Address 94
Change the Firewall Management Center IP Address 106
Change Both Firewall Management Center and Threat Defense IP Addresses 107
Change the Manager Access Interface 111
Troubleshooting the Management Connection 117
Manually Roll Back the Configuration if the Firewall Management Center Loses Connectivity 118
Troubleshoot Management Connectivity on a Data Interface 120
Troubleshoot Management Connectivity on a Data Interface in a High Availability Pair 124
View Inventory Details 129
Edit Applied Policies 130
Edit Advanced Settings 131
Configure Automatic Application Bypass 132
Configure Object Group Search 133
Configure Interface Object Optimization 134
Edit Deployment Settings 135
Edit Cluster Health Monitor Settings 138
History for Device Settings 143

CHAPTER 6 **Change Management** 145
About Change Management 145
How to Configure Devices in the Change Management Workflow 146
Creating Separate Approver and Configuration Roles 146
Policies and Objects that Support Change Management 147
Requirements and Prerequisites for Change Management 148
Guidelines and Limitations for Change Management 149
Enabling or Disabling Change Management 150
Managing Tickets 150
Creating Change Management Tickets 152
Opening a Ticket for Configuration Changes 152
Previewing a Ticket 153
Submitting a Ticket 153

Discarding a Ticket 154
Approving or Rejecting a Ticket 154
History for Change Management 155

CHAPTER 7 Users 157
About Users 157
Internal and External Users 157
CLI Access 157
CLI User Roles 158
Requirements and Prerequisites for User Accounts for Devices 158
Guidelines and Limitations for User Accounts for Devices 159
Add an Internal User at the CLI 159
Troubleshooting LDAP Authentication Connections 161

CHAPTER 8 Configuration Deployment 165
About Configuration Deployment 165
Configuration Changes that Require Deployment 165
Deployment Preview 166
Selective Policy Deployment 167
System Username 169
Auto-Enabling of Application Detectors 170
Asset Rediscovery with Network Discovery Policy Changes 170
Snort Restart Scenarios 170
Restart Warnings for Devices 170
Inspect Traffic During Policy Apply 171
Snort Restart Traffic Behavior 172
Configurations that Restart the Snort Process When Deployed or Activated 174
Changes that Immediately Restart the Snort Process 175
Requirements and Prerequisites for Policy Management 175
Best Practices for Deploying Configuration Changes 176
Deploy the Configuration 177
Deploy Configuration Changes 177
Redeploy Existing Configurations to a Device 183
Manage Deployments 185

View Deployment Status 185
View Deployment History 185
Download Policy Changes Report for Multiple Devices 189
Compare Policies 190
Generate Current Policy Reports 191
History for Configuration Deployment 193

PART III **System Settings** 195

CHAPTER 9 **System Configuration** 197
Requirements and Prerequisites for the System Configuration 197
Manage the Secure Firewall Management Center System Configuration 197
Access Control Preferences 198
Audit Log 199
Stream Audit Logs to Syslog 200
Stream Audit Logs to an HTTP Server 201
Filter Syslogs from Audit Logs 202
Audit Log Certificate 203
Securely Stream Audit Logs 203
Obtain a Signed Audit Log Client Certificate for the Firewall Management Center 204
Import an Audit Log Client Certificate into the Firewall Management Center 205
Require Valid Audit Log Server Certificates 206
View the Audit Log Client Certificate on the Firewall Management Center 208
Change Reconciliation 208
Configuring Change Reconciliation 208
Change Reconciliation Options 209
Email Notification 209
External Database Access 209
Enabling External Access to the Database 210
Intrusion Policy Preferences 210
Set Intrusion Policy Preferences 211
Manager Remote Access 211
Network Analysis Policy Preferences 212

CHAPTER 10 Users 213

About Users 213

Internal and External Users 213

User Roles 213

Create a User Record with Your Security Cloud Control Username 216

Troubleshooting LDAP Authentication Connections 217

Configure User Preferences 218

Change the Web Interface Appearance 218

Setting Your Default Time Zone 219

Configure How-To Settings 219

CHAPTER 11 Updates 221

Product Upgrades 221

Content Updates 221

Guidelines and Limitations for Content Updates 222

Update the Vulnerability Database (VDB) 222

Schedule VDB Updates 223

Manually Update the VDB 223

Update the Geolocation Database (GeoDB) 224

Schedule GeoDB Updates 224

Manually Update the GeoDB 225

Update Intrusion Rules 225

Schedule Intrusion Rule Updates 227

Manually Update Intrusion Rules 227

Import Local Intrusion Rules 228

Best Practices for Importing Local Intrusion Rules 229

View Intrusion Rule Update Logs 230

Intrusion Rule Update Log Details 230

CHAPTER 12 Licenses 233

About Licenses 233

Smart Software Manager and Accounts 234

How Licensing Works for the Management Center and Devices 234

Periodic Communication with the Smart Software Manager 234
Cloud-Delivered Firewall Management Center and Threat Defense Licenses 234
Out-of-Compliance State 235
Unregistered State 236
End-User License Agreement 236
License Types and Restrictions 236
Essentials Licenses 238
Malware Defense Licenses 238
IPS Licenses 239
Carrier License 239
URL Filtering Licenses 240
Secure Client Licenses 241
Licensing for Export-Controlled Functionality 242
Firewall Threat Defense Virtual Licenses 243
License PIDs 244
Requirements and Prerequisites for Licensing 249
Requirements and Prerequisites for Licensing for High Availability, Clustering, and Multi-Instance 250
Licensing for Device High-Availability 250
Licensing for Device Clusters 250
Create a Cisco Account 250
Create a Smart Account and Add Licenses 251
Configure Smart Licensing 253
Register the Firewall Management Center for Smart Licensing 253
Register the Firewall Management Center with the Smart Software Manager 253
Assign Licenses to Devices 255
Assign Licenses to a Single Device 255
Assign Licenses to Multiple Managed Devices 256
Manage Smart Licensing 257
Deregister the Firewall Management Center 257
Monitoring Smart License Status 258
Monitoring Smart Licenses 258
Troubleshooting Smart Licensing 259
Configure Legacy Firewall Management Center PAK-Based Licenses 260

Additional Information about Licensing 261

CHAPTER 13 **Security Certifications Compliance** 263

Security Certifications Compliance Modes 263

Security Certifications Compliance Characteristics 264

Security Certifications Compliance Recommendations 265

Appliance Hardening 266

Protecting Your Network 267

PART IV **Health and Monitoring** 269

CHAPTER 14 **Health** 271

Requirements and Prerequisites for Health Monitoring 271

About Health Monitoring 271

Health Modules 273

Configuring Health Monitoring 279

Health Policies 279

Default Health Policy 279

Creating Health Policies 280

Apply a Health Policy 280

Edit a Health Policy 281

Delete a Health Policy 282

Send Vendor-Neutral Telemetry Streams Using OpenConfig 283

Generate Certificates and Private Keys 284

Configure OpenConfig Streaming Telemetry 286

Troubleshoot OpenConfig Streaming Telemetry 287

Device Exclusion in Health Monitoring 288

Excluding Appliances from Health Monitoring 289

Excluding Health Policy Modules 289

Expired Health Monitor Exclusions 290

Health Monitor Alerts 291

Health Monitor Alert Information 291

Creating Health Monitor Alerts 292

Editing Health Monitor Alerts 292

Deleting Health Monitor Alerts 293
About the Health Monitor 293
Device Health Monitors 294
Viewing System Details and Troubleshooting 295
Viewing the Device Health Monitor 296
Cluster Health Monitor 299
Viewing the Cluster Health Monitor 300
Health Monitor Status Categories 301
Health Event Views 302
Viewing Health Events 302
Viewing the Health Events Table 303
The Health Events Table 304
About System Auditing 305
Audit Records 305
Audit Log Workflow Fields 305
The Audit Events Table View 306

CHAPTER 15 **Troubleshooting** 307
Guidelines and Best Practices for Troubleshooting 307
System Messages 308
Message Types 308
Message Management 310
View Basic System Information 310
View Appliance Information 311
Manage System Messages 311
View Deployment Messages 311
View Upgrade Messages 312
View Health Messages 313
View Task Messages 313
Manage Task Messages 314
Memory Usage Thresholds for Health Monitor Alerts 314
Disk Usage and Drain of Events Health Monitor Alerts 316
Health Monitor Reports for Troubleshooting 319
Generate Troubleshooting Files for Specific System Functions 320

Download Advanced Troubleshooting Files 320
General Troubleshooting 321
Connection-Based Troubleshooting 321
Troubleshoot a Connection 322
Advanced Troubleshooting for the Secure Firewall Threat Defense Device 322
Packet Capture Overview 322
Use the Capture Trace 325
Packet Tracer Overview 326
Use the Packet Tracer 327
Use the Firewall Threat Defense Diagnostic CLI from the Web Interface 329
Feature-Specific Troubleshooting 330

PART V **Tools** 333

CHAPTER 16 **Backup/Restore** 335
About Backup and Restore 335
Requirements for Backup and Restore 336
Guidelines and Limitations for Backup and Restore 337
Best Practices for Backup and Restore 338
Back Up Managed Devices 340
Back Up a Firewall Threat Defense Device from Cloud-delivered Firewall Management Center 340
Restore Security Cloud Control-Managed Devices 341
Restore a Firewall Threat Defense Device 342
Restore Firewall Threat Defense from Backup: Firewall Threat Defense Virtual 345

CHAPTER 17 **Scheduling** 349
About Task Scheduling 349
Requirements and Prerequisites for Task Scheduling 350
Configuring a Recurring Task 350
Scheduled Backups 351
Schedule Remote Device Backups 351
Automating Policy Deployment 352
Automating Intrusion Policy Deployment 353
Software Upgrade Automation 353

Automating Software Downloads 354
Automating Software Pushes 354
Automating Software Installs 355
Vulnerability Database Update Automation 356
Automating VDB Update Downloads 356
Automating VDB Update Installs 357
Automating URL Filtering Updates Using a Scheduled Task 357
Scheduled Task Review 358
Task List Details 359
Viewing Scheduled Tasks on the Calendar 359
Editing Scheduled Tasks 360
Deleting Scheduled Tasks 360

CHAPTER 18 **Import/Export 363**
About Import/Export 363
Exceptions to Export Behavior 363
Importing Objects and Object Groups 364
Conflict Resolution for Duplicate Configurations 364
Requirements and Prerequisites for Import/Export 366
Guidelines for Import/Export 366
Export Configurations 367
Import Configurations 367

PART VI **Reporting and Alerting 369**

CHAPTER 19 **External Alerting with Alert Responses 371**
Secure Firewall Management Center Alert Responses 371
Configurations Supporting Alert Responses 372
Requirements and Prerequisites for Alert Responses 372
Creating an SNMP Alert Response 372
Creating a Syslog Alert Response 374
Syslog Alert Facilities 375
Syslog Severity Levels 376
Creating an Email Alert Response 376

CHAPTER 20 **External Alerting for Intrusion Events** 379

About External Alerting for Intrusion Events 379

License Requirements for External Alerting for Intrusion Events 380

Requirements and Prerequisites for External Alerting for Intrusion Events 380

Configuring SNMP Alerting for Intrusion Events 380

Intrusion SNMP Alert Options 381

Configuring Syslog Alerting for Intrusion Events 382

Facilities and Severities for Intrusion Syslog Alerts 383

Configuring Email Alerting for Intrusion Events 384

Intrusion Email Alert Options 384

PART VII **Event and Asset Analysis Tools** 387

CHAPTER 21 **Lookups** 389

Introduction to Lookups 389

Performing Whois Lookups 389

CHAPTER 22 **Event Investigation Using Web-Based Resources** 391

Event Investigation Using Web-Based Resources 391

About Managing Contextual Cross-Launch Resources 391

Requirements for Custom Contextual Cross-Launch Resources 392

Add Contextual Cross-Launch Resources 392

Investigate Events Using Contextual Cross-Launch 393

PART VIII **Events and Assets** 395

CHAPTER 23 **Security Analytics and Logging (SaaS) for Cloud-Delivered Firewall Management Center-Managed Devices** 397

About Security Analytics and Logging 397

Comparison of SAL Remote Event Storage and Monitoring Options 398

About SAL (OnPrem) 398

Licensing for SAL (OnPrem) 399

Manage SAL (OnPrem) for Security Cloud Control-Managed Firewall Threat Defense Devices 399

Configure SAL (OnPrem) Integration 401
Configure a Secure Network Analytics Manager 401
Configure a Secure Network Analytics Data Store 403
About SAL (SaaS) 404
Licensing for SAL (SaaS) 405

CHAPTER 24 FTD Dashboard 407
About the FTD Dashboard 407
View the FTD Dashboard 408
FTD Dashboard Widgets 409
Top Intrusion Rules Widget 409
Top Intrusion Attackers Widget 409
Top Intrusion Targets Widget 410
Top Malware Signatures Widget 410
Top Malware Senders Widget 410
Top Malware Receivers Widget 410
Malware Events by Disposition Widget 410
Network Activity Widget 410
Event Activity Widget 410
Access Control Actions Widget 410
Top Access Control Policies Widget 410
Top Access Control Rules Widget 411
Top Devices Widget 411
Top Users Widget 411
Top Users by Blocked Connections Widget 411
Top Devices with Health Alerts Widget 411
Top Loaded Devices Widget 411
Top Web Applications Widget 411
Top Client Applications Widget 411
Top Blocked Web Applications Widget 411
Modify Time Settings for the FTD Dashboard 412

CHAPTER 25 Connection Logging 413
About Connection Logging 413

Connections That Are Always Logged 414
Other Connections You Can Log 414
How Rules and Policy Actions Affect Logging 415
Logging for Fastpathed Connections 416
Logging for Monitored Connections 416
Logging for Trusted Connections 416
Logging for Blocked Connections 416
Logging for Allowed Connections 418
Beginning vs End-of-Connection Logging 419
Limitations of Connection Logging 420
Best Practices for Connection Logging 420
Requirements and Prerequisites for Connection Logging 422
Configure Connection Logging 422
Logging Connections with Tunnel and Prefilter Rules 423
Logging Decryptable Connections with TLS/SSLDecryption Rules 423
Logging Connections with Security Intelligence 424
Logging Connections with Access Control Rules 425
Logging Connections with a Policy Default Action 426
Limiting Logging of Long URLs 426

PART IX **Device Operations** 429

CHAPTER 26 **Transparent or Routed Firewall Mode** 431
About the Firewall Mode 431
About Routed Firewall Mode 431
About Transparent Firewall Mode 432
Using the Transparent Firewall in Your Network 432
Passing Traffic For Routed-Mode Features 432
About Bridge Groups 433
Bridge Virtual Interface (BVI) 433
Bridge Groups in Transparent Firewall Mode 433
Bridge Groups in Routed Firewall Mode 434
Allowing Layer 3 Traffic 435
Allowed MAC Addresses 435

BPDU Handling 435
MAC Address vs. Route Lookups 436
Unsupported Features for Bridge Groups in Transparent Mode 437
Unsupported Features for Bridge Groups in Routed Mode 438
Default Settings 439
Guidelines for Firewall Mode 439
Set the Firewall Mode 440

CHAPTER 27 **Logical Devices on the Firepower 4100/9300** 443
About Interfaces 443
Chassis Management Interface 443
Interface Types 444
FXOS Interfaces vs. Application Interfaces 446
Shared Interface Scalability 448
Shared Interface Best Practices 448
Shared Interface Usage Examples 450
Viewing Shared Interface Resources 456
Inline Set Link State Propagation for the Firewall Threat Defense 457
About Logical Devices 457
Standalone and Clustered Logical Devices 458
Logical Device Application Instances: Container and Native 458
Container Instance Interfaces 458
How the Chassis Classifies Packets 459
Classification Examples 459
Cascading Container Instances 463
Typical Multi-Instance Deployment 464
Automatic MAC Addresses for Container Instance Interfaces 465
Container Instance Resource Management 466
Performance Scaling Factor for Multi-Instance Capability 466
Container Instances and High Availability 466
Container Instances and Clustering 466
Licenses for Container Instances 466
Requirements and Prerequisites for Logical Devices 467
Requirements and Prerequisites for Hardware and Software Combinations 467

Requirements and Prerequisites for Container Instances 469
Requirements and Prerequisites for High Availability 470
Requirements and Prerequisites for Clustering 471
Guidelines and Limitations for Logical Devices 474
Guidelines and Limitations for Interfaces 474
General Guidelines and Limitations 477
Configure Interfaces 478
Enable or Disable an Interface 478
Configure a Physical Interface 478
Add an EtherChannel (Port Channel) 479
Add a VLAN Subinterface for Container Instances 482
Configure Logical Devices 483
Add a Resource Profile for Container Instances 483
Add a Standalone Firewall Threat Defense 484
Add a Standalone Threat Defense for the Cisco Security Cloud Control 489
Add a High Availability Pair 495
Change an Interface on a Firewall Threat Defense Logical Device 496
Connect to the Console of the Application 498

CHAPTER 28 **Multi-Instance Mode for the Secure Firewall 3100** 501
About Multi-Instance Mode 501
Multi-Instance Mode vs. Appliance Mode 501
Chassis Management Interface 502
Instance Interfaces 502
Interface Types 502
Chassis Interfaces vs. Instance Interfaces 503
Shared Interface Scalability 505
Shared Interface Best Practices 505
How the Chassis Classifies Packets 507
Classification Examples 508
Cascading Instances 511
Typical Multi-Instance Deployment 512
Automatic MAC Addresses for Instance Interfaces 513
Performance Scaling Factor for Multi-Instance Mode 514

Instances and High Availability 514
Licenses for Instances 514
Requirements and Prerequisites for Instances 514
Guidelines and Limitations for Instances 516
Configure Instances 518
518
518
Onboard the Multi-Instance Chassis 518
Configure Chassis Interfaces 522
Configure a Physical Interface 522
Configure an EtherChannel 525
Configure a Subinterface 529
Add an Instance 531
Customize the System Configuration 538
Configure SNMP 538
Import or Export the Chassis Configuration 539
Configure Chassis Platform Settings 541
Create a Chassis Platform Settings Policy 541
Configure DNS 542
Configure SSH and SSH Access List 543
Configure Syslog 548
Configure Time Synchronization 553
Configure Time Zones 555
Manage Multi-Instance Mode 556
Change Interfaces Assigned to an Instance 556
Change Chassis Management Settings at the FXOS CLI 558
Monitoring Multi-Instance Mode 561
Monitoring Multi-Instance Setup 561
Monitoring Instance Interfaces 562
History for Multi-Instance Mode 564

CHAPTER 29 **High Availability** 565
About Secure Firewall Threat Defense High Availability 565

High Availability Support on Firewall Threat Defense Devices in a Remote Branch Office Deployment 566
High Availability System Requirements 566
Hardware Requirements 566
Software Requirements 567
License Requirements for Firewall Threat Defense Devices in a High Availability Pair 567
Failover and Stateful Failover Links 567
Failover Link 568
Stateful Failover Link 569
Avoiding Interrupted Failover and Data Links 570
MAC Addresses and IP Addresses in High Availability 571
Stateful Failover 572
Supported Features 572
Unsupported Features 574
Bridge Group Requirements for High Availability 574
Failover Health Monitoring 575
Unit Health Monitoring 575
Heartbeat Module Redundancy 575
Interface Monitoring 576
Failover Triggers and Detection Timing 577
About Active/Standby Failover 578
Primary/Secondary Roles and Active/Standby Status 579
Active Unit Determination at Startup 579
Failover Events 579
Config-Sync Optimization 580
Requirements and Prerequisites for High Availability 581
Guidelines for High Availability 581
Add a High Availability Pair 584
Configure Optional High Availability Parameters 587
Configure Standby IP Addresses and Interface Monitoring 587
Edit High Availability Failover Criteria 588
Configure Virtual MAC Addresses 588
Manage High Availability 589
Switch the Active Peer in the Firewall Threat Defense High Availability Pair 589

Refresh Node Status for a Single Firewall Threat Defense High Availability Pair 590
Suspend and Resume High Availability 590
Replace a Unit in Firewall Threat Defense High Availability Pair 591
Replace a Primary Firewall Threat Defense HA Unit with no Backup 591
Replace a Secondary Firewall Threat Defense HA Unit with no Backup 592
Break a High Availability Pair 593
Remove a High Availability Pair 595
Monitoring High Availability 595
View Failover History 596
View Stateful Failover Statistics 596
Troubleshooting High Availability Break in a Remote Branch Deployment 596
How to Break a High Availability Pair in Active-Active State 597
How to Break a High Availability Pair when Active or Standby Unit has Lost Connectivity 598
How to a Break High Availability Pair when the Secondary Device is in a Failed or Disabled State 600
History for High Availability 602

CHAPTER 30 **Clustering for the Secure Firewall 3100** 605
About Clustering for the Secure Firewall 3100 605
How the Cluster Fits into Your Network 605
Control and Data Node Roles 606
Cluster Interfaces 606
Cluster Control Link 606
Configuration Replication 606
Management Network 606
Licenses for Clustering 607
Requirements and Prerequisites for Clustering 607
Guidelines for Clustering 608
Configure Clustering 612
About Cluster Interfaces 612
Cluster Control Link 612
Spanned EtherChannels 614
Cable and Add Devices to the Firewall Management Center 617
Create a Cluster 619
Configure Interfaces 625

Configure Cluster Health Monitor Settings 626
Manage Cluster Nodes 631
Add a New Cluster Node 631
Break a Node 633
Break the Cluster 634
Disable Clustering 635
Rejoin the Cluster 636
Change the Control Node 636
Edit the Cluster Configuration 637
Reconcile Cluster Nodes 638
Delete (Unregister) the Cluster or Nodes and Register to a New Firewall Management Center 640
Monitoring the Cluster 641
Cluster Health Monitor Dashboard 643
Viewing Cluster Health 644
Cluster Metrics 645
Examples for Clustering 646
Firewall on a Stick 646
Traffic Segregation 647
Reference for Clustering 647
Firewall Threat Defense Features and Clustering 647
Unsupported Features with Clustering 647
Centralized Features for Clustering 648
Connection Settings and Clustering 649

Sample Data Flow for ICMP and UDP 706
History for Threat Defense Virtual Clustering in a Private Cloud 708

CHAPTER 32 **Clustering for Threat Defense Virtual in a Public Cloud 709**
About Threat Defense Virtual Clustering in the Public Cloud 710
How the Cluster Fits into Your Network 710
Individual Interfaces 710
Control and Data Node Roles 711
Cluster Control Link 711
Cluster Control Link Traffic Overview 711
Configuration Replication 712
Management Network 712
Licenses for Threat Defense Virtual Clustering 712
Requirements and Prerequisites for Threat Defense Virtual Clustering 713
Guidelines for Threat Defense Virtual Clustering 714
Deploy the Cluster in AWS 716
AWS Gateway Load Balancer and Geneve Single-Arm Proxy 716
Sample Topology 717
End-to-End Process for Deploying Threat Defense Virtual Cluster on AWS 717
Templates 719
Deploy the Stack in AWS Using a CloudFormation Template 720
Deploy the Cluster in AWS Manually 732
Create the Day0 Configuration for AWS 732
Deploy Cluster Nodes 733
Deploy the Cluster in Azure 734
Sample Topology for GWLB-based Cluster Deployment 734
Azure Gateway Load Balancer and Paired Proxy 735
End-to-End Process for Deploying Threat Defense Virtual Cluster in Azure with GWLB 736
Templates 738
Prerequisites 738
Deploy Cluster on Azure with GWLB Using an Azure Resource Manager Template 738

Sample Topology for NLB-based Cluster Deployment 741
End-to-End Process for Deploying Threat Defense Virtual Cluster in Azure with NLB 742
Templates 743
Prerequisites 744
Deploy Cluster on Azure with NLB Using an Azure Resource Manager Template 744
Deploy the Cluster in Azure Manually 746
Create the Day0 Configuration for Azure 746
Deploy Cluster Nodes Manually - GWLB-based Deployment 748
Deploy Cluster Nodes Manually - NLB-based Deployment 749
Troubleshooting Cluster Deployment in Azure 751
Deploy the Cluster in GCP 752
Sample Topology of GCP Clustering Autoscale Solution 752
End-to-End Process for Deploying Threat Defense Virtual Cluster in GCP 753
Templates 754
Deploy the Instance Group in GCP Using an Instance Template 755
Deploy the Cluster in GCP Manually 756
Create the Day0 Configuration for GCP 756
Deploy Cluster Nodes Manually 758
Allow Health Checks for GCP Network Load Balancers 759
Add the Cluster to the Management Center (Manual Deployment) 760
Configure Cluster Health Monitor Settings 766
Manage Cluster Nodes 771
Disable Clustering 771
Rejoin the Cluster 772
Reconcile Cluster Nodes 772
Delete (Unregister) the Cluster or Nodes and Register to a New Firewall Management Center 773
Monitoring the Cluster 774
Cluster Health Monitor Dashboard 777
Viewing Cluster Health 778

Rejoining the Cluster 787
Data Path Connection State Replication 788
How the Cluster Manages Connections 788
Connection Roles 788
New Connection Ownership 790
Sample Data Flow for TCP 790
Sample Data Flow for ICMP and UDP 791
History for Threat Defense Virtual Clustering in the Public Cloud 792

CHAPTER 33 **Clustering for the Firepower 4100/9300** 795
About Clustering on the Firepower 4100/9300 Chassis 795
Bootstrap Configuration 796
Cluster Members 796
Cluster Control Link 796
Size the Cluster Control Link 797
Cluster Control Link Redundancy 797
Cluster Control Link Reliability for Inter-Chassis Clustering 798
Cluster Control Link Network 798

Management Network 798
Management Interface 798
Cluster Interfaces 798
Spanned EtherChannels 798
Configuration Replication 799
Licenses for Clustering 799
Requirements and Prerequisites for Clustering 800
Clustering Guidelines and Limitations 803
Configure Clustering 807
FXOS: Add a Firewall Threat Defense Cluster 807
Create a Firewall Threat Defense Cluster 807
Add More Cluster Nodes 818
Firewall Management Center: Add a Cluster 821
Firewall Management Center: Configure Cluster, Data Interfaces 827
Firewall Management Center: Configure Cluster Health Monitor Settings 829
FXOS: Remove a Cluster Node 833
Firewall Management Center: Manage Cluster Members 835
Add a New Cluster Member 835
Replace a Cluster Member 835
Deactivate a Member 837
Rejoin the Cluster 838
Delete (Unregister) a Data Node 838
Change the Control Unit 839
Reconcile Cluster Members 840
Firewall Management Center: Monitoring the Cluster 840
Cluster Health Monitor Dashboard 842
Viewing Cluster Health 843
Cluster Metrics 845
Examples for Clustering 845
Firewall on a Stick 846
Traffic Segregation 847
Reference for Clustering 847
Firewall Threat Defense Features and Clustering 847
Unsupported Features with Clustering 847

Centralized Features for Clustering 848
Connection Settings 849

Cisco TrustSec and Clustering 852
VPN and Clustering 852
Performance Scaling Factor 852
Control Unit Election 852
High Availability Within the Cluster 853
Chassis-Application Monitoring 853
Unit Health Monitoring 853
Interface Monitoring 854
Decorator Application Monitoring 854
Status After Failure 854
Rejoining the Cluster 854
Data Path Connection State Replication 855
How the Cluster Manages Connections 856
Connection Roles 856
New Connection Ownership 857
Sample Data Flow for TCP 857
Sample Data Flow for ICMP and UDP 858
History for Clustering 859

PART X **Interfaces and Device Settings** 865

CHAPTER 34 **Interface Overview** 867
Management Interface 867
Management Interface 867

Diagnostic Interface 868
Interface Mode and Types 868
Security Zones and Interface Groups 869
Auto-MDI/MDIX Feature 870
Redundant Interfaces (Deprecated) 871
Default Settings for Interfaces 871
Create Security Zone and Interface Group Objects 871
Enable the Physical Interface and Configure Ethernet Settings 872
Configure EtherChannel Interfaces 875
About EtherChannels 875
About EtherChannels 875
Guidelines for EtherChannels 878
Configure an EtherChannel 880
Sync Interface Changes with the Firewall Management Center 883
Manage the Network Module for the Secure Firewall 3100 886
Configure Breakout Ports 887
Add a Network Module 890
Hot Swap the Network Module 892
Replace the Network Module with a Different Type 894
Remove the Network Module 897
Merge the Management and Diagnostic Interfaces 900
Unmerge the Management Interface 906
History for Interfaces 907

CHAPTER 35 **Regular Firewall Interfaces 911**
Requirements and Prerequisites for Regular Firewall Interfaces 911
Configure Firepower 1010 Switch Ports 911
About Switch Ports 912
Understanding Switch Ports and Interfaces 912
Auto-MDI/MDIX Feature 913
Guidelines and Limitations for Switch Ports 913
Configure Switch Ports and Power Over Ethernet 914
Enable or Disable Switch Port Mode 914
Configure a VLAN Interface 915

Configure Switch Ports as Access Ports 917
Configure Switch Ports as Trunk Ports 919
Configure Power Over Ethernet 922
Configure Loopback Interfaces 923
About Loopback Interfaces 923
Guidelines and Limitations for Loopback Interfaces 924
Configure a Loopback Interface 924
Rate-Limit Traffic to the Loopback Interface 924
Configure VLAN Subinterfaces and 802.1Q Trunking 928
Guidelines and Limitations for VLAN Subinterfaces 928
Maximum Number of VLAN Subinterfaces by Device Model 929
Add a Subinterface 930
Configure VXLAN Interfaces 932
About VXLAN Interfaces 932
Encapsulation 932
VXLAN Tunnel Endpoint 932
VTEP Source Interface 933
VNI Interfaces 933
VXLAN Packet Processing 934
Peer VTEPs 934
VXLAN Use Cases 935
Requirements and Prerequisites for VXLAN Interfaces 939
Guidelines for VXLAN Interfaces 939
Configure VXLAN or Geneve Interfaces 940
Configure VXLAN Interfaces 940
Configure Geneve Interfaces 943
Allow Gateway Load Balancer Health Checks 945
Configure Routed and Transparent Mode Interfaces 945
About Routed and Transparent Mode Interfaces 945
Dual IP Stack (IPv4 and IPv6) 946
31-Bit Subnet Mask 946
Guidelines and Limitations for Routed and Transparent Mode Interfaces 947
Configure Routed Mode Interfaces 948
Configure Bridge Group Interfaces 953

Configure General Bridge Group Member Interface Parameters 953
Configure the Bridge Virtual Interface (BVI) 956
Configure IPv6 Addressing 957
About IPv6 957
Configure the IPv6 Prefix Delegation Client 958
Configure a Global IPv6 Address 961
Configure IPv6 Neighbor Discovery 966
Configure Advanced Interface Settings 968
About Advanced Interface Configuration 968
About MAC Addresses 968
About the MTU 969
About the TCP MSS 970
ARP Inspection for Bridge Group Traffic 971
MAC Address Table 972
Default Settings 972
Guidelines for ARP Inspection and the MAC Address Table 973
Configure the MTU 973
Configure the MAC Address 974
Add a Static ARP Entry 975
Add a Static MAC Address and Disable MAC Learning for a Bridge Group 976
Set Security Configuration Parameters 976
History for Regular Firewall Interfaces 978

CHAPTER 36 **Inline Sets and Passive Interfaces** 985
About IPS Interfaces 985
Inline Sets 985
Multiple Inline Pairs and Asynchronous Routing 986
Passive Interfaces 987
About Hardware Bypass for Inline Sets 987
Hardware Bypass Triggers 987
Hardware Bypass Switchover 988
Snort Fail Open vs. Hardware Bypass 988
Hardware Bypass Status 988
Requirements and Prerequisites for Inline Sets 988

Guidelines for Inline Sets and Passive Interfaces 990
Configure a Passive Interface 991
Configure an Inline Set 993

CHAPTER 37 DHCP and DDNS 997
About DHCP and DDNS Services 997
About the DHCPv4 Server 997
DHCP Options 997
About the DHCPv6 Stateless Server 998
About the DHCP Relay Agent 998
Requirements and Prerequisites for DHCP and DDNS 999
Guidelines for DHCP and DDNS Services 999
Configure the DHCPv4 Server 1001
Configure the DHCPv6 Stateless Server 1002
Create the DHCP IPv6 Pool 1002
Enable the DHCPv6 Stateless Server 1005
Configure the DHCP Relay Agent 1007
Configure Dynamic DNS 1008
History for DHCP and DDNS 1014

CHAPTER 38 SNMP for the Firepower 1000/2100 1015
About SNMP for the Firepower 1000/2100 1015
Enabling SNMP and Configuring SNMP Properties for Firepower 1000/2100 1015
Creating an SNMP Trap for Firepower 1000/2100 1017
Creating an SNMP User for Firepower 1000/2100 1018

CHAPTER 39 Quality of Service 1021
Introduction to QoS 1021
About QoS Policies 1021
Requirements and Prerequisites for QoS 1022
Rate Limiting with QoS Policies 1022
Creating a QoS Policy 1023
Setting Target Devices for a QoS Policy 1024
Configuring QoS Rules 1024

QoS Rule Components 1025
QoS Rule Conditions 1026
Interface Rule Conditions 1026
Network Rule Conditions 1027
User Rule Conditions 1027
Application Rule Conditions 1027
Port Rule Conditions 1029
URL Rule Conditions 1030
Custom SGT Rule Conditions 1030
ISE SGT vs Custom SGT Rule Conditions 1030
Autotransition from Custom SGTs to ISE SGTs 1031

CHAPTER 40 **Platform Settings** 1033
Introduction to Platform Settings 1034
Requirements and Prerequisites for Platform Settings Policies 1034
Manage Platform Settings Policies 1034
ARP Inspection 1035
Banner 1036
DNS 1037
External Authentication 1040
Fragment Settings 1045
HTTP Access 1046
ICMP Access 1047
NetFlow 1048
Add Collector in NetFlow 1049
Add Traffic Class to NetFlow 1050
SSH Access 1050
SMTP Server 1052
SNMP 1053
About SNMP 1054
SNMP Terminology 1054
MIBs and Traps 1055
Supported Tables and Objects in MIBs 1056
Add SNMPv3 Users 1060

Add SNMP Hosts 1062
Configure SNMP Traps 1064
Configure SSL Settings 1066
About SSL Settings 1067
Syslog 1070
About Syslog 1070
Severity Levels 1071
Syslog Message Filtering 1072
Syslog Message Classes 1072
Guidelines for Logging 1075
Configure Syslog Logging for Firewall Threat Defense Devices 1077
Firewall Threat Defense Platform Settings That Apply to Security Event Syslog Messages 1078
Enable Logging and Configure Basic Settings 1078
Enable Logging Destinations 1080
Send Syslog Messages to an E-mail Address 1081
Create a Custom Event List 1082
Limit the Rate of Syslog Message Generation 1083
Configure Syslog Settings 1084
Configure a Syslog Server 1085
Timeouts 1087
Time Synchronization 1089
Time Zone 1090
UCAPL/CC Compliance 1091
Performance Profile 1092

CHAPTER 41 **Network Address Translation** 1095
Why Use NAT? 1095
NAT Basics 1096
NAT Terminology 1096
NAT Types 1096
NAT in Routed and Transparent Mode 1097
NAT in Routed Mode 1097
NAT in Transparent Mode or Within a Bridge Group 1098
Auto NAT and Manual NAT 1099

Auto NAT 1099
Manual NAT 1099
Comparing Auto NAT and Manual NAT 1100
NAT Rule Order 1100
NAT Interfaces 1102
NAT Exemption 1103
Configuring Routing for NAT 1103
Addresses on the Same Network as the Mapped Interface 1104
Addresses on a Unique Network 1104
The Same Address as the Real Address (Identity NAT) 1104
Requirements and Prerequisites for NAT Policies 1105
Guidelines for NAT 1105
Firewall Mode Guidelines for NAT 1105
IPv6 NAT Guidelines 1105
IPv6 NAT Best Practices 1106
NAT Support for Inspected Protocols 1106
FQDN Destination Guidelines 1108
Additional Guidelines for NAT 1109
Manage NAT Policies 1111
Creating NAT Policies 1112
Configuring NAT Policy Targets 1112
Configure NAT for Threat Defense 1113
Customizing NAT Rules for Multiple Devices 1115
Searching and Filtering the NAT Rule Table 1117
Enabling, Disabling, or Deleting Multiple Rules 1118
Dynamic NAT 1118
About Dynamic NAT 1118
Dynamic NAT Disadvantages and Advantages 1120
Configure Dynamic Auto NAT 1120
Configure Dynamic Manual NAT 1121
Dynamic PAT 1123
About Dynamic PAT 1124
Dynamic PAT Disadvantages and Advantages 1124
PAT Pool Object Guidelines 1124

Configure Dynamic Auto PAT 1126
Configure Dynamic Manual PAT 1128
Configure PAT with Port Block Allocation 1131
Static NAT 1133
About Static NAT 1133
Configure Static Auto NAT 1137
Configure Static Manual NAT 1139
Identity NAT 1142
Configure Identity Auto NAT 1143
Configure Identity Manual NAT 1144
NAT Rule Properties for Firewall Threat Defense 1146
Interface Objects NAT Properties 1147
Translation Properties for Auto NAT 1148
Translation Properties for Manual NAT 1149
PAT Pool NAT Properties 1150
Advanced NAT Properties 1151
Translating IPv6 Networks 1152
NAT64/46: Translating IPv6 Addresses to IPv4 1153
NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet 1153
NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet and DNS Translation 1155
NAT66: Translating IPv6 Addresses to Different IPv6 Addresses 1159
NAT66 Example, Static Translation between Networks 1159
NAT66 Example, Simple IPv6 Interface PAT 1162
Monitoring NAT 1165
Examples for NAT 1166
Providing Access to an Inside Web Server (Static Auto NAT) 1166
Dynamic Auto NAT for Inside Hosts and Static NAT for an Outside Web Server 1168
Inside Load Balancer with Multiple Mapped Addresses (Static Auto NAT, One-to-Many) 1175
Single Address for FTP, HTTP, and SMTP (Static Auto NAT-with-Port-Translation) 1178
Different Translation Depending on the Destination (Dynamic Manual PAT) 1186
Different Translation Depending on the Destination Address and Port (Dynamic Manual PAT) 1192
NAT and Site-to-Site VPN 1198
Rewriting DNS Queries and Responses Using NAT 1203
DNS64 Reply Modification 1204

DNS Reply Modification, DNS Server on Outside 1211
DNS Reply Modification, DNS Server on Host Network 1214

CHAPTER 42 **Alarms for the Cisco ISA 3000** 1219
About Alarms 1219
Alarm Input Interfaces 1220
Alarm Output Interface 1220
Syslog Alarms 1221
SNMP Alarms 1221
Defaults for Alarms 1221
Requirements and Prerequisites for Alarms 1222
Configure the Alarms for the ISA 3000 1222
Configure Alarm Input Contacts 1222
Configure Power Supply Alarms 1225
Configure Temperature Alarms 1227
Monitoring Alarms 1230
Monitoring Alarm Status 1230
Monitoring Syslog Messages for Alarms 1230
Turning Off the External Alarm 1231

PART XI **Routing** 1233

CHAPTER 43 **Static and Default Routes** 1235
About Static and Default Routes 1235
Default Route 1235
Static Routes 1236
Route to null0 Interface to Drop Unwanted Traffic 1236
Route Priorities 1236
Transparent Firewall Mode and Bridge Group Routes 1236
Static Route Tracking 1237
Requirements and Prerequisites for Static Routes 1237
Guidelines for Static and Default Routes 1238
Add a Static Route 1238
Reference for Routing 1240

Path Determination 1240
Supported Route Types 1240
Static Versus Dynamic 1240
Single-Path Versus Multipath 1241
Flat Versus Hierarchical 1241
Link-State Versus Distance Vector 1241
Supported Internet Protocols for Routing 1241
Routing Table 1242
How the Routing Table Is Populated 1242
How Forwarding Decisions Are Made 1244
Dynamic Routing and High Availability 1245
Dynamic Routing in Clustering 1245
Dynamic Routing in Individual Interface Mode 1246
Routing Table for Management Traffic 1247
Equal-Cost Multi-Path (ECMP) Routing 1248
About Route Maps 1249
Permit and Deny Clauses 1249
Match and Set Clause Values 1249

CHAPTER 44 **Virtual Routers** 1251
About Virtual Routers and Virtual Routing and Forwarding (VRF) 1251
About Virtual Routers and Dynamic VTI 1252
How to Configure a Virtual Router with Dynamic VTI 1252
Applications of Virtual Routers 1252
Global and User-Defined Virtual Routers 1253
Configuring Policies to be Virtual-Router-Aware 1254
Interconnecting Virtual Routers 1255
Overlapping IP Addresses 1256
Configuring SNMP on User-Defined Virtual Routers 1257
Maximum Number of Virtual Routers By Device Model 1258
Requirements and Prerequisites for Virtual Routers 1259
Guidelines and Limitations for Virtual Routers 1259
Modifications to the Firewall Management Center Web Interface - Routing Page 1261
Manage Virtual Routers 1262

Create a Virtual Router 1262
Configure a Virtual Router 1262
Modify a Virtual Router 1264
Remove Virtual Routers 1265
Monitoring Virtual Routers 1265
Configuration Examples for Virtual Routers 1266
How to Route to a Distant Server through Virtual Routers 1266
How to Provide Internet Access with Overlapping Address Spaces 1271
How to Allow RA VPN Access to Internal Networks in Virtual Routing 1278
How to Secure Traffic from Networks in Multiple Virtual Routers over a Site-to-Site VPN 1281
How to Secure Traffic from Networks with Multiple Virtual Routers over a Site-to-Site VPN with Dynamic VTI 1284
How to Route Traffic between Two Overlapping Network Host in Virtual Routing 1286
How to Manage Overlapping Segments in Routed Firewall Mode with BVI Interfaces 1289
How to Configure User Authentication with Overlapping Networks 1293
How to Interconnect Virtual Routers using BGP 1299

CHAPTER 45 **ECMP** 1305
About ECMP 1305
Guidelines and Limitations for ECMP 1305
Manage ECMP Page 1306
Create an ECMP Zone 1307
Configure an Equal Cost Static Route 1308
Modify an ECMP Zone 1309
Remove an ECMP Zone 1309
Configuration Example for ECMP 1310

CHAPTER 46 **Bidirectional Forwarding Detection Routing** 1313
About BFD Routing 1313
Guidelines for BFD Routing 1313
Configure BFD 1314
Configure BFD Policies 1315
Configure Single-Hop BFD Policies 1316
Configure Multi-Hop BFD Policies 1316

History for BFD Routing 1317

CHAPTER 47 OSPF 1319

OSPF 1319

About OSPF 1319

OSPF Support for Fast Hello Packets 1321

Prerequisites for OSPF Support for Fast Hello Packets 1321

OSPF Hello Interval and Dead Interval 1321

OSPF Fast Hello Packets 1321

Benefits of OSPF Fast Hello Packets 1321

Implementation Differences Between OSPFv2 and OSPFv3 1322

Requirements and Prerequisites for OSPF 1322

Guidelines for OSPF 1322

Configure OSPFv2 1325

Configure OSPF Areas, Ranges, and Virtual Links 1325

Configure OSPF Redistribution 1328

Configure OSPF Inter-Area Filtering 1329

Configure OSPF Filter Rules 1330

Configure OSPF Summary Addresses 1331

Configure OSPF Interfaces and Neighbors 1332

Configure OSPF Advanced Properties 1334

Configure OSPFv3 1337

Configure OSPFv3 Areas, Route Summaries, and Virtual Links 1337

Configure OSPFv3 Redistribution 1339

Configure OSPFv3 Summary Prefixes 1341

Configure OSPFv3 Interfaces, Authentication, and Neighbors 1341

Configure OSPFv3 Advanced Properties 1344

History for OSPF 1347

CHAPTER 48 EIGRP 1349

About EIGRP Routing 1349

Requirements and Prerequisites for EIGRP 1350

Guidelines and Limitations of EIGRP Routing 1350

Configure EIGRP 1352

Configure EIGRP Settings 1352
Configure EIGRP Neighbors Settings 1353
Configure EIGRP Filter Rules Settings 1353
Configure EIGRP Redistribution Settings 1354
Configure EIGRP Summary Address Settings 1355
Configure EIGRP Interfaces Settings 1356
Configure EIGRP Advanced Settings 1356

CHAPTER 49 BGP 1359
About BGP 1359
Routing Table Changes 1359
When to Use BGP 1360
BGP Path Selection 1361
BGP Multipath 1361
Requirements and Prerequisites for BGP 1362
Guidelines for BGP 1362
Configure BGP 1363
Configure BGP Basic Settings 1364
Configure BGP General Settings 1366
Configure BGP Neighbor Settings 1367
Configure BGP Aggregate Address Settings 1371
Configure BGPv4 Filtering Settings 1372
Configure BGP Network Settings 1373
Configure BGP Redistribution Settings 1373
Configure BGP Route Injection Settings 1374
Configure BGP Route Import/Export Settings 1375

CHAPTER 50 RIP 1379
About RIP 1379
Routing Update Process 1379
RIP Routing Metric 1380
RIP Stability Features 1380
RIP Timers 1380
Requirements and Prerequisites for RIP 1381

Guidelines for RIP 1381
Configure RIP 1382

CHAPTER 51 Multicast 1385
About Multicast Routing 1385
IGMP Protocol 1385
Stub Multicast Routing 1386
PIM Multicast Routing 1386
PIM Source Specific Multicast Support 1387
Multicast Bidirectional PIM 1388
PIM Bootstrap Router (BSR) 1388
PIM Bootstrap Router (BSR) Terminology 1388
Multicast Group Concept 1389
Multicast Addresses 1389
Clustering 1389
Requirements and Prerequisites for Multicast Routing 1390
Guidelines for Multicast Routing 1390
Configure IGMP Features 1391
Enable Multicast Routing 1391
Configure IGMP Protocol 1392
Configure IGMP Access Groups 1393
Configure IGMP Static Groups 1394
Configure IGMP Join Groups 1395
Configure PIM Features 1395
Configure PIM Protocol 1396
Configure PIM Neighbor Filters 1397
Configure PIM Bidirectional Neighbor Filters 1398
Configure PIM Rendezvous Points 1398
Configure PIM Route Trees 1399
Configure PIM Request Filters 1400
Configure the Secure Firewall Threat Defense Device as a Candidate Bootstrap Router 1401
Configure Multicast Routes 1402
Configure Multicast Boundary Filters 1402

CHAPTER 52 **Policy Based Routing** 1405

About Policy Based Routing 1405

Guidelines and Limitations for Policy Based Routing 1407

Path Monitoring 1409

Configure Path Monitoring Settings 1411

Configure Policy-Based Routing Policy 1411

Add Path Monitoring Dashboard 1414

Configuration Example for Policy Based Routing 1415

Configuration Example for PBR with Path Monitoring 1420

PART XII **Objects and Certificates** 1423

CHAPTER 53 **Object Management** 1425

Introduction to Objects 1426

The Object Manager 1428

Importing Objects 1428

Editing Objects 1431

Viewing Objects and Their Usage 1431

Filtering Objects or Object Groups 1432

Object Groups 1433

Grouping Reusable Objects 1433

Object Overrides 1434

Managing Object Overrides 1435

Allowing Object Overrides 1436

Adding Object Overrides 1436

Editing Object Overrides 1437

AAA Server 1437

Add a RADIUS Server Group 1437

RADIUS Server Group Options 1438

RADIUS Server Options 1439

Add a Single Sign-on Server 1440

Access List 1442

Configure Extended ACL Objects 1442

Configure Standard ACL Objects 1445
Address Pools 1446
Application Filters 1447
AS Path 1447
BFD Template 1448
Cipher Suite List 1449
Creating Cipher Suite Lists 1449
Community List 1450
Extended Community 1451
DHCP IPv6 Pool 1453
Distinguished Name 1453
Creating Distinguished Name Objects 1455
DNS Server Group 1455
Creating DNS Server Group Objects 1455
External Attributes 1456
Dynamic Objects 1456
Create Dynamic Objects with Cloud-Delivered Firewall Management Center 1457
Create Dynamic Objects with Cloud-Delivered Firewall Management Center and On-Premises Cisco Secure Dynamic Attributes Connector 1458
Work With Dynamic Objects 1460
Dynamic Object Mappings 1460
About API-Created Dynamic Objects 1460
Security Group Tag 1462
Creating Security Group Tag Objects 1462
File List 1462
Source Files for File Lists 1463
Adding Individual SHA-256 Values to File Lists 1464
Uploading Individual Files to File Lists 1464
Uploading Source Files to File Lists 1465
Editing SHA-256 Values in File Lists 1466
Downloading Source Files from File Lists 1467
FlexConfig 1467
Geolocation 1468
Creating Geolocation Objects 1468

Interface 1468
Key Chain 1469
Creating Key Chain Objects 1470
Network 1471
Network Wildcard Mask 1472
Creating Network Objects 1473
Importing Network Objects 1474
Editing and Deleting Network Objects and Groups 1474
PKI 1475
Internal Certificate Authority Objects 1476
CA Certificate and Private Key Import 1476
Importing a CA Certificate and Private Key 1477
Generating a New CA Certificate and Private Key 1477
New Signed Certificates 1477
Creating an Unsigned CA Certificate and CSR 1478
Uploading a Signed Certificate Issued in Response to a CSR 1478
CA Certificate and Private Key Downloads 1479
Downloading a CA Certificate and Private Key 1479
Trusted Certificate Authority Objects 1479
Trusted CA Object 1480
Adding a Trusted CA Object 1480
Certificate Revocation Lists in Trusted CA Objects 1481
Adding a Certificate Revocation List to a Trusted CA Object 1481
External Certificate Objects 1481
Adding External Certificate Objects 1482
Internal Certificate Objects 1482
Adding Internal Certificate Objects 1483
Certificate Enrollment Objects 1483
Adding Certificate Enrollment Objects 1485
Add Certificate Enrollment 1487
Certificate Enrollment Object EST Options 1487
Certificate Enrollment Object SCEP Options 1488
Certificate Enrollment Object Certificate Parameters 1488
Certificate Enrollment Object Key Options 1489

Certificate Enrollment Object Revocation Options 1491
Policy List 1492
Port 1493
Creating Port Objects 1494
Importing Port Objects 1495
Prefix List 1495
Configure IPv6 Prefix List 1495
Configure IPv4 Prefix List 1496
Route Map 1496
Security Intelligence 1500
How to Modify Security Intelligence Objects 1501
Global and Domain Security Intelligence Lists 1502
Security Intelligence Lists and Multitenancy 1502
Delete Entries from Global Security Intelligence Lists 1503
List and Feed Updates for Security Intelligence 1504
Changing the Update Frequency for Security Intelligence Feeds 1504
Custom Security Intelligence Lists and Feeds 1504
Custom Lists and Feeds: Requirements 1504
URL Lists and Feeds: URL Syntax and Matching Criteria 1505
Custom Security Intelligence Feeds 1506
Custom Security Intelligence Lists 1508
Sinkhole 1510
Creating Sinkhole Objects 1510
SLA Monitor 1511
Time Range 1512
Creating Time Range Objects 1512
Time Zone 1514
Tunnel Zone 1514
URL 1514
Creating URL Objects 1515
Variable Set 1516
Variable Sets in Intrusion Policies 1517
Variables 1517
Predefined Default Variables 1518

Network Variables 1520
Port Variables 1521
Advanced Variables 1522
Variable Reset 1523
Adding Variables to Sets 1523
Nesting Variables 1525
Managing Variable Sets 1526
Creating Variable Sets 1527
Managing Variables 1527
Adding Variables 1529
Editing Variables 1529
VLAN Tag 1530
Creating VLAN Tag Objects 1531
VPN 1531
Certificate Map Objects 1531
Secure Client Custom Attributes Objects 1532
Add Secure Client Custom Attributes Objects 1533
Add Custom Attributes to a Group Policy 1534
Firewall Threat Defense Group Policy Objects 1535
Configure Group Policy Objects 1535
Group Policy General Options 1536
Group Policy Secure Client Options 1538
Group Policy Advanced Options 1541
Firewall Threat Defense IPsec Proposals 1542
Configure IKEv1 IPsec Proposal Objects 1543
Configure IKEv2 IPsec Proposal Objects 1543
Firewall Threat Defense IKE Policies 1544
Configure IKEv1 Policy Objects 1544
Configure IKEv2 Policy Objects 1546
Secure Client Customization 1547
File Objects 1548

CHAPTER 54 **Certificates** 1551
Requirements and Prerequisites for Certificates 1551

Secure Firewall Threat Defense VPN Certificate Guidelines and Limitations 1551
Managing Firewall Threat Defense Certificates 1552
Automatically Update CA Bundles 1553
Installing a Certificate Using Self-Signed Enrollment 1555
Installing a Certificate using EST Enrollment 1556
Installing a Certificate Using SCEP Enrollment 1557
Installing a Certificate Using Manual Enrollment 1557
Installing a Certificate Using a PKCS12 File 1558
Troubleshooting Firewall Threat Defense Certificates 1559
History for Certificates 1560

PART XIII VPN 1561

CHAPTER 55 VPN Overview 1563
VPN Types 1563
VPN Basics 1564
Internet Key Exchange (IKE) 1565
IPsec 1565
VPN Packet Flow 1566
IPsec Flow Offload 1567
VPN Licensing 1567
How Secure Should a VPN Connection Be? 1568
Complying with Security Certification Requirements 1568
Deciding Which Encryption Algorithm to Use 1568
Deciding Which Hash Algorithms to Use 1569
Deciding Which Diffie-Hellman Modulus Group to Use 1569
Deciding Which Authentication Method to Use 1570
Pre-shared Keys 1570
PKI Infrastructure and Digital Certificates 1571
Removed or Deprecated Hash Algorithms, Encryption Algorithms, and Diffie-Hellman Modulus Groups 1572
VPN Topology Options 1573
Point-to-Point VPN Topology 1573
Hub and Spoke VPN Topology 1573

Full Mesh VPN Topology 1574
Implicit Topologies 1575

CHAPTER 56 Site-to-Site VPNs 1577
About Site-to-Site VPN 1577
Secure Firewall Threat Defense Site-to-site VPN Guidelines and Limitations 1579
Types of Site-to-Site VPN Topologies 1580
Requirements and Prerequisites for Site-to-Site VPN 1580
Manage Site-to-Site VPNs 1581
Configure a Policy-based Site-to-Site VPN 1582
Firewall Threat Defense VPN Endpoint Options 1583
Firewall Threat Defense VPN IKE Options 1587
Firewall Threat Defense VPN IPsec Options 1590
Firewall Threat Defense Advanced Site-to-site VPN Deployment Options 1592
Firewall Threat Defense VPN Advanced IKE Options 1592
Firewall Threat Defense VPN Advanced IPsec Options 1594
Firewall Threat Defense Advanced Site-to-site VPN Tunnel Options 1594
About Virtual Tunnel Interfaces 1595
Static VTI 1596
Dynamic VTI 1597
Guidelines and Limitations for Virtual Tunnel Interfaces 1599
Add a VTI Interface 1603
Create a Route-based Site-to-Site VPN 1604
Configure Endpoints for a Point to Point Topology 1605
Advanced Configurations for a Point to Point Topology in a Route-based VPN 1607
Configure Endpoints for a Hub and Spoke Topology 1608
Advanced Configurations for Hub and Spokes in a Route-based VPN 1610
Configure Multiple Hubs in a Route-based VPN 1611
Configure Routing for Multiple Hubs in a Route-based VPN 1613
Verify the Multiple Hubs Configuration in a Route-based VPN 1615
Route Traffic Through a Backup VTI Tunnel 1615
Configure Dynamic VTI for a Route-based Site-to-Site VPN 1617
How to Configure a Virtual Router with Dynamic VTI 1617
Configure Routing and AC Policies for VTI 1617

View Virtual Tunnel Information 1620
Deploy a SASE Tunnel on Umbrella 1620
Guidelines and Limitations for Configuring SASE Tunnels on Umbrella 1621
How to Deploy a SASE Tunnel on Umbrella 1622
Prerequisites for Configuring Umbrella SASE Tunnels 1623
Map Management Center Umbrella Parameters and Cisco Umbrella API Keys 1623
Configure a SASE Tunnel for Umbrella 1625
View SASE Tunnel Status 1626
Monitoring the Site-to-Site VPNs 1627
History for Site-to-Site VPN 1633

CHAPTER 57 **Remote Access VPN** 1635
Remote Access VPN Overview 1635
Remote Access VPN Features 1636
Secure Client Components 1638
Remote Access VPN Authentication 1638
Understanding Policy Enforcement of Permissions and Attributes 1640
Understanding AAA Server Connectivity 1640
License Requirements for Remote Access VPN 1641
Requirements and Prerequisites for Remote Access VPN 1641
Remote Access VPN Guidelines and Limitations 1642
Configuring a New Remote Access VPN Connection 1645
Prerequisites for Configuring Remote Access VPN 1646
Create a New Remote Access VPN Policy 1646
Update the Access Control Policy on the Secure Firewall Threat Defense Device 1649
(Optional) Configure NAT Exemption 1650
Configure DNS 1651
Add Secure Client Profile XML File 1651
(Optional) Configure Split Tunneling 1652
(Optional) Configure Dynamic Split Tunneling 1653
Verify Dynamic Split Tunneling Configuration 1654
Verify the Configuration 1654
Create a Copy of an Existing Remote Access VPN Policy 1655
Set Target Devices for a Remote Access VPN Policy 1655

Associate Local Realm with Remote Access VPN Policy 1656
Additional Remote Access VPN Configurations 1656
Configure Connection Profile Settings 1656
Configure IP Addresses for VPN Clients 1657
Configure AAA Settings for Remote Access VPN 1659
Create or Update Aliases for a Connection Profile 1674
Configure Access Interfaces for Remote Access VPN 1675
Configure Advanced Options for Remote Access VPN 1677
Cisco Secure Client Image 1677
Remote Access VPN Address Assignment Policy 1679
Configure Certificate to Connection Profile Mapping 1680
Configure Group Policies 1680
Configuring LDAP Attribute Mapping 1681
Configuring VPN Load Balancing 1683
Configure IPsec Settings 1686
Customize Cisco Secure Client 1691
Configure Secure Client Management VPN Tunnel 1702
Requirements and Prerequisites for Secure Client Management VPN Tunnel 1703
Limitations of Secure Client Management VPN Tunnel 1703
Configuring Secure Client Management VPN Tunnel on Firewall Threat Defense 1703
Multiple Certificate Authentication 1706
Guidelines and Limitations of Multiple Certificate Authentication 1706
Configuring Multiple Certificate Authentication 1706
Customizing Remote Access VPN AAA Settings 1707
Authenticate VPN Users via Client Certificates 1707
Configure VPN User Authentication via Client Certificate and AAA Server 1709
Manage Password Changes over VPN Sessions 1711
Send Accounting Records to the RADIUS Server 1711
Delegating Group Policy Selection to Authorization Server 1712
Override the Selection of Group Policy or Other Attributes by the Authorization Server 1713
Deny VPN Access to a User Group 1714
Restrict Connection Profile Selection for a User Group 1715
Update the Secure Client Profile for Remote Access VPN Clients 1715
RADIUS Dynamic Authorization 1716

Configuring RADIUS Dynamic Authorization 1717
Two-Factor Authentication 1718
Configuring RSA Two-Factor Authentication 1718
Configuring Duo Two-Factor Authentication 1719
Secondary Authentication 1721
Configure Remote Access VPN Secondary Authentication 1721
Single Sign-On Authentication with SAML 2.0 1723
Guidelines and Limitations for SAML 2.0 1724
Configuring a SAML Single Sign-On Authentication 1725
Configuring SAML Authorization 1726
Advanced Secure Client Configurations 1728
Configure Secure Client Modules on a Firewall Threat Defense 1728
Types of Secure Client Modules 1728
Prerequisites for Configuring Secure Client Modules 1729
Guidelines for Configuring Secure Client Modules 1730
Install Secure Client Modules using a Firewall Threat Defense 1731
Configure a Remote Access VPN Group Policy with Secure Client Modules 1732
Verify Secure Client Modules Configuration 1732
Configure Application-Based (Per App VPN) Remote Access VPN on Mobile Devices 1733
Prerequisites and Licensing for Configuring Per App VPN Tunnels 1733
Determine the Application IDs for Mobile Applications 1734
Configure Application-Based VPN Tunnels 1735
Verify Per App Configuration 1736
Remote Access VPN Examples 1736
How to Limit Secure Client Bandwidth Per User 1736
How to Use VPN Identity for User-Id Based Access Control Rules 1737
Configure Firewall Threat Defense Multiple Certificate Authentication 1737

CHAPTER 58 **Dynamic Access Policies** 1743
About Secure Firewall Threat Defense Dynamic Access Policy 1743
Hierarchy of Policy Enforcement of Permissions and Attributes in Firewall Threat Defense 1743
Prerequisites for Dynamic Access Policy 1745
Guidelines and Limitations for Dynamic Access Policies 1745
Configure a Dynamic Access Policy (DAP) 1745

Create a Dynamic Access Policy 1745
Create a Dynamic Access Policy Record 1746
Configure AAA Criteria Settings for DAP 1746
Configure Endpoint Attribute Selection Criteria in DAP 1747
Add an Anti-Malware Endpoint Attribute to a DAP 1748
Add a Device Endpoint Attribute to a DAP 1749
Add Secure Client Endpoint Attributes to a DAP 1749
Add NAC Endpoint Attributes to a DAP 1750
Add an Application Attribute to a DAP 1750
Add a Personal Firewall Endpoint Attribute to a DAP 1750
Add an Operating System Endpoint Attribute to a DAP 1751
Add a Process Endpoint Attribute to a DAP 1751
Add a Registry Endpoint Attribute to a DAP 1751
Add a File Endpoint Attribute to a DAP 1752
Add Certificate Authentication Attributes to a DAP 1752
Configure Advanced Settings for DAP 1753
Associate Dynamic Access Policy with Remote Access VPN 1753
History for Dynamic Access Policy 1754

CHAPTER 59 **VPN Monitoring and Troubleshooting in Security Cloud Control 1755**
Site-to-Site VPN Summary Page 1755
Monitor Remote Access VPN Sessions 1755
SD-WAN Summary Dashboard 1755
Prerequisites for Using SD-WAN Summary Dashboard 1756
Monitor WAN Devices and Interfaces Using the SD-WAN Summary Dashboard 1757
Monitor Application Performance Metrics of WAN Interfaces Using the SD-WAN Summary Dashboard 1759
System Messages 1759
Debug Commands 1759
debug aaa 1761
debug crypto 1761
debug crypto ca 1762
debug crypto ikev1 1763
debug crypto ikev2 1763

debug crypto ipsec 1764
debug ldap 1764
debug ssl 1765
debug webvpn 1765

PART XIV Access Control 1769

CHAPTER 60 Access Control Overview 1771
Introduction to Access Control 1771
Introduction to Rules 1772
Filtering Rules by Device 1772
Rule and Other Policy Warnings 1773
Access Control Policy Default Action 1774
Deep Inspection Using File and Intrusion Policies 1776
Access Control Traffic Handling with Intrusion and File Policies 1777
File and Intrusion Inspection Order 1778
Access Control Policy Inheritance 1779
Best Practices for Application Control 1780
Recommendations for Application Control 1780
Best Practices for Configuring Application Control 1782
Application Characteristics 1783
Application-Specific Notes and Limitations 1784
Best Practices for Access Control Rules 1785
General Best Practices for Access Control 1785
Best Practices for Ordering Rules 1786
Rule Preemption 1787
Rule Actions and Rule Order 1788
Application Rule Order 1788
URL Rule Order 1789
Best Practices for Simplifying and Focusing Rules 1789
Maximum Number of Access Control Rules and Intrusion Policies 1790

CHAPTER 61 Access Control Policies 1791
Access Control Policy Components 1791

System-Created Access Control Policies 1792
Requirements and Prerequisites for Access Control Policies 1792
Managing Access Control Policies 1793
Creating a Basic Access Control Policy 1794
Editing an Access Control Policy 1795
Locking an Access Control Policy 1797
Managing Access Control Policy Inheritance 1798
Choosing a Base Access Control Policy 1798
Inheriting Access Control Policy Settings from the Base Policy 1799
Locking Settings in Descendant Access Control Policies 1799
Requiring an Access Control Policy in a Domain 1800
Assigning Devices to an Access Control Policy 1800
Logging Settings for Access Control Policies 1801
Access Control Policy Advanced Settings 1802
Associating Other Policies with Access Control 1807
Viewing Rule Hit Counts 1808
Analyzing Rule Conflicts and Warnings 1810
Searching for Rules 1812
History for Access Control Policies 1813

CHAPTER 62 **Access Control Rules** 1817
Introduction to Access Control Rules 1817
Access Control Rule Management 1819
Access Control Rule Components 1820
Access Control Rule Order 1821
Access Control Rule Actions 1822
Access Control Rule Monitor Action 1822
Access Control Rule Trust Action 1822
Access Control Rule Blocking Actions 1823
Access Control Rule Interactive Blocking Actions 1824
Access Control Rule Allow Action 1824
Requirements and Prerequisites for Access Control Rules 1825
Guidelines and Limitations for Access Control Rules 1826
Managing Access Control Rules 1827

Adding an Access Control Rule Category 1827
Create and Edit Access Control Rules 1827
Access Control Rule Conditions 1829
Enabling and Disabling Access Control Rules 1836
Copying Access Control Rules from One Access Control Policy to Another 1836
Moving Access Control Rules to a Prefilter Policy 1837
Positioning an Access Control Rule 1839
Adding Comments to an Access Control Rule 1840
Examples for Access Control Rules 1840
How to Control Access Using Security Zones 1840
How to Control Application Usage 1841
How to Block Threats 1842

CHAPTER 63 **Cisco Secure Dynamic Attributes Connector** 1845
About the Cisco Secure Dynamic Attributes Connector 1845
How It Works 1847
About the Dashboard 1848
Dashboard of an Unconfigured System 1848
Dashboard of a Configured System 1849
Add, Edit, or Delete Connectors 1851
Add, Edit, or Delete Dynamic Attributes Filters 1852
Create a Connector 1854
Amazon Web Services Connector—About User Permissions and Imported Data 1854
Create an AWS User with Minimal Permissions for the Cisco Secure Dynamic Attributes Connector 1855
Create an AWS Connector 1856
Amazon Web Services Security Groups Connector—About User Permissions and Imported Data 1857
Create an AWS Security Groups Connector 1857
Create an AWS Service Tags Connector 1858
Azure Connector—About User Permissions and Imported Data 1859
Create an Azure User with Minimal Permissions for the Cisco Secure Dynamic Attributes Connector 1860
Create an Azure Connector 1862
Create an Azure Service Tags Connector 1863

Create a Multicloud Defense Connector 1864
Create a Cisco Cyber Vision Connector 1865
Create a Generic Text Connector 1866
Manually Get a Certificate Authority (CA) Chain 1868
Create a GitHub Connector 1870
Google Cloud Connector—About User Permissions and Imported Data 1871
Create a Google Cloud User with Minimal Permissions for the Cisco Secure Dynamic Attributes Connector 1871
Create a Google Cloud Connector 1873
Create an Office 365 Connector 1874
Create a Webex Connector 1875
Create a Zoom Connector 1876
Create an Adapter 1876
How to Create an On-Prem Firewall Management Center Adapter 1877
How to Create a Cloud-Delivered Firewall Management Center Adapter 1878
Create Dynamic Attributes Filters 1879
Dynamic Attribute Filter Examples 1880
Use Dynamic Objects in Access Control Policies 1881
About Dynamic Objects in Access Control Rules 1881
Dynamic Attributes Rule Conditions 1881
Create Access Control Rules Using Dynamic Attributes Filters 1882
Troubleshoot the Cisco Secure Dynamic Attributes Connector 1883
Troubleshoot Error Messages 1883
Get Your Tenant ID 1884

CHAPTER 64 **URL Filtering** 1885
URL Filtering Overview 1885
About URL Filtering with Category and Reputation 1886
URL Category and Reputation Descriptions 1887
URL Filtering Data from the Cisco Cloud 1887
Best Practices for URL Filtering 1887
Filtering HTTPS Traffic 1890
Use Categories in URL Filtering 1891
License Requirements for URL Filtering 1892

Requirements and Prerequisites for URL Filtering 1892
How to Configure URL Filtering with Category and Reputation 1893
Enable URL Filtering Using Category and Reputation 1894
URL Filtering Options 1894
Configuring URL Conditions 1896
Rules with URL Conditions 1897
URL Rule Order 1898
DNS Filtering: Identify URL Reputation and Category During DNS Lookup 1898
Enable DNS Filtering to Identify URLs During Domain Lookup 1898
DNS Filtering Limitations 1899
DNS Filtering and Events 1899
Manual URL Filtering 1899
Manual URL Filtering Options 1900
Supplement or Selectively Override Category and Reputation-Based URL Filtering 1900
Configure HTTP Response Pages 1901
Limitations to HTTP Response Pages 1901
Requirements and Prerequisites for HTTP Response Pages 1902
Choosing HTTP Response Pages 1902
Configure Interactive Blocking with HTTP Response Pages 1903
Configuring Interactive Blocking 1904
Setting the User Bypass Timeout for a Blocked Website 1904
Configure URL Filtering Health Monitors 1905
Dispute URL Category and Reputation 1905
If the URL Category Set Changes, Take Action 1906
URL Category and Reputation Changes: Effect on Events 1907
Troubleshoot URL Filtering 1907

CHAPTER 65 **Security Intelligence** 1911
About Security Intelligence 1911
Best Practices for Security Intelligence 1912
License Requirements for Security Intelligence 1912
Requirements and Prerequisites for Security Intelligence 1913
Security Intelligence Sources 1913
Configure Security Intelligence 1914

Security Intelligence Options 1916
Security Intelligence Categories 1917
Block List Icons 1919
Configuration Example: Security Intelligence Blocking 1919
Security Intelligence Monitoring 1920
Override Security Intelligence Blocking 1921
Troubleshooting Security Intelligence 1921
Security Intelligence Categories Are Missing from the Available Options List 1922

CHAPTER 66 DNS Policies 1923
DNS Policy Overview 1923
Cisco Umbrella DNS Policies 1924
DNS Policy Components 1924
License Requirements for DNS Policies 1925
Requirements and Prerequisites for DNS Policies 1925
Managing DNS and Umbrella DNS Policies 1926
Creating Basic DNS Policies 1926
Editing DNS Policies 1927
DNS Rules 1928
Creating and Editing DNS Rules 1928
DNS Rule Management 1929
Enabling and Disabling DNS Rules 1929
DNS Rule Order Evaluation 1930
DNS Rule Actions 1930
DNS Rule Conditions 1931
Security Zone Rule Conditions 1931
Network Rule Conditions 1932
VLAN Tags Rule Conditions 1932
DNS Policy Rule Conditions 1933
How to Create DNS Rules 1933
Controlling Traffic Based on DNS and Security Zone 1933
Controlling Traffic Based on DNS and Network 1933
Controlling Traffic Based on DNS and VLAN 1934
Controlling Traffic Based on DNS List or Feed 1935

DNS Policy Deploy 1935
Cisco Umbrella DNS Policies 1936
How to Redirect DNS Requests to Cisco Umbrella 1936
Prerequisites for Configuring the Umbrella DNS Connector 1937
Configure Cisco Umbrella Connection Settings 1938
Create an Umbrella DNS Policy 1939
Edit Umbrella DNS Policies and Rules 1939
Associate the Umbrella DNS Policy with an Access Control Policy 1940

CHAPTER 67 **Prefiltering and Prefilter Policies** 1941
About Prefiltering 1941
About Prefilter Policies 1941
Tunnel vs Prefilter Rules 1942
Prefiltering vs Access Control 1943
Passthrough Tunnels and Access Control 1945
Best Practices for Fastpath Prefiltering 1946
Best Practices for Encapsulated Traffic Handling 1946
Requirements and Prerequisites for Prefilter Policies 1947
Configure Prefiltering 1948
Tunnel and Prefilter Rule Components 1949
Prefilter Rule Conditions 1951
Interface Rule Conditions 1951
Network Rule Conditions 1951
VLAN Tags Rule Conditions 1952
Port Rule Conditions for Prefilter Rules 1952
Time and Day Rule Conditions 1953
Tunnel Rule Conditions 1953
Encapsulation Rule Conditions 1953
Tunnel Zones and Prefiltering 1954
Using Tunnel Zones 1954
Creating Tunnel Zones 1956
Moving Prefilter Rules to an Access Control Policy 1957
Prefilter Policy Hit Counts 1959
Large Flow Offloads 1959

Flow Offload Limitations 1960

CHAPTER 68 **Service Policies** 1963

About Threat Defense Service Policies 1963

How Service Policies Relate to FlexConfig and Other Features 1964

What Are Connection Settings? 1964

Requirements and Prerequisites for Service Policies 1965

Guidelines and Limitations for Service Policies 1965

Configure Threat Defense Service Policies 1966

Configure a Service Policy Rule 1966

Bypass TCP State Checks for Asymetrical Routing (TCP State Bypass) 1969

The Asymetrical Routing Problem 1970

Guidelines and Limitations for TCP State Bypass 1971

Configure TCP State Bypass 1971

Disable TCP Sequence Randomization 1973

Examples for Service Policy Rules 1974

Protect Servers from a SYN Flood DoS Attack (TCP Intercept) 1974

Make the Firewall Threat Defense Device Appear on Traceroutes 1977

Monitoring Service Policies 1979

CHAPTER 69 **Elephant Flow Detection** 1981

About Elephant Flow Detection and Remediation 1981

Elephant Flow Upgrade from Intelligent Application Bypass 1981

Configure Elephant Flow 1982

CHAPTER 70 **Intelligent Application Bypass** 1987

Introduction to IAB 1987

IAB Options 1988

Requirements and Prerequisites for Intelligent Application Bypass 1990

Configuring Intelligent Application Bypass 1990

IAB Logging and Analysis 1991

CHAPTER 71 **Content Restriction** 1995

About Content Restriction 1995

Requirements and Prerequisites for Content Restriction 1996
Guidelines and Limitations for Content Restriction 1997
Using Access Control Rules to Enforce Content Restriction 1997
Safe Search Options for Access Control Rules 1998
Using a DNS Sinkhole to Enforce Content Restriction 1998

CHAPTER 72 **Zero Trust Access** 2001
Zero Trust Access 2001
How Threat Defense Works with Zero Trust Access 2002
Why Use Zero Trust Access? 2002
Components of a Clientless Zero Trust Network Access Configuration 2003
Clientless Zero Trust Network Access Workflow 2004
Limitations for Clientless Zero Trust Network Access 2005
Prerequisites for Zero Trust Application Policy 2006
Manage Zero Trust Application Policies 2006
Create a Zero Trust Application Policy 2007
Create an Application Group 2008
Create an Application 2009
Set Targeted Devices for Zero Trust Access Policy 2011
Edit a Zero Trust Application Policy 2012
Monitor Zero Trust Sessions 2013

PART XV **Intrusion Detection and Prevention** 2015

CHAPTER 73 **An Overview of Network Analysis and Intrusion Policies** 2017
About Network Analysis and Intrusion Policies 2017
Snort Inspection Engine 2018
Snort 3 2019
Guidelines and Limitations for Network Analysis and Intrusion Policies 2021
How Policies Examine Traffic For Intrusions 2022
Decoding, Normalizing, and Preprocessing: Network Analysis Policies 2023
Access Control Rules: Intrusion Policy Selection 2024
Intrusion Inspection: Intrusion Policies, Rules, and Variable Sets 2025
Intrusion Event Generation 2026

System-Provided and Custom Network Analysis and Intrusion Policies 2027
System-Provided Network Analysis and Intrusion Policies 2028
Benefits of Custom Network Analysis and Intrusion Policies 2029
Benefits of Custom Network Analysis Policies 2029
Benefits of Custom Intrusion Policies 2030
Limitations of Custom Policies 2031
Prerequisites for Network Analysis and Intrusion Policies 2033

CHAPTER 74 **Migrate from Snort 2 to Snort 3** 2035
Snort 3 Inspection Engine 2035
Prerequisites for Network Analysis and Intrusion Policies 2036
How to Migrate from Snort 2 to Snort 3 2036
Prerequisites for Migrating from Snort 2 to Snort 3 2036
Enable Snort 3 on an Individual Device 2037
Enable Snort 3 on Multiple Devices 2037
Convert Snort 2 Custom IPS Rules to Snort 3 2038
Convert all Snort 2 Custom Rules across all Intrusion Policies to Snort 3 2038
Convert Snort 2 Custom Rules of a Single Intrusion Policy to Snort 3 2039
View Snort 2 and Snort 3 Base Policy Mapping 2040
Synchronize Snort 2 Rules with Snort 3 2040
Deploy Configuration Changes 2041

CHAPTER 75 **Get Started with Snort 3 Intrusion Policies** 2045
Overview of Intrusion Policies 2045
Prerequisites for Network Analysis and Intrusion Policies 2046
Create a Custom Snort 3 Intrusion Policy 2046
Edit Snort 3 Intrusion Policies 2047
Rule Group Reporting 2051
Rule Action Logging 2051
Change the Base Policy of an Intrusion Policy 2052
Manage Intrusion Policies 2052
Access Control Rule Configuration to Perform Intrusion Prevention 2053
Access Control Rule Configuration and Intrusion Policies 2054
Configure an Access Control Rule to Perform Intrusion Prevention 2054

Deploy Configuration Changes 2055

CHAPTER 76 **Tune Intrusion Policies Using Rules** 2057

Overview of Tuning Intrusion Rules 2057

Intrusion Rule Types 2058

Prerequisites for Network Analysis and Intrusion Policies 2059

Custom Rules in Snort 3 2059

View Snort 3 Intrusion Rules in an Intrusion Policy 2062

Intrusion Rule Action 2063

Intrusion Rule Action Options 2063

Set Intrusion Rule Action 2063

Intrusion Event Notification Filters in an Intrusion Policy 2064

Intrusion Event Thresholds 2064

Set Intrusion Event Thresholds 2064

Set Threshold for an Intrusion Rule in Snort 3 2066

View and Delete Intrusion Event Thresholds 2067

Intrusion Policy Suppression Configuration 2067

Intrusion Policy Suppression Types 2067

Set Suppression for an Intrusion Rule in Snort 3 2068

View and Delete Suppression Conditions 2068

Add Intrusion Rule Comments 2069

Snort 2 Custom Rules Conversion to Snort 3 2069

Convert all Snort 2 Custom Rules across all Intrusion Policies to Snort 3 2070

Convert Snort 2 Custom Rules of a Single Intrusion Policy to Snort 3 2071

Add Custom Rules to Rule Groups 2071

Add Rule Groups with Custom Rules to an Intrusion Policy 2072

Manage Custom Rules in Snort 3 2073

Delete Custom Rules 2074

Delete Rule Groups 2074

Intrusion Rule State Options 2075

Setting Intrusion Rule States 2076

CHAPTER 77 **Tailor Intrusion Protection for Your Network Assets** 2077

Snort 3 Rule Changes in LSP Updates 2077

Overview of Secure Firewall Recommended Rules 2077
Prerequisites for Network Analysis and Intrusion Policies 2078
Generate New Secure Firewall Recommendations in Snort 3 2079

CHAPTER 78 **Custom Intrusion Rules** 2083

Custom Intrusion Rules Overview 2083
License Requirements for the Intrusion Rule Editor 2084
Requirements and Prerequisites for the Intrusion Rule Editor 2084
Rule Anatomy 2084
The Intrusion Rule Header 2085
Intrusion Rule Header Action 2086
Intrusion Rule Header Protocol 2086
Intrusion Rule Header Direction 2087
Intrusion Rule Header Source and Destination IP Addresses 2087
Intrusion Rule Header Source and Destination Ports 2090
Intrusion Event Details 2091
Adding a Custom Classification 2094
Defining an Event Priority 2095
Defining an Event Reference 2095
Custom Rule Creation 2095
Writing New Rules 2096
Modifying Existing Rules 2097
Adding Comments to Intrusion Rules 2098
Deleting Custom Rules 2099
Searching for Rules 2099
Search Criteria for Intrusion Rules 2100
Rule Filtering on the Intrusion Rules Editor Page 2101
Filtering Guidelines 2101
Keyword Filtering 2102
Character String Filtering 2103
Combination Keyword and Character String Filtering 2103
Filtering Rules 2103
Keywords and Arguments in Intrusion Rules 2104
The content and protected_content Keywords 2104

Basic content and protected_content Keyword Arguments 2106
content and protected_content Keyword Search Locations 2107
Overview: HTTP content and protected_content Keyword Arguments 2109
Overview: content Keyword Fast Pattern Matcher 2113
The replace Keyword 2115
The byte_jump Keyword 2116
The byte_test Keyword 2119
The byte_extract Keyword 2121
The byte_math Keyword 2124
Overview: The pcre Keyword 2126
pcre Syntax 2127
pcre Modifier Options 2129
pcre Example Keyword Values 2132
The metadata Keyword 2134
Service Metadata 2135
Metadata Search Guidelines 2140
IP Header Values 2141
ICMP Header Values 2143
TCP Header Values and Stream Size 2144
The stream_reassembly Keyword 2148
SSL Keywords 2148
The appid Keyword 2150
Application Layer Protocol Values 2151
The RPC Keyword 2151
The ASN.1 Keyword 2151
The urilen Keyword 2152
DCE/RPC Keywords 2153
SIP Keywords 2156
GTP Keywords 2158
SCADA Keywords 2170
Modbus Keywords 2170
DNP3 Keywords 2171
CIP and ENIP Keywords 2174
S7Commplus Keywords 2175

Packet Characteristics 2176
Active Response Keywords 2178
The resp Keyword 2178
The react Keyword 2179
The detection_filter Keyword 2180
The tag Keyword 2181
The flowbits Keyword 2182
flowbits Keyword Options 2182
Guidelines for Using the flowbits Keyword 2184
flowbits Keyword Examples 2184
The http_encode Keyword 2189
http_encode Keyword Syntax 2190
http_encode Keyword example: Using Two http_endcode Keywords to Search for Two Encodings 2190
Overview: The file_type and file_group Keywords 2190
The file_type and file_group Keywords 2191
The file_data Keyword 2192
The pkt_data Keyword 2193
The base64_decode and base64_data Keywords 2193

CHAPTER 79 **Intrusion Prevention Performance Tuning** 2195
About Intrusion Prevention Performance Tuning 2195
License Requirements for Intrusion Prevention Performance Tuning 2196
Requirements and Prerequisites for Intrusion Prevention Performance Tuning 2196
Limiting Pattern Matching for Intrusions 2196
Regular Expression Limits Overrides for Intrusion Rules 2197
Overriding Regular Expression Limits for Intrusion Rules 2198
Per Packet Intrusion Event Generation Limits 2199
Limiting Intrusion Events Generated Per Packet 2199
Packet and Intrusion Rule Latency Threshold Configuration 2200
Latency-Based Performance Settings 2200
Packet Latency Thresholding 2200
Packet Latency Thresholding Notes 2201
Enabling Packet Latency Thresholding 2202

Configuring Packet Latency Thresholding 2202
Rule Latency Thresholding 2203
Rule Latency Thresholding Notes 2204
Configuring Rule Latency Thresholding 2205
Intrusion Performance Statistic Logging Configuration 2206
Configuring Intrusion Performance Statistic Logging 2206

CHAPTER 80 **Get Started with Snort 3 Network Analysis Policies** 2209
Overview of Network Analysis Policies 2209
Manage Network Analysis Policies 2210
Snort 3 Definitions and Terminologies for Network Analysis Policy 2211
Prerequisites for Network Analysis and Intrusion Policies 2213
Custom Network Analysis Policy Creation for Snort 3 2213
Common Industrial Protocol Safety 2217
Detect and Block Safety Segments in CIP Packets 2218
Network Analysis Policy Mapping 2218
View Network Analysis Policy Mapping 2219
Create a Network Analysis Policy 2219
Modify the Network Analysis Policy 2219
Search for an Inspector on the Network Analysis Policy Page 2220
Copy the Inspector Configuration 2220
Customize the Network Analysis Policy 2221
Make Inline Edit for an Inspector to Override Configuration 2224
Revert Unsaved Changes during Inline Edits 2225
View the List of Inspectors with Overrides 2226
Revert Overridden Configuration to Default Configuration 2226
Validate Snort 3 Policies 2227
Examples of Custom Network Analysis Policy Configuration 2229
Network Analysis Policy Settings and Cached Changes 2240

CHAPTER 81 **Encrypted Visibility Engine** 2241
Overview of Encrypted Visibility Engine 2241
How EVE Works 2242
Indications of Compromise Events 2243

QUIC Fingerprinting in EVE 2243
Configure EVE 2243
View Encrypted Visibility Engine Events 2245
View EVE Dashboard 2246
Configure EVE Exception Rules 2246
Add Exception Rule from Unified Events 2247

CHAPTER 82 Elephant Flow Detection 2249
About Elephant Flow Detection and Remediation 2249
Elephant Flow Upgrade from Intelligent Application Bypass 2249
Configure Elephant Flow 2250

CHAPTER 83 Use Case - Migrate from Snort 2 to Snort 3 In Secure Firewall Management Center 2255
Migrate from Snort 2 to Snort 3 2255
Benefits of Migrating to Snort 3 2255
Sample Business Scenario 2256
Best Practices for Migrating from Snort 2 to Snort 3 2256
Prerequisites 2256
End-to-End Migration Workflow 2256
Enable Snort 3 on Threat Defense 2257
Convert Snort 2 Rules of a Single Intrusion Policy to Snort 3 2258
Deploy Configuration Changes 2263

CHAPTER 84 Use Case - Generate Snort 3 Recommendations In Secure Firewall Management Center 2265
Snort 3 Rule Recommendations 2265
Benefits 2266
Sample Business Scenario 2266
Best Practices 2266
Prerequisites 2266
Generate Snort 3 Recommendations 2266
Deploy Configuration Changes 2269

CHAPTER 85 Use Case - Block Traffic Based on the EVE Threat Confidence Score 2273
About Encrypted Visibility Engine 2273

Benefits 2273
Sample Business Scenario 2273
Prerequisites 2274
High-Level Workflow 2274
Configure Block Thresholds in EVE 2274
View EVE Events 2277
Additional References 2278

CHAPTER 86 Use Case - Configure Elephant Flow Detection Outcomes 2279
About Elephant Flows 2279
Benefits of Elephant Flow Detection and Remediation 2279
Elephant Flow Workflow 2280
Sample Business Scenario 2280
Prerequisites 2281
Configure Elephant Flow Parameters 2281
View Events for Elephant Flows 2284
Configure Elephant Flow Remediation Exemption 2285
View Events for Elephant Flow Remediation Exemption 2288
Additional References 2288

CHAPTER 87 Mitigate Threats Using MITRE Framework in Snort 3 Intrusion Policies 2289
About MITRE ATT&CK Framework 2289
Benefits of MITRE Framework 2289
Sample Business Scenario for MITRE Network 2290
Prerequisites for MITRE Framework 2290
View and Edit Your Snort 3 Intrusion Policy 2290
View Intrusion Events 2295

PART XVI Network Malware Protection and File Policies 2299

CHAPTER 88 Network Malware Protection and File Policies 2301
About Network Malware Protection and File Policies 2301
File Policies 2302

Requirements and Prerequisites for File Policies 2302
License Requirements for File and Malware Policies 2303
Best Practices for File Policies and Malware Detection 2303
File Rule Best Practices 2303
File Detection Best Practices 2304
File Blocking Best Practices 2304
File Policy Best Practices 2305
How to Configure Malware Protection 2306
Plan and Prepare for Malware Protection 2307
Configure File Policies 2307
Add File Policies to Your Access Control Configuration 2308
Configuring an Access Control Rule to Perform Malware Protection 2309
Set Up Maintenance and Monitoring of Malware Protection 2310
Cloud Connections for Malware Protection 2310
AMP Cloud Connection Configurations 2311
Change AMP Options 2311
Dynamic Analysis Connections 2312
Requirements for Dynamic Analysis 2312
Viewing the Default Dynamic Analysis Connection 2312
Enabling Access to Dynamic Analysis Results in the Public Cloud 2312
Maintain Your System: File Types Eligible for Dynamic Analysis 2313
File Policies and File Rules 2314
Create or Edit a File Policy 2314
Advanced and Archive File Inspection Options 2315
Managing File Policies 2318
File Rules 2318
File Rule Components 2319
File Rule Actions 2320
Creating File Rules 2327
Access Control Rule Logging for Malware Protection 2329
Retrospective Disposition Changes 2329
File and Malware Inspection Performance and Storage Options 2329
Tuning File and Malware Inspection Performance and Storage 2330
(Optional) Malware Protection with Secure Endpoint 2331

Comparison of Malware Protection: Firepower vs. Secure Endpoint 2332
About Integrating Firepower with Secure Endpoint 2332
Benefits of Integrating Firepower and Secure Endpoint 2333
Secure Endpoint and AMP Private Cloud 2333
Integrate Firepower and Secure Endpoint 2333
History for Network Malware Protection and File Policies 2335

PART XVII **Policy Tools** 2337

CHAPTER 89 **Analyzing, Detecting, and Fixing Policy Anomalies Using Policy Analyzer and Optimizer** 2339
About Policy Analyzer and Optimizer 2339
Analysis, Remediation, and Reporting 2340
Prerequisites to Use Policy Analyzer and Optimizer 2341
Policy Analyzer and Optimizer Licensing Requirements 2341
Enable Policy Analyzer and Optimizer for Cloud-Delivered Firewall Management Center 2342
Enable Policy Analyzer and Optimizer for Security Cloud Control-managed On-Premises Firewall Management Center 2342
Policy Analysis 2343
Analyze Cloud-Delivered Firewall Management Center Policies 2343
Analyze On-Premises Firewall Management Center Policies 2344
Policy Reporting 2345
Policy Analysis Summary 2345
Duplicate Rules 2347
Overlapping Objects 2347
Expired Rules 2348
Mergeable Rules 2348
Policy Insights 2349
Policy Remediation 2349
Apply Policy Remediation 2350
What Does the Policy Remediation Report Contain? 2351
Troubleshooting Policy Analyzer and Optimizer 2351
Policy Analyzer and Optimizer Does Not Analyze Policies 2351
Policy Analyzer and Optimizer Does Not Fetch Policies 2352
Frequently Asked Questions About Policy Analyzer and Optimizer 2352

PART XVIII **Encrypted Traffic Handling** 2355

CHAPTER 90 **Traffic Decryption Overview** 2357

Traffic Decryption Explained 2357

TLS/SSL Handshake Processing 2358

ClientHello Message Handling 2359

ServerHello and Server Certificate Message Handling 2362

Decryption Rule and Policy Basics 2364

The Case for Decryption 2364

When to Decrypt Traffic, When Not to Decrypt 2365

Decrypt and Resign (Outgoing Traffic) 2366

Known Key Decryption (Incoming Traffic) 2367

Other Decryption Rule Actions 2367

Decryption Rule Components 2367

Decryption Rule Order Evaluation 2368

Multi-Rule Example 2369

History for Decryption Policy 2372

CHAPTER 91 **Decryption Policies** 2375

About Decryption Policies 2375

Requirements and Prerequisites for Decryption Policies 2376

Create a Decryption Policy 2376

Create a Create a Decryption Policy with Outbound Connection Protection 2376

Create a Create a Decryption Policy with Inbound Connection Protection 2378

Decryption Policy Exclusions 2379

Generate an Internal CA for Outbound Protection 2382

Upload an Internal CA for Outbound Protection 2383

Upload an Internal Certificate for Inbound Protection 2384

Create a Create a Decryption Policy with Other Rule Actions 2385

Decryption Policy Default Actions 2386

Default Handling Options for Undecryptable Traffic 2387

Set Default Handling for Undecryptable Traffic 2388

Decryption Policy Advanced Options 2389

TLS 1.3 Decryption Best Practices 2390

CHAPTER 92 **Decryption Rules** 2393

Decryption Rules Overview 2393
Requirements and Prerequisites for Decryption Rules 2393
Decryption Rule Guidelines and Limitations 2394
Guidelines for Using TLS/SSL Decryption 2394
Decryption Rule Unsupported Features 2395
TLS/SSL Do Not Decrypt Guidelines 2395
TLS/SSL Decrypt - Resign Guidelines 2397
TLS/SSL Decrypt - Known Key Guidelines 2399
TLS/SSL Block Guidelines 2400
TLS/SSL Certificate Pinning Guidelines 2400
TLS/SSL Heartbeat Guidelines 2400
TLS/SSL Anonymous Cipher Suite Limitation 2400
TLS/SSL Normalizer Guidelines 2401
Other Decryption Rule Guidelines 2401
Decryption Rule Traffic Handling 2401
Encrypted Traffic Inspection Configuration 2403
Decryption Rule Order Evaluation 2404
Decryption Rule Conditions 2405
Security Zone Rule Conditions 2406
Network Rule Conditions 2407
VLAN Tags Rule Conditions 2407
User Rule Conditions 2407
Application Rule Conditions 2408
Port Rule Conditions 2409
Category Rule Conditions 2410
Server Certificate-Based Decryption Rule Conditions 2410
Certificate Decryption Rule Conditions 2411
Distinguished Name (DN) Rule Conditions 2411
Trusting External Certificate Authorities 2416
Certificate Status Decryption Rule Conditions 2417
Cipher Suite Decryption Rule Conditions 2420

Encryption Protocol Version Decryption Rule Conditions 2423
Decryption Rule Actions 2423
Decryption Rule Monitor Action 2423
Decryption Rule Do Not Decrypt Action 2424
Decryption Rule Blocking Actions 2425
Decryption Rule Decrypt Actions 2425
Troubleshoot Decryption Rules 2426
About TLS/SSL Oversubscription 2426
Troubleshoot TLS/SSL Oversubscription 2426
About TLS Heartbeat 2428
Troubleshoot TLS Heartbeat 2428
About TLS/SSL Pinning 2429
Troubleshoot TLS/SSL Pinning 2430
Troubleshoot Unknown or Bad Certificates or Certificate Authorities 2432
Verify TLS/SSL Cipher Suites 2434

CHAPTER 93 **Decryption Rules and Policy Example** 2437
Decryption Rule Examples 2437
2437
: Decrypt Specific Test Traffic 2438
Decryption Rules: Block or Monitor Certificates and Protocol Versions 2438
Example: Decryption Rule to Monitor or Block Certificate Status 2438
Example: Decryption Rule to Monitor or Block Protocol Versions 2439
Optional Example: Manual Decryption Rule to Monitor or Block Certificate Distinguished Name 2441
Associate the Decryption Policy with an Access Control Policy and Advanced Settings 2442
Traffic to Prefilter 2444
Decryption Rule Settings 2445

PART XIX **User Identity** 2447

CHAPTER 94 **User Identity Overview** 2449
About User Identity 2449
Identity Terminology 2450
About User Identity Sources 2450

Best Practices for User Identity 2452
Identity Deployments 2453
How to Set Up an Identity Policy 2454
The User Activity Database 2457
The Users Database 2457
Identity Realm Limit 2458
Cloud-Delivered Firewall Management Center Host and User Limits 2458
Cloud-Delivered Firewall Management Center Host Limit 2458
Cloud-Delivered Firewall Management Center User Limit 2459
User Limits for Microsoft Azure Active Directory Realms 2460

CHAPTER 95 **Realms** 2463
License Requirements for Realms 2463
Requirements and Prerequisites for Realms 2463
Create a Proxy Sequence 2464
Create an LDAP Realm or an Active Directory Realm and Realm Directory 2465
About Realms and Realm Sequences 2468
Realms and Trusted Domains 2470
Supported Servers for Realms 2473
Supported Server Object Class and Attribute Names 2474
Prerequisites for Kerberos Authentication 2475
Realm Fields 2475
Realm Directory and Synchronize fields 2478
Connect Securely to Active Directory or LDAP 2481
Find the Active Directory Server's Name 2481
Export the Active Directory Server's Root Certificate 2482
Synchronize Users and Groups 2484
Create a Realm Sequence 2485
Configure the Firewall Management Center for Cross-Domain-Trust: The Setup 2486
Configure the Cisco Security Cloud Control for Cross-Domain-Trust Step 1: Configure Realms and Directories 2487
Configure the Cisco Security Cloud Control for Cross-Domain-Trust Step 2: Synchronize Users and Groups 2492
Configure the Cisco Security Cloud Control for Cross-Domain-Trust Step 3: Resolve Issues 2493

Manage a Realm 2494
Compare Realms 2495
Troubleshoot Realms and User Downloads 2495
Troubleshoot Cross-Domain Trust 2498
History for Realms 2501

CHAPTER 96 User Control with ISE/ISE-PIC 2503
The ISE/ISE-PIC Identity Source 2503
Source and Destination Security Group Tag (SGT) Matching 2504
License Requirements for ISE/ISE-PIC 2505
Requirements and Prerequisites for ISE/ISE-PIC 2505
ISE/ISE-PIC Guidelines and Limitations 2505
How to Configure ISE/ISE-PIC for User Control 2508
How to Configure ISE/ISE-PIC Without a Realm 2508
How to Configure ISE/ISE-PIC for User Control Using a Realm 2509
Configure ISE/ISE-PIC 2511
Configure Security Groups and SXP Publishing in ISE 2512
Export Certificates from the ISE/ISE-PIC Server for Use in the Firewall Management Center 2514
Export a System Certificate 2515
Generate a Self-Signed Certificate 2516
Import ISE/ISE-PIC Certificates 2516
Configure ISE for User Control 2517
ISE/ISE-PIC Configuration Fields 2519
Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues 2520
History for ISE/ISE-PIC 2522

CHAPTER 97 User Control with Captive Portal 2525
The Captive Portal Identity Source 2525
About Hostname Redirect 2526
License Requirements for Captive Portal 2526
Requirements and Prerequisites for Captive Portal 2526
Captive Portal Guidelines and Limitations 2526
How to Configure the Captive Portal for User Control 2529
Configure the Captive Portal Part 1: Create a Network Object 2530

Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule 2532
Update a Custom Authentication Form 2534
Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule 2534
Configure the Captive Portal Part 4: Create a User Access Control Rule 2535
Captive Portal Example: Create a Decryption Policy with an Outbound Rule 2536
Configure Captive Portal Part 6: Associate Identity and Decryption Policies with the Access Control Policy 2538
Captive Portal Fields 2539
Exclude Applications from Captive Portal 2540
Troubleshoot the Captive Portal Identity Source 2541
History for Captive Portal 2542

CHAPTER 98 **User Control with Remote Access VPN** 2543
The Remote Access VPN Identity Source 2543
Configure RA VPN for User Control 2544
Troubleshoot the Remote Access VPN Identity Source 2544
Not Observing Correct Settings for VPN Statistics 2545

CHAPTER 99 **User Control with TS Agent** 2547
The Terminal Services (TS) Agent Identity Source 2547
TS Agent Guidelines 2548
User Control with TS Agent 2548
Troubleshoot the TS Agent Identity Source 2548
History for TS Agent 2549

CHAPTER 100 **User Identity Policies** 2551
About Identity Policies 2551
License Requirements for Identity Policies 2552
Requirements and Prerequisites for Identity Policies 2552
Create an Identity Policy 2553
Create an Identity Mapping Filter 2554
Identity Rule Conditions 2555
Security Zone Rule Conditions 2555
Network Rule Conditions 2556

Redirect to Host Name Network Rule Conditions 2556
VLAN Tags Rule Conditions 2557
Port Rule Conditions 2557
Port, Protocol, and ICMP Code Rule Conditions 2558
Realm & Settings Rule Conditions 2559
Create an Identity Rule 2561
Identity Rule Fields 2562
Sample Identity Policies and Rules 2563
Create an Identity Policy with a Passive Authentication Rule 2564
Create a Sample Identity Policy with an Active Authentication Rule 2566
Active Authentication Using a Realm 2568
Active Authentication Using a Realm Sequence 2569
Manage an Identity Policy 2570
Manage an Identity Rule 2571
Troubleshoot User Control 2571

PART XX **Network Discovery** 2573

CHAPTER 101 **Network Discovery Overview** 2575
About Detection of Host, Application, and User Data 2575
Host and Application Detection Fundamentals 2576
Passive Detection of Operating System and Host Data 2576
Active Detection of Operating System and Host Data 2577
Current Identities for Applications and Operating Systems 2577
Current User Identities 2578
Application and Operating System Identity Conflicts 2579
NetFlow Data 2579
Requirements for Using NetFlow Data 2580
Differences between NetFlow and Managed Device Data 2580

CHAPTER 102 **Host Identity Sources** 2583
Overview: Host Data Collection 2583
Requirements and Prerequisites for Host Identity Sources 2584
Determining Which Host Operating Systems the System Can Detect 2584

Identifying Host Operating Systems 2584
Custom Fingerprinting 2585
Managing Fingerprints 2586
Activating and Deactivating Fingerprints 2586
Editing an Active Fingerprint 2587
Editing an Inactive Fingerprint 2587
Creating a Custom Fingerprint for Clients 2588
Creating a Custom Fingerprint for Servers 2590
Host Input Data 2593
Requirements for Using Third-Party Data 2593
Third-Party Product Mappings 2594
Mapping Third-Party Products 2594
Mapping Third-Party Product Fixes 2595
Mapping Third-Party Vulnerabilities 2596
Custom Product Mappings 2597
Creating Custom Product Mappings 2598
Editing Custom Product Mapping Lists 2599
Activating and Deactivating Custom Product Mappings 2599

CHAPTER 103 **Application Detection** 2601
Overview: Application Detection 2601
Application Detector Fundamentals 2602
Identification of Application Protocols in the Web Interface 2603
Implied Application Protocol Detection from Client Detection 2604

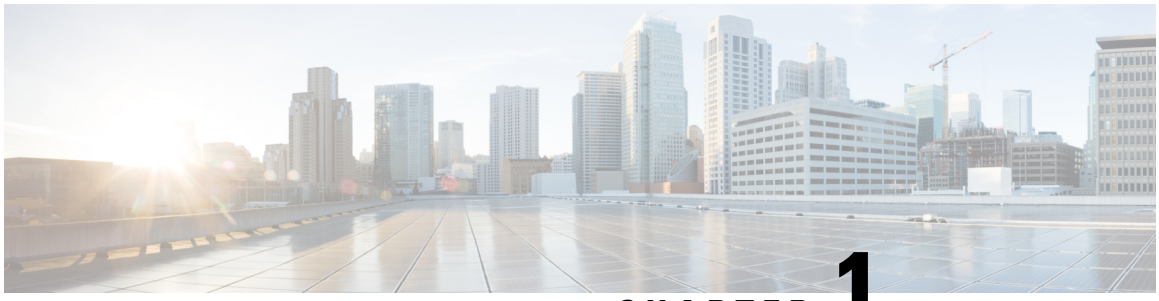
Cisco Security Cloud Control Management: Cloud-Delivered Firewall Management Center for Government

- Introduction, on page 1



CHAPTER 1

Introduction

- Introduction to Cloud-Delivered Firewall Management Center, on page 1
- Enable Cloud-Delivered Firewall Management Center on Your Security Cloud Control Tenant, on page 3
- Hardware and Software Support, on page 3
- **Security Cloud Control Platform Maintenance Schedule**, on page 4

Introduction to Cloud-Delivered Firewall Management Center

The Cloud-Delivered Firewall Management Center is a software-as-a-service (SaaS) product that manages Secure Firewall Threat Defense devices and is delivered via Security Cloud Control. The Cloud-Delivered Firewall Management Center offers many of the same functions as an On-Premises Management Center.

The Cloud-Delivered Firewall Management Center has the same appearance and behavior as an On-Premises Management Center and uses the same FMC API.

As a SaaS product, the Security Cloud Control operations team is responsible for deploying and maintaining Cloud-Delivered Firewall Management Center software. As new features are introduced, the Security Cloud Control operations team updates your Security Cloud Control tenant's Cloud-Delivered Firewall Management Center for you.

A migration wizard is available to help you migrate your Secure Firewall Threat Defense devices from your On-Premises Management Center to the Cloud-Delivered Firewall Management Center. The devices must have Threat Defense software Version 7.0.3 or a later 7.0.x release, or Version 7.2 or later installed to be migrated. Threat Defense 7.1 releases are not supported.

Onboarding Secure Firewall Threat Defense devices is carried out in Security Cloud Control using familiar processes such as onboarding a device with its serial number or using a CLI command that includes a registration key. Once the device is onboarded, it is visible both in Security Cloud Control and in the Cloud-Delivered Firewall Management Center, however, you configure the device in the Cloud-Delivered Firewall Management Center. In Security Cloud Control, you can view device-specific information such as version, configuration status, connectivity, health status, and node status. When you click on the health status from Security Cloud Control, you are taken to the respective device's health monitoring page in the Cloud-Delivered Firewall Management Center user interface.

Security Cloud Control provides high availability support for the threat defense devices that it manages through the data interface. This feature is supported for devices running software version 7.2 or later.

You can analyze syslog events generated by your onboarded threat defense devices using Security Analytics and Logging (SaaS) or Security Analytics and Logging (On-Premises). The SaaS version stores events in the

cloud and you view the events in Security Cloud Control. The on-premises version stores events in an on-premises Secure Network Analytics appliance and analysis is done in the On-Premises Management Center. In both cases, just as with an On-Premises Management Center today, you can still send logs to a log collector of your choice directly from the sensors.

The license for Cloud-Delivered Firewall Management Center is a per-device-managed license and there is no license required for the Cloud-Delivered Firewall Management Center itself. Existing Secure Firewall Threat Defense devices re-use their existing smart licenses and new Secure Firewall Threat Defense devices provision new smart licenses for each feature implemented on the Secure Firewall Threat Defense.

To learn how to have a Cloud-Delivered Firewall Management Center provisioned on your tenant, see Enable Cloud-delivered Firewall Management Center on Your Security Cloud Control Tenant.

Enable Cloud-Delivered Firewall Management Center on Your Security Cloud Control Tenant

If you want to manage your Secure Firewall Threat Defense devices, you can enable the Cloud-Delivered Firewall Management Center on your tenant. You need to have an admin or a super admin user role to perform this task.

Procedure

Step 1 From the Security Cloud Control menu, click **Administration** > **Integrations** > **Firewall Management Center** and click **Enable Cloud-Delivered FMC**.

Step 2 Security Cloud Control starts provisioning a Cloud-Delivered Firewall Management Center instance in the background; it typically takes 15 to 30 minutes for this to be complete. You can track the provisioning progress on the **Status** column of **Cloud-Delivered FMC**.

After the provisioning is complete, the status changes to **Active**. In addition, you get a **Cloud-Delivered Firewall Management Center is Ready** notification on the Security Cloud Control notifications panel and on the applications on which you have configured incoming webhooks. See Notification Settings for more information.

Note
After you receive the **Cloud-Delivered Firewall Management Center is Ready** notification, ensure that you log out of and log in back to your tenant once, to see the **Cloud-Delivered FMC** right pane options, such as **Actions**, **Management**, and **System**.

You can then onboard your Firewall Threat Defense devices to the Cloud-Delivered Firewall Management Center and manage them.

Hardware and Software Support

Cloud-Delivered Firewall Management Center supports these Secure Firewall Threat Defense software versions when they are installed on any supported hardware or virtual device:

- Verion 7.0.3 or later 7.0.x versions.
- Version 7.2 and later versions.

Note Software Version 7.1 is _not_ supported.

See Firepower Threat Defense Support Specifics for more information.

Security Cloud Control Platform Maintenance Schedule

Security Cloud Control updates its platform every week with new features and quality improvements. Updates are made during a 3-hour period according to this schedule:

Day of the Week	Time of Day (24-hour time, UTC)
Thursday	09:00 UTC - 12:00 UTC

During this maintenance period, you can still access your organization and if you have a cloud-delivered Firewall Management Center or Multicloud Defense Controller, you can access those portals as well. Additionally, the devices that you have onboarded to Security Cloud Control continue to enforce their security policies.

Note

- We advise against using Security Cloud Control to deploy configuration changes on the devices it manages during maintenance periods.
- If there is any issue that stops Security Cloud Control from communicating, we address that failure on all affected tenants as quickly as possible, even if it is outside the maintenance window.

PART II

Onboard Devices to Cloud-Delivered Firewall Management Center

CHAPTER 2

Onboard a Secure Firewall Threat Defense to the Cloud-Delivered Firewall Management Center

Read the following information for onboarding prerequisties and procedures.

- Onboarding Overview, on page 7
- Prerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center, on page 8
- Onboard a Device with a CLI Registration Key, on page 10
- Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 12
- Onboard a Firewall Threat Defense Device to On-Prem Firewall Management Center using Zero-Touch Provisioning, on page 13
- Onboard Firewall Threat Defense Devices using Device Templates to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 15
- Deploy a Threat Defense Device with AWS, on page 16
- Deploy a Firewall Threat Defense Device in Azure, on page 18
- Deploy a Firewall Threat Defense Device to Google Cloud Platform, on page 21
- Onboard a Secure Firewall Threat Defense Cluster, on page 24
- Onboard a Chassis, on page 25
- Delete Devices from Cloud-Delivered Firewall Management Center, on page 27
- Troubleshooting, on page 27

Onboarding Overview

Review the following use cases and supported sofware versions that are compatible with cloud-delivered Firewall Management Center management.

Note You must ensure that the Firewall Threat Defense device ports have external and outbound access for the cloud-delivered Firewall Management Center to onboard them. There is no requirement for an on-premises or cloud-based Security Device Controller (SDC) for this operation. For more information, see Network Requirements.

To send Firewall Threat Defense Syslog events to the Cisco cloud, you can set up the Secure Event Connector (SEC). For more information, see Installing Secure Event Connectors.

Firewall Threat Defense Devices Currently Managed by Cloud-Delivered Firewall Management Center

The following scenarios occur when you either move or migrate a device to the cloud-delivered Firewall Management Center:

- If you delete a device from an on-premises management center or Secure Firewall Threat Defense Firewall Device Manager to onboard to the cloud-delivered Firewall Management Center, the change of managers wipes any policies configured through the on-premises management center.
- If you **migrate** a device from an on-premises management center to the cloud-delivered Firewall Management Center, the device retains the majority of your previously configured policies.

Note If you do not know if your device is already managed by an alternative manager, use the `show managers` command in the device's CLI.

Onboarding Methods

Cloud-Delivered Firewall Management Center supports the following onboarding methods:

- Registration Key - Onboard a device with a registration key. The initial device setup wizard is complete on the device.
- Zero-Touch Provisioning - Onboard a new factory-shipped device with its serial number. Note that this method only supports Firepower 1000, Firepower 2100, or Secure Firewall 3100 devices.

Note Version 7.0.3 does not support zero-touch provisioning.

- Zero-Touch Provisioning using a device template - Onboard new factory-shipped devices using serial numbers and a device template. Note that this method only supports Firepower 1000, Firepower 2100, Secure Firewall 1200 or Secure Firewall 3100 devices.

Prerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center

Onboard Limitations and Requirements

Be aware of the following limitations when onboarding a device to the cloud-delivered Firewall Management Center:

- Devices **must** be running version 7.0.3, or version 7.2 and later. We **strongly** recommend version 7.2 or later.
- You can migrate an HA pair that is managed by an On-Premises Firewall Management Center by following the Migrate FTD to Cloud-Delivered Firewall Management Center process. Confirm both peers are in a healthy state prior to migrating.

- Only devices that are configured for local management and are managed by a Firewall Device Manager can be onboarded with the serial number and zero-touch provisioning methods.
- If the device is managed by an on-premises management center, you can either onboard the device to cloud-delivered Firewall Management Center or migrate the device. Migrating retains any existing policies and objects, whereas onboarding the device removes most policies and all objects. See Migrate FTD to Cloud-Delivered Firewall Management Center for more information.
- If your device is currently managed by a Firewall Device Manager, unregister all your smart licenses before you onboard the device. Even if you switch device management, the Cisco Smart Software Manager will retain the smart licenses.
- If you have previously onboarded a device that was managed by a Firewall Device Manager and deleted the device from Security Cloud Control with the intention of re-onboarding for cloud management, you **must** register the Firewall Device Manager to the Security Services Exchange cloud after deleting the device. See the "Access Security Services Exchange" chapter in the *Firepower and Cisco SecureX Threat Response Integration Guide.*

Tip Onboarding a device to the cloud-delivered Firewall Management Center removes any policies and most objects configured through the previous manager. If your device is currently managed by an on-premises management center, it is possible to migrate the device and retain your policies and objects. See Migrate FTD to Cloud-Delivered Firewall Management Center for more information.

Network Requirements

Before you onboard a device, ensure the following ports have external and outbound access. Confirm the following ports on the device are allowed. If communication ports are blocked behind a firewall, onboarding the device may fail.

Note You cannot configure these ports in the Security Cloud Control UI. You must enable these ports through the device's SSH.

Table 1: Device Port Requirements

Port	Protocol / Feature	Details
443/tcp	HTTPS	Send and receive data from the internet.
443	HTTPS	Communicate with the AMP cloud (public or private)
8305/tcp	Appliance communications	Securely communicate between appliances in a deployment.

Management and Data Interfaces

Make sure your device is correctly configured with either a management or data interface.

To configure a management or data interface on your device, see Complete the Initial Configuration of a Secure Firewall Threat Defense Device Using the CLI, on page 2931.

Onboard a Device with a CLI Registration Key

Use the procedure below to onboard a device for cloud-delivered Firewall Management Center with a CLI registration key.

Note If your device is currently managed by an on-premises management center, onboarding the device will fail. You can either delete the device from the on-premises management center and onboard as a fresh, new device with no policies or objects, or you can migrate the device and retain the existing policies and objects. See Migrate FTD to Cloud-Delivered Firewall Managmenet Center for more information.

Important You can create a Security Cloud Control-managed, standalone logical Firewall Threat Defense device using the Secure Firewall chassis manager or the FXOS CLI.

Before you begin

Before you onboard a device, be sure to complete the following tasks:

- Cloud-Delivered Firewall Management Center is enabled for your tenant.
- Confirm the device's CLI configuration is successfully completed. See Complete the Initial Configuration of a Secure Firewall Threat Defense Device Using the CLI, on page 2931 for more information.
- Review the prerequesites and limitations before you onboard the device. See "Prerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center" in Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control for more information.
- The device can be configured for either local management with Secure Firewall Device Manager or remote management with Secure Firewall Management Center.

Note If you want the device to maintain management from the Secure Firewall Device Manager, select **FDM** and see Onboard an FDM-Managed Device Running Software Version 6.6+ Using a Registration Key for more information.

- Device must be running version 7.0.3, or 7.2.0 and later.
- You have reset the device's SSH password as part of the bootstrap process. If you have you not reset the SSH password, Security Cloud Control recommends using the Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 12 method

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 In the left pane, click **Security Devices**.

Step 3 In the top-right corner, click **Onboard** ( ).

Step 4 Click the **FTD** tile.

Step 5 Under **Management Mode**, ensure you select **FTD**. By selecting **FTD** under **Management Mode**, you will not be able to manage the device using the previous management platform. All existing policy configurations except for interface configurations will be reset. You must re-configure policies after you onboard the device.

Step 6 Select **Use CLI Registration Key** as the onboarding method.

Step 7 Enter the device name in the **Device Name** field and click **Next**.

Step 8 In the **Policy Assignment** step, use the drop-down menu to select an access control policy to deploy once the device is onboarded. If you have no policies configured, select the **Default Access Control Policy**.

Step 9 Specify whether the device you are onboarding is a physical or virtual device. If you are onboarding a virtual device, you must select the device's performance tier from the drop-down menu.

Step 10 Select the subscription licenses you want to apply to the device. Click **Next**.

Step 11 Security Cloud Control generates a command with the registration key. Connect to the device you are onboarding using SSH. Log in as "admin" or a user with equivalent admin privileges and paste the entire registration key as is into the device's CLI.

Note: For Firepower 1000, Firepower 2100, ISA 3000, and Firewall Threat Defense Virtual devices, open an SSH connection to the device and log in as `admin`. Copy the entire registration command and paste it into the device's CLI interface at the prompt. In the CLI, enter **Y** to complete the registration. If your device was previously managed by Firewall Device Manager, enter **Yes** to confirm the submission.

Step 12 Click **Next** in the Security Cloud Control onboarding wizard.

Step 13 (Optional) Add labels to your device to help sort and filter the **Security Devices** page. Enter a label and select the blue plus button. Labels are applied to the device after it's onboarded to Security Cloud Control.

What to do next

Once the device is synchronized, select the device you just onboarded from the **Security Devices** page and select any of the options listed under the **Device Management** pane located to the right. We strongly recommend the following actions:

- If you did not already, create a custom access control policy to customize the security for your environment. See Access Control Overview in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.
- Enable Cisco Security Analytics and Logging (SAL) to view events in the Security Cloud Control dashboard **or** register the device to an Secure Firewall Management Center for security analytics. See Cisco Security Analytics and Logging in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.

Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning

Only the Firepower 1000, Firepower 2100, Secure Firewall 1200, and Secure Firewall 3100 devices can be onboarded with the zero-touch provisioning method.

Before you begin

Confirm that the following is completed before onboarding:

- You have a Security Cloud Control tenant. If you do not, see Request a Security Cloud Control Tenant for more information.
- Cloud-Delivered Firewall Management Center is enabled for your tenant.
- The device is freshly installed but has never been logged into by either the device CLI, a Firewall Management Center, or the Firewall Device Manager.
- The device is running version 7.2 or later. Version 7.0.3 does **not** support zero-touch provisioning.
- The device's outside or management interface should be able to access the Security Services Exchange domain registration.us.sse.itd.cisco.com.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 In the left pane, click **Security Devices**.

Step 3 In the top-right corner, click **Onboard** (+).

Step 4 Click the **FTD** tile.

Step 5 Under **Management Mode**, ensure you select **FTD**. By selecting **FTD** under **Management Mode**, you will not be able to manage the device using the previous management platform. All existing policy configurations except for interface configurations will be reset. You must re-configure policies after you onboard the device.

Step 6 Click the **Use Serial Number** tile.

Step 7 Select Cloud-Delivered Firewall Management Center from the drop-down list. Click **Next**.

For information on onboarding a threat defense device to On-Prem Firewall Management Center, see Onboard a Threat Defense Device to On-Prem Firewall Management Center using Zero-Touch Provisioning.

Step 8 Enter the **Device Serial Number** and the **Device Name**. Select **Next**.

Step 9 Choose an option depending on whether the device is logged into and configured for a manager:

- If your device is brand new and has never been configured for a manager, click **Yes, this new device has never been logged into or configured for a manager**.
- If your device has been previously registered for a manager or is **still** registered to a manager, click **No, this device has been logged into and configured for a manager**.

Step 10 Click **Next**.

Step 11 In the **Policy Assignment** step, use the drop-down menu to select an access control policy to deploy once the device is onboarded. If you have no policies configured, select the **Default Access Control Policy**.

Step 12 Select the subscription licenses you want to apply to the device. Click **Next**.

What to do next

Once the device is synchronized, select the device you just onboarded from the **Security Devices** page and select any of the options listed under the **Device Management** pane located to the right. We strongly recommend the following actions:

- If you did not already, create a custom access control policy to customize the security for your environment. See Access Control Overview in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.
- Enable Cisco Security Analytics and Logging (SAL) to view events in the Security Cloud Control dashboard **or** register the device to an Secure Firewall Management Center for security analytics. See Cisco Security Analytics and Logging in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.

Onboard a Firewall Threat Defense Device to On-Prem Firewall Management Center using Zero-Touch Provisioning

Only the Firepower 1000, Firepower 2100, Secure Firewall 1200, and Secure Firewall 3100 devices can be onboarded to on-premises management center using the zero-touch provisioning method.

Before you begin

Confirm the following is completed prior to onboarding:

- You have a Security Cloud Control tenant. If you do not, see Request a Security Cloud Control Tenant for more information.
- Before onboarding any new devices, ensure an on-prem FMC is fully set up, configured, and recognized as a management center within your Security Cloud Control tenant.
- The device is freshly installed and has never been logged into through the device CLI, a Firewall Management Center, or the Firewall Device Manager.
- The device is running version 7.2 or later. Version 7.0.3 does **not** support zero-touch provisioning.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 In the left pane, click **Security Devices**.

Step 3 In the top-right corner, click **Onboard** ( ).

Step 4 Click the **FTD** tile.

Step 5 Under **Management Mode**, ensure you select **FTD**. By selecting **FTD** under **Management Mode**, you will not be able to manage the device using the previous management platform. All existing policy configurations except for interface configurations will be reset. You must re-configure policies after you onboard the device.

Step 6 Click **Use Serial Number**.

Step 7 Select an available on-prem FMC from the drop-down list. Click **Next**.

Note

- On-prem FMCs running version 7.4 or later and onboarded with Cisco Security Cloud are displayed in the drop-down.
- Provide the **Public IP address** or **FQDN** value of the selected on-prem FMC unless
  - The FTD is publicly reachable
  - The FTD is running a version earlier than 7.4
  - The connection is being made through the data interface

For information on onboarding a threat defense device to a cloud-delivered Firewall Management Center, see Onboard a Threat Defense Device to Cloud-delivered Firewall Management Center using Zero-Touch Provisioning.

Step 8 Enter the **Device Serial Number** and the **Device Name**. Click **Next**.

Step 9 Choose an option depending on whether the device is logged into and configured for a manager:

- If your device is brand new and has never been configured for a manager, click **Yes, this new device has never been logged into or configured for a manager**.
- If your device has been previously registered for a manager or is **still** registered to a manager, click **No, this device has been logged into and configured for a manager**.

Step 10 Click **Next**.

Step 11 In the **Policy Assignment** step, use the drop-down menu to select an access control policy to deploy once the device is onboarded. If you have no policies configured, select the **Default Access Control Policy**.

Step 12 Select the subscription licenses you want to apply to the device. Click **Next**.

What to do next

Once the device is synchronized, select the device you just onboarded from the **Security Devices** page and select any of the options listed under the **Device Management** pane located to the right. We strongly recommend these actions:

- If you did not already, create a custom access control policy to customize the security for your environment.

  For more information, see Access Control Overview.

- You can enable Cisco Security Analytics and Logging to view events in the Security Cloud Control dashboard, or register the device to a Secure Firewall Management Center for security analytics.

For more information, see Cisco Security Analytics and Logging.

Onboard Firewall Threat Defense Devices using Device Templates to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning

Only the Firepower 1000, Firepower 2100, Secure Firewall 1200, and Secure Firewall 3100 devices can be onboarded with the zero-touch provisioning method.

Before you begin

Confirm that the following is completed before onboarding:

- You have a Security Cloud Control tenant. If you do not, see Request a Security Cloud Control Tenant for more information.
- Cloud-Delivered Firewall Management Center is enabled for your tenant.
- The device is freshly installed but has never been logged into by either the device CLI, a Firewall Management Center, or the Firewall Device Manager.
- The device is running version 7.4 or later.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 In the left pane, click **Security Devices**.

Step 3 In the top-right corner, click **Onboard** ( ).

Step 4 Click the **FTD** tile.

Step 5 Click the **Bulk Onboard using CSV File** tile.

Step 6 In the **Template Assignment** field, select a template from the drop-down list. The access control policy associated with the template and the supported device models for the selected template are then displayed. Click **Next**.

Step 7 In the **Upload CSV File** field, **Drag & drop** your CSV template file or **Click** to select the CSV template file that you want to upload.

You can download a **CSV Sample Template File** to have a look at the required header details that have to be used in the template. The CSV template file must be less than 2 MB in size. The filename must satisfy the following criteria:

- Can have a maximum of 64 characters.
- Only alphanumeric characters and special characters such as dash (-), period (.), and underscore (_) are allowed.
- Must not contain any spaces.

A properly formatted .csv file has the following fields:

- Mandatory fields
  - Display Name - Name of the device. Type: string. Example: test1
  - Serial Number - Serial number of the device. Type: string, Example: JADX345670EG
- Optional fields
  - Device Group - Name of the device group, Type: string, Example: testgroup
  - Admin Password - Password for admin access, Type: string, Example: E28@2OiUrhx
- Variables - Use the following format: $<*varName*>. Sample variable: $LAN-Devices-IPv4Address - IPv4 address of the LAN device. Type: string. Example: 1.2.3.4.
- Network object overrides - Use the following format:<*objType*>:<*objName*>. Sample network object override: Network:LAN-Devices-Network - IP address of the network of LAN devices. Type: string. Example: 1.2.3.4.

A sample CSV template file containing configuration for two devices is as given below.

DisplayName	SerialNumber	AdminPassword	$WANLinkIP	Host:gateway
Branch A FTD	JADX345410AB	C15c05n0rt#	10.20.30.1	10.2.3.1
Branch B FTD	JADX345670CE	Admin123!	10.20.30.5	10.2.3.1

Step 8 Click **Next**.

Step 9 A statement mentioning that the devices are being onboarded is displayed. You can check the onboarding status of the devices in the **Security Devices** window.

What to do next

Once the device is synchronized, select the device you just onboarded from the **Security Devices** page and select any of the options listed under the **Device Management** pane located to the right. We strongly recommend the following actions:

- If you did not already, create a custom access control policy to customize the security for your environment. See Access Control Overview in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.
- Enable Cisco Security Analytics and Logging (SAL) to view events in the Security Cloud Control dashboard **or** register the device to an Secure Firewall Management Center for security analytics. See Cisco Security Analytics and Logging in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.

Deploy a Threat Defense Device with AWS

Use the following procedure to onboard and preliminarily provision the firewall of a Firewall Threat Defense device that is associated with an AWS VPC to be managed by cloud-delivered Firewall Management Center.

Before you begin

Confirm the following prerequisites are fulfilled prior to generating a virtual Firewall Threat Defense and deploying to an AWS environment:

- You must have the cloud-delivered Firewall Management Center feature enabled and associated with your tenant.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 In the navigation pane, click **Security Devices** and click the blue plus button.

Step 3 Select the **FTD** tile.

Step 4 Under **Management Mode**, be sure **FTD** is selected.

Step 5 Select **Use AWS VPC** as the onboarding method. If there is no AWS VPC already onboarded, you can click the provided link from this step and onboard the virtual environment.

Step 6 Select the **availability zone** from the drop-down menu. Select the zone where the cloud Firewall Threat Defense is located, and not where your local computer is located.

Step 7 Select the management interface subnet with either of the following options:

- **Use existing subnets** - Expand the drop-down menus and select the appropriate subnets for the management interface, inside interface, and outside interface subnets.
- **Create new subnets** - Add a set of subnet interfaces for the device to use once onboarded. Security Cloud Control automatically creates these subnets and applies them to the AWS VPC as part of the onboarding procedure.

Note that the diagnostic interface will use the same interface as the management interface.

Step 8 Click **Select** to assign the subnets. Click **Next**.

Step 9 Enter the device name in the **Device Name** field and click **Next**.

Step 10 In the Policy Assignment step, use the drop-down menu to select an access control policy to deploy once the device is onboarded. If you have no policies configured, select the **Default Access Control Policy**.

Step 11 Select the **Subscription Licenses** you want applied to the device. You must have at least the URL license selected for virtual Firewall Threat Defense devices.

What to do next

It may take a few minutes for the device to appear in Security Cloud Control's **Security Devices** page as it cannot synchronize until Security Cloud Control has successfully deployed the cloud formation, initliaized the device connections, and established communication with both the virtual device and the AWS VPC environment.

If necessary, you can modfiy the virtual Firewall Threat Defense device performance tier selection after onboarding through the cloud-delivered Firewall Management Center UI.

Deploy a Firewall Threat Defense Device in Azure

This is a two-part process that involves onboarding an Azure account to Security Cloud Control as well as generating a virtual Firewall Threat Defense and simultaneously deploying it to your Azure instance.

Onboard an Azure VNet Environment

Use the following procedure to onboard an Azure VNet for cloud-delivered Firewall Management Center management:

Before you begin

You must have the following completed prior to this onboarding procedure:

- Cloud-Delivered Firewall Management Center is enabled for your tenant.
- You must have at least one resource group available in your Azure account with an empty Azure VNet instance. If you do not have a resource group to host the virtual device, create one with the Azure portal. See Microsoft Azure's **Manage Azure resource groups by using the Azure portal** guide for more information.
- Your resource group in the Azure portal must have a virtual network created for the virtual device. If you do not have one, create one in the Azure portal. See Microsoft Azure's **Create a virtual network using the Azure portal** quickstart guide for more information.
- You **must** register Security Cloud Control to your Microsoft account to ensure successful communication between Azure and Security Cloud Control. See the "Quickstart: Register an application with the Microsoft identity platform" section of the Azure product documentation for more information.
- You **must** assign a built-in role, or create a custom role, within the Azure environment and assign it a member or group that will access both Azure and Security Cloud Control. See the "Azure custom role" section or the "Azure custom roles" of the Azure product documentation for more information.
- You **must** enable all of the following permissions in the Azure environment in order to successully communicate with and onboard to Security Cloud Control:

```
"Microsoft.Network/virtualNetworks/write"
"Microsoft.Network/virtualNetworks/join/action"
"Microsoft.Network/virtualNetworks/subnets/read"
"Microsoft.Network/virtualNetworks/subnets/write"
"Microsoft.Network/virtualNetworks/subnets/prepareNetworkPolicies/action"
"Microsoft.Network/networkSecurityGroups/read"
"Microsoft.Network/networkSecurityGroups/write"
"Microsoft.Network/networkSecurityGroups/join/action"
"Microsoft.Network/networkSecurityGroups/securityRules/write"
"Microsoft.Network/networkSecurityGroups/securityRules/read"
"Microsoft.Network/networkSecurityGroups/securityRules/delete"
"Microsoft.Storage/storageAccounts/write"
"Microsoft.Storage/storageAccounts/read"
"Microsoft.Resources/deployments/write"
"Microsoft.Resources/deployments/read"
"Microsoft.Network/publicIPAddresses/read"
"Microsoft.Network/publicIPAddresses/write"
```

```
"Microsoft.Network/routeTables/read"
"Microsoft.Network/routeTables/write"
"Microsoft.Network/networkInterfaces/read"
"Microsoft.Network/networkInterfaces/write"
"Microsoft.Compute/virtualMachines/write"
"Microsoft.Resources/deployments/operationstatuses/read"
"Microsoft.Resources/subscriptions/resourcegroups/deployments/operationstatuses/read"
"Microsoft.Network/routeTables/join/action"
"Microsoft.Network/virtualNetworks/subnets/join/action"
"Microsoft.Network/publicIPAddresses/join/action"
"Microsoft.Network/networkInterfaces/join/action"
"Microsoft.Compute/virtualMachines/read"
"Microsoft.Resources/subscriptions/resourceGroups/write"
"Microsoft.Resources/subscriptions/resourceGroups/delete"
```

Procedure

Step 1 Review the prerequisites listed above. You must register Security Cloud Control to your Microsoft account, create a user role, and enable all the applicable permissions prior to onboarding a virtual environment.

Step 2 Log in to Security Cloud Control.

Step 3 In the navigation pane, click **Security Devices** and click the blue plus button.

Step 4 Select the **Azure VNet** tile.

Step 5 Enter the following credentials to continue with the onboarding wizard, then click **Next**:

- **Azure Tenant ID (Directory ID) -** A directory ID is a unique identifier for the tenant in the world of Microsoft cloud services. There is only one directory ID per tenant. To locate it, log into the Azure portal and navigate to **Azure Services** > **Azure Active Directory** and locate the Tenant ID listed on that page.
- **Client ID (Application ID) -** An application ID is a unique identifier assigned toSecurity Cloud Control by Azure AD when the app was registered. To locate it, log into the Azure portal and navigate to **Azure Services** > **Azure Active Directory** > **App Registrations** and view the application ID in the list of apps. If there is no application ID for Security Cloud Control, click **New Registrations** to create one for this onboarding procedure.
- **Client Secret -** You must manually request a client secret, although the Azure portal auto-generates a unique string to protect your tenant. To locate it, log into the Azure portal and navigate to **Azure Services** > **Azure Active Directory** > **App Registrations**, then expand the application for Security Cloud Control. In the panel on the left, click **Certificates & secrets**. If there is no secret, click **New client secret** to create one. Copy the **Value** entry for this onboarding procedure, not the Secret ID entry.
- **Subscription ID -** A subscription is a tenant-based agreement to use Microsoft cloud services; in this case, Azure VNet. The subscription ID is the unique code associated between the tenant and this particular cloud service. To locate it, log into the Azure portal and navigate to **Azure Services** > **Subscriptions**. If there are no subscriptions available for Security Cloud Control, click **Add** to create one.

Step 6 In the Security Cloud Control onboarding wizard, use the drop-down menu to select the **Azure VNet** you want to onboard.

Step 7 Enter the **Device Name** and select **Next**. This device name is what the Azure VNet is displayed as in the Inventory page.

Step 8 (Optional) Add labels to your device to help sort and filter the **Security Devices** page. Enter a label and select the blue plus button. Labels are applied to the device after it's onboarded to Security Cloud Control.

What to do next

Onboard a virtual device in Security Cloud Control with this instance of Azure VNet as the manager. See Deploy a Firewall Threat Defense Virtual in Azure, on page 20 for more information.

Deploy a Firewall Threat Defense Virtual in Azure

Onboard a Firewall Threat Defense Virtual for Azure that is managed by cloud-delivered Firewall Management Center.

The Azure environment can only support one Firewall Threat Defense Virtual. To onboard multiple devices, you must have a separate Azure instance for each of those devices.

Before you begin

Ensure that you have an active Azure subscription.

Procedure

Step 1 Log into Security Cloud Control.

Step 2 In the left pane, click **Security Devices** and click the plus icon.

Step 3 Under **Select a Device or Service Type**, click the **FTD** tile.

Step 4 Under **Management Mode**, ensure that **FTD** is selected.

Warning
By selecting **FTD** under **Management Mode**, the device is reconfigured to use the Cloud-Delivered Firewall Management Center as the manager.

Step 5 Click **Deploy an FTD to a cloud environment** as the onboarding method.

Step 6 Choose **Azure** as your cloud provider from the drop-down list.

Step 7 (Optional) If you have not registered your Security Cloud Control account to an Azure subscription, you can do so now. Click **Azure Cloud Shell** to launch the Azure cloud shell and paste the script that is provided. If you have registered your account or if you have completed executing the script, click **Next**.

Step 8 Choose a **Region** to deploy the Azure subscription from the drop-down list.

Step 9 Enter the **FTD Password** that you wish to use for SSH console access.

Step 10 Enter a **Device Name**. This name is applied to the Firewall Threat Defense Virtual in the **Security Devices** page and Azure resource group.

Step 11 In the **Policy Assignment** step, use the drop-down menu to select an access control policy to deploy once the device is onboarded. If you have no policies configured, select the **Default Access Control Policy**.

Step 12 Select the licenses you want to apply to the device. You must select at least the Essentials license as the base license for this device. Click **Next**.

Step 13 Click **Complete onboarding**.

This completes the onboarding wizard. It may take up to 20 minutes for the device to fully onboard and synchronize. To monitor the creation process, expand the **Workflows** option of the Azure subscription that is hosting the device.

What to do next

Once the device is synchronized, select the device you just onboarded from the **Security Devices** page and select any of the options listed under the **Device Management** pane located to the right. We strongly recommend the following actions:

- If you did not already, create a custom access control policy to customize the security for your environment. See Access Control Overview in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.
- Enable Cisco Security Analytics and Logging (SAL) to view events in the Security Cloud Control dashboard **or** register the device to an Secure Firewall Management Center for security analytics. See Cisco Security Analytics and Logging in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.

Deploy a Firewall Threat Defense Device to Google Cloud Platform

Deploy a Firewall Threat Defense device on your Google Cloud Platform (GCP) account to protect your Google Cloud workloads. The security policy for this device will be managed on your Cloud-Delivered Firewall Management Center.

You must first have a GCP account, a GCP project created, and several networks established for effective communication between Cloud-Delivered Firewall Management Center and GCP. Once you have established the GCP settings, onboard a Firewall Threat Defense device to be deployed to the GCP.

Use the following procedures to onboard and deploy a Firewall Threat Defense device to GCP.

Create VPC Networks for GCP

The Firewall Threat Defense virtual deployment requires four networks which you must create prior to deploying the Firewall Threat Defense virtual. The networks are as follows:

- Management VPC for the management subnet.
- Diagnostic VPC or the diagnostic subnet.
- Inside VPC for the inside subnet.
- Outside VPC for the outside subnet.

Additionally, you may have to set up the route tables and GCP firewall rules to allow traffic flow through the Firewall Threat Defense virtual. The route tables and firewall rules are separate from those that are configured on the Firewall Threat Defense virtual itself. Name the GCP route tables and firewall rules according to associated network and functionality

Procedure

Step 1 In the GCP console, choose **VPC networks**, then click **Create VPC Network**.

Step 2 In the **Name** field, enter the desired name.

Step 3 From the Subnet creation mode, click **Custom**.

Step 4 In the **Name** field under **New subnet**, enter the desired name.

Step 5 From the **Region** drop-down list, select the region appropriate for your deployment. All four networks must be in the same region.

Step 6 From the **IP address range** field, enter the first network's subnet in CIDR format, such as 10.10.0.0/24.

Step 7 Accept the defaults for all other settings, then click **Create**.

Step 8 Repeat steps 1-7 to create the remaining three VPC networks.

What to do next

You may have to create firewall rules to apply to your newly created VPC networks. Go to the GCP console and navigate to **Networking** > **VPC network** > **Firewall** and then click **Create Firewall Rule**. See GCP documentation for more information.

Once your GCP VPC networks have been finalized, continue on to deploy the Firewall Threat Defense virtual.

Deploy a Firewall Threat Defense Device on Google Cloud Platform

Before you begin

When you perform this procedure, Security Cloud Control creates the Firewall Threat Defense Virtual as part of the onboarding wizard. You cannot use this procedure with physical Firewall Threat Defense device or a device that is already onboarded to Security Cloud Control.

The following prerequisites must be met prior to onboarding a Firewall Threat Defense that is currently associated with a Google Cloud Platform (GCP) environment:

- You must have Cloud-Delivered Firewall Management Center enabled for your tenant.
- You must have a GCP account and already have a project created. See GCP documentation for more information.
- Management interfaces (2) — One used to connect the Firewall Threat Defense virtual to the management center, second used for diagnostics; cannot be used for through traffic.

  Traffic interfaces (2) — Used to connect the Firewall Threat Defense virtual to inside hosts and to the public network. See Create VPC Networks for GCP, on page 21 for more information.
- You **must** enable all of the following permissions in the GCP environment in order to successully communicate with and onboard to Security Cloud Control:

```
deploymentmanager.deployments.create
deploymentmanager.deployments.get
compute.networks.list
```

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 In the navigation pane, click **Security Devices** and click the blue plus button (+) to add a new device.

Step 3 Select the **FTD** tile.

Step 4 Under **Management Mode**, select **FTD**.

Step 5 Select **Use GCP VPC** as the onboarding method.

Step 6 **IF** you have not authenticated your GCP environment with Security Cloud Control before this point, copy the bash command that Security Cloud Control generates and run it on your bash environment or on the Google Cloud Shell to authenticate your GCP account and allow communication between the applications. **IF** you have already authenticated your GCP account prior, ignore the account integration steps and click **Next**.

Step 7 Use the drop-down menu to select the GCP project you want to associate with the device you are going to onboard. If there are no projects immeidately available, click **+ Link New Project**. If you click **+ Link New Project**, follow these steps:

a) Enter the GCP project ID when prompted. Locate this value in the GCP UI. To locate the project ID, see GCP documentation.

b) **Upload Credentials File.** Click **Browse** and navigate to where the the .JSON file generated from the script in Step 1 of the onboarding wizard is locally stored. Select it and click **Save**.

Step 8 Click **Next**.

Step 9 Use the drop-down menus to select the following paramters and click **Next**:

- **Inside VPC**
- **Inside Sub Network**
- **Outside VPC**
- **Outside Sub Network**
- **Management VPC**
- **Management Sub Network**
- **Diagnostic Network**
- **Diagnostic Sub Network**

Step 10 Enter a name for the Firewall Threat Defense device in the **Device Name** field and click **Next**.

Step 11 In the Policy Assignment step, use the drop-down menu to select an access control policy to deploy once the device is onboarded. If you have no policies configured in the Cloud-Delivered Firewall Management Center associated with your Security Cloud Control tenant, select the **Default Access Control Policy**.

Step 12 Select the **Subscription Licenses** you want applied to the device. You must have at least the URL license selected for virtual threat defense devices.

Step 13 Click **Complete Onboarding**.

What to do next

Navigate to the **Security Devices** page to view the progress of the device registration there. Once the device is synchronized, we strongly recommend cross-launching to Cloud-Delivered Firewall Management Center and customize your access control policy and device status.

Onboard a Secure Firewall Threat Defense Cluster

Note If you must delete a cluster, delete the cluster from the Security Cloud Control **Security Devices** page. See Delete Devices from Cloud-Delivered Firewall Management Center, on page 27 for more information.

The following table provides information about device models that support cluster onboarding and creation on the Cloud-Delivered Firewall Management Center:

Secure Firewall Threat Defense Platforms	Minimum Secure Firewall Threat Defense Version for Cluster Management	Support cluster creation from Cloud-Delivered Firewall Management Center?
VMware, KVM	7.2.1	Yes
AWS, GCP	7.2.1	No
Azure	7.3	No
Secure Firewall 3100	7.2.1	Yes
Firepower 4100	7.0.6	No
Secure Firewall 4200	7.4	Yes
Firepower 9300	7.0.6	No

Before you begin

Read through the following limitations:

- Firepower 4100 and Firepower 9300 devices must be clustered through the device's Firewall Chassis Manager.
- Secure Firewall 3100 devices, Secure Firewall 4200 devices, KVM, and VMware environments must be clustered through the Secure Firewall Management Center UI.
- Azure, AWS, and GCP environment clusters must be created through their own environment and onboarded to Secure Firewall Management Center.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 In the left pane, click **Security Devices**.

Step 3 Click the **FTD** tile.

Step 4 Under **Management Mode**, ensure you select **FTD**. By selecting **FTD** under **Management Mode**, you will not be able to manage the device using the previous management platform. All existing policy configurations except for interface configurations will be reset. You must re-configure policies after you onboard the device.

Step 5 Select **Use CLI Registration Key**.

Step 6 Enter the device name in the **Device Name** field and click **Next**.

Step 7 In the **Policy Assignment** step, use the drop-down menu to select an access control policy to deploy once the device is onboarded. If you have no policies configured, select the **Default Access Control Policy**.

Step 8 Specify whether the device you are onboarding is a physical or virtual device. If you are onboarding a virtual device, you must select the device's performance tier from the drop-down menu.

Step 9 Select the subscription licenses you want to apply to the device. Click **Next**.

Step 10 Security Cloud Control generates a command with the registration key. Paste the entire registration key as is into the device's CLI.

Step 11 (Optional) Add labels to your device to help sort and filter the **Security Devices** page. Enter a label and select the blue plus button. Labels are applied to the device after it's onboarded to Security Cloud Control.

What to do next

Once the device is synchronized, select the device you just onboarded from the **Security Devices** page and select any of the options listed under the **Device Management** pane located to the right. We strongly recommend the following actions:

- If you did not already, create a custom access control policy to customize the security for your environment. See Access Control Overview in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.
- Enable Cisco Security Analytics and Logging (SAL) to view events in the Security Cloud Control dashboard **or** register the device to an Secure Firewall Management Center for security analytics. See Cisco Security Analytics and Logging in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for more information.

Onboard a Chassis

You can add a Firepower 4100/9300 chassis to the Cloud-Delivered Firewall Management Center. The management center and the chassis share a separate management connection using the chassis MGMT interface. The Firewall Management Center offers chassis-level health alerts. For configuration, you still need to use the Firewall Chassis Manager or FXOS CLI.

Security Cloud Control does not record the processes on the **Workflow** page when you onboard a chassis or provision a multi-instance Firewall Management CenterFirewall Threat Defense device from the Cloud-Delivered Firewall Management Center chassis manager page.

Note For the Secure Firewall 3100, you need to first convert to multi-instance mode. See Onboard the Multi-Instance Chassis, on page 518.

Procedure

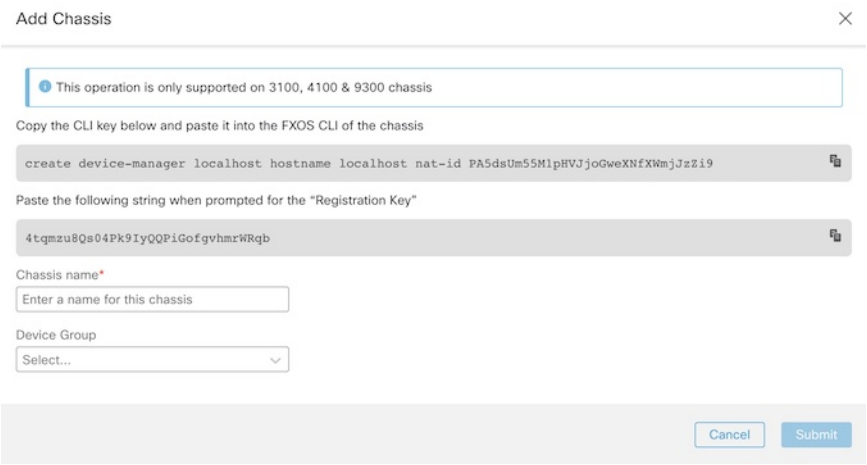
Step 1 Connect to the chassis FXOS CLI, either using the console port or SSH.

Step 2 In the Security Cloud Control navigation pane, click **Security Devices**, then click the blue plus button ( ) to **Onboard** a device.

Step 3 Click the **FTD Chassis** tile to open the **Add Chassis** dialog box.

Figure 1: FTD Chassis Tile

Figure 2: Add Chassis



Step 4 Click **Copy** ( ) to copy the top generated command, then paste it at the FXOS CLI of your chassis.

Step 5 When prompted for the Registration Key at the FXOS CLI, click **Copy** ( ) on the **Add Chassis** dialog box for the generated registration key and paste it at the FXOS CLI.

You can disconnect from the FXOS CLI at this point.

Step 6 In the Cloud-Delivered Firewall Management Center **Chassis Name** field, enter a name for the chassis as you want it to display in the Firewall Management Center.

Step 7 (Optional) Add the chassis to a **Device Group**.

Step 8 Click **Submit**.

The chassis is added to the **Device** > **Device Management** page.

Delete Devices from Cloud-Delivered Firewall Management Center

Though devices may be registered to Cloud-Delivered Firewall Management Center, Security Cloud Control still manages device enrollment. You must delete the device from the Security Cloud Control dashboard to remove a device from cloud-delivered Firewall Management Center.

Note Security Cloud Control does not synchronize the deletion of devices that are associated with an AWS VPC environment. You must delete a device direclty from the AWS VPC UI. See AWS documentation for more information.

Procedure

Step 1 Log into Security Cloud Control and click **Security Devices**.

Step 2 Locate the device you want to delete by using the filters or search bar. Select it so the device row is highlighted. If your device is part of a high availability pair, locate and select the active device.

Step 3 In the Device Actions pane located to the right, click **Remove**.

Step 4 When prompted, select **OK** to confirm the removal of the selected device. Click **Cancel** to keep the device onboarded.

Troubleshooting

Use the following scenarios to troubleshoot any onboarding issues.

Troubleshoot Cloud-Delivered Firewall Management Center Connectivity with TCP

Use the following procedure to troubleshoot connectivity between the Cloud-Delivered Firewall Management Center and a Firewall Threat Defense device with TCP port 8305.

Procedure

Step 1 Log into Security Cloud Control.

Step 2 Navigate to **Tools & Services** in the left panel and select **Firewall Management Center** to open the **Services** page. Choose **Cloud-Delivered FMC** and locate the Cloud-Delivered Firewall Management Center's FQDN in the top righthand corner.

Step 3 Make sure the Firewall Threat Defense device's state in Security Cloud Control is currently **Onboarding**. Cloud-Delivered Firewall Management Center will not respond if the device is not in an onboarding state. If onboarding has failed, click **Retry Onboarding**.

Step 4 Log into the Firewall Threat Defense device with SSH.

Step 5 Enter into Expert mode with the following command:

```
> expert
admin@devicename:~$
```

Step 6 Execute a TCP handshake:

```
admin@devicename:~$ nc -v xxxxxx.cdo.cisco.com 8305
Connection to xxxxxx.cdo.cisco.com 8305 port [tcp/*] succeeded!
^C (CTRL-C to exit netcat)
admin@devicename:~$.
```

What to do next

If there is still no response from the Cloud-Delivered Firewall Management Center, then there is a chance that outbound port TCP 8305 may be blocked upstream from your Firewall Threat Defense device and that network path will need to be assured before your Firewall Threat Defense will be able to connect to Cloud-Delivered Firewall Management Center.

Troubleshoot Firewall Threat Defense Device Connectivity

Test connectivity to the Internet from the management-plane of the Firewall Threat Defense device:

Procedure

	Command or Action	Purpose
Step 1	Log into the Firewall Threat Defense device with SSH.	
Step 2	Ping one or both of the following:	• system 208.67.222.222 • system cisco.com

What to do next

If either of these tests fail, there is likely an L1-L3 issue and you will need to check your management networking configuration (`show network`) and/or a DNS issue.

Troubleshoot Device Connectivity Loss After Cloud-delivered Firewall Management Center Update

A Cloud-Delivered Firewall Management Center is assigned a dynamic IP address when it is added to a Security Cloud Control tenant. When the management center is updated, the management center receives a new dynamic IP address.

If you have a firewall inspecting the outbound traffic from your threat defense device to the Cloud-Delivered Firewall Management Center, your firewall rules must allow the threat defense traffic to flow to the FQDN and port of the management center rather than its IP address, or the management center will not be able to manage your threat defense device.

For example, if your network traffic rule allowing management traffic from your threat defense device to the Cloud-Delivered Firewall Management Center looks like this:

```
allow all traffic <my-threat-defense-ip-src> to 200.165.200.225
```

where 200.165.200.225 is the management address of the cloud-delivered Firewall Management Center, change the one allow rule to these two allow rules as both ports 443 and 8305 need to be open:

```
allow all traffic <my-threat-defense-ip-src > to <my-cdfFMC-FQDN>:443
```

```
allow all traffic <my-threat-defense-ip-src > to <my-cdfFMC-FQDN>:8305
```

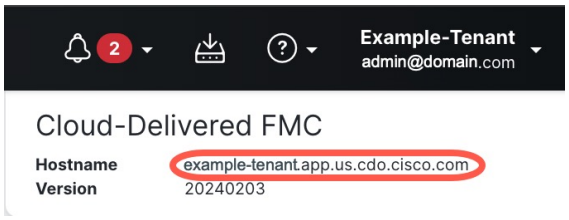
See “Network Requirements” in Prerequisites to Onboard a Device to Cloud-delivered Firewall Management Center for more port information.

Where do I find the domain name of my Cloud-Delivered Firewall Management Center?

Where do I find the domain name of my cloud-delivered Firewall Management Center?

1. Log in to Security Cloud Control.
2. In the left pane, click **Administration** > **Integrations** > **Firewall Management Center**
3. Select **Cloud-Delivered FMC** in the FMC table.
4. In the top-right corner of the screen, you will see the Hostname of the management center. This is the FQDN.

Figure 3: Cloud-delivered FMC FQDN



Troubleshoot Onboarding a Device to the Cloud-Delivered Firewall Management Center Using the CLI Registration Key

Error: Device Remains in Pending Setup State After Onboarding

When a device fails to register, the device's connectivity status is displayed as **Pending Setup**. In the panel located to the right, Security Cloud Control displays a **Registration Failed** message as well as a **Retry Onboarding** button to immediately allow you to reattempt onboarding the device.

If you fail to execute the `configuration manager` command in the device CLI within 3 mins after onboarding it to Security Cloud Control, the device's registration attempt expires and results in a registrationg failure. Use the following procedure to resolve the issue:

Procedure

Step 1 Log into Security Cloud Control and navigate to the **Security Devices** page. Locate the device that failed to register.

Step 2 In the panel located to the right, locate the **Registration Failed** window. Beside the device's CLI registration key, click **Copy**. This actions copies the CLI key to a local clipboard.

Step 3 Open an SSH connection to the device and log in as `admin`.

Step 4 Paste the CLI registration key into the device's CLI interface. In the CLI, enter **Y** to complete the registration. If your device was previously managed by Firewall Device Manager, enter **Yes** to confirm the submission.

Troubleshoot Onboarding a Device to Cloud-Delivered Firewall Management Center Using the Serial Number

Device is Offline or Unreachable

If the device is unreachable during the onboarding proess, or at any point post-onboarding, Security Cloud Control displays an **Unreachable** connectivity status. The device will not be able to fully onboard to Security Cloud Control until the device is able to connect. The following scenarios might be the cause:

- The device is cabled incorrectly.
- Your network may require a static IP address for the device.
- Your network uses custom DNS, or there is external DNS blocking the network.
- If your device is associated with the European region (https://defenseorchestrator.eu/), you may need to enable PPPoE authentication.For other domains, review the domain requirements.
- The device may be blocked by a firewall, or is incorrectly blocking a port for connectivity. Review the device Network Requirements, on page 9 and confirm the correct outgoing ports are enabled.

Error: Serial Number Already Claimed

The Device was Purchased From an External Vendor

If the device was purchased from an external vendor and fails to onboard with a **Serial Number Already Claimed** error, it's possible the device is still associated to the vendor's tenant. Use the following steps to claim the device and its serial number:

1. Delete the device from your Security Cloud Control tenant.
2. Install the FXOS image on the device. For more information, see the "Reimage Procedures" chapter of the Cisco FXOS Troubleshooting Guide for the Firepower 1000/21000 and Secure Firewall 3100 Firepower Threat Defense guide.
3. Connect a laptop to the device's console port.
4. Connect to the FXOS CLI and log in as **admin**.

5. In the FXOS CLI, connect to **local-mgmt** with the `firepower # connect local-mgmt` command.
6. Execute the `firepower(local-mgmt) # cloud deregister` command to deregister the device from the cloud tenancy.
7. Once the device is successfully unregistered, the CLI interface returns a success message. An example of the message:

```
Example: firepower(local-mgmt) # cloud deregister Release Image Detected RESULT=success
 MESSAGE=SUCCESS 10, X-Flow-Id: 2b3c9e8b-76c3-4764-91e4-cfd9828e73f9
```

Note If the device was never registered to another Security Cloud Control tenant, the message above states `RESULT=success MESSAGE=DEVICE_NOT_FOUND.`

8. Onboard the device to your Security Cloud Control tenant with its serial number. See Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 12 for more information.

The Device is Claimed By a Security Cloud Control Tenant in Another Region

The device may have been previously managed by another Security Cloud Control instance in a different region and is still registered to that tenant.

If you **do** have access to the tenant the device is currently registered to, use the following procedure:

1. Delete the device from the incorrect Security Cloud Control tenant.
2. Log into the device's Firewall Device Manager UI.
3. Navigate to **System Settings** > **Cloud Services**.
4. Click **Cloud Services** and select **Unregister Cloud Services** from the drop-down list.
5. Confirm the action and click **Unregister**. This action generates a warning to indicate that the device has been removed from Security Cloud Control. This is expected behavior.
6. Log into Security Cloud Control tenant in the correct region and onboard the device. See Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 12 for more information.
7. Navigate to **System Settings** > **Cloud Services**.
8. Click **Cloud Services** and select **Unregister Cloud Services** from the drop-down list.
9. Select the **Auto-enroll with Tenancy from Security Cloud Control** and click **Register**. The device maps to the new tenant that belongs to the new region and Security Cloud Control onboards the device.

If you **do not** have access to the tenant, use the procedure below:

1. Connect to the FXOS CLI from the console port and log in as **admin**. For information on how to log into the FXOS CLI, see Accessing the FXOS CLI.
2. In the FXOS CLI, connect to **local-mgmt** with the `firepower # connect local-mgmt` command.
3. Execute the `firepower(local-mgmt) # cloud deregister` command to deregister the device from the cloud tenancy.

4. Once the device is successfully unregistered, the CLI interface returns a success message. An example of the message:

```
Example: firepower(local-mgmt) # cloud deregister Release Image Detected RESULT=success
 MESSAGE=SUCCESS 10, X-Flow-Id: 2b3c9e8b-76c3-4764-91e4-cfd9828e73f9
```

Note If the device was never registered to another Security Cloud Control tenant, the message above states `RESULT=success MESSAGE=DEVICE_NOT_FOUND`.

5. In your Security Cloud Control tenant in the correct domain, onboard the device. See Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 12 for more information.
6. In the device's Firewall Device Manager UI, navigate to **System Settings** > **Cloud Services**.
7. Select the **Auto-enroll with Tenancy from Security Cloud Control** and click **Register**. The device maps to the new tenant that belongs to the new region and Security Cloud Control onboards the device.

Error: Claim Error

If you enter the wrong serial number when onboarding a device, Security Cloud Control generates a **Claim Error** status.

Note Confirm that the device is claimed in the correct region within Security Cloud Control.

Resolve this issue with the provedure below:

Procedure

Step 1 Log into Security Cloud Control and navigate to the **Security Devices** page. Locate the device with the error.

Step 2 Select the device so it is highlighted and **Remove** the device from Security Cloud Control.

Step 3 Confirm the following:

- The device is online and can reach the internet.
- The device has not already been onboarded to your Security Cloud Control instance or claimed by a Security Cloud Control tenant in another region.

Step 4 Locate the device's serial number. You can use one of the following methods:

- For the 1000, 2100 and 3100 series model, locate the serial number on the physical device.
- Open an SSH connection to the device and issue the `show serial-number` command.

Step 5 In Security Cloud Control, onboard the device with the correct serial number. See Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 12 for more information.

Error: Failed to Claim

If you see an **Error: Failed to Claim** connectivity status or error message after attempting to onboard a device, the following might be the cause:

- The Security Services Exchange platform may have temporary issues that result in no connectivity.
- The Security Cloud Control server may be down.

Follow the procedure below to resolve this issue:

Procedure

Step 1 Log into Security Cloud Control and navigate to the **Security Devices** page. Locate the device that failed to register.

Step 2 Select the device so it is highlighted and **Remove** the device from your Security Cloud Control tenant.

Step 3 Wait at least 10 minutes before attempting to onboard the device back to your Security Cloud Control tenant. See Onboard a Firewall Threat Defense Device to Cloud-Delivered Firewall Management Center using Zero-Touch Provisioning, on page 12 for more information.

What to do next

If you are still unable to claim the device, review the device's workflow to see is there is an error message. If there is,Export the Workflow and open a support case to further troubleshoot the issue.

Error: Provisional Error

Device Password Has Not Been Changed

If you did not change the default password of the device when configuring the device for remote management and selected the **No, this device has been logged into and configured for a manager** option when onboarding the device to Security Cloud Control, the device will generate an **UnProvisioned** connectivity status in the **Security Devices** page.

Use the following procedure to resolve this issue:

1. Log into Security Cloud Control and navigate to the **Security Devices** page.
2. Locate and select the device with the **UnProvisioned** connectivity status so it is highlighted.
3. In the pane located to the right, locate the **Change Password** window.
4. Click **Change Password** and enter a new password for your device. This overwrites the default password.

It may take a few minutes for the device to onboard and fully synchronize to Security Cloud Control.

Device Password Has Already Been Changed

If you **did** change the default password of the device when configuring the device for remote management and selected the **Is this a new device that has never been logged into or configured before?** option when onboarding the device to Security Cloud Control, Security Cloud Control generates an **UnProvisioned** connectivity status in the **Security Devices** page.

Use the following procedure to resolve this issue:

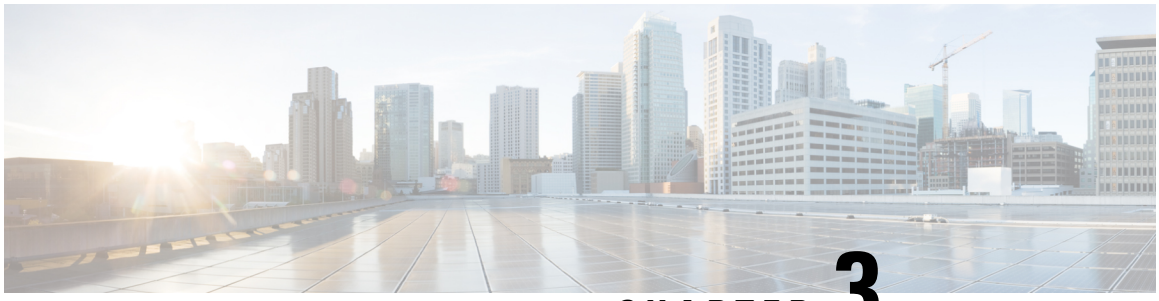
1. Log into Security Cloud Control and navigate to the **Security Devices** page.
2. Locate and select the device with the **UnProvisioned** connectivity status so it is highlighted.
3. In the pane located to the right, locate the **Confirm and Proceed** window.
4. Click **Confirm and Proceed**. This action ignores the password that was provided in the onboarding wizard and reinstates the default password for the device. Security Cloud Control then continues to onboard the device.

Other Provisional Error Scenarios

Regardless of the default password configuration of the device, it is still possible for a device to result in an **UnProvisioned** conectivity status during the onboarding process. If you confirm the password selection in the onboarding wizard is accurate for the state of the device, consider the following options to resolve the issue:

- Select the device so it is highlighted. In the window located on the right pane of the screen, click **Retry** to force Security Cloud Control to re-onboard the device with existing provisional parameters.
- Delete the device from the **Security Devices** page and attempt to re-onboard the device.
- In the device's Firewall Device Manager UI, navigate to **System Settings** > **Cloud Services**. Select the **Auto-enroll with Tenancy from Security Cloud Control** and click **Register**.

If you are still unable to claim the device, review the device's workflow to see is there is an error message. If there is,Export the Workflow and open a support case to further troubleshoot the issue.



CHAPTER 3

Migrate On-Premises Management Center Managed Secure Firewall Threat Defense to Cloud-delivered Firewall Management Center

- About Migrating Firewall Threat Defense to Cloud-delivered Firewall Management Center, on page 35
- Supported On-Premises Firewall Management Center and Firewall Threat Defense Software for Migration, on page 36
- Licensing, on page 37
- Supported Features, on page 37
- Unsupported Features, on page 41

- Migrate Firewall Threat Defense to Cloud-Delivered Firewall Management Center, on page 46
- View a Firewall Threat Defense Migration Job, on page 49
- Enable Notification Settings, on page 55
- Troubleshoot Firewall Threat Defense Migration to Cloud-Delivered Firewall Management Center, on page 55

About Migrating Firewall Threat Defense to Cloud-delivered Firewall Management Center

Security Cloud Control admin users can migrate Firewall Threat Defense devices to the cloud-delivered Firewall Management Center from on-premises management centers. For supported versions, see Supported On-Premises Firewall Management Center and Firewall Threat Defense Software for Migration, on page 36.

Before initiating the migration process, it is important to upgrade the on-premises management center models to a Security Cloud Control-supported version and onboard it to Security Cloud Control. Only after this step, you can proceed with migrating the devices that are associated with the on-premises management center.

You have a 14-day evaluation period to review and assess the migration changes that are made to the Firewall Threat Defense devices before Security Cloud Control automatically commits them. During this evaluation period, if you are not satisfied with the changes, you can either undo the changes and continue managing the device with the on-premises management center or commit the migration changes. It's important to note that

after the evaluation period expires, Security Cloud Control will automatically commit the changes, and it will no longer be possible to undo them.

After migrating the devices, the cloud-delivered Firewall Management Center onboards the Firewall Threat Defense devices and imports all shared policies and associated objects, device-specific policies, and device configuration from the on-premises management center to the cloud-delivered Firewall Management Center. In addition, the devices can be found in Security Cloud Control's **Security Devices** page.

Note Cloud-delivered Firewall Management Center handles all duplicate policy and object names that are identified during the on-premises management center migration process. This behavior is explained in detail later in this document.

User Roles

The user roles of the on-premises management center are no longer applicable in Security Cloud Control after migration. Your authorization to perform tasks on the migrated device is based on your user role in Security Cloud Control. See the Users topic to understand the on-premises management center and cloud-delivered Firewall Management Center user role mapping.

Pause Migration to Review Imported Shared Policies

Security Cloud Control provides an option that allows the migration to be paused once the shared access policies, including Access Control and NAT policies, have been prepared within the cloud-delivered Firewall Management Center. This strategic pause prevents the start of the 14-day evaluation period, ensuring the device's current state or the device's manager is affected during the review phase. This window provides an opportunity for a thorough evaluation of the staged configuration.

Upon a satisfactory review of the configuration within the planned migration window, the process can be resumed. Resuming migration will import the device-specific settings, such as routing and interfaces, and will register the Firewall Threat Defenses with the cloud-delivered Firewall Management Center. Note that this action starts the 14-day evaluation period. Post-migration, it is mandatory to execute deployment from the cloud-delivered Firewall Management Center to finalize the migration successfully.

Supported On-Premises Firewall Management Center and Firewall Threat Defense Software for Migration

Supported Virtual On-Premises Firewall Management Center and Firewall Threat Defense

This section describes the minimum software requirements for migrating Firewall Threat Defense devices from the following on-premises management center version:

- Minimum on-premises management center: 7.2
- Minimum Firewall Threat Defense: 7.0.3 or 7.2 (not supported for Version 7.1)

Supported Physical On-Premises Management Center 1000/2500/4500 Model-Managed Firewall Threat Defense

You can migrate Firewall Threat Defense devices to the Cloud-Delivered Firewall Management Center from a physical on-premises management center 1000/2500/4500 model. We support a *temporary* upgrade from Version 7.0 to Version 7.4. You can download the upgrade package here.

Note The physical on-premises management center 1000/2500/4500, you would have migrated devices from Version 7.4, which is unsupported for general operations but serves as an interim solution until the migration is complete. To return the on-premises management center to a supported version you must remove the re-migrated devices, reimage back to Version 7.0.x, restore from backup, and re-register the devices.

Unzip (but do not untar) the upgrade package before uploading it to the on-premises management center. To upgrade to Version 7.4, see Cisco Secure Firewall Management Center Upgrade Guide, Version 6.0-7.0.

We recommend upgrading the devices to Version 7.0.x before upgrading the on-premises management center to Version 7.4.

Important An upgrade is required because Version 7.0 on-premises management centers do not support device migration to the cloud. Version 7.4 is only supported during the device migration and evaluation process. These on-premises management centers will not run any intermediate versions. Only standalone and high availability Firewall Threat Defense devices running Version 7.0.3+ (7.0.5 recommended) are eligible for migration.

Licensing

- When the Firewall Threat Defense is migrated to the cloud, all feature licenses associated with the device are transferred to Security Cloud Control and released from the Firewall Management Center to the Smart License pool. The device reclaims the device-specific licenses during its registration with Security Cloud Control. You need not apply license on the device again.
- The device-specific licenses are not required if you want to keep devices in the Firewall Management Center for analytics.
- Ensure you have registered the cloud-delivered Firewall Management Center with a smart license.

Supported Features

Handling Shared Policies and Objects

When the migration process begins, the shared policies and associated objects that are associated with the Firewall Threat Defense devices are imported first and then followed by the device configuration.

The following shared policies are imported to Security Cloud Control after changing the manager on Firewall Threat Defense devices:

- Access control

- IPS
- SSL
- Prefilter
- NAT
- QoS
- Identity
- Platform settings
- Flex config
- Network analysis
- DNS
- Malware & file
- Health
- Remote Access VPN
- Site-to-Site VPN

If a policy or object in Security Cloud Control has the same name as the policy or object that is imported from the on-premises management center, Security Cloud Control takes the following actions after changing the management successfully.

Policies, Objects	Condition	Action
Access control, SSL, IPS, Prefilter, NAT, QoS, Identity, Platform settings, Network analysis, DNS, Malware & File policies.	Name of the cloud-delivered Firewall Management Center policy matches the on-premises management center policy.	The cloud-delivered Firewall Management Center policy is used instead of the imported policy from the on-premises management center.
RA VPN Default group policy **DfltGrpPolicy**	The default group policy**DfltGrpPolicy** from the on-premises management center is ignored.	The existing cloud-delivered Firewall Management Center default group policy **DfltGrpPolicy** is used instead.
Network, Port objects	Name and content of network and port objects in the cloud-delivered Firewall Management Center match the ones in the on-premises management center.	The existing cloud-delivered Firewall Management Center network and port objects with the same name and content are used instead of imported objects from the on-premises management center. If the object has the same name but different content, an object override is created.

Policies, Objects	Condition	Action
All other objects		The existing cloud-delivered Firewall Management Center object is used instead of the imported object from the on-premises management center.

Any Syslog alert object that is associated with the access control policy is imported into Security Cloud Control.

Migration Support for Firewall Threat Defense in a High-Availability Pair

You can migrate a device in a high-availability pair to the cloud-delivered Firewall Management Center. The device management of both active and standby devices shifts to the cloud-delivered Firewall Management Center.

Important We strongly recommend committing the manager changes before performing any advanced operations, such as creating high-availability configurations or breaking high-availability configurations from the Firewall Management Center on the devices that are being migrated.

Performing such tasks during the evaluation period is not supported and may result in migration commit failure.

Migration Support for Firewall Management Center in a High Availability Pair

You can migrate the Firewall Threat Defense devices in a high availability from on-premises management center to the cloud.

The on-premises management center can be onboarded using the auto-onboarding of on-premises management center method or credentials method. Always onboard the active management center and not the standby.

Note If you have already onboarded a standalone management center and later configured it as a standby, delete the standby management center and onboard the active one.

Points to Remember:

- **Auto-onboarding On-Premises Management Center Method**
  - High availability break is not supported during the 14 days evaluation period. You can break high availability after committing the changes manually or automatically after the evaluation period.
  - High availability switchover is supported during the 14 days evaluation period.
- **Onboarding On-Premises Management Center Method Using SDC**
  - High availability break or high availability switchover is not supported during the 14 days evaluation period. You can perform these operations after committing the changes manually or automatically after the evaluation period.

- After a switchover, onboard the new active unit, which was previously in standby mode, and then start a migration job on the devices.

Note During the 14-day evaluation period after migrating a Firewall Threat Defense device, if you have performed advanced operations on the device, such as converting it to a multi-instance chassis, note that the evaluation period becomes nullified, and you will not be able to revert the device management back to the On-Premises Firewall Management Center.

If you want to manage a multi-instance chassis using Cloud-Delivered Firewall Management Center, onboard the chassis manually to Security Cloud Control.

Migration Support for Firewall Threat Defense Cluster

Migration of the Firewall Threat Defense cluster from the on-premises management center to the cloud-delivered Firewall Management Center is supported as long as the minimum supported versions of the Firewall Threat Defense on the following platforms are met.

Secure Firewall Threat Defense Platforms	Minimum Secure Firewall Threat Defense Version for Cluster Migration	Minimum On-Premises Management Center Version for Cluster Migration
VMware, KVM	7.2.1	7.4.1
AWS, GCP	7.2.1	7.4.1
Azure	7.3	7.4.1
Secure Firewall 3100	7.2.1	7.4.1
Firepower 4100	7.0.6	7.4.1
Secure Firewall 4200	7.4	7.4.1
Firepower 9300	7.0.6	7.4.1

Important Before migrating the Firewall Threat Defense cluster, it is important to keep in mind the following points:

- Do not attempt to migrate the Firewall Threat Defense cluster during any clustering-related operations initiated from the on-premises management center.
- After the cluster migration, it is recommended to commit the manager changes manually before carrying out any advanced operations, such as adding a node, breaking a node, or breaking a cluster from the on-premises management center on the clusters. This is because performing such tasks during the evaluation period is not supported and may result in migration commit failure.

Migration Support for Multi-instance Firewall Threat Defense Devices

You can migrate a multi-instance Firewall Threat Defense device that is part of a chassis (Secure Firewall 3100). The multi-instance device gets listed as one of the devices in the **Select Devices** page, and you can choose it to proceed with the migration. This migration is supported in Firewall Threat Defense device versions 7.6 or later.

If you decide to do such a multi-instance Firewall Threat Defense device migration, it is strongly recommended that you unregister the corresponding chassis device manually from the on-premises management center and onboard it to Security Cloud Control, by navigating to the **Security Devices** page.

Unsupported Features

Migration of a Firewall Threat Defense device registered only for analytics-only with the Firewall Management Center feature is not currently supported.

The following configuration are not imported from the Firewall Management Center to Security Cloud Control as part of migration:

- Custom Widgets, Application Detectors, Correlation, SNMP and Email Alerts, Scanners, Groups, Dynamic Access Policy, Custom AMP Configuration, Users, Domains, Scheduled Deployment Tasks, ISE configuration, Scheduled GeoDB Updates, Threat Intelligence Director configuration, Dynamic Analysis Connections.
- ISE internal certificate object is not imported as part of the migration. You must export a new system certificate or a certificate and its associated private key from ISE and import it into Security Cloud Control.

Secure Firewall Recommended Rules

Migrating Firewall Threat Defense to the cloud mirates the rule recommendations that are already associated with any of the intrusion policies. However, the Cloud-Delivered Firewall Management Center does not allow the generation of new rule recommendations or auto-update the already migrated recommendations post migration. This is because the Cloud-Delivered Firewall Management Center does not support rule recommendations. See Auto Cisco Recommended Rules.

Custom Network Analysis

If the device is associated with a custom network analysis policy, you must remove all references to this policy from the on premise before migration.

1. Log on to the on-premises management center.
2. Choose **Policies** > **Access Control**.
3. Click the edit icon on the access control policy you want to disassociate the custom NAP and then click the **Advanced** tab.
4. In the **Network Analysis and Intrusion Policies** area, click the edit icon.
5. In the **Default Network Analysis Policy** list, select a system-provided policy.
6. Click **OK**.
7. Click **Save** to save the changes and then click **Deploy** to download the changes to the device.

After migration, you can manually create the Network Analysis Policy in Security Cloud Control.

Migration Guidelines and Limitations for VPN Configuration

Keep the following in mind when you migrate a device with VPN configuration.

Migration Support for Remote Access VPN Policy

Security Cloud Control imports all remote access VPN policy settings, with the following exceptions:

- Object overrides.

  If overrides are used in the address pool object, you must manually add them to the imported object using Security Cloud Control, after migration.

- Local users.

  If the authentication server is configured to a local database for user authentication, the associated local realm object is imported into Security Cloud Control. However, you must manually add the local users to the imported local realm object using Security Cloud Control, after migration. See Create a Realm and Realm Directory.

- Remote Access VPN load-balancing configuration.
- Remote Access VPN certificate enrollment with domain configuration.

  Perform the following after migration to enroll the certificate with domain configuration:

  1. In Security Cloud Control, click **Security Devices**.
  2. Select the migrated FTD and in the **Device Management** on the right, click **Device Overview**.
  3. Choose **Devices** > **Certificates**.

     Perform one of the following tasks:

     - If the certificates are imported in an **Error** state, click the **Refresh certificate status** icon to synchronize the certificate status with the device. The certificate status turns green.
     - If the certificates are not imported, you must manually add the certificates defined in the Remote Access VPN policy that is configured in the Firewall Management Center.

Migration Support for Site-to-Site VPN Policy

After you've selected a Firewall Threat Defense device with a site-to-site VPN configuration, Security Cloud Control will automatically select all its peers from different topologies. This is because devices in the site-to-site VPN topology must be migrated together to ensure a migration to succeed.

Note Although the migration wizard doesn't list the extranet devices that are associated with them, they will still be included automatically during the migration process.

Security Cloud Control imports all the settings of a site-to-site VPN policy, with the following exceptions:

- If object overrides are used in the network object, you must manually add them to the imported object using Security Cloud Control, after migration.
- If the authentication type is configured as "Preshared Automatic Key" in the on-premises management center, Security Cloud Control defines a new pre-shared key for the VPN postmigration deployment. The updated pre-shared key does not break existing tunnels, and the new tunnels start using the new pre-shared key.
- When the devices are moved to Security Cloud Control, and the changes have yet to be committed, the site-to-site VPN policy that is associated with those devices can be edited using the on-premises management center, however, it doesn't update the device configuration in Security Cloud Control.
- If devices are configured for SASE tunnels on Cisco Umbrella, refrain from migrating such devices.

Managing Threat Defense Events and Analytics

The events and analytics management can be retained in the on-premises management center or transferred to Security Cloud Control, where the devices must be configured to send events to Security Cloud Control. While initiating the migration process, you are allowed to choose the manager to which the device events must be sent for analytics.

Attention If you are migrating devices from on-premises management center 1000/2500/4500, it is not possible to use the on-premises management center for managing events due to limited availability. Therefore, you must use Security Analytics and Logging (OnPrem) or Security Analytics and Logging (SAAS) for devices to send events for analytics. See Cisco Security Analytics and Logging.

If you select the on-premises management center for analytics, Security Cloud Control becomes the manager for selected devices but retains a copy of those devices on the on-premises management center in analytics-only mode. The devices continue to send events to the on-premises management center, and Security Cloud Control manages the configuration changes.

If you select Security Cloud Control for analytics, Security Cloud Control becomes the manager for the selected devices and deletes these devices from the on-premises management center. Security Cloud Control manages both configuration changes and events and analytics management. You must configure threat defense devices to send events to the Cisco cloud. You can use either Security Services Exchange or the Secure Event Connector (SEC) to send events from the devices to the Cisco Secure Analytics and Logging (SAL) in the cloud.

If you select on-premises management center for analytics during the migration process, Security Cloud Control provides a 14-day evaluation period to modify the settings and select Security Cloud Control for analytics. After you commit the threat defense migration or the 14-day evaluation period ends, you cannot change the analytics settings, and events will continue to appear in the on-premises management center. To this settings after committing to the threat defense migration or after the 14-day evaluation period has expired, see Troubleshoot Firewall Threat Defense Migration to Cloud-Delivered Firewall Management Center, on page 55.

eStreamer Server Streaming

When you manage a Firewall Threat Defense device with Cloud-Delivered Firewall Management Center, the device supports sending only fully-qualified events (FQE) to eStreamer clients. If you have configured

eStreamer clients in the on-prem Firewall Management Center, ensure that the clients support the detailed data formats used by FQE when you migrate the device management to Cloud-Delivered Firewall Management Center. Any legacy clients, security information and event management (SIEM) systems, or log management solutions that do not support the data format of FQE or lack the necessary storage to handle the larger volume of FQE data will not work when you migrate.

Before You Begin Migration

Before you begin the process, ensure that the following prerequisites are met:

- A provisioned Security Cloud Control tenant is registered with a Smart License.
- **DNS Server Configuration**:

  The Firewall Threat Defenses must have correct DNS server configuration to resolve Cloud-Delivered Firewall Management Center hostnames. To check device connectivity with Cloud-Delivered Firewall Management Center, see Check device connectivity with Cloud-Delivered Firewall Management Center.
- **Network Access**:

  The required network access is enabled for Firewall Threat Defenses to reach Cloud-Delivered Firewall Management Center through the TCP port 8305. Note that outbound connectivity from the Firewall Threat Defenses to Cloud-Delivered Firewall Management Center is sufficient.
- **Firewall Threat Defense Outbound Port 443**:

  The Firewall Threat Defenses must have outbound port 443 open to access cloud to use Security Cloud Control event viewer.
- **On-Premises Management Center Outbound Port 443**:

  The on-premises management center must have outbound port 443 open to access the "*.cdo.cisco.com" domain.
- The on-premises management center is onboarded to Security Cloud Control. Onboarding the on-premises management center also onboards all the Firewall Threat Defense devices registered to that on-premises management center. See Onboard an On-Prem FMC.

Note Create a new user in the on-premises management center with Administrator role or a custom user role with "Devices" and "System" permissions for onboarding purposes.

Caution If you onboard an on-premises management center to Security Cloud Control and simultaneously sign in to that on-premises management center with the same user name, the onboarding fails.

- For the on-premises management center 1000/2500/4500 migration:
  - Run Version 7.4 (available for these models on a temporary basis). We recommend devices be running Version 7.0.5.

- We recommend that you create a backup of on-premises management center.

  For versions on-premises management center Version 6.5 to 7.1, see the *Back up the FMC* topic in the Firepower Management Center Configuration Guide.

  For on-premises management center Version 7.2 and later, see the *Back up the Management Center* topic in the Cisco Secure Firewall Management Center Administration Guide.

- The Firewall Threat Defense devices must be synchronized and not have pending changes on them. The migration fails on a device if Security Cloud Control identifies pending changes on that device.
- All peer devices in a site-to-site VPN topology must be online and have no pending deployment.
- On-Premises Management Center should allow outbound HTTP/HTTPS to upload configurations to Amazon S3.
- Security Cloud Control imports Syslog alert object used in the access control policy from the on-premises management center. If Security Cloud Control already contains an alert object with the same name but a different type (SNMP, Email), it is reused during configuration import.

  The user must check whether the Syslog object name matches the existing SNMP or Email alert object in Security Cloud Control. If the name matches, you must rename the Syslog object in the on-premises management center before starting the migration process.
- If you attempt to migrate firewalls with modified system defined FlexConfig text objects from an on-premises management center to the cloud-delivered Firewall Management Center, the values of the modified system defined FlexConfig text objects are not migrated to the cloud-delivered Firewall Management Center, and the deployment will fail.

  To avoid this, perform these tasks before you start the migration:

  - Copy the modified system defined FlexConfig text object values from the on-premises management center to cloud-delivered Firewall Management Center before migration.
  - Initiate migration from on-premises management center to cloud-delivered Firewall Management Center after verifying the predefined FlexConfig text objects.

High Availability Failover Link Must Be Up

The high availability failover link should be up for a successful migration. Before initiating the migration process on Security Cloud Control, determine the health status of the failover link on the on-premises management center.

1. Identify the failover interfaces of all HA pairs you want to migrate to cloud-delivered Firewall Management Center.
   a. Choose **Devices** > **Device Management**.
   b. Next to the device high-availability pair you want to edit, click **Edit** ( ).
   c. Click the **High Availability** tab.
   d. In the **High Availability Link** area, the **Interface** field shows the failover interface used in the pair.
   e. Identify the interfaces used for failover communication if there are multiple HA pairs for migration.
2. Check the health status of the failover interfaces.

a. Choose **Devices** > **Device Management**.

b. Next to the device high-availability pair you want, click **Health Monitor**.

c. In the left pane, expand the high availability pair to see the Firewall Threat Defense devices.

d. Click the device indicated in the exclamation mark ( ).

e. Click the **Critical** button at the top.

The **Interface Status** shows the errors associated with interfaces.

f. If the failover interface is down, the **Interface 'failover_interfacename' has no link** message is displayed.

Note However, you can migrate the HA pair to cloud-delivered Firewall Management Center if you see any other data interface issues except for the failover interface.

g. Rectify the issue and click **Sync from onprem fmc now** to obtain the latest changes on the device.

Migrate Firewall Threat Defense to Cloud-Delivered Firewall Management Center

Procedure

Step 1 In the navigation bar on the left, click **Administration** > **Migration** > **Migrate FTD to cdFMC**.

Step 2 Click + and choose **On-Prem FMC-managed FTD to cdFMC**.

Note
You can initiate only one migration job at one time.

Step 3 In the **Select OnPrem FMC** area, perform the following:

a. You can click the **Onboard an FMC** link to onboard the on-premises management center if you have not done already. See Onboard an FMC.

b. Select the on-premises management center from the available list and click **Next**.

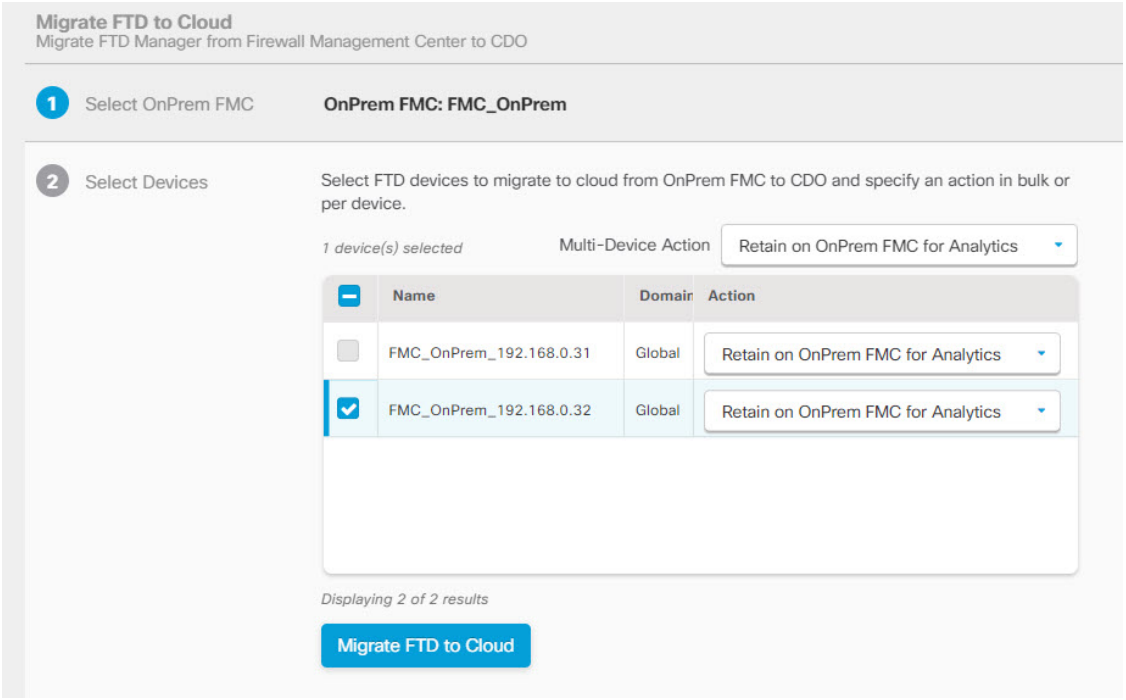
In the **Select Devices** step, you will see the Firewall Threat Defense devices that the selected on-premises management center manages. If a high-availability pair is set up on the on-premise on-premises management center, the high availability node will be shown instead of the active and standby devices.

The **Last Synced time** field indicates the time that is elapsed since the device configuration is synchronized into the on-premises management center. You can click **Sync from OnPrem FMC Now** to fetch the latest device changes.

Step 4 In the **Select Devices** step, perform the following:

a) Select the devices that you want to migrate.

These devices can include standalone, high-availability pairs, or clusters. If you have a high-availability pair or a cluster, select the node that represents it. Also, you can hover your mouse pointer over the cluster to view more details about the control node.



Note

- The devices running on unsupported versions are not available for selection.
- The devices that are registered for analytics only with the on-premises management center or have pending changes to be deployed are not eligible for migration.
- When you select a device that is associated with a site-to-site VPN topology, Security Cloud Control automatically selects its peer devices belonging to either the same topology or a different topology, because all devices in the site-to-site VPN topology must be migrated together for a successful migration to take place. The wizard does not list the extranet devices, if any. However, Security Cloud Control migrates extranet devices.

  The **S2S VPN Topology** column indicates the number of site-to-site VPN topologies in which a selected device participates. You click the topology link to view the topologies and devices that are migrated along with the selected device. This field is not applicable to devices that are not part of the site-to-site VPN topology.
- A high availability pair is presented as a single node. You must select this node to include active and standby devices in the migration.

b) In the **Multi-Device Action** list, you can choose a common action to apply on all devices.
c) In the **Commit Action** column, you can choose one of the following actions for the selected device:

- **Retain on OnPrem FMC for Analytics**: After the migration process is completed, the analytics management for selected Firewall Threat Defense devices is retained on the on-premises management center.
- **Delete FTD from OnPrem FMC**: After the migration process is completed, the selected devices are removed from the on-premises management center and are available for Security Cloud Control to handle the analytics. You must configure the devices to send events to Security Cloud Control for managing analytics. When the devices are deleted from the on-premises management center, they cannot be revoked.

  Important
  For the on-premises management center 1000/2500/4500, when you select devices to migrate, make sure you choose **Delete FTD from OnPrem FMC**. Note that the device is not fully deleted unless you commit the changes or 14 days pass.

Note
The actions that are specified here are committed automatically after the 14 days evaluation period or after the changes are committed manually.

Step 5 (Optional) Check the **Pause migration to review imported shared policies** check box.

When you enable this option, the migration process will pause after the shared access policies like Access Control and NAT policies are staged in the Cloud-Delivered Firewall Management Center. This pause ensures that the evaluation doesn't start and that the device's current state and manager remain unaffected. It gives you ample time to review the imported configuration for accuracy. After you've assessed everything, you can resume the migration during the planned migration interval, which will then kick off the 15-day evaluation period.

Step 6 Check the **Auto deploy to FTDs after successful migration** check box to deploy the migrated configuration automatically to the device after successfully migrating and registering the device with the Cloud-Delivered Firewall Management Center.

However, if you prefer to review and manually deploy the configuration from the Cloud-Delivered Firewall Management Center after successful migration, you can uncheck this option and proceed to the next step.

Step 7 Click **Migrate FTD to cdFMC**.

Step 8 Click **View Migration to Cloud Progress** to see the progress.

What to do next

If you have paused the migration for review, you must manually click **Proceed Migration** to import the remaining configuration. See Proceed Migration Process, on page 50.

You can view the overall and individual status of migration jobs and generate a report when a job is completed successfully. See View a Firewall Threat Defense Migration Job, on page 49.

View a Firewall Threat Defense Migration Job

The migration dashboard provides the status of all migration jobs initiated from the Security Cloud Control. You can expand a specific job to see the status of individual devices associated with that tenant. This helps you keep track of the progress of your migration and identify issues, if any, that need to be addressed.

If you have set up alerts for device workflows, click the notifications icon to see the alerts that have been triggered during the migration process. Additionally, if you have opted to receive email notifications from Security Cloud Control, you will also receive an email notification regarding alerts, if any.

About the 14-day Evaluation Period

When a migration job is successful, you have 14 days to test and assess migration changes using cloud-delivered Firewall Management Center. If you are convinced about the migration changes, we recommend that you commit the devices manually, and not wait for Security Cloud Control to automatically commit the migration changes. See Commit Migration Changes Manually.

Note that for the on-premises management center 1000/2500/4500, you would have migrated devices from Version 7.4, which is unsupported for general operations. To return the on-premises management center to a supported version you must remove the re-migrated devices, reimage back to Version 7.0.x, restore from backup, and re-register the devices.

Note

- You cannot revoke the actions that are specified in the migration commit window after committing the changes.
- You can cancel the migration during the evaluation period and return the device to the on-premises management center.
- You cannot delete a device from either the on-premises management center or cloud-delivered Firewall Management Center during the evaluation period.

Important Changes can be made and deployed to the device using Security Cloud Control during the evaluation period. If you switch device management back to the on-premises management center, Security Cloud Control-specific changes made during the evaluation period is not saved on the device once it is reverted to the source Security Cloud Control tenant. You must deploy the changes from the on-premises management center to the device after reverting the device's manager.

- **Name**: Represents the job name that shows the on-premises management center name and the date and time when the job was initiated.
- **Number of FTDs**: Shows the total number of devices that are being migrated to the cloud.
- **Status**: Shows the status of the job. Expand the job to see the status of individual devices.

  When a job is completed successfully, the **FTD Migration job is successful message** appears in the **Status** column. You can click the tooltip to see the number of days remaining for evaluating the manager.

You can click Commit Migration Changes to commit the changes manually before the 14 days evaluation period ends.

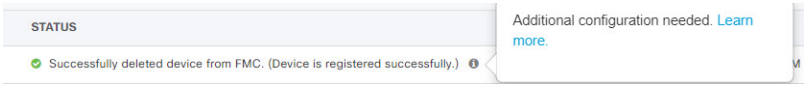
- **Last Update**: Shows the date and time that are updated only when a change is made to the device.
- **Actions**: Click to execute the following actions:
  - **Workflows**: Takes you to the **Workflows** to monitor the job.
  - **Download Report**: Allows you to generate and download a report of every job that is completed successfully. See Generate a Firewall Threat Defense Migration Report, on page 54.
  - **Commit Manager Changes**: Allows you to apply the changes manually to devices before the evaluation period ends. See Commit Migration Changes Manually to Cloud-delivered Firewall Management Center, on page 51.
  - **Remove Migration Job**: Allows you to remove a completed job. Link is available only for completed jobs. See Delete a Migration Job, on page 54.

After a successful migration, Security Cloud Control deploys the configuration to the device. If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors. If the deployment fails, see the *Best Practices for Deploying Configuration Changes* section of Firepower Management Center Device Configuration Guide X.Y.

Configure Relam Sequence for Identity Policy

If the device contains an identity policy with a Realm or ISE configuration, configure your device as a proxy for Security Cloud Control to communicate with the identity source. The identity policies don't function if Security Cloud Control fails to connect to the Identity Realms.

A tooltip appears in the **Status** column for a device that requires additional configuration.



1. Click the tooltip icon and then click **Learn more**.
2. In the **Configure Proxy** window, click **Configure my realms**.

   To add a proxy sequence, see the *Create a Proxy Sequence* section in the Firepower Management Center Device Configuration Guide, 7.2.

Proceed Migration Process

If the **Pause migration to review imported shared policies** option was checked during the migration setup, the migration process will pause after the shared access policies were staged in the Cloud-Delivered Firewall Management Center. After you've reviewed the staged configurations, you must manually instruct Security Cloud Control to resume the migration, which will then import device-specific configurations such as routing and interfaces, as well as register the Firewall Threat Defense with the Cloud-Delivered Firewall Management Center. Completion of the migration triggers a 14-day evaluation period.

To proceed, go to the migration job page and click **Proceed with migration** for the relevant job.

Remember that deployment from the Cloud-Delivered Firewall Management Center must be done after a successful migration.

Commit Migration Changes Manually to Cloud-delivered Firewall Management Center

We recommend that you commit migration changes manually if you are convinced with your changes and not waiting for Security Cloud Control to auto commit changes. The **Commit Migration Changes** window shows the remaining days to commit the migration to Cloud-Delivered Firewall Management Center or revert the device to on-premises management center. During the evaluation period, you can modify the actions for selected threat defense devices before committing the changes. Once the changes are committed, you can't revoke the actions.

Note The commit manager changes actions are disabled in the following conditions:

- The 14-day evaluation period has passed.
- The Firewall Threat Defense devices have either been reverted to the on-premises management center or deleted from on-premises management center, in which case, no further actions can be taken.

Procedure

Step 1 In the migration jobs page, click the ... under the **Actions** column of a completed job.

Step 2 Click **Commit Migration Changes**. (This link is available only after a job is completed successfully.)

Step 3 Select a device and in the **Commit Actions** list, choose one of the following actions:

- **Retain on OnPrem FMC for Analytics**: After committing the changes, analytics management for selected Firewall Threat Defense devices is retained on the management center.
- **Delete**Firewall Threat Defense **from OnPrem FMC**: After committing the changes, the selected devices are removed from the on-premises management center and are available for Security Cloud Control to handle the analytics. You must configure the Firewall Threat Defense to send events to Security Cloud Control for managing analytics. After the Firewall Threat Defense devices are deleted from the on-premises management center, they cannot be revoked.

Note
If you want to revert the device management to on-premises management center, refer to Revert the Firewall Threat Defense Management to On-Premises Firewall Management Center, on page 52.

Step 4 Click **Commit** executes your specified actions immediately without further confirmation.

On the migration jobs screen, you can expand the job to check the progress of the actions specified.

The migrated devices appear on Security Cloud Control's **Security Devices** page. These devices can be managed using the Cloud-Delivered Firewall Management Center portal that is linked to Security Cloud Control. Ensure you deploy the changes to the devices from Cloud-Delivered Firewall Management Center.

Revert the Firewall Threat Defense Management to On-Premises Firewall Management Center

You can revert the device management to the on-premises management center during the evaluation period. This means that the devices will no longer be managed through the Security Cloud Control platform. However, it is important to note that any changes made during the migration process in the Security Cloud Control will not be reflected in the on-premises management center after reverting Firewall Threat Defense management.

Note When the Firewall Threat Defense management has been returned to the on-premises management center , you can begin the migration job again to switch the Firewall Threat Defense management to Security Cloud Control.

Procedure

Step 1 In the migration jobs page, click the ... under the **Actions** column of a completed job.

Step 2 Click **Commit Migration Changes**. (This link is available only after a job is completed successfully.)

Step 3 Select a device and in the **Commit Actions** list, choose **Revert Manager to OnPrem FMC**.

Step 4 Click **Commit** executes your specified actions immediately without further confirmation.

Step 5 Deploy the changes to the device from the on-premises management center.

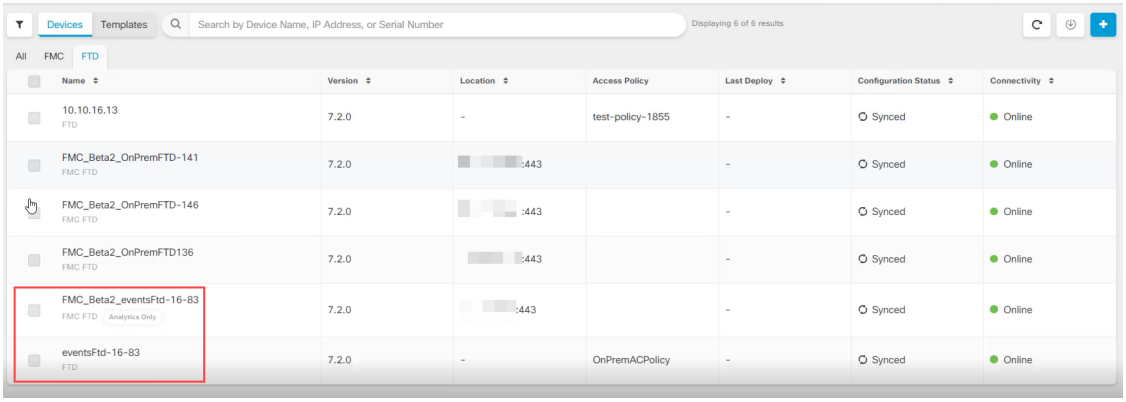
View Migrated Devices

The migrated devices appear on the **Security Devices** page in Security Cloud Control. You can cross-launch and configure the required feature on the Cloud-Delivered Firewall Management Center.

Note The devices on the Cloud-Delivered Firewall Management Center device listing page may show `No-IP` instead of the device's management IP address. Because the device registration uses the NAT ID, the device initiates the process, and therefore, the management IPs aren't discovered or used for the connection. Note that this applies to newly onboarded devices and devices migrated from the on-premises management center.

Analytics Only Firewall Threat Defense Device Example

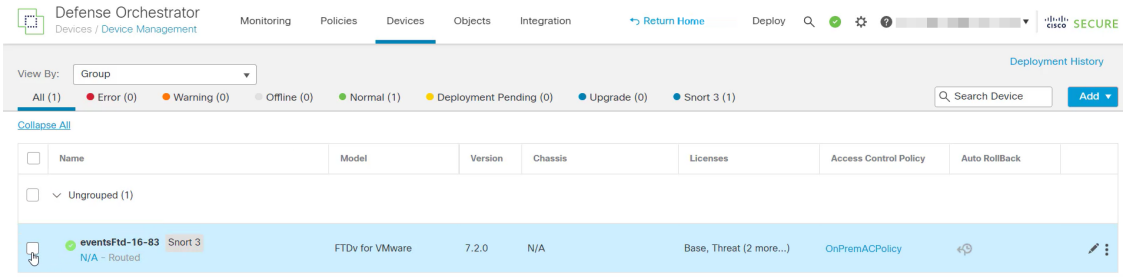
Security Cloud Control creates two instances of the same device that is configured to retain on the Firewall Management Center for analytics.



The device instance with **FMC FTD** and **Analytics Only** labels shows that the Firewall Management Center handles the analytics. The device instance with the **FTD** label indicates that Security Cloud Control manages its configuration.

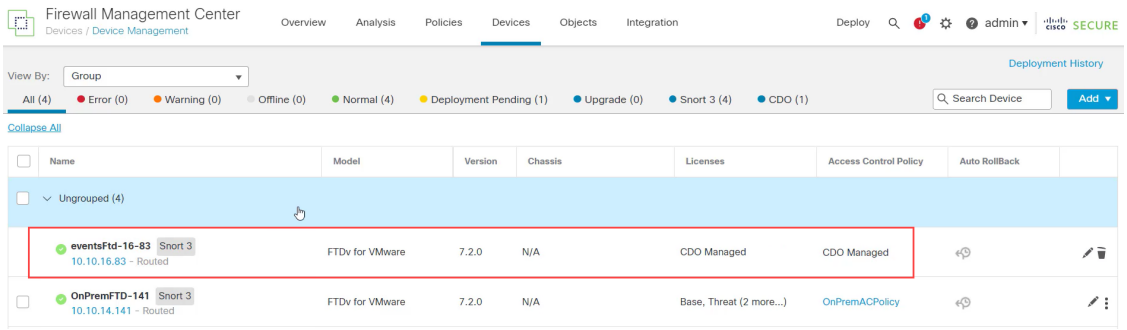
You can manage the configuration of the device using Security Cloud Control. To see the device in the Cloud-Delivered Firewall Management Center, do the following:

Select the device having **FTD** label and in the **Management** pane on the right, click **Device Summary**.



You can view the events from the device in the Firewall Management Center. To see the events, do the following:

1. Select the device having **FMC FTD** and **Analytics Only** labels and on the right, click the **Manage Devices** link.
2. Log on to the on premise Firewall Management Center.
3. Choose **Device** > **Device Management**.



You can't select this device as Security Cloud Control manages the configuration. The Firewall Management Center shows the **Security Cloud Control Managed** label for this device.

To see the live events in the Firewall Management Center, click **Analysis** > **Events**.

Generate a Firewall Threat Defense Migration Report

When a migration job is successful, you can generate and download a report in PDF format to analyze every parameter imported from the on-premises management center to cloud-delivered Firewall Management Center. The report provides details of each device associated with the job. Details include information about devices, values of shared policies, objects, routing details, interfaces, network settings, and more.

On the migration jobs page, click the ... under the **Actions** column of a completed job and then click **Download Report.**. You must download a report within a year of the job being triggered.

Delete a Migration Job

If you have completed a migration job and no longer need it to be displayed on the migration page, you can easily remove it by deleting it. This cleans up the migration page and make it easier to navigate.

Attention If you want to delete a migration job during the evaluation period, you must first commit the migration changes or revert the manager to the on-prem management center. Failing to do so may result in an inconsistent state of the on-prem management center, which could be unrecoverable. See Commit Migration Changes Manually.

If you don't have access to your on-premises management center or if it is no longer available and you are blocked from performing a commit or revert, you can delete the job.

Procedure

Step 1 Click **Administration** > **Migration** > **Migrate FTD to cdFMC**.

Step 2 Click the ... under the **Actions** column and then click **Remove Migration Job**.

Step 3 Click **Delete** to confirm your action.

Enable Notification Settings

You can subscribe to get email notifications from Security Cloud Control whenever a device associated with your tenant experiences a specific action when migrating a Firewall Threat Defense device to Security Cloud Control.

Security Cloud Control sends an email if you enable to receive a notification for the following states during migration:

- **Failed**: When a migration job fails.
- **Started**: When a migration job is initiated.
- **Succeeded**: When a migration job is completed successfully.
- **Commit Pending**: When the manager changes have to be committed.

To enable notification settings, see Notification Settings.

Troubleshoot Firewall Threat Defense Migration to Cloud-Delivered Firewall Management Center

This section details how to troubleshoot specific errors that may occur when migrating Firewall Threat Defense devices to cloud-delivered Firewall Management Center.

Configuration export from On-Premises Firewall Management Center failed

Cause:

- Disk space is full or nearly full, preventing the export process from being completed.
- Concurrent operations such as device upgrade, upgrade revert, moving a device between domains, device import and export, device template import and export, or policy analysis are running in on-premises management center.
- Connectivity issues exist between the on-premises management center and Security Cloud Control.

Workaround:

1. Perform these actions according to your requirements:
   - Ensure that at least 10% of disk space is available to accommodate the creation of necessary export files.
   - Ensure that no parallel operations are running during the migration.
   - Ensure that the network connection between on-premises management center and Security Cloud Control is stable and reliable.
2. Retry the migration.
3. If the issue persists, contact Cisco TAC.

Failed to initiate import in Security Cloud Control

Cause:

Import can fail if:

- Disk space is full or nearly full, preventing the import process from being completed.
- Concurrent operations such as device upgrade, upgrade revert, moving a device between domains, device import and export, device template import and export, or policy analysis are running in Cloud-Delivered Firewall Management Center.

Workaround:

1. Ensure that no other operations are running during import and retry migration.
2. If the issue persists, contact Cisco TAC.

Failed to retrieve the most recent device information from On-Premises Firewall Management Center

Cause:

- Network connectivity issues.
- DNS settings.
- Device synchronization issues.

Workaround:

1. Perform these actions according to your requirements:
   - Ensure that the network connection between Security Cloud Control and on-premises management center is stable.
   - Ensure that DNS settings for resolving Firewall Management Center hostnames are correct.
   - Ensure network access for Firewall Threat Defense devices through TCP ports 8305 and 443.
   - Ensure outbound connectivity to port 443 to Security Cloud Control and Cloud-Delivered Firewall Management Center hosts.
   - Ensure that the devices are synchronized without any pending changes.
2. Retry migration.
3. If the issue persists, contact Cisco TAC.

Failed to select Security Cloud Control as the manager for events and analytics

Cause:

Selected on-premises management center for analytics during Firewall Threat Defense migration and committed it or the Security Cloud Control automatically committed it after the 14-day evaluation period.

Workaround:

1. Log in to the on-premises management center and remove the Firewall Threat Defense device from the on-premises management center.

2. Enable the Firewall Threat Defense device to send events to Security Analytics and Logging (SaaS) directly. For more information, see Send Cloud-delivered Firewall Management Center-Managed Event Logs to SAL (SaaS) Using a Direct Connection.
3. Verify if the SSE Connector is running in the Firewall Threat Defense device. To verify, access Firewall Threat DefenseCLI and do the following:

```
# more /ngfw/etc/sf/connector.properties

registration_interval=180

connector_port=8989

connector_fqdn=api-sse.cisco.com
```

4. Verify the connectivity between Firewall Threat Defense and the SSE portal. The following URLs need to be allowed as IPs can change:
   - api.apj.sse.itd.cisco.com (primary SSE cloud API endpoint)
   - est.sco.cisco.com (common endpoint across geographies)
   - mx.apj.sse.itd.cisco.com
   - dex.apj.sse.itd.cisco.com (for customer success services)
   - eventing-ingest.apj.sse.itd.cisco.com (for Cisco XDR and Security Cloud Control services)
   - registration.apj.sse.itd.cisco.com (enables Firewall Threat Defense device registration to the regional Cisco cloud)
5. access Firewall Threat Defense CLI and perform a CURL request to validate tenant details using the following command:

```
root@firepower:/home/admin# curl localhost:8989/v1/contexts/default/tenant
```

6. Verify that the event logs are appearing in Security Cloud Control.

Failed to import configuration from On-Premises Firewall Management Center

Cause:

The On-Premises Firewall Management Center configuration may include policies or object configurations that are unsupported or are conflicting, leading to migration failure.

Workaround:

1. Check the On-Premises Firewall Management Center configuration for unsupported policies or object configurations to ensure compatibility.
2. Retry migration.
3. If the issue persists, contact Cisco TAC.

Failed to complete device discovery

Cause:

Conflicts or unhandled scenarios exist in the device configuration or within Security Cloud Control's internal operations, such as incompatible settings or unsupported conditions that Security Cloud Control does not support.

Workaround:

1. Perform these actions according to your requirements:
    - Inspect the device configuration in On-Premises Firewall Management Center for incompatible settings or unsupported scenarios that Security Cloud Control does not support and make necessary updates.
    - Check system logs for errors and confirm that both the On-Premises Firewall Management Center and the device are functioning properly.
2. Retry migration.
3. If the issue persists, contact Cisco TAC.

Failed to connect the device to Security Cloud Control

Cause:

Possible causes include the device being powered off, network connectivity issues, or a firewall blocking the necessary ports.

Workaround:

1. Perform these actions according to your requirements:
    - Confirm that the device is powered on, and network connection is stable. Look for Firewall issues, blocked ports, and incorrect cabling.
    - Ensure that your device has the correct DNS server configuration for resolving Security Cloud Control hostnames.
2. Retry migration.
3. If the issue persists, contact Cisco TAC.

Failed to register the device, causing the manager to revert to On-Premises Firewall Management Center

Cause:

The device failed to register with Cloud-Delivered Firewall Management Center during migration, causing the system to revert the device manager to On-Premises Firewall Management Center. This may be because of connectivity issues.

Workaround:

1. Perform these actions according to your requirements:
    - Verify DNS settings for resolving Security Cloud Control hostnames.
    - Ensure that network access is enabled for TCP port 8305, allowing the Firewall Threat Defense devices to connect to the Cloud-Delivered Firewall Management Center.

- Allow outbound HTTPS connections on Firewall Threat Defense devices to reach the Cloud-Delivered Firewall Management Center and upload configurations to Security Cloud Control.

2. Retry migration.
3. If the issue persists, contact Cisco TAC.

Failed to unregister the device due to an ongoing deployment

Cause:

Migration failed because a deployment is in progress on the device.

Workaround:

1. Perform these actions according to your requirements:
   - Wait for the ongoing deployment to finish.
   - Confirm that the device is stable, with no pending tasks.
2. Retry migration.
3. If the issue persists, contact Cisco TAC for support.

Report generation failed after successful FTD migration to Cloud-Delivered Firewall Management Center

Cause:

The report generation failure may be because of temporary system glitches.

Workaround:

- Generate the report after some time to overcome the temporary system issues that might have caused the initial failure.
- If the issue persists, contact Cisco TAC.

Failed to initiate FTD migration to Cloud-Delivered Firewall Management Center

Cause:

- Ongoing migration in the source manager.
- Unsupported device version.
- Incorrect DNS and network configuration.

Workaround:

1. Perform these actions according to your requirements:
   - Confirm that no other migration jobs are active in the same source manager.
   - Verify that the devices are on supported versions, have no pending changes to be deployed, and are active.

- Ensure that the DNS settings are correct, and network access is available to communicate with Cloud-Delivered Firewall Management Center.

2. If the issue persists, contact Cisco TAC.

Failed to deploy changes from Security Cloud Control

Cause:

Device migration to Cloud-Delivered Firewall Management Center failed during deployment.

Workaround:

1. Perform these actions according to your requirements:
   - Attempt the deployment again from the **Deployment** page on Cloud-Delivered Firewall Management Center.
   - Check for out-of-band changes, which are changes made directly in the device, and not through Security Cloud Control. If out-of-band changes exist, they may interfere with the deployment. Use Security Cloud Control's **Check for changes** functionality to identify and address out-of-band changes.
   - Ensure that all the configurations are supported and do not conflict with the current device settings.
   - Verify that the device is onboarded and reachable by both the Security Cloud Control and management center, with the necessary internet access and communication capabilities.
2. If the issue persists, contact Cisco TAC.

Failed to commit FTD migration to Cloud-Delivered Firewall Management Center

Cause:

- The 14-day evaluation period has expired.
- Firewall Threat Defense devices have been reverted to or deleted from the On-Premises Firewall Management Center, preventing further actions.

Workaround:

1. Try committing again to address any transient network or device issues.
2. If the issue persists, contact Cisco TAC.

Failed to retain device on On-Premises Firewall Management Center for Analytics

Cause:

If your source manager is an On-Premises Firewall Management Center 1000/2500/4500, it cannot support retaining for Analytics because of the limited resources.

Workaround:

1. Ensure that the **Retain on On-Prem FMC for Analytics** option is selected during the migration process.
2. If the issue persists, contact Cisco TAC.

Failed to revert the device manager to On-Premises Firewall Management Center

Cause:

- The device cannot be reverted if the 14-day evaluation period has expired.
- Firewall Threat Defense devices have been reverted to or deleted from the On-Premises Firewall Management Center, preventing further actions.

Workaround:

1. Perform these actions according to your requirements:
    - Try committing the changes again to address the temporary server or network issues.
    - If changes have occurred in the high availability configuration after migration, reset the devices to their original migration state before attempting to commit.
2. If the issue persists, contact Cisco TAC.

Failed to configure Security Cloud Control as the configuration manager

Cause:

The device already has a configuration manager.

Workaround:

1. If another configuration manager is present, remove it manually and retry the migration.
2. If the issue persists, contact Cisco TAC.

Failed to commit migration; the device is ineligible

Cause:

- The device has pending changes that have to be deployed.
- The device to be migrated is part of FTD high availability (HA), but the current state is invalid, for example, it is in Active/Active state.
- The device to be migrated is connected in Analytics-only mode.
- Cluster migration is supported only for FTDs version 7.4 and above.
- Migration for chassis and MI FTDs on models 3100/4200 is currently not supported.

Workaround:

1. Perform these actions according to your requirements:
    - Verify that the device is up to date with On-Premises Firewall Management Center, then retry migration.
    - Ensure all pending changes on the devices are deployed.
    - Confirm that the Firewall Threat Defense device is in a valid state, such as Active/Standby. If the status isn't correctly reflected in On-Premises Firewall Management Center, use the **Force refresh node status** option on the device listing page to update the correct status on management center.

2. If the issue persists, contact Cisco TAC.

Failed to import site-to-site VPN policies from On-Premises Firewall Management Center

Cause:

The failure may be due to various factors, such as VPN policy configuration or network connectivity issues.

Workaround:

1. Perform these actions according to your requirements:
   - Verify your site-to-site VPN policies in On-Premises Firewall Management Center to ensure there are no configuration errors. If object overrides are used within network objects, manually add these overrides to Security Cloud Control after migration.
   - Ensure that both the On-Premises Firewall Management Center and the targeted device have stable and reliable network connections to Security Cloud Control.
   - If the authentication type is set as **Pre-shared Automatic Key** in On-Premises Firewall Management Center, Security Cloud Control generates a new pre-shared key for the VPN post-migration deployment without disrupting existing tunnels.
2. Retry migration.
3. If the issue persists, contact Cisco TAC.

Failed to migrate as all devices within the topology need to be migrated simultaneously

Cause:

Migrating multiple devices, particularly those within the same network topology, requires synchronizing their migrations to avoid inconsistencies and potential errors. All devices should be migrated within the same timeframe.

Workaround:

1. Perform these actions according to your requirements:
   - Devices registered for Analytics -only with the On-Premises Firewall Management Center or those with pending changes are not eligible for migration.
   - When selecting a device associated with a site-to-site VPN topology, Security Cloud Control automatically selects peer devices from the same or different topology, as all devices in the topology must be migrated together for success. Extranet devices, if any, are not listed by the wizard.
   - The **S2S VPN Topology** column shows the number of site-to-site VPN topologies a device is part of. Click the topology link to view the topologies and devices migrating with the selected device. This field does not apply to devices outside the site-to-site VPN topology.
   - A high-availability pair is shown as a single node. Select this node to include both active and standby devices in the migration.
2. If the issue persists, contact Cisco TAC.

HTTP status code 201 (created) found in On-Premises Firewall Management Center response

Cause:

The Secure Device Connector (SDC) version is not compatible.

Workaround:

1. Ensure that the SDC is upgraded to version **202205191350** or later.
    - In the left pane, click **Administration** > **Integrations** > **Secure ConnectorsAdministration** > **Secure Connectors**.
    - Click the SDC to view the existing version in the **Details** pane on the right.
    - Update your Secure Device Connector.

Verify Firewall Threat Defense Connectivity with Cloud-delivered Firewall Management Center

This section provides the commands to determine the Firewall Threat Defense connectivity with the cloud-delivered Firewall Management Center.

Check internet connectivity on the device

Execute the **ping system** <*any OpenDNS server address*> command to check whether the device can reach the internet.

1. Connect to the CLI of the device, either from the console port or using SSH.
2. Log in with the Admin username and password.
3. Enter **ping system** <*OpenDNS IPAddress*>.

```
ping system 208.67.222.222
PING 208.67.222.222 (208.67.222.222) 56(84) bytes of data.
64 bytes from 208.67.222.222: icmp_seq=1 ttl=48 time=22.10 ms
64 bytes from 208.67.222.222: icmp_seq=2 ttl=48 time=22.10 ms
64 bytes from 208.67.222.222: icmp_seq=3 ttl=48 time=22.8 ms
64 bytes from 208.67.222.222: icmp_seq=4 ttl=48 time=22.6 ms
^C
--- 208.67.222.222 ping statistics ---
4 packets transmitted, 4 received, 0% packet loss, time 7ms
rtt min/avg/max/mdev = 22.588/22.841/22.995/0.223 ms
```

The above example shows that the device can connect to the internet using the OpenDNS Server IP address. Also, the number of packets transmitted is the same as received, indicating that internet connectivity is available on the device. This shows that the device can reach the internet.

Note If your results don't match, check the internet connection manually.

Check device connectivity with Cloud-delivered Firewall Management Center

1. Obtain the host name of the cloud-delivered Firewall Management Center.
   a. In the Security Cloud Control left pane, click **Administration** > **Integrations** > **Firewall Management Center**.
   b. Choose **Cloud-Delivered FMC** to see the cloud-delivered Firewall Management Center details on the right pane.
   c. In the **Hostname** field, copy only the hostname shown in the following example image.

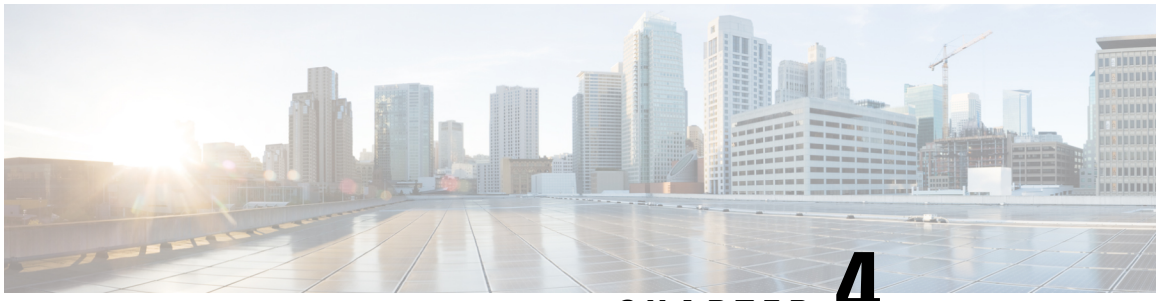
   In the above figure, the highlighted text is the hostname (*Security Cloud Control-acc10.app.us.Security Cloud Control.cisco.com*) of the FMC to be copied.

2. Connect to the CLI of the device, either from the console port or using SSH.
3. Enter **ping system** <*hostname of the FMC*>.

```
ping system cdo-acc10.app.us.cdo.cisco.com
PING cdo-acc10.app.us.cdo.cisco.com (54.187.125.161) 56(84) bytes of data.
^C
--- cdo-acc10.app.us.cdo.cisco.com ping statistics ---
2 packets transmitted, 0 received, 100% packet loss, time 64ms
```

In the above example, the hostname is resolved with the IP address, indicating your connection is successful. Ignore the "100% packet loss" message shown in the response.

Note If you can't connect to the host, you can rectify the DNS configuration in the CLI using **configure network dns** <*address*>.



CHAPTER 4

Device Management

This guide applies to an *on-premises* Secure Firewall Management Center, either as your primary manager or as an analytics-only manager. When using the Cisco Security Cloud Control (Security Cloud Control) Cloud-Delivered Firewall Management Center as your primary manager, you can use an on-prem Firewall Management Center for analytics. Do not use this guide for cloud-delivered Firewall Management Center management; see Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Cisco Security Cloud Control.

You canmanage devices in the Secure Firewall Management Center.

- Log Into the Command-Line Interface on the Device, on page 65
- Manage Devices, on page 67
- Hot Swap an SSD on the Secure Firewall 3100 Series, on page 75

Log Into the Command-Line Interface on the Device

You can log directly into the command-line interface on Firewall Threat Defense devices. If this is your first time logging in, complete the initial setup process using the default **admin** user; see Complete the Initial Configuration of a Secure Firewall Threat Defense Device Using the CLI, on page 2931.

Note If a user makes three consecutive failed attempts to log into the CLI via SSH, the system terminates the SSH connection.

Before you begin

- Create additional user accounts that can log into the CLI using the **configure user add** command.
- If you get unreadable characters when connecting to the console port, verify the port settings. If they are correct, try the cable with another device using the same settings. If the cable is good, you might need to replace the hardware for the console port. Also consider trying a different workstation to make the connection.

Procedure

Step 1 Connect to the Firewall Threat Defense CLI, either from the console port or using SSH.

You can SSH to the management interface of the Firewall Threat Defense device. You can also connect to the address on a data interface if you open the interface for SSH connections. SSH access to data interfaces is disabled by default. See SSH Access, on page 1050 to allow SSH connections to specific data interfaces.

For physical devices, you can directly connect to the console port on the device. See the hardware guide for your device for more information about the console cable. Use the following serial settings:

- 9600 baud
- 8 data bits
- No parity
- 1 stop bit

The CLI on the console port is FXOS (with the exception of the ISA 3000, where it is the regular Firewall Threat Defense CLI). Use the Firewall Threat Defense CLI for basic configuration, monitoring, and normal system troubleshooting. See the FXOS documentation for information on FXOS commands.

Step 2 Log in with the **admin** username and password.

Example:

```
firepower login: admin
Password:
Last login: Thu May 16 14:01:03 UTC 2019 on ttyS0
Successful login attempts for user 'admin' : 1

firepower#
```

Step 3 If you used the console port, access the Firewall Threat Defense CLI.

connect ftd

Note
This step does not apply to the ISA 3000.

Example:

```
firepower# connect ftd
>
```

Step 4 At the CLI prompt (>), use any of the commands allowed by your level of command line access.

To return to FXOS on the console port, enter **exit**.

Step 5 (Optional) If you used SSH, you can connect to FXOS.

connect fxos

To return to the Firewall Threat Defense CLI, enter **exit**.

Step 6 (Optional) Access the diagnostic CLI:

system support diagnostic-cli

Use this CLI for advanced troubleshooting. This CLI includes additional **show** and other commands.

This CLI has submodes: user EXEC mode, privileged EXEC mode. More commands are available in privileged EXEC mode than user EXEC mode. To enter privileged EXEC mode, enter the **enable** command; press enter without entering a password when prompted.

Example:

```
> system support diagnostic-cli
firepower> enable
Password:
firepower#
```

To return to the regular CLI, type **Ctrl-a**, **d**.

Manage Devices

Register and unregister devices to the Firewall Management Center.

About the Device Management Page

The **Devices** > **Device Management** page provides you with range of information and options.

- **View By**—View devices based on group, licenses, model, version, or access control policy.
- **Device State**—View devices based on state (**Error**, **Warning**, etc.). You can click on a state icon to view the devices belonging to it. The number of devices belonging to the states are provided within brackets.
- **Search Device**—Search for a device by device name, host name, or IP address.
- **Add**—Add devices and other manageable components.
- Columns—Click the column head to sort by that column.
  - **Name**
  - **Model**
  - **Version**
  - **Chassis**—For supported models, click **Manage** to bring up the integrated Chassis Manager. For the Firepower 4100/9300, the link cross-launches the Firewall Chassis Manager.
  - **Licenses**
  - **Access Control Policy**—Click on the link in the Access Control Policy column to view the policy that is deployed to the device.
  - **Auto-Rollback**—Shows whether auto-rollback of the configuration is enabled ( ) or disabled ( ) if the deployment causes the management connection to go down. See Edit Deployment Settings, on page 135.

- **Edit**—For each device, use the **Edit** ( ) icon to edit the device settings.

  You can also just click on the device name or IP address.

- **More**—For each device, click the **More** ( ) icon to execute other actions:
  - **Packet Tracer**—To navigate to the packet tracer page for examining policy configuration on the device by injecting a model packet into the system.
  - **Packet Capture**—To navigate to the packet capture page, where, you can view the verdicts and actions the system takes while processing a packet.
  - **Revert Upgrade**—To revert the upgrade and configuration changes that were made after the last upgrade. This action results in restoring the device to the version that was before the upgrade.
  - **Health Monitor**—To navigate to the device's health monitoring page.
  - **Troubleshoot Files**—Generate troubleshooting files, where you can choose the type of data to be included in the report.

Add a Device Group

The Firewall Management Center allows you to group devices so you can easily deploy policies and install updates on multiple devices. You can expand and collapse the list of devices in the group.

If you add the primary device in a high-availability pair to a group, both devices are added to the group. If you break the high-availability pair, both devices remain in that group.

Groups are not supported in a multidomain environment.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 From the **Add** drop-down menu, choose **Add Group**.

To edit an existing group, click **Edit** ( ) for the group you want to edit.

Step 3 Enter a **Name**.

Step 4 Under **Available Devices**, choose one or more devices to add to the device group. Use Ctrl or Shift while clicking to choose multiple devices.

Step 5 Click **Add** to include the devices you chose in the device group.

Step 6 Optionally, to remove a device from the device group, click **Delete** ( ) next to the device you want to remove.

Step 7 Click **OK** to add the device group.

Register With a New Management Center

This procedure shows how to register with a new Firewall Management Center. You should perform these steps even if the new Firewall Management Center uses the old Firewall Management Center's IP address.

Procedure

Step 1 On the old Firewall Management Center, if present, delete the managed device.

You cannot change the Firewall Management Center IP address if you have an active connection with the Firewall Management Center.

Step 2 Connect to the device CLI, for example using SSH.

Step 3 Configure the new Firewall Management Center.

configure manager add {*hostname* | *IPv4_address* | *IPv6_address* | **DONTRESOLVE** } *regkey* [*nat_id*] [*display_name*]

- {*hostname* | *IPv4_address* | *IPv6_address*}—Sets the Firewall Management Center hostname, IPv4 address, or IPv6 address.
- **DONTRESOLVE**—If the Firewall Management Center is not directly addressable, use **DONTRESOLVE** instead of a hostname or IP address. If you use **DONTRESOLVE** , then a *nat_id* is required. When you add this device to the Firewall Management Center, make sure that you specify both the device IP address and the *nat_id*; one side of the connection needs to specify an IP address, and both sides need to specify the same, unique NAT ID.
- *regkey*—Make up a registration key to be shared between the Firewall Management Center and the device during registration. You can choose any text string for this key between 1 and 37 characters; you will enter the same key on the Firewall Management Center when you add the Firewall Threat Defense.
- *nat_id*—Make up an alphanumeric string from 1 to 37 characters used only during the registration process between the Firewall Management Center and the device when one side does not specify an IP address. This NAT ID is a one-time password used only during registration. Make sure the NAT ID is unique, and not used by any other devices awaiting registration. Specify the same NAT ID on the Firewall Management Center when you add the Firewall Threat Defense.
- *display_name*—Provide a display name for showing this manager with the **show managers** command. This option is useful if you are identifying Security Cloud Control as the primary manager and an on-prem Firewall Management Center for analytics only. If you don't specify this argument, the firewall auto-generates a display name using one of the following methods:
  - *hostname* | *IP_address* (if you don't use the **DONTRESOLVE** keyword)
  - **manager-***timestamp*

Example:

```
> configure manager add DONTRESOLVE abc123 efg456
Manager successfully configured.
Please make note of reg_key as this will be required while adding Device in FMC.

>
```

Step 4 Add the device to the Firewall Management Center.

Shut Down or Restart the Device

It's important that you shut down your system properly. Simply unplugging the power or pressing the power switch can cause serious file system damage. Remember that there are many processes running in the background all the time, and unplugging or shutting off the power does not allow the graceful shutdown of your firewall.

See the following task to shut down or restart your system properly.

Note After restarting your device, you may see an error that the management connection could not be reestablished. In some cases, the connection is attempted before the Management interface on the device is ready. The connection will be retried automatically and should come up within 15 minutes.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device that you want to restart, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 To restart the device:

a) Click **Restart Device** ( ).
b) When prompted, confirm that you want to restart the device.

Step 5 To shut down the device:

a) Click **Shut Down Device** ( ) in the **System** section.
b) When prompted, confirm that you want to shut down the device.
c) If you have a console connection to the firewall, monitor the system prompts as the firewall shuts down. You will see the following prompt:

```
System is stopped.
It is safe to power off now.
Do you want to reboot instead? [y/N]
```

If you do not have a console connection, wait approximately 3 minutes to ensure the system has shut down.

For the ISA 3000, when shutdown is complete, the System LED will turn off. Wait at least 10 seconds before you remove the power.

Download the Managed Device List

You can download a report of all the managed devices.

Before you begin

To perform the following task, you must be an Admin user.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click the **Download Device List Report** link.

Step 3 You can download the device list in CSV or PDF format. Choose **Download CSV** or **Download PDF** to download the report.

Migrate Firewall Threat Defense Devices

The Secure Firewall Threat Defense model migration wizard enables you to migrate configurations from an earlier Firewall Threat Defense model. After the migration, all routing and interface configurations from the source Firewall Threat Defense device are available in the target Firewall Threat Defense.

The wizard supports multiple models as source and target devices, for more information see Supported Devices for Migration, on page 71.

Supported Devices for Migration

Supported Source Devices

- Cisco Firepower 1120
- Cisco Firepower 1140
- Cisco Firepower 1150
- Cisco Firepower 2110
- Cisco Firepower 2120
- Cisco Firepower 2130
- Cisco Firepower 2140

Supported Target Devices

- Cisco Secure Firewall 3105
- Cisco Secure Firewall 3110
- Cisco Secure Firewall 3120
- Cisco Secure Firewall 3130
- Cisco Secure Firewall 3140

Supported Migration Paths

The following table lists the supported target Firewall Threat Defense models that you can migrate to from your source Firewall Threat Defense model.

License for Migration

- Your Smart Licensing account must have the license entitlements for the target device.
- You must register and enroll the device with the Smart Licensing account. The migration copies the source device licenses to the target device.

Prerequisites for Migration

- **General device prerequisites**
  - Register the source and the target devices to the Firewall Management Center.
  - Ensure that the target device is a newly registered device without any configurations.
  - Source and target devices must be in the same state and modes:
    - Domain
    - Firewall mode: Routed or Transparent
    - Compliance mode (CC or UCAPL)
  - Ensure that you have permission for modifications on the devices.
  - Ensure that the configurations on the source device are valid and have no errors.
  - Deployment, import, or export tasks must not run on either of the devices during the migration. The source device can have pending deployments.
- **Prerequisites for HA devices**

What Configurations Does the Wizard Migrate?

The migration wizard copies the following configurations from the source device to the target device:

- Licenses
- Interface configurations
- Inline sets configurations
- Routing configurations
- DHCP and DDNS configurations
- Virtual router configurations
- Policies
- Associated objects and object overrides
- Platform settings

- Remote branch deployment configurations

The migration wizard copies the following policy configurations from the source device to the target device:

- Health policy
- NAT policy
- QoS policy
- Remote access VPN policy
- FlexConfig policy
- Access control policy
- Prefilter policy
- IPS policy
- DNS policy
- SSL policy
- Malware and File policy
- Identity policy

The migration wizard copies the following routing configurations from the source device to the target device:

- ECMP
- BFD
- OSPFv2/v3
- EIGRP
- RIP
- BGP
- Policy Based Routing
- Static Route
- Multicast Routing
- Virtual Router

The migration wizard copies the following interfaces from the source device to the target device:

- Physical interfaces
- Sub-interfaces
- EtherChannel interfaces
- Bridge group interfaces
- VTI interfaces

- VNI interfaces
- Loopback interfaces

The migration wizard retains the device group of the target device.

Limitations for Migration

Limitations

- The migration wizard does not migrate:
  - Site-to-site VPN policies
- You can perform only one migration at a time.
- Remote access VPN trustpoint certificates are not enrolled after migration.
- For HA devices:
  - Target device: You cannot migrate a standalone device to an HA device.

Best Practices for Threat Defense Device Migration

After a successful migration, we recommend that you perform the following actions before the deployment:

- IP addresses of the interfaces are copied to the target device from the source device. Change the IP addresses of the target device interfaces, if the source device is live
- Ensure that you update your NAT policies with the modified IP addresses.
- Configure the interface speeds if they are set to default values after migration.
- Re-enroll the device certificates, if any, on the target device.
- (Optional) Configure SNMP for Firepower 1100 and 2100 using the platform settings for the device.
- (Optional) Configure remote branch deployment configurations.

  If the source or target device had manager access through a data interface, after the migration, the manager access will be lost. Update the manager access configuration on the target device. For more information, see the *Change the Manager Access Interface from Management to Data* topic in the Cisco Secure Firewall Management Center Device Configuration Guide or the Online Help.
- Configure site-to-site VPN, if required. These configurations are not migrated from the source device.
- View the deployment preview before the deployment. From the **Deploy** drop-down menu, click **Advanced Deploy**, and then click the **Preview** ( ) icon for the device.
- Monitor the health of the device in the health monitor (choose **System** ( ) > **Health** > **Monitor**). After migration, the health policy of the source device becomes the health policy of the target device. You can also configure a new health policy for the device.

  After migration, the device monitoring dashboard may temporarily display redundant colored lines because the device has different UUIDs before and after migration. This redundancy appears only during the migration time. An hour after migration, the dashboard will show a single line per metric.

Hot Swap an SSD on the Secure Firewall 3100 Series

If you have two SSDs, they form a RAID when you boot up. You can perform the following tasks at the Firewall Threat Defense CLI while the firewall is powered up:

- Hot swap one of the SSDs—If an SSD is faulty, you can replace it. Note that if you only have one SSD, you cannot remove it while the firewall is powered on.
- Remove one of the SSDs—If you have two SSDs, you can remove one.
- Add a second SSD—If you have one SSD, you can add a second SSD and form a RAID.

Caution Do not remove an SSD without first removing it from the RAID using this procedure. You can cause data loss.

Procedure

Step 1 Remove one of the SSDs.

a) Remove the SSD from the RAID.

configure raid remove-secure local-disk {**1** | **2**}

The **remove-secure** keyword removes the SSD from the RAID, disables the self-encrypting disk feature, and performs a secure erase of the SSD. If you only want to remove the SSD from the RAID and want to keep the data intact, you can use the **remove** keyword.

Example:

```
> configure raid remove-secure local-disk 2
```

b) Monitor the RAID status until the SSD no longer shows in the inventory.

show raid

After the SSD is removed from the RAID, the **Operability** and **Drive State** will show as **degraded**. The second drive will no longer be listed as a member disk.

Example:

```
> show raid
Virtual Drive
ID:                         1
Size (MB):                  858306
Operability:                operable
Presence:                   equipped
Lifecycle:                  available
Drive State:                optimal
Type:                       raid
Level:                      raid1
Max Disks:                  2
Meta Version:               1.0
```

```
Array State:                active
Sync Action:                idle
Sync Completed:             unknown
Degraded:                   0
Sync Speed:                 none

RAID member Disk:
Device Name:                nvme0n1
Disk State:                 in-sync
Disk Slot:                  1
Read Errors:                0
Recovery Start:             none
Bad Blocks:
Unacknowledged Bad Blocks:

Device Name:                nvme1n1
Disk State:                 in-sync
Disk Slot:                  2
Read Errors:                0
Recovery Start:             none
Bad Blocks:
Unacknowledged Bad Blocks:

> show raid
Virtual Drive
ID:                         1
Size (MB):                  858306
Operability:                degraded
Presence:                   equipped
Lifecycle:                  available
Drive State:                degraded
Type:                       raid
Level:                      raid1
Max Disks:                  2
Meta Version:               1.0
Array State:                active
Sync Action:                idle
Sync Completed:             unknown
Degraded:                   1
Sync Speed:                 none

RAID member Disk:

Unacknowledged Bad Blocks:
```

c) Physically remove the SSD from the chassis.

Step 2 Add an SSD.

a) Physically add the SSD to the empty slot.

b) Add the SSD to the RAID.

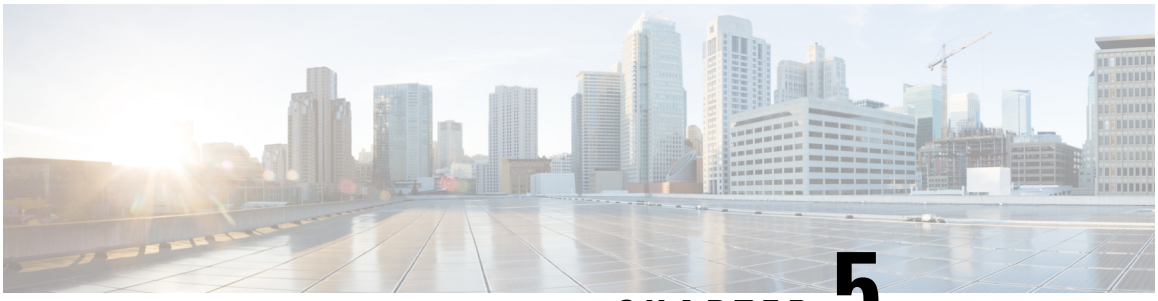
configure raid add local-disk {**1** | **2**}

It can take several hours to complete syncing the new SSD to the RAID, during which the firewall is completely operational. You can even reboot, and the sync will continue after it powers up. Use the **show raid** command to show the status.

If you install an SSD that was previously used on another system, and is still locked, enter the following command:

configure raid add local-disk {**1** | **2**} *psid*

The *psid* is printed on the label attached to the back of the SSD. Alternatively, you can reboot the system, and the SSD will be reformatted and added to the RAID.



CHAPTER 5

Device Settings

After you add a device, you can edit device-related settings on the **Device** page.

1. Choose **Devices** > **Device Management**.
2. Next to the device you want to modify, click **Edit** ( ).
3. Click **Device**.

- Edit General Settings, on page 79
- Edit License Settings, on page 86
- View System Information, on page 87
- View the Inspection Engine, on page 88
- Edit Health Settings, on page 88
- Edit Management Settings, on page 89
- View Inventory Details, on page 129
- Edit Applied Policies, on page 130
- Edit Advanced Settings, on page 131
- Edit Deployment Settings, on page 135
- Edit Cluster Health Monitor Settings, on page 138
- History for Device Settings, on page 143

Edit General Settings

The **General** section of the **Device** page displays the settings described in the table below.

Figure 4: General

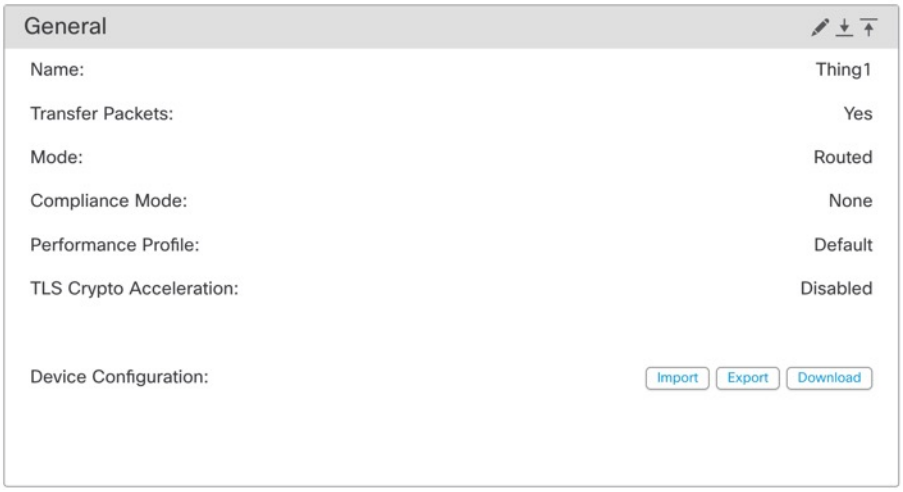


Table 2: General Section Table Fields

Field	Description
Name	The display name of the device on the Firewall Management Center.
Transfer Packets	This displays whether or not the managed device sends packet data with the events to the Firewall Management Center.
Mode	The displays the mode of the management interface for the device: **routed** or **transparent**.
Compliance Mode	This displays the security certifications compliance for a device. Valid values are CC, UCAPL and None.
Performance Profile	This displays the core allocation performance profile for the device, as configured in the platform settings policy.
TLS Crypto Acceleration:	Shows whether TLS crypto acceleration is enabled or disabled.
Device Configuration	Lets you copy, export, or import a configuration. See Copy a Configuration to Another Device, on page 81 and Export and Import the Device Configuration, on page 82.
OnBoarding Method	Shows whether the device was registered using a registration key or using the serial number (zero-touch provisioning).

You can edit some of these settings from this section.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device you want to modify, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **General** section, click **Edit** ( ).

a) Enter a **Name** for the managed device.

b) Check **Transfer Packets** to allow packet data to be stored with events on the Firewall Management Center.

c) Click **Force Deploy** to force deployment of current policies and device configuration to the device.

Note
Force-deploy consumes more time than the regular deployment since it involves the complete generation of the policy rules to be deployed on the Firewall Threat Defense.

Step 5 For **Device Configuration** actions, see Copy a Configuration to Another Device, on page 81 and Export and Import the Device Configuration, on page 82.

Step 6 Click **Deploy**.

What to do next

- Deploy configuration changes.

Copy a Configuration to Another Device

When a new device is deployed in the network you can easily copy configurations and policies from a pre-configured device, instead of manually reconfiguring the new device.

Before you begin

Confirm that:

- The source and destination devices are the same model and are running the same version of the software.
- The source is either a standalone device or a high availability pair.
- The destination device is a standalone device.
- The source and destination devices have the same number of physical interfaces.
- The source and destination devices are in the same firewall mode: routed or transparent.
- The source and destination devices are in the same security-certifications-compliance mode.
- The source and destination devices are in the same domain.
- Configuration deployment is not in progress on either the source or the destination devices.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device you want to modify, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **General** section, do one of the following:

- Click **Get Device Configuration** ( ) to copy device configuration from another device to the new device. On the **Get Device Configuration** page, select the source device in the **Select Device** drop-down list.
- Click **Push Device Configuration** ( ) to copy device configuration from the current device to the new device. On the **Push Device Configuration** page, select the destination to which configuration is to be copied in the **Target Device** drop-down list.

Step 5 (Optional) Check **Include shared policies configuration** check box to copy policies.

Shared policies like AC policy, NAT, Platform Settings and FlexConfig policies can be shared across multiple devices.

Step 6 Click **OK**.

You can monitor the status of the copy device configuration task on **Tasks** in the Message Center.

When the copy device configuration task is initiated, it erases the configuration on the target device and copies the configuration of the source device to the destination device.

Warning When you have completed the copy device configuration task, you cannot revert the target device to its original configuration.

Export and Import the Device Configuration

You can export all of the the device-specific configuration configurable on the Device pages, including:

- Interfaces
- Inline Sets
- Routing
- DHCP
- VTEP
- Associated objects

You can then import the saved configuration for the same device in the following use cases:

- Moving the device to a different Firewall Management Center—First unregister the device from the original Firewall Management Center, then add the device to the new Firewall Management Center. Then you can import the saved configuration.
- Restore an old configuration—If you deployed changes that negatively impacted the operation of the device, you can import a backup copy of a known working configuration to restore a previous operational state.

- Reregistering a device—If you delete a device from the Firewall Management Center, but then want to add it back, you can import the saved configuration.

See the following guidelines:

- You can only import the configuration to the same device (the UUID must match). You cannot import a configuration to a different device, even if it is the same model.
- Do not change the version running on the device between exporting and importing; the version must match.
- If you make inventory changes after your export (such as adding or deleting network modules or configuring or joining breakout ports), the device inventory will not match the Firewall Management Center. In this case, the device inventory will be maintained, and you will be prompted to sync the interfaces (see Sync Interface Changes with the Firewall Management Center, on page 883) and discard incompatible configuration in the Firewall Management Center when you try to deploy. You will have to repeat the inventory changes and related configuration in the Firewall Management Center.
- If you export a standalone configuration, you cannot import it to a high availability pair or vice versa.
- If an object doesn't exist, it will be created. If an object exists, but the value is different, see below:

Table 3: Object Import Action

Scenario	Import Action
Object exists with the same name and value.	Reuse existing objects.
Object exists with the same name but different value.	Network and Port objects: Create object overrides for this device. See Object Overrides, on page 1434. Interface objects: Create new objects. For example, if both the type (security zone or interface group) and the interface type (routed or switched, for example) do not match, then a new object is created. All other objects: Reuse existing objects even though the values are different.
Object doesn't exist.	Create new objects.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device you want to edit, click **Edit** ( ).

Step 3 Click **Device**.

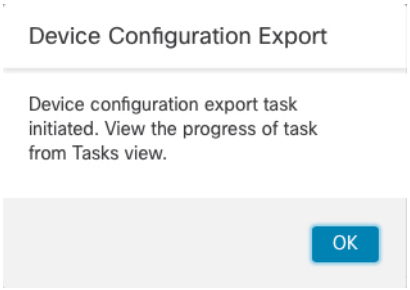
Step 4 Export the configuration.

a) In the **General** area, click **Export**.

Figure 5: Export Device Configuration

You are prompted to acknowledge the export; click **OK**.

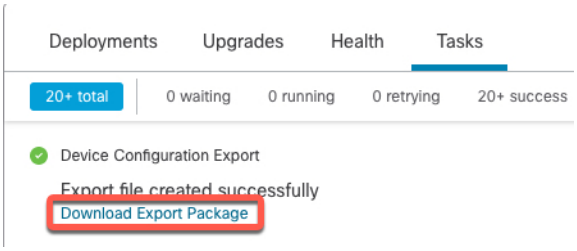
Figure 6: Acknowledge Export



You can view the export progress in the **Tasks** page.

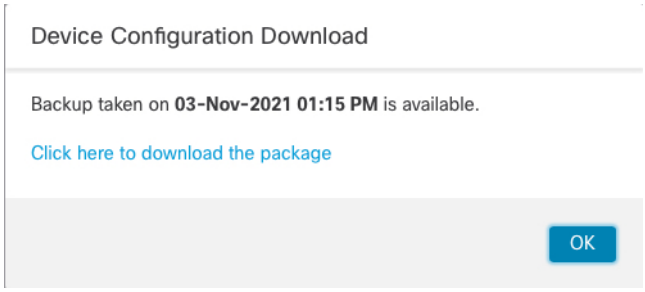
b) Click **Notifications**, and then click the **Tasks** tab. Verify if the export has completed, and then click **Download Export Package**. Alternatively, you can click the **Download** button in the **General** area.

Figure 7: Export Task



You are prompted to download the package; click **Click here to download the package** to save the file locally, and then click **OK** to exit the dialog box.

Figure 8: Download Package



Step 5 Import the configuration.

a) In the **General** area, click **Import**.

Figure 9: Import Device Configuration

You are prompted to acknowledge that the current configuration will be replaced. Click **Yes** and then navigate to the configuration package (with the suffix .sfo; note that this file is different from the Backup/Restore files).

Figure 10: Import Package

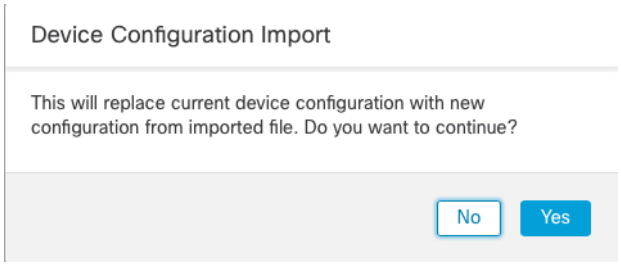


Figure 11: Navigate to Package

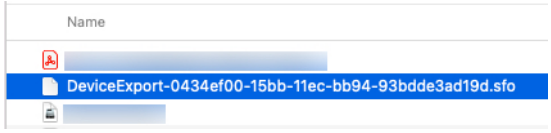
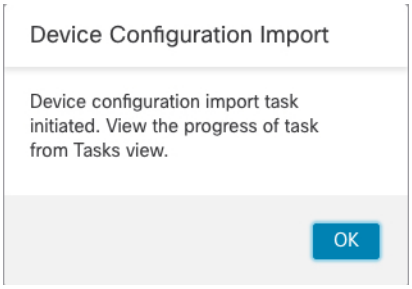


You are prompted to acknowledge the import; click **OK**.

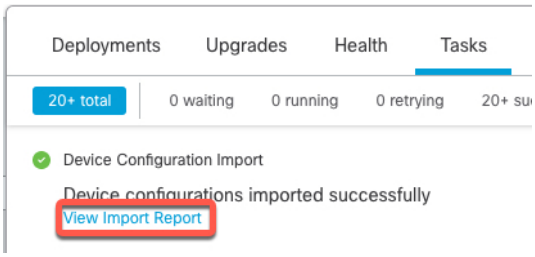
Figure 12: Acknowledge Import



You can view the import progress in the **Tasks** page.

b) To view the import reports so that you can see what was imported, click **Notifications**, and then click the **Tasks** tab. Click **View Import Report**.

Figure 13: View Import Report



The **Device Configuration Import Reports** page provides links to available reports.

Cisco Firepower Management Center

Device Configuration Import Reports

Device	Shared Policies	Device Configurations
0434ef00-15bb-11ec-bb94-93bdde3ad19d	Report does not exist	Device configurations import report

c) Deploy configuration changes.

Edit License Settings

The **License** section of the **Device** page displays the licenses enabled for the device.

You can enable licenses on your device if you have available licenses on your Firewall Management Center.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to enable or disable licenses, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **License** section, click **Edit** ( ).

Step 5 Check or clear the check box next to the license you want to enable or disable for the managed device.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes.

View System Information

The **System** section of the **Device** page displays a read-only table containing system information, as described in the following table.

You can also shut down or restart the device from this pane, using the icons at the top-right corner.

Figure 14: System

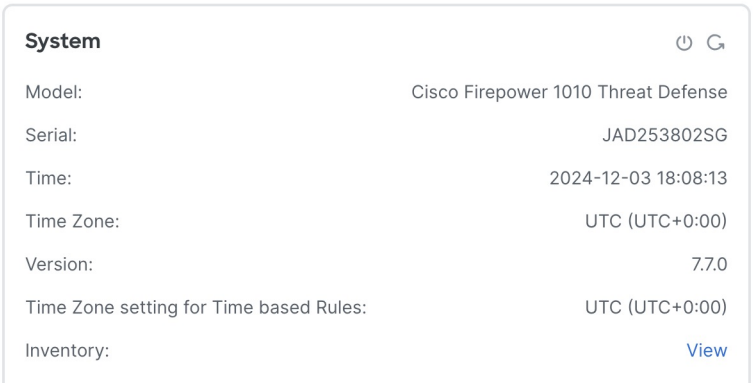


Table 4: System Section Table Fields

Field	Description
Shut Down Device ( )	Shuts down the device. See Shut Down or Restart the Device, on page 70.
Restart Device ( )	Restarts the device. See Shut Down or Restart the Device, on page 70.
Model	Model name and number of the managed device.
Serial	Serial number of the managed device's chassis.
Time	Current system time of the device.
Time Zone	Time zone.

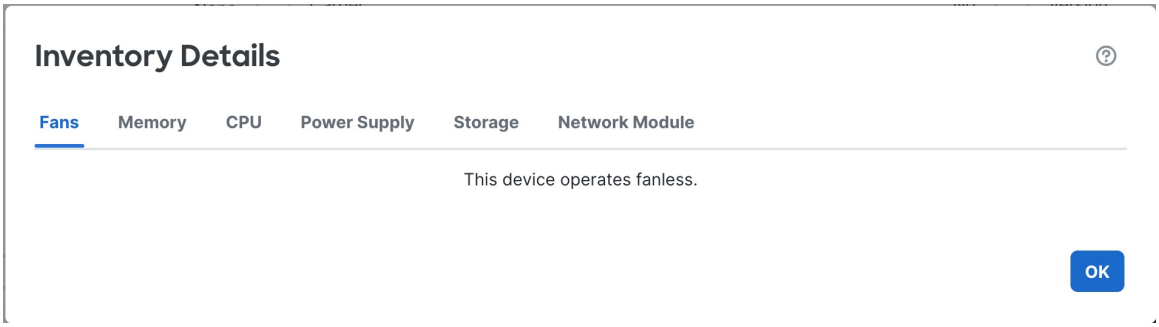
Field	Description
Version	Version of the software currently installed on the managed device.
Time Zone setting for Time based rules	Current system time of the device in the time zone specified in device platform settings.
Inventory	Inventory details. See View Device Inventory.

View Device Inventory

Click **View** next to **Inventory** in the **System** section to view a table of device inventory information including Fans, Memory, CPU, Power Supply, Storage, and Network Modules.

The **Inventory Details** table displays information about all the Cisco products installed in the Firewall Threat Defense devices assigned with a product identifier (PID). The PID is the product name using which the product can be ordered.

Figure 15: Inventory Details



View the Inspection Engine

The Inspection Engine section of the **Device** page shows whether your device uses Snort 2 or Snort 3. To switch the inspection engine, see *Enable Snort 3 on an Individual Device* in the Cisco Secure Firewall Management Center Snort 3 Configuration Guide .

Edit Health Settings

The **Health** section of the **Device** page displays the information described in the table below.

Table 5: Health Section Table Fields

Field	Description
Status	An icon that represents the current health status of the device. Clicking the icon displays the Health Monitor for the appliance.

Field	Description
Policy	A link to a read-only version of the health policy currently deployed at the device.
Excluded	A link to the **Health Exclude** page, where you can enable and disable health exclusion modules.

Edit Management Settings

These settings control how the Firewall Management Center establishes the management connection with the device.

Configure a Redundant Manager Access Data Interface

When you use a data interface for manager access, you can configure a secondary data interface to take over management functions if the primary interface goes down. You can configure only one secondary interface. The device uses SLA monitoring to track the viability of the static routes and an ECMP zone that contains both interfaces so management traffic can use both interfaces.

High availability is not supported.

Before you begin

- The secondary interface needs to be in a separate security zone from the primary interface.
- All of the same requirements apply to the secondary interface as apply to the primary interface. See Using the Firewall Threat Defense Data Interface for Management.

Procedure

Step 1 On the **Devices** > **Device Management** page, click **Edit** (✎) for the device.

Step 2 Enable manager access for the secondary interface.

This setting is in addition to standard interface settings such as enabling the interface, setting the name, setting the security zone, and setting a static IPv4 address.

a) Choose **Interfaces** > **Edit Physical Interface** > **Manager Access**.
b) Check **Enable management on this interface for the Manager**.
c) Click **OK**.

Both interfaces show **(Manager Access)** in the interface listing.

Figure 16: Interface Listing

Interface	Logical Name	Type	Security Zones
Diagnostic1/1	diagnostic	Physical	
Ethernet1/1 (Manager Access)	outside	Physical	outside
Ethernet1/2		Physical	
Ethernet1/3		Physical	
Ethernet1/4		Physical	
Ethernet1/5		Physical	
Ethernet1/6		Physical	
Ethernet1/7		Physical	
Ethernet1/8 (Manager Access)	redundant	Physical	mgmt

Step 3 Add the secondary address to the **Management** settings.

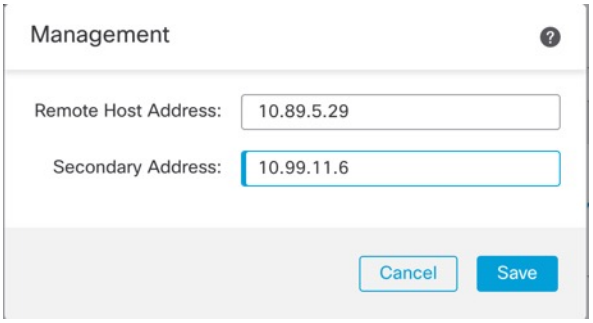
a) Click **Device**, and view the **Management** area.

b) Click **Edit** ( ).

Figure 17: Edit Management Address

c) In the **Management** dialog box, modify the name or IP address in the **Secondary Address** field

Figure 18: Management IP Address

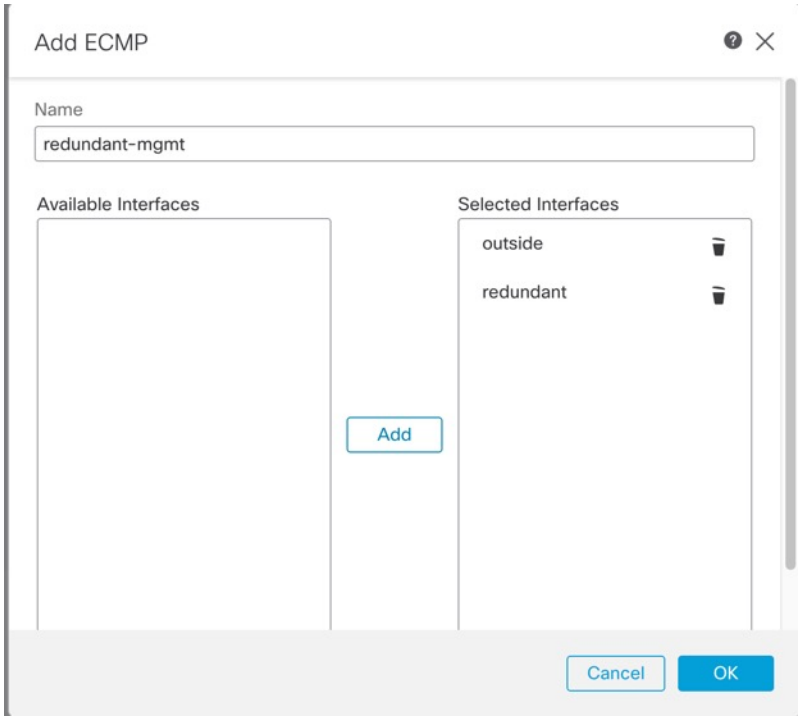


d) Click **Save**.

Step 4 Create an ECMP zone with both interfaces.

a) Click **Routing**.
b) From the virtual router drop-down, choose the virtual router in which the primary and secondary interfaces reside.
c) Click **ECMP**, and then click **Add**.
d) Enter a **Name** for the ECMP zone.
e) Select the primary and secondary interfaces under the **Available Interfaces** box, and then click **Add**.

Figure 19: Add an ECMP Zone

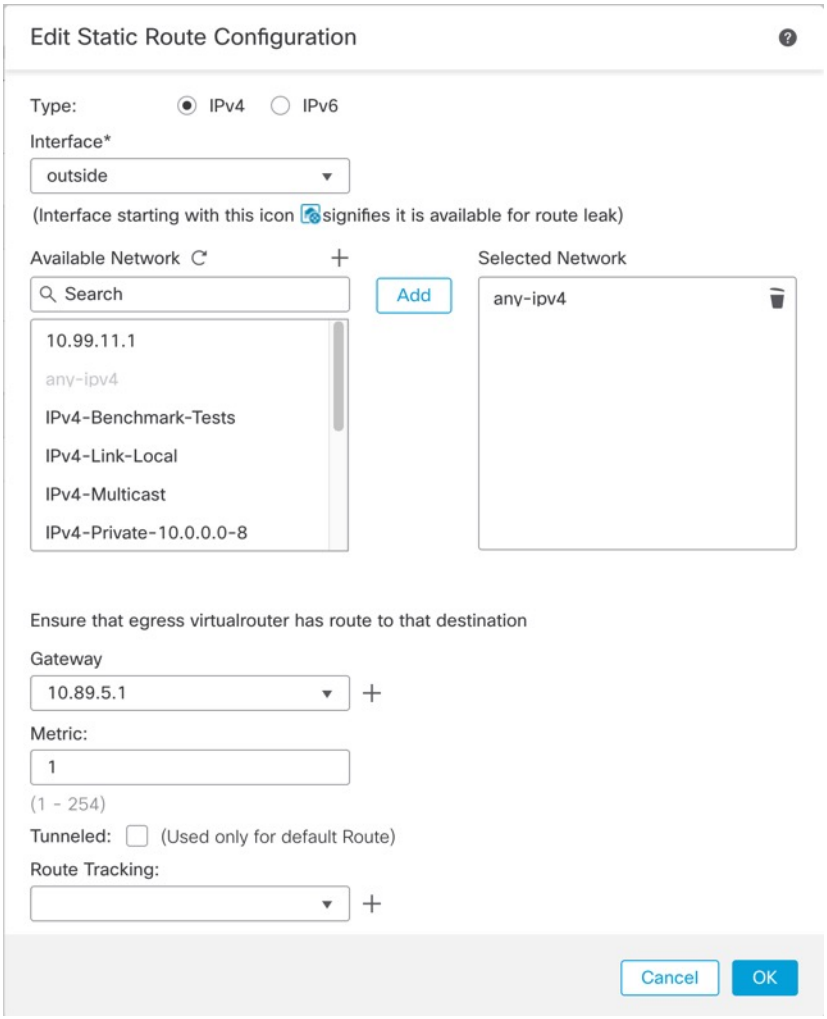


f) Click **OK**, and then **Save**.

Step 5 Add equal-cost default static routes for both interfaces and enable SLA tracking on both.

The routes should be identical except for the gateway and should both have metric 1. The primary interface should already have a default route that you can edit.

Figure 20: Add/Edit Static Route



a) Click **Static Route**.

b) Either click **Add Route** to add a new route, or click **Edit** (✎) for an existing route.

c) From the **Interface** drop-down, choose the interface.

d) For the destination network, select **any-ipv4** from the **Available Networks** box and click **Add**.

e) Enter the default **Gateway**.

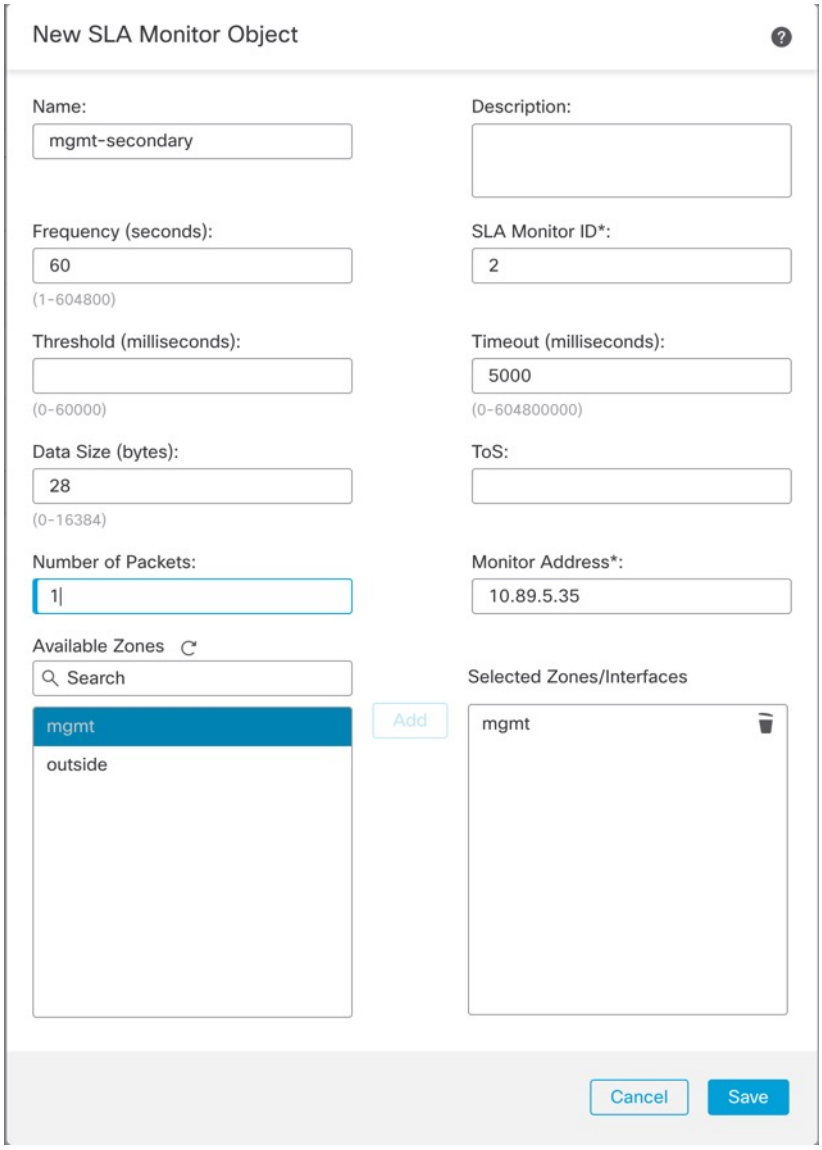
f) For **Route Tracking**, click **Add** (+) to add a new SLA monitor object.

g) Enter the required parameters including the following:

- The **Monitor Address** as the Firewall Management Center IP address.
- The zone for the primary or secondary management interface in **Available Zones**; for example, choose the outside zone for the primary interface object, and the mgmt zone for the secondary interface object.

See SLA Monitor, on page 1511 for more information.

Figure 21: Add SLA Monitor



h) Click **Save**, then choose the SLA object you just created in the **Route Tracking** drop-down list.
i) Click **OK**, and then **Save**.
j) Repeat for the default route for the other management interface.

Step 6 Deploy configuration changes.

As part of the deployment for this feature, the Firewall Management Center enables the secondary interface for management traffic, including auto-generated policy-based routing configuration for management traffic to get to the right data interface. The Firewall Management Center also deploys a second instance of the **configure network management-data-interface** command. Note that if you edit the secondary interface at the CLI, you cannot configure the gateway or otherwise alter the default route, because the static route for this interface can only be edited in the Firewall Management Center.

Change Manager Access Interface Settings

Changing any manager interface settings on the device or on the Firewall Management Center can disrupt the management connection. See the following scenarios to change interface settings and reestablish the management connection.

Change the Device IP Address

Change the device IP address, and then update the address in the Firewall Management Center.

Set the Device IP Address

Use one of the following methods to set the manager access interface IP address.

Modify Firewall Threat Defense Management Interfaces at the CLI

Modify the management interface settings on the managed device using the CLI. Many of these settings are ones that you set when you performed the initial setup; this procedure lets you change those settings, and set additional settings such as enabling an event interface if your model supports it, or adding static routes.

Note This topic applies to the dedicated Management interface. You can alternatively configure a data interface for management. If you want to change network settings for that interface, you should do so within Firewall Management Center and not at the CLI. If you need to troubleshoot a disrupted management connection, and need to make changes directly on the Firewall Threat Defense, see Modify the Firewall Threat Defense Data Interface Used for Management at the CLI, on page 100.

For information about the Firewall Threat Defense CLI, see the Cisco Secure Firewall Threat Defense Command Reference.

Note When using SSH, be careful when making changes to the management interface; if you cannot re-connect because of a configuration error, you will need to access the device console port.

Note If you change the device management IP address, then see the following tasks for Firewall Management Center connectivity depending on how you identified the Firewall Management Center during initial device setup using the **configure manager add** command:

- **IP address—No action.** If you identified the Firewall Management Center using a reachable IP address, then the management connection will be reestablished automatically after several minutes. We recommend that you also change the device IP address shown in Firewall Management Center to keep the information in sync; see Update the Hostname or IP Address in the Firewall Management Center, on page 104. This action can help the connection reestablish faster. **Note**: If you specified an unreachable Firewall Management Center IP address, then see the procedure for NAT ID below.
- **NAT ID only—Manually reestablish the connection.** If you identified the Firewall Management Center using only the NAT ID, then the connection cannot be automatically reestablished. In this case, change the device management IP address in Firewall Management Center according to Update the Hostname or IP Address in the Firewall Management Center, on page 104.

Note In a High Availability Firewall Management Center configuration, when you modify the management IP address from the device CLI or from the Firewall Management Center, the secondary Firewall Management Center does not reflect the changes even after an HA synchronization. To ensure that the secondary Firewall Management Center is also updated, switch roles between the two Firewall Management Centers, making the secondary Firewall Management Center the active unit. Modify the management IP address of the registered device on the device management page of the now active Firewall Management Center.

Before you begin

- You can create user accounts that can log into the CLI using the **configure user add** command; see Add an Internal User at the CLI, on page 159. You can also configure AAA users according to External Authentication, on page 1040.

Procedure

Step 1 Connect to the device CLI, either from the console port or using SSH.

Step 2 Log in with the Admin username and password.

Step 3 (Firepower 4100/9300 only) Enable the second management interface as an event-only interface.

configure network management-interface enable management1

configure network management-interface disable-management-channel management1

You always need a management interface for management traffic. If your device has a second management interface, you can enable it for event-only traffic.

You can optionally disable events for the main management interface using the **configure network management-interface disable-events-channel** command. In either case, the device will try to send events on the event-only interface, and if that interface is down, it will send events on the management interface even if you disable the event channel.

You cannot disable both event and management channels on an interface.

To use a separate event interface, you also need to enable an event interface on the Firewall Management Center. See the Cisco Secure Firewall Management Center Administration Guide.

Example:

```
> configure network management-interface enable management1
Configuration updated successfully

> configure network management-interface disable-management-channel management1
Configuration updated successfully

>
```

Step 4 Configure the IP address of the management interface and/or event interface:

If you do not specify the *management_interface* argument, then you change the network settings for the default management interface. When configuring an event interface, be sure to specify the *management_interface*

argument. The event interface can be on a separate network from the management interface, or on the same network. If you are connected to the interface you are configuring, you will be disconnected. You can re-connect to the new IP address.

a) Configure the IPv4 address:

- Manual configuration:

  configure network ipv4 manual *ip_address netmask gateway_ip* [*management_interface*]

  Note that the *gateway_ip* in this command is used to create the default route for the device. If you configure an event-only interface, then you must enter the *gateway_ip* as part of the command; however, this entry just configures the default route to the value you specify and does not create a separate static route for the eventing interface. If you are using an event-only interface on a different network from the management interface, we recommend that you set the *gateway_ip* for use with the management interface, and then create a static route separately for the event-only interface using the **configure network static-routes** command.

  Example:

```
> configure network ipv4 manual 10.10.10.45 255.255.255.0 10.10.10.1 management1
Setting IPv4 network configuration.
Network settings changed.

>
```

- DHCP (supported on the default management interface only):

  configure network ipv4 dhcp

b) Configure the IPv6 address:

- Stateless autoconfiguration:

  configure network ipv6 router [*management_interface*]

  Example:

```
> configure network ipv6 router management0
Setting IPv6 network configuration.
Network settings changed.

>
```

- Manual configuration:

  configure network ipv6 manual *ip6_address ip6_prefix_length* [*ip6_gateway_ip*] [*management_interface*]

  Note that the *ipv6_gateway_ip* in this command is used to create the default route for the device. If you configure an event-only interface, then you must enter the *ipv6_gateway_ip* as part of the command; however, this entry just configures the default route to the value you specify and does not create a separate static route for the eventing interface. If you are using an event-only interface on a different network from the management interface, we recommend that you set the *ipv6_gateway_ip* for use with the management interface, and then create a static route separately for the event-only interface using the **configure network static-routes** command.

  Example:

```
> configure network ipv6 manual 2001:0DB8:BA98::3210 64 management1
Setting IPv6 network configuration.
Network settings changed.

>
```

- DHCPv6 (supported on the default management interface only):

  configure network ipv6 dhcp

Step 5 For IPv6, enable or disable ICMPv6 Echo Replies and Destination Unreachable messages. These messages are enabled by default.

configure network ipv6 destination-unreachable {**enable** | **disable**}

configure network ipv6 echo-reply {**enable** | **disable**}

You might want to disable these packets to guard against potential denial of service attacks. Disabling Echo Reply packets means you cannot use IPv6 ping to the device management interfaces for testing purposes.

Example:

```
> configure network ipv6 destination-unreachable disable
> configure network ipv6 echo-reply disable
```

Step 6 Enable a DHCP server on the default management interface to provide IP addresses to connected hosts:

configure network ipv4 dhcp-server-enable *start_ip_address end_ip_address*

Example:

```
> configure network ipv4 dhcp-server-enable 10.10.10.200 10.10.10.254
DHCP Server Enabled

>
```

You can only configure a DHCP server when you set the management interface IP address manually. This command is not supported on the Firewall Management Center Virtual. To display the status of the DHCP server, enter **show network-dhcp-server**:

```
> show network-dhcp-server
DHCP Server Enabled
10.10.10.200-10.10.10.254
```

Step 7 Add a static route for the event-only interface if the Firewall Management Center is on a remote network; otherwise, all traffic will match the default route through the management interface.

configure network static-routes {**ipv4** | **ipv6**} **add** *management_interface destination_ip netmask_or_prefix gateway_ip*

For the *default* route, do not use this command; you can only change the default route gateway IP address when you use the **configure network ipv4** or **ipv6** commands (see Step 4, on page 95).

Example:

```
> configure network static-routes ipv4 add management1 192.168.6.0 255.255.255.0 10.10.10.1
Configuration updated successfully

> configure network static-routes ipv6 add management1 2001:0DB8:AA89::5110 64
2001:0DB8:BA98::3211
Configuration updated successfully

>
```

To display static routes, enter **show network-static-routes** (the default route is not shown):

```
> show network-static-routes
---------------[ IPv4 Static Routes ]---------------
Interface                : management1
Destination              : 192.168.6.0
Gateway                  : 10.10.10.1
Netmask                  : 255.255.255.0
[…]
```

Step 8 Set the hostname:

configure network hostname *name*

Example:

```
> configure network hostname farscape1.cisco.com
```

Syslog messages do not reflect a new hostname until after a reboot.

Step 9 Set the search domains:

configure network dns searchdomains *domain_list*

Example:

```
> configure network dns searchdomains example.com,cisco.com
```

Set the search domain(s) for the device, separated by commas. These domains are added to hostnames when you do not specify a fully-qualified domain name in a command, for example, **ping system**. The domains are used only on the management interface, or for commands that go through the management interface.

Step 10 Set up to 3 DNS servers, separated by commas:

configure network dns servers *dns_ip_list*

Example:

```
> configure network dns servers 10.10.6.5,10.20.89.2,10.80.54.3
```

Step 11 Set the remote management port for communication with the Firewall Management Center:

configure network management-interface tcpport *number*

Example:

```
> configure network management-interface tcpport 8555
```

The Firewall Management Center and managed devices communicate using a two-way, TLS-1.3-encrypted communication channel, which by default is on port 8305. Do not change the management port when using multi-instance mode; only port 8305 is supported.

Note
Cisco **strongly** recommends that you keep the default settings for the remote management port, but if the management port conflicts with other communications on your network, you can choose a different port. If you change the management port, you must change it for **all** devices in your deployment that need to communicate with each other.

Step 12 (Firewall Threat Defense only) Set the management or eventing interface MTU. The MTU is 1500 bytes by default.

configure network mtu [*bytes*] [*interface_id*]

- *bytes*—Sets the MTU in bytes. For the management interface, the value can be between 64 and 1500 if you enable IPv4, and 1280 to 1500 if you enable IPv6. For the eventing interface, the value can be between 64 and 9000 if you enable IPv4, and 1280 to 9000 if you enable IPv6. If you enable both IPv4 and IPv6, then the minimum is 1280. If you do not enter the *bytes*, you are prompted for a value.
- *interface_id*—Specifies the interface ID on which to set the MTU. Use the **show network** command to see available interface IDs, for example management0, management1, br1, and eth0, depending on the platform. If you do not specify an interface, then the management interface is used.

Example:

```
> configure network mtu 8192 management1
MTU set successfully to 1500 from 8192 for management1
Refreshing Network Config...
NetworkSettings::refreshNetworkConfig MTU value at start 8192

Interface management1 speed is set to '10000baseT/Full'
NetworkSettings::refreshNetworkConfig MTU value at end 8192
>
```

Step 13 Configure an HTTP proxy. The device is configured to directly-connect to the internet on ports TCP/443 (HTTPS) and TCP/80 (HTTP). You can use a proxy server, to which you can authenticate via HTTP Digest. After issuing the command, you are prompted for the HTTP proxy address and port, whether proxy authentication is required, and if it is required, the proxy username, proxy password, and confirmation of the proxy password.

Note
For proxy password on Firewall Threat Defense, you can use A-Z, a-z, and 0-9 characters only.

configure network http-proxy

Example:

```
> configure network http-proxy
Manual proxy configuration
Enter HTTP Proxy address: 10.100.10.10
Enter HTTP Proxy Port: 80
Use Proxy Authentication? (y/n) [n]: Y
Enter Proxy Username: proxyuser
```

```
Enter Proxy Password: proxypassword
Confirm Proxy Password: proxypassword
```

Step 14 If you change the device management IP address, then see the following tasks for Firewall Management Center connectivity depending on how you identified the Firewall Management Center during initial device setup using the **configure manager add** command:

- **IP address—No action.** If you identified the Firewall Management Center using a reachable IP address, then the management connection will be reestablished automatically after several minutes. We recommend that you also change the device IP address shown in Firewall Management Center to keep the information in sync; see Update the Hostname or IP Address in the Firewall Management Center, on page 104. This action can help the connection reestablish faster. **Note**: If you specified an unreachable Firewall Management Center IP address, then you must manually reestablish the connection using Update the Hostname or IP Address in the Firewall Management Center, on page 104.
- **NAT ID only—Manually reestablish the connection.** If you identified the Firewall Management Center using only the NAT ID, then the connection cannot be automatically reestablished. In this case, change the device management IP address in Firewall Management Center according to Update the Hostname or IP Address in the Firewall Management Center, on page 104.

Modify the Firewall Threat Defense Data Interface Used for Management at the CLI

If the management connection between the Firewall Threat Defense and the Firewall Management Center was disrupted, and you want to specify a new data interface to replace the old interface, use the Firewall Threat Defense CLI to configure the new interface.

If the management connection is active, then you should make any changes to an existing data interface using the Firewall Management Center (see Modify the Firewall Threat Defense Data Interface Used for Management in the GUI, on page 103). For initial setup of the data management interface, see the **configure network management-data-interface** command.

For high-availability pairs, perform all CLI steps on both units. Within the Firewall Management Center, perform steps only on the active unit. Once the configuration changes are deployed, the standby unit synchronizes configuration and other state information from the active unit.

Note This topic applies to the data interface that you configured for Management, not the dedicated Management interface. If you want to change network settings for the Management interface, see Modify Firewall Threat Defense Management Interfaces at the CLI, on page 94.

For information about the Firewall Threat Defense CLI, see the Cisco Secure Firewall Threat Defense Command Reference.

Procedure

Step 1 If you are changing the data management interface to a new interface, move the current interface cable to the new interface.

Step 2 Connect to the device CLI.

You should use the console port when using these commands. If you are performing initial setup, then you may be disconnected from the Management interface. If you are editing the configuration due to a disrupted management connection, and you have SSH access to the dedicated Management interface, then you can use that SSH connection.

Step 3 Log in with the **admin** username and password.

Step 4 Disable the interface so you can reconfigure its settings.

configure network management-data-interface disable

Note
If you only want to set a new IPv4 address on the same interface and not make any other changes, you can skip this step. Other changes require you to disable the interface first.

Example:

```
> configure network management-data-interface disable

 Configuration updated successfully..!!

Configuration disable was successful, please update the default route to point to a gateway
 on management interface using the command 'configure network'
```

Step 5 Configure the new data interface for manager access.

configure network management-data-interface

You are then prompted to configure basic network settings for the data interface.

If you change the data management interface to a new interface on the same network, use the same settings as for the previous interface except the interface ID. In addition, for the **Do you wish to clear all the device configuration before applying ? (y/n) [n]:** option, choose **y**. This choice will clear the old data management interface configuration, so that you can successfully reuse the IP address and interface name on the new interface.

```
> configure network management-data-interface
Data interface to use for management: ethernet1/4
Specify a name for the interface [outside]: internet
IP address (manual / dhcp) [dhcp]: manual
IPv4/IPv6 address: 10.10.6.7
Netmask/IPv6 Prefix: 255.255.255.0
Default Gateway: 10.10.6.1
Comma-separated list of DNS servers [none]: 208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]: y

Configuration done with option to allow manager access from any network, if you wish to
change the manager access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.

>
```

Step 6 (Optional) Limit data interface access to the Firewall Management Center on a specific network.

configure network management-data-interface client *ip_address netmask*

By default, all networks are allowed.

Step 7 Update the Hostname or IP Address in the Firewall Management Center, on page 104.

The connection may be reestablished automatically, but disabling and reenabling the connection in the Firewall Management Center will help the connection reestablish faster. Or you may need to update the device IP address in the Firewall Management Center according to the linked procedure.

Step 8 Check that the management connection was reestablished.

sftunnel-status-brief

See the following sample output for a connection that is up, with peer channel and heartbeat information shown:

```
> sftunnel-status-brief
PEER:10.10.17.202
Peer channel Channel-A is valid type (CONTROL), using 'eth0', connected to '10.10.17.202'
via '10.10.17.222'
Peer channel Channel-B is valid type (EVENT), using 'eth0', connected to '10.10.17.202' via
 '10.10.17.222'
Registration: Completed.
IPv4 Connection to peer '10.10.17.202' Start Time: Wed Jun 10 14:27:12 2020 UTC
Heartbeat Send Time: Mon Jun 15 09:02:08 2020 UTC
Heartbeat Received Time: Mon Jun 15 09:02:16 2020 UTC
```

Step 9 In the Firewall Management Center, choose **Devices** > **Device Management**, and click **Edit** (). In the **Device** area, against the **Management** field, click **Refresh** next to **Manager Access - Configuration Details**.

The Firewall Management Center detects the interface and default route configuration changes and blocks deployment to the device. When you change the data interface settings locally on the device, you must reconcile those changes in the Firewall Management Center manually. You can view the discrepancies between the Firewall Management Center and the device on the **Configuration** tab.

Step 10 Choose **Interfaces**, and make the following changes.

a) Remove the IP address and name from the old data management interface and disable manager access for this interface.

b) Configure the new data management interface with the new settings (the ones you used at the CLI) and enable manager access for it.

Step 11 Click the **Routing** tab, click **Static Route**, and then change the default route from the old data management interface to the new one.

Step 12 Return to the **Manager Access - Configuration Details** dialog box, and click **Acknowledge** to remove the deployment block.

The next time you deploy, the Firewall Management Center configuration will overwrite any remaining conflicting settings on the Firewall Threat Defense. It is your responsibility to manually fix the configuration in the Firewall Management Center before you re-deploy.

You will see expected messages of "Config was cleared" and "Manager access changed and acknowledged."

Modify the Firewall Threat Defense Data Interface Used for Management in the GUI

If the management connection is up, but you want to change the IP address of the data interface used for manager access, follow these steps. For example, if you register a device using zero-touch provisioning, then you need to change the IP address to a static address before you can enable high availability.

You can alternatively change interface settings at the CLI, but we recommend only using that method if the management connection is down. Any changes you make at the CLI will have to be replicated in the GUI anyway.

Procedure

Step 1 Choose **Devices** > **Device Management**, and click **Edit** ( ) next to the device.

Step 2 Choose **Interfaces**.

Step 3 If you want to change the interface used for manager access:

a) Remove the IP address and name from the old data management interface and disable manager access for this interface.

b) Configure the new data management interface with the new settings and enable manager access for it.

c) If you use a static IP address, you are reminded to make sure you have a default route. Click **Yes**.

d) Click **OK** to exit the interface.

e) Click **Save** on the **Interfaces** page.

Step 4 If you only want to change the IP address:

a) Change the IP address.

b) For a static IP address, you are reminded to make sure you have a default route. Click **Yes**.

c) Click **OK** to exit the interface.

d) Click **Save** on the **Interfaces** page.

Step 5 Click the **Routing** tab, click **Static Route**, and then add or change the default or static route for the manager access interface.

Step 6 Deploy configuration changes.

The Firewall Management Center will deploy the configuration changes over the current connection. After the deployment, the data interface will have a new IP address, so the management connection will need to be reestablished.

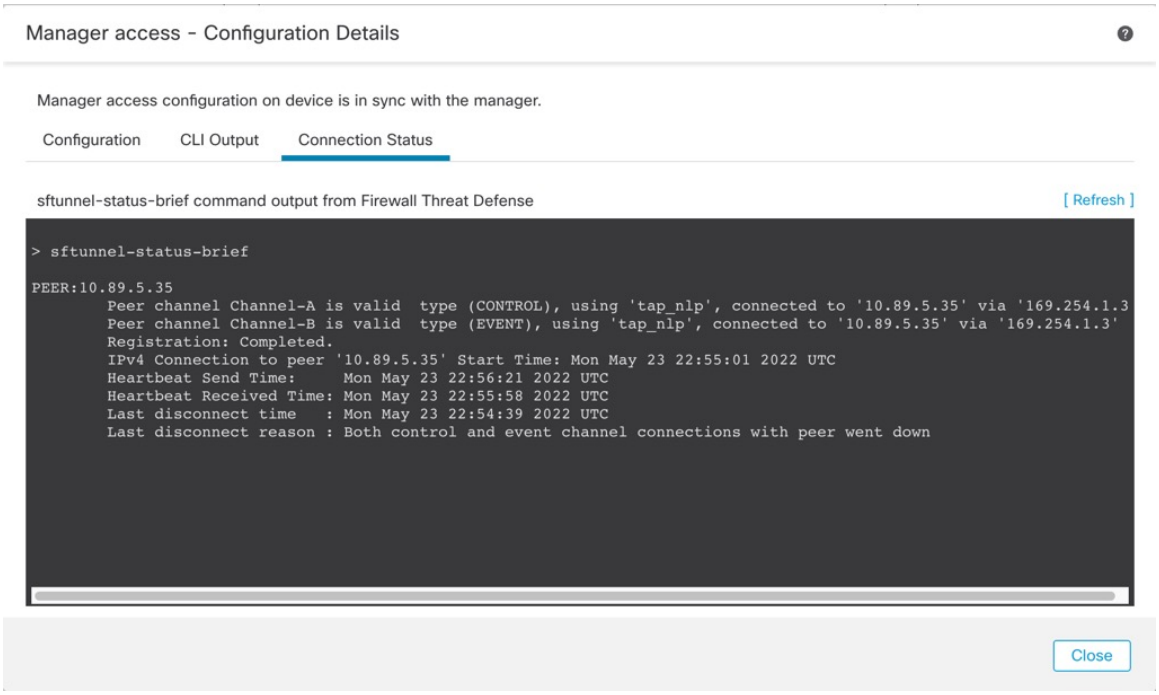
Step 7 Update the Hostname or IP Address in the Firewall Management Center, on page 104.

Step 8 Ensure the management connection is reestablished.

In the **Device** area, against the **Management** field, click **Manager Access Details: Configuration** and then click **Connection Status**.

The following status shows a successful connection for a data interface, showing the internal "tap_nlp" interface.

Figure 22: Connection Status



If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 120.

Update the Hostname or IP Address in the Firewall Management Center

If you edit the hostname or IP address of a device after you added it to the Firewall Management Center (using the device's CLI, for example), you need to use the procedure below to manually update the hostname or IP address on the managing Firewall Management Center.

To change the device management IP address on the device, see Modify Firewall Threat Defense Management Interfaces at the CLI, on page 94.

If you used only the NAT ID when registering the device, then the IP shows as **NO-IP** on this page, and you do not need to update the IP address/hostname.

If you used zero-touch provisioning to register the device on the outside interface, the hostname is automatically generated along with a matching DDNS configuration; you cannot edit the hostname in this case.

Procedure

Step 1 Choose **Devices** > **Device Management**.

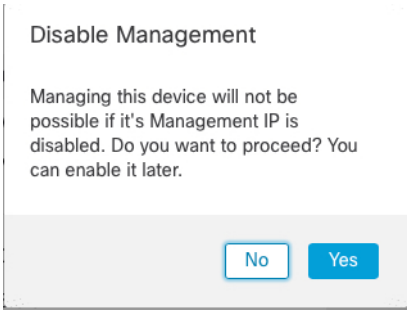
Step 2 Next to the device where you want to modify management options, click **Edit** ( ).

Step 3 Click **Device**, and view the **Management** area.

Step 4 Disable management temporarily by clicking the slider so it is disabled **Slider disabled** ( ).

Figure 23: Disable Management

You are prompted to proceed with disabling management; click **Yes**.



Disabling management blocks the connection between the Firewall Management Center and the device, but does **not** delete the device from the Firewall Management Center.

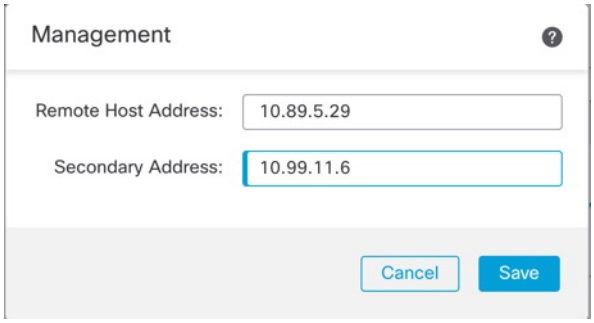
Step 5 Edit the **Remote Host Address** IP address and optional **Secondary Address** (when using a redundant data interface) or hostname by clicking **Edit** ( ).

Figure 24: Edit Management Address

Step 6 In the **Management** dialog box, modify the name or IP address in the **Remote Host Address** field and the optional **Secondary Address** field, and click **Save**.

For information about using a secondary manager access data interface, see Configure a Redundant Manager Access Data Interface, on page 89.

Figure 25: Management IP Address



Step 7 Reenable management by clicking the slider so it is enabled **Slider enabled** ( ).

Figure 26: Enable Management Connection

Change the Firewall Management Center IP Address

If you change the Firewall Management Center IP address or hostname, you should also change the value at the device CLI so the configurations match. Although in most cases, the management connection will be reestablished without changing the Firewall Management Center IP address or hostname on the device, in at least one case, you must perform this task for the connection to be reestablished: when you added the device to the Firewall Management Center and you specified the NAT ID only. Even in other cases, we recommend keeping the Firewall Management Center IP address or hostname up to date for extra network resiliency.

Procedure

Step 1 Change the Firewall Management Center IP address.

Caution
Be careful when making changes to the Firewall Management Center interface to which you are connected; if you cannot re-connect because of a configuration error, you need to access the Firewall Management Center console port to re-configure the network settings in the Linux shell. You must contact Cisco TAC to guide you in this operation.

a) Choose **System** ( ) > **Configuration** > **Management Interfaces**.
b) In the **Interfaces** area, click **Edit** next to the interface that you want to configure.
c) Change the IP address, and click **Save**.

Step 2 At the Firewall Threat Defense CLI, view the Firewall Management Center identifier.

show managers

Example:

```
> show managers
Type                      : Manager
Host                      : 10.10.1.4
Display name              : 10.10.1.4
Identifier                : f7ffad78-bf16-11ec-a737-baa2f76ef602
Registration              : Completed
Management type           : Configuration
```

Step 3 At the Firewall Threat Defense CLI, edit the Firewall Management Center IP address or hostname.

configure manager edit *identifier* {**hostname** {*ip_address* | *hostname*} | **displayname** *display_name*}

If the Firewall Management Center was originally identified by **DONTRESOLVE** and a NAT ID, you can change the value to a hostname or IP address using this command. You cannot change an IP address or hostname to **DONTRESOLVE**.

The management connection will go down, and then reestablish. You can monitor the state of the connection using the **sftunnel-status** command.

Example:

```
> configure manager edit f7ffad78-bf16-11ec-a737-baa2f76ef602 hostname 10.10.5.1
```

Change Both Firewall Management Center and Threat Defense IP Addresses

You might want to change both Firewall Management Center and Firewall Threat Defense IP addresses if you need to move them to a new network.

Procedure

Step 1 Disable the management connection.

For a high-availability pair or cluster, perform these steps on all units.

a) Choose **Devices** > **Device Management**.

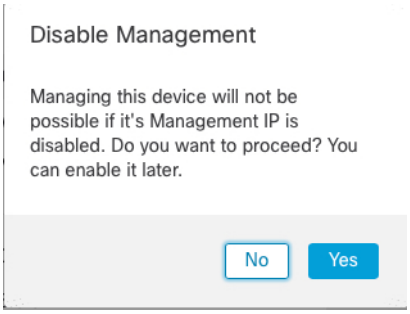
b) Next to the device, click **Edit** ( ).

c) Click **Device**, and view the **Management** area.

d) Disable management temporarily by clicking the slider so it is disabled ( ).

Figure 27: Disable Management

You are prompted to proceed with disabling management; click **Yes**.



Step 2 Change the device IP address in the Firewall Management Center to the new device IP address.

You will change the IP address on the device later.

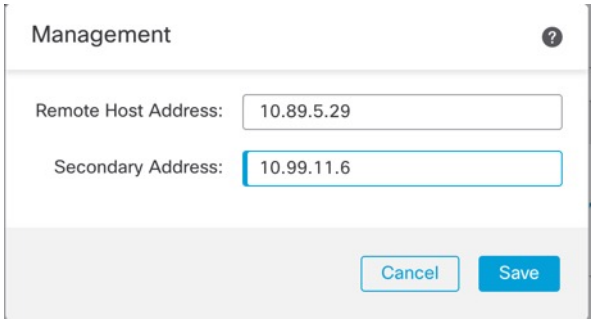
For a high-availability pair or cluster, perform these steps on all units.

a) Edit the **Remote Host Address** IP address and optional **Secondary Address** (when using a redundant data interface) or hostname by clicking **Edit** ( ).

Figure 28: Edit Management Address

b) In the **Management** dialog box, modify the name or IP address in the **Remote Host Address** field and the optional **Secondary Address** field, and click **Save**.

Figure 29: Management IP Address



Step 3 Change the Firewall Management Center IP address.

Caution
Be careful when making changes to the Firewall Management Center interface to which you are connected; if you cannot re-connect because of a configuration error, you need to access the Firewall Management Center console port to re-configure the network settings in the Linux shell. You must contact Cisco TAC to guide you in this operation.

a) Choose **System** (⚙) > **Configuration** > **Management Interfaces**.
b) In the **Interfaces** area, click **Edit** next to the interface that you want to configure.
c) Change the IP address, and click **Save**.

Step 4 Change the manager IP address on the device.

For a high-availability pair or cluster, perform these steps on all units.

a) At the Firewall Threat Defense CLI, view the Firewall Management Center identifier.

show managers

Example:

```
> show managers
Type                      : Manager
Host                      : 10.10.1.4
Display name              : 10.10.1.4
Identifier                : f7ffad78-bf16-11ec-a737-baa2f76ef602
Registration              : Completed
Management type           : Configuration
```

b) Edit the Firewall Management Center IP address or hostname.

configure manager edit *identifier* {**hostname** {*ip_address* | *hostname*} | **displayname** *display_name*}

If the Firewall Management Center was originally identified by **DONTRESOLVE** and a NAT ID, you can change the value to a hostname or IP address using this command. You cannot change an IP address or hostname to **DONTRESOLVE**.

Example:

```
> configure manager edit f7ffad78-bf16-11ec-a737-baa2f76ef602 hostname 10.10.5.1
```

Step 5 Change the IP address of the manager access interface at the console port.

For a high-availability pair or cluster, perform these steps on all units.

If you use the dedicated Management interface:

configure network ipv4

configure network ipv6

If you use the dedicated Management interface:

configure network management-data-interface disable

configure network management-data-interface

Step 6 Reenable management by clicking the slider so it is enabled ( ).

For a high-availability pair or cluster, perform these steps on all units.

Figure 30: Enable Management Connection

Step 7 (If using a data interface for manager access) Refresh the data interface settings in the Firewall Management Center.

For a high-availability pair, perform this step on both units.

a) Choose **Devices** > **Device Management**, and click **Manager Access - Configuration Details**, and then click **Refresh**.
b) Choose **Devices** > **Device Management**, and click the **Interfaces** tab and set the IP address to match the new address.
c) Return to the **Manager Access - Configuration Details** dialog box, and click **Acknowledge** to remove the deployment block.

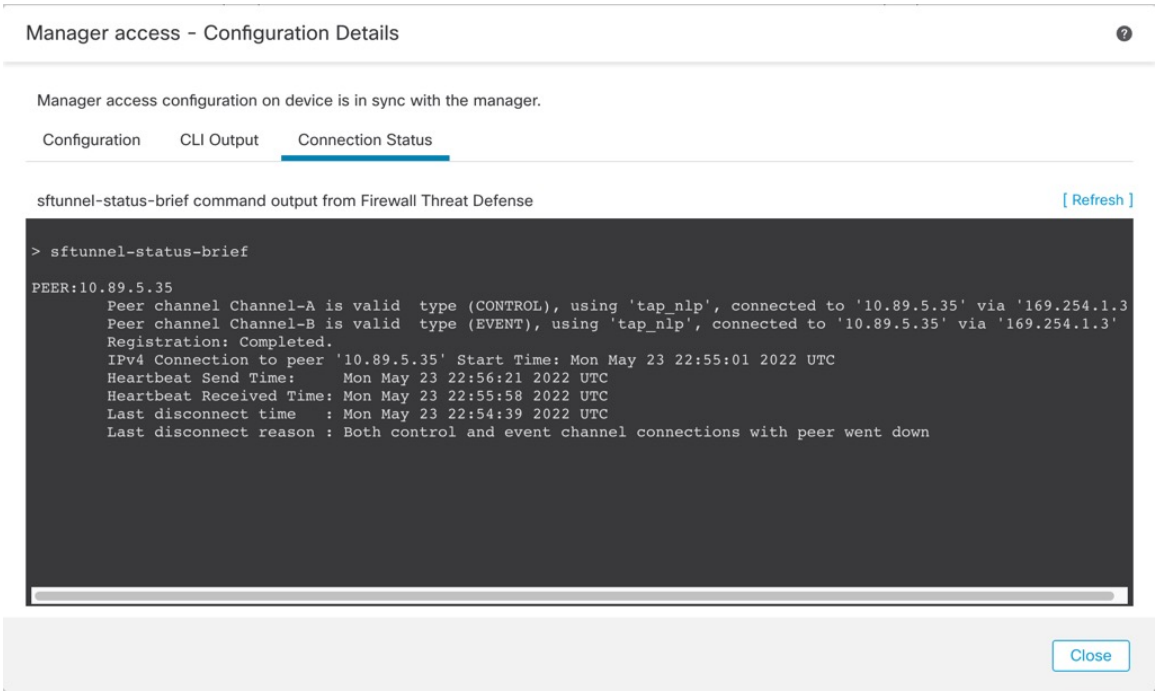
Step 8 Ensure the management connection is reestablished.

In the Firewall Management Center, check the management connection status. Navigate to the **Devices** > **Device Management**, and click **Management** section under the **Device** tab. Then, click **Manager Access - Configuration Details** to view the **Connection Status** page.

At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

The following status shows a successful connection for a data interface, showing the internal "tap_nlp" interface.

Figure 31: Connection Status



Step 9 (For a high-availability Firewall Management Center pair) Repeat configuration changes on the secondary Firewall Management Center.

a) Change the secondary Firewall Management Center IP address.
b) Specify the new peer addresses on both units.
c) Make the secondary unit the active unit.
d) Disable the device management connection.
e) Change the device IP address in the Firewall Management Center.
f) Reenable the management connection.

Change the Manager Access Interface

After you register the device, you can change the manager access interface, between the Management interface a data interface.

Change the Manager Access Interface from Management to Data

You can manage the Firewall Threat Defense from either the dedicated Management interface or from a data interface. If you want to change the manager access interface after you added the device to the Firewall Management Center, follow these steps to migrate from the Management interface to a data interface. To migrate the other direction, see Change the Manager Access Interface from Data to Management, on page 115.

Initiating the manager access migration from Management to data causes the Firewall Management Center to apply a block on deployment to the Firewall Threat Defense. To remove the block, enable manager access on the data interface.

See the following steps to enable manager access on a data interface and also configure other required settings.

Before you begin

For high-availability pairs, unless stated otherwise, perform all steps only on the active unit. Once the configuration changes are deployed, the standby unit synchronizes configuration and other state information from the active unit.

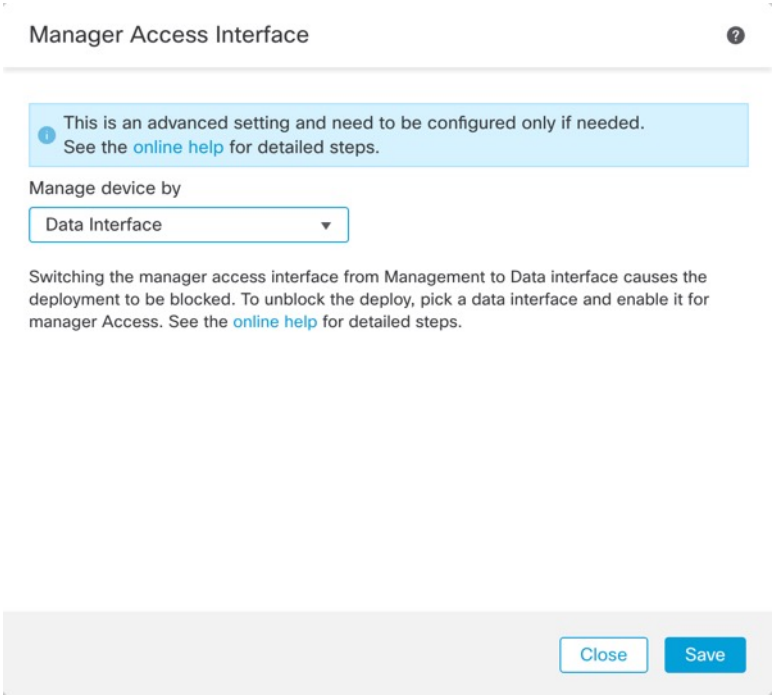
Procedure

Step 1 Initiate the interface migration.

a) On the **Devices** > **Device Management** page, click **Edit** (✎) for the device. Click **Device**, and in the **Management** area, click the **Manager Access Interface** link.

The **Manager Access Interface** field shows the current Management interface. When you click the link, choose the new interface type, **Data Interface**, in the **Manage device by** drop-down list.

Figure 32: Manager Access Interface



b) Click **OK** and then **Close**.

You must now complete the remaining steps in this procedure to enable manager access on the data interface. The **Management** area now shows **Manager Access Interface: Data Interface**, and **Manager Access Details: Configuration**.

Figure 33: Manager Access

If you click **Configuration**, the **Manager Access - Configuration Details** dialog box opens. The **Manager Access Mode** shows a Deploy pending state.

Step 2 Enable manager access on the data interface(s). Click **Interfaces**, click **Edit** (✎) for the interface, and then click **Manager Access**.

Check **Enable management access** and click **OK**. By default, all networks are allowed, but you can limit access as long as the Firewall Management Center address is allowed.

If the manager access interface uses a static IP address, you are reminded to configure routing for it.

Click **Save** on the **Interfaces** page. See Configure Routed Mode Interfaces, on page 948 for more information about interface settings. You can enable manager access on one routed data interface, plus an optional secondary interface. Make sure these interfaces are fully configured with a name and IP address and that they are enabled.

If you use a secondary interface for redundancy, see Configure a Redundant Manager Access Data Interface, on page 89 for additional required configuration.

Step 3 (Optional) If you use DHCP for the interface, enable the web type DDNS method on the **DDNS** page. Navigate to **Devices** > **Device Management**, and then click **DDNS** under the **DHCP** tab.

See Configure Dynamic DNS, on page 1008. DDNS ensures the Firewall Management Center can reach the Firewall Threat Defense at its Fully-Qualified Domain Name (FQDN) if the FTD's IP address changes.

Step 4 Make sure the Firewall Threat Defense can route to the Firewall Management Center through the data interface; add a static route if necessary on the Static Route page. Navigate to **Devices** > **Device Management** and then click **Static Route** under the **Routing** tab.

See Add a Static Route, on page 1238.

Step 5 (Optional) Configure DNS in a Platform Settings policy: choose **Devices** > **Platform Settings**, and click **DNS**. Apply the policy to this device.

See DNS, on page 1037. DNS is required if you use DDNS. You may also use DNS for FQDNs in your security policies.

Step 6 (Optional) Enable SSH for the data interface in a Platform Settings policy, and apply it to this device at **Devices** > **Device Management** page. Click **Edit** (✎) for the device and then click **SSH Access**.

See SSH Access, on page 1050. SSH is not enabled by default on the data interfaces, so if you want to manage the Firewall Threat Defense using SSH, you need to explicitly allow it.

Step 7 Deploy configuration changes.

You will see a validation error to confirm that you are changing the manager access interface. Check **Ignore warnings** and deploy again.

The Firewall Management Center will deploy the configuration changes over the current Management interface. After the deployment, the data interface is now ready for use, but the original management connection to Management is still active.

Step 8 At the Firewall Threat Defense CLI (preferably from the console port), set the Management interface to use a static IP address and set the gateway to use the data interfaces. For high availability, perform this step on both units.

configure network {**ipv4** | **ipv6**} **manual** *ip_address netmask* **data-interfaces**

- *ip_address netmask*—Although you do not plan to use the Management interface, you must set a static IP address, for example, a private address so that you can set the gateway to **data-interfaces** (see the next bullet). You cannot use DHCP because the default route, which must be **data-interfaces**, might be overwritten with one received from the DHCP server.
- **data-interfaces**—This setting forwards management traffic over the backplane so it can be routed through the manager access data interface.

We recommend that you use the console port instead of an SSH connection because when you change the Management interface network settings, your SSH session will be disconnected.

Step 9 If necessary, re-cable the Firewall Threat Defense so it can reach the Firewall Management Center on the data interface. For high availability, perform this step on both units.

Step 10 In the Cloud-Delivered Firewall Management Center, disable the management connection for the Firewall Threat Defense in the **Devices** > **Device Management** page in the **Management** area under the **Device** tab, and then reenable the connection.

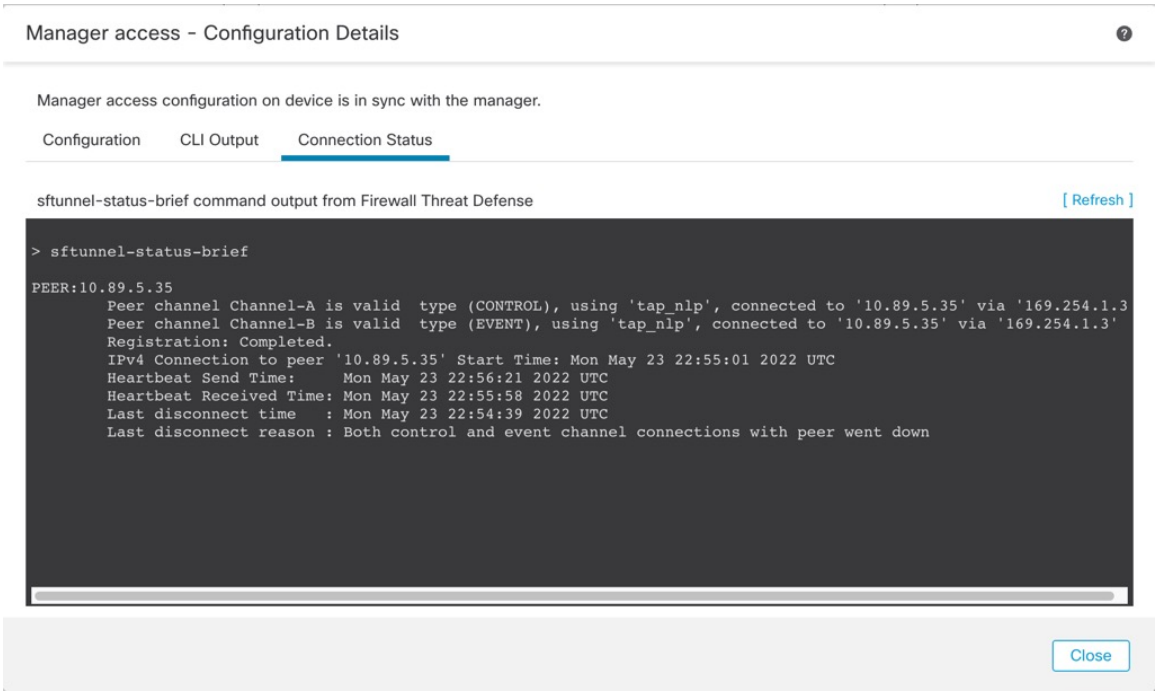
Step 11 Ensure the management connection is reestablished.

In the **Devices** > **Device Management** page, click **Manager Access Details: Configuration** and then click **Connection Status**.

Alternatively, you can check at the Firewall Threat Defense CLI. Enter the **sftunnel-status-brief** command to view the management connection status.

The following status shows a successful connection for a data interface, showing the internal "tap_nlp" interface.

Figure 34: Connection Status



If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 120.

Change the Manager Access Interface from Data to Management

You can manage the Firewall Threat Defense from either the dedicated Management interface or from a data interface. If you want to change the manager access interface after you added the device to the Firewall Management Center, follow these steps to migrate from a data interface to the Management interface. To migrate the other direction, see Change the Manager Access Interface from Management to Data, on page 111.

Initiating the manager access migration from data to Management causes the Firewall Management Center to apply a block on deployment to the Firewall Threat Defense. You must disable manager access on the data interface to remove the block.

See the following steps to disable manager access on a data interface, and also configure other required settings.

Before you begin

For high-availability pairs, unless stated otherwise, perform all steps only on the active unit. Once the configuration changes are deployed, the standby unit synchronizes configuration and other state information from the active unit.

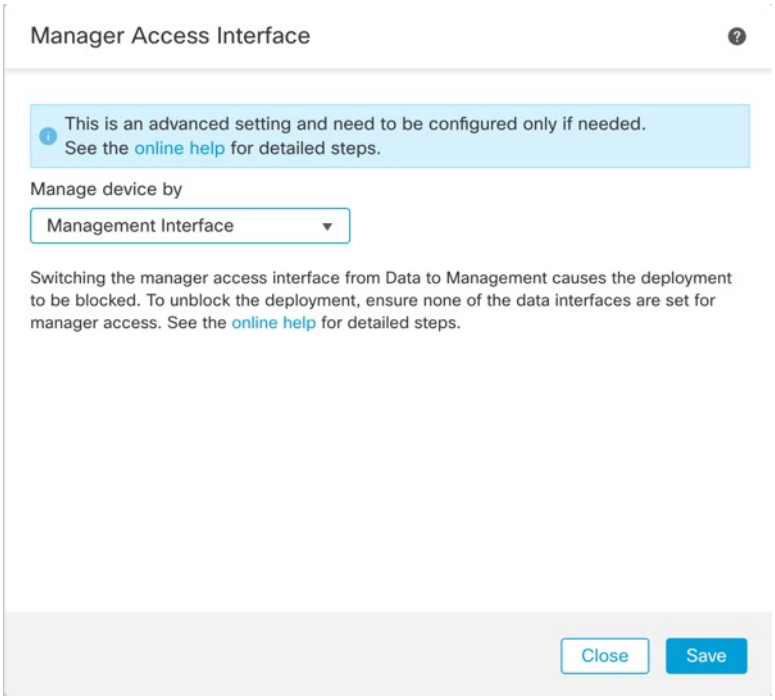
Procedure

Step 1 Initiate the interface migration.

a) On the **Devices** > **Device Management** page, click **Edit** (✎) for the device. Click **Device**, and in the **Management** area, click the link for **Manager Access Interface**.

The **Manager Access Interface** field shows the current management interface as data. When you click the link, choose the new interface type, **Management Interface**, in the **Manage device by** drop-down list.

Figure 35: Manager Access Interface



b) Click **Save**.

Click **OK** and then **Close**.

You must now complete the remaining steps in this procedure to enable manager access on the Management interface. The **Management** area now shows the **Manager Access Interface: Management Interface**.

Figure 36: Manager Access

Step 2 Disable manager access on the data interface(s). Click **Interfaces**, click **Edit** (✎) for the interface, and then click **Manager Access**.

Uncheck **Enable management access** and click **OK**. Click **Save** on the **Interfaces** page. This step removes the block on deployment.

Step 3 If you have not already done so, configure DNS settings for the data interface in a Platform Setting policy, and apply it to this device at **Devices** > **Device Management** page. Click **Edit** (✎) for the device and then click **DNS**.

See DNS, on page 1037. The Firewall Management Center deployment that disables manager access on the data interface will remove any local DNS configuration. If that DNS server is used in any security policy, such as an FQDN in an Access Rule, then you must re-apply the DNS configuration using the Firewall Management Center.

Step 4 Deploy configuration changes.

The Firewall Management Center will deploy the configuration changes over the current data interface.

Step 5 If necessary, re-cable the Firewall Threat Defense so it can reach the Firewall Management Center on the Management interface. For High Availability, perform this step on both units.

Step 6 At the Firewall Threat Defense CLI, configure the Management interface IP address and gateway using a static IP address or DHCP. For high availability, perform this step on both units.

When you originally configured the data interface for manager access, the Management gateway was set to data-interfaces, which forwarded management traffic over the backplane so it could be routed through the manager access data interface. You now need to set an IP address for the gateway on the management network.

Static IP address:

configure network {**ipv4** | **ipv6**} **manual** *ip_address netmask gateway_ip*

DHCP:

configure network{**ipv4** | **ipv6**} **dhcp**

Step 7 In the Cloud-Delivered Firewall Management Center, disable the management connection for the Firewall Threat Defense in the **Devices** > **Device Management**, **Management** section under **Device** tab, and then reenable the connection.

Step 8 Ensure the management connection is reestablished.

In the Firewall Management Center, check the management connection status on the **Devices** > **Device Management**, **Management** section under **Device** tab, **Status** field or view notifications in the Firewall Management Center.

At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 120.

Troubleshooting the Management Connection

-

Manually Roll Back the Configuration if the Firewall Management Center Loses Connectivity

If you use a data interface on the Firewall Threat Defense for manager access, and you deploy a configuration change from the Firewall Management Center that affects the network connectivity, you can roll back the configuration on the Firewall Threat Defense to the last-deployed configuration so you can restore management connectivity. You can then adjust the configuration settings in Firewall Management Center so that the network connectivity is maintained, and re-deploy. You can use the rollback feature even if you do not lose connectivity; it is not limited to this troubleshooting situation.

Alternatively, you can enable auto rollback of the configuration if you lose connectivity after a deployment; see Edit Deployment Settings, on page 135.

See the following guidelines:

- Only the previous deployment is available locally on the Firewall Threat Defense; you cannot roll back to any earlier deployments.
- Rollback is supported for high availability but not supported for clustering deployments.
- Rollback is not supported immediately after high availability creation.
- The rollback only affects configurations that you can set in the Firewall Management Center. For example, the rollback does not affect any local configuration related to the dedicated Management interface, which you can only configure at the Firewall Threat Defense CLI. Note that if you changed data interface settings after the last Firewall Management Center deployment using the **configure network management-data-interface** command, and then you use the rollback command, those settings will not be preserved; they will roll back to the last-deployed Firewall Management Center settings.
- UCAPL/CC mode cannot be rolled back.
- Out-of-band SCEP certificate data that was updated during the previous deployment cannot be rolled back.
- During the rollback, connections will drop because the current configuration will be cleared.

Procedure

Step 1 At the Firewall Threat Defense CLI, roll back to the previous configuration.

configure policy rollback

Note
For a high availability pair, this command is allowed only on the active unit.

After the rollback, the Firewall Threat Defense notifies the Firewall Management Center that the rollback was completed successfully. In the Firewall Management Center, the deployment screen will show a banner stating that the configuration was rolled back.

Note
If the rollback failed and the Firewall Management Center management is restored, refer to https://www.cisco.com/c/en/us/support/docs/security/firepower-ngfw-virtual/215258-troubleshooting-firepower-threat-defense.html for common deployment problems. In some cases, the rollback can fail after the Firewall Management Center management access is restored; in this case, you can

resolve the Firewall Management Center configuration issues, and redeploy from the Firewall Management Center.

Example:

For the Firewall Threat Defense that uses a data interface for manager access:

```
> configure policy rollback

The last deployment to this FTD was on June 1, 2020 and its status was Successful.
Do you want to continue [Y/N]?

Y

Rolling back complete configuration on the FTD. This will take time.
.....................
Policy rollback was successful on the FTD.
Configuration has been reverted back to transaction id:
Following is the rollback summary:
...................
.....................
>
```

Example:

For Firewall Threat Defenses in a high availability pair that use a data interface for Firewall Management Center access:

```
> configure policy rollback

Checking Eligibility ....
============= DEVICE DETAILS =============
Device Version: 7.2.0
Device Type: FTD
Device Mode: Offbox
Device in HA: true
Is HA disabled: false
HA state: active - standby ready
==========================================
Device is eligible for policy rollback
Do you want to continue [YES/NO]?

YES

Starting rollback...
    Preparing policy configuration on the device.           Status: success
    Applying updated policy configuration on the device.    Status: success
    Applying Lina File Configuration on the device.         Status: success
    Applying Lina Configuration on the device.              Status: success
    Commit Lina Configuration.                              Status: success
    Commit Lina File Configuration.                         Status: success
    Commit Lina File Configuration.                         Status: success
================================================================
POLICY ROLLBACK STATUS: SUCCESS
================================================================
>
```

Step 2 Check that the management connection was reestablished.

In Firewall Management Center, check the management connection status on the Connection Status page. Navigate to **Devices** > **Device Management** and then navigate to **Management** area under the **Devices** tab. Then in the **Manager Access - Configuration Details** screen, click **Connection Status**.

At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 120.

Troubleshoot Management Connectivity on a Data Interface

When you use a data interface for manager access instead of using the dedicated Management interface, you must be careful about changing the interface and network settings for the Firewall Threat Defense in the Firewall Management Center so you do not disrupt the connection. If you change the management interface type after you add the Firewall Threat Defense to the Firewall Management Center (from data to Management, or from Management to data), if the interfaces and network settings are not configured correctly, you can lose management connectivity.

This topic helps you troubleshoot the loss of management connectivity.

View management connection status

In the Firewall Management Center, check the management connection status on the **Devices** > **Device Management** page.

At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status. You can also use **sftunnel-status** to view more complete information.

See the following sample output for a connection that is down; there is no peer channel "connected to" information, nor heartbeat information shown:

```
> sftunnel-status-brief
PEER:10.10.17.202
Registration: Completed.
Connection to peer '10.10.17.202' Attempted at Mon Jun 15 09:21:57 2020 UTC
Last disconnect time : Mon Jun 15 09:19:09 2020 UTC
Last disconnect reason : Both control and event channel connections with peer went down
```

See the following sample output for a connection that is up, with peer channel and heartbeat information shown:

```
> sftunnel-status-brief
PEER:10.10.17.202
Peer channel Channel-A is valid type (CONTROL), using 'eth0', connected to '10.10.17.202'
 via '10.10.17.222'
Peer channel Channel-B is valid type (EVENT), using 'eth0', connected to '10.10.17.202'
 via '10.10.17.222'
Registration: Completed.
IPv4 Connection to peer '10.10.17.202' Start Time: Wed Jun 10 14:27:12 2020 UTC
Heartbeat Send Time: Mon Jun 15 09:02:08 2020 UTC
Heartbeat Received Time: Mon Jun 15 09:02:16 2020 UTC
```

View the Firewall Threat Defense network information

At the Firewall Threat Defense CLI, view the Management and manager access data interface network settings:

show network

```
> show network
===============[ System Information ]===============

Configuration             : Disabled
```

Check that the Firewall Threat Defense registered with the Firewall Management Center

At the Firewall Threat Defense CLI, check that the Firewall Management Center registration was completed. Note that this command will not show the *current* status of the management connection.

show managers

```
> show managers
Type                      : Manager
Host                      : 10.10.1.4
Display name              : 10.10.1.4
Identifier                : f7ffad78-bf16-11ec-a737-baa2f76ef602
```

```
Registration              : Completed
Management type           : Configuration
```

Ping the Firewall Management Center

At the Firewall Threat Defense CLI, use the following command to ping the Firewall Management Center from the data interfaces:

ping *fmc_ip*

At the Firewall Threat Defense CLI, use the following command to ping the Firewall Management Center from the Management interface, which should route over the backplane to the data interfaces:

ping system *fmc_ip*

Capture packets on the Firewall Threat Defense internal interface

At the Firewall Threat Defense CLI, capture packets on the internal backplane interface (nlp_int_tap) to see if management packets are being sent:

capture *name* **interface nlp_int_tap trace detail match ip any any**

show capture*name* **trace detail**

Check the internal interface status, statistics, and packet count

At the Firewall Threat Defense CLI, see information about the internal backplane interface, nlp_int_tap:

show interface detail

```
> show interface detail
[...]
Interface Internal-Data0/1 "nlp_int_tap", is up, line protocol is up
  Hardware is en_vtun rev00, BW Unknown Speed-Capability, DLY 1000 usec
 (Full-duplex), (1000 Mbps)
 Input flow control is unsupported, output flow control is unsupported
 MAC address 0000.0100.0001, MTU 1500
 IP address 169.254.1.1, subnet mask 255.255.255.248
 37 packets input, 2822 bytes, 0 no buffer
 Received 0 broadcasts, 0 runts, 0 giants
 0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
 0 pause input, 0 resume input
 0 L2 decode drops
 5 packets output, 370 bytes, 0 underruns
 0 pause output, 0 resume output
 0 output errors, 0 collisions, 0 interface resets
 0 late collisions, 0 deferred
 0 input reset drops, 0 output reset drops
 input queue (blocks free curr/low): hardware (0/0)
 output queue (blocks free curr/low): hardware (0/0)
  Traffic Statistics for "nlp_int_tap":
 37 packets input, 2304 bytes
 5 packets output, 300 bytes
 37 packets dropped
      1 minute input rate 0 pkts/sec,  0 bytes/sec
      1 minute output rate 0 pkts/sec,  0 bytes/sec
      1 minute drop rate, 0 pkts/sec
      5 minute input rate 0 pkts/sec,  0 bytes/sec
      5 minute output rate 0 pkts/sec,  0 bytes/sec
      5 minute drop rate, 0 pkts/sec
  Control Point Interface States:
 Interface number is 14
 Interface config status is active
```

```
 Interface state is active
```

Check routing and NAT

At the Firewall Threat Defense CLI, check that the default route (S*) was added and that internal NAT rules exist for the Management interface (nlp_int_tap).

show route

```
> show route

Codes: L - local, C - connected, S - static, R - RIP, M - mobile, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2, V - VPN
       i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
       ia - IS-IS inter area, * - candidate default, U - per-user static route
       o - ODR, P - periodic downloaded static route, + - replicated route
       SI - Static InterVRF
Gateway of last resort is 10.89.5.1 to network 0.0.0.0

S*       0.0.0.0 0.0.0.0 [1/0] via 10.89.5.1, outside
C        10.89.5.0 255.255.255.192 is directly connected, outside
L        10.89.5.29 255.255.255.255 is directly connected, outside

>
```

show nat

```
> show nat

Auto NAT Policies (Section 2)
1 (nlp_int_tap) to (outside) source static nlp_server_0_sftunnel_intf3 interface  service
 tcp 8305 8305
    translate_hits = 0, untranslate_hits = 6

    translate_hits = 0, untranslate_hits = 0
>
```

Check other settings

See the following commands to check that all other settings are present. You can also see many of these commands on the Firewall Management Center's **Devices** > **Device Management** page.

show running-config sftunnel

```
> show running-config sftunnel
sftunnel interface outside
sftunnel port 8305
```

show running-config ip-client

```
> show running-config ip-client
ip-client outside
```

show conn address *fmc_ip*

```
> show conn address 10.89.5.35
5 in use, 16 most used
Inspect Snort:
        preserve-connection: 0 enabled, 0 in effect, 0 most enabled, 0 most in effect

TCP nlp_int_tap  10.89.5.29(169.254.1.2):51231 outside  10.89.5.35:8305, idle 0:00:04,
 bytes 86684, flags UxIO
TCP nlp_int_tap  10.89.5.29(169.254.1.2):8305 outside  10.89.5.35:52019, idle 0:00:02,
 bytes 1630834, flags UIO
>
```

Check for a successful DDNS update

At the Firewall Threat Defense CLI, check for a successful DDNS update:

debug ddns

```
> debug ddns
DDNS update request = /v3/update?hostname=domain.example.org&myip=209.165.200.225
Successfully updated the DDNS sever with current IP addresses
DDNS: Another update completed, outstanding = 0
DDNS: IDB SB total = 0
```

If the update failed, use the **debug http** and **debug ssl** commands. For certificate validation failures, check that the root certificates are installed on the device:

show crypto ca certificates *trustpoint_name*

To check the DDNS operation:

show ddns update interface *fmc_access_ifc_name*

```
> show ddns update interface outside

Dynamic DNS Update on outside:
    Update Method Name Update Destination
    RBD_DDNS not available

Last Update attempted on 04:11:58.083 UTC Thu Jun 11 2020
Status : Success
FQDN : domain.example.org
IP addresses : 209.165.200.225
```

Check Firewall Management Center log files

See https://cisco.com/go/fmc-reg-error.

Troubleshoot Management Connectivity on a Data Interface in a High Availability Pair

This topic helps you troubleshoot the loss of management connectivity on a data interface in High Availability.

Model Support—Threat Defense

The management connection between the active peer and the Security Cloud Control can be disrupted due to the following reasons:

- Data interface used for management on the Active unit has connectivity issues.

  You should manually fail over to the standby unit and then configure a new data interface for Security Cloud Control access.

- Internet Service Provider has changed.

  You should manually update the new network details on the active unit using the CLI commands to restore the device connectivity with Security Cloud Control .

Data Management Interface on Active unit has Connectivity Issues

1. In Security Cloud Control, manually switch the active unit to standby. See Switch the Active Peer in the Firewall Threat Defense High Availability Pair, on page 589.

   Alternatively, you can run the **no failover active** command on the active unit.

   The standby device becomes the new active device in the high availability pair and establishes communication with Security Cloud Control.

2. Next to the device high-availability pair you want to edit, click **Edit** ( ).

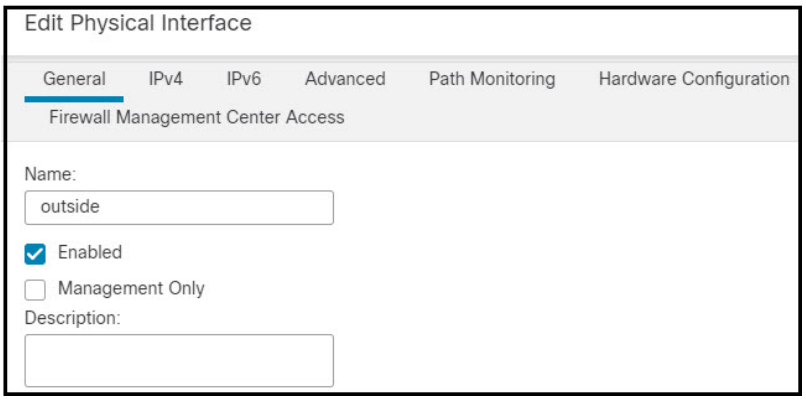
3. Choose **Routing** > **Static Route** and delete the static route defined for the old data management interface.

4. Click the **Interfaces** tab, and make the following changes.

   a. Remove the IP address and name from the old data management interface, and disable Security Cloud Control Access for this interface.

Note Before removing the old data management interface information, remember the details if you want to use the same information.

1. Click the **Edit** ( ) next to the interface you want to remove.



2. Clear the content in the **Name** field.

3. Uncheck the **Enabled** checkbox.

4. In the **IPv4** or **IPv6** tab, remove the active address.

5. In the **Firewall Management Center Access** tab, uncheck **Enable management on this interface for the Firepower Management Center**.
6. Click **OK**.
7. Click **Yes** to confirm the changes.

b. Configure the new data management interface with the settings of the old interface (the ones you used at the CLI), and enable Security Cloud Control Access for it.

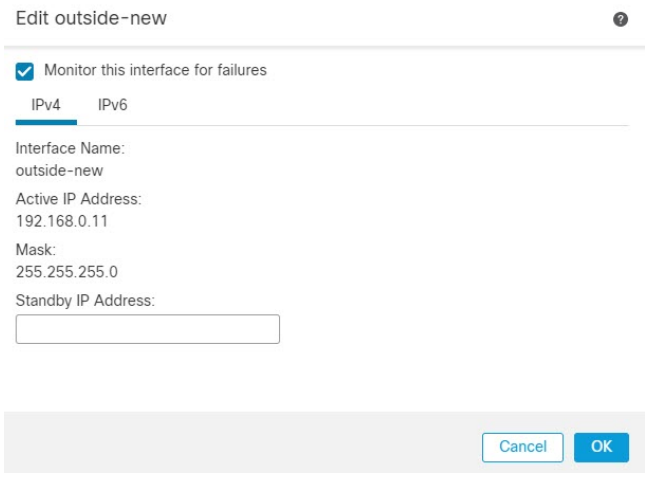
1. Click **Edit** (✎) next to the data interface you want for handling management traffic.
2. In the **Name** field, specify a name for the interface.
3. Check the **Enabled** checkbox.
4. In the **IPv4** or **IPv6** tab, specify the active address.
5. In the **Firewall Management Center Access** tab, check **Enable management on this interface for the Firepower Management Center**.
6. Click **OK**.
7. Click **Yes** to confirm the changes.

5. Click the **High Availability** tab, and make the following changes.

a. In the **Monitored Interfaces** area, click the **Edit** (✎) next to the new data management interface.

The **Active IP Address** shows the active device's IP address.

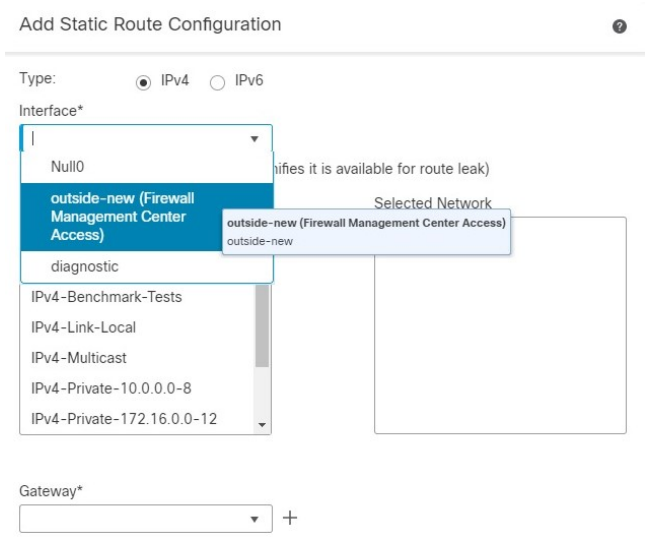
b. On the **IPv4** tab, enter the **Standby IP Address** and **Gateway** address.



c. If you configured the IPv6 address manually, on the IPv6 tab, click **Edit** (✎) next to the active IP address, enter the **Standby IP Address**, and click **OK**.

d. Click **OK**.

6. Click **Save** at the top-right corner to save the changes.
7. Choose **Routing > Static Route** and add the static route defined for the new data management interface. The new data interface appears in the **Interface** list.



8. Click **Save** at the top-right corner to save the changes.
9. Deploy configuration changes..
10. When the deployment completes around 90 percent, the new management interface takes effect. At this stage, you must re-cable the FTD so that the Security Cloud Control reaches FTD on the new interface and completes the deployment successfully.

Note After you re-cable, the deployment may fail if it timed out before re-establishing the management connection to the new interface. In that case, you must reinitiate the deployment after re-cabling for a successful deployment.

11. Ensure the management connection is reestablished.

    In Firewall Management Center, check the management connection status on the **Devices** > **Device Management** > **Device** > **Management** > **FMC Access Details** > **Connection Status** page.

    Alternatively, at the FTD CLI, enter the **sftunnel-status-brief** command to view the management connection status.

Internet Service Provider has Changed

If you have changed your ISP, you can lose management connectivity, even though High Availability health is normal. Configure the new network details of the management interface using the CLI commands.

Note These commands are available only on the active unit and not on standby.

For information about the Firewall Threat Defense CLI, see the FTD command reference.

1. Connect to the device CLI.

   You should use the console port when using these commands. If you are editing the configuration due to a disrupted management connection, and you have SSH access to the dedicated Management interface, then you can use that SSH connection.

   See Log Into the Command-Line Interface on the Device, on page 65.

2. Log in with the Admin username and password.
3. Use one of the following commands depending on the network value you want to update:
   - **configure network management-data-interface ipv4 manual** *ip_address ip_netmask* **interface** *interface_id*
   - **configure network management-data-interface ipv4** *gateway_ip* **interface** *interface_id*
   - **configure network management-data-interface ipv4 manual** *ip_address ipv4_netmask gateway_ip* **interface** *interface_id*

   Example:

   ```
   Configure network management-data-interface ipv4 manual 10.10.6.7 255.255.255.0 interface
    gig0/0
   Configuration updated successfully..!!
   ```

Note All other CLI commands of **configure network management-data-interface** are not supported on devices in a High Availability pair.

   The configuration is automatically pushed to the standby device.

4. **Optional:**Limit data interface access to Security Cloud Control on a specific network.

   configure network management-data-interface client *ip_address netmask*

   By default, all networks are allowed.

5. Check that the management connection was reestablished.

   sftunnel-status-brief

   See the following sample output for a connection that is up, with peer channel and heartbeat information shown:

   ```
   > sftunnel-status-brief
   PEER:10.10.17.202
   Peer channel Channel-A is valid type (CONTROL), using 'eth0', connected to '10.10.17.202'
    via '10.10.17.222'
   Peer channel Channel-B is valid type (EVENT), using 'eth0', connected to '10.10.17.202'
    via '10.10.17.222'
   Registration: Completed.
   IPv4 Connection to peer '10.10.17.202' Start Time: Wed Jun 10 14:27:12 2020 UTC
   ```

```
Heartbeat Send Time: Mon Jun 15 09:02:08 2020 UTC
Heartbeat Received Time: Mon Jun 15 09:02:16 2020 UTC
```

6. In Security Cloud Control, click **Security Devices** > **FTD**.
7. Select your Firewall Threat Defense and in the **Management** pane on the right, click **Device Summary**.
8. In **Management** > **FMC Access Details**, click **Refresh**.

   The Security Cloud Control detects the interface and default route configuration changes, and blocks deployment to the FTD. When you change the data interface settings locally on the device, you must reconcile those changes in Security Cloud Control manually. You can view the discrepancies between Security Cloud Control and the Firewall Threat Defense on the **Configuration** tab.
9. Return to the **FMC Access Details** dialog box, and click **Acknowledge** to remove the deployment block.

   The next time you deploy, the Security Cloud Control configuration will overwrite any remaining conflicting settings on the FTD. It is your responsibility to manually fix the configuration in the Security Cloud Control before you re-deploy.

   You will see expected messages of "Config was cleared" and "FMC Access changed and acknowledged."

   The configuration change made on the active unit is automatically pushed to standby. Once the Security Cloud Control restores its connectivity with the active unit, Security Cloud Control updates the standby IP address.

View Inventory Details

The **Inventory Details** section of the **Device** page shows chassis details such as the CPU and memory.

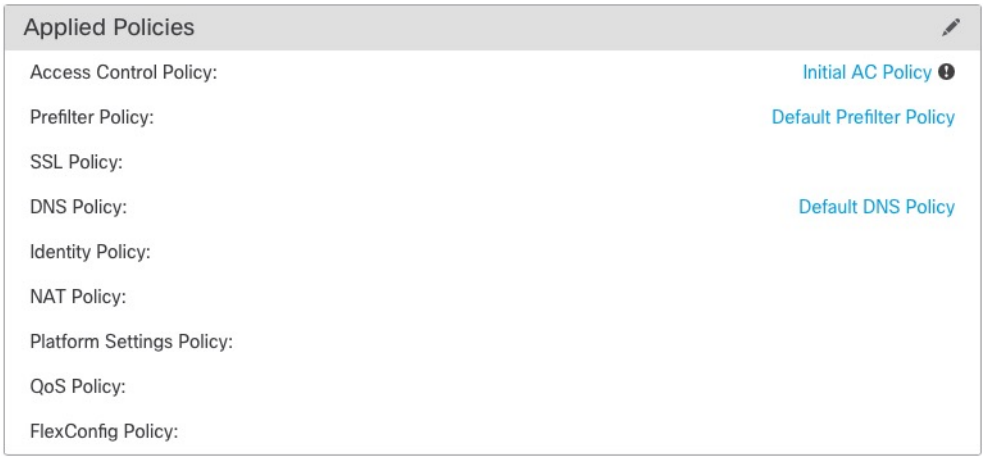
Figure 37: Inventory Details

To update information, click **Refresh** ( ).

Edit Applied Policies

The **Applied Policies** section of the **Device** page displays the following policies applied to your firewall:

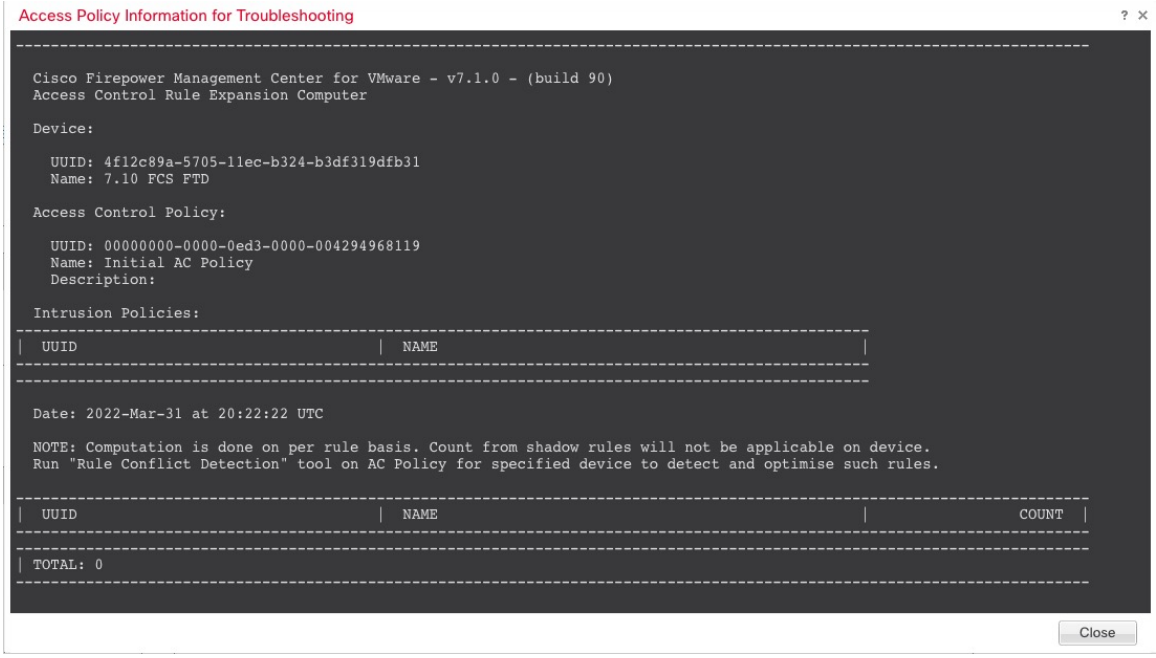
Figure 38: Applied Policies



For policies with links, you can click the link to view the policy.

For the Access Control Policy, view the **Access Policy Information for Troubleshooting** dialog box by clicking the **Exclamation** ( ) icon. This dialog box shows how access rules are expanded into access control entries (ACEs).

Figure 39: Access Policy Information for Troubleshooting



You can assign policies to an individual device from the **Device Management** page.

Procedure

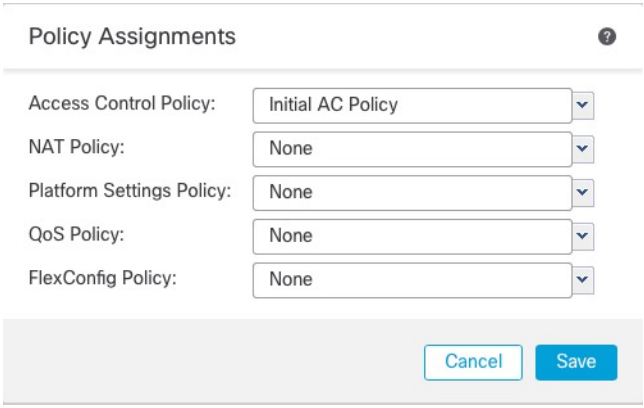
Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to assign policies, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **Applied Policies** section, click **Edit** ( ).

Figure 40: Policy Assignments



Step 5 For each policy type, choose a policy from the drop-down menu. Only existing policies are listed.

Step 6 Click **Save**.

What to do next

- Deploy configuration changes.

Edit Advanced Settings

The **Advanced Settings** section of the **Device** page displays a table of advanced configuration settings, as described below. You can edit any of these settings.

Table 6: Advanced Section Table Fields

Field	Description
Application Bypass	The state of Automatic Application Bypass on the device.
Bypass Threshold	The Automatic Application Bypass threshold, in milliseconds.

Field	Description
Object Group Search	The state of object group search on the device. While operating, the FTD device expands access control rules into multiple access control list entries based on the contents of any network or interface objects used in the access rule. You can reduce the memory required to search access control rules by enabling object group search. With object group search enabled, the system does not expand network or interface objects, but instead searches access rules for matches based on those group definitions. Object group search does not impact how your access rules are defined or how they appear in Firepower Management Center. It impacts only how the device interprets and processes them while matching connections to access control rules. **Note** By default, the **Object Group Search** is enabled when you add threat defense for the first time in the management center.
Interface Object Optimization	The state of interface object optimization on the device. During deployment, interface groups and security zones used in the access control and prefilter policies generate separate rules for each source/destination interface pair. If you enable interface object optimization, the system will instead deploy a single rule per access control/prefilter rule, which can simplify the device configuration and improve deployment performance. If you select this option, also select the **Object Group Search** option to reduce memory usage on the device.

The following topics explain how to edit the advanced device settings.

Note For information about the Transfer Packets setting, see Edit General Settings, on page 79.

Configure Automatic Application Bypass

Automatic Application Bypass (AAB) allows packets to bypass detection if Snort is down or, for a Classic device, if a packet takes too long to process. AAB causes Snort to restart within ten minutes of the failure, and generates troubleshooting data that can be analyzed to investigate the cause of the Snort failure.

Caution AAB activation partially restarts the Snort process, which temporarily interrupts the inspection of a few packets. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 172 for more information.

See the following behavior:

Firewall Threat Defense Behavior: If Snort is down, then AAB is triggered after the specified timer duration. If Snort is up, then AAB is never triggered, even if packet processing exceeds the configured timer.

Classic Device Behavior: AAB limits the time allowed to process packets through an interface. You balance packet processing delays with your network's tolerance for packet latency.

The feature functions with any deployment; however, it is most valuable in inline deployments.

Typically, you use Rule Latency Thresholding in the intrusion policy to fast-path packets after the latency threshold value is exceeded. Rule Latency Thresholding does not shut down the engine or generate troubleshooting data.

If detection is bypassed, the device generates a health monitoring alert.

By default the AAB is disabled; to enable AAB follow the steps described.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to edit advanced device settings, click **Edit** ( ).

Step 3 Click **Device**, then click **Edit** ( ) in the **Advanced Settings** section.

Step 4 Check **Automatic Application Bypass**.

Step 5 Enter a **Bypass Threshold** from 250 ms to 60,000 ms. The default setting is 3000 milliseconds (ms).

Step 6 Click **Save**.

What to do next

- Deploy configuration changes.

Configure Object Group Search

While operating, the Firewall Threat Defense device expands access control rules into multiple access control list entries based on the contents of any network or interface objects used in the access rule. You can reduce the memory required to search access control rules by enabling object group search. With object group search enabled, the system does not expand network or interface objects, but instead searches access rules for matches based on those group definitions. Object group search does not impact how your access rules are defined or how they appear in Firewall Management Center. It impacts only how the device interprets and processes them while matching connections to access control rules.

Enabling object group search reduces memory requirements for access control policies that include network or interface objects. However, it is important to note that object group search might also decrease rule lookup performance and thus increase CPU utilization. You should balance the CPU impact against the reduced memory requirements for your specific access control policy. In most cases, enabling object group search provides a net operational improvement.

By default, the object group search is enabled for the threat defense devices that are added for the first time in the Firewall Management Center. In the case of upgraded devices, if the device is configured with disabled object group search, then you need to manually enable it. You can enable it on one device at a time; you cannot enable it globally. We recommend that you enable it on any device to which you deploy access rules that use network or interface objects.

Note If you enable object group search and then configure and operate the device for a while, be aware that subsequently disabling the feature might lead to undesirable results. When you disable object group search, your existing access control rules will be expanded in the device's running configuration. If the expansion requires more memory than is available on the device, your device can be left in an inconsistent state and you might see a performance impact. If your device is operating normally, you should not disable object group search once you have enabled it.

Before you begin

- Model Support—Threat Defense
- We recommend that you also enable transactional commit on each device. From the device CLI, enter the **asp rule-engine transactional-commit access-group** command.
- Changing this setting can be disruptive to system operation while the device recompiles the ACLs. We recommend that you change this setting during a maintenance window.
- You can use FlexConfig to configure the **object-group-search threshold** command to enable a threshold to help prevent performance degradation. When operating with a threshold, for each connection, both the source and destination IP addresses are matched against network objects. If the number of objects matched by the source address times the number matched by the destination address exceeds 10,000, the connection is dropped. Configure your rules to prevent an excessive number of matches.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the Firewall Threat Defense device where you want to configure the rule, click the **Edit** ( ).

Step 3 Click the **Device** tab, then click the **Edit** ( ) in the **Advanced Settings** section.

Step 4 Check **Object Group Search**.

Step 5 To have object group search work on interface objects in addition to network objects, check **Interface Object Optimization**.

If you do not select **Interface Object Optimization**, the system deploys separate rules for each source/interface pair, rather that use the security zones and interface groups used in the rules. This means the interface groups are not available for object group search processing.

Step 6 Click **Save**.

Configure Interface Object Optimization

During deployment, interface groups and security zones used in the access control and prefilter policies generate separate rules for each source/destination interface pair. If you enable interface object optimization, the system will instead deploy a single rule per access control/prefilter rule, which can simplify the device configuration and improve deployment performance. If you select this option, also select the **Object Group Search** option to reduce memory usage on the device.

Interface object optimization is disabled by default. You can enable it on one device at a time; you cannot enable it globally.

Note If you disable interface object optimization, your existing access control rules will be deployed without using interface objects, which might make deployment take longer. In addition, if object group search is enabled, its benefits will not apply to interface objects, and you might see expansion in the access control rules in the device's running configuration. If the expansion requires more memory than is available on the device, your device can be left in an inconsistent state and you might see a performance impact.

Before you begin

Model Support—Threat Defense

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the Firewall Threat Defense device where you want to configure the rule, click the **Edit** ( ).

Step 3 Click the **Device** tab, then click **Edit** ( ) in the **Advanced Settings** section.

Step 4 Check **Interface Object Optimization**.

Step 5 Click **Save**.

Edit Deployment Settings

The **Deployment Settings** section of the **Device** page displays the information described in the table below.

Figure 41: Deployment Settings

Table 7: Deployment Settings

Field	Description
Auto Rollback Deployment if Connectivity Fails	Enabled or Disabled. You can enable auto rollback if the management connection fails as a result of the deployment; specifically if you use data for management center access, and then you misconfigure the data interface.
Connectivity Monitor Interval (in Minutes)	Shows the amount of time to wait before rolling back the configuration.

You can set deployment settings from the **Device Management** page. Deployment settings include enabling auto rollback of the deployment if the management connection fails as a result of the deployment; specifically if you use data for management center access, and then you misconfigure the data interface. You can alternatively manually roll back the configuration using the **configure policy rollback** command (see Manually Roll Back the Configuration if the Firewall Management Center Loses Connectivity, on page 118).

See the following guidelines:

- Only the previous deployment is available locally on the Firewall Threat Defense; you cannot roll back to any earlier deployments.
- Rollback is supported for high availability but not supported for clustering deployments.
- Rollback is not supported immediately after high availability creation.
- The rollback only affects configurations that you can set in the Firewall Management Center. For example, the rollback does not affect any local configuration related to the dedicated Management interface, which you can only configure at the Firewall Threat Defense CLI. Note that if you changed data interface settings after the last Firewall Management Center deployment using the **configure network management-data-interface** command, and then you use the rollback command, those settings will not be preserved; they will roll back to the last-deployed Firewall Management Center settings.
- UCAPL/CC mode cannot be rolled back.
- Out-of-band SCEP certificate data that was updated during the previous deployment cannot be rolled back.
- During the rollback, connections will drop because the current configuration will be cleared.

Procedure

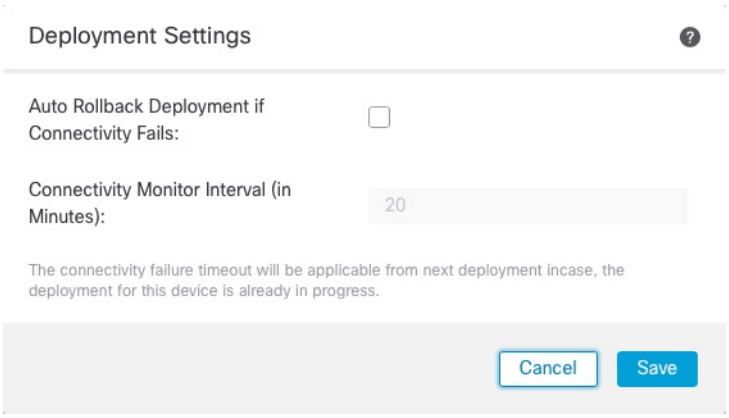
Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to assign policies, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 In the **Deployment Settings** section, click **Edit** ( ).

Figure 42: Deployment Settings



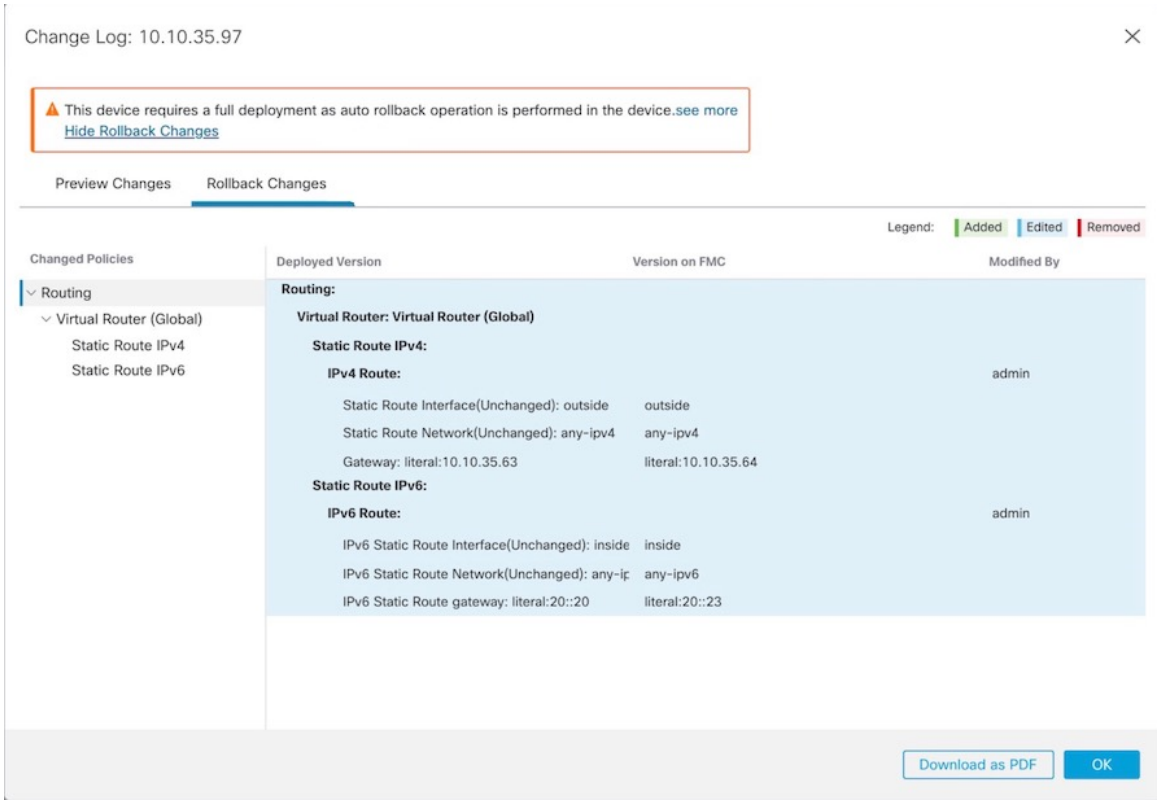
Step 5 Check **Auto Rollback Deployment if Connectivity Fails** to enable auto rollback.

Step 6 Set the **Connectivity Monitor Interval (in Minutes)** to set the amount of time to wait before rolling back the configuration. The default is 20 minutes.

Step 7 If a rollback occurs, see the following for next steps.

- If the auto rollback was successful, you see a success message instructing you to do a full deployment.
- You can also go to the **Deploy**and then **Advanced Deploy** screen and click the **Preview** ( ) icon to view the parts of the configuration that were rolled back (see Deploy Configuration Changes, on page 177). Click **Show Rollback Changes** to view the changes, and **Hide Rollback Changes** to hide the changes.

Figure 43: Rollback Changes



- In the Deployment History Preview, you can view the rollback changes. See View Deployment History, on page 185.

Step 8 Check that the management connection was reestablished.

In Firewall Management Center, check the management connection status on the connection status page. Navigate to **Devices** > **Device Management** and then in **Management** area under the **Devices** tab, click **Connection Status** to view the **Connection Status** page.

At the Firewall Threat Defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See Troubleshoot Management Connectivity on a Data Interface, on page 120.

Edit Cluster Health Monitor Settings

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings described in the table below.

Figure 44: Cluster Health Monitor Settings

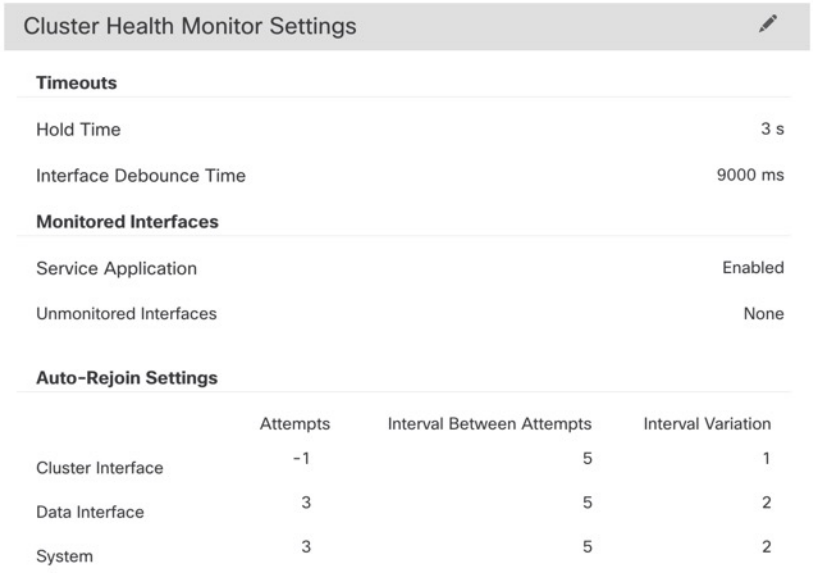


Table 8: Cluster Health Monitor Settings Section Table Fields

Field	Description
Timeouts	
Hold Time	Between .3 and 45 seconds; The default is 3 seconds. To determine node system health, the cluster nodes send heartbeat messages on the cluster control link to other nodes. If a node does not receive any heartbeat messages from a peer node within the hold time period, the peer node is considered unresponsive or dead.
Interface Debounce Time	Between 300 and 9000 ms. The default is 500 ms. The interface debounce time is the amount of time before the node considers an interface to be failed, and the node is removed from the cluster.

Field	Description
Monitored Interfaces	The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster.
Service Application	Shows whether the Snort and disk-full processes are monitored.
Unmonitored Interfaces	Shows unmonitored interfaces.
Auto-Rejoin Settings	
Cluster Interface	Shows the auto-rejoin settings after a cluster control link failure.
Attempts	Between -1 and 65535. The default is -1 (unlimited). Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 1x the interval duration. Defines if the interval duration increases at each attempt.
Data Interfaces	Shows the auto-rejoin settings after a data interface failure.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.
System	Shows the auto-rejoin settings after internal errors. Internal failures include: application sync timeout; inconsistent application statuses; and so on.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.

Note If you disable the system health check, fields that do not apply when the system health check is disabled will not show.

You can change these settings from this section.

You can monitor any port-channel ID, single physical interface ID, as well as the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link; it is always monitored.

Procedure

Step 1 Choose **Devices** > **Device Management**.

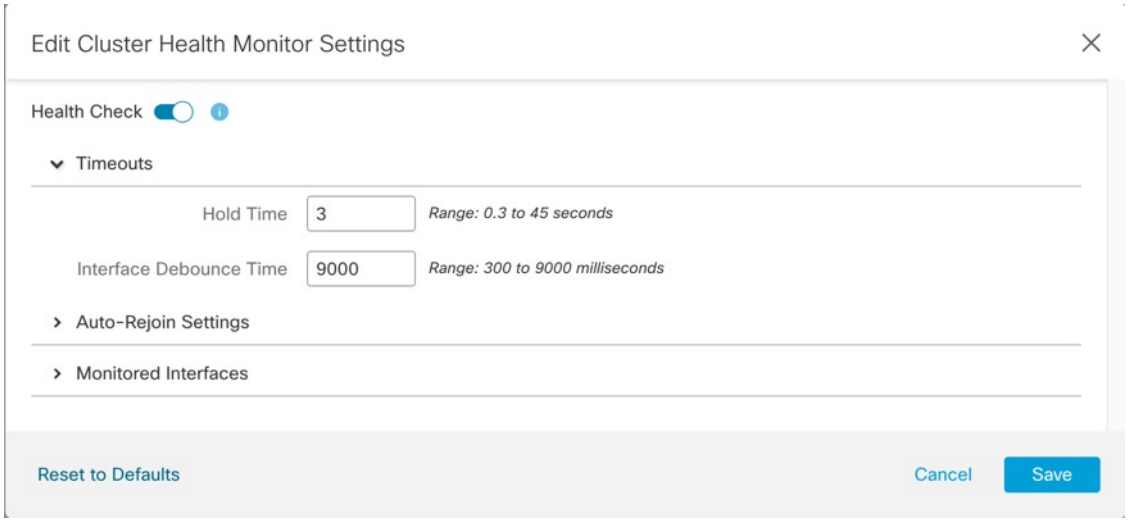
Step 2 Next to the cluster you want to modify, click **Edit** ( ).

Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider .

Figure 45: Disable the System Health Check



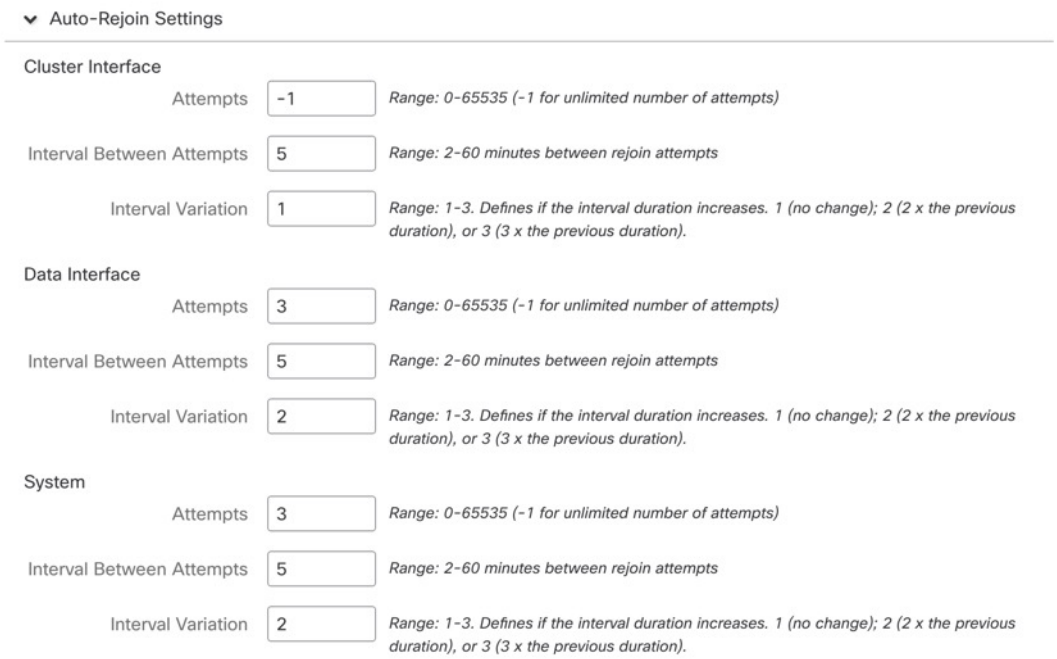
When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between .3 and 45 seconds; The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the number of milliseconds specified before marking the interface as failed, and the node is removed from the cluster. In the case of an EtherChannel that transitions from a down state to an up state (for example, the switch reloaded, or the switch enabled an EtherChannel), a longer debounce time can prevent the interface from appearing to be failed on a cluster node just because another cluster node was faster at bundling the ports.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 46: Configure Auto-Rejoin Settings

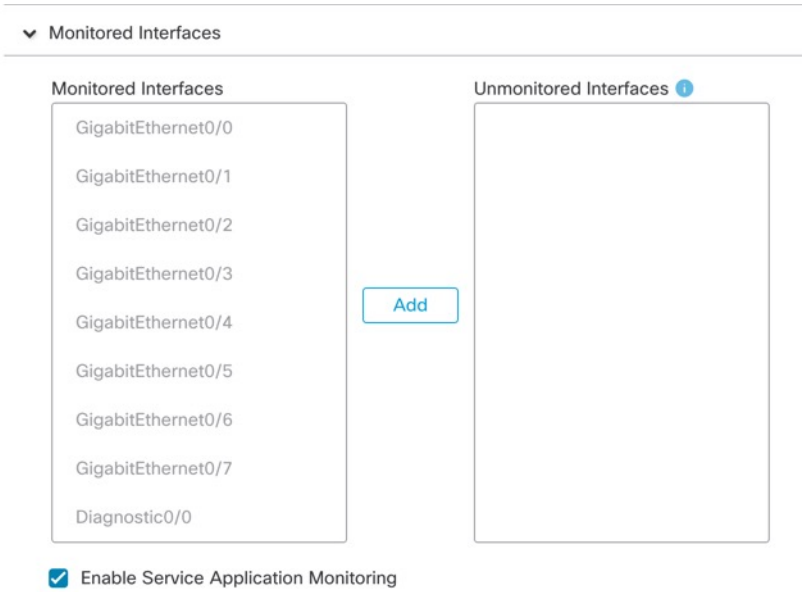


Set the following values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 47: Configure Monitored Interfaces



The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. Health check is enabled by default for all interfaces and for the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

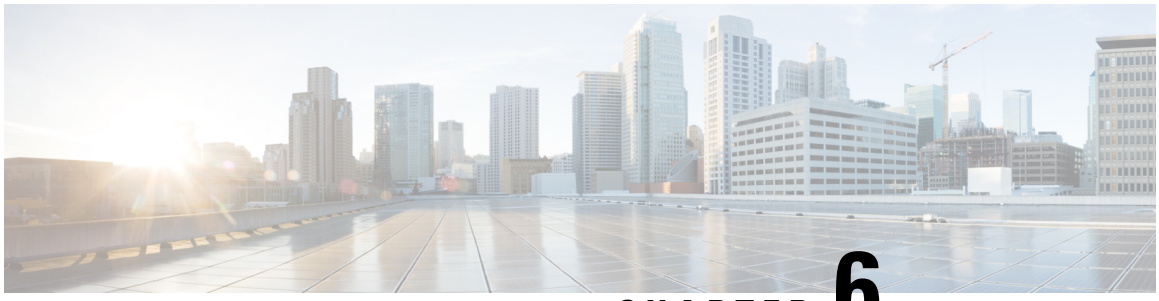
Step 9 Click **Save**.

Step 10 Deploy configuration changes.

History for Device Settings

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Cluster health monitor settings.	20221213	Any	You can now edit cluster health monitor settings. New/modified screens: **Devices** > **Device Management** > **Cluster** > **Cluster Health Monitor Settings** **Note** If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.
Redundant manager access data interface.	20221213	7.3.0	When you use a data interface for manager access, you can configure a secondary data interface to take over management functions if the primary interface goes down. The device uses SLA monitoring to track the viability of the static routes and an ECMP zone that contains both interfaces so management traffic can use both interfaces. New/modified screens: • **Devices** > **Device Management** > **Device** > **Management** • **Devices** > **Device Management** > **Device** > **Interfaces** > **Manager Access**
Policy rollback support for high availability devices.	20220609	7.2.0	The **configure policy rollback** command is supported for high availability devices.
Auto rollback of a deployment that causes a loss of management connectivity.	20220609		You can now enable auto rollback of the configuration if a deployment causes the management connection between the management center and the threat defense to go down. Previously, you could only manually rollback a configuration using the **configure policy rollback** command. New/modified screens: • **Devices** > **Device Management** > **Device** > **Deployment Settings** • **Deploy** > **Advanced Deploy** > **Preview** • **Deploy** > **Deployment History** > **Preview**
Object group search is enabled by default for access control rules.	20220609	7.2.0	The **Object Group Search** setting is enabled by default for managed devices starting with Version 7.2.0. This option is in the **Advanced Settings** section when editing device settings on the Device Management page.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Import and export device configurations.	20220609	7.2.0	You can export the device-specific configuration, and you can then import the saved configuration for the same device in the following use cases: • Moving the device to a different FMC. • Restore an old configuration. • Reregistering a device. New/modified screens: **Devices** > **Device Management** > **Device** > **General**
Update the FMC IP address on FTD.	20220609	7.0.3	If you change the FMC IP address, you can now use the FTD CLI to update the device. New/modified commands: **configure manager edit**



CHAPTER 6

Change Management

You can enable Change Management if your organization needs to implement more formal processes for configuration changes, including audit tracking and official approval before changes are deployed.

- About Change Management, on page 145
- Requirements and Prerequisites for Change Management, on page 148
- Guidelines and Limitations for Change Management, on page 149
- Enabling or Disabling Change Management, on page 150
- Managing Tickets, on page 150
- History for Change Management, on page 155

About Change Management

Some organizations need to implement a formal approach to deploying configuration changes. This might include more auditing, and an official approval process that must happen before configuration changes can be made to a device.

If your organization uses a more formal configuration change process, you can enable Change Management to enforce the process. With Change Management, administrators must open tickets before they can make configuration changes. Then, once the change is complete, they must submit the ticket for approval before they can deploy the proposed changes. This allows you to enforce your official approval process and ensure that the right employees make the final decisions.

When using Change Management, administrators can see their own changes within a ticket, but they cannot see changes anyone else has made within a ticket. Because a policy is locked once a user makes a change within a ticket, users should not be able to make interfering changes. However, users will not be able to make changes while another user has made a change that is pending approval.

Administrators can create multiple tickets so that a single ticket contains only logically-related policy changes. Tickets with a more limited scope are also easier to evaluate and approve quickly.

The following topics explain the Change Management Workflow and which policies and objects are subject to the ticketing and approval process.

How to Configure Devices in the Change Management Workflow

When you enable Change Management, users who configure devices need to change their approach slightly. Configuration specialists need to take the following approach when making configuration changes to supported policies and objects.

Procedure

Step 1 Create a ticket.

Step 2 Open the ticket.

Step 3 Make the configuration changes.

Note that the procedures explained in the online help and user guides assume that Change Management is not active, and omit any steps for creating, opening, or submitting tickets.

Step 4 Optionally, preview and validate the ticket to ensure the changes are complete and correct.

Step 5 Submit the ticket. At this point, the approver can either approve or reject the ticket.

- If the ticket is approved, deploy the changes.
- If the ticket is rejected, address the issues, and resubmit the ticket.

Creating Separate Approver and Configuration Roles

Some system-defined roles have permissions to modify (create/open/discard) and review (approve/reject) tickets:

- To both modify and review tickets:
  - Admin
- To modify tickets only:
  - Edit Only
- To review tickets only:
  - Deploy Only

Note A Read Only user cannot use the Change Management feature.

If you need more granular roles to separate these activities due to your organizational requirements, you can create separate roles to ensure that ticket approval is assigned only to those users who have the organizational authority to approve changes. To create a new user, navigate back to Security Cloud Control and from the Security Cloud Control navigation bar, choose **Settings** > **User Management**.

The approach you take depends on your precise requirements. For example:

- If your approvers should also be allowed to make configuration changes, you can simply assign them the system-defined roles, such as Administrator. Then, create custom configuration-only roles that include the same permissions but not the Review Tickets permission.
- If you need complete separation between approvers and those who make configuration changes, create custom roles for both, limiting the roles to either the Modify Tickets or the Review Tickets permission plus all other needed permissions for viewing or changing the supported policies and objects.

Policies and Objects that Support Change Management

If a policy or object supports the change management workflow, then creating, editing, or deleting the policy or object, including assigning a policy to a device, must be done in an open ticket.

Any action, policy, or object that does not support the change management workflow can be created, edited, or deleted, and so forth, without an open ticket. Even if a ticket is open, the changes made to unsupported policies are not included in the ticketed changes and are available for deployment immediately.

The following lists include the policies and objects that are supported. Anything not listed is unsupported.

Supported Policies

- Access Control, including rules, references to other policies, and inheritance settings. Cloning access control policies is not included within a ticket. The clone is immediately accepted and available to all users.
- Device Configuration policies:
  - Interfaces
  - Inline Sets
  - DHCP
  - VTEP
  - All Routing
- FlexConfig
- Intrusion policy and Network Analysis Policy (NAP), Snort 3 only.
- Network Address Translation (NAT)
- Platform Settings
- Prefilter
- QoS
- Umbrella SASE Topology
- VPN policies, both site-to-site and remote access
- Zero Trust Access

Supported Objects

- AAA Server
- Access List
- Address Pools
- AS Path
- Community List
- DHCP IPv6 Pools
- DNS Server Group
- FlexConfig objects
- Group policy
- Interface
- Key Chain
- Network
- Policy List
- Port
- Prefix List
- Route Map
- SLA Monitor
- Time Range
- Time Zone
- Tunnel Zone
- URL
- Variable Set
- VLAN Tag
- VPN objects (IKEv1, IKEv2 IPSec and policy, PKI enrollment, certificate map)

Requirements and Prerequisites for Change Management

Model Support

Management Center

User Roles

- To enable or disable Change Management: Admin.
- To both modify and review tickets:
  - Admin
- To modify tickets only:
  - Edit Only
- To review tickets only:
  - Deploy Only

Guidelines and Limitations for Change Management

- When operating in change management mode, users can make changes to supported policies, but they cannot save the changes. For example, you could go through the dialog box to create a new Platform Settings policy without an open ticket, but when you click OK to actually create the policy, you will get an error and the policy will not be created.
- The following activities require that all tickets be in a terminal state, that is, approved or discarded: backup/restore.
- Deleting a device from the inventory requires that all tickets involving that device be approved or discarded.
- Some processes, such as deployment and backup/restore, prevent you from changing the Change Management mode. Wait until the process completes to change the mode.
- Your ability to create objects while configuring a feature is constrained based on whether the feature and objects are all supported by change management. For example, importing a configuration is not supported by change management. Therefore, you cannot create security zone objects, which are supported, during the import. On the other hand, you can create new objects while configuring access control rules, because both are supported.

  When you create an object from Security Cloud Control, the system automatically creates a ticket internally and allows the object to be associated with the cloud-delivered Firewall Management Center. You do not have to create or have an open ticket to do this. However, when you want to create an object from the cloud-delivered Firewall Management Center, you need an existing ticket or create one. The object is synchronized to Security Cloud Control only after the ticket is approved.
- When using Cloud-Delivered Firewall Management Center, a user defined in Cisco Security Cloud Control is available to be assigned tickets only after the user cross-launches cdFMC at least once. Until the first cross-launch, the user does not exist in cdFMC.

Enabling or Disabling Change Management

The default is that the Change Management workflow is disabled. Users do not need to open tickets and get approval when making configuration changes. If you want to enforce the Change Management workflow, you must enable it globally for the system.

Before you begin

There are several system processes that prevent you from enabling/disabling change management. If any of the following are in process, you need to wait for them to complete before changing these settings: backup/restore; import/export; domain movement; upgrade; Flexconfig migration; device registration; high-availability registration, creation, break, or switch; cluster create, registration, break, edit, add or remove nodes; EPM break out or join.

An access control policy cannot be locked when you change these settings. If a policy is locked, you must wait for the lock to be released before enabling/disabling this feature.

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Change Management**.

Step 3 Select **Enable Change Management**.

To disable the feature, deselect the option. All tickets must be approved or discarded to disable Change Management. You cannot disable Change Management if any ticket is in the In Progress, On Hold, Rejected, or Pending Approval state.

Step 4 Select the **Number of approvals required**, which is how many administrators must approve the change for the ticket to be approved and deployable. The default is 1, but you can require up to 5 approvers per ticket. Users can override this number when creating tickets.

Step 5 Select the **Ticket Purge Duration**, which is the number of days to keep approved tickets, from 1-100 days. The default is 5 days.

Step 6 (Optional.) Enter the **Reply to Address** and the email addresses for the **List of Approver Addresses**. You must also configure the Email Notification system settings for email to work.

Step 7 Click **Save**.

The system adds the **Ticket** (📄) shortcut to the menu bar, and the **System** (⚙) > **Change Management Workflow** command. Users can manage tickets using these methods.

Managing Tickets

When you enable Change Management, configuration changes for supported policies must be done within the context of a ticket. You open a ticket, make your changes, then submit the ticket for approval.

You can see a list of tickets, and create new ones, either on the Change Management page or through the Ticket quick-access menu. All ticket changes are synchronized in each menu, so you can switch back and forth at your convenience and use whichever method you prefer.

Note When you open a ticket and make a change to a supported policy, that policy is locked from changes by other users or through other tickets. The policy remains locked until the ticket is approved or discarded.

Procedure

Step 1 Do any of the following:

- Choose **System** ( ) > **Change Management Workflow** to open a page showing existing tickets.
- Click the **Ticket** ( ) quick-access menu. The icon can either be named Select a Ticket (if no ticket is opened), the ticket name if a ticket is opened, or unnamed if no tickets exist.

Both pages are organized the same. The **Ticket** tab lists all tickets, whereas the **Review** tab lists tickets that have been submitted for approval. The default view shows your tickets only.

Step 2 On the **Ticket** tab, take any of these actions:

- To create a new ticket, click **Add Ticket**.
- To view the details of a ticket, click the > next to the ticket name. The Details page includes UUID, name, description, user, last modified date, and comments. The History page includes the status changes for the ticket. The image at the top shows where the ticket stands in the overall workflow.
- To preview the configuration changes for an open ticket, click **Preview** ( ).
- To validate the configuration changes in an open ticket, click **Validate** ( ) or **More** ( ) > **Validate**. A dialog box opens showing error, warning, and informational messages, if there are any validation errors.
- To open a ticket, click **Open** ( ) or **More** ( ) > **Open**.
- To close an open ticket, click **Put Ticket on Hold (X)** or **More** ( ) > **Put Ticket on Hold**. Closing a ticket does not submit it for review, nor does it release any locks placed on edited policies.
- To submit an open ticket for review and approval, click **Submit for Approval** ( ) or **More** ( ) > **Submit for Approval**. The ticket must be open to be submitted.
- To discard a ticket, click **Discard** ( ) or **More** ( ) > **Discard**.
- To search for a ticket, type a string in the search box. The search looks at ticket name, description, and responsible user.
- To filter the list by ticket status (on the Change Management Workflow page), click the status above the list: **New**, **Open**, **On Hold** (ticket was closed), **Rejected**, **Pending Approval**, **Approved**. Each status has a count of the number of tickets in that state. Click **All** under **My Tickets** to return to the default of showing all of your tickets, or **All** under **Tickets in System** to see everyone's tickets.

Step 3 On the **Reviews** tab, take any of these actions on submitted tickets. The list is empty if there are no submitted tickets. In addition, only users with Review Ticket permissions can see this tab.

- To preview the configuration changes for a ticket, click **Preview** ( ).
- To validate the configuration changes in an open ticket, click **Validate** ( ) or **More** ( ) > **Validate**.
- To approve the ticket, click **Approve** ( ) or **More** ( ) > **Approve**.
- To disapprove the ticket, click **Reject** ( ) or **More** ( ) > **Reject**.

Creating Change Management Tickets

When using the Change Management workflow, you must do all configuration changes within the context of an open ticket. If you do not already have a ticket, you must create a new one.

Procedure

Step 1 Choose **System** ( ) > **Change Management Workflow**, or click the **Ticket** ( ) shortcut menu.

Step 2 Click **Add Ticket**.

Step 3 Configure the ticket options:

- **Name**—The name of the ticket. The name can include letters, numbers, spaces, and the following special characters: #-_!
- **Description**—An optional description of what you intend to configure using this ticket. For example, if you have a case number related to what you intend to fix using this ticket, that would be useful information in a description.
- **Number of Approvers**—How many administrators must approve the change for the ticket to be approved and deployable. You can specify 1-5.
- **Assign to**—Select the user who will own the ticket and be responsible for implementing the changes. Choose **self** to assign it to yourself.

Step 4 Click one of the following: .

- **Create**—The ticket is added to the list of tickets, but it is not opened. You need to open it before you can work within the context of the ticket.
- **Create and Open**—The ticket is added to the list of tickets and also opened.

Opening a Ticket for Configuration Changes

Before you can make changes within a ticket, you must open the ticket.

If you have another ticket open, the system puts it on hold (closes it) for you before opening the new one.

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📄) shortcut menu.

Step 2 On the **Tickets** tab, click **Open** (📂) or **More** (⋮) > **Open** for the ticket.

Step 3 Optionally, enter a comment for the action.

Step 4 Click **Open**.

You can now start your configuration changes. The name of the Ticket icon changes to the name of the open ticket.

Previewing a Ticket

You can preview a ticket while making your configuration changes, or before approving it. The preview shows all configuration changes made within the context of the ticket.

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📄) shortcut menu.

Step 2 Click **Preview** (🔍) for the ticket.

The Preview dialog box opens. Changes are color coded according to the legend at the top of the dialog box.

Step 3 Select the policy whose changes you want to view in the Changed Policies list.

You are shown both the current version of the policy as it is defined in Secure Firewall Management Center (on the left) and the proposed changes defined within the ticket.

For policies that contain pages, such as Platform Settings, you can select the overall policy to see all changes, or specific pages within the policy, in the Changed Policies list.

You cannot alter the changes from within the preview. If you need to change something, you must close the preview and return to the policy you want to change.

Step 4 Optionally, click **Download as PDF** to save the preview to a PDF file for offline viewing or archival purposes.

Step 5 Click **OK**.

Submitting a Ticket

After you have completed the changes needed for a ticket, you can preview and validate the changes. Then, when you are satisfied with the changes, submit the ticket for review and approval.

Changes made within the ticket are not applied until you submit the ticket and the ticket is approved. Until approval happens, all policies modified within a ticket are locked to that ticket and cannot be changed by anyone else.

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📄) shortcut menu.

Step 2 Click **Submit for Approval** (⬆) or **More** (⋮) > **Submit for Approval** for the open ticket.

Step 3 Optionally, enter a comment for your action.

Step 4 Click **Submit**.

Discarding a Ticket

If you no longer need to make the changes for which you created a ticket, you can discard the ticket. When you discard a ticket, any changes that you made within the ticket are removed.

You cannot undo this action and retrieve a ticket with its changes. If you need them, you must create a new ticket and start over.

You cannot discard a ticket after you submit it. However, if the approver rejects the ticket, you can then discard it.

Note If you have permission to modify tickets, you can discard tickets that belong to another user. This makes it possible to deal with situations where an admin is on vacation or otherwise unavailable to manage an in-process ticket.

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📄) shortcut menu.

Step 2 Click **Discard** (🗑) or **More** (⋮) > **Discard** for the ticket.

Step 3 Optionally, enter a comment for your action.

Step 4 Click **Discard**.

Approving or Rejecting a Ticket

When a user submits a ticket, it must be approved for the changes made within the ticket to become active and available for deployment.

Whether you can approve your own tickets, or there is a separate approver, depends on your workplace policies and how user roles are assigned, not on the management software.

The Details view includes a summary of how many approvers are required for the ticket, and who has approved the ticket.

If the changes are inadequate or undesirable, you can reject the ticket. Rejected tickets go back to the submitter, who can then make additional changes and resubmit the ticket, or simply discard the ticket and the configuration changes it contains.

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📄) shortcut menu.

Step 2 On the **Review** tab, click **Preview** (📄) for the ticket and evaluate the proposed changes.

You can also click **Validate** (📄) or **More** (⋮) > **Validate** to check for errors.

Step 3 After completing your evaluation, do one of the following:

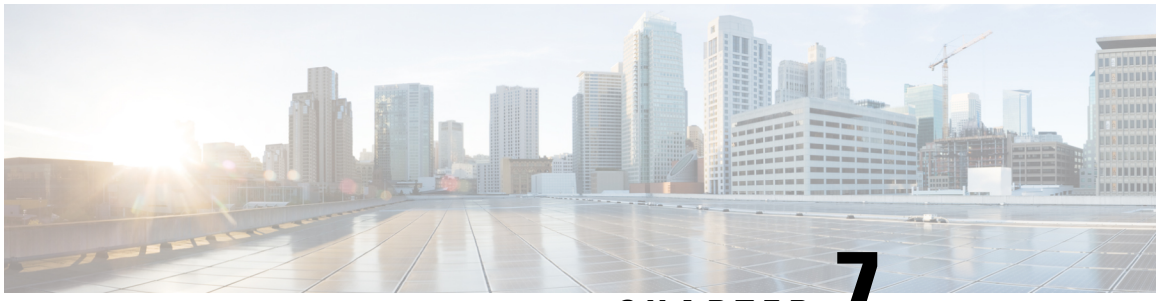
- To approve the ticket, click **Approve** (✓) or **More** (⋮) > **Approve**.
- To disapprove the ticket, click **Reject** (🚫) or **More** (⋮) > **Reject**.

Step 4 Optionally, enter a comment for your action.

Step 5 Click **Approve** or **Reject**, as appropriate.

History for Change Management

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Change management.	20240514	Any	You can enable change management if your organization needs to implement more formal processes for configuration changes, including audit tracking and official approval before changes are deployed. We added the **System**(⚙) > **Configuration** > **Change Management** page to enable the feature. When enabled, there is a **System**(⚙) > **Change Management Workflow** page, and a new **Ticket**(📄) quick access icon in the menu. See: Change Management



CHAPTER 7

Users

Managed devices include a default **admin** account for CLI access. This chapter discusses how to create custom user accounts.

- About Users, on page 157
- Requirements and Prerequisites for User Accounts for Devices, on page 158
- Guidelines and Limitations for User Accounts for Devices, on page 159
- Add an Internal User at the CLI, on page 159
- Troubleshooting LDAP Authentication Connections, on page 161

About Users

You can add custom user accounts on managed devices, either as internal users or as external users on a LDAP or RADIUS server. Each managed device maintains separate user accounts. For example, when you add a user to the Firewall Management Center, that user only has access to the Firewall Management Center; you cannot then use that username to log directly into a managed device. You must separately add a user on the managed device.

Internal and External Users

Managed devices support two types of users:

- Internal user—The device checks a local database for user authentication.
- External user—If the user is not present in the local database, the system queries an external LDAP or RADIUS authentication server.

CLI Access

Firepower devices include a Firepower CLI that runs on top of Linux. You can create internal users on devices using the CLI. You can establish external users on Firewall Threat Defense devices using the Firewall Management Center.

Caution Users with CLI Config level access can access the Linux shell using the **expert** command, and obtain `sudoers` privileges in the Linux shell, which can present a security risk. For system security reasons, we strongly recommend:

- Only use the Linux shell under TAC supervision or when explicitly instructed by Firepower user documentation.
- Make sure that you restrict the list of users with CLI access appropriately.
- When granting CLI access privileges, restrict the list of users with Config level access.
- Do not add users directly in the Linux shell; only use the procedures in this chapter.
- Do not access Firepower devices using CLI expert mode unless directed by Cisco TAC or by explicit instructions in the Firepower user documentation.

CLI User Roles

On managed devices, user access to commands in the CLI depends on the role you assign.

None

The user cannot log into the device on the command line.

Config

The user can access all commands, including configuration commands. Exercise caution in assigning this level of access to users.

Basic

The user can access non-configuration commands only. Only internal users and Firewall Threat Defense external RADIUS users support the Basic role.

Requirements and Prerequisites for User Accounts for Devices

Model Support

- Threat Defense—Internal and external users

Supported Domains

Any

User Roles

Configure external users—Super Admin or Admin user

Configure internal users—Super Admin or Admin user

Guidelines and Limitations for User Accounts for Devices

Usernames

- You cannot add the same username for both internal and external users. If the external server uses a duplicate username, the deployment to the device fails.
- The username must be Linux-valid:
  - Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
  - All lowercase
  - Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Defaults

All devices include an **admin** user as a local user account; you cannot delete the **admin** user. The default initial password is **Admin123**; the system forces you to change this during the initialization process. The agent stores the modified credentials in the Windows registry and uses the same encryption as the Firewall Management Center, which is Cipher Block Chaining (CBC). See the getting started guide for your model for more information about system initialization.

Number of User Accounts

You can create a maximum of 43 user accounts for the Firepower 1000 and 2100.

Add an Internal User at the CLI

Use the CLI to create internal users on the Firewall Threat Defense.

Procedure

Step 1 Log into the device CLI using an account with Config privileges.

The **admin** user account has the required privileges, but any account with Config privileges will work. You can use an SSH session or the Console port.

For certain Firewall Threat Defense models, the Console port puts you into the FXOS CLI. Use the **connect ftd** command to get to the Firewall Threat Defense CLI.

Step 2 Create the user account.

configure user add *username* {**basic** | **config**}

- *username*—Sets the username. The username must be Linux-valid:
  - Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)

- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

- **basic**—Gives the user basic access. This role does not allow the user to enter configuration commands.
- **config**—Gives the user configuration access. This role gives the user full administrator rights to all commands.

Example:

The following example adds a user account named johncrichton with Config access rights. The password is not shown as you type it.

```
> configure user add johncrichton config
Enter new password for user johncrichton: newpassword
Confirm new password for user johncrichton: newpassword
> show user
Login              UID   Auth Access  Enabled Reset    Exp Warn  Str Lock Max
admin             1000  Local Config  Enabled    No  Never  N/A  Dis   No N/A
johncrichton      1001  Local Config  Enabled    No  Never  N/A  Dis   No   5
```

Note
Tell users they can change their own passwords using the **configure password** command.

Step 3 (Optional) Adjust the characteristics of the account to meet your security requirements.

You can use the following commands to change the default account behavior.

- **configure user aging** *username max_days warn_days*

  Sets an expiration date for the user's password. Specify the maximum number of days for the password to be valid followed by the number of days before expiration the user will be warned about the upcoming expiration. Both values are 1 to 9999, but the warning days must be less than the maximum days. When you create the account, there is no expiration date for the password.

- **configure user forcereset** *username*

  Forces the user to change the password on the next login.

- **configure user maxfailedlogins** *username number*

  Sets the maximum number of consecutive failed logins you will allow before locking the account, from 1 to 9999. Use the **configure user unlock** command to unlock accounts. The default for new accounts is 5 consecutive failed logins.

- **configure user minpasswdlen** *username number*

  Sets a minimum password length, which can be from 1 to 127.

- **configure user strengthcheck** *username* {**enable** | **disable**}

  Enables or disables password strength checking, which requires a user to meet specific password criteria when changing their password. When a user's password expires or if the **configure user forcereset** command is used, this requirement is automatically enabled the next time the user logs in.

Step 4 Manage user accounts as necessary.

Users can get locked out of their accounts, or you might need to remove accounts or fix other issues. Use the following commands to manage the user accounts on the system.

- **configure user access** *username* {**basic** | **config**}

  Changes the privileges for a user account.

- **configure user delete** *username*

  Deletes the specified account.

- **configure user disable** *username*

  Disables the specified account without deleting it. The user cannot log in until you enable the account.

- **configure user enable** *username*

  Enables the specified account.

- **configure user password** *username*

  Changes the password for the specified user. Users should normally change their own password using the **configure password** command.

  Caution
  Do not use the Linux **passwd** command in Expert Mode to change the admin user password. This command can cause file system corruption. Only use the regular Firewall Threat Defense CLI **configure user password admin** command (if you are not admin) or **configure password** command (if you are admin). If you don't know the password and can't log in at all, see the password recovery procedure.

- **configure user unlock** *username*

  Unlocks a user account that was locked due to exceeding the maximum number of consecutive failed login attempts.

Troubleshooting LDAP Authentication Connections

If you create an LDAP authentication object and it either does not succeed in connecting to the server you select or does not retrieve the list of users you want, you can tune the settings in the object.

If the connection fails when you test it, try the following suggestions to troubleshoot your configuration:

- Use the messages displayed at the top of the web interface screen and in the test output to determine which areas of the object are causing the issue.
- Check that the user name and password you used for the object are valid:
  - Check that you have the rights to browse to the directory indicated in your base-distinguished name by connecting to the LDAP server using a third-party LDAP browser.
  - Check that the user name is unique to the directory information tree for the LDAP server.
  - If you see an LDAP bind error 49 in the test output, the user binding for the user failed. Try authenticating to the server through a third-party application to see if the binding fails through that connection as well.

- Check that you have correctly identified the server:
  - Check that the server IP address or host name is correct.
  - Check that you have TCP/IP access from your local appliance to the authentication server where you want to connect.
  - Check that access to the server is not blocked by a firewall and that the port you have configured in the object is open.
  - If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used for the server.
  - Check that you have not used an IPv6 address for the server connection if you are authenticating CLI access.
  - If you used server type defaults, check that you have the correct server type and click **Set Defaults** again to reset the default values.
- If you typed in your base-distinguished name, click **Fetch DNs** to retrieve all the available base distinguished names on the server, and select the name from the list.
- If you are using any filters, access attributes, or advanced settings, check that each is valid and typed correctly.
- If you are using any filters, access attributes, or advanced settings, try removing each setting and testing the object without it.
- If you are using a base filter or a CLI access filter, make sure that the filter is enclosed in parentheses and that you are using a valid comparison operator (maximum 450 characters, including the enclosing parentheses).
- To test a more restricted base filter, try setting it to the base distinguished name for the user to retrieve just that user.
- If you are using an encrypted connection:
  - Check that the name of the LDAP server in the certificate matches the host name that you use to connect.
  - Check that you have not used an IPv6 address with an encrypted server connection.
- If you are using a test user, make sure that the user name and password are typed correctly.
- If you are using a test user, remove the user credentials and test the object.
- Test the query that you are using by connecting to the LDAP server and using this syntax:

```
ldapsearch -x -b 'base_distinguished_name'
-h LDAPserver_ip_address -p port -v -D
'user_distinguished_name' -W 'base_filter'
```

For example, if you are trying to connect to the security domain on `myrtle.example.com` using the `domainadmin@myrtle.example.com` user and a base filter of (`cn=*`), you could test the connection using this statement:

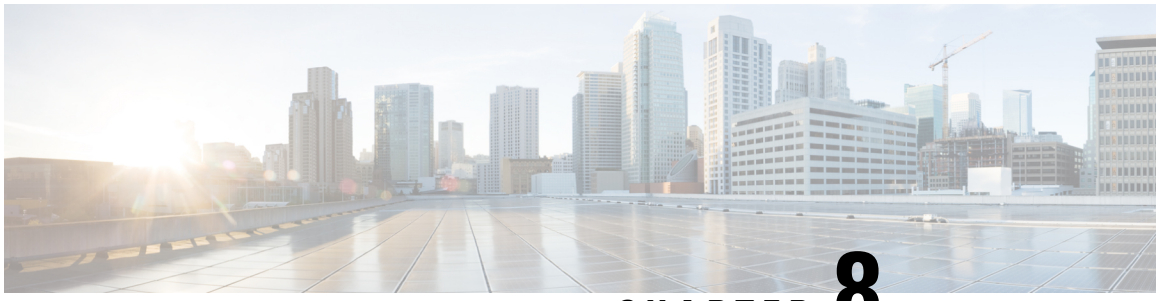
```
ldapsearch -x -b 'CN=security,DC=myrtle,DC=example,DC=com'
```

```
-h myrtle.example.com -p 389 -v -D
'domainadmin@myrtle.example.com' -W '(cn=*)'
```

If you can test your connection successfully but authentication does not work after you deploy a platform settings policy, check that authentication and the object you want to use are both enabled in the platform settings policy that is applied to the device.

If you connect successfully but want to adjust the list of users retrieved by your connection, you can add or change a base filter or CLI access filter or use a more restrictive or less restrictive base DN.

While authenticating a connection to Active Directory (AD) server, rarely the connection event log indicates blocked LDAP traffic although the connection to AD server is successful. This incorrect connection log occurs when the AD server sends a duplicate reset packet. The Firewall Threat Defense device identifies the second reset packet as part of a new connection request and logs the connection with Block action.



CHAPTER 8

Configuration Deployment

This chapter describes how to download configuration changes to one or more managed devices.

- About Configuration Deployment, on page 165
- Requirements and Prerequisites for Policy Management, on page 175
- Best Practices for Deploying Configuration Changes, on page 176
- Deploy the Configuration, on page 177
- Manage Deployments, on page 185
- History for Configuration Deployment, on page 193

About Configuration Deployment

All device configuration is managed by the Firewall Management Center and then deployed to the managed devices.

Configuration Changes that Require Deployment

The system marks out-of-date policies with red status text that indicates how many of its targeted devices need a policy update. To clear this status, you must re-deploy the policy to the devices.

Deployment Required

Configuration changes that require a deployment include:

- Modifying an access control policy: any changes to access control rules, the default action, policy targets, Security Intelligence filtering, advanced options including preprocessing, and so on.
- Modifying any of the policies that the access control policy invokes: the SSL policy, network analysis policies, intrusion policies, file policies, identity policies, or DNS policies.
- Changing any reusable object or configuration used in an access control policy or policies it invokes:
  - network, port, VLAN tag, URL, and geolocation objects
  - Security Intelligence lists and feeds
  - application filters or detectors
  - intrusion policy variable sets

- file lists
- decryption-related objects and security zones

- Updating the system software, intrusion rules, or the vulnerability database (VDB).

Keep in mind that you can change some of these configurations from multiple places in the web interface. For example, you can modify security zones using the object manager (**Objects** > **Object Management**), but modifying an interface type in a device's configuration (**Devices** > **Device Management**) can also change a zone and require a deployment.

Deployment Not Required

Note that the following updates do **not** require a deployment:

- automatic updates to Security Intelligence feeds and additions to the Security Intelligence global Block or Do Not Block list using the context menu
- automatic updates to URL filtering data
- scheduled geolocation database (GeoDB) updates

Deployment Preview

Preview provides a snapshot of all the policy and object changes to be deployed on the device. The policy changes include the new policies, changes in the existing policies, and the deleted policies. The object changes include the added and modified objects which are used in policies. The unused object changes are not displayed because they are not deployed on the device.

The preview shows all the default values, even when they are not altered, along with the other configured settings when an interface or a platform settings policy is added for the first time. Similarly, the high availability-related policies and default values for settings are shown, even when they are not altered, in the first preview after a high availability pair is configured or disrupted.

To view changes due to an auto rollback, see Edit Deployment Settings, on page 135.

Unsupported Features

- Object additions and attribute changes are displayed in the preview only if the objects are associated with any device or interface. Object deletions are not displayed.
- Preview is not supported for the following policies:
  - High availability
  - Network discovery
  - Network analysis
  - Device settings
- User information at the rule level is not available for intrusion policies.
- The preview does not show the reordering of rules across policies.

For DNS policies, reordered rules appear in the preview list as rule additions and deletions. For example, moving a rule from position 1 to position 3 in the rule order is displayed as if the rule was deleted from position 1 and added as a new rule in position 3. Similarly, when a rule is deleted, the rules under it are listed as edited rules as they have changed their positions. The changes are displayed in the final order in which they appear in the policy.

- Preview is not supported in the following HA scenarios:
  - If a device was in standalone mode and if a chain is made, then an auto-deployment is triggered. For that particular job, preview is not supported. On hover over the **Preview** (), a message is displayed that it is a HA bootstrap deployment, and no preview is supported.
  - **Configuration groups** - Consider a flow in which a device was initially standalone. Subsequently, three deployments took place. In the fourth deployment, the device was a HA bootstrap deployment. After these, the user deploys devices 5, 6, and 7. The deployment 7 is an HA break deployment, and the user deploys devices 8, 9, and 10.

    In this flow, the preview between 3 and 5 is not supported because 4 was a HA deployment. Similarly, the preview between 8 and 3 is also not supported. Preview is supported only from 3 to 1, 7,6, 5, 4, and 10, 9, and 8.
  - If a device is broken (HA is broken) then the new device is considered as a fresh device.

Selective Policy Deployment

The Firewall Management Center allows you to select a specific policy within the list of all the changes on the device that are due for deployment and deploy only the selected policy. Selective deployment is available only for the following policies:

- Access control policies
- Intrusion policies
- Malware and file policies
- DNS policies
- Identity policies
- SSL policies
- QoS policies
- Prefilter policies
- Network discovery
- NAT policies
- Routing policies
- VPN policies

There are certain limitations to selectively deploying policies. Follow the contents in the table below to understand when selective policy deployment can be used.

Table 9: Limitations for Selective Deployment

Type	Description	Scenarios
Full deployment	Full deployment is necessary for specific deploy scenarios, and the Firewall Management Center does not support selective deployment in such scenarios. If you encounter an error in such scenarios, you may choose to proceed by selecting all the changes for deployment on the device.	Scenarios wherein a full deployment is required are: • The first deployment after you have upgraded the Firewall Threat Defense or the Firewall Management Center. • The first deployment after you have restored the Firewall Threat Defense. • The first deployment after modifications in the Firewall Threat Defense interface settings. • The first deployment after modifications in the virtual router settings. • When the Firewall Threat Defense device is moved to a new domain (global to sub-domain or sub-domain to global).
Associated policy deployment	The Firewall Management Center identifies interdependent policies which are interlinked. When one of the interlinked policies is selected, the remaining interlinked policies are automatically selected.	Scenarios wherein an associated policy is automatically selected: • When a new object is associated with an existing policy. • When an existing policy's object is modified. Scenarios wherein multiple policies are automatically selected: • When a new object is associated with an existing policy, and the same object is already associated with other policies, all the associated policies are automatically selected. • When a shared object is modified, all the associated policies are automatically selected.

Type	Description	Scenarios
Interdependent policy changes (shown using color-coded tags)	The Firewall Management Center dynamically detects dependencies in-between policies, and between the shared objects and the policies. The interdependency of the objects or policies is shown using color-coded tags.	Scenarios wherein color-coded interdependent policies or objects are automatically selected: • When all the out-of-date policies have interdependent changes. For example, when an access control policy, an intrusion policy, and a NAT policy are out-of-date. Since access control policy and NAT policy share an object, all policies are selected together for deployment. • When all out-of-date policies share an object, and the object is modified.
Access Policy Group specifications	Access Policy Group policies are listed together in the preview window under **Access Policy Group** when you click **View** ( ).	The scenarios and the expected behavior for Access Policy Group policies are: • If the access control policy is out-of-date, all other out-of-date policies under this group, except file policy and intrusion policy, are selected when the access control policy is selected for deployment. However, if the access control policy is out-of-date, intrusion and file policies can be individually selected or deselected irrespective of whether the access control policy is selected or not, unless there are any dependent changes. For example, if a new intrusion policy is assigned to an access control rule, it indicates that there are dependent changes, then both the access control policy and the intrusion policy will be automatically selected when either of them is selected. • If no access control policy is out-of-date, other out-of-date policies in this group can be selected and deployed individually.

System Username

The Firewall Management Center displays the username as **system** for the following operations:

- Rollback
- Upgrade
- Firewall Threat Defense backup and restore
- SRU update

- LSP update
- VDB update

Auto-Enabling of Application Detectors

If you are performing application control but disable required detectors, the system automatically enables the appropriate system-provided detectors upon policy deploy. If none exist, the system enables the most recently modified user-defined detector for the application.

Asset Rediscovery with Network Discovery Policy Changes

When you deploy changes to a network discovery policy, the system deletes and then rediscovers MAC address, TTL, and hops information from the network map for the hosts in your monitored networks. Also, the affected managed devices discard any discovery data that has not yet been sent to the Firewall Management Center.

Snort Restart Scenarios

When the traffic inspection engine referred to as *the Snort process* on a managed device restarts, inspection is interrupted until the process resumes. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 172 for more information. Additionally, resource demands may result in a small number of packets dropping without inspection when you deploy, regardless of whether the Snort process restarts.

Any of the scenarios in the following table cause the Snort process to restart.

Table 10: Snort Restart Scenarios

Restart Scenario	More Information
Deploying a specific configuration that requires the Snort process to restart.	Configurations that Restart the Snort Process When Deployed or Activated, on page 174
Modifying a configuration that immediately restarts the Snort process.	Changes that Immediately Restart the Snort Process, on page 175
Traffic-activation of the currently deployed Automatic Application Bypass (AAB) configuration.	Configure Automatic Application Bypass, on page 132
Enabling or disabling "Logging connection events to RAM disk" feature.	See the section **Log to Ramdisk** in Troubleshoot Drain of FMC Unprocessed Events.

Related Topics

Access Control Policy Advanced Settings, on page 1802
Configurations that Restart the Snort Process When Deployed or Activated, on page 174

Restart Warnings for Devices

When you deploy, the **Inspect Interruption** column in the deploy page specifies whether a deployed configuration restarts the Snort process on the Firewall Threat Defense device. When the traffic inspection

engine referred to as *the Snort process* restarts, inspection is interrupted until the process resumes. Whether traffic is interrupted or passes without inspection during the interruption depends on how the device handles traffic. Note that you can proceed with the deployment, cancel the deployment and modify the configuration, or delay the deployment until a time when deploying would have the least impact on your network.

When the **Inspect Interruption** column indicates **Yes** and you expand the device configuration listing, the system indicates any specific configuration type that would restart the Snort process with an **Inspect Interruption** ( ). When you hover your mouse over the icon, a message informs you that deploying the configuration may interrupt traffic.

The following table summarizes how the deploy page displays inspection interruption warnings.

Table 11: Inspection Interruption Indicators

Type	Inspect Interruption	Description
Firewall Threat Defense	**Inspect Interruption** ( )Yes	At least one configuration would interrupt inspection on the device if deployed, and might interrupt traffic depending on how the device handles traffic. You can expand the device configuration listing for more information.
	--	Deployed configurations will not interrupt traffic on the device.
	Undetermined	The system cannot determine if a deployed configuration may interrupt traffic on the device. Undetermined status is displayed before the first deployment after a software upgrade, or in some cases during a Support call.
	Errors ( )	The system cannot determine the status due to an internal error. Cancel the operation and click **Deploy** again to allow the system to redetermine the **Inspect Interruption** status. If the problem persists, contact Support.
sensor	--	The device identified as *sensor* is not the Firewall Threat Defense device; the system does not determine if a deployed configuration may interrupt traffic on this device.

For information on all configurations that restart the Snort process for all device types, see Configurations that Restart the Snort Process When Deployed or Activated, on page 174.

Inspect Traffic During Policy Apply

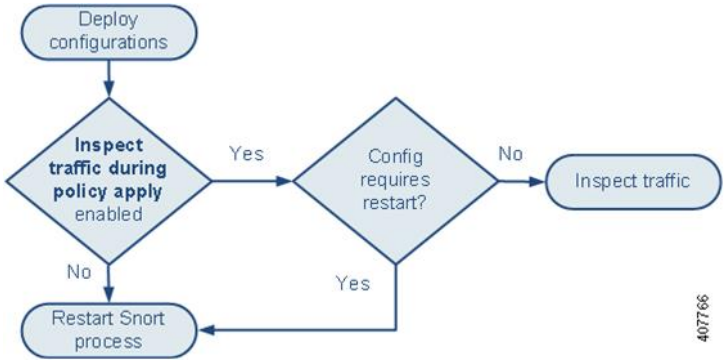
Inspect traffic during policy apply is an advanced access control policy general setting that allows managed devices to inspect traffic while deploying configuration changes; this is the case unless a configuration that you deploy requires the Snort process to restart. You can configure this option as follows:

- Enabled — Traffic is inspected during the deployment unless certain configurations require the Snort process to restart.

  When the configurations you deploy do not require a Snort restart, the system initially uses the currently deployed access control policy to inspect traffic, and switches during deployment to the access control policy you are deploying.

- Disabled — Traffic is not inspected during the deployment. The Snort process always restarts when you deploy.

The following graphic illustrates how Snort restarts can occur when you enable or disable **Inspect traffic during policy apply**.



Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 172 and Configurations that Restart the Snort Process When Deployed or Activated, on page 174.

Snort Restart Traffic Behavior

The following tables explain how different devices handle traffic when the Snort process restarts.

Table 12: The Firewall Threat Defense and the Firewall Threat Defense Virtual Restart Traffic Effects

Interface Configuration	Restart Traffic Behavior
inline: **Snort Fail Open: Down**: disabled	dropped
inline: **Snort Fail Open: Down**: enabled	passed without inspection Some packets can be delayed in buffer for several seconds before the system recognizes that Snort is down. This delay can vary depending upon the load distribution. However, the buffered packets are eventually passed.

Interface Configuration	Restart Traffic Behavior
routed, transparent (including EtherChannel, redundant, subinterface): **preserve-connection** enabled (**configure snort preserve-connection enable**; default) For more information, see Cisco Secure Firewall Threat Defense Command Reference.	existing TCP/UDP flows: passed without inspection so long as at least one packet arrives while Snort is down new TCP/UDP flows and all non-TCP/UDP flows: dropped Note that the following traffic drops even when **preserve-connection** is enabled: • plaintext, passthrough prefilter tunnel traffic that matches an **Analyze** rule action or an **Analyze all tunnel traffic** default policy action • connections that do not match an access control rule and are instead handled by the default action. • decrypted TLS/SSL traffic • a safe search flow • a captive portal flow
routed, transparent (including EtherChannel, redundant, subinterface): **preserve-connection** disabled (**configure snort preserve-connection disable**)	dropped
inline: tap mode	egress packet immediately, copy bypasses Snort
passive	uninterrupted, not inspected

Note In addition to traffic handling when the Snort process is down while it restarts, traffic can also pass without inspection or drop when the Snort process is busy, depending on the configuration of the Snort Fail Open **Busy** option (see Configure an Inline Set, on page 993). A device supports either the Failsafe option or the Snort Fail Open option, but not both.

Note When the Snort process is busy but not down during configuration deployment, some packets may drop on routed, switched, or transparent interfaces if the total CPU load exceeds 60 percent.

Warning Do not reboot the system while the Snort Rule Update is in progress.

Snort-busy drops happen when snort is not able to process the packets fast enough. Lina does not know whether Snort is busy due to processing delay, or if is stuck or due to call blocking. When transmission queue is full, snort-busy drops occur. Based on Transmission queue utilization, Lina will try to access if the queue is being serviced smoothly.

Configurations that Restart the Snort Process When Deployed or Activated

Deploying any of the following configurations except AAB restarts the Snort process as described. Deploying AAB does not cause a restart, but excessive packet latency activates the currently deployed AAB configuration, causing a partial restart of the Snort process.

Access Control Policy Advanced Settings

- Deploy when **Inspect Traffic During Policy Apply** is disabled.
- Add or remove an SSL policy.

File Policy

Deploy the first or last of any one of the following configurations; note that while otherwise deploying these file policy configurations does not cause a restart, deploying non-file-policy configurations can cause restarts.

- Take either of the following actions:
  - Enable or disable **Inspect Archives** when the deployed access control policy includes at least one file policy.
  - Add the first or remove the last file policy rule when **Inspect Archives** is enabled (note that at least one rule is required for **Inspect Archives** to be meaningful).
- Enable or disable **Store files** in a **Detect Files** or **Block Files** rule.
- Add the first or remove the last active file rule that combines the **Malware Cloud Lookup** or **Block Malware** rule action with an analysis option (**Spero Analysis or MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware, Unknown**, **Clean**, or **Custom**).

Note that access control rules that deploy these file policy configurations to security zones or tunnel zones cause a restart only when your configuration meets the following conditions:

- Source or destination security zones in your access control rule must match the security zones associated with interfaces on the target devices.
- Unless the destination zone in you access control rule is *any*, a source tunnel zone in the rule must match a tunnel zone assigned to a tunnel rule in the prefilter policy.

Identity Policy

- When SSL decryption is disabled (that is, when the access control policy does not include an SSL policy), add the first or remove the last active authentication rule.

  An active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

Network Discovery

- Enable or disable non-authoritative, traffic-based user detection over the HTTP, FTP, or MDNS protocols, using the network discovery policy.

Device Management

- MTU: Change the highest MTU value among all non-management interfaces on a device.
- Automatic Application Bypass (AAB): The currently deployed AAB configuration activates when a malfunction of the Snort process or a device misconfiguration causes a single packet to use an excessive amount of processing time. The result is a partial restart of the Snort process to alleviate extremely high latency or prevent a complete traffic stall. This partial restart causes a few packets to pass without inspection, or drop, depending on how the device handles traffic.

Updates

- System update: Deploy configurations the first time after a software update that includes a new version of the Snort binary or data acquisition library (DAQ).
- For managed devices running Snort 3, deploying configurations the first time after installing a vulnerability database (VDB) update may temporarily interrupt application detection, but there will be no traffic interruptions.

Related Topics

Deploy Configuration Changes, on page 177
Snort Restart Scenarios, on page 170

Changes that Immediately Restart the Snort Process

The following changes immediately restart the Snort process without going through the deploy process. How the restart affects traffic depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 172 for more information.

- Take any of the following actions involving applications or application detectors:
  - Activate or deactivate a system or custom application detector.
  - Delete an activated custom detector.
  - **Save and Reactivate** an activated custom detector.
  - Create a user-defined application.

  A message warns you that continuing restarts the Snort process, and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains.
- Create or break a Firewall Threat Defense high availability pair.

  A message warns you that continuing to create a high availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Best Practices for Deploying Configuration Changes

The following are guidelines for deploying configuration changes.

Reliable Management Connection

The management connection between the Firewall Management Center and the device is a secure, TLS-1.3-encrypted communication channel between itself and the device.

You do not need to run this traffic over an additional encrypted tunnel such as Site-to-Site VPN for security purposes. If the VPN goes down, for example, you will lose your management connection, so we recommend a simple management path.

Caution We recommend against a device's management connection going through a VPN tunnel that terminates on the device itself. If you deploy a configuration change that causes the VPN to go down, the management connection will be disconnected and you will not have any way to recover the configuration without connecting directly to the device.

If management traffic exits a VPN-terminating interface, be sure to exclude the management traffic from the VPN tunnel.

Maximum Concurrent Deployments

You should not deploy to more than 25% of the maximum devices allowed for a Firewall Management Center in the same job. For example, for the FMCv300, the maximum job size should be 75 devices (25% of 300). Concurrent deployment to more devices can cause performance issues.

Deployment of Shared Policies

For best performance, deploy to devices that use the same policies. Create separate deployment jobs for each group of devices that share policies.

Time to Deploy and Memory Limitations

The time it takes to deploy depends on multiple factors, including (but not limited to):

- The configurations you send to the device. For example, if you dramatically increase the number of Security Intelligence entries you block, deployment can take longer.
- Device model and memory. On lower-memory devices, deploying can take longer.

Do not exceed the capability of your devices. If you exceed the maximum number of rules or policies supported by a target device, the system displays a warning. The maximum depends on a number of factors—not only memory and the number of processors on the device, but also on policy and rule complexity. For information on optimizing policies and rules, see Best Practices for Access Control Rules, on page 1785.

Use a Maintenance Window to Lessen the Impact of Traffic Interruptions

We *strongly* recommend you deploy in a maintenance window or at a time when interruptions will have the least impact.

When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 172 and Configurations that Restart the Snort Process When Deployed or Activated, on page 174.

For the Firewall Threat Defense devices, the **Inspect Interruption** column in the Deploy dialog warns you when deploying might interrupt traffic flow or inspection. You can either proceed with, cancel, or delay deployment; see Restart Warnings for Devices, on page 170 for more information.

Related Topics

Snort Restart Scenarios, on page 170

Deploy the Configuration

After you configure your deployment, and any time you change that configuration, you must deploy the changes to affected devices. You can view deployment status in the Message Center.

Deploying updates the following components:

- Device and interface configurations
- Device-related policies: NAT, VPN, QoS, platform settings
- Access control and related policies: DNS, file, identity, intrusion, network analysis, prefilter, SSL
- Network discovery policy
- Intrusion rule updates
- Configurations and objects associated with any of these elements

You can configure the system to deploy automatically by scheduling a deploy task or by setting the system to deploy when importing intrusion rule updates. Automating policy deployment is especially useful if you allow intrusion rule updates to modify system-provided base policies for intrusion and network analysis. Intrusion rule updates can also modify default values for the advanced preprocessing and performance options in your access control policies.

Deploy Configuration Changes

After you change configurations, deploy them to the affected devices. We *strongly* recommend that you deploy in a maintenance window or at a time when any interruptions to traffic flow and inspection will have the least impact.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 172 and Configurations that Restart the Snort Process When Deployed or Activated, on page 174.

Before you begin

- Be sure all managed devices use the same revision of the Security Zones object. If you have edited security zone objects: Do not deploy configuration changes to any device until you edit the zone setting for interfaces on *all* devices you want to sync. You must deploy to all managed devices at the same time.
- To preview the deployment changes, enable REST API access. To enable the REST API access, follow the steps in *Enabling REST API Access* in the Cisco Secure Firewall Management Center Administration Guide.

Note The deployment process fails if the device configuration is being read at the device CLI during deployment. Do not execute commands such as **show running-config** during the deployment.

Procedure

Step 1 On the Firewall Management Center menu bar, click **Deploy**.

Step 2 For a quick deployment, check specific devices and then click **Deploy**, or click **Deploy All** to deploy to all devices. Otherwise, for additional deployment options, click **Advanced Deploy**.

The rest of this procedure applies to the **Advanced Deploy** screen.

Figure 48: Quick Deploy

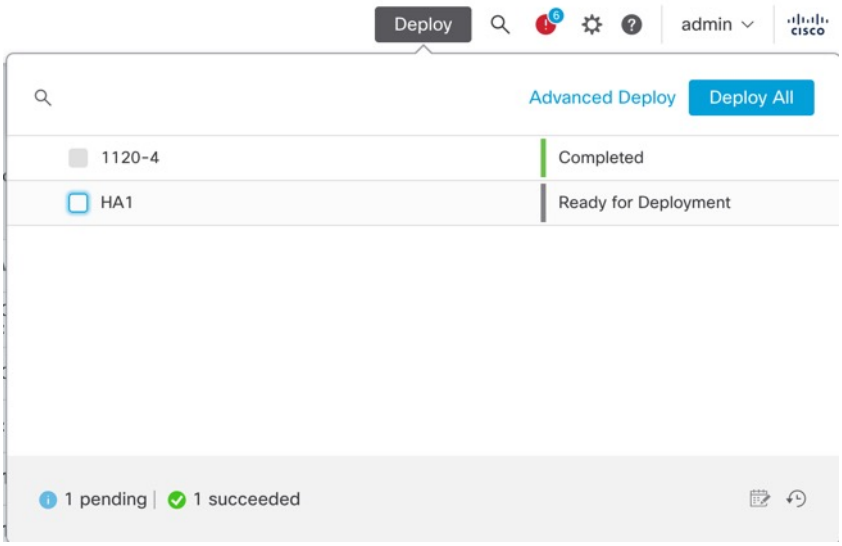

Figure 49: Advanced Deploy

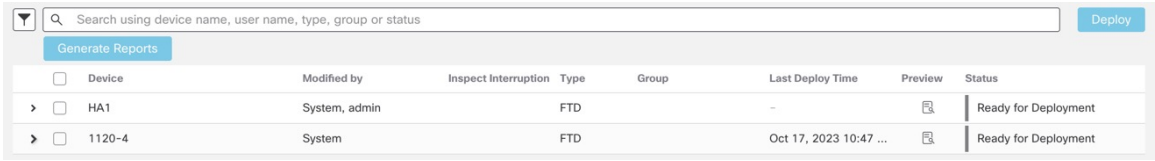
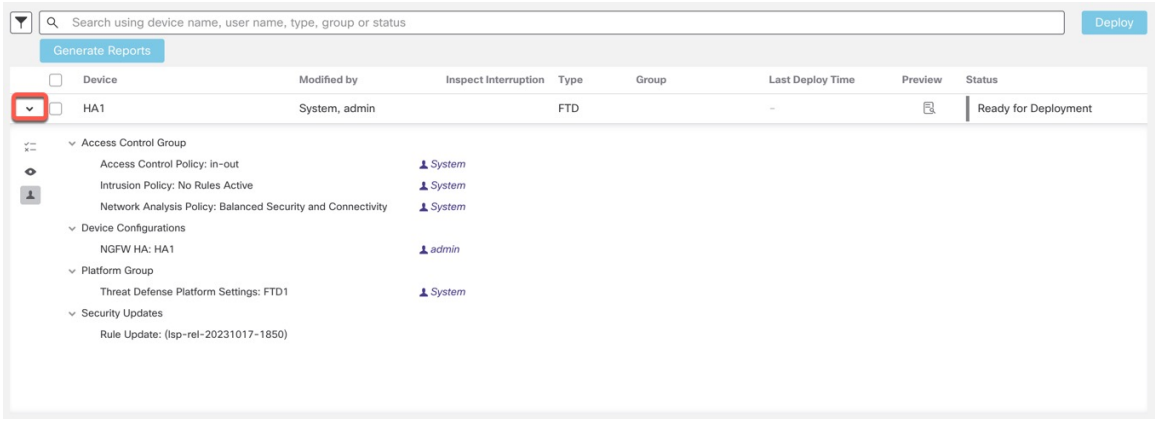


Step 3 Click **Expand Arrow** ( ) to view device-specific configuration changes to be deployed.

Figure 50: Expand



- The **Modified By** column lists the users who have modified the policies or objects. On expanding the device listing, you can view the users who have modified the policies against each policy listing. For information about when the **System** user is shown (instead of the logged-in user), see System Username, on page 169.

  Note
  Usernames are not provided for deleted policies and objects.

- The **Inspect Interruption** column indicates if traffic inspection interruption may be caused in the device during deployment.

  When the status indicates (Yes) that deploying will interrupt inspection, and perhaps traffic, on the Firewall Threat Defense device, the expanded list indicates the specific configurations causing the interruption with the **Inspect Interruption** ( ).

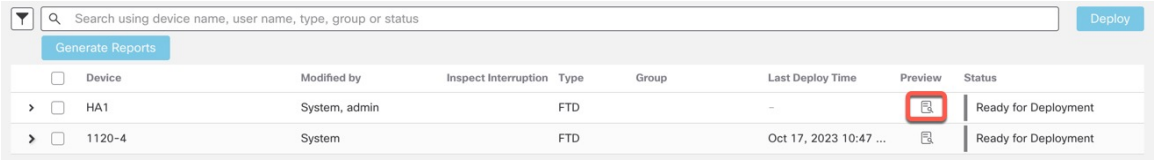
  If the entry is blank in this column for a device, then it indicates that there will be no traffic inspection interruptions on that device during deployment.

  See Restart Warnings for Devices, on page 170 for information to help you identify configurations that interrupt traffic inspection and might interrupt traffic when deployed to the Firewall Threat Defense devices.

- The **Last Modified Time** column specifies when you last made the configuration changes.
- The **Preview** column allows you to preview the changes for the next deployment.
- The **Status** column provides the status for each deployment. For more information, see View Deployment Status, on page 185.

Step 4 In the **Preview** column, click **Preview** ( ) to see the configuration changes that you can deploy.

Figure 51: Preview



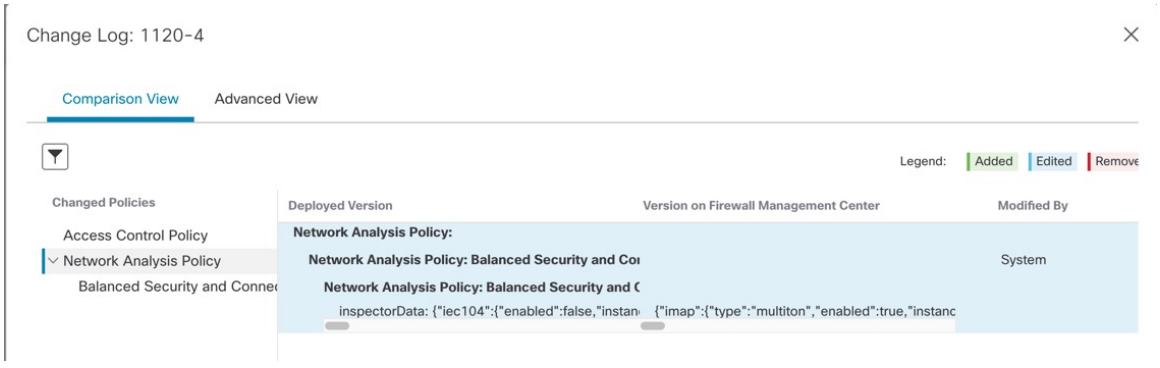
Note

If you change the Firewall Management Center name in **System** ( ) > **Configuration** > **Information**, the deployment preview does not specify this change, yet it requires a deployment.

For unsupported features for Preview, see Deployment Preview, on page 166.

The **Comparison View** tab lists all the policy and object changes. The left pane lists all the different policy types that have changed on the device, organized in a tree structure.

Figure 52: Comparison View



The **Filter**( ) lets you filter the policies at the user level and policy level.

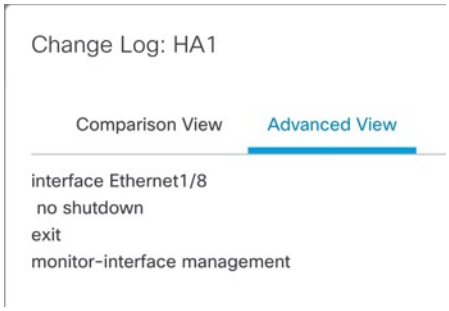
The right pane lists all the additions, changes, or deletions in the policy, or the object selected in the left pane. The two columns on the right pane provide the last deployed configuration settings (in the **Deployed Version** column) versus the changes that are due for deployment (in the **Version on Firewall Management Center** column). The last-deployed configuration settings are derived from a snapshot of the last saved deployment in the Firewall Management Center and not from the device. The background colors of the settings are color-coded as per the legend available on the top-right of the page.

The **Modified By** column lists the users who have modified, or added the configuration settings. At the policy level, the Firewall Management Center displays all the users who have modified the policy, and at the rule level, the Firewall Management Center displays only the last user who has modified the rule.

You can download a copy of the change log by clicking the **Download Report** button.

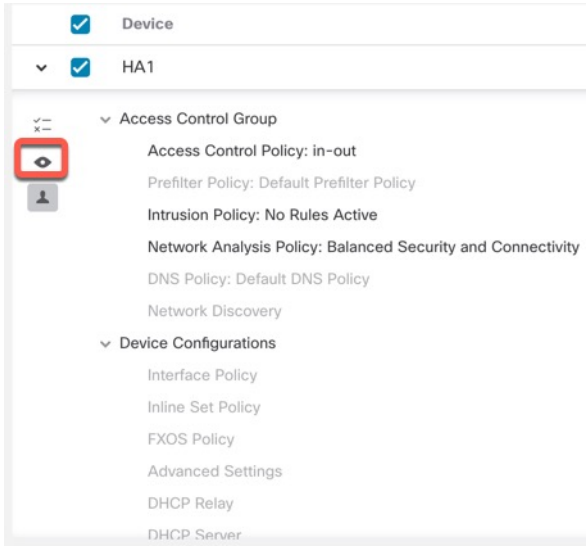
The **Advanced View** tab shows the CLI commands that will be applied. This view is useful if you are familiar with ASA CLI, which is used on the back end of the Firewall Threat Defense.

Figure 53: Advanced View



Step 5 Use **Show or Hide Policy** ( ) to selectively view or hide the associated unmodified policies.

Figure 54: Show or Hide Policy



Step 6 Check the box next to the device name to deploy all configuration changes, or click **Policy selection** ( ) to select individual policies or configurations to deploy while withholding the remaining changes without deploying them.

You can also view the interdependent changes for a certain policy or configuration using this option. The Firewall Management Center dynamically detects dependencies between policies (for example, between an access control policy and an intrusion policy), and between the shared objects and the policies. Interdependent changes are indicated using color-coded tags to identify a set of interdependent deployment changes. When one of the deployment changes is selected, the interdependent changes are automatically selected.

For more details, see Selective Policy Deployment, on page 167.

Note

- When the changes in shared objects are deployed, the impacted policies should also be deployed along with them. When you select a shared object during deployment, the impacted policies are automatically selected.
- Selective deployment is not supported for scheduled deployments and deployments using REST APIs. You can only opt for complete deployment of all the changes in these cases.
- The pre-deployment checks for warnings and errors are performed not only on the selected policies, but on all the policies that are out-of-date. Therefore, the warnings or errors list shows the deselected policies as well.
- Similarly, the **Inspect Interruption** column indication on the Deployment page considers all out-of-date policies and not just the selected policies. For information on the **Inspect Interruption** column, see Restart Warnings for Devices, on page 170.

Step 7 After you select the devices or policies to deploy, click **Estimate** to get a rough estimate of the deployment duration.

Figure 55: Estimate

Figure 56: Deploy Time

The time duration is a rough estimate (having around 70% accuracy), and the actual time taken for deployment may vary for a few scenarios. The estimate is dependable for deployments of up to 20 devices.

When an estimate is not available, it indicates that the data is not available, since the first successful deployment on the selected device is pending. This situation could occur after the Firewall Management Center reimage, version upgrade, or after a high availability failover.

Note
The estimate is incorrect and unreliable for bulk policy changes (in case of bulk policy migrations), and selective deployments because the estimate is based on the heuristic technique.

Step 8 Click **Deploy**.

Step 9 If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors.

You have the following choices:

- Deploy—Continue deploying without resolving warning conditions. Check the **Ignore warnings** checkbox, to ignore warnings and deploy the changes. You cannot proceed if the system identifies errors.
- Close—Exit without deploying. Resolve the error and warning conditions, and attempt to deploy the configuration again.

What to do next

- (Optional) Monitor deployment status; see *Viewing Deployment Messages* in the Cisco Secure Firewall Management Center Administration Guide.
- If the deployment fails, see Best Practices for Deploying Configuration Changes, on page 176.
- During deployment, if there are specific configuration changes in the deployment, the deployment failure may lead to traffic being interrupted. For example, in a cluster environment, an erroneous configuration of an IP address that is not in the same subnet as the Site IPs is configured on the interface. Due to this error, deployment fails and the device attempts to clear the configuration while the rollback operation is being processed. These events collectively lead to a deployment failure that interrupts the traffic.

  See the following table to know what configuration changes may cause traffic interruption when deployment fails.

Configuration Changes	Exists?	Traffic Impacted?
Threat Defense Service changes in an access control policy	Yes	Yes
VRF	Yes	Yes
Interface	Yes	Yes
QoS	Yes	Yes

Note The configuration changes interrupting traffic during deployment is valid only if both the Firewall Management Center and the Firewall Threat Defense are of version 6.2.3 or higher.

Related Topics

Snort Restart Scenarios, on page 170

Redeploy Existing Configurations to a Device

You can force-deploy existing (unchanged) configurations to a single managed device. We *strongly* recommend you deploy in a maintenance window or at a time when any interruptions to traffic flow and inspection will have the least impact.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 172 and Configurations that Restart the Snort Process When Deployed or Activated, on page 174.

Before you begin

Review the guidelines described in Best Practices for Deploying Configuration Changes, on page 176.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device where you want to force deployment.

Step 3 Click **Device**.

Step 4 Click **Edit** ( ) next to the **General** section heading.

Step 5 Click **Force Deploy** ( ).

Note
Force-deploy takes more time than the regular deployment because it involves the complete generation of the policy rules to be deployed on the Firewall Threat Defense.

Step 6 Click **Deploy**.

The system identifies any errors or warnings with the configurations you are deploying. You can click **Proceed** to continue without resolving warning conditions. However, you cannot proceed if the system identifies an error.

What to do next

- (Optional) Monitor deployment status; see *Viewing Deployment Messages* in the Cisco Secure Firewall Management Center Administration Guide.
- If deploy fails, see Best Practices for Deploying Configuration Changes, on page 176.

Related Topics

Snort Restart Scenarios, on page 170

Manage Deployments

View Deployment Status

On the Deployment page, the **Status** column provides the deployment status for each device. If a deployment is in progress, then the live status of the deployment progress is displayed, else one of the following statuses is displayed:

- Pending—Indicates that there are changes in the device that are to be deployed.
- Warnings or errors—Indicates that the pre-deployment checks have identified warnings or errors for the deployment, and you have not proceeded with the deployment. You can continue with the deployment if there are any warnings, but not if there are any errors.

Note The status column provides the warning or error status only for a single user session on the deployment page. If you navigate away from the page or refresh the page, the status changes to pending.

- Failed—Indicates that the previous deployment attempt failed. Click on the status to view the details.
- In queue—Indicates that deployment is initiated, and the system is yet to start the deployment process.
- Completed—Indicates that deployment has completed successfully.

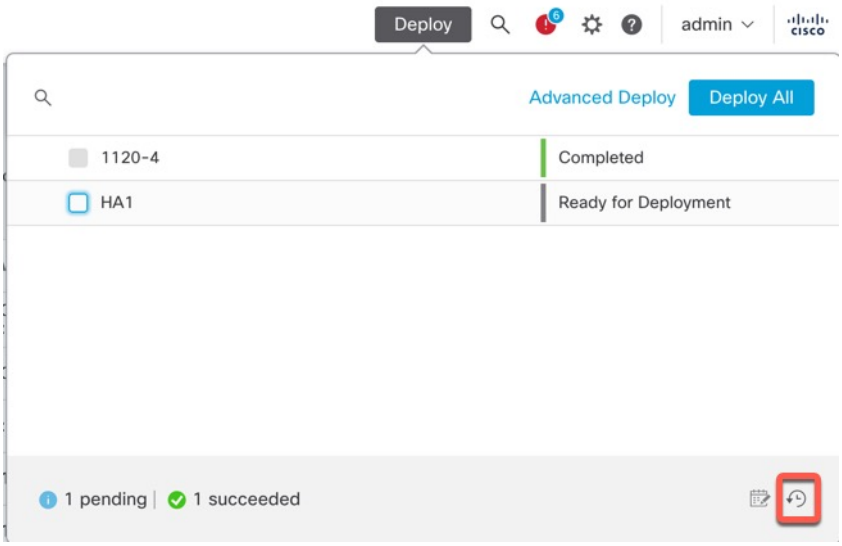
View Deployment History

In the deployment history, the last 10 successful deployments, the last 5 failed deployments, and last 5 rollback deployments are captured.

Procedure

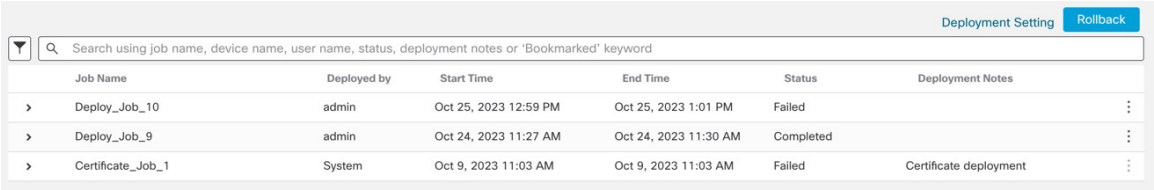
Step 1 On the Firewall Management Center menu bar, click **Deploy** and then click **Deployment History** ( ).

Figure 57: Deployment History Icon



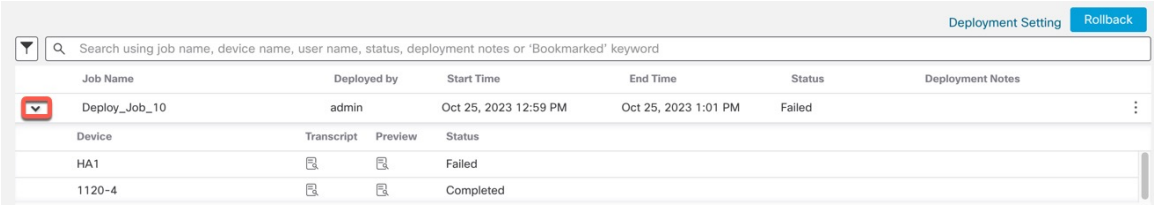
A list of all the previous deployment and rollback jobs is displayed in reverse chronological order.

Figure 58: Deployment History Page



Step 2 Click **Expand Arrow** (›) next to the required deployment job to view the devices included in the job and their deployment statuses.

Figure 59: Expand



- View notes in the **Deployment Notes** column.

  Deployment notes are custom notes that a user can add as part of the deployment, and these notes are optional.

Step 3 (Optional) Click **Transcript Details** ( ) to view the commands sent to the device, and the responses received.

Figure 60: Transcript Details Icon

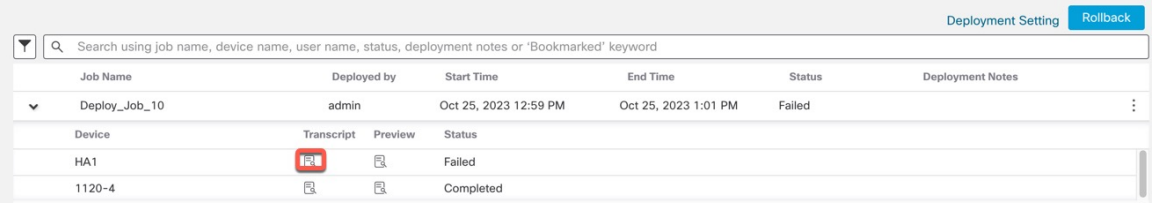


Figure 61: Transcript Details

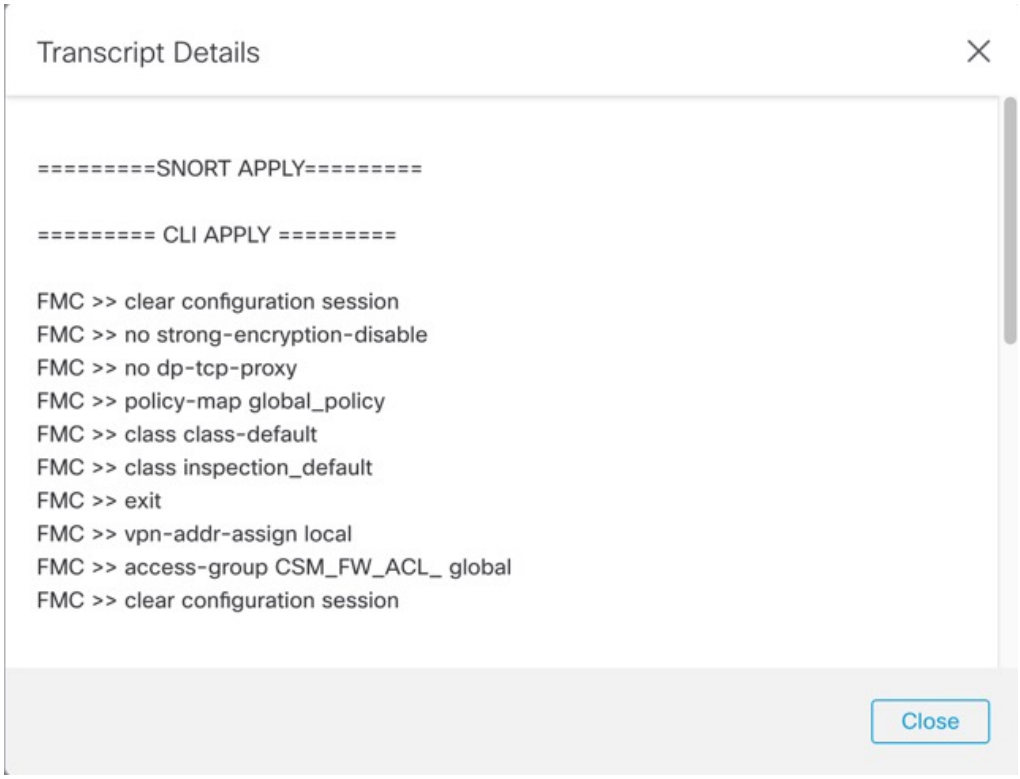


The transcript includes the following sections:

- **Snort Apply**—If there are any failures or responses from Snort-related policies, then the messages are displayed in this section. Normally, the section is empty.
- **CLI Apply**—This section covers features that are configured using commands that are sent to the device.
- **Infrastructure Messages**—This section shows the status of different deployment modules.

In the **CLI Apply** section, the deployment transcript includes commands that are sent to the device, and any responses returned from the device. These responses can be informative messages or error messages. For failed deployments, look for messages that indicate errors with the commands. Examining these errors can be particularly helpful if you are using FlexConfig policies to configure customized features. These errors can help you correct the script in the FlexConfig object that is trying to configure the commands.

Note
There is no distinction that is made in the transcript between commands that are sent for managed features and those generated from FlexConfig policies.

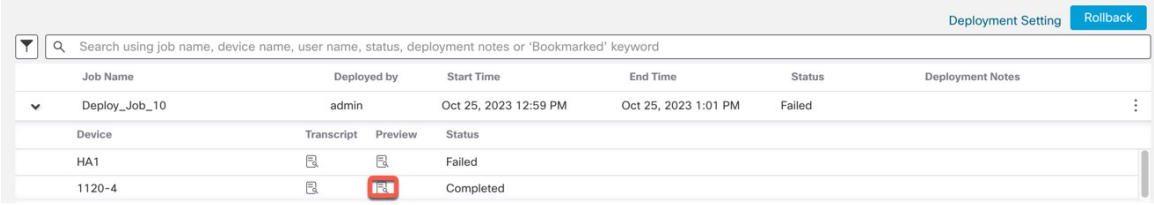
For example, the following sequence shows that Firewall Management Center sent commands to configure GigabitEthernet0/0 with the logical name **outside**. The device responded that it automatically set the security level to 0. Firewall Threat Defense does not use the security level for anything.

```
========= CLI APPLY =========

FMC >> interface GigabitEthernet0/0
FMC >>  nameif outside
FTDv 192.168.0.152 >> [info] : INFO: Security level for "outside" set to 0 by default.
```

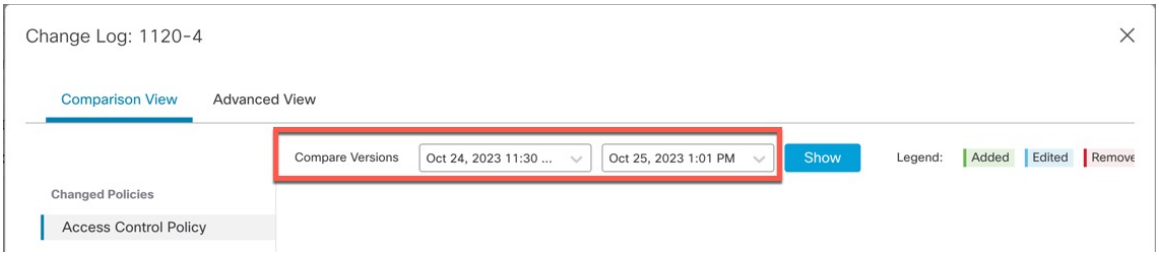
Step 4 (Optional) Click **Preview** ( ) to view the policy and object changes deployed on the device versus the previously deployed version.

Figure 62: Preview Icon



a. To compare any two versions and view the change log, choose the required versions in the drop-down boxes and click the **Show** button. The drop-down boxes show the deployment job name and the end time of the deployment.

Figure 63: Compare Versions



Note
The drop-down boxes also show failed deployments.

b. The **Modified By** column lists the users who have modified the policies or objects.

1. At the policy level, Firewall Management Center displays all the user names who have modified the policy.
2. At the rule level, Firewall Management Center displays the last user who has modified the rule.

c. You can also download a copy of the change log by clicking **Download Report**.

Note

- Deployment history preview is not supported for certificate enrollments, HA operations, and failed deployments.
- When a device is registered, preview is not supported for the job history record that is created.

Step 5 (Optional) Against each deployment job, click the **More** (⋮) icon and execute other actions:

- **Bookmark**—To bookmark the deployment job.
- **Edit Deployment Notes**—To edit your custom deployment notes that you added for a deployment job.
- **Generate Report**—To generate a deployment report, which can be used for auditing. This report includes job properties with preview and transcript information, and the report can be downloaded as a PDF file.

  a. Click **Generate Report** to generate a deployment report.

  Figure 64: Generate Report

  b. In the **Generate Report** popup window, check the **Email** checkbox.

  c. In the **Recipient List**, you can enter multiple email adddresses, separated by semicolons.

  d. Click **Generate** to generate the report, and this report is emailed to the recipients.

  e. In the Notifications task tab, you can track the progress. After the report generation is complete, click the link in the notification task tab to download the PDF report.

Download Policy Changes Report for Multiple Devices

Download reports on the policy and object changes made since your last deployment for multiple Firewall Threat Defense devices. You can download the reports in the form of a zip file that contains the following reports:

- A pending changes report for each device, that previews the additions, updates, or deletions in the policy, or the objects that are to be deployed on the device. For more information, see Deploy Configuration Changes, on page 177 and Deployment Preview.
- A consolidated report that categorizes each device based on the report status.

Procedure

Step 1 Choose **Deploy** > **Advanced Deploy**.

Step 2 Check the check box next to the devices for which you want to generate a pending policy changes report, and then click **Pending Changes Reports**.

Step 3 Click **Pending Changes Reports**. Reports are generated in the background.

Step 4 On the Firewall Management Center menu bar, choose **Notifications** > **Tasks** to view the report generation task.

When the report request task is complete, the download link appears within the task notification.

Step 5 Click the **Download Report(s)** link to download the reports.

Compare Policies

To review policy changes for compliance with your organization's standards or to optimize system performance, you can examine the differences between two policies or between a saved policy and the running configuration.

You can compare the following policy types:

- DNS
- File
- Health
- Identity
- Network Analysis
- SSL

The comparison view displays both policies in a side-by-side format. Differences between the two policies are highlighted:

- Blue indicates that the highlighted setting is different in the two policies, and the difference is noted in red text.
- Green indicates that the highlighted setting appears in one policy but not the other.

Before you begin

You can compare policies only if you have access rights and any required licenses for the specific policy, and you are in the correct domain for configuring the policy.

Procedure

Step 1 Access the management page for the policy you want to compare:

- DNS—**Policies** > **Access Control heading** > **DNS**
- File—**Policies** > **Access Control heading** > **Malware & File**
- Health—**System** (⚙) > **Health** > **Policy**
- Identity—**Policies** > **Access Control heading** > **Identity**
- Network Analysis—**Policies** > **Access Control heading** > **Access Control**, and then click **Network Analysis Policy** or **Policies** > **Access Control heading** > **Intrusion**, and then click **Network Analysis Policies**.

  Note
  If your custom user role limits access to the first path listed here, use the second path to access the policy.

- SSL—**Policies** > **Access Control heading** > **Decryption**

Step 2 Click **Compare Policies**.

Step 3 From the **Compare Against** drop-down list, choose the type of comparison you want to make:

- To compare two different policies, choose **Other Policy**.
- To compare two revisions of the same policy, choose **Other Revision**.
- To compare another policy to the currently active policy, choose **Running Configuration**.

Step 4 Depending on the comparison type you choose, you have the following choices:

- If you are comparing two different policies, choose the policies you want to compare from the **Policy A** and **Policy B** drop-down lists.
- If you are comparing the running configuration to another policy, choose the second policy from the **Policy B** drop-down list.

Step 5 Click **OK**.

Step 6 Review the comparison results:

- Comparison Viewer—To use the comparison viewer to navigate individually through policy differences, click **Previous** or **Next** above the title bar.
- Comparison Report—To generate a PDF report that lists the differences between the two policies, click **Comparison Report**.

Generate Current Policy Reports

For most policies, you can generate two kinds of reports. A report on a single policy provides details on the policy's current saved configuration, while a comparison report lists only the differences between two policies. You can generate a single-policy report for all policy types except health.

Note Intrusion policy reports combine the settings in the base policy with the settings of the policy layers, and make no distinction between which settings originated in the base policy or policy layer.

Before you begin

You can generate policy reports only if you have access rights and any required licenses for the specific policy, and you are in the correct domain for configuring the policy.

Procedure

Step 1 Access the management page for the policy for which you want to generate a report:

- Access Control—**Policies** > **Access Control heading** > **Access Control**
- DNS—**Policies** > **Access Control heading** > **DNS**
- File—**Policies** > **Access Control heading** > **Malware & File**
- Health—**System** (⚙) > **Health** > **Policy**
- Identity—**Policies** > **Access Control heading** > **Identity**
- Intrusion—**Policies** > **Access Control heading** > **Intrusion**
- NAT—**Devices** > **NAT**
- Network Analysis—**Policies** > **Access Control heading** > **Access Control**, and then click **Network Analysis Policy** or **Policies** > **Access Control heading** > **Intrusion**, and then click **Network Analysis Policies**

  Note
  If your custom user role limits access to the first path listed here, use the second path to access the policy.

- SSL—**Policies** > **Access Control heading** > **Decryption**

Step 2 Click **Report** (📄) next to the policy for which you want to generate a report.

History for Configuration Deployment

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
View and generate reports on configuration changes since your last deployment.	7.2.6 7.4.1	Any	You can generate, view, and download the reports as a zip file on configuration changes since your last deployment: • A *policy changes* report for each device that previews the additions, changes, or deletions in the policy, or the objects that are to be deployed on the device. • A *consolidated* report that categorizes each device based on the status of policy changes report generation. This is especially useful after you upgrade Firewall Threat Defense, so that you can see the changes made by the upgrade before you deploy. New/modified screens: **Deploy** > **Advanced Deploy**. See: Download Policy Changes Report for Multiple Devices
Generate and email a report when you deploy configuration changes.	7.2	Any	You can now generate a report for any deployment. New/modified screens: **Deploy** > **Deployment History icon** > **More** > **Generate Report**

User Roles

Admin

Manage the Secure Firewall Management Center System Configuration

The system configuration identifies basic settings for the Firewall Management Center.

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Use the navigation panel to choose configurations to change.

Access Control Preferences

Configure access control preferences on **System** (⚙) > **Configuration** > **Access Control Preferences**.

Requiring Comments on Rule Changes

You can track changes to access control rules by allowing (or requiring) users to comment when they save. This allows you to quickly assess why critical policies in a deployment were modified. By default, this feature is disabled.

Object Optimization

When you deploy rule policies to a firewall device, you can configure the Firewall Management Center to evaluate and optimize the network/host policy objects that you use in the rules when it creates the associated network object groups on the device. Optimization merges adjacent networks and removes redundant network entries. This reduces the runtime access list data structures and the size of the configuration, which can be beneficial to some firewall devices that are memory-constrained.

Note Object optimization applies to objects created by the Firewall Management Center only. These are objects created if you directly add IP addresses to an access control rule, rather than using your own network objects. User-defined network objects are not changed.

For example, consider a network/host object that contains the following entries and that is used in an access rule:

```
192.168.1.0/24
192.168.1.23
10.1.1.0
10.1.1.1
10.1.1.2/31
```

When optimization is enabled, when you deploy the policy, the resulting object group configuration is generated:

```
object-group network test
description (Optimized by management center)
network-object 10.1.1.0 255.255.255.252
network-object 192.168.1.0 255.255.255.0
```

When optimization is disabled, the group configuration would be as follows:

```
object-group network test
```

```
network-object 192.168.1.0 255.255.255.0
network-object 192.168.1.23 255.255.255.255
network-object 10.1.1.0 255.255.255.255
network-object 10.1.1.1 255.255.255.255
network-object 10.1.1.2 255.255.255.254
```

This optimization does not change the definition of the network/host object, nor does it create a new network/host policy object. If a network object-group contains another network, host object, or object-groups, the objects are not combined. Instead, each network object-group is optimized separately. Also, only inline values of network object-groups are being modified as part of the optimization process during a deployment.

Important The optimizations occur on the *managed device* on the *first deploy* after the feature is enabled on the Firewall Management Center. If you have a high number of rules, the system can take several minutes to an hour to evaluate your policies and perform object optimization. During this time, you may also see higher CPU use on your devices. A similar thing occurs on the first deploy after the feature is disabled. After this feature is enabled or disabled, we recommend you deploy when it will have the least impact, such as a maintenance window or a low-traffic time.

This feature is enabled by default. To disable it, contact Cisco TAC.

Audit Log

The Firewall Management Center records user activity in read-only audit logs. You can review audit log data in several ways:

- Use the web interface: .

  Audit logs are presented in a standard event view where you can view, sort, and filter audit log messages based on any item in the audit view. You can easily delete and report on audit information and you can view detailed reports of the changes that users make.

- Stream audit log messages to the syslog: Stream Audit Logs to Syslog, on page 200.
- Stream audit log messages to an HTTP server: Stream Audit Logs to an HTTP Server, on page 201.

Streaming audit log data to an external server allows you to conserve space on the Firewall Management Center. Note that sending audit information to an external URL may affect system performance.

Optionally, you can secure the channel for audit log streaming, enable TLS and mutual authentication using TLS certificates ; see Audit Log Certificate, on page 203.

Streaming to Multiple Syslog Servers

You can stream audit log data to a maximum of five syslog servers. However, if you have enabled TLS for secured audit log streaming, you can stream only to a single syslog server.

Streaming Configuration Changes to Syslog

You can stream configuration changes as part of audit log data to syslog by specifying the configuration data format and the hosts. The Firewall Management Center supports backup and restore of the audit configuration log. In case of high availability, only the active Firewall Management Center sends the configuration changes syslog to the external syslog servers. The log file is synchronized between the HA pairs so that during a failover or switchover, the new active Firewall Management Center would resume sending the change logs.

In case the HA pair is working in split-brain mode, both Firewall Management Centers in the pair sends the config change syslog to the external servers.

Stream Audit Logs to Syslog

When this feature is enabled, audit log records appear in the syslog in the following format:

```
Date Time Host: [Tag] Sender: User_Name@User_IP, Subsystem, Action
```

Where the local date, time, and originating hostname precede the bracketed optional tag, and the sending device name precedes the audit log message.

For example, if you specify a tag of `FMC-AUDIT-LOG` for audit log messages from your management center, a sample audit log message from your Firewall Management Center could appear as follows:

```
Mar 01 14:45:24 localhost: [FMC-AUDIT-LOG] Dev-MC7000: admin@10.1.1.2, Operations >
Monitoring, Page View
```

If you specify a severity and facility, these values do not appear in syslog messages; instead, they tell the system that receives the syslog messages how to categorize them.

Before you begin

Make sure the Firewall Management Center can communicate with the syslog server. When you save your configuration, the system uses ICMP/ARP and TCP SYN packets to verify that the syslog server is reachable. Then, the system by default uses port 514/UDP to stream audit logs. If you secure the channel, you must manually configure port 1470 for TCP.

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Audit Log**.

Step 3 Choose **Enabled** from the **Send Audit Log to Syslog** drop-down menu.

Step 4 The following fields are applicable only for audit logs sent to syslog:

Option	Description
Send Configuration Changes	To include configuration changes syslog in the audit log streaming, from the drop-down, select the relevant options: • JSON—the syslog includes detailed differences in the configuration changes. • API—the syslog includes API to retrieve the detailed differences in the configuration changes. • None—to have all other audit logs except details of the configuration changes.
Host	The IP address or the fully qualified name of the syslog server to which you will send audit logs. You can add a maximum of five syslog hosts, separated by commas. **Note** You can specify multiple syslog hosts, only when TLS is disabled for the Audit Server Certificate.

Option	Description
Facility	The subsystem that creates the message. Choose a facility described in Syslog Alert Facilities, on page 375. For example, choose AUDIT.
Severity	The severity of the message. Choose a severity described in Syslog Severity Levels, on page 376.
Tag	An optional tag to include in audit log syslog messages. Best practice: Enter a value in this field to easily differentiate audit log messages from other, similar syslog messages such as health alerts. For example, if you want all audit log records sent to the syslog to be labeled with `FMC-AUDIT-LOG`, enter `FMC-AUDIT-LOG` in the field.

Step 5 (Optional) To test whether the IP address of the syslog servers is valid, click **Test Syslog Server**.

The system sends the following packets to verify whether the syslog server is reachable:

a. ICMP echo request

b. TCP SYN on 443 and 80 ports

c. ICMP time stamp query

d. TCP SYN on random ports

Note
If the Firewall Management Center and syslog server are in the same subnet, ARP is used instead of ICMP.

The system displays the result for each server.

Step 6 Click **Save**.

Stream Audit Logs to an HTTP Server

When this feature is enabled, the appliance sends audit log records to an HTTP server in the following format:

```
Date Time Host: [Tag] Sender: User_Name@User_IP, Subsystem, Action
```

Where the local date, time, and originating hostname precede the bracketed optional tag, and the sending appliance name precedes the audit log message.

For example, if you specify a tag of `FROMMC`, a sample audit log message could appear as follows:

```
Mar 01 14:45:24 localhost: [FROMMC] Dev-MC7000: admin@10.1.1.2, Operations > Monitoring,
Page View
```

Before you begin

Make sure the device can communicate with the HTTP server.

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Audit Log**.

Step 3 Optionally, in the **Tag** field, enter the tag name that you want to appear with the message. For example, if you want all audit log records to be preceded with `FROMMC`, enter `FROMMC` in the field.

Step 4 Choose **Enabled** from the **Send Audit Log to HTTP Server** drop-down list.

Step 5 In the **URL to Post Audit** field, designate the URL where you want to send the audit information. Enter a URL that corresponds to a Listener program that expects the HTTP POST variables as listed:

- `subsystem`
- `actor`
- `event_type`
- `message`
- `action_source_ip`
- `action_destination_ip`
- `result`
- `time`
- `tag` (if defined; see Step 3)

Caution
To allow encrypted posts, use an HTTPS URL. Sending audit information to an external URL may affect system performance.

Step 6 Click **Save**.

Filter Syslogs from Audit Logs

When you enable **Send Audit Log to Syslog** and provide **Host** information, syslog messages are also sent to the configured host in addition to the audit logs. This behavior is caused by the fact that the `/etc/syslog-ng.d/syslog-tls.conf` is created when you deploy the Firepower platform settings policy, which results in syslog messages being forwarded/sent to the configured host, instead of only sending the audit logs.

If your auditing policy does not want or require these syslog records, you can prevent those syslogs from being streamed to the configured host. To filter syslogs from audit logs, you must have access to an appliance's **admin** user account, and you must be able to either access the appliance's console or open a secure shell.

⚠

Caution Make sure that only authorized personnel have access to the appliance and to its **admin** account.

Procedure

Step 1 In the `/etc/syslog-ng.conf` file, comment out the `@include "/etc/syslog-ng.d/*.conf"` line.

Example:

```
#@include "/etc/syslog-ng.d/*.conf"
```

Step 2 Reload the syslog configuration file. Use the `syslog-ng-ctl reload` command to reload the configuration file without having to restart the application.

Example:

```
syslog-ng-ctl reload
```

Audit Log Certificate

You can use Transport Layer Security (TLS) certificates to secure communications between the Firewall Management Center and a trusted audit log server.

Client Certificates (Required)

Generate a certificate signing request (CSR), submit it to a Certificate Authority (CA) for signing, then import the signed certificate onto the Firewall Management Center. Use the local system configuration: Obtain a Signed Audit Log Client Certificate for the Firewall Management Center, on page 204 and Import an Audit Log Client Certificate into the Firewall Management Center, on page 205.

Server Certificates (Optional)

For additional security, we recommend you require mutual authentication between the Firewall Management Center and the audit log server. To accomplish this, load one or more certificate revocation lists (CRLs). You cannot stream audit logs to servers with revoked certificates listed in those CRLs.

Secure Firewall supports CRLs encoded in Distinguished Encoding Rules (DER) format. Note that these are the same CRLs that the system uses to validate HTTPS client certificates for the Firewall Management Center web interface.

Use the local system configuration: Require Valid Audit Log Server Certificates, on page 206.

Securely Stream Audit Logs

If you stream the audit log to a trusted HTTP server or syslog server, you can use Transport Layer Security (TLS) certificates to secure the channel between the Firewall Management Center and the server. You must generate a unique client certificate for each appliance you want to audit.

Procedure

Step 1 Obtain and install a signed client certificate on the Firewall Management Center:

a) Obtain a Signed Audit Log Client Certificate for the Firewall Management Center, on page 204:

Generate a Certificate Signing Request (CSR) from the Firewall Management Center based on your system information and the identification information you supply.

Submit the CSR to a recognized, trusted certificate authority (CA) to request a signed client certificate.

If you will require mutual authentication between the Firewall Management Center and the audit log server, the client certificate must be signed by the same CA that signed the server certificate to be used for the connection.

b) After you receive the signed certificate from the certificate authority, import it into the Firewall Management Center. See Import an Audit Log Client Certificate into the Firewall Management Center, on page 205.

Step 2 Configure the communication channel with the server to use Transport Layer Security (TLS) and enable mutual authentication.

Step 3 Configure audit log streaming if you have not yet done so.

See Stream Audit Logs to Syslog, on page 200 or Stream Audit Logs to an HTTP Server, on page 201.

Obtain a Signed Audit Log Client Certificate for the Firewall Management Center

Important The **Audit Log Certificate** page is not available on a standby Firewall Management Center in a high availability setup. You cannot perform this task from a standby Firewall Management Center.

The system generates certificate request keys in Base-64 encoded PEM format.

Before you begin

Keep the following in mind:

- To ensure security, use a globally recognized and trusted Certificate Authority (CA) to sign your certificate.
- If you will require mutual authentication between the appliance and the audit log server, the same Certificate Authority must sign both the client certificate and the server certificate.

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Audit Log Certificate**.

Step 3 Click **Generate New CSR**.

Step 4 Enter a country code in the **Country Name (two-letter code)** field.

Step 5 Enter a state or province postal abbreviation in the **State or Province** field.

Step 6 Enter a **Locality or City**.

Step 7 Enter an **Organization** name.

Step 8 Enter an **Organizational Unit (Department)** name.

Step 9 Enter the fully qualified domain name of the server for which you want to request a certificate in the **Common Name** field.

Note
If the common name and the DNS hostname do not match, audit log streaming will fail.

Step 10 Click **Generate**.

Step 11 Open a new blank file with a text editor.

Step 12 Copy the entire block of text in the certificate request, including the `BEGIN CERTIFICATE REQUEST` and `END CERTIFICATE REQUEST` lines, and paste it into a blank text file.

Step 13 Save the file as *`clientname`*`.csr`, where *`clientname`* is the name of the appliance where you plan to use the certificate.

Step 14 Click **Close**.

What to do next

- Submit the certificate signing request to the certificate authority that you selected using the guidelines in the "Before You Begin" section of this procedure.
- When you receive the signed certificate, import it to the appliance; see Import an Audit Log Client Certificate into the Firewall Management Center, on page 205.

Import an Audit Log Client Certificate into the Firewall Management Center

In the Firewall Management Center high availability setup, you *must* use the active peer.

Before you begin

- Obtain a Signed Audit Log Client Certificate for the Firewall Management Center, on page 204.
- Make sure you are importing the signed certificate for the correct Firewall Management Center.
- If the signing authority that generated the certificate requires you to trust an intermediate CA, be prepared to provide the necessary certificate chain (or certificate path). The CA that signed the client certificate must be the same CA that signed any intermediate certificates in the certificate chain.

Procedure

Step 1 On the Firewall Management Center, choose **System** (⚙) > **Configuration**.

Step 2 Click **Audit Log Certificate**.

Step 3 Click **Import Audit Client Certificate**.

Step 4 Open the client certificate in a text editor, copy the entire block of text, including the `BEGIN CERTIFICATE` and `END CERTIFICATE` lines. Paste this text into the **Client Certificate** field.

Step 5 To upload a private key, open the private key file and copy the entire block of text, including the `BEGIN RSA PRIVATE KEY` and `END RSA PRIVATE KEY` lines. Paste this text into the **Private Key** field.

Step 6 Open any required intermediate certificates, copy the entire block of text for each, and paste it into the **Certificate Chain** field.

Step 7 Click **Save**.

Require Valid Audit Log Server Certificates

The system supports validating audit log server certificates using imported CRLs in Distinguished Encoding Rules (DER) format.

Note If you choose to verify certificates using CRLs, the system uses the same CRLs to validate both audit log server certificates and certificates used to secure the HTTP connection between an appliance and a web browser.

Important You cannot perform this procedure on the standby Firewall Management Center in a high availability pair.

Before you begin

- Understand the ramifications of requiring mutual authentication and of using certificate revocation lists (CRLs) to ensure that certificates are still valid. See Audit Log Certificate, on page 203.
- Obtain and import the client certificate following the steps in Securely Stream Audit Logs, on page 203 and the topics referenced in that procedure.

Procedure

Step 1 On the Firewall Management Center, choose **System** (⚙) > **Configuration**.

Step 2 Click **Audit Log Certificate**.

Step 3 To use Transport Layer Security to securely stream the audit log to an external server, select **Enable TLS**.

When TLS is enabled, the syslog client (Firewall Management Center) verifies the certificate received from the server. The connection between the client and the server succeeds only if server certificate verification is successful. For this verification process, the following conditions must be met:

- Configure the syslog server to send the certificate to the client.
- Add (import) a CA certificate to the client to verify the server certificate:
  - You must import the CA certificate during the import of the client certificate.
  - If the issuing CA is a subordinate CA, you have to add the issuing CA before adding the signing CA from the subordinate CA (Root CA), and so on.

Step 4 If you do not want the client to authenticate itself against the server, but accept the server certificate when the certificate is issued by the same CA (not recommended):

a) Deselect **Enable Mutual Authentication**.

Important
Ensure that the server is configured to trust the client without verifying any client certificates.

b) Click **Save** and skip the remainder of this procedure.

Step 5 (Optional) To enable client certificate verification by the audit log server, select **Enable Mutual Authentication**.

Important
The **Enable Mutual Authentication** option is applicable only when TLS is enabled.

When mutual authentication is enabled, the syslog client (Firewall Management Center) sends a client certificate to the syslog server for verification. The client uses the same CA certificate of the CA who signed the server certificate of the syslog server. The connection succeeds only if client certificate verification is successful. For this verification process, the following conditions must be met:

- Configure the syslog server to verify the certificate received from the client.
- Add a client certificate to be sent to the syslog server. This certificate must be signed by the same CA who signed the server certificate of the syslog server.

Note
To use mutual authentication for streaming Audit Log to the Syslog server, use PKCS#8 format for the private key instead of PKCS#1 format. Use the following command line to convert PKCS#1 keys to PKCS#8 format:

```
openssl pkcs8 -topk8 -inform PEM -outform PEM
-nocrypt -in PKCS1 key file name -out PKCS8 key filename
```

Step 6 (Optional) To automatically recognize server certificates that are no longer valid:

a) Select **Enable Fetching of CRL**.

Important
This option is displayed only when you select the **Enable Mutual Authentication** check box. However, the **Enable Fetching of CRL** option is applicable only when the TLS option is enabled. The use of CRL is for server certification verification, and it is not dependent on the use of Mutual Authentication which is for enabling client certificate verification.

Enabling fetching of the CRL creates a scheduled task for the client to regularly update (download) the CRL or CRLs. The CRL(s) are used for server certificate verification, where, the verification fails if there is a CRL from the CA specifying that the server certificate being verified has been revoked by the CA.

b) Enter a valid URL to an existing CRL file and click **Add CRL**.

Repeat to add up to 25 CRLs.

c) Click **Refresh CRL** to load the current CRL or CRLs from the specified URL or URLs.

Step 7 Verify that you have a valid server certificate generated by the same certificate authority that created the client certificate.

Step 8 Click **Save**.

What to do next

(Optional) Set the frequency of CRL updates. .

View the Audit Log Client Certificate on the Firewall Management Center

You can view the audit log client certificate only for the appliance that you are logged in to. In Firewall Management Center high availability pairs, you can view the certificate only on the active peer.

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Audit Log Certificate**.

Change Reconciliation

To monitor the changes that users make and ensure that they follow your organization's preferred standard, you can configure the system to send, via email, a detailed report of changes made over the past 24 hours. Whenever a user saves changes to the system configuration, a snapshot is taken of the changes. The change reconciliation report combines information from these snapshots to present a clear summary of recent system changes.

The following sample graphic displays a User section of an example change reconciliation report and lists both the previous value for each configuration and the value after changes. When users make multiple changes to the same configuration, the report lists summaries of each distinct change in chronological order, beginning with the most recent.

You can view changes made during the previous 24 hours.

Configuring Change Reconciliation

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Change Reconciliation**.

Step 3 Check the **Enable** check box.

Step 4 Choose the time of day you want the system to send out the change reconciliation report from the **Time to Run** drop-down lists.

Step 5 Enter email addresses in the **Email to** field.

Tip
Once you have added email addresses, click **Resend Last Report** to send recipients another copy of the most recent change reconciliation report.

Step 6 If you want to include policy changes, check the **Include Policy Configuration** check box.

Step 7 If you want to include all changes over the past 24 hours, check the **Show Full Change History** check box.

Step 8 Click **Save**.

Related Topics

Using the Audit Log to Examine Changes

Change Reconciliation Options

The **Include Policy Configuration** option controls whether the system includes records of policy changes in the change reconciliation report. This includes changes to access control, intrusion, system, health, and network discovery policies. If you do not select this option, the report will not show changes to any policies. This option is available on Firewall Management Centers only.

The **Show Full Change History** option controls whether the system includes records of all changes over the past 24 hours in the change reconciliation report. If you do not select this option, the report includes only a consolidated view of changes for each category.

Note The change reconciliation report does not include changes to Firewall Threat Defense interfaces and routing settings.

Email Notification

You cannot configure a mail host. The mail relay host is hardcoded to be used from a static host. It is set to email-smtp.us-west-2.amazonaws.com with authorization. For notifications, the email sender is set to cdo-alert@cisco.com

External Database Access

You can configure the Firewall Management Center to allow read-only access to its database by a third-party client. This allows you to query the database using SQL using any of the following:

- industry-standard reporting tools such as Actuate BIRT, JasperSoft iReport, or Crystal Reports
- any other reporting application (including a custom application) that supports JDBC SSL connections
- the Cisco-provided command-line Java application called RunQuery, which you can either run interactively or use to obtain comma-separated results for a single query

Use the Firewall Management Center's system configuration to enable database access and create an access list that allows selected hosts to query the database. Note that this access list does not also control appliance access.

You can also download a package that contains the following:

- RunQuery, the Cisco-provided database query tool

- InstallCert, a tool that you can use to retrieve and accept the SSL certificate from the Firewall Management Center that you want to access
- the JDBC driver you must use to connect to the database

See the *Secure Firewall Management Center Database Access Guide* for information on using the tools in the package you downloaded to configure database access.

Enabling External Access to the Database

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **External Database Access**.

Step 3 Select the **Allow External Database Access** check box.

Step 4 Enter an appropriate value in the **Server Hostname** field. Depending on your third-party application requirements, this value can be either the fully qualified domain name (FQDN), IPv4 address, or IPv6 address of the Firewall Management Center.

Note
In Firewall Management Center high availability setups, enter only the active peer details. We do not recommend entering details of the standby peer.

Step 5 Next to **Client JDBC Driver**, click **Download** and follow your browser's prompts to download the `client.zip` package.

Step 6 To add database access for one or more IP addresses, click **Add Hosts**. An **IP Address** field appears in the **Access List** field.

Step 7 In the **IP Address** field, enter an IP address or address range, or `any`.

Step 8 Click **Add**.

Step 9 Click **Save**.

Tip
If you want to revert to the last saved database settings, click **Refresh**.

Related Topics

IP Address Conventions

Intrusion Policy Preferences

Configure various intrusion policy preferences to monitor and track changes to the critical policies in your deployment.

Set Intrusion Policy Preferences

Configure the intrusion policy preferences.

Procedure

Step 1 Choose **System** (⚙) > **Configuration**.

Step 2 Click **Intrusion Policy Preferences**.

Step 3 You have the following options:

- **Comments on policy change**: Check this check box to track policy-related changes using the comment functionality when users modify intrusion policies. With policy change comments enabled, administrators can quickly assess why critical policies in a deployment were modified.

  If you enable comments on policy changes, you can make the comment optional or mandatory. The Firewall Management Center prompts the user for a comment when each new change to a policy is saved.

- **Write changes in Intrusion Policy to audit log**: Check this check box to record the changes to the intrusion policies to the audit logs. This option is enabled by default.

- **Retain user overrides for deleted Snort 3 rules**: Check this check box to get notifications for changes to any *overridden* system-defined rules during LSP updates. When enabled, the system retains the rule overrides in the new replacement rules that are added as part of the LSP update. On the Firewall Management Center menu bar, click **Notifications** (message center), and then click **Tasks** to view the notifications. This option is enabled by default.

Manager Remote Access

If managed devices do not have a public IP address or FQDN, or you use the Management interface for zero-touch provisioning, set a public IP address/FQDN for the Firewall Management Center so the device can initiate the management connection.

For example, if the Firewall Management Center's management interface IP address is being NATted by an upstream router, provide the *public* NAT address here. An FQDN is preferred because it guards against IP address changes.

If you use the serial number (zero-touch provisioning) method to register a device, then this field is used automatically for the initial configuration of the manager IP address/hostname. If you use the manual registration key method, you can refer to the value on this screen when you perform the device's initial configuration to identify the public Firewall Management Center IP address/hostname.

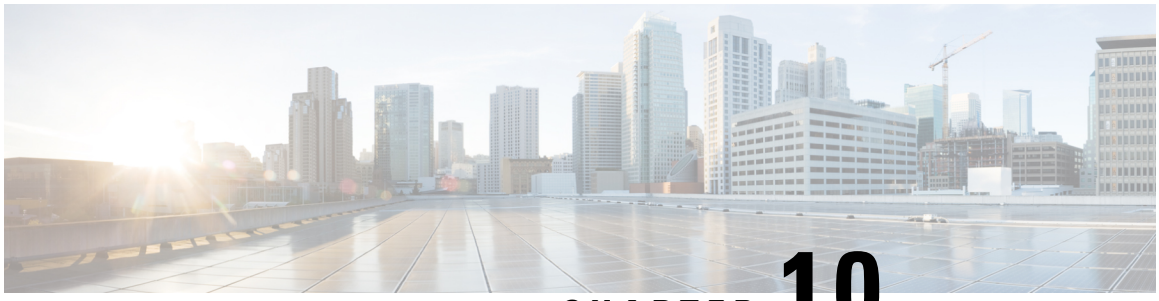
Figure 65: Manager Remote Access

Network Analysis Policy Preferences

You can configure the system to track policy-related changes using the comment functionality when users modify network analysis policies. With policy change comments enabled, administrators can quickly assess why critical policies in a deployment were modified.

If you enable comments on policy changes, you can make the comment optional or mandatory. The system prompts the user for a comment when each new change to a policy is saved.

Optionally, you can have changes to network analysis policies written to the audit log.



CHAPTER 10

Users

The Firewall Management Center includes default **admin** accounts for web and CLI access. This chapter discusses how to create custom user accounts.

- About Users, on page 213
- Create a User Record with Your Security Cloud Control Username, on page 216
- Troubleshooting LDAP Authentication Connections, on page 217
- Configure User Preferences, on page 218

About Users

You can add custom user accounts on managed devices, either as internal users or as external users on a LDAP or RADIUS server. Each managed device maintains separate user accounts. For example, when you add a user to the Firewall Management Center, that user only has access to the Firewall Management Center; you cannot then use that username to log directly into a managed device. You must separately add a user on the managed device.

Internal and External Users

Managed devices support two types of users:

- Internal user—The device checks a local database for user authentication.
- External user—If the user is not present in the local database, the system queries an external LDAP or RADIUS authentication server.

User Roles

Web Interface User Roles

There are a variety of user roles in Security Cloud Control (Security Cloud Control): Read-Only, Edit-Only, Deploy-only, Admin, and Super Admin. User roles are configured for each user on each tenant. If a Security Cloud Control user has access to more than one tenant, they may have the same user ID but different roles on different tenants. A user may have a read-only role on one tenant and a Super Admin role on another. When the interface or the documentation refers to a Read-only user, Deploy Only, Edit Only, an Admin user, or a Super Admin user we are describing that user's permission level on a particular tenant. Note that you

cannot create user roles in the cloud-delivered Firewall Management Center because it uses Security Cloud Control user roles.

Read Only

Read Only users can view all device configurations but not change them.

Deploy Only

Deploy Only users can audit queued changes made to device configurations and deploy them but cannot change them.

Edit Only

Edit Only users can make changes to all device configurations but cannot deploy them to devices.

Super Admin and Admin

Super Admin and Admin users can access everything in the product. The difference between Super Admin and Admin users is that Super Admins can create accounts for other users on a tenant and modify existing user roles, while admins cannnot.

To know more about user roles in Security Cloud Control, see User Roles.

The following table maps the user roles in On-Premises Firewall Management Center to their equivalent roles in the cloud-delivered Firewall Management Center in Security Cloud Control.

Tip We recommend that you read through the table only if you are familiar with the user roles in On-Premises Firewall Management Center.

Table 13: Secure Firewall Management Center and Cloud-delivered Firewall Management Center User Role Mapping

On-Premises Firewall Management Center User Role	Equivalent Cloud-delivered Firewall Management Center User Role	Capabilities
Access Admin, Discovery Admin, Intrusion Admin, Maintenance User	Edit Only	You can search, filter, or view the following: • Access control policies and associated features • Intrusion policies • Intrusion rules • Network discovery rules • Custom detectors • Correlation policies • Objects • Rulesets • Interfaces • VPN configurations • Monitoring- and maintenance-related settings You can back up or restore a device but cannot deploy policies to the devices.
Administrator	Super Admin	You can access all features of the cloud-delivered Firewall Management Center and perform tasks, including create, read, modify, or delete policies or objects and deploy those changes to the devices. You can also edit user roles or create user records in Security Cloud Control.
Network Admin	Admin	You can access all features of the cloud-delivered Firewall Management Center and perform tasks, including create, read, modify, or delete policies or objects and deploy those changes to the devices. However, you cannot edit user roles or create user records in Security Cloud Control.

On-Premises Firewall Management Center User Role	Equivalent Cloud-delivered Firewall Management Center User Role	Capabilities
Security Analyst, Security Analyst (Read Only)	Read Only	You can view device information, policies, objects, and their related settings but cannot do the following: • Create or edit objects • Create or edit policies • Modify device configurations • Backup or restore devices
Security Approver	Deploy Only	You can view most settings and deploy staged changes to devices but cannot create or modify objects or policies.

Create a User Record with Your Security Cloud Control Username

Only a Security Cloud Control user with **Super Admin** privileges can create the Security Cloud Control user record. The **Super Admin** must create the user record with the same email address that was specified in the **Create Your Security Cloud Control Username** task above.

Use the following procedure to create a user record with an appropriate user role:

Procedure

Step 1 Login to Security Cloud Control.

Step 2 In the left pane, choose **Settings** > **User Management**.

Step 3 Click + to add a new user to your tenant.

Step 4 Provide the email address of the user.

Note
The user's email address must correspond to the email address of the Cisco Secure Log-On account.

Step 5 From the **Role** drop-down list, select the user's role.

Step 6 Click **OK**.

Troubleshooting LDAP Authentication Connections

If you create an LDAP authentication object and it either does not succeed in connecting to the server you select or does not retrieve the list of users you want, you can tune the settings in the object.

If the connection fails when you test it, try the following suggestions to troubleshoot your configuration:

- Use the messages displayed at the top of the web interface screen and in the test output to determine which areas of the object are causing the issue.
- Check that the user name and password you used for the object are valid:
  - Check that you have the rights to browse to the directory indicated in your base-distinguished name by connecting to the LDAP server using a third-party LDAP browser.
  - Check that the user name is unique to the directory information tree for the LDAP server.
  - If you see an LDAP bind error 49 in the test output, the user binding for the user failed. Try authenticating to the server through a third-party application to see if the binding fails through that connection as well.
- Check that you have correctly identified the server:
  - Check that the server IP address or host name is correct.
  - Check that you have TCP/IP access from your local appliance to the authentication server where you want to connect.
  - Check that access to the server is not blocked by a firewall and that the port you have configured in the object is open.
  - If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used for the server.
  - Check that you have not used an IPv6 address for the server connection if you are authenticating CLI access.
  - If you used server type defaults, check that you have the correct server type and click **Set Defaults** again to reset the default values.
- If you typed in your base-distinguished name, click **Fetch DNs** to retrieve all the available base distinguished names on the server, and select the name from the list.
- If you are using any filters, access attributes, or advanced settings, check that each is valid and typed correctly.
- If you are using any filters, access attributes, or advanced settings, try removing each setting and testing the object without it.
- If you are using a base filter or a CLI access filter, make sure that the filter is enclosed in parentheses and that you are using a valid comparison operator (maximum 450 characters, including the enclosing parentheses).
- To test a more restricted base filter, try setting it to the base distinguished name for the user to retrieve just that user.

- If you are using an encrypted connection:
  - Check that the name of the LDAP server in the certificate matches the host name that you use to connect.
  - Check that you have not used an IPv6 address with an encrypted server connection.
- If you are using a test user, make sure that the user name and password are typed correctly.
- If you are using a test user, remove the user credentials and test the object.
- Test the query that you are using by connecting to the LDAP server and using this syntax:

```
ldapsearch -x -b 'base_distinguished_name'
-h LDAPserver_ip_address -p port -v -D
'user_distinguished_name' -W 'base_filter'
```

For example, if you are trying to connect to the security domain on `myrtle.example.com` using the `domainadmin@myrtle.example.com` user and a base filter of (`cn=*`), you could test the connection using this statement:

```
ldapsearch -x -b 'CN=security,DC=myrtle,DC=example,DC=com'
-h myrtle.example.com -p 389 -v -D
'domainadmin@myrtle.example.com' -W '(cn=*)'
```

If you can test your connection successfully but authentication does not work after you deploy a platform settings policy, check that authentication and the object you want to use are both enabled in the platform settings policy that is applied to the device.

If you connect successfully but want to adjust the list of users retrieved by your connection, you can add or change a base filter or CLI access filter or use a more restrictive or less restrictive base DN.

While authenticating a connection to Active Directory (AD) server, rarely the connection event log indicates blocked LDAP traffic although the connection to AD server is successful. This incorrect connection log occurs when the AD server sends a duplicate reset packet. The Firewall Threat Defense device identifies the second reset packet as part of a new connection request and logs the connection with Block action.

Configure User Preferences

Depending on your user role, you can specify certain preferences for your user account.

Change the Web Interface Appearance

You can change the way the web interface appears when you are using the light theme.

Procedure

Step 1 From the drop-down list under your username, choose **User Preference**.

Step 2 Under **Light theme variant**, click the **Use new design** toggle button to enable or disable the new design.

Enable the toggle to use the left navigation menu and disable it to use the top navigation menu.

Note
This toggle works only if you are using the light theme. If you want to switch between dark theme and light theme, you must do this from the **General Preference** page in Cisco Security Cloud Control. For more information, see Change the Security Cloud Control Web Interface Appearance.

Setting Your Default Time Zone

This setting determines the times displayed in the web interface for your user account only, for things like task scheduling and viewing dashboards. This setting does not change the system time or affect any other user, and does not affect data stored in the system, which generally uses UTC.

Warning The Time Zone function (in User Preferences) assumes that the system clock is set to UTC time. DO NOT ATTEMPT TO CHANGE THE SYSTEM TIME. Changing the system time from UTC is NOT supported, and doing so will require you to reimage the device to recover from an unsupported state.

Note This feature does not affect the time zone used for time-based policy application. Set the time zone for a device in **Devices** > **Platform Settings**.

Procedure

Step 1 From the drop-down list under your user name, choose **User Preferences**.

Step 2 Click **Time Zone** drop-down.

Step 3 Choose the continent or country and the state name that corresponds with the time zone you want to use.

Configure How-To Settings

How To is a widget that provides walkthroughs to navigate through tasks on the Firewall Management Center. The walkthroughs guide you to perform the steps required to achieve a task by taking you through each step, one after the other irrespective of the various UI screens that you may have to navigate, to complete the task. The **How To** widget is enabled by default.

For a list of feature walkthroughs supported in the Firewall Management Center, see Feature Walkthroughs Supported in Secure Firewall Management Center.

Procedure

Step 1 From the drop-down list under your user name, choose **User Preferences**.

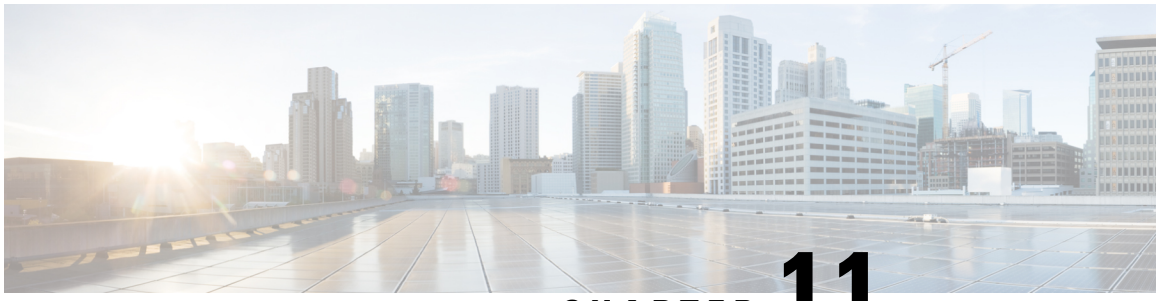
Step 2 Click the **How-To Settings** tab.

Step 3 Check the **Enable How-Tos** check box to enable How-Tos.

Step 4 Click **Save**.

What to do next

To open the How To widget, choose **Help** (?) > **On-screen Assistance** > **How-Tos**. You can search for How-To walkthroughs that address tasks of interest.



CHAPTER 11

Updates

- Product Upgrades, on page 221
- Content Updates, on page 221
- Guidelines and Limitations for Content Updates, on page 222
- Update the Vulnerability Database (VDB), on page 222
- Update the Geolocation Database (GeoDB), on page 224
- Update Intrusion Rules, on page 225

Product Upgrades

This guide does not include information on how to upgrade firewall software or chassis. Instead, see the Cisco Secure Firewall Threat Defense Upgrade Guide for Cloud-Delivered Firewall Management Center.

Content Updates

The system can obtain content updates from the internet. We recommend you schedule or enable automatic content updates whenever possible. Some updates are auto-enabled by the initial setup process or when you enable the related feature. After initial setup, we recommend you review all auto-updates and adjust them if necessary.

Table 14: Content Updates

Component	Description	Details
Vulnerability database (VDB)	The Cisco vulnerability database (VDB) is a database of known vulnerabilities to which hosts may be susceptible, as well as fingerprints for operating systems, clients, and applications. The system uses the VDB to help determine whether a particular host increases your risk of compromise.	**Schedule:** As a scheduled task. **Uninstall:** Starting with VDB 357, you can install any VDB as far back as the baseline VDB for the Firewall Management Center. **See:** Update the Vulnerability Database (VDB), on page 222
Geolocation database (GeoDB)	The Cisco geolocation database (GeoDB) maps IP addresses to countries/continents.	**Schedule:** From its own update page **Uninstall:** No. **See:** Update the Geolocation Database (GeoDB), on page 224

Component	Description	Details
Intrusion rules (SRU/LSP)	Intrusion rule updates provide new and updated intrusion rules and preprocessor rules, modified states for existing rules, and modified default intrusion policy settings. Rule updates may also delete rules, provide new rule categories and default variables, and modify default variable values.	**Schedule:** From its own update page. **Uninstall:** No. **See:** Update Intrusion Rules, on page 225
Security Intelligence feeds	Security Intelligence feeds are collections of IP addresses, domain names, and URLs that you can use to quickly filter traffic that matches an entry.	**Schedule:** From the object manager. **Uninstall:** No. **See:** List and Feed Updates for Security Intelligence, on page 1504
URL categories and reputations	URL filtering allows you to control access to websites based on the URL's general classification (category) and risk level (reputation).	**Schedule:** When you configure integrations/cloud services, or as a scheduled task. **Uninstall:** No. **See:** Enable URL Filtering Using Category and Reputation, on page 1894

Guidelines and Limitations for Content Updates

Release Notes

We recommend you read any release notes or advisory text that accompanies a content update. These provide critical and release-specific information, including compatibility, prerequisites, new capabilities, behavior changes, and warnings.

Scheduled Updates

Review scheduled updates to be sure they occur when you intend. The system schedules tasks — including updates — in UTC. This means that when they occur locally depends on the date and your specific location. Also, because updates are scheduled in UTC, they do not adjust for Daylight Saving Time, summer time, or any such seasonal adjustments that you may observe in your location. If you are affected, scheduled updates occur one hour "later" in the summer than in the winter, according to local time.

Update the Vulnerability Database (VDB)

The Cisco vulnerability database (VDB) is a database of known vulnerabilities to which hosts may be susceptible, as well as fingerprints for operating systems, clients, and applications. The system uses the VDB to help determine whether a particular host increases your risk of compromise.

Cisco issues periodic updates to the VDB. The time it takes to update the VDB and its associated mappings on the Firewall Management Center depends on the number of hosts in your network map. As a rule of thumb, divide the number of hosts by 1000 to determine the approximate number of minutes to perform the update.

The initial setup on the Firewall Management Center automatically downloads and installs the latest VDB from Cisco as a one-time operation. It also schedules a weekly task to download the latest available software updates, which includes the latest VDB. We recommend you review this weekly task and adjust if necessary. Optionally, schedule a new weekly task to actually update the VDB and deploy configurations. For more information, see Vulnerability Database Update Automation, on page 356.

For VDB 343+, all application detector information is available through Cisco Secure Firewall Application Detectors. This site includes a searchable database of application detectors. The release notes provide information on changes for a particular VDB release.

For VDB 363+, the system installs a smaller VDB (also called *VDB lite*) on lower memory devices running Snort 2. This smaller VDB contains the same applications, but fewer detection patterns. Devices using the smaller VDB can miss some application identification versus devices using the full VDB.

Schedule VDB Updates

We recommend you schedule regular VDB updates. See Vulnerability Database Update Automation, on page 356.

Manually Update the VDB

Use this procedure to manually update the VDB. Starting with VDB 357, you can install any VDB as far back as the baseline VDB for the Firewall Management Center.

Caution Do not perform tasks related to mapped vulnerabilities while the VDB is updating. Even if the Message Center shows no progress for several minutes or indicates that the update has failed, do not restart the update. Instead, contact Cisco TAC.

In most cases, the first deploy after a VDB update restarts the Snort process, interrupting traffic inspection. The system warns you when this will happen (updated application detectors and operating system fingerprints require a restart; vulnerability information does not). Whether traffic drops or passes without further inspection during this interruption depends on how the targeted device handles traffic. For more information, see Snort Restart Traffic Behavior, on page 172.

Before you begin

If you are installing an older VDB, get it yourself: https://www.cisco.com/go/firepower-software. Choose any management center model, then browse to the *Coverage and Content Updates* page.

Procedure

Step 1 Choose **System** (⚙) > **Content Updates** > **VDB Updates**.

Step 2 Choose how you want to get the VDB onto the Firewall Management Center.

- Direct download: Click the **Download Updates** button.
- Manual upload: Click **Upload Update**, then **Choose File** and browse to the VDB. After you choose the file, click **Upload**.

Step 3 Install the VDB.

a) Next to the Vulnerability and Fingerprint Database update you want to install, click either the **Install** icon (for a newer VDB) or the **Rollback** icon (for an older VDB).
b) Choose the Firewall Management Center.
c) Click **Install**.

Monitor update progress in the Message Center. After the update completes, the system uses the new vulnerability information. However, you must deploy before updated application detectors and operating system fingerprints can take effect.

Step 4 Verify update success.

The VDB update page shows the current version.

What to do next

- Deploy configuration changes.
- If you based configurations on vulnerabilities, application detectors, or fingerprints that are no longer available, examine those configurations to make sure you are handling traffic as expected. Also, keep in mind a scheduled task to update the VDB can undo a rollback. To avoid this, change the scheduled task or delete any newer VDB packages.

Update the Geolocation Database (GeoDB)

The geolocation database (GeoDB) is a database that you can leverage to view and filter traffic based on geographical location. We issue periodic updates to the GeoDB, and you must regularly update the GeoDB to have accurate geolocation information. As part of the initial configuration, the system schedules weekly GeoDB updates. We recommend you review this task and make changes if necessary, as described in Schedule GeoDB Updates, on page 224.

A GeoDB update overrides any previous versions. The Firewall Management Center automatically updates its managed devices, and unless the update adds new countries (this is rare) you do not need to redeploy. You can see your current version on **System** (⚙) > **Content Updates** > **Geolocation Updates**.

Schedule GeoDB Updates

As part of the initial configuration, the system schedules weekly GeoDB updates. We recommend you review this task and make changes if necessary, as described in this procedure.

Note that the system does not automatically deploy after GeoDB updates because in most cases it is not necessary. However, after a scheduled GeoDB update adds a new country (this is rare), deploy as soon as you are able. This allows the new country to count as part of its continent. For example, if an update adds Country to Continent, rules that filter based on "Continent" do not match traffic through Country until you deploy.

Procedure

Step 1 Choose **System** (⚙) > **Content Updates** > **Geolocation Updates**.

Step 2 Under **Recurring Geolocation Updates**, check **Enable Recurring Weekly Updates...**.

Step 3 Specify the **Update Start Time**.

Step 4 Click **Save**.

Manually Update the GeoDB

Use this procedure to perform an on-demand GeoDB update.

Procedure

Step 1 Choose **System** (⚙) > **Content Updates** > **Geolocation Updates**.

Step 2 Under **One-Time Geolocation Update**, choose how you want to update the GeoDB.

- Direct download: Choose **Download and install...**.
- Manual upload: Choose **Upload and install...**, then click **Choose File** and browse to the package you downloaded earlier.

Step 3 Click **Import**.

Monitor update progress in the Message Center.

Step 4 Verify update success.

The GeoDB update page shows the current version.

What to do next

If the update adds a new country (this is rare), deploy now. Until you deploy, the new country does not count as part of its continent. For example, if an update adds Country to Continent, rules that filter based on "Continent" do not match traffic through Country until you deploy.

Update Intrusion Rules

As new vulnerabilities become known, the Talos Intelligence Group releases intrusion rule updates. These updates affect intrusion rules, preprocessor rules, and the policies that use the rules. Intrusion rule updates are cumulative and we recommend you keep the system up to date. You cannot import an intrusion rule update that either matches or predates the version of the currently installed rules.

An intrusion rule update may provide the following:

- **New and modified rules and rule states**—Rule updates provide new and updated intrusion and preprocessor rules. For new rules, the rule state may be different in each system-provided intrusion policy. For example, a new rule may be enabled in the Security over Connectivity intrusion policy and disabled in the Connectivity over Security intrusion policy. Rule updates may also change the default state of existing rules, or delete existing rules entirely.
- **New rule categories**—Rule updates may include new rule categories, which are always added.
- **Modified preprocessor and advanced settings**—Rule updates may change the advanced settings in the system-provided intrusion policies and the preprocessor settings in system-provided network analysis policies. They can also update default values for the advanced preprocessing and performance options in your access control policies.
- **New and modified variables**—Rule updates may modify default values for existing default variables, but do not override your changes. New variables are always added.

Understanding When Intrusion Rule Updates Modify Policies

Intrusion rule updates can affect both system-provided and custom network analysis policies, as well as all access control policies:

- **System provided**—Changes to system-provided network analysis and intrusion policies, as well as any changes to advanced access control settings, automatically take effect when you re-deploy the policies after the update.
- **Custom**—Because every custom network analysis and intrusion policy uses a system-provided policy as its base, or as the eventual base in a policy chain, rule updates can affect custom network analysis and intrusion policies. However, you can prevent rule updates from automatically making those changes. This allows you to update system-provided base policies manually, on a schedule independent of rule update imports. Regardless of your choice (implemented on a per-custom-policy basis), updates to system-provided policies do not override any settings you customized.

Note that importing a rule update discards all cached changes to network analysis and intrusion policies. For your convenience, the Rule Updates page lists policies with cached changes and the users who made those changes.

Deploying Intrusion Rule Updates

For changes made by an intrusion rule update to take effect, you must redeploy configurations. When importing a rule update, you can configure the system to automatically redeploy to affected devices. This approach is especially useful if you allow the intrusion rule update to modify system-provided base intrusion policies.

Caution Although a rule update by itself does not restart the Snort process when you deploy, other changes you have made may. Restarting Snort briefly interrupts traffic flow and inspection on all devices, including those configured for high availability/scalability. Interface configurations determine whether traffic drops or passes without inspection during the interruption. When you deploy without restarting Snort, resource demands may result in a small number of packets dropping without inspection.

Recurring Intrusion Rule Updates

As part of the initial configuration, the system schedules daily intrusion rule updates. We recommend you review this task and make changes if necessary, as described in Schedule Intrusion Rule Updates, on page 227. You may want to change the frequency, or enable automatic deploy after rule imports.

Importing Local Intrusion Rules

A local intrusion rule is a custom standard text rule that you import from a local machine as a plain text file with ASCII or UTF-8 encoding. You can create local rules using the instructions in the Snort users manual, which is available at http://www.snort.org.

Schedule Intrusion Rule Updates

As part of the initial configuration, the system schedules daily intrusion rule updates. We recommend you review this task and make changes if necessary, as described in this procedure.

Before you begin

- Make sure your process for updating intrusion rules complies with your security policies.
- Consider the update's effect on traffic flow and inspection due to bandwidth constraints and Snort restarts. We recommend performing updates in a maintenance window.

Procedure

Step 1 Choose **System** (⚙) > **Content Updates** > .

Step 2 Under **Recurring Rule Update Imports**, check **Enable Recurring Rule Update Imports**.

Step 3 Specify the **Import Frequency** and start time.

Step 4 (Optional) Check **Reapply all policies...** to deploy after each update.

Step 5 Click **Save**.

Manually Update Intrusion Rules

Use this procedure to perform an on-demand intrusion rule update.

Before you begin

- Make sure your process for updating intrusion rules complies with your security policies.
- Consider the update's effect on traffic flow and inspection due to bandwidth constraints and Snort restarts. We recommend performing updates in a maintenance window.

Procedure

Step 1 Choose **System** (⚙) > **Content Updates** > .

Step 2 Under **One-Time Rule Update/Rules Import**, choose how you want to update intrusion rules.

- Direct download: Choose **Download new rule update...**.
- Manual upload: Choose **Rule update or text rule file...**, then click **Choose File** and browse to the intrusion rule update.

Step 3 (Optional) Check **Reapply all policies...** to deploy after the update.

Step 4 Click **Import**.

Monitor update progress in the Message Center. Even if the Message Center shows no progress for several minutes or indicates that the update has failed, do not restart the update. Instead, contact Cisco TAC.

Step 5 Verify update success.

The rule update page shows the current version.

What to do next

If you did not deploy as a part of the update, deploy now.

Import Local Intrusion Rules

Use this procedure to import local intrusion rules. Imported intrusion rules appear in the local rule category in a disabled state.

Before you begin

- Make sure your local rule file follows the guidelines described in Best Practices for Importing Local Intrusion Rules, on page 229.
- Make sure your process for importing local intrusion rules complies with your security policies.
- Consider the import's effect on traffic flow and inspection due to bandwidth constraints and Snort restarts. We recommend scheduling rule updates during maintenance windows.

Procedure

Step 1 Choose **System** (⚙) > **Content Updates** > .

You can also click **Import Rules** in the intrusion rules editor (**Objects** > **Intrusion Rules**).

Step 2 (Optional) Delete existing local rules.

Click **Delete All Local Rules**, then confirm that you want to move all created and imported intrusion rules to the deleted folder.

Step 3 Under **One-Time Rule Update/Rules Import**, choose **Rule update or text rule file to upload and install**, then click **Choose File** and browse to your local rule file.

Step 4 Click **Import**.

You can monitor import progress in the Message Center. Even if the Message Center shows no progress for several minutes or indicates that the update has failed, do not restart the import. Instead, contact Cisco TAC.

What to do next

- Edit intrusion policies and enable the rules you imported.
- Deploy configuration changes.

Best Practices for Importing Local Intrusion Rules

Observe the following guidelines when importing a local rule file:

- The rules importer requires that all custom rules are imported in a plain text file encoded in ASCII or UTF-8.
- The text file name can include alphanumeric characters, spaces, and no special characters other than underscore (_), period (.), and dash (-).
- The system imports local rules preceded with a single pound character (#), but they are flagged as deleted.
- The system imports local rules preceded with a single pound character (#), and does not import local rules preceded with two pound characters (##).
- Rules cannot contain any escape characters.
- You do not have to specify a Generator ID (GID) when importing a local rule. If you do, specify only GID 1 for a standard text rule.
- When importing a rule for the first time, do *not* specify a Snort ID (SID) or revision number. This avoids collisions with SIDs of other rules, including deleted rules. The system will automatically assign the rule the next available custom rule SID of 1000000 or greater, and a revision number of 1.

  If you must import rules with SIDs, a SID can be any unique number 1,000,000 or greater.
- When importing an updated version of a local rule you have previously imported, or when reinstating a local rule you have deleted, you *must* include the SID assigned by the system and a revision number greater than the current revision number. You can determine the revision number for a current or deleted rule by editing the rule.

Note The system automatically increments the revision number when you delete a local rule; this is a device that allows you to reinstate local rules. All deleted local rules are moved from the local rule category to the deleted rule category.

- Import local rules on the primary Firewall Management Center in a high availability pair to avoid SID numbering issues.
- The import fails if a rule contains any of the following: .
  - A SID greater than 2147483647.
  - A list of source or destination ports that is longer than 64 characters.
- Policy validation fails if you enable an imported local rule that uses the deprecated `threshold` keyword in combination with the intrusion event thresholding feature in an intrusion policy.
- All imported local rules are automatically saved in the local rule category.
- The system always sets local rules that you import to the disabled rule state. You must manually set the state of local rules before you can use them in your intrusion policy.

View Intrusion Rule Update Logs

The system generates logs of rule updates/imports, listed by timestamp, user, and whether each update succeeded or failed. These logs contain detailed import information on all updated rules and components; see Intrusion Rule Update Log Details, on page 230. Use this procedure to view rule import logs. Note that deleting an import log does not delete the imported objects.

Procedure

Step 1 Choose **System** (⚙) > **Content Updates** > .

Step 2 Click **Rule Update Log**.

Step 3 (Optional) View details for any rule update by clicking **View** (👁) next to the log file.

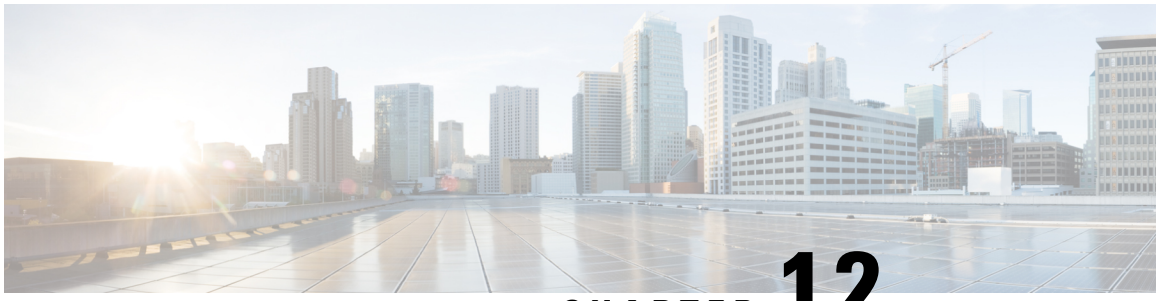
Intrusion Rule Update Log Details

Tip You search the entire Rule Update Import Log database even when you initiate a search by clicking **Search** on the toolbar from the Rule Update Import Log detailed view with only the records for a single import file displayed. Make sure you set your time constraints to include all objects you want to include in the search.

Table 15: Intrusion Rule Update Log Details

Field	Description
Action	An indication that one of the following has occurred for the object type: • `new` (for a rule, this is the first time the rule has been stored on this appliance) • `changed` (for a rule update component or rule, the rule update component has been modified, or the rule has a higher revision number and the same GID and SID) • `collision` (for a rule update component or rule, import was skipped because its revision conflicts with an existing component or rule on the appliance) • `deleted` (for rules, the rule has been deleted from the rule update) • `enabled` (for a rule update edit, a preprocessor, rule, or other feature has been enabled in a default policy provided with the system) • `disabled` (for rules, the rule has been disabled in a default policy provided with the system) • `drop` (for rules, the rule has been set to Drop and Generate Events in a default policy provided with the system) • `error` (for a rule update or local rule file, the import failed) • `apply` (the **Reapply all policies after the rule update import completes** option was enabled for the import)
Default Action	The default action defined by the rule update. When the imported object type is `rule`, the default action is `Pass`, `Alert`, or `Drop`. For all other imported object types, there is no default action.
Details	A string unique to the component or rule. For rules, the GID, SID, and previous revision number for a changed rule, displayed as `previously (GID:SID:Rev)`. This field is blank for a rule that has not changed.
GID	The generator ID for a rule. For example, `1` (standard text rule, Global domain or legacy GID) or `3` (shared object rule).
Name	The name of the imported object, which for rules corresponds to the rule Message field, and for rule update components is the component name.
Policy	For imported rules, this field displays `All`. This means that the rule was imported successfully, and can be enabled in all appropriate default intrusion policies. For other types of imported objects, this field is blank.
Rev	The revision number for a rule.
Rule Update	The rule update file name.
SID	The SID for a rule.
Time	The time and date the import began.

Field	Description
Type	The type of imported object, which can be one of the following: • `rule update component` (an imported component such as a rule pack or policy pack) • `rule` (for rules, a new or updated rule) • `policy apply` (the **Reapply all policies after the rule update import completes** option was enabled for the import)
Count	The count (`1`) for each record. The Count field appears in a table view when the table is constrained, and the Rule Update Log detailed view is constrained by default to rule update records. This field is not searchable.



CHAPTER 12

Licenses

This chapter provides in-depth information about the different license types, service subscriptions, licensing requirements and more.

Note The Firewall Management Center supports either a Smart License or a legacy PAK (Product Activation Keys) license for its platform license.

- About Licenses, on page 233
- Requirements and Prerequisites for Licensing, on page 249
- Create a Cisco Account, on page 250
- Create a Smart Account and Add Licenses, on page 251
- Configure Smart Licensing, on page 253
- Configure Legacy Firewall Management Center PAK-Based Licenses, on page 260
- Additional Information about Licensing, on page 261

About Licenses

Cisco Smart Licensing is a flexible licensing model that provides you with an easier, faster, and more consistent way to purchase and manage software across the Cisco portfolio and across your organization. And it's secure—you control what users can access. With Smart Licensing you get:

- **Easy Activation:** Smart Licensing establishes a pool of software licenses that can be used across the entire organization—no more PAKs (Product Activation Keys).
- **Unified Management:** My Cisco Entitlements (MCE) provides a complete view into all of your Cisco products and services in an easy-to-use portal, so you always know what you have and what you are using.
- **License Flexibility:** Your software is not node-locked to your hardware, so you can easily use and transfer licenses as needed.

To use Smart Licensing, you must first set up a Smart Account on Cisco Software Central (software.cisco.com).

For a more detailed overview on Cisco Licensing, go to cisco.com/go/licensingguide

Smart Software Manager and Accounts

When you purchase one or more licenses, you manage them in the Smart Software Manager: https://software.cisco.com/#module/SmartLicensing. The Smart Software Manager lets you create a primary account for your organization. If you do not yet have an account, click the link to set up a new account. The Smart Software Manager lets you create a primary account for your organization. For instructions, see Create a Cisco Account.

By default, your licenses are assigned to the Default Virtual Account under your primary account. As the account administrator, you can create additional virtual accounts; for example, for regions, departments, or subsidiaries. Multiple virtual accounts help you manage large numbers of licenses and devices.

You manage licenses by virtual account. Only that virtual account's devices can use the licenses assigned to the account. If you need additional licenses, you can transfer an unused license from another virtual account. You can also transfer devices between virtual accounts.

How Licensing Works for the Management Center and Devices

The Firewall Management Center registers with the Smart Software Manager, and then assigns licenses for each managed device. Devices do not register directly with the Smart Software Manager.

A physical Firewall Management Center does not require a license for its own use.

Periodic Communication with the Smart Software Manager

In order to maintain your product license entitlement, your product must communicate periodically with the Smart Software Manager.

You use a Product Instance Registration Token to register the Firewall Management Center with the Smart Software Manager. The Smart Software Manager issues an ID certificate for communication between the Firewall Management Center and the Smart Software Manager. This certificate is valid for one year, although it will be renewed every six months. If an ID certificate expires (after a year with no communication), the Firewall Management Center may be removed from your account.

The Firewall Management Center communicates with the Smart Software Manager on a periodic basis. If you make changes in the Smart Software Manager, you can refresh the authorization on the Firewall Management Center so the changes immediately take effect. You also can wait for the Firewall Management Center to communicate as scheduled.

Your Firewall Management Center must either have direct internet access to the Smart Software Manager. In non-airgapped deployments, normal license communication occurs every 30 days, but with the grace period, your Firewall Management Center will operate for up to 90 days without contacting the Smart Software Manager. Ensure that the Firewall Management Center contacts the Smart Software Manager before 90 days have passed, or else the Firewall Management Center will revert to an unregistered state.

Cloud-Delivered Firewall Management Center and Threat Defense Licenses

You do not have to purchase a separate license to use the Cloud-Delivered Firewall Management Center in Security Cloud Control; the base subscription for a Security Cloud Control tenant includes the cost for the Cloud-Delivered Firewall Management Center.

Cloud-delivered Firewall Management Center Evaluation License

The cloud-delivered Firewall Management Center comes provisioned with a 90-day evaluation license. After the evaluation period has elapsed, you can still onboard Firewall Threat Defense devices to the cloud-delivered Firewall Management Center. However, any manually triggered or scheduled deployments are blocked, until you register your cloud-delivered Firewall Management Center with the Cisco Smart Software Manager (CSSM). As your evaluation license approaches the expiry date, Security Cloud Control notifies you through alerts on the notifications window.

We also recommend that, after registering to CSSM, you purchase the required licenses for the features you want to use. Purchasing licenses keeps the cloud-delivered Firewall Management Center from going out of compliance.

To know more about how to register the cloud-delivered Firewall Management Center with CSSM, see Register the Management Center with the Smart Software Manager.

To learn how to get a cloud-delivered Firewall Management Center provisioned on your Security Cloud Control tenant, see Request a Cloud-delivered Firewall Management Center for your Security Cloud Control Tenant.

Note The Cloud-Delivered Firewall Management Center does not support specific license reservation (SLR) for devices in air-gapped networks.

Threat Defense Licenses for Cloud-Delivered Firewall Management Center

You need individual licenses for each Secure Firewall Threat Defense device managed by the Cloud-Delivered Firewall Management Center. See Licensing in *Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Security Cloud Control* for information.

To know how Security Cloud Control handles licensing for the devices migrated to the Cloud-Delivered Firewall Management Center, see Migrate Threat Defense from Management Center to Cloud.

Note The Talos certificate for Evaluation Mode in Secure Firewall version 7.6.0 is set to expire on March 31, 2025. After this date, access to Talos-hosted services in Evaluation Mode (specifically those related to web reputation / categorization lookups) will be discontinued.

Out-of-Compliance State

The Firewall Management Center can become out of compliance in the following situations:

- License expiration—When a managed device term-based license expires.

In an out-of-compliance state, see the following effects:

- All managed device licenses—Operation is not affected.

After you resolve the licensing problem, the Firewall Management Center will show that it is now in compliance after its regularly scheduled authorization with the Smart Software Manager. To force an authorization, click **Re-Authorize** on the **System** (⚙) > **Licenses** > **Smart Licenses** page.

Unregistered State

The Firewall Management Center can become unregistered in the following situations:

- Evaluation mode expiration—Evaluation mode expires after 90 days.
- Manual deregistration of the Firewall Management Center
- Lack of communication with the Smart Software Manager—The Firewall Management Center does not communicate with the Smart Software Manager for 1 year. Note: After 90 days, the Firewall Management Center authorization expires, but it can successfully resume communication within one year to automatically re-authorize. After a year, the ID certificate expires, and the Firewall Management Center is removed from your account so you will have to manually re-register the Firewall Management Center.

In an unregistered state, the Firewall Management Center cannot deploy any configuration changes to devices *for features that require licenses*.

End-User License Agreement

The Cisco end-user license agreement (EULA) and any applicable supplemental agreement (SEULA) that governs your use of this product are available from http://www.cisco.com/go/softwareterms.

License Types and Restrictions

This section describes the types of licenses available.

Table 16: Smart Licenses

License You Assign	Duration	Granted Capabilities
Essentials	Perpetual or Subscription **Note** Essentials subscription licenses are supported only on Firewall Threat Defense Virtual.	Except for Specific License Reservation and the Secure Firewall 3100, Essentials perpetual licenses are automatically assigned with all Firewall Threat Defenses. User and application control Switching and routing NAT For details, see Essentials Licenses, on page 238.
IPS	Subscription	Intrusion detection and prevention File control Security Intelligence filtering For details, see IPS Licenses, on page 239

License You Assign	Duration	Granted Capabilities
Malware defense	Subscription	Malware defense Secure Malware Analytics File storage (IPS license is a prerequisite for a Malware defense license.) For details, see Malware Defense Licenses, on page 238 and *License Requirements for File and Malware Policies* in the Cisco Secure Firewall Management Center Device Configuration Guide.
Carrier	Subscription for Firepower 4100/9300, Secure Firewall 3100, and Firewall Threat Defense Virtual	Diameter, GTP/GPRS, M3UA, and SCTP inspection For details, see Carrier License, on page 239.
URL Filtering	Subscription	Category and reputation-based URL filtering For details, see URL Filtering Licenses, on page 240. (IPS license is a prerequisite for a URL Filtering license.)
Export-Controlled Features	Perpetual	Features that are subject to national security, foreign policy, and anti-terrorism laws and regulations; see Licensing for Export-Controlled Functionality, on page 242.
Remote Access VPN: • Secure Client Premier • Secure Client Advantage • Secure Client VPN Only	Subscription or perpetual	Remote access VPN configuration. Your account must allow export-controlled functionality to configure remote access VPN. You select whether you meet export requirements when you register the device. The Firewall Threat Defense can use any valid Secure Client license. The available features do not differ based on license type. For more information, see Secure Client Licenses, on page 241 and *VPN Licensing* in the Cisco Secure Firewall Management Center Device Configuration Guide.

Note Subscription licenses are term-based licenses.

Essentials Licenses

The Essentials license allows you to:

- Configure your devices to perform switching and routing (including DHCP relay and NAT)
- Configure devices as a high availability pair
- Configure clustering
- Implement user and application control by adding user and application conditions to access control rules
- Update the Vulnerability database (VDB) and geolocation database (GeoDB).
- Download intrusion rules such as SRU/LSP. However, you cannot deploy access control policy or rules that have intrusion policy to the device unless IPS license is enabled.

Secure Firewall 3100

You obtain a Essentials license when you purchase the Secure Firewall 3100.

Other Models

Except in deployments using Specific License Reservation, a Essentials license is automatically added to your account when you register a device to the Firewall Management Center. For Specific License Reservation, you need to add the Essentials license to your account.

Malware Defense Licenses

A Malware defense license lets you perform Malware Defense and Secure Malware Analytics. With this feature, you can use devices to detect and block malware in files transmitted over your network. To support this feature license, you can purchase the Malware defense (AMP) service subscription as a stand-alone subscription or in combination with IPS (TM) or IPS and URL Filtering (TMC) subscriptions. IPS license is a prerequisite for a Malware defense license.

Note Managed devices with Malware defense licenses enabled periodically attempt to connect to the Secure Malware Analytics Cloud even if you have not configured dynamic analysis. Because of this, the device's Interface Traffic dashboard widget shows transmitted traffic; this is expected behavior.

You configure Malware Defense as part of a file policy, which you then associate with one or more access control rules. File policies can detect your users uploading or downloading files of specific types over specific application protocols. Malware Defense allows you to use local malware analysis and file preclassification to inspect a restricted set of those file types for malware. You can also download and submit specific file types to the Secure Malware Analytics Cloud for dynamic and Spero analysis to determine whether they contain malware. For these files, you can view the network file trajectory, which details the path the file has taken through your network. The Malware Defense license also allows you to add specific files to a file list and enable the file list within a file policy, allowing those files to be automatically allowed or blocked on detection.

Note that a Malware defense license is required only if you deploy Malware Defense and Secure Malware Analytics. Without a Malware defense license, the Firewall Management Center can receive Secure Endpoint malware events and indications of compromise (IOC) from the Secure Malware Analytics Cloud.

See also important information at *License Requirements for File and Malware Policies* in the Cisco Secure Firewall Management Center Device Configuration Guide.

When you disable this license:

- The system stops querying the Secure Malware Analytics Cloud, and also stops acknowledging retrospective events sent from the Secure Malware Analytics Cloud.
- You cannot re-deploy existing access control policies if they include Malware Defense configurations.
- For a very brief time after a Malware defense license is disabled, the system can use existing cached file dispositions. After the time window expires, the system assigns a disposition of `Unavailable` to those files.

If the license expires, your entitlement for the above capabilities ceases and the Firewall Management Center moves to the out-of-compliance state.

IPS Licenses

A IPS license allows you to perform intrusion detection and prevention, file control, and Security Intelligence filtering:

- *Intrusion detection and prevention* allows you to analyze network traffic for intrusions and exploits and, optionally, drop offending packets.
- *File control* allows you to detect and, optionally, block users from uploading (sending) or downloading (receiving) files of specific types over specific application protocols. *Malware defense*, which requires a Malware defense license, allows you to inspect and block a restricted set of those file types based on their dispositions.
- *Security Intelligence filtering* allows you to block —deny traffic to and from—specific IP addresses, URLs, and DNS domain names, before the traffic is subjected to analysis by access control rules. Dynamic feeds allow you to immediately block connections based on the latest intelligence. Optionally, you can use a "monitor-only" setting for Security Intelligence filtering.

You can purchase a IPS license as a stand-alone subscription (T) or in combination with URL Filtering (TC), Malware defense (TM), or both (TMC).

When you disable this license:

- The Firewall Management Center stops acknowledging intrusion and file events from the affected devices. As a consequence, correlation rules that use those events as a trigger criteria stop firing.
- The Firewall Management Center does not contact the internet for either Cisco-provided or third-party Security Intelligence information.
- You cannot re-deploy existing intrusion policies until you re-enable IPS.

If the license expires, your entitlement for the above capabilities ceases and the Firewall Management Center moves to the out-of-compliance state.

Carrier License

The Carrier license enables the inspection of the following protocols:

- Diameter—Diameter is an Authentication, Authorization, and Accounting (AAA) protocol used in next-generation mobile and fixed telecom networks such as EPS (Evolved Packet System) for LTE (Long

Term Evolution) and IMS (IP Multimedia Subsystem). It replaces RADIUS and TACACS in these networks.

- GTP/GPRS—GPRS Tunneling Protocol (GTP) is used in GSM, UMTS, and LTE networks for general packet radio service (GPRS) traffic. GTP provides a tunnel control and management protocol to provide GPRS network access for a mobile station by creating, modifying, and deleting tunnels. GTP also uses a tunneling mechanism for carrying user data packets.
- M3UA—MTP3 User Adaptation (M3UA) is a client/server protocol that provides a gateway to the Signaling System 7 (SS7) network for IP-based applications that interface with the SS7 Message Transfer Part 3 (MTP3) layer. M3UA makes it possible to run the SS7 User Parts (such as ISUP) over an IP network.
- SCTP—Stream Control Transmission Protocol (SCTP) is a transport-layer protocol that supports the SS7 protocol over IP networks. It supports the 4G LTE mobile network architecture. SCTP can handle multiple simultaneous streams, multiplexed streams, and provides more security features.

Note After you enable this license on a device, use a FlexConfig policy to enable the protocol inspection.

The Carrier license PIDs are available per family and not per device model. You can enable this license for each device either in the evaluation mode or with a Smart License.

The Carrier license for Firepower 4100/9300, Secure Firewall 3100, and Firewall Threat Defense Virtual is term-based. This license also supports Specific License Reservation.

Supported Devices

The devices that support the Carrier License are:

- Secure Firewall 3110
- Secure Firewall 3120
- Secure Firewall 3130
- Secure Firewall 3140
- Firepower 4112
- Firepower 4115
- Firepower 4125
- Firepower 4145
- Firepower 9300
- Firewall Threat Defense Virtual

URL Filtering Licenses

The URL Filtering license allows you to write access control rules that determine the traffic that can traverse your network based on URLs requested by monitored hosts, correlated with information about those URLs. To support this feature license, you can purchase the URL Filtering service subscription as a stand-alone

subscription or in combination with IPS (TC) or Threat and Malware defense (TMC) subscriptions. IPS license is a prerequisite for this license.

Tip Without a URL Filtering license, you can specify individual URLs or groups of URLs to allow or block. This option gives you granular, custom control over web traffic, but does not allow you to use URL category and reputation data to filter network traffic.

Although you can add category and reputation-based URL conditions to access control rules without a URL Filtering license, the Firewall Management Center will not download URL information. You cannot deploy the access control policy until you first add a URL Filtering license to the Firewall Management Center, then enable it on the devices targeted by the policy.

When you disable this license:

- You may lose access to filtering network traffic based on the URL category and reputation ACP rules. The manual URL filtering options will continue to be supported.
- Access control rules with URL conditions immediately stop filtering URLs.
- Your Firewall Management Center can no longer download updates to URL data.
- You cannot re-deploy existing access control policies if they include rules with category and reputation-based URL conditions.

If the license expires, your entitlement for the above capabilities ceases and the Firewall Management Center moves to the out-of-compliance state.

Secure Client Licenses

You can configure remote access VPN using the Secure Client and standards-based IPSec/IKEv2.

To enable remote access VPN, you must purchase and enable one of the following licenses: Secure Client Advantage, Secure Client Premier, or Secure Client VPN Only. You can select Secure Client Advantage and Secure Client Premier if you have both licenses and you want to use them both. The Secure Client VPN Onlylicense cannot be used with **Apex** or **Plus**. The Secure Client license must be shared with the Smart Account. For more instructions, see http://www.cisco.com/c/dam/en/us/products/collateral/security/anyconnect-og.pdf.

You cannot deploy the remote access VPN configuration to the device if the specified device does not have the entitlement for a minimum of one of the specified Secure Client license types. If the registered license moves out of compliance or entitlements expire, the system displays licensing alerts and health events.

While using remote access VPN, your Smart Account must have the export controlled features (strong encryption) enabled. The Firewall Threat Defense requires strong encryption (which is higher than DES) for successfully establishing remote access VPN connections with Secure Clients.

You cannot deploy remote access VPN if the following are true:

- Smart Licensing on the Firewall Management Center is running in evaluation mode.
- Your Smart Account is not configured to use export-controlled features (strong encryption).

Licensing for Export-Controlled Functionality

Features that require export-controlled functionality

Certain software features are subject to national security, foreign policy, and anti-terrorism laws and regulations. These export-controlled features include:

- Security certifications compliance
- Remote access VPN
- Site-to-site VPN with strong encryption
- SSH platform policy with strong encryption
- SSL policy with strong encryption
- Functionality such as SNMPv3 with strong encryption

How to determine whether export-controlled functionality is currently enabled for your system

To determine whether export-controlled functionality is currently enabled for your system: Go to**System** (⚙) > **Licenses** > **Smart Licenses** and see if **Export-Controlled Features** displays **Enabled**.

About enabling export-controlled functionality

If **Export-Controlled Features** shows **Disabled** and you want to use features that require strong encryption, there are two ways to enable strong cryptographic features. Your organization may be eligible for one or the other (or neither), but not both.

- If there is *no* option to enable export-controlled functionality when you generate a new Product Instance Registration Token in the Smart Software Manager, contact your account representative.
- If the option “Allow export-controlled functionality on the products registered with this token” appears when you generate a new Product Instance Registration Token in the Smart Software Manager, make sure you check it before generating the token.

  If you did not enable export-controlled functionality for the Product Instance Registration Token that you used to register the Firewall Management Center, then you must deregister and then re-register the Firewall Management Center using a new Product Instance Registration Token with export-controlled functionality enabled.

If you registered devices to the Firewall Management Center in evaluation mode or before you enabled strong encryption on the Firewall Management Center, reboot each managed device to make strong encryption available. In a high availability deployment, the active and standby devices must be rebooted together to avoid an Active-Active condition.

The entitlement is perpetual and does not require a subscription.

More Information

For general information about export controls, see https://www.cisco.com/c/en/us/about/legal/global-export-trade.html.

Firewall Threat Defense Virtual Licenses

This section describes the performance-tiered license entitlements available for the Firewall Threat Defense Virtual.

Any Firewall Threat Defense Virtual license can be used on any supported Firewall Threat Defense Virtual vCPU/memory configuration. This allows Firewall Threat Defense Virtual customers to run on a wide variety of VM resource footprints. This also increases the number of supported AWS and Azure instances types. When configuring the Firewall Threat Defense Virtual VM, the maximum supported number of cores (vCPUs) is 16 ; and the maximum supported memory is 32 GB RAM .

Performance Tiers for Firewall Threat Defense Virtual Smart Licensing

Session limits for RA VPNs are determined by the installed Firewall Threat Defense Virtual platform entitlement tier, and enforced via a rate limiter. The following table summarizes the session limits based on the entitlement tier and rate limiter.

Table 17: Firewall Threat Defense Virtual Licensed Feature Limits Based on Entitlement

Performance Tier	Device Specifications (Core/RAM)	Rate Limit	RA VPN Session Limit
FTDv5, 100Mbps	4 core/8 GB	100Mbps	50
FTDv10, 1Gbps	4 core/8 GB	1Gbps	250
FTDv20, 3Gbps	4 core/8 GB	3Gbps	250
FTDv30, 5Gbps	8 core/16 GB	5Gbps	250
FTDv50, 10Gbps	12 core/24 GB	10Gbps	750
FTDv100, 16Gbps	16 core/32 GB	16Gbps	10,000

Firewall Threat Defense Virtual Performance Tier Licensing Guidelines and Limitations

Please keep the following guidelines and limitations in mind when licensing your Firewall Threat Defense Virtual device.

- The Firewall Threat Defense Virtual supports performance-tiered licensing that provides different throughput levels and VPN connection limits based on deployment requirements.
- Any Firewall Threat Defense Virtual license can be used on any supported Firewall Threat Defense Virtual core/memory configuration. This allows the Firewall Threat Defense Virtual customers to run on a wide variety of VM resource footprints.
- You can select a performance tier when you deploy the Firewall Threat Defense Virtual, whether your device is in evaluation mode or is already registered with Cisco Smart Software Manager.

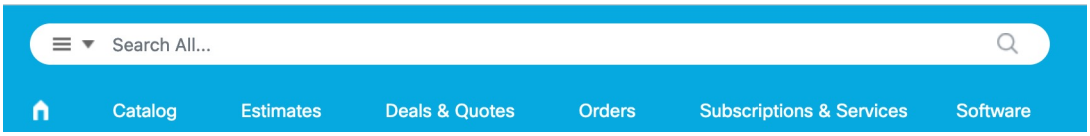
Note Make sure your Smart Licensing account contains the available licenses you need. It's important to choose the tier that matches the license you have in your account. If you are upgrading your Firewall Threat Defense Virtual to Version 7.0, you can choose **FTDv - Variable** to maintain your current license compliance. Your Firewall Threat Defense Virtual continues to perform with session limits based on your device capabilities (number of cores/RAM).

- The default performance tier is FTDv50 when deploying a new Firewall Threat Defense Virtual device, or when provisioning the Firewall Threat Defense Virtual using the REST API.
- Essentials licenses are subscription-based and mapped to performance tiers. Your virtual account needs to have the Essentials license entitlements for the Firewall Threat Defense Virtual devices, as well as for IPS, Malware Defense, and URL Filtering licenses.
- Each HA peer consumes one entitlement, and the entitlements on each HA peer must match, including Essentials license.
- A change in performance tier for an HA pair should be applied to the primary peer.
- You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.
- Universal PLR licensing is applied to each device in an HA pair separately. The secondary device will not automatically mirror the performance tier of the primary device. It must be updated manually.

License PIDs

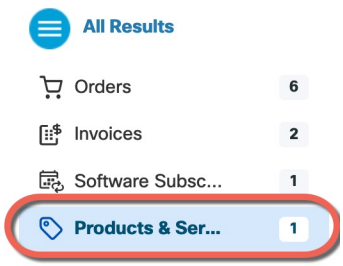
When you bought your device from Cisco or a reseller, your licenses should have been linked to your Smart Software License account. However, if you need to add licenses yourself, use the **Search All** field on the Cisco Commerce Workspace.

Figure 66: License Search



Choose **Products & Services** from the results.

Figure 67: Results



Firewall Threat Defense Virtual PIDs

When you order FTDV-SEC-SUB, you must choose a Essentials license and optional feature licenses (12 month term):

- Essentials license:
  - FTD-V-5S-BSE-K9
  - FTD-V-10S-BSE-K9
  - FTD-V-20S-BSE-K9
  - FTD-V-30S-BSE-K9
  - FTD-V-50S-BSE-K9
  - FTD-V-100S-BSE-K9
- IPS, Malware defense, and URL license combination:
  - FTD-V-5S-TMC
  - FTD-V-10S-TMC
  - FTD-V-20S-TMC
  - FTD-V-30S-TMC
  - FTD-V-50S-TMC
  - FTD-V-100S-TMC
- Carrier—FTDV_CARRIER
- Cisco Secure Client—See the Cisco Secure Client Ordering Guide.

Firepower 1010 PIDs

- IPS, Malware defense, and URL license combination:
  - L-FPR1010T-TMC=

  When you add the above PID to your order, you can then choose a term-based subscription corresponding with one of the following PIDs:
  - L-FPR1010T-TMC-1Y
  - L-FPR1010T-TMC-3Y
  - L-FPR1010T-TMC-5Y
- Cisco Secure Client—See the Cisco Secure Client Ordering Guide.

Firepower 1100 PIDs

- IPS, Malware defense, and URL license combination:
  - L-FPR1120T-TMC=

- L-FPR1140T-TMC=
- L-FPR1150T-TMC=

When you add one of the above PIDs to your order, you can then choose a term-based subscription corresponding with one of the following PIDs:

- L-FPR1120T-TMC-1Y
- L-FPR1120T-TMC-3Y
- L-FPR1120T-TMC-5Y
- L-FPR1140T-TMC-1Y
- L-FPR1140T-TMC-3Y
- L-FPR1140T-TMC-5Y
- L-FPR1150T-TMC-1Y
- L-FPR1150T-TMC-3Y
- L-FPR1150T-TMC-5Y

- Cisco Secure Client—See the Cisco Secure Client Ordering Guide.

Firepower 2100 PIDs

- IPS, Malware defense, and URL license combination:
  - L-FPR2110T-TMC=
  - L-FPR2120T-TMC=
  - L-FPR2130T-TMC=
  - L-FPR2140T-TMC=

  When you add one of the above PIDs to your order, you can then choose a term-based subscription corresponding with one of the following PIDs:
  - L-FPR2110T-TMC-1Y
  - L-FPR2110T-TMC-3Y
  - L-FPR2110T-TMC-5Y
  - L-FPR2120T-TMC-1Y
  - L-FPR2120T-TMC-3Y
  - L-FPR2120T-TMC-5Y
  - L-FPR2130T-TMC-1Y
  - L-FPR2130T-TMC-3Y
  - L-FPR2130T-TMC-5Y

- L-FPR2140T-TMC-1Y
- L-FPR2140T-TMC-3Y
- L-FPR2140T-TMC-5Y

- Cisco Secure Client—See the Cisco Secure Client Ordering Guide.

Secure Firewall 3100 PIDs

- Essentials license:
  - *Included automatically*
- IPS, Malware defense, and URL license combination:
  - L-FPR3110T-TMC=
  - L-FPR3120T-TMC=
  - L-FPR3130T-TMC=
  - L-FPR3140T-TMC=

  When you add one of the above PIDs to your order, you can then choose a term-based subscription corresponding with one of the following PIDs:
  - L-FPR3105T-TMC-1Y
  - L-FPR3105T-TMC-3Y
  - L-FPR3105T-TMC-5Y
  - L-FPR3110T-TMC-1Y
  - L-FPR3110T-TMC-3Y
  - L-FPR3110T-TMC-5Y
  - L-FPR3120T-TMC-1Y
  - L-FPR3120T-TMC-3Y
  - L-FPR3120T-TMC-5Y
  - L-FPR3130T-TMC-1Y
  - L-FPR3130T-TMC-3Y
  - L-FPR3130T-TMC-5Y
  - L-FPR3140T-TMC-1Y
  - L-FPR3140T-TMC-3Y
  - L-FPR3140T-TMC-5Y
- Carrier—L-FPR3K-FTD-CAR=
- Cisco Secure Client—See the Cisco Secure Client Ordering Guide.

Firepower 4100 PIDs

- IPS, Malware defense, and URL license combination:
  - L-FPR4112T-TMC=
  - L-FPR4115T-TMC=
  - L-FPR4125T-TMC=
  - L-FPR4145T-TMC=

  When you add one of the above PIDs to your order, you can then choose a term-based subscription corresponding with one of the following PIDs:
  - L-FPR4112T-TMC-1Y
  - L-FPR4112T-TMC-3Y
  - L-FPR4112T-TMC-5Y
  - L-FPR4115T-TMC-1Y
  - L-FPR4115T-TMC-3Y
  - L-FPR4115T-TMC-5Y
  - L-FPR4125T-TMC-1Y
  - L-FPR4125T-TMC-3Y
  - L-FPR4125T-TMC-5Y
  - L-FPR4145T-TMC-1Y
  - L-FPR4145T-TMC-3Y
  - L-FPR4145T-TMC-5Y
- Carrier—L-FPR4K-FTD-CAR=
- Cisco Secure Client—See the Cisco Secure Client Ordering Guide.

Firepower 9300 PIDs

- IPS, Malware defense, and URL license combination:
  - L-FPR9K-40T-TMC=
  - L-FPR9K-48T-TMC=
  - L-FPR9K-56T-TMC=

  When you add one of the above PIDs to your order, you can then choose a term-based subscription corresponding with one of the following PIDs:
  - L-FPR9K-40T-TMC-1Y
  - L-FPR9K-40T-TMC-3Y
  - L-FPR9K-40T-TMC-5Y

- L-FPR9K-48T-TMC-1Y
- L-FPR9K-48T-TMC-3Y
- L-FPR9K-48T-TMC-5Y
- L-FPR9K-56T-TMC-1Y
- L-FPR9K-56T-TMC-3Y
- L-FPR9K-56T-TMC-5Y

- Carrier—L-FPR9K-FTD-CAR=
- Cisco Secure Client—See the Cisco AnyConnect Ordering Guide.

ISA 3000 PIDs

- IPS, Malware defense, and URL license combination:
  - L-ISA3000T-TMC=

  When you add the above PID to your order, you can then choose a term-based subscription corresponding with one of the following PIDs:
  - L-ISA3000T-TMC-1Y
  - L-ISA3000T-TMC-3Y
  - L-ISA3000T-TMC-5Y
- Cisco Secure Client—See the Cisco AnyConnect Ordering Guide.

Requirements and Prerequisites for Licensing

General Prerequisites

- Make sure NTP is configured on the Firewall Management Center and managed devices. Time must be synchronized for registration to succeed.

  For a Firepower 4100/9300, you must configure NTP on the chassis using the same NTP server for the chassis as for the Firewall Management Center.

Supported Domains

Global, except where indicated.

User Roles

- Admin

Requirements and Prerequisites for Licensing for High Availability, Clustering, and Multi-Instance

This section describes the licensing requirements for device High Availability.

FTD Services does not support clustering or multi-instance deployments.

Licensing for Device High-Availability

Both Firewall Threat Defense units in a high availability configuration must have the same licenses.

High availability configurations require two license entitlements: one for each device in the pair.

Before high availability is established, it does not matter which licenses are assigned to the secondary/standby device. During high availability configuration, the Firewall Management Center releases any unnecessary licenses assigned to the standby unit and replaces them with identical licenses assigned to the primary/active unit. For example, if the active unit has a Essentials license and a IPS license, and the standby unit has only a Essentials license, the Firewall Management Center communicates with the Smart Software Manager to obtain an available IPS license from your account for the standby unit. If your license account does not include enough purchased entitlements, your account becomes Out-of-Compliance until you purchase the correct number of licenses.

Licensing for Device Clusters

Each Firewall Threat Defense Virtual cluster node requires the same performance tier license. We recommend using the same number of CPUs and memory for all members, or else performance will be limited on all nodes to match the least capable member. The throughput level will be replicated from the control node to each data node so they match.

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add the control node to the Firewall Management Center, you can specify the feature licenses you want to use for the cluster. Before you create the cluster, it doesn't matter which licenses are assigned to the data nodes; the license settings for the control node are replicated to each of the data nodes. You can modify licenses for the cluster by clicking **Edit Licenses** in **System** (⚙) > **Licenses** > **Smart Licenses** or choosing **Devices** > **Device Management**, clicking **Edit** (✎) for the cluster, and then in the **License** area, clicking **Edit** (✎).

Note If you add the cluster before the Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Create a Cisco Account

You must have a Cisco account to request a Smart Account and license any Cisco products.

Procedure

Step 1 Open the URL https://id.cisco.com/signin/register to create a new account.

Step 2 Enter all the required fields to create an account.

The following figure shows an example.

Step 3 Click **Register**.

An email with an activation code is sent to verify your email address.

Note
If you haven't received an email yet, send an email to the registration support team at web-help@cisco.com.

Step 4 In the **Verify with your email** page, enter the activation code to complete the registration process and click **Verify**.

After successful registration, you will be redirected to the login page.

What to do next

Enter the newly created account details on the login page to request a Smart Account. See Create a Smart Account and Add Licenses, on page 251.

Create a Smart Account and Add Licenses

You should set up this account before you purchase licenses.

Before you begin

Your account representative or reseller may have set up a Smart Account on your behalf. If so, obtain the necessary information to access the account from that person instead of using this procedure, then verify that you can access the account.

You must create a new Cisco account if you don't already have one. For instructions, see Create a Cisco Account.

For general information about Smart Accounts, see http://www.cisco.com/go/smartaccounts.

Procedure

Step 1 Go to the Create a Smart Account page. You are prompted to log in with your Cisco account.

In the **Create a Smart Account** page, your basic account information is displayed.

Step 2 Click the **My Account** icon appearing in the top right corner and click **Manage Profile**.

Step 3 Click **Personal**.

Step 4 In the **Your Company Details** section, click **Edit**.

Step 5 In the **Company or organization** field, type your organization name.

Step 6 If your company information is already present in our database, it will appear in the list. You can select your company.

In the **Address** drop-down list, select the address of your company.

Step 7 If your company is not listed in our database, you can continue to enter your company information in the **Company or organization** field.

a) In the **Address** drop-down list, click the drop-down arrow and click **Add New Address**.

b) You can select one of the following **Address Type** options:

- **Company/Organization**: To provide your organization's address. Cisco verifies this address. If the address and company name cannot be validated with the country, you may not be able to proceed. Therefore, you must ensure that the correct address is provided.
- **Personal**: To provide your personal address.

Step 8 Enter all the mandatory fields associated with your company and click **Update**.

The **Your Company Details** section displays the company details you entered.

A success message appears if your company details are validated.

Step 9 Click **Update**.

A success message appears if your company details are validated.

Step 10 Open the **Create a Smart Account** page, which was opened in the previous tab. Refresh the page if changes are not reflecting.

Alternatively, you can open this page using the https://software.cisco.com/software/company/smartaccounts/home?route=module/accountcreation URL and login using your credentials.

Step 11 Click **Create Account**.

The Account Summary page displays your account details.

Step 12 Click **Done**.

Step 13 Wait for an email telling you that your Smart Account is ready to set up. When it arrives, click the link it contains, as directed.

Step 14 Make sure your Smart Licensing account contains the available licenses you need.

For license PIDs, see License PIDs, on page 244.

What to do next

To configure Smart License using the Smart Software Manager, see Configure Smart Licensing, on page 253.

Configure Smart Licensing

This section describes how to use Smart Licensing using the Smart Software Manager or the Smart Software Manager On-Prem.

Register the Firewall Management Center for Smart Licensing

You can register the Firewall Management Center directly to the Smart Software Manager over the internet, or when using an air-gapped network, with the Smart Software Manager On-Prem.

Register the Firewall Management Center with the Smart Software Manager

Register the Firewall Management Center with the Smart Software Manager.

Before you begin

- Make sure your Smart Licensing account contains the available licenses you need.

  When you bought your device from Cisco or a reseller, your licenses should have been linked to your Smart Account. However, if you need to add licenses yourself, see Cisco Commerce Workspace. For license PIDs, see License PIDs, on page 244.

- Ensure that the Firewall Management Center can reach the Smart Software Manager at smartreceiver.cisco.com.

- Make sure you configure NTP. During registration, a key exchange occurs between the Smart Agent and the Smart Software Manager, so time must be in sync for proper registration.

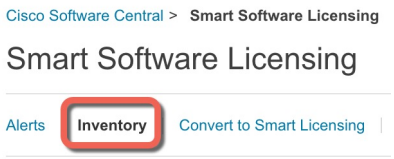
  For the Firepower 4100/9300, you must configure NTP on the chassis using the same NTP server for the chassis as for the Firewall Management Center.

- If your organization has multiple Firewall Management Centers, make sure each Firewall Management Center has a unique name that clearly identifies and distinguishes it from other Firewall Management Centers that may be registered to the same virtual account. This name is critical for managing your Smart License entitlements and ambiguous names will lead to problems later.

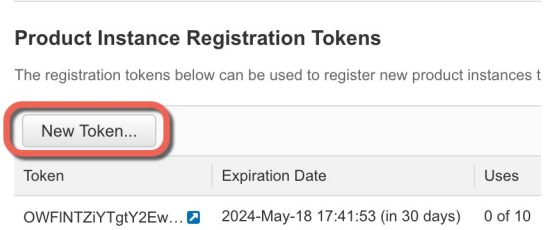
Procedure

Step 1 In the Smart Software Manager, request and copy a registration token for the virtual account to which you want to add this device.

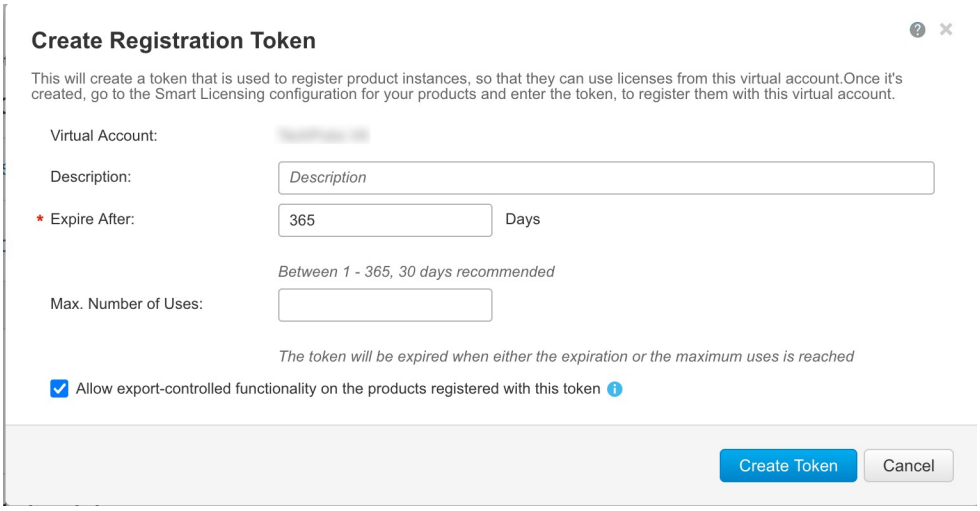
a) Click **Inventory**.



b) On the **General** tab, click **New Token**.



c) On the **Create Registration Token** dialog box enter the following settings, and then click **Create Token**:



- **Description**
- **Expire After**—Cisco recommends 30 days.
- **Max. Number of Uses**
- **Allow export-controlled functionality on the products registered with this token**—Enables the export-compliance flag if you are in a country that allows for strong encryption. You must select this option now if you plan to use this functionality. If you enable this functionality later, you will need to re-register your device with a new product key and reload the device. If you do not see this option, your account does not support export-controlled functionality.

The token is added to your inventory.

d) Click the arrow icon to the right of the token to open the **Token** dialog box so you can copy the token ID to your clipboard. Keep this token ready for later in the procedure when you need to register the Firewall Threat Defense.

Figure 68: View Token

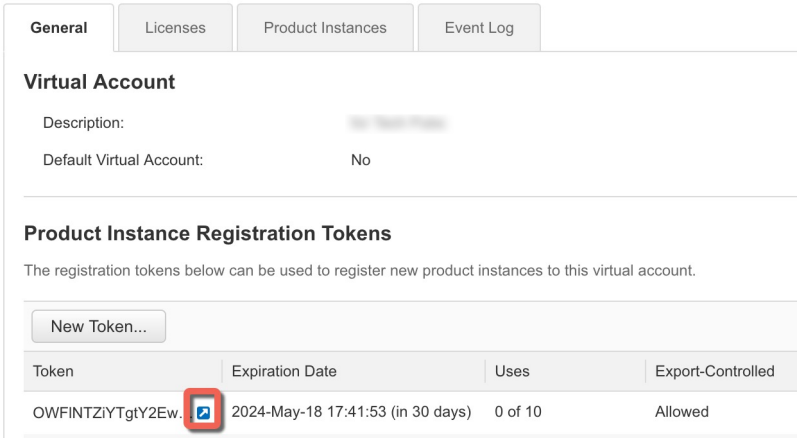


Figure 69: Copy Token

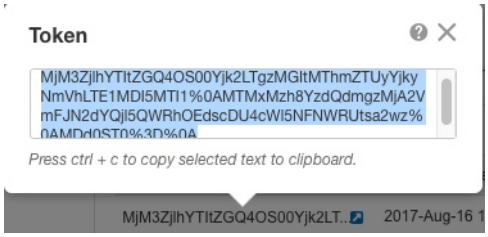


Step 2 In the Firewall Management Center, choose **System** (⚙) > **Licenses** > **Smart Licenses**.

Step 3 Click **Register**.

Step 4 Paste the token you generated from Smart Software Manager into the **Product Instance Registration Token** field.

Make sure there are no empty spaces or blank lines at the beginning or end of the text.

Step 5 Click **Apply Changes**.

What to do next

- Add a Device to the Firewall Management Center; see *Add a Device to the Firewall Management Center* in the Cisco Secure Firewall Management Center Device Configuration Guide.

Assign Licenses to Devices

You can assign most licenses when you register a device to the Firewall Management Center. You can also assign licenses per device, or for multiple devices.

Assign Licenses to a Single Device

Although there are some exceptions, you cannot use the features associated with a license if you disable it on a managed device.

Note For container instances on the same security module/engine, you apply the license to each instance; note that the security module/engine consumes only one license per feature for all instances on the security module/engine.

Note For the Firewall Threat Defense cluster, you apply the licenses to the cluster as a whole; note that each unit in the cluster consumes a separate license per feature.

Before you begin

You must have Admin or Network Admin privileges to perform this task. When operating with multiple domains, you must do this task in leaf domains.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device where you want to assign or disable a license, click **Edit** ( ).

Step 3 Click **Device**.

Step 4 Next to the **License** section, click **Edit** ( ).

Step 5 Check or clear the appropriate check boxes to assign or disable licenses for the device.

Step 6 Click **Save**.

Step 7 Deploy configuration changes.

What to do next

Verify license status: Go to **System** ( ) > **Licenses** > **Smart Licenses**, enter the hostname or IP address of the device into the filter at the top of the Smart Licenses table, and verify that only a green circle with a **Check Mark** ( ) appears for each device, for each license type. If you see any other icon, hover over the icon for more information.

Assign Licenses to Multiple Managed Devices

Devices managed by the Firewall Management Center obtain their licenses via the Firewall Management Center, not directly from the Smart Software Manager.

Use this procedure to enable licensing on multiple devices at once.

Note For container instances on the same security module/engine, you apply the license to each instance; note that the security module/engine consumes only one license per feature for all instances on the security module/engine.

Note For the Firewall Threat Defense cluster, you apply the licenses to the cluster as a whole; note that each unit in the cluster consumes a separate license per feature.

Procedure

Step 1 Choose **System** (⚙) > **Licenses** > **Smart Licenses** or **Specific Licenses**.

Step 2 Click **Edit Licenses**.

Step 3 For each type of license you want to add to a device:

a) Click the tab for that type of license.
b) Click a device in the list on the left.
c) Click **Add** to move that device to the list on the right.
d) Repeat for each device to receive that type of license.

For now, don't worry about whether you have licenses for all of the devices you want to add.

e) Repeat this subprocedure for each type of license you want to add.
f) To remove a license, click the **Delete** ( ) next to the device.
g) Click **Apply**.

You can select a cluster and assign any license to all nodes of a cluster.

What to do next

Verify that your licenses are correctly installed. Follow the procedure in Monitoring Smart Licenses, on page 258.

Manage Smart Licensing

This section describes how to manage Smart Licensing.

Deregister the Firewall Management Center

Deregister your Firewall Management Center from the Smart Software Manager to release all of the license entitlements back to your Smart Account so they can be used for other devices. For example, deregister if you need to decommission the Firewall Management Center or reimage it.

See Unregistered State, on page 236 for more information about license enforcement in an unregistered state.

Procedure

Step 1 Choose **System** (⚙) > **Licenses** > **Smart Licenses**.

Step 2 Click **Deregister** ( ).

Monitoring Smart License Status

The **Smart License Status** section of the **System** ( ) > **Licenses** > **Smart Licenses** page provides an overview of license usage on the Firewall Management Center, as described below.

Usage Authorization

Possible status values are:

- **In-compliance** ( ) — All licenses assigned to managed devices are in compliance and the Firewall Management Center is communicating successfully with the Smart Software Manager.
- **License is in compliance but communication with licensing authority has failed**— Device licenses are in compliance, but the Firewall Management Center is not able to communicate with the Cisco licensing authority.
- **Out-of-compliance icon or unable to communicate with License Authority**— One or more managed devices is using a license that is out of compliance, or the Firewall Management Center has not communicated with the Smart Software Manager in more than 90 days.

Product Registration

Specifies the last date when the Firewall Management Center contacted the Smart Software Manager and registered.

Assigned Virtual Account

Specifies the Virtual Account under the Smart Account that you used to generate the Product Instance Registration Token and register the Firewall Management Center. If this deployment is not associated with a particular virtual account within your Smart Account, this information is not displayed.

Export-Controlled Features

If this option is enabled, you can deploy restricted features. For details, see Licensing for Export-Controlled Functionality, on page 242.

Cisco Success Network

Specifies whether you have enabled Cisco Success Network for the Firewall Management Center. If this option is enabled, you provide usage information and statistics to Cisco which are essential to provide you with technical support. This information also allows Cisco to improve the product and make you aware of unused available features so that you can maximize the value of the product in your network.

Monitoring Smart Licenses

To view the license status for the Firewall Management Center and its managed devices, use the Smart Licenses page.

For each type of license in your deployment, the page lists the total number of licenses consumed, whether the license is in compliance or out of compliance, the device type, and the domain and group where the device

is deployed. You can also view the Firewall Management Center's Smart License Status. Container instances on the same security module/engine only consume one license per security module/engine. Therefore, even though the Firewall Management Center lists each container instance separately under each license type, the number of licenses consumed for feature license types will only be one.

Other than the **Smart Licenses** page, there are a few other ways you can view licenses:

- The **Product Licensing** dashboard widget provides an at-a-glance overview of your licenses.
- The **Device Management** page (**Devices** > **Device Management**) lists the licenses applied to each of your managed devices.
- The **Smart License Monitor** health module communicates license status when used in a health policy.

Procedure

Step 1 Choose **System** (⚙) > **Licenses** > **Smart Licenses**.

Step 2 In the **Smart Licenses** table, click the arrow at the left side of each **License Type** folder to expand that folder.

Step 3 In each folder, verify that each device has a green circle with a **Check Mark** (✓) in the **License Status** column.

If all devices show a green circle with a **Check Mark** (✓), your devices are properly licensed and ready to use.

If you see any License Status other than a green circle with a **Check Mark** (✓), hover over the status icon to view the message.

What to do next

- If you had any devices that did not have a green circle with a **Check Mark** (✓), you may need to purchase more licenses.

Troubleshooting Smart Licensing

Expected Licenses Do Not Appear in My Smart Account

If the licenses you expect to see are not in your Smart Account, try the following:

- Make sure they are not in a different Virtual Account. Your organization's license administrator may need to assist you with this.
- Check with the person who sold you the licenses to be sure that transfer to your account is complete.

Unable to Connect to Smart License Server

Check the obvious causes first. For example, make sure your Firewall Management Center has outside connectivity. See Internet Resources Accessed by Managed Devices, on page 2948.

Unexpected Out-of-Compliance Notification or Other Error

- If a device is already registered to a different Firewall Management Center, you need to deregister the original Firewall Management Center before you can license the device under a new Firewall Management Center. See Deregister the Firewall Management Center, on page 257.
- Check if the term of the subscription license has expired.

Troubleshoot Other Issues

For solutions to other common issues, see https://www.cisco.com/c/en/us/support/docs/security/firepower-management-center/215838-fmc-and-ftd-smart-license-registration-a.html

Configure Legacy Firewall Management Center PAK-Based Licenses

The Firewall Management Center supports either a Smart License or a legacy PAK (Product Activation Key) license for its platform license. This procedure describes how to apply a PAK-based license.

After re-registration of your Smart Account, you must manually add the classic licenses for all classic devices.

Before you begin

- Make sure you have the product activation key (PAK) from the Software Claim Certificate that Cisco provided when you purchased the license. If you have a legacy, pre-Cisco license, contact Support.

Procedure

Step 1 The license key uniquely identifies the Firewall Management Center in the Smart Software Manager. It is composed of a product code (for example, 66) and the MAC address of the management port (eth0) of the Firewall Management Center; for example, 66:00:00:77:FF:CC:88.

a) Choose **System** (⚙) > **Licenses** > **Classic Licenses**.
b) Click **Add New License**.
c) Note the value in the **License Key** field at the top of the **Add Feature License** dialog.

Step 2 Choose **System** (⚙) > **Licenses** > **Classic Licenses**.

Step 3 Click **Add New License**.

Step 4 Continue as appropriate:

- If you have already obtained the license text, skip to Step 8.
- If you still need to obtain the license text, go to the next step.

Step 5 Click **Get License** to open the License Registration Portal.

Note
If you cannot access the Internet using your current computer, switch to a computer that can, and browse to http://cisco.com/go/license.

Step 6 Generate a license from the PAK in the License Registration Portal: https://cisco.com/go/license.

This step requires the PAK you received during the purchase process, as well as the license key for the Firewall Management Center.

For more information on using this portal, see:

https://slexui.cloudapps.cisco.com/SWIFT/LicensingUI/Quickstart

You will need your account credentials in order to access these links.

Step 7 Copy the license text from either the License Registration Portal display, or the email the License Registration Portal sends you.

Important
The licensing text block in the portal or email message may include more than one license. Each license is bounded by a BEGIN LICENSE line and an END LICENSE line. Make sure that you copy and paste only one license at a time.

Step 8 Return to the **Add Feature License** page in the management center virtual's web interface.

Step 9 Paste the license text into the **License** field.

Step 10 Click **Verify License**.

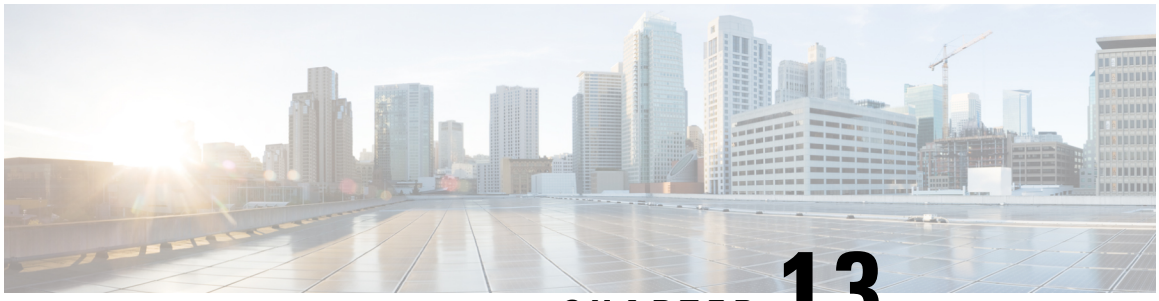
If the license is invalid, make sure that you correctly copied the license text.

Step 11 Click **Submit License**.

Additional Information about Licensing

For additional information to help resolve common licensing questions, see the following documents:

- FAQ—Licensing FAQ
- License Roadmap



CHAPTER 13

Security Certifications Compliance

The following topics describe how to configure your system to comply with security certifications standards:

- Security Certifications Compliance Modes, on page 263
- Security Certifications Compliance Characteristics, on page 264
- Security Certifications Compliance Recommendations, on page 265

Security Certifications Compliance Modes

Your organization might be required to use only equipment and software complying with security standards established by the U.S. Department of Defense and global certification organizations. Secure Firewall supports compliance with the following security certifications standards:

- Common Criteria (CC): a global standard established by the international Common Criteria Recognition Arrangement, defining properties for security products
- Unified Capabilities Approved Products List (UCAPL): a list of products meeting security requirements established by the U.S. Defense Information Systems Agency (DISA)

Note The U.S. Government has changed the name of the Unified Capabilities Approved Products List (UCAPL) to the Department of Defense Information Network Approved Products List (DODIN APL). References to UCAPL in this documentation and the Secure Firewall Management Center web interface can be interpreted as references to DODIN APL.

- Federal Information Processing Standards (FIPS) 140: a requirements specification for encryption modules

You can enable security certifications compliance in CC mode or UCAPL mode. Enabling security certifications compliance does not guarantee strict compliance with all requirements of the security mode selected. For more information on hardening procedures, refer to the guidelines for this product provided by the certifying entity.

Caution After you enable this setting, you cannot disable it. If you need to take an appliance out of CC or UCAPL mode, you must reimage.

Security Certifications Compliance Characteristics

The following table describes behavior changes when you enable CC or UCAPL mode. (Restrictions on login accounts refers to command line access, not web interface access.)

System Change	Secure Firewall Management Center		Classic Managed Devices		Secure Firewall Threat Defense	
	CC Mode	UCAPL Mode	CC Mode	UCAPL Mode	CC Mode	UCAPL Mode
FIPS compliance is enabled.	Yes	Yes	Yes	Yes	Yes	Yes
The system does not allow remote storage for backups or reports.	Yes	Yes	—	—	—	—
The system starts an additional system audit daemon.	No	Yes	No	Yes	No	No
The system boot loader is secured.	No	Yes	No	Yes	No	No
The system applies additional security to login accounts.	No	Yes	No	Yes	No	No
The system disables the reboot key sequence Ctrl+Alt+Del.	No	Yes	No	Yes	No	No
The system enforces a maximum of ten simultaneous login sessions.	No	Yes	No	Yes	No	No
Passwords must be at least 15 characters long, and must consist of alphanumeric characters of mixed case and must include at least one numeric character.	No	Yes	No	Yes	No	No
The minimum required password length for the local `admin` user can be configured using the local device CLI.	No	No	No	No	Yes	Yes
Passwords cannot be a word that appears in a dictionary or include consecutive repeating characters.	No	Yes	No	Yes	No	No
The system locks out users other than `admin` after three failed login attempts in a row. In this case, the password must be reset by an administrator.	No	Yes	No	Yes	No	No
The system stores password history by default.	No	Yes	No	Yes	No	No
The `admin` user can be locked out after a maximum number of failed login attempts configurable through the web interface.	Yes	Yes	Yes	Yes	—	—

System Change	Secure Firewall Management Center		Classic Managed Devices		Secure Firewall Threat Defense	
	CC Mode	UCAPL Mode	CC Mode	UCAPL Mode	CC Mode	UCAPL Mode
The `admin` user can be locked out after a maximum number of failed login attempts configurable through the local appliance CLI.	No	No	Yes, regardless of security certifications compliance enablement.	Yes, regardless of security certifications compliance enablement.	Yes	Yes
The system automtically rekeys an SSH session with an appliance: • After a key has been in use for one hour of session activity • After a key has been used to transmit 1 GB of data over the connection	Yes	Yes	Yes	Yes	Yes	Yes
The system performs a file system integrity check (FSIC) at boot-time. If the FSIC fails, Secure Firewall software does not start, remote SSH access is disabled, and you can access the appliance only via local console. If this happens, contact Cisco TAC.	Yes	Yes	Yes	Yes	Yes	Yes

Security Certifications Compliance Recommendations

Cisco recommends that you observe the following best practices when using a system with security certifications compliance enabled:

- To enable security certifications compliance in your deployment, enable it first on the Secure Firewall Management Center, then enable it in the same mode on all managed devices.

Caution The Secure Firewall Management Center will not receive event data from a managed device unless both are operating in the same security certifications compliance mode.

- For all users, enable password strength checking and set the minimum password length to the value required by the certifying agency.
- To use Secure Firewall Management Centers in a high-availability configuration, configure them both to use the same security certifications compliance mode before forming the high availability pair.

- When you configure Secure Firewall Threat Defense on a Firepower 4100/9300 to operate in CC or UCAPL mode, you should also configure the Firepower 4100/9300 to operate in CC mode. For more information, see the *Cisco Firepower 4100/9300 FXOS Chassis Manager Configuration Guide*.
- Do not configure the system to use any of the following features:
  - Email reports, alerts, or data pruning notifications.
  - Nmap Scan, Cisco IOS Null Route, Set Attribute Value, or ISE EPS remediations.
  - Third-party client access to the system database.
  - External notifications or alerts transmitted via email (SMTP), SNMP trap, or syslog.
  - Audit log messages transmitted to an HTTP server or to a syslog server without using SSL certificates to secure the channel between the appliance and the server.
- Do not enable external authentication using LDAP or RADIUS in deployments using CC mode.
- Do not enable CACs in deployments using CC mode.
- Disable access to the Secure Firewall Management Center and managed devices via the Secure Firewall REST API in deployments using CC or UCAPL mode.
- Enable CACs in deployments using UCAPL mode.
- Do not configure SSO in deployments using CC mode.

Note The system does not support CC or UCAPL mode for:

- Secure Firewall Threat Defense devices in clusters
- Secure Firewall Threat Defense container instances on the Firepower 4100/9300
- Exporting event data to an external client using eStreamer.

Appliance Hardening

For information about features you can use to further harden your system, see the latest versions of the *Cisco Secure Firewall Management Center Hardening Guide* and the *Cisco Secure Firewall Threat Defense Hardening Guide*, as well as the following topics within this document:

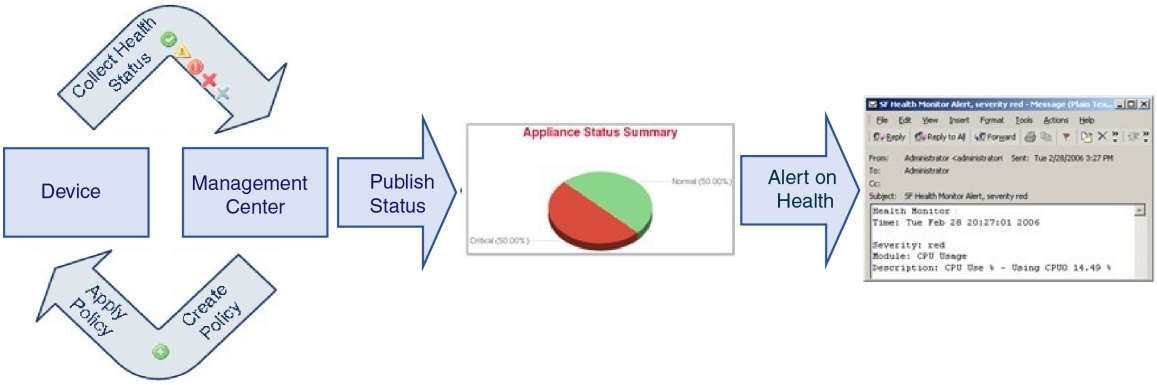
About Health Monitoring

The health monitor on the Firewall Management Center tracks various health indicators to ensure that the hardware and software in the system are working correctly. You can use the health monitor to check the status of critical functionality across your deployment.

You can configure the frequency for running the health modules for alerting. The Firewall Management Center also supports time series data collection. You can configure the frequency of collecting the time series data on the device and its health modules. The device monitor reports these metrics in several predefined health

monitor dashboards by default. The metric data is collected for analysis and hence no alerting is associated with it.



You can use the health monitor to create a collection of tests, referred to as a *health policy*, and apply the health policy to one or more appliances. The tests, referred to as *health modules*, are scripts that test for the criteria you specify. You can modify a health policy by enabling or disabling tests or by changing test settings, and you can delete health policies that you no longer need. You can also suppress messages from selected appliances by excluding them.

The health monitoring system run the tests in a health policy at the configured intervals. You can also run all tests, or a specific test, on demand. The health monitor collects health events based on the test conditions configured.

Note All appliances automatically report their hardware status via the Hardware Alarms health module. The Firewall Management Center also automatically reports status using the modules configured in the default health policy. Some health modules, such as the Appliance Heartbeat module, run on the Firewall Management Center and report the status of the Firewall Management Center's managed devices. For the health modules to provide managed device status, you must deploy all health policies to the device.

You can use the health monitor to access health status information for the entire system and for a particular appliance. In a multi-domain deployment, you can view the health status summary for a device in the domain where the device is located.

If you are A hexagon-shaped widget and status tables on the **Health Status** page provide a visual summary of the status of all appliances on your network, including the Firewall Management Center. Individual appliance health monitors let you drill down into health details for a specific appliance.

Fully customizable event views allow you to quickly and easily analyze the health status events gathered by the health monitor. These event views allow you to search and view event data and to access other information that may be related to the events you are investigating. For example, if you want to see all the occurrences of CPU usage with a certain percentage, you can search for the CPU usage module and enter the percentage value.

You can also configure email, SNMP, or syslog alerting in response to health events. A *health alert* is an association between a standard alert and a health status level. For example, if you want to make sure an appliance never fails due to hardware overload, you can set up an email alert. You can then create a health alert that triggers an email alert whenever CPU, disk, or memory usage reaches the Warning level you configure in the health policy applied to that appliance. You can set alerting thresholds to minimize the number of repeating alerts you receive.

Note The health monitoring can take 5–6 minutes from the occurrence of the health event to generate the health alert.

You can also generate troubleshooting files for an appliance if you are asked to do so by Support.

Only users with administrator user role privileges can access system health data.

High Availability Pair

In a Firewall Management Center high-availability deployment running Version 6.7 or higher, the active Firewall Management Center creates a health monitor page that uses REST APIs to show detailed metric-based information. The standby Firewall Management Center creates the health monitor page that shows the alert information and provide a visual summary of the status of all appliances on your network using pie charts and status tables. The standby Firewall Management Center does not display the metric-based information.

Health Modules

Health modules, or *health tests,* test for the conditions that you specify in a health policy.

The two types of health module are alerts and metrics. Alerts modules (sometimes called *legacy* modules) monitor system infrastructure and report only the health status. When the conditions specified in the health policy for these monitored systems are met, these modules raise health alerts. Metrics modules (sometimes called *telegraf* modules) collect statistics (sometimes called *time series data*) that you can view on the health monitoring dashboard. You can create custom dashboards with your preferred health metrics, allowing you to monitor statistics or troubleshoot appliance health issues.

Table 18: Device Health Modules

Module	Type	Description
AMP Connection Status	Metrics	The module alerts if the device cannot connect to the AMP cloud or Cisco AMP Private Cloud after an initial successful connection, or if the private cloud cannot contact the public AMP cloud. Disabled by default.
AMP Threat Grid Connectivity	Metrics	The module alerts if the device cannot connect to the AMP Threat Grid cloud after an initial successful connection.
ASP Drop	Metrics	Monitors the connections dropped by the data plane accelerated security path.
Automatic Application Bypass	Alert	Monitors bypassed detection applications.
Chassis Environment Status	Alert	Monitors chassis parameters such as fan speed and chassis temperature, and enables you to set a warning threshold and critical threshold for temperature. The **Critical Chassis Temperature (Celsius)** default value is `85`. The **Warning Chassis Temperature (Celsius)** default value is `75`.
Cluster/HA Failover Status	Alert	For threat defense clusters, alerts when a unit joins, leaves, or is elected primary.

Module	Type	Description
Configuration Resource Utilization	Alert	Alerts if the size of your deployed configurations puts a device at risk of running out of memory. The alert shows you how much memory your configurations require, and by how much this exceeds the available memory. If this happens, reevaluate your configurations. You may be able to reduce the number or complexity of access control rules or intrusion policies.
Connection Statistics	Metrics	Monitors connection statistics and NAT translation counts.
CPU Usage (per core)	Metrics	Alerts when CPU core use exceeds a configurable threshold.
Critical Process Statistics	Metrics	Monitors the state of critical processes, their resource consumption, and the restart counts.
CPU Usage Date Plane	Metrics	Alerts when data plane CPU use exceeds a configurable threshold.
Memory Usage Data Plane	Metrics	Alerts when data plane memory use exceeds a configurable threshold.
Deployed Configuration Statistics	Metrics	Monitors statistics about the deployed configuration, such as the number of ACEs and IPS rules.
Disk Status	Alert	Alerts if there is an issue with the hard disk or RAID controller. If this module alerts, contact Cisco TAC. This will prevent upgrade.
Disk Usage	Metrics	This module compares disk usage on the appliance's hard drive to the limits configured for the module and alerts when usage exceeds the thresholds configured for the module. This module also alerts when the system excessively deletes files in monitored disk usage categories, or when disk usage excluding those categories reaches excessive levels, based on module thresholds. Use the Disk Usage health status module to monitor disk usage for the `/` and `/volume` partitions on the appliance and track draining frequency. Although the disk usage module lists the `/boot` partition as a monitored partition, the size of the partition is static so the module does not alert on the boot partition.
File System Integrity Check	Alert	This module performs a file system integrity check and runs if the system has CC mode or UCAPL mode enabled, or if the system runs an image signed with a DEV key.
Firewall Threat Defense HA	Alert	Alerts if a threat defense high availability pair is split brain.
Firewall Threat Defense Platform Faults	Alert	Monitors Secure Firewall 1000/2100/3100 platform faults and generate health alerts for the faults. A platform fault represents a failure in the Firewall Threat Defense instance or an alarm threshold that has been raised. During the lifecycle of a platform fault, it can change from one state or severity to another. Each fault includes information about the operational state of the affected object at the time the fault was raised. If the fault is transitional and the failure is resolved, then the object transitions to a functional state. For more information, see the *Cisco Firepower 1000/2100 FXOS Faults and Error Messages Guide*.
Flow Offload Statistics	Metrics	Monitors hardware flow offload.

Module	Type	Description
Hardware Alarms	Alert	This module determines if hardware needs to be replaced on a physical managed device and alerts based on the hardware status. It also reports on the status of hardware-related daemons.
Inline Link Mismatch Alarms	Alert	Alerts if inline pair interfaces negotiate different speeds.
Interface Status	Alert	Determines if the device currently collects traffic and alerts based on the traffic status of physical interfaces and aggregate interfaces. For physical interfaces, the information includes interface name, link state, and bandwidth. For aggregate interfaces, the information includes interface name, number of active links, and total aggregate bandwidth. **Note** This module also monitors the high availability standby device traffic flow. Though it is known that the standby device would not be receiving any traffic yet, the Firewall Management Center alerts that the interface is not receiving any traffic. The same alerting principle is applied when traffic is not received by some of the subinterfaces on a port channel. This module displays the traffic rates according to the values from Lina. However, if you use the **show interface** CLI command to know the interface statistics of your device, the input and output rates in the CLI command result can be different from the traffic rates that appear in the **Interface** widget. The sampling intervals of Lina and the Firewall Management Center interface statistics are different. Due to the difference in sampling interval, throughput values in the Firewall Management Center GUI can be different from the throughput values appears in the device CLI result. Note that traffic rates in the **Interface Traffic Rate** widget (**Overview** > **Dashboards heading** > **Dashboard** page) can be different as it displays the input and output rates from Snort.
Intrusion and File Event Rate	Alert	Alerts if intrusion events per second exceed a configurable threshold. We recommend a warning threshold of 1.5 times your average intrusion event rate, and a critical threshold of 2.5 times. For example, for an average event rate on network segment of 20 events per second, we recommend a warning value of 30 and a critical value of 50. The critical limit must be lower than1000, and higher than the warning limit. Event rates for your devices are available on **System** (⚙) > **Monitoring** > **Statistics**. If the rate is zero, the Snort process may be down or the device may not be sending events.
Link State Propagation	Alert	For the ISA 3000, alerts when an interface in a inline set fails.

Module	Type	Description
Memory Usage	Alert	Alerts when memory use exceeds configurable thresholds. For appliances with more than 4 GB of memory, the preset alert thresholds are based on a formula that accounts for proportions of available memory likely to cause system problems. On >4 GB appliances, because the interval between Warning and Critical thresholds may be very narrow, its recommended that you manually set the **Warning Threshold %** value to `50`. This will further ensure that you receive memory alerts for your appliance in time to address the issue. Complex access control policies and rules can command significant resources and negatively affect performance.
Network Card Reset	Alert	Alerts when a network card restarts due to hardware failure.
NTP Statistics	Metrics	Monitors NTP synchronization status. Disabled by default.
Firewall Management Center Access Configuration Changes	Alert	Monitors configuration changes made on the Firewall Management Center directly using the **configure network management-data-interface** command. This module alerts when there is a conflict between the existing Firewall Management Center configuration and the out of band configuration changes made.
Process Status	Alert	Alerts when processes on the appliance exit or terminate outside of the process manager. If a process is deliberately exited outside of the process manager, the module status changes to Warning and the health event message indicates which process exited, until the module runs again and the process has restarted. If a process terminates abnormally or crashes outside of the process manager, the module status changes to Critical and the health event message indicates the terminated process, until the module runs again and the process has restarted.
Routing Statistics	Metrics	Monitors the current state of routing table.
Snort 3 Statistics	Metrics	Collects Snort 3 statistics for events, flows, and packets. This module also monitors metrics for sending advanced logging events and generates the following alerts: • **Advanced logging events to syslog servers were dropped**: This alert appears when syslog messages are dropped due to memory overflow. • **Advanced Logging events failed to transmit to syslog servers**: This alert appears when the syslog messages failed to transmit due to a connection issue with the syslog server or a configuration error. Check your syslog server status and syslog configuration in Firewall Management Center.
CPU Usage Snort	Metrics	This module checks that the average CPU usage of the Snort processes on the device is not overloaded and alerts when CPU usage exceeds the percentages configured for the module. The **Warning Threshold %** default value is `80`. The **Critical Threshold %** default value is `90`.

Module	Type	Description
Snort Identity Memory Usage	Alert	Enables you to set a warning threshold for Snort identity processing and alerts when memory usage exceeds the level configured for the module. The **Critical Threshold %** default value is `80`. This health module specifically keeps track of the total space used for the user identity information in Snort. It displays the current memory usage details, the total number of user-to-IP bindings, and user-group mapping details. Snort records these details in a file. If the memory usage file is not available, the Health Alert for this module displays *Waiting for data*. This could happen during a Snort restart due to a new install or a major update, switch from Snort 2 to Snort 3 or back, or major policy deployment. Depending on the health monitoring cycle, and when the file is available, the warning disappears, and the health monitor displays the details for this module with its status turned Green.
Memory Usage Snort	Metrics	This module checks the percentage of allocated memory used by the Snort process and alerts when memory usage exceeds the percentages configured for the module. The **Warning Threshold %** default value is `80`. The **Critical Threshold %** default value is `90`.
Snort Reconfiguring Detection	Metrics	Alerts if a device reconfiguration has failed. This module detects reconfiguration failure for both Snort 2 and Snort 3 instances.
Snort Statistics	Metrics	Monitors Snort statistics for events, flows, and packets.
SSE Connection Status	Metrics	The module alerts if the device cannot connect to the security services exchange cloud after an initial successful connection. Disabled by default.
CPU Usage System	Metrics	This module checks that the average CPU usage of all system processes on the device is not overloaded and alerts when CPU usage exceeds the percentages configured for the module. The **Warning Threshold %** default value is `80`. The **Critical Threshold %** default value is `90`.

Module	Type	Description
Threat Data Updates on Devices	Alert	Certain intelligence data and configurations that devices use to detect threats are updated on the Firewall Management Center from the cloud every 30 minutes. This module alerts you if this information has not been updated on the devices within the time period you have specified. Monitored updates include: • Local URL category and reputation data • Security Intelligence URL lists and feeds, including global Block and Do Not Block lists and URLs from Threat Intelligence Director • Security Intelligence network lists and feeds (IP addresses), including global Block and Do Not Block lists and IP addresses from Threat Intelligence Director • Security Intelligence DNS lists and feeds, including global Block and Do Not Block lists and domains from Threat Intelligence Director • Local malware analysis signatures (from ClamAV) • SHA lists from Threat Intelligence Director, as listed on the **Objects > Object Management > Security Intelligence > Network Lists and Feeds** page • Dynamic analysis settings configured on the **Administration** > **Dynamic Attributes Connector** page • Threat Configuration settings related to expiration of cached URLs, including the Cached URLs Expire setting on the **Integration** > **Other Integrations** > **Cloud Services** page. (Updates to the URL cache are not monitored by this module.) • Communication issues with the Cisco cloud for sending events. See the **Cisco Cloud** box on the **Integration** > **Other Integrations> Cloud Services** page. **Note** Threat Intelligence Director updates are included only if TID is configured on your system and you have feeds. By default, this module sends a warning after 1 hour and a critical alert after 24 hours. If this module indicates failure on the Firewall Management Center or on any devices, verify that the Firewall Management Center can reach the devices.
VPN Statistics	Metrics	Monitors site-to-site and remote access VPN tunnels between Firewall Threat Defense devices.
XTLS Counters	Metrics	Monitors XTLS/SSL flows, memory and cache effectiveness. Disabled by default.

Configuring Health Monitoring

Procedure

Step 1 Determine which health modules you want to monitor as discussed in Health Modules, on page 273.

You can set up specific policies for each kind of appliance, enabling only the appropriate tests for that appliance.

Tip
To quickly enable health monitoring without customizing the monitoring behavior, you can apply the default policy provided for that purpose.

Step 2 Apply a health policy to each appliance where you want to track health status as discussed in Creating Health Policies, on page 280.

Step 3 (Optional.) Configure health monitor alerts as discussed in Creating Health Monitor Alerts, on page 292.

You can set up email, syslog, or SNMP alerts that trigger when the health status level reaches a particular severity level for specific health modules.

Health Policies

A health policy contains configurable health test criteria for several modules. You can control which health modules run against each of your appliances and configure the specific limits used in the tests run by each module.

When you configure a health policy, you decide whether to enable each health module for that policy. You also select the criteria that control which health status each enabled module reports each time it assesses the health of a process.

You can create one health policy that can be applied to every appliance in your system, customize each health policy to the specific appliance where you plan to apply it, or use the default health policy provided for you.

Note When you register an appliance, the Firewall Management Center automatically assigns it the default health policy. To disassociate a health policy from an appliance, you must first associate a different health policy with it. An appliance must have at least one health policy assigned.

Default Health Policy

The Firewall Management Center setup process creates and applies an initial health policy, in which most—but not all—available health modules are enabled. The system also applies this initial policy to devices added to the Firewall Management Center.

This initial health policy is based on a default health policy, which you can neither view nor edit, but which you can copy when you create a custom health policy.

Upgrades and the Default Health Policy

When you upgrade the Firewall Management Center, any new health modules are added to all health policies, including the initial health policy, default health policy, and any other custom health policies. Usually, new health modules are added in an enabled state.

Note For a new health module to begin monitoring and alerting, reapply health policies after upgrade.

Creating Health Policies

If you want to customize a health policy to use with your appliances, you can create a new policy. The settings in the policy initially populate with the settings from the health policy you choose as a basis for the new policy. You can edit the policy to specify your preferences, such as enable or disable modules within the policy, change the alerting criteria for each module as needed, and specify the run time intervals.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Policy**.

Step 2 Click **Create Policy**.

Step 3 Enter a name for the policy.

Note that the following names are reserved for the default policies, and you cannot create a health policy using these names:

- Default Device Policy
- Default Health Policy

Step 4 Choose the existing policy that you want to use as the basis for the new policy from the **Base Policy** drop-down list.

Step 5 Enter a description for the policy.

Step 6 Choose **Save**.

What to do next

- Apply the health policy on devices as described in Apply a Health Policy, on page 280.
- Edit the policy to specify the module-level policy settings as described in Edit a Health Policy, on page 281.

Apply a Health Policy

When you apply a health policy to an appliance, the health tests for all the modules you enabled in the policy automatically monitor the health of the processes and hardware on the appliance. Health tests then continue

to run at the intervals you configured in the policy, collecting health data for the appliance and forwarding that data to the Firewall Management Center.

If you enable a module in a health policy and then apply the policy to an appliance that does not require that health test, the health monitor reports the status for that health module as disabled.

If you apply a policy with all modules disabled to an appliance, it removes all applied health policies from the appliance, so no health policy is applied. However, you must have at least one health policy assigned to an appliance.

When you apply a different policy to an appliance that already has a policy applied, expect some latency in the display of new data based on the newly applied tests.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Policy**.

Step 2 Click the **Deploy health policy** (📥) next to the policy you want to apply.

Step 3 Choose the appliances where you want to apply the health policy.

Note
An appliance must have at least one health policy assigned to it. To stop health monitoring for an appliance, create a health policy with all modules disabled and apply it to the appliance. To disassociate a health policy from an appliance, you must first associate a different health policy with it.

Step 4 Click **Apply** to apply the policy to the appliances you chose.

What to do next

- Optionally, monitor the task status; see View Task Messages, on page 313.

  Monitoring of the appliance starts when the policy is successfully applied.

Edit a Health Policy

You can edit a health policy that you want to modify.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Policy**.

Step 2 Click **Edit** (✎) next to the policy you want to modify.

Step 3 To edit the policy name and its description, click the **Edit** (✎) icon provided against the policy name.

Step 4 The **Health Modules** tab displays all the device modules and its attributes. Configure your health modules using the following actions:

- Click the toggle button that is provided against the module and its attributes—turn on () or turn off ( ) to enable or disable testing of health status respectively.
- To execute a bulk enable or disable testing on the health modules, click the **Select All** toggle button

Note

- The modules and attributes are flagged with the supporting appliances—Firewall Threat Defense, Firewall Management Center, or both.
- You cannot choose to include or exclude the individual attributes of CPU and Memory modules.

For information on the modules, see Health Modules, on page 273.

Step 5 Where appropriate, set the **Critical** and **Warning** threshold percentages.

Step 6 In the **Settings** tab, enter the relevant values in the fields:

- **Health Module Run Time Interval**—The frequency for running the health modules. The minimum interval is 5 minutes.
- **Metric Collection Interval**—The frequency of collecting the time series data on the device and its health modules. The device monitor reports these metrics in several predefined health monitor dashboards by default. For detailed information on the dashboard, see Viewing the Device Health Monitor, on page 296. The metric data is collected for analysis and hence no alerting is associated with it.
- **OpenConfig Streaming Telemetry**—Configure a health metrics telemetry stream from the Firewall Threat Defense devices to an external data collection system which uses the vendor neutral, OpenConfig model. See Configure OpenConfig Streaming Telemetry for details.

Step 7 To view and modify the devices to which the policy is assigned, do the following:

a) Click **Policy Assignments & Deploy**.
b) From the **Available Devices** list, click the + icon next to the device to which you want to assign the health policy.
c) Click **Apply**.

Alternatively, you can apply the health policy to your appliance as described in Apply a Health Policy, on page 280

Apply the health policy to each appliance where you want to track health status. When you apply the health policy to an appliance, all the modules you enabled in the policy monitor the health of the processes and hardware on the appliance, and forwards that data to the Firewall Management Center.

Step 8 Click **Save**.

Delete a Health Policy

You can delete health policies that you no longer need. However, an appliance must have at least one health policy assigned to it. If you delete a policy that is still applied to an appliance, the policy settings remain in effect until you apply a different policy. In addition, if you delete a health policy that is applied to a device, any health monitoring alerts in effect for the device remain active until you disable the underlying associated alert response.

Tip To stop health monitoring for an appliance, create a health policy with all modules disabled and apply it to the appliance.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Policy**.

Step 2 Click **Delete** (🗑) next to the policy that you want to delete, and then click **Delete health policy** to delete it.

Send Vendor-Neutral Telemetry Streams Using OpenConfig

OpenConfig is a vendor-independent software layer that provides a single way of streaming network telemetry data to multiple vendors to manage and monitor networks. The OpenConfig streaming telemetry option in the secure firewall uses gNMI (gRPC Network Management Interface) protocol and allows you to control and generate telemetry streams from your Firewall Threat Defense devices to a data collection system.

The firewall threat defense health policy contains all the configurations to support and enable the OpenConfig streaming telemetry functionality. When you deploy the health policy to the device, the OpenConfig streaming telemetry configuration activates a gNMI server and starts listening to Remote Procedure Call (RPC) messages from the data collectors.

Subscription Model of OpenConfig Streaming Telemetry

OpenConfig uses a subscription-based model where the data collectors query the Firewall Threat Defense devices for telemetry data or act as collector for the streamed telemetry data. When a data collector wishes to receive updates and metrics from the Firewall Threat Defense device, it sends a subscribeRequest RPC message to the Firewall Threat Defense gNMI server. The subscription request includes details of one or more paths to which the data collector wishes to subscribe. The message also includes subscription mode which describes the longevity of the subscription. The Firewall Threat Defense server supports the following subscription modes:

- *Once subscription*—The Firewall Threat Defense device sends requested data to the gNMI paths only once.
- *Stream subscription*—The Firewall Threat Defense continuously streams telemetry data according to the triggers specified in the `SubscribeRequest` RPC message.
  - *Sampled subscription*—The Firewall Threat Defense server streams the requested data as per the interval specified in the subscription message. The minimum interval that the threat defense support is one minute.
  - *On-change subscription*—The Firewall Threat Defense sends the data whenever the requested values change.

The Firewall Threat Defense server generates `SubscribeResponse` RPC messages according to the type of subscription that is created, at the frequency requested by the data collectors.

Deployment Modes for OpenConfig Streaming Telemetry

You can use the following deployment modes for OpenConfig streaming telemetry configuration:

- **DIAL-IN**—In this mode, the gNMI server opens a port on the Firewall Threat Defense and waits for `SubscribeRequest` RPC messages from data collectors. In the device health policy, you can specify the port number to use by the gNMI server and the IP address of the data collector that can connect with the gNMI service. If not specified, the gNMI server uses port number 50051. The Dial-in mode is ideal to use in a trusted network where the endpoint that subscribes to telemetry streams are trusted.
- **DIAL-OUT**—The gNMI service is designed to work in server mode where it accepts subscription requests from gNMI data collectors and serve the telemetry data. If the gNMI data collectors cannot reach the gNMI server, the Firewall Threat Defense uses a tunnel client and establishes a gRPC tunnel with the external server. This tunnel allows exchange of RPC messages between gNMI server and client. The Dial-Out mode is ideal to use when the data collectors are hosted on the cloud or outside the trusted network.

In both dial-in and dial-out mode, all the communication between gNMI server and gNMI client uses TLS encryption and this requires to generate a set of certificates with private keys for the TLS encryption. Dial-out mode requires extra keys for the tunnel infrastructure. See How to Generate Certificate with Private Key for more information.

Generate Certificates and Private Keys

Generate the CA, server, and client certificate and private key sets required for OpenConfig streaming telemetry configuration.

Note To ensure that you generate certificates using the same CA, run the following commands together and from the same endpoint. If you want to retry the commands, you must retry all commands.

Before you begin

Procedure

Step 1 Make a folder, for example `keys`, in the endpoint where you want to run the following commands.

Example:

```
mkdir keys
```

Step 2 Create a self-signed CA certificate with a corresponding private key.

Example:

Following sample command generates a new RSA private key and uses it to create a self-signed X.509 certificate with provided subject information:

```
openssl req -x509 -newkey rsa:4096 -days 365 -nodes -keyout keys/ca-key.pem -out
keys/ca-cert.pem -subj "/C=XX
/ST=YY/L=ZZZ/O=Example/OU=EN/CN=gnmi-ca/emailAddress=abc@example.com"
```

The subject information includes the provided Country (C), State (ST), Locality (L), Organization (O), Organizational Unit (OU), Common Name (CN), and email address.

The private key is saved as `ca-key.pem` file, and the certificate is saved as `ca-cert.pem` file in the `keys` folder.

Step 3 Create a self-signed server certificate with the specified Common Name (CN) and Subject Alternative Name (SAN):

Example:

Following sample command generates a new RSA private key and uses it to create a self-signed X.509 certificate with provided subject information. In this example, 192.168.0.200 is the IP address of the Firewall Threat Defense device and 192.168.0.202 is the IP address of the client.

Note
Client IP is not required if you want to use this certificate and key sets in dial-in mode.

```
CN="192.168.0.200"
SAN="IP:192.168.0.200,IP:192.168.0.202"
openssl req -newkey rsa:4096 -nodes -keyout keys/server-key.pem -out keys/server-req.pem
-subj "/C=XX/ST=YY/L=ZZZ/O=Example/OU=EN/CN=${CN}/emailAddress=abc@example.com}"
openssl x509 -req -extfile <(printf "subjectAltName=${SAN}") -in keys/server-req.pem -days
 60 -CA keys/ca-cert.pem -CAkey keys/ca-key.pem -CAcreateserial -out keys/server-cert.pem
cat keys/server-key.pem keys/server-cert.pem keys/ca-cert.pem > keys/server-combined.pem
```

The `openssl req` command generates a new RSA private key and a Certificate Signing Request (CSR). The private key is saved as `server-key.pem` file, and the CSR is saved as `server-req.pem` file in the `keys` folder.

The `openssl x509` command processes the CSR and generates a server certificate. The server certificate is saved as `server-cert.pem` file in the `keys` folder.

The `cat` command combines the server key, server certificate, and the CA certificate into a single file named `server-combined.pem` and saves the file in the keys folder.

You have to upload the `server-combined.pem` while configuring **OpenConfig Streaming telemetry** from the Firewall Management Center. The gNMI server that runs on the Firewall Threat Defense and the tunnel server (dial-out mode) uses this certificate for TLS communication. If you encrypt the private key with a passphrase, ensure that you specify the passphrase while uploading the certificate to the Firewall Management Center.

Step 4 Create client certificate with the specified Common Name (CN) and Subject Alternative Name (SAN).

Example:

Following sample command generates a new RSA private key and uses it to create a self-signed X.509 certificate with provided subject information. In this example, 192.168.0.202 is the IP address of the client.

```
CN="192.168.0.202"
SAN="IP:192.168.0.202"
openssl req -newkey rsa:4096 -nodes -keyout keys/client-key.pem -out keys/client-req.pem
-subj "/C=XX/ST=YY/L=ZZZ/O=example/OU=EN/CN=${CN}/emailAddress=abc@example.com"
openssl x509 -req -extfile <(printf "subjectAltName=${SAN}") -in keys/client-req.pem -days
 60 -CA keys/ca-cert.pem -CAkey keys/ca-key.pem -CAcreateserial -out keys/client-cert.pem
```

The gNMI client uses the client certificate `client-cert.pem` and the private key for TLS communication.

Step 5 (Optional) For dial-out mode, create the tunnel server certificate with the specified Common Name (CN) and Subject Alternative Name (SAN).

Example:

Following sample command generates a new RSA private key and uses it to create a self-signed X.509 certificate with provided subject information. In this example, 192.168.0.202 is the IP address of the client.

```
CN="192.168.0.202"
SAN="IP:192.168.0.202"
```

```
openssl req -newkey rsa:4096 -nodes -keyout keys/tunnel-server-key.pem -out
keys/tunnel-server-req.pem -subj "
/C=XX/ST=YY/L=ZZZ/O=Example/OU=EN/CN=${CN}/emailAddress=abc@example.com}"
openssl x509 -req -extfile <(printf "subjectAltName=${SAN}") -in keys/tunnel-server-req.pem
 -days 60 -CA keys/ca-cert.pem -CAkey keys/ca-key.pem -CAcreateserial -out
keys/tunnel-server-cert.pem
```

Configure OpenConfig Streaming Telemetry

Before you begin

- Ensure that the Firewall Threat Defense device where you want to deploy the health policy configuration allows installation of the SSL certificate and private key.
- Ensure that you configure a gNMI client that supports the OpenConfig streaming telemetry implementation, from which you can make the gRPC requests to the gNMI server on the Firewall Threat Defense.
- To use dial-out mode and configure OpenConfig streaming telemetry, ensure that you configure a gRPC tunnel server and client on the management system. This tunnel configuration enables communication between the gNMI client and the Firewall Threat Defense device.
- You must be an admin user to perform the following task.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Policy**.

Step 2 Click the **Edit health policy** icon next to the threat defense health policy that you want to modify.

Step 3 Go to **Settings** tab.

Step 4 Move the **OpenConfig Streaming Telemetry** slider to enable the configuration. This configuration is disabled by default.

Step 5 Upload the **SSL Certificate**. The gNMI server uses this certificate to enable server authentication for the TLS connection and encrypt all communications through the channel.

The OpenConfig streaming telemetry configuration supports only certificate with PEM format.

Step 6 (Optional) Specify the Passphrase if the private key files are encrypted.

Step 7 Choose the deployment mode to use for streaming telemetry over gNMI protocol.

For **DIAL-IN** mode:

a. Assign a port number for the gNMI service.

The gNMI server opens the port and waits for gRPC requests from the collector.

b. Specify the IPv4/IPv6 address of the gNMI collectors that can connect to the Firewall Threat Defense device.

c. Click **Add Collector** to add more gNMI collectors. You can add a maximum of five collectors.

For **DIAL-OUT** mode:

a. Specify the hostname and port number for the gNMI collector, which can subscribe to streaming telemetry from the Firewall Threat Defense device.

b. Click **Add Collector** to add more gNMI collectors. You can add a maximum of five collectors.

Step 8 Specify the username and password to validate the gNMI collector.

The Firewall Threat Defense server uses this credential to authenticate the gNMI collector when receiving the `SubscribeRequest` RPC message. Each telemetry message is not authenticated using the username and password. The system uses the previously authenticated encrypted streaming channel to carry telemetry messages.

Step 9 Click **Save**.

What to do next

Deploy the health policy to your Firewall Threat Defense device, for the configuration changes to take effect.

Troubleshoot OpenConfig Streaming Telemetry

Certificate signed by unknown authority

- Ensure that you have uploaded the correct certificate to the Firewall Management Center.
- Verify the certificate and key generation steps. Ensure that the IP Subject Alternative Name (SAN) is specified correctly.

Certificate is not valid

If the Firewall Management Center displays the error "Request was made for (IP), but the certificate is not valid for (IP)" then verify the server certificate and key generation steps.

- Ensure sure that the IP SAN is correctly specified in the server certificate. If the configuration applies to more than one Firewall Threat Defense device, you must specify all the devices in the IP SAN field.
- If you are using dial-out mode, ensure that the client IP is specified in the server certificate.

Failed to generate response object

If you receive "Failed to generate response object, did not receive any data" error, the gNMI input plug-in is waiting for metric export. Below is the sample response that appears when the telegraph is restarting:

```
root@cronserver:/home/secanup/openconfig-test# gnmic -a $ADDRESS:$PORT --tls-cert $CLIENTCERT
 --tls-ca $CACERT --tls-key $CLIENTKEY -u $USER -p $PASS sub --mode once --path
"openconfig-system/system/memory"
rpc error: code = Aborted desc = Error in gnmi_server: failed to generate response object.did
 not receive any data
Error: one or more requests failed
```

Wait for the gNMI input plug-in to restart and retry your request.

Restart telegraph

When telegraph is not responding, restart the process using the following command on the Firewall Threat Defense CLI console:

```
pmtool restartbyid hmdaemon
```

Get current status of gNMI server

When OpenConfig streaming telemetry is enabled, to know the status of the gNMI server, run the following command using the Firewall Threat Defense CLI console:

```
curl localhost:9275/OpenConfig/status
```

Below is the sample response to the command:

```
root@firepower:/home/admin# curl localhost:9275/openconfig/status
Mode (Dialin/Dialout): DialIn

```

Device Exclusion in Health Monitoring

In the course of normal network maintenance, you disable appliances or make them temporarily unavailable. Because those outages are deliberate, you do not want the health status from those appliances to affect the summary health status on your Firewall Management Center.

You can use the health monitor exclude feature to disable health monitoring status reporting on an appliance or module. For example, if you know that a segment of your network will be unavailable, you can temporarily disable health monitoring for a managed device on that segment to prevent the health status on the Firewall Management Center from displaying a warning or critical state because of the lapsed connection to the device.

When you disable health monitoring status, health events are still generated, but they have a disabled status and do not affect the health status for the health monitor. If you remove the appliance or module from the excluded list, the events that were generated during the exclusion continue to show a status of disabled.

To temporarily disable health events from an appliance, go to the exclusion configuration page and add an appliance to the device exclude list. After the setting takes effect, the system no longer considers the excluded appliance when calculating the overall health status. The Health Monitor Appliance Status Summary lists the appliance as disabled.

You can also disable an individual health module. For example, when you reach the host limit on the Firewall Management Center, you can disable Host Limit status messages. Excluding health modules for individual interfaces is not supported on devices operating in transparent mode.

Note that on the main Health Monitor page you can distinguish between appliances that are excluded if you expand to view the list of appliances with a particular status by clicking the arrow in that status row.

Note On Firewall Management Center, Health Monitor exclusion settings are local configuration settings. Therefore, if you exclude a device, then delete it and later re-register it with the Firewall Management Center, the exclusion settings remain persistent. The newly re-registered device remains excluded.

Excluding Appliances from Health Monitoring

You can exclude appliances individually or by group, model, or associated health policy.

If you need to set the events and health status for an individual appliance to disabled, you can exclude the appliance. After the exclusion settings take effect, the appliance shows as disabled in the Health Monitor Appliance Module Summary, and health events for the appliance have a status of disabled.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Exclude**.

Step 2 Click **Add Device**.

Step 3 In the **Device Exclusion** dialog box, under **Available Devices**, click **Add** (⊕) against the device that you want to exclude from health monitoring.

Step 4 Click **Exclude**. The selected device is displayed in the exclusion main page.

Step 5 To remove the device from the exclusion list, click **Delete** (🗑).

Step 6 Click **Apply**.

What to do next

To exclude individual health policy modules on appliances, see Excluding Health Policy Modules, on page 289.

Excluding Health Policy Modules

You can exclude individual health policy modules on appliances. This allows you to prevent health events from the module from changing the status for the appliance to warning or critical.

Note Excluding health modules for individual interfaces is not supported on devices operating in transparent mode.

After the exclusion settings take effect, the appliance shows the number of modules being excluded in the device from health monitoring.

Tip Make sure that you keep track of individually excluded modules so you can reactivate them when you need them. You may miss essential warning or critical messages if you accidentally leave a module disabled.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Exclude**.

Step 2 Click **Edit** (✎) next to the Firewall Threat Defense device you want to modify.

Step 3 In the **Exclude Health Modules** dialog box, by default, all the modules of the device are excluded from health monitoring. Certain modules are applicable to specific device only; for more information, see Health Modules, on page 273.

Step 4 To choose modules to be excluded from health monitoring, click the **Enable Module Level Exclusion** link. The **Exclude Health Modules** dialog box displays all the modules of the device. The modules that are not applicable for the associated health policies are disabled by default. To exclude a module, perform the following:

a. Click the **Slider** (⬭) button next to the desired module.

b. To specify the duration of the exclusion for the selected modules, from the **Exclude Period** drop-down list, select the duration.

Step 5 If you select an **Exclude Period** other than **Permanent**, for your exclusion configuration, you can choose to automatically delete the configuration when it expires. To enable this setting, check the **Auto-delete expired configurations** check box.

Step 6 Click **OK**.

Step 7 Click **Apply**.

Expired Health Monitor Exclusions

When the exclusion period for a device or modules lapses, you can choose to clear or renew the exclusion.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Exclude**.

The **Warning** (⚠) icon is displayed against the device indicating the expiry of the duration of exclusion of the device or the modules from alerting.

Step 2 To renew the exclusion of the device, click **Edit** ( ) next to the appliance. In the **Exclude Health Modules** dialog box, click the **Renew** link. The exclusion period of the device is extended with the current value.

Step 3 To clear the device from being excluded, click **Delete** ( ) next to the appliance, click **Remove the device from exclusion**, and then click **Apply**.

Step 4 To renew or clear the modules from exclusion, click **Edit** ( ) next to the appliance. In the **Exclude Health Modules** dialog box, click the **Enable Module Level Exclusion** link, and then click the **Renew** or **Clear** link against the modules. When you click **Renew**, the exclusion period is extended on the module with the current value.

Health Monitor Alerts

You can set up alerts to notify you through email, through SNMP, or through the syslog when the status changes for the modules in a health policy. You can associate an existing alert response with health event levels to trigger and alert when health events of a particular level occur.

For example, if you are concerned that your appliances may run out of hard disk space, you can automatically send an email to a system administrator when the remaining disk space reaches the warning level. If the hard drive continues to fill, you can send a second email when the hard drive reaches the critical level.

Health Monitor Alert Information

The alerts generated by the health monitor contain the following information:

- Severity, which indicates the severity level of the alert.
- Module, which specifies the health module whose test results triggered the alert.
- Description, which includes the health test results that triggered the alert.

The table below describes these severity levels.

Table 19: Alert Severities

Severity	Description
Critical	The health test results met the criteria to trigger a Critical alert status.
Warning	The health test results met the criteria to trigger a Warning alert status.
Normal	The health test results met the criteria to trigger a Normal alert status.
Error	The health test did not run.
Recovered	The health test results met the criteria to return to a normal alert status, following a Critical or Warning alert status.

Creating Health Monitor Alerts

You must be an Admin user to perform this procedure.

When you create a health monitor alert, you create an association between a severity level, a health module, and an alert response. You can use an existing alert or configure a new one specifically to report on system health. When the severity level occurs for the selected module, the alert triggers.

If you create or update a threshold in a way that duplicates an existing threshold, you are notified of the conflict. When duplicate thresholds exist, the health monitor uses the threshold that generates the fewest alerts and ignores the others. The timeout value for the threshold must be between 5 and 4,294,967,295 minutes.

Before you begin

- Configure an alert response that governs the Firewall Management Center's communication with the SNMP, syslog, or email server where you send the health alert; see Secure Firewall Management Center Alert Responses, on page 371.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor Alerts**.

Step 2 Click **Add**.

Step 3 In the **Add Health Alert** dialog box, enter a name for the health alert in the **Health Alert Name** field.

Step 4 From the **Severity** drop-down list, choose the severity level you want to use to trigger the alert.

Step 5 From the **Alert** drop-down list, choose the alert response that you want to trigger when the specified severity level is reached. If you have not yet configured the alert responses, click **Alerts** to visit the **Alerts** page and set them.

Step 6 From the **Health Modules** list, choose the health policy modules for which you want the alert to apply.

Step 7 Optionally, in the **Threshold Timeout** field, enter the number of minutes that should elapse before each threshold period ends and the threshold count resets.

Even if the policy run time interval value is less than the threshold timeout value, the interval between two reported health events from a given module is always greater. For example, if you change the threshold timeout to 8 minutes and the policy run time interval is 5 minutes, there is a 10-minute interval (5 x 2) between reported events.

Step 8 Click **Save** to save the health alert.

Editing Health Monitor Alerts

You must be an Admin user to perform this procedure.

You can edit existing health monitor alerts to change the severity level, health module, or alert response associated with the health monitor alert.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor Alerts**.

Step 2 Click the **Edit** (✎) icon that is provided against the required health alert that you want to modify.

Step 3 In the **Edit Health Alert** dialog box, from the **Alert** drop-down list, select the required alert entry, or click **Alerts** link to configure a new alert entry.

Step 4 Click **Save**.

Deleting Health Monitor Alerts

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor Alerts**.

Step 2 Click **Delete** (🗑) next to the health alert you want to delete, and then click **Delete health alert** to delete it.

What to do next

- Disable or delete the underlying alert response to ensure that alerting does not continue; see Secure Firewall Management Center Alert Responses, on page 371.

About the Health Monitor

You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

The health monitor provides the compiled health status for all devices managed by the Firewall Management Center, plus the Firewall Management Center itself. The health monitor is composed of:

- The Health Status summary page — Provides you with an at-a-glance view of the health of the Firewall Management Center and all of the devices that the Firewall Management Center manages. In a multi-domain deployment, you can view the health status summary for a device in the domain where the device is located. Devices are listed individually, or grouped according to their geolocation, high availability, or cluster status where applicable.
  - View the health summary of the Firewall Management Center and any device when you hover on the hexagon that represents the device health.
  - The dot to the left of a device indicates its health:
    - Green — No alarms.
    - Orange — At least one health warning.

- Red — At least one critical health alarm.

- The Monitoring navigation pane — Allows you to navigate the device hierarchy. You can view health monitors for individual devices from the navigation pane.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Step 2 View the status of the Firewall Management Center and its managed devices in the **Health Status** landing page.

a) Hover your pointer over a hexagon to view the health summary of a device. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

b) In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of health alerts for a device.

When you expand the row, all of the health alerts are listed, including the status, title, and details.

Note
Health alerts are sorted by their severity level.

Step 3 Use the Monitoring navigation pane to access device-specific health monitors. When you use the Monitoring navigation pane:

a) In the device list, click **Expand** (>) and **Collapse** (⌄) to expand and collapse the list of managed devices.

When you expand the row, all of the devices are listed.

b) Click on a device to view a device-specific health monitor.

c) In the health monitor, hover over a graph to view all metrics and their respective values at that specific point on the graph. Click on the graph to pin the metrics statistics box, allowing you to explore the metrics and their values in detail. To close the statistics box and move to another point on the graph, simply click the close button.

What to do next

- See Device Health Monitors, on page 294 for information about the compiled health status and metrics for any device managed by the Firewall Management Center.

Device Health Monitors

The device health monitor provides the compiled health status for any device managed by the Firewall Management Center. The device health monitor collects health metrics for Secure Firewall devices in order to predict and respond to system events. The device health monitor is comprised of the following components:

- System Details — Displays information about the managed device, including the installed Secure Firewall version and other deployment details.
- Troubleshooting & Links — Provides convenient links to frequently used troubleshooting topics and procedures.
- Health alerts — A health alert monitor provides an at-a-glance view of the health of the device.
- Time range — An adjustable time window to constrain the information that appears in the various device metrics windows.
- Device metrics — An array of key firewall device health metrics categorized across predefined dashboards, including:
  - CPU — CPU utilization, including the CPU usage by process and by physical cores. The Firewall Threat Defense CPU core allocation dashboard shows core assignments for these categories:
    - **Data Plane**: Handles basic network functions, including core packet forwarding and network data processing.
    - **Snort**: Manages intrusion detection and deep packet inspection features.
    - **System**: Includes all other system processes. While some processes may have dedicated CPU cores allocated, their usage is combined and displayed under the **System** category in the dashboard.
  - Memory — Device memory utilization, including data plane and Snort memory usage.
  - Interfaces — Interface status and aggregate traffic statistics.
  - Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
  - Snort — Statistics related to the Snort process.
  - Disk Usage — Device disk usage, including the disk size and disk utilization per partition.
  - Critical Processes — Statistics related to managed processes, including process restarts and other select health monitors such as CPU and memory utilization.

See Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Viewing System Details and Troubleshooting

You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

The System Details section provides a general system information for a selected device. You can also launch troubleshooting tasks for that device.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access device-specific health monitors.

Step 2 In the device list, click **Expand**( ) and **Collapse** ( ) to expand and collapse the list of managed devices.

Step 3 Click on a device to view a device-specific health monitor.

Step 4 Click the link for **View System & Troubleshoot Details …**

This panel is collapsed by default. Clicking on the link expands the collapsed section to see **System Details** and **Troubleshooting & Links** for the device. The system details include:

- **Version:** The Secure Firewall software version.
- **Model:** The device model.
- **Mode:** The firewall mode. The Firewall Threat Defense device supports two firewall modes for regular firewall interfaces: Routed mode and Transparent mode.
- **VDB:** The Cisco vulnerability database (VDB) version.
- **SRU:** The intrusion rule set version.
- **Snort:** The Snort version.

Step 5 You have the following troubleshoot choices:

- Generate troubleshooting files; see Generate Troubleshooting Files for Specific System Functions, on page 320
- Generate and download advanced troubleshooting files; see Download Advanced Troubleshooting Files, on page 320.
- Create and modify health policies; see Creating Health Policies, on page 280.
- Create and modify health monitor alerts; see Creating Health Monitor Alerts, on page 292.

Viewing the Device Health Monitor

You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

The device health monitor provides a detailed view of the health status of a firewall device. The device health monitor compiles device metrics and provides health status and trends of the device in an array of dashboards.

Procedure

Step 1 Choose **System** ( ) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access device-specific health monitors.

Step 2 In the device list, click **Expand**( ) and **Collapse** ( ) to expand and collapse the list of managed devices.

Step 3 View the **Health Alerts** for the device in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the device. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

Step 4 You can configure the time range from the drop-down in the upper-right corner. The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click the **Show the deployment details on top of the graph** ( ) icon for a deployment overlay on the trend graph, with respect to the selected time range.

The icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. In the case of multiple deployments, multiple bands/lines can appear. Click the icon on top of the dotted line to view the deployment details.

Step 6 The device monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU — CPU utilization, including the CPU usage by process and by physical cores.
- Memory — Device memory utilization, including data plane and Snort memory usage.
- Interfaces — Interface status and aggregate traffic statistics.
- Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort — Statistics related to the Snort process.
- ASP Drops — Statistics related to the Accelerated Security Path (ASP) performance and behavior.

Note
The **Process Health** widget in Firewall Management Center displays the CPU% usage for each process. The CPU% metric reflects usage relative to the number of cores in the Firewall Threat Defense device, where 100% corresponds to full utilization of one core. For example, on an 8-core device, 200% indicates two fully utilized cores, leaving six available for other processes. To monitor overall system CPU usage, use the **CPU** widget instead of the **Process Health** widget.

You can navigate through the various metrics dashboards by clicking on the labels. See Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 7 Click the **Add New Dashboard**( ) to create a custom correlation dashboard by building your own variable set from the available metric groups; see Correlating Device Metrics, on page 297.

Correlating Device Metrics

The device health monitor includes an array of key Firewall Threat Defense device metrics that serve to predict and respond to system events. The health of any Firewall Threat Defense device can be determined by these reported metrics.

The device monitor reports these metrics in several predefined dashboards by default. These dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU — CPU utilization, including the CPU usage by process and by physical cores.
- Memory — Device memory utilization, including data plane and Snort memory usage.
- Interfaces — Interface status and aggregate traffic statistics.
- Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort — Statistics related to the Snort process.
- ASP Drops — Statistics related to the Accelerated Security Path (ASP) performance and behavior.

You can add custom dashboards to correlate metrics that are interrelated. Select from predefined correlation groups, such as CPU and Snort; or create a custom correlation dashboard by building your own variable set from the available metric groups. See Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Before you begin

- To view and correlate the time series data (device metrics) in the health monitor dashboard, enable REST API (**System** (⚙) > **Configuration** > **REST API Preferences**).
- You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

Note Correlating device metrics is available only for Firewall Threat Defense 6.7 and later versions. Hence, for Firewall Threat Defense versions earlier than 6.7, the health monitor dashboard does not display these metrics even if you enable REST API.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access device-specific health monitors.

Step 2 In the **Devices** list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed devices.

Step 3 Choose the device for which you want to modify the dashboard.

Step 4 Click the **Add New Dashboard**(+)icon to add a new dashboard.

Step 5 Specify a name to identity the dashboard.

Step 6 To create a dashboard from a predefined correlation group, click **Add from Predefined Correlations** drop-down, choose the group, and click **Add Dashboard**.

Step 7 To create a custom correlation dashboard, choose a group from the **Select Metric Group** drop-down, then choose corresponding metrics from the **Select Metrics** drop-down.

See Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 8 Click **Add Metrics** to add and select metrics from another group.

Step 9 To remove an individual metric, click the Remove ✕ icon on the right side of the item. Click the delete icon to remove the entire group.

Step 10 Click **Add Dashboard** to add the dashboard to the health monitor.

Step 11 You can **Edit** or **Delete** the predefined dashboards and the custom correlation dashboards.

Cluster Health Monitor

When a Firewall Threat Defense is the control node of a cluster, the Firewall Management Center collects various metrics periodically from the device metric data collector. The cluster health monitor is comprised of the following components:

- Overview dashboard—Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the Firewall Management Center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

  - The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.

- Load Distribution dashboard—Displays load distribution across the cluster nodes in two widgets:
  - The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
  - The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.

- Member Performance dashboard—Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard—Displays, graphically, the cluster control link data namely, the input, and output rate.

- Troubleshooting and Links — Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range—An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard—Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

Viewing the Cluster Health Monitor

You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

- Ensure you have created a cluster from one or more devices in the Firewall Management Center.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

Step 2 In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.

Step 3 To view the cluster health statistics, click on the cluster name. The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution — Traffic and packet distribution across the cluster nodes.
- Member Performance — Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL — Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, see Cisco Secure Firewall Threat Defense Health Metrics.

Step 4 You can configure the time range from the drop-down in the upper-right corner. The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

Step 6 (For node-specific health monitor) View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

Step 7 (For node-specific health monitor) The device monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU — CPU utilization, including the CPU usage by process and by physical cores.
- Memory — Device memory utilization, including data plane and Snort memory usage.
- Interfaces — Interface status and aggregate traffic statistics.
- Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort — Statistics that are related to the Snort process.
- ASP drops — Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. See Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 8 Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Health Monitor Status Categories

Available status categories are listed by severity in the table below.

Table 20: Health Status Indicator

Status Level	Status Icon	Status Color in Pie Chart	Description
Error	**Error** (✖)	Black	Indicates that at least one health monitoring module has failed on the appliance and has not been successfully re-run since the failure occurred. Contact your technical support representative to obtain an update to the health monitoring module.

Status Level	Status Icon	Status Color in Pie Chart	Description
Critical	**Critical** ( )	Red	Indicates that the critical limits have been exceeded for at least one health module on the appliance and the problem has not been corrected.
Warning	**Warning** ( )	Yellow	Indicates that warning limits have been exceeded for at least one health module on the appliance and the problem has not been corrected. This status also indicates a transitionary state, where, the required data is temporarily unavailable or could not be processed because of changes in the device configuration. Depending on the monitoring cycle, this transitionary state is auto-corrected.
Normal	**Normal** ( )	Green	Indicates that all health modules on the appliance are running within the limits configured in the health policy applied to the appliance.
Recovered	**Recovered** ( )	Green	Indicates that all health modules on the appliance are running within the limits configured in the health policy applied to the appliance, including modules that were in a Critical or Warning state.
Disabled	**Disabled** ( )	Blue	Indicates that an appliance is disabled or excluded, that the appliance does not have a health policy applied to it, or that the appliance is currently unreachable.

Health Event Views

The Health Event View page allows you to view health events logged by the health monitor on the Firewall Management Center logs health events. The fully customizable event views allow you to quickly and easily analyze the health status events gathered by the health monitor. You can search event data to easily access other information that may be related to the events you are investigating. If you understand what conditions each health module tests for, you can more effectively configure alerting for health events.

You can perform many of the standard event view functions on the health event view pages.

Viewing Health Events

You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

The Table View of Health Events page provides a list of all health events on the specified appliance.

When you access health events from the Health Monitor page on your Firewall Management Center, you retrieve all health events for all managed appliances.

Tip You can bookmark this view to allow you to return to the page in the health events workflow containing the Health Events table of events. The bookmarked view retrieves events within the time range you are currently viewing, but you can then modify the time range to update the table with more recent information if needed.

Procedure

Choose **System** (⚙) > **Health** > **Events**.

Tip
If you are using a custom workflow that does not include the table view of health events, click **(switch workflow)**. On the Select Workflow page, click **Health Events**.

Note
If no events appear, you may need to adjust the time range.

Viewing the Health Events Table

You can view and modify the Health Events Table.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Events**.

Step 2 You have the following choices:

- Bookmark — To bookmark the current page so that you can quickly return to it, click **Bookmark This Page**, provide a name for the bookmark, and click **Save**.
- Change Workflow — To choose another health events workflow, click **(switch workflow)**.
- Delete Events — To delete health events, check the check box next to the events you want to delete, and click **Delete**. To delete all the events in the current constrained view, click **Delete All**, then confirm you want to delete all the events.
- Generate Reports — Generate a report based on data in the table view — click **Report Designer**.
- Modify — Modify the time and date range for events listed in the Health table view. Note that events that were generated outside the appliance's configured time window (whether global or event-specific) may appear in an event view if you constrain the event view by time. This may occur even if you configured a sliding time window for the appliance.
- Navigate — Navigate through event view pages.
- Navigate Bookmark — To navigate to the bookmark management page, click **View Bookmarks** from any event view.
- Navigate Other — Navigate to other event tables to view associated events.
- Sort — Sort the events that appear, change what columns display in the table of events, or constrain the events that appear

- View All — To view event details for all events in the view, click **View All**.
- View Details — To view the details associated with a single health event, click the down arrow link on the left side of the event.
- View Multiple — To view event details for multiple health events, choose the check box next to the rows that correspond with the events you want to view details for and then click **View**.
- View Status — To view all events of a particular status, click status in the Status column for an event with that status.

The Health Events Table

The Health Monitor modules you choose to enable in your health policy run various tests to determine appliance health status. When the health status meets criteria that you specify, a health event is generated.

The table below describes the fields that can be viewed and searched in the health events table.

Table 21: Health Event Fields

Field	Description
Module Name	Specify the name of the module which generated the health events you want to view. For example, to view events that measure CPU performance, type `CPU`. The search should retrieve applicable CPU Usage and CPU temperature events.
Test Name (Search only)	The name of the health module that generated the event.
Time (Search only)	The timestamp for the health event.
Description	The description of the health module that generated the event. For example, health events generated when a process was unable to execute are labeled `Unable to Execute`.
Value	The value (number of units) of the result obtained by the health test that generated the event. For example, if the Firewall Management Center generates a health event whenever a device it is monitoring is using 80 percent or more of its CPU resources, the value could be a number from 80 to 100.
Units	The units descriptor for the result. You can use the asterisk (*) to create wildcard searches. For example, if the Firewall Management Center generates a health event when a device it is monitoring is using 80 percent or more of its CPU resources, the units descriptor is a percentage sign (%).
Status	The status (Critical, Yellow, Green, or Disabled) reported for the appliance.
Device	The appliance where the health event was reported.

About System Auditing

The appliances that are part of the system generate an audit record for each user interaction with the web interface.

Audit Records

Secure Firewall Management Centers log read-only auditing information for user activity. Audit logs are presented in a standard event view that allows you to view, sort, and filter audit log messages based on any item in the audit view. You can easily delete and report on audit information and can view detailed reports of the changes that users make.

The audit log stores a maximum of 100,000 entries. When the number of audit log entries exceeds 100,000, the appliance prunes the oldest records from the database to reduce the number to 100,000.

The audit logs do not display the user or the source IP for login errors:

- When wrong password is used, the source IP is not displayed.
- When the user account does not exist, both source IP and the user are not displayed.
- If the attempt for an LDAP user fails, no audit log is triggered.

Related Topics

SSO Guidelines for the Firewall Management Center

Audit Log Workflow Fields

The following table describes the audit log fields that can be viewed and searched.

Table 22: Audit Log Fields

Field	Description
Time	Time and date that the appliance generated the audit record.
User	User name of the user that triggered the audit event.
Subsystem	In a few cases where a menu path is not relevant, the Subsystem field displays only the event type. For example, **Login** classifies user login attempts.
Message	The action the user performed or the button the user clicked on the page. For example, `Page View` signifies that the user simply viewed the page indicated in the Subsystem, while `Save` means that the user clicked the **Save** button on the page. Changes made to the system appear with a **Compare icon** that you can click to see a summary of the changes.
Source IP	IP address associated with the host used by the user. Note: When searching this field you must type a specific IP address; you cannot use IP ranges when searching audit logs.

Field	Description
Domain	The current domain of the user when the audit event was triggered. This field is only present if you have ever configured the Firewall Management Center for multitenancy.
Configuration Change (search only)	Specifies whether to view audit records of configuration changes in the search results. (`yes` or `no`)
Count	The number of events that match the information that appears in each row. Note that the Count field appears only after you apply a constraint that creates two or more identical rows. This field is not searchable.

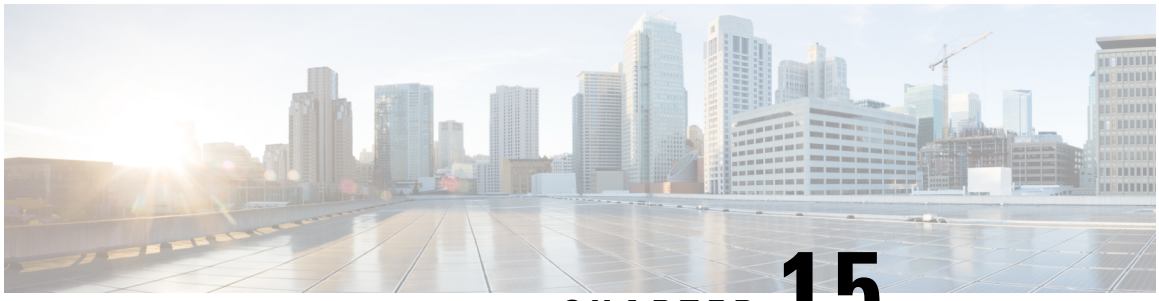
The Audit Events Table View

You can change the layout of the event view or constrain the events in the view by a field value. When disabling columns, after you click the **Close** ( ) in the column heading that you want to hide, in the pop-up window that appears, click **Apply**. When you disable a column, it is disabled for the duration of your session (unless you add it back later). Note that when you disable the first column, the Count column is added.

To hide or show other columns, or to add a disabled column back to the view, select or clear the appropriate check boxes before you click **Apply**.

Clicking a value within a row in a table view constrains the table view and does not drill down to the next page in the workflow.

Tip Table views always include “Table View” in the page name.



CHAPTER 15

Troubleshooting

The following topics describe ways to diagnose problems you may encounter:

- Guidelines and Best Practices for Troubleshooting, on page 307
- System Messages, on page 308
- View Basic System Information, on page 310

Guidelines and Best Practices for Troubleshooting

- Before you make changes to try to fix a problem, generate a troubleshooting file to capture the original problem. See Health Monitor Reports for Troubleshooting, on page 319 and its subsections.

  You may need this troubleshooting file if you need to contact Cisco TAC for support.

- Start your investigation by looking at error and warning messages in the Message Center. See System Messages, on page 308

- Look for applicable Tech Notes and other troubleshooting resources under the "Troubleshoot and Alerts" heading on the product documentation page for your product.

- During the troubleshooting process, as several commands are executed simultaneously, the CPU usage becomes high. We recommend that you perform troubleshooting during periods of lower network traffic and fewer users.

- The time taken to troubleshoot the system depends on the configuration settings and the number of devices configured. This duration can range from nine to sixty minutes.

System Messages

When you need to track down problems occurring in the system, the Message Center is the place to start your investigation. This feature allows you to view the messages that the system continually generates about system activities and status.

To open the Message Center, click on the System Status icon, located next to the Deploy menu in the main menu. This icon can take one of the following forms, depending on the system status:

- **Error** ( ) — Indicates one or more errors and any number of warnings are present on the system.
- **Warning** ( ) — Indicates one or more warnings and no errors are present on the system.
- **Success** ( ) — Indicates no warnings or errors are present on the system.

If a number is displayed with the icon, it indicates the total current number of error or warning messages.

To close the Message Center, click anywhere outside of it within the web interface.

In addition to the Message Center, the web interface displays pop-up notifications in immediate response to your activities and ongoing system activities. Some pop-up notifications automatically disappear after five seconds, while others are "sticky," meaning they display until you explicitly dismiss them by clicking **Dismiss** ( ). Click the **Dismiss** link at the top of the notifications list to dismiss all notifications at once.

Tip Hovering your cursor over a non-sticky pop-up notification causes it to be sticky.

The system determines which messages it displays to users in pop-up notifications and the Message Center based on their licenses, domains, and access roles.

Message Types

The Message Center displays messages reporting system activities and status organized into three different tabs:

Deployments

This tab displays current status related to configuration deployment for each appliance in your system, grouped by domain. The system reports the following deployment status values on this tab. You can get additional detail about the deployment jobs by clicking **Show History**.

- Running (**Spinning**) — The configuration is in the process of deploying.
- **Success** — The configuration has successfully been deployed.
- **Warning** ( ) — Warning deployment statuses contribute to the message count displayed with the **Warning System Status icon**.
- **Failure** — The configuration has failed to deploy; see Configuration Changes that Require Deployment, on page 165. Failed deployments contribute to the message count displayed with the **Error System Status icon**.

Upgrades

This tab displays the current status related to software upgrade tasks for the managed devices. The system reports the following upgrade status values on this tab:

- **In progress**—Indicates that the upgrade task is in progress.
- **Completed**—Indicates that the software upgrade task is completed successful.
- **Failed**—Indicates that the software upgrade task has failed to complete.

Health

This tab displays current health status information for each appliance in your system, grouped by domain. Health status is generated by health modules as described in About Health Monitoring, on page 271. The system reports the following health status values on this tab:

- **Warning** ( ) — Indicates that warning limits have been exceeded for a health module on an appliance and the problem has not been corrected. The Health Monitoring page indicates these conditions with a **Yellow Triangle** ( ). Warning statuses contribute to the message count displayed with the **Warning System Status icon**.
- **Critical** ( ) — Indicates that critical limits have been exceeded for a health module on an appliance and the problem has not been corrected. The Health Monitoring page indicates these conditions with a **Critical** ( ) icon. Critical statuses contribute to the message count displayed with the **Error System Status icon**.
- **Error** ( ) — Indicates that a health monitoring module has failed on an appliance and has not been successfully re-run since the failure occurred. The Health Monitoring page indicates these conditions with a **Error icon**. Error statuses contribute to the message count displayed with the **Error System Status icon**.

You can click on links in the Health tab to view related detailed information on the Health Monitoring page. If there are no current health status conditions, the Health tab displays no messages.

Tasks

Certain tasks (such as configuration backups or update installation) can require some time to complete. This tab displays the status of these long-running tasks, and can include tasks initiated by you or, if you have appropriate access, other users of the system. The tab presents messages in reverse chronological order based on the most recent update time for each message. Some task status messages include links to more detailed information about the task in question. The system reports the following task status values on this tab:

- **Waiting**() — Indicates a task that is waiting to run until another in-progress task is complete. This message type displays an updating progress bar.
- **Running** — Indicates a task that is in-progress. This message type displays an updating progress bar.
- **Retrying** — Indicates a task that is automatically retrying. Note that not all tasks are permitted to try again. This message type displays an updating progress bar.
- **Success** — Indicates a task that has completed successfully.

- **Failure** — Indicates a task that did not complete successfully. Failed tasks contribute to the message count displayed with the **Error System Status icon**.
- **Stopped or Suspended** — Indicates a task that was interrupted due to a system update. Stopped tasks cannot be resumed. After normal operations are restored, start the task again.
- Skipped — A process in progress prevented the task from starting. Try again to start the task.

New messages appear in this tab as new tasks are started. As tasks complete (status success, failure, or stopped), this tab continues to display messages with final status indicated until you remove them. Cisco recommends you remove messages to reduce clutter in the Tasks tab as well as the message database.

Message Management

From the Message Center you can:

- Choose to display pop-up notifications.
- Display more task status messages from the system database (if any are available that have not been removed).
- Download a report of all the task manager notifications.
- Remove individual task status messages. (This affects all users who can view the removed messages.)
- Remove task status messages in bulk. (This affects all users who can view the removed messages.)

Tip Cisco recommends that you periodically remove accumulated task status messages from the Task tab to reduce clutter in the display as well the database. When the number of messages in the database approaches 100,000, the system automatically deletes task status messages that you have removed.

View Basic System Information

The About page displays information about your appliance, including the model, serial number, and version information for various components of the system. It also includes Cisco copyright information.

Procedure

Step 1 Click **Help** (?) in the toolbar at the top of the page.

Step 2 Choose **About**.

View Appliance Information

Procedure

Choose **System** (⚙) > **Configuration**.

Manage System Messages

Procedure

Step 1 Click **Notifications** to display the Message Center.

Step 2 You have the following choices:

- Click **Deployments** to view messages related to configuration deployments. See View Deployment Messages, on page 311. You must be an Admin user or have the **Deploy Configuration to Devices** permission to view these messages.
- Click **Upgrades** to view messages related to device upgrade tasks. See Viewing Upgrade Messages. See Viewing Upgrade Messages. You must be an Admin user or have **Updates** permission to view these messages.
- Click **Health** to view messages related to the health of your Firewall Management Center and the devices registered to it. See View Health Messages, on page 313. You must be an Admin user or have the **Health** permission to view these messages.

  You can navigate to the Health Monitor page by clicking the **Health monitor** link.

- Click **Tasks** to view or manage messages related to long-running tasks. See View Task Messages, on page 313 or Manage Task Messages, on page 314. Everyone can see their own tasks. To see the tasks of other users, you must be an Admin user or have the **View Other Users' Tasks** permission. You can remove the completed tasks from the notification by clicking the **Remove completed tasks** link.
- Click the **Download Report** icon to generate a report of all the notifications in the task manager. Choose **Download CSV** or **Download PDF** to download the report.
- Click **Show Notifications** slider to enable or disable pop-up notification display.

View Deployment Messages

You must be an Admin user or have the **Deploy Configuration to Devices** permission to view these messages.

Procedure

Step 1 Click **Notifications** to display the Message Center.

Step 2 Click **Deployments**.

Step 3 You have the following choices:

- Click **total** to view all current deployment statuses.
- Click a status value to view only messages with that deployment status.
- Hover your cursor over the time elapsed indicator for a message (for example, **1m 5s**) to view the elapsed time, and start and stop times for the deployment.

Step 4 Click **show deployment history** to view more detailed information about the deployment jobs.

The Deployment History table lists the deployment jobs in the left column in reverse chronological order.

a) Select a deployment job.

The table in the right column shows each device that was included in the job, and the deployment status per device.

b) To view responses from the device, and commands sent to the device during deployment, click download in the **Transcript** column for the device.

The transcript includes the following sections:

- **Snort Apply**—If there are any failures or responses from Snort-related policies, messages appear in this section. Normally, the section is empty.
- **CLI Apply**—This section covers features that are configured using commands sent to the Lina process.
- **Infrastructure Messages**—This section shows the status of different deployment modules.

In the **CLI Apply** section, the deployment transcript includes commands sent to the device, and any responses returned from the device. These response can be informative messages or error messages. For failed deployments, look for messages that indicate errors with the commands. Examining these errors can be particularly helpful if you are using FlexConfig policies to configure customized features. These errors can help you correct the script in the FlexConfig object that is trying to configure the commands.

Note
There is no distinction made in the transcript between commands sent for managed features and those generated from FlexConfig policies.

For example, the following sequence shows that the Firewall Management Center sent commands to configure GigabitEthernet0/0 with the logical name outside. The device responded that it automatically set the security level to 0. The Firewall Threat Defense does not use the security level for anything.

```
========= CLI APPLY =========

FMC >> interface GigabitEthernet0/0
FMC >>  nameif outside
FTDv 192.168.0.152 >> [info] : INFO: Security level for "outside" set to 0 by default.
```

View Upgrade Messages

You must be an Admin user or have the **Updates** permission to view these messages.

Procedure

Step 1 Click **Notifications** to display the Message Center.

Step 2 Click **Upgrades**.

Step 3 You can do the following:

- Click **total** to view all current upgrade tasks.
- Click on a status value to see messages with only that status.
- Click **Device Management** for more details on the upgrade task.

View Health Messages

You must be an Admin user or have the **Health** permission to view these messages.

Procedure

Step 1 Click **Notifications** to display the Message Center.

Step 2 Click **Health**.

Step 3 You have the following choices:

- Click **total** to view all current health statuses. The break-up of the severity, namely, warning, critical, and error is also displayed.
- Click on a status value to view only messages with that status.
- Hover your cursor over the relative time indicator for a message (for example, **3 day(s) ago**) to view the time of the most recent update for that message.
- To view detailed health status information for a particular message, click the message.
- To view complete health status on the Health Monitoring page, click **Health Monitor**.

View Task Messages

Everyone can see their own tasks. To see the tasks of other users, you must be an Admin user or have the **View Other Users' Tasks** permission.

Procedure

Step 1 Click **Notifications** to display the Message Center.

Step 2 Click **Tasks**.

Step 3 You have the following choices:

- Click **total** to view all current task statuses. To view the tasks based on the status, namely, waiting, running, retrying, success, and failures, click on them.
- Click a status value to view only messages for tasks with the that status.

  Note
  Messages for stopped tasks appear only in the total list of task status messages. You cannot filter on stopped tasks.

- Hover your cursor over the relative time indicator for a message (e.g., **3 day(s) ago**) to view the time of the most recent update for that message.
- Click any link within a message to view more information about the task.
- If more task status messages are available for display, click **Fetch more messages** at the bottom of the message list to retrieve them.

Manage Task Messages

Everyone can see their own tasks. To see the tasks of other users, you must be an Admin user or have the **View Other Users' Tasks** permission.

Procedure

Step 1 Click System Status to display the Message Center.

Step 2 Click Tasks.

Step 3 You have the following choices:

- If more task status messages are available for display, click on **Fetch more messages** at the bottom of the message list to retrieve them.
- To remove a single message for a completed task (status stopped, success, or failure), click on **Remove** ( ) next to the message.
- To remove all messages for all tasks that have completed (status stopped, success, or failure), filter the messages on **total** and click on **Remove all completed tasks**.
- To remove all messages for all tasks that have completed successfully, filter the messages on **success**, and click on **Remove all successful tasks**.
- To remove all messages for all tasks that have failed, filter the messages on **failure**, and click on **Remove all failed tasks**.

Memory Usage Thresholds for Health Monitor Alerts

The Memory Usage health module compares memory usage on an appliance to the limits configured for the module and alerts when usage exceeds the levels. The module monitors data from managed devices and from the Firewall Management Center itself.

Two configurable thresholds for memory usage, Critical and Warning, can be set as a percentage of memory used. When these thresholds are exceeded, a health alarm is generated with the severity level specified. However, the health alarm system does not calculate these thresholds in an exact manner.

With high memory devices, certain processes are expected to use a larger percentage of total system memory than in a low memory footprint device. The design is to use as much of the physical memory as possible while leaving a small value of memory free for ancillary processes.

Compare two devices, one with 32 GB of memory and one with 4 GB of memory. In the device with 32 GB of memory, 5% of memory (1.6GB) is a much larger value of memory to leave for ancillary processes than in the device with 4 GB of memory (5% of 4GB = 200MB).

To account for the higher percentage use of system memory by certain processes, the Firewall Management Center calculates the total memory to include both total physical memory and total swap memory. Thus the enforced memory threshold for the user-configured threshold input can result in a Health Event where the "Value" column of the event does not match the value that was entered to determine the exceeded threshold.

Beginning with version 7.4.1, the memory usage health module calculates memory usage by taking into account the free memory available, swap memory available, and buffer cache. To avoid premature memory usage health alerts, it is recommended not to exceed the warning and critical alarm thresholds of 88% and 90%, respectively.

The following table shows examples of user-input thresholds and the enforced thresholds, depending on the installed system memory.

Note The values in this table are examples. You can use this information to extrapolate thresholds for devices that do not match the installed RAM shown here, or you can contact Cisco TAC for more precise threshold calculations.

Table 23: Memory Usage Thresholds Based On Installed RAM

User-Input Threshold Value	Enforced Threshold Per Installed Memory (RAM)			
	4 GB	6 GB	32 GB	48 GB
10%	10%	34%	72%	81%
20%	20%	41%	75%	83%
30%	30%	48%	78%	85%
40%	40%	56%	81%	88%
50%	50%	63%	84%	90%
60%	60%	70%	88%	92%
70%	70%	78%	91%	94%
80%	80%	85%	94%	96%
90%	90%	93%	97%	98%
100%	100%	100%	100%	100%

Disk Usage and Drain of Events Health Monitor Alerts

The Disk Usage health module compares disk usage on a managed device's hard drive and malware storage pack to the limits configured for the module and alerts when usage exceeds the percentages configured for the module. This module also alerts when the system excessively deletes files in monitored disk usage categories, or when disk usage excluding those categories reaches excessive levels, based on module thresholds.

This topic describes the symptoms and troubleshooting guidelines for two health alerts generated by the Disk Usage health module:

- Frequent Drain of Events
- Drain of Unprocessed Events

The disk manager process manages the disk usage of a device. Each type of file monitored by the disk manager is assigned with a silo. Based on the amount of disk space available on the system the disk manager computes a High Water Mark (HWM) and a Low Water Mark (LWM) for each silo.

To display detailed disk usage information for each part of the system, including silos, LWMs, and HWMs, use the **show disk-manager** command.

Examples

The following is an example of the disk manager information:

```
> show disk-manager
Silo                                Used        Minimum     Maximum
Temporary Files                     0 KB        499.197 MB  1.950 GB
Action Queue Results                0 KB        499.197 MB  1.950 GB
User Identity Events                0 KB        499.197 MB  1.950 GB
UI Caches                           4 KB        1.462 GB    2.925 GB
Backups                             0 KB        3.900 GB    9.750 GB
Updates                             0 KB        5.850 GB    14.625 GB
Other Detection Engine              0 KB        2.925 GB    5.850 GB
Performance Statistics              33 KB       998.395 MB  11.700 GB
Other Events                        0 KB        1.950 GB    3.900 GB
IP Reputation & URL Filtering       0 KB        2.437 GB    4.875 GB
Archives & Cores & File Logs        0 KB        3.900 GB    19.500 GB
Unified Low Priority Events         1.329 MB    4.875 GB    24.375 GB
RNA Events                          0 KB        3.900 GB    15.600 GB
File Capture                        0 KB        9.750 GB    19.500 GB
Unified High Priority Events        0 KB        14.625 GB   34.125 GB
IPS Events                          0 KB        11.700 GB   29.250 GB
```

Health Alert Format

When the Health Monitor process on the Firewall Management Center runs (once every 5 minutes or when a manual run is triggered), the Disk Usage module looks into the diskmanager.log file and, if the correct conditions are met, the health alert is triggered.

The structures of these health alerts are as follows:

- Frequent drain of <*SILO NAME*>
- Drain of unprocessed events from <*SILO NAME*>

For example,

- Frequent drain of Low Priority Events
- Drain of unprocessed events from Low Priority Events

Its possible for any silo to generate a *Frequent drain of <SILO NAME>* health alert. However, the most commonly seen are the alerts related to events. Among the event silos, the *Low Priority Events* are often seen because device generates this type of events frequently.

A *Frequent drain of <SILO NAME>* event has a **Warning** severity level when seen in relation to an event-related silo, because events will be queued to be sent to the Firewall Management Center. For a non-event related silo, such as the *Backups* silo, the alert has a **Critical** severity level because this information is lost.

Important Only event silos generate a *Drain of unprocessed events from <SILO NAME>* health alert. This alert always has a **Critical** severity level.

Additional symptoms besides the alerts can include:

- Slowness on the Firewall Management Center user interface
- Loss of events

Common Troubleshoot Scenarios

A *Frequent drain of <SILO NAME>* event is caused by too much input into the silo for its size. In this case, the disk manager drains (purges) that file at least twice in the last 5-minute interval. In an event type silo, this is typically caused by excessive logging of that event type.

A *Drain of unprocessed events of <SILO NAME>* health alert is caused by a bottleneck in the event processing path.

There are three potential bottlenecks with respect to these Disk Usage alerts:

- Excessive logging — The EventHandler process on Firewall Threat Defense is oversubscribed (it reads slower than what Snort writes).
- Sftunnel bottleneck — The Eventing interface is unstable or oversubscribed.
- SFDataCorrelator bottleneck — The data transmission channel between the Firewall Management Center and the managed device is oversubscribed.

Excessive Logging

One of the most common causes for the health alerts of this type is excessive input. The difference between the Low Water Mark (LWM) and High Water Mark (HWM) gathered from the **show disk-manager** command shows how much space there is available to take on that silo to go from LWM (freshly drained) to the HWM value. If there are frequent drain of events (with or without unprocessed events), review the logging configuration.

- Check for double logging — Double logging scenarios can be identified if you look at the correlator *perfstats* on the Firewall Management Center:

```
admin@FMC:~$ sudo perfstats -Cq < /var/sf/rna/correlator-stats/now
```

- Check logging settings for the ACP — Review the logging settings of the Access Control Policy (ACP). If the logging setting includes both "Beginning" and "End" of connection, modify the setting to log only the end to reduce the number of events.

Communications Bottleneck – Sftunnel

Sftunnel is responsible for encrypted communications between the Firewall Management Center and the managed device. Events are sent over the tunnel to the Firewall Management Center. Connectivity issues and/or instability in the communication channel (sftunnel) between the managed device and the Firewall Management Center can be due to:

- Sftunnel is down or is unstable (flaps).

  Ensure that the Firewall Management Center and the managed device have reachability between their management interfaces on TCP port 8305.

  The sftunnel process should be stable and should not restart unexpectedly. Verify this by checking the **/var/log/message** file and search for messages that contain the ***sftunneld*** string.

- Sftunnel is oversubscribed.

  Review trend data from the Heath Monitor and look for signs of oversubscription of the Firewall Management Center's management interface, which can be a spike in management traffic or a constant oversubscription.

  Use as a secondary management interface for eventing. To use this interface, you must configure its IP address and other parameters at the Firewall Threat Defense CLI using the **configure network management-interface** command.

Communications Bottleneck – SFDataCorrelator

The SFDataCorrelator manages data transmission between the Firewall Management Center and the managed device; on the Firewall Management Center, it analyzes binary files created by the system to generate events, connection data, and network maps. The first step is to review the **diskmanager.log** file for important information to be gathered, such as:

- The frequency of the drain.
- The number of files with Unprocessed Events drained.
- The occurrence of the drain with Unprocessed Events.

Each time the disk manager process runs it generates an entry for each of the different silos on its own log file, which is located under **[/ngfw]/var/log/diskmanager.log**. Information gathered from the diskmanager.log (in CSV format) can be used to help narrow the search for a cause.

Additional troubleshooting steps:

- The command **stats_unified.pl** can help you to determine if the managed device does have some data which must be sent to Firewall Management Center. This condition can happen when the managed device and the Firewall Management Center experience a connectivity issue. The managed device stores the log data on to a hard drive.

  ```
  admin@FMC:~$ sudo stats_unified.pl
  ```

- The **manage_proc.pl** command can reconfigure the correlator on the Firewall Management Center side.

```
root@FMC:~# manage_procs.pl
```

Before You Contact Cisco TAC

It is highly recommended to collect these items before you contact Cisco TAC:

- Screenshots of the health alert seen.
- Troubleshoot file generated from the Firewall Management Center.
- Troubleshoot file generated from the affected managed device.
- Date and Time when the problem was first seen.
- Information about any recent changes done to the policies (if applicable).
- The output of the stats_unified.pl command as described in Communications Bottleneck — SFDataCorrelator, on page 318.

Health Monitor Reports for Troubleshooting

In some cases, if you have a problem with your appliance, Support may ask you to supply troubleshooting files to help them diagnose the problem. The system can produce troubleshooting files with information targeted to specific functional areas, as well as advanced troubleshooting files you retrieve in cooperation with Support. You can select any of the options listed in the table below to customize the contents of a troubleshooting file for a specific function.

Note that some options overlap in terms of the data they report, but the troubleshooting files will not contain redundant copies, regardless of what options you select.

Table 24: Selectable Troubleshoot Options

This option...	Reports...
Snort Performance and Configuration	data and configuration settings related to Snort on the appliance
Hardware Performance and Logs	data and logs related to the performance of the appliance hardware
System Configuration, Policy, and Logs	configuration settings, data, and logs related to the current system configuration of the appliance
Detection Configuration, Policy, and Logs	configuration settings, data, and logs related to detection on the appliance
Interface and Network Related Data	configuration settings, data, and logs related to inline sets and network configuration of the appliance
Discovery, Awareness, VDB Data, and Logs	configuration settings, data, and logs related to the current discovery and awareness configuration on the appliance
Upgrade Data and Logs	data and logs related to prior upgrades of the appliance
All Database Data	all database-related data that is included in a troubleshoot report
All Log Data	all logs collected by the appliance database

This option...	Reports...
Network Map Information	current network topology data

Generate Troubleshooting Files for Specific System Functions

You can generate and download customized troubleshooting files that you can send to Support.

Before you begin

You must be an Admin, Maintenance, Security Analyst, or Security Analyst (Read Only) user to perform this task.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**, click the device in the left panel, then **View System & Troubleshoot Details**, and then click **Generate Troubleshooting Files**.

Note
- Troubleshooting files generated from the Firewall Management Center web interface are stored on the Firewall Management Center. Only the latest troubleshooting file for each appliance is stored.
- Troubleshooting files generated from the CLI are stored locally and are not overwritten.

Step 2 Choose **All Data** to generate all possible troubleshooting data, or check individual boxes as described in View Task Messages, on page 313.

Step 3 Click **Generate.**

Step 4 View task messages in the Message Center; see View Task Messages, on page 313.

Step 5 Find the task that corresponds to the troubleshooting files you generated.

Step 6 After the appliance generated the troubleshooting files and the task status changes to `Completed`, click **Click to retrieve generated files**.

Step 7 Follow your browser's prompts to download the file. (The troubleshooting files are downloaded in a single `.tar.gz` file.)

Step 8 Follow the directions from Support to send the troubleshooting files to Cisco.

Download Advanced Troubleshooting Files

You can download troubleshooting files.

Before you begin

You must be an Admin, Maintenance, Security Analyst, or Security Analyst (Read Only) user to perform this task.

Procedure

Step 1 View the health monitor for the appliance.

Step 2 Choose **System** (⚙) > **Health** > **Monitor** >, click the device in the left panel, then **View System & Troubleshoot Details**, and then click **Advanced Troubleshooting.**

Step 3 In **File Download**, enter the file name supplied by Support.

Step 4 Click **Download.**

Step 5 Follow your browser's prompts to download the file.

Note
For managed devices, the system renames the file by prepending the device name to the file name.

Step 6 Follow the directions from Support to send the troubleshooting files to Cisco.

General Troubleshooting

An internal power failure (hardware failure, power surge, and so on) or an external power failure (unplugged cord) can result in an ungraceful shutdown or reboot of the system. This can result in data corruption.

Connection-Based Troubleshooting

Connection-based troubleshooting or debugging provides uniform debugging across modules to collect appropriate logs for a specific connection. It also supports level-based debugging up to seven levels and enables uniform log collection mechanism across modules. Connection-based debugging supports the following:

- A common connection-based debugging subsystem to troubleshoot issues in Firewall Threat Defense
- Uniform format for debug messages across modules
- Persistent debug messages across reboots
- End-to-end debugging across modules based on an existing connection
- Debugging ongoing connections

Note Connection-based debugging is not supported on Firepower 2100 Series devices.

For more information about the troubleshooting connections, see Troubleshoot a Connection , on page 322.

Troubleshoot a Connection

Procedure

Step 1 Configure a filter to identify a connection using the **debug packet-condition** command.

Example:

```
Debug packet-condition match tcp 192.168.100.177 255.255.255.255 192.168.102.177
255.255.255.255
```

Step 2 Enable debugs for the interested modules and the corresponding levels. Enter the **debug packet** command.

Example:

```
Debug packet acl 5
```

Step 3 Start debugging the packets using the following command:

```
debug packet-start
```

Step 4 Fetch the debug messages from database to analyze the debug messages using the following command:

```
show packet-debugs
```

Step 5 Stop debugging the packets using the following command:

```
debug packet-stop
```

Advanced Troubleshooting for the Secure Firewall Threat Defense Device

You can use Packet Tracer and Packet Capture features to perform an in-depth troubleshooting analysis on a Secure Firewall Threat Defense device. A packet tracer allows a firewall administrator to inject a virtual packet into a security appliance and track the flow from ingress to egress. Along the way, the packet is evaluated against flow and route lookups, ACLs, protocol inspection, NAT, and intrusion detection. This utility is effective because it can simulate real-world traffic by specifying source and destination addresses with protocol and port information. Packet capture is available with the trace option, which provides you with a verdict as to whether the packet is dropped or successful.

For more information about the troubleshooting files, see Download Advanced Troubleshooting Files, on page 320.

Packet Capture Overview

The packet capture feature with trace option allows real packets that are captured on the ingress interface to be traced through the system. The trace information is displayed at a later stage. These packets are not dropped on the egress interface, as they are real data-path traffic. Packet capture for Firewall Threat Defense devices supports troubleshooting and analysis of data packets.

Once the packet is acquired, Snort detects the tracing flag that is enabled in the packet. Snort writes tracer elements, through which the packet traverses. Snort verdict as a result of capturing packets can be one of .the following:

Table 25: Snort Verdicts

Verdict	Description
Pass	Allow analyzed packet.
Block	Packet not forwarded.
Replace	Packet modified.
AllowFlow	Flow passed without inspection.
BlockFlow	Flow was blocked.
Ignore	Flow was blocked; occurs only for sessions with flows blocked on passive interfaces.
Retry	Flow is stalled, waiting on a enamelware or URL category/reputation query. In the event of a timeout, processing continues with an unknown result: in the case of enamelware, the file is allowed; in the case of URL category/reputation, AC rule lookup continues with an uncategorized and unknown reputation.

Based on the Snort verdict, the packets are dropped or allowed. For example, the packet is dropped if the Snort verdict is **BlockFlow**, and the subsequent packets in the session are dropped before reaching Snort. When the Snort verdict is **Block** or **BlockFlow**, the **Drop Reason** can be one of the following:

Table 26: Drop Reasons

Blocked or Flow Blocked by...	Cause
Snort	Snort is unable to process the packet, erg., snort can't decode packet since it is corrupted or has invalid format.
the App Id preprocessed	App Id module/preprocessed does not block packet by itself; but this may indicate that App Id detection causes other module (erg., firewall) to match a blocking rule.
the SSL preprocessed	There is a block/reset rule in SSL policy to match the traffic.
the firewall	There is a block/reset rule in firewall policy to match the traffic.
the captive portal preprocessed	There is a block/reset rule using the identity policy to match the traffic.

Blocked or Flow Blocked by...	Cause
the safe search preprocessed	There is a block/reset rule using the safe-search feature in firewall policy to match the traffic.
the SI preprocessed	There is a block/reset rule a in Security Intelligence tab of AC Policy to block the traffic, erg., DNS or URL SI rule.
the filterer preprocessed	There is a block/reset rule in filterer tab of AC policy to match the traffic.
the stream preprocessed	There is an intrusion rule blocking/reset stream connection, erg., blocking when TCP normalization error.
the session preprocessed	This session was already blocked earlier by some other module, so session preprocessed is blocking further packets of the same session.
the fragmentation preprocessed	Blocking because earlier fragment of the data is blocked.
the snort response preprocessed	There is a react snort rule, erg., sending a response page on a particular HTTP traffic.
the snort response preprocessed	There is a snort rule to send custom response on packets matching conditions.
the reputation preprocessed	Packet matches a reputation rule, erg., blocking a given IP address.
the x-Link2State preprocessed	Blocking due to buffer overflow vulnerability detected in SMTP.
back orifice preprocessed	Blocking due to detection of back orifice data.
the SMB preprocessed	There is a snort rule to block SMB traffic.
the file process preprocessed	There is file policy that blocks a file, erg., enamelware blocking.
the IPS preprocessed	There is a snort rule using IPS, erg., rate filtering.

The packet capture feature allows you to capture and download packets that are stored in the system memory. However, the buffer size is limited to 32 MB due to memory constraint. Systems capable of handling very high volume of packet captures exceed the maximum buffer size quickly and thereby the necessity of increasing the packet capture limit is required. It is achieved by using the secondary memory (by creating a file to write the capture data). The maximum supported file size is 10 GB.

When the **file-size** is configured, the captured data gets stored to the file and the file name is assigned based on the capture name **recapture** .

The **file-size** option is used when you need to capture packets with the size limit more than 32 MB.

For information, see the Cisco Secure Firewall Threat Defense Command Reference.

Use the Capture Trace

Packet capture is a utility that provides a live snapshot of network traffic passing the specified interface of a device based on a defined criteria. This process continues to capture the packets as long as it has not paused, or the allocated memory has not exhausted.

Packet capture data includes information from Snort and preprocessors about verdicts and actions the system takes while processing a packet. Multiple packet captures are possible at a time. You can configure the system to modify, delete, clear, and save captures.

Note Capturing packet data requires packet copy. This operation may cause delays while processing packets and may also degrade the packet throughput. We recommend that you use packet filters to capture specific traffic data.

Before you begin

To use the packet capture tool on Secure Firewall Threat Defense devices, you must be an Admin or Maintenance user.

Procedure

Step 1 On the Firewall Management Center, choose **Devices** > **Troubleshoot** > **Packet Capture**.

Step 2 Select a device.

Step 3 Click **Add Capture**.

Step 4 Enter the **Name** for capturing the trace.

Step 5 Select the **Interface** for the capturing the trace.

Step 6 Specify **Match Criteria** details:

a) Select the **Protocol**.
b) Enter the IP address for the **Source Host**.
c) Enter the IP address for the **Destination Host**.
d) (Optional) Check **SGT number** check box, and enter a Security Group Tag (SGT).

Step 7 Specify **Buffer** details:

a) (Optional) Enter a maximum **Packet Size**.
b) (Optional) Enter a minimum **Buffer Size**.
c) Select either **Continuous Capture** if you want the traffic captured without interruption, or **Stop when full** if you want the capture to stop when the maximum buffer size is reached.

Note
If **Continues Capture** is enabled, and when the allocated memory is full, the oldest captured packets in the memory is overwritten by the new captured packets.

d) Check the check box of **Trace**, if you want to capture the details for each packet.
e) Enter the value in **Trace Count** field. Default value is 128. You can enter values in the range of 1-1000.

Step 8 Click **Save**.

The packet capture screen displays the packet capture details and its status. To have the packet capture page auto refreshed, check the **Enable Auto Refresh** check box and enter the auto refresh interval in seconds.

You can do the following on the packet capture:

- **Edit** ( ) to modify the capture criteria.
- **Delete** ( ) to delete the packet capture and the captured packets.
- **Clear** ( ) to erase all the captured packets from a Packet Capture. To erase the captured packets from all of the existing packet captures, click **Clear All Packets**.
- **Pause** ( ) to temporarily halt capturing packets.
- **Save** ( ) to save a copy of captured packets on a local machine in ASCII or PCAP format. Choose the required format option, and click **Save**. The saved packet capture is downloaded to your local machine.
- To view the details of the packets being captured, click the required capture row.

Packet Tracer Overview

The Packet Tracer tool allows you to test policy configuration by modeling a packet with source and destination addresses, and protocol characteristics. The trace does a policy lookup to validate if the packet will be permitted or denied access based on the configured access rules, NAT, routing, access policies and rate-limiting policies. The packet flow is simulated based on interfaces, source address, destination address, ports, and protocols. This method of testing the packets allows you to verify the effectiveness of your policies and test whether the types of traffic you want to allow or deny are handled as required.

Besides verifying your configuration, you can use the tracer to debug unexpected behavior, such as packets being denied access when they should be allowed. To simulate a packet fully, the packet tracer traces the data path—slow-path and fast-path modules. Initially, processing was transacted on per-session and per-packet basis. The Packet Tracer tool and Capture with Trace feature log the tracing data on per packet basis when the firewall processes packets per session or per packet.

PCAP File

You can initiate a packet tracer using a PCAP file, and that has a complete flow. Currently, only a PCAP with a single TCP/UDP-based flow and a maximum of 100 packets is supported. The packet tracer tool reads the PCAP file, and initializes the state for client and server replay entities. The tool starts replaying the packets in a synchronized manner by collecting and storing the trace output of each packet within the PCAP for subsequent processing and display.

PCAP Replay

Packet replay is executed by the sequence of the packet in the PCAP file, and interferences, if any, to the replay activity terminates it and concludes the replay. The trace output is generated for all the packets in the PCAP on the specified ingress interface and egress interface, thereby providing a complete context for flow evaluation.

PCAP replay is not supported for some features that dynamically modify the packet during replay, such as IPsec, VPN, SSL , HTTPs decryption, NAT, and so on.

Use the Packet Tracer

To use a packet tracer on Secure Firewall Threat Defense devices, you must be an Admin or Maintenance user.

Procedure

Step 1 In Firewall Management Center, choose **Devices** > **Troubleshoot** > **Packet Tracer**.

Step 2 From the **Select Device** drop-down list, choose the device on which you want to run the trace.

Step 3 Choose **Use Protocol** to perform the configuration manually, or **Upload or Edit a PCAP file** to upload a packet capture (PCAP) file.

Step 4 If you choose to upload a PCAP file, do the following:

a) Click the **Upload or Edit a PCAP file** drop-down list, and choose the **Upload a PCAP file** option. To use a recently uploaded file, click the file name from the available list.

Note
- Only .pcap and .pcapng file formats are supported.
- The file can contain up to 100 packets. All packets must be from the same Ethernet connection or from the same VLAN-encapsulated TCP or UDP connection.
- Multiflow PCAP files are not supported. Upload only single-flow PCAP files.

b) If you choose to upload a PCAP file, drag and drop the PCAP file into the **Upload PCAP** dialog box or browse and select the PCAP file. After you select the file, the upload process starts automatically.

Note
- After you upload the file, the **Protocol**, **Source Type**, and **Destination Type** fields will be grayed, and cannot be edited. To make changes to these fields, you must upload a new PCAP file.
- You can edit the source and destination IP addresses, source and destination ports, VLAN ID, destination MAC address (for a firewall in transparent mode), and the PCAP file name.

c) Go to Step 7.

Step 5 If you choose to perform a manual configuration, do the following:

a) From the **Ingress Interface** drop-down list, choose the ingress interface for the packet trace.

Note
Do not select **VTI**, because VTI as ingress interface is not supported for packet tracer.

b) To define the trace parameters, from the **Protocol** drop-down list, select the packet type for the trace, and specify the protocol characteristics:

- **ICMP**: Enter the ICMP type, ICMP code (0-255), and optionally, the ICMP identifier.
- **TCP**/**UDP**/**SCTP**: Enter the source and destination port numbers.
- **GRE**/**IPIP**: Enter the protocol number, 0-255.
- **ESP**: Enter the Security Parameter Index (SPI) value for the source. Valid range is 0-4294967295.

- **RAWIP**: Enter the port number. Valid range is 0-255.

c) Select the **Source Type** for the packet trace, and enter the source IP address.

Source and destination types include IPv4, IPv6, and fully-qualified domain names (FQDN). You can specify IPv4 or IPv6 addresses and FQDN, if you use Cisco TrustSec.

d) Select the **Source Port** for the packet trace.

e) Select the **Destination Type** for the packet trace, and enter the destination IP address.

Destination type options vary depending on the source type that you select.

f) Select the **Destination Port** for the packet trace.

g) If you want the packet tracer to enter a parent interface, which is later redirected to a subinterface, enter a **VLAN ID**.

This value is optional for non-subinterfaces only, since all the interface types can be configured in a subinterface.

h) Specify a **Destination MAC Address** for the packet trace.

If the Secure Firewall Threat Defense device is running in transparent firewall mode, and the ingress interface is VTEP, **Destination MAC Address** is required if you enter a value in **VLAN ID**. However if the interface is a bridge group member, **Destination MAC Address** is optional if you enter a **VLAN ID** value, but is required if you do not enter a **VLAN ID** value.

If the Secure Firewall Threat Defense device is running in routed firewall mode, **VLAN ID** and **Destination MAC Address** are optional if the input interface is a bridge group member.

i) (Optional) If you want the packet tracer to ignore the security checks in the simulated packet, click **Bypass all security checks for simulated packet**. This enables packet tracer to continue with tracing the packet through the system, which otherwise, would have been dropped.

j) (Optional) To allow the packet to be sent out through the egress interface from the device, click **Allow simulated packet to transmit from device**.

k) (Optional) If you want the packet tracer to consider the injected packet as an IPsec/SSL VPN-decrypted packet, click **Treat simulated packet as IPsec/SSL VPN decrypt**.

Step 6 To use a PCAP replay in the packet tracer, do the following:

a) Click **Select a PCAP File**.

b) To upload a new PCAP file, click **Upload a PCAP file**. To reuse a recently uploaded file, click the file name from the list.

Note
Only .pcap and .pcapng file formats are supported. The PCAP file can contain only a single TCP/UDP-based flow with a maximum of 100 packets. The maximum character limit for the PCAP file name (including the file formats) is 64.

c) In the **Upload PCAP** box, you can either drag a PCAP file or click to browse to the location where the file is stored, and select the file. When you select the file, the upload process starts automatically.

Step 7 Click **Trace**.

Step 8 (Optional) If you want to modify any values, ensure you click **Save PCAP** and save the values before proceeding with the trace.

Step 9 (Optional) If you do not save the modified values of the PCAP file and click **Trace**, the **Unsaved PCAP changes** dialog box is displayed, which prompts you to save the file.

a. Check the **Save PCAP file** check box.

b. Enter a name for the PCAP file in the **Name** field.

c. Click **Save and Trace** to save the changes and proceed with packet trace.

Note
The PCAP file name changes to the name entered in the **Name** field.

Step 10 You can track the status of trace in the **Events & Logs** > **Analysis** > **Audit Logs** window. The following tasks can be tracked:

- Saving a PCAP file
- Uploading a PCAP file
- Details of the packet trace

The **Trace Result** displays the results for each phase that the PCAP packets have traveled through the system. Click an individual packet to view the traces results for the packet. You can do the following:

- Copy (Copy) the trace results to the clipboard.
- Expand or collapse (Expand or collapse) the displayed results.
- Maximize (Maximize) the trace result window.

The time elapsed information, useful to gauge the processing efforts, is displayed for each phase. The results section also displays the total time taken for packets flowing from an ingress to an egress interface.

The **Trace History** pane displays the stored trace details for each PCAP trace. It can store up to 100 packet traces. You can select a saved trace and run the packet trace activity again. You can do the following:

- Search for a trace using any of the trace parameters.
- Disable saving of the trace to history using the Slider button.
- Delete specific trace results.
- Clear all the traces.

Use the Firewall Threat Defense Diagnostic CLI from the Web Interface

You can execute the selected Firewall Threat Defense diagnostic CLI commands from the Firewall Management Center. The commands **ping** (except **ping system**), **traceroute**, and select **show** commands run in the diagnostic CLI rather than the regular CLI.

When you run the **show** commands, if the message `Unable to execute the command properly. Please see logs for more details` is displayed, it means that the command is not valid in the diagnostic CLI. For example, **show access-list** works, but this message will be displayed if you enter **show access-control-policy**. To use non-diagnostic commands, use SSH to log in to a device outside management center.

For more information on the Firewall Threat Defense CLI, see the Cisco Secure Firewall Threat Defense Command Reference.

Before you begin

- You must be an Admin, Maintenance, or Security Analyst to use the diagnostic CLI.
- The purpose of diagnostic CLI is to enable the quick use of a few commands that are useful in troubleshooting a device. For access to the full range of commands, open an SSH session directly with the device.
- In deployments using Firewall Management Center high availability,diagnostic CLI is available only in the active Firewall Management Center.

Procedure

Step 1 Choose **Devices** > **Troubleshoot** > **Threat Defense CLI**.

You can also access the CLI tool through the health monitor for the device (**System** (⚙) > **Health** > **Monitor**). From there, you can select the device, click the **View System and Troubleshoot Details** link, click **Advanced Troubleshooting**, then click **Threat Defense CLI** on that page.

Step 2 From the **Device** drop-down list, choose the device on which to execute the diagnostic command.

Step 3 From the **Command** drop-down list, choose the command that you want to execute.

Step 4 Enter the command parameters in the **Parameters** field.

See the Cisco Secure Firewall Threat Defense Command Reference for the valid parameters.

For example, to execute **show access-list** command, choose **show** from the **Command** drop-down list, then enter **access-list** in the **Parameters** field.

Note
Do not type the full command in the **Parameters** field. Type only the relevant keywords.

Step 5 Click **Execute** to view the command output.

If the message `Unable to execute the command properly. Please see logs for more details.` is displayed, examine the parameters closely. There might be syntax errors.

This message can also mean that the command you are trying to execute is not a valid command within the context of the diagnostic CLI (which you have accessed from the device using the **system support diagnostic-cli** command). Log in to the device using SSH to use these commands.

Feature-Specific Troubleshooting

See the following table for feature-specific troubleshooting tips and techniques.

CHAPTER 16

Backup/Restore

- About Backup and Restore, on page 335
- Requirements for Backup and Restore, on page 336
- Guidelines and Limitations for Backup and Restore, on page 337
- Best Practices for Backup and Restore, on page 338
- Back Up Managed Devices, on page 340
- Restore Security Cloud Control-Managed Devices, on page 341

About Backup and Restore

The ability to recover from a disaster is an essential part of any system maintenance plan. As part of your disaster recovery plan, we recommend that you perform periodic backups.

On-Demand Backups

You can perform on-demand backups for Secure Firewall Threat Defense devices in Security Cloud Control.

For more information, see Back Up Managed Devices, on page 340.

Scheduled Backups

You can use the scheduler on Cloud-Delivered Firewall Management Center to automate backups. You can also schedule remote device backups from Security Cloud Control.

The Cloud-Delivered Firewall Management Center setup process schedules weekly configuration-only backups, to be stored in Cisco's secure cloud storage. This is not a substitute for full off-site backups. After initial setup finishes, you must review your scheduled tasks and adjust them to fit your organization's needs.

For more information, see Schedule Remote Device Backups, on page 351.

Store Backup Files

When you back up a device, the Cloud-Delivered Firewall Management Center stores the backup files in its secure cloud storage.

Note Cloud-Delivered Firewall Management Center stores only the 5 most recent Firewall Threat Defense backups per device.

To know how to download an existing backup file, see Step 3 in Restore a Firewall Threat Defense Device, on page 342.

For more information, see Back Up Managed Devices, on page 340.

Restore Managed Devices

You must use the Firewall Threat Defense CLI to restore the Firewall Threat Defense device.

For more information, see Restore Security Cloud Control-Managed Devices, on page 341.

What Is Backed Up?

Device backups are always configuration-only.

What Is Restored?

Restoring configurations overwrites *all* backed-up configurations.

Make sure you understand and plan for the following:

- You cannot restore what is not backed up.
- The Firewall Threat Defense restore process removes VPN certificates and all VPN configurations from Firewall Threat Defense devices, including certificates added after the backup was taken. After you restore a Firewall Threat Defense device, you must re-add/re-enroll all VPN certificates, and redeploy the device.

Requirements for Backup and Restore

Backup and restore have the following requirements:

Model Requirements: Backup

You can back up:

- Firewall Threat Defense standalone devices, native instances, container instances, HA pairs, and clusters
- Firewall Threat Defense Virtual for VMware devices, either standalone or HA pairs, and clusters

Backup is *not* supported for:

- Firewall Threat Defense Virtual implementations *other than* for VMware

If you must replace a device where backup and restore is not supported, you must manually recreate device-specific configurations.

Model Requirements: Restore

A replacement managed device must be the same model as the one you are replacing, with the same number of network modules and same type and number of physical interfaces.

Version Requirements

As the first step in any backup, note the patch level. To restore a backup, the old and the new appliance must be running the same Firewall version, including patches.

License Requirements

Address licensing or orphan entitlement concerns as described in the best practices and procedures. If you notice licensing conflicts, contact Cisco TAC.

Guidelines and Limitations for Backup and Restore

Backup and restore have the following guidelines and limitations.

Caution Users with CLI access can access the Linux shell access with the **expert** command, which can present a security risk. For system security reasons, we strongly recommend:

- Only use the Linux shell under TAC supervision or when explicitly instructed by Firewall and Security Cloud Control user documentation.
- Restrict the list of users with Linux shell access..
- Do not add users directly in the Linux shell; only use the procedures in this chapter.

Backup and Restore Is for Disaster Recovery/Return Material Authorization

Backup and restore are primarily intended for Return Material Authorization (RMA) scenarios. Before you begin the restore process of a faulty or failed physical appliance, contact for replacement hardware.

Backup and Restore Is Not Configuration Import/Export

A backup file contains information that uniquely identifies an appliance, and cannot be shared. Do not use the backup and restore process to copy configurations between appliances or devices, or as a way to save configurations while testing new ones. Instead, use the import/export feature.

For example, Firewall Threat Defense device backups include the device's management IP address and all information the device needs to connect to its managing Security Cloud Control. Do not restore an FTD backup to a device being managed by a different manager; the restored device attempts to connect to the manager specified in the backup.

Restore Is Individual and Local

You restore threat defense devices individually and locally. This means:

- You cannot batch-restore to high availability (HA) devices. The restore procedures in this guide explain how to restore in an HA environment.

- You cannot use Security Cloud Control to restore a device. For Firewall Threat Defense devices, you must use the Firewall Threat Defense CLI, except for the ISA 3000 zero-touch restore, which uses an SD card and the reset button.
- You cannot use a Security Cloud Control user account to log into and restore one of its managed devices. Security Cloud Control and Firewall Threat Defense devices maintain their own user accounts.

Best Practices for Backup and Restore

Backup and restore have the following best practices.

When to Back Up

We recommend backing up during a maintenance window or other time of low use.

You must back up in the following situations:

- Regular backups.

  As part of your disaster recovery plan, we recommend that you perform periodic backups.

- Before upgrade or reimage.

  If an upgrade fails catastrophically, you may have to reimage and restore. Reimaging returns most settings to factory defaults, including the system password. If you have a recent backup, you can return to normal operations more quickly.

- After upgrade.

  Ensure that you back up the device after upgrade, so that you have a freshly upgraded device backup.

Maintaining Backup File Security

Backup files are stored as unencrypted archive (.tar) files; they should be stored in a secure repository.

Private keys in PKI objects, which represent the public key certificates and paired private keys that are required to support your deployment are decrypted before they are backed up. The keys are reencrypted with a randomly generated key when you restore the backup.

Backup file should be stored securely.

Backup and Restore in Firewall Threat Defense High Availability Deployments

In a Firewall Threat Defense HA deployment, you must:

- Back up the device pair from the cloud-delivered Firewall Management Center, but restore individually and locally from the Firewall Threat Defense CLI.

  The backup process produces unique backup files for Firewall Threat Defense HA devices. Do not restore one HA peer with the backup file from the other. A backup file contains information that uniquely identifies an appliance, and cannot be shared.

  A Firewall Threat Defense HA device's role is noted in its backup file name. When you restore, make sure you choose the appropriate backup file: primary vs secondary.

- Do *not* suspend or break HA before you restore.

Maintaining the HA configuration ensures that replacement devices can easily reconnect after restore. Note that you will have to resume HA synchronization to make this happen.

- Do *not* run the restore CLI command on both peers at the same time.

  Assuming you have successful backups, you can replace either or both peers in an HA pair. Any physical replacement tasks that you can perform simultaneously: unracking, reracking, and so on. However, do *not* run the restore command on the second device until the restore process completes for the first device, including the reboot.

Backup and Restore in Firewall Threat Defense Clustering Deployments

In the Firewall Threat Defense clustering deployment, you must:

- Back up the entire cluster from the cloud-delivered Firewall Management Center, but restore nodes individually and locally from the threat defense CLI.

  The backup process produces a bundled tar file that includes unique backup files for each cluster node. Do not restore one node with the backup file from another. A backup file contains information that uniquely identifies a device, and cannot be shared.

  The node's role is noted in its backup file name. When you restore, make sure you choose the appropriate backup file: control or data.

  You cannot back up individual nodes. If a data node fails to back up, the management center will still back up all other nodes. If the control node fails to back up, the backup is canceled.

- All the nodes that are part of the cluster must be registered in the management center, for the backup to be successful.

- Do *not* suspend or break clustering before you restore. Maintaining the cluster configuration ensures replacement devices can easily reconnect after restore.

- Do *not* run the **restore** CLI command on multiple nodes at the same time. We recommend that you restore the control node first and wait until it rejoins the cluster before you restore any data nodes.

  Assuming you have successful backups, you can replace multiple nodes in the cluster. Any physical replacement tasks you can perform simultaneously: unracking, reracking, and so on. However, do *not* run the **restore** command on an additional node until the restore process completes for the previous node, including the reboot.

Before Restore

Before restore, you must:

- Revert licensing changes.

  Revert any licensing changes made since you took backup.

  Otherwise, you may have license conflicts or orphan entitlements after the restore. However, do *not* unregister from Cisco Smart Software Manager (CSSM). If you unregister from CSSM, you must unregister again after you restore, then re-register.

  After the restore completes, reconfigure licensing. If you notice licensing conflicts or orphan entitlements, contact Cisco TAC.

- Disconnect faulty appliances.

Disconnect the management interface, and for devices, the data interfaces.

Restoring a Firewall Threat Defense device sets the management IP address of the replacement device to the management IP address of the old device. To avoid IP address conflicts, disconnect the old device from the management network before you restore the backup on its replacement.

- Do *not* unregister managed devices.

  Whether you are restoring a managed device, do not unregister devices from the Security Cloud Control, even if you physically disconnect an appliance from the network.

  If you unregister, you must redo some device configurations, such as security zone to interface mappings. After you restore, Security Cloud Control and devices should begin communicating normally.

- Reimage.

  In an RMA scenario, the replacement appliance arrives configured with factory defaults. However, if the replacement appliance is already configured, we recommend you reimage. Reimaging returns most settings to factory defaults, including the system password. You can only reimage to major versions, so you must patch after you reimage.

  If you do not reimage, keep in mind that Security Cloud Control intrusion events and file lists are merged rather than overwritten.

After Restore

After restore, you must:

- Reconfigure anything that was not restored.

  This can include reconfiguring licensing and audit log server certificate settings. You also must re-add/re-enroll failed Firewall Threat Defense VPN certificates.

- Deploy.

  After you restore a device, deploy to that device. You *must* deploy. If the device or devices are not marked out of date, force deploy from the Device Management page.

Back Up Managed Devices

You can perform on-demand or scheduled backups for supported Secure Firewall Threat Defense devices using Cloud-Delivered Firewall Management Center without a backup profile.

For more information, see Back Up a Firewall Threat Defense Device from Cloud-delivered Firewall Management Center, on page 340.

Related Information

Back Up a Firewall Threat Defense Device from Cloud-delivered Firewall Management Center

Use this procedure to perform an on-demand backup of any of the following devices:

- Firewall Threat Defense: Physical devices, standalone, HA, or cluster

- Firewall Threat Defense Virtual: VMware, standalone, HA, or cluster

Backup and restore is not supported for any other platforms or configurations.

Before you begin

You must read and understand the requirements, guidelines, limitations, and best practices. Do not skip any steps or ignore security concerns. Careful planning and preparation can help you avoid missteps.

- Requirements for Backup and Restore, on page 336
- Guidelines and Limitations for Backup and Restore, on page 337
- Best Practices for Backup and Restore, on page 338

Caution Users with CLI access can access the Linux shell access with the **expert** command, which can present a security risk. For system security reasons, we strongly recommend:

- Only use the Linux shell under TAC supervision or when explicitly instructed by Firewall and Security Cloud Control user documentation.
- Restrict the list of users with Linux shell access..
- Do not add users directly in the Linux shell; only use the procedures in this chapter.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 From the Security Cloud Control menu, navigate **Administration** > **Firewall Management Center** to open the **Services** page.

Step 3 Select **Cloud-Delivered FMC** and in the **Actions** pane, click **Devices** to navigate to the Cloud-Delivered Firewall Management Center user interface.

Step 4 Select **System**(⚙) and then navigate **Tools** > **Backup/Restore**.

Step 5 Click **Managed Device Backup**.

Step 6 Select one or more Firewall Threat Defense devices in **Managed Devices**.

For clustering, choose the cluster. You cannot perform backups on individual nodes.

Step 7 Click **Start Backup** to start the on-demand backup.

Step 8 Monitor the progress under **Tasks** in the **Notifications** pane.

Restore Security Cloud Control-Managed Devices

For Firewall Threat Defense devices, you must use the Firewall Threat Defense CLI to restore from backup. You cannot use the Firewall Management Center to restore a device.

Related Information:

Restore a Firewall Threat Defense Device

Firewall Threat Defense backup and restore is intended for RMA. Restoring the configurations overwrites *all* configurations on the device, including the management IP address. It also reboots the device.

In case of hardware failure, this procedure outlines how to replace a firewall device, either standalone or in an HA pair. It assumes you have access to a successful backup of the device or devices you are replacing.

Note Do *not* unregister from the Security Cloud Control, even when disconnecting a device from the network. In a Firewall Threat Defense HA deployment, do *not* suspend or break HA. Maintaining these links ensures replacement devices can automatically reconnect after a restore.

In a Firewall Threat Defense HA deployment, you can use this procedure to replace either or both peers. To replace both, perform all steps on both devices simultaneously, except the restore CLI command itself. You cannot replace a Firewall Threat Defense HA device without a successful backup.

Note Starting from the next upgrade of Cloud-Delivered Firewall Management Center, Cisco will only store the 5 most recent Firewall Threat Defense backups per device and purge all the other backups. If you require the other backups for compliance purposes, we recommend that you download them to your private environment by May 31, 2025.

To know how to download an existing backup file, see Step 3 in the procedure below.

Before you begin

You must read and understand the requirements, guidelines, limitations, and best practices. Do not skip any steps or ignore security concerns. Careful planning and preparation can help you avoid missteps.

- Requirements for Backup and Restore, on page 336
- Guidelines and Limitations for Backup and Restore, on page 337
- Best Practices for Backup and Restore, on page 338

Procedure

Step 1 Contact Cisco TAC for replacement hardware.

Obtain an identical model, with the same number of network modules and same type and number of physical interfaces. You can begin the RMA process from the Cisco Returns Portal.

Step 2 Navigate **System(⚙) > Tools > Backup/Restore**.

Step 3 Locate a successful backup of the faulty device from **Device Backups** under **Backup Management**.

Use **Download** that downloads the backup file(s) to your local storage or **Export Backup Links** that generates a URL to download the backup and exports it to a CSV file that gets downloaded. Use the URL to download

the backup to a secure location. Note that the URL is valid only for six hours, after which you must export it again to get a different URL.

In a Firewall Threat Defense HA deployment, you back up the pair as a unit but the backup process produces unique backup files for each device in the pair. The device's role is noted in the backup file name.

If the only copy of the backup is on the faulty device, copy it somewhere else now. If you reimage the device, the backup will be erased. If something else goes wrong, you may not be able to recover the backup.

The replacement device will need the backup, but can retrieve it with the secure copy (SCP) command during the restore process. We recommend you put the backup somewhere SCP-accessible to the replacement device. Or, you can copy the backup to the replacement device itself.

Step 4 Remove (unrack) the faulty device and disconnect all interfaces. In threat defense HA deployments, this includes the failover link.

See the hardware installation and getttign started guides for your model: Cisco Firepower NGFW: Install and Upgrade Guides.

Note
Do not unregister from the management center, even when disconnecting a device from the network. In threat defense HA deployments, do not suspend or break HA. Maintaining these links ensures replacement devices can automatically reconnect after restore.

Step 5 Install the replacement device and connect it to the management network.

Connect the device to power and the management interface to the management network. In Firewall Threat Defense HA deployments, connect the failover link. However, do *not* connect the data interfaces.

See the hardware installation guide for your model: Cisco Firepower NGFW: Install and Upgrade Guides.

Step 6 (Optional) Reimage the replacement device.

In an RMA scenario, the replacement device will arrive configured with factory defaults. If the replacement device is not running the same major version as the faulty device, we recommend you reimage.

See the Cisco Secure Firewall ASA and Threat Defense Reimage Guide.

Step 7 Perform initial configuration on the replacement device.

Access the Firewall Threat Defense CLI as the admin user. You can use the console or you can SSH to the factory-default management interface IP address (192.168.45.45). A setup wizard prompts you to configure the management IP address, gateway, and other basic network settings.

See the initial configuration topics in the getting started guide for your model: Cisco Firepower NGFW: Install and Upgrade Guides.

Note
If you need to patch the replacement device, start the management center registration process as described in the getting started guide. If you do *not* need to patch, do not register.

Step 8 Make sure the replacement device is running the same Firewall software version, including patches, as the faulty device.

The existing device should not be deleted from the management center. The replacement device should be unmanaged from the physical network and the new hardware as well as the replacing Firewall Threat Defense patch should have the same version. The Firewall Threat Defense CLI does not have an upgrade command. To patch:

a) From the management center web interface, complete the device registration process: See *Add a Device to the Management Center* in Cisco Secure Firewall Management Center Device Configuration Guide.

   Create a new AC policy and use the default action "Network Discovery". Leave this policy as is; do not add any features or modifications. This is being used to register the device and deploy a policy with no features so that you do not require licenses, and you will then be able to patch the device. Once backup is restored, it should restore the licensing and policy into the expected state.

b) Patch the device: Cisco Firewall Management Center Upgrade Guide.

c) Unregister the freshly patched device from the management center: See *Delete a Device from the Management Center* in Cisco Secure Firewall Management Center Device Configuration Guide.

   If you do not unregister, you will have a ghost device registered to the management center after the restore process brings your "old" device back up.

Step 9 Make sure the replacement device has access to the backup file.

The restore process can retrieve the backup with SCP, so we recommend you put the backup somewhere accessible. Or, you can manually copy the backup to the replacement device itself, to `/var/sf/backup`.

Step 10 From the FTD CLI, restore the backup.

Access the Firewall Threat Defense CLI as the admin user. You can use the console or you can SSH to the newly configured management interface (IP address or hostname). Keep in mind that the restore process will change this IP address.

To restore:

- With SCP: **restore remote-manager-backup location scp-hostname username filepath backup tar-file**
- From the local device: **restore remote-manager-backup backup tar-file**

Step 11 Log in to Security Cloud Control and wait for the devices to connect.

When the restore is done, the device logs you out of the CLI, reboots, and automatically connects to Security Cloud Control. At this time, the device should appear out of date.

At this time, the device should appear out of date.

Step 12 Before you deploy, perform any post-restore tasks and resolve any post-restore issues:

- Resolve licensing conflicts or orphan entitlements. Contact Cisco TAC.
- Resume HA synchronization.
- Re-add/re-enroll all VPN certificates. The restore process removes VPN certificates from FTD devices, including certificates added after the backup was taken.

Step 13 Deploy configurations.

You must deploy. If a restored device is not marked out of date, force deploy from the Device Management page.

Step 14 Connect the device's data interfaces.

See the hardware installation guide for your model: Cisco Secure Firewall Threat Defense: Install and Upgrade Guides.

Restore Firewall Threat Defense from Backup: Firewall Threat Defense Virtual

Use this procedure to replace a faulty or failed Firewall Threat Defense Virtual device for VMware.

In Firewall Threat Defense HA and clustering deployments, you can use this procedure to replace all peers. To replace all, perform all steps on all devices simultaneously, except the **restore** CLI command itself.

Note Do *not* unregister from the Firewall Management Center, even when disconnecting a device from the network. In Firewall Threat Defense HA and clustering deployments, do *not* suspend or break high availibility or clusters. Maintaining registration ensures that replacement devices can automatically reconnect after restore.

Before you begin

You must read and understand the requirements, guidelines, limitations, and best practices. Do not skip any steps or ignore security concerns. Careful planning and preparation can help you avoid missteps.

- Requirements for Backup and Restore, on page 336
- Guidelines and Limitations for Backup and Restore, on page 337
- Best Practices for Backup and Restore, on page 338

Procedure

Step 1 Navigate **System(⚙) > Tools > Backup/Restore**.

Step 2 Locate a successful backup of the faulty device from **Device Backups** under **Backup Management**.

For clustering, node backup files are bundled together in a single compressed file for the cluster (*cluster_name.timestamp***.tar.gz**). Before you can restore nodes, you need to extract the individual node backup files (*node_name***_control_***timestamp***.tar** or *node_name***_data_***timestamp***.tar**).

Use **Download** that downloads the backup file(s) to your local storage or **Export Backup Links** that generates a URL to download the backup and exports it to a CSV file that gets downloaded. Use the URL to download the backup to a secure location. Note that the URL is valid only for six hours, after which you must export it again to get a different URL.

In Firewall Threat Defense HA deployments, you back up the pair as a unit, but the backup process produces unique backup files for each device in the pair. The device's role is noted in the backup file name.

If the only copy of the backup is on the faulty device, copy it somewhere else now. If you reimage the device, the backup will be erased. If something else goes wrong, you may not be able to recover the backup.

The replacement device needs the backup, but can retrieve it with SCP during the restore process. We recommend you put the backup somewhere SCP-accessible to the replacement device. Or, you can copy the backup to the replacement device itself.

Step 3 Remove the faulty device.

Shut down, power off, and delete the virtual machine. For procedures, see the documentation for your virtual environment.

Step 4 Deploy a replacement device.

See the Cisco Firepower Threat Defense Virtual for VMware Getting Started Guide.

Step 5 Perform initial configuration on the replacement device.

Use the VMware console to access the Firewall Threat Defense Virtual CLI as the admin user. A setup wizard prompts you to configure the management IP address, gateway, and other basic network settings.

Do not set the same management IP address as the faulty device. This can cause problems if you need to register the device in order to patch it. The restore process will correctly reset the management IP address.

See the CLI setup topics in the getting started guide: Cisco Firepower Threat Defense Virtual for VMware Getting Started Guide.

Step 6 Make sure that the replacement device is running the same Firewall software version, including patches, as the faulty device.

Ensure that the existing device should not be deleted from the Security Cloud Control. The replacement device should be unmanaged from the physical network and the new hardware and the replacing Firewall Threat Defense Virtual patch should have the same version. The Firewall Threat Defense Virtual CLI does not have an upgrade command. To patch:

a. Complete the Firewall Threat Defense Virtual registration process in Security Cloud Control.

b. Patch the Firewall Threat Defense Virtual device.

c. Unregister the freshly patched device from Security Cloud Control.

Step 7 Make sure that the replacement device has access to the backup file.

The restore process can retrieve the backup with SCP, so we recommend you put the backup somewhere accessible. Or, you can manually copy the backup to the replacement device itself, to `/var/sf/backup`. For clusters, make sure you extract the individual node backup file from the main cluster bundle.

Step 8 From the Firewall Threat Defense CLI, restore the backup.

Access the Firewall Threat Defense Virtual CLI as the admin user. You can use the console or you can SSH to the newly configured management interface (IP address or hostname). Keep in mind that the restore process will change this IP address.

To restore:

- With SCP: **restore remote-manager-backup location scp-hostname username filepath backup tar-file**
- From the local device: **restore remote-manager-backup backup tar-file**

In Firewall Threat Defense HA and clustering deployments, make sure you choose the appropriate backup file: primary vs secondary, or control vs. data. The role is noted in the backup file name. If you are restoring all devices, do this sequentially. Do not run the **restore** command on the next device until the restore process completes for the first device, including the reboot.

Step 9 Log into Security Cloud Control and wait for the devices to connect.

When the restore is done, the device logs you out of the CLI, reboots, and automatically connects to Security Cloud Control. At this time, the device should appear out of date.

At this time, the device should appear out of date.

Step 10 Before you deploy, perform any post-restore tasks and resolve any post-restore issues:

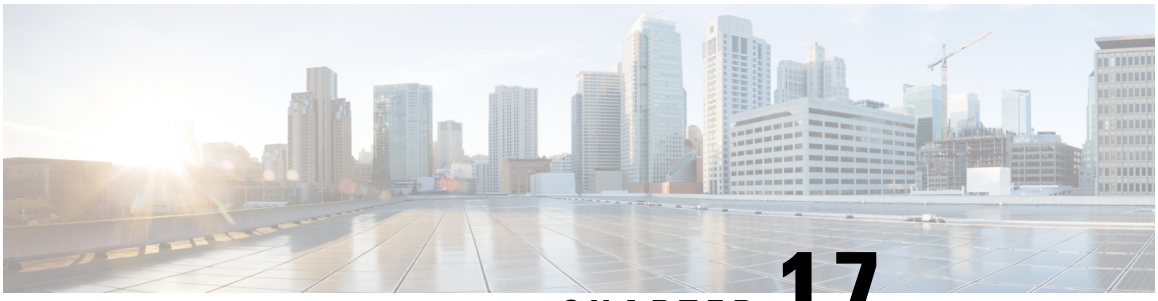
- Resolve licensing conflicts or orphan entitlements. Contact Cisco TAC.
- Resume HA synchronization.
- Re-add/re-enroll all VPN certificates. The restore process removes VPN certificates from Firewall Threat Defense Virtual devices, including certificates added after the backup was taken.

Step 11 Deploy configurations.

You must deploy. If a restored device is not marked out of date, force deploy from the Device Management page.

Step 12 Connect the device's data interfaces.

See the hardware installation guide for your model: Cisco Secure Firewall Threat Defense: Install and Upgrade Guides.



CHAPTER 17

Scheduling

The following topics explain how to schedule tasks:

- About Task Scheduling, on page 349
- Requirements and Prerequisites for Task Scheduling, on page 350
- Configuring a Recurring Task, on page 350
- Scheduled Task Review, on page 358

About Task Scheduling

You can schedule various tasks to run at designated times, either once or on a recurring basis.

Tasks are scheduled in UTC on the back end, which means when they occur locally depends on the date and your specific location. Also, because tasks are scheduled in UTC, they do not adjust for Daylight Saving Time, summer time, or any such seasonal adjustments that you may observe in your location. If you are affected, scheduled tasks occur one hour "later" in the summer than in the winter, according to local time.

Some tasks are automatically scheduled or performed by the initial setup process:

- A one-time task to download and install the latest VDB.
- A weekly scheduled task to download the latest available software updates and VDB.

You should review the weekly tasks and adjust if necessary. Optionally, schedule new recurring tasks to actually update the VDB and/or software, and deploy configurations.

Important We *strongly* recommend you review scheduled tasks to be sure they occur when you intend. Some tasks (such as those involving automated software updates or that require pushing updates to managed devices) may place a significant load on networks with low bandwidths. You should schedule tasks like these to run during periods of low network use. Other tasks, such as deploying configurations, can cause traffic interruptions. You should schedule tasks like these during maintenance windows.

Requirements and Prerequisites for Task Scheduling

Model Support

Any.

Supported Domains

Any

User Roles

- Admin
- Maintenance User

Configuring a Recurring Task

You set the frequency for a recurring task using the same process for all types of tasks.

Note that the time displayed on most pages on the web interface is the local time, which is determined by using the time zone you specify in your local configuration. Further, the Firewall Management Center automatically adjusts its local time display for daylight saving time (DST), where appropriate. However, recurring tasks that span the transition dates from DST to standard time and back do not adjust for the transition. That is, if you create a task scheduled for 2:00 AM during standard time, it will run at 3:00 AM during DST. Similarly, if you create a task scheduled for 2:00 AM during DST, it will run at 1:00 AM during standard time.

Procedure

Step 1 Select **System** (⚙) > **Tools** > **Scheduling**.

Step 2 Click **Add Task**.

Step 3 From the **Job Type** drop-down list, select the type of task that you want to schedule.

- Backup - Schedule backup jobs as described in Schedule Remote Device Backups, on page 351 .
- Deploy Policies - Schedule policy deployment as described in Automating Policy Deployment, on page 352.
- Queue Intrusion Policy Apply - Schedule deployment of selected intrustion policies to selected devices as described in Automating Intrusion Policy Deployment, on page 353.
- Download Latest Update - Automate software and vulnerability downloads as described in Automating Software Downloads, on page 354 and Automating VDB Update Downloads, on page 356.
- Install Latest Update - Automate software isntallation as described in Automating Software Installs, on page 355.

- Push Latest Update - Schedule pushing software to a device before updating it, as described in Automating Software Pushes, on page 354.
- Update URL Filtering Database - Automating URL Filtering Updates Using a Scheduled Task, on page 357.

Step 4 Click **Recurring** next to the **Schedule task to run** option.

Step 5 In the **Start On** field, specify the date when you want to start your recurring task.

Step 6 In the **Repeat Every** field, specify how often you want the task to recur.

You can either type a number or click **Up** ( ) and **Down** ( ) to specify the interval. For example, type `2` and click **Days** to run the task every two days.

Step 7 In the **Run At** field, specify the time when you want to start your recurring task.

Step 8 For a task to be run on a weekly or monthly basis, select the days when you want to run the task in the **Repeat On** field.

Step 9 Give the job a name.

Step 10 Click **Save**.

Scheduled Backups

You can schedule backups of Secure Firewall Threat Defense devices from the Cloud-Delivered Firewall Management Center. Note that not all devices support remote backups.

No more than 20 Firewall Threat Defense devices should be scheduled during one job. Backup jobs should be spaced at least 30 minutes apart.

For more information on backups, see Backup/Restore, on page 335.

Schedule Remote Device Backups

You can use the scheduler onCloud-Delivered Firewall Management Center to automate device backups. Note that not all devices support remote backups. For more information, see Backup/Restore, on page 335.

Procedure

Step 1 Choose **System** ( ) > **Tools** > **Scheduling**.

Step 2 From the **Job Type** list, select **Backup**.

Step 3 Specify whether you want to back up **Once** or **Recurring**.

- For one-time tasks, use the drop-down lists to specify the start date and time.
- For recurring tasks, see Configuring a Recurring Task, on page 350.

Step 4 Enter a **Job Name**.

Step 5 For the **Backup Type**, click **Device**.

Step 6 Select one or more devices.

If your device is not listed, it does not support remote backup.

Step 7 (Optional) Enter a **Comment**.

Keep comments brief. They will appear in the Task Details section of the schedule calendar page.

Step 8 (Optional) Enter an email address, or a comma-separated list of email addresses, in the **Email Status To:** field.

Step 9 Click **Save**.

Automating Policy Deployment

After modifying configuration settings in the Firewall Management Center, you must deploy those changes to the affected devices.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See Snort Restart Traffic Behavior, on page 172 and Configurations that Restart the Snort Process When Deployed or Activated, on page 174.

Procedure

Step 1 Select **System** (⚙) > **Tools** > **Scheduling**.

Step 2 Click **Add Task**.

Step 3 From **Job Type**, select **Deploy Policies**.

Step 4 Specify how you want to schedule the task, **Once** or **Recurring**:

- For one-time tasks, use the drop-down lists to specify the start date and time.
- For recurring tasks, see Configuring a Recurring Task, on page 350 for details.

Step 5 Type a name in the **Job Name** field.

Step 6 In the **Device** field, select a device where you want to deploy policies.

Step 7 Select or deselect the **Skip deployment for up-to-date devices** check box, as required.

By default, the **Skip deployment for up-to-date devices** option is enabled to improve performance during the policy deployment process.

Note
The system does not perform a scheduled policy deployment task if a policy deployment initiated from the Firewall Management Center web interface is in progress. Correspondingly, the system does not permit you to initiate a policy deployment from the web interface if a scheduled policy deployment task is in-progress.

Step 8 If you want to comment on the task, type a comment in the **Comment** field.

The comment field appears in the Task Details section of the schedule calendar page. The comment field must contain between 3 and 255 characters and cannot include any special characters other than hyphen (-), colon (:), and parentheses ().

Step 9 If you want to email task status messages, type an email address (or multiple email addresses separated by commas) in the **Email Status To:** field. You must have a valid email relay server configured to send status messages.

Step 10 Click **Save**.

Related Topics

Configuration Changes that Require Deployment, on page 165

Automating Intrusion Policy Deployment

After modifying configuration settings in the Cloud-Delivered Firewall Management Center, you must deploy those changes to the affected devices.

Procedure

Step 1 Select **System** (⚙) > **Tools** > **Scheduling**.

Step 2 Click **Add Task**.

Step 3 From **Job Type**, select **Queue Intrusion Policy Apply**.

Step 4 Specify how you want to schedule the task, **Once** or **Recurring**:

- For one-time tasks, use the drop-down lists to specify the start date and time.
- For recurring tasks, see Configure a Recurring Task for details.

Step 5 Type a name in the **Job Name** field.

Step 6 In the **Intrusion Policy** drop-down, choose the intrusion policy that you want to deploy.

Step 7 In the **Device** field, select a device where you want to deploy policies.

Step 8 If you want to comment on the task, type a comment in the **Comment** field.

The comment field appears in the **Task Details** section of the schedule calendar page. The comment field must contain between 3 and 255 characters and cannot include any special characters other than hyphen (-), colon (:), and parentheses ().

Step 9 If you want to email task status messages, type an email address (or multiple email addresses separated by commas) in the **Email Status To:** field. You must have a valid email relay server configured to send status messages.

Step 10 Click **Save**.

Software Upgrade Automation

You can automatically download patches, and apply maintenance releases and patches.

To upgrade managed devices, schedule Download, Push, and Install tasks. Make sure you leave adequate time between the tasks; for example, installations scheduled to occur while a push is still running will fail.

This feature is not supported for major releases. When scheduling upgrades to device groups, the upgrade will run on all grouped devices simultaneously.

Note As part of the initial configuration, the system schedules weekly downloads. We recommend you review this task and make changes if necessary, as described in Automating Software Downloads, on page 354. This task only downloads the updates. It is your responsibility to install any updates this task downloads.

Related Topics

Updates, on page 221

Automating Software Downloads

Use this procedure to schedule patch downloads.

Procedure

Step 1 Select **System** (⚙) > **Tools** > **Scheduling**.

Step 2 Click **Add Task**.

Step 3 From the **Job Type** list, select **Download Latest Update**.

Step 4 Specify how you want to schedule the task, **Once** or **Recurring**:

- For one-time tasks, use the drop-down lists to specify the start date and time.
- For recurring tasks, see Configuring a Recurring Task, on page 350 for details.

Step 5 Type a name in the **Job Name** field.

Step 6 Next to **Update Items**, check **Software** check box.

Step 7 If you want to comment on the task, type a comment in the **Comment** field.

The comment field appears in the Task Details section of the schedule calendar page; keep comments brief.

Step 8 If you want to email task status messages, type an email address (or multiple email addresses separated by commas) in the **Email Status To:** field. You must have a valid email relay server configured to send status messages.

Step 9 Click **Save**.

Automating Software Pushes

If you want to automate the installation of software updates on managed devices, you must push the updates to the devices before installing.

When you create the task to push software updates to managed devices, make sure you allow enough time between the push task and a scheduled install task for the updates to be copied to the device.

You must be in the global domain to perform this task.

Procedure

Step 1 Select **System** (⚙) > **Tools** > **Scheduling**.

Step 2 Click **Add Task**.

Step 3 From the **Job Type** list, select **Push Latest Update**.

Step 4 Specify how you want to schedule the task, **Once** or **Recurring**:

- For one-time tasks, use the drop-down lists to specify the start date and time.
- For recurring tasks, see Configuring a Recurring Task, on page 350 for details.

Step 5 Type a name in the **Job Name** field.

Step 6 From the **Device** drop-down list, select the device that you want to update.

Step 7 If you want to comment on the task, type a comment in the **Comment** field.

The comment field appears in the Task Details section of the schedule calendar page; keep comments brief.

Step 8 If you want to email task status messages, type an email address (or multiple email addresses separated by commas) in the **Email Status To:** field. You must have a valid email relay server configured to send status messages.

Step 9 Click **Save**.

Automating Software Installs

Make sure you allow enough time between the task that pushes the update to a managed device and the task that installs the update.

You must be in the global domain to perform this task.

⚠

Caution Depending on the update being installed, the appliance may reboot after the software is installed.

Procedure

Step 1 Select **System** (⚙) > **Tools** > **Scheduling**.

Step 2 Click **Add Task**.

Step 3 From the **Job Type** list, select **Install Latest Update**.

Step 4 Specify how you want to schedule the task, **Once** or **Recurring**:

- For one-time tasks, use the drop-down lists to specify the start date and time.
- For recurring tasks, see Configuring a Recurring Task, on page 350 for details.

Step 5 Type a name in the **Job Name** field.

Step 6 From the **Device** drop-down list, select the appliance where you want to install the update.

Step 7 Next to **Update Items**, check the **Software** check box.

Step 8 If you want to comment on the task, type a comment in the **Comment** field.

The comment field appears in the Task Details section of the schedule calendar page; keep comments brief.

Step 9 If you want to email task status messages, type an email address (or multiple email addresses separated by commas) in the **Email Status To:** field. You must have a valid email relay server configured to send status messages.

Step 10 Click **Save**.

Vulnerability Database Update Automation

You can use the scheduling feature to update the Cisco vulnerability database (VDB), thereby ensuring that you are using the most up-to-date information to evaluate the hosts on your network. You must schedule the download, install, and subsequent deploy as separate tasks, allowing enough time between tasks.

Note The initial setup on the Firewall Management Center automatically downloads and installs the latest VDB from Cisco as a one-time operation. It also schedules a weekly task to download the latest available software updates, which includes the latest VDB. We recommend you review this weekly task and adjust if necessary. Optionally, schedule a new weekly task to actually update the VDB and deploy configurations.

Automating VDB Update Downloads

Procedure

Step 1 Select **System** (⚙) > **Tools** > **Scheduling**.

Step 2 Click **Add Task**.

Step 3 From the **Job Type** list, select **Download Latest Update**.

Step 4 Specify how you want to schedule the task, **Once** or **Recurring**:

- For one-time tasks, use the drop-down lists to specify the start date and time.
- For recurring tasks, see Configuring a Recurring Task, on page 350 for details.

Step 5 Type a name in the **Job Name** field.

Step 6 Next to **Update Items**, check the **Vulnerability Database** check box.

Step 7 (Optional) Type a brief comment in the **Comment** field.

Step 8 If you want to email task status messages, type an email address (or multiple email addresses separated by commas) in the **Email Status To:** field. You must have a valid email relay server configured to send status messages.

Step 9 Click **Save**.

Automating VDB Update Installs

Allow enough time between the task that downloads the VDB update and the task that installs the update.

You must be in the global domain to perform this task.

Caution In most cases, the first deploy after a VDB update restarts the Snort process, interrupting traffic inspection. The system warns you when this will happen (updated application detectors and operating system fingerprints require a restart; vulnerability information does not). Whether traffic drops or passes without further inspection during this interruption depends on how the targeted device handles traffic. For more information, see Snort Restart Traffic Behavior, on page 172.

Procedure

Step 1 Select **System** (⚙) > **Tools** > **Scheduling**.

Step 2 Click **Add Task**.

Step 3 From the **Job Type** list, select **Install Latest Update**.

Step 4 Specify how you want to schedule the task, **Once** or **Recurring**:

- For one-time tasks, use the drop-down lists to specify the start date and time.
- For recurring tasks, see Configuring a Recurring Task, on page 350 for details.

Step 5 Type a name in the **Job Name** field.

Step 6 From the **Device** drop-down list, select the Firewall Management Center.

Step 7 Next to **Update Items**, check the **Vulnerability Database** check box.

Step 8 (Optional) Type a brief comment in the **Comment** field.

Step 9 If you want to email task status messages, type an email address (or multiple email addresses separated by commas) in the **Email Status To:** field. You must have a valid email relay server configured to send status messages.

Step 10 Click **Save**.

Automating URL Filtering Updates Using a Scheduled Task

In order to ensure that threat data for URL filtering is current, the system must obtain data updates from the Cisco Collective Security Intelligence (CSI) cloud.

By default, when you enable URL filtering, automatic updates are enabled. However, if you need to control when these updates occur, use the procedure described in this topic instead of the default update mechanism.

Although daily updates tend to be small, if it has been more than five days since your last update, new URL filtering data may take up to 20 minutes to download, depending on your bandwidth. Then, it may take up to 30 minutes to perform the update itself.

Before you begin

- Make sure you have a URL Filtering license and enable URL filtering. For more information, see the *Enable URL Filtering Using Category and Reputation* in the Cisco Secure Firewall Management Center Device Configuration Guide.
- Verify that **Enable Automatic Updates** is not selected under **URL Filtering** on **Integration** > **Other Integrations** > **Cloud Services**.

Procedure

Step 1 Select **System** (⚙) > **Tools** > **Scheduling**.

Step 2 Click **Add Task**.

Step 3 From the **Job Type** list, select **Update URL Filtering Database**.

Step 4 Specify how you want to schedule the update, **Once** or **Recurring**:

- For one-time tasks, use the drop-down lists to specify the start date and time.
- For recurring tasks, see Configuring a Recurring Task, on page 350.

Step 5 Type a name in the **Job Name** field.

Step 6 If you want to comment on the task, type a comment in the **Comment** field.

The comment field appears in the Task Details section of the schedule calendar page. Keep comments brief.

Step 7 If you want to email task status messages, type an email address (or multiple email addresses separated by commas) in the **Email Status To:** field. You must have a valid email relay server configured to send status messages.

Step 8 Click **Save**.

Scheduled Task Review

After adding scheduled tasks, you can view them and evaluate their status. The View Options section of the page allows you to view scheduled tasks using a calendar and a list of scheduled tasks.

The Calendar view option allows you to view which scheduled tasks occur on which day.

The Task List shows a list of tasks along with their status. The task list appears below the calendar when you open the calendar. In addition, you can view it by selecting a date or task from the calendar.

You can edit a scheduled task that you previously created. This feature is especially useful if you want to test a scheduled task once to make sure that the parameters are correct. Later, after the task completes successfully, you can change it to a recurring task.

There are two types of deletions you can perform from the Schedule View page. You can delete a specific one-time task that has not yet run or you can delete every instance of a recurring task. If you delete an instance of a recurring task, all instances of the task are deleted. If you delete a task that is scheduled to run once, only that task is deleted.

Task List Details

Table 28: Task List Columns

Column	Description
Name	Displays the name of the scheduled task and the comment associated with it.
Type	Displays the type of scheduled task.
Start Time	Displays the scheduled start date and time.
Frequency	Displays how often the task is run.
Last Run Time	Displays the actual start date and time. For a recurring task, this applies to the most recent execution.
Last Run Status	Describes the current status for a scheduled task: • A **Check mark**( ) indicates that the task ran successfully. • A question mark icon (**Question Mark** ( )) indicates that the task is in an unknown state. • An exclamation mark icon ( ) indicates that the task failed. For a recurring task, this applies to the most recent execution.
Next Run Time	Displays the next execution time for a recurring task. Displays N/A for a one-time task.
Creator	Displays the name of the user that created the scheduled task.
Edit	Edits the scheduled task.
Delete	Deletes the scheduled task.

Viewing Scheduled Tasks on the Calendar

You can view a scheduled task on the calendar.

Procedure

Step 1 Select **System** (⚙) > **Tools** > **Scheduling**.

Step 2 You can perform the following tasks using the calendar view:

- Click **Double Left Arrow** (⏪) to move back one year.
- Click **Single Left Arrow** (◀) to move back one month.
- Click **Single Right Arrow** (▶) to move forward one month.
- Click **Double Right Arrow** (⏩) to move forward one year.
- Click **Today** to return to the current month and year.
- Click **Add Task** to schedule a new task.
- Click a date to view all scheduled tasks for the specific date in a task list table below the calendar.
- Click a specific task on a date to view the task in a task list table below the calendar.

Editing Scheduled Tasks

You can edit scheduled tasks.

Procedure

Step 1 Select **System** (⚙) > **Tools** > **Scheduling**.

Step 2 On the calendar, click either the task that you want to edit or the day on which the task appears.

Step 3 In the **Task Details** table, click **Edit** (✎) next to the task you want to edit.

Step 4 Edit the task.

Step 5 Click **Save**.

Deleting Scheduled Tasks

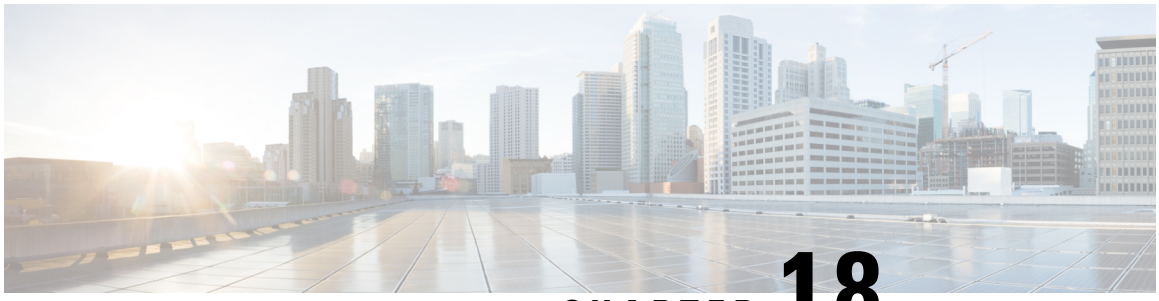
You can delete a scheduled task.

Procedure

Step 1 Select **System** (⚙) > **Tools** > **Scheduling**.

Step 2 In the calendar, click the task you want to delete. For a recurring task, click an instance of the task.

Step 3 In the **Task Details** table, click **Delete** (🗑), then confirm your choice.



CHAPTER 18

Import/Export

The following topics explain how to use the Import/Export feature:

- About Import/Export, on page 363
- Requirements and Prerequisites for Import/Export, on page 366
- Guidelines for Import/Export, on page 366
- Export Configurations, on page 367
- Import Configurations, on page 367

About Import/Export

You can use the Import/Export feature to copy configurations between Firewall Management Centers. Import/Export is not a backup tool but can simplify the process of adding a new Firewall Management Center.

You can export a single configuration, or you can export a set of configurations (of the same type or of different types) with a single action. When you later import the package onto another Firewall Management Center, you can choose which configurations in the package to import.

An exported package contains revision information for that configuration, which determines whether you can import that configuration onto another Firewall Management Center. When the Firewall Management Center are compatible, but the package includes a duplicate configuration, the Firewall Management Center offers resolution options.

Exceptions to Export Behavior

When you export a configuration, the Firewall Management Center also exports other required configurations. For example, exporting an access control policy also exports any subpolicies it invokes, objects and object groups it uses, ancestor policies, and so on. As another example, if you export a platform settings policy with external authentication enabled, the authentication object is exported as well.

There are some exceptions, however:

- System-provided databases and feeds—The Firewall Management Center does not export URL filtering category and reputation data, Cisco Intelligence Feed data, or the geolocation database (GeoDB). Each Firewall Management Center needs to obtain up-to-date information from Cisco.
- Global Security Intelligence lists—The Firewall Management Center exports Global Security Intelligence Block and Do Not Block lists associated with exported configurations. The import process converts these lists to user-created lists, then uses those new lists in the imported configurations. This ensures that

imported lists do not conflict with existing Global Block and Do Not Block lists. To use Global lists on the importing Firewall Management Center, manually add the lists to your imported configurations.

- Intrusion policy shared layers—The export process breaks intrusion policy shared layers. The previously shared layer is included in the package, and imported intrusion policies do not contain shared layers.
- Intrusion policy default variable set—The export package includes a default variable set with custom variables and system-provided variables with user-defined values. The import process updates the default variable set on the importing Firewall Management Center with the imported values. However, the import process does **not** delete custom variables not present in the export package. The import process also does not revert user-defined values on the importing Firewall Management Center, for values not set in the export package. Therefore, an imported intrusion policy may behave differently than expected if the importing Firewall Management Center has differently configured default variables.
- Custom user objects—If you have created custom user groups or objects in your Firewall Management Center, and if such a custom user object is a part of any rule in your access control policy, note that the export file (.sfo) does not carry the user object information, and therefore while importing such a policy, any reference to such custom user objects will be removed and will not be imported to the destination Firewall Management Center. To avoid detection issues due to the missing user group, add the customized user objects manually to the new Firewall Management Center, and re-configure the access control policy after import.

Importing Objects and Object Groups

When you import objects and object groups:

- Generally, the import process imports objects and groups as new, and you cannot replace existing objects and groups. However, if network and port objects or groups in an imported configuration match existing objects or groups, the imported configuration reuses the existing objects/groups, rather than creating new objects/groups. The Firewall Management Center determines a match by comparing the name (minus any autogenerated number) and content of each network and port object/group.
- If the names of imported objects match existing objects on the importing Firewall Management Center, the Firewall Management Center appends autogenerated numbers to the imported object and group names to make them unique.
- You must map any security zones and interface groups used in the imported configurations to matching-type zones and groups managed by the importing Firewall Management Center.
- If you export a configuration that uses PKI objects containing private keys, the Firewall Management Center decrypts the private keys before export. On import, the Firewall Management Center encrypts the keys with a randomly generated key.

Conflict Resolution for Duplicate Configurations

Default Resolution Behavior

When you attempt to import a configuration, the Firewall Management Center determines whether a configuration of the same name and type already exists. When an import includes a duplicate configuration, the Firewall Management Center offers resolution options:

- **Keep existing**

The Firewall Management Center does not import that configuration.

- **Replace existing**

  The Firewall Management Center overwrites the current configuration with the configuration selected for import. This option is not available if the duplicate is in ancestor or descendant domain.

- **Keep newest**

  The Firewall Management Center imports the selected configuration only if its timestamp is more recent than the timestamp on the current configuration. This option is not available if the duplicate is in ancestor or descendant domain.

Note If you import a configuration that contains Microsoft Active Directory users and groups we strongly recommend you download all users and groups after the import to avoid issues in decryption policies, access control policies, and possibly other policies. (**Integration** > **Other Integrations** > **Realms** > **Realms**, then click **Download Now**( ) (**Download Now**).

- **Import as new**

  The Firewall Management Center imports the selected duplicate configuration, appending a system-generated number to the name to make it unique. (You can change this name before completing the import process.) The original configuration remains unchanged.

Note If you modify an imported configuration on the Firewall Management Center and later re-import that configuration to the same Firewall Management Center, you must choose which version of the configuration to keep.

File List Resolution Behavior

When you import an access control policy with a file policy that uses clean or custom detection file lists, and a file list presents a duplicate name conflict, the Firewall Management Center offers conflict resolution options as described, but the action taken varies as described in the table:

Resolution Option	Resolution Behavior for the Access Control Policy
Keep existing	Unchanged
Replace existing	Imported as new; file lists are merged
Import as new	Imported as new; file lists are merged
Keep newest and access control policy being imported is the newest	Imported as new; file lists are merged
Keep newest and existing access control policy is the newest	Unchanged

Requirements and Prerequisites for Import/Export

Version Requirements

- Both Firewall Management Centers need to be the same software version.
- For access control and its subpolicies (including intrusion policies), the intrusion rule update version must match.

  You cannot use the Import/Export feature to update intrusion rules. Instead, download and apply the latest rule update version.

Domain Requirements

Both Firewall Management Centers need to have the same domain hierarchy.

Note If you import a configuration without the same domains, to recover, you need to re-export the configuration after first renaming the domains. Then you can add those new domains to the target Firewall Management Center and import the new configuration.

User Roles

- Admin

Guidelines for Import/Export

Supported Configurations

- Access control policies and the policies they invoke: prefilter, network analysis, intrusion, SSL, file, Service Policy
- Intrusion policies, independently of access control
- NAT policies
- FlexConfig policies. However, the contents of any secret key variables are cleared when you export the policy. You must manually edit the values of all secret keys after importing a FlexConfig policy that uses secret keys.
- Platform settings
- Health policies
- Alert responses
- Application detectors (both user-defined and those provided by Cisco Professional Services)
- Dashboards

- Custom tables
- Custom workflows
- Saved searches
- Custom user roles
- Report templates
- Third-party product and vulnerability mappings
- Users and groups for user control

Export Configurations

Depending on the number of configurations being exported and the number of objects those configurations reference, the export process may take several minutes.

Tip Many list pages include a **YouTube EDU** ( ) icon next to list items. Where this icon is present, you can use it as a quick alternative to the export procedure that follows.

Procedure

Step 1 Choose **System** ( ) > **Tools** > **Import/Export**.

Step 2 Click **Collapse** ( ) and **Expand** ( ) to collapse and expand the list of available configurations.

Step 3 Check the configurations you want to export and click **Export**.

Step 4 Follow your web browser's prompts to save the exported package to your computer.

Import Configurations

Depending on the number of configurations being imported and the number of objects those configurations reference, the import process may take several minutes.

Note If you log out of the Firewall Management Center or if your user session expires after you click **Import**, the import process continues in the background until it is complete. We recommend that you wait for the import process to complete before creating any new objects or policies. Attempting to create them while the import process is still running might result in failures.

Procedure

Step 1 On the importing Firewall Management Center, choose **System** (⚙) > **Tools** > **Import/Export**.

Step 2 Click **Upload Package**.

Step 3 Enter the path to the exported package or browse to its location, then click **Upload**.

Step 4 If there are no version mismatches or other issues, choose the configurations you want to import, then click **Import**.
If you do not need to perform any conflict resolution or interface object mapping, the import completes and a success message appears. Skip the rest of this procedure.

Step 5 If prompted, on the Import Conflict Resolution page, map interface objects used in the imported configurations to zones and groups with matching interface types managed by the importing Firewall Management Center.

Interface object type (security zone or interface group) and interface type (passive, inline, routed, and so on) of source and destination objects must match. For information, see Interface, on page 1468.

If the configurations you are importing reference security zones or interface groups that do not already exist, you can map them to existing interface objects, or create new ones.

Note
For individual access control policies, you have the option of replacing an existing policy with the imported ones. However, for nested access control policies, you can only import them as new policies.

Step 6 Click **Import**.

Step 7 If prompted, on the Import Resolution page, expand each configuration and choose the appropriate option as described in Conflict Resolution for Duplicate Configurations, on page 364.

Step 8 Click **Import**.

Step 9 Update all feeds.

For example, go to **Objects** > **Object Management** > **Security Intelligence** and click the **Update Feed** button on the URL, Network, and DNS Lists and Feeds pages.

Imported policies do not include feed contents.

Step 10 Wait for all feed updates to complete before deploying the policies to devices.

What to do next

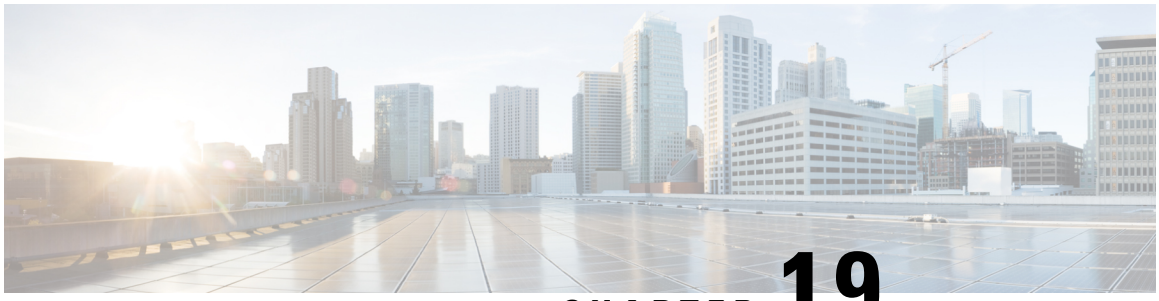
Note If you import a configuration that contains Microsoft Active Directory users and groups we strongly recommend you download all users and groups after the import to avoid issues in decryption policies, access control policies, and possibly other policies. (**Integration** > **Other Integrations** > **Realms** > **Realms**, then click **Download Now**( ) (**Download Now**).

- Optionally, view a report summarizing the imported configurations; see View Task Messages, on page 313.

PART VI

Reporting and Alerting

- External Alerting with Alert Responses, on page 371
- External Alerting for Intrusion Events, on page 379



CHAPTER 19

External Alerting with Alert Responses

The following topics describe how to send external event alerts from the Secure Firewall Management Center using alert responses:

- Secure Firewall Management Center Alert Responses, on page 371
- Requirements and Prerequisites for Alert Responses, on page 372
- Creating an SNMP Alert Response, on page 372
- Creating a Syslog Alert Response, on page 374
- Creating an Email Alert Response, on page 376

Secure Firewall Management Center Alert Responses

External event notification via SNMP, syslog, or email can help with critical-system monitoring. The Secure Firewall Management Center uses configurable *alert responses* to interact with external servers. An *alert response* is a configuration that represents a connection to an email, SNMP, or syslog server. They are called *responses* because you can use them to send alerts in response to events detected by Secure Firewall. You can configure multiple alert responses to send different types of alerts to different monitoring servers and/or people.

Note Depending on your device and Secure Firewall version, alert responses may not be the best way to send syslog messages. See the *About Syslog* chapter in the Cisco Secure Firewall Management Center Device Configuration Guide.

Note Alerts that use alert responses are sent by the Secure Firewall Management Center. Intrusion email alerts, which do not use alert responses, are also sent by the Secure Firewall Management Center. By contrast, SNMP and syslog alerts that are based on individual intrusion rules triggering are sent directly by managed devices.

In most cases, the information in an external alert is the same as the information in any associated event you logged to the database. However, for correlation event alerts where the correlation rule contains a connection tracker, the information you receive is the same as for an alert on a traffic profile change, regardless of the base event type.

You create and manage alert responses on the Alerts page (**Policies** > **Actions** > **Alerts**). New alert responses are automatically enabled. To temporarily stop alert generation, you can disable alert responses rather than deleting them.

Changes to alert responses take effect immediately, except when sending connection logs to an SNMP trap or syslog server.

Configurations Supporting Alert Responses

After you create an alert response, you can use it to send the following external alerts from the Secure Firewall Management Center.

Alert/Event Type	For More Information
Health events, by health module and severity level	Creating Health Monitor Alerts, on page 292

Requirements and Prerequisites for Alert Responses

Model Support

Any.

Supported Domains

Any

User Roles

- Admin

Creating an SNMP Alert Response

You can create SNMP alert responses using SNMPv1, SNMPv2, or SNMPv3 for Firewall Threat Defense devices.

Note When selecting SNMP versions for the SNMP protocol, note that SNMPv2 only supports read-only communities and SNMPv3 only supports read-only users. SNMPv3 also supports encryption with AES128.

If you want to monitor 64-bit values with SNMP, you must use SNMPv2 or SNMPv3. SNMPv1 does not support 64-bit monitoring.

Before you begin

- If your network management system requires the Firewall Management Center's management information base (MIB) file, obtain it at `/etc/sf/DCEALERT.MIB`.

Procedure

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 From the **Create Alert** drop-down menu, choose **Create SNMP Alert**.

Step 3 Edit the SNMP Alert Configuration fields:

a) **Name—**Enter a name to identify the SNMP response.

b) **Trap Server—**Enter the hostname or IP address of the SNMP trap server.

Note
The system does **not** warn you if you enter an invalid IPv4 address (such as 192.169.1.456) in this field. Instead, the invalid address is treated as a hostname.

c) **Version—**Choose the SNMP version you want to use from the drop-down list. SNMPv3 is the default.

Choose from:

- **SNMPv1** or **SNMPv2**: Enter a read-only SNMP community name in the **Community String** field, then skip to the end of the procedure.

  Note
  Do not include special characters (< > / % # & ? ', etc.) in the SNMP community string name.

- For **SNMPv3**: Enter the name of the user that you want to authenticate with the SNMP server in the **User Name** field and continue to the next step.

d) **Authentication Protocol—**Choose the protocol you want to use to encrypt authentication from the drop-down list.

Choose from:

- **MD5**—Message Digest 5 (MD5) hash function.
- **SHA**—Secure Hash Algorithm (SHA) hash function.

e) **Authentication Password—**Enter the password to enable authentication.

f) **Privacy Protocol—**Choose the protocol you want to use to encrypt a private password from the drop-down list.

Choose from:

- **DES**—Data Encryption Standard (DES) using 56-bit keys in a symmetric secret-key block algorithm.
- **AES**—Advanced Encryption Standard (AES) using 56-bit keys in a symmetric cipher algorithm.
- **AES128**—AES using 128-bit keys in a symmetric cipher algorithm. A longer key provides higher security but a reduction in performance.

g) **Privacy Password—**Enter the privacy password required by the SNMP server. If you specify a private password, privacy is enabled, and you must also specify an authentication password.

h) **Engine ID—**Enter an identifier for the SNMP engine, in hexadecimal notation, using an even number of digits.

When you use SNMPv3, the system uses an Engine ID value to encode the message. Your SNMP server requires this value to decode the message.

Cisco recommends that you use the hexadecimal version of the Firewall Management Center's IP address. For example, if the Firewall Management Center has an IP address of 10.1.1.77, use 0a01014D0.

Step 4 Click **Save**.

What to do next

Changes take effect immediately, except if you are using alert responses to send connection logs, you must deploy configuration changes after you edit those alert responses.

Creating a Syslog Alert Response

When configuring a syslog alert response, you can specify the severity and facility associated with the syslog messages to ensure that they are processed properly by the syslog server. The facility indicates the subsystem that creates the message and the severity defines the severity of the message. Facilities and severities are not displayed in the actual message that appears in the syslog, but are instead used to tell the system that receives the syslog message how to categorize it. These fields allow you to set the severity and facility in the syslog events configured from the Management Center web interface but these fields are not meant for filtering event types.

Tip For more detailed information about how syslog works and how to configure it, refer to the documentation for your system. On UNIX systems, the `man` pages for `syslog` and `syslog.conf` provide conceptual information and configuration instructions.

Although you can choose any type of facility when creating a syslog alert response, you should choose one that makes sense based on your syslog server; not all syslog servers support all facilities. For UNIX syslog servers, the `syslog.conf` file should indicate which facilities are saved to which log files on the server.

Syslog messages are transmitted over either UDP or TCP, depending on the configuration of the syslog server.

Before you begin

- This procedure is not the recommended way to send syslog messages in many cases.
- Confirm that the syslog server can accept remote messages.

Procedure

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 From the **Create Alert** drop-down menu, choose **Create Syslog Alert**.

Step 3 Enter a **Name** for the alert.

Step 4 In the **Host** field, enter the hostname or IP address of your syslog server.

Note
The system does **not** warn you if you enter an invalid IPv4 address (such as 192.168.1.456) in this field. Instead, the invalid address is treated as a hostname.

Step 5 In the **Port** field, enter the port the server uses for syslog messages. By default, this value is 514.

Step 6 From the **Facility** list, choose a facility described in Syslog Alert Facilities, on page 375.

Step 7 From the **Severity** list, choose a severity described in Syslog Severity Levels, on page 376.

Step 8 In the **Tag** field, enter the tag name that you want to appear with the syslog message.

For example, if you wanted all messages sent to the syslog to be preceded with `FromMC`, enter `FromMC` in the field.

Step 9 Click **Save**.

What to do next

Changes take effect immediately, EXCEPT:

If you are using alert responses to send connection logs to a syslog server, you must deploy configuration changes after you edit those alert responses.

Syslog Alert Facilities

The following table lists the syslog facilities you can select.

Table 29: Available Syslog Facilities

Facility	Description
AUTH	A message associated with security and authorization.
AUTHPRIV	A restricted access message associated with security and authorization. On many systems, these messages are forwarded to a secure file.
CONSOLE	An alert message.
CRON	A message generated by the clock daemon. Note that syslog servers running a Linux operating system will use the `CRON` facility.
DAEMON	A message generated by a system daemon.
FTP	A message generated by the FTP daemon.
KERN	A message generated by the kernel. On many systems, these messages are printed to the console when they appear.
LOCAL0-LOCAL7	A message generated by an internal process.
LPR	A message generated by the printing subsystem.
MAIL	A message generated by a mail system.

Facility	Description
NEWS	A message generated by the network news subsystem.
NTP	A message generated by the NTP daemon.
SECURITY	A message generated by the audit subsystem.
SYSLOG	A message generated by the syslog daemon.
SOLARIS-CRON	A message generated by the clock daemon. Note that syslog servers running a Windows operating system will use the `CLOCK` facility.
USER	A message generated by a user-level process.
UUCP	A message generated by the UUCP subsystem.

Syslog Severity Levels

The following table lists the standard syslog severity levels you can select.

Table 30: Syslog Severity Levels

Level	Description
ALERT	A condition that should be corrected immediately.
CRIT	A critical condition.
DEBUG	Messages that contain debugging information.
EMERG	A panic condition broadcast to all users.
ERR	An error condition.
INFO	Informational messages.
NOTICE	Conditions that are not error conditions, but require attention.
WARNING	Warning messages.

Creating an Email Alert Response

Before you begin

- Ensure that the Secure Firewall Management Center can reverse-resolve its own IP address. Some mail servers may perform reverse DNS lookups to verify the sender's identity as a measure to prevent spam and unauthorized access.

Procedure

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 From the **Create Alert** drop-down menu, choose **Create Email Alert**.

Step 3 Enter a **Name** for the alert response.

Step 4 In the **To** field, enter the email addresses where you want to send alerts, separated by commas.

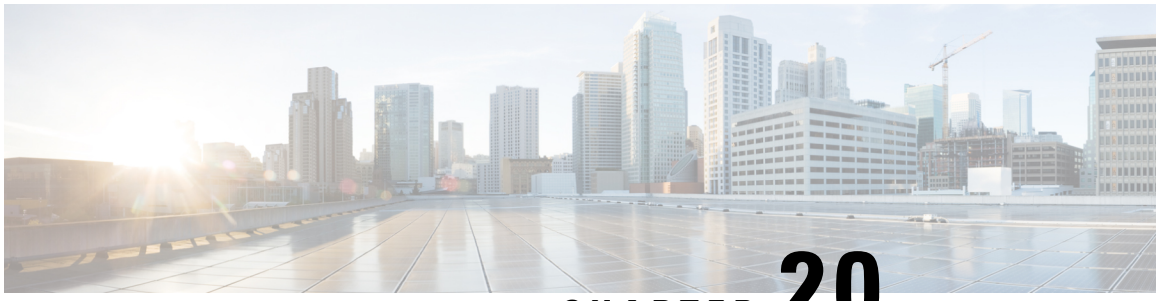
Step 5 In the **From** field, enter the email address that you want to appear as the sender of the alert.

Step 6 Next to **Relay Host**, verify the listed mail server is the one that you want to use to send the alert.

Tip

To change the email server, click **Edit** ( ).

Step 7 Click **Save**.



CHAPTER 20

External Alerting for Intrusion Events

The following topics describe how to configure external alerting for intrusion events:

- About External Alerting for Intrusion Events, on page 379
- License Requirements for External Alerting for Intrusion Events, on page 380
- Requirements and Prerequisites for External Alerting for Intrusion Events, on page 380
- Configuring SNMP Alerting for Intrusion Events, on page 380
- Configuring Syslog Alerting for Intrusion Events, on page 382
- Configuring Email Alerting for Intrusion Events, on page 384

About External Alerting for Intrusion Events

External intrusion event notification can help with critical-system monitoring:

- SNMP—Configured per intrusion policy and sent from managed devices. You can enable SNMP alerting per intrusion rule.
- Syslog—Configured per intrusion policy and sent from managed devices. When you enable syslog alerting in an intrusion policy, you turn it on for every rule in the policy.
- Email—Configured across all intrusion policies and sent from the Secure Firewall Management Center. You can enable email alerts per intrusion rule, as well as limit their length and frequency.

Keep in mind that if you configured intrusion event suppression or thresholding, the system may not generate intrusion events (and thus may not send alerts) every time a rule triggers.

Note The Secure Firewall Management Center also uses SNMP, syslog, and email *alert responses* to send different types of external alerts; see Secure Firewall Management Center Alert Responses, on page 371. The system does **not** use alert responses to send alerts based on individual intrusion events.

Configuring SNMP Alerting for Intrusion Events

After you enable external SNMP alerting in an intrusion policy, you can configure individual rules to send SNMP alerts when they trigger. These alerts are sent from the managed device.

Procedure

Step 1 In the intrusion policy editor's navigation pane, click **Advanced Settings**.

Step 2 Make sure **SNMP Alerting** is **Enabled**, then click **Edit**.
A message at the bottom of the page identifies the intrusion policy layer that contains the configuration.

Step 3 Choose an **SNMP Version**, then specify configuration options as described in Intrusion SNMP Alert Options, on page 381.

Step 4 In the navigation pane, click **Rules**.

Step 5 In the rules pane, choose the rules where you want to set SNMP alerts, then from the **Alerting** drop-down list, choose **Add SNMP Alert**.

Step 6 To save changes you made in this policy since the last policy commit, choose **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

What to do next

- Deploy configuration changes.

Intrusion SNMP Alert Options

If your network management system requires a management information base file (MIB), you can obtain it from the Secure Firewall Management Center at `/etc/sf/DCEALERT.MIB`.

SNMP v2 Options

Option	Description
Trap Type	The trap type to use for IP addresses that appear in the alerts. If your network management system correctly renders the INET_IPV4 address type, choose **as Binary**. Otherwise, choose **as String**. For example, HP OpenView requires **as String**.
Trap Server	The server that will receive SNMP traps notification. You can specify a single IP address or hostname.
Community String	The community name.

SNMP v3 Options

Managed devices encode SNMPv3 alerts with an Engine ID value. To decode the alerts, your SNMP server requires this value, which is the hexadecimal version of the sending device's management interface IP address, appended with "01."

For example, if the device sending the SNMP alert has a management interface IP address of 172.16.1.50, the Engine ID value is 0xAC10013201.

Option	Description
Trap Type	The trap type to use for IP addresses that appear in the alerts. If your network management system correctly renders the INET_IPV4 address type, choose **as Binary**. Otherwise, choose **as String**. For example, HP OpenView requires **as String**.
Trap Server	The server that will receive SNMP traps notification. You can specify a single IP address or hostname.

Option	Description
Authentication Password	The password required for authentication. SNMP v3 uses either the Message Digest 5 (MD5) hash function or the Secure Hash Algorithm (SHA) hash function to encrypt this password, depending on configuration. If you specify an authentication password, authentication is enabled.
Private Password	The SNMP key for privacy. SNMP v3 uses the Data Encryption Standard (DES) block cipher to encrypt this password. When you enter an SNMP v3 password, the password displays in plain text during initial configuration but is saved in encrypted format. If you specify a private password, privacy is enabled, and you must also specify an authentication password.
User Name	Your SNMP user name.

Configuring Syslog Alerting for Intrusion Events

After you enable syslog alerting in an intrusion policy, the system sends all intrusion events to the syslog, either on the managed device itself or to an external host or hosts. If you specify an external host, syslog alerts are sent from the managed device.

Procedure

Step 1 In the intrusion policy editor's navigation pane, click **Advanced Settings**.

Step 2 Make sure **Syslog Alerting** is **Enabled**, then click **Edit**.
A message at the bottom of the page identifies the intrusion policy layer that contains the configuration. The **Syslog Alerting** page is added under **Advanced Settings**.

Step 3 Enter the IP addresses of the **Logging Hosts** where you want to send syslog alerts.

If you leave the **Logging Hosts** field blank, the logging hosts details are taken from Logging in the associated Access Control Policy.

Step 4 Choose **Facility** and **Severity** levels as described in Facilities and Severities for Intrusion Syslog Alerts, on page 383.

Step 5 To save changes you made in this policy since the last policy commit, choose **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

What to do next

- Deploy configuration changes.

Facilities and Severities for Intrusion Syslog Alerts

Managed devices can send intrusion events as syslog alerts using a particular facility and **Severity**, so that the logging host can categorize the alerts. The *facility* specifies the subsystem that generated it. These facility and **Severity** values do not appear in the actual syslog messages.

Choose values that make sense based on your environment. Local configuration files (such as syslog.conf on UNIX-based logging hosts) may indicate which facilities are saved to which log files.

Syslog Alert Facilities

Facility	Description
AUTH	A message associated with security and authorization.
AUTHPRIV	A restricted access message associated with security and authorization. On many systems, these messages are forwarded to a secure file.
CONSOLE	An alert message.
CRON	A message generated by the clock daemon.
DAEMON	A message generated by a system daemon.
FTP	A message generated by the FTP daemon.
KERN	A message generated by the kernel. On many systems, these messages are printed to the console when they appear.
LOCAL0-LOCAL7	A message generated by an internal process.
LPR	A message generated by the printing subsystem.
MAIL	A message generated by a mail system.
NEWS	A message generated by the network news subsystem.
SYSLOG	A message generated by the syslog daemon.
USER	A message generated by a user-level process.
UUCP	A message generated by the UUCP subsystem.

Syslog Alert Severities

Level	Description
EMERG	A panic condition broadcast to all users
ALERT	A condition that should be corrected immediately
CRIT	A critical condition
ERR	An error condition

Level	Description
WARNING	Warning messages
NOTICE	Conditions that are not error conditions, but require attention
INFO	Informational messages
DEBUG	Messages that contain debug information

Configuring Email Alerting for Intrusion Events

If you enable intrusion email alerting, the system can send email when it generates an intrusion event, regardless of which managed device or intrusion policy detected the intrusion. These alerts are sent from the Secure Firewall Management Center.

Before you begin

- Ensure that the Secure Firewall Management Center can reverse-resolve is own IP address. Some mail servers may perform reverse DNS lookups to verify the sender's identity as a measure to prevent spam and unauthorized access.

Procedure

Step 1 Choose **Policies** > **Actions** > **Alerts**.

Step 2 Click **Intrusion Email**.

Step 3 Choose alerting options, including the intrusion rules or rule groups for which you want to alert, as described in Intrusion Email Alert Options, on page 384.

Step 4 Click **Save**.

Intrusion Email Alert Options

On/Off

Enables or disables intrusion email alerts.

Note Enabling it will enable alerting for all rules unless individual rules are selected.

From/To Addresses

The email sender and recipients. You can specify a comma-separated list of recipients.

Max Alerts and Frequency

The maximum number of email alerts (**Max Alerts**) that the Secure Firewall Management Center will send per time interval (**Frequency**).

Coalesce Alerts

Reduces the number of alerts sent by grouping alerts that have the same source IP and rule ID.

Summary Output

Enables brief alerts, suitable for text-limited devices. Brief alerts contain:

- Timestamp
- Protocol
- Source and destination IPs and ports
- Message
- The number of intrusion events generated against the same source IP

For example: `2011-05-18 10:35:10 10.1.1.100 icmp 10.10.10.1:8 -> 10.2.1.3:0 snort_decoder: Unknown Datagram decoding problem! (116:108)`

If you enable **Summary Output**, also consider enabling **Coalesce Alerts**. You may also want to lower **Max Alerts** to avoid exceeding text-message limits.

Time Zone

The time zone for alert timestamps.

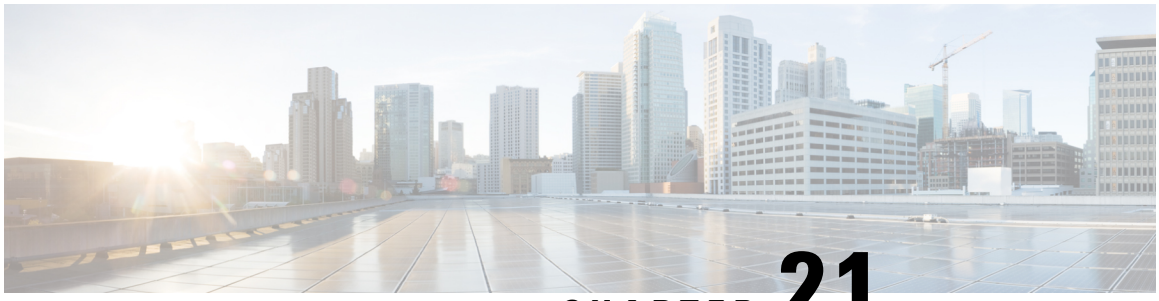
Email Alerting on Specific Rules Configuration

Allows you to choose the rules where you want to set email alerts.

PART VII

Event and Asset Analysis Tools

- Lookups, on page 389
- Event Investigation Using Web-Based Resources, on page 391



CHAPTER 21

Lookups

The following topics explain how to look up information about entities that may or may not be known to the system:

- Introduction to Lookups, on page 389
- Performing Whois Lookups, on page 389

Introduction to Lookups

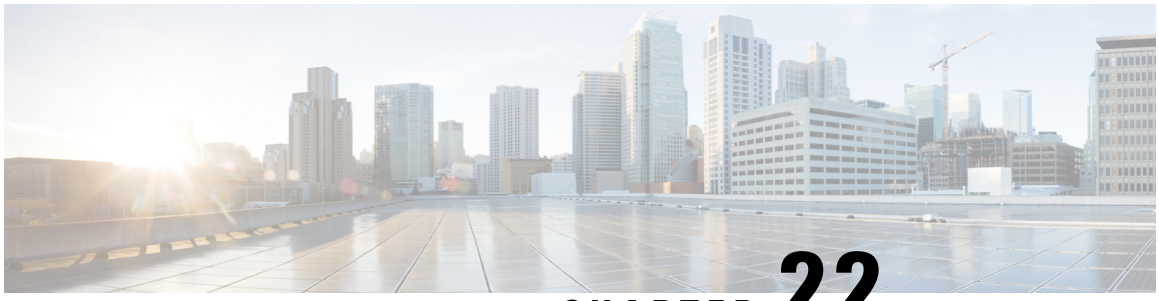
You can use manual lookup features to find the Regional Information Registries (RIR) information (whois) for any IP address.

Performing Whois Lookups

Procedure

Step 1 Choose **Analysis** > **Advanced** > **Whois**.

Step 2 Enter an IP address and click **Search**.



CHAPTER 22

Event Investigation Using Web-Based Resources

• Event Investigation Using Web-Based Resources, on page 391

Event Investigation Using Web-Based Resources

Use the contextual cross-launch feature to quickly find more information about potential threats in web-based resources outside of the Secure Firewall Management Center. For example, you might:

- Look up a suspicious source IP address in a Cisco or third-party cloud-hosted service that publishes information about known and suspected threats, or
- Look for past instances of a particular threat in your organization's historical logs, if your organization stores that data in a Security Information and Event Management (SIEM) application.
- Look for information about a particular file, including file trajectory information, if your organization has deployed Cisco Secure Endpoint.

When investigating an event, you can click directly from an event in the event viewer or dashboard in the Secure Firewall Management Center to the relevant information in the external resource. This lets you quickly gather context around a specific event based on its IP addresses, ports, protocol, domain, and/or SHA 256 hash.

For example, suppose you are looking at the Top Attackers dashboard widget and you want to find out more information about one of the source IP addresses listed. You want to see what information Talos publishes about this IP address, so you choose the "Talos IP" resource. The Talos web site opens to a page with information about this specific IP address.

You can choose from a set of pre-defined links to commonly used Cisco and third-party threat intelligence services, and add custom links to other web-based services, and to SIEMs or other products that have a web interface. Note that some resources may require an account or a product purchase.

About Managing Contextual Cross-Launch Resources

Manage external web-based resources using the **Analysis** > **Advanced** > **Contextual Cross-Launch** page.

Pre-defined resources offered by Cisco are marked with the Cisco logo. The remaining links are third-party resources.

You can disable or delete any resources that you do not need, or you can rename them, for example by prefixing a name with a lower-case "z" so the resource sorts to the bottom of the list. Disabling a cross-launch resource disables it for all users. You cannot reinstate deleted resources, but you can re-create them.

To add a resource, see Add Contextual Cross-Launch Resources, on page 392.

Requirements for Custom Contextual Cross-Launch Resources

When adding custom contextual cross-launch resources:

- Resources must be accessible via web browser.
- Only http and https protocols are supported.
- Only GET requests are supported; POST requests are not.
- Encoding of variables in URLs is not supported. While IPv6 addresses may require colon separators to be encoded, most services do not require this encoding.
- Up to 100 resources can be configured, including pre-defined resources.

Add Contextual Cross-Launch Resources

You can add contextual cross-launch resources such as threat intelligence services and Security Information and Event Management (SIEM) tools.

In multidomain deployments, you can see and use resources in parent domains, but you can only create and edit resources in the current domain. The total number of resources across all domains is limited to 100.

Before you begin

- If you are adding links to a Secure Network Analytics appliance, check to see if the links you want already exist; most links are automatically created for you when you configure Security Analytics and Logging (On Premises).
- See Requirements for Custom Contextual Cross-Launch Resources, on page 392.
- If needed for the resource you will link to, create or obtain an account and the credentials needed for access. Optionally, assign and distribute credentials for each user who needs access.
- Determine the syntax of the query link for the resource that you will link to:

  Access the resource via browser and, using the documentation for that resource as needed, formulate the query link needed to search for a specific sample of the type of information you want your query link to find, such as an IP address.

  Run the query, then copy the resulting URL from the browser's location bar.

  For example, you might have the query URL `https://www.talosintelligence.com/reputation_center/lookup?search=10.10.10.10`.

Procedure

Step 1 Choose **Analysis** > **Advanced** > **Contextual Cross-Launch**.

Step 2 Click **New Cross-launch**.

In the form that appears, all fields marked with an asterisk require a value.

Step 3 Enter a unique resource name.

Step 4 Paste the working URL string from your resource into the **URL Template** field.

Step 5 Replace the specific data (such as an IP address) in the query string with an appropriate variable: Position your cursor, then click a variable (for example, **ip**) once to insert the variable.

In the example from the "Before You Begin" section above, the resulting URL might be `https://www.talosintelligence.com/reputation_center/lookup?search={ip}`. When the contextual cross-launch link is used, the {ip} variable in the URL will be replaced by the IP address that the user right-clicks on in the event viewer or dashboard.

For a description of each variable, hover over the variable.

You can create multiple contextual cross-launch links for a single tool or service, using different variables for each.

Step 6 Click **Test with example data** ( ) to test your link with example data.

Step 7 Fix any problems.

Step 8 Click **Save**.

Investigate Events Using Contextual Cross-Launch

Before you begin

If the resource you will access requires credentials, make sure you have those credentials.

Procedure

Step 1 In the Secure Firewall Management Center, click **Analysis** > **Unified Events**.

Step 2 Right-click the event of interest and choose the contextual cross-launch resource to use.

If necessary, scroll down in the context menu to see all available options.

The data type you right-click on determines the options you see; for example, if you right-click an IP address, you will only see contextual cross-launch options that are relevant to IP addresses.

For example, to get threat intelligence from Cisco Talos about a source IP address in the intrusion event, choose **Talos SrcIP** or **Talos IP**.

If a resource includes multiple variables, the option to choose that resource is available only for events that have a single possible value for each included variable.

The contextual cross-launch resource opens in a separate browser window.

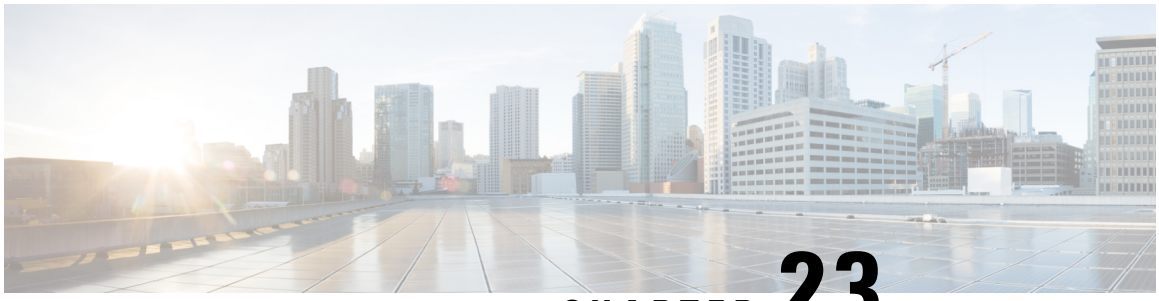
It may take some time for the query to be processed, depending on the amount of data to be queried, speed of and demand on the resource, and so on.

Step 3 Sign in to the resource if necessary.

PART VIII

Events and Assets

- Security Analytics and Logging (SaaS) for Cloud-Delivered Firewall Management Center-Managed Devices, on page 397
- FTD Dashboard, on page 407
- Connection Logging, on page 413



CHAPTER 23

Security Analytics and Logging (SaaS) for Cloud-Delivered Firewall Management Center-Managed Devices

- About Security Analytics and Logging, on page 397
- Comparison of SAL Remote Event Storage and Monitoring Options, on page 398
- About SAL (OnPrem), on page 398
- Manage SAL (OnPrem) for Security Cloud Control-Managed Firewall Threat Defense Devices, on page 399
- Configure SAL (OnPrem) Integration, on page 401
- About SAL (SaaS), on page 404

About Security Analytics and Logging

Security Analytics and Logging (SAL) is a central log management and advanced threat detection service which delivers scalable Cisco firewall logging and correlated analytics. Central logging helps in providing visibility, helps troubleshoot network access issues including disruptions, and enables device and overall network health monitoring. Analytics provide detection against advanced threats.

The SAL service is available in the following two methods:

- Security Analytics and Logging (SaaS)—A hosted software as a service (SaaS) which stores events and provides data for security analytics using Secure Cloud Analytics (formerly Stealthwatch Cloud). This service connects the Security Analytics and Logging cloud data store to the firewall cloud manager, Cisco Security Cloud Control (Security Cloud Control).

  In this documentation, this method is also referred to as SAL (SaaS).

- Security Analytics and Logging (On Premises)—A service that runs on the Secure Network Analytics (formerly Stealthwatch) appliances to store event logs at the customer's own premises. This service connects the Security Analytics and Logging (On Premises) data to the on-premises manager, Secure Firewall Management Center.

  In this documentation, this method is also referred to as SAL (OnPrem).

For more information about Security Analytics and Logging, see https://www.cisco.com/c/en/us/products/security/security-analytics-logging/index.html.

Comparison of SAL Remote Event Storage and Monitoring Options

SAL integration shows similar options for storing event data externally to a Firewall Management Center and Security Cloud Control:

	SAL (OnPrem)	SAL (SaaS)
Why choose this solution?	You want to increase your on-premises firewall event data storage capacity, retain this data for a longer period, and export your event data to the Secure Network Analytics appliance.	You want to send firewall events for storage and optionally make your firewall event data available for security analytics using Secure Cloud Analytics.
Licensing	Purchase license and set-up the storage system behind your firewall. For more information, see Licensing for SAL (OnPrem), on page 399	Purchase license and a data storage plan and send your data to the Cisco cloud. For more information, see Licensing for SAL (SaaS), on page 405
Supported event types	• Connection • File and Malware • Intrusion • LINA • Security Intelligence	• Connection • File and Malware • Intrusion • Security Intelligence
Supported methods to send events	Supports both, syslog and direct integration.	Supports both, syslog and direct integration.
Event viewing	• View events on the Secure Network Analytics Manager. • Cross-launch from the Firewall Management Center event viewer to view events on the Secure Network Analytics Manager. • View remotely stored connection and security intelligence events in the management center.	View events in Security Cloud Control or Secure Network Analytics Manager, depending on your license. Cross-launch from the Firewall Management Center event viewer.

About SAL (OnPrem)

You can configure SAL (OnPrem) to store firewall event data for increased storage at a larger retention period. By deploying Secure Network Analytics appliances and integrating them with your firewall deployment, you can export your event data to a Secure Network Analytics appliance.

This provides you with the following capabilities:

- Store events on the Secure Network Analytics appliance.
- Specify this remote data source to view these events in the management center.
- Review event data from the Secure Network Analytics Manager (formerly Stealthwatch Management Console) Web App UI using the *Event Viewer*.
- Cross-launch from the management center UI to the *Event Viewer* to view additional context on the information from which you cross-launched.

Licensing for SAL (OnPrem)

You must obtain the Logging and Troubleshooting smart license to use SAL (OnPrem). You can obtain the license based on the amount of data you anticipate while sending the syslog data from your firewall deployment to your Secure Network Analytics appliance on a daily basis.

For information on licensing the Secure Network Analytics appliances, see Secure Network Analytics Smart Software Licensing Guide.

For information on the available SAL (OnPrem) licensing options, see the Cisco Security Analytics and Logging Ordering Guide.

Note For license calculation purposes, the amount of data is reported to the nearest whole GB. For example, If you send 4.9 GB in a day, it is reported as 4 GB.

Manage SAL (OnPrem) for Security Cloud Control-Managed Firewall Threat Defense Devices

Starting with Secure Firewall Threat Defense(formerly Firepower Threat Defense) version 7.2, you can choose to send fully qualified events that are generated by Security Cloud Control-managed Firewall Threat Defense devices to the Firewall Management Center. The Firewall Management Center receives and displays data analytics for these events. The Firewall Management Center receiving and displaying the event data is also referred to as an analytics-only management center. .

If your devices are enabled to send connection events to a Secure Network Analytics Manager using SAL (OnPrem), you can view and work with these remotely stored events in the management center event viewer and context explorer, and include them when generating reports. By deploying the Secure Network Analytics appliance and integrating it with the firewall deployment, you can export the event data to the Secure Network Analytics appliance. This allows you to view and manage the events in the management center UI. From the management center interface, you can also cross-launch to Secure Network Analytics Manager to view and manage the events data.

The management center can receive and display event analytics for the following Security Cloud Control-managed Firewall Threat Defense devices:

- New or existing Firewall Threat Defense devices onboarded to Security Cloud Control

For information on onboarding a Firewall Threat Defense device to Security Cloud Control, see Prerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center, on page 8.

The workflow is as follows:

1. Onboard a Firewall Threat Defense device to Security Cloud Control.

   Onboard the Firewall Threat Defense devices using the onboarding methods that are described in Prerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center, on page 8. The onboarding process includes assigning policies and choosing the appropriate licenses.

2. Register this Firewall Threat Defense device in the appropriate management center.

   For the management center to display events generated by a Security Cloud Control-managed Firewall Threat Defense device, you must register the Firewall Threat Defense device in the management center. To register this device in the Firewall Management Center, enable the device to be registered using the **configure manager add** {*hostname* | *IPv4_address* | *IPv6_address*}*reg_key*[*nat_id*] CLI, and then add the device to the Firewall Management Center using the **Security Cloud Control Managed Device** check box.

Note The registration key and the NAT ID must be unique from those used while onboarding the device to Security Cloud Control.

   For more information, see *Add a Device to the Management Center* and *Complete the Threat Defense Initial Configuration Using the CLI* in Firepower Management Center Device Configuration Guide.

3. View events in the management center or cross-launch to a configured Secure Network Analytics Manager.

   To view and work with the events in the management center event viewer. If the Secure Network Analytics appliance is deployed and integrated with the firewall deployment, you can export the event data to the Secure Network Analytics appliance. This allows you to cross-launch from the management center UI to the Secure Network Analytics Manager to view and manage the events data.

   For more information, see *Events and Assets* and *Event Analysis Using External Tools*.

- Existing Firewall Threat Defense devices on the management center.

  You can change the management of the Firewall Threat Defense devices from management center to Security Cloud Control using the change threat defense manager functionality. The change threat defense manager functionality provides you to ability to change the management of Firewall Threat Defense devices from management center to Security Cloud Control. While changing the manager, you can choose to retain the events data generated by these threat defense devices on the management center. If you choose to retain the events data on the management center, a copy of the Firewall Threat Defense device in an analytics-only mode is retained on the management center.

  For more information, see Migrate Secure Firewall Threat Defense to Cloud.

  The workflow is as follows:

  1. Onboard the management center to Security Cloud Control

     To onboard the existing Firewall Threat Defense devices from management center to Security Cloud Control, you must onboard the appropriate management center to Security Cloud Control.

For more information, see Onboard an FMC.

2. Complete the change threat defense management process

   During the change threat defense management process, while changing the device manager, you can choose to retain events data generated by these Firewall Threat Defense devices on the management center.

   For more information, see Migrate Secure Firewall Threat Defense to Cloud.

3. View events in the management center or cross-launch to configured Secure Network Analytics appliance.

   To view and work with the events in the management center event viewer. If the Secure Network Analytics appliance is deployed and integrated with the firewall deployment, you can export the event data to the Secure Network Analytics appliance. This allows you to cross-launch from the management center UI to the Secure Network Analytics Manager to view and manage the events data.

   For more information, see Events and Assets and Event Analysis Using External Tools.

Configure SAL (OnPrem) Integration

Security Cloud Control to send events to the Secure Network Analytics appliance using one of the following deployment options:

- Secure Network Analytics Manager Only—Deploy a standalone manager to receive and store events. The threat defense devices send event data to the Network Analytics Manager. All event data is stored on the Network Analytics Manager. From the management center user interface, you can cross-launch the manager to view more information about the stored events.

Note **Manager Only** deployment is not supported on Secure Network Analytics appliance version 7.5.1 or later. For more information, see Cisco Security Analytics and Logging documentation.

- Secure Network Analytics Data Store—Deploy a Cisco Secure Network Analytics Flow Collector to receive events, a Cisco Secure Network Analytics Data Store (containing 3 Cisco Secure Network Analytics Data Nodes) to store events, and a manager . The threat defense devices send event data to the flow collector from where the events are sent to the Data Store for storage. From the management center user interface, you can cross-launch the manager to view more information about the stores events.

  Starting with Firewall Threat Defense version 7.2, you can choose to associate different flow collectors to different devices.

Configure a Secure Network Analytics Manager

Configure the Secure Network Analytics Manager deployment to integrate SAL (OnPrem) with Security Cloud Control-managed Firewall Threat Defense devices.

Before you begin

Ensure the following:

- You have a provisioned Security Cloud Control tenant and have the following Security Cloud Control user roles:
  - Admin
  - Super admin
- Your Firewall Threat Defense devices are working as expected and are generating events.
- If you are currently using syslog to send events to the Secure Network Analytics Manager from device versions that support sending events directly, disable syslog for those devices (or assign those devices an access control policy that does not include syslog configurations) to avoid duplicating events on the remote volume.
- You have the hostname or the IP address of your Secure Network Analytics Manager.

Note You may be logged out of the Secure Network Analytics Manager during the registration process; complete any work in progress before you start with the deployment wizard.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 From the Security Cloud Control menu, navigate **Administration** > **Firewall Management Center** to open the **Services** page.

Step 3 Select **Cloud-Delivered FMC** and then click **Configuration**.

Step 4 Navigate to **Integration** > **Security Analytics & Logging**.

Step 5 In the **Secure Network Analytics Manager Only** widget, click **Start**.

Step 6 Enter the hostname or the IP address and port number of the Secure Network Analytics Manager and click **Next**.

Step 7 Deploy the changes to the managed devices.

The event data is not logged to the SAL (OnPrem) until the logging policy changes are deployed to the registered Firewall Threat Defense devices.

Note
If you must change any of these configurations, run the wizard again. If you disable the configuration or run he wizard again, all settings except the account credentials are retained.

You can view and work with these remotely stored events in the event viewer and context explorer in the management center, and include them when generating reports. You can also cross-launch from an event in the management center to view related data on your Secure Network Analyticss appliance.

For more information, see the online help for the management center.

Step 8 Click **OK**.

Configure a Secure Network Analytics Data Store

Configure a Secure Network Analytics data store deployment to integrate SAL (OnPrem) with Firewall Threat Defense devices that are Security Cloud Control-managed.

Before you begin

Ensure the following:

- You have a provisioned Security Cloud Control tenant and have the following Security Cloud Control user roles:
  - Admin
  - Super admin
- Your Firewall Threat Defense devices are working as expected and generating events.
- If you are currently using syslog to send events to the Secure Network Analytics appliance from device versions that support sending events directly, disable syslog for those devices (or assign those devices an access control policy that does not include syslog configurations) to avoid duplicate events on the remote volume.
- Gather the following information:
  - The hostname or the IP address of your Secure Network Analytics Manager.
  - The IP address of your flow collector.

Note You may be logged out of the Secure Network Analytics Manager during the registration process; complete any work in progress before you start with the deployment wizard.

Procedure

Step 1 Log in to Security Cloud Control.

Step 2 From the Security Cloud Control menu, navigate **Administration** > **Firewall Management Center** to open the **Services** page.

Step 3 Choose **Cloud-Delivered FMC** and click **Configuration**.

Step 4 Navigate to **Integration** > **Security Analytics & Logging**.

Step 5 In the **Secure Network Analytics Data Store** widget, click **Start**.

Step 6 Enter the hostname or the IP address and port number of the flow collector.

To add more flow collectors, click **+Add another Flow Collector**.

Step 7 If you have configured more than one flow collector, associate the managed devices with different flow collectors:

Note
By default, all the managed devices are assigned to the default flow collector.

a) Click **Assign Devices**.
b) Select the managed devices that you want to assign.
c) From the reassign device drop-down list, choose the flow collector.

If you do not want a managed device to send event data to any of the flow collectors, select that device, and choose **Do not log to flow collector from the reassign device drop-down list.**

You can change the default flow collector by hovering over the intended flow collector and clicking **Set default**.

d) Click **Apply Changes**.
e) Click **Next**.

Step 8 Click **Next**.

Step 9 Deploy the changes to the registered managed devices.

The event data is not logged to the SAL (OnPrem) until the logging policy changes are deployed to the registered Firewall Threat Defense devices.

Note
If you must change any of these configurations, run the wizard again. If you disable the configuration or run he wizard again, all settings except the account credentials are retained.

You can view and work with these remotely stored events in the event viewer and context explorer in the management center, and include them when generating reports. You can also cross-launch from an event in the management center to view related data on your Secure Network Analytics Manager.

For more information, see the online help for the management center.

About SAL (SaaS)

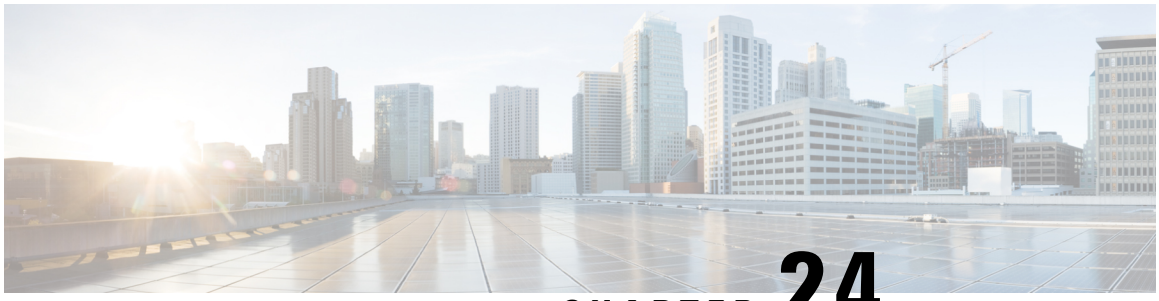
SAL (SaaS) allows you to capture connection, intrusion, file, malware, and Security Intelligence events from all of your threat defense devices and view them in one place in Security Cloud Control. The events are stored in the Cisco cloud and are viewable from the Event Logging page in Security Cloud Control, where you can filter and review them to gain a clear understanding of what security rules are triggering in your network.

With additional licensing, after you capture these events, you can cross-launch from Security Cloud Control to the Secure Cloud Analytics portal provisioned for you. Secure Cloud Analytics is a software as a service (SaaS) solution that tracks the state of your network by performing a behavioral analysis on events and network flow data. By gathering information about your network traffic from sources including firewall events and network flow data, it creates observations about the traffic and automatically identifies roles for network entities based on their traffic patterns. Using this information combined with other sources of threat intelligence, such as Talos, Secure Cloud Analytics generates alerts, which constitute a warning that there is behavior that may be malicious in nature. Along with the alerts, Secure Cloud Analytics provides network and host visibility, and contextual information it has gathered to provide you with a better basis to research the alert and locate sources of malicious behavior.

Licensing for SAL (SaaS)

The SAL (SaaS) licenses allows you to use a Security Cloud Control tenant to view firewall logs and a Cisco Secure Cloud Analytics instance for analytics, without holding separate licenses for either of these products.

For details on the available SAL (SaaS) licensing options, see the Cisco Security Analytics and Logging Ordering Guide.



CHAPTER 24

FTD Dashboard

- About the FTD Dashboard, on page 407
- View the FTD Dashboard, on page 408
- FTD Dashboard Widgets, on page 409
- Modify Time Settings for the FTD Dashboard, on page 412

About the FTD Dashboard

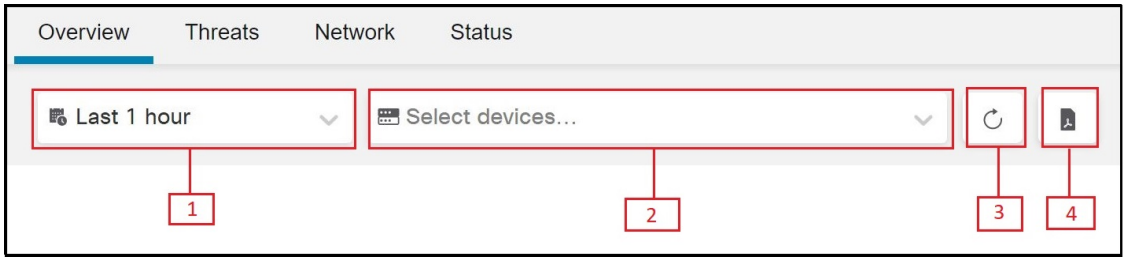
The FTD dashboard provides you an at-a-glance view of the status, including events data collected and generated by all Security Cloud Control-managed Firewall Threat Defense devices.

You can use this dashboard to view collective information that is related to the device status and the overall health of the devices in your deployment. The information that the FTD dashboard provides depends on how you license, configure, and deploy the devices in your system. Although, the FTD dashboard displays data for all Security Cloud Control-managed Firewall Threat Defense devices, you can choose to filter device-based data. You can also choose the time range to display for specific time range.

This dashboard uses tabs to display predefined widgets: small, self-contained components that provide insights into different aspects of the system. For example, the Network Activity widget shows you event graphs that display information about all connection, malware, and intrusion events. The widgets in the dashboard are predefined and cannot be customized. This dashboard is visible to all Security Cloud Control users who have access to a Security Cloud Control tenant.

- The dashboard does not displays any event statistics for historic events.
- Since the aggregation service batch processes the events to aggregate every five minutes, you can expect a five-minute latency between the time the events are aggregated to the time the statistics are displayed.

Figure 70: FTD Dashboard



Number	Description
1	Allows you to change the time range to reflect a period as short as the last hour or as long as the last year. When you change the time range, the widgets automatically update the events data to reflect the new time range.
2	Allows you to filter the events data based on selected devices. If no devices are selected, the widgets display all available events data.
3	Reinitiates the events data query
4	Displays the events data in a PDF output format. You can choose to download or save a copy of this PDF on your local machine.

View the FTD Dashboard

From the Security Cloud Control menu, choose **Monitor** > **Insights & Reports** > **AIOps Insights** > **Firewall Threat Defense** > **Dashboard** to view the **FTD Dashboard**.

By default, the home page for your tenant displays the **Overview** tab.

The dashboard includes widgets that are listed under each tab: Threat, Network, Applications, and Status tab.

The following table lists the widgets available under each tab:

Name of the Tab	Available Widgets
Overview	All available widgets
Threat	• Top Intrusion Rules • Top Intrusion Attackers • Top Intrusion Targets • Top Malware Signatures • Top Malware Senders • Top Malware Receivers • Malware Events by Disposition

Name of the Tab	Available Widgets
Network	• Network Activity • Event Activity • Access Control Actions • Top Access Control Policies • Top Access Control Rules • Top Devices • Top Users • Top Users by Blocked Connections
Status	• Top Devices with Health Alerts • Top Loaded Devices
Applications	• Top Web Applications • Top Client Applications • Blocked Web Applications

FTD Dashboard Widgets

The FTD dashboard displays predefined widgets that can provide you with at-a-glance views of the current system status. These views include:

- Data about the events collected and generated by Firewall Threat Defense devices managed FMC.
- Information about the status and the overall health of the devices in your deployment.

Top Intrusion Rules Widget

The **Top Intrusion Rules** widget displays counts of the intrusion events that have occurred over the specified time range and are organized by priority. These counts include statistics on intrusion events with dropped packets and different impacts. The generated list is scrollable.

Top Intrusion Attackers Widget

The **Top Intrusion Attackers** widget displays counts of intrusion events for the top attacking host IP addresses (causing those events) on your monitored network.

Top Intrusion Targets Widget

The **Top Intrusion Targets** widget displays counts of intrusion events for the top target host IP addresses (targeted in the connections causing those events) on your monitored network.

Top Malware Signatures Widget

The **Top Malware Signatures** widget displays counts of the top malware signatures detected in the network traffic for top file-sending host IP addresses.

Top Malware Senders Widget

The **Top Malware Senders** widget displays counts of the top malware threats that are detected in the network traffic for top file-sending host IP addresses.

Top Malware Receivers Widget

The **Top Malware Receivers** widget displays counts of the top malware threats that are detected in the network traffic for all top file-receiving host IP addresses.

Malware Events by Disposition Widget

The **Malware Events by Disposition** widget displays counts of all disposition of malware events that are generated when the managed device detects a file containing malware.

Network Activity Widget

The **Network Activity** widget displays all ingress and egress data rate that is based on information from the connection events.

Event Activity Widget

The **Event Activity** widget displays counts of events that have occurred in the last hour and the total number of each event type that is available in the database.

Access Control Actions Widget

The **Access Control Actions** widget displays counts of events that are logged based on the allowed or blocked access control actions for each event. If you hover on the pie chart, you can view the percentage of the allowed and blocked actions.

Top Access Control Policies Widget

The **Top Access Control Policies** widget displays counts of top access control policies generating events.

Top Access Control Rules Widget

The **Top Access Control Rules** widget displays the top five counts of the access control rules that are used for each event. These counts can be sorted by bytes or events.

Top Devices Widget

The **Top Devices** widget displays counts of events per devices. These count can be sorted by bytes or events.

Top Users Widget

The **Top Users** widget displays a list of users on your monitored network that are associated with the highest intrusion event counts. It draws data primarily from the intrusion detection (IDS) User Statistics and Intrusion Events tables. It displays authoritative user data.

Top Users by Blocked Connections Widget

The **Top Users by Blocked Connections** widget displays users who have the highest number of blocked connection events associated with them in your monitored network.

Top Devices with Health Alerts Widget

The **Top Devices with Health Alerts** widget displays the current compiled health status for Security Cloud Control-managed Firewall Threat Defense devices.

Top Loaded Devices Widget

The **Top Loaded Devices** widget displays a list of Secure Firewall Threat Defense devices along with the CPU usage information.

Top Web Applications Widget

The **Top Web Applications** widget displays the web applications that are associated with the highest number of connection events in your monitored network. You can sort this list based on bytes or event count.

Top Client Applications Widget

The **Top Client Applications** widget displays the most used client applications in your monitored network. You can sort this list based on bytes or event count.

Top Blocked Web Applications Widget

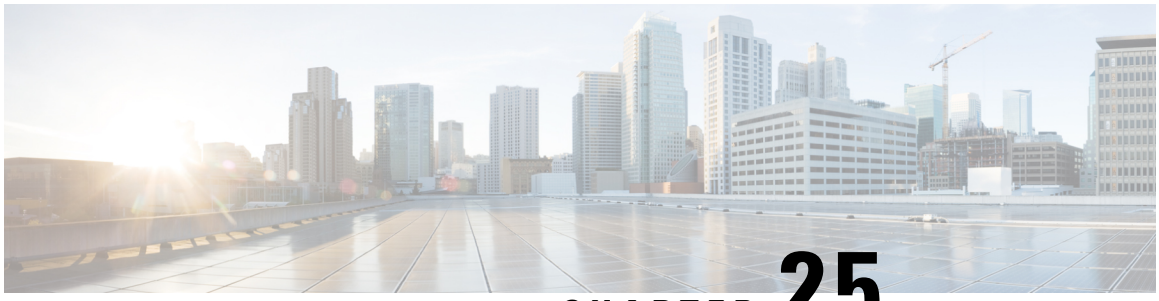
The **Top Web Applications** widget displays the top web applications that are associated with blocked connection events and the count of blocked connection events in your monitored network.

Modify Time Settings for the FTD Dashboard

You can change the time range to reflect a period as short as the last hour (the default) or as long as the last year. When you change the time range, the widgets that can be constrained by time automatically update to reflect the new time range.

The maximum number of data points in any graph is 300, and the time setting determines how much time is summarized within each data point. Following is the number of data points, and the time span covered, in the FTD dashboard for each time range:

- 1 hour = 12 data points, 5 minutes each
- 6 hours = 72 data points, 5 minutes each
- 1 day = 288 data points, 5 minutes each
- 1 week = 300 data points, 33.6 minutes each
- 2 weeks = 300 data points, 67.2 minutes each
- 30 days = 300 data points, 144 minutes each
- 90 days = 300 data points, 432 minutes each
- 180 days = 300 data points, 864 minutes each
- 1 year = 300 data points, 1752 minutes each



CHAPTER 25

Connection Logging

The following topics describe how to configure the system to log connections made by hosts on your monitored network:

- About Connection Logging, on page 413
- Limitations of Connection Logging, on page 420
- Best Practices for Connection Logging, on page 420
- Requirements and Prerequisites for Connection Logging, on page 422
- Configure Connection Logging, on page 422

About Connection Logging

The system can generate logs of the connections its managed devices detect. These logs are called *connection events*. Settings in rules and policies give you granular control over which connections you log, when you log them, and where you store the data. Special connection events, called *security-related connection events*, represent connections that were blocked by the reputation-based Security Intelligence feature.

Connection events contain data about the detected sessions. The information available for any individual connection event depends on several factors, but in general includes:

- Basic connection properties: timestamp, source and destination IP address, ingress and egress zones, the device that handled the connection, and so on
- Additional connection properties discovered or inferred by the system: applications, requested URLs, or users associated with the connection, and so on
- Metadata about why the connection was logged: which configuration handled the traffic, whether the connection was allowed or blocked, details about encrypted and decrypted connections, and so on

Log connections according to the security and compliance needs of your organization. When setting up connection logging, keep in mind that the system can log a connection for multiple reasons, and that disabling logging in one place does not mean that matching connections will not be logged.

The information in a connection event depends on several factors, including traffic characteristics, the configuration that ultimately handled the connection, and so on.

Note You can supplement the connection logs gathered by your managed devices with connection data generated from exported NetFlow records. This is especially useful if you have NetFlow-enabled routers or other devices deployed on networks that your managed devices cannot monitor.

Connections That Are Always Logged

Unless you disable connection event storage, the system automatically saves the following end-of-connection events to the Firewall Management Center database, regardless of any other logging configurations.

Connections Associated with Intrusions

The system automatically logs connections associated with intrusion events, unless the connection is handled by the access control policy's default action.

When an intrusion policy associated with the access control default action generates an intrusion event, the system does *not* automatically log the end of the associated connection. Instead, you must explicitly enable default action connection logging. This is useful for intrusion prevention-only deployments where you do not want to log any connection data.

However, if you enable beginning-of-connection logging for the default action, the system *does* log the end of the connection when an associated intrusion policy triggers, in addition to logging the beginning of the connection.

Connections Associated with File and Malware Events

The system automatically logs connections associated with file and malware events.

Note File events generated by inspecting NetBIOS-SSN (SMB) traffic do not immediately generate connection events because the client and server establish a persistent connection. The system generates connection events after the client or server ends the session.

Connections Associated with Intelligent Application Bypass

The system automatically logs bypassed and would-have-bypassed connections associated with IAB.

Monitored Connections

The system always logs the ends of connections for monitored traffic, even if the traffic matches no other rules and you do not enable default action logging. For more information, see Logging for Monitored Connections, on page 416.

Other Connections You Can Log

So that you log only critical connections, enable connection logging on a per-rule basis. If you enable connection logging for a rule, the system logs all connections handled by that rule.

You can also log connections handled by policy default actions. Depending on the rule or default action (and for access control, a rule's inspection configuration), your logging options differ.

Prefilter Policy: Rules and Default Action

You can log connections (including entire plaintext, passthrough tunnels) that you fastpath or block with a prefilter policy.

Prefiltering uses outer-header criteria to handle traffic. For tunnels that you log, the resulting connection events contain information from the outer, encapsulation headers.

For traffic subject to further analysis, logging in the prefilter policy is disabled, although matching connections may still be logged by other configurations. The system performs all further analysis using inner headers, that is, the system independently handles and logs each connection within an allowed tunnel.

Decryption Policy: Rules and Default Action

You can log connections that match a decryption rule or decryption policy default action.

For blocked connections, the system immediately ends the session and generates an event. For monitored connections and connections that you pass to access control rules, the system generates an event when the session ends.

Access Control Policy: Security Intelligence Decisions

You can log a connection whenever it is blocked by the reputation-based Security Intelligence feature.

Optionally, and recommended in passive deployments, you can use a monitor-only setting for Security Intelligence filtering. This allows the system to further analyze connections that would have been blocked by Security Intelligence, but still log the match. Security Intelligence monitoring also allows you to create traffic profiles using Security Intelligence information.

When the system logs a connection event as the result of Security Intelligence filtering, it also logs a matching Security Intelligence event, which is a special kind of connection event that you can view and analyze separately, and that is also stored and pruned separately. So that you can identify the matching IP address in the connection, host icons beside blocked and monitored IP addresses look slightly different in the tables on the pages under the **Analysis** > **Connections** > **Events** menus.

Access Control Policy: Rules and Default Action

You can log connections that match an access control rule or access control policy default action.

Related Topics

How Rules and Policy Actions Affect Logging, on page 415

How Rules and Policy Actions Affect Logging

Connection events contain metadata about why the connection was logged, including which configurations handled the traffic. Where you can configure connection logging, rule actions, and policy default actions determine not only how the system inspects and handles matching traffic, but also when and how you can log details about matching traffic.

Related Topics

Connection and Security-Related Connection Event Fields

Logging for Fastpathed Connections

You can log fastpathed connections and non-encrypted tunnels, which includes traffic matching the following rules and actions in the prefilter policy:

- Tunnel rules—**Fastpath** action (logs the outer session)
- Prefilter rules—**Fastpath** action

Fastpathed traffic bypasses the rest of access control and QoS, so connection events for fastpathed connections contain limited information.

Logging for Monitored Connections

The system always logs the ends of connections for traffic matching the following configurations, even if the traffic matches no other rules and you do not enable default action logging:

- Security Intelligence—Block lists set to monitor (also generates a Security Intelligence event)
- SSL rules—**Monitor** action
- Access control rules—**Monitor** action

The system does not generate a separate event each time a single connection matches a Monitor rule. Because a single connection can match multiple Monitor rules, each connection event can include and display information on the first eight Monitor access control rules that the connection matches, as well as the first matching SSL Monitor rule.

Similarly, if you send connection events to an external syslog or SNMP trap server, the system does not send a separate alert each time a single connection matches a Monitor rule. Rather, the alert that the system sends at the end of the connection contains information on the Monitor rules the connection matched.

Logging for Trusted Connections

You can log the beginnings and ends of trusted connections, which includes traffic matching the following rules and actions:

- Access control rules—**Trust** action
- Access control default action—**Trust All Traffic**

Note Although you *can* log trusted connections, we recommend you do not do so because trusted connections are not subject to deep inspection or discovery, so connection events for trusted connections contain limited information.

TCP connections detected by a Trust rule on the first packet generate only an end-of-connection event. The system generates the event one hour after the final session packet.

Logging for Blocked Connections

You can log blocked connections, which includes traffic matching the following rules and actions:

- Tunnel rules—**Block**

- Prefilter rules—**Block**
- Prefilter default action—**Block all tunnel traffic**
- Security Intelligence—Block lists not set to Monitor (also generates a Security Intelligence event)
- Decryption rules—**Block** and **Block with reset**
- SSL default action—**Block** and **Block with reset**
- Access control rules—**Block**, **Block with reset**, and **Interactive Block**
- Access control default action—**Block All Traffic**

Only devices deployed inline (that is, using routed, switched, or transparent interfaces, or inline interface pairs) can block traffic. Because blocked connections are not actually blocked in passive deployments, the system may report multiple beginning-of-connection events for each blocked connection.

Caution Firewall Threat Defense device logs end-of-connection events for TCP connections where the three-way handshake does not complete, including SYN-only, SYN-SYN/ACK (no ACK), and SYN-RST/ACK scenarios (except when TLS Identity is enabled). These logs provide visibility into incomplete or suspicious connection attempts. However, logging blocked TCP connections during a Denial of Service (DoS) attack can affect system performance and overwhelm the database with multiple similar events. Before you enable logging for a Block rule, consider whether the rule monitors traffic on an Internet-facing interface or other interface vulnerable to DoS attack.

Beginning vs End-of-Connection Logging for Blocked Connections

When you log a blocked connection, how the system logs it depends on why the connection was blocked; this is important to keep in mind when configuring correlation rules based on connection logs:

- For decryption rules and decryption policy default actions that block encrypted traffic, the system logs **end**-of-connection events. This is because the system cannot determine if a connection is encrypted using the first packet in the session.
- For other blocking actions, the system logs **beginning**-of-connection events. Matching traffic is denied without further inspection.

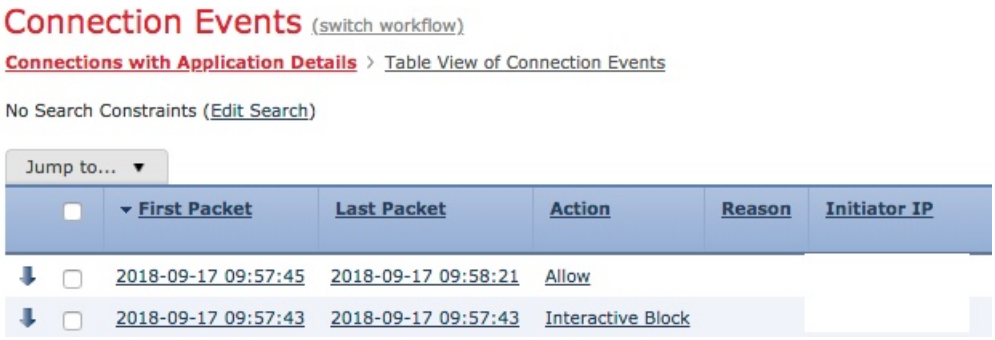
Logging Bypassed Interactive Blocks

Interactive blocking access control rules, which cause the system to display a warning page when a user browses to a prohibited website, allow you to configure end-of-connection logging. This is because if the user clicks through the warning page, the connection is considered a new, allowed connection which the system can monitor and log.

Therefore, for packets that match an Interactive Block or Interactive Block with Reset rule, the system can generate the following connection events:

- A beginning-of-connection event when a user's request is initially blocked and the warning page is displayed; this event has an associated action of `Interactive Block` or `Interactive Block with Reset`
- Multiple beginning- or end-of-connection events if the user clicks through the warning page and loads the originally requested page; these events have an associated action of `Allow` and a reason of `User Bypass`

The following figure shows an example of an interactive block followed by allow.



Logging for Allowed Connections

You can log allowed connections, which includes traffic matching the following rules and actions:

- SSL rules—**Decrypt** action
- SSL rules—**Do not decrypt** action
- SSL default action—**Do not decrypt**
- Access control rules—**Allow** action
- Access control default action—**Network Discovery Only** and any intrusion prevention option

Enabling logging for these configurations ensures the connection is logged, while also permitting (or specifying) the next phase of inspection and traffic handling. SSL logging is always end-of-connection; access control configurations also allow beginning-of-connection logging.

Although the **Analyze** action in tunnel and prefilter rules also allows connections to continue with access control, logging is disabled for rules with this action. Matching connections may still be logged by other configurations. Allowed tunnels might have their encapsulated sessions evaluated and logged individually.

When you allow traffic with an access control rule or default action, you can use an associated intrusion policy to further inspect traffic and block intrusions. For access control rules, you can also use a file policy to detect and block prohibited files, including malware. Unless you disable connection event storage, the system automatically logs most allowed connections associated with intrusion, file, and malware events. For detailed information, see Connections That Are Always Logged, on page 414.

Connections with encrypted payloads are not subject to deep inspection, so connection events for encrypted connections contain limited information.

File and Malware Event Logging for Allowed Connections

When a file policy detects or blocks a file, it logs one of the following events to the Firewall Management Center database:

- *File events*, which represent detected or blocked files, including malware files.
- *Malware events*, which represent detected or blocked malware files only.
- *Retrospective malware events*, which are generated when the malware disposition for a previously detected file changes.

You can disable this logging on a per-access-control-rule basis. You can also disable file and malware event storage entirely.

Note We recommend you leave file and malware event logging enabled.

Beginning vs End-of-Connection Logging

You can log a connection at its beginning or its end, with the following exceptions for blocked traffic:

- Blocked traffic—Because blocked traffic is immediately denied without further inspection, usually you can log only beginning-of-connection events for blocked traffic. There is no unique end of connection to log.
- Blocked encrypted traffic—When you enable connection logging in a decryption policy, the system logs end-of-connection rather than beginning-of-connection events. This is because the system cannot determine if a connection is encrypted using the first packet in the session, and thus cannot immediately block encrypted sessions.

To optimize performance, log either the beginning or the end of any connection, but not both. Monitoring a connection for any reason forces end-of-connection logging. For a single non-blocked connection, the end-of-connection event contains all of the information in the beginning-of-connection event, as well as information gathered over the duration of the session.

The following table details the differences between beginning and end-of-connection events, including the advantages to logging each.

Table 31: Comparing Beginning and End-of-Connection Events

	Beginning-of-Connection Events	**End-of-Connection Events**
Can be generated...	When the system detects the beginning of a connection (or, after the first few packets if event generation depends on application or URL identification).	When the system: • Detects the close of a connection. • Does not detect the end of a connection after a period of time. • Can no longer track the session due to memory constraints.
Can be logged for...	All connections except those blocked by the decryption policy.	Most connections.

	Beginning-of-Connection Events	End-of-Connection Events
Contain...	Only information that can be determined in the first packet (or the first few packets, if event generation depends on application or URL identification).	All information in the beginning-of-connection event, plus information determined by examining traffic over the duration of the session; for example, the total amount of data transmitted or the timestamp of the last packet in the connection. **Note** The connection event does not count the amount of data transmitted after the threat defense returns a snort verdict for the connection or if you fastpath the connection.
Are useful...	If you want to log: • Blocked connections. • Only the beginning of a connection because the end-of-connection information does not matter to you.	If you want to: • Log encrypted connections handled by a decryption policy. • Perform any kind of detailed analysis on, or trigger correlation rules using, information collected over the duration of the session. • View connection summaries (aggregated connection data) in custom workflows, view connection data in graphical format, or create and use traffic profiles.

Limitations of Connection Logging

You cannot log:

- The outer session of a plaintext, passthrough tunnel whose encapsulated connections are inspected by access control.
- TCP connections if the three-way handshake is not completed, to avoid denial-of-service attacks against your firewalls. To monitor or debug failed connections, you can use the packet capture feature (Packet Capture Overview, on page 322).

Best Practices for Connection Logging

Use the following best practices to ensure that you log *only* the connections you want to log.

So that you log only critical connections, enable connection logging on a per-access-control-rule basis.

Connections that are always logged

The system automatically logs the following:

- Some connections associated with detected files, malware, intrusions, and Intelligent Application Bypass (IAB).

  For more information, see Connections That Are Always Logged, on page 414.

- Monitored connections.

  For more information, see Logging for Monitored Connections, on page 416.

Connections to never log

Do not enable logging for the following:

- Access control rules with a Trust action.

  Trusted connections are not subject to deep inspection or discovery, so connection events for trusted connections contain limited information.

- Do not enable logging for Block rules in passive deployments. To log connections that the system *would have blocked* if your devices were deployed inline, use a Monitor rule instead of a Block rule.

  Only devices deployed inline (that is, using routed, switched, or transparent interfaces, or inline interface pairs) can block traffic. Because blocked connections are not actually blocked in passive deployments, the system may report multiple beginning-of-connection events for each blocked connection.

- Traffic you're not interested in. Examples follow:

  - Specific allowed traffic, such as DNS requests to a trusted DNS host.
  - Infrastructure traffic that is not related to your service offering.

  (As previously mentioned, you can still monitor this traffic for threats.)

As discussed in Connections That Are Always Logged, on page 414, even if you disable logging for the preceding, intrusion events, malware, and IAB are still logged.

Avoid logging what's being logged elsewhere

If another device or service is logging connection data for a network segment, disable logging for that segment's data in the Firewall Management Center. Examples follow:

- If a router logs connection events on the same network segment as the Firewall Management Center, avoid logging the same connections on the Firewall Management Center unless you need those connection events for something else, such as correlation policies or traffic profiles.
- If you use Secure Network Analytics to leverage NetFlow records reported from switches and routers to identify potential behavioral anomalies and suspicious traffic patterns, you can disable connection logging for rules monitoring those segments and instead rely on Secure Network Analytics for behavioral analytics for those parts of your network.

  For more information, consult the Secure Network Analytics documentation.

Log either the beginning or end of the connection (not both)

If you have a choice between beginning and end-of-connection logging, enable end-of-connection logging. This is because end-of-connection logs information from beginning-of-connection events, as well as information gathered over the duration of the session.

Log the beginning of connections *only* if you want to log blocked connections, or if end-of-connection information does not matter to you.

For more information, see Beginning vs End-of-Connection Logging, on page 419.

Logging for blocked traffic

Because blocked traffic is immediately denied without further inspection, usually you can log only beginning-of-connection events.

For more information, see Logging for Blocked Connections, on page 416.

Log events to an external location

If your company's security policy permits it, you can save disk space on your Firewall Management Center by streaming logs to an external source using any of the following:

- eStreamer, which enables you to stream logs from a Firewall Management Center to a custom-developed client application. For more information, see the *Secure Firewall Management Center Event Streamer Integration Guide* .
- Syslog or SNMP trap, which are referred to as *alert responses*. For more information, see Secure Firewall Management Center Alert Responses, on page 371.

Control what is displayed in connection events

To specify the number of rows displayed in connection events, click your username in the upper right of the Firewall Management Center, click **User Preferences**, and then click the **Event View Settings**tab. The maximum you can set is 1000 events per page.

Requirements and Prerequisites for Connection Logging

Configure Connection Logging

The following sections describe how to set up connection logging to match various rules and conditions.

Logging Connections with Tunnel and Prefilter Rules

The prefilter policy applies to Secure Firewall Threat Defense devices only.

Before you begin

- Set the rule action to **Block** or **Fastpath**. Logging is disabled for the **Analyze** action, which allows connections to continue with access control, where other configurations determine their handling and logging.
- Logging is performed on inner flows, not on the encapsulating flow.

Procedure

Step 1 In the prefilter policy editor, click **Edit** ( ) next to the rule where you want to configure logging.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Click **Logging**.

Step 3 Specify whether you want to **Log at Beginning of Connection** or **Log at End of Connection**.

To optimize performance, log either the beginning or the end of any connection, but not both. Because blocked traffic is immediately denied without further inspection, you cannot log end-of-connection events for Block rules.

Step 4 Specify where to send connection events:

Step 5 Click **Save** to save the rule.

Step 6 Click **Save** to save the prefilter policy.

What to do next

- Deploy configuration changes.

Logging Decryptable Connections with TLS/SSLDecryption Rules

Procedure

Step 1 In the decryption policy editor, click **Edit** ( ) next to the rule where you want to configure logging.

If **View** ( ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Click **Logging**.

Step 3 Check the **Log at End of Connection** check box.

For monitored traffic, end-of-connection logging is required.

Step 4 Specify where to send connection events.

Send events to the event viewer if you want to perform Firewall Management Center-based analysis on these connection events. For monitored traffic, this is required.

Step 5 Click **Save** to save the rule.

Step 6 Click **Save** to save the decryption policy.

What to do next

- Deploy configuration changes.

Logging Connections with Security Intelligence

The Security Intelligence policy requires the Threat Smart License or Protection Classic License.

Procedure

Step 1 In the access control policy editor, click **Security Intelligence**.

Step 2 Click the **Logging** ( ) icon to enable Security Intelligence logging using the following criteria:

- By IP address—Click the logging icon next to **Networks**.
- By URL—Click the logging icon next to **URLs**.
- By Domain Name—Click the logging icon next to the **DNS Policy** drop-down list.

If the logging icon is disabled, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 3 Check the **Log Connections** check box.

Step 4 Specify where to send connection and Security-Related connection events.

Send events to the Security Cloud Control if you want to perform Security Cloud Control-based analysis, or if you set a Block list to monitor-only.

Step 5 Click **OK** to set logging options.

Step 6 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

Logging Connections with Access Control Rules

Depending on your choices for the rule action and deep inspection options, your logging options differ; see How Rules and Policy Actions Affect Logging, on page 415.

Procedure

Step 1 In the access control policy editor, click **Edit** ( ) next to the rule where you want to configure logging.

If **View** ( ) appears instead, the configuration is inherited from an ancestor policy, belongs to an ancestor domain, or you do not have permission to modify the configuration.

Step 2 Click **Logging**.

Step 3 Specify whether you want to **Log at Beginning of Connection** or **Log at End of Connection**.

To optimize performance, log either the beginning or the end of any connection, but not both.

Step 4 (Optional) Check the **Log Files** check box to log file and malware events associated with the connection.

It is recommended to leave this option enabled.

Step 5 Specify where to send the connection events:

- **Event Viewers**: Send events to the Firewall Management Center. When using cloud management, send events to the cloud-delivered Firewall Management Center and to an on-premises Firewall Management Center if you have configured it to perform event analytics only. You can view the events in the event viewer of either product.
- **Syslog Server**: Send connection events to the syslog server configured in the Logging tab in Access Control Policy, unless overridden.

  Show Overrides: Displays the options to override the settings configured in the access control policy.

  - **Override Severity**: When you choose this option and select a severity for the rule, connection events for this rule will have the selected severity regardless of the severity configured in the Logging tab in Access Control Policy.
  - **Override Default Syslog Destination**: Send the syslog generated for the connection event for this rule to destination specified in this alert.

- **SNMP Trap**: Connection events are sent to the selected SNMP trap.

Step 6 Click **Confirm**.

Step 7 Click **Apply** to save the rule.

What to do next

- Deploy configuration changes.

Logging Connections with a Policy Default Action

A policy's default action determines how the system handles traffic that matches none of the rules in the policy (except Monitor rules in access control and decryption policies, which match and log—but do not handle or inspect—traffic).

Logging settings for the decryption policies default action also govern how the system logs undecryptable sessions.

Before you begin

- For prefilter default action logging, set the default action to **Block all tunnel traffic**. Logging is disabled for the **Allow all tunnel traffic** action, which allows connections to continue with access control, where other configurations determine their handling and logging.

Procedure

Step 1 In the policy editor, click the **Default Logging and Inspection** ⚙ next to the **Default Action** drop-down list.

Step 2 Specify when you want to log matching connections:

- Log at Beginning of Connection—Not supported for SSL default actions.
- Log at End of Connection—Not supported if you choose the access control **Block All Traffic** default action or the prefilter **Block all tunnel traffic** default action.

To optimize performance, log either the beginning or the end of any connection, but not both.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration. In an access control policy, the configuration may also be inherited from an ancestor policy.

Step 3 Specify where to send connection events.

Send events to the event viewer if you want to perform Firewall Management Center-based analysis on these connection events.

Step 4 Click **Apply**.

Step 5 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

Limiting Logging of Long URLs

End-of-connection events for HTTP traffic record the URL requested by monitored hosts. Disabling or limiting the number of stored URL characters may improve system performance. Disabling URL logging (storing zero characters) does not affect URL filtering. The system filters traffic based on requested URLs even though the system does not record them.

Procedure

Step 1 In the access control policy editor, click **More** > **Advanced Settings**, then click **Edit** (✎) next to **General Settings**.

If **View** (👁) appears instead, the configuration is inherited from an ancestor policy, belongs to an ancestor domain, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Step 2 Enter the **Maximum URL characters to store in connection events**.

Step 3 Click **OK**.

Step 4 Click **Save** to save the policy.

What to do next

- Deploy configuration changes.

CHAPTER 26

Transparent or Routed Firewall Mode

This chapter describes how to set the firewall mode to routed or transparent, as well as how the firewall works in each firewall mode.

Note The firewall mode only affects regular firewall interfaces, and not IPS-only interfaces such as inline sets or passive interfaces. IPS-only interfaces can be used in both firewall modes. See Inline Sets and Passive Interfaces, on page 985 for more information about IPS-only interfaces. Inline sets might be familiar to you as "transparent inline sets," but the inline interface type is unrelated to the transparent firewall mode described in this chapter or the firewall-type interfaces.

Caution

- Use FTD CLI commands to set "Firewall Mode."

- About the Firewall Mode, on page 431
- Default Settings, on page 439
- Guidelines for Firewall Mode, on page 439
- Set the Firewall Mode, on page 440

About the Firewall Mode

The Firewall Threat Defense supports two firewall modes for regular firewall interfaces: Routed Firewall mode and Transparent Firewall mode.

About Routed Firewall Mode

In routed mode, the Firewall Threat Defense device is considered to be a router hop in the network. Each interface that you want to route between is on a different subnet.

With Integrated Routing and Bridging, you can use a "bridge group" where you group together multiple interfaces on a network, and the Firewall Threat Defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. The Firewall Threat Defense device routes between BVIs and regular routed interfaces. If you do not need clustering or EtherChannel member interfaces, you might consider using routed

mode instead of transparent mode. In routed mode, you can have one or more isolated bridge groups like in transparent mode, but also have normal routed interfaces as well for a mixed deployment.

About Transparent Firewall Mode

Traditionally, a firewall is a routed hop and acts as a default gateway for hosts that connect to one of its screened subnets. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices. However, like any other firewall, access control between interfaces is controlled, and all of the usual firewall checks are in place.

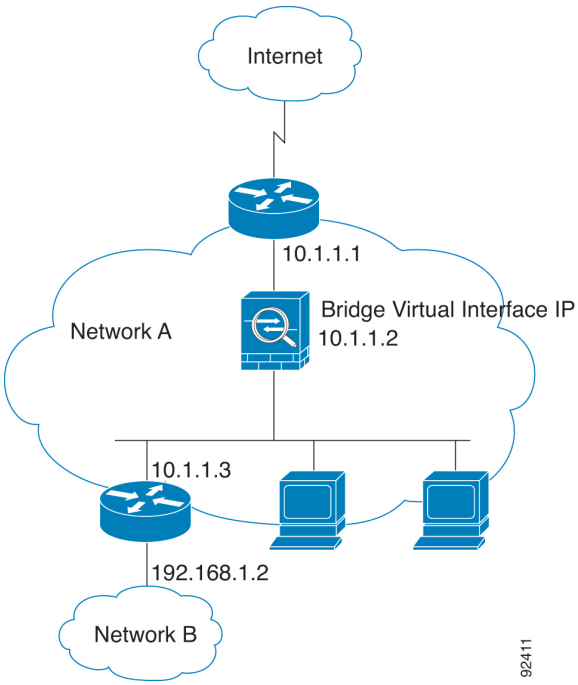
Layer 2 connectivity is achieved by using a "bridge group" where you group together the inside and outside interfaces for a network, and the Firewall Threat Defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. You can have multiple bridge groups for multiple networks. In transparent mode, these bridge groups cannot communicate with each other.

Using the Transparent Firewall in Your Network

The Firewall Threat Defense device connects the same network between its interfaces. Because the firewall is not a routed hop, you can easily introduce a transparent firewall into an existing network.

The following figure shows a typical transparent firewall network where the outside devices are on the same subnet as the inside devices. The inside router and hosts appear to be directly connected to the outside router.

Figure 71: Transparent Firewall Network



Passing Traffic For Routed-Mode Features

For features that are not directly supported on the transparent firewall, you can allow traffic to pass through so that upstream and downstream routers can support the functionality. For example, by using an access rule,

you can allow DHCP traffic (instead of the unsupported DHCP relay feature) or multicast traffic such as that created by IP/TV. You can also establish routing protocol adjacencies through a transparent firewall; you can allow OSPF, RIP, EIGRP, or BGP traffic through based on an access rule. Likewise, protocols like HSRP or VRRP can pass through the Firewall Threat Defense device.

About Bridge Groups

A bridge group is a group of interfaces that the Firewall Threat Defense device bridges instead of routes. Bridge groups are supported in both transparent and routed firewall mode. Like any other firewall interfaces, access control between interfaces is controlled, and all of the usual firewall checks are in place.

Bridge Virtual Interface (BVI)

Each bridge group includes a Bridge Virtual Interface (BVI). The Firewall Threat Defense device uses the BVI IP address as the source address for packets originating from the bridge group. The BVI IP address must be on the same subnet as the bridge group member interfaces. The BVI does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.

In transparent mode: Only bridge group member interfaces are named and can be used with interface-based features.

In routed mode: The BVI acts as the gateway between the bridge group and other routed interfaces. To route between bridge groups/routed interfaces, you must name the BVI. For some interface-based features, you can use the BVI itself:

- DHCPv4 server—Only the BVI supports the DHCPv4 server configuration.
- Static routes—You can configure static routes for the BVI; you cannot configure static routes for the member interfaces.
- Syslog server and other traffic sourced from the Firewall Threat Defense device—When specifying a syslog server (or SNMP server, or other service where the traffic is sourced from the Firewall Threat Defense device), you can specify either the BVI or a member interface.

If you do not name the BVI in routed mode, then the Firewall Threat Defense device does not route bridge group traffic. This configuration replicates transparent firewall mode for the bridge group. If you do not need clustering or EtherChannel member interfaces, you might consider using routed mode instead. In routed mode, you can have one or more isolated bridge groups like in transparent mode, but also have normal routed interfaces as well for a mixed deployment.

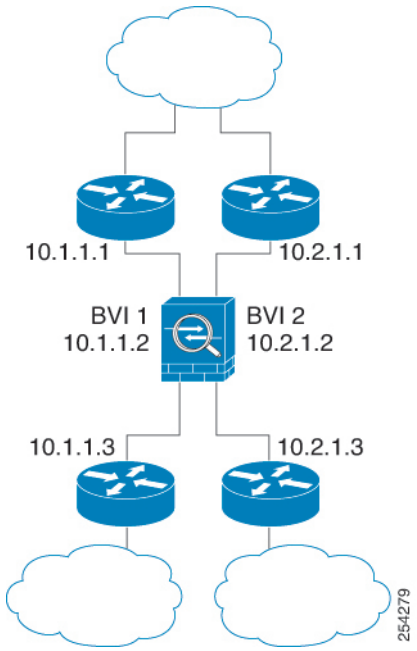
Bridge Groups in Transparent Firewall Mode

Bridge group traffic is isolated from other bridge groups; traffic is not routed to another bridge group within the Firewall Threat Defense device, and traffic must exit the Firewall Threat Defense device before it is routed by an external router back to another bridge group in the Firewall Threat Defense device. Although the bridging functions are separate for each bridge group, many other functions are shared between all bridge groups. For example, all bridge groups share a syslog server or AAA server configuration.

You can include multiple interfaces per bridge group. See Guidelines for Firewall Mode, on page 439 for the exact number of bridge groups and interfaces supported. If you use more than 2 interfaces per bridge group, you can control communication between multiple segments on the same network, and not just between inside and outside. For example, if you have three inside segments that you do not want to communicate with each other, you can put each segment on a separate interface, and only allow them to communicate with the outside interface. Or you can customize the access rules between interfaces to allow only as much access as desired.

The following figure shows two networks connected to the Firewall Threat Defense device, which has two bridge groups.

Figure 72: Transparent Firewall Network with Two Bridge Groups

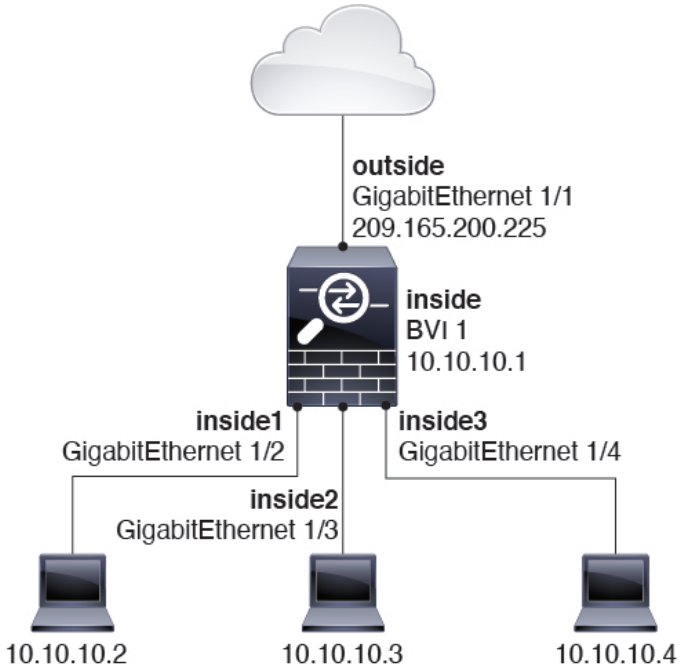


Bridge Groups in Routed Firewall Mode

Bridge group traffic can be routed to other bridge groups or routed interfaces. You can choose to isolate bridge group traffic by not assigning a name to the BVI interface for the bridge group. If you name the BVI, then the BVI participates in routing like any other regular interface.

One use for a bridge group in routed mode is to use extra interfaces on the Firewall Threat Defense instead of an external switch. For example, the default configuration for some devices include an outside interface as a regular interface, and then all other interfaces assigned to the inside bridge group. Because the purpose of this bridge group is to replace an external switch, you need to configure an access policy so all bridge group interfaces can freely communicate.

Figure 73: Routed Firewall Network with an Inside Bridge Group and an Outside Routed Interface



Allowing Layer 3 Traffic

- Unicast IPv4 and IPv6 traffic requires an access rule to be allowed through the bridge group.
- ARPs are allowed through the bridge group in both directions without an access rule. ARP traffic can be controlled by ARP inspection.
- IPv6 neighbor discovery and router solicitation packets can be passed using access rules.
- Broadcast and multicast traffic can be passed using access rules.

Allowed MAC Addresses

The following destination MAC addresses are allowed through the bridge group if allowed by your access policy (see Allowing Layer 3 Traffic, on page 435). Any MAC address not on this list is dropped.

- TRUE broadcast destination MAC address equal to FFFF.FFFF.FFFF
- IPv4 multicast MAC addresses from 0100.5E00.0000 to 0100.5EFE.FFFF
- IPv6 multicast MAC addresses from 3333.0000.0000 to 3333.FFFF.FFFF
- BPDU multicast address equal to 0100.0CCC.CCCD

BPDU Handling

To prevent loops using the Spanning Tree Protocol, BPDUs are passed by default.

By default BPDUs are also forwarded for advanced inspection, which is unnecessary for this type of packet, and which can cause problems if they are blocked due to an inspection restart, for example. We recommend

that you always exempt BPDUs from advanced inspection. To do so, use FlexConfig to configure an EtherType ACL that trusts BPDUs and exempts them from advanced inspection on each member interface. See FlexConfig Policies, on page 2645.

The FlexConfig object should deploy the following commands, where you replace <if-name> with an interface name. Add as many access-group commands as needed to cover each bridge group member interface on the device. You can also choose a different name for the ACL.

```
access-list permit-bpdu ethertype trust bpdu
access-group permit-bpdu in interface <if-name>
```

MAC Address vs. Route Lookups

For traffic within a bridge group, the outgoing interface of a packet is determined by performing a destination MAC address lookup instead of a route lookup.

Route lookups, however, are necessary for the following situations:

- Traffic originating on the Firewall Threat Defense device—Add a default/static route on the Firewall Threat Defense device for traffic destined for a remote network where a syslog server, for example, is located.
- Voice over IP (VoIP) and TFTP traffic, and the endpoint is at least one hop away—Add a static route on the Firewall Threat Defense device for traffic destined for the remote endpoint so that secondary connections are successful. The Firewall Threat Defense device creates a temporary "pinhole" in the access control policy to allow the secondary connection; and because the connection might use a different set of IP addresses than the primary connection, the Firewall Threat Defense device needs to perform a route lookup to install the pinhole on the correct interface.

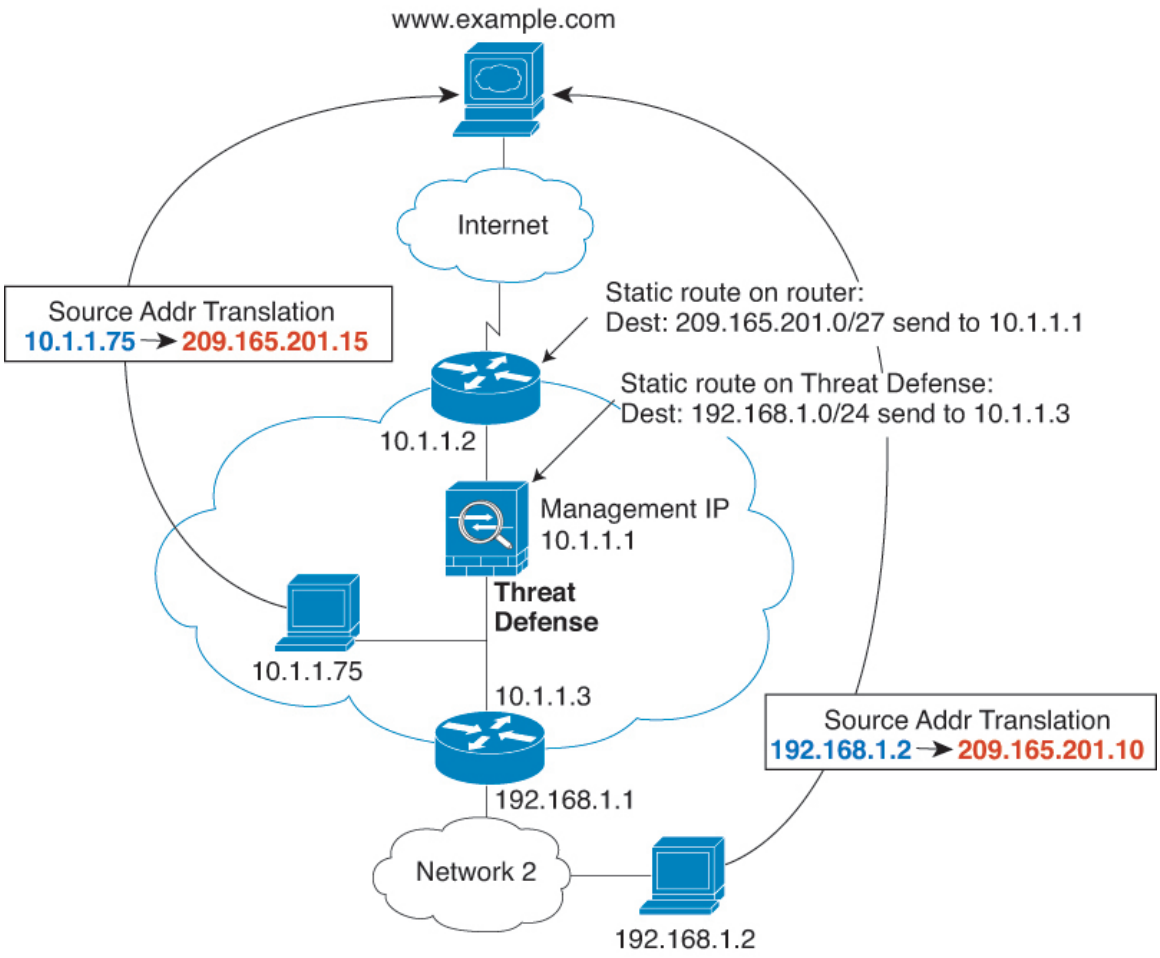
  Affected applications include:

  - H.323
  - RTSP
  - SIP
  - Skinny (SCCP)
  - SQL*Net
  - SunRPC
  - TFTP

- Traffic at least one hop away for which the Firewall Threat Defense device performs NAT—Configure a static route on the Firewall Threat Defense device for traffic destined for the remote network. You also need a static route on the upstream router for traffic destined for the mapped addresses to be sent to the Firewall Threat Defense device.

  This routing requirement is also true for embedded IP addresses for VoIP and DNS with NAT enabled, and the embedded IP addresses are at least one hop away. The Firewall Threat Defense device needs to identify the correct egress interface so it can perform the translation.

Figure 74: NAT Example: NAT within a Bridge Group



Unsupported Features for Bridge Groups in Transparent Mode

The following table lists the features are not supported in bridge groups in transparent mode.

Table 32: Unsupported Features in Transparent Mode

Feature	Description
Dynamic DNS	—
DHCPv6 stateless server	Only the DHCPv4 server is supported on bridge group member interfaces.
DHCP relay	The transparent firewall can act as a DHCPv4 server, but it does not support DHCP relay. DHCP relay is not required because you can allow DHCP traffic to pass through using two access rules: one that allows DCHP requests from the inside interface to the outside, and one that allows the replies from the server in the other direction.

Feature	Description
Dynamic routing protocols	You can, however, add static routes for traffic originating on the Firewall Threat Defense device for bridge group member interfaces. You can also allow dynamic routing protocols through the Firewall Threat Defense device using an access rule.
Multicast IP routing	You can allow multicast traffic through the Firewall Threat Defense device by allowing it in an access rule.
QoS	—
VPN termination for through traffic	The transparent firewall supports site-to-site VPN tunnels for management connections only on bridge group member interfaces. It does not terminate VPN connections for traffic through the Firewall Threat Defense device. You can pass VPN traffic through the Firewall Threat Defense device using an access rule, but it does not terminate non-management connections.

Unsupported Features for Bridge Groups in Routed Mode

The following table lists the features are not supported in bridge groups in routed mode.

Table 33: Unsupported Features in Routed Mode

Feature	Description
EtherChannel member interfaces	Only physical interfaces, redundant interfaces, and subinterfaces are supported as bridge group member interfaces. Management interfaces are also not supported.
Clustering	Bridge groups are not supported in clustering.
Dynamic DNS	—
DHCPv6 stateless server	Only the DHCPv4 server is supported on BVIs.
DHCP relay	The routed firewall can act as a DHCPv4 server, but it does not support DHCP relay on BVIs or bridge group member interfaces.
Dynamic routing protocols	You can, however, add static routes for BVIs. You can also allow dynamic routing protocols through the Firewall Threat Defense device using an access rule. Non-bridge group interfaces support dynamic routing.
Multicast IP routing	You can allow multicast traffic through the Firewall Threat Defense device by allowing it in an access rule. Non-bridge group interfaces support multicast routing.
QoS	Non-bridge group interfaces support QoS.

Feature	Description
VPN termination for through traffic	You cannot terminate a VPN connection on the BVI. Non-bridge group interfaces support VPN. Bridge group member interfaces support site-to-site VPN tunnels for management connections only. It does not terminate VPN connections for traffic through the Firewall Threat Defense device. You can pass VPN traffic through the bridge group using an access rule, but it does not terminate non-management connections.

Default Settings

Bridge Group Defaults

By default, all ARP packets are passed within the bridge group.

Guidelines for Firewall Mode

Bridge Group Guidelines (Transparent and Routed Mode)

- You can create up to 250 bridge groups, with 64 interfaces per bridge group.
- Each directly-connected network must be on the same subnet.
- The Firewall Threat Defense device does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.
- An IP address for the BVI is required for each bridge group for to-the-device and from-the-device management traffic, as well as for data traffic to pass through the Firewall Threat Defense device. For IPv4 traffic, specify an IPv4 address. For IPv6 traffic, specify an IPv6 address.
- You can only configure IPv6 addresses manually.
- The BVI IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255).
- Management interfaces are not supported as bridge group members.
- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- For the Firewall Threat Defense Virtual on VMware with bridged ixgbevf interfaces, transparent mode is not supported, and bridge groups are not supported in routed mode.
- For the Firepower 2100 series, bridge groups are not supported in routed mode.
- For the Firepower 1010, you cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.
- For the Firepower 4100/9300, data-sharing interfaces are not supported as bridge group members.

- In transparent mode, you must use at least 1 bridge group; data interfaces must belong to a bridge group.
- In transparent mode, do not specify the BVI IP address as the default gateway for connected devices; devices need to specify the router on the other side of the Firewall Threat Defense as the default gateway.
- In transparent mode, the *default* route, which is required to provide a return path for management traffic, is only applied to management traffic from one bridge group network. This is because the default route specifies an interface in the bridge group as well as the router IP address on the bridge group network, and you can only define one default route. If you have management traffic from more than one bridge group network, you need to specify a regular static route that identifies the network from which you expect management traffic.
- Transparent mode is not supported on threat defense virtual instances deployed on Amazon Web Services, Microsoft Azure, Google Cloud Platform, and Oracle Cloud Infrastructure.
- In routed mode, to route between bridge groups and other routed interfaces, you must name the BVI.
- In routed mode, Firewall Threat Defense-defined EtherChannel interfaces are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the Firewall Threat Defense when using bridge group members. If there are two neighbors on either side of the Firewall Threat Defense running BFD, then the Firewall Threat Defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.

Set the Firewall Mode

You can set the firewall mode when you perform the initial system setup at the CLI. We recommend setting the firewall mode during setup because changing the firewall mode erases your configuration to ensure you do not have incompatible settings. If you need to change the firewall mode later, you must do so from the CLI.

Procedure

Step 1 Unregister the Firewall Threat Defense device from the Firewall Management Center.

You cannot change the mode until you unregister the device.

a) Performance profiles are retained across firewall mode changes and can't be changed after you re-register. You must set the performance profile to Default. See the **Performance Profile** page in your platform settings policy (choose **Devices** > **Platform Settings**, and then click **Edit** ( ) for your policy).

Deploy the configuration to make these changes.

b) Choose **Devices** > **Device Management**.

c) Next to the device you want to unregister, click **More** ( ), and then click **Delete**.

Step 2 Access the Firewall Threat Defense device CLI, preferably from the console port.

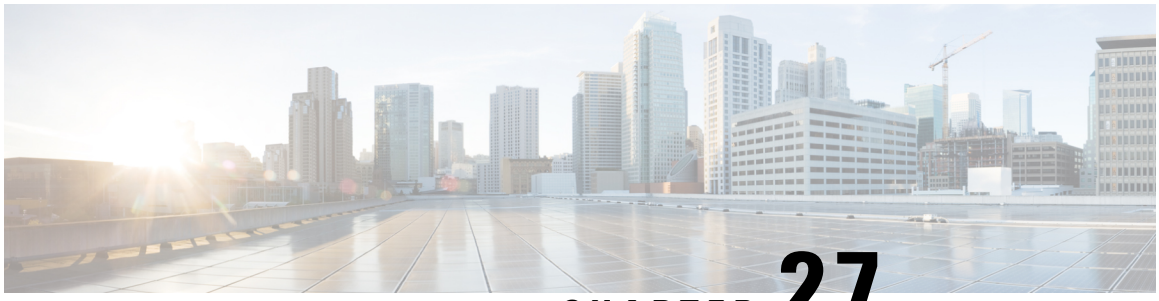
Step 3 Change the firewall mode:

configure firewall [**routed** | **transparent**]

Example:

```
> configure firewall transparent
This will destroy the current interface configurations, are you sure that you want to
proceed? [y/N] y
The firewall mode was changed successfully.
```

Step 4 Re-register with the Firewall Management Center.



CHAPTER 27

Logical Devices on the Firepower 4100/9300

The Firepower 4100/9300 is a flexible security platform on which you can install one or more *logical devices*. Before you can add the Firewall Threat Defense to the Firewall Management Center, you must configure chassis interfaces, add a logical device, and assign interfaces to the device on the Firepower 4100/9300 chassis using the Secure Firewall Chassis Manager or the FXOS CLI. This chapter describes basic interface configuration and how to add a standalone or High Availability logical device using the Secure Firewall Chassis Manager. To use the FXOS CLI, see the FXOS CLI configuration guide. For more advanced FXOS procedures and troubleshooting, see the FXOS configuration guide.

- About Interfaces, on page 443
- About Logical Devices, on page 457
- Licenses for Container Instances, on page 466
- Requirements and Prerequisites for Logical Devices, on page 467
- Guidelines and Limitations for Logical Devices, on page 474
- Configure Interfaces, on page 478
- Configure Logical Devices, on page 483

About Interfaces

The Firepower 4100/9300 chassis supports physical interfaces, VLAN subinterfaces for container instances, and EtherChannel (port-channel) interfaces. EtherChannel interfaces can include up to 16 member interfaces of the same type.

Chassis Management Interface

The chassis management interface is used for management of the FXOS Chassis by SSH or Firewall Chassis Manager. This interface appears at the top of the **Interfaces** tab as **MGMT**, and you can only enable or disable this interface on the **Interfaces** tab. This interface is separate from the mgmt-type interface that you assign to the logical devices for application management.

To configure parameters for this interface, you must configure them from the CLI. To view information about this interface in the FXOS CLI, connect to local management and show the management port:

Firepower # **connect local-mgmt**

Firepower(local-mgmt) # **show mgmt-port**

Note that the chassis management interface remains up even if the physical cable or SFP module are unplugged, or if the **mgmt-port shut** command is performed, or if the logical device is offline.

Note The chassis management interface does not support jumbo frames.

Interface Types

Physical interfaces, VLAN subinterfaces for container instances, and EtherChannel (port-channel) interfaces can be one of the following types:

- Data—Use for regular data. Data interfaces cannot be shared between logical devices, and logical devices cannot communicate over the backplane to other logical devices. For traffic on Data interfaces, all traffic must exit the chassis on one interface and return on another interface to reach another logical device.
- Data-sharing—Use for regular data. Only supported with container instances, these data interfaces can be shared by one or more logical devices/container instances (Firewall Threat Defense-using-Firewall Management Center only). Each container instance can communicate over the backplane with all other instances that share this interface. Shared interfaces can affect the number of container instances you can deploy. Shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode), inline sets, passive interfaces, clusters, or failover links.
- Mgmt—Use to manage application instances. These interfaces can be shared by one or more logical devices to access external hosts; logical devices cannot communicate over this interface with other logical devices that share the interface. You can only assign one management interface per logical device. Depending on your application and manager, you can later enable management from a data interface; but you must assign a Management interface to the logical device even if you don't intend to use it after you enable data management. For information about the separate chassis management interface, see Chassis Management Interface, on page 443.

Note Mgmt interface change will cause reboot of the logical device, for example one change mgmt from e1/1 to e1/2 will cause the logical device to reboot to apply the new management.

- Eventing—Use as a secondary management interface for Firewall Threat Defense-using-Firewall Management Center devices. To use this interface, you must configure its IP address and other parameters at the Firewall Threat Defense CLI. For example, you can separate management traffic from events (such as web events). See the management center configuration guide for more information. Eventing interfaces can be shared by one or more logical devices to access external hosts; logical devices cannot communicate over this interface with other logical devices that share the interface. If you later configure a data interface for management, you cannot use a separate eventing interface.

Note A virtual Ethernet interface is allocated when each application instance is installed. If the application does not use an eventing interface, then the virtual interface will be in an admin down state.

```
Firepower # show interface Vethernet775
Firepower # Vethernet775 is down (Administratively down)
Bound Interface is Ethernet1/10
Port description is server 1/1, VNIC ext-mgmt-nic5
```

- Cluster—Use as the cluster control link for a clustered logical device. By default, the cluster control link is automatically created on Port-channel 48. The Cluster type is only supported on EtherChannel interfaces. For multi-instance clustering, you cannot share a Cluster-type interface across devices. You can add VLAN subinterfaces to the Cluster EtherChannel to provide separate cluster control links per cluster. If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster. The Firewall Device Manager and Security Cloud Control does not support clustering.

Note This chapter discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the Firewall Threat Defense application. See FXOS Interfaces vs. Application Interfaces, on page 446 for more information.

See the following table for interface type support for the Firewall Threat Defense and ASA applications in standalone and cluster deployments.

Table 34: Interface Type Support

Application		Data	Data: Subinterface	Data-Sharing	Data-Sharing: Subinterface	Mgmt	Eventing	Cluster (EtherChannel only)	Cluster: Subinterface
Firewall Threat Defense	Standalone Native Instance	**Yes**	—	—	—	**Yes**	**Yes**	—	—
	Standalone Container Instance	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**	**Yes**	—	—
	Cluster Native Instance	**Yes** (EtherChannel only for inter-chassis cluster)	—	—	—	**Yes**	**Yes**	**Yes**	—
	Cluster Container Instance	**Yes** (EtherChannel only for inter-chassis cluster)	—	—	—	**Yes**	**Yes**	**Yes**	**Yes**

Application		Data	Data: Subinterface	Data-Sharing	Data-Sharing: Subinterface	Mgmt	Eventing	Cluster (EtherChannel only)	Cluster: Subinterface
ASA	Standalone Native Instance	**Yes**	—	—	—	**Yes**	—	**Yes**	—
	Cluster Native Instance	**Yes** (EtherChannel only for inter-chassis cluster)	—	—	—	**Yes**	—	**Yes**	—

FXOS Interfaces vs. Application Interfaces

The Firepower 4100/9300 manages the basic Ethernet settings of physical interfaces, VLAN subinterfaces for container instances, and EtherChannel (port-channel) interfaces. Within the application, you configure higher level settings. For example, you can only create EtherChannels in FXOS; but you can assign an IP address to the EtherChannel within the application.

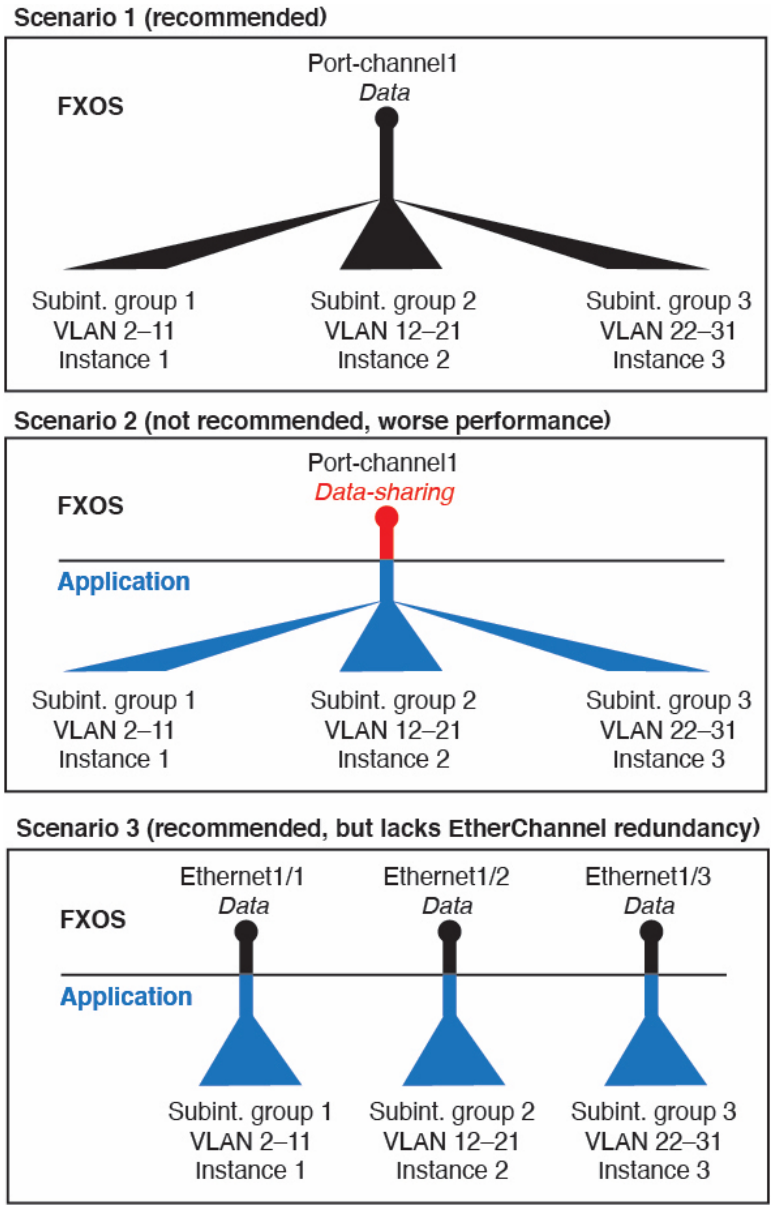
The following sections describe the interaction between FXOS and the application for interfaces.

VLAN Subinterfaces

For all logical devices, you can create VLAN subinterfaces within the application.

For container instances in standalone mode only, you can *also* create VLAN subinterfaces in FXOS. Multi-instance clusters do not support subinterfaces in FXOS except on the Cluster-type interface. Application-defined subinterfaces are not subject to the FXOS limit. Choosing in which operating system to create subinterfaces depends on your network deployment and personal preference. For example, to share a subinterface, you must create the subinterface in FXOS. Another scenario that favors FXOS subinterfaces comprises allocating separate subinterface groups on a single interface to multiple instances. For example, you want to use Port-channel1 with VLAN 2–11 on instance A, VLAN 12–21 on instance B, and VLAN 22–31 on instance C. If you create these subinterfaces within the application, then you would have to share the parent interface in FXOS, which may not be desirable. See the following illustration that shows the three ways you can accomplish this scenario:

Figure 75: VLANs in FXOS vs. the Application for Container Instances



Independent Interface States in the Chassis and in the Application

You can administratively enable and disable interfaces in both the chassis and in the application. For an interface to be operational, the interface must be enabled in both operating systems. Because the interface state is controlled independently, you may have a mismatch between the chassis and application.

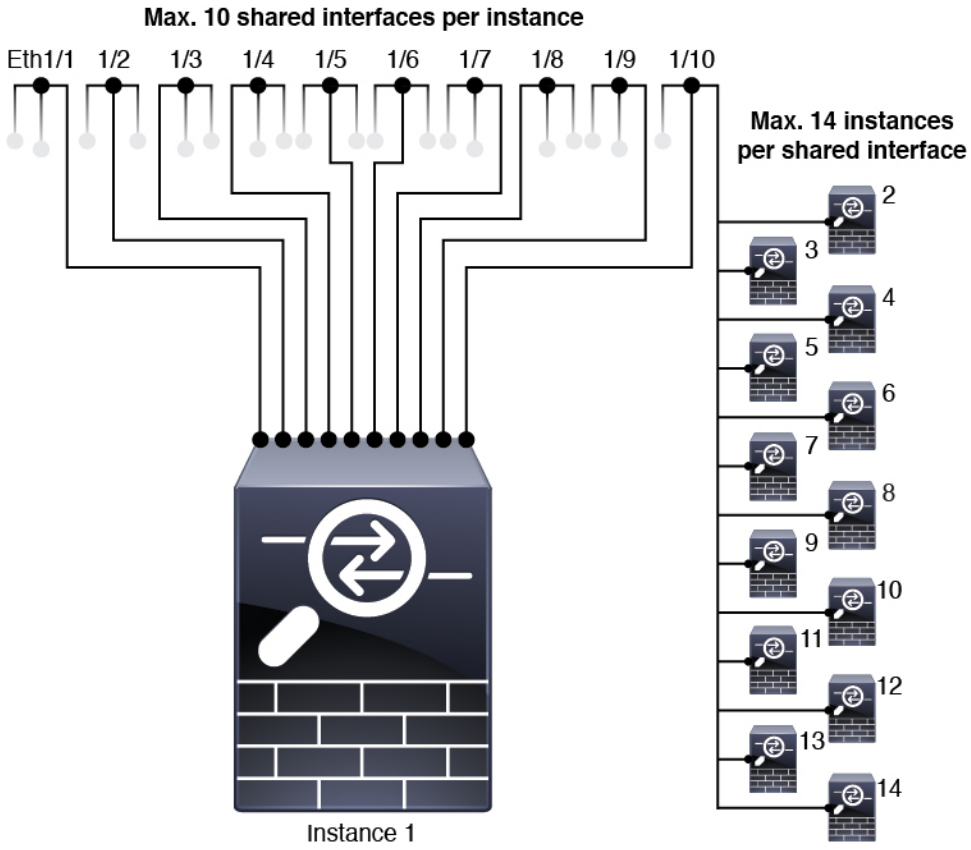
The default state of an interface within the application depends on the type of interface. For example, the physical interface or EtherChannel is disabled by default within the application, but a subinterface is enabled by default.

Shared Interface Scalability

Instances can share data-sharing type interfaces. This capability lets you conserve physical interface usage as well as support flexible networking deployments. When you share an interface, the chassis uses unique MAC addresses to forward traffic to the correct instance. However, shared interfaces can cause the forwarding table to grow large due to the need for a full mesh topology within the chassis (every instance must be able to communicate with every other instance that is sharing the same interface). Therefore, there are limits to how many interfaces you can share.

In addition to the forwarding table, the chassis maintains a VLAN group table for VLAN subinterface forwarding. You can create up to 500 VLAN subinterfaces.

See the following limits for shared interface allocation:



Shared Interface Best Practices

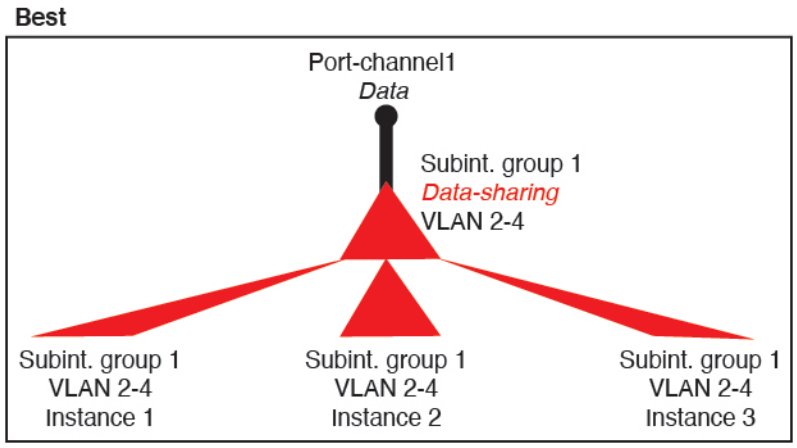
For optimal scalability of the forwarding table, share as few interfaces as possible. Instead, you can create up to 500 VLAN subinterfaces on one or more physical interfaces and then divide the VLANs among the container instances.

When sharing interfaces, follow these practices in the order of most scalable to least scalable:

1. Best—Share subinterfaces under a single parent, and use the same set of subinterfaces with the same group of instances.

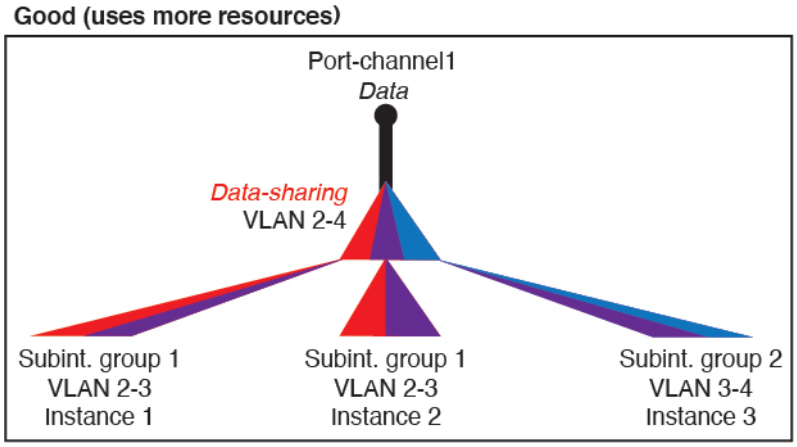
For example, create a large EtherChannel to bundle all of your like-kind interfaces together, and then share subinterfaces of that EtherChannel: Port-Channel1.2, 3, and 4 instead of Port-Channel2, Port-Channel3, and Port-Channel4. When you share subinterfaces from a single parent, the VLAN group table provides better scaling of the forwarding table than when sharing physical/EtherChannel interfaces or subinterfaces across parents.

Figure 76: Best: Shared Subinterface Group on One Parent



If you do not share the same set of subinterfaces with a group of instances, your configuration can cause more resource usage (more VLAN groups). For example, share Port-Channel1.2, 3, and 4 with instances 1, 2, and 3 (one VLAN group) instead of sharing Port-Channel1.2 and 3 with instances 1 and 2, while sharing Port-Channel1.3 and 4 with instance 3 (two VLAN groups).

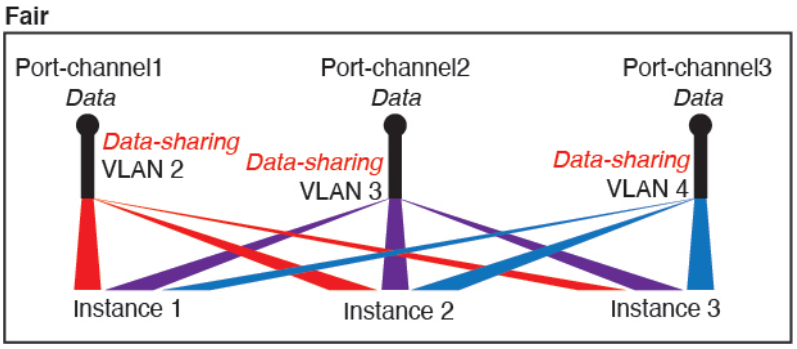
Figure 77: Good: Sharing Multiple Subinterface Groups on One Parent



2. Fair—Share subinterfaces across parents.

   For example, share Port-Channel1.2, Port-Channel2.3, and Port-Channel3.4 instead of Port-Channel2, Port-Channel4, and Port-Channel4. Although this usage is not as efficient as only sharing subinterfaces on the same parent, it still takes advantage of VLAN groups.

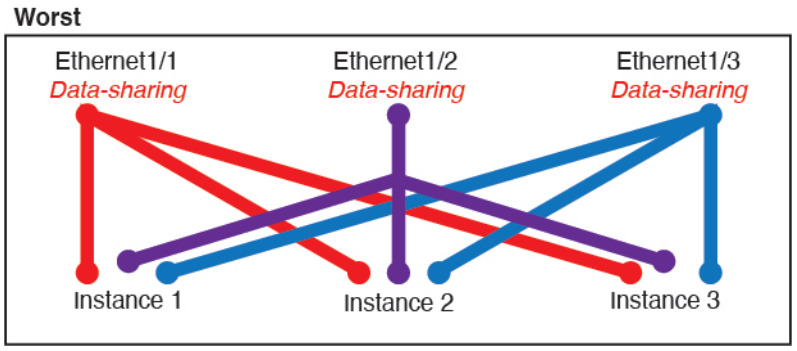
Figure 78: Fair: Shared Subinterfaces on Separate Parents



3. Worst—Share individual parent interfaces (physical or EtherChannel).

   This method uses the most forwarding table entries.

Figure 79: Worst: Shared Parent Interfaces



Shared Interface Usage Examples

See the following tables for examples of interface sharing and scalability. The below scenarios assume use of one physical/EtherChannel interface for management shared across all instances, and another physical or EtherChannel interface with dedicated subinterfaces for use with High Availability.

- Table 35: Physical/EtherChannel Interfaces and Instances on a Firepower 9300 with Three SM-44s, on page 451
- Table 36: Subinterfaces on One Parent and Instances on a Firepower 9300 with Three SM-44s, on page 452
- Table 37: Physical/EtherChannel Interfaces and Instances on a Firepower 9300 with One SM-44, on page 454
- Table 38: Subinterfaces on One Parent and Instances on a Firepower 9300 with One SM-44, on page 455

Firepower 9300 with Three SM-44s

The following table applies to three SM-44 security modules on a 9300 using only physical interfaces or EtherChannels. Without subinterfaces, the maximum number of interfaces are limited. Moreover, sharing multiple physical interfaces uses more forwarding table resources than sharing multiple subinterfaces.

Each SM-44 module can support up to 14 instances. Instances are split between modules as necessary to stay within limits.

Table 35: Physical/EtherChannel Interfaces and Instances on a Firepower 9300 with Three SM-44s

Dedicated Interfaces	Shared Interfaces	Number of Instances	% Forwarding Table Used
32: • 8 • 8 • 8 • 8	**0**	**4:** • Instance 1 • Instance 2 • Instance 3 • Instance 4	16%
30: • 15 • 15	**0**	**2:** • Instance 1 • Instance 2	14%

14: • *12 (2 ea.)*	***10***	***7:*** • *Instance 1-Instance 7*	*109%* DISALLOWED

The following table applies to the Firepower 9300 with one SM-44 using subinterfaces on a single parent physical interface. For example, create a large EtherChannel to bundle all of your like-kind interfaces together, and then share subinterfaces of that EtherChannel. Sharing multiple physical interfaces uses more forwarding table resources than sharing multiple subinterfaces.

The Firepower 9300 with one SM-44 can support up to 14 instances.

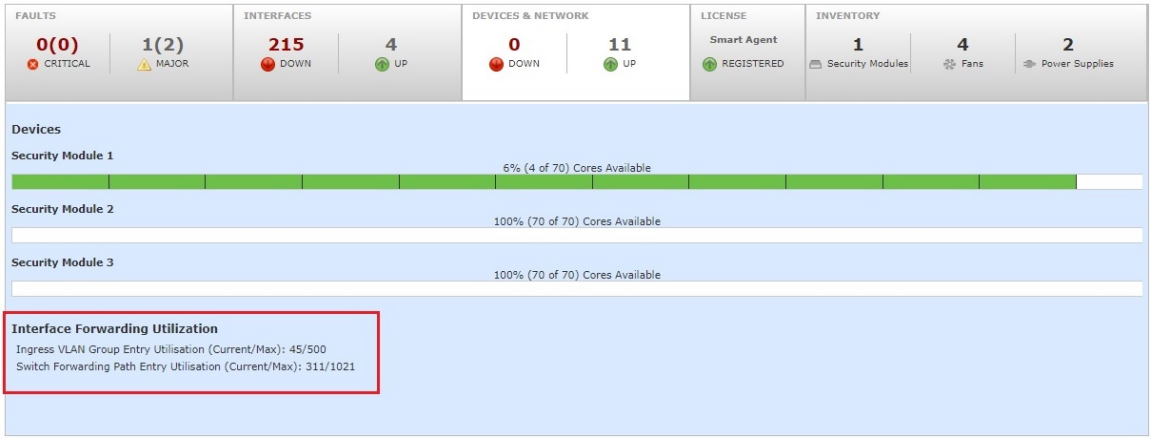
Table 38: Subinterfaces on One Parent and Instances on a Firepower 9300 with One SM-44

Dedicated Subinterfaces	Shared Subinterfaces	Number of Instances	% Forwarding Table Used
112: • 112 (8 ea.)	**0**	**14:** • Instance 1-Instance 14	17%
224: • 224 (16 ea.)	**0**	**14:** • Instance 1-Instance 14	17%
14: • 14 (1 ea.)	**1**	**14:** • Instance 1-Instance 14	46%

Dedicated Subinterfaces	Shared Subinterfaces	Number of Instances	% Forwarding Table Used
14: • 7 (1 ea.) • 7 (1 ea.)	**2:** • 1 • 1	**14:** • Instance 1-Instance 7 • Instance 8-Instance 14	37%
112: • 112 (8 ea.)	**1**	**14:** • Instance 1-Instance 14	46%
112: • 56 (8 ea.) • 56 (8 ea.)	**2:** • 1 • 1	**14:** • Instance 1-Instance 7 • Instance 8-Instance 14	37%
112: • 112 (8 ea.)	**2**	**14:** • Instance 1-Instance 14	46%
112: • 56 (8 ea.) • 56 (8 ea.)	**4:** • 2 • 2	**14:** • Instance 1-Instance 7 • Instance 8-Instance 14	37%
140: • 140 (10 ea.)	**10**	**14:** • Instance 1-Instance 14	46%
140: • 70 (10 ea.) • 70 (10 ea.)	**20:** • 10 • 10	**14:** • Instance 1-Instance 7 • Instance 8-Instance 14	37%

Viewing Shared Interface Resources

To view forwarding table and VLAN group usage, see the **Devices & Network** > **Interface Forwarding Utilization** area. For example:



Inline Set Link State Propagation for the Firewall Threat Defense

An inline set acts like a bump on the wire, and binds two interfaces together to slot into an existing network. This function allows the system to be installed in any network environment without the configuration of adjacent network devices. Inline interfaces receive all traffic unconditionally, but all traffic received on these interfaces is retransmitted out of an inline set unless explicitly dropped.

When you configure an inline set in the Firewall Threat Defense application and enable link state propagation, the Firewall Threat Defense sends inline set membership to the FXOS chassis. Link state propagation means that the chassis automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. When the downed interface comes back up, the second interface automatically comes back up, also. In other words, if the link state of one interface changes, the chassis senses the change and updates the link state of the other interface to match it. Note that the chassis requires up to 4 seconds to propagate link state changes. Link state propagation is especially useful in resilient network environments where routers are configured to reroute traffic automatically around network devices that are in a failure state.

Note Do not enable Hardware Bypass and link state propagation for the same inline set.

About Logical Devices

A logical device lets you run one application instance (either ASA or Firewall Threat Defense) and also one optional decorator application (Radware DefensePro) to form a service chain.

When you add a logical device, you also define the application instance type and version, assign interfaces, and configure bootstrap settings that are pushed to the application configuration.

Note For the Firepower 9300, you can install different application types (ASA and Firewall Threat Defense) on separate modules in the chassis. You can also run different versions of an application instance type on separate modules.

Standalone and Clustered Logical Devices

You can add the following logical device types:

- Standalone—A standalone logical device operates as a standalone unit or as a unit in a High Availability pair.
- Cluster—A clustered logical device lets you group multiple units together, providing all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. Multiple module devices, like the Firepower 9300, support intra-chassis clustering. For the Firepower 9300, all three modules must participate in the cluster, for both native and container instances. The Firewall Device Manager does not support clustering.

Logical Device Application Instances: Container and Native

Application instances run in the following deployment types:

- Native instance—A native instance uses all of the resources (CPU, RAM, and disk space) of the security module/engine, so you can only install one native instance.
- Container instance—A container instance uses a subset of resources of the security module/engine, so you can install multiple container instances. Multi-instance capability is only supported for the Firewall Threat Defense using Firewall Management Center; it is not supported for the ASA or the Firewall Threat Defense using Firewall Device Manager.

Note Multi-instance capability is similar to ASA multiple context mode, although the implementation is different. Multiple context mode partitions a single application instance, while multi-instance capability allows independent container instances. Container instances allow hard resource separation, separate configuration management, separate reloads, separate software updates, and full Firewall Threat Defense feature support. Multiple context mode, due to shared resources, supports more contexts on a given platform. Multiple context mode is not available on the Firewall Threat Defense.

For the Firepower 9300, you can use a native instance on some modules, and container instances on the other module(s).

Container Instance Interfaces

To provide flexible physical interface use for container instances, you can create VLAN subinterfaces in FXOS and also share interfaces (VLAN or physical) between multiple instances. Native instances cannot use VLAN subinterfaces or shared interfaces. A multi-instance cluster cannot use VLAN subinterfaces or shared interfaces. An exception is made for the cluster control link, which can use a subinterface of the Cluster EtherChannel. See Shared Interface Scalability, on page 448 and Add a VLAN Subinterface for Container Instances, on page 482.

Note This document discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the Firewall Threat Defense application. See FXOS Interfaces vs. Application Interfaces, on page 446 for more information.

How the Chassis Classifies Packets

Each packet that enters the chassis must be classified, so that the chassis can determine to which instance to send a packet.

- Unique Interfaces—If only one instance is associated with the ingress interface, the chassis classifies the packet into that instance. For bridge group member interfaces (in transparent mode or routed mode), inline sets, or passive interfaces, this method is used to classify packets at all times.
- Unique MAC Addresses—The chassis automatically generates unique MAC addresses for all interfaces, including shared interfaces. If multiple instances share an interface, then the classifier uses unique MAC addresses assigned to the interface in each instance. An upstream router cannot route directly to an instance without unique MAC addresses. You can also set the MAC addresses manually when you configure each interface within the application.

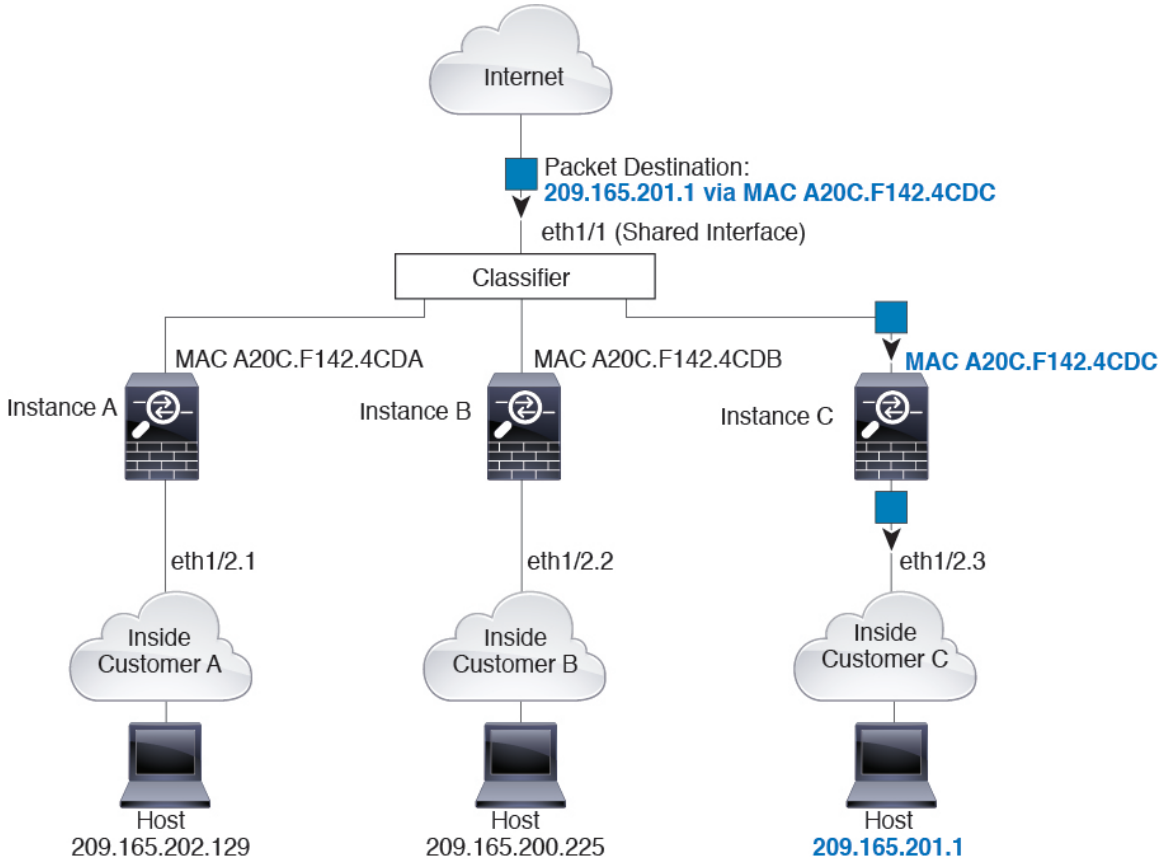
Note If the destination MAC address is a multicast or broadcast MAC address, the packet is duplicated and delivered to each instance.

Classification Examples

Packet Classification with a Shared Interface Using MAC Addresses

The following figure shows multiple instances sharing an outside interface. The classifier assigns the packet to Instance C because Instance C includes the MAC address to which the router sends the packet.

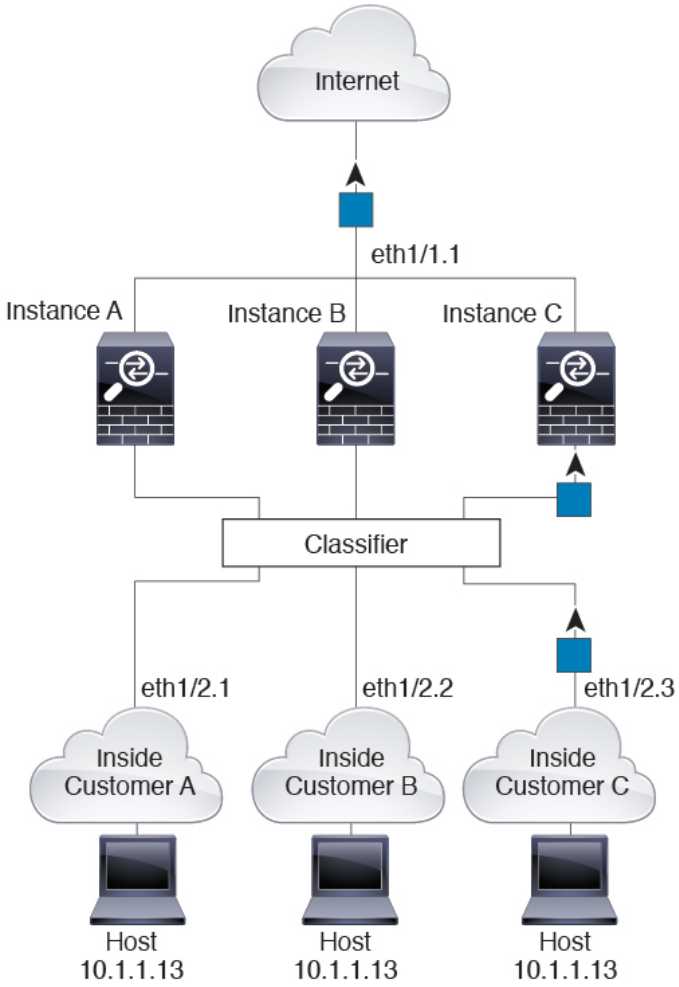
Figure 80: Packet Classification with a Shared Interface Using MAC Addresses



Incoming Traffic from Inside Networks

Note that all new incoming traffic must be classified, even from inside networks. The following figure shows a host on the Instance C inside network accessing the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/2.3, which is assigned to Instance C.

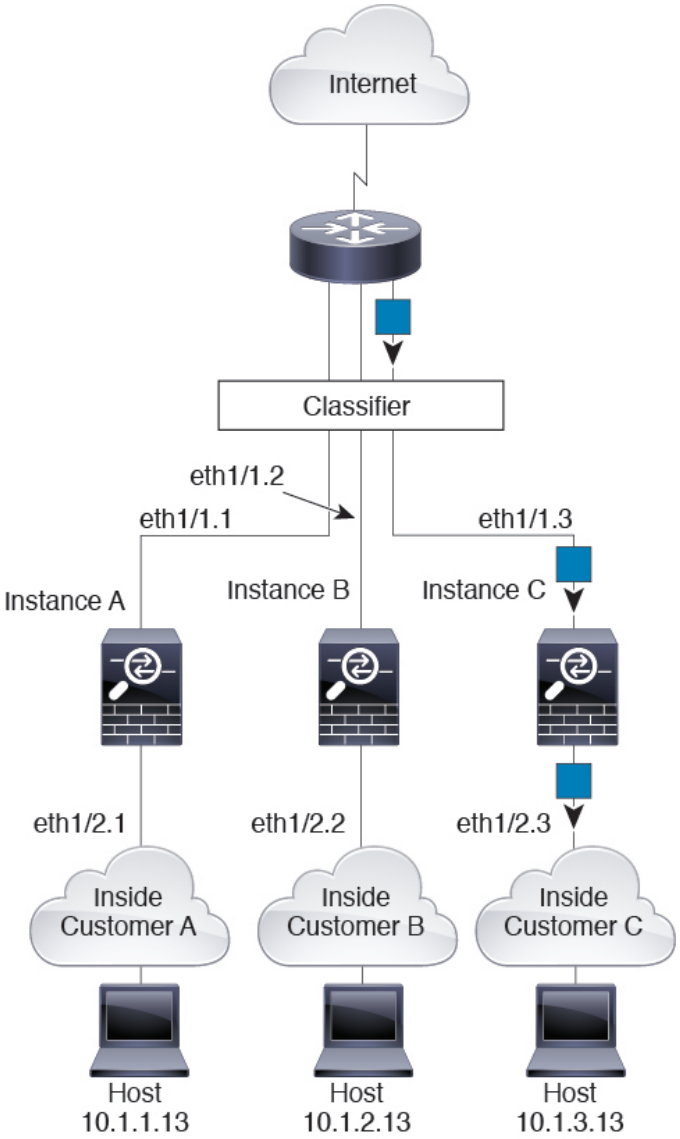
Figure 81: Incoming Traffic from Inside Networks



Transparent Firewall Instances

For transparent firewalls, you must use unique interfaces. The following figure shows a packet destined to a host on the Instance C inside network from the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/2.3, which is assigned to Instance C.

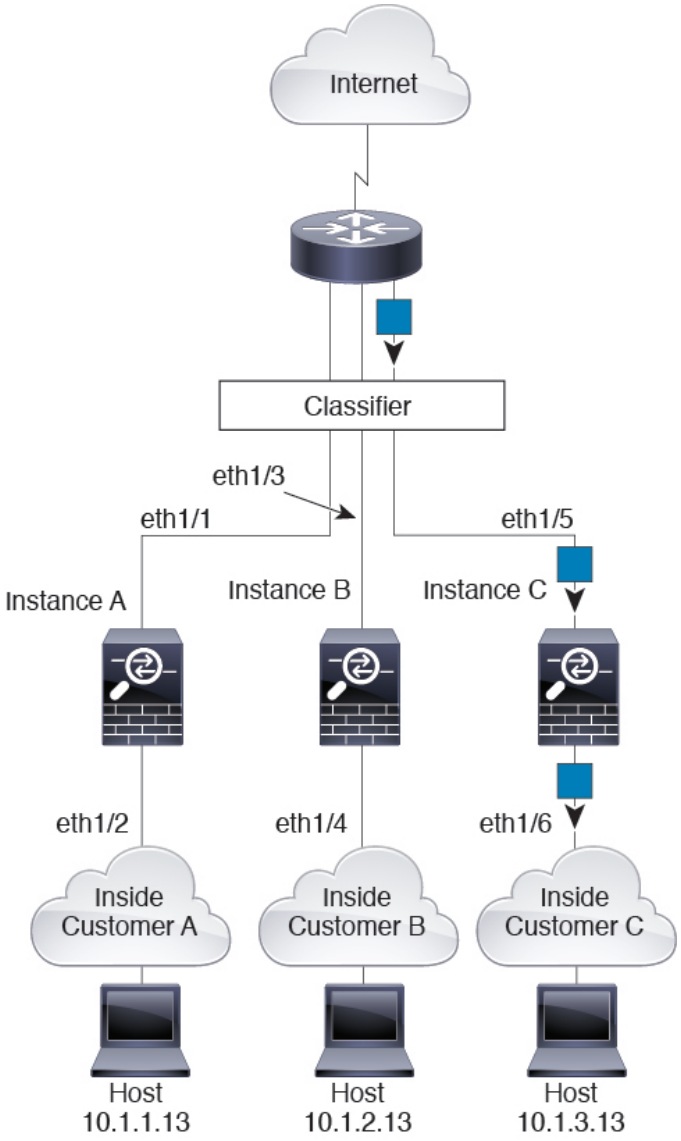
Figure 82: Transparent Firewall Instances



Inline Sets

For inline sets, you must use unique interfaces and they must be physical interfaces or EtherChannels. The following figure shows a packet destined to a host on the Instance C inside network from the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/5, which is assigned to Instance C.

Figure 83: Inline Sets

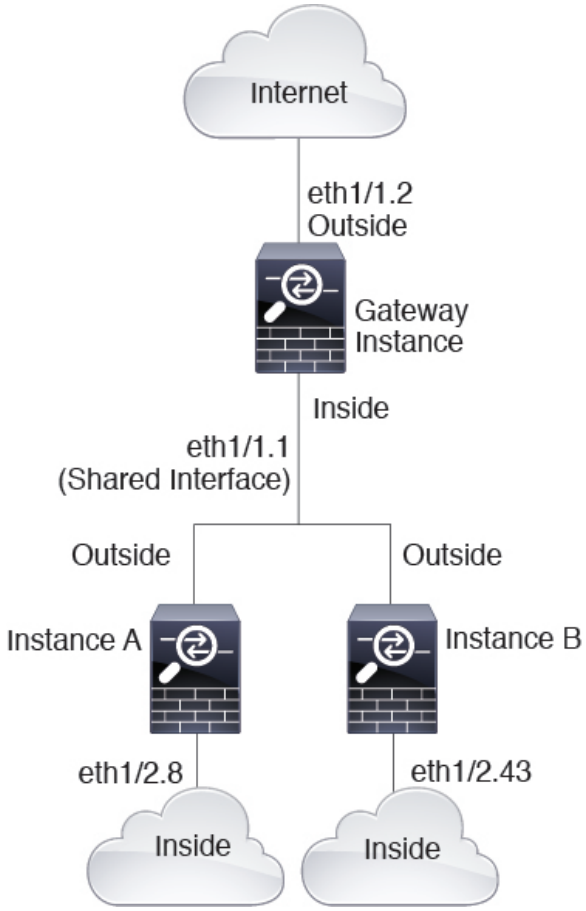


Cascading Container Instances

Placing an instance directly in front of another instance is called *cascading instances*; the outside interface of one instance is the same interface as the inside interface of another instance. You might want to cascade instances if you want to simplify the configuration of some instances by configuring shared parameters in the top instance.

The following figure shows a gateway instance with two instances behind the gateway.

Figure 84: Cascading Instances



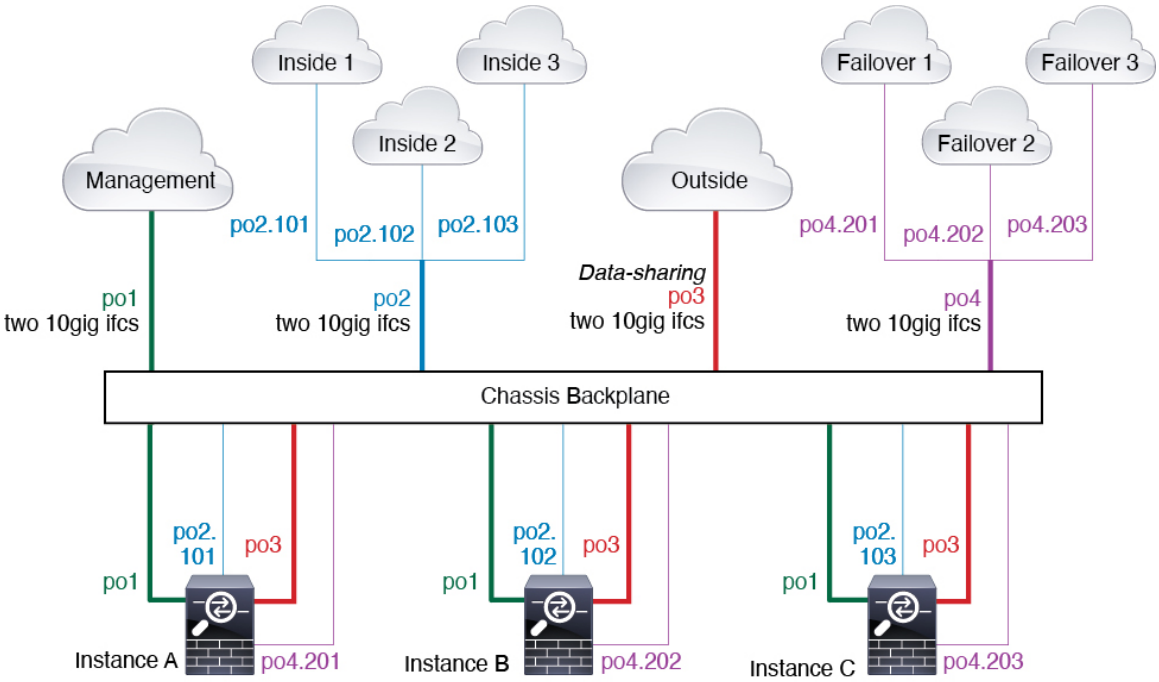
Note Do not use cascading instances (using a shared interface) with High Availability. After a failover occurs and the standby unit rejoins, MAC addresses can overlap temporarily and cause an outage. You should instead use unique interfaces for the gateway instance and inside instance using an external switch to pass traffic between the instances.

Typical Multi-Instance Deployment

The following example includes three container instances in routed firewall mode. They include the following interfaces:

- Management—All instances use the Port-Channel1 interface (management type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Within each application, the interface uses a unique IP address on the same management network.
- Inside—Each instance uses a subinterface on Port-Channel2 (data type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Each subinterface is on a separate network.

- Outside—All instances use the Port-Channel3 interface (data-sharing type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Within each application, the interface uses a unique IP address on the same outside network.
- Failover—Each instance uses a subinterface on Port-Channel4 (data type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Each subinterface is on a separate network.



Automatic MAC Addresses for Container Instance Interfaces

The chassis automatically generates MAC addresses for instance interfaces, and guarantees that a shared interface in each instance uses a unique MAC address.

If you manually assign a MAC address to a shared interface within the instance, then the manually-assigned MAC address is used. If you later remove the manual MAC address, the autogenerated address is used. In the rare circumstance that the generated MAC address conflicts with another private MAC address in your network, we suggest that you manually set the MAC address for the interface within the instance.

Because autogenerated addresses start with A2, you should not start manual MAC addresses with A2 due to the risk of overlapping addresses.

The chassis generates the MAC address using the following format:

A2*xx.yyzz.zzzz*

Where *xx.yy* is a user-defined prefix or a system-defined prefix, and *zz.zzzz* is an internal counter generated by the chassis. The system-defined prefix matches the lower 2 bytes of the first MAC address in the burned-in MAC address pool that is programmed into the IDPROM. Use **connect fxos**, then **show module** to view the MAC address pool. For example, if the range of MAC addresses shown for module 1 is b0aa.772f.f0b0 to b0aa.772f.f0bf, then the system prefix will be f0b0.

The user-defined prefix is an integer that is converted into hexadecimal. For an example of how the user-defined prefix is used, if you set a prefix of 77, then the chassis converts 77 into the hexadecimal value 004D (*yyxx*). When used in the MAC address, the prefix is reversed (*xxyy*) to match the chassis native form:

A2**4D.00**zz.zzzz

For a prefix of 1009 (03F1), the MAC address is:

A2**F1.03**zz.zzzz

Container Instance Resource Management

To specify resource usage per container instance, create one or more resource profiles in FXOS. When you deploy the logical device/application instance, you specify the resource profile that you want to use. The resource profile sets the number of CPU cores; RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance. To view the available resources per model, see Requirements and Prerequisites for Container Instances, on page 469. To add a resource profile, see Add a Resource Profile for Container Instances, on page 483.

Performance Scaling Factor for Multi-Instance Capability

The maximum throughput (connections, VPN sessions, and TLS proxy sessions) for a platform is calculated for a native instance's use of memory and CPU (and this value is shown in **show resource usage**). If you use multiple instances, then you need to calculate the throughput based on the percentage of CPU cores that you assign to the instance. For example, if you use a container instance with 50% of the cores, then you should initially calculate 50% of the throughput. Moreover, the throughput available to a container instance may be less than that available to a native instance.

For detailed instructions on calculating the throughput for instances, see https://www.cisco.com/c/en/us/products/collateral/security/firewalls/white-paper-c11-744750.html.

Container Instances and High Availability

You can use High Availability using a container instance on 2 separate chassis; for example, if you have 2 chassis, each with 10 instances, you can create 10 High Availability pairs. Note that High Availability is not configured in FXOS; configure each High Availability pair in the application manager.

For detailed requirements, see Requirements and Prerequisites for High Availability, on page 470 and Add a High Availability Pair, on page 495.

Container Instances and Clustering

You can create a cluster of container instances using one container instance per security module/engine.

Licenses for Container Instances

All licenses are consumed per security engine/chassis (for the Firepower 4100) or per security module (for the Firepower 9300), and not per container instance. See the following details:

- Essentials licenses are automatically assigned: one per security module/engine.
- Feature licenses are manually assigned to each instance; but you only consume one license per feature per security module/engine. For example, for the Firepower 9300 with 3 security modules, you only need

one URL Filtering license per module for a total of 3 licenses, regardless of the number of instances in use.

For example:

Table 39: Sample License Usage for Container Instances on a Firepower 9300

Firepower 9300	Instance	Licenses
Security Module 1	Instance 1	Essentials, URL Filtering, Malware Defense
	Instance 2	Essentials, URL Filtering
	Instance 3	Essentials, URL Filtering
Security Module 2	Instance 4	Essentials, IPS
	Instance 5	Essentials, URL Filtering, Malware Defense, IPS
Security Module 3	Instance 6	Essentials, Malware Defense, IPS
	Instance 7	Essentials, IPS

Table 40: Total Number of Licenses

Essentials	URL Filtering	Malware Defense	IPS
3	2	3	2

Requirements and Prerequisites for Logical Devices

See the following sections for requirements and prerequisites.

Requirements and Prerequisites for Hardware and Software Combinations

The Firepower 4100/9300 supports multiple models, security modules, application types, and high availability and scalability features. See the following requirements for allowed combinations.

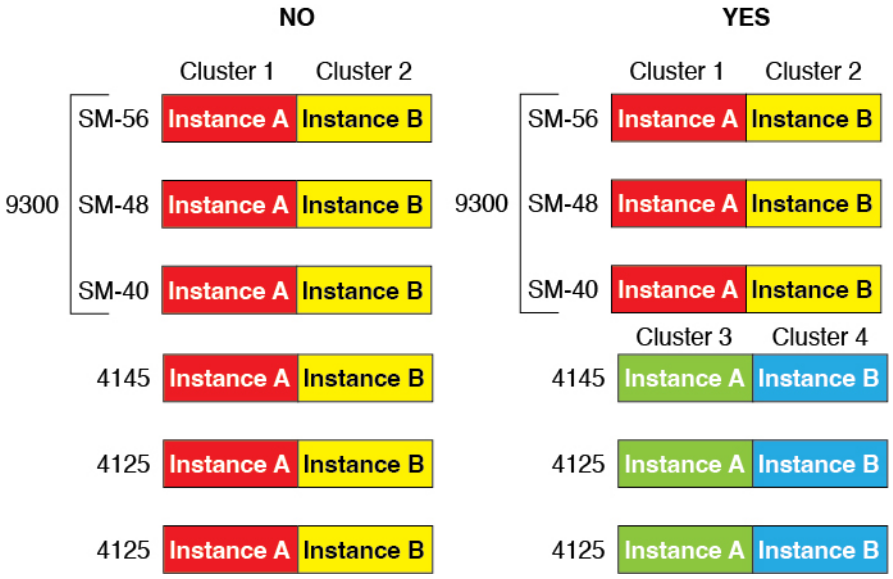
Firepower 9300 Requirements

The Firepower 9300 includes 3 security module slots and multiple types of security modules. See the following requirements:

- Security Module Types—You can install modules of different types in the Firepower 9300. For example, you can install the SM-48 as module 1, SM-40 as module 2, and SM-56 as module 3.
- Native instance Clustering—All security modules in the cluster, whether it is intra-chassis or inter-chassis, must be the same type. You can have different quantities of installed security modules in each chassis, although all modules present in the chassis must belong to the cluster including any empty slots. For

example, you can install 2 SM-40s in chassis 1, and 3 SM-40s in chassis 2. You cannot use clustering if you install 1 SM-48 and 2 SM-40s in the same chassis.

- Container instance Clustering—You can create a cluster using instances on different model types. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. You *cannot* mix the Firepower 9300 and the Firepower 4100 in the same cluster, however.

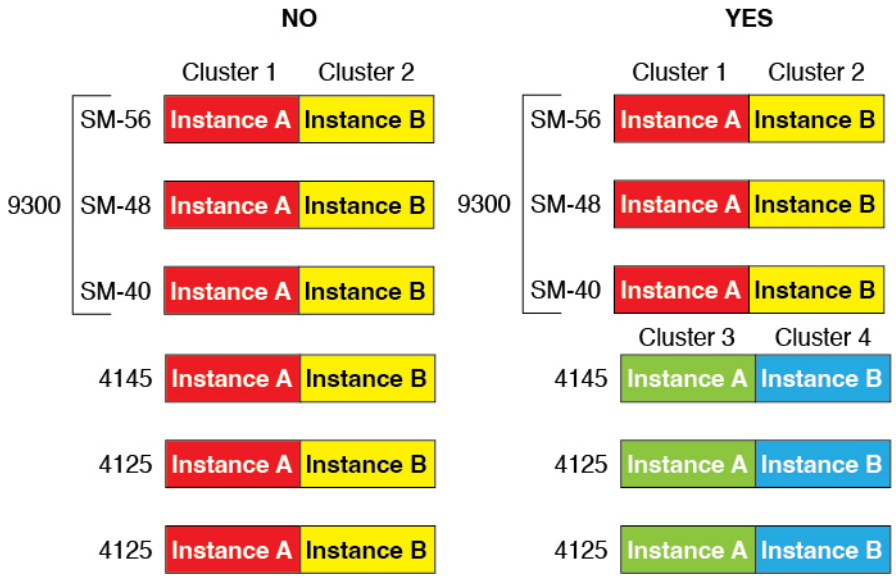


- High Availability—High Availability is only supported between same-type modules on the Firepower 9300. However, the two chassis can include mixed modules. For example, each chassis has an SM-40, SM-48, and SM-56. You can create High Availability pairs between the SM-40 modules, between the SM-48 modules, and between the SM-56 modules.
- ASA and Firewall Threat Defense application types—You can install different application types on separate modules in the chassis. For example, you can install ASA on module 1 and module 2, and Firewall Threat Defense on module 3.
- ASA or Firewall Threat Defense versions—You can run different versions of an application instance type on separate modules, or as separate container instances on the same module. For example, you can install the Firewall Threat Defense 6.3 on module 1, Firewall Threat Defense 6.4 on module 2, and Firewall Threat Defense 6.5 on module 3.

Firepower 4100 Requirements

The Firepower 4100 comes in multiple models. See the following requirements:

- Native and Container instances—When you install a container instance on a Firepower 4100, that device can only support other container instances. A native instance uses all of the resources for a device, so you can only install a single native instance on the device.
- Native instance Clustering—All chassis in the cluster must be the same model.
- Container instance Clustering—You can create a cluster using instances on different model types. For example, you can create a cluster using an instance on a Firepower 4145 and a 4125. You *cannot* mix the Firepower 9300 and the Firepower 4100 in the same cluster, however.



- High Availability—High Availability is only supported between same-type models.
- ASA and Firewall Threat Defense application types—The Firepower 4100 can only run a single application type.
- The Firewall Threat Defense container instance versions—You can run different versions of Firewall Threat Defense as separate container instances on the same module.

Requirements and Prerequisites for Container Instances

For information about high-availability or clustering requirements with multi-instance, see Requirements and Prerequisites for High Availability, on page 470 and see Requirements and Prerequisites for Clustering, on page 471.

Supported Application Types

- The Firewall Threat Defense using Firewall Management Center

Maximum Container Instances and Resources per Model

For each container instance, you can specify the number of CPU cores to assign to the instance. RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance.

Table 41: Maximum Container Instances and Resources per Model

Model	Max. Container Instances	Available CPU Cores	Available RAM	Available Disk Space
Firepower 4112	3	22	78 GB	308 GB
Firepower 4115	7	46	162 GB	308 GB
Firepower 4125	10	62	162 GB	644 GB

Model	Max. Container Instances	Available CPU Cores	Available RAM	Available Disk Space
Firepower 4140	7	70	222 GB	311.8 GB
Firepower 4145	14	86	344 GB	608 GB
Firepower 9300 SM-40 security module	13	78	334 GB	1359 GB
Firepower 9300 SM-48 security module	15	94	334 GB	1341 GB
Firepower 9300 SM-56 security module	18	110	334 GB	1314 GB

Firewall Management Center Requirements

For all instances on a Firepower 4100 chassis or Firepower 9300 module, you must use the same Firewall Management Center due to the licensing implementation.

Requirements and Prerequisites for High Availability

- The two units in a High Availability Failover configuration must:
  - Be on a separate chassis; intra-chassis High Availability for the Firepower 9300 is not supported.
  - Be the same model.
  - Have the same interfaces assigned to the High Availability logical devices.
  - Have the same number and types of interfaces. All interfaces must be preconfigured in FXOS identically before you enable High Availability.
- High Availability is only supported between same-type modules on the Firepower 9300; but the two chassis can include mixed modules. For example, each chassis has an SM-56, SM-48, and SM-40. You can create High Availability pairs between the SM-56 modules, between the SM-48 modules, and between the SM-40 modules.
- For container instances, each unit must use the same resource profile attributes.
- For container instances: Do not use cascading instances (using a shared interface) with High Availability. After a failover occurs and the standby unit rejoins, MAC addresses can overlap temporarily and cause an outage. You should instead use unique interfaces for the gateway instance and inside instance using an external switch to pass traffic between the instances.
- For other High Availability system requirements, see High Availability System Requirements, on page 566.

Requirements and Prerequisites for Clustering

Cluster Model Support

The Threat Defense supports clustering on the following models:

- Firepower 9300— You can include up to 16 nodes in the cluster. For example, you can use 1 module in 16 chassis, or 2 modules in 8 chassis, or any combination that provides a maximum of 16 modules. Supports clustering with multiple chassis and clustering isolated to security modules within one chassis.
- Firepower 4100—Supported for up to 16 nodes using clustering with multiple chassis.

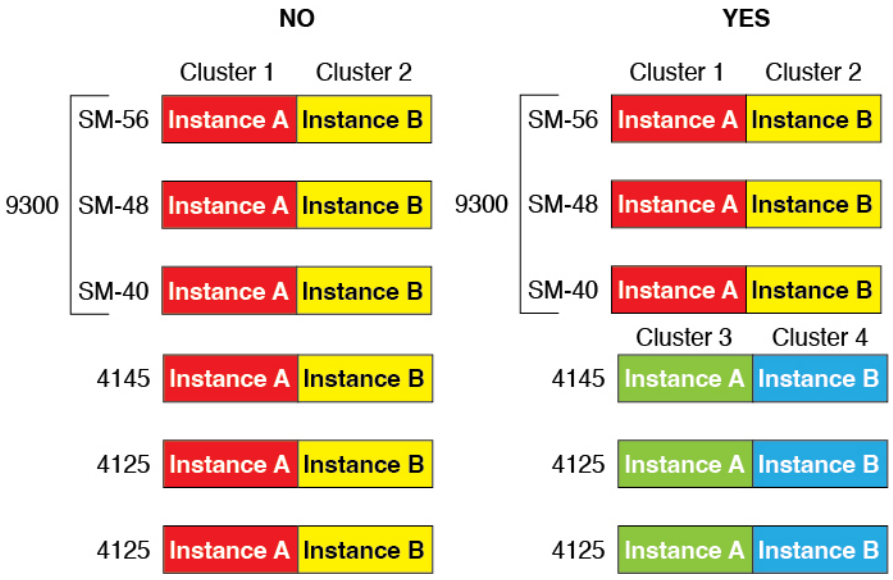
User Roles

- Admin
- Access Admin
- Network Admin

Clustering Hardware and Software Requirements

All chassis in a cluster:

- Native instance clustering—For the Firepower 4100: All chassis must be the same model. For the Firepower 9300: All security modules must be the same type. For example, if you use clustering, all modules in the Firepower 9300 must be SM-40s. You can have different quantities of installed security modules in each chassis, although all modules present in the chassis must belong to the cluster including any empty slots.
- Container instance clustering—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.

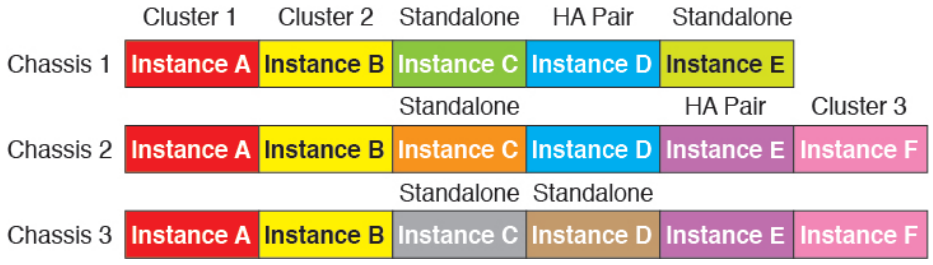


- Must run the identical FXOS and application software except at the time of an image upgrade. Mismatched software versions can lead to poor performance, so be sure to upgrade all nodes in the same maintenance window.
- Must include the same interface configuration for interfaces you assign to the cluster, such as the same Management interface, EtherChannels, active interfaces, speed and duplex, and so on. You can use different network module types on the chassis as long as the capacity matches for the same interface IDs and interfaces can successfully bundle in the same spanned EtherChannel. Note that all data interfaces must be EtherChannels in clusters with multiple chassis. If you change the interfaces in FXOS after you enable clustering (by adding or removing interface modules, or configuring EtherChannels, for example), then perform the same changes on each chassis, starting with the data nodes, and ending with the control node.
- Must use the same NTP server. For Firewall Threat Defense, the Firewall Management Center must also use the same NTP server. Do not set the time manually.

Multi-Instance Clustering Requirements

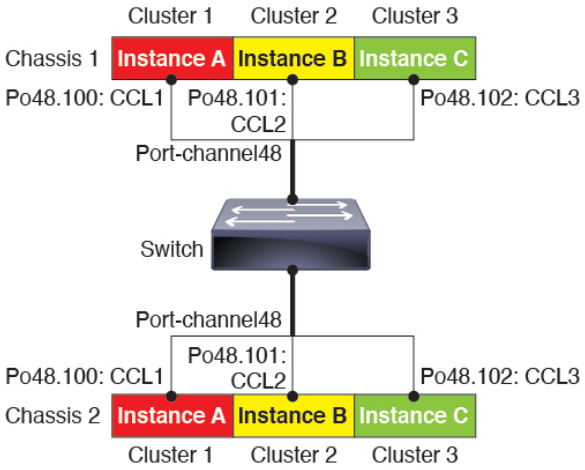
- No intra-security-module/engine clustering—For a given cluster, you can only use a single container instance per security module/engine. You cannot add 2 container instances to the same cluster if they are running on the same module.

- Mix and match clusters and standalone instances—Not all container instances on a security module/engine need to belong to a cluster. You can use some instances as standalone or High Availability nodes. You can also create multiple clusters using separate instances on the same security module/engine.



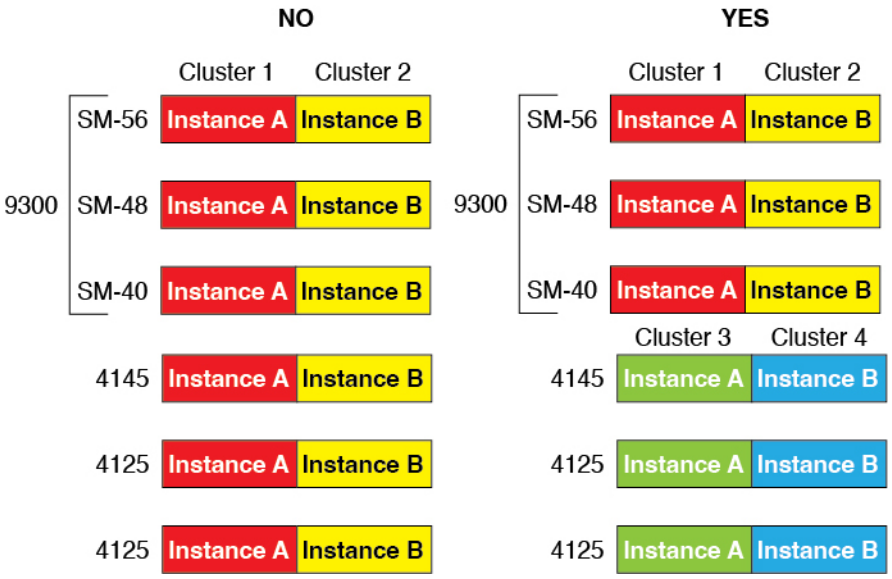
- All 3 modules in a Firepower 9300 must belong to the cluster—For the Firepower 9300, a cluster requires a single container instance on all 3 modules. You cannot create a cluster using instances on module 1 and 2, and then use a native instance on module 3, or example.

- Match resource profiles—We recommend that each node in the cluster use the same resource profile attributes; however, mismatched resources are allowed when changing cluster nodes to a different resource profile, or when using different models.
- Dedicated cluster control link—For clusters with multiple chassis, each cluster needs a dedicated cluster control link. For example, each cluster can use a separate subinterface on the same cluster-type EtherChannel, or use separate EtherChannels.



- No shared interfaces—Shared-type interfaces are not supported with clustering. However, the same Management and Eventing interfaces can used by multiple clusters.
- No subinterfaces—A multi-instance cluster cannot use FXOS-defined VLAN subinterfaces. An exception is made for the cluster control link, which can use a subinterface of the Cluster EtherChannel.
- Mix chassis models—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300

security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.



- Maximum 6 nodes—You can use up to six container instances in a cluster.

Switch Requirements

- Be sure to complete the switch configuration and successfully connect all the EtherChannels from the chassis to the switch(es) before you configure clustering on the Firepower 4100/9300 chassis.
- For supported switch characteristics, see Cisco FXOS Compatibility.

Guidelines and Limitations for Logical Devices

See the following sections for guidelines and limitations.

Guidelines and Limitations for Interfaces

VLAN Subinterfaces

- This document discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the Firewall Threat Defense application. See FXOS Interfaces vs. Application Interfaces, on page 446 for more information.
- Subinterfaces (and the parent interfaces) can only be assigned to container instances.

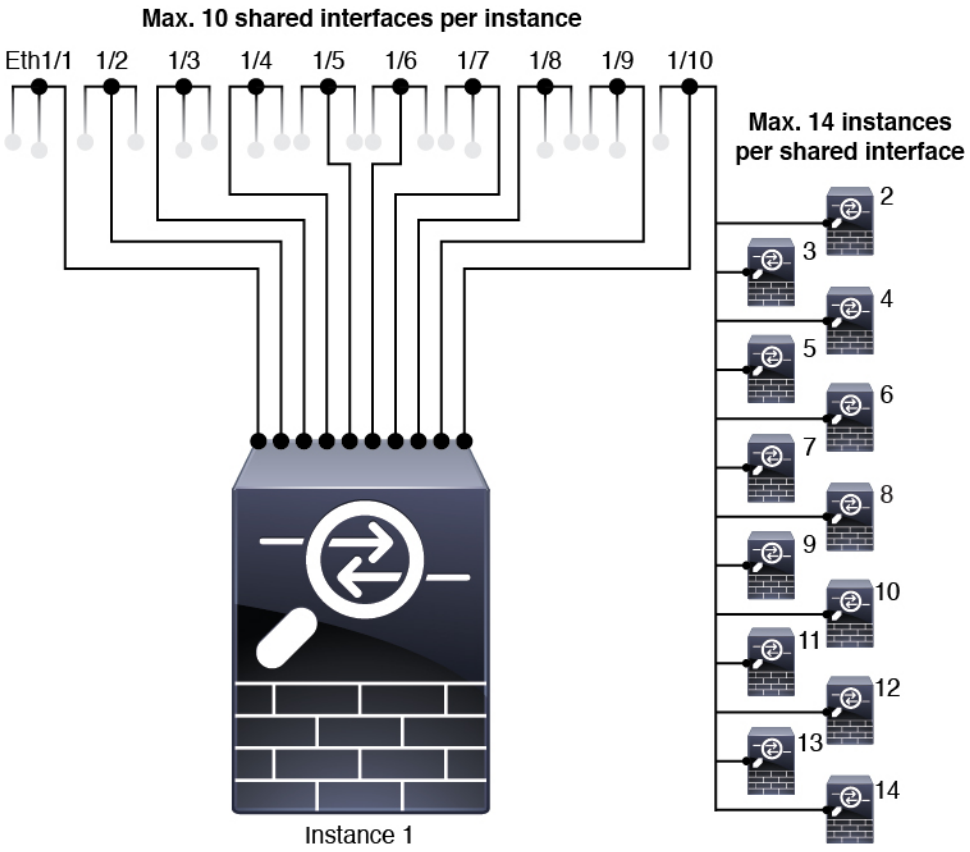
Note If you assign a parent interface to a container instance, it only passes untagged (non-VLAN) traffic. Do not assign the parent interface unless you intend to pass untagged traffic. For Cluster type interfaces, the parent interface cannot be used.

- Subinterfaces are supported on Data or Data-sharing type interfaces, as well as Cluster type interfaces. If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster.
- For multi-instance clustering, FXOS subinterfaces are not supported on Data interfaces. However, subinterfaces are supported for the cluster control link, so you can use either a dedicated EtherChannel or a subinterface of an EtherChannel for the cluster control link. Note that *application*-defined subinterfaces are supported for Data interfaces.
- You can create up to 500 VLAN IDs.
- See the following limitations within the logical device application; keep these limitations in mind when planning your interface allocation.
  - You cannot use subinterfaces for an Firewall Threat Defense inline set or as a passive interface.
  - If you use a subinterface for the failover link, then all subinterfaces on that parent, and the parent itself, are restricted for use as failover links. You cannot use some subinterfaces as failover links, and some as regular data interfaces.

Data-sharing Interfaces

- You cannot use a data-sharing interface with a native instance.
- Maximum 14 instances per shared interface. For example, you can allocate Ethernet1/1 to Instance1 through Instance14.

  Maximum 10 shared interfaces per instance. For example, you can allocate Ethernet1/1.1 through Ethernet1/1.10 to Instance1.



- You cannot use a data-sharing interface in a cluster.
- See the following limitations within the logical device application; keep these limitations in mind when planning your interface allocation.
  - You cannot use a data-sharing interface with a transparent firewall mode device.
  - You cannot use a data-sharing interface with Firewall Threat Defense inline sets or passive interfaces.
  - You cannot use a data-sharing interface for the failover link.

Inline Sets for Firewall Threat Defense

- Supported for physical interfaces (both regular and breakout ports) and EtherChannels. Subinterfaces are not supported.
- Link state propagation is supported.
- Do not enable Hardware Bypass and link state propagation for the same inline set.

Hardware Bypass

- Supported for the Firewall Threat Defense; you can use them as regular interfaces for the ASA.
- The Firewall Threat Defense only supports Hardware Bypass with inline sets.

- Hardware Bypass-capable interfaces cannot be configured for breakout ports.
- You cannot include Hardware Bypass interfaces in an EtherChannel and use them for Hardware Bypass; you can use them as regular interfaces in an EtherChannel.
- Hardware Bypass is not supported with High Availability.
- Do not enable Hardware Bypass and link state propagation for the same inline set.

Default MAC Addresses

For native instances:

Default MAC address assignments depend on the type of interface.

- Physical interfaces—The physical interface uses the burned-in MAC address.
- EtherChannels—For an EtherChannel, all interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. The port-channel interface uses a unique MAC address from a pool; interface membership does not affect the MAC address.

For container instances:

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. See Automatic MAC Addresses for Container Instance Interfaces, on page 465.

General Guidelines and Limitations

Firewall Mode

You can set the firewall mode to routed or transparent in the bootstrap configuration for the Firewall Threat Defense.

High Availability

- Configure high availability within the application configuration.
- You can use any data interfaces as the failover and state links. Data-sharing interfaces are not supported.

Multi-Instance

- Multi-instance capability with container instances is only available for the Firewall Threat Defense using Firewall Management Center.
- For Firewall Threat Defense container instances, a single Firewall Management Center must manage all instances on a security module/engine.
- For Firewall Threat Defense container instances, the following features are not supported:
  - Radware DefensePro link decorator

- Firewall Management Center UCAPL/CC mode
- Flow offload to hardware

Configure Interfaces

By default, physical interfaces are disabled. You can enable interfaces, add EtherChannels, add VLAN subinterfaces, and edit interface properties.

Enable or Disable an Interface

You can change the **Admin State** of each interface to be enabled or disabled. By default, physical interfaces are disabled. For VLAN subinterfaces, the admin state is inherited from the parent interface.

Procedure

Step 1 Choose **Interfaces** to open the Interfaces page.

The Interfaces page shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.

Step 2 To enable the interface, click the disabled **Slider disabled** ( ) so that it changes to the enabled **Slider enabled** ( ).

Click **Yes** to confirm the change. The corresponding interface in the visual representation changes from gray to green.

Step 3 To disable the interface, click the enabled **Slider enabled** ( ) so that it changes to the disabled **Slider disabled** ( ).

Click **Yes** to confirm the change. The corresponding interface in the visual representation changes from green to gray.

Configure a Physical Interface

You can physically enable and disable interfaces, as well as set the interface speed and duplex. To use an interface, it must be physically enabled in FXOS and logically enabled in the application.

Note

- For QSFPH40G-CUxM, auto-negotiation is always enabled by default and you cannot disable it.
- If you replace an SFP on a port with a different SFP module, the speed, duplex, and auto-negotiation of the interface is not updated automatically. You must manually re-configure the interface.

Before you begin

- Interfaces that are already a member of an EtherChannel cannot be modified individually. Be sure to configure settings before you add it to the EtherChannel.

Procedure

Step 1 Choose **Interfaces** to open the Interfaces page.

The **All Interfaces** page shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.

Step 2 Click **Edit** in the row for the interface you want to edit to open the **Edit Interface** dialog box.

Step 3 To enable the interface, check the **Enable** check box. To disable the interface, uncheck the **Enable** check box.

Step 4 Choose the interface **Type**:

See Interface Types, on page 444 for details about interface type usage.

- **Data**
- **Data-sharing**—For container instances only.
- **Mgmt**
- **Firepower-eventing**—For Firewall Threat Defense only.
- **Cluster**—Do not choose the **Cluster** type; by default, the cluster control link is automatically created on Port-channel 48.

Step 5 (Optional) Choose the speed of the interface from the **Speed** drop-down list.

Step 6 (Optional) If your interface supports **Auto Negotiation**, click the **Yes** or **No** radio button.

If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the platform interface as well. For example, N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, for the port to be connected you must disable the default auto-negotiation on the platform and the switch.

Step 7 (Optional) Choose the duplex of the interface from the **Duplex** drop-down list.

Step 8 (Optional) Explicitly configure **Debounce Time (ms)**. Enter a value between 0-15000 milli-seconds.

Note
Configuring Debounce Time is not supported on 1G interfaces.

Step 9 Click **OK**.

Add an EtherChannel (Port Channel)

An EtherChannel (also known as a port channel) can include up to 16 member interfaces of the same media type and capacity, and must be set to the same speed and duplex. The media type can be either RJ-45 or SFP;

SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface. The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices.

You can configure each physical Data or Data-sharing interface in an EtherChannel to be:

- Active—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- On—The EtherChannel is always on, and LACP is not used. An "on" EtherChannel can only establish a connection with another "on" EtherChannel.

Note It may take up to three minutes for an EtherChannel to come up to an operational state if you change its mode from On to Active or from Active to On.

Non-data interfaces only support active mode.

LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. "On" mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

When the Firepower 4100/9300 chassis creates an EtherChannel, the EtherChannel stays in a **Suspended** state for Active LACP mode or a **Down** state for On LACP mode until you assign it to a logical device, even if the physical link is up. The EtherChannel will be brought out of this **Suspended** state in the following situations:

- The EtherChannel is added as a data or management interface for a standalone logical device
- The EtherChannel is added as a management interface or cluster control link for a logical device that is part of a cluster
- The EtherChannel is added as a data interface for a logical device that is part of a cluster and at least one unit has joined the cluster

Note that the EtherChannel does not come up until you assign it to a logical device. If the EtherChannel is removed from the logical device or the logical device is deleted, the EtherChannel will revert to a **Suspended** or **Down** state.

Procedure

Step 1 Choose **Interfaces** to open the Interfaces page.

The **All Interfaces** page shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.

Step 2 Click **Add Port Channel** above the interfaces table to open the **Add Port Channel** dialog box.

Step 3 Enter an ID for the port channel in the **Port Channel ID** field. Valid values are between 1 and 47.

Port-channel 48 is reserved for the cluster control link when you deploy a clustered logical device. If you do not want to use Port-channel 48 for the cluster control link, you can delete it and configure a Cluster type EtherChannel with a different ID.You can add multiple Cluster type EtherChannels and add VLAN subinterfaces for use with multi-instance clustering. For intra-chassis clustering, do not assign any interfaces to the Cluster EtherChannel.

Step 4 To enable the port channel, check the **Enable** check box. To disable the port channel, uncheck the **Enable** check box.

Step 5 Choose the interface **Type**:

See Interface Types, on page 444 for details about interface type usage.

- **Data**
- **Data-sharing**—For container instances only.
- **Mgmt**
- **Firepower-eventing**—For Firewall Threat Defense only.
- **Cluster**

Step 6 Set the required **Admin Speed** for the member interfaces from the drop-down list.

If you add a member interface that is not at the specified speed, it will not successfully join the port channel.

Step 7 For Data or Data-sharing interfaces, choose the LACP port-channel **Mode**, **Active** or **On**.

For non-Data or non-Data-sharing interfaces, the mode is always active.

Step 8 Set the required **Admin Duplex** for the member interfaces, **Full Duplex** or **Half Duplex**.

If you add a member interface that is configured with the specified duplex, it will not successfully join the port channel.

Step 9 To add an interface to the port channel, select the interface in the **Available Interface** list and click **Add Interface** to move the interface to the Member ID list.

You can add up to 16 member interfaces of the same media type and capacity. The member interfaces must be set to the same speed and duplex, and must match the speed and duplex that you configured for this port channel. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface.

Tip
You can add multiple interfaces at one time. To select multiple individual interfaces, click on the desired interfaces while holding down the **Ctrl** key. To select a range of interfaces, select the first interface in the range, and then, while holding down the **Shift** key, click to select the last interface in the range.

Step 10 To remove an interface from the port channel, click the **Delete** button to the right of the interface in the Member ID list.

Step 11 Click **OK**.

Add a VLAN Subinterface for Container Instances

You can add between 250 and 500 VLAN subinterfaces to the chassis, depending on your network deployment. You can add up to 500 subinterfaces to your chassis.

For multi-instance clustering, you can only add subinterfaces to the Cluster-type interface; subinterfaces on data interfaces are not supported.

VLAN IDs per interface must be unique, and within a container instance, VLAN IDs must be unique across all assigned interfaces. You can reuse VLAN IDs on *separate* interfaces as long as they are assigned to different container instances. However, each subinterface still counts towards the limit even though it uses the same ID.

This document discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the Firewall Threat Defense application. For more information on when to use FXOS subinterfaces vs. application subinterfaces, see FXOS Interfaces vs. Application Interfaces, on page 446.

Procedure

Step 1 Choose **Interfaces** to open the **All Interfaces** tab.

The **All Interfaces** tab shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.

Step 2 Click **Add New** > **Subinterface** to open the **Add Subinterface** dialog box.

Step 3 Choose the interface **Type**:

See Interface Types, on page 444 for details about interface type usage.

- **Data**
- **Data-sharing**
- **Cluster**—If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster.

For Data and Data-sharing interfaces: The type is independent of the parent interface type; you can have a Data-sharing parent and a Data subinterface, for example.

Step 4 Choose the parent **Interface** from the drop-down list.

You cannot add a subinterface to a physical interface that is currently allocated to a logical device. If other subinterfaces of the parent are allocated, you can add a new subinterface as long as the parent interface itself is not allocated.

Step 5 Enter a **Subinterface ID**, between 1 and 4294967295.

This ID will be appended to the parent interface ID as *interface_id***.***subinterface_id*. For example, if you add a subinterface to Ethernet1/1 with the ID of 100, then the subinterface ID will be: Ethernet1/1.100. This ID is not the same as the VLAN ID, although you can set them to match for convenience.

Step 6 Set the **VLAN ID** between 1 and 4095.

Step 7 Click **OK**.

Expand the parent interface to view all subinterfaces under it.

Configure Logical Devices

Add a standalone logical device or a High Availability pair on the Firepower 4100/9300.

Add a Resource Profile for Container Instances

To specify resource usage per container instance, create one or more resource profiles. When you deploy the logical device/application instance, you specify the resource profile that you want to use. The resource profile sets the number of CPU cores; RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance.

- The minimum number of cores is 6.

Note Instances with a smaller number of cores might experience relatively higher CPU utilization than those with larger numbers of cores. Instances with a smaller number of cores are more sensitive to traffic load changes. If you experience traffic drops, try assigning more cores.

- You can assign cores as an even number (6, 8, 10, 12, 14 etc.) up to the maximum.
- The maximum number of cores available depends on the security module/chassis model; see Requirements and Prerequisites for Container Instances, on page 469.

The chassis includes a default resource profile called "Default-Small," which includes the minimum number of cores. You can change the definition of this profile, and even delete it if it is not in use. Note that this profile is created when the chassis reloads and no other profile exists on the system.

Changing the resource profile after you assign it is disruptive. See the following guidelines:

- You cannot change the resource profile settings if it is currently in use. You must disable any instances that use it, then change the resource profile, and finally reenable the instance.
- If you change the resource profile settings after you add the Firewall Threat Defense instance to the Firewall Management Center, then update the inventory for each unit on the Firewall Management Center.

  Choose **Devices** > **Device Management**, click **Edit** ( ) for the instance, then click **Refresh** () on the **Device** > **Inventory Details** area.
- If you assign a different profile to an instance, it reboots.
- If you assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:
  1. Break high availability.
  2. Assign the new profile to both units.
  3. Re-establish high availability.

- If you assign a different profile to instances in an established cluster, which allows mismatched profiles, then apply the new profile on the data nodes first; after they all come back up, you can apply the new profile to the control node.

Procedure

Step 1 Choose **Platform Settings** > **Resource Profiles** , and click **Add**.

The **Add Resource Profile** dialog box appears.

Step 2 Set the following paramters.

- **Name**—Sets the name of the profile between 1 and 64 characters. Note that you cannot change the name of this profile after you add it.
- **Description**—Sets the description of the profile up to 510 characters.
- **Number of Cores**—Sets the number of cores for the profile, between 6 and the maximum, depending on your chassis, as an even number.

Step 3 Click **OK**.

Add a Standalone Firewall Threat Defense

Standalone logical devices work either alone or in a High Availability pair. On the Firepower 9300 with multiple security modules, you can deploy either a cluster or standalone devices. The cluster must use all modules, so you cannot mix and match a 2-module cluster plus a single standalone device, for example.

You can use native instances on some modules, and container instances on the other module(s).

Before you begin

- Download the application image you want to use for the logical device from Cisco.com, and then upload that image to the Firepower 4100/9300 chassis.

Note For the Firepower 9300, you can install different application types (ASA and Firewall Threat Defense) on separate modules in the chassis. You can also run different versions of an application instance type on separate modules.

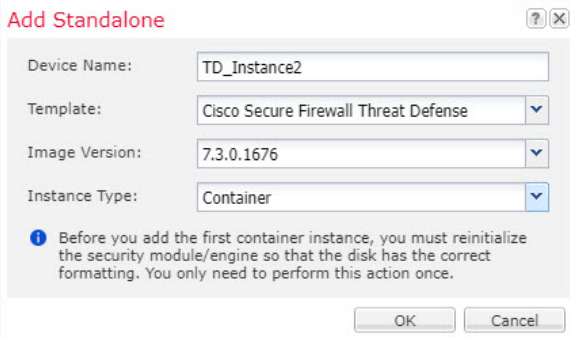
- Configure a management interface to use with the logical device. The management interface is required. Note that this management interface is not the same as the chassis management port that is used only for chassis management (and that appears at the top of the **Interfaces** tab as **MGMT**).
- You can later enable management from a data interface; but you must assign a Management interface to the logical device even if you don't intend to use it after you enable data management. See the **configure network management-data-interface** command in the FTD command reference for more information.

- You must also configure at least one Data type interface. Optionally, you can also create a firepower-eventing interface to carry all event traffic (such as web events). See Interface Types, on page 444 for more information.
- For container instances, if you do not want to use the default profile, add a resource profile according to Add a Resource Profile for Container Instances, on page 483.
- For container instances, before you can install a container instance for the first time, you must reinitialize the security module/engine so that the disk has the correct formatting. Choose **Security Modules** or **Security Engine**, and click the **Reinitialize icon**. An existing logical device will be deleted and then reinstalled as a new device, losing any local application configuration. If you are replacing a native instance with container instances, you will need to delete the native instance in any case. You cannot automatically migrate a native instance to a container instance.
- Gather the following information:
  - Interface IDs for this device
  - Management interface IP address and network mask
  - Gateway IP address
  - Firewall Management Center IP address and/or NAT ID of your choosing
  - DNS server IP address
  - Firewall Threat Defense hostname and domain name

Procedure

Step 1 Choose **Logical Devices**.

Step 2 Click **Add** > **Standalone**, and set the following parameters:



a) Provide a **Device Name**.

This name is used by the chassis supervisor to configure management settings and to assign interfaces; it is not the device name used in the application configuration.

Note
You cannot change this name after you add the logical device.

b) For the **Template**, choose **Cisco Firepower Threat Defense**.

c) Choose the **Image Version**.

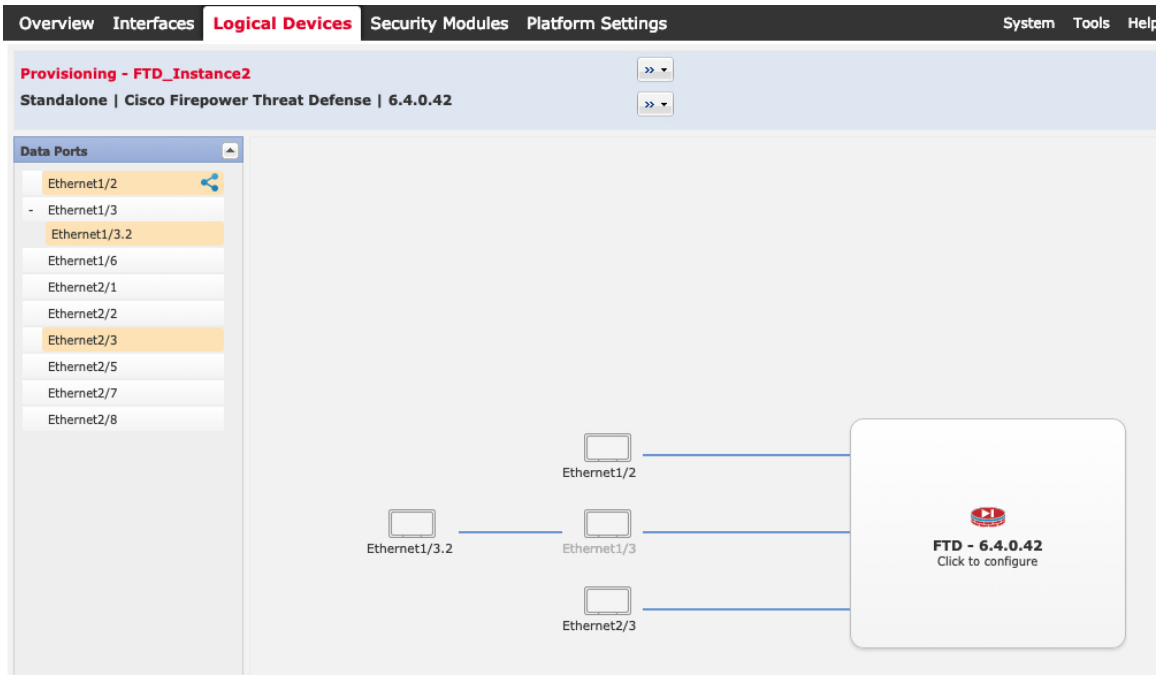
d) Choose the **Instance Type**: **Container** or **Native**.

A native instance uses all of the resources (CPU, RAM, and disk space) of the security module/engine, so you can only install one native instance. A container instance uses a subset of resources of the security module/engine, so you can install multiple container instances.

e) Click **OK**.

You see the Provisioning - *device name* window.

Step 3 Expand the **Data Ports** area, and click each interface that you want to assign to the device.



You can only assign data and data-sharing interfaces that you previously enabled on the **Interfaces** page. You will later enable and configure these interfaces in Firewall Management Center, including setting the IP addresses.

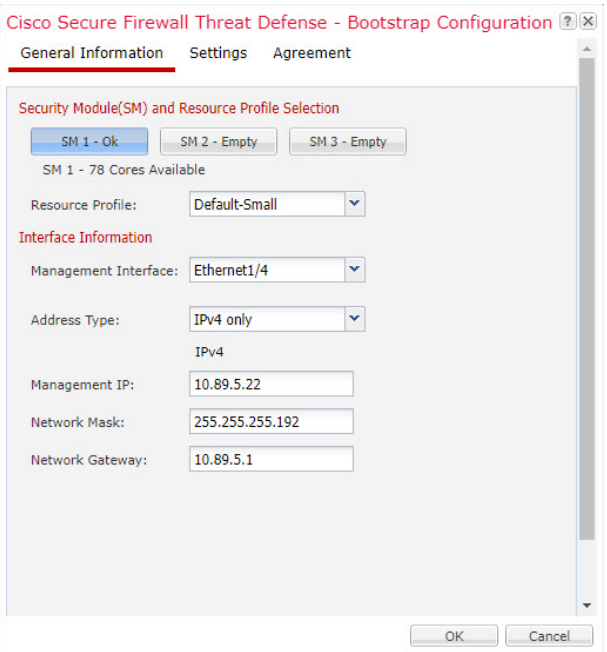
You can only assign up to 10 data-sharing interfaces to a container instance. Also, each data-sharing interface can be assigned to at most 14 container instances. A data-sharing interface is indicated by the sharing icon ( ).

Hardware Bypass-capable ports are shown with the following icon: . For certain interface modules, you can enable the Hardware Bypass feature for Inline Set interfaces only (see the Firewall Management Center configuration guide). Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures. If you do not assign both interfaces in a Hardware Bypass pair, you see a warning message to make sure your assignment is intentional. You do not need to use the Hardware Bypass feature, so you can assign single interfaces if you prefer.

Step 4 Click the device icon in the center of the screen.

A dialog box appears where you can configure initial bootstrap settings. These settings are meant for initial deployment only, or for disaster recovery. For normal operation, you can later change most values in the application CLI configuration.

Step 5 On the **General Information** page, complete the following:



a) (For the Firepower 9300) Under **Security Module Selection** click the security module that you want to use for this logical device.

b) For a container instance, specify the **Resource Profile**.

If you later assign a different resource profile, then the instance will reload, which can take approximately 5 minutes.

Note
If you later assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:

1. Break high availability.
2. Assign the new profile to both units.
3. Re-establish high availability.

c) Choose the **Management Interface**.

This interface is used to manage the logical device. This interface is separate from the chassis management port.

d) Choose the management interface **Address Type**: **IPv4 only**, **IPv6 only**, or **IPv4 and IPv6**.

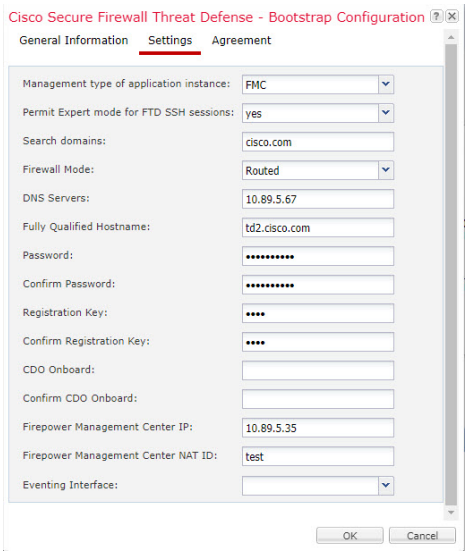
e) Configure the **Management IP** address.

Set a unique IP address for this interface.

f) Enter a **Network Mask** or **Prefix Length**.

g) Enter a **Network Gateway** address.

Step 6 On the **Settings** tab, complete the following:



a) For a native instance, in the **Management type of application instance** drop-down list, choose **FMC**.

Native instances also support Firewall Device Manager as a manager. After you deploy the logical device, you cannot change the manager type.

b) Enter the **Firepower Management Center IP** of the managing Firewall Management Center. If you do not know the Firewall Management Center IP address, leave this field blank and enter a passphrase in the **Firepower Management Center NAT ID** field.

c) For a container instance, **Permit Expert mode from FTD SSH sessions**: **Yes** or **No**. Expert Mode provides Firewall Threat Defense shell access for advanced troubleshooting.

If you choose **Yes** for this option, then users who access the container instance directly from an SSH sesssion can enter Expert Mode. If you choose **No**, then only users who access the container instance from the FXOS CLI can enter Expert Mode. We recommend choosing **No** to increase isolation between instances.

Use Expert Mode only if a documented procedure tells you it is required, or if the Cisco Technical Assistance Center asks you to use it. To enter this mode, use the **expert** command in the Firewall Threat Defense CLI.

d) Enter the **Search Domains** as a comma-separated list.

e) Choose the **Firewall Mode**: **Transparent** or **Routed**.

In routed mode, the Firewall Threat Defense is considered to be a router hop in the network. Each interface that you want to route between is on a different subnet. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices.

The firewall mode is only set at initial deployment. If you re-apply the bootstrap settings, this setting is not used.

f) Enter the **DNS Servers** as a comma-separated list.

The Firewall Threat Defense uses DNS if you specify a hostname for the Firewall Management Center, for example.

g) Enter the **Fully Qualified Hostname** for the Firewall Threat Defense.

h) Enter a **Registration Key** to be shared between the Firewall Management Center and the device during registration.

You can choose any text string for this key between 1 and 37 characters; you will enter the same key on the Firewall Management Center when you add the Firewall Threat Defense.

i) Enter a **Password** for the Firewall Threat Defense admin user for CLI access.

j) Choose the **Eventing Interface** on which events should be sent. If not specified, the management interface will be used.

This interface must be defined as a Firepower-eventing interface.

k) For a container instance, set the **Hardware Crypto** as **Enabled** or **Disabled**.

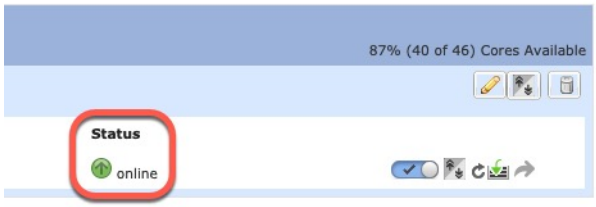
This setting enables TLS crypto acceleration in hardware, and improves performance for certain types of traffic. This feature is enabled by default. You can enable TLS crypto acceleration for up to 16 instances per security module. This feature is always enabled for native instances. To view the percentage of hardware crypto resources allocated to this instance, enter the **show hw-crypto** command.

Step 7 On the **Agreement** tab, read and accept the end user license agreement (EULA).

Step 8 Click **OK** to close the configuration dialog box.

Step 9 Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for the status of the new logical device. When the logical device shows its **Status** as **online**, you can start configuring the security policy in the application.



Step 10 See the Firewall Management Center configuration guide to add the Firewall Threat Defense as a managed device and start configuring your security policy.

Add a Standalone Threat Defense for the Cisco Security Cloud Control

You can use Security Cloud Control with both native and container instances. Standalone logical devices work either alone or in a High Availability pair.

Before you begin

- Download the application image you want to use for the logical device from Cisco.com, and then upload that image to the Firepower 4100/9300 chassis.

Note For the Firepower 9300, you can install different application types (ASA and Firewall Threat Defense) on separate modules in the chassis. You can also run different versions of an application instance type on separate modules.

- Configure a management interface to use with the logical device. The management interface is required. Note that this management interface is not the same as the chassis management port that is used only for chassis management (and that appears at the top of the **Interfaces** tab as **MGMT**).
- You must also configure at least one Data type interface.
- You must onboard the FTD device in Security Cloud Control.
- Gather the following information:
  - Interface IDs for this device
  - Management interface IP address and network mask
  - Gateway IP address
  - DNS server IP address
  - Threat Defense hostname and domain name
  - Security Cloud Control onboard string
  - Firewall Threat Defense hostname and domain name

Procedure

Step 1 Choose **Logical Devices**.

Step 2 Click **Add** > **Standalone**, and set the following parameters:

a) Provide a **Device Name**.

This name is used by the chassis supervisor to configure management settings and to assign interfaces; it is not the device name used in the application configuration.

Note
You cannot change this name after you add the logical device.

b) For the **Template**, choose **Cisco Firepower Threat Defense**.
c) Choose the **Image Version**.
d) Choose the **Instance Type**: **Container** or **Native**.

A native instance uses all of the resources (CPU, RAM, and disk space) of the security module/engine, so you can only install one native instance. A container instance uses a subset of resources of the security module/engine, so you can install multiple container instances.

e) Click **OK**.

You see the Provisioning - *device name* window.

Step 3 Expand the **Data Ports** area, and click each interface that you want to assign to the device.

You can only assign data and data-sharing interfaces that you previously enabled on the **Interfaces** page. You will later enable and configure these interfaces in Firewall Management Center, including setting the IP addresses.

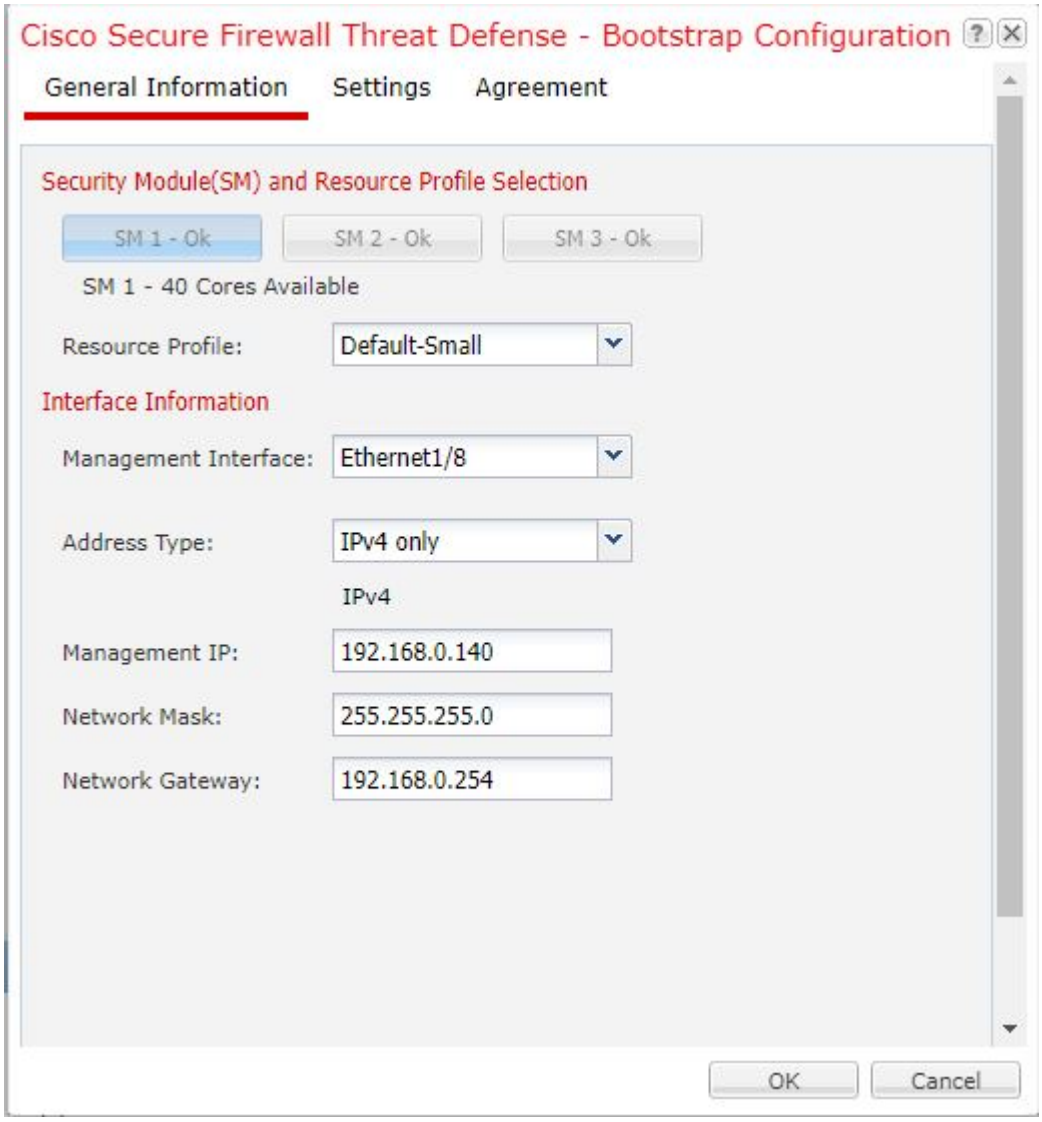
You can only assign up to 10 data-sharing interfaces to a container instance. Also, each data-sharing interface can be assigned to at most 14 container instances. A data-sharing interface is indicated by the sharing icon ( ).

Hardware Bypass-capable ports are shown with the following icon: . For certain interface modules, you can enable the Hardware Bypass feature for Inline Set interfaces only (see the Firewall Management Center configuration guide). Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures. If you do not assign both interfaces in a Hardware Bypass pair, you see a warning message to make sure your assignment is intentional. You do not need to use the Hardware Bypass feature, so you can assign single interfaces if you prefer.

Step 4 Click the device icon in the center of the screen.

A dialog box appears where you can configure initial bootstrap settings. These settings are meant for initial deployment only, or for disaster recovery. For normal operation, you can later change most values in the application CLI configuration.

Step 5 On the **General Information** page, complete the following:



a) (For the Firepower 9300) Under **Security Module Selection** click the security module that you want to use for this logical device.

b) For a container instance, specify the **Resource Profile**.

If you later assign a different resource profile, then the instance will reload, which can take approximately 5 minutes.

Note
If you later assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:

1. Break high availability.
2. Assign the new profile to both units.
3. Re-establish high availability.

c) Choose the **Management Interface**.

This interface is used to manage the logical device. This interface is separate from the chassis management port.

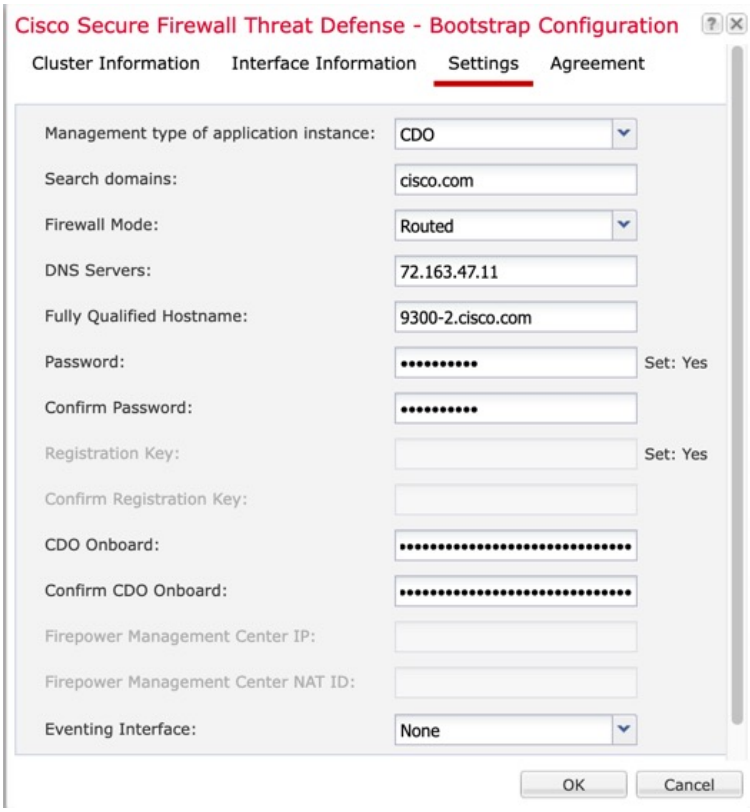
d) Choose the management interface **Address Type**: **IPv4 only**, **IPv6 only**, or **IPv4 and IPv6**.
e) Configure the **Management IP** address.

Set a unique IP address for this interface.

f) Enter a **Network Mask** or **Prefix Length**.
g) Enter a **Network Gateway** address.

Step 6 On the **Settings** tab, complete the following:

Figure 85: Settings



a) In the **Management type of application instance** drop-down list, choose **Security Cloud Control**.
b) Enter the **Search Domains** as a comma-separated list.
c) Choose the **Firewall Mode**: **Transparent** or **Routed**.
d) Enter the **DNS Servers** as a comma-separated list.
e) Enter the **Fully Qualified Hostname** for the threat defense.
f) Enter a **Password** for the threat defense admin user for CLI access.
g) Re-enter the password in **Confirm Password** for the threat defense admin user for CLI access
h) Enter the **Security Cloud Control Onboard** command string for the threat defense.

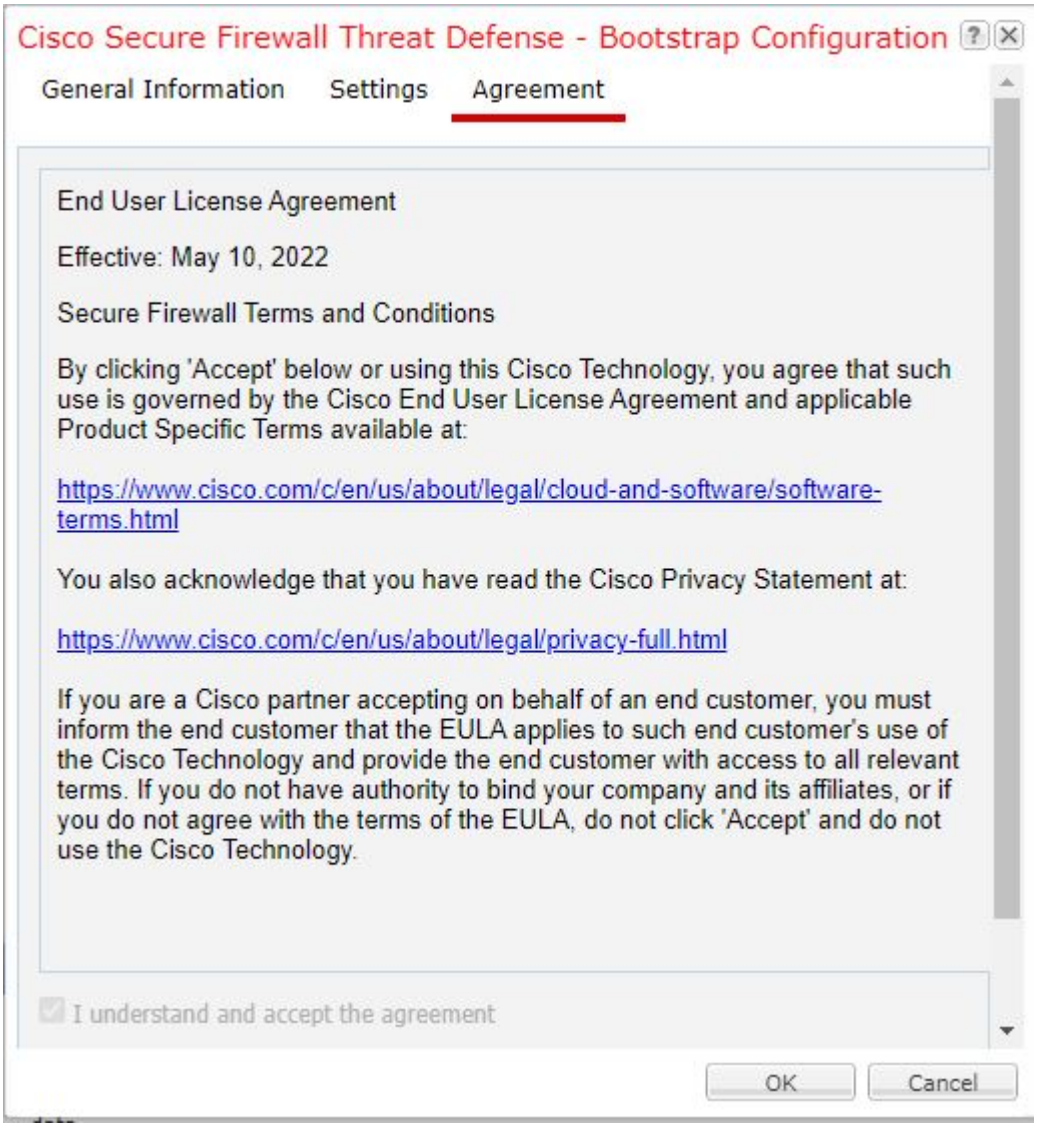
Security Cloud Control generates an onboarding command string once you onboard your FTD. Copy that string and place it in the **Security Cloud Control Onboard** field.

For example:

```
configure manager add cisco-sapphire.app.staging.cdo.cisco.com
TuNDBm6peReVDbUkOpZCgtJ1GqWKbD30
o9B064UXEwmr3AYAEpuflf4qE2E3JKY5 cisco-sapphire.app.staging.cdo.cisco.com
```

i) Re-enter the command string in **Confirm Security Cloud Control Onboard**.
j) A separate **Eventing Interface** is not supported for Security Cloud Control, so this setting will be ignored.

Step 7 On the **Agreement** tab, read and accept the end user license agreement (EULA).

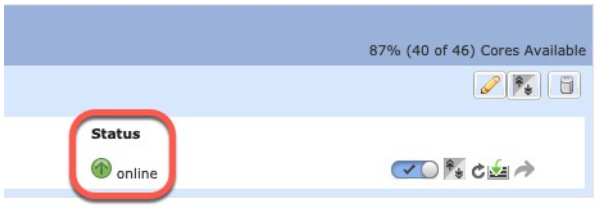


Step 8 Click **OK** to close the configuration dialog box.

Step 9 Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page

for the status of the new logical device. When the logical device shows its **Status** as **online**, you can start configuring the security policy in the application.



Step 10 Save the configuration.

commit-buffer

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the status of the deployment using the **show app-instance** command. The application instance is running and ready to use when the **Admin State** is **Enabled** and the **Oper State** is **Online**.

Example:

```
Firepower /ssa/logical-device* # commit-buffer
Firepower /ssa/logical-device # exit
Firepower /ssa # show app-instance
App Name   Identifier Slot ID    Admin State Oper State      Running Version Startup Version
 Deploy Type Profile Name Cluster State   Cluster Role
---------- ---------- ---------- ----------- ---------------- --------------- ---------------
 ----------- ------------ --------------- ------------
asa        asa1       2          Disabled    Not Installed                    9.12.1
    Native                   Not Applicable  None
ftd        ftd1       1          Enabled     Online           7.3.0           7.3.0
  Container   Default-Small Not Applicable  None
```

Step 11 See the Security Cloud Control configuration guide to start configuring your security policy.

Add a High Availability Pair

Firewall Threat Defense High Availability (also known as failover) is configured within the application, not in FXOS. However, to prepare your chassis for high availability, see the following steps.

Before you begin

See Requirements and Prerequisites for High Availability, on page 470.

Procedure

Step 1 Allocate the same interfaces to each logical device.

Step 2 Allocate 1 or 2 data interfaces for the failover and state link(s).

These interfaces exchange high availability traffic between the 2 chassis. We recommend that you use a 10 GB data interface for a combined failover and state link. If you have available interfaces, you can use separate failover and state links; the state link requires the most bandwidth. You cannot use the management-type interface for the failover or state link. We recommend that you use a switch between the chassis, with no other device on the same network segment as the failover interfaces.

For container instances, data-sharing interfaces are not supported for the failover link. We recommend that you create subinterfaces on a parent interface or EtherChannel, and assign a subinterface for each instance to use as a failover link. Note that you must use all subinterfaces on the same parent as failover links. You cannot use one subinterface as a failover link and then use other subinterfaces (or the parent interface) as regular data interfaces.

Step 3 Enable High Availability on the logical devices. See High Availability, on page 565.

Step 4 If you need to make interface changes after you enable High Availability, perform the changes on the standby unit first, and then perform the changes on the active unit.

Change an Interface on a Firewall Threat Defense Logical Device

You can allocate or unallocate an interface, or replace a management interface on the Firewall Threat Defense logical device. You can then sync the interface configuration in the Firewall Management Centerthe .

Adding a new interface, or deleting an unused interface has minimal impact on the Firewall Threat Defense configuration. However, deleting an interface that is used in your security policy will impact the configuration. Interfaces can be referenced directly in many places in the Firewall Threat Defense configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Policies that refer to security zones are not affected. You can also edit the membership of an allocated EtherChannel without affecting the logical device or requiring a sync on the Firewall Management Centerthe .

Deleting an interface will delete any configuration associated with that interface.

Before you begin

- Configure your interfaces, and add any EtherChannels according to Configure a Physical Interface, on page 478 and Add an EtherChannel (Port Channel), on page 479.
- If you want to add an already-allocated interface to an EtherChannel (for example, all interfaces are allocated by default to a cluster), you need to unallocate the interface from the logical device first, then add the interface to the EtherChannel. For a new EtherChannel, you can then allocate the EtherChannel to the device.
- If you want to replace the management or eventing interface with a management EtherChannel, then you need to create the EtherChannel with at least 1 unallocated data member interface, and then replace the current management interface with the EtherChannel. After the Firewall Threat Defense device reboots (management interface changes cause a reboot), and you sync the configuration in the Firewall

Management Centerthe , you can add the (now unallocated) management interface to the EtherChannel as well.

- For clustering or High Availability, make sure you add or remove the interface on all units before you sync the configuration in the Firewall Management Centerthe . We recommend that you make the interface changes on the data/standby unit(s) first, and then on the control/active unit. Note that new interfaces are added in an administratively down state, so they do not affect interface monitoring.
- In mult-instance mode, for changing a sub-interface with an another sub-interface with the same vlan tag, you must first remove all the configuration (including nameif config) of the interface and then unalloacte the interface from Firewall Chassis Manager. Once unallocated, add the new interface and then use sync interfaces from the Firewall Management Center.

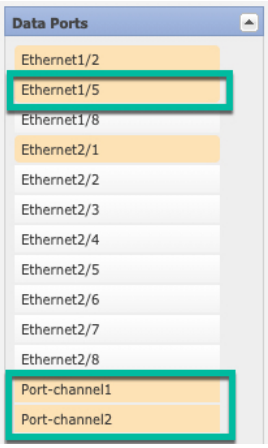
Procedure

Step 1 In the Firewall Chassis Manager, choose **Logical Devices**.

Step 2 Click the **Edit** icon at the top right to edit the logical device.

Step 3 Allocate a new data interface by selecting the interface in the **Data Ports** area.

Do not delete any interfaces yet.



Step 4 Replace the management or eventing interface:

For these types of interfaces, the device reboots after you save your changes.

a) Click the device icon in the center of the page.
b) On the **General** or **Cluster Information** tab, choose the new **Management Interface** from the drop-down list.
c) On the **Settings** tab, choose the new **Eventing Interface** from the drop-down list.
d) Click **OK**.

If you change the IP address of the Management interface, then you must also change the IP address for the device in the Firewall Management Center: go to **Devices** > **Device Management** > **Device/Cluster**. In the **Management** area, set the IP address to match the bootstrap configuration address.

Step 5 Click **Save**.

Step 6 Sync the interfaces in the Firewall Management Center.

a) Log into the Firewall Management Center.

b) Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

c) Click the **Sync Device** button on the top left of the **Interfaces** page.

d) After the changes are detected, you will see a red banner on the **Interfaces** page indicating that the interface configuration has changed. Click the **Click to know more** link to view the interface changes.

e) If you plan to delete an interface, manually transfer any interface configuration from the old interface to the new interface.

Because you have not yet deleted any interfaces, you can refer to the existing configuration. You will have additional opportunity to fix the configuration after you delete the old interface and re-run the validation. The validation will show you all locations in which the old interface is still used.

f) Click **Validate Changes** to make sure your policy will still work with the interface changes.

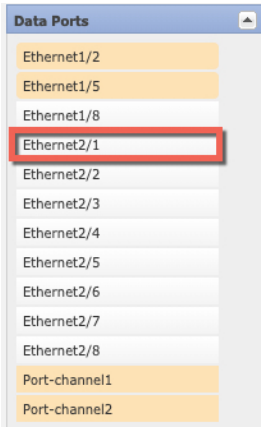
If there are any errors, you need to change your policy and rerun the validation.

g) Click **Save**.

h) Click **Deploy** > **Deployment**.

i) Select the devices and click **Deploy** to deploy the policy to the assigned devices. The changes are not active until you deploy them.

Step 7 In the Firewall Chassis Manager, unallocate a data interface by de-selecting the interface in the **Data Ports** area.



Step 8 Click **Save**.

Step 9 Sync the interfaces again in the Firewall Management Centerthe .

Connect to the Console of the Application

Use the following procedure to connect to the console of the application.

Procedure

Step 1 Connect to the module CLI using a console connection or a Telnet connection.

connect module *slot_number* {**console** | **telnet**}

To connect to the security engine of a device that does not support multiple security modules, always use **1** as the *slot_number*.

The benefits of using a Telnet connection is that you can have multiple sessions to the module at the same time, and the connection speed is faster.

Example:

```
Firepower# connect module 1 console
Telnet escape character is '~'.
Trying 127.5.1.1...
Connected to 127.5.1.1.
Escape character is '~'.

CISCO Serial Over LAN:
Close Network Connection to Exit

Firepower-module1>
```

Step 2 Connect to the application console.

connect ftd *name*

To view the instance names, enter the command without a name.

Example:

```
Firepower-module1> connect ftd ftd1
Connecting to ftd(ftd-native) console... enter exit to return to bootCLI
[...]
>
```

Step 3 Exit the application console to the FXOS module CLI.

- Firewall Threat Defense—Enter **exit**

Step 4 Return to the supervisor level of the FXOS CLI.

Exit the console:

a) Enter **~**

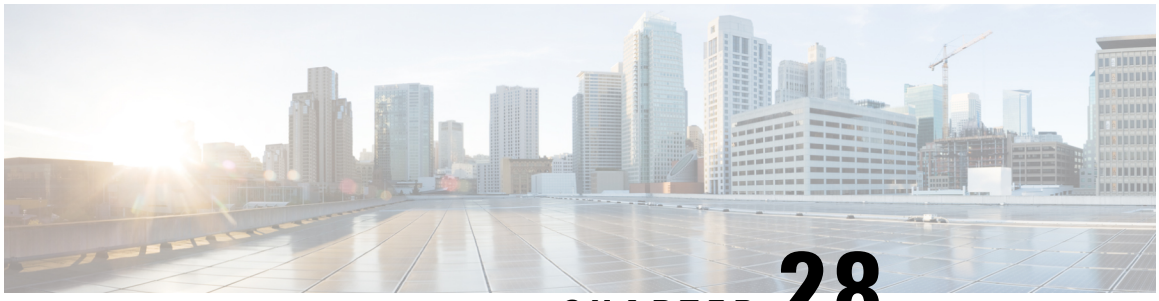
You exit to the Telnet application.

b) To exit the Telnet application, enter:

telnet>**quit**

Exit the Telnet session:

a) Enter **Ctrl-], .**



CHAPTER 28

Multi-Instance Mode for the Secure Firewall 3100

You can deploy the Secure Firewall 3100 as a single device (*appliance mode*) or as multiple container instances (*multi-instance mode*). This chapter describes how to deploy the device in multi-instance mode.

- About Multi-Instance Mode, on page 501
- Licenses for Instances, on page 514
- Requirements and Prerequisites for Instances, on page 514
- Guidelines and Limitations for Instances, on page 516
- Configure Instances, on page 518
- Monitoring Multi-Instance Mode, on page 561
- History for Multi-Instance Mode, on page 564

About Multi-Instance Mode

In multi-instance mode, you can deploy multiple container instances on a single chassis that act as completely independent devices.

Multi-Instance Mode vs. Appliance Mode

You can run the device in either multi-instance mode or appliance mode.

Appliance Mode

Appliance mode is the default. The device runs the native Firewall Threat Defense image and acts as a single device. The only chassis-level configuration available (on the **Chassis Manager** page) is for network module management (breakout ports or enabling/disabling a network module).

Multi-Instance Mode

If you change to multi-instance mode, the device runs the Secure Firewall eXtensible Operating System (FXOS) on the chassis, while each instance runs separate Firewall Threat Defense images. You can configure the mode using the FXOS CLI.

Because multiple instances run on the same chassis, you need to perform chassis-level management of:

- CPU and memory resources using resource profiles.

- Interface configuration and assignment.
- Deployment and monitoring of instances.

For a multi-instance device, you add the *chassis* to the Firewall Management Center and configure chassis-level settings on the **Chassis Manager** page.

Chassis Management Interface

Chassis Management

The chassis uses the dedicated Management interface on the device. Multi-instance mode does not support using a data interface for chassis management or DHCP addressing for the Management interface.

You can only configure the chassis Management interface at the Firewall Threat Defense CLI (at initial setup) or FXOS CLI (after you convert to multi-instance mode). See Onboard the Multi-Instance Chassis, on page 518 for initial setup. See Change Chassis Management Settings at the FXOS CLI, on page 558 to change Management interface settings in multi-instance mode.

Note By default, SSH is not allowed to this interface in multi-instance mode unless you enable the SSH server and an SSH access list. This difference means that you can connect to the application-mode threat defense Management interface using SSH, but after you convert to multi-instance mode, you can no longer connect using SSH by default. See Configure SSH and SSH Access List, on page 543.

Instance Management

All instances share the chassis management interface, and each instance has its own IP address on the Management network. After you add the instance and specify the IP address, you can make changes to the network settings at the Firewall Threat Defense CLI.

The instance Management IP address allows SSH by default.

Instance Interfaces

To provide flexible physical interface use for instances, you can create VLAN subinterfaces on the chassis and also share interfaces (VLAN or physical) between multiple instances. See Shared Interface Scalability, on page 505 and Configure a Subinterface, on page 529.

Note This chapter discusses *chassis* VLAN subinterfaces only. You can separately create subinterfaces within the Firewall Threat Defense instance. See Chassis Interfaces vs. Instance Interfaces, on page 503 for more information.

Interface Types

Physical interfaces, VLAN subinterfaces, and EtherChannel interfaces can be one of the following types:

- Data—Use for regular data or the failover link. Data interfaces cannot be shared between instances, and instances cannot communicate over the backplane to other instances. For traffic on Data interfaces, all traffic must exit the chassis on one interface and return on another interface to reach another instance. You can add VLAN subinterfaces to a data interface to provide separate failover links per High Availability pair.
- Data-sharing—Use for regular data. These data interfaces can be shared by one or more instances. Each instance can communicate over the backplane with all other instances that share this interface. Shared interfaces can affect the number of instances you can deploy. Shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode), inline sets, passive interfaces, or failover links.

Chassis Interfaces vs. Instance Interfaces

At the chassis level, you manage the basic Ethernet settings of physical interfaces, VLAN subinterfaces for instances, and EtherChannel interfaces. Within the instance, you configure higher level settings. For example, you can only create EtherChannels in the chassis; but you can assign an IP address to the EtherChannel within the instance.

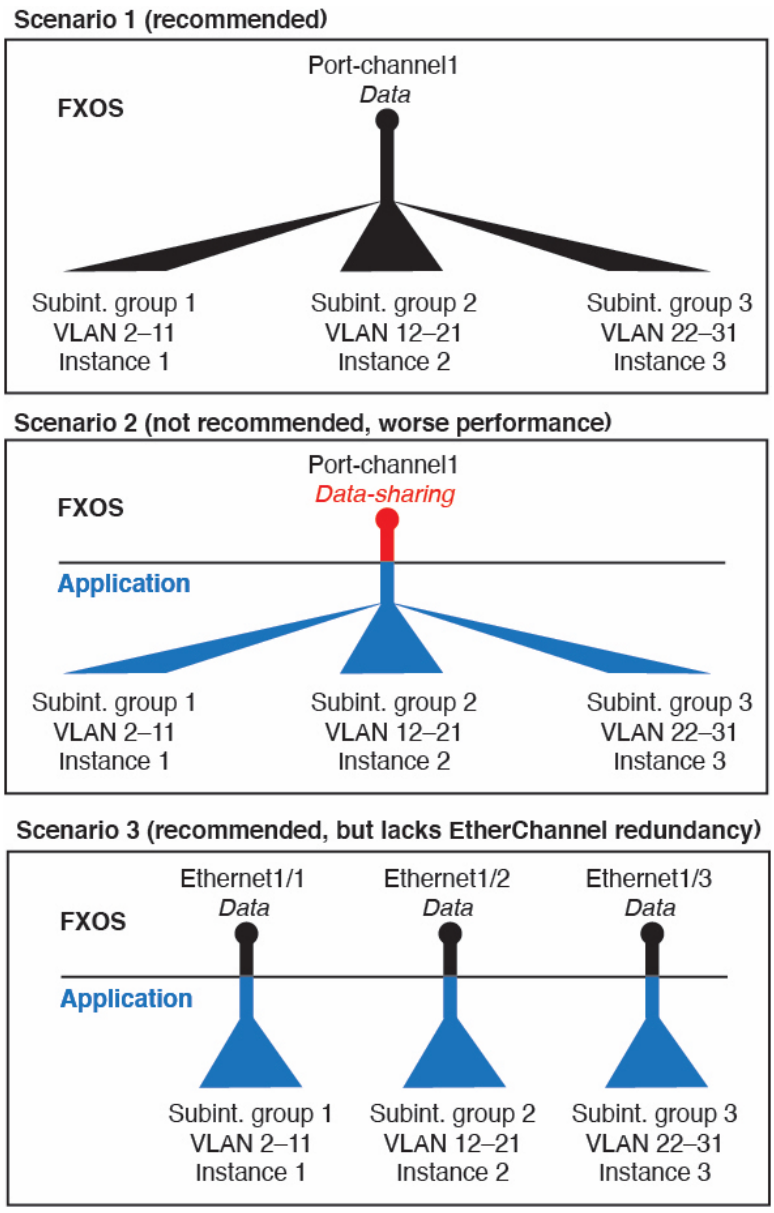
The following sections describe the interaction between the chassis and the instance for interfaces.

VLAN Subinterfaces

You can create VLAN subinterfaces within the instance, just as you would for any device.

You can *also* create VLAN subinterfaces in the chassis. The instance-defined subinterfaces are not subject to the chassis limit. Choosing in which location to create subinterfaces depends on your network deployment and personal preference. For example, to share a subinterface, you must create the subinterface on the chassis. Another scenario that favors chassis subinterfaces comprises allocating separate subinterface groups on a single interface to multiple instances. For example, you want to use Port-channel1 with VLAN 2–11 on instance A, VLAN 12–21 on instance B, and VLAN 22–31 on instance C. If you create these subinterfaces in the instance, then you would have to share the parent interface in the chassis, which may not be desirable. See the following illustration that shows the three ways you can accomplish this scenario:

Figure 86: VLANs in the Chassis vs. the Instance



Independent Interface States in the Chassis and in the Instance

You can administratively enable and disable interfaces in both the chassis and in the instance. For an interface to be operational, the interface must be enabled in both locations. Because the interface state is controlled independently, you may have a mismatch between the chassis and instance.

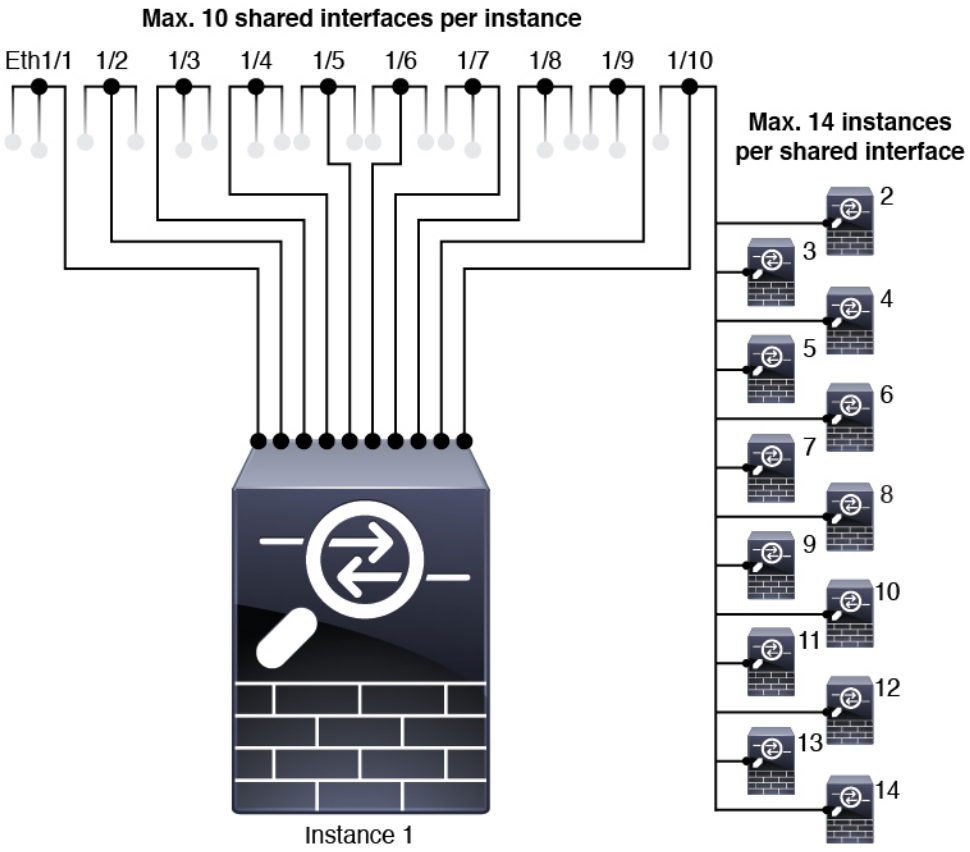
The default state of an interface within the instance depends on the type of interface. For example, the physical interface or EtherChannel is disabled by default within the instance, but a subinterface is enabled by default.

Shared Interface Scalability

Instances can share data-sharing type interfaces. This capability lets you conserve physical interface usage as well as support flexible networking deployments. When you share an interface, the chassis uses unique MAC addresses to forward traffic to the correct instance. However, shared interfaces can cause the forwarding table to grow large due to the need for a full mesh topology within the chassis (every instance must be able to communicate with every other instance that is sharing the same interface). Therefore, there are limits to how many interfaces you can share.

In addition to the forwarding table, the chassis maintains a VLAN group table for VLAN subinterface forwarding. You can create up to 500 VLAN subinterfaces.

See the following limits for shared interface allocation:



Shared Interface Best Practices

For optimal scalability of the forwarding table, share as few interfaces as possible. Instead, you can create up to 500 VLAN subinterfaces on one or more physical interfaces and then divide the VLANs among the container instances.

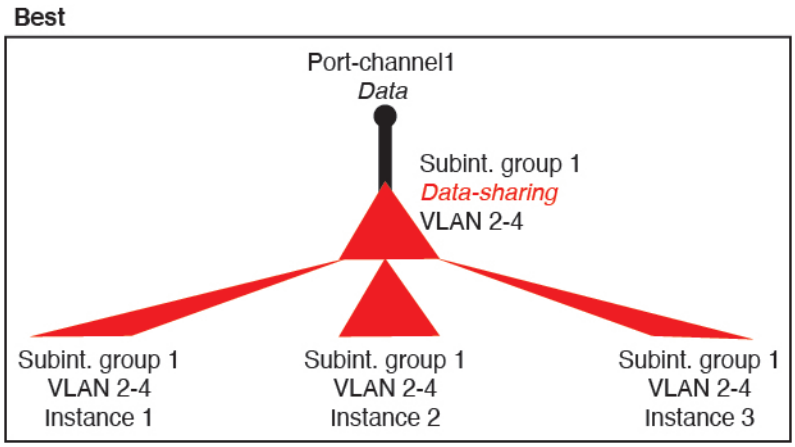
When sharing interfaces, follow these practices in the order of most scalable to least scalable:

1. Best—Share subinterfaces under a single parent, and use the same set of subinterfaces with the same group of instances.

   For example, create a large EtherChannel to bundle all of your like-kind interfaces together, and then share subinterfaces of that EtherChannel: Port-Channel1.2, 3, and 4 instead of Port-Channel2,

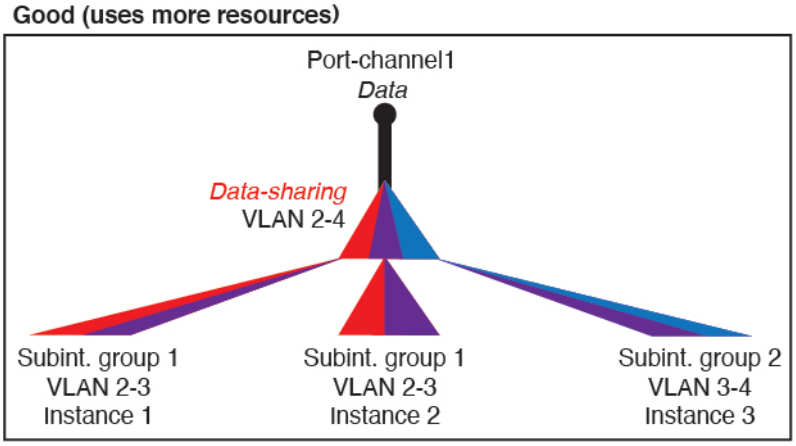
Port-Channel3, and Port-Channel4. When you share subinterfaces from a single parent, the VLAN group table provides better scaling of the forwarding table than when sharing physical/EtherChannel interfaces or subinterfaces across parents.

Figure 87: Best: Shared Subinterface Group on One Parent



If you do not share the same set of subinterfaces with a group of instances, your configuration can cause more resource usage (more VLAN groups). For example, share Port-Channel1.2, 3, and 4 with instances 1, 2, and 3 (one VLAN group) instead of sharing Port-Channel1.2 and 3 with instances 1 and 2, while sharing Port-Channel1.3 and 4 with instance 3 (two VLAN groups).

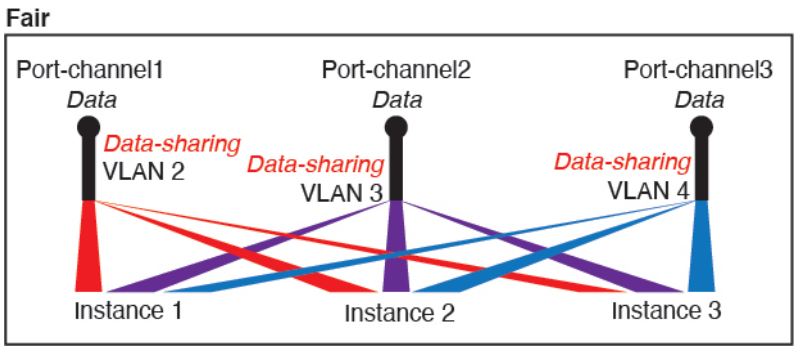
Figure 88: Good: Sharing Multiple Subinterface Groups on One Parent



2. Fair—Share subinterfaces across parents.

   For example, share Port-Channel1.2, Port-Channel2.3, and Port-Channel3.4 instead of Port-Channel2, Port-Channel4, and Port-Channel4. Although this usage is not as efficient as only sharing subinterfaces on the same parent, it still takes advantage of VLAN groups.

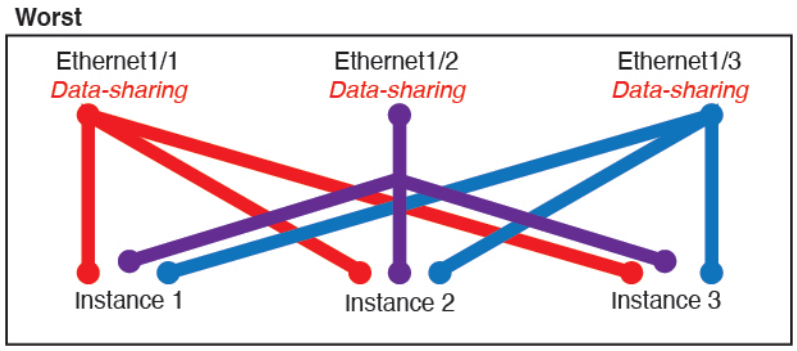
Figure 89: Fair: Shared Subinterfaces on Separate Parents



3. Worst—Share individual parent interfaces (physical or EtherChannel).

   This method uses the most forwarding table entries.

Figure 90: Worst: Shared Parent Interfaces



How the Chassis Classifies Packets

Each packet that enters the chassis must be classified, so that the chassis can determine to which instance to send a packet.

- Unique Interfaces—If only one instance is associated with the ingress interface, the chassis classifies the packet into that instance. For bridge group member interfaces (in transparent mode or routed mode), inline sets, or passive interfaces, this method is used to classify packets at all times.
- Unique MAC Addresses—The chassis automatically generates unique MAC addresses for all interfaces, including shared interfaces. If multiple instances share an interface, then the classifier uses unique MAC addresses assigned to the interface in each instance. An upstream router cannot route directly to an instance without unique MAC addresses. You can also set the MAC addresses manually when you configure each interface within the application.

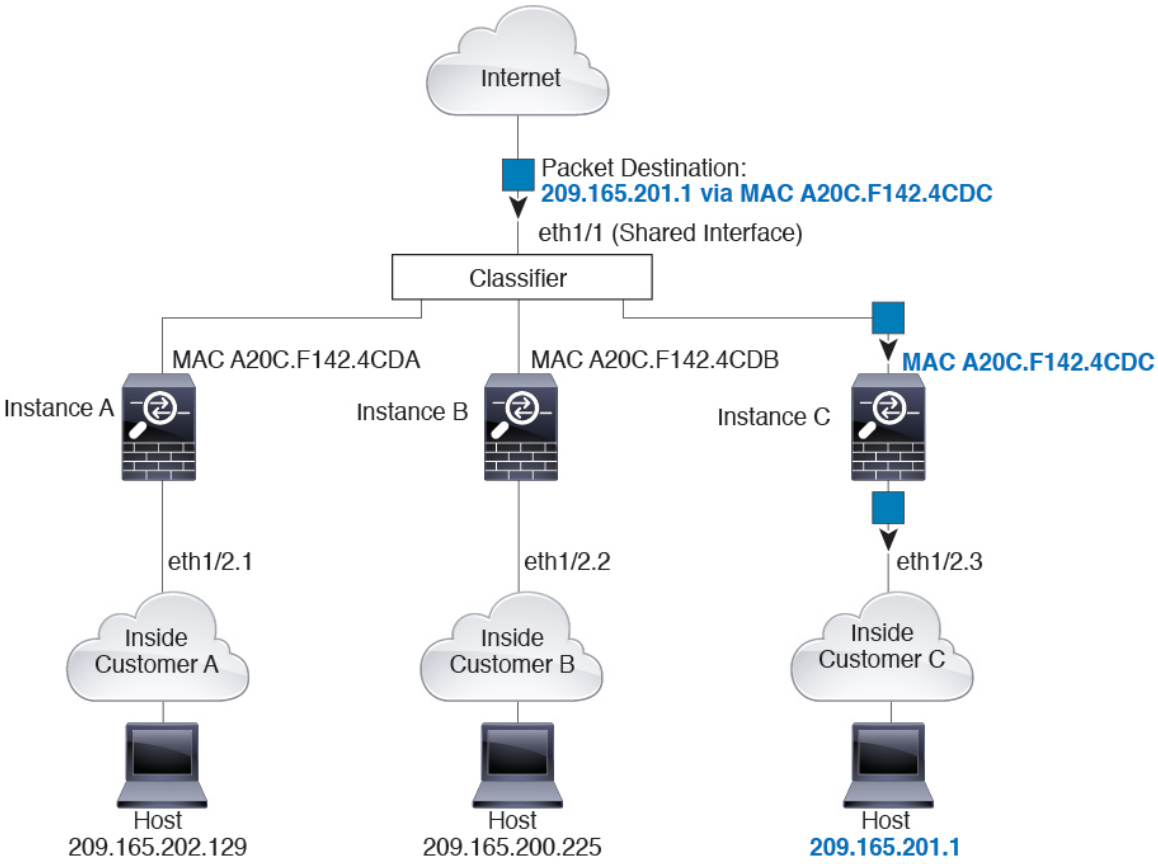
Note If the destination MAC address is a multicast or broadcast MAC address, the packet is duplicated and delivered to each instance.

Classification Examples

Packet Classification with a Shared Interface Using MAC Addresses

The following figure shows multiple instances sharing an outside interface. The classifier assigns the packet to Instance C because Instance C includes the MAC address to which the router sends the packet.

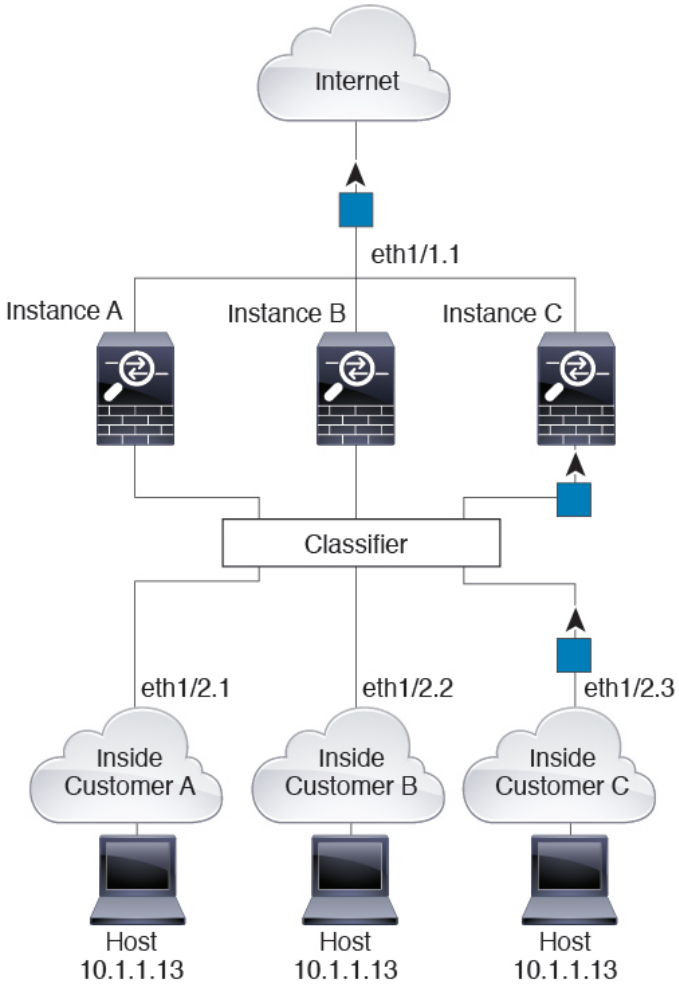
Figure 91: Packet Classification with a Shared Interface Using MAC Addresses



Incoming Traffic from Inside Networks

Note that all new incoming traffic must be classified, even from inside networks. The following figure shows a host on the Instance C inside network accessing the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/2.3, which is assigned to Instance C.

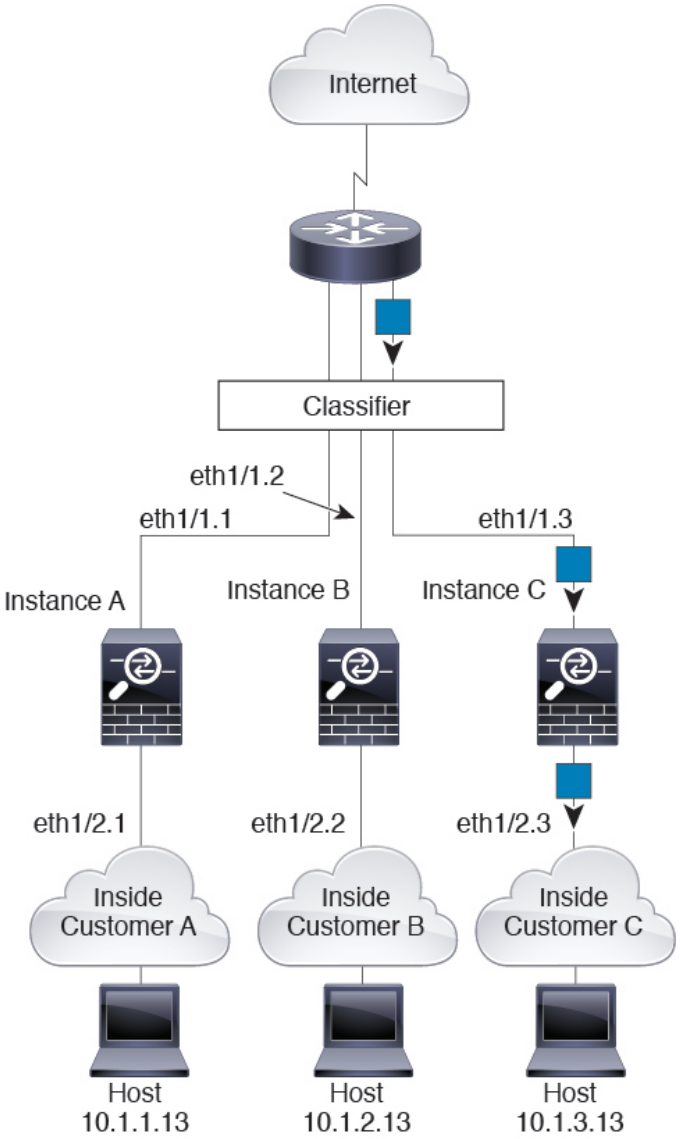
Figure 92: Incoming Traffic from Inside Networks



Transparent Firewall Instances

For transparent firewalls, you must use unique interfaces. The following figure shows a packet destined to a host on the Instance C inside network from the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/2.3, which is assigned to Instance C.

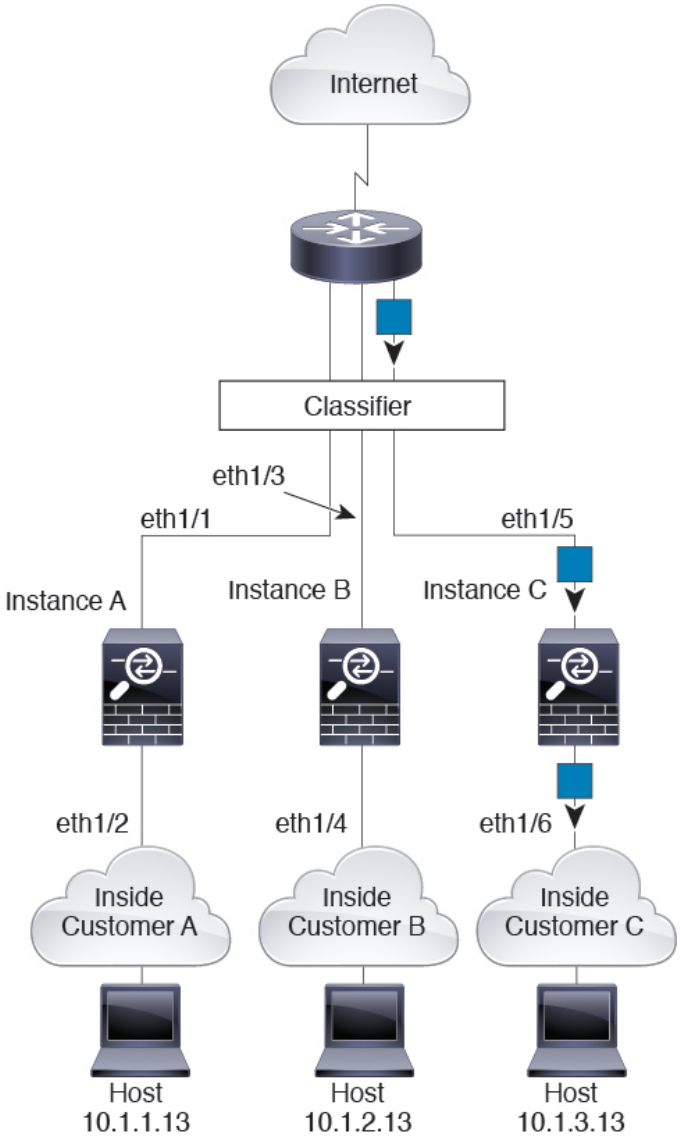
Figure 93: Transparent Firewall Instances



Inline Sets

For inline sets, you must use unique interfaces and they must be physical interfaces or EtherChannels. The following figure shows a packet destined to a host on the Instance C inside network from the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/5, which is assigned to Instance C.

Figure 94: Inline Sets

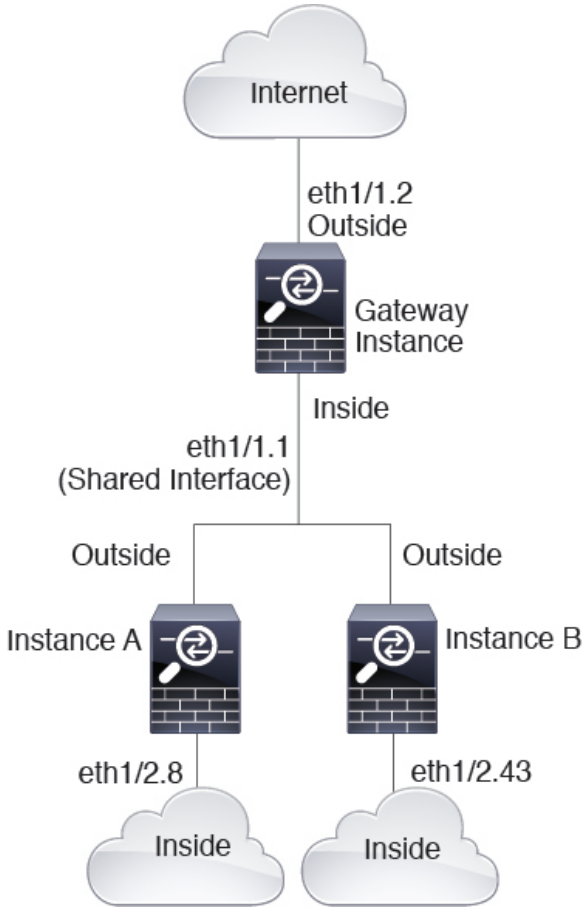


Cascading Instances

Placing an instance directly in front of another instance is called *cascading instances*; the outside interface of one instance is the same interface as the inside interface of another instance. You might want to cascade instances if you want to simplify the configuration of some instances by configuring shared parameters in the top instance.

The following figure shows a gateway instance with two instances behind the gateway.

Figure 95: Cascading Instances



Note Do not use cascading instances (using a shared interface) with High Availability. After a failover occurs and the standby unit rejoins, MAC addresses can overlap temporarily and cause an outage. You should instead use unique interfaces for the gateway instance and inside instance using an external switch to pass traffic between the instances.

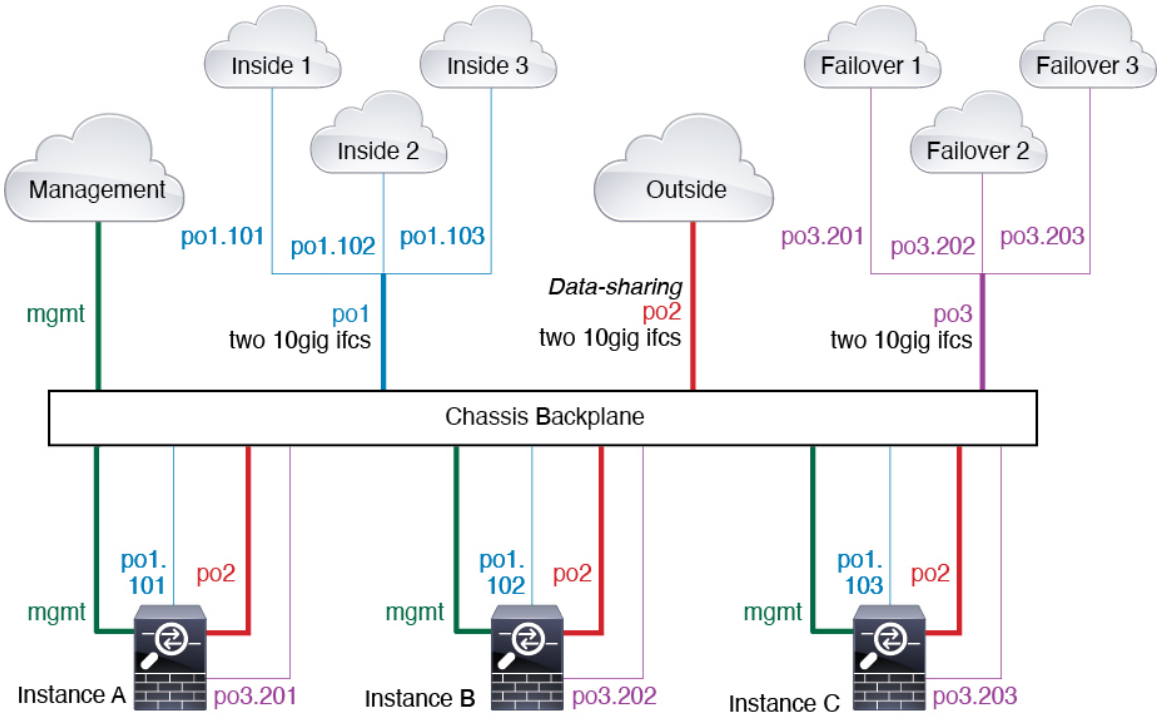
Typical Multi-Instance Deployment

The following example includes three container instances in routed firewall mode. They include the following interfaces:

- Management—All instances and the chassis use the dedicated Management interface. Within each instance (and the chassis), the interface uses a unique IP address on the same management network.
- Inside—Each instance uses a subinterface on Port-Channel1 (data type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Each subinterface is on a separate network.

- Outside—All instances use the Port-Channel2 interface (data-sharing type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Within each application, the interface uses a unique IP address on the same outside network.
- Failover—Each instance uses a subinterface on Port-Channel3 (data type). This EtherChannel includes two 10 Gigibit Ethernet interfaces. Each subinterface is on a separate network.

Figure 96: Typical Multi-Instance Deployment



Automatic MAC Addresses for Instance Interfaces

The chassis automatically generates MAC addresses for instance interfaces, and guarantees that a shared interface in each instance uses a unique MAC address.

If you manually assign a MAC address to a shared interface within the instance, then the manually-assigned MAC address is used. If you later remove the manual MAC address, the autogenerated address is used. In the rare circumstance that the generated MAC address conflicts with another private MAC address in your network, we suggest that you manually set the MAC address for the interface within the instance.

Because autogenerated addresses start with A2, you should not start manual MAC addresses with A2 due to the risk of overlapping addresses.

The chassis generates the MAC address using the following format:

A2*xx.yyzz.zzzz*

Where *xx.yy* is a user-defined prefix or a system-defined prefix, and *zz.zzzz* is an internal counter generated by the chassis. The system-defined prefix matches the lower 2 bytes of the first MAC address in the burned-in MAC address pool that is programmed into the IDPROM. Use **connect fxos**, then **show module** to view the

MAC address pool. For example, if the range of MAC addresses shown for module 1 is b0aa.772f.f0b0 to b0aa.772f.f0bf, then the system prefix will be f0b0.

The user-defined prefix is an integer that is converted into hexadecimal. For an example of how the user-defined prefix is used, if you set a prefix of 77, then the chassis converts 77 into the hexadecimal value 004D (*yyxx*). When used in the MAC address, the prefix is reversed (*xxyy*) to match the chassis native form:

A2**4D.00***zz.zzzz*

For a prefix of 1009 (03F1), the MAC address is:

A2**F1.03***zz.zzzz*

Performance Scaling Factor for Multi-Instance Mode

The maximum throughput (connections, VPN sessions) for a platform is calculated for an appliance mode device's use of memory and CPU (and this value is shown in **show resource usage**). If you use multiple instances, then you need to calculate the throughput based on the percentage of CPU cores that you assign to the instance. For example, if you use an instance with 50% of the cores, then you should initially calculate 50% of the throughput. Moreover, the throughput available to an instance may be less than that available to an appliance.

For detailed instructions on calculating the throughput for instances, see https://www.cisco.com/c/en/us/products/collateral/security/firewalls/white-paper-c11-744750.html.

Instances and High Availability

You can use High Availability using an instance on 2 separate chassis; for example, if you have 2 chassis, each with 10 instances, you can create 10 High Availability pairs. You can also have standalone instances on the same chassis as High Availability instances. For detailed requirements, see Requirements and Prerequisites for Instances, on page 514.

Note Clustering is not supported.

Licenses for Instances

All licenses are consumed per chassis and not per instance. See the following details:

- Essentials licenses are assigned to the chassis as a whole, one per chassis.
- Feature licenses are assigned to each instance, but you only *consume* one license per feature per chassis.

Requirements and Prerequisites for Instances

Model Support

- Secure Firewall 3110

- Secure Firewall 3120
- Secure Firewall 3130
- Secure Firewall 3140

Note The Secure Firewall 3105 is not supported.

Maximum Container Instances and Resources per Model

For each container instance, you can specify the number of CPU cores (or more specifically, threads) to assign to the instance. We use the term "core" generically to account for different hardware architecture. RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance.

Table 42: Maximum Container Instances and Resources per Model

Model	Max. Container Instances	Available CPU Cores (Threads)
Secure Firewall 3110	3	22
Secure Firewall 3120	5	30
Secure Firewall 3130	7	46
Secure Firewall 3140	10	62

Software Requirements

- You can run different versions of Firewall Threat Defense software on each instance as long as they are all compatible with the version of FXOS running on the chassis.
- You cannot deploy an instance with a patch version of the Firewall Threat Defense software because it is not a complete bundle. You need to first deploy the major or maintenance version, and then patch it after deployment.

High Availability Requirements

- The two instances in a High Availability configuration must:
  - Be on separate chassis.
  - Be on the same model.
  - Have the same interfaces assigned. All interfaces must be preconfigured in the chassis identically before you enable High Availability.
  - Use the same resource profile attributes. The profile names can be different, but the definitions need to match.

Firewall Management Center Requirements

For chassis management and all instances on the chassis, you must use the same Firewall Management Center due to the licensing implementation.

Guidelines and Limitations for Instances

General Guidelines

- A single Firewall Management Center must manage all instances on a chassis, as well as manage the chassis itself.
- For instances, the following features are not supported:
  - TLS crypto acceleration
  - Clustering
  - Firewall Management Center UCAPL/CC mode
  - Flow offload to hardware
  - LLDP
- Primary management of the chassis by Security Cloud Control cloud-delivered Firewall Management Center and separate analytics-only management of the chassis by an on-prem Firewall Management Center is not supported. You can however add Security Cloud Control-managed instances to an analytics-only on-prem Firewall Management Center.

Management Interface

- No support for a data interface for chassis management; only the dedicated Management interface can be used
- No DHCP addressing for the Management interface
- The management connection requires TCP port 8305; do not change the value from the default.

VLAN Subinterfaces

- This document discusses *chassis* VLAN subinterfaces only. You can separately create subinterfaces within the instance.
- If you assign a parent interface to an instance, it only passes untagged (non-VLAN) traffic. Do not assign the parent interface unless you intend to pass untagged traffic.
- Subinterfaces are supported on Data or Data-sharing type interfaces.
- You can create up to 500 VLAN IDs.
- You cannot use subinterfaces for an inline set or as a passive interface.

- If you use a subinterface for the failover link, then all subinterfaces on that parent, and the parent itself, are restricted for use as failover links. You cannot use some subinterfaces as failover links, and some as regular data interfaces.

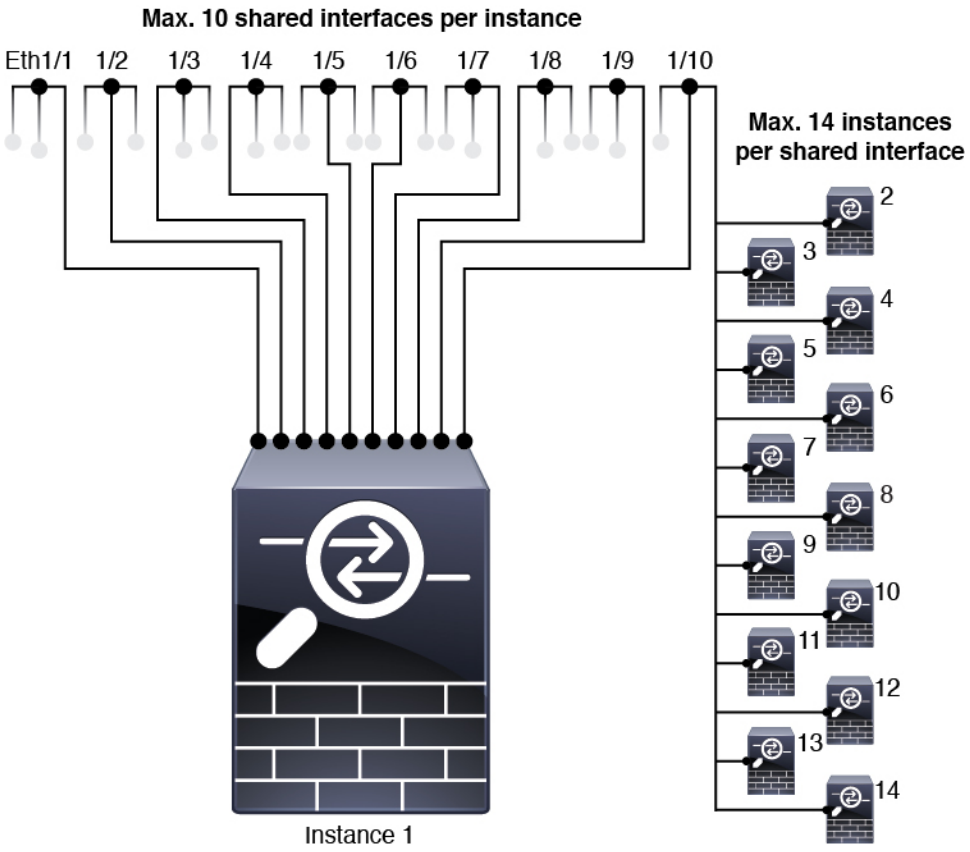
EtherChannels

- You can configure up to 48 EtherChannels, limited by the number of physical interfaces.
- The EtherChannel can have up to 8 active interfaces.
- All interfaces in the EtherChannel must be the same media type and speed capacity. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, unless you set the speed to **Detect SFP**; in this case, you can use different interface capacities, and the lowest common speed is used.
- The chassis does not support LACPDUs that are VLAN-tagged. If you enable native VLAN tagging on the neighboring switch using the Cisco IOS **vlan dot1Q tag native** command, then the chassis will drop the tagged LACPDUs. Be sure to disable native VLAN tagging on the neighboring switch.
- In Cisco IOS software versions earlier than 15.1(1)S2, the chassis did not support connecting an EtherChannel to a switch stack. With default switch settings, if the chassis EtherChannel is connected cross stack, and if the primary switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.

Data-sharing Interfaces

- Maximum 14 instances per shared interface. For example, you can allocate Ethernet1/1 to Instance1 through Instance14.

  Maximum 10 shared interfaces per instance. For example, you can allocate Ethernet1/1.1 through Ethernet1/1.10 to Instance1.



- You cannot use a data-sharing interface with a transparent firewall mode instance.
- You cannot use a data-sharing interface with inline sets or passive interfaces.
- You cannot use a data-sharing interface for the failover link.

Default MAC Addresses

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. See Automatic MAC Addresses for Instance Interfaces, on page 513.

Configure Instances

Before you configure instances, you need to enable multi-instance mode, add the chassis to the Firewall Management Center, and configure chassis interfaces. You can also customize the chassis settings.

Onboard the Multi-Instance Chassis

You need to connect to the chassis FXOS CLI at the console port to enable multi-instance mode and perform initial setup. After you configure the chassis, you can add it to the Cloud-Delivered Firewall Management

Center. The management center and the chassis share a separate management connection using the chassis MGMT interface.

Note Although you can connect to SSH on the management port, we recommend using the console port to avoid multiple disconnections. If you use SSH before you switch to multi-instance mode, you connect to the Firewall Threat Defense CLI and need to connect to FXOS using **connect fxos**. This procedure covers the console port.

Use the Cloud-Delivered Firewall Management Center to configure all chassis settings as well as instances. The Secure Firewall Chassis Manager or configuration at the FXOS CLI is not supported.

Procedure

Step 1 Connect to the chassis console port.

The console port connects to the FXOS CLI.

Step 2 Log in with the username **admin** and the password **Admin123**.

The first time you log in to FXOS, you are prompted to change the password.

Note
If the password was already changed, and you do not know it, you must reimage the device to reset the password to the default. See the FXOS troubleshooting guide for the reimage procedure.

Example:

```
firepower login: admin
Password: Admin123
Successful login attempts for user 'admin' : 1

[...]

Hello admin. You must change your password.
Enter new password: ********
Confirm new password: ********
Your password was updated successfully.

[...]

firepower#
```

Step 3 Check your current mode, Native or Container. If the mode is Native, you can continue with this procedure to convert to multi-instance (Container) mode.

show system detail

Example:

```
firepower # show system detail

Systems:
```

```
    Name: firepower
    Mode: Stand Alone
    System IP Address: 172.16.0.50
    System IPv6 Address: ::
    System Owner:
    System Site:
    Deploy Mode: Native
    Description for System:
firepower #
```

Step 4 Enable multi-instance mode.

scope system

set deploymode container

You are prompted to reboot.

Example:

```
firepower# scope system
firepower /system # set deploymode container
All configuration and bootable images will be lost and system will reboot.
If there was out of band upgrade, it might reboot with the base version and need to re-image
 to get the expected running version.
Do you still want to change deploy mode? (yes/no):yes
firepower /system #
```

To change the mode back to appliance mode, enter **set deploymode native**.

Step 5 After the chassis finishes rebooting, set the Management IP address. You can use IPv4 and/or IPv6. The default address is 192.168.45.45/24 with a gateway of 192.168.45.1.

IPv4:

scope fabric-interconnect

set out-of-band static ip *ip_address* **netmask** *network_mask* **gw** *gateway_ip_address*

IPv6:

scope fabric-interconnect

scope ipv6-config

set out-of-band static ipv6 *ipv6_address* **ipv6-prefix** *prefix_length* **ipv6-gw** *gateway_address*

Example:

IPv4:

```
firepower-3110# scope fabric-interconnect
firepower-3110 /fabric-interconnect # set out-of-band static ip 10.5.23.8 netmask
255.255.255.0 gw 10.5.23.1
```

IPv6:

```
firepower-3110# scope fabric-interconnect
firepower-3110 / fabric-interconnect # scope ipv6-config
firepower-3110 / fabric-interconnect /ipv6-config # set out-of-band static ipv6 2001:DB8::34
```

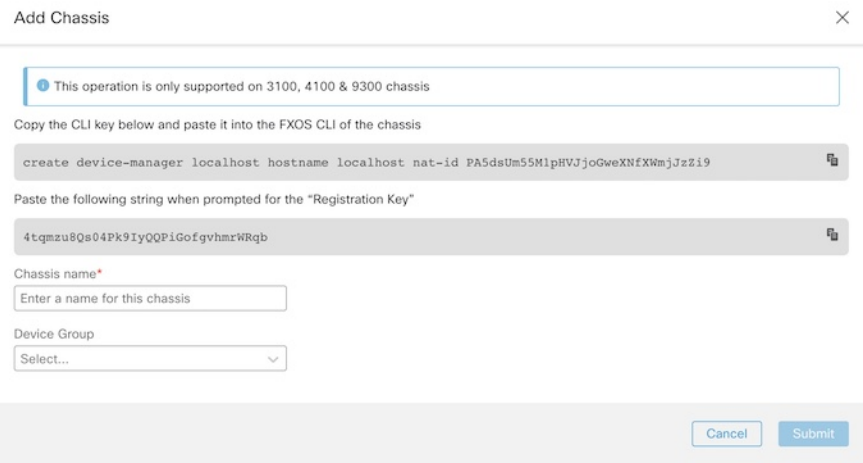
```
ipv6-prefix 64 ipv6-gw 2001:DB8::1
```

Step 6 In the Security Cloud Control navigation pane, click **Security Devices**, then click the blue plus button ( ) to **Onboard** a device.

Step 7 Click the **FTD Chassis** tile to open the **Add Chassis** dialog box.

Figure 97: FTD Chassis Tile

Figure 98: Add Chassis



Step 8 Click **Copy** ( ) to copy the top generated command, then paste it at the FXOS CLI of your chassis.

Step 9 When prompted for the Registration Key at the FXOS CLI, click **Copy** ( ) on the **Add Chassis** dialog box for the generated registration key and paste it at the FXOS CLI.

You can disconnect from the FXOS CLI at this point.

Step 10 In the Cloud-Delivered Firewall Management Center **Chassis Name** field, enter a name for the chassis as you want it to display in the Firewall Management Center.

Step 11 (Optional) Add the chassis to a **Device Group**.

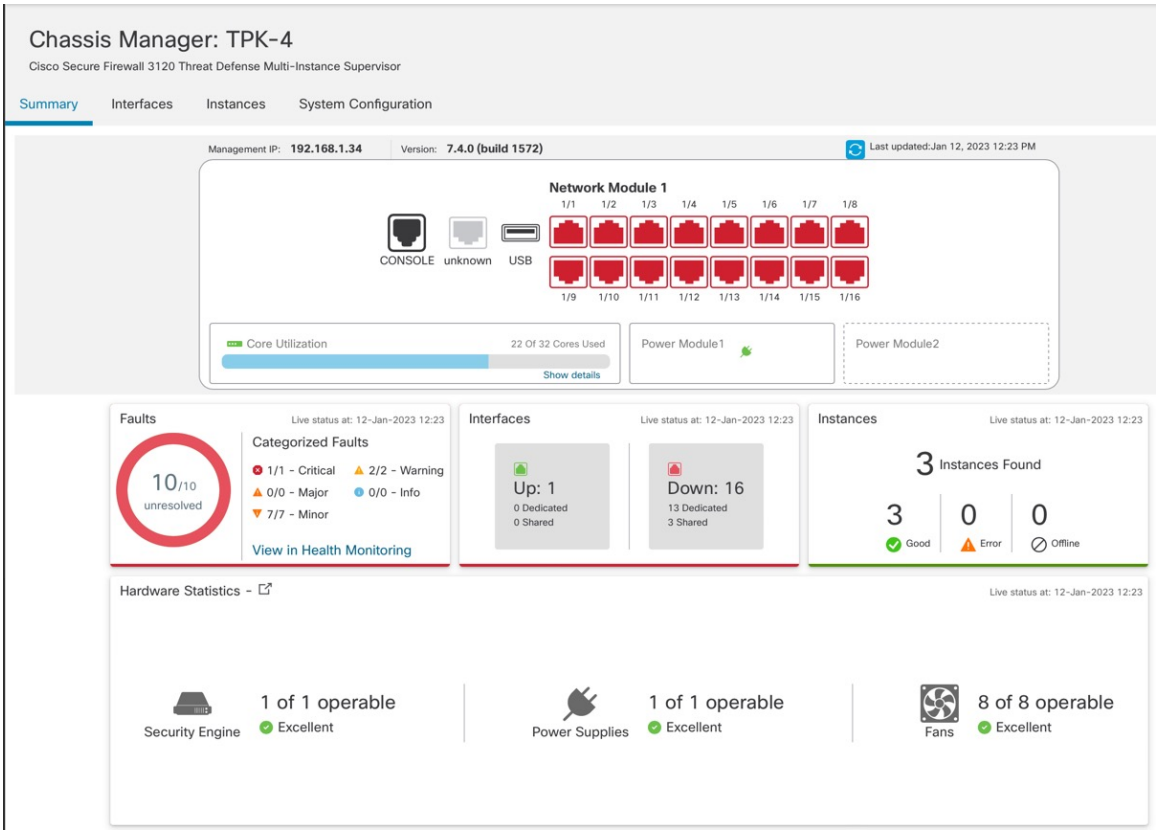
Step 12 Click **Submit**.

The chassis is added to the **Device** > **Device Management** page.

Step 13 To view and configure the chassis, click **Manage** in the **Chassis** column, or click **Edit** ( ) .

The **Chassis Manager** page opens for the chassis to the **Summary** page.

Figure 99: Chassis Summary



Configure Chassis Interfaces

At the chassis-level, you configure basic Ethernet settings of physical interfaces, VLAN subinterfaces for instances, and EtherChannel interfaces. By default, physical interfaces are disabled.

Note To configure breakout ports and perform other network module operations, see Manage the Network Module for the Secure Firewall 3100, on page 886.

Note For information about the **Sync Device** button, see Sync Interface Changes with the Firewall Management Center, on page 883.

Configure a Physical Interface

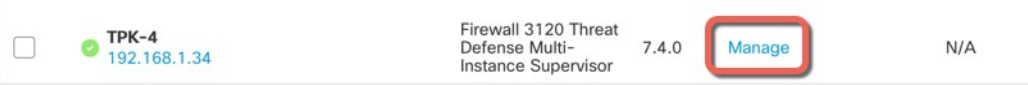
You can physically enable and disable interfaces, as well as set the interface speed and duplex and other hardware settings. To use an interface, it must be physically enabled for the chassis and logically enabled in

the instance. By default, physical interfaces are disabled. For VLAN subinterfaces, the admin state is inherited from the parent interface.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

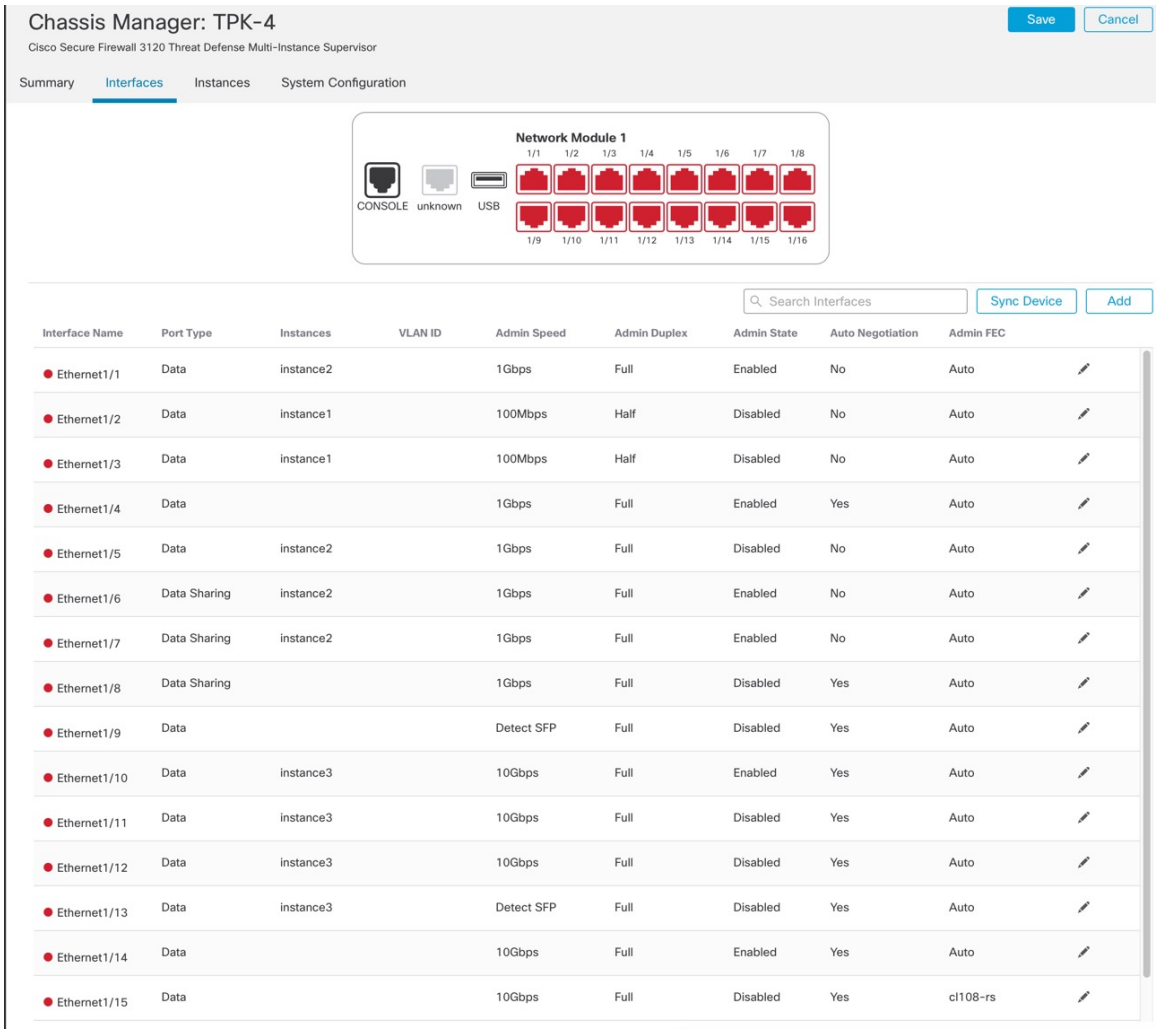
Figure 100: Manage Chassis



The **Chassis Manager** page opens for the chassis to the **Summary** page.

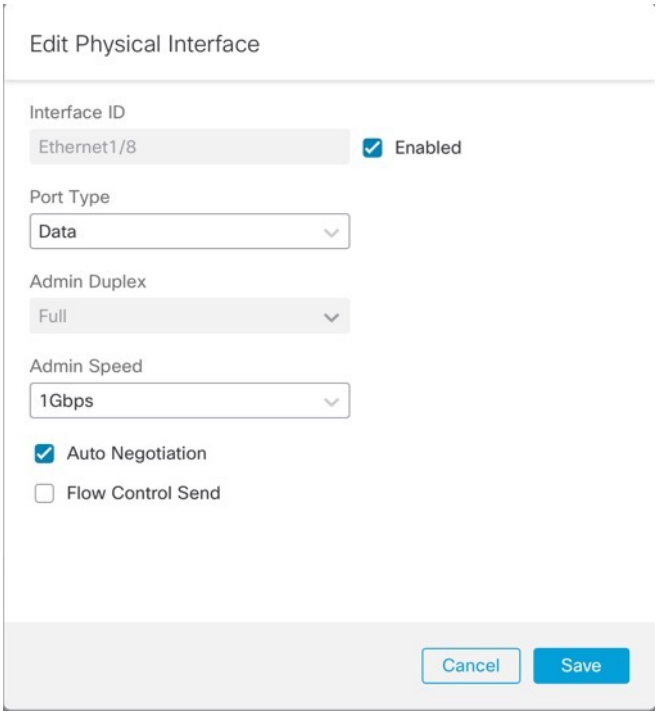
Step 2 Click **Interfaces**.

Figure 101: Interfaces



Step 3 Click **Edit** ( ) for the interface you want to edit.

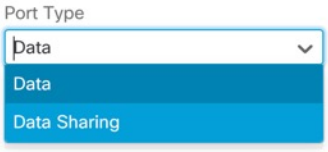
Figure 102: Edit Physical Interface



Step 4 Enable the interface by checking the **Enabled** check box.

Step 5 For the **Port Type**, choose **Data** or **Data Sharing**.

Figure 103: Port Type



Step 6 Set the **Admin Duplex**.

Speeds of 1Gbps and higher only support **Full** duplex. SFP interfaces only support **Full** duplex.

Step 7 Set the **Admin Speed**.

For SFPs, Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.

Step 8 (Optional) Check **Flow Control Send** to enable pause (XOFF) frames for flow control.

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If the threat defense port experiences congestion (exhaustion of queuing resources on the internal switch) and cannot receive any more traffic, it notifies the other port by

sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

Note
The Firewall Threat Defense supports transmitting pause frames so that the remote peer can rate-control the traffic.

However, receiving of pause frames is not supported.

The internal switch has a global pool of 8000 buffers of 250 bytes each, and the switch allocates buffers dynamically to each port. A pause frame is sent out every interface with flow control enabled when the buffer usage exceeds the global high-water mark (2 MB (8000 buffers)); and a pause frame is sent out of a particular interface when its buffer exceeds the port high-water mark (.3125 MB (1250 buffers)). After a pause is sent, an XON frame can be sent when the buffer usage is reduced below the low-water mark (1.25 MB globally (5000 buffers); .25 MB per port (1000 buffers)). The link partner can resume traffic after receiving an XON frame.

Only flow control frames defined in 802.3x are supported. Priority-based flow control is not supported.

Step 9 (Optional) Check **Auto Negotiation** to set the interface to negotiate the speed, link status, and flow control. You cannot edit this setting for speeds lower than 1Gbps. For SFP interfaces, you can only disable auto-negotiation when the speed is set to 1Gbps.

Step 10 Click **Save** and then **Save** in the top right of the **Interfaces** page.

You can now **Deploy** the policy to the chassis. The changes are not active until you deploy them.

Configure an EtherChannel

An EtherChannel (also known as a port channel) can include up to 8 member interfaces of the same media type and capacity, and must be set to the same speed and duplex. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, unless you set the speed to **Detect SFP**; in this case, you can use different interface capacities, and the lowest common speed is used.

The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices. LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. “On” mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

When the chassis creates an EtherChannel, the EtherChannel stays in a **Suspended** state for Active LACP mode or a **Down** state for On LACP mode until you assign it to a logical device, even if the physical link is up. The EtherChannel will be brought out of this **Suspended** state when it is added to an instance.

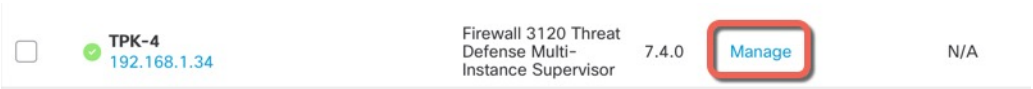
Before you begin

Enable physical interfaces and set hardware parameters. See Configure a Physical Interface, on page 522.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

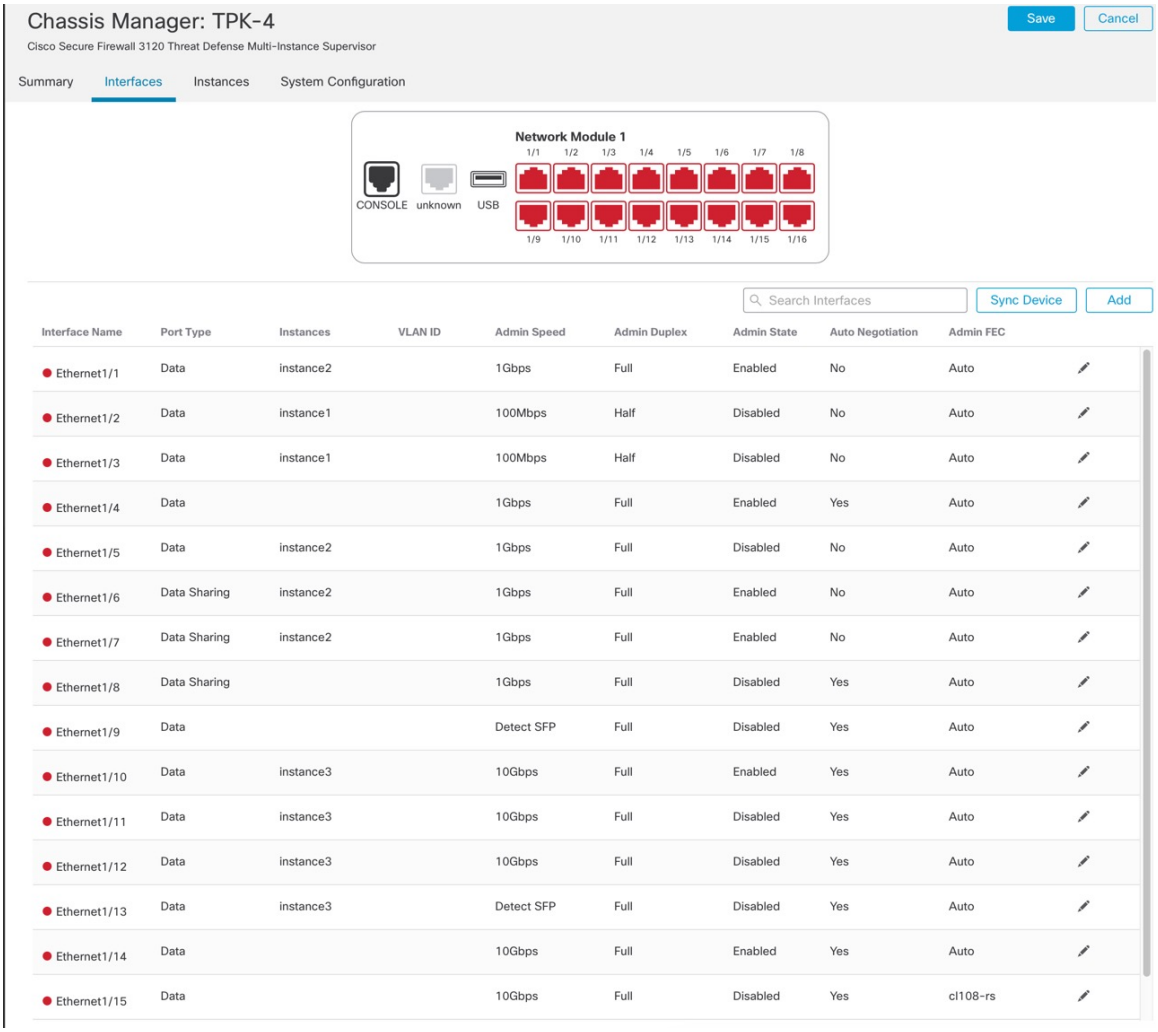
Figure 104: Manage Chassis



The **Chassis Manager** page opens for the chassis to the **Summary** page.

Step 2 Click **Interfaces**.

Figure 105: Interfaces

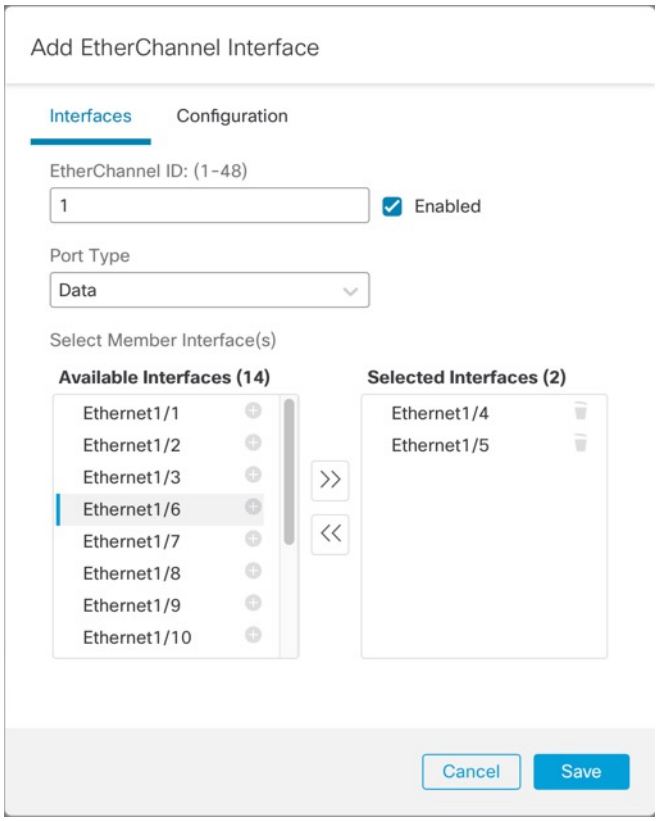


Step 3 Click **Add** > **EtherChannel Interface**.

Figure 106: Add EtherChannel

Step 4 Set the following **Interfaces** parameters.

Figure 107: Interfaces Settings



a) For the **EtherChannel ID**, specify an ID between 1 and 48.
b) Check **Enabled**.
c) For the **Port Type**, choose **Data** or **Data Shared**.

   For information about the port type, see Interface Types, on page 502.

d) To add a physical interface to the EtherChannel, select click **Add** (⊕) in the **Available Interfaces** list to move it to the **Selected Interfaces** list.

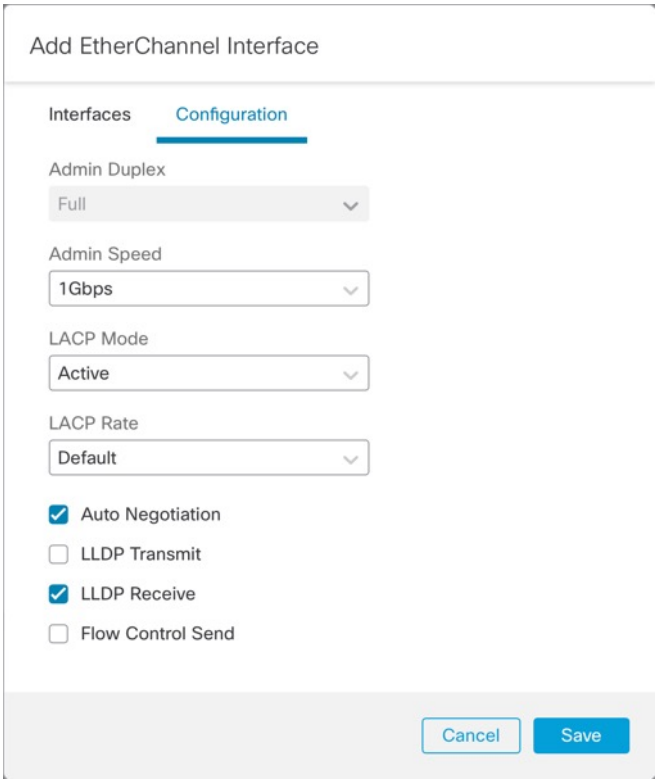
   To add or remove all interfaces, click the double arrow button.

   Note
   You cannot add an interface that is already assigned to an instance.

Step 5 (Optional) Set the following **Configuration** parameters.

Many of these settings (excluding the LACP settings) set the requirements for interfaces to be included in the EtherChannel; they do not override the settings of member interfaces. So if you check **LLDP Transmit**, for example, you should only add interfaces that have that setting. If you set the **Admin Speed** to 1Gbps, then only 1Gbps interfaces can be included.

Figure 108: Configuration Settings



a) Choose the required **Admin Duplex** for the member interfaces, **Full Duplex** or **Half Duplex**.

If you add a member interface that is configured with the specified duplex, it will not successfully join the port channel.

b) Choose the required **Admin Speed** for the member interfaces from the drop-down list.

If you add a member interface that is not at the specified speed, it will not successfully join the port channel.

c) Choose the **LACP Mode**, **Active** or **On**.

- **Active**—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- **On**—The EtherChannel is always on, and LACP is not used. An "on" EtherChannel can only establish a connection with another "on" EtherChannel.

Note
It may take up to three minutes for an EtherChannel to come up to an operational state if you change its mode from On to Active or from Active to On.

d) Choose the **LACP Rate**, **Default**, **Fast**, or **Normal**.

The default is **Fast**.

e) Choose the required Link Layer Discovery Protocol (LLDP) settings for member interfaces by checking **LLDP Transmit** and/or **LLDP Receive**.

f) Check the required **Flow Control Send** setting for member interfaces.

Step 6 Click **Save** and then **Save** in the top right of the **Interfaces** page.

You can now **Deploy** the policy to the chassis. The changes are not active until you deploy them.

Configure a Subinterface

You can add up to 500 subinterfaces to your chassis.

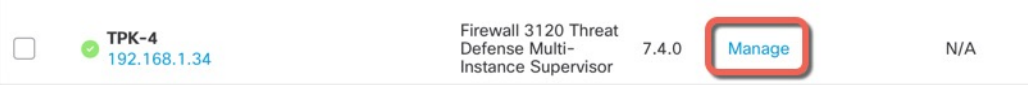
VLAN IDs per interface must be unique, and within an instance, VLAN IDs must be unique across all assigned interfaces. You can reuse VLAN IDs on *separate* interfaces as long as they are assigned to different instances. However, each subinterface still counts towards the limit even though it uses the same ID.

This section discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the instance. See Chassis Interfaces vs. Instance Interfaces, on page 503.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

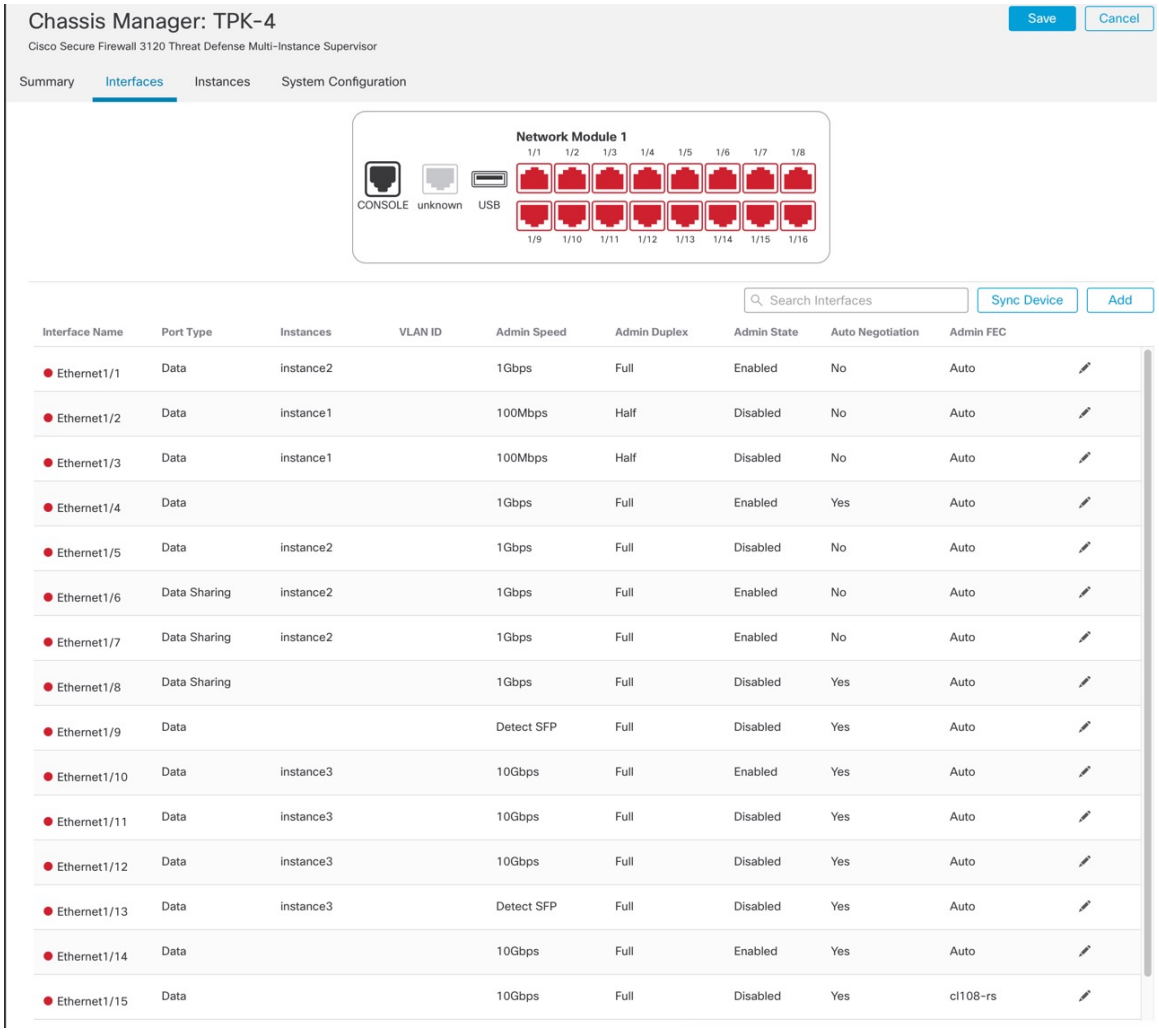
Figure 109: Manage Chassis



The **Chassis Manager** page opens for the chassis to the **Summary** page.

Step 2 Click **Interfaces**.

Figure 110: Interfaces

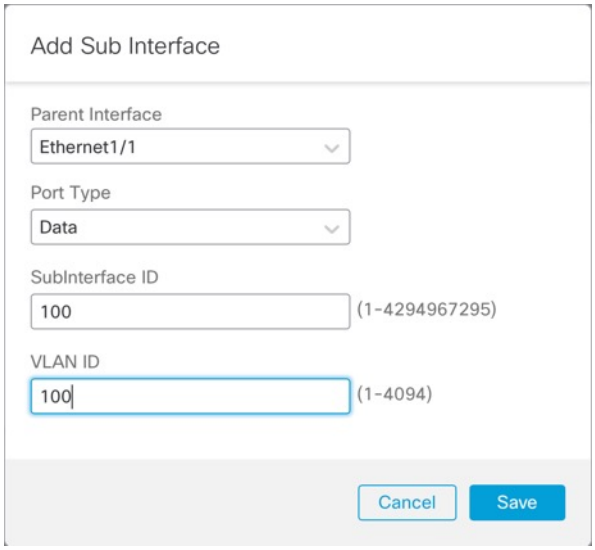


Step 3 Click **Add** > **Subinterface**.

Figure 111: Add Subinterface

Step 4 Set the following parameters.

Figure 112: Subinterface Settings



a)

Step 5 Click **Save** and then **Save** in the top right of the **Interfaces** page.

You can now **Deploy** the policy to the chassis. The changes are not active until you deploy them.

Add an Instance

You can add one or more instances to a chassis in multi-instance mode. The number of supported instances depends on your model; see Requirements and Prerequisites for Instances, on page 514.

Before you begin

Onboard the Multi-Instance Chassis, on page 518.

Procedure

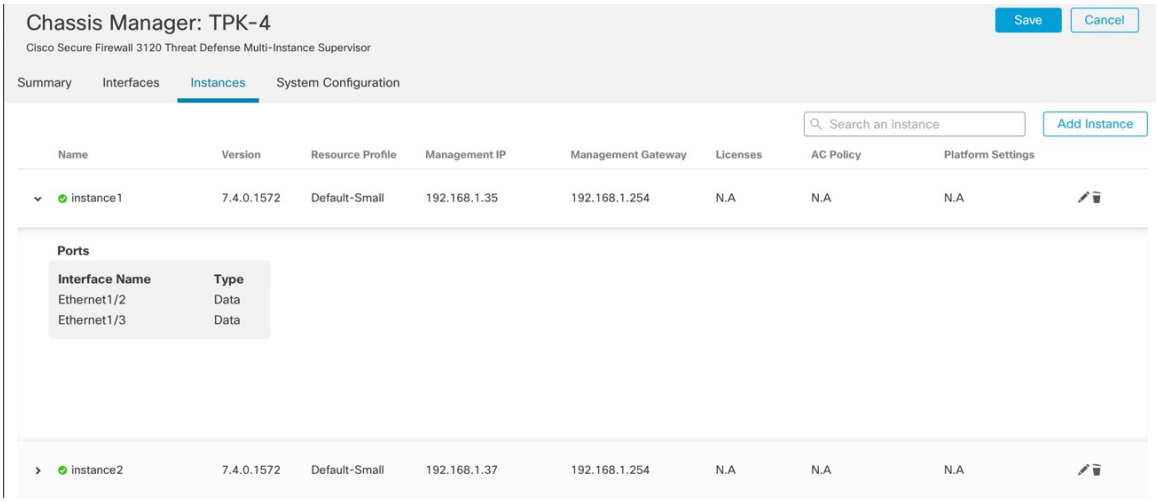
Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

Figure 113: Manage Chassis

The **Chassis Manager** page opens for the chassis to the **Summary** page.

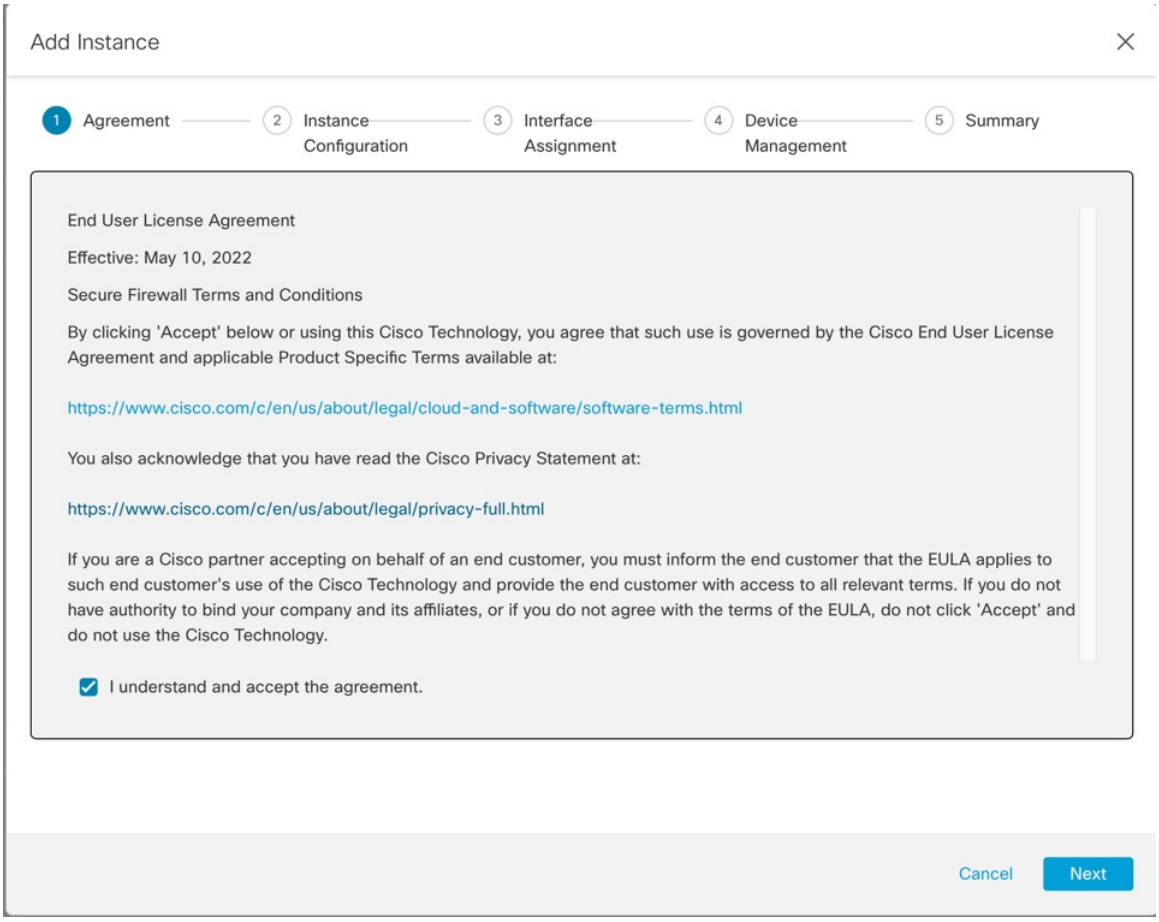
Step 2 Click **Instances**, and click **Add Instance**.

Figure 114: Instances



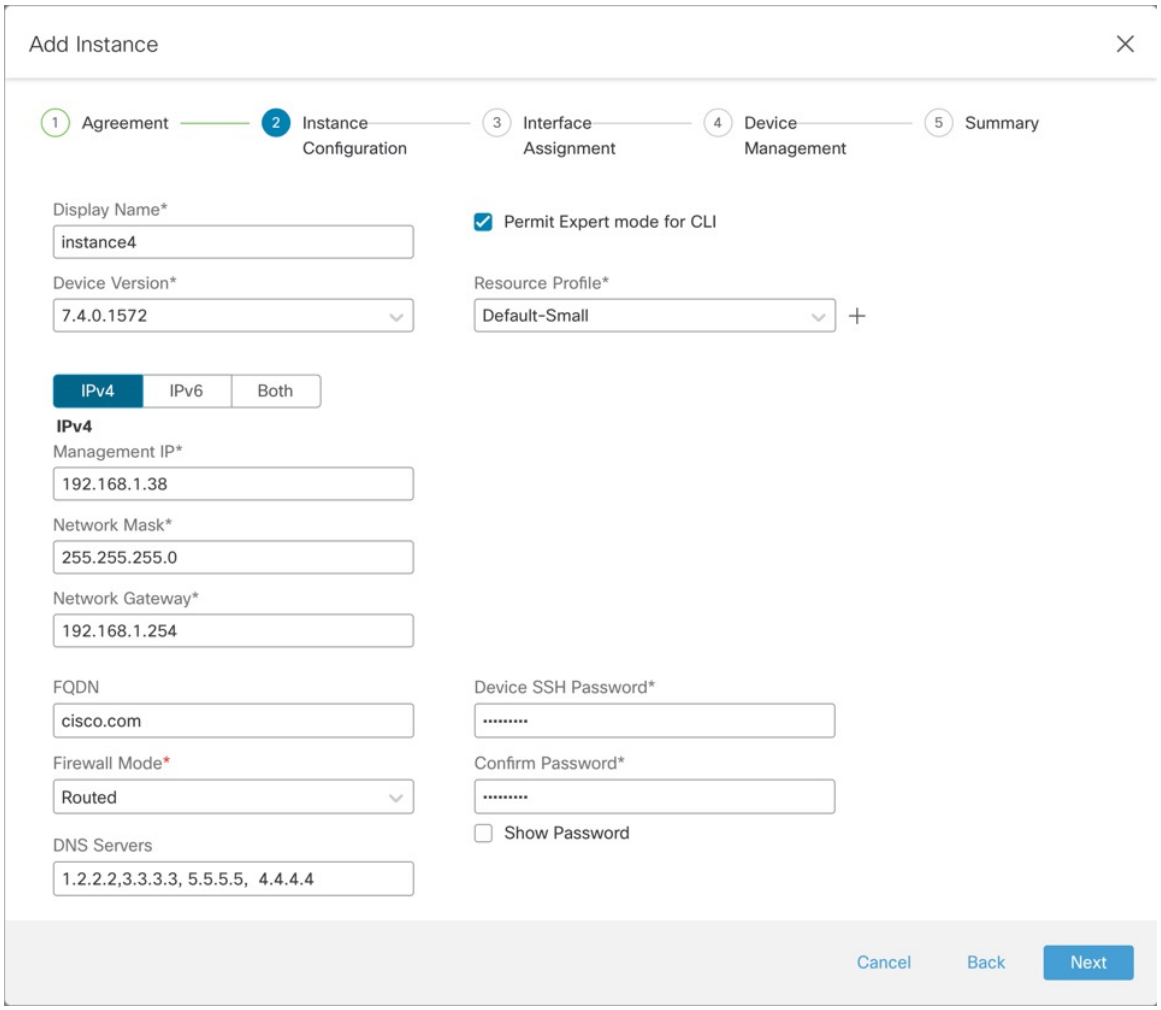
Step 3 On **Agreement**, check **I understand and accept the agreement**, then click **Next**.

Figure 115: Agreement



Step 4 On **Instance Configuration**, set the instance parameters, then click **Next**.

Figure 116: Instance Configuration



- **Display Name**
- **Device Version**—Versions listed are packages currently downloaded to the chassis. Patch versions are not listed and cannot be used because they don't contain the entire bundle. To upgrade to a new package, see **Devices** > **Upgrade** > **Chassis Upgrade**. When you upgrade, both the old Firewall Threat Defense version and the new Firewall Threat Defense version will be listed in the menu. To download an older package, you need to use the FXOS CLI. Note: Both FXOS and Firewall Threat Defense images are included in the same package. See the troubleshooting guide for more information.

  For example:

```
firepower-3110# scope firmware
firepower-3110# download image
https://10.10.7.89/Cisco_FTD_SSP_FP3K_Upgrade-7.4.1-1.sh.DEV.tar
Please use the command 'show download-task' or 'show download-task detail' to check
download progress.
% Download-task Cisco_FTD_SSP_FP3K_Upgrade-7.4.1-1.sh.DEV.tar : completed successfully.
```

- **IPv4**, **IPv6**, or **Both**—Set a **Management IP** address on the same network as the chassis Management interface. Set the **Network Mask** and gateway (likely the same gateway as the chassis). The chassis Management interface is shared with each instance, and each instance has its own IP address on the network. You can SSH to this IP address by default to reach the Firewall Threat Defense CLI.
- (Optional) **FQDN**
- **Firewall Mode**—**Routed** or **Transparent**. For more information about the firewall mode, see Transparent or Routed Firewall Mode, on page 431.
- **DNS Servers**—Enter a comma-separated list of DNS servers for management traffic only.
- (Optional) **Permit Expert Mode for CLI**—Expert Mode provides Firewall Threat Defense shell access for advanced troubleshooting.

  If you enable this option, then users who access the instance directly from an SSH session can enter Expert Mode. If you disable this option, then only users who access the instance from the FXOS CLI can enter Expert Mode. We recommend disabling this option to increase isolation between instances.

  Use Expert Mode only if a documented procedure tells you it is required, or if the Cisco Technical Assistance Center asks you to use it. To enter this mode, use the **expert** command in the Firewall Threat Defense CLI.
- **Resource Profile**—The resource profile sets the number of CPU cores; RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance. The chassis includes the following default resource profiles: Default-Small, Default-Medium, and Default-Large. You can add additional profiles for this chassis by clicking **Add** (+). You cannot later edit the resource profile.

Figure 117: Add Resource Profile

  - The minimum number of cores is 6.

  Note

Instances with a smaller number of cores might experience relatively higher CPU utilization than those with larger numbers of cores. Instances with a smaller number of cores are more sensitive to traffic load changes. If you experience traffic drops, try assigning more cores.

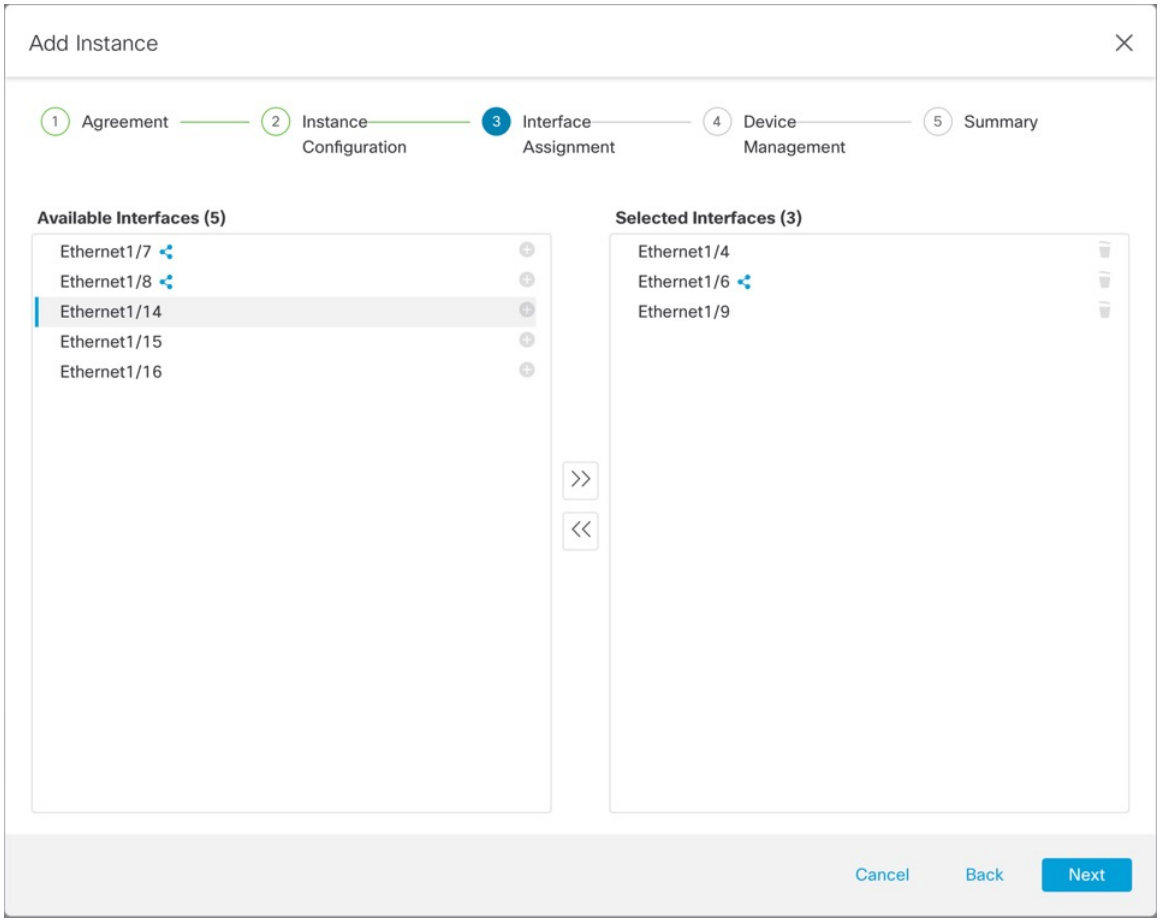
- You can assign cores as an even number (6, 8, 10, 12, 14 etc.) up to the maximum.
- The maximum number of cores available depends on the model; see Requirements and Prerequisites for Instances, on page 514.

If you later assign a different resource profile, then the instance will reload, which can take approximately 5 minutes. Note that for an established High Availability pair, if you assign a different-sized resource profile, be sure to make all members the same size as soon as possible.

- **Device SSH Password**—Set the Firewall Threat Defense admin user password for CLI access, either SSH or console. Repeat the password in the **Confirm Password** field.

Step 5 On **Interface Assignment**, assign the chassis interfaces to the instance, then click **Next**.

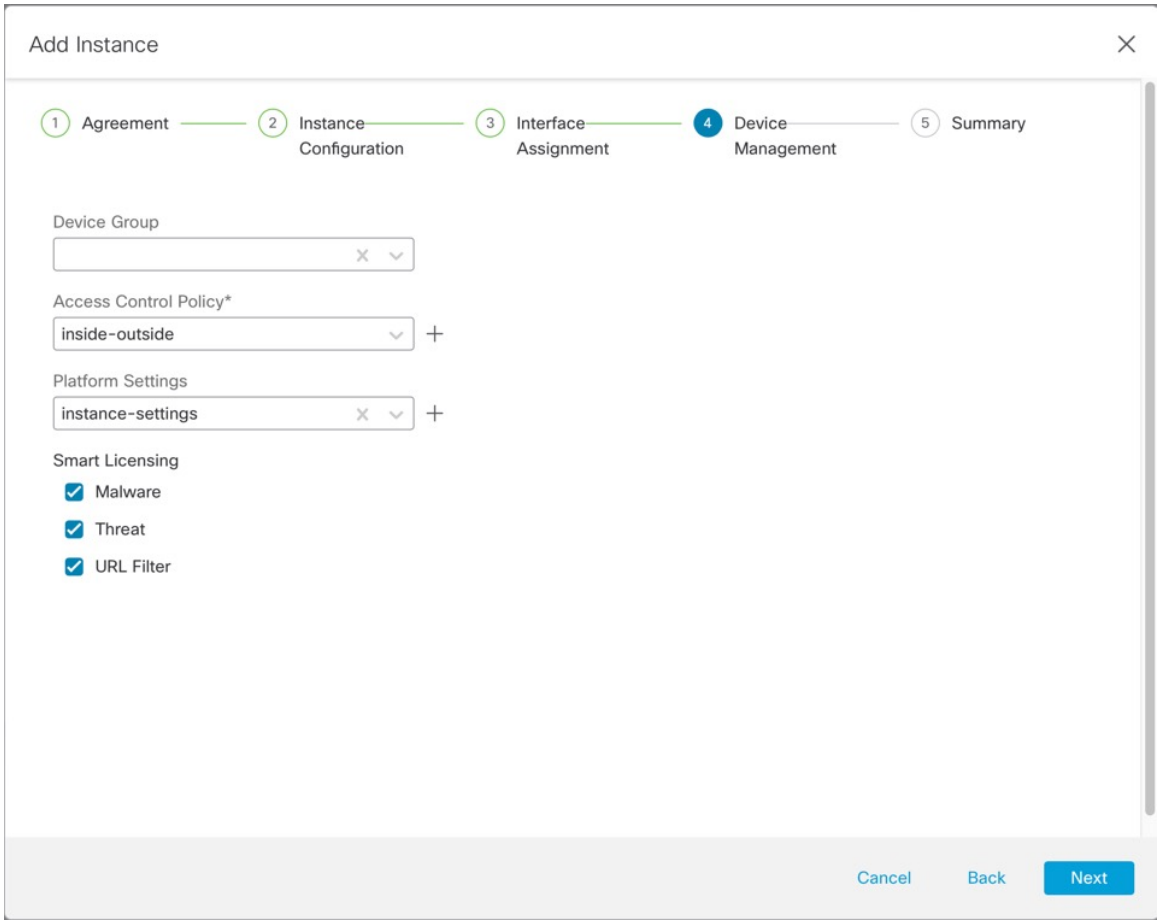
Figure 118: Interface Assignment



Shared interfaces show the sharing icon ( ).

Step 6 On **Device Management**, set the device-specific settings, then click **Next**.

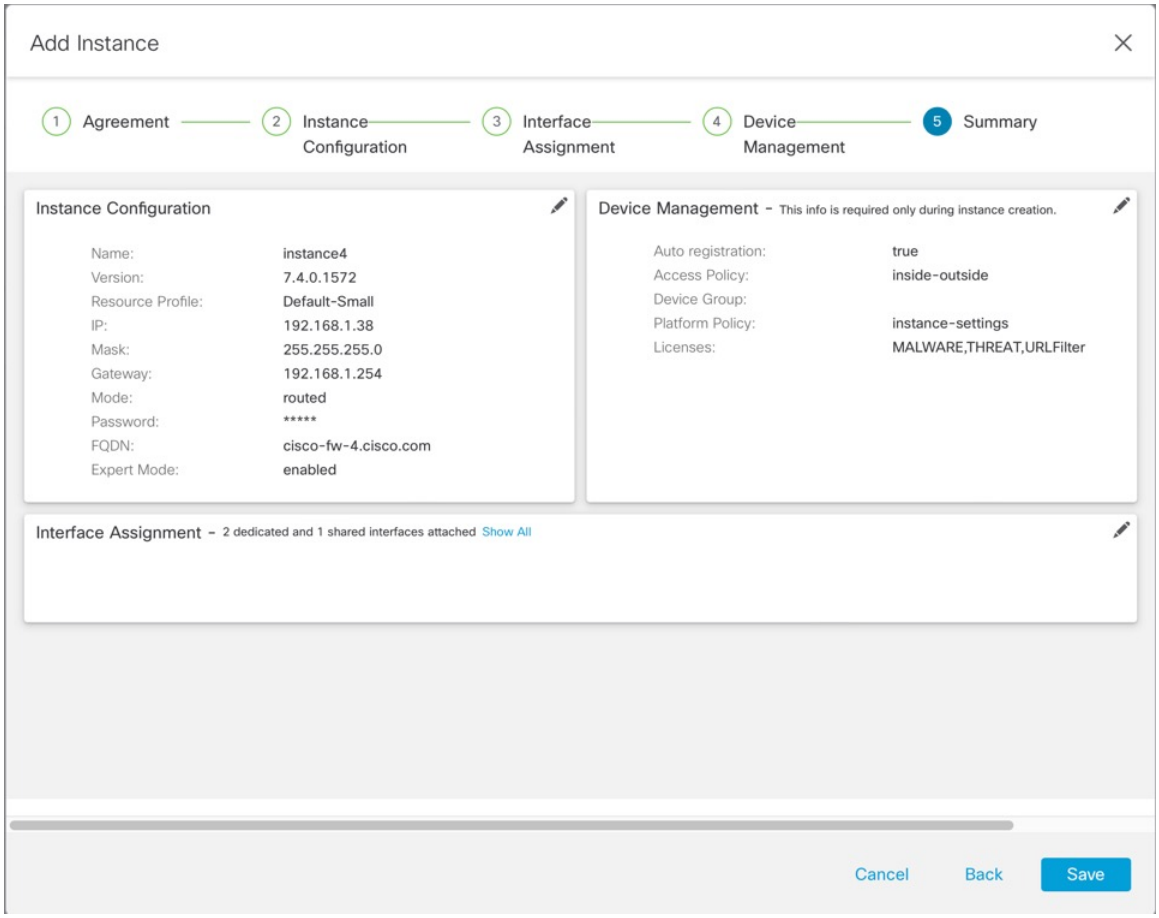
Figure 119: Device Management



- **Device Group**
- **Access Control Policy**—Choose an existing access control policy, or create a new policy.
- **Platform Settings**—Choose an existing platform setting policy, or create a new policy.
- **Smart Licensing**

Step 7 On **Summary**, confirm your settings, then click **Save**.

Figure 120: Summary



You can edit any settings on this screen before saving the instance. After you save, the instance is added to the **Instances** screen.

Step 8 On the **Instances** screen, click **Save**.

Step 9 Deploy the chassis configuration.

Step 10 Manually add the instance to Security Cloud Control as an FTD.

a) Add the instance **Using a CLI Registration Key**. See Onboard a Device with a CLI Registration Key, on page 10.

For the **Device Name**, you can use the instance name that you specified or any other name.

b) Access the chassis CLI and connect to the instance CLI. See Log Into the Command-Line Interface on the Device, on page 65.

connect ftd *name*

c) Delete the current manager; this manager needs to be deleted and reconfigured.

configure manager delete

d) Paste the generated **configure manager add** command from Security Cloud Control.

Customize the System Configuration

You can configure chassis-level settings such as SNMP. You can also import or export the chassis FXOS configuration.

Configure SNMP

You can access chassis-level MIBs through the data interface of one of the instances, which you specify in the chassis system configuration. You can only use this instance for chassis SNMP information. You cannot access SNMP through the chassis Management interface.

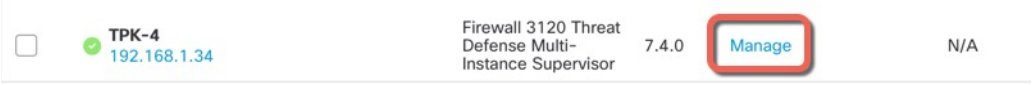
Before you begin

- Configure SNMP for one of the instances. See SNMP, on page 1053.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

Figure 121: Manage Chassis

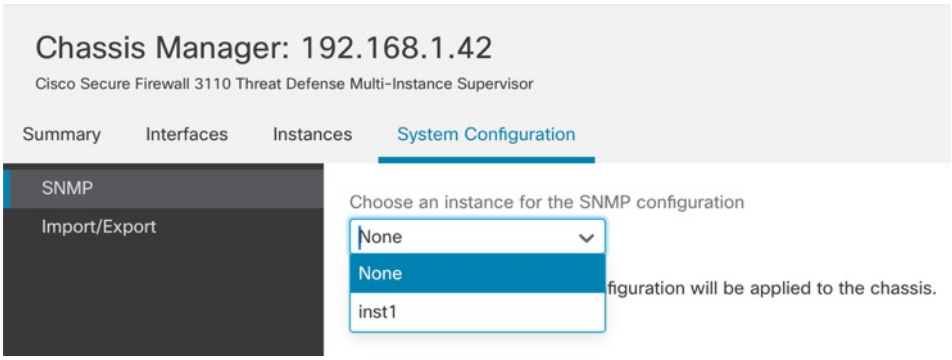


The **Chassis Manager** page opens for the chassis to the **Summary** page.

Step 2 Click **System Configuration**.

Step 3 Click **SNMP**, and choose the instance from the drop-down list.

Figure 122: SNMP



SNMP on the chassis will be accessible from the selected instance.

Step 4 Click **Save**.

Step 5 Deploy the chassis configuration.

Import or Export the Chassis Configuration

You can use the configuration export feature to export an XML file containing chassis configuration settings to your local computer. You can later import that configuration file to quickly apply the configuration settings to your chassis to return to a known good configuration or to recover from a system failure. You can also import the chassis configuration to a new chassis, for example for an RMA, as long as the prerequisites are met.

When exporting, only chassis configurations are exported; instance configuration settings are not exported. Instances need to be backed up separately using the device backup/restore feature.

When importing, all existing configurations on the chassis will be replaced by the configuration in the import file.

Before you begin

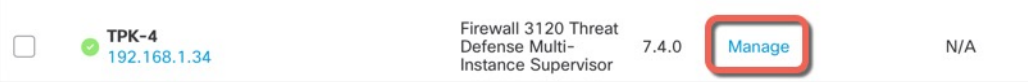
For the chassis where you want to import a configuration, the following characteristics must match:

- Same chassis software version
- Same Firewall Threat Defense instance images
- Same network modules

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

Figure 123: Manage Chassis



The **Chassis Manager** page opens for the chassis to the **Summary** page.

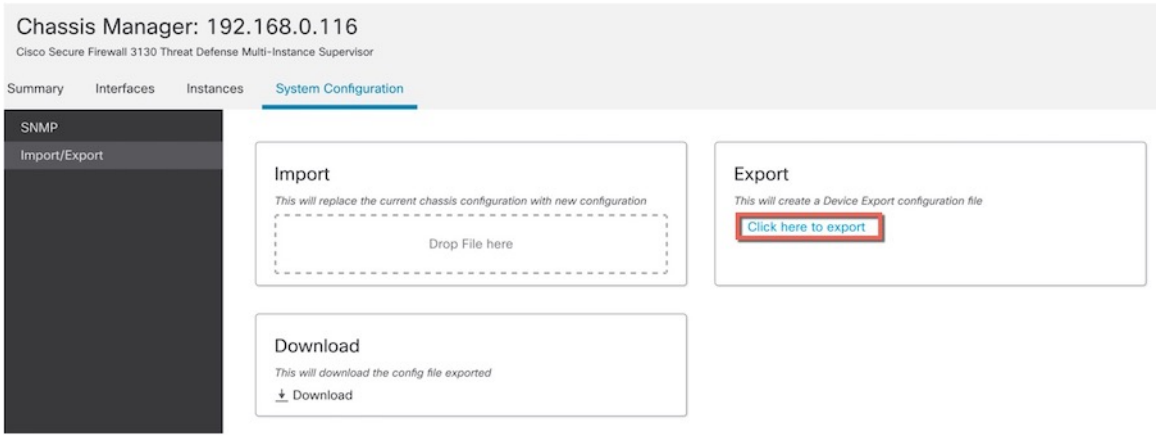
Step 2 Click **System Configuration**.

Step 3 Click **Import/Export**.

Step 4 To export the configuration, follow these steps.

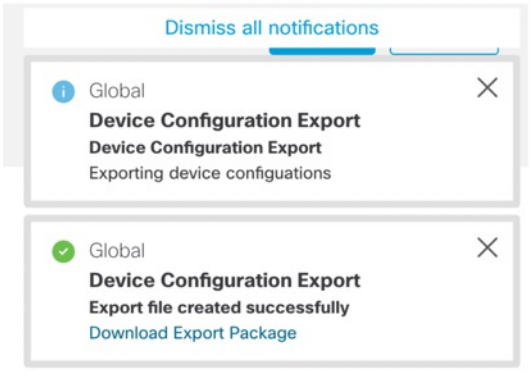
a) In the **Export** area, click **Click here to export**.

Figure 124: Create Export File



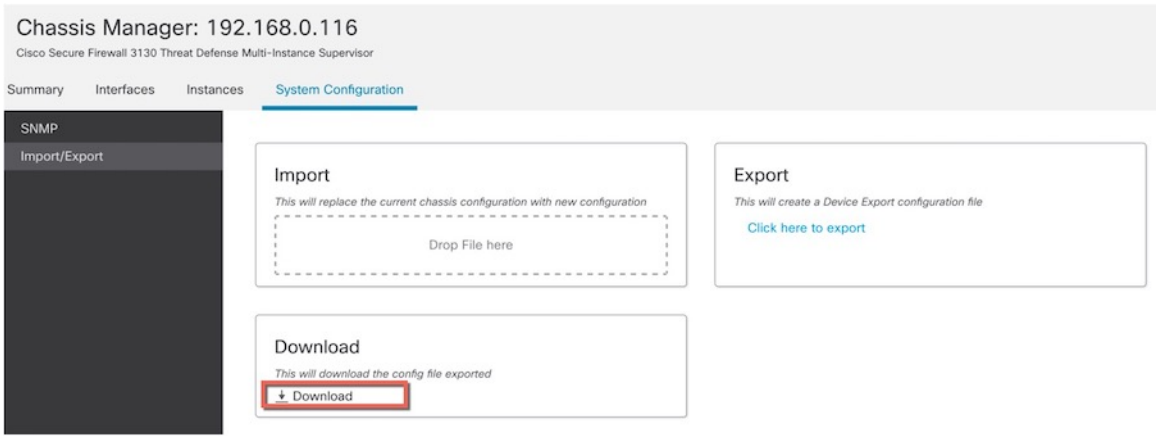
b) Monitor the notifications for the **Export file created successfully** message.

Figure 125: Export File Created Successfully



c) Download the export file by clicking the notification message (**Download Export Package**) or by clicking **Download**.

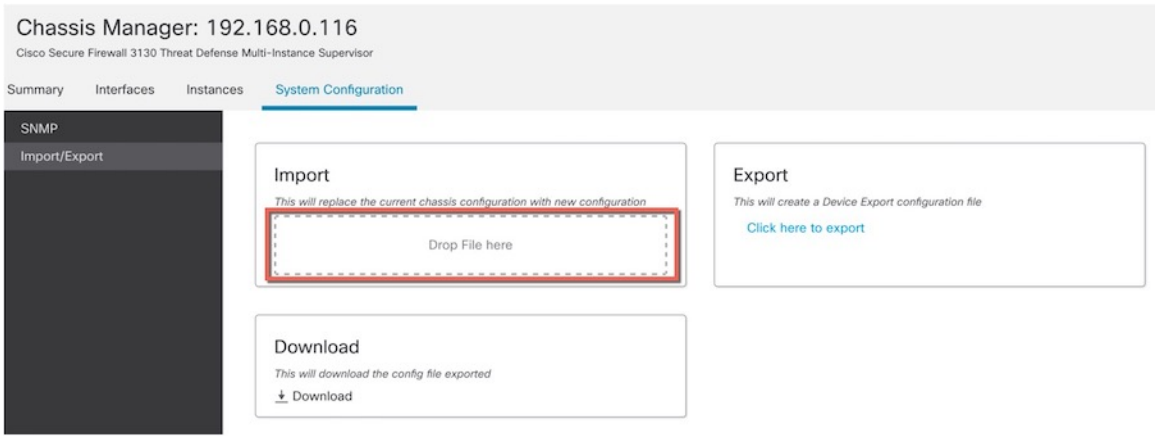
Figure 126: Download



The file is saved with the **.sfo** extension.

Step 5 To import a configuration, drag the **.sfo** file on the **Import** > **Drop File here** area.

Figure 127: Import



Configure Chassis Platform Settings

Chassis platform settings configure a range of features for managing the chassis. You can share the policy among multiple chassis. If you want different settings per chassis, you must create multiple policies.

Create a Chassis Platform Settings Policy

Use the **Platform Settings** page (**Devices** > **Platform Settings**) to manage platform settings policies. This page indicates the type of device for each policy. The **Status** column shows the device targets for the policy.

Procedure

Step 1 Choose **Devices** > **Platform Settings**.

Step 2 For an existing policy, you can **Copy** ( ), **Edit** ( ), or **Delete** ( ) the policy.

Caution
You should not delete a policy that is the last-deployed policy on any of its target devices, even if it is out of date. Before you delete the policy completely, it is good practice to deploy a different policy to those targets.

Step 3 To create a new policy, click **New Policy**.

a) Choose **Chassis Platform Settings** from the drop-down list.
b) Enter a **Name** for the new policy and optionally, a **Description**.
c) Optionally, choose the **Available Chassis** where you want to apply the policy and click **Add** to add the selected chassis.
d) Click **Save**.

The system creates the policy and opens it for editing.

Step 4 To change the target chassis for a policy, click **Edit** ( ) next to the platform settings policy that you want to edit.

a) Click **Policy Assignment**.

b) To assign a chassis to the policy, select it in the **Available Chassis** list and click **Add**.

c) To remove a chassis assignment, click **Delete** ( ) next to a chassis in the **Selected Chassis** list.

d) Click **OK**.

Configure DNS

You need to specify a DNS server if the chassis requires resolution of hostnames to IP addresses. These chassis DNS settings are separate from the DNS settings per instance, which are configured in the device platform settings.

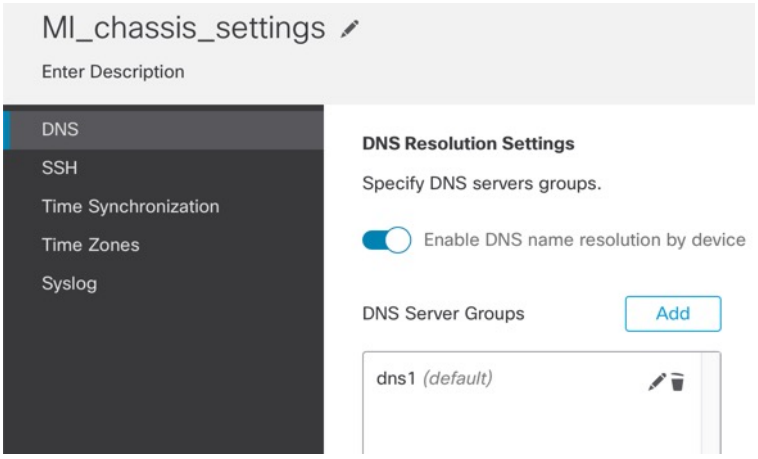
When you configure multiple DNS servers, the chassis uses servers in a random order. You can configure up to four servers across four DNS server groups. For example, you can configure a single server group with four servers, or you can configure four server groups with one server each.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **DNS**.

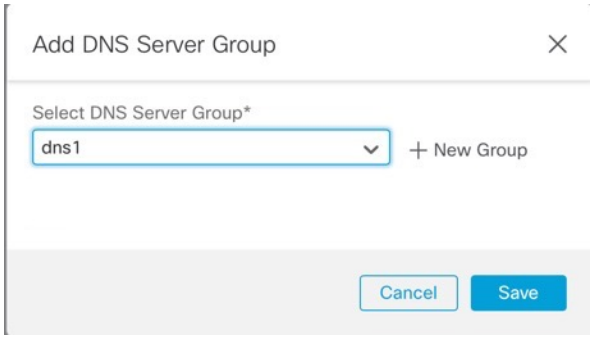
Figure 128: DNS



Step 3 Enable the **Enable DNS name resolution by device** slider.

Step 4 Click **Add** to add a DNS server group.

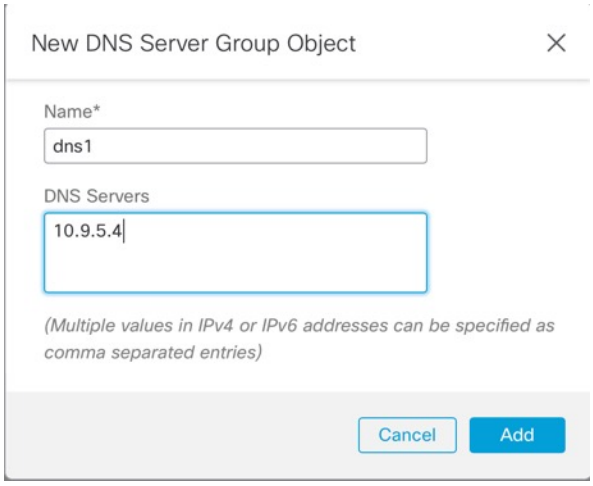
Figure 129: Add DNS Server Group



Step 5 Either select an existing DNS server group (see Creating DNS Server Group Objects, on page 1455), or click (+) **New Group**.

If you add a new group, you see the following dialog box. Provide a name and up to four DNS server IP addresses as comma-separated values, and click **Add**.

Figure 130: New DNS Server Group Object



Step 6 Click **Save** to add the DNS server to the list.

Step 7 Repeat these steps to add additional server groups.

Make sure you only identify a maximum of four DNS servers in all groups combined.

Step 8 Click **Save** to save all policy changes.

Configure SSH and SSH Access List

To allow SSH sessions from the admin user to the chassis on the Management interface, enable the SSH server and configure the allowed networks.

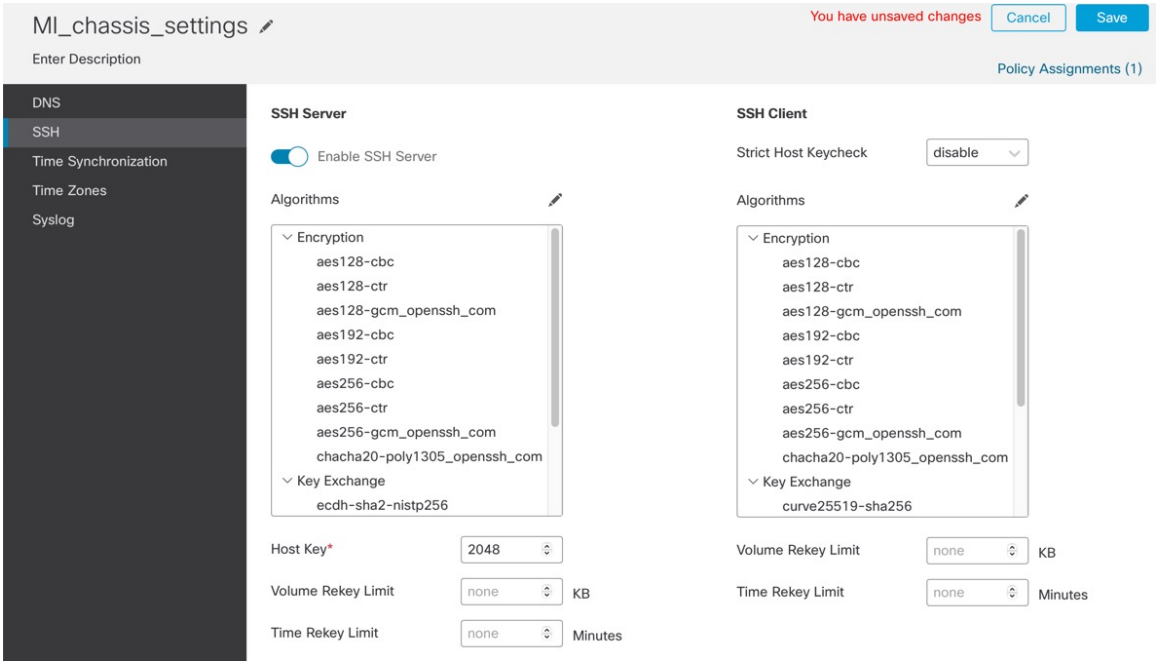
Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **SSH**.

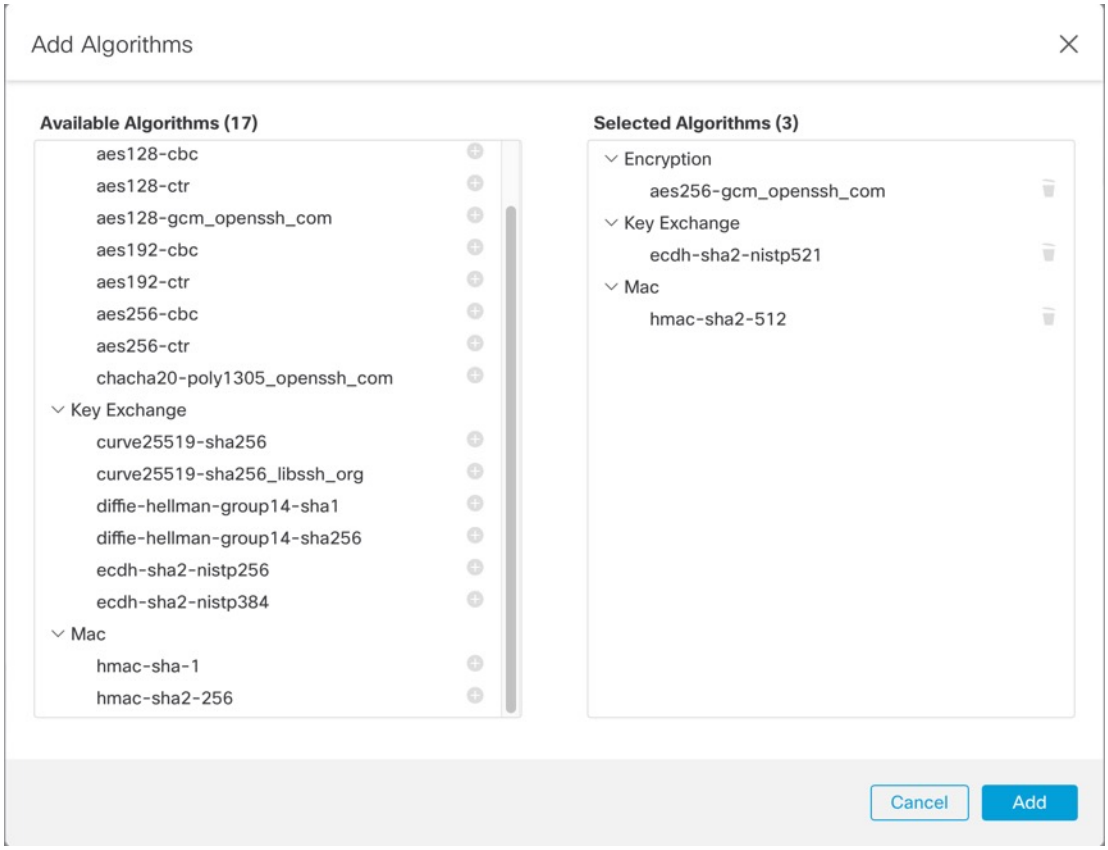
Step 3 To enable SSH access to the chassis, enable the **Enable SSH Server** slider.

Figure 131: SSH



Step 4 To set the allowed **Algorithms**, click **Edit** ( ).

Figure 132: Add Algorithms



a) Select the **Encryption** algorithms.
b) Select the **Key Exchange** algorithms.

   The key exchange provides a shared secret that cannot be determined by either party alone. The key exchange is combined with a signature and the host key to provide host authentication. This key-exchange method provides explicit server authentication.

c) Select the **Mac** integrity algorithms.

Step 5 For **Host Key**, enter the modulus size for the RSA key pairs.

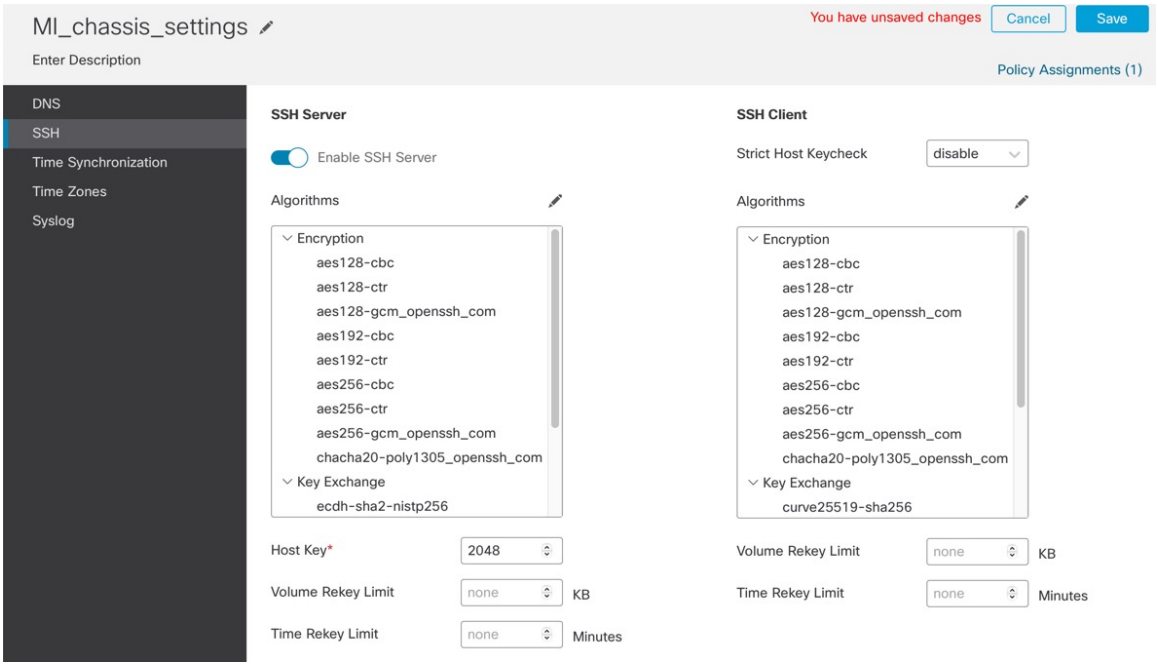
The modulus value (in bits) is in multiples of 8 from 1024 to 2048. The larger the key modulus size you specify, the longer it takes to generate an RSA key pair. We recommend a value of 2048.

Step 6 For the server **Volume Rekey Limit**, set the amount of traffic in KB allowed over the connection before FXOS disconnects from the session.

Step 7 For the server **Time Rekey Limit**, set the minutes for how long an SSH session can be idle before FXOS disconnects the session.

Step 8 For the **SSH Client**, configure the following settings.

Figure 133: SSH

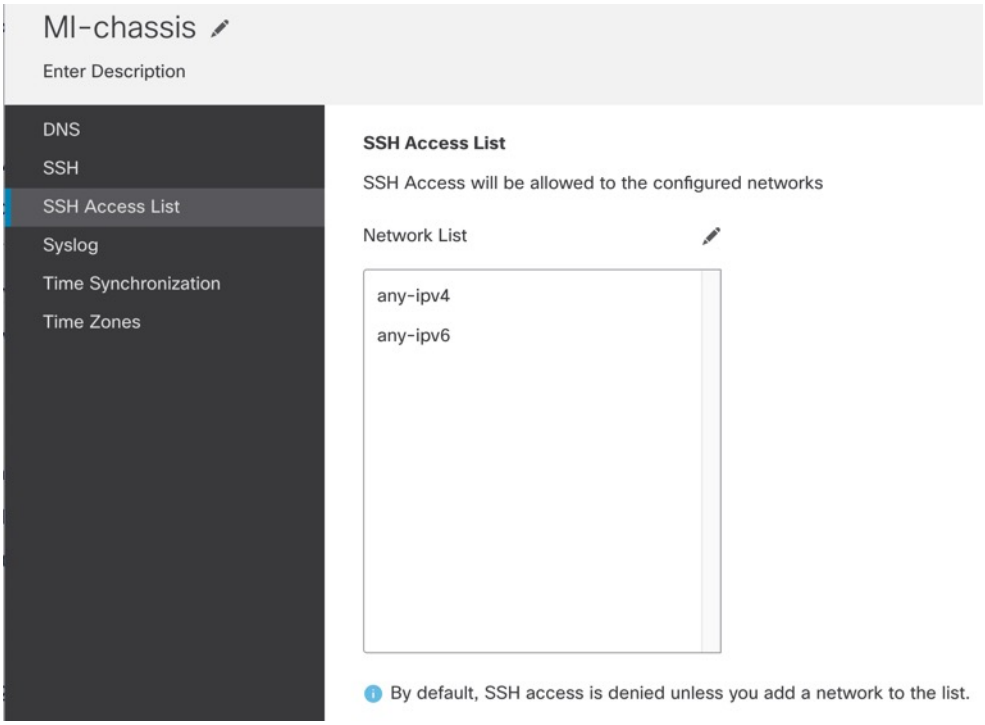


- **Strict Host Keycheck**—Choose **enable**, **disable**, or **prompt** to control SSH host key checking.
  - **enable**—The connection is rejected if the host key is not already in the FXOS known hosts file. You must manually add hosts at the FXOS CLI using the **enter ssh-host** command in the system/services scope.
  - **prompt**—You are prompted to accept or reject the host key if it is not already stored on the chassis.
  - **disable**—(The default) The chassis accepts the host key automatically if it was not stored before.
- **Algorithms**—Click **Edit** (✎). and select the **Encryption**, **Key Exchange**, and **Mac** algorithms.
- **Volume Rekey Limit**—Set the amount of traffic in KB allowed over the connection before FXOS disconnects from the session.
- **Time Rekey Limit**—Set the minutes for how long an SSH session can be idle before FXOS disconnects the session.

Step 9 Choose **SSH Access List**. You need to allow access to IP addresses or networks before you can use SSH.

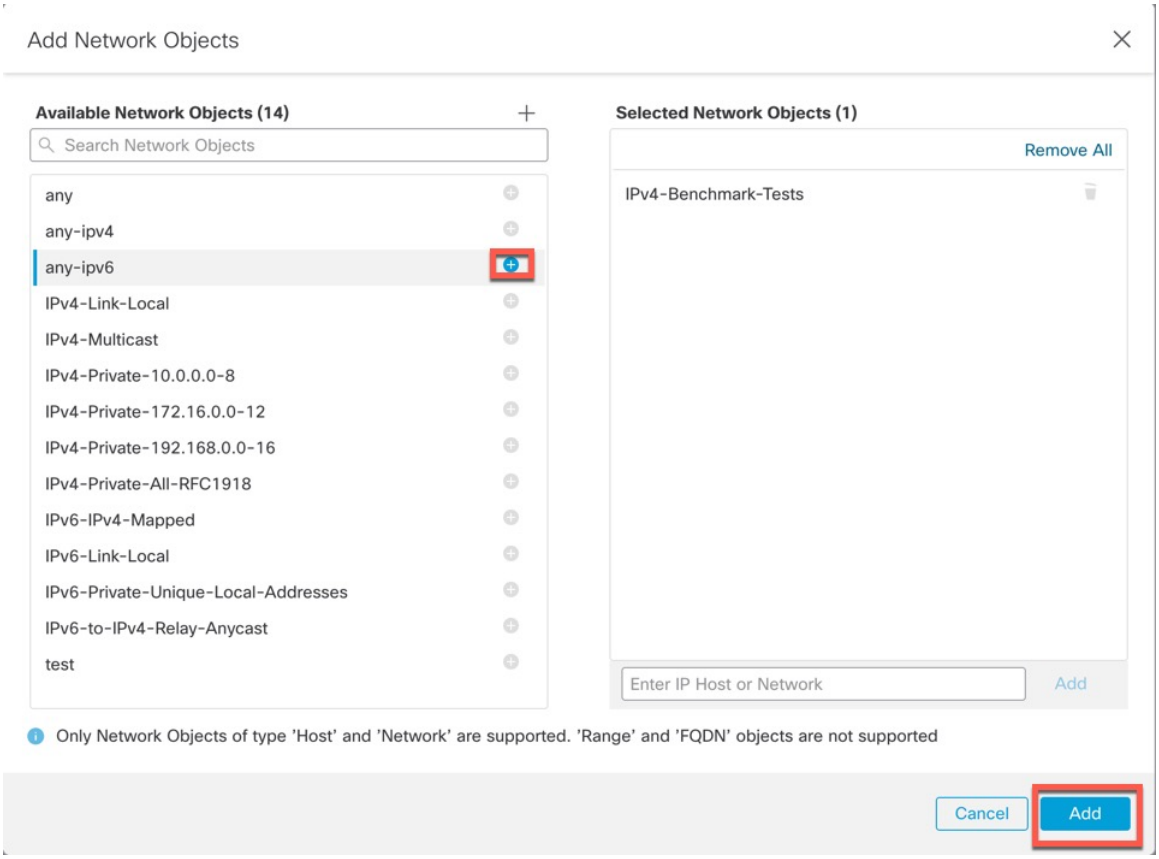
You can add up to 25 access lists.

Figure 134: SSH Access List



Step 10 Click **Edit** (✎) to add network objects and click **Save**. You can also manually enter IP addresses.

Figure 135: Network Objects



Step 11 Click **Save** to save all policy changes.

Configure Syslog

You can enable syslogs from the chassis. These syslogs come from the chassis' FXOS operating system.

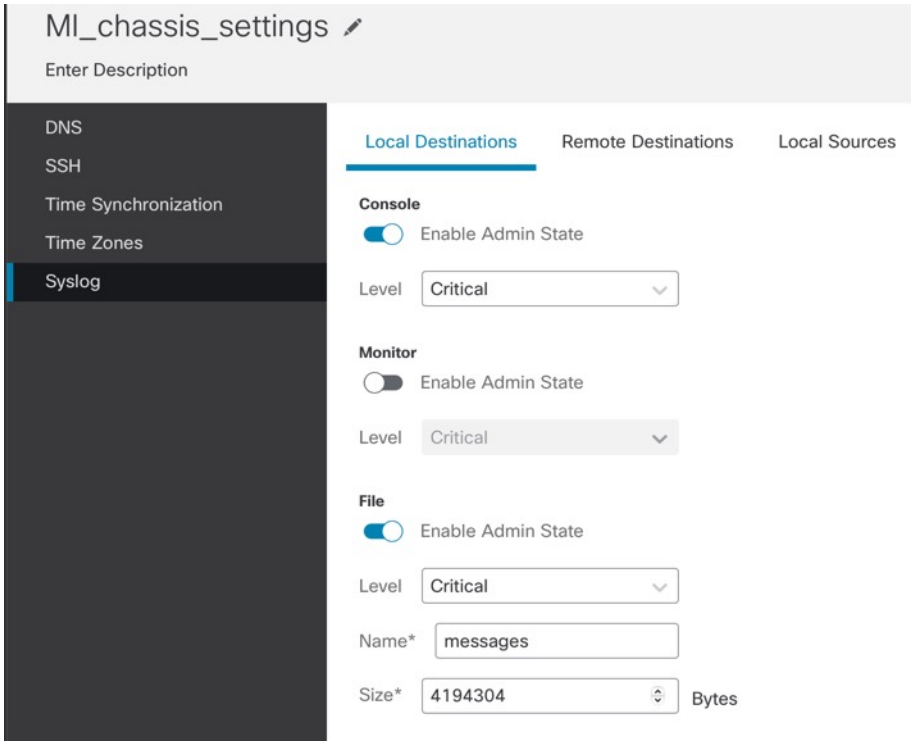
Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **Syslog**.

Step 3 Click the **Local Destinations** tab, and complete the following fields.

Figure 136: Syslog Local Destinations

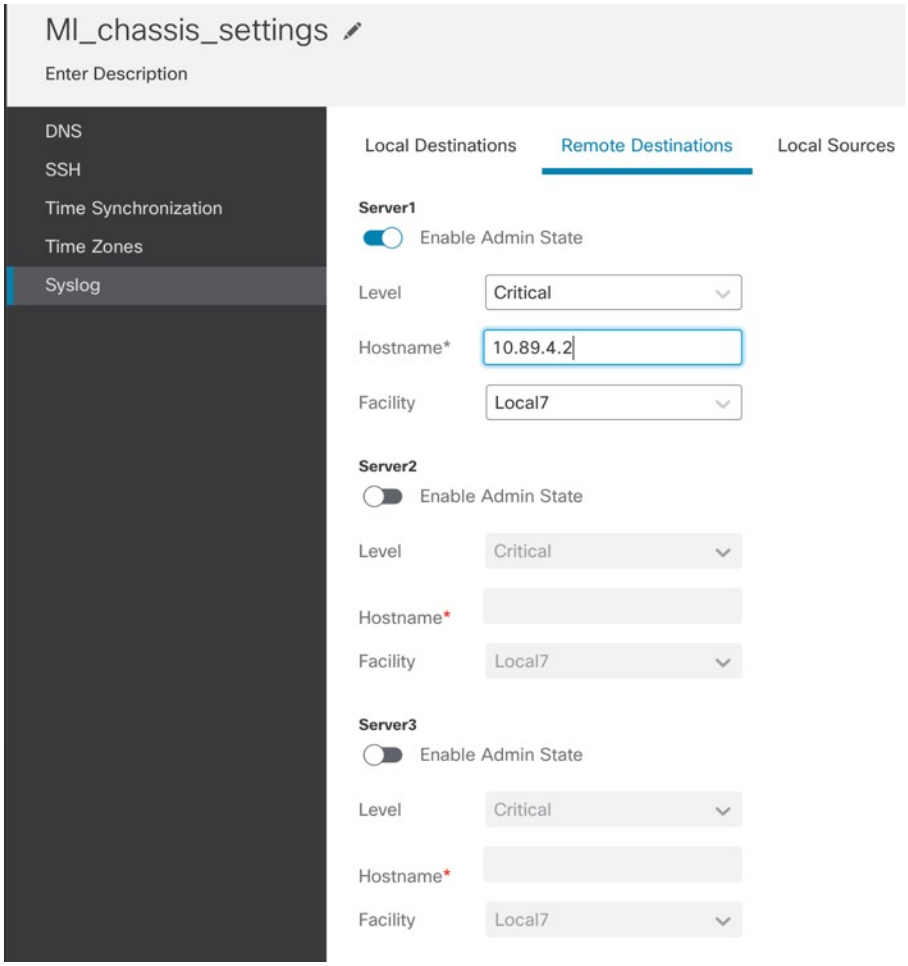


Name	Description
Console Section	
Admin State field	Whether the chassis displays syslog messages on the console. Check the **Enable** check box if you want to have syslog messages displayed on the console as well as added to the log. If the **Enable** check box is unchecked, syslog messages are added to the log but are not displayed on the console.
Level field	If you checked the **Enable** check box for **Console - Admin State**, select the lowest message level that you want displayed on the console. The chassis displays that level and above on the console. This can be one of the following: • **Emergencies** • **Alerts** • **Critical**
Monitor Section	

Name	Description
Admin State field	Whether the chassis displays syslog messages on the monitor. Check the **Enable** check box if you want to have syslog messages displayed on the monitor as well as added to the log. If the **Enable** check box is unchecked, syslog messages are added to the log but are not displayed on the monitor.
Level drop-down list	If you checked the **Enable** check box for **Monitor - Admin State**, select the lowest message level that you want displayed on the monitor. The system displays that level and above on the monitor. This can be one of the following: • **Emergencies** • **Alerts** • **Critical** • **Errors** • **Warnings** • **Notifications** • **Information** • **Debugging**

Step 4 On the **Remote Destinations** tab, complete the following fields for up to three external logs that can store messages generated by the chassis:

Figure 137: Syslog Remote Destinations



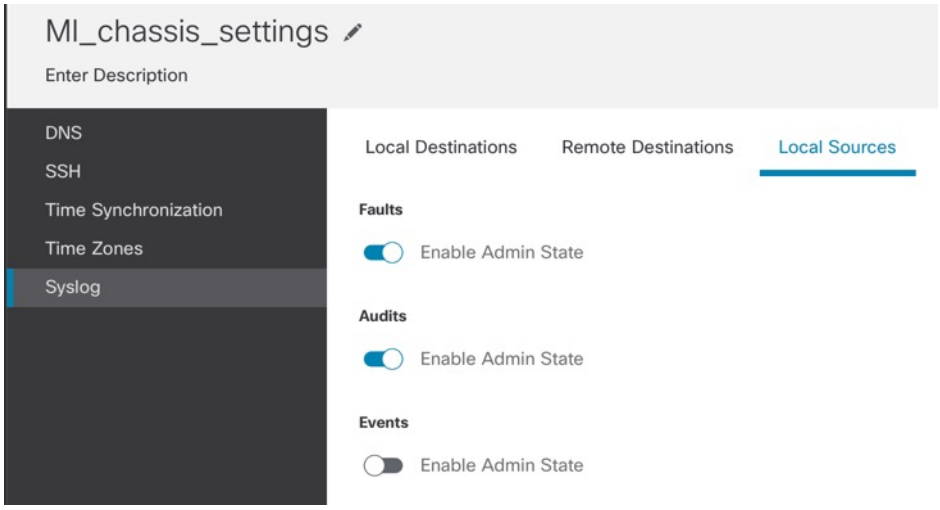
By sending syslog messages to a remote destination, you can archive messages according to the available disk space on the external syslog server, and manipulate logging data after it is saved. For example, you could specify actions to be executed when certain types of syslog messages are logged, extract data from the log and save the records to another file for reporting, or track statistics using a site-specific script.

Name	Description
Admin State field	Check the **Enable** check box if you want to have syslog messages stored in a remote log file.

Name	Description
Level drop-down list	Select the lowest message level that you want the system to store. The system stores that level and above in the remote file. This can be one of the following: • **Emergencies** • **Alerts** • **Critical** • **Errors** • **Warnings** • **Notifications** • **Information** • **Debugging**
Hostname/IP Address field	The hostname or IP address on which the remote log file resides. **Note** You must configure a DNS server if you use a hostname rather than an IP address.
Facility drop-down list	Choose a system log facility for syslog servers to use as a basis to file messages. This can be one of the following: • **Local0** • **Local1** • **Local2** • **Local3** • **Local4** • **Local5** • **Local6** • **Local7**

Step 5 Click the **Local Sources** tab, and complete the following fields.

Figure 138: Syslog Local Sources



Name	Description
Faults > **Enable Admin State**	Enable system fault logging.
Audits > **Enable Admin State**	Enable audit logging.
Events > **Enable Admin State**	Enable system event logging.

Step 6 Click **Save** to save all policy changes.

Configure Time Synchronization

NTP is used to implement a hierarchical system of servers that provide a precisely synchronized time among network systems. This kind of accuracy is required for time-sensitive operations, such as validating CRLs, which include a precise time stamp. You can configure up to four NTP servers.

Note

- FXOS uses NTP version 3.
- If the stratum value of an external NTP server is 13 or greater, the application instance cannot sync to the NTP server on the FXOS chassis. Each time a NTP client syncs to a NTP server, the stratum value increases by one.

  If you have set up your own NTP server, you can find its stratum value in the /etc/ntp.conf file on the server. If the NTP server has stratum value of 13 or greater you can either change the stratum value in the ntp.conf file and restart the server, or use a different NTP server (for example: pool.ntp.org).

Before you begin

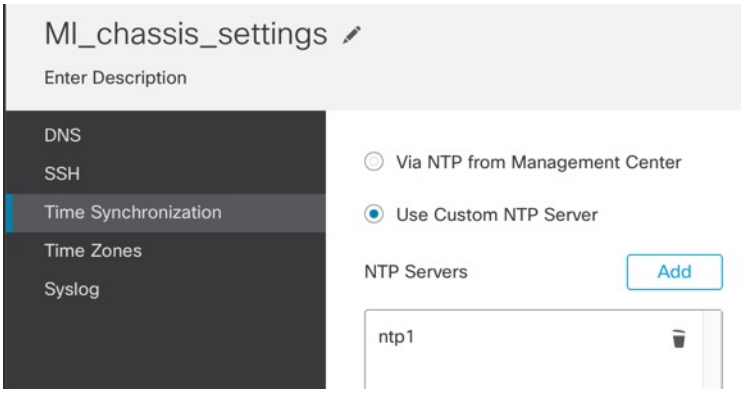
If you use a hostname for the NTP server, you must configure a DNS server. See Configure DNS, on page 542.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **Time Synchronization**.

Figure 139: Time Synchronization



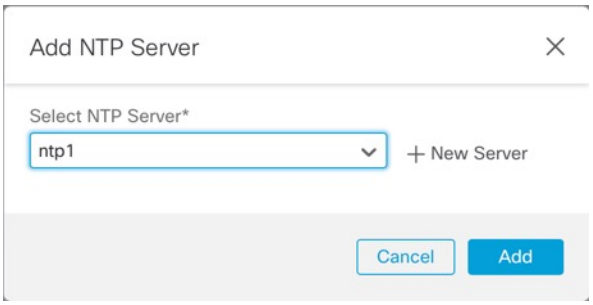
Step 3 If you want to obtain the time from the Firewall Management Center, click **Via NTP from Management Center**.

This option ensures both the chassis and the Firewall Management Center have the same time.

Step 4 To use an external NTP server, click **Use Custom NTP Server**.

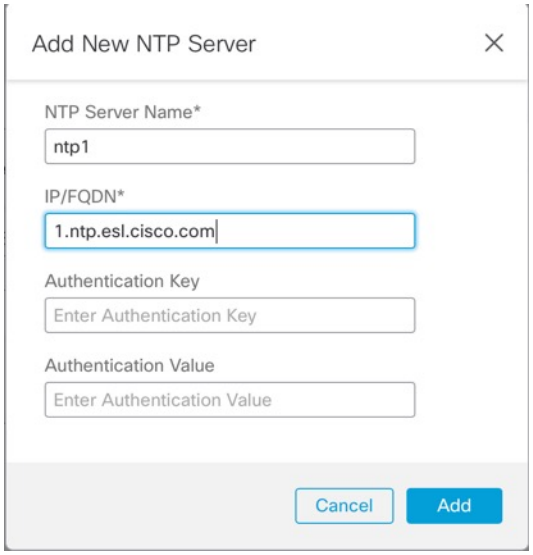
a) Click **Add** to add a server.

Figure 140: Add NTP Server



b) Choose any already-defined servers from the drop-down menu and click **Add**, or click **New Server** to add a new server.

Figure 141: Add New NTP Server



c) For a new server, enter the following fields, and click **Add**.

- **NTP Server Name**—A name to identify this server.
- **IP/FQDN**—The IP address or hostname of the server.
- **Authentication Key** and **Authentication Value**—Obtain the key ID and value from the NTP server. For example, to generate the SHA1 key on NTP server Version 4.2.8p8 or later with OpenSSL installed, enter the **ntp-keygen -M** command, and then view the key ID and value in the ntp.keys file. The key is used to tell both the client and server which value to use when computing the message digest.

  Only SHA1 is supported for NTP server authentication.

Step 5 Click **Save** to save all policy changes.

Configure Time Zones

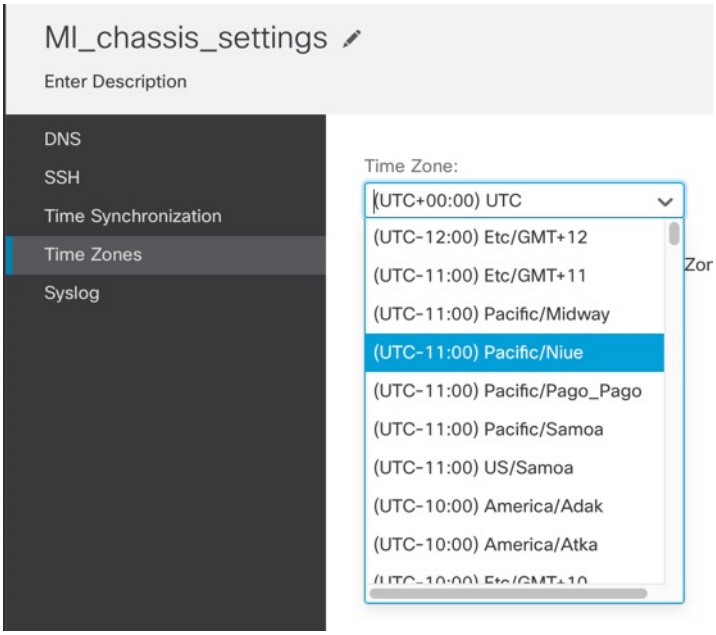
Set the time zone for the chassis.

Procedure

Step 1 Choose **Devices** > **Platform Settings** and create or edit the chassis policy.

Step 2 Choose **Time Zones**.

Figure 142: Time Zones



Step 3 Choose your **Time Zone** from the drop-down menu.

Step 4 Click **Save** to save all policy changes.

Manage Multi-Instance Mode

This section describes less common tasks, including changing settings at the FXOS CLI or changing interfaces assigned to the chassis.

Change Interfaces Assigned to an Instance

You can allocate or unallocate an interface on the instance. Adding a new interface, or deleting an unused interface, has minimal impact on the instance configuration. You can also edit the membership of an allocated EtherChannel without affecting the instance. However, deleting an interface that is used in your security policy will impact the configuration.

Interfaces can be referenced directly in many places in the instance configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface.

Policies that refer to security zones are not affected.

Note For high availability, you need to make the same interface changes for the other unit. Otherwise, high availability might not operate correctly.

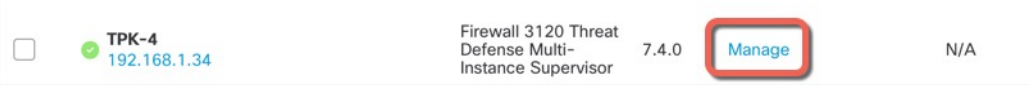
Before you begin

- Configure your interfaces according to Configure Instances, on page 518.
- If you want to add an already-allocated interface to an EtherChannel, you need to unallocate the interface from the instance first, then add the interface to the EtherChannel. For a new EtherChannel, you can then allocate the EtherChannel to the instance.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column or click **Edit** ( ).

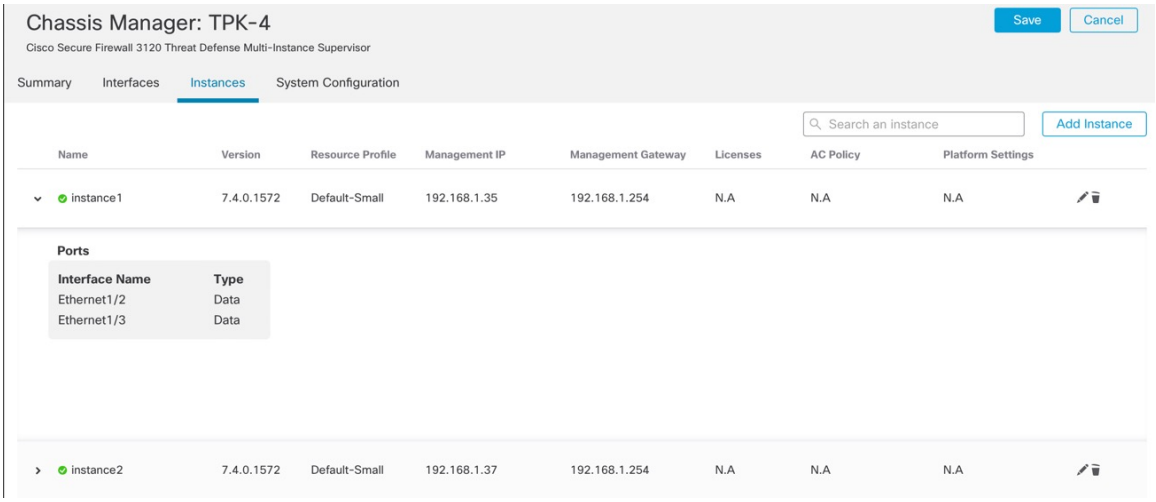
Figure 143: Manage Chassis



The **Chassis Manager** page opens for the chassis to the **Summary** page.

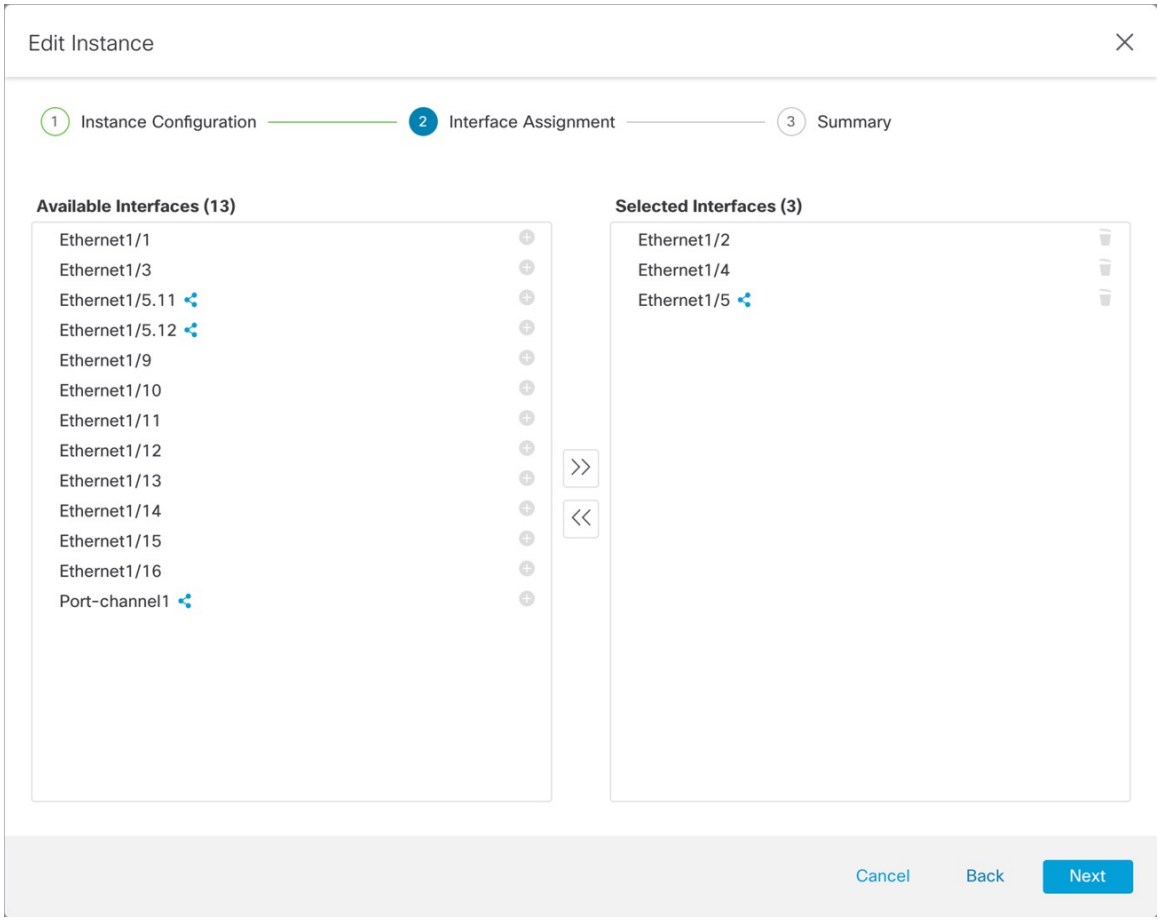
Step 2 Click **Instances**, and click **Edit** ( ) next to the instance for which you want to change interfaces.

Figure 144: Instances



Step 3 Click **Next** until you get to the **Interface Assignment** screen.

Figure 145: Interface Assignment



Shared interfaces show the sharing icon ( ).

Step 4 Make your interface changes, and then click **Next**.

Step 5 Click **Save** on the **Summary** screen.

Step 6 For high availability, you need to make the same interface changes for the other unit. Otherwise, high availability might not operate correctly.

Change Chassis Management Settings at the FXOS CLI

If you want to change the chassis management interface IP address and gateway, change the Firewall Management Center to a new manager, change the admin password, or disable multi-instance mode, you can do so from the FXOS CLI.

Procedure

Step 1 Connect to the chassis console port.

The console port connects to the FXOS CLI.

Note
We recommend using the console port. You can also connect using SSH to the management interface, if configured in the chassis platform settings in the Firewall Management Center; however, if you change the management IP address, you will be disconnected.

Step 2 Log in with the username **admin** and the password you set during initial setup.

Step 3 Change the Management IP address. You can use a static IPv4 and/or IPv6 address.

IPv4:

scope fabric-interconnect

set out-of-band static ip *ip_address* **netmask** *network_mask* **gw** *gateway_ip_address*

IPv6:

scope fabric-interconnect

scope ipv6-config

set out-of-band static ipv6 *ipv6_address* **ipv6-prefix** *prefix_length* **ipv6-gw** *gateway_address*

Example:

IPv4:

```
firepower-3110# scope fabric-interconnect
firepower-3110 /fabric-interconnect # set out-of-band static ip 10.5.23.8 netmask
255.255.255.0
gw 10.5.23.1
```

IPv6:

```
firepower-3110# scope fabric-interconnect
firepower-3110 / fabric-interconnect # scope ipv6-config
firepower-3110 / fabric-interconnect /ipv6-config # set out-of-band static ipv6 2001:DB8::34
ipv6-prefix 64 ipv6-gw 2001:DB8::1
```

Step 4 Change the Firewall Management Center.

You should first unregister the chassis from the current Firewall Management Center.

enter device-manager *manager_name* [**hostname** {*hostname* | *ipv4_address* | *ipv6_address*}] [**nat-id** *nat_id*]

You are prompted for the registration key.

You can enter this command from any scope.

- **hostname** {*hostname* | *ipv4_address* | *ipv6_address*}—Specifies either the FQDN or IP address of the Firewall Management Center. At least one of the devices, either the Firewall Management Center or the chassis, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices. If you do not specify a **hostname**, then the chassis must have a reachable IP address or hostname and you must specify the **nat-id**.
- **nat-id** *nat_id*—Specifies a unique, one-time string of your choice that you will also specify on the Firewall Management Center when you register the chassis when one side does not specify a reachable IP address

or hostname. It is required if you do not specify a **hostname**, however we recommend that you always set the NAT ID even when you specify a hostname or IP address. The NAT ID must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the Firewall Management Center.

- **Registration Key:** *reg_key*—You will be prompted for a one-time registration key of your choice that you will also specify on the Firewall Management Center when you register the chassis. The registration key must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-).

Example:

```
firepower-3110# enter device-manager boulder_fmc hostname 10.89.5.35 nat-id 93002
(Valid registration key characters: [a-z],[A-Z],[0-9],[-]. Length: [2-36])
Registration Key: Impala67
```

Step 5 Change the admin password.

scope security

set password

Enter a password: *password*

Confirm the password: *password*

Example:

```
firepower-3110# scope security
firepower-3110 /security # set password
Enter new password: Sw@nsong67
Confirm new password: Sw@nsong67
firepower-3110 /security #
```

Step 6 Disable multi-instance mode and set the system back to appliance mode.

scope system

set deploymode native

You are prompted to reboot.

Example:

```
firepower-3110# scope system
firepower-3110 /system # set deploymode native
All configuration and bootable images will be lost and system will reboot.
If there was out of band upgrade, it might reboot with the base version and
need to re-image to get the expected running version.
Do you still want to change deploy mode? (yes/no):yes
firepower-3110 /system #
```

To change the mode back to multi-instance mode, enter **set deploymode container**. You can check the current mode using the **show system detail** command.

Monitoring Multi-Instance Mode

This section helps you troubleshoot and diagnose your multi-instance mode chassis and instances.

Monitoring Multi-Instance Setup

show system detail

This FXOS command shows the current mode, Native or Container. If the mode is Native (also known as appliance mode), you can convert to multi-instance (Container) mode. Note that the prompt/name in multi-instance mode is generic "firepower-<model>" while the prompt in appliance mode is the hostname you set for the Firewall Threat Defense (by default "firepower")

```
firepower # show system detail

Systems:
    Name: firepower
    Mode: Stand Alone
    System IP Address: 172.16.0.50
    System IPv6 Address: ::
    System Owner:
    System Site:
    Deploy Mode: Native
    Description for System:
firepower #
```

scope system > show

This FXOS command shows the current mode in a table format. Note that the prompt/name in multi-instance mode is generic "firepower-<model>" while the prompt in appliance mode is the hostname you set for the Firewall Threat Defense.

```
firepower-3110# scope system
firepower-3110 /system # show

Systems:
    Name       Mode        Deploy Mode System IP Address System IPv6 Address
    ---------- ----------- ----------- ----------------- -------------------
    firepower-3110
               Stand Alone Container   10.89.5.42        ::

3110-1# scope system
3110-1 /system # show

Systems:
    Name       Mode        Deploy Mode System IP Address System IPv6 Address
    ---------- ----------- ----------- ----------------- -------------------
    3110-1     Stand Alone Native      10.89.5.41        ::
3110-1 /system #
```

Monitoring Instance Interfaces

show portmanager switch forward-rules hardware mac-filter

This command shows the internal switch-forwarding rule for two instances with a dedicated physical interface assigned to each instance. Ethernet 1/2 is assigned to ftd1 and Ethernet 1/1 is assigned to ftd2.

ECMP group 1540 is assigned to ftd1 and ECMP group 1541 is assigned to ftd2.

```
secfw-3140(local-mgmt)# show portmanager switch forward-rules hardware mac-filter
      VLAN    SRC_PORT    PC_ID    SRC_ID    DST_PORT      PKT_CNT       DMAC
1        0          17        0        17          19        29164  0:0:0:0:0:0
2        0          19        0        19          17        67588  0:0:0:0:0:0
3        0           1        0       101        1541            0  a2:5b:83:0:0:15
4        0           1        0       101        1541         8181  ff:ff:ff:ff:ff:ff
5        0           2        0       102        1540            0  a2:5b:83:0:0:18
6        0           2        0       102        1540          431  ff:ff:ff:ff:ff:ff
7        0          17        0         0           0        11133  0:0:0:0:0:0
8        0          17        0         0           0            0  0:0:0:0:0:0
```

This command shows the internal switch-forwarding rule for two instances with shared physical interfaces assigned to two instances. Ethernet 1/1 is shared between ftd1 and ftd2.

ECMP group 1540 is assigned to ftd1 and ECMP group 1541 is assigned to ftd2.

MCAST group 4096 is used for replicating broadcast traffic between ftd1 and ftd2.

```
firepower-3140(local-mgmt)# show portmanager switch forward-rules hardware mac-filter
      VLAN    SRC_PORT    PC_ID    SRC_ID    DST_PORT      PKT_CNT       DMAC
1        0          17        0        17          19         2268  0:0:0:0:0:0
2        0          19        0        19          17         4844  0:0:0:0:0:0
3        0           1        0       101        1541            0  a2:5b:83:0:0:9
4        0           1        0       101        4096          546  ff:ff:ff:ff:ff:ff
5        0           1        0       101        1540            0  a2:5b:83:0:0:c
6        0          17        0         0           0         1263  0:0:0:0:0:0
7        0          17        0         0           0            0  0:0:0:0:0:0
```

This command shows the internal switch-forwarding rule for two instances with shared subinterfaces assigned to both instances. Ethernet 1/1.2452 is shared between ftd1 and ftd2.

ECMP group 1540 is assigned to ftd1 and ECMP group 1541 is assigned to ftd2.

MCAST group 4097 is used for replicating broadcast traffic between ftd1 and ftd2.

```
firepower-3140(local-mgmt)# show portmanager switch forward-rules hardware mac-filter
      VLAN    SRC_PORT    PC_ID    SRC_ID    DST_PORT      PKT_CNT       DMAC
1        0          17        0        17          19        21305  0:0:0:0:0:0
2        0          19        0        19          17        50976  0:0:0:0:0:0
3     2452           1        0       101        1541          430  a2:5b:83:0:0:f
4     2452           1        0       101        4097            0  ff:ff:ff:ff:ff:ff
5     2452           1        0       101        1540            0  a2:5b:83:0:0:12
6        0          17        0         0           0        11038  0:0:0:0:0:0
7        0          17        0         0           0            0  0:0:0:0:0:0
```

show portmanager switch ecmp-groups detail

Use this command to list each Instance Ecmp-Vport-Physical port mapping detail.

Note Physical-Port 18 is the backplane uplink interface between the internal switch and the instance.

```
firepower-3140(local-mgmt)# show portmanager switch ecmp-groups detail
       ECMP-GROUP  VPORT      PHYSICAL-PORT
1      1536        256        18
2      1537        257        18
3      1538        258        18
4      1539        259        18
5      1540        260        18
6      1541        261        18
7      1542        262        18
8      1543        263        18
9      1544        264        18
10     1545        265        18
```

show portmanager switch mcast-groups detail

Use this command to list MCAST group membership details.

```
firepower-3140(local-mgmt)# show portmanager switch mcast-groups detail
       MCAST-GROUP
1      4096
       Member-ports
       Ethernet 1/1
       ECMP-ID 1541
       ECMP-ID 1540
```

show portmanager counters mcast-group

Use this command to check the MCAST group packet counter.

```
firepower-3140(local-mgmt)# show portmanager counters mcast-group 4096
PKT_CNT: 8106
```

show portmanager counters ecmp

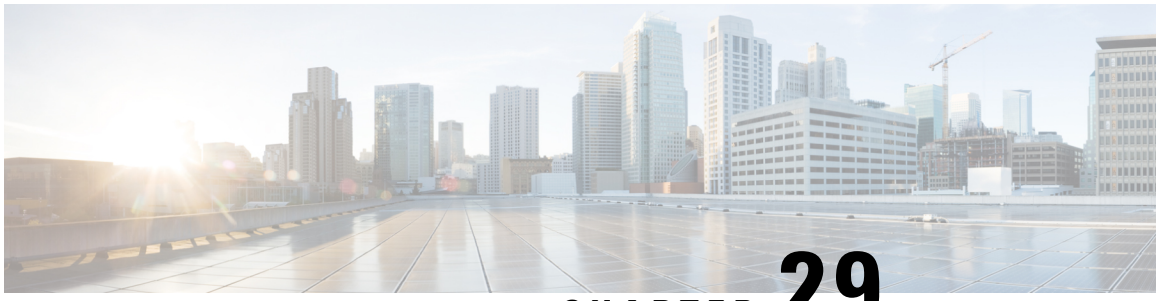
Use this command to check the ECMP group packet counter.

```
firepower-3140(local-mgmt)# show portmanager counters ecmp 1541
PKT_CNT: 430
```

History for Multi-Instance Mode

Table 43:

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Multi-instance mode for the Secure Firewall 3100.	20240203	7.4.1	You can deploy the Secure Firewall 3100 as a single device (*appliance mode*) or as multiple container instances (*multi-instance mode*). In multi-instance mode, you can deploy multiple container instances on a single chassis that act as completely independent devices. Note that in multi-instance mode, you upgrade the operating system and the firmware (*chassis upgrade*) separately from the container instances (*Firewall Threat Defense upgrade*). New/modified screens: • **Inventory** > **FTD Chassis** • **Devices** > **Device Management** > **Device** > **Chassis Manager** • **Devices** > **Platform Settings** > **New Policy** > **Chassis Platform Settings** • **Devices** > **Chassis Upgrade** New/modified Firewall Threat Defense CLI commands: **configure multi-instance network ipv4**, **configure multi-instance network ipv6** New/modified FXOS CLI commands: **create device-manager**, **set deploymode** Platform restrictions: Not supported on the Secure Firewall 3105. See: Use Multi-Instance Mode for the Secure Firewall 3100/4200 and Cisco Secure Firewall Threat Defense Upgrade Guide for Cloud-Delivered Firewall Management Center



CHAPTER 29

High Availability

The following topics describe how to configure Active/Standby failover to accomplish high availability of the Firewall Threat Defense.

- About Secure Firewall Threat Defense High Availability, on page 565
- Config-Sync Optimization, on page 580
- Requirements and Prerequisites for High Availability, on page 581
- Guidelines for High Availability, on page 581
- Add a High Availability Pair, on page 584
- Configure Optional High Availability Parameters, on page 587
- Manage High Availability, on page 589
- Monitoring High Availability, on page 595
- Troubleshooting High Availability Break in a Remote Branch Deployment, on page 596
- History for High Availability, on page 602

About Secure Firewall Threat Defense High Availability

Configuring high availability, also called failover, requires two identical Firewall Threat Defense devices connected to each other through a dedicated failover link and, optionally, a state link. Firewall Threat Defense supports Active/Standby failover, where one unit is the active unit and passes traffic. The standby unit does not actively pass traffic, but synchronizes configuration and other state information from the active unit. When a failover occurs, the active unit fails over to the standby unit, which then becomes active.

The health of the active unit (hardware, interfaces, software, and environmental status) is monitored to determine if specific failover conditions are met. If those conditions are met, failover occurs.

Note High availability is not supported on Firewall Threat Defense Virtual running in the public cloud. See the Cisco Secure Firewall Threat Defense Virtual Getting Started Guide for more information about configuring the Firewall Threat Defense Virtual device for high availability.

High Availability Support on Firewall Threat Defense Devices in a Remote Branch Office Deployment

In a remote branch office deployment, the data interface of the Firewall Threat Defense device is used for Cisco Security Cloud Control management instead of the Management interface on the device. Because most remote branch offices only have a single internet connection, outside Security Cloud Control access makes centralized management possible.

You can use *any* data interface for Security Cloud Control access, for example, the inside interface if you have an inside Security Cloud Control. However, this guide primarily covers outside interface access, because it is the most likely scenario for remote branch offices.

Security Cloud Control provides high availability support on the Firewall Threat Defense devices that it manages through the data interface. This feature is supported on devices running on software version 7.2 or later.

For more information, see *Firepower Threat Defense Deployment with a Remote FMC* in the Cisco Firepower Getting Started Guide.

High Availability System Requirements

This section describes the hardware, software, and license requirements for Firewall Threat Defense devices in a High Availability configuration.

Hardware Requirements

The two units in a High Availability configuration must:

- Be the same model. In addition, for container instances, they must use the same resource profile attributes.

  For the Firepower 9300, High Availability is only supported between same-type modules; but the two chassis can include mixed modules. For example, each chassis has an SM-56, SM-48, and SM-40. You can create High Availability pairs between the SM-56 modules, between the SM-48 modules, and between the SM-40 modules.

  If you change the resource profile after you add the High Availability pair to the Security Cloud Control, update the inventory for each unit on the **Devices** > **Device Management** > **Device** > **System** > **Inventory** dialog box.

  If you assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:

  1. Break high availability.
  2. Assign the new profile to both units.
  3. Re-establish high availability.

- Have the same number and types of interfaces.

  For the Firepower 4100/9300 chassis, all interfaces must be preconfigured in FXOS identically before you enable High Availability. If you change the interfaces after you enable High Availability, make the interface changes in FXOS on the Standby unit, and then make the same changes on the Active unit.

- Have the following settings in a remote branch deployment:

- Have the same data management interface to handle management traffic in a remote deployment.

  For example, if you have used eth0 in device 1, use the same interface (eth0) in device 2 as well.

- Use data management interface for management traffic.

  You cannot have one unit managed using a data interface and the other using a management interface.

If you are using units with different flash memory sizes in your High Availability configuration, make sure the unit with the smaller flash memory has enough space to accommodate the software image files and the configuration files. If it does not, configuration synchronization from the unit with the larger flash memory to the unit with the smaller flash memory will fail.

Software Requirements

The two units in a High Availability configuration must:

- Be in the same firewall mode (routed or transparent).
- Have the same software version.
- Be in the same domain or group on the Firewall Management Center.
- Have the same NTP configuration. See Configure NTP Time Synchronization for Threat Defense.
- Be fully deployed on the Firewall Management Center with no uncommitted changes.
- Not have DHCP or PPPoE configured in any of their interfaces.
- (Firepower 4100/9300) Have the same flow offload mode, either both enabled or both disabled.

License Requirements for Firewall Threat Defense Devices in a High Availability Pair

Both Firewall Threat Defense units in a high availability configuration must have the same licenses.

High availability configurations require two license entitlements: one for each device in the pair.

Before high availability is established, it does not matter which licenses are assigned to the secondary/standby device. During high availability configuration, the Firewall Management Center releases any unnecessary licenses assigned to the standby unit and replaces them with identical licenses assigned to the primary/active unit. For example, if the active unit has a Essentials license and a IPS license, and the standby unit has only a Essentials license, the Firewall Management Center communicates with the Smart Software Manager to obtain an available IPS license from your account for the standby unit. If your license account does not include enough purchased entitlements, your account becomes Out-of-Compliance until you purchase the correct number of licenses.

Failover and Stateful Failover Links

The failover link and the optional stateful failover link are dedicated connections between the two units. Cisco recommends to use the same interface between two devices in a failover link or a stateful failover link. For example, in a failover link, if you have used eth0 in device 1, use the same interface (eth0) in device 2 as well.

Failover Link

The two units in a failover pair constantly communicate over a failover link to determine the operating status of each unit.

Failover Link Data

The following information is communicated over the failover link:

- The unit state (active or standby)
- Hello messages (keep-alives)
- Network link status
- MAC address exchange
- Configuration replication and synchronization

Interface for the Failover Link

You can use an unused data interface (physical, or EtherChannel) as the failover link; however, you cannot specify an interface that is currently configured with a name. You cannot use a data management interface if the interface is configured for communication with Security Cloud Control. You also cannot use a subinterface with the exception of a subinterface defined on the chassis for multi-instance mode. The failover link interface is not configured as a normal networking interface; it exists for failover communication only. This interface can only be used for the failover link (and also for the state link).

The Firewall Threat Defense does not support sharing interfaces between user data and the failover link. You also cannot use separate subinterfaces on the same parent for the failover link and for data (multi-instance chassis subinterfaces only). If you use a chassis subinterface for the failover link, then all subinterfaces on that parent, and the parent itself, are restricted for use as failover links.

Note When using an EtherChannel as the failover or state link, you must confirm that the same EtherChannel with the same member interfaces exists on both devices before establishing high availability.

See the following guidelines for the failover link:

- Firepower 4100/9300—You cannot use the management-type interface for the failover link.
- See the following guidelines for sizing the link.

Table 44: Failover Link Size

Model	Interface Size for Combined Failover and State Link
Firepower 1010	1 Gbps
Firepower 1100	1 Gbps

Model	Interface Size for Combined Failover and State Link
Secure Firewall 3100	Secure Firewall 3105—1 Gbps Secure Firewall 3110—1 Gbps Secure Firewall 3120—1 Gbps Secure Firewall 3130—10 Gbps Secure Firewall 3140—10 Gbps
Firepower 4100	10 Gbps
Firepower 9300	10 Gbps

The alternation frequency is equal to the unit hold time.

Note If you have a large configuration and a low unit hold time, alternating between the member interfaces can prevent the secondary unit from joining/re-joining. In this case, disable one of the member interfaces until after the secondary unit joins.

For an EtherChannel used as the failover link, to prevent out-of-order packets, only one interface in the EtherChannel is used. If that interface fails, then the next interface in the EtherChannel is used. You cannot alter the EtherChannel configuration while it is in use as a failover link.

Connecting the Failover Link

Connect the failover link in one of the following two ways:

- Using a switch, with no other device on the same network segment (broadcast domain or VLAN) as the failover interfaces of the Firewall Threat Defense device.
- Using an Ethernet cable to connect the units directly, without the need for an external switch.

If you do not use a switch between the units, if the interface fails, the link is brought down on both peers. This condition may hamper troubleshooting efforts because you cannot easily determine which unit has the failed interface and caused the link to come down.

Stateful Failover Link

To use Stateful Failover, you must configure a Stateful Failover link (also known as the state link) to pass connection state information.

Shared with the Failover Link

Sharing a failover link is the best way to conserve interfaces. However, you must consider a dedicated interface for the state link and failover link, if you have a large configuration and a high traffic network.

Dedicated Interface for the Stateful Failover Link

You can use a dedicated data interface (physical or EtherChannel) for the state link. See Interface for the Failover Link, on page 568 for requirements for a dedicated state link, and Connecting the Failover Link, on page 569 for information about connecting the state link as well.

For optimum performance when using long distance failover, the latency for the state link should be less than 10 milliseconds and no more than 250 milliseconds. If latency is more than 10 milliseconds, some performance degradation occurs due to retransmission of failover messages.

Avoiding Interrupted Failover and Data Links

We recommend that failover links and data interfaces travel through different paths to decrease the chance that all interfaces fail at the same time. If the failover link is down, the failover operation is suspended until the health of the failover link is restored.

See the following connection scenarios to design a resilient failover network.

Scenario 1—Not Recommended

If a single switch or a set of switches are used to connect both failover and data interfaces between two Firewall Threat Defense devices, then when a switch or inter-switch-link is down, both Firewall Threat Defense devices become active. Therefore, the two connection methods shown in the following figures are **not** recommended.

Figure 146: Connecting with a Single Switch Not Recommended

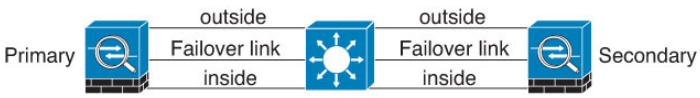


Figure 147: Connecting with a Double-Switch—Not Recommended

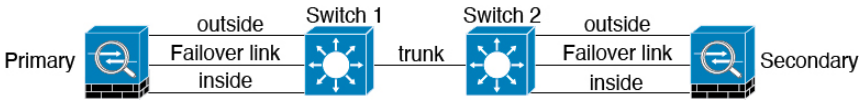

Scenario 2—Recommended

We recommend that failover links not use the same switch as the data interfaces. Instead, use a different switch or use a direct cable to connect the failover link, as shown in the following figures.

Figure 148: Connecting with a Different Switch

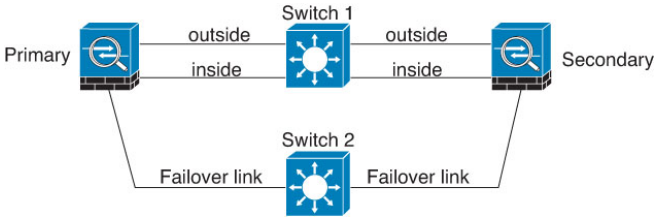

Figure 149: Connecting with a Cable

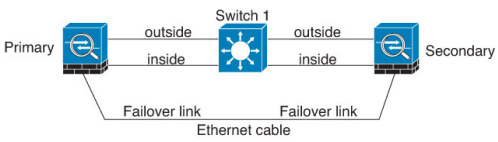
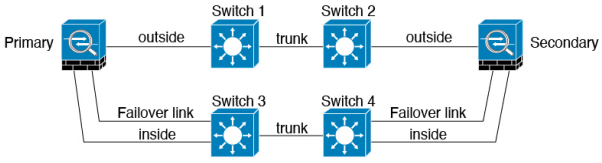


Scenario 3—Recommended

If the Firewall Threat Defense data interfaces are connected to more than one set of switches, then a failover link can be connected to one of the switches, preferably the switch on the secure (inside) side of network, as shown in the following figure.

Figure 150: Connecting with a Secure Switch



MAC Addresses and IP Addresses in High Availability

When you configure your interfaces, you can specify an active IP address and a standby IP address on the same network. Generally, when a failover occurs, the new active unit takes over the active IP addresses and MAC addresses. Because network devices see no change in the MAC to IP address pairing, no ARP entries change or time out anywhere on the network.

Note Although recommended, the standby address is not required. Without a standby IP address, the active unit cannot perform network tests to check the standby interface health; it can only track the link state. You also cannot connect to the standby unit on that interface for management purposes.

The IP address and MAC address for the state link do not change at failover.

Active/Standby IP Addresses and MAC Addresses

For Active/Standby High Availability, see the following for IP address and MAC address usage during a failover event:

1. The active unit always uses the primary unit's IP addresses and MAC addresses.
2. When the active unit fails over, the standby unit assumes the IP addresses and MAC addresses of the failed unit and begins passing traffic.
3. When the failed unit comes back online, it is now in a standby state and takes over the standby IP addresses and MAC addresses.

However, if the secondary unit boots without detecting the primary unit, then the secondary unit becomes the active unit and uses its own MAC addresses, because it does not know the primary unit MAC addresses. When the primary unit becomes available, the secondary (active) unit changes the MAC addresses to those of the primary unit, which can cause an interruption in your network traffic. Similarly, if you swap out the primary unit with new hardware, a new MAC address is used.

If you disable high availability and set the failover configurations to a disabled state, you will need to manually resume high availability, or reboot the device. It is recommended to use the command **configure high-availability resume** and resume the high availability instead of rebooting the device. If you reload the standby unit with the failover configuration disabled, the standby unit boots up as the active unit and uses the primary unit's IP addresses and MAC addresses. This leads to duplicate IP addresses and causes network

traffic disruptions. Use the command **configure high-availability resume** to enable failover and restore the traffic flow.

Note If you enable failover on a standalone device, the data interfaces go down at negotiation state of failover, interrupting traffic.

Virtual MAC addresses guard against this disruption, because the active MAC addresses are known to the secondary unit at startup, and remain the same in the case of new primary unit hardware. We recommend that you configure the virtual MAC address on both the primary and secondary units to ensure that the secondary unit uses the correct MAC addresses when it is the active unit, even if it comes online before the primary unit. If you do not configure virtual MAC addresses, you might need to clear the ARP tables on connected routers to restore traffic flow. The Firewall Threat Defense device does not send gratuitous ARPs for static NAT addresses when the MAC address changes, so connected routers do not learn of the MAC address change for these addresses.

Virtual MAC Addresses

The Firewall Threat Defense device has multiple methods to configure virtual MAC addresses. We recommend using only one method. If you set the MAC address using multiple methods, the MAC address used depends on many variables, and might not be predictable.

For multi-instance capability, the FXOS chassis autogenerates only primary MAC addresses for all interfaces. You can overwrite the generated MAC address with a virtual MAC address with both the primary and secondary MAC addresses, but predefining the secondary MAC address is not essential; setting the secondary MAC address does ensure that to-the-box management traffic is not interrupted in the case of new secondary unit hardware.

MAC Address Table Update in Failover

During failover, the device that is designated as the new active device generates multicast packets for each MAC address entry in the MAC table and sends them to all the bridge group interfaces. This action prompts the upstream switches in the bridge group to update their routing tables with the new active device's interface to ensure accurate traffic forwarding.

The time taken to generate multicast packets and update the routing tables of the upstream switches depends on the number of entries in the MAC address table and the number of bridge group interfaces. Use the **show failover statistics state-switch-delay** command to display statistics related to the delays encountered during failover events.

Stateful Failover

During Stateful Failover, the active unit continually passes per-connection state information to the standby unit. After a failover occurs, the same connection information is available at the new active unit. Supported end-user applications are not required to reconnect to keep the same communication session.

Supported Features

For Stateful Failover, the following state information is passed to the standby Firewall Threat Defense device:

- NAT translation table.

- TCP and UDP connections and states, including HTTP connection states. Other types of IP protocols, and ICMP, are not parsed by the active unit, because they get established on the new active unit when a new packet arrives.
- Snort connection states, inspection results, and pin hole information, including strict TCP enforcement.
- The ARP table
- The Layer 2 bridge table (for bridge groups)
- The ISAKMP and IPsec SA table
- GTP PDP connection database
- SIP signaling sessions and pin holes.
- Static and dynamic routing tables—Stateful Failover participates in dynamic routing protocols, like OSPF and EIGRP, so routes that are learned through dynamic routing protocols on the active unit are maintained in a Routing Information Base (RIB) table on the standby unit. Upon a failover event, packets travel normally with minimal disruption to traffic because the active secondary unit initially has rules that mirror the primary unit. Immediately after failover, the re-convergence timer starts on the newly active unit. Then the epoch number for the RIB table increments. During re-convergence, OSPF and EIGRP routes become updated with a new epoch number. Once the timer is expired, stale route entries (determined by the epoch number) are removed from the table. The RIB then contains the newest routing protocol forwarding information on the newly active unit.

Note Routes are synchronized only for link-up or link-down events on an active unit. If the link goes up or down on the standby unit, dynamic routes sent from the active unit may be lost. This is normal, expected behavior.

- DHCP Server—DHCP address leases are not replicated. However, a DHCP server configured on an interface will send a ping to make sure an address is not being used before granting the address to a DHCP client, so there is no impact to the service. State information is not relevant for DHCP relay or DDNS.
- Access control policy decisions—Decisions related to traffic matching (including URL, URL category, geolocation, and so forth), intrusion detection, malware, and file type are preserved during failover. However, for connections being evaluated at the moment of failover, there are the following caveats:
  - AVC—App-ID verdicts are replicated, but not detection states. Proper synchronization occurs as long as the App-ID verdicts are complete and synchronized before failover occurs.
  - Intrusion detection state—Upon failover, once mid-flow pickup occurs, new inspections are completed, but old states are lost.
  - File malware blocking—The file disposition must become available before failover.
  - File type detection and blocking—The file type must be identified before failover. If failover occurs while the original active device is identifying the file, the file type is not synchronized. Even if your file policy blocks that file type, the new active device downloads the file.
- User identity decisions from the identity policy, including the user-to-IP address mappings gathered passively through ISE Session Directory, and active authentication through captive portal. Users who are actively authenticating at the moment of failover might be prompted to authenticate again.

- Network AMP—Cloud lookups are independent from each device, so failover does not affect this feature in general. Specifically:
  - Signature Lookup—If failover occurs in the middle of a file transmission, no file event is generated and no detection occurs.
  - File Storage—If failover occurs when the file is being stored, it is stored on the original active device. If the original active device went down while the file was being stored, the file does not get stored.
  - File Pre-classification (Local Analysis)—If failover occurs in the middle of pre-classification, detection fails.
  - File Dynamic Analysis (Connectivity to the cloud)—If failover occurs, the system might submit the file to the cloud.
  - Archive File Support—If failover occurs in the middle of an analysis, the system loses visibility into the file/archive.
  - Custom Blocking—If failover occurs, no events are generated.
- Security Intelligence decisions. However, DNS-based decisions that are in process at the moment of failover are not completed.
- RA VPN—Remote access VPN end users do not have to reauthenticate or reconnect the VPN session after a failover. However, applications operating over the VPN connection could lose packets during the failover process and not recover from the packet loss.
- From all the connections, only established ones will be replicated on the Standby device.

Unsupported Features

For Stateful Failover, the following state information is not passed to the standby Firewall Threat Defense device:

- Sessions in plaintext tunnels other than GREv0 and IPv4-in-IP. Sessions inside tunnels are not replicated and the new active node will not be able to reuse existing inspection verdicts to match the correct policy rules.
- Decrypted TLS/SSL connections—The decryption states are not synchronized, and if the active unit fails, then decrypted connections will be reset. New connections will need to be established to the new active unit. Connections that are not decrypted (in other words, those that match a TLS/SSL Do Not Decrypt rule action) are not affected and are replicated correctly.
- TCP state bypass connections
- Multicast routing.

Bridge Group Requirements for High Availability

There are special considerations for high availability when using bridge groups.

When the active unit fails over to the standby unit, the switch port running Spanning Tree Protocol (STP) can go into a blocking state for 30 to 50 seconds when it senses the topology change. To avoid traffic loss on the

bridge group member interfaces while the port is in a blocking state, you can configure one of the following workarounds:

- Switch port is in Access mode—Enable the STP PortFast feature on the switch:

```
interface interface_id
  spanning-tree portfast
```

  The PortFast feature immediately transitions the port into STP forwarding mode upon linkup. The port still participates in STP. So if the port is to be a part of the loop, the port eventually transitions into STP blocking mode.

- If the switch port is in Trunk mode, or you cannot enable STP PortFast, then you can use one of the following less desirable workarounds that impacts failover functionality or STP stability:
  - Disable interface monitoring on the bridge group and member interfaces.
  - Increase the interface hold time in the failover criteria to a high value that will allow STP to converge before the unit fails over.
  - Decrease the STP timers on the switch to allow STP to converge faster than the interface hold time.

Failover Health Monitoring

The Firewall Threat Defense device monitors each unit for overall health and for interface health. This section includes information about how the Firewall Threat Defense device performs tests to determine the state of each unit.

Unit Health Monitoring

The Firewall Threat Defense device determines the health of the other unit by monitoring the failover link with hello messages. When a unit does not receive three consecutive hello messages on the failover link, the unit sends LANTEST messages on each data interface, including the failover link, to validate whether or not the peer is responsive. The action that the Firewall Threat Defense device takes depends on the response from the other unit. See the following possible actions:

- If the Firewall Threat Defense device receives a response on the failover link, then it does not fail over.
- If the Firewall Threat Defense device does not receive a response on the failover link, but it does receive a response on a data interface, then the unit does not failover. The failover link is marked as failed. You should restore the failover link as soon as possible because the unit cannot fail over to the standby while the failover link is down.
- If the Firewall Threat Defense device does not receive a response on any interface, then the standby unit switches to active mode and classifies the other unit as failed.

Heartbeat Module Redundancy

Each unit in the HA periodically sends a broadcast keepalive heartbeat packet over the cluster control link. If the control plane is too busy handling traffic, sometimes the heartbeat packets do not reach the peers, or the peers do not process the heartbeat packets due to CPU overloading. When peers cannot communicate the keepalive status within the configurable timeout period, a false failover or split-brain scenario occurs.

The heartbeat module in the data plane helps to avoid the occurrence of false failover or split-brain due to traffic congestion in the control plane.

- The additional heartbeat module works similarly to the control plane module but sends and receives heartbeat messages using the data plane transport infrastructure.
- When the peer receives heartbeat packets in the data plane, a counter gets incremented.
- If the heartbeat transfer in the control plane fails, the node checks the heartbeat counter in the data plane. If the counter is incrementing, then the peer is alive, and the cluster does not perform a failover in this situation.

Note

- The additional heartbeat module is enabled by default whenever HA is enabled. You do not have to set a poll interval for the additional heartbeat module in the data plane. This module uses the same heartbeat interval that you set for the control plane.

Interface Monitoring

When a unit does not receive hello messages on a monitored interface for 15 seconds, it runs interface tests. If one of the interface tests fails for an interface, but this same interface on the other unit continues to successfully pass traffic, then the interface is considered to be failed, and the device stops running tests.

If the threshold you define for the number of failed interfaces is met (see **Devices** > **Device Management**, and then **High Availability** > **Failover Trigger Criteria**), and the active unit has more failed interfaces than the standby unit, then a failover occurs. If an interface fails on both units, then both interfaces go into the "Unknown" state and do not count towards the failover limit defined by failover interface policy.

An interface becomes operational again if it receives any traffic. A failed device returns to standby mode if the interface failure threshold is no longer met.

If an interface has IPv4 and IPv6 addresses configured on it, the device uses the IPv4 addresses to perform the health monitoring. If an interface has only IPv6 addresses configured on it, then the device uses IPv6 neighbor discovery instead of ARP to perform the health monitoring tests. For the broadcast ping test, the device uses the IPv6 all nodes address (FE02::1).

Interface Tests

The Firewall Threat Defense device uses the following interface tests. The duration of each test is approximately 1.5 seconds.

1. Link Up/Down test—A test of the interface status. If the Link Up/Down test indicates that the interface is down, then the device considers it failed, and testing stops. If the status is Up, then the device performs the Network Activity test.
2. Network Activity test—A received network activity test. At the start of the test, each unit clears its received packet count for its interfaces. As soon as a unit receives any eligible packets during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then the device starts the ARP test.
3. ARP test—A test for successful ARP replies. Each unit sends a single ARP request for the IP address in the most recent entry in its ARP table. If the unit receives an ARP reply or other network traffic during the test, then the interface is considered operational. If the unit does not receive an ARP reply, then the

device sends a single ARP request for the IP address in the *next* entry in the ARP table. If the unit receives an ARP reply or other network traffic during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic, and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then the device starts the Broadcast Ping test.

4. Broadcast Ping test—A test for successful ping replies. Each unit sends a broadcast ping, and then counts all received packets. If the unit receives any packets during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic, and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then testing starts over again with the ARP test. If both units continue to receive no traffic from the ARP and Broadcast Ping tests, then these tests will continue running in perpetuity.

Interface Status

Monitored interfaces can have the following status:

- Unknown—Initial status. This status can also mean the status cannot be determined.
- Normal—The interface is receiving traffic.
- Normal (Waiting)—The interface is up, but has not yet received a hello packet from the corresponding interface on the peer unit.
- Normal (Not-Monitored)—The interface is up, but is not monitored by the failover process.
- Testing—Hello messages are not heard on the interface for five poll times.
- Link Down—The interface or VLAN is administratively down.
- Link Down (Waiting)—The interface or VLAN is administratively down and has not yet received a hello packet from the corresponding interface on the peer unit.
- Link Down (Not-Monitored)—The interface or VLAN is administratively down, but is not monitored by the failover process.
- No Link—The physical link for the interface is down.
- No Link (Waiting)—The physical link for the interface is down and has not yet received a hello packet from the corresponding interface on the peer unit.
- No Link (Not-Monitored)—The physical link for the interface is down, but is not monitored by the failover process.
- Failed—No traffic is received on the interface, yet traffic is heard on the peer interface.

Failover Triggers and Detection Timing

The following events trigger failover in a Firepower high availability pair:

- More than 50% of the Snort instances on the active unit are down.
- Disk space on the active unit is more than 90% full.

- The **no failover active** command is run on the active unit or the **failover active** command is run on the standby unit.
- The active unit has more failed interfaces than the standby unit.
- Interface failure on the active device exceeds the threshold configured.

  By default, failure of a single interface causes failover. You can change the default value by configuring a threshold for the number of interfaces or a percentage of monitored interfaces that must fail for the failover to occur. If the threshold breaches on the active device, failover occurs. If the threshold breaches on the standby device, the unit moves to **Fail** state.

  To change the default failover criteria, enter the following command in global configuration mode:

Table 45:

Command	Purpose
failover interface-policy num [%] `hostname (config)# failover interface-policy 20%`	Changes the default failover criteria. When specifying a specific number of interfaces, the *num* argument can be from 1 to 250. When specifying a percentage of interfaces, the *num* argument can be from 1 to 100.

The following table shows the failover triggering events and associated failure detection timing. If failover occurs, you can view the reason for the failover in the Message Center, along with various operations pertaining to the high availability pair. You can configure these thresholds to a value within the specified minimum-maximum range.

Table 46: Firewall Threat Defense Failover Times

Failover Triggering Event	Minimum	Default	Maximum
Active unit loses power, hardware goes down, or the software reloads or crashes. When any of these occur, the monitored interfaces or failover link do not receives any hello message.	800 milliseconds	15 seconds	45 seconds
Active unit interface physical link down.	500 milliseconds	5 seconds	15 seconds
Active unit interface up, but connection problem causes interface testing.	5 seconds	25 seconds	75 seconds

About Active/Standby Failover

Active/Standby failover lets you use a standby Firewall Threat Defense device to take over the functionality of a failed unit. When the active unit fails, the standby unit becomes the active unit.

Primary/Secondary Roles and Active/Standby Status

When setting up Active/Standby failover, you configure one unit to be primary and the other to be secondary. During configuration, the primary unit's policies are synchronized to the secondary unit. At this point, the two units act as a single device for device and policy configuration. However, for events, dashboards, reports and health monitoring, they continue to display as separate devices.

The main differences between the two units in a failover pair are related to which unit is active and which unit is standby, namely which IP addresses to use and which unit actively passes traffic.

However, a few differences exist between the units based on which unit is primary (as specified in the configuration) and which unit is secondary:

- The primary unit always becomes the active unit if both units start up at the same time (and are of equal operational health).
- The primary unit MAC addresses are always coupled with the active IP addresses. The exception to this rule occurs when the secondary unit becomes active and cannot obtain the primary unit MAC addresses over the failover link. In this case, the secondary unit MAC addresses are used.

Active Unit Determination at Startup

The active unit is determined by the following:

- If a unit boots and detects a peer already running as active, it becomes the standby unit.
- If a unit boots and does not detect a peer, it becomes the active unit.
- If both units boot simultaneously, then the primary unit becomes the active unit, and the secondary unit becomes the standby unit.

Failover Events

In Active/Standby failover, failover occurs on a unit basis.

The following table shows the failover action for each failure event. For each failure event, the table shows the failover policy (failover or no failover), the action taken by the active unit, the action taken by the standby unit, and any special notes about the failover condition and actions.

Table 47: Failover Events

Failure Event	Policy	Active Unit Action	Standby Unit Action	Notes
Active unit failed (power or hardware)	Failover	n/a	Become active Mark active as failed	No hello messages are received on any monitored interface or the failover link.
Formerly active unit recovers	No failover	Become standby	No action	None.
Standby unit failed (power or hardware)	No failover	Mark standby as failed	n/a	When the standby unit is marked as failed, then the active unit does not attempt to fail over, even if the interface failure threshold is surpassed.

Failure Event	Policy	Active Unit Action	Standby Unit Action	Notes
Failover link failed during operation	No failover	Mark failover link as failed	Mark failover link as failed	You should restore the failover link as soon as possible because the unit cannot fail over to the standby unit while the failover link is down.
Failover link failed at startup	No failover	Become active Mark failover link as failed	Become active Mark failover link as failed	If the failover link is down at startup, both units become active.
State link failed	No failover	No action	No action	State information becomes out of date, and sessions are terminated if a failover occurs.
Interface failure on active unit above threshold	Failover	Mark active as failed	Become active	None.
Interface failure on standby unit above threshold	No failover	No action	Mark standby as failed	When the standby unit is marked as failed, then the active unit does not attempt to fail over even if the interface failure threshold is surpassed.

Config-Sync Optimization

When a device reboots or rejoins following a suspend or resume high availability, the joining device clears its running configuration. The active device then sends its entire configuration to the joining device for a full configuration synchronization. If the active device has a large configuration, this process can take several minutes.

The configuration sync optimization functionality enables comparing the configuration of the joining device and the active device by exchanging configuration hash values. If the hash computed on both active and joining devices match, the joining device skips full configuration synchronization and rejoin the high availability configuration. This functionality ensures faster peering and reduces maintenance window and upgrade time.

Guidelines and Limitations of Config-Sync Optimization

- The configuration sync optimization functionality is enabled by default.
- Firewall Threat Defense multiple context mode supports configuration sync optimization by sharing the context order during full configuration synchronization, allowing comparison of context order during subsequent node-rejoin.
- If you configure passphrase and failover IPsec key, then configuration sync optimization is not effective as the hash value computed in the active and standby devices differs.
- If you configure the device with dynamic ACL or SNMPv3, configuration sync optimization is not effective.

- Active device synchronizes full configuration with flapping LAN links as default behavior. During failover flaps between active and standby devices, configuration sync optimization is not triggered and devices perform a full configuration synchronization.
- Configuration sync optimization gets triggered when the high availability configuration recovers from an interruption or loss of network communication between the active and standby devices.

Monitoring Config-Sync Optimization

When configuration sync optimization functionality is enabled, syslog messages are generated displaying whether the hash values computed on the active and joining unit match, does not match, or if the operation timeout expires. The syslog message also displays the time elapsed, from the time of sending the hash request to the time of getting and comparing the hash response.

Note The Configuration State in **show failover state** command displays the config sync state status during HA joining. This state does not reflect the later config deployments or changes, and replication on device until a resync has been initiated.

Guidelines for High Availability

Model Support

- Firepower 1010:
  - You should not use the switch port functionality when using High Availability. Because the switch ports operate in hardware, they continue to pass traffic on both the active *and* the standby units. High Availability is designed to prevent traffic from passing through the standby unit, but this feature does not extend to switch ports. In a normal High Availability network setup, active switch ports on both units will lead to network loops. We suggest that you use external switches for any switching capability. Note that VLAN interfaces can be monitored by failover, while switch ports cannot. Though Firewall Management Center allows you to configure switch ports / VLAN interfaces in HA, it may lead to misconfiguration due to network loops when connecting to external switches.

    - You can only use a firewall interface as the failover link.

- Firepower 9300—Intra-chassis High Availability is not supported.
- The Firewall Threat Defense Virtual on public cloud networks such as Microsoft Azure and Amazon Web Services are not supported with High Availability because Layer 2 connectivity is required.

Additional Guidelines

- When the active unit fails over to the standby unit, the connected switch port running Spanning Tree Protocol (STP) can go into a blocking state for 30 to 50 seconds when it senses the topology change. To avoid traffic loss while the port is in a blocking state, you can enable the STP PortFast feature on the switch:

  interface *interface_id* **spanning-tree portfast**

  This workaround applies to switches connected to both routed mode and bridge group interfaces. The PortFast feature immediately transitions the port into STP forwarding mode upon linkup. The port still participates in STP. So if the port is to be a part of the loop, the port eventually transitions into STP blocking mode.
- Configuring port security on the switches connected to the Firewall Threat Defense device failover pair can cause communication problems when a failover event occurs. This problem occurs when a secure MAC address configured or learned on one secure port moves to another secure port, a violation is flagged by the switch port security feature.
- For Active/Standby High Availability and a VPN IPsec tunnel, you cannot monitor both the active and standby units using SNMP over the VPN tunnel. The standby unit does not have an active VPN tunnel, and will drop traffic destined for the NMS. You can instead use SNMPv3 with encryption so the IPsec tunnel is not required.
- Both the peer devices go into unknown state and high-availability configuration fails if you run clish in any of the peer devices while creating a High Availability pair.
- Immediately after failover, the source address of syslog messages will be the failover interface address for a few seconds.
- For better convergence (during a failover), you must shut down the interfaces on a HA pair that are not associated with any configuration or instance.
- If you configure failover encryption in evaluation mode, the systems use DES for the encryption. If you then register the devices using an export-compliant account, the devices will use AES after a reboot. Thus, if a system reboots for any reason, including after installing an upgrade, the peers will be unable to communicate and both units will become the active unit. We recommend that you do not configure encryption until after you register the devices. If you do configure this in evaluation mode, we recommend you remove the encryption before registering the devices.
- When using SNMPv3 with failover, if you replace a failover unit, then SNMPv3 users are not replicated to the new unit. You must remove the users, re-add them, and then redeploy your configuration to force the users to replicate to the new unit.
- The device does not share SNMP client engine data with its peer.
- If you have a very large number of access control and NAT rules, the size of the configuration can prevent efficient configuration replication, resulting in the standby unit taking an excessively long time to reach standby ready state. This can also impact your ability to connect to the standby unit during replication

through the console or SSH session. To enhance configuration replication performance, enable transactional commit for both access rules and NAT, using the **asp rule-engine transactional-commit access-group** and **asp rule-engine transactional-commit nat** commands.

- A unit in a High Availability pair transitioning to the standby role synchronizes its clock with the active unit.

  Example:

```
firepower#show clock
01:00:52 UTC Mar 1 2022

...
01:01:18 UTC Mar 1 2022 <======= Incorrect (previous) clock
Cold Standby               Sync Config               Detected an Active mate

19:38:21 UTC Apr 9 2022 <======= Updated clock
Sync Config                Sync File System          Detected an Active mate
...
firepower/sec/stby#show clock
19:38:40 UTC Apr 9 2022
```

- The units in High Availability do not dynamically synchronize the clock. Here are some examples of events when synchronization takes place:
  - A new High Availability pair is created.
  - High Availability is broken and re-created.
  - Communication over the failover link was disrupted and reestablished.
  - Failover status was manually changed at the CLI using the **no failover/failover** or **configure high-availability suspend/resume** (Firewall Threat Defense) commands.
- Enabling High Availability forces all routes to be deleted and are re-added after the High Availability progression changes to the Active state. You could experience connection loss during this phase.
- If you replace the primary unit, then when you re-create high-availability, you should set the replacement unit as the *secondary* unit so that the configurations are replicated from the former secondary unit to the replacement unit. If you set the replacement unit as primary, you will accidentally overwrite the configuration that is present on the operational unit.
- Deploying Firepower 1100 and 2100 devices in high availability with hundreds of interfaces configured on them can result in increased delay in the failover time (seconds).
- In the High Availability configuration, short-lived connections, usually using port 53, are closed quickly and never transferred or synchronized from Active to Standby, so there might be a difference in the number of connections on both High Availability devices. This is expected behavior for short-lived connections. You can try to compare the connections that are long-lived (for example, more than 30-60 seconds).
- In the High Availability configuration, embryonic connections—connection requests that have not yet completed the three-way handshake process—are closed quickly and not synchronized between the active and standby devices. This design ensures HA system efficiency and security. For this reason, there might be a difference in the number of connections on both High Availability devices, which is to be expected.
- If the failover LAN link is not connected back-to-back and instead connected through one or more switches, a failure within the intermediate path can cause the active unit to lose connectivity with the standby unit, resulting in inconsistent active/standby states. Although this does not impact High Availability

functionality, it is recommended to check and recover the failover-link path between the active and standby units.

When the failover LAN link is down, it is not recommended to deploy any configuration, as it may not be replicated to the peer unit.

- See the Cisco Secure Firewall Threat Defense Virtual Getting Started Guide and review your Firewall Threat Defense Virtual device configurations for high availability.
- In OSPF, after the failover event, the firewall creates an invalid OSPF connection with the peer device. You must terminate the invalid connection. Then, establish a new OSPF connection to restore OSPF functionality.
- In transparent mode, if you have problems with the active unit losing the MAC address of the hot-standby router (HSRP), create a static mapping for the MAC address.
- UCAPL or CC compliance mode cannot be changed if the threat defense device is in high availability. Modify the compliance mode before forming the high availability pair.

Add a High Availability Pair

When establishing an Active/Standby high-availability pair, you designate one of the devices as primary and the other as secondary. The Firewall Management Center deploys a merged configuration to the paired devices. If there is a conflict, the primary device setting is used.

Note The failover link and the stateful failover link are in a private IP space and are only used for communication between peers in a high-availability pair. After high availability is established, selected interface links and encryption settings cannot be modified without breaking the high-availability pair and reconfiguring it.

Caution Creating or breaking a high-availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 172 for more information. The system warns you that continuing to create a high-availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Before you begin

Confirm that both devices:

- Are the same model.
- Have the same number and type of interfaces.
- Are in the same domain and group.
- Have normal health status and are running the same software.
- Are either in routed or transparent mode.

Note Only routed mode is supported for manager access on a data interface.

- Have the same NTP configuration. See Time Synchronization, on page 1089.
- Are fully deployed with no uncommitted changes.
- Do not have DHCP or PPPoE configured on any interfaces.
- For manager access on a data interface:
  - Use the same data interface on both devices for manager access.
  - Redundant manager access data interface is not supported.
  - You cannot use DHCP; only a static IP address is supported. Features that rely on DHCP cannot be used, including DDNS and zero-touch provisioning.

Note If you use zero-touch provisioning to register the device, when you use the outside interface for manager access, it uses DHCP by default. Before you can enable high availability, you need to change the IP address to a static address. See Change the Device IP Address, on page 94. Alternatively, you can use the Management interface instead; DHCP is supported on Management with high availability.

- Have different static IP addresses in the same subnet.
- Use the same manager configuration (**configure manager add** command) to ensure that the connectivity is the same.
- You cannot use the data interface as the failover or state link.

Note The high availability formation is possible between the two Firewall Threat Defense devices when the certificate available on the primary device is not present on the secondary device. When high availability is formed, the certificate will be synched on the secondary device.

Procedure

Step 1 In the Security Cloud Control navigation bar, click **Security Devices**.

Step 2 Click the **Devices** tab to locate your device.

Step 3 Click the **FTD** tab and select the device you want to establish as the primary device.

Step 4 In the **Management** pane, click **High Availability**.

Step 5 Enter a display **Name** for the high-availability pair.

Step 6 Under **Device Type**, choose **Firepower Threat Defense**.

Step 7 Choose the **Primary Peer** device for the high-availability pair.

Step 8 Choose the **Secondary Peer** device for the high-availability pair.

Note
In the remote deployment, the devices appearing in the **Secondary Peer** list depend on the active device selected in the **Primary Peer** list:

- If the selected primary peer uses a data interface for management, only the data interface managed devices are listed in the secondary peer list.
- If the data management interface on the primary peer has an IPv4 address configured on it, then the secondary peer lists only the data interface managed devices that have an IPv4 address configured on them. The same rule applies to IPv6-managed devices as well.
- The data management interface names of primary and secondary devices should be the same. Devices with different interface names will not be listed in the secondary peer list.

Step 9 Click **Continue**.

Step 10 Under **LAN Failover Link**, choose an **Interface** with enough bandwidth to reserve for failover communications.

Note
Only interfaces that do not have a logical name, do not belong to a security zone, and are not used for handling management traffic, will be listed in the **Interface** drop-down in the **Add High Availability Pair** dialog.

Step 11 Type any identifying **Logical Name**.

Step 12 Type a **Primary IP** address for the failover link on the active unit.

This address should be on an unused subnet.

Note
169.254.1.0/24 and fd00:0:0:*::/64 are internally used subnets and cannot be used for the failover or state links.

Step 13 Optionally, choose **Use IPv6 Address**.

Step 14 Type a **Secondary IP** address for the failover link on the standby unit. This IP address must be in the same subnet as the primary IP address.

Step 15 If IPv4 addresses are used, type a **Subnet Mask** that applies to both the primary and secondary IP addresses.

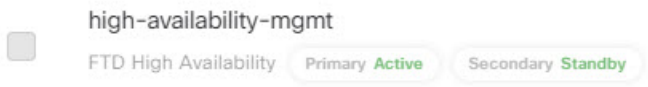
Step 16 Optionally, under **Stateful Failover Link**, choose the same **Interface**, or choose a different interface and enter the high availability configuration information.

Note
169.254.1.0/24 and fd00:0:0:*::/64 are internally used subnets and cannot be used for the failover or state links.

Step 17 Optionally, choose **Enabled** and choose the **Key Generation** method for IPsec Encryption between the failover links.

Step 18 Click **OK**. This process takes a few minutes as the process synchronizes system data.

After a successful configuration, you can see the **FTD High Availability** label on the Firewall Threat Defense node on the Security Cloud Control **Security Devices** page. Select the node to see the active and standby devices you configured for high availability



.

What to do next

Back up the devices. You can use the backup to quickly replace the devices when they fail and to restore the high availability service without being delinked from the Firewall Management Center.

Configure Optional High Availability Parameters

You can view the initial High Availability Configuration on the Firewall Management Center. You cannot edit these settings without breaking the high availability pair and then re-establishing it.

You can edit the Failover Trigger Criteria to improve failover results. Interface Monitoring allows you to determine which interfaces are better suited for failover.

Configure Standby IP Addresses and Interface Monitoring

For each interface, set a standby IP address. Although recommended, the standby address is not required. Without a standby IP address, the active unit cannot perform network tests to check the standby interface health; it can only track the link state.

By default, monitoring is enabled on all physical interfaces, for the Firepower 1010 all VLAN interfaces, with logical names configured. You might want to exclude interfaces attached to less critical networks from affecting your failover policy. Firepower 1010 switch ports are not eligible for interface monitoring.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click the **Edit** ( ).

Step 3 Click the **High Availability** tab.

Step 4 In the **Monitored Interfaces** area, click the **Edit** ( ) next to the interface you want to edit.

Step 5 Check the **Monitor this interface for failures** check box.

Step 6 On the **IPv4** tab, enter the **Standby IP Address**.

This address must be a free address on the same network as the active IP address.

Step 7 If you configured the IPv6 address manually, on the **IPv6** tab, click the **Edit** ( ) next to the active IP address, enter the **Standby IP Address**, and click **OK**.

This address must be a free address on the same network as the active IP address. For autogenerated and **Enforce EUI 64** addresses, the standby address is automatically generated.

Step 8 Click **OK**.

Edit High Availability Failover Criteria

You can customize failover criteria based on your network deployment.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click the **Edit** ( ).

Step 3 Choose **High Availability**.

Step 4 Next to **Failover Trigger Criteria**, click the **Edit** ( ).

Step 5 Under **Interface Failure Threshold**, choose the number or percentage of interfaces that must fail before the device fails over.

Step 6 Under **Hello packet Intervals**, choose how often hello packets are sent over the failover link.

Note
If you use remote access VPN on the Firepower 2100, use the default hello packet intervals. Otherwise, you might see high CPU usage that can cause a failover to occur.

Step 7 Click **OK**.

Configure Virtual MAC Addresses

You can configure active and standby MAC addresses for failover using the following methods in the Secure Firewall Management Center:

- From the **Advanced tab** on the **Edit Interface** page during interface configuration; see Configure the MAC Address, on page 974.
- From the **Add Interface MAC Address** dialog-box which is accessed from the **High Availability** page; see this procedure.

Note To configure the MAC address in both primary and secondary units (so that the MAC address is transferred to all sub-interfaces to both the high-availability units), the recommended approach is to use the **Interfaces** tab to replicate the MAC addresses on sub-interfaces over both active and standby high-availability units.

If you configure active and standby MAC addresses in both locations, the addresses defined during interface configuration take precedence for failover.

You can minimize loss of traffic during failover by designating active and standby MAC addresses to the physical interface. This feature offers redundancy against IP address mapping for failover.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click **Edit** ( ).

Step 3 Click **High Availability**.

Step 4 Click the **Add** ( ) icon next to Interface MAC Addresses.

Step 5 Choose a **Physical Interface**.

Step 6 Enter the **Active Interface Mac Address**.

Step 7 Enter the **Standby Interface Mac Address**.

Step 8 Click **OK**.

Note
For detailed information, see Task 2, steps from 10 to 14 in Configure FTD High Availability on Firepower Appliances.

.

Manage High Availability

This section describes how to manage High Availability units after you enable High Availability, including how to change the High Availability setup and how to force failover from one unit to another.

Switch the Active Peer in the Firewall Threat Defense High Availability Pair

After you establish the Firewall Threat Defense high availability pair, you can manually switch the active and standby units, effectively forcing failover for reasons such as persistent fault or health events on the current active unit. Both units should be fully deployed before you complete this procedure.

Before you begin

Refresh Node Status for a Single Firewall Threat Defense High Availability Pair, on page 590. This ensures that the status on the Firewall Threat Defense high availability device pair is in sync with the status on the Firewall Management Center.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the high availability pair where you want to change the active peer, click the **Switch Active Peer**.

Step 3 You can:

- Click **Yes** to immediately make the standby device the active device in the high availability pair.
- Click **No** to cancel and return to the Device Management page.

Refresh Node Status for a Single Firewall Threat Defense High Availability Pair

Whenever active or standby devices in the Firewall Threat Defense high availability pair are rebooted, the Firewall Management Center may not display accurate high availability status for either device. This is because when the device reboots, the high availability status is immediately updated on the device and its corresponding event is sent to the Firewall Management Center. However, the status may not be updated on the Firewall Management Center because the communication between the device and the Firewall Management Center is yet to be established.

Communication failures or weak communication channels between the Firewall Management Center and devices may result in out of sync data. When you switch the active and standby devices in a high availability pair, the change may not be reflected in the Firewall Management Center even after a significant time duration.

In these scenarios, you can refresh the high availability node status to obtain accurate information about the active and standby device in a high availability pair.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the high availability pair where you want to refresh the node status, click the **Refresh HA Node Status**.

Step 3 Click **Yes** to refresh the node status.

Suspend and Resume High Availability

You can suspend a unit in a high-availability pair, which is useful when:

- Both units are in an active-active situation, and fixing the communication on the failover link does not correct the problem.
- You want to troubleshoot an active or standby unit and do not want the units to fail over during that time.

When you suspend high availability, the currently active device remains active, handling all user connections. However, failover criteria are no longer monitored, and the system will never fail over to the now pseudo-standby device.

When using a data interface for manager access, the management connection will be broken until after you resume.

The key difference between suspending high availability and breaking high availability is that on a suspended high-availability device, the high-availability configuration is retained. When you break high availability, the

configuration is erased. Thus, you have the option to resume high availability on a suspended system, which enables the existing configuration and makes the two devices function as a failover pair again.

To suspend high availability, use the **configure high-availability suspend** command.

```
> configure high-availability suspend
Please ensure that no deployment operation is in progress before suspending
high-availability.
Please enter 'YES' to continue if there is no deployment operation in
progress and 'NO' if you wish to abort: YES
Successfully suspended high-availability.
```

If you suspend high availability from the active unit, the configuration is suspended on both the active and standby units. The standby unit interface configuration is also erased. If you suspend it from the standby unit, it is suspended on the standby unit only, but the active unit will not attempt to fail over to a suspended unit.

To resume failover, use the **configure high-availability resume** command.

```
> configure high-availability resume
Successfully resumed high-availablity.
```

You can resume a unit only if it is in Suspended state. The unit will negotiate active/standby status with the peer unit.

Note Suspending high availability is a temporary state. If you reload a unit, it resumes the high-availability configuration automatically and negotiates the active/standby state with the peer.

Replace a Unit in Firewall Threat Defense High Availability Pair

To replace a failed unit in the Firewall Threat Defense high availability pair using a backup file, see *Restoring Firewall Management Centers and Managed Devices* in the Cisco Secure Firewall Management Center Administration Guide.

If you do not have a backup of the failed device, you must break high availability. Then, register the replacement device to the Secure Firewall Management Center and reestablish high availability. The process varies depending on whether the device is primary or secondary:

- Replace a Primary Firewall Threat Defense HA Unit with no Backup, on page 591
- Replace a Secondary Firewall Threat Defense HA Unit with no Backup, on page 592

Replace a Primary Firewall Threat Defense HA Unit with no Backup

Follow the steps below to replace a failed primary unit in the Firewall Threat Defense high availability pair. Failing to follow these steps can overwrite the existing high availability configuration.

Caution Creating or breaking the Firewall Threat Defense high availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 172 for more information. The system warns you that continuing to create a high availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Caution Never move a disk from sensor or Firewall Management Center to another device without reimaging the disk. This is an unsupported configuration and can cause breakage in functionality.

Procedure

Step 1 Choose **Force Break** to separate the high availability pair; see Break a High Availability Pair, on page 593.

Note
The break operation removes all the configuration related to HA from Firewall Threat Defense and Firewall Management Center, and you need to recreate it manually later. To successfully configure the same HA pair, ensure that you save the IPs, MAC addresses, and monitoring configuration of all the interfaces/subinterfaces prior to executing the HA break operation.

Step 2 Unregister the failed primary Firewall Threat Defense device from the Firewall Management Center.

Step 3 Register the replacement Firewall Threat Defense to the Firewall Management CenterPrerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center, on page 8.

Step 4 Configure high availability, using the existing secondary/active unit as the primary device and the replacement device as the secondary/standby device during registration; see Add a High Availability Pair, on page 584.

Replace a Secondary Firewall Threat Defense HA Unit with no Backup

Follow the steps below to replace a failed secondary unit in the Firewall Threat Defense high availability pair.

Caution Creating or breaking the Firewall Threat Defense high availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 172 for more information. The system warns you that continuing to create a high availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Procedure

Step 1 Choose **Force Break** to separate the high availability pair; see Break a High Availability Pair, on page 593.

Note
The break operation removes all the configuration related to HA from Firewall Threat Defense and Firewall Management Center, and you need to recreate it manually later. To successfully configure the same HA pair, ensure that you save the IPs, MAC addresses, and monitoring configuration of all the interfaces/subinterfaces prior to executing the HA break operation.

Step 2 Unregister the secondary Firewall Threat Defense device from the Firewall Management Center.

Step 3 Register the replacement Firewall Threat Defense to the Firewall Management CenterPrerequisites to Onboard a Device to Cloud-Delivered Firewall Management Center, on page 8.

Step 4 Configure high availability, using the existing primary/active unit as the primary device and the replacement device as the secondary/standby device during registration; see Add a High Availability Pair, on page 584.

Break a High Availability Pair

When you break a high-availability pair, the high-availability configuration is removed from both units.

When using the Management interface for manager access: The active unit remains up and passing traffic. The standby unit interface configuration is erased.

When using a data interface for manager access: See the following details.

- The active unit remains up and passing traffic.
- The standby unit data interfaces are shut down except for the manager access interface, which remains up using the standby IP address so it can maintain the management connection.
- In a remote branch deployment setup, all standby unit data interfaces that are assigned with a logical name are shut down except for the manager access interface, which remains up to maintain the management connection.
- If the primary unit is in the standby state:
  - The IP addresses for manager access are swapped permanently in the Firewall Management Center configuration: the primary unit uses the standby IP address, and the secondary unit uses the active IP address.

Policies that were not deployed to the active unit prior to the break operation continue to remain un-deployed after the break operation is complete. Deploy the policies on the standalone device after the break operation is complete.

Note

- When IPsec is enabled on high availability interfaces on the Firewall Threat Defense device, the device cannot prioritize the encrypted packets into the high-priority receive queue. As a result, during high-volume data traffic scenarios, attempts to break high availability may fail as the device cannot efficiently manage and prioritize the large number of encrypted connections. To view the device's resource usage and the maximum throughput, use the `show resource usage` command.
- If you cannot reach the high-availability pair using the Firewall Management Center, connect to the CLI on each device and enter **configure high-availability disable** to manually break high availability. See also Remove a High Availability Pair , on page 595.

Caution Breaking the Firewall Threat Defense high-availability pair immediately restarts the Snort process on the primary and secondary units, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the assigned device handles traffic. See Snort Restart Traffic Behavior, on page 172 for more information.

Before you begin

- Refresh Node Status for a Single Firewall Threat Defense High Availability Pair, on page 590. This ensures that the status on the high-availability pair is in sync with the status on the Firewall Management Center.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the high-availability pair you want to break, click **More** (⋮) and choose **Break**.

Step 3 If the standby peer does not respond, check **Force Break**.

Step 4 Click **Yes**.

The Break operation removes the high-availability configuration from the active and standby units.

A FlexConfig policy deployed on the active unit may show a deployment failure after the break high-availability operation. You must alter and re-deploy the FlexConfig policy on the active unit.

What to do next

If you are using a FlexConfig policy on the active unit, alter and re-deploy the FlexConfig policy to eliminate deployment errors.

Note After you break high availability, the Firewall Threat Defense device that was operating as the active unit will still have the standby unit's IP address listed in its configuration. To resolve this, do an additional deployment on the formerly active Firewall Threat Defense device to remove the standby unit's IP address from its configuration.

Remove a High Availability Pair

You can unregister the pair from the Firewall Management Center, which keeps the High Availability pair intact. You might want to unregister the pair if you want to register it to a new Firewall Management Center or if the Firewall Management Center can no longer reach the pair.

Unregistering a High Availability pair:

- Severs all communication between the Firewall Management Center and the pair.
- Removes the pair from the **Device Management** page.
- Returns the pair to local time management if the pair's platform settings policy is configured to receive time from the Firewall Management Center using NTP.
- Leaves the configuration intact, so the pair continues to process traffic.

  Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the pair again to the same or a different Firewall Management Center causes the configuration to be removed, so the pair will stop processing traffic at that point; the High Availability configuration remains intact so you can add the pair as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.

Before you begin

- This procedure requires CLI access to the primary unit.

Procedure

Step 1 Log into Security Cloud Control and click **Security Devices**.

Step 2 Click the **FTD** tab and locate the High Availability pair you want to unregister. Select it so the device row is highlighted.

Step 3 In the **Device Actions** pane located to the right, click **Remove**.

Step 4 When prompted, select **OK** to confirm the removal of the selected device.

Monitoring High Availability

This section lets you monitor the High Availability status.

View Failover History

You can view the failover history of both high availability devices in a single view. The history displays in chronological order and includes the reason for any failover.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click **Edit** ( ).

Step 3 Choose **Summary**.

Step 4 Under General, click **View** ( ).

View Stateful Failover Statistics

You can view the stateful failover link statistics of both the primary and secondary devices in the high availability pair.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Next to the device high-availability pair you want to edit, click **Edit** ( ).

Step 3 Choose **High Availability**.

Step 4 Under Stateful Failover Link, click **View** ( ).

Step 5 Choose a device to view statistics.

Troubleshooting High Availability Break in a Remote Branch Deployment

This section describes how to solve some of the common problems you may encounter when breaking a High Availability pair in a remote deployment.

- Both Units are in Active-Active State.
- The primary or secondary device has lost connectivity with Security Cloud Control, and the failover link has become non-operational.
- The secondary device is in failed or disabled state and has lost connectivity with Security Cloud Control.

How to Break a High Availability Pair in Active-Active State

Both units in a remote deployment are in an active-active state because the failover interface became non-operational and they stopped receiving a response on their data interfaces. In this case, both units use the active IP address on their data management interface, which results in an unstable network between the units and Security Cloud Control.

You can determine if the units are both in active mode by logging into the device CLI and using the “show failover state” command on both units. The device status of both units shows ‘active’, and the same active IP address is assigned to both units.

Note You can try rectifying the failover interface to restore the communication between the two peers and then perform the **Force Break** operation.

If you cannot repair the connectivity issues of the failover interface, then perform the following steps:

Procedure

Step 1 Identify a device you want to remove from the network among the two units.

Step 2 Connect to the CLI of the identified device, either from the console port or using SSH.

Step 3 Log in with the Admin username and password.

Step 4 Enter the **pmtool disablebyid sftunnel** command.

Note
Only use **pmtool** commands under the direction of the Cisco Technical Assistance Center.

Step 5 Disconnect all the interfaces from the device you want to remove from the network.

Step 6 Enter **configure network management-data-interface ipv4 manual** *ip_address ipv4_netmask gateway_ip_address* **interface***interface_id* command.

In *ip_address*specify the IP address of the standby device.

Example:

```
Configure network management-data-interface ipv4 manual 10.10.6.7 255.255.255.0 interface
gig0/0
Configuration updated successfully..!!
```

Step 7 Enter **configure high-availability suspend** to suspend HA.

```
configure high-availability suspend
Please ensure that no deployment operation is in progress before suspending
high-availability.
Please enter 'YES' to continue if there is no deployment operation in
progress and 'NO' if you wish to abort: YES
Successfully suspended high-availability.
```

Step 8 In the Security Cloud Control navigation bar, click **Security Devices**.

Step 9 Click the **Devices** tab to locate your device.

Step 10 Click the **FTD** tab and select the primary device.

Step 11 In the **Management** pane on the left, click **High Availability**.

Step 12 Choose **Device** > **Device Management**.

Step 13 Next to the high availability pair where you want to separate the high availability pair, click **Force Break**.

A message is displayed that the high-availability pair is separated successfully.

Step 14 Connect all the interfaces to the device.

Step 15 At the FTD CLI, enter **pmtool enablebyId sftunnel**.

The threat defense device establishes its connection with Security Cloud Control in sometime.

Note
It may take up to 5 minutes for the device to establish communication with Security Cloud Control.

Step 16 Enter the **sftunnel-status-brief** command to view the management connection status.

```
sftunnel-status-brief
PEER:10.10.17.202
Registration: Completed.
Connection to peer '10.10.17.202' Attempted at Wed Feb 9 09:21:57 2020 UTC
Last disconnect time : Wed Feb 9 09:19:09 2020 UTC
```

Step 17 Choose **Deploy** > **Deployment** to deploy the changes.

Before the Security Cloud Control deploys the changes, it will detect the configuration differences and stop the deployment. Security Cloud Control detects the IP address change made to the device outside of the Security Cloud Control.

Step 18 Synchronize interface changes with Security Cloud Control. See Sync Interface Changes with the Firewall Management Center, on page 883.

Step 19 You can now deploy the pending changes to the device. See Deploy configuration changes..

The device now becomes a standalone device with a new the IP address of the standby device.

What to do next

(optional) Deploy any pending changes to the other device having the IP address of the active device.

How to Break a High Availability Pair when Active or Standby Unit has Lost Connectivity

Problem: One of the peers has lost connectivity with Firewall Management Center, and the failover link has become non-operational.

Table 48: Scenario:

Primary Device State	Secondary Device Stat	Primary Device Connectivity with Security Cloud Control?	Secondary Device Connectivity with Security Cloud Control?	Failover link Operational? (Connectivity between Primary and Secondary devices)
Active	Standby	Yes	No	No
Standby	Active	No	Yes	No

Solution:

First, you can try rectifying the failover interface to restore the communication between the two peers and then perform the break or force break operation to separate the units.

If you cannot repair the connectivity issues of the failover interface, then you must complete additional steps using the device CLI after performing a high availability break operation.

Procedure

Step 1 In the Security Cloud Control navigation bar, click **Security Devices**.

Step 2 Click the **Devices** tab to locate your device.

Step 3 Click the **FTD** tab and select the primary device.

Step 4 In the **Management** pane on the left, click **High Availability**.

Step 5 Choose **Devices** > **Device Management**.

Step 6 Next to the high-availability pair you want to break, click the **Break HA** .

Step 7 Optionally, you can also check the check box to force break as one of the peers does not respond.

Step 8 Click **Yes**.

Step 9 Delete the standby device from Security Cloud Control.

a) Choose **Devices** > **Device Management**.
b) Next to the device you want to delete, click **Delete**.

Step 10 Connect to the standby device's CLI, either from the console port or using SSH.

Step 11 Log in with the Admin username and password.

Step 12 Enter **configure manager delete** to delete the manager.

This command disables the current manager Security Cloud Control.

Step 13 Enter **configure high-availability disable** to remove the failover configuration and disable the data management interface on the device.

Step 14 Enter **configure network management-data-interface**.

Example:

```
configure network management-data-interface
Data interface to use for management: ethernet1/1
Specify a name for the interface [outside]: internet
```

```
IP address (manual / dhcp) [dhcp]: manual
IPv4/IPv6 address: 10.10.6.7
Netmask/IPv6 Prefix: 255.255.255.0
Default Gateway: 10.10.6.1
Comma-separated list of DNS servers [none]: 208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]:

Configuration done with option to allow FMC access from any network, if you wish to change
 the FMC access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.
```

The new newtwork settings are assigned to the data device.

What to do next

You can onboard the device as a standalone device to Security Cloud Control if required.

How to a Break High Availability Pair when the Secondary Device is in a Failed or Disabled State

Problem: The secondary device is in a failed or disabled state and has lost connectivity with Security Cloud Control. In addition, the failover link may or may not be operational.

Table 49: Scenario:

Primary Device State	Secondary Device Stat	Primary Device Connectivity with Security Cloud Control?	Secondary Device Connectivity with Security Cloud Control?	Failover link Operational? (Connectivity between Primary and Secondary devices)
Active	Failed	Yes	No	Yes or No
Active	Disabled	Yes	No	Yes or No

Solution:

Perform a high availability force break to separate the units and then use the device CLI to remove the configuration from the standby unit and make the device a standalone device.

Procedure

Step 1 In the Security Cloud Control navigation bar, click **Security Devices**.

Step 2 Click the **Devices** tab to locate your device.

Step 3 Click the **FTD** tab and select the primary device.

Step 4 In the **Management** pane on the left, click **High Availability**.

Step 5 Choose **Devices** > **Device Management**.

Step 6 Next to the high-availability pair you want to break, click the **Break HA** .

Step 7 Check the check box to force break as one of the peers does not respond.

Step 8 Click **Yes**.

Step 9 Delete the standby device from Security Cloud Control.

a) Choose **Devices** > **Device Management**.

b) Next to the device you want to delete, click **Delete**.

Step 10 Connect to the standby device's CLI, either from the console port or using SSH.

Step 11 Log in with the Admin username and password.

Step 12 Enter **configure high-availability disable** to remove the failover configuration and disable the data management interface on the device.

Step 13 Enter **configure network management-data-interface**.

Example:

```
configure network management-data-interface
Data interface to use for management: ethernet1/1
Specify a name for the interface [outside]: internet
IP address (manual / dhcp) [dhcp]: manual
IPv4/IPv6 address: 10.10.6.7
Netmask/IPv6 Prefix: 255.255.255.0
Default Gateway: 10.10.6.1
Comma-separated list of DNS servers [none]: 208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]:

Configuration done with option to allow FMC access from any network, if you wish to change
 the FMC access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.
```

The new newtwork settings are assigned to the data device.

What to do next

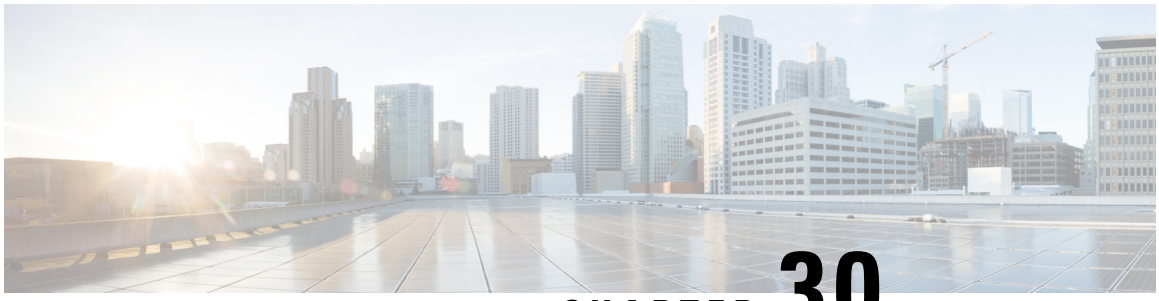
You can onboard the device as a standalone device to Security Cloud Control if required.

History for High Availability

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
High availability support for the manager access data interface	7.4	7.4	You can now use a data interface for manager access with Firewall Threat Defense high availability.
Unregistering a high-availability pair now allows you to re-register without breaking the pair	7.3	Any	When you delete (unregister) a high-availability pair, you no longer have to manually break the pair at the CLI and re-register standalone devices. You can now add the primary unit to a new Firewall Management Center, and the standby unit will be discovered automatically. Re-registering the pair will still erase the configuration, and your policies will need to be re-applied.
Policy rollback support for high availability	7.2	Any	The **configure policy rollback** command is supported for high availability.
Config-Sync Optimization feature for faster HA peering	7.2	Any	The Config-Sync Optimization feature enables comparing the configuration of the joining unit and the active unit by exchanging config-hash values. If the hash computed on both active and joining units match, the joining unit skips full config-sync and rejoin the HA. This feature enables faster HA peering and reduces maintenance window and upgrade time.
Improvements to the upgrade workflow for clustered and high-availability devices	7.1	Any	We made the following improvements to the upgrade workflow for clustered and high-availability devices: • The upgrade wizard now correctly displays clustered and high-availability units as groups, rather than as individual devices. The system can identify, report, and preemptively require fixes for group-related issues you might have. For example, you cannot upgrade a cluster on the Firepower 4100/9300 if you have made unsynced changes on Firepower Chassis Manager. • We improved the speed and efficiency of copying upgrade packages to clusters and high-availability pairs. Previously, the FMC copied the package to each group member sequentially. Now, group members can get the package from each other as part of their normal sync process. • You can now specify the upgrade order of data units in a cluster. The control unit always upgrades last.
Clearing routes in a high-availability group or cluster.	7.1	Any	In previous releases, the **clear route** command cleared the routing table on the unit only. Now, when operating in a high-availability group or cluster, the command is available on the active or control unit only, and clears the routing table on all units in the group or cluster.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details

FTD High Availability Hardening	6.2.3	Any	Version 6.2.3 introduces the following features for FTD devices in high availability:
			• Whenever active or standby FTD devices in a high-availability pair restart, the FMC may not display accurate high-availability status for either managed device. However, the status may not upgrade on the FMC because the communication between the device and the FMC is not established yet. The **Refresh Node Status** option on the **Devices** > **Device Management** page allows you to refresh the high-availability unit status to obtain accurate information about the active and standby device in a high-availability pair.
			• The **Devices** > **Device Management** page of the FMC UI has a new **Switch Active Peer** icon.
			• Version 6.2.3 includes a new REST API object, **Device High Availability Pair Services**, that contains four functions:
			  • **DELETE ftddevicehapairs**
			  • **PUT ftddevicehapairs**
			  • **POST ftddevicehapairs**
			  • **GET ftddevicehapairs**



CHAPTER 30

Clustering for the Secure Firewall 3100

Clustering lets you group multiple Firewall Threat Defense units together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices.

Note Some features are not supported when using clustering. See Unsupported Features with Clustering, on page 647.

About Clustering for the Secure Firewall 3100

This section describes the clustering architecture and how it works.

How the Cluster Fits into Your Network

The cluster consists of multiple firewalls acting as a single unit. To act as a cluster, the firewalls need the following infrastructure:

- Isolated, high-speed backplane network for intra-cluster communication, known as the *cluster control link*.
- Management access to each firewall for configuration and monitoring.

When you place the cluster in your network, the upstream and downstream routers need to be able to load-balance the data coming to and from the cluster using Spanned EtherChannels. Interfaces on multiple members of the cluster are grouped into a single EtherChannel; the EtherChannel performs load balancing between units.

Control and Data Node Roles

One member of the cluster is the control node. If multiple cluster nodes come online at the same time, the control node is determined by the priority setting; the priority is set between 1 and 100, where 1 is the highest priority. All other members are data nodes. When you first create the cluster, you specify which node you want to be the control node, and it will become the control node simply because it is the first node added to the cluster.

All nodes in the cluster share the same configuration. The node that you initially specify as the control node will overwrite the configuration on the data nodes when they join the cluster, so you only need to perform initial configuration on the control node before you form the cluster.

Some features do not scale in a cluster, and the control node handles all traffic for those features.

Cluster Interfaces

You can configure data interfaces as either Spanned EtherChannels. See About Cluster Interfaces, on page 612 for more information.

You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces).

Note Individual interfaces are not supported, with the exception of a management interface.

Cluster Control Link

Each unit must dedicate at least one hardware interface as the cluster control link. See Cluster Control Link, on page 612 for more information.

Configuration Replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Management Network

You must manage each node using the Management interface; management from a data interface is not supported with clustering.

Licenses for Clustering

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add the control node to the Firewall Management Center, you can specify the feature licenses you want to use for the cluster. Before you create the cluster, it doesn't matter which licenses are assigned to the data nodes; the license settings for the control node are replicated to each of the data nodes. You can modify licenses for the cluster by clicking **Edit Licenses** in **System** (⚙) > **Licenses** > **Smart Licenses** or choosing **Devices** > **Device Management**, clicking **Edit** (✎) for the cluster, and then in the **License** area, clicking **Edit** (✎).

Note If you add the cluster before the Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Requirements and Prerequisites for Clustering

Model Requirements

- Secure Firewall 3100—Maximum 8 nodes

User Roles

- Admin
- Access Admin
- Network Admin

Hardware and Software Requirements

All units in a cluster:

- Must be the same model.
- Must include the same interfaces.
- The Firewall Management Center access must be from the Management interface; data interface management is not supported.
- Must run the identical software except at the time of an image upgrade. Hitless upgrade is supported.
- Must be in the same firewall mode, routed or transparent.
- Must be in the same domain.

- Must be in the same group.
- Must not have any deployment pending or in progress.
- The control node must not have any unsupported features configured (see Unsupported Features with Clustering, on page 647).
- Data nodes must not have any VPN configured. The control node can have site-to-site VPN configured.

Switch Requirements

- Be sure to complete the switch configuration before you configure clustering. Make sure the ports connected to the cluster control link have the correct (higher) MTU configured. By default, the cluster control link MTU is set to 100 bytes higher than the data interfaces. If the switches have an MTU mismatch, the cluster formation will fail.

Guidelines for Clustering

Firewall Mode

The firewall mode must match on all units.

High Availability

High Availability is not supported with clustering.

IPv6

The cluster control link is only supported using IPv4.

Switches

- Make sure connected switches match the MTU for both cluster data interfaces and the cluster control link interface. You should configure the cluster control link interface MTU to be at least 100 bytes higher than the data interface MTU, so make sure to configure the cluster control link connecting switch appropriately. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. In addition, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For Cisco IOS XR systems, if you want to set a non-default MTU, set the IOS XR interface MTU to be 14 bytes higher than the cluster device MTU. Otherwise, OSPF adjacency peering attempts may fail unless the **mtu-ignore** option is used. Note that the cluster device MTU should match the IOS XR *IPv4* MTU. This adjustment is not required for Cisco Catalyst and Cisco Nexus switches.
- On the switch(es) for the cluster control link interfaces, you can optionally enable Spanning Tree PortFast on the switch ports connected to the cluster unit to speed up the join process for new units.
- On the switch, we recommend that you use one of the following EtherChannel load-balancing algorithms: **source-dest-ip** or **src-dst-mixed-ip-port** (see the Cisco Nexus OS and Cisco IOS-XE **port-channel load-balance** command). Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the devices in a cluster.

- If you change the load-balancing algorithm of the EtherChannel on the switch, the EtherChannel interface on the switch temporarily stops forwarding traffic, and the Spanning Tree Protocol restarts. There will be a delay before traffic starts flowing again.
- Switches on the cluster control link path should not verify the L4 checksum. Redirected traffic over the cluster control link does not have a correct L4 checksum. Switches that verify the L4 checksum could cause traffic to be dropped.
- Port-channel bundling downtime should not exceed the configured keepalive interval.
- On Supervisor 2T EtherChannels, the default hash distribution algorithm is adaptive. To avoid asymmetric traffic in a VSS design, change the hash algorithm on the port-channel connected to the cluster device to fixed:

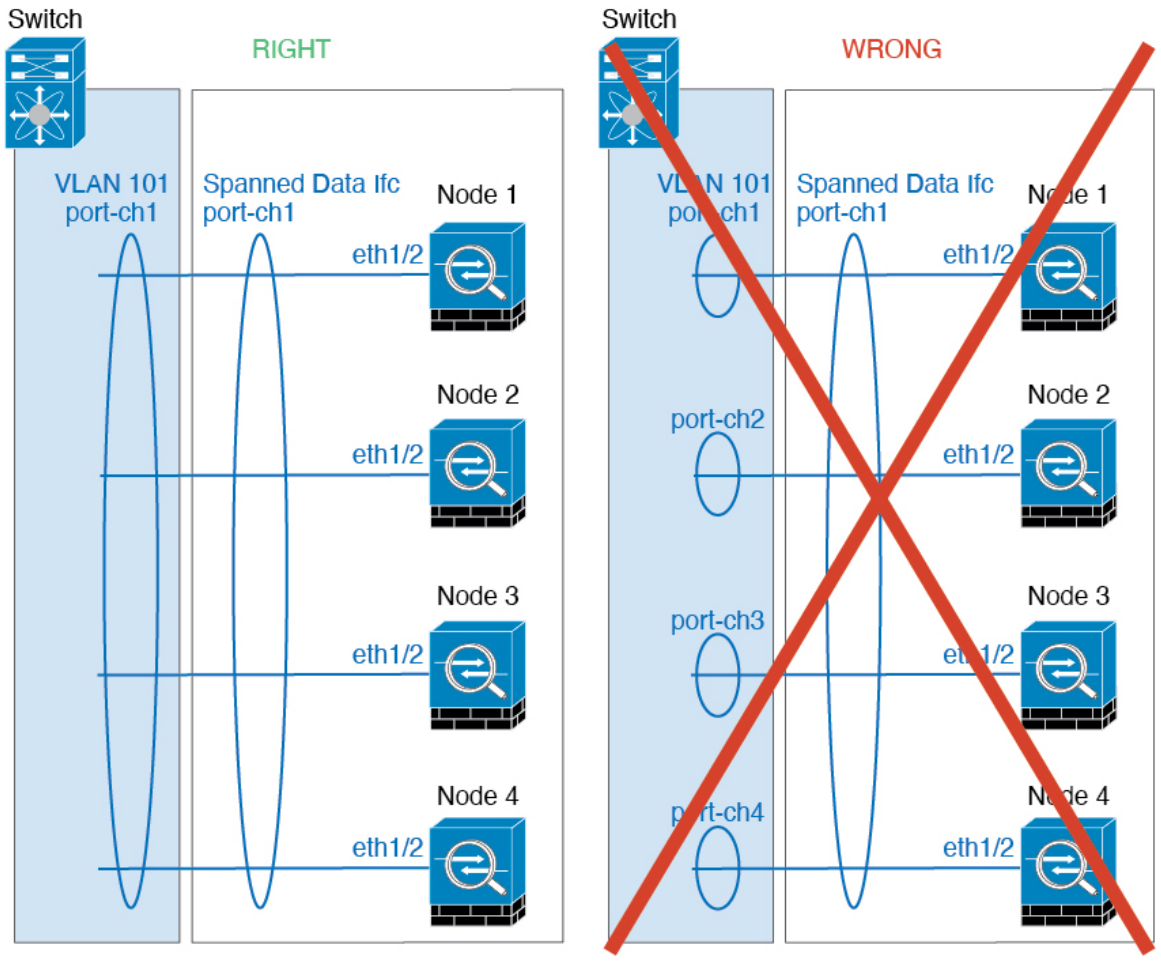
  router(config)# **port-channel** *id* **hash-distribution fixed**

  Do not change the algorithm globally; you may want to take advantage of the adaptive algorithm for the VSS peer link.

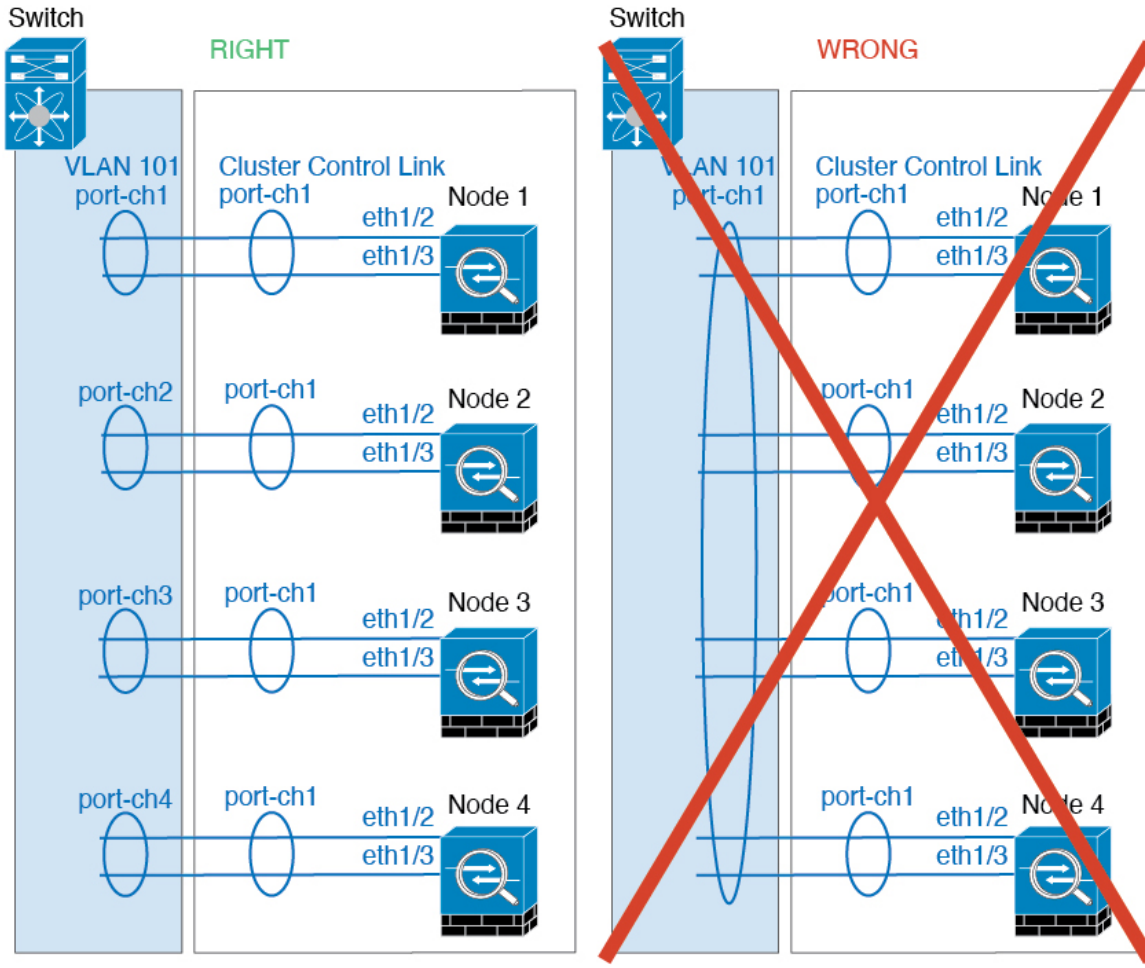
- You should disable the LACP Graceful Convergence feature on all cluster-facing EtherChannel interfaces for Cisco Nexus switches.

EtherChannels

- In Catalyst 3750-X Cisco IOS software versions earlier than 15.1(1)S2, the cluster unit did not support connecting an EtherChannel to a switch stack. With default switch settings, if the cluster unit EtherChannel is connected cross stack, and if the control unit switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.
- Spanned vs. Device-Local EtherChannel Configuration—Be sure to configure the switch appropriately for Spanned EtherChannels vs. Device-local EtherChannels.
  - Spanned EtherChannels—For cluster unit *Spanned* EtherChannels, which span across all members of the cluster, the interfaces are combined into a single EtherChannel on the switch. Make sure each interface is in the same channel group on the switch.



- Device-local EtherChannels—For cluster unit *Device-local* EtherChannels including any EtherChannels configured for the cluster control link, be sure to configure discrete EtherChannels on the switch; do not combine multiple cluster unit EtherChannels into one EtherChannel on the switch.



Additional Guidelines

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Firewall Threat Defense or the switch, adding an additional switch to form a VSS or vPC) you should disable the health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.
- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- If you use a Windows 2003 server connected to a Spanned EtherChannel, when the syslog server port is down and the server does not throttle ICMP error messages, then large numbers of ICMP messages are sent back to the ASA cluster. These messages can result in some units of the ASA cluster experiencing high CPU, which can affect performance. We recommend that you throttle ICMP error messages.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a

new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Defaults for Clustering

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Configure Clustering

To add a cluster to the Firewall Management Center, add each node to the Firewall Management Center as a standalone unit, configure interfaces on the unit you want to make the control node, and then form the cluster.

About Cluster Interfaces

You can configure data interfaces as Spanned EtherChannels.

You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces).

Each unit must also dedicate at least one hardware interface as the cluster control link.

Cluster Control Link

Each unit must dedicate at least one hardware interface as the cluster control link. We recommend using an EtherChannel for the cluster control link if available.

Cluster Control Link Traffic Overview

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Control node election.
- Configuration replication.
- Health monitoring.

Data traffic includes:

- State replication.
- Connection ownership queries and data packet forwarding.

Cluster Control Link Interfaces and Network

You can use any physical interface or EtherChannel for the cluster control link. You cannot use a VLAN subinterface as the cluster control link. You also cannot use the Management interface.

Each cluster control link has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the cluster control link interfaces.

Note For a 2-member cluster, do not directly-connect the cluster control link from one node to the other node. If you directly connect the interfaces, then when one unit fails, the cluster control link fails, and thus the remaining healthy unit fails. If you connect the cluster control link through a switch, then the cluster control link remains up for the healthy unit. If you need to directly-connect the units (for testing purposes, for example), then you should configure and enable the cluster control link interface on both nodes before you form the cluster.

Size the Cluster Control Link

If possible, you should size the cluster control link to match the expected throughput of each chassis so the cluster control link can handle the worst-case scenarios.

Cluster control link traffic is comprised mainly of state update and forwarded packets. The amount of traffic at any given time on the cluster control link varies. The amount of forwarded traffic depends on the load-balancing efficacy or whether there is a lot of traffic for centralized features. For example:

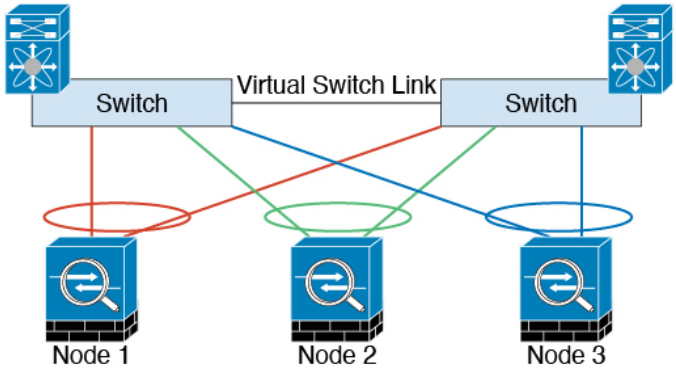
- NAT results in poor load balancing of connections, and the need to rebalance all returning traffic to the correct units.
- When membership changes, the cluster needs to rebalance a large number of connections, thus temporarily using a large amount of cluster control link bandwidth.

A higher-bandwidth cluster control link helps the cluster to converge faster when there are membership changes and prevents throughput bottlenecks.

Note If your cluster has large amounts of asymmetric (rebalanced) traffic, then you should increase the cluster control link size.

Cluster Control Link Redundancy

The following diagram shows how to use an EtherChannel as a cluster control link in a Virtual Switching System (VSS), Virtual Port Channel (vPC), StackWise, or StackWise Virtual environment. All links in the EtherChannel are active. When the switch is part of a redundant system, then you can connect firewall interfaces within the same EtherChannel to separate switches in the redundant system. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch. Note that this EtherChannel is device-local, not a Spanned EtherChannel.



Cluster Control Link Reliability

To ensure cluster control link functionality, be sure the round-trip time (RTT) between units is less than 20 ms. This maximum latency enhances compatibility with cluster members installed at different geographical sites. To check your latency, perform a ping on the cluster control link between units.

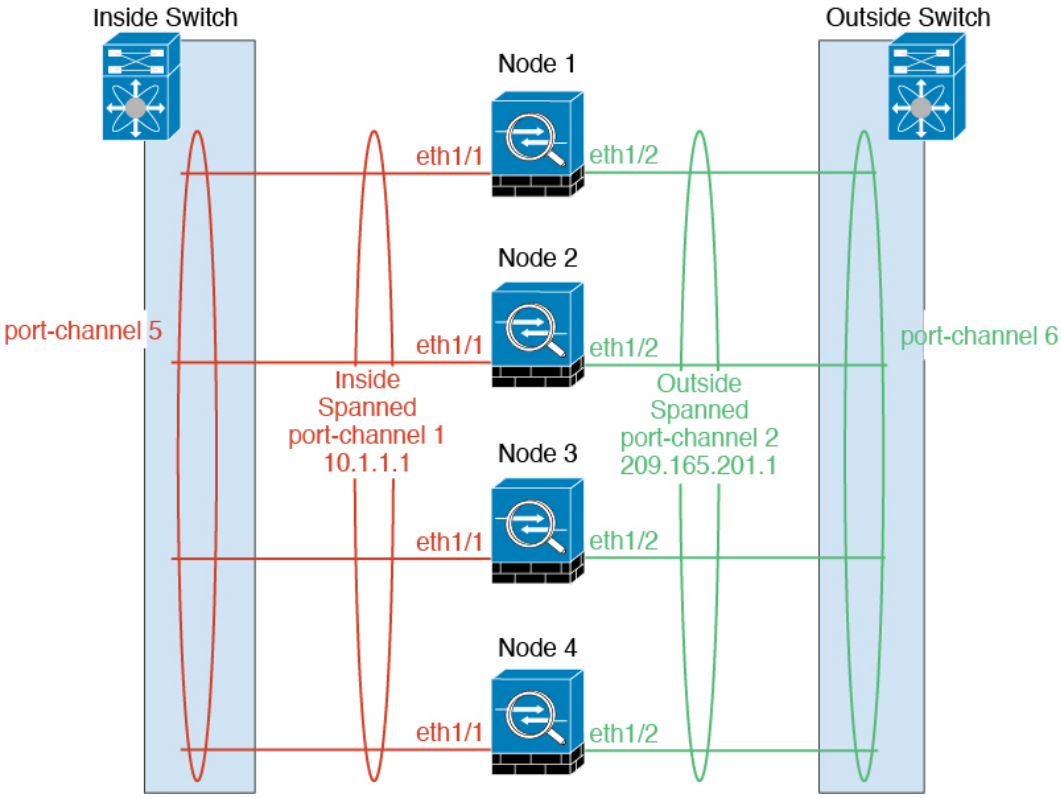
The cluster control link must be reliable, with no out-of-order or dropped packets; for example, for inter-site deployment, you should use a dedicated link.

Spanned EtherChannels

You can group one or more interfaces per chassis into an EtherChannel that spans all chassis in the cluster. The EtherChannel aggregates the traffic across all the available active interfaces in the channel.

For regular firewall interfaces:A Spanned EtherChannel can be configured in both routed and transparent firewall modes. In routed mode, the EtherChannel is configured as a routed interface with a single IP address. In transparent mode, the IP address is assigned to the BVI, not to the bridge group member interface.

The EtherChannel inherently provides load balancing as part of basic operation.



Guidelines for Maximum Throughput

To achieve maximum throughput, we recommend the following:

- Use a load-balancing hash algorithm that is "symmetric," meaning that packets from both directions will have the same hash and will be sent to the same Firewall Threat Defense in the Spanned EtherChannel. We recommend using the source and destination IP address (the default) or the source and destination port as the hashing algorithm.
- Use the same type of line cards when connecting the Firewall Threat Defenses to the switch so that hashing algorithms applied to all packets are the same.

Load Balancing

The EtherChannel link is selected using a proprietary hash algorithm, based on source or destination IP addresses and TCP and UDP port numbers.

Note On the switch, we recommend that you use one of the following algorithms: **source-dest-ip** or **source-dest-ip-port** (see the Cisco Nexus OS or Cisco IOS **port-channel load-balance** command). Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the nodes in a cluster.

The number of links in the EtherChannel affects load balancing.

Symmetric load balancing is not always possible. If you configure NAT, then forward and return packets will have different IP addresses and/or ports. Return traffic will be sent to a different unit based on the hash, and the cluster will have to redirect most returning traffic to the correct unit.

EtherChannel Redundancy

The EtherChannel has built-in redundancy. It monitors the line protocol status of all links. If one link fails, traffic is re-balanced between remaining links. If all links in the EtherChannel fail on a particular unit, but other units are still active, then the unit is removed from the cluster.

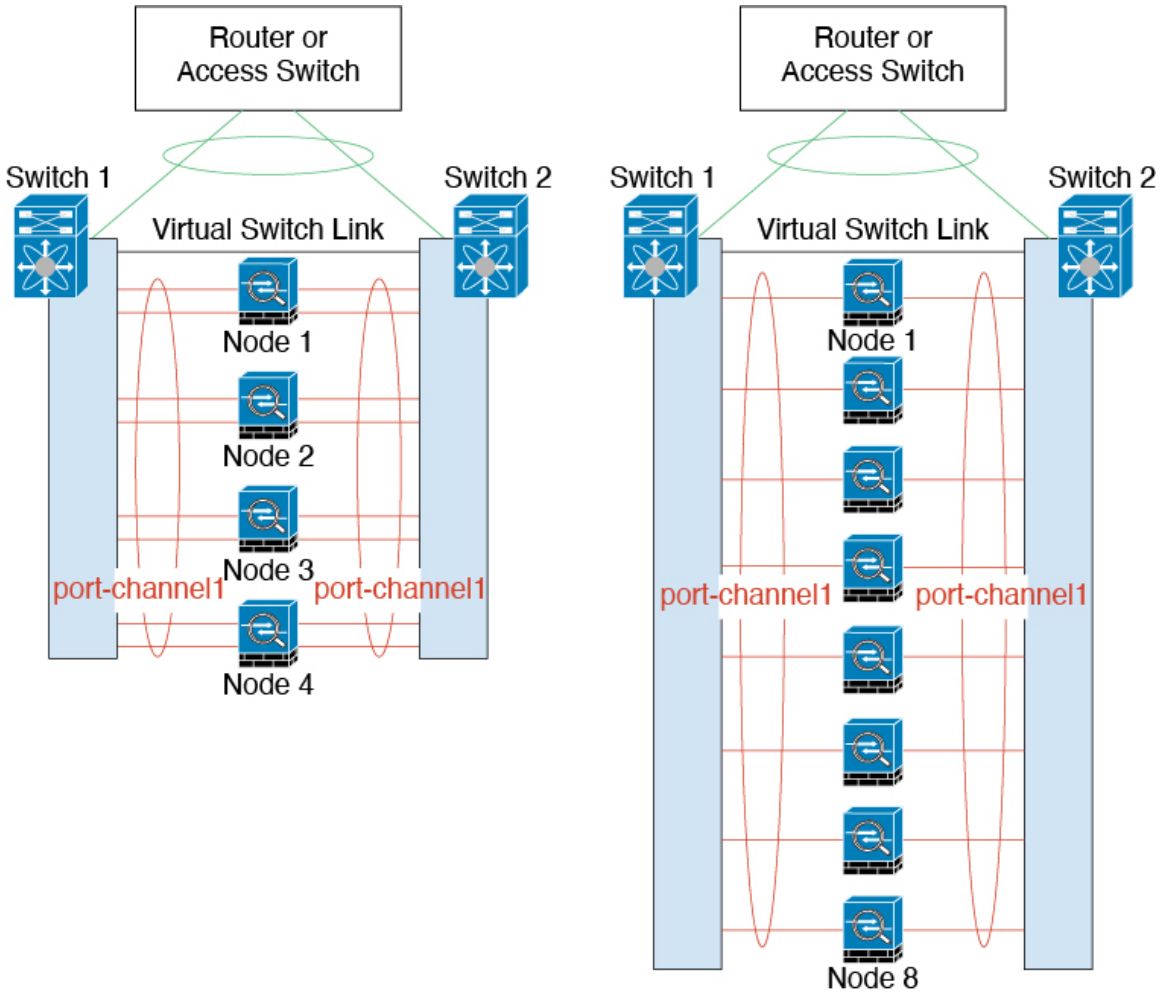
Connecting to a Redundant Switch System

You can include multiple interfaces per Firewall Threat Defense in the Spanned EtherChannel. Multiple interfaces per Firewall Threat Defense are especially useful for connecting to both switches in a VSS, vPC, StackWise, or StackWise Virtual system.

Depending on your switches, you can configure up to 32 active links in the spanned EtherChannel. This feature requires both switches in the vPC to support EtherChannels with 16 active links each (for example the Cisco Nexus 7000 with F2-Series 10 Gigabit Ethernet Module).

For switches that support 8 active links in the EtherChannel, you can configure up to 16 active links in the spanned EtherChannel when connecting to two switches in a redundant system.

The following figure shows a 16-active-link spanned EtherChannel in a 4-node cluster and an 8-node cluster.



Cable and Add Devices to the Firewall Management Center

Before configuring clustering, you need to prepare your devices. In particular, the cluster will not come up unless all nodes can communicate over the cluster control link. Therefore, before you form the cluster, the cluster control link must be ready to go.

Procedure

Step 1 Cable the cluster control link network, management network, and data networks.

Step 2 Configure the upstream and downstream equipment.

a) For the cluster control link network, set the MTU to be at least 100 bytes higher than the data interface MTU.

By default, the data interface MTU is 1500 bytes, so the cluster control link MTU on the cluster node will be set to 1600 bytes. If you use higher MTUs on your data interfaces, increase the cluster control link MTU on connecting switches accordingly.

b) Configure cluster control link interfaces on upstream and downstream equipment, including for an optional EtherChannel.

See Cluster Control Link Interfaces and Network, on page 613 for cluster control link requirements.

c) Configure data interfaces on upstream and downstream equipment, including Spanned EtherChannels.

See About Cluster Interfaces, on page 612 for information about how to cable Spanned EtherChannels.

Step 3 Add each node to the Firewall Management Center as a standalone device in the same domain and group.

You can create a cluster with a single device, and then add more nodes later. The initial settings (licensing, access control policy) that you set when you add a device will be inherited by all cluster nodes from the control node. You will choose the control node when forming the cluster.

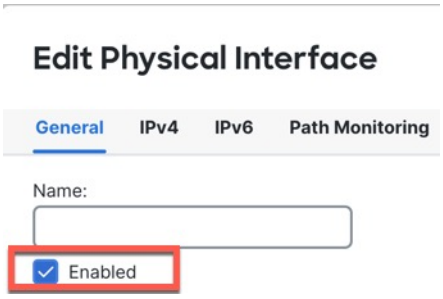
Step 4 Enable the cluster control link on the device you want to be the control node.

When you add the other nodes, they will inherit the cluster control link configuration.

Note
Do *not* configure the name or IP addressing for the cluster control link. The MTU of the cluster control link interface is automatically set to 100 bytes more than the highest data interface MTU when you form the cluster, so you do not need to set it now. However, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation. If the MTU is set in this range when you add the cluster, we recommend returning to the **Interfaces** page and manually increasing it above 8362. When a node joins the cluster, it checks MTU compatibility by sending a ping to the control node with a packet size matching the cluster control link MTU. If the ping fails, a notification is generated so you can fix the MTU mismatch on connecting switches and try again.

a) On the device you want to be the control node, choose **Devices** > **Device Management**, and click **Edit** (✎).
b) Click **Interfaces**.
c) Enable the interface. If you are going to use an EtherChannel for the cluster control link, enable all members. See Enable the Physical Interface and Configure Ethernet Settings, on page 872.

Figure 151: Enable the Cluster Control Link Interface



d) (Optional) Add an EtherChannel. See Configure an EtherChannel, on page 880.

We recommend using the On mode for cluster control link member interfaces to reduce unnecessary traffic on the cluster control link (Active mode is the default). The cluster control link does not need the overhead of LACP traffic because it is an isolated, stable network. **Note:** We recommend setting *data* EtherChannels to Active mode.

e) Click **Save** and then **Deploy** to deploy the interface changes to the control node.

Create a Cluster

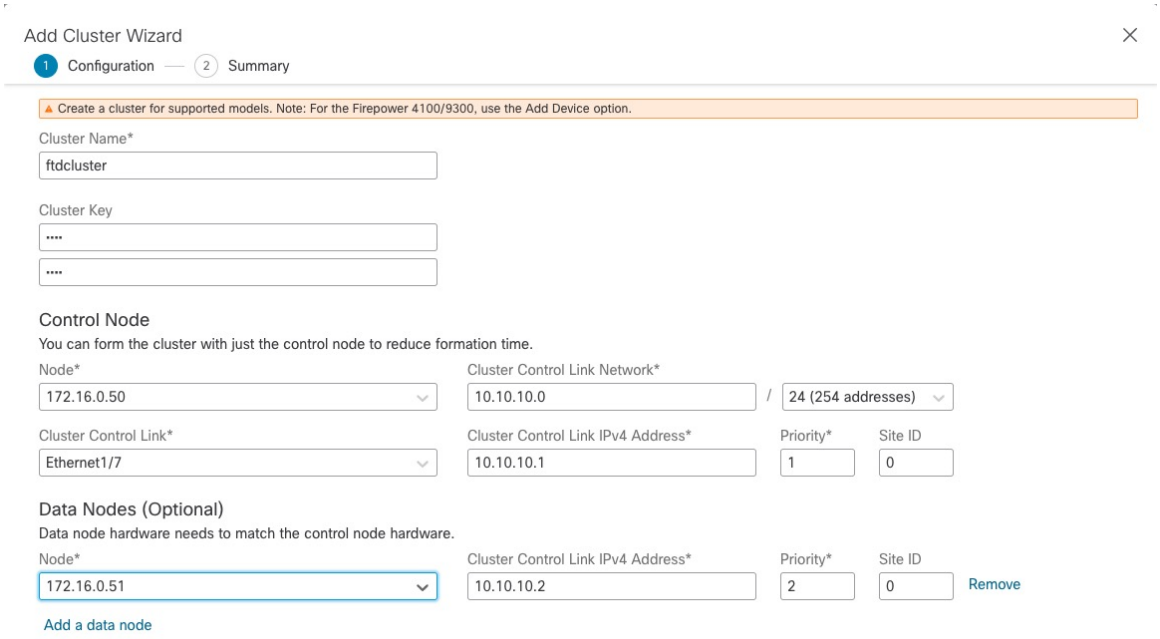
Form a cluster from one or more devices in the Firewall Management Center.

Procedure

Step 1 Choose **Devices** > **Device Management**, and then choose **Add** > **Cluster**.

The **Add Cluster Wizard** appears.

Figure 152: Add Cluster Wizard



Step 2 Specify a **Cluster Name** and an authentication **Cluster Key** for control traffic.

- **Cluster Name**—An ASCII string from 1 to 38 characters.
- **Cluster Key**—An ASCII string from 1 to 63 characters. The **Cluster Key** value is used to generate the encryption key. This encryption does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in the clear.

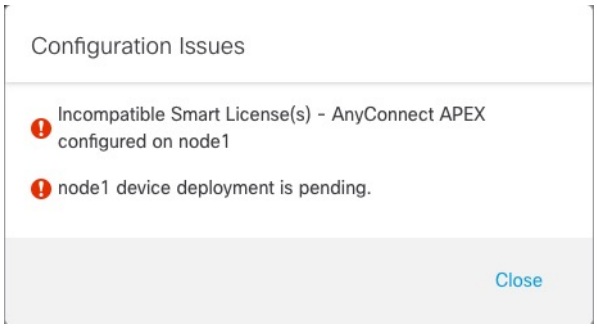
Step 3 For the **Control Node**, set the following:

- **Node**—Choose the device that you want to be the control node initially. When the Firewall Management Center forms the cluster, it will add this node to the cluster first so it will be the control node.

  Note

If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation. For example:

Figure 153: Configuration Issues



To resolve the above issues, remove the unsupported VPN license and deploy pending configuration changes to the device.

- **Cluster Control Link Network**—Specify an IPv4 subnet; IPv6 is not supported for this interface. Specify a **24**, **25**, **26**, or **27** subnet.
- **Cluster Control Link**—Choose the physical interface or EtherChannel you want to use for the cluster control link.

  Note
  The MTU of the cluster control link interface is automatically set to 100 bytes more than the highest data interface MTU; by default, the MTU is 1600 bytes. We do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation. If the MTU is set in this range when you add the cluster, we recommend increasing the MTU above 8362 on the **Devices** > **Device Management** and then click on **Interfaces** page.

  Make sure you configure switches connected to the cluster control link to the correct (higher) MTU; otherwise, cluster formation will fail. When a node joins the cluster, it checks MTU compatibility by sending a ping to the control node with a packet size matching the cluster control link MTU. If the ping fails, a notification is generated so you can fix the MTU mismatch on connecting switches and try again.

- **Cluster Control Link IPv4 Address**—This field will be auto-populated with the first address on the cluster control link network. You can edit the host address if desired.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority. Even if you set the priority to be lower than other nodes, this node will still be the control node when the cluster is first formed.
- **Site ID**—(FlexConfig feature) Enter the site ID for this node between 1 and 8. A value of 0 disables inter-site clustering. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature.

Step 4 For **Data Nodes (Optional)**, click **Add a data node** to add a node to the cluster.

You can form the cluster with only the control node for faster cluster formation, or you can add all nodes now. Set the following for each data node:

- **Node**—Choose the device that you want to add.

Note

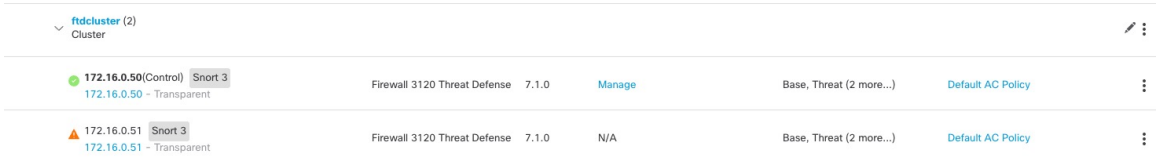
If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation.

- **Cluster Control Link IPv4 Address**—This field will be auto-populated with the next address on the cluster control link network. You can edit the host address if desired.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority.
- **Site ID**—(FlexConfig feature) Enter the site ID for this node between 1 and 8. A value of 0 disables inter-site clustering. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature.

Step 5 Click **Continue**. Review the **Summary**, and then click **Save**.

The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster nodes.

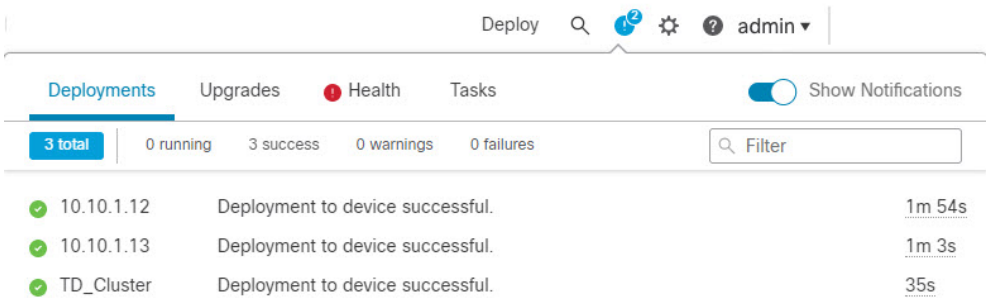
Figure 154: Cluster Management



A node that is currently registering shows the loading icon.

Figure 155: Node Registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**. The Firewall Management Center updates the Cluster Registration task as each node registers.

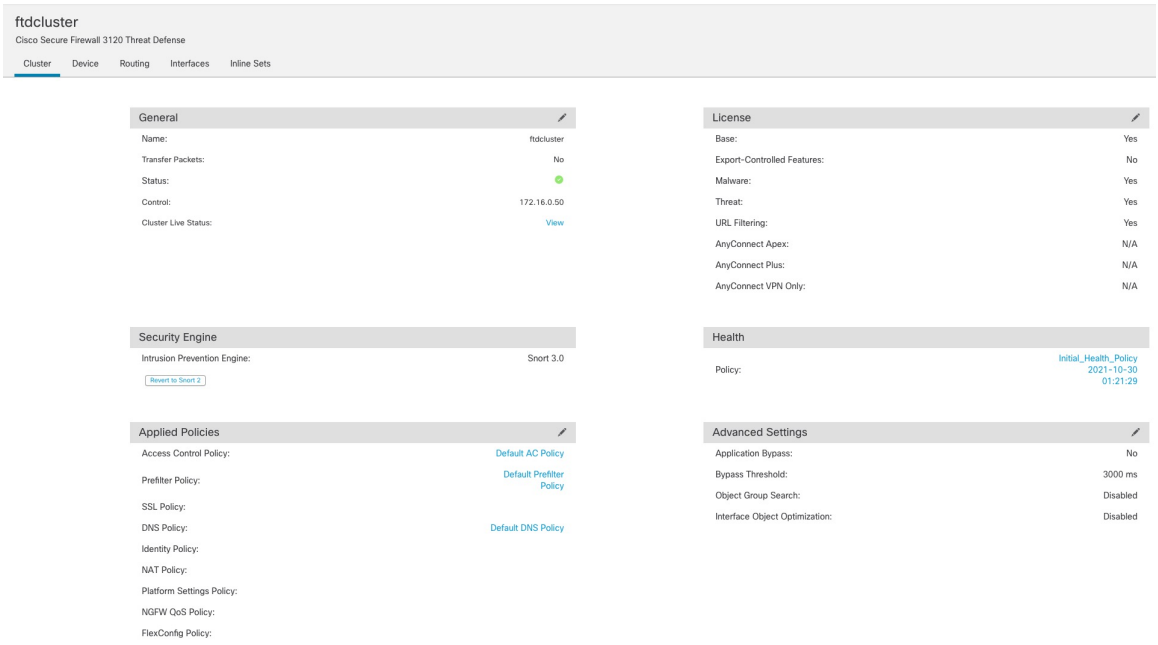


Step 6 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

Most configuration can be applied to the cluster as a whole, and not nodes in the cluster. For example, you can change the display name per node, but you can only configure interfaces for the whole cluster.

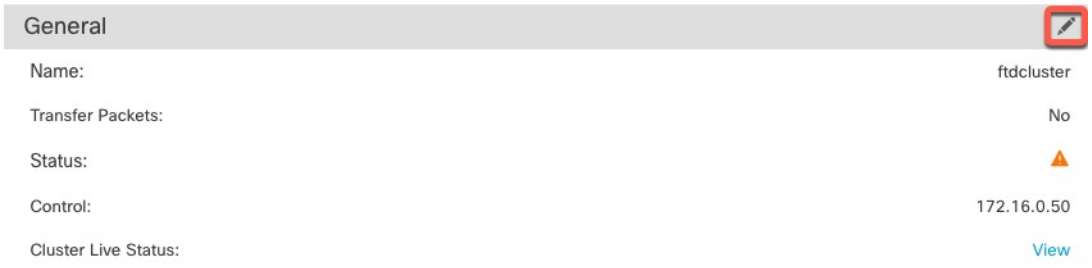
Step 7 On the **Devices** > **Device Management** and then choose **Add**, **Cluster** screen, you see **General** and other settings for the cluster.

Figure 156: Cluster Settings

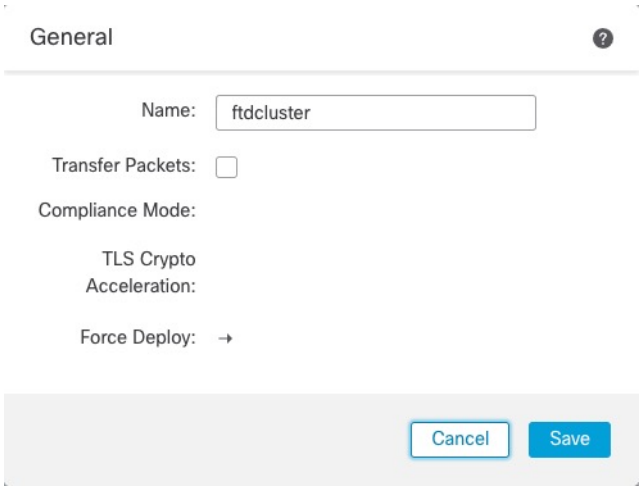


See the following cluster-specific items in the **General** area:

- **General > Name**—Change the cluster display name by clicking the **Edit** (✎).

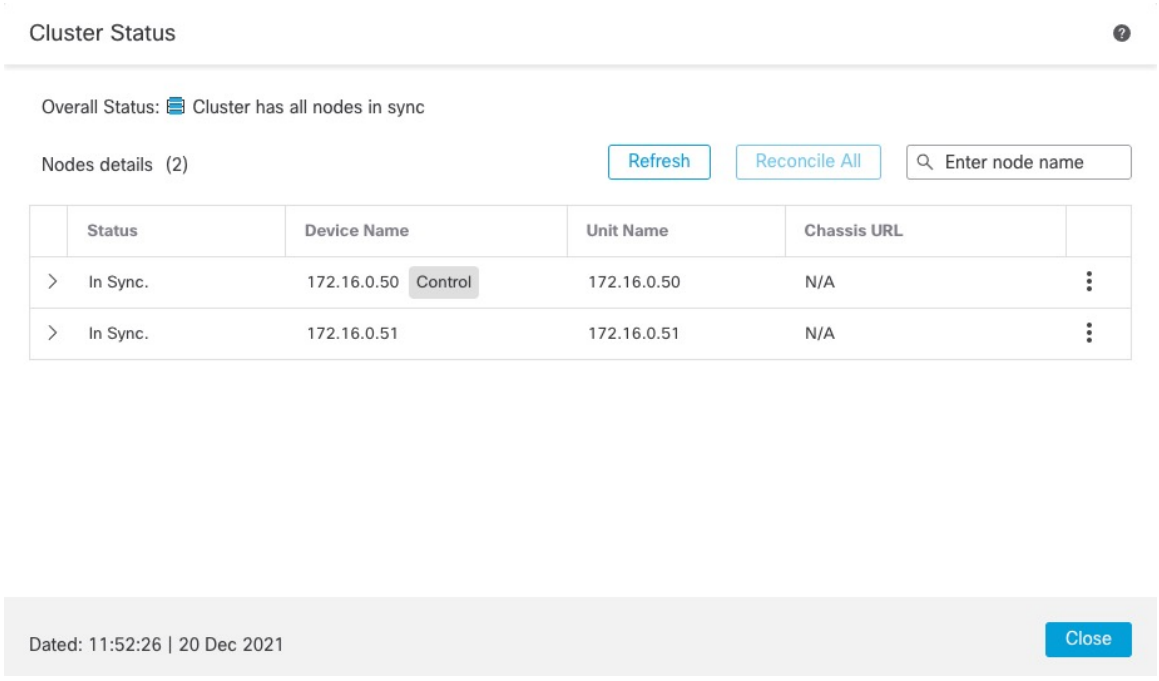


Then set the **Name** field.



- **General > Cluster Live Status**—Click the **View** link to open the **Cluster Status** dialog box.

The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile All**.



Step 8 On the **Devices** > **Device Management** and then choose **Add**, **Device**, you can choose each member in the cluster from the top right drop-down menu and configure the following settings.

Figure 157: Device Settings

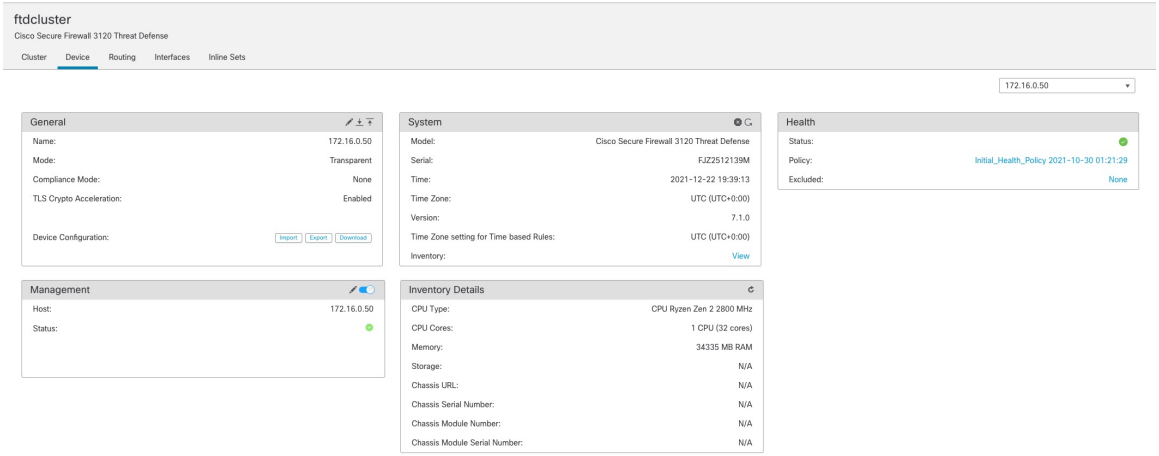


Figure 158: Choose Node

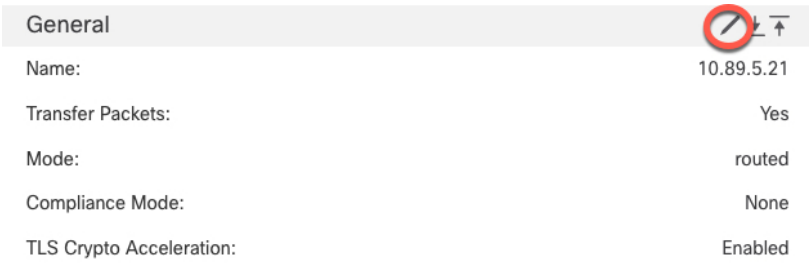
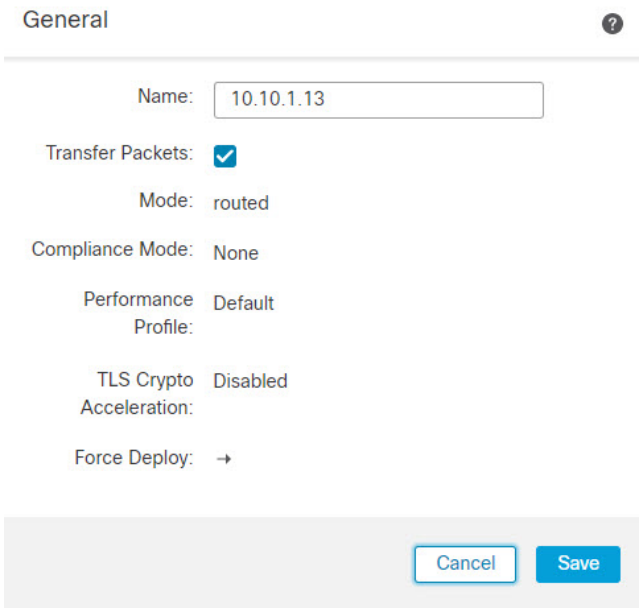
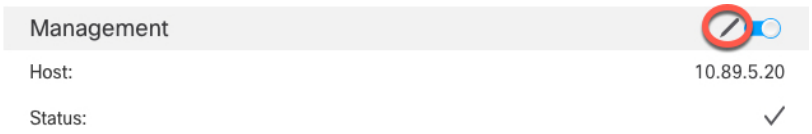
- **General > Name**—Change the cluster member display name by clicking the **Edit** ( ).



Then set the **Name** field.



- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the Firewall Management Center so that it can reach the device on the network. First disable the connection, edit the **Host** address in the **Management** area, then re-enable the connection.



Configure Interfaces

Configure data interfaces as Spanned EtherChannels.

Procedure

Step 1 Choose **Devices** > **Device Management**, and click **Edit** (✎) next to the cluster.

Step 2 Click **Interfaces**.

Step 3 Configure Spanned EtherChannel data interfaces.

a) Configure one or more EtherChannels. See Configure an EtherChannel, on page 880.

You can include one or more member interfaces in the EtherChannel. Because this EtherChannel is spanned across all of the nodes, you only need one member interface per node; however, for greater throughput and redundancy, multiple members are recommended.

b) (Optional) For regular firewall interfaces, configure VLAN subinterfaces on the EtherChannel. The rest of this procedure applies to the subinterfaces. See Add a Subinterface, on page 930.

c) Click **Edit** ( ) for the EtherChannel interface.

d) Configure the name and other parameters. For regular firewall interfaces, see Configure Routed Mode Interfaces, on page 948 or, for transparent mode, Configure Bridge Group Interfaces, on page 953. For IPS-only interfaces, see Inline Sets and Passive Interfaces, on page 985.

- If the cluster control link interface MTU is not at least 100 bytes higher than the data interface MTU, you will see an error that you must reduce the MTU of the data interface. By default, the cluster control link MTU is 1600 bytes. If you want to increase the MTU of data interfaces, first increase the cluster control link MTU. Note that we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For routed mode, DHCP, PPPoE, IPv6 autoconfig and manual link-local addresses are not supported. For point-to-point connections, you can specify a 31-bit subnet mask (255.255.255.254). In this case, no IP addresses are reserved for the network or broadcast addresses.

e) Set a unique, manual global MAC address for the EtherChannel. Click **Advanced**, and in the **Active Mac Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

Do not set the **Standby Mac Address**; it is ignored.

You must configure a unique MAC address not currently in use on your network for a Spanned EtherChannel to avoid potential network connectivity problems. With a manually-configured MAC address, the MAC address stays with the current control unit. If you do not configure a MAC address, then if the control unit changes, the new control unit uses a new MAC address for the interface, which can cause a temporary network outage.

f) Click **OK**. Repeat the above steps for other data interfaces.

Step 4 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Cluster Health Monitor Settings

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings described in the table below.

Figure 159: Cluster Health Monitor Settings

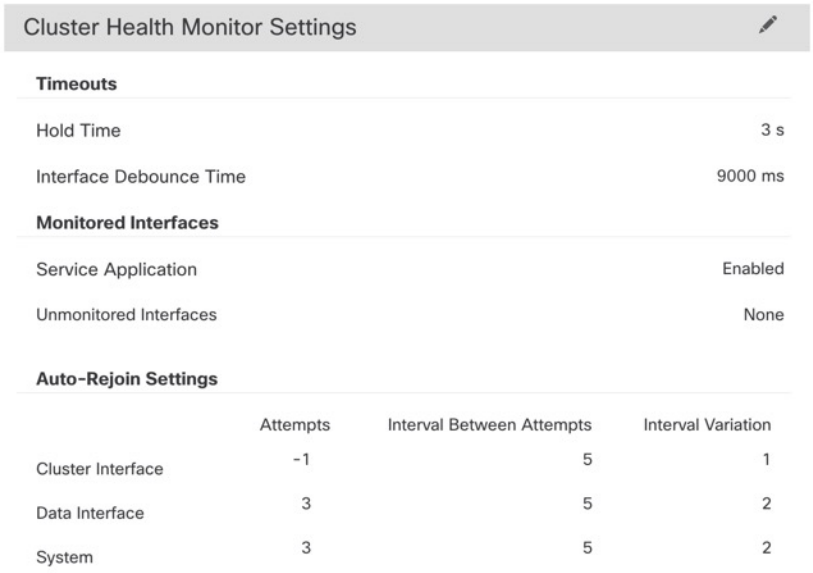


Table 50: Cluster Health Monitor Settings Section Table Fields

Field	Description
Timeouts	
Hold Time	Between .3 and 45 seconds; The default is 3 seconds. To determine node system health, the cluster nodes send heartbeat messages on the cluster control link to other nodes. If a node does not receive any heartbeat messages from a peer node within the hold time period, the peer node is considered unresponsive or dead.
Interface Debounce Time	Between 300 and 9000 ms. The default is 500 ms. The interface debounce time is the amount of time before the node considers an interface to be failed, and the node is removed from the cluster.
Monitored Interfaces	The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster.
Service Application	Shows whether the Snort and disk-full processes are monitored.
Unmonitored Interfaces	Shows unmonitored interfaces.
Auto-Rejoin Settings	
Cluster Interface	Shows the auto-rejoin settings after a cluster control link failure.

Field	Description
Attempts	Between -1 and 65535. The default is -1 (unlimited). Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 1x the interval duration. Defines if the interval duration increases at each attempt.
Data Interfaces	Shows the auto-rejoin settings after a data interface failure.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.
System	Shows the auto-rejoin settings after internal errors. Internal failures include: application sync timeout; inconsistent application statuses; and so on.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.

Note If you disable the system health check, fields that do not apply when the system health check is disabled will not show.

You can change these settings from this section.

You can monitor any port-channel ID, single physical interface ID, as well as the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link; it is always monitored.

Procedure

Step 1 Choose **Devices** > **Device Management**.

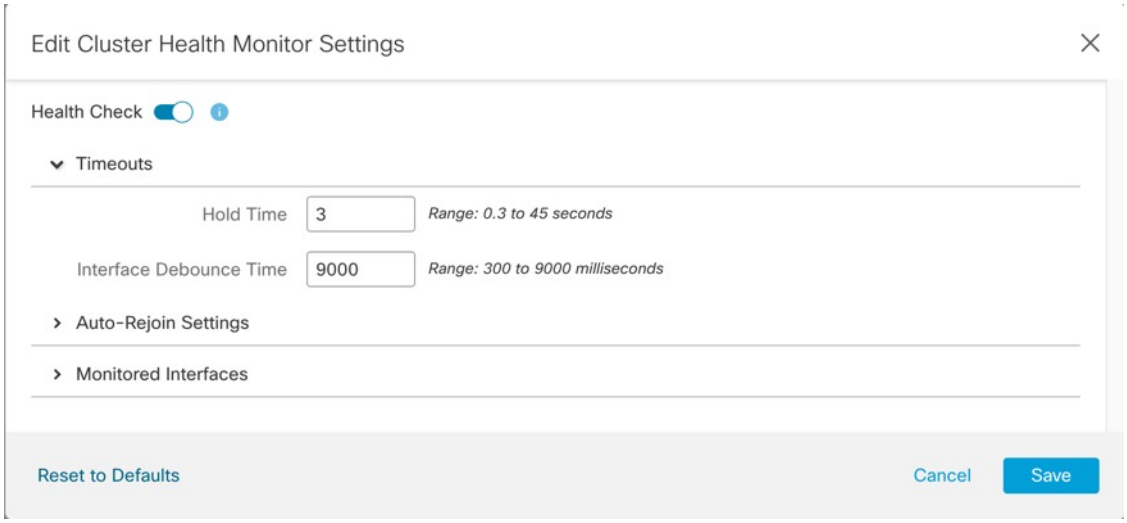
Step 2 Next to the cluster you want to modify, click **Edit** ( ).

Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider .

Figure 160: Disable the System Health Check



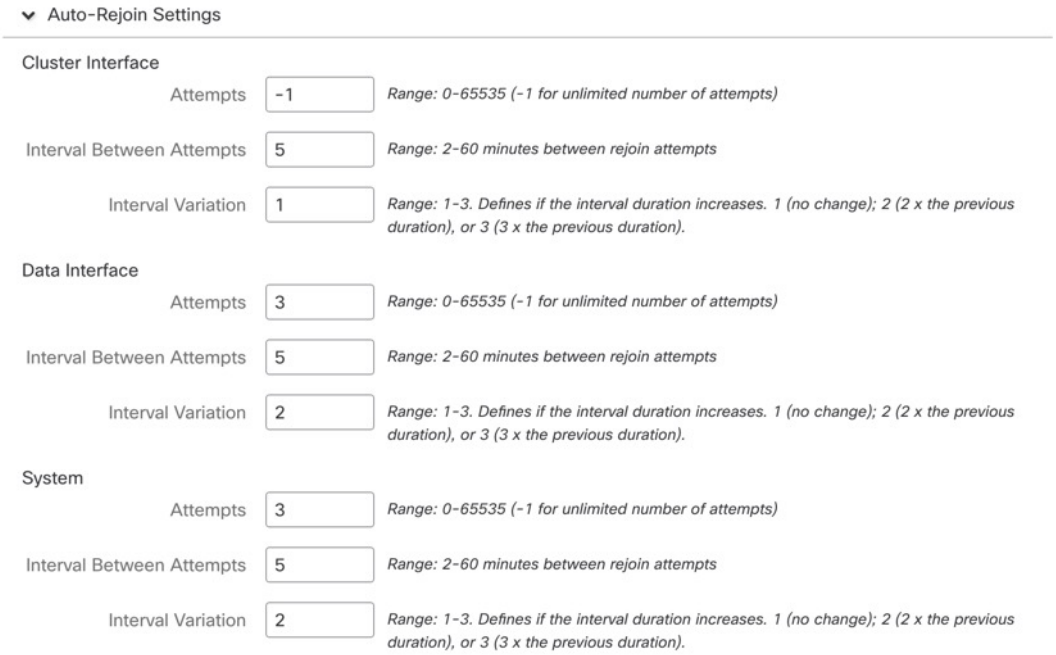
When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between .3 and 45 seconds; The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the number of milliseconds specified before marking the interface as failed, and the node is removed from the cluster. In the case of an EtherChannel that transitions from a down state to an up state (for example, the switch reloaded, or the switch enabled an EtherChannel), a longer debounce time can prevent the interface from appearing to be failed on a cluster node just because another cluster node was faster at bundling the ports.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 161: Configure Auto-Rejoin Settings

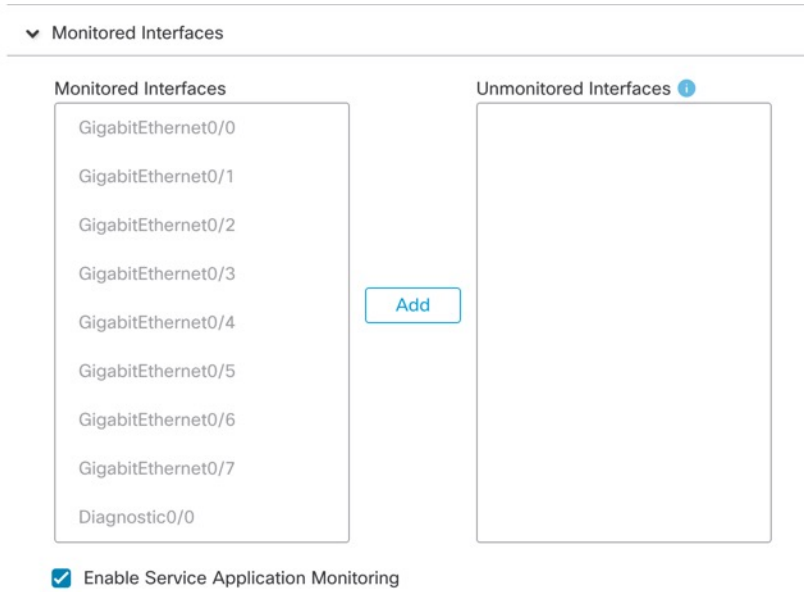


Set the following values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 162: Configure Monitored Interfaces



The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. Health check is enabled by default for all interfaces and for the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save**.

Step 10 Deploy configuration changes.

Manage Cluster Nodes

After you deploy the cluster, you can change the configuration and manage cluster nodes.

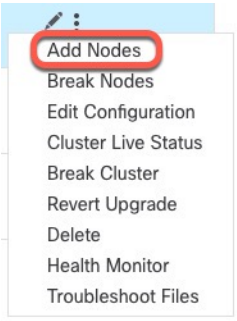
Add a New Cluster Node

You can add one or more new cluster nodes to an existing cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster, and choose **Add Nodes**.

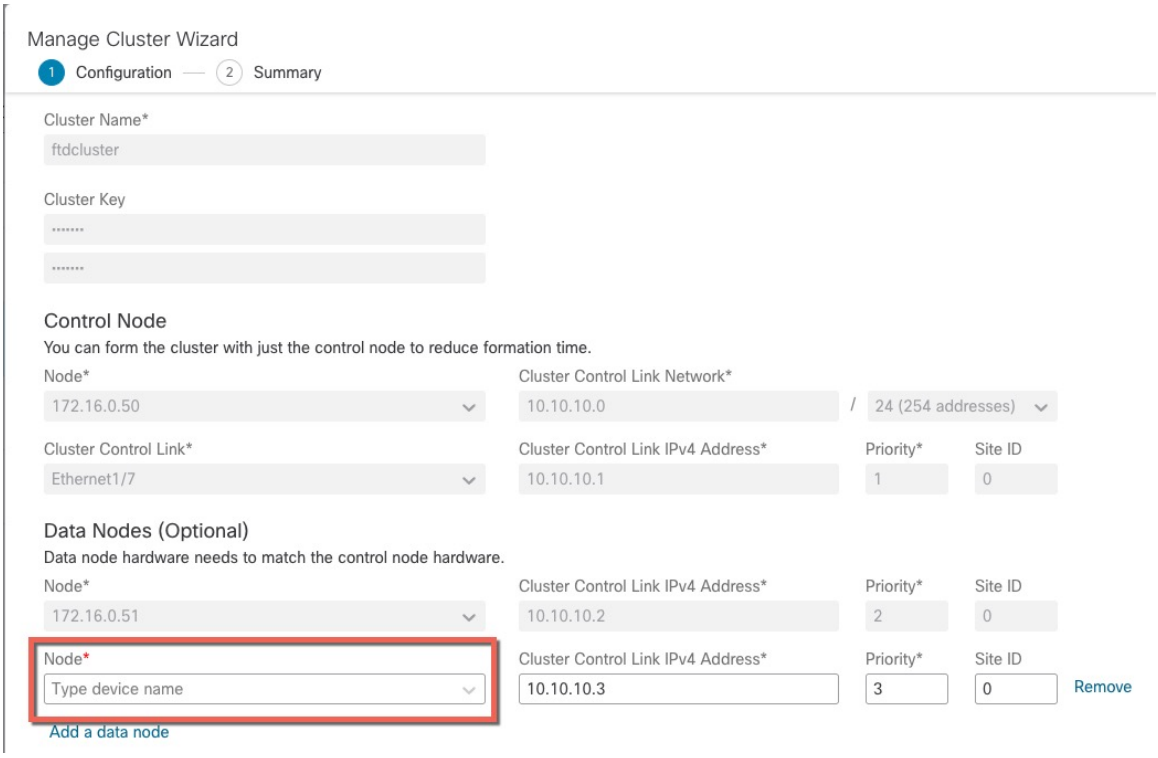
Figure 163: Add Nodes



The **Manage Cluster Wizard** appears.

Step 2 From the **Node** menu, choose a device, adjust the IP address, priority, and Site ID if desired.

Figure 164: Manage Cluster Wizard

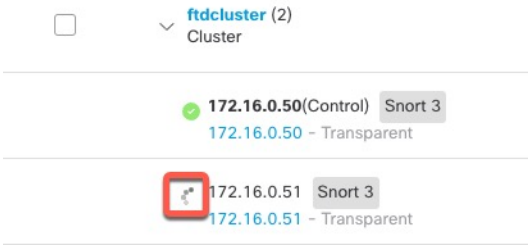


Step 3 To add additional nodes, click **Add a data node**.

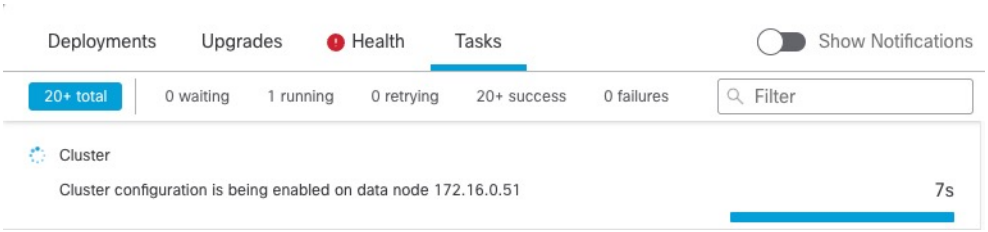
Step 4 Click **Continue**. Review the **Summary**, and then click **Save**

The node that is currently registering shows the loading icon.

Figure 165: Node Registration



You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**.



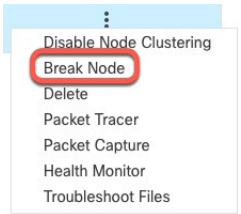
Break a Node

You can remove a node from the cluster so that it becomes a standalone device. You cannot break the control node unless you break the entire cluster. The data node has its configuration erased.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the node you want to break, and choose **Break Node**.

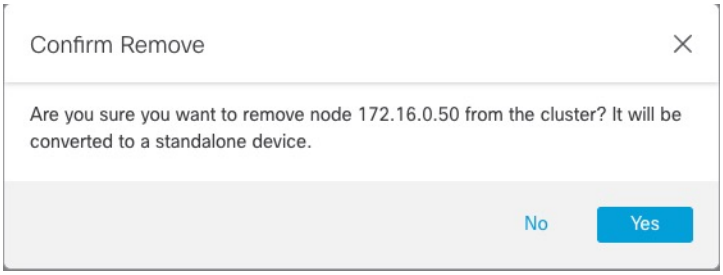
Figure 166: Break a Node



You can optionally break one or more nodes from the cluster More menu by choosing **Break Nodes**.

Step 2 You are prompted to confirm the break; click **Yes**.

Figure 167: Confirm Break



You can monitor the cluster node break by clicking the **Notifications** icon and choosing **Tasks**.

Break the Cluster

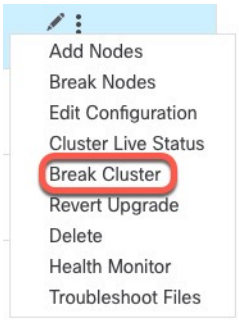
You can break the cluster and convert all nodes to standalone devices. The control node retains the interface and security policy configuration, while data nodes have their configuration erased.

Procedure

Step 1 Make sure all cluster nodes are being managed by the Firewall Management Center by reconciling nodes. See Reconcile Cluster Nodes, on page 638.

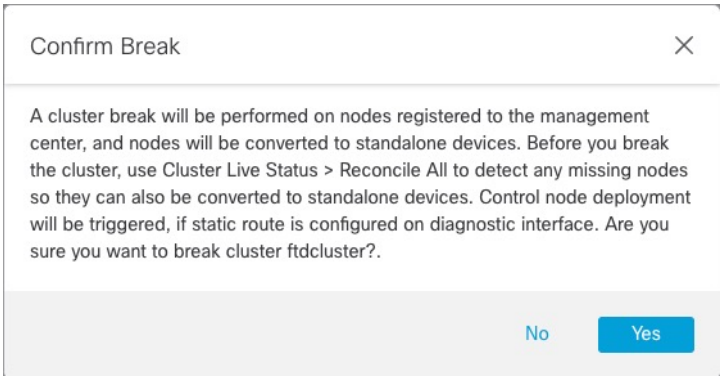
Step 2 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster, and choose **Break Cluster**.

Figure 168: Break Cluster



Step 3 You are prompted to break the cluster; click **Yes**.

Figure 169: Confirm Break



You can monitor the cluster break by clicking the **Notifications** icon and choosing **Tasks**.

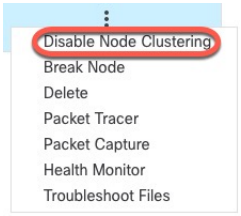
Disable Clustering

You may want to deactivate a node in preparation for deleting the node, or temporarily for maintenance. This procedure is meant to temporarily deactivate a node; the node will still appear in the Firewall Management Center device list. When a node becomes inactive, all data interfaces are shut down.

Procedure

Step 1 For the unit you want to disable, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Disable Node Clustering**.

Figure 170: Disable Clustering



If you disable clustering on the control node, one of the data nodes will become the new control node. Note that for centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node. You cannot disable clustering on the control node if it is the only node in the cluster.

Step 2 Confirm that you want to disable clustering on the node.

The node will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.

Step 3 To reenable clustering, see Rejoin the Cluster, on page 636.

Rejoin the Cluster

If a node was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster.

Procedure

Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Enable Node Clustering**.

Step 2 Confirm that you want to enable clustering on the unit.

Change the Control Node

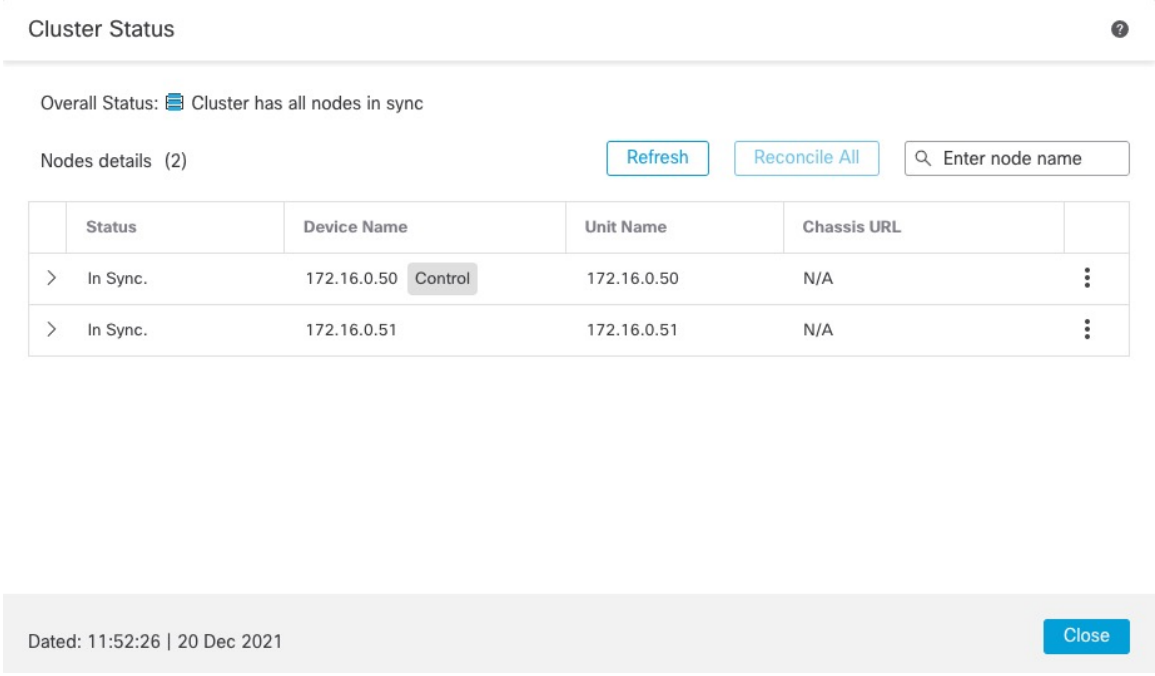
Caution The best method to change the control node is to disable clustering on the control node, wait for a new control election, and then re-enable clustering. If you must specify the *exact* unit you want to become the control node, use the procedure in this section. Note that for centralized features, if you force a control node change using either method, then all connections are dropped, and you have to re-establish the connections on the new control node.

To change the control node, perform the following steps.

Procedure

Step 1 Open the **Cluster Status** dialog box by choosing **Devices** > **Device Management More** (⋮) **Cluster Live Status**.

Figure 171: Cluster Status



Step 2 For the unit you want to become the control unit, choose **More** (⋮) **Change Role to Control**.

Step 3 You are prompted to confirm the role change. Check the checkbox, and click **OK**.

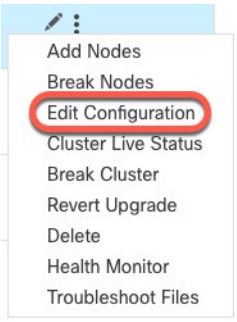
Edit the Cluster Configuration

You can edit the cluster configuration. If you change the cluster key, cluster control link interface, or cluster control link network, the cluster will be broken and reformed automatically. Until the cluster is reformed, you may experience traffic disruption. If you change the cluster control link IP address for a node, node priority, or site ID, only the affected nodes are broken and readded to the cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster, and choose **Edit Configuration**.

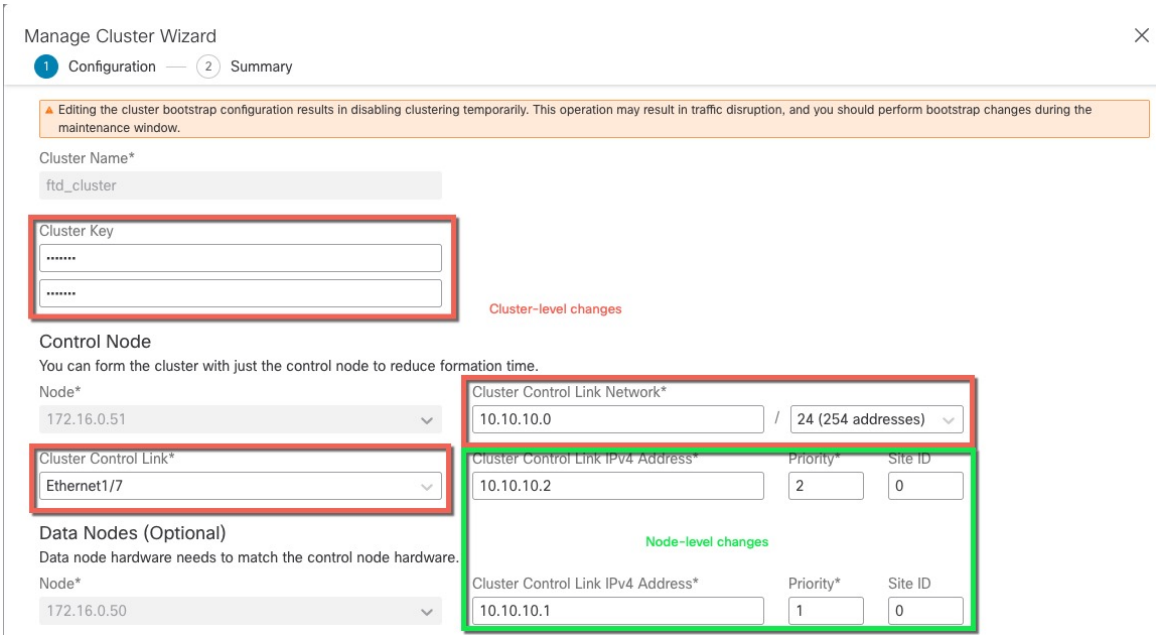
Figure 172: Edit Configuration



The **Manage Cluster Wizard** appears.

Step 2 Update the cluster configuration.

Figure 173: Manage Cluster Wizard



If the cluster control link is an EtherChannel, you can edit the interface membership and LACP configuration by clicking **Edit** (✎) next to the interface drop-down menu.

Step 3 Click **Continue**. Review the **Summary**, and then click **Save**

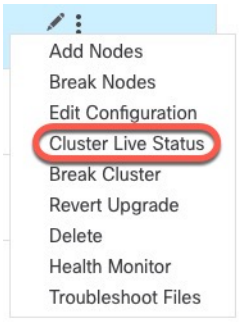
Reconcile Cluster Nodes

If a cluster node fails to register, you can reconcile the cluster membership from the device to the Firewall Management Center. For example, a data node might fail to register if the Firewall Management Center is occupied with certain processes, or if there is a network issue.

Procedure

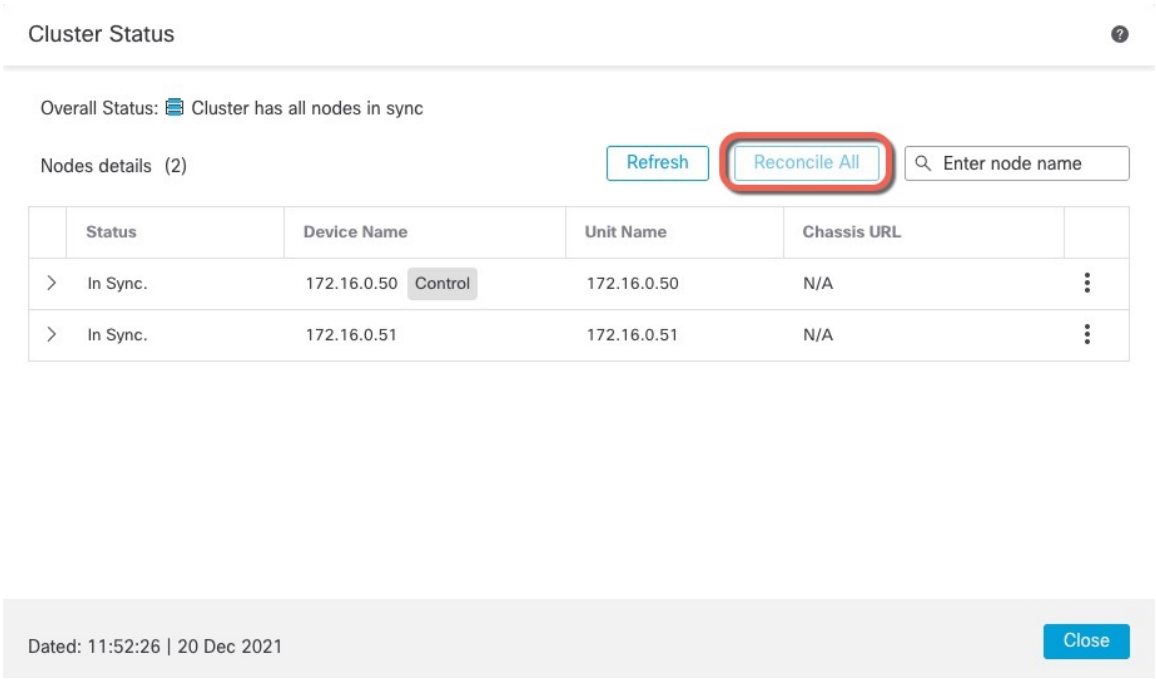
Step 1 Choose **Devices** > **Device Management More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

Figure 174: Cluster Live Status



Step 2 Click **Reconcile All**.

Figure 175: Reconcile All



For more information about the cluster status, see Monitoring the Cluster, on page 641.

Delete (Unregister) the Cluster or Nodes and Register to a New Firewall Management Center

You can unregister the cluster from the Firewall Management Center, which keeps the cluster intact. You might want to unregister the cluster if you want to add the cluster to a new Firewall Management Center.

You can also unregister a node from the Firewall Management Center without breaking the node from the cluster. Although the node is not visible in the Firewall Management Center, it is still part of the cluster, and it will continue to pass traffic and could even become the control node. You cannot unregister the current control node. You might want to unregister the node if it is no longer reachable from the Firewall Management Center, but you still want to keep it as part of the cluster while you troubleshoot management connectivity.

Unregistering a cluster:

- Severs all communication between the Firewall Management Center and the cluster.
- Removes the cluster from the **Device Management** page.
- Returns the cluster to local time management if the cluster's platform settings policy is configured to receive time from the Firewall Management Center using NTP.
- Leaves the configuration intact, so the cluster continues to process traffic.

  Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the cluster again to the same or a different Firewall Management Center causes the configuration to be removed, so the cluster will stop processing traffic at that point; the cluster configuration remains intact so you can add the cluster as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.

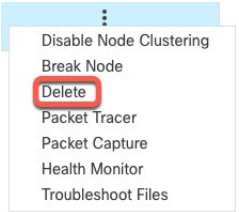
Before you begin

This procedure requires CLI access to one of the nodes.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster or node, and choose **Delete**.

Figure 176: Delete Cluster or Node



Step 2 You are prompted to delete the cluster or node; click **Yes**.

Step 3 You can register the cluster to a new (or the same) Firewall Management Center by adding one of the cluster members as a new device.

You only need to add one of the cluster nodes as a device, and the rest of the cluster nodes will be discovered.

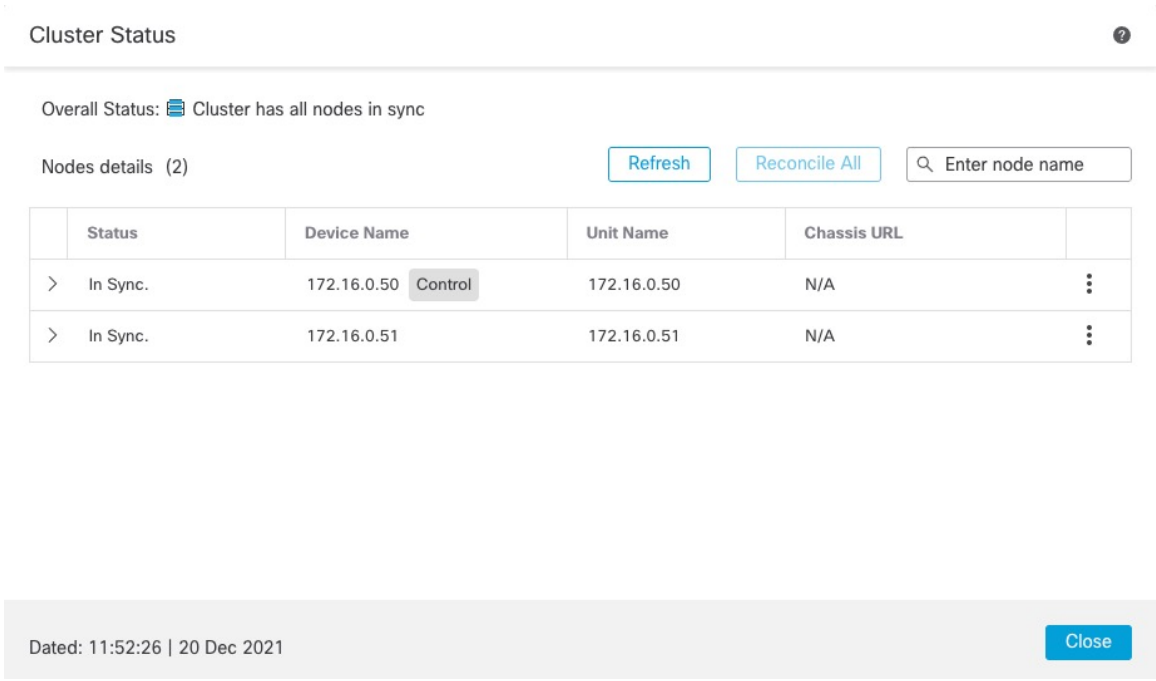
Step 4 To re-add an unregistered node, see Reconcile Cluster Nodes, on page 638.

Monitoring the Cluster

You can monitor the cluster in the Firewall Management Center and at the Firewall Threat Defense CLI.

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management More** (⋮) icon or from the **Devices** > **Device Management** > **Cluster** page **General** area **Cluster Live Status** link.

Figure 177: Cluster Status



The Control node has a graphic indicator identifying its role.

Cluster member **Status** includes the following states:

- In Sync.—The node is registered with the Firewall Management Center.
- Pending Registration—The node is part of the cluster, but has not yet registered with the Firewall Management Center. If a node fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The node is registered with the Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the node from the cluster.
- Joining cluster...—The node is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Firewall Management Center.

For each node, you can view the **Summary** or the **History**.

Figure 178: Node Summary

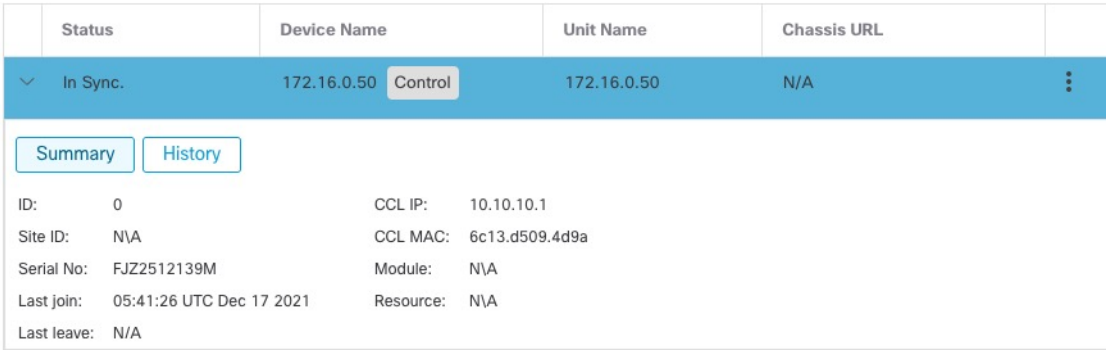


Figure 179: Node History

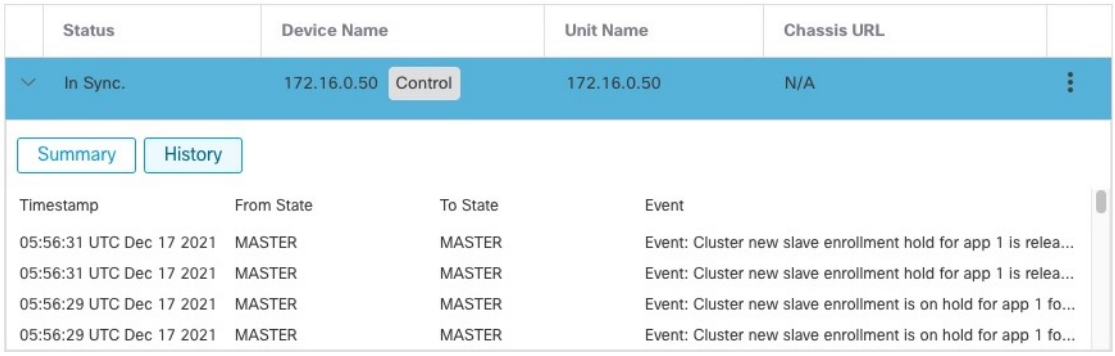


- **System** (⚙) > **Tasks** page.

  The **Tasks** page shows updates of the Cluster Registration task as each node registers.

- **Devices** > **Device Management***cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member nodes, including the control node shown with its role next to the IP address. For nodes that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

Cluster Health Monitor Dashboard

Cluster Health Monitor

When a Firewall Threat Defense is the control node of a cluster, the Firewall Management Center collects various metrics periodically from the device metric data collector. The cluster health monitor is comprised of the following components:

- Overview dashboard—Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the Firewall Management Center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

  - The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.

- Load Distribution dashboard—Displays load distribution across the cluster nodes in two widgets:
  - The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
  - The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.
- Member Performance dashboard—Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard—Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links — Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range—An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard—Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

Viewing Cluster Health

You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

- Ensure you have created a cluster from one or more devices in the Firewall Management Center.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

Step 2 In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.

Step 3 To view the cluster health statistics, click on the cluster name. The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution — Traffic and packet distribution across the cluster nodes.
- Member Performance — Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL — Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, see Cisco Secure Firewall Threat Defense Health Metrics.

Step 4 You can configure the time range from the drop-down in the upper-right corner. The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

Step 6 (For node-specific health monitor) View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

Step 7 (For node-specific health monitor) The device monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU — CPU utilization, including the CPU usage by process and by physical cores.
- Memory — Device memory utilization, including data plane and Snort memory usage.
- Interfaces — Interface status and aggregate traffic statistics.
- Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort — Statistics that are related to the Snort process.
- ASP drops — Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. See Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 8 Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Cluster Metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

Table 51: Cluster Metrics

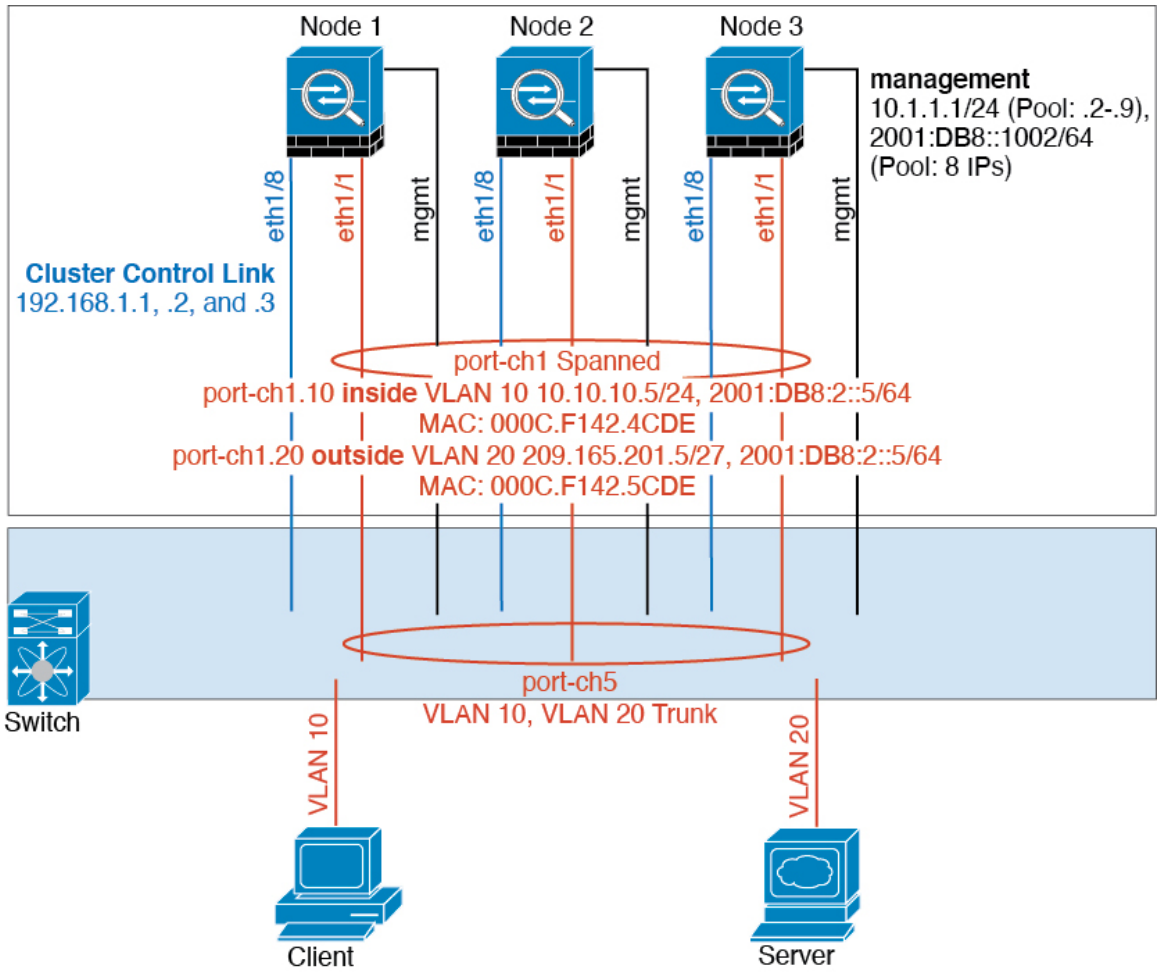
Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number
Distribution	Connection distribution count in the cluster for every second.	number

Metric	Description	Format
Packets	Packet distribution count in the cluster for every second.	number

Examples for Clustering

These examples include examples for typical deployments.

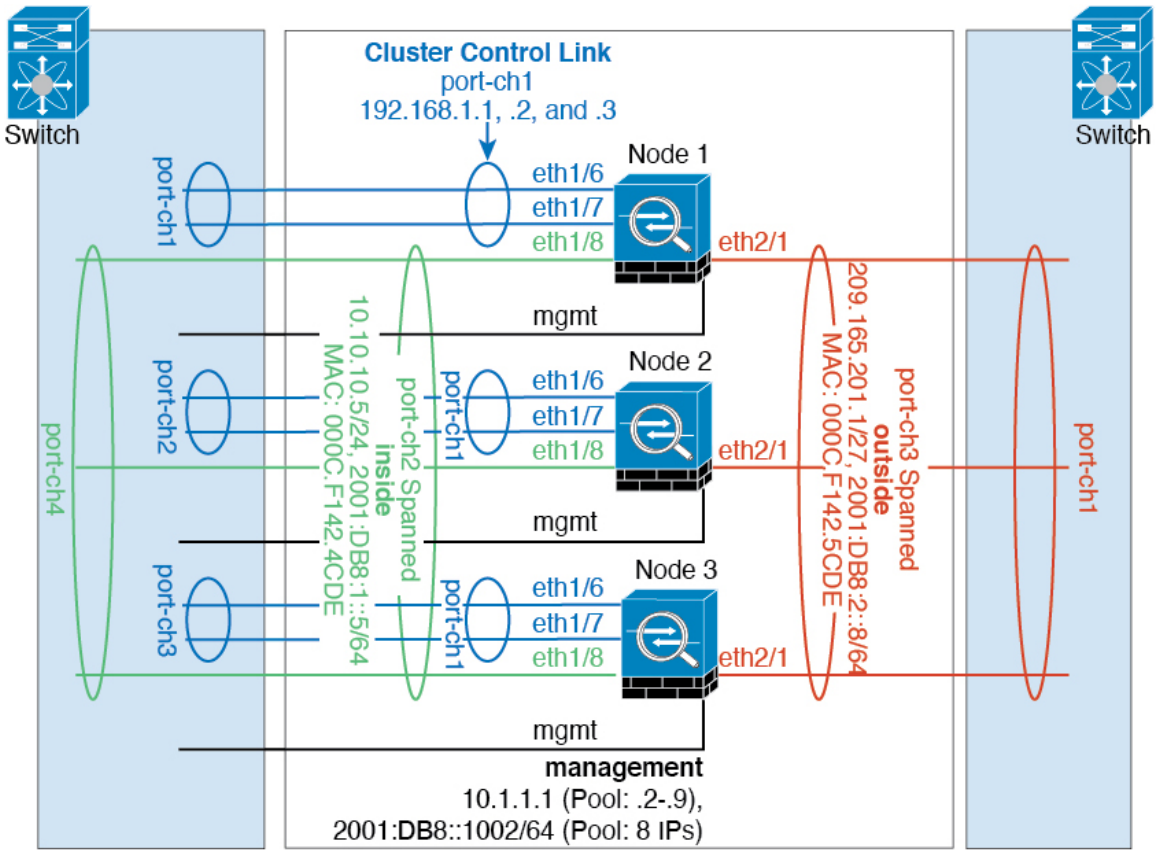
Firewall on a Stick



Data traffic from different security domains are associated with different VLANs, for example, VLAN 10 for the inside network and VLAN 20 for the outside network. Each has a single physical port connected to the external switch or router. Trunking is enabled so that all packets on the physical link are 802.1q encapsulated. The is the firewall between VLAN 10 and VLAN 20.

When using Spanned EtherChannels, all data links are grouped into one EtherChannel on the switch side. If the becomes unavailable, the switch will rebalance traffic between the remaining units.

Traffic Segregation



You may prefer physical separation of traffic between the inside and outside network.

As shown in the diagram above, there is one Spanned EtherChannel on the left side that connects to the inside switch, and the other on the right side to outside switch. You can also create VLAN subinterfaces on each EtherChannel if desired.

Reference for Clustering

This section includes more information about how clustering operates.

Firewall Threat Defense Features and Clustering

Some Firewall Threat Defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported Features with Clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

Note To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Firewall Management Center GUI. See FlexConfig Policies, on page 2645.

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- Firewall Management Center UCAPL/CC mode
- DHCP client, server, and proxy. DHCP relay is supported.

Centralized Features for Clustering

The following features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Firewall Management Center GUI. See FlexConfig Policies, on page 2645.

- The following application inspections:
  - DCERPC
  - ESMTP
  - NetBIOS
  - PPTP
  - RSH
  - SQLNET

- SUNRPC
- TFTP
- XDMCP

- Static route monitoring
- Site-to-site VPN
- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Dynamic routing

Connection Settings and Clustering

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

FTP and Clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

Multicast Routing in Individual Interface Mode

In Individual interface mode, units do not act independently with multicast. All data and routing packets are processed and forwarded by the control unit, thus avoiding packet replication.

NAT and Clustering

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different Firewall Threat Defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the Firewall Threat Defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.

- Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
- On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
- When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.

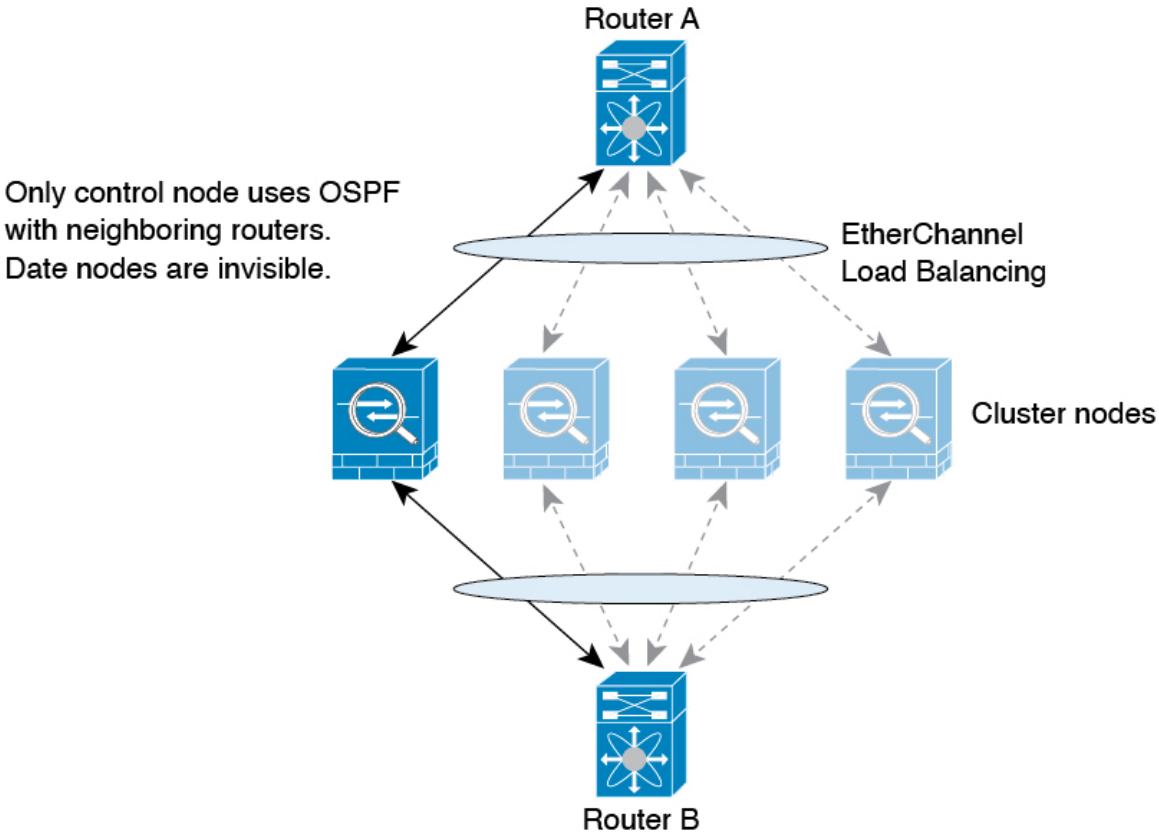
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP
  - RSH
  - SQLNET
  - TFTP
  - XDMCP
  - SIP

- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

Dynamic Routing

The routing process only runs on the control node, and routes are learned through the control node and replicated to data nodes. If a routing packet arrives at a data node, it is redirected to the control node.

Figure 180: Dynamic Routing in Spanned EtherChannel Mode



After the data node learn the routes from the control node, each node makes forwarding decisions independently.

The OSPF LSA database is not synchronized from the control node to data nodes. If there is a control node switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

SIP Inspection and Clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and Clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and Clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

Cisco TrustSec and Clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

VPN and Clustering

Site-to-site VPN is a centralized feature; only the control node supports VPN connections.

Note Remote access VPN is not supported with clustering.

VPN functionality is limited to the control node and does not take advantage of the cluster high availability capabilities. If the control node fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control node is elected, you must reestablish the VPN connections.

When you connect a VPN tunnel to a Spanned EtherChannel address, connections are automatically forwarded to the control node.

VPN-related keys and certificates are replicated to all nodes.

Performance Scaling Factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

For example, if your model can handle approximately 10 Gbps of traffic when running alone, then for a cluster of 8 units, the maximum combined throughput will be approximately 80% of 80 Gbps (8 units x 10 Gbps): 64 Gbps.

Control Node Election

Nodes of the cluster communicate over the cluster control link to elect a control node as follows:

1. When you enable clustering for a node (or when it first starts up with clustering already enabled), it broadcasts an election request every 3 seconds.
2. Any other nodes with a higher priority respond to the election request; the priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a node does not receive a response from another node with a higher priority, then it becomes the control node.

Note If multiple nodes tie for the highest priority, the cluster node name and then the serial number is used to determine the control node.

4. If a node later joins the cluster with a higher priority, it does not automatically become the control node; the existing control node always remains as the control node unless it stops responding, at which point a new control node is elected.
5. In a "split brain" scenario when there are temporarily multiple control nodes, then the node with highest priority retains the role while the other nodes return to data node roles.

Note You can manually force a node to become the control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node.

High Availability Within the Cluster

Clustering provides high availability by monitoring node and interface health and by replicating connection states between nodes.

Node Health Monitoring

Each node periodically sends a broadcast heartbeat packet over the cluster control link. If the control node does not receive any heartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining nodes.

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role.

See Control Node Election, on page 653 for more information.

Interface Monitoring

Each node monitors the link status of all named hardware interfaces in use, and reports status changes to the control node.

- Spanned EtherChannel—Uses cluster Link Aggregation Control Protocol (cLACP). Each node monitors the link status and the cLACP protocol messages to determine if the port is still active in the EtherChannel. The status is reported to the control node.

When you enable health monitoring, all physical interfaces (including the main EtherChannel) are monitored by default; you can optionally disable monitoring per interface. Only named interfaces can be monitored. For example, the named EtherChannel must fail to be considered failed, which means all member ports of an EtherChannel must fail to trigger cluster removal.

A node is removed from the cluster if its monitored interfaces fail. The amount of time before the Firewall Threat Defense removes a member from the cluster depends on whether the node is an established member or is joining the cluster. If the interface is down on an established member, then the Firewall Threat Defense removes the member after 9 seconds. The Firewall Threat Defense does not monitor interfaces for the first 90 seconds that a node joins the cluster. Interface status changes during this time will not cause the Firewall Threat Defense to be removed from the cluster. For non-EtherChannels, the node is removed after 500 ms, regardless of the member state.

Status After Failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The Firewall Threat Defense automatically tries to rejoin the cluster, depending on the failure event.

Note When the Firewall Threat Defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoining the Cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The Firewall Threat Defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The Firewall Threat Defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the Firewall Threat Defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means

the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The Firewall Threat Defense application attempts to rejoin the cluster every 5 seconds.

- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from Firewall Management Center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

Data Path Connection State Replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 52: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—
Dynamic routing	Yes	—
SNMP Engine ID	**No**	—

How the Cluster Manages Connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection Roles

See the following roles defined for each connection:

- Owner—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.

- Backup owner—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

  As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

  For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.

- Director—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

  As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

  ICMP/ICMPv6 hash details:

  - For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.

- Forwarder—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- Fragment Owner—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new

connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

Port Address Translation Connections

New Connection Ownership

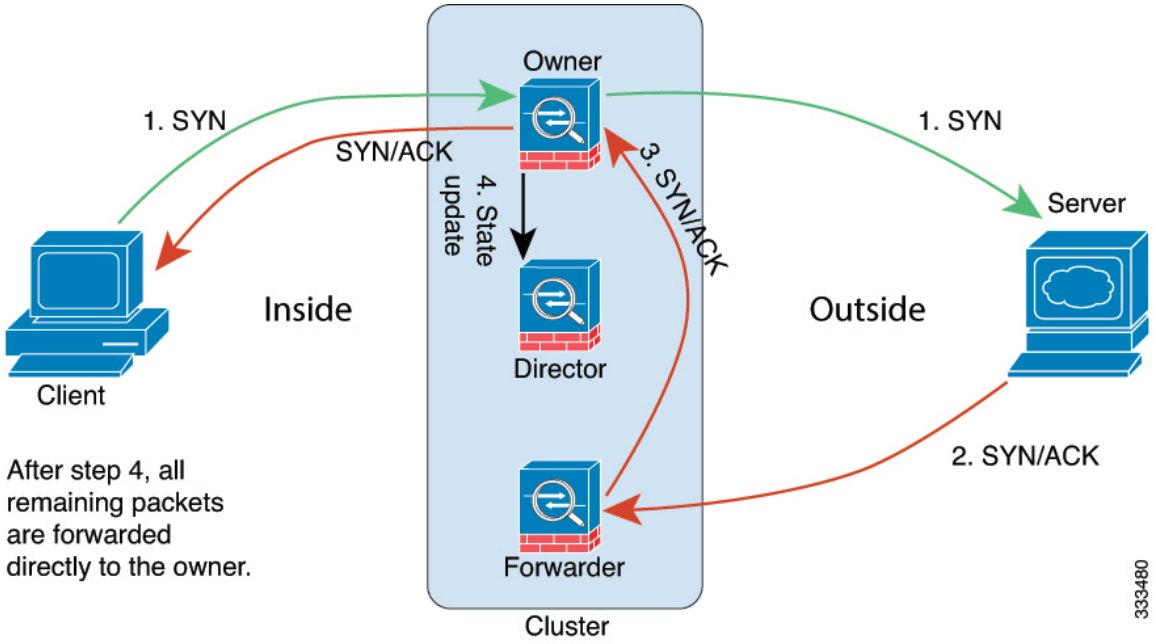
When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

Traffic redirection is not supported in this release. When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. All the subsequent packets for the same connection should arrive the same node. If any connection packets arrive at a different node, they will be dropped. If a reverse flow arrives at a different node, it will be dropped as well. For centralized features, if the connections do not arrive on the control node, they will be dropped.

By default, AWS GWLB uses 5-tuple to maintain flow stickiness. It is recommended to enable 2-tuple or 3-tuple stickiness on AWS GWLB to ensure the same flows are sent to the same node.

Sample Data Flow for TCP

The following example shows the establishment of a new connection.



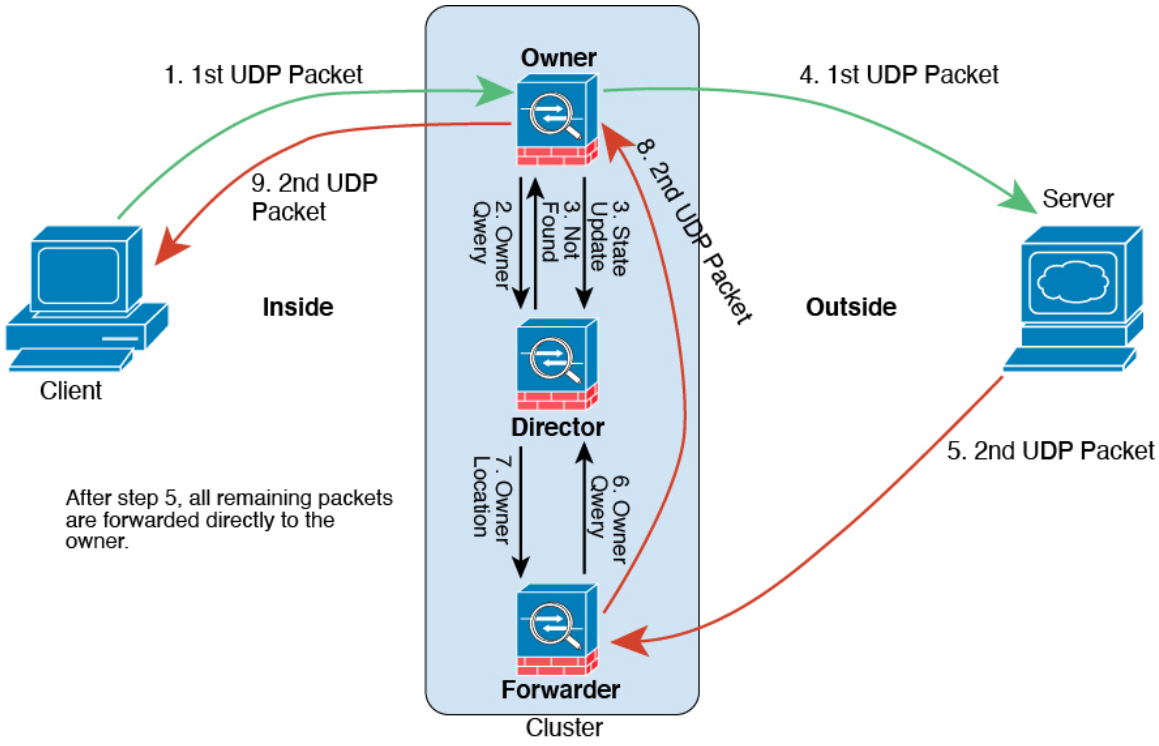
1. The SYN packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different Firewall Threat Defense (based on the load balancing method). This Firewall Threat Defense is the forwarder.

3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample Data Flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. ***Figure 181: ICMP and UDP Data Flow***



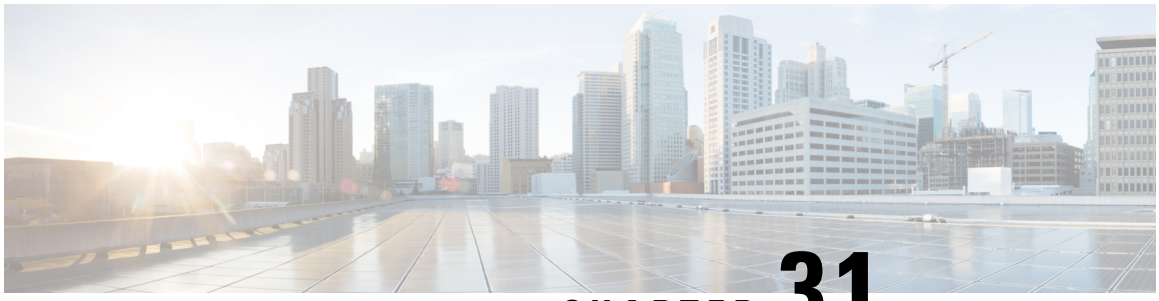
The first UDP packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.

5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

History for Clustering

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Cluster health monitor settings	20221213	Any	You can now edit cluster health monitor settings. New/modified screens: **Devices** > **Device Management** > **Cluster** > **Cluster Health Monitor Settings** **Note** If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.
Cluster health monitor dashboard	20221213	Any	You can now view cluster health on the cluster health monitor dashboard. New/modified screens: **System** > **Health** > **Monitor**
Automatic configuration of the cluster control link MTU	20220609	7.2.0	The MTU of the cluster control link interface is now automatically set to 100 bytes more than the highest data interface MTU; by default, the MTU is 1600 bytes.
Clustering for the Secure Firewall 3100	20220609	7.1.0	The Secure Firewall 3100 supports Spanned EtherChannel clustering for up to 8 nodes. New/modified screens: • **Devices** > **Device Management** > **Add Cluster** • **Devices** > **Device Management** > **More** menu • **Devices** > **Device Management** > **Cluster** Supported platforms: Secure Firewall 3100



CHAPTER 31

Clustering for Threat Defense Virtual in a Private Cloud

Clustering lets you group multiple Firewall Threat Defense Virtuals together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. You can deploy Firewall Threat Defense Virtual clusters in a private cloud using VMware and KVM. Only routed firewall mode is supported.

Note Some features are not supported when using clustering. See Unsupported Features and Clustering, on page 696.

About Threat Defense Virtual Clustering in the Private Cloud

This section describes the clustering architecture and how it works.

How the Cluster Fits into Your Network

The cluster consists of multiple firewalls acting as a single device. To act as a cluster, the firewalls need the following infrastructure:

- Isolated network for intra-cluster communication, known as the *cluster control link*, using VXLAN interfaces. VXLANs, which act as Layer 2 virtual networks over Layer 3 physical networks, let the Firewall Threat Defense Virtual send broadcast/multicast messages over the cluster control link.

- Management access to each firewall for configuration and monitoring. The Firewall Threat Defense Virtual deployment includes a Management 0/0 interface that you will use to manage the cluster nodes.

When you place the cluster in your network, the upstream and downstream routers need to be able to load-balance the data coming to and from the cluster using Layer 3 Individual interfaces and one of the following methods:

- Policy-Based Routing—The upstream and downstream routers perform load balancing between nodes using route maps and ACLs.
- Equal-Cost Multi-Path Routing—The upstream and downstream routers perform load balancing between nodes using equal cost static or dynamic routes.

Note Layer 2 Spanned EtherChannels are not supported.

Control and Data Node Roles

One member of the cluster is the control node. If multiple cluster nodes come online at the same time, the control node is determined by the priority setting; the priority is set between 1 and 100, where 1 is the highest priority. All other members are data nodes. When you first create the cluster, you specify which node you want to be the control node, and it will become the control node simply because it is the first node added to the cluster.

All nodes in the cluster share the same configuration. The node that you initially specify as the control node will overwrite the configuration on the data nodes when they join the cluster, so you only need to perform initial configuration on the control node before you form the cluster.

Some features do not scale in a cluster, and the control node handles all traffic for those features.

Individual Interfaces

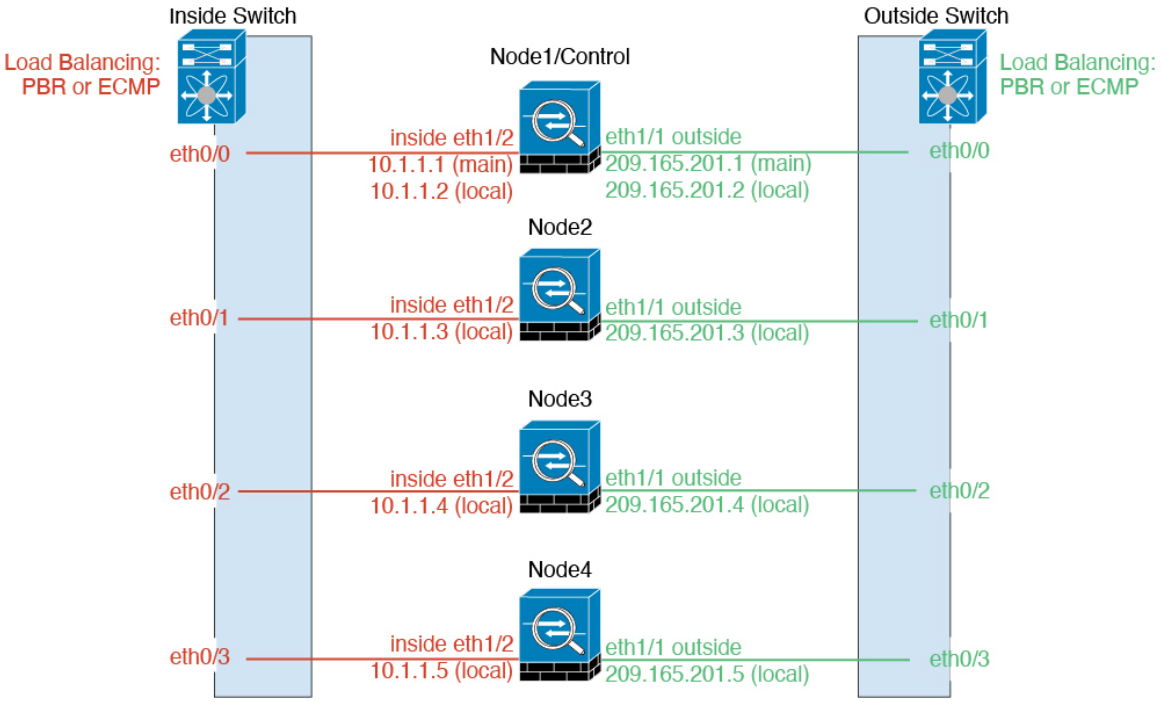
You can configure cluster interfaces as *Individual interfaces*.

Individual interfaces are normal routed interfaces, each with their own *Local IP address* used for routing. The *Main cluster IP address* for each interface is a fixed address that always belongs to the control node. When the control node changes, the Main cluster IP address moves to the new control node, so management of the cluster continues seamlessly.

IPS-only interfaces (inline sets and passive interfaces) are not supported as Individual interfaces.

Because interface configuration must be configured only on the control node, you configure a pool of IP addresses to be used for a given interface on the cluster nodes, including one for the control node.

Load balancing must be configured separately on the upstream switch.



Note Layer 2 Spanned EtherChannels are not supported.

Policy-Based Routing

When using Individual interfaces, each Firewall Threat Defense interface maintains its own IP address and MAC address. One method of load balancing is Policy-Based Routing (PBR).

We recommend this method if you are already using PBR, and want to take advantage of your existing infrastructure.

PBR makes routing decisions based on a route map and ACL. You must manually divide traffic between all Firewall Threat Defenses in a cluster. Because PBR is static, it may not achieve the optimum load balancing result at all times. To achieve the best performance, we recommend that you configure the PBR policy so that forward and return packets of a connection are directed to the same Firewall Threat Defense. For example, if you have a Cisco router, redundancy can be achieved by using Cisco IOS PBR with Object Tracking. Cisco IOS Object Tracking monitors each Firewall Threat Defense using ICMP ping. PBR can then enable or disable route maps based on reachability of a particular Firewall Threat Defense. See the following URLs for more details:

http://www.cisco.com/c/en/us/solutions/data-center-virtualization/intelligent-traffic-director/index.html

http://www.cisco.com/en/US/products/ps6599/products_white_paper09186a00800a4409.shtml

Equal-Cost Multi-Path Routing

When using Individual interfaces, each Firewall Threat Defense interface maintains its own IP address and MAC address. One method of load balancing is Equal-Cost Multi-Path (ECMP) routing.

We recommend this method if you are already using ECMP, and want to take advantage of your existing infrastructure.

ECMP routing can forward packets over multiple “best paths” that tie for top place in the routing metric. Like EtherChannel, a hash of source and destination IP addresses and/or source and destination ports can be used to send a packet to one of the next hops. If you use static routes for ECMP routing, then the Firewall Threat Defense failure can cause problems; the route continues to be used, and traffic to the failed Firewall Threat Defense will be lost. If you use static routes, be sure to use a static route monitoring feature such as Object Tracking. We recommend using dynamic routing protocols to add and remove routes, in which case, you must configure each Firewall Threat Defense to participate in dynamic routing.

Cluster Control Link

Each node must dedicate one interface as a VXLAN (VTEP) interface for the cluster control link. For more information about VXLAN, see Configure VXLAN Interfaces, on page 940.

VXLAN Tunnel Endpoint

VXLAN tunnel endpoint (VTEP) devices perform VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

VTEP Source Interface

The VTEP source interface is a regular Firewall Threat Defense Virtual interface with which you plan to associate the VNI interface. You can configure one VTEP source interface to act as the cluster control link. The source interface is reserved for cluster control link use only. Each VTEP source interface has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the cluster control link interfaces.

VNI Interface

A VNI interface is similar to a VLAN interface: it is a virtual interface that keeps network traffic separated on a given physical interface by using tagging. You can only configure one VNI interface. Each VNI interface has an IP address on the same subnet.

Peer VTEPs

Unlike regular VXLAN for data interfaces, which allows a single VTEP peer, The Firewall Threat Defense Virtual clustering allows you to configure multiple peers.

Cluster Control Link Traffic Overview

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Control node election.
- Configuration replication.
- Health monitoring.

Data traffic includes:

- State replication.
- Connection ownership queries and data packet forwarding.

Configuration Replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Management Network

You must manage each node using the Management interface; management from a data interface is not supported with clustering.

Licenses for Threat Defense Virtual Clustering

Each Firewall Threat Defense Virtual cluster node requires the same performance tier license. We recommend using the same number of CPUs and memory for all members, or else performance will be limited on all nodes to match the least capable member. The throughput level will be replicated from the control node to each data node so they match.

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add the control node to the Firewall Management Center, you can specify the feature licenses you want to use for the cluster. Before you create the cluster, it doesn't matter which licenses are assigned to the data nodes; the license settings for the control node are replicated to each of the data nodes. You can modify licenses for the cluster by clicking **Edit Licenses** in **System** (⚙) > **Licenses** > **Smart Licenses** or choosing **Devices** > **Device Management**, clicking **Edit** (✎) for the cluster, and then in the **License** area, clicking **Edit** (✎).

Note If you add the cluster before the Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Requirements and Prerequisites for Threat Defense Virtual Clustering

Model Requirements

- FTDv5, FTDv10, FTDv20, FTDv30, FTDv50, FTDv100
- VMware or KVM
- A maximum of 4 nodes in a cluster in a 2x2 configuration is supported. You can set up a maximum of two hosts with a maximum of two threat defense virtual instances in each host.

Hardware and Software Requirements

All units in a cluster:

- Must have jumbo frame reservation enabled for the cluster control link. Do this in the Day 0 configuration when you deploy the Firewall Threat Defense Virtual by setting `"DeploymentType": "Cluster"`. Otherwise, you must restart each node to enable jumbo frames after the cluster has formed and is healthy.
- (KVM only) Must use CPU hard partitioning (CPU pinning) for all VMs on the KVM host.
- Must be the same performance tier. We recommend using the same number of CPUs and memory for all nodes, or performance will be limited on all nodes to match the least capable node.
- Must use the management interface for Firewall Management Center communications. Data interface management is not supported.
- Must run the same version, except during upgrade. Hitless upgrade is supported.
- Must be in the same group.
- Must not have any deployment pending or in progress.
- Must not have any unsupported features configured on the control node: Unsupported Features and Clustering, on page 696.
- Must not have VPN configured on the data nodes. The control node can have site-to-site VPN configured.

Firewall Management Center Requirements

Make sure the Firewall Management Center NTP server is set to a reliable server that is reachable by all cluster nodes to ensure proper clock sync. By default, the device uses the same NTP server as the Firewall Management Center. If the time is not set to be the same on all cluster nodes, they can be removed automatically from the cluster.

Switch Requirements

Be sure to complete the switch configuration before you configure clustering. Make sure the ports connected to the cluster control link have the correct (higher) MTU configured. By default, the cluster control link MTU is set to 154 bytes higher than the data interfaces. If the switches have an MTU mismatch, the cluster formation will fail.

Guidelines for Threat Defense Virtual Clustering

High Availability

High Availability is not supported with clustering.

IPv6

The cluster control link is only supported using IPv4.

Additional Guidelines

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Firewall Threat Defense Virtual, adding an additional switch to form a VSS or vPC) you should disable the health check feature and also disable interface monitoring for the interfaces that are affected by the topology changes. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.
- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.
- We do not support VXLANs for data interfaces; only the cluster control link supports VXLAN.

Defaults for Clustering

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Configure Threat Defense Virtual Clustering

To configure clustering after you deploy your Firewall Threat Defense Virtuals, perform the following tasks.

Add Nodes to the Management Center

Before configuring clustering, deploy each cluster node, then add the devices as standalone units on the Firewall Management Center.

Procedure

Step 1 Deploy each cluster node according the Cisco Secure Firewall Threat Defense Virtual Getting Started Guide.

All units in a cluster:

- Must have jumbo frame reservation enabled for the cluster control link. Do this in the Day 0 configuration when you deploy the Firewall Threat Defense Virtual by setting `"DeploymentType": "Cluster"`. Otherwise, you must restart each node to enable jumbo frames after the cluster has formed and is healthy.
- (KVM only) Must use CPU hard partitioning (CPU pinning) for all VMs on the KVM host.

Step 2 Add each node to the Firewall Management Center as a standalone device in the same domain and group.

You can create a cluster with a single device, and then add more nodes later. The initial settings (licensing, access control policy) that you set when you add a device will be inherited by all cluster nodes from the control node. You will choose the control node when forming the cluster.

Create a Cluster

Form a cluster from one or more devices in the Firewall Management Center.

Before you begin

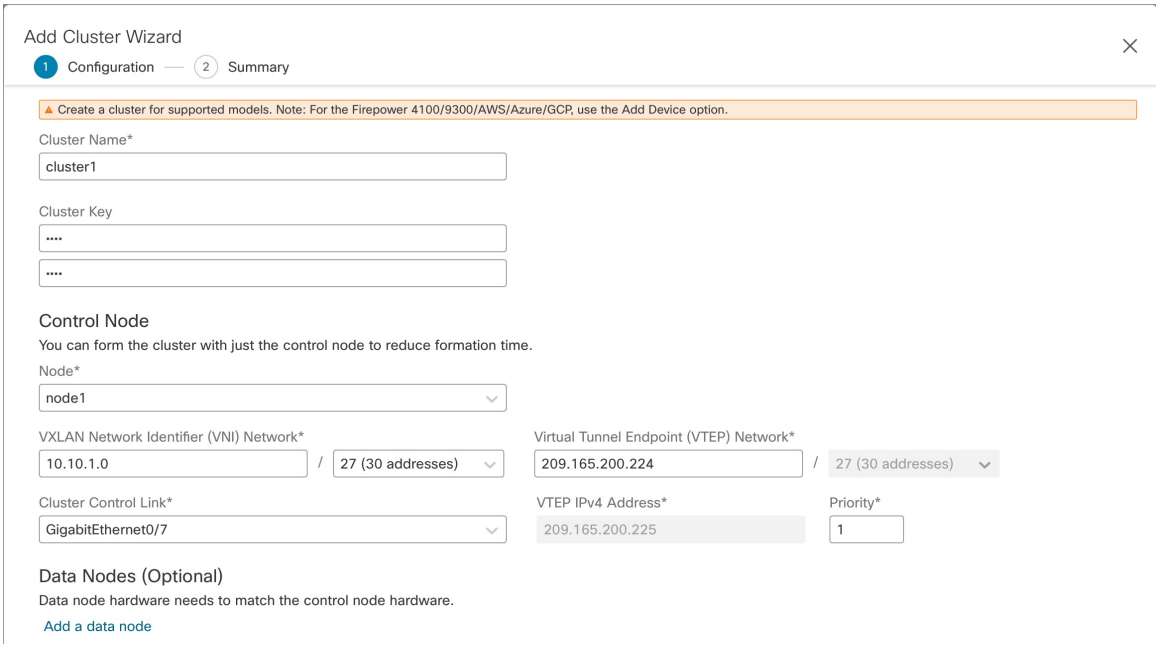
Some features are not compatible with clustering, so you should wait to perform configuration until after you enable clustering. Some features will block cluster creation if they are already configured. For example, do not configure any IP addresses on interfaces, or unsupported interface types such as BVIs.

Procedure

Step 1 Choose **Devices** > **Device Management**, and then choose **Add** > **Cluster**.

The **Add Cluster Wizard** appears.

Figure 182: Add Cluster Wizard



Step 2 Specify a **Cluster Name** and an authentication **Cluster Key** for control traffic.

- **Cluster Name**—An ASCII string from 1 to 38 characters.
- **Cluster Key**—An ASCII string from 1 to 63 characters. The **Cluster Key** value is used to generate the encryption key. This encryption does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in the clear.

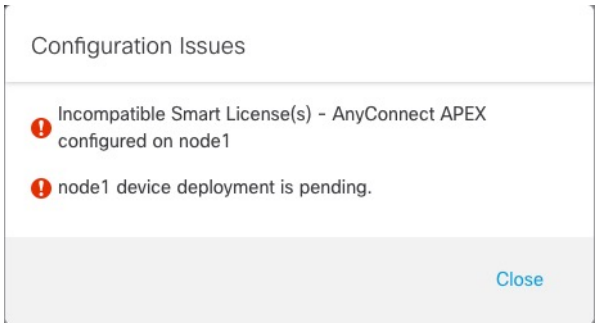
Step 3 For the **Control Node**, set the following:

- **Node**—Choose the device that you want to be the control node initially. When the Firewall Management Center forms the cluster, it will add this node to the cluster first so it will be the control node.

  Note

  If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation. For example:

  Figure 183: Configuration Issues



To resolve the above issues, remove the unsupported VPN license and deploy pending configuration changes to the device.

- **VXLAN Network Identifier (VNI) Network**—Specify an IPv4 subnet for the VNI network; IPv6 is not supported for this network. Specify a **24**, **25**, **26**, or **27** subnet. An IP address will be auto-assigned to each node on this network. The VNI network is the encrypted virtual network that runs on top of the physical VTEP network.
- **Cluster Control Link**—Choose the physical interface you want to use for the cluster control link.
- **Virtual Tunnel Endpoint (VTEP) Network**—Specify an IPv4 subnet for the physical interface network; IPv6 is not supported for this network. The VTEP network is a different network than the VNI network, and it is used for the physical cluster control link.
- **VTEP IPv4 Address**—This field will be auto-populated with the first address on the VTEP network.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority. Even if you set the priority to be lower than other nodes, this node will still be the control node when the cluster is first formed.

Step 4 For **Data Nodes (Optional)**, click **Add a data node** to add a node to the cluster.

You can form the cluster with only the control node for faster cluster formation, or you can add all nodes now. Set the following for each data node:

- **Node**—Choose the device that you want to add.

  Note

  If you see an **Error** ( ) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation.

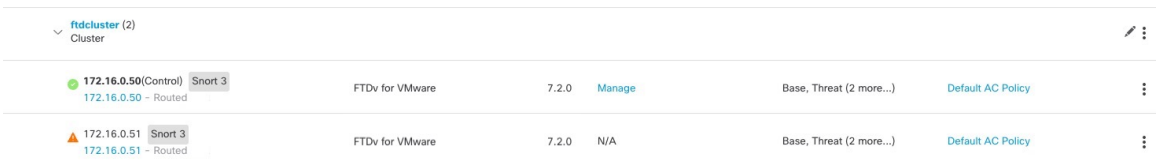
- **VTEP IPv4 Address**—This field will be auto-populated with the next address on the VTEP network.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority.

Step 5 Click **Continue**. Review the **Summary**, and then click **Save**.

The cluster bootstrap configuration is saved to the cluster nodes. The bootstrap configuration includes the VXLAN interface used for the cluster control link.

The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster nodes.

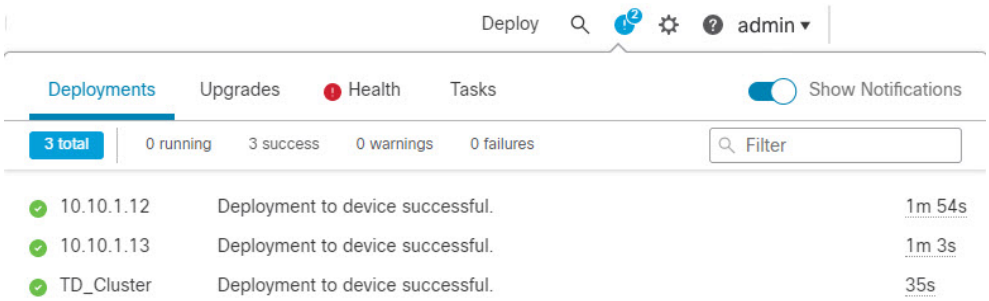
Figure 184: Cluster Management



A node that is currently registering shows the loading icon.

Figure 185: Node Registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**. The Firewall Management Center updates the Cluster Registration task as each node registers.

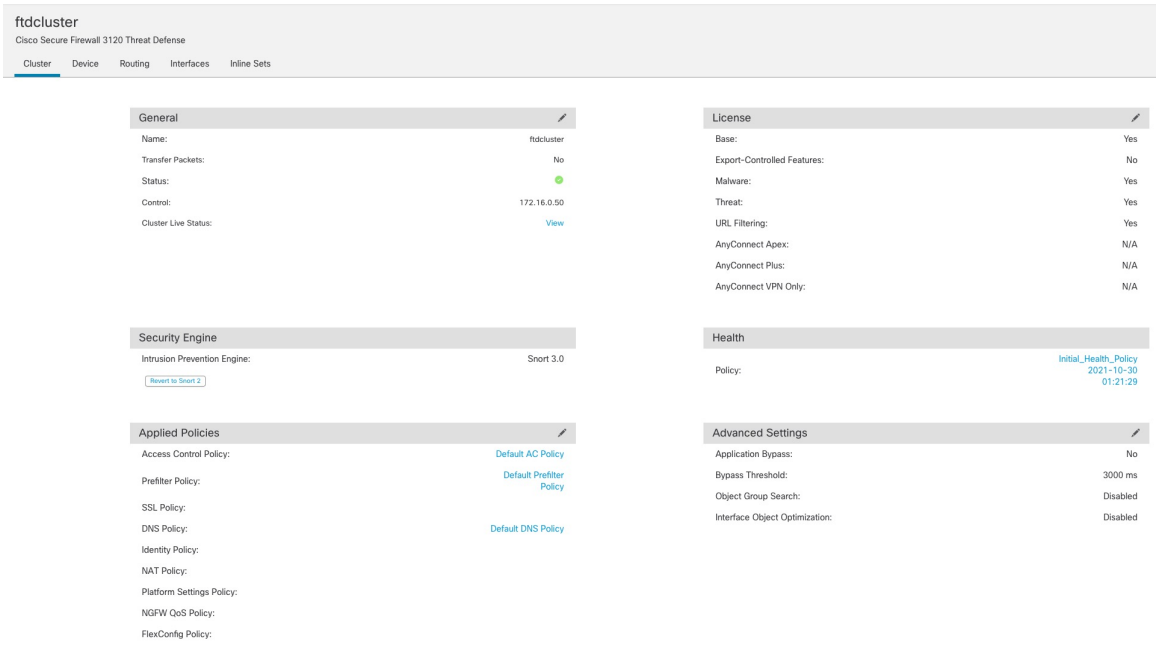


Step 6 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

Most configuration can be applied to the cluster as a whole, and not nodes in the cluster. For example, you can change the display name per node, but you can only configure interfaces for the whole cluster.

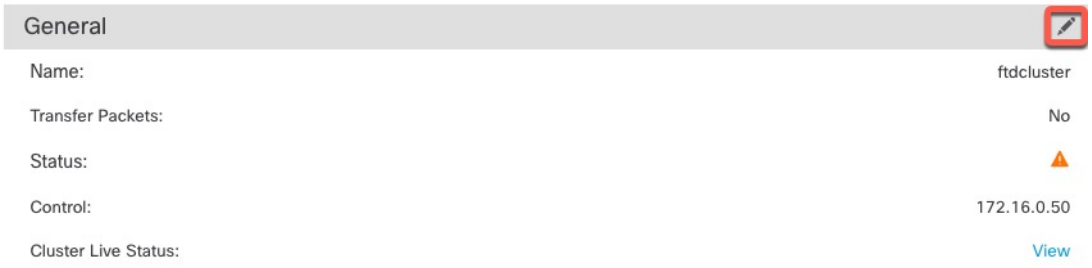
Step 7 On the **Devices** > **Device Management**, **Cluster** screen, you see **General** and other settings for the cluster.

Figure 186: Cluster Settings

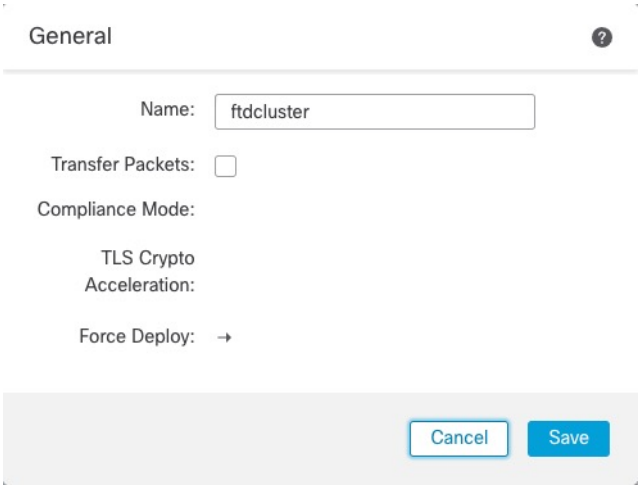


See the following cluster-specific items in the **General** area:

- **General > Name**—Change the cluster display name by clicking the **Edit** (✎).

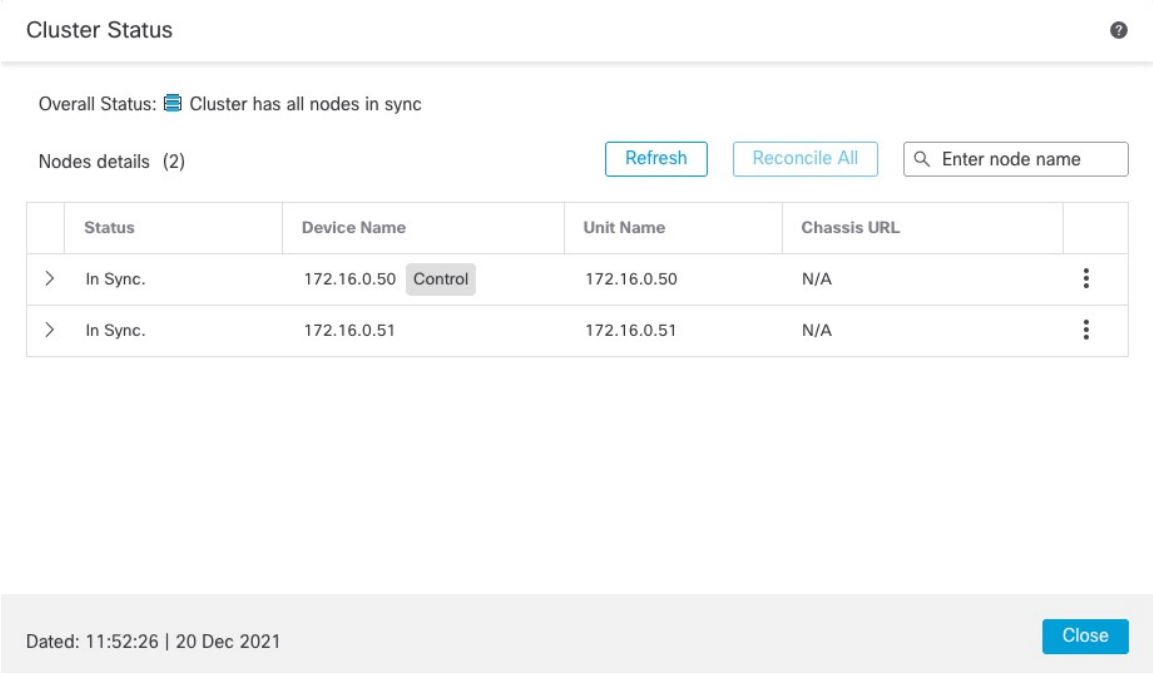


Then set the **Name** field.



- **General > View**—Click the **View** link to open the **Cluster Status** dialog box.

The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile All**.



Step 8 On the **Devices** > **Device Management** and then click **Add** > **Device**, you can choose each member in the cluster from the top right drop-down menu and configure the following settings.

Figure 187: Device Settings

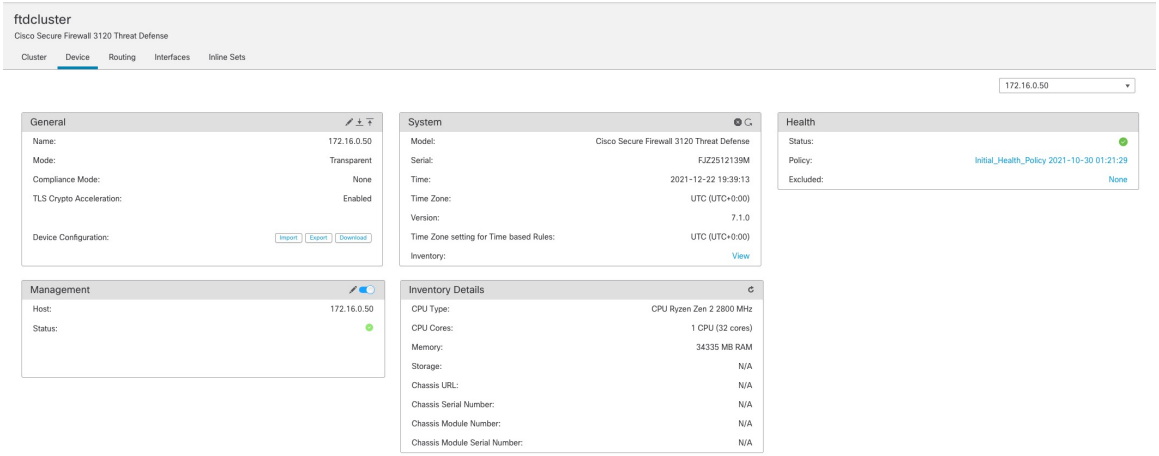


Figure 188: Choose Node

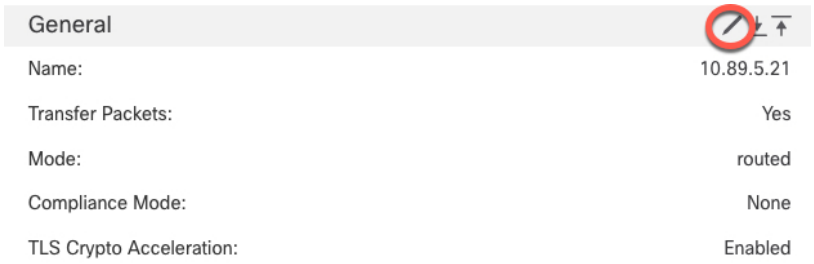
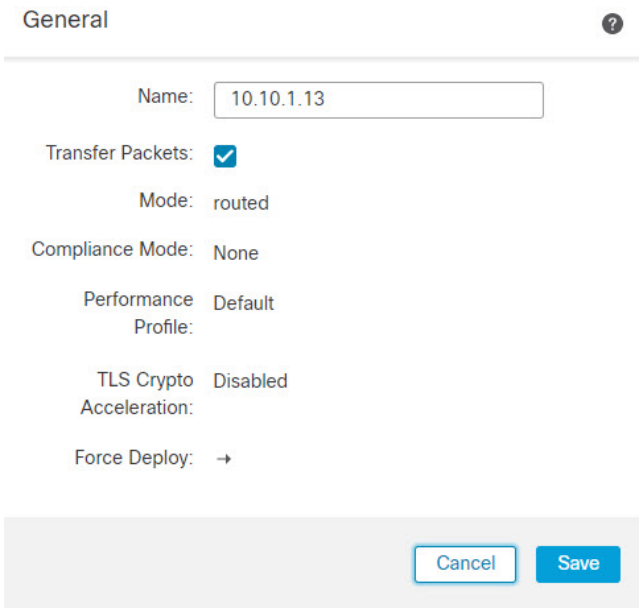
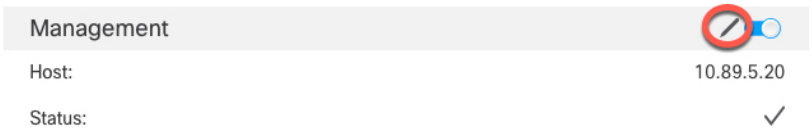
- **General > Name**—Change the cluster member display name by clicking the **Edit** ( ).



Then set the **Name** field.



- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the Firewall Management Center so that it can reach the device on the network. First disable the connection, edit the **Host** address in the **Management** area, then re-enable the connection.



Step 9 If you deployed your cluster nodes without enabling jumbo-frame reservation, then restart all cluster nodes to enable jumbo frames, which are required for the cluster control link. See Shut Down or Restart the Device, on page 70.

If you previously enabled jumbo-frame reservation, you can skip this step.

Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead (100 bytes) and VXLAN overhead (54 bytes). When you create the cluster, the MTU is set to 154 bytes higher than the highest data interface MTU (1654 by default). If you later increase the data interface MTU, be sure to also increase the cluster control link MTU. For example, because the maximum MTU is 9198 bytes, then the highest data interface MTU can be 9044, while the cluster control link can be set to 9198. See Configure the MTU, on page 973.

Note
Make sure you configure switches connected to the cluster control link to the correct (higher) MTU; otherwise, cluster formation will fail.

Configure Interfaces

This section describes how to configure interfaces to be Individual interfaces compatible with clustering. Individual interfaces are normal routed interfaces, each with their own IP address taken from a pool of IP addresses. The Main cluster IP address is a fixed address for the cluster that always belongs to the current control node. All data interfaces must be Individual interfaces.

Note You cannot use subinterfaces.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Address Pools** to add an IPv4 and/or IPv6 address pool. See Address Pools, on page 1446.

Include at least as many addresses as there are units in the cluster. The Virtual IP address is not a part of this pool, but needs to be on the same network. You cannot determine the exact Local address assigned to each unit in advance.

Step 2 Choose **Devices** > **Device Management**, and click **Edit** (✎) next to the cluster.

Step 3 Click **Interfaces**, and then click **Edit** (✎) for a data interface.

Step 4 On the **IPv4**, enter the **IP Address** and mask. This IP address is a fixed address for the cluster, and always belongs to the current control unit.

Step 5 From the **IPv4 Address Pool** drop-down list, choose the address pool you created.

Note
If you want to manually assign a MAC address to this interface, you need to create a **mac-address pool** using FlexConfig.

Step 6 On **IPv6** > **Basic**, from the **IPv6 Address Pool** drop-down list, choose the address pool you created.

Step 7 Configure other interface settings as normal.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Cluster Health Monitor Settings

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings described in the table below.

Figure 189: Cluster Health Monitor Settings

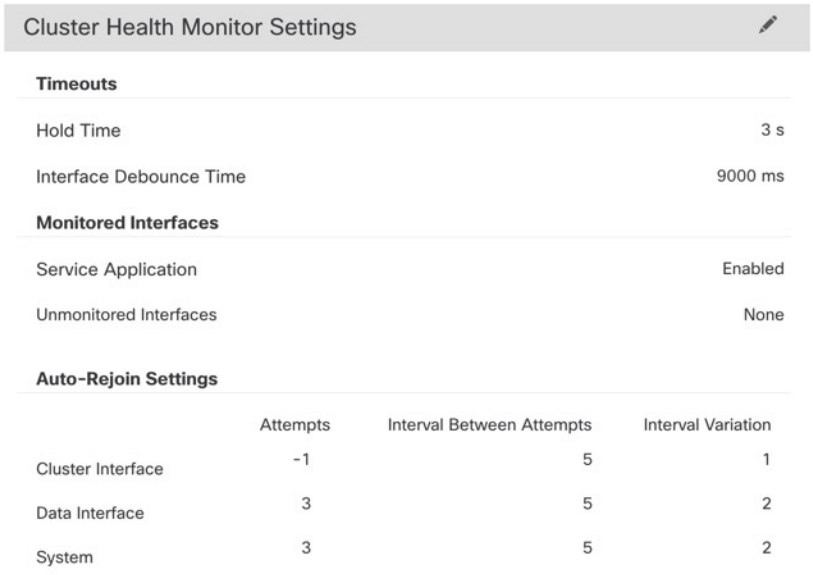


Table 53: Cluster Health Monitor Settings Section Table Fields

Field	Description
Timeouts	
Hold Time	Between .3 and 45 seconds; The default is 3 seconds. To determine node system health, the cluster nodes send heartbeat messages on the cluster control link to other nodes. If a node does not receive any heartbeat messages from a peer node within the hold time period, the peer node is considered unresponsive or dead.
Interface Debounce Time	Between 300 and 9000 ms. The default is 500 ms. The interface debounce time is the amount of time before the node considers an interface to be failed, and the node is removed from the cluster.
Monitored Interfaces	The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster.
Service Application	Shows whether the Snort and disk-full processes are monitored.
Unmonitored Interfaces	Shows unmonitored interfaces.
Auto-Rejoin Settings	
Cluster Interface	Shows the auto-rejoin settings after a cluster control link failure.

Field	Description
Attempts	Between -1 and 65535. The default is -1 (unlimited). Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 1x the interval duration. Defines if the interval duration increases at each attempt.
Data Interfaces	Shows the auto-rejoin settings after a data interface failure.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.
System	Shows the auto-rejoin settings after internal errors. Internal failures include: application sync timeout; inconsistent application statuses; and so on.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.

Note If you disable the system health check, fields that do not apply when the system health check is disabled will not show.

You can change these settings from this section.

You can monitor any port-channel ID, single physical interface ID, as well as the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link; it is always monitored.

Procedure

Step 1 Choose **Devices** > **Device Management**.

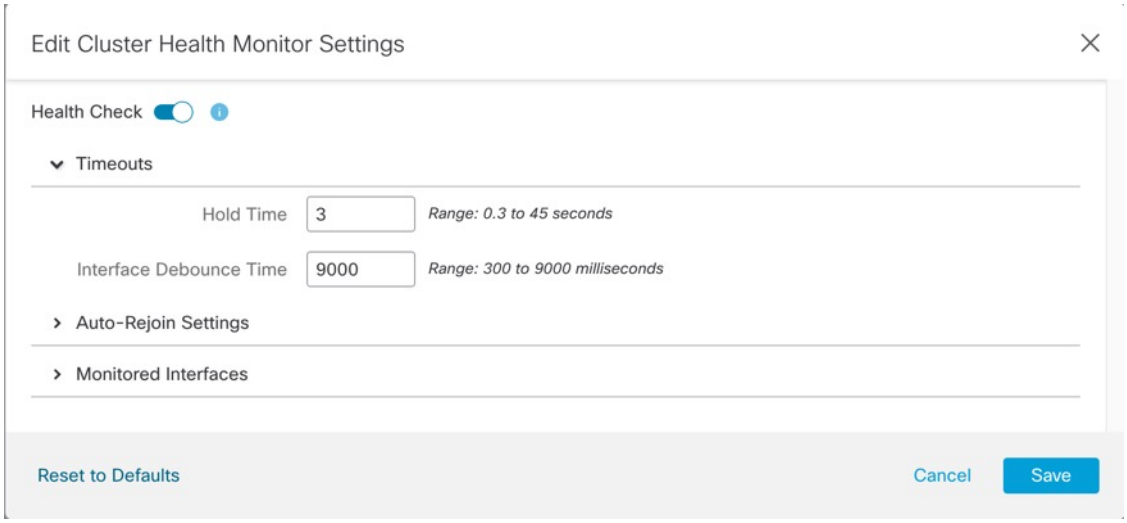
Step 2 Next to the cluster you want to modify, click **Edit** ( ).

Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider .

Figure 190: Disable the System Health Check



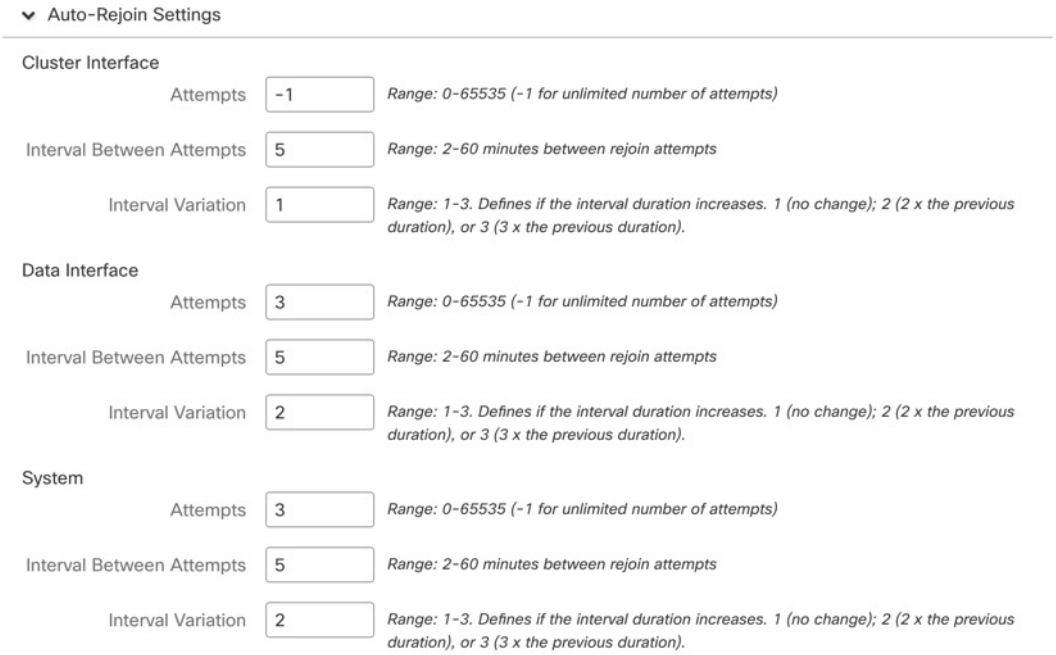
When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between .3 and 45 seconds; The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the number of milliseconds specified before marking the interface as failed, and the node is removed from the cluster. In the case of an EtherChannel that transitions from a down state to an up state (for example, the switch reloaded, or the switch enabled an EtherChannel), a longer debounce time can prevent the interface from appearing to be failed on a cluster node just because another cluster node was faster at bundling the ports.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 191: Configure Auto-Rejoin Settings

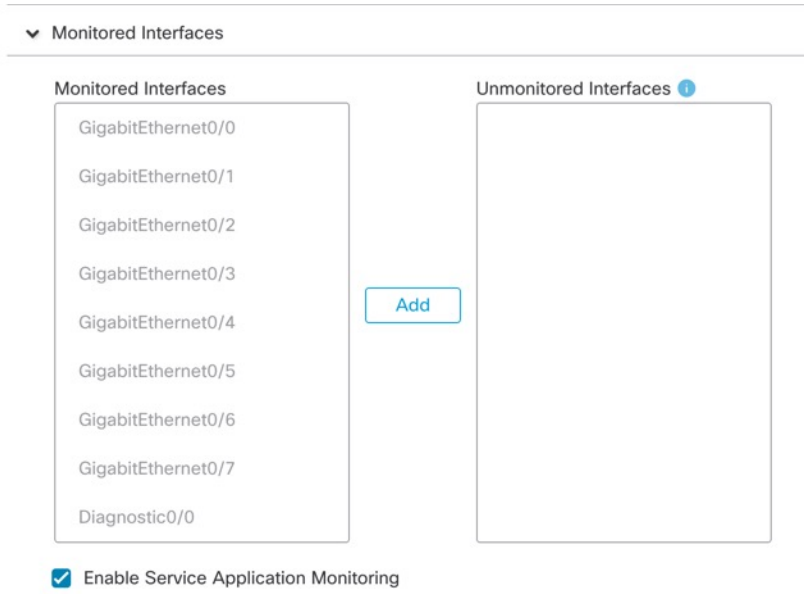


Set the following values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 192: Configure Monitored Interfaces



The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. Health check is enabled by default for all interfaces and for the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save**.

Step 10 Deploy configuration changes.

Manage Cluster Nodes

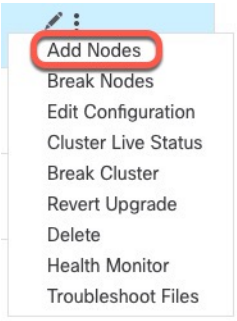
Add a New Cluster Node

You can add one or more new cluster nodes to an existing cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click the **More** (⋮) for the cluster, and choose **Add Nodes**.

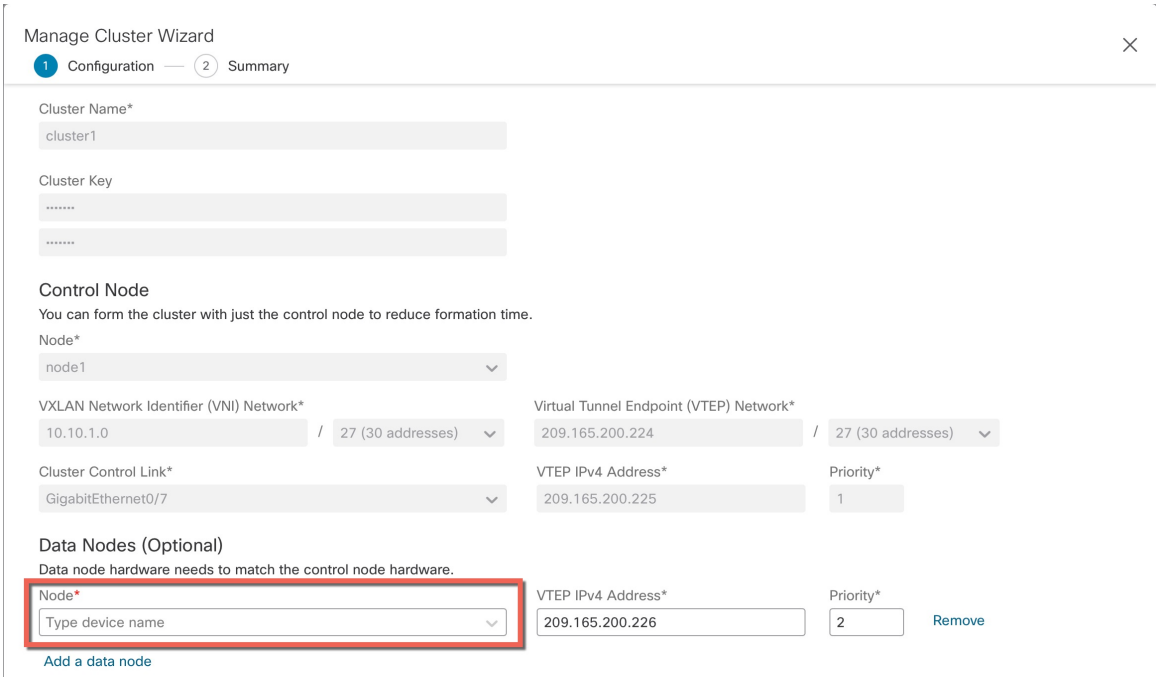
Figure 193: Add Nodes



The **Manage Cluster Wizard** appears.

Step 2 From the **Node** menu, choose a device, and adjust the IP address and priority if desired.

Figure 194: Manage Cluster Wizard

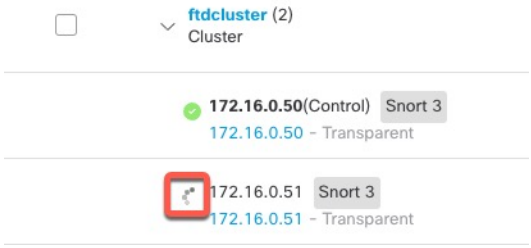


Step 3 To add additional nodes, click **Add a data node**.

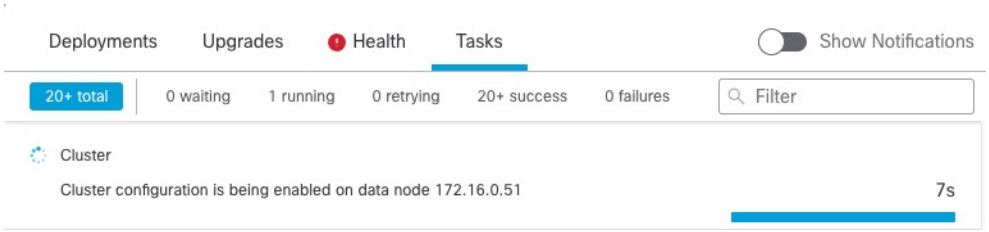
Step 4 Click **Continue**. Review the **Summary**, and then click **Save**

The node that is currently registering shows the loading icon.

Figure 195: Node Registration



You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**.



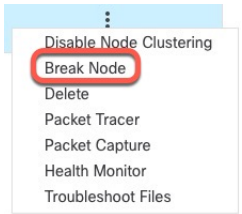
Break a Node

You can remove a node from the cluster so that it becomes a standalone device. You cannot break the control node unless you break the entire cluster. The data node has its configuration erased.

Procedure

Step 1 Choose **Devices** > **Device Management**, click the **More** (⋮) for the node you want to break, and choose **Break Node**.

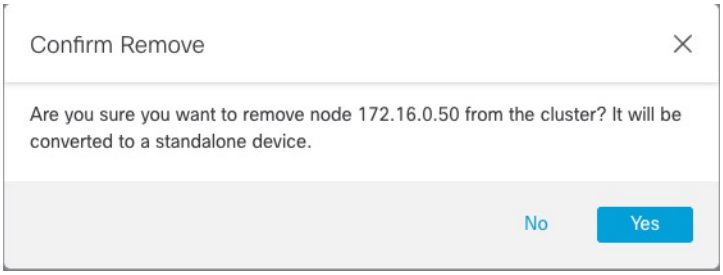
Figure 196: Break a Node



You can optionally break one or more nodes from the cluster More menu by choosing **Break Nodes**.

Step 2 You are prompted to confirm the break; click **Yes**.

Figure 197: Confirm Break



You can monitor the cluster node break by clicking the **Notifications** icon and choosing **Tasks**.

Break the Cluster

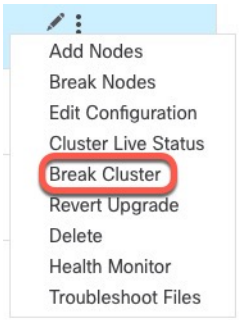
You can break the cluster and convert all nodes to standalone devices. The control node retains the interface and security policy configuration, while data nodes have their configuration erased.

Procedure

Step 1 Make sure all cluster nodes are being managed by the Firewall Management Center by reconciling nodes. See Reconcile Cluster Nodes, on page 688.

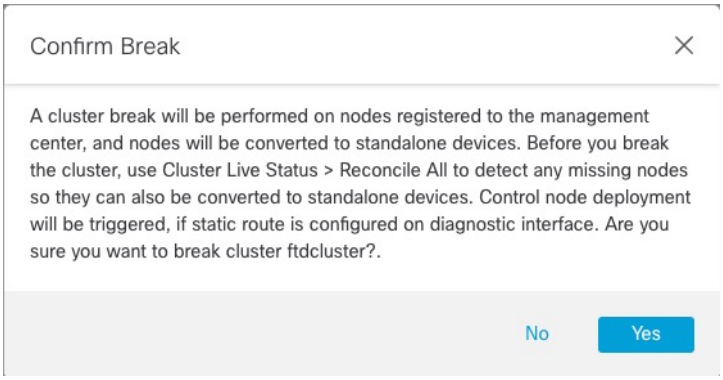
Step 2 Choose **Devices** > **Device Management**, click the **More** (⋮) for the cluster, and choose **Break Cluster**.

Figure 198: Break Cluster



Step 3 You are prompted to break the cluster; click **Yes**.

Figure 199: Confirm Break



You can monitor the cluster break by clicking the **Notifications** icon and choosing **Tasks**.

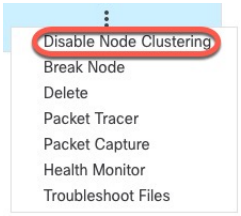
Disable Clustering

You may want to deactivate a node in preparation for deleting the node, or temporarily for maintenance. This procedure is meant to temporarily deactivate a node; the node will still appear in the Firewall Management Center device list. When a node becomes inactive, all data interfaces are shut down.

Procedure

Step 1 For the unit you want to disable, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Disable Node Clustering**.

Figure 200: Disable Clustering



If you disable clustering on the control node, one of the data nodes will become the new control node. Note that for centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node. You cannot disable clustering on the control node if it is the only node in the cluster.

Step 2 Confirm that you want to disable clustering on the node.

The node will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.

Step 3 To reenable clustering, see Rejoin the Cluster, on page 686.

Rejoin the Cluster

If a node was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster.

Procedure

Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management**, click **More** (⋮), and choose **Enable Node Clustering**.

Step 2 Confirm that you want to enable clustering on the node.

Change the Control Node

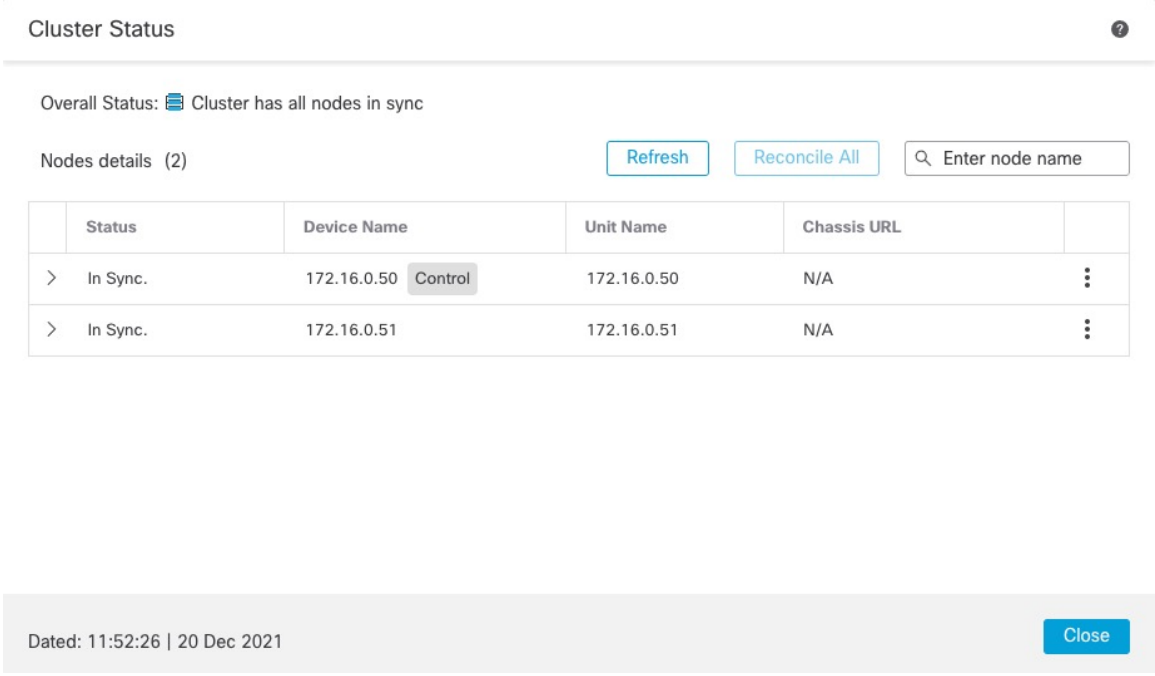
Caution The best method to change the control node is to disable clustering on the control node, wait for a new control election, and then re-enable clustering. If you must specify the *exact* unit you want to become the control node, use the procedure in this section. Note that for centralized features, if you force a control node change using either method, then all connections are dropped, and you have to re-establish the connections on the new control node.

To change the control node, perform the following steps.

Procedure

Step 1 Open the **Cluster Status** dialog box by choosing **Devices** > **Device Management**, **More** (⋮) > **Cluster Live Status**.

Figure 201: Cluster Status



Step 2 For the unit you want to become the control unit, choose **More** (⋮) > **Change Role to Control**.

Step 3 You are prompted to confirm the role change. Check the checkbox, and click **OK**.

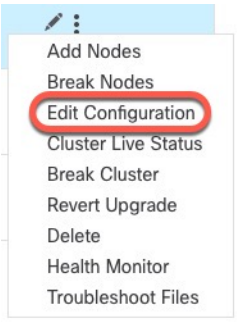
Edit the Cluster Configuration

You can edit the cluster configuration. If you change any values other than the VTEP IP address for a node or node priority, the cluster will be broken and reformed automatically. Until the cluster is reformed, you may experience traffic disruption. If you change the VTEP IP address for a node or node priority, only the affected nodes are broken and readded to the cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, click the **More** (⋮) for the cluster, and choose **Edit Configuration**.

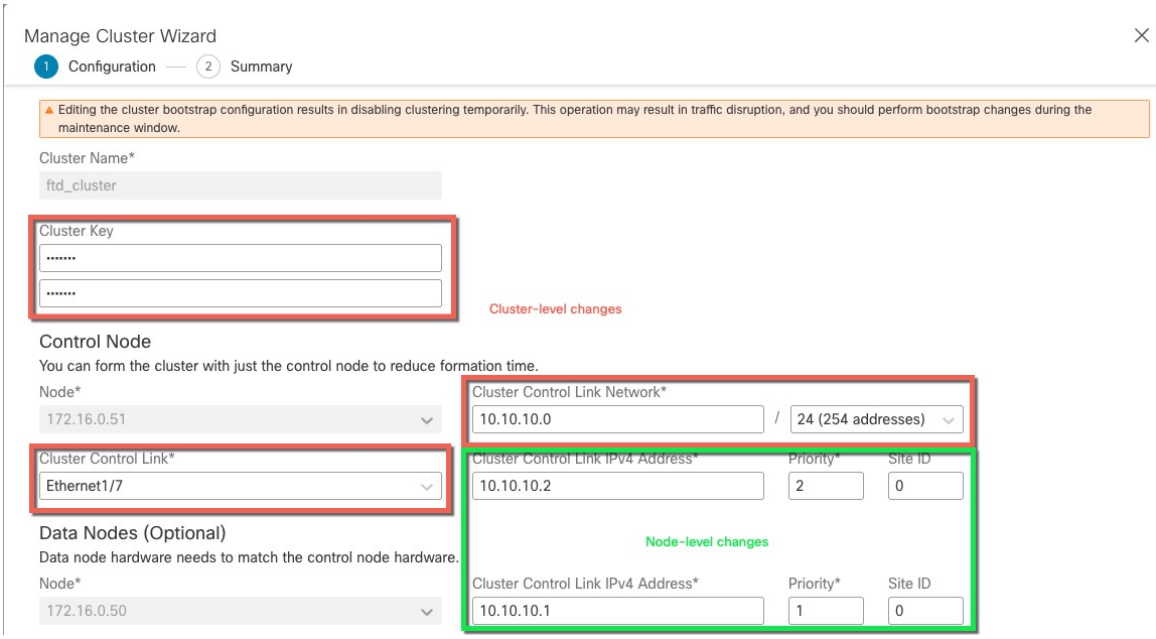
Figure 202: Edit Configuration



The **Manage Cluster Wizard** appears.

Step 2 Update the cluster configuration.

Figure 203: Manage Cluster Wizard



Step 3 Click **Continue**. Review the **Summary**, and then click **Save**

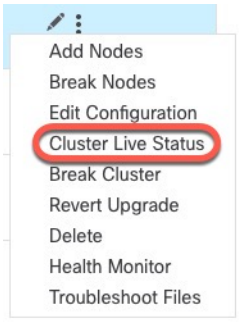
Reconcile Cluster Nodes

If a cluster node fails to register, you can reconcile the cluster membership from the device to the Firewall Management Center. For example, a data node might fail to register if the Firewall Management Center is occupied with certain processes, or if there is a network issue.

Procedure

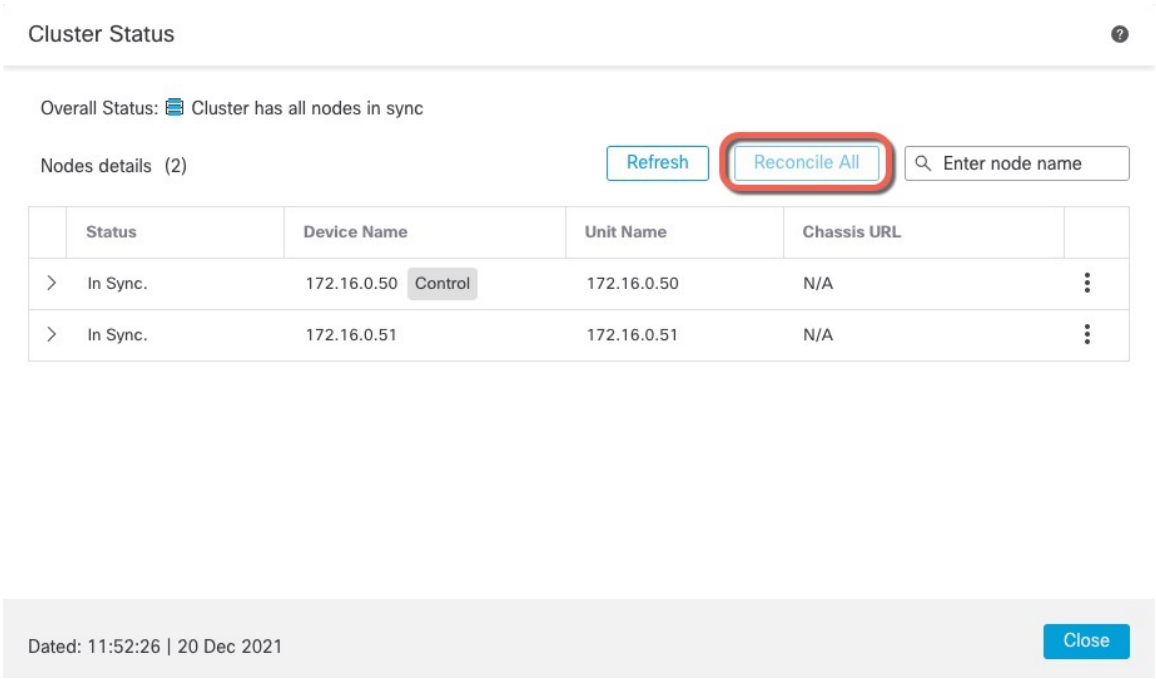
Step 1 Choose **Devices** > **Device Management**, **More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

Figure 204: Cluster Live Status



Step 2 Click **Reconcile All**.

Figure 205: Reconcile All



For more information about the cluster status, see Monitoring the Cluster, on page 690.

Delete the Cluster or Nodes from the Management Center

You can delete the cluster from the Security Cloud Control, which keeps the cluster intact. You might want to delete the cluster if you want to add the cluster to a new Security Cloud Control.

You can also delete a node from the Security Cloud Control without breaking the node from the cluster. Although the node is not visible in the Security Cloud Control, it is still part of the cluster, and it will continue to pass traffic and could even become the control node. You cannot delete the current control node. You might want to delete the node if it is no longer reachable from the Security Cloud Control, but you still want to keep it as part of the cluster.

Procedure

Step 1 Log into Security Cloud Control and click **Security Devices**.

Step 2 Click the **FTD** tab and locate the cluster you want. Select it so the device row is highlighted.

Step 3 Do the following:

- To delete a node within the cluster, in the **Cluster** pane to the right, click the delete icon appearing beside the device you want to delete.
- To delete the cluster, in the **Device Actions** pane to the right, click **Remove**.

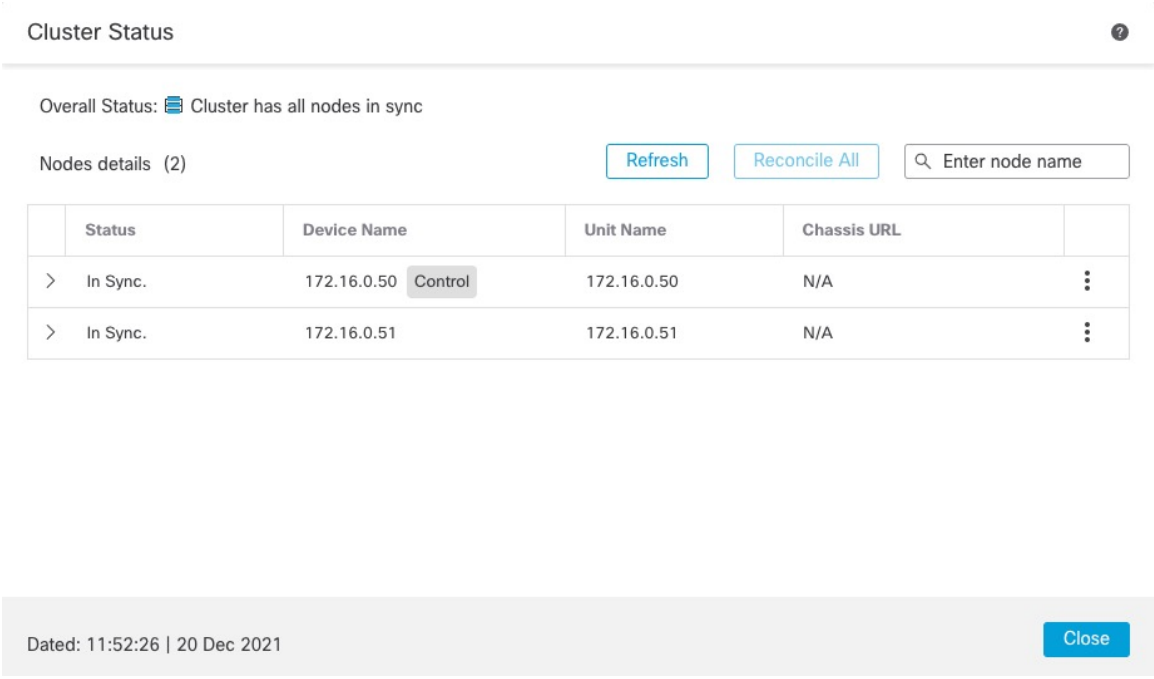
Step 4 When prompted, select **OK** to confirm the removal of the selected device.

Monitoring the Cluster

You can monitor the cluster in the Firewall Management Center and at the Firewall Threat Defense CLI.

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management**, **More** (⋮) icon or from the **Devices** > **Device Management**, click **Add**, choose the **Cluster** page **General** area **Cluster Live Status** link.

Figure 206: Cluster Status



The Control node has a graphic indicator identifying its role.

Cluster member **Status** includes the following states:

- In Sync.—The node is registered with the Firewall Management Center.
- Pending Registration—The node is part of the cluster, but has not yet registered with the Firewall Management Center. If a node fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The node is registered with the Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the node from the cluster.
- Joining cluster...—The node is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Firewall Management Center.

For each node, you can view the **Summary** or the **History**.

Figure 207: Node Summary

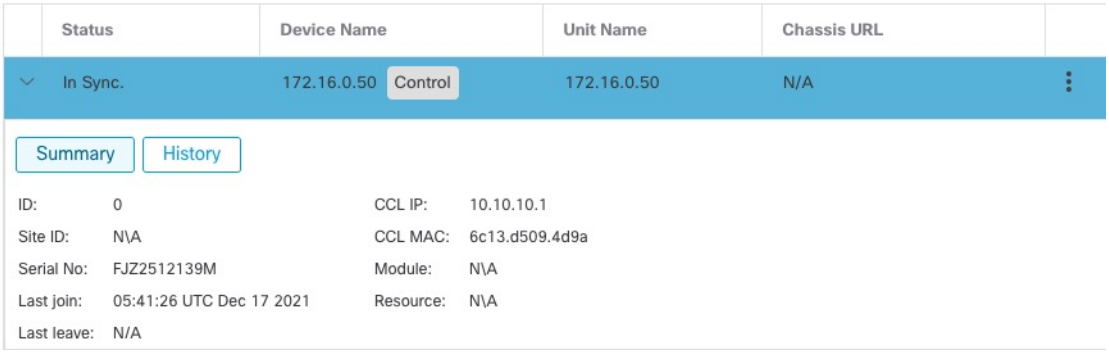


Figure 208: Node History

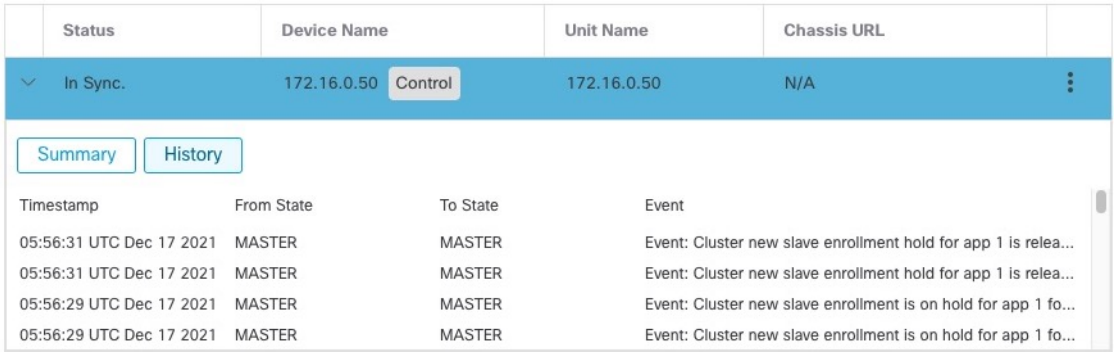


- **System** (⚙) > **Tasks** page.

  The **Tasks** page shows updates of the Cluster Registration task as each node registers.

- **Devices** > **Device Management** and then click **Add** > **Device** *cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member nodes, including the control node shown with its role next to the IP address. For nodes that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

Cluster Health Monitor Dashboard

Cluster Health Monitor

When a Firewall Threat Defense is the control node of a cluster, the Firewall Management Center collects various metrics periodically from the device metric data collector. The cluster health monitor is comprised of the following components:

- Overview dashboard—Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the Firewall Management Center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

  - The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.

- Load Distribution dashboard—Displays load distribution across the cluster nodes in two widgets:
  - The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
  - The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.
- Member Performance dashboard—Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard—Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links — Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range—An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard—Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

Viewing Cluster Health

You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

- Ensure you have created a cluster from one or more devices in the Firewall Management Center.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

Step 2 In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.

Step 3 To view the cluster health statistics, click on the cluster name. The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution — Traffic and packet distribution across the cluster nodes.
- Member Performance — Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL — Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, see Cisco Secure Firewall Threat Defense Health Metrics.

Step 4 You can configure the time range from the drop-down in the upper-right corner. The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

Step 6 (For node-specific health monitor) View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

Step 7 (For node-specific health monitor) The device monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU — CPU utilization, including the CPU usage by process and by physical cores.
- Memory — Device memory utilization, including data plane and Snort memory usage.
- Interfaces — Interface status and aggregate traffic statistics.
- Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort — Statistics that are related to the Snort process.
- ASP drops — Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. See Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 8 Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Cluster Metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

Table 54: Cluster Metrics

Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number
Distribution	Connection distribution count in the cluster for every second.	number

Metric	Description	Format
Packets	Packet distribution count in the cluster for every second.	number

Reference for Clustering

This section includes more information about how clustering operates.

Threat Defense Features and Clustering

Some Firewall Threat Defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported Features and Clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

Note To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Firewall Management Center GUI. See FlexConfig Policies, on page 2645.

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- Firewall Management Center UCAPL/CC mode
- DHCP client, server, and proxy. DHCP relay is supported.

Centralized Features for Clustering

The following features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Firewall Management Center GUI. See FlexConfig Policies, on page 2645.

- The following application inspections:
  - DCERPC
  - ESMTP
  - NetBIOS
  - PPTP
  - RSH
  - SQLNET
  - SUNRPC
  - TFTP
  - XDMCP
- Static route monitoring

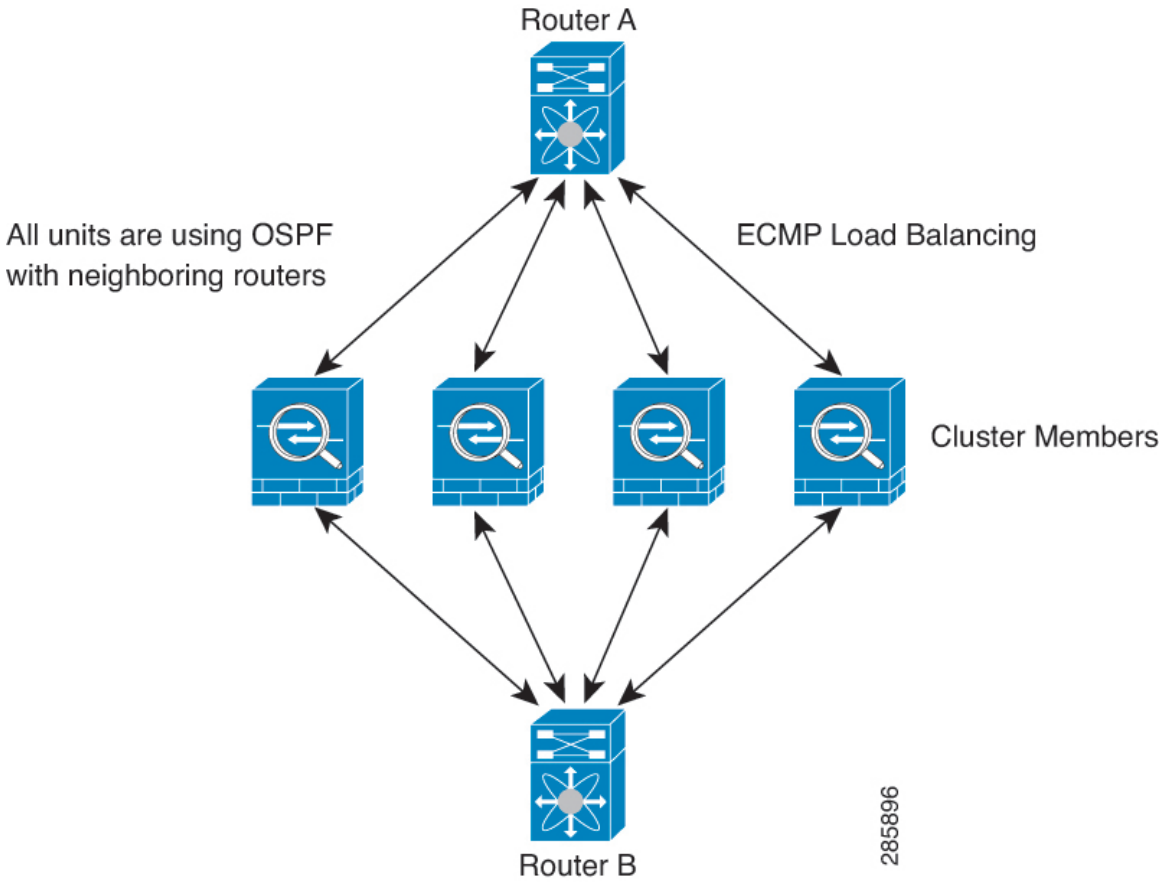
Connection Settings and Clustering

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

Dynamic Routing and Clustering

In Individual interface mode, each node runs the routing protocol as a standalone router, and routes are learned by each node independently.

Figure 209: Dynamic Routing in Individual Interface Mode



In the above diagram, Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when talking to external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

FTP and Clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

NAT and Clustering

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different Firewall Threat Defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the Firewall Threat Defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving

node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- No Proxy ARP—For Individual interfaces, a proxy ARP reply is never sent for mapped addresses. This prevents the adjacent router from maintaining a peer relationship with an ASA that may no longer be in the cluster. The upstream router needs a static route or PBR with Object Tracking for the mapped addresses that points to the Main cluster IP address.
- No interface PAT on an Individual interface—Interface PAT is not supported for Individual interfaces.
- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
  - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
  - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
  - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.

- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP
  - RSH
  - SQLNET
  - TFTP
  - XDMCP
  - SIP
- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

SIP Inspection and Clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and Clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and Clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

Cisco Trustsec and Clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

VPN and Clustering

VPN functionality is limited to the control node and does not take advantage of the cluster high availability capabilities. If the control node fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control node is elected, you must reestablish the VPN connections.

For connections to an Individual interface when using PBR or ECMP, you must always connect to the Main cluster IP address, not a Local address.

VPN-related keys and certificates are replicated to all nodes.

Note Remote access VPN is not supported with clustering.

Performance Scaling Factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

For example, if your model can handle approximately 10 Gbps of traffic when running alone, then for a cluster of 8 units, the maximum combined throughput will be approximately 80% of 80 Gbps (8 units x 10 Gbps): 64 Gbps.

Control Node Election

Nodes of the cluster communicate over the cluster control link to elect a control node as follows:

1. When you enable clustering for a node (or when it first starts up with clustering already enabled), it broadcasts an election request every 3 seconds.
2. Any other nodes with a higher priority respond to the election request; the priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a node does not receive a response from another node with a higher priority, then it becomes the control node.

Note If multiple nodes tie for the highest priority, the cluster node name and then the serial number is used to determine the control node.

4. If a node later joins the cluster with a higher priority, it does not automatically become the control node; the existing control node always remains as the control node unless it stops responding, at which point a new control node is elected.
5. In a "split brain" scenario when there are temporarily multiple control nodes, then the node with highest priority retains the role while the other nodes return to data node roles.

Note You can manually force a node to become the control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node.

High Availability within the Cluster

Clustering provides high availability by monitoring node and interface health and by replicating connection states between nodes.

Node Health Monitoring

Each node periodically sends a broadcast heartbeat packet over the cluster control link. If the control node does not receive any heartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining nodes.

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node’s role.

Interface Monitoring

Each node monitors the link status of all named hardware interfaces in use, and reports status changes to the control node.

All physical interfaces are monitored; only named interfaces can be monitored. You can optionally disable monitoring per interface.

A node is removed from the cluster if its monitored interfaces fail. The node is removed after 500 ms.

Status After Failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The Firewall Threat Defense automatically tries to rejoin the cluster, depending on the failure event.

Note When the Firewall Threat Defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoining the Cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The Firewall Threat Defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The Firewall Threat Defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the Firewall Threat Defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The Firewall Threat Defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from Firewall Management Center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

Data Path Connection State Replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 55: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—
Dynamic routing	Yes	—

Traffic	State Support	Notes
SNMP Engine ID	**No**	—

How the Cluster Manages Connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection Roles

See the following roles defined for each connection:

- Owner—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- Backup owner—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

  As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

  For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.
- Director—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

  As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

  ICMP/ICMPv6 hash details:

  - For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.
- Forwarder—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner.

A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- Fragment Owner—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

Port Address Translation Connections

New Connection Ownership

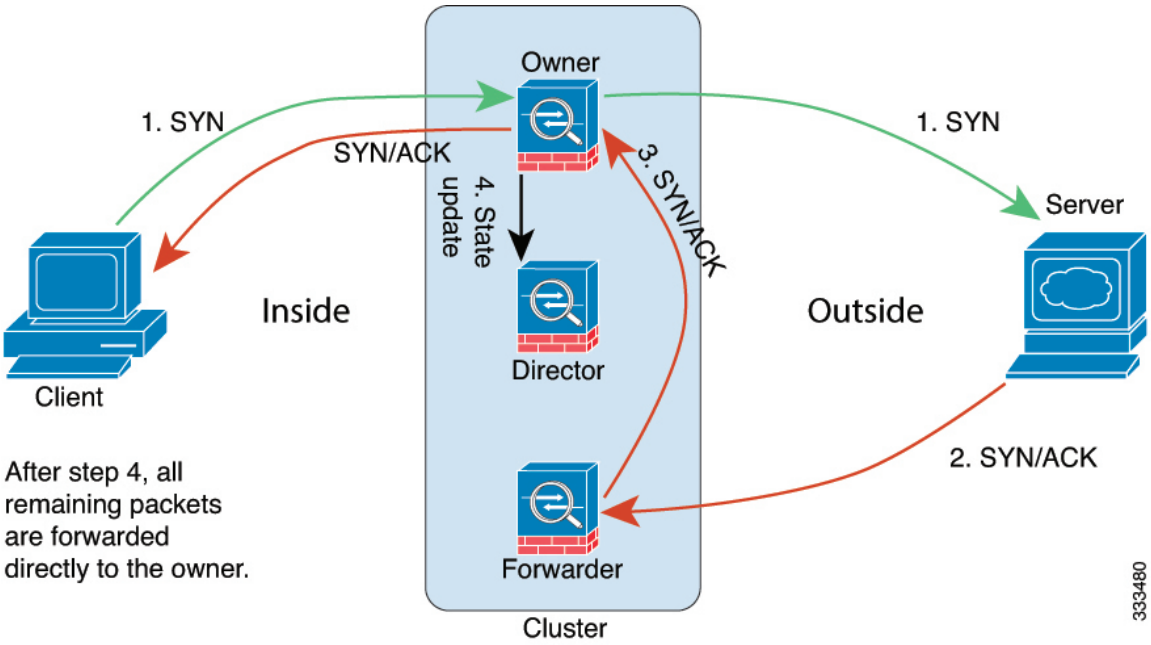
When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

Traffic redirection is not supported in this release. When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. All the subsequent packets for the same connection should arrive the same node. If any connection packets arrive at a different node, they will be dropped. If a reverse flow arrives at a different node, it will be dropped as well. For centralized features, if the connections do not arrive on the control node, they will be dropped.

By default, AWS GWLB uses 5-tuple to maintain flow stickiness. It is recommended to enable 2-tuple or 3-tuple stickiness on AWS GWLB to ensure the same flows are sent to the same node.

Sample Data Flow for TCP

The following example shows the establishment of a new connection.

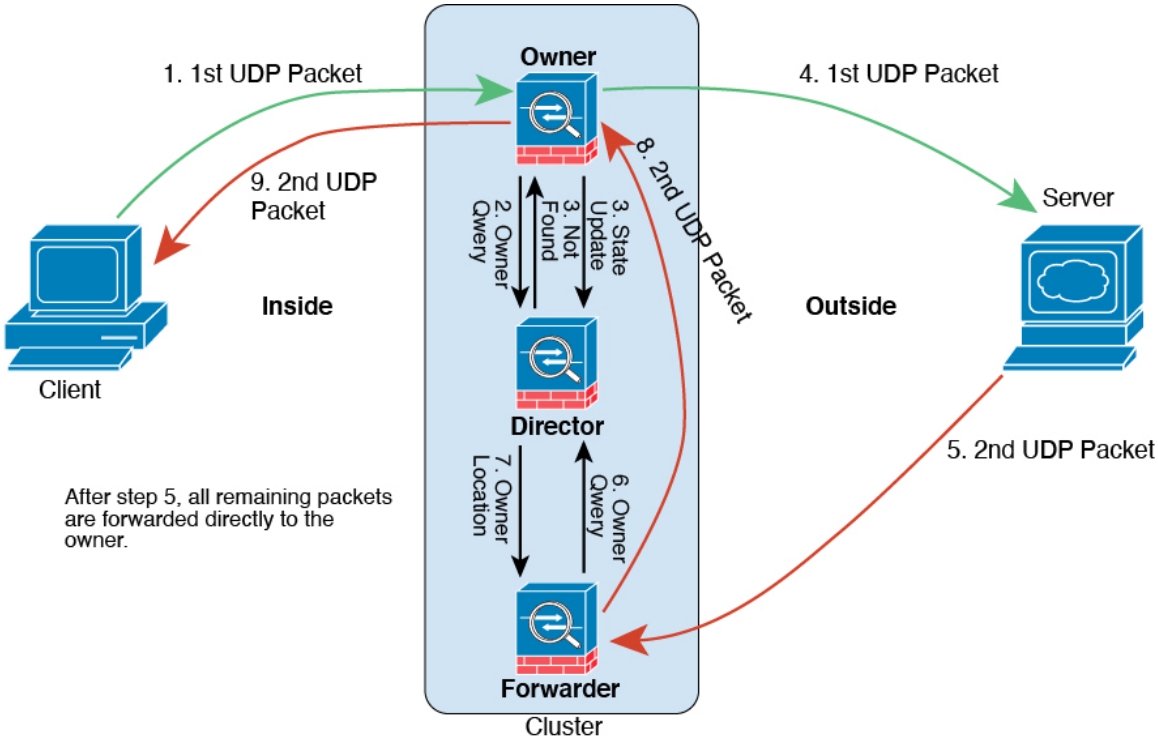


1. The SYN packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different Firewall Threat Defense (based on the load balancing method). This Firewall Threat Defense is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample Data Flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. *Figure 210: ICMP and UDP Data Flow*

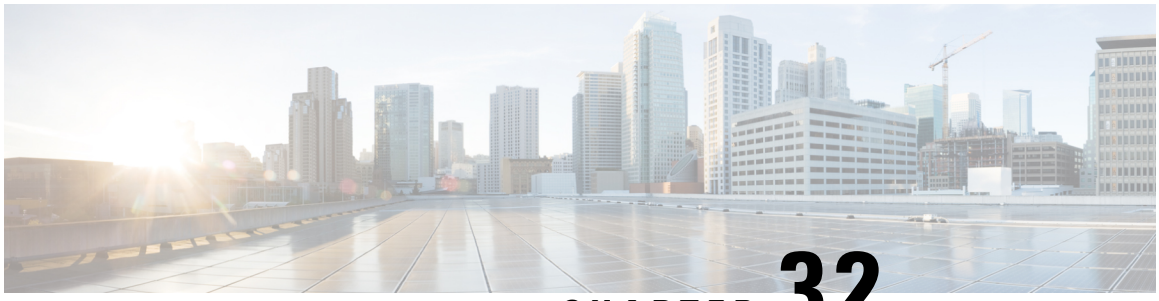


The first UDP packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

History for Threat Defense Virtual Clustering in a Private Cloud

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Cluster health monitor settings	20221213	Any	You can now edit cluster health monitor settings. New/Modified screens: **Devices** > **Device Management** > **Cluster** > **Cluster Health Monitor Settings** **Note** If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.
Cluster health monitor dashboard	20221213	Any	You can now view cluster health on the cluster health monitor dashboard. New/Modified screens: **System** > **Health** > **Monitor**
Clustering for the Firewall Threat Defense Virtual on VMware and KVM	Any	7.2.0	The Firewall Threat Defense Virtual supports Individual interface clustering for up to 4 nodes on VMware and KVM. New/Modified screens: • **Devices** > **Device Management** > **Add Cluster** • **Devices** > **Device Management** > **More** menu • **Devices** > **Device Management** > **Cluster** Supported platforms: Firewall Threat Defense Virtual on VMware and KVM



CHAPTER 32

Clustering for Threat Defense Virtual in a Public Cloud

Clustering lets you group multiple Firewall Threat Defense Virtuals together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. You can deploy Firewall Threat Defense Virtual clusters in a public cloud using the following public cloud platforms:

- Amazon Web Services (AWS)
- Microsoft Azure
- Google Cloud Platform (GCP)

Currently, only routed firewall mode is supported.

Note Some features are not supported when using clustering. See Unsupported Features and Clustering, on page 781.

About Threat Defense Virtual Clustering in the Public Cloud

This section describes the clustering architecture and how it works.

How the Cluster Fits into Your Network

The cluster consists of multiple firewalls acting as a single device. To act as a cluster, the firewalls need the following infrastructure:

- Isolated network for intra-cluster communication, known as the *cluster control link*, using VXLAN interfaces. VXLANs, which act as Layer 2 virtual networks over Layer 3 physical networks, let the Firewall Threat Defense Virtual send broadcast/multicast messages over the cluster control link.
- Load Balancer(s)—For external load balancing, you have the following options depending on your public cloud:
  - AWS Gateway Load Balancer

    The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The Firewall Threat Defense Virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint) using a Geneve interface single-arm proxy.
  - Azure Gateway Load Balancer

    In an Azure service chain, Firewall Threat Defense Virtuals act as a transparent gateway that can intercept packets between the internet and the customer service. The Firewall Threat Defense Virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy.
  - Native GCP load balancers, internal and external
  - Equal-Cost Multi-Path Routing (ECMP) using inside and outside routers such as Cisco Cloud Services Router

    ECMP routing can forward packets over multiple “best paths” that tie for top place in the routing metric. Like EtherChannel, a hash of source and destination IP addresses and/or source and destination ports can be used to send a packet to one of the next hops. If you use static routes for ECMP routing, then the Firewall Threat Defense failure can cause problems; the route continues to be used, and traffic to the failed Firewall Threat Defense will be lost. If you use static routes, be sure to use a static route monitoring feature such as Object Tracking. We recommend using dynamic routing protocols to add and remove routes, in which case, you must configure each Firewall Threat Defense to participate in dynamic routing.

Note Layer 2 Spanned EtherChannels are not supported for load balancing.

Individual Interfaces

You can configure cluster interfaces as *Individual interfaces*.

Individual interfaces are normal routed interfaces, each with their own local IP address. The IP address for the interface will be configured automatically via DHCP. Static IP configuration is not supported.

Control and Data Node Roles

One member of the cluster is the control node. If multiple cluster nodes come online at the same time, the control node is determined by the priority setting; the priority is set between 1 and 100, where 1 is the highest priority. All other members are data nodes. When you first create the cluster, you specify which node you want to be the control node, and it will become the control node simply because it is the first node added to the cluster.

All nodes in the cluster share the same configuration. The node that you initially specify as the control node will overwrite the configuration on the data nodes when they join the cluster, so you only need to perform initial configuration on the control node before you form the cluster.

Some features do not scale in a cluster, and the control node handles all traffic for those features.

Cluster Control Link

Each node must dedicate one interface as a VXLAN (VTEP) interface for the cluster control link. For more information about VXLAN, see Configure VXLAN Interfaces, on page 940.

VXLAN Tunnel Endpoint

VXLAN tunnel endpoint (VTEP) devices perform VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

VTEP Source Interface

The VTEP source interface is a regular Firewall Threat Defense Virtual interface with which you plan to associate the VNI interface. You can configure one VTEP source interface to act as the cluster control link. The source interface is reserved for cluster control link use only. Each VTEP source interface has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the cluster control link interfaces.

VNI Interface

A VNI interface is similar to a VLAN interface: it is a virtual interface that keeps network traffic separated on a given physical interface by using tagging. You can only configure one VNI interface. Each VNI interface has an IP address on the same subnet.

Peer VTEPs

Unlike regular VXLAN for data interfaces, which allows a single VTEP peer, The Firewall Threat Defense Virtual clustering allows you to configure multiple peers.

Cluster Control Link Traffic Overview

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Control node election.
- Configuration replication.
- Health monitoring.

Data traffic includes:

- State replication.
- Connection ownership queries and data packet forwarding.

Configuration Replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Management Network

You must manage each node using the Management interface; management from a data interface is not supported with clustering.

Licenses for Threat Defense Virtual Clustering

Each Firewall Threat Defense Virtual cluster node requires the same performance tier license. We recommend using the same number of CPUs and memory for all members, or else performance will be limited on all nodes to match the least capable member. The throughput level will be replicated from the control node to each data node so they match.

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add the control node to the Firewall Management Center, you can specify the feature licenses you want to use for the cluster. You can modify licenses for the cluster in the **Devices** > **Device Management**, **Cluster** > **License** area.

Note If you add the cluster before the Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Requirements and Prerequisites for Threat Defense Virtual Clustering

Model Requirements

- FTDv5, FTDv10, FTDv20, FTDv30, FTDv50, FTDv100

Note FTDv5 and FTDv10 do not support Amazon Web Services (AWS) Gateway Load Balancer (GWLB) and Azure GWLB.

- The following public cloud services:
  - Amazon Web Services (AWS)
  - Microsoft Azure
  - Google Cloud Platform (GCP)
- Maximum 16 nodes

See also the general requirements for the Firewall Threat Defense Virtual in the Cisco Secure Firewall Threat Defense Virtual Getting Started Guide.

User Roles

- Admin
- Access Admin
- Network Admin

Hardware and Software Requirements

All units in a cluster:

- Must be in the same performance tier. We recommend using the same number of CPUs and memory for all nodes, or else performance will be limited on all nodes to match the least capable node.
- The Firewall Management Center access must be from the Management interface; data interface management is not supported.
- Must run the identical software except at the time of an image upgrade. Hitless upgrade is supported.
- All units in a cluster must be deployed in the same availability zone.
- Cluster control link interfaces of all units must be in the same subnet.

MTU

Make sure the ports connected to the cluster control link have the correct (higher) MTU configured. If there is an MTU mismatch, the cluster formation will fail.

The cluster control link MTU should be 154 bytes higher than the data interfaces. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead (100 bytes) plus VXLAN overhead (54 bytes).

For AWS with GWLB, the data interface uses Geneve encapsulation. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. You should set the source interface MTU to be the network MTU + 306 bytes. So for the standard 1500 MTU network path, the source interface MTU should be 1806, and the cluster control link MTU should be +154, 1960.

For Azure with GWLB, the data interface uses VXLAN encapsulation. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. You should set the cluster control link MTU to be the source interface MTU + 80 bytes.

The following table shows the default values for the cluster control link MTU and the data interface MTU.

Note We do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.

Table 56: Default MTU

Public Cloud	Cluster Control Link MTU	Data Interface MTU
AWS with GWLB	1980	1826
AWS	1654	1500
Azure with GWLB	1454	1374
Azure	1454	1300
GCP	1554	1400

Guidelines for Threat Defense Virtual Clustering

High Availability

High Availability is not supported with clustering.

IPv6

The cluster control link is only supported using IPv4.

Additional Guidelines

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Firewall Threat Defense or the switch, adding an additional switch to

form a VSS or vPC or VNet) you should disable the health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.

- When adding a node to an existing cluster, or when reloading a node, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- Do not power off a node without first disabling clustering on the node.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new node. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.
- Dynamic scaling is not supported.
- Stateful Target Failover is not supported when you deploy the cluster on AWS.
- Perform a global deployment after the completion of each maintenance window.
- Ensure that you do not remove more than one device at a time from the auto scale group (AWS) / instance group (GCP) / scale set (Azure). We also recommend that you run the **cluster disable** command on the device before removing the device from the auto scale group (AWS) / instance group (GCP) / scale set (Azure).
- If you want to disable data nodes and the control node in a cluster, we recommend that you disable the data nodes before disabling the control node. If a control node is disabled while there are other data nodes in the cluster, one of the data nodes has to be promoted to be the control node. Note that the role change could disturb the cluster.
- In the customized day 0 configuration scripts given in this guide, you can change the IP addresses as per your requirement, provide custom interface names, and change the sequence of the CCL-Link interface.
- If you experience CCL instability issues, such as intermittent ping failures, after deploying a Threat Defense Virtual cluster on a cloud platform, we recommend that you address the reasons that are causing CCL instability. Also, you can increase the hold time as a temporary workaround to mitigate CCL instability issues to a certain extent. For more information on how to change the hold time, see Edit Cluster Health Monitor Settings.
- When you are configuring your security firewall rule or security group for the Management Center virtual, you must include both Private and Public IP addresses of the Firewall Threat Defense Virtual in the Source IP address range. Also, ensure to specify the Private and Public IP addresses of the Firewall Management Center Virtual in the security firewall rule or security group of the Firewall Threat Defense Virtual. This is important to ensure proper registration of nodes during clustering deployment.

Defaults for Clustering

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.

- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Deploy the Cluster in AWS

To deploy a cluster in AWS, you can either manually deploy or use CloudFormation templates to deploy a stack. You can use the cluster with AWS Gateway Load Balancer, or with a non-native load-balancer such as the Cisco Cloud Services Router.

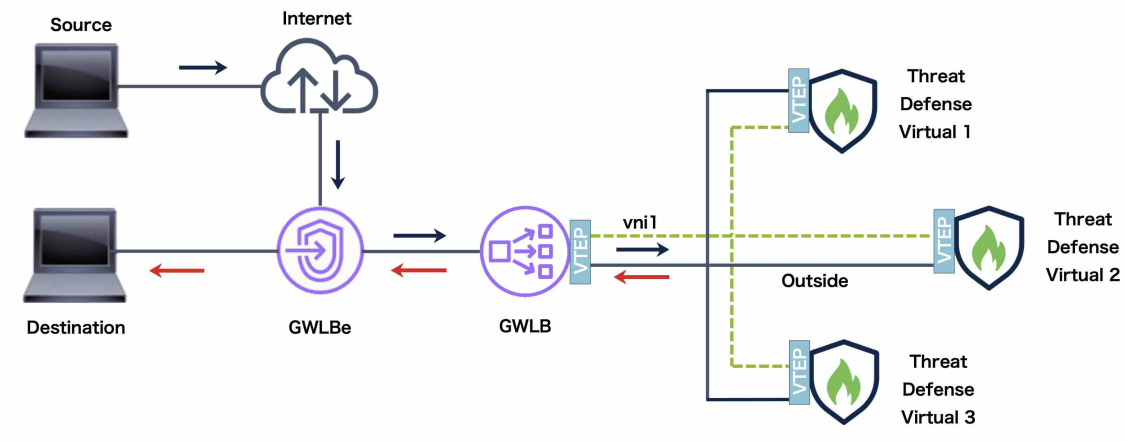
AWS Gateway Load Balancer and Geneve Single-Arm Proxy

Note This use case is the only currently supported use case for Geneve interfaces.

The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The Threat Defense Virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint). The following figure shows traffic forwarded to the Gateway Load Balancer from the Gateway Load Balancer endpoint. The Gateway Load Balancer balances traffic among multiple Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer (U-turn traffic). The Gateway Load Balancer then sends the traffic back to the Gateway Load Balancer endpoint and to the destination.

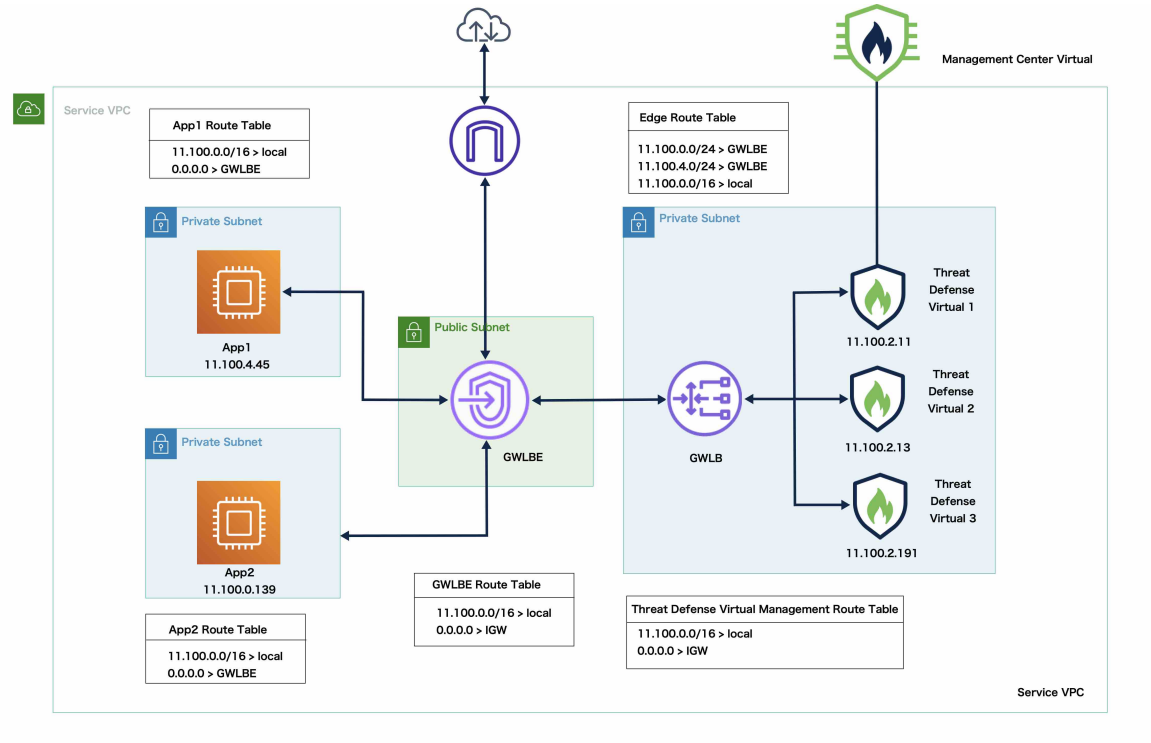
Note Transport Layer Security (TLS) Server Identity Discovery is not supported with Geneve single-arm setup on AWS.

Figure 211: Geneve Single-Arm Proxy



Sample Topology

The topology given below depicts both inbound and outbound traffic flow. There are three Threat Defense Virtual instances in the cluster that is connected to a GWLB. A Management Center Virtual instance is used to manage the cluster.



Inbound traffic from the internet goes to the GWLB endpoint which then transmits the traffic to the GWLB. Traffic is then forwarded to the Threat Defense Virtual cluster. After the traffic has been inspected by a Threat Defense Virtual instance in the cluster, it is forwarded to the application VM, App1 /App2.

Outbound traffic from App1/App2 is transmitted to the GWLB endpoint which then sends it out to the internet.

End-to-End Process for Deploying Threat Defense Virtual Cluster on AWS

Template-based Deployment

The following flowchart illustrates the workflow for template-based deployment of the Threat Defense Virtual cluster on AWS.

	Workspace	Steps
1	Local Host	Clone the repository from GitHub
2	Local Host	Modify *infrastructure.yaml* and *deploy_ngfw_cluster.yaml* templates.
3	Local Host	Update the *Configuration.json* file with FMC object names.
4	Linux Host	Create *cluster_layer.zip* file.
5	Local Host	Copy *cluster_layer.zip* file to the Lambda python files folder.
6	Local Host	Create *cluster_manager.zip*, *custom_metrics_publisher.zip*, and *cluster_lifecycle.zip* files.
7	Local Host	Build zip files from Python files for Lambda functions and copy to target folder.
8	AWS Console	Deploy *infrastructure.yaml* template.
9	AWS Console	Upload *cluster_layer.zip*, *cluster_lifecycle.zip*, *custom_metrics_publisher.zip*, and *cluster_manager.zip* to the S3 bucket.
10	AWS Console	Deploy *deploy_ngfw_cluster.yaml* template.
11	AWS Console	Log in and verify cluster deployment.

Manual Deployment

The following flowchart illustrates the workflow for manual deployment of the Threat Defense Virtual cluster on AWS.

	Workspace	Steps
1	Local Host	Create day 0 configuration script.
2	AWS Console	Deploy Threat Defense Virtual instance.
3	AWS Console	Attach interfaces to instance.
4	AWS Console	Verify if nodes have joined cluster.
5	AWS Console	Create target group and GWLB; attach target group to the GWLB.
6	AWS Console	Register instances with the target group using data interface IP.
7	Management Center	Register control node.

Templates

The templates given below are available in GitHub. The parameter values are self-explanatory with the parameter names, default values, allowed values, and description, given in the template.

- infrastructure.yaml – Template for infrastructure deployment.
- deploy_ngfw_cluster.yaml – Template for cluster deployment.

Note Ensure that you check the list of supported AWS instance types before deploying cluster nodes. This list is found in the *deploy_ngfw_cluster.yaml* template, under allowed values for the parameter InstanceType.

Deploy the Stack in AWS Using a CloudFormation Template

Deploy the stack in AWS using the customized CloudFormation template.

Before you begin

- You need a Amazon Linux virtual machine with Python 3.
- To allow the cluster to auto-register with the Firewall Management Center, you need to create *two* users with administrative privileges on the Firewall Management Center that can use the REST API. See the Cisco Secure Firewall Management Center Administration Guide.
- Add an access policy in the Firewall Management Center that matches the name of the policy that you specified in `Configuration.json`.

Procedure

Step 1 Prepare the template.

a) Clone the GitHub repository to your local folder. See https://github.com/CiscoDevNet/cisco-ftdv/tree/master/cluster/aws.

b) Modify **infrastructure.yaml** and **deploy_ngfw_cluster.yaml** with the required parameters.

c) Modify **cluster/aws/lambda-python-files/Configuration.json** with initial settings.

For example:

```
{
  "licenseCaps": ["BASE", "MALWARE", "THREAT"],
  "performanceTier": "FTDv50",
  "fmcIpforDeviceReg": "DONTRESOLVE",
  "RegistrationId": "cisco",
  "NatId": "cisco",
  "fmcAccessPolicyName": "AWS-ACL"
}
```

- Keep the fmcIpforDeviceReg setting as DONTRESOLVE.
- The fmcAccessPolicyName needs to match an access policy on the Firewall Management Center.

Note
FTDv5 and FTDv10 tiers are not supported.

d) Create a file named **cluster_layer.zip** to provide essential Python libraries to Lambda functions.

We recommend to use the Amazon Linux with Python 3.9 installed to create the **cluster_layer.zip** file.

Note
If you need an Amazon Linux environment, you can create an EC2 instance using Amazon Linux 2023 AMI or use AWS Cloudshell, which runs the latest version of Amazon Linux.

For creating the cluster-layer.zip file, you need to first create **requirements.txt** file that consists of the python library package details and then run the shell script.

1. Create the **requirements.txt** file by specifying the python package details.

The following is the sample package details that you provide in the **requirements.txt** file:

```
$ cat requirements.txt
pycryptodome
paramiko
requests
scp
jsonschema
cffi
zipp
importlib-metadata
```

2. Run the following shell script to create **cluster_layer.zip** file.

```
$ pip3 install --platform manylinux2014_x86_64
--target=./python/lib/python3.9/site-packages
--implementation cp --python-version 3.9 --only-binary=:all:
--upgrade -r requirements.txt
$ zip -r cluster_layer.zip ./python
```

Note
If you encounter a dependency conflict error during installation, such as urllib3 or cryptography, it is recommended that you include the conflicting packages along with their recommended versions in the **requirements.txt** file. After that, you can run the installation again to resolve the conflict.

e) Copy the resulting **cluster_layer.zip** file to the lambda python files folder - `cluster/aws/lambda-python-files`.

f) Create the **cluster_layer.zip**, **custom_metrics_publisher.zip**, **cluster_manger.zip** and **lifecycle_ftdv.zip** files.

A **make.py** file can be found in the cloned repository (`cluster/aws/make.py`). This will zip the python files into a Zip file and copy to a target folder.

python3 make.py build

Note
If you are using a private IP address for the Management Center Virtual registration, then make sure that you set USE_PUBLIC_IP_FOR_FMC_CONN to False in the `cisco-ftdv/cluster/aws/lambda-python-files/constant.py` file.

Step 2 Deploy **infrastructure.yaml** and note the output values for cluster deployment. Before deploying the infrastructure stack, it is important to identify the AWS region and the availability zones that will be used. Each AWS region has a different set of availability zones and VPC infrastructure, therefore it is essential to select the correct region and availability zones for your deployment.

a) On the AWS Console, go to **CloudFormation** and click **Create stack**; select **With new resources(standard)**.

b) Select **Upload a template file**, click **Choose file**, and select **infrastructure.yaml** from the target folder.

c) Click **Next** and provide the required information.

Parameter	Allowed Values/Type	Description
ClusterName	String	Enter unique Cluster name.
ClusterNumber	Number	Enter unique Cluster number.
VpcCidr	String	Enter the CIDR block for a new VPC

Parameter	Allowed Values/Type	Description
NoOfAZs	Number	Select 2 or 3 Availability Zones (AZs) for releases 7.6.0 and above; for lower releases, Select 1AZ. Management, Inside, Outside and CCL subnets will be distributed across the chosen AZs accordingly.
ListOfAZs	List	Select Availability Zones (Count should match with Number of Availability Zones)
MgmtSubnetNames	CommaDelimitedList	Management subnets name (With Internet GW as Route)
MgmtSubnetCidrs	CommaDelimitedList	Management subnets Cidr list
InsideSubnetNames	CommaDelimitedList	Inside subnets name (With Private Route)
InsideSubnetCidrs	CommaDelimitedList	Inside subnets Cidr list
CCLSubnetNames	CommaDelimitedList	Enter CCL subnet name
CCLSubnetCidrs	CommaDelimitedList	Enter CCL subnet CIDR
LambdaAZs	List	Select 2 Availability Zones for Lambda
LambdaSubnetNames	CommaDelimitedList	Enter Lambda Subnets name (With NAT GW as Route), for Lambda Functions
LambdaSubnetCidrs	CommaDelimitedList	Enter Lambda Subnet CIDRs

d) Enter a unique **Cluster Name** and **Cluster Number** for the cluster.
e) Select the availability zone from the **Availability Zone** list. This field lists only availability zones based on the AWS region that you select for deploying the infrastructure stack using the ClusterFormation template.
f) Click **Next**, then **Create stack**.
g) After the deployment is complete, go to **Outputs** and note the S3 **BucketName**.

Figure 212: Output of infrastructure.yaml

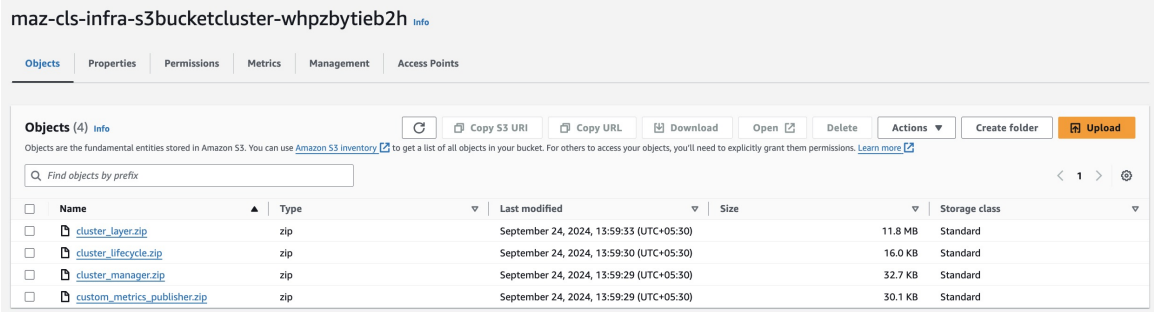
Outputs (13)

Search outputs

Key	Value	Description	Export name
BucketName	maz-cls-infra-s3bucketcluster-whpzbytieb2h	Name of the Amazon S3 bucket	-
BucketUrl	http://maz-cls-infra-s3bucketcluster-whpzbytieb2h.s3-website-us-east-1.amazonaws.com	URL of S3 Bucket Static Website	-
CCLSubnetIds	subnet-0bc04e2cc9e53e5c0,subnet-0d7d046a0fca25615,subnet-03ef42bf527551569	List of CCL subnet IDs (comma seperated)	-
EIPforNATgw	3.218.44.132	EIP reserved for NAT GW	-
FmcInstanceSGID	sg-076880aa64df2db5c	Security Group ID for FMC if user would like to launch in this VPC itself	-
InInterfaceSGId	sg-06ed933d6624fe51b	Security Group ID for Inside Interfaces	-
InsideSubnetIds	subnet-03d12cab8ee0eafff,subnet-0be9158b0970aebab,subnet-0b53c96fceb7c1f4d	List of Inside subnet IDs (comma seperated)	-
InstanceSGId	sg-0680b74be473186aa	Security Group ID for Instances Management Interface	-
LambdaSecurityGroupId	sg-057da2a9954e0d204	Security Group ID for Lambda Functions	-
LambdaSubnetIds	subnet-03439803d989e6bdf,subnet-087488a9d6ffc95cd	List of lambda subnet IDs (comma seperated)	-
ListOfAZs	us-east-1a,us-east-1b,us-east-1c	Availability zones for NGFWv instances	-
MgmtSubnetIds	subnet-06f0bbbd3f207a504,subnet-0c339dc43688cddc9,subnet-0a67629632a655de7	List of Mangement subnet IDs (comma seperated)	-
VpcName	vpc-09c2b0ad995e2fb24	Name of the VPC created	-

Step 3 Upload **cluster_layer.zip**, **cluster_manager.zip**, **custom_metrics_publisher.zip**, and **cluster_lifecycle.zip** to the S3 bucket created by **infrastructure.yaml**.

Figure 213: S3 Bucket



Note
Make sure that the Elastic IP address of the Lambda NAT Gateway is added to the security group associated with the Management Center Virtual.

Step 4 Deploy **deploy_ngfw_cluster.yaml**.

a) Go to **CloudFormation** and click on **Create stack**; select **With new resources(standard)**.
b) Select **Upload a template file**, click **Choose file**, and select **deploy_ngfw_cluster.yaml** from the target folder.
c) Click **Next** and provide the required information.
d) Provide the following cluster and infrastructure configuration information.

Parameter	Allowed Values/Type	Description
Cluster Configuration		
ClusterGrpNamePrefix	String	This is the cluster name Prefix. The cluster number will be added as a suffix.
ClusterNumber	String	This is the cluster number. This will be suffixed to the cluster name (msa-ftdv-infra). For example, if this value is **1**, the group name will be *msa-ftdv-infra-1*. It should be at least 1 digit, but not more than 3 digits. Default: 1.
ClusterSize	Numbers	This is the total number of Firewall Threat Defense Virtual nodes in a cluster. Minimum: 1 Maximum:16
Infrastructure Details		
NoOfAZs	String	This is the total number of availability zones into which Firewall Threat Defense Virtual is deployed. (The number of availability zones varies from a Minimum 1 to Maximum 3 depending on a region). The subnet will be created in these availability zones.

Parameter	Allowed Values/Type	Description
		The availability zones available in this list is based on the region selected for deploying the cluster. **Note** Management, Inside, and Cluster Control Link (CCL) subnets are created across three availability zones based on this parameters.
AZ	String	The availability zone list is based on the region you plan to deploy. In Availability Zone list, select the valid availability zone (1 availability zone or 2 availability zones or 3 availability zones). Count should match with the value of Number of Availability Zones parameter.
NotifyEmailID	String	Email address to which cluster events email will be sent. You must accept a subscription email request to receive this email notification. Example: admin@company.com
VpcId	String	The VPC ID for the cluster group. Type: AWS::EC2::VPC::Id
S3BktName	String	The S3 Bucket that contains the uploaded Lambda zip files. You must specify correct bucket name.
MgmtSubnetIds	List	Enter only *one* subnet per availability zone. If you select multiple subnets from a same availability zone, then selecting an incorrect subnet may cause issues while deploying the Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::Subnet::Id>
InsideSubnetIds	List	Enter at least *one* subnet per availability zone. If multiple subnets from the same Availability Zone are selected, then selecting an incorrect subnet may cause issues while deploying the Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::Subnet::Id>
LambdaSubnets	List	Enter at least *two* subnet for the Lambda functions. The *two* subnets you enter must have a NAT gateway to enable the Lambda functions to communicate with AWS services, which are public DNS. Type: List<AWS::EC2::Subnet::Id>

Parameter	Allowed Values/Type	Description
CCLSubnetIds	String	Enter at least *one* subnet per availability zone. If multiple subnets from the same Availability Zone are selected, then selecting an incorrect subnet may cause issues while deploying the Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::Subnet::Id>
CCLSubnetRanges	String	Enter IP addresses range of CCL subnets for different availability zones. Exclude first 4 reserved IP addresses. IP address pool for Cluster Control Link (CCL). IP address is allocated to the CCL interfaces of the Firewall Threat Defense Virtual instance from CCL IP address pool.
MgmtInterfaceSG	List	Select security group ID for the Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::SecurityGroup::Id>
InsideInterfaceSG	List	Select security group ID for the inside interface of Firewall Threat Defense Virtual instances. Type: List<AWS::EC2::SecurityGroup::Id>
LambdaSG	List	Select a security group for the Lambda functions. Ensure outbound connections is set to **ANYWHERE**. Type: List<AWS::EC2::SecurityGroup::Id>
CCLInterfaceSG	List	Select a security group ID for CCL interface of the Firewall Threat Defense Virtual instances.
GWLB Configuration		
DeployGWLBE	String	Click **Yes** to deploy the GWLB endpoint. By default, the value is set to **No**.
VpcIdLBE	String	Enter VPC to deploy Gateway Load Balancer Endpoint. **Note** Do not enter any value in this field if you are not deploying the GWLB endpoint.
GWLBESubnetId	String	Enter only one subnet ID. **Note** Do not enter any value in this field if you are not deploying the GWLB endpoint.

Parameter	Allowed Values/Type	Description
		Ensure that the subnet belongs to the correct VPC, and the availability zones that you have specified.
TargetFailover	String	Enable Target Failover support when a target fails or deregisters. (By default, the value of this parameter is set to **rebalance**). • **no_rebalance**: Directs existing flows to failed targets and new flows to healthy targets, ensuring backward compatibility. • **rebalance**: Redistributes existing flows while ensuring that new flows go to healthy targets. *rebalance* is supported from Firewall Threat Defense Virtual Version 7.4.1 and later.
TgHealthPort	String	Enter Health Check Port for GWLB. **Note** By default, this port must not be used for traffic. Ensure the value you provide is a valid TCP port. Default: 8080
Cisco NGFWv Instance Configuration		
InstanceType	String	Cisco Firewall Threat Defense Virtual EC2 instance type. Ensure that the AWS Region supports Instance Type you select. By default, **c5.xlarge** is selected.
LicenseType	String	Choose Cisco Firewall Threat Defense Virtual EC2 instance license type. Ensure that the AMI ID that you enter in **AMI-ID** parameter is of the same licensing type. By default, **BYOL** is selected.
AssignPublicIP	String	Set the value as **true** to assign a public IP address for Firewall Threat Defense Virtual from the AWS IP address pool.
AmiID	String	Choose the correct AMI ID as per the region, version, and license type (BYOL or PAYG). Firewall Threat Defense Virtual 7.2 and later support clustering, and Firewall Threat Defense Virtual Version 7.6 and later support the autoscaling and multiple availability zone enhancements.

Parameter	Allowed Values/Type	Description
		Type: AWS::EC2::Image::Id
ngfwPassword	String	Firewall Threat Defense Virtual instance password. All Firewall Threat Defense Virtual instances come up with a default password, which is in the Userdata field of the Launch Template (Cluster Group). The password is activated after Firewall Threat Defense Virtual is accessible. Minimum length must be 8 characters. The password can either be a plain text password or a KMS encrypted password.
KmsArn	String	Enter ARN of an existing KMS (AWS KMS key to encrypt at rest). If you specify a value in this field, then the Firewall Threat Defense Virtual instance's ***admin*** password must be an encrypted password. Example of generating an encrypted password: "*aws kms encrypt --key-id <KMS ARN> --plaintext <password>* " The password encryption must be done using only the specified ARN.
FMC Automation Configuration		
fmcDeviceGrpName	String	Enter a unique name for the cluster group in management center.
fmcPublishMetrics	String	Select **`true`** to create a Lambda Function to poll management center and publish specific device group metrics to AWS CloudWatch. Allowed values: • true • false By default, the value is set to **true**.
fmcMetricsUsername	String	Enter a unique internal user name for polling memory metrics from management center. The user must have privileges of **Network Admin** and **Maintenance User** or more .
fmcMetricsPassword	String	Enter the password.

Parameter	Allowed Values/Type	Description
		If you have mentioned KMS Master Key ARN parameter, ensure to provide an encrypted password. Ensure to enter the correct password because entering incorrect password may result in failure of metrics collection.
fmcServer	String	The IP address can be an external IP address or the IP address reachable in Firewall Threat Defense Virtual management subnet in the VPC. Minimum length: 7 Maximum length:15
fmcOperationsUsername	String	Provide a unique internal user name for Firewall Management Center Virtual for CloudWatch. The user must have **Administrator** privileges.
fmcOperationsPassword	String	Enter the password. If you have mentioned KMS Master Key ARN parameter, ensure to provide an encrypted password.
Scaling Configuration		
CpuThresholds	CommaDelimitedList	(Optional) Specifying non-zero lower and upper thresholds will create scale policies. If (0,0) is selected, no CPU scaling alarm or policies will be created. Evaluation points and data points are at default or recommended values. By default, **Autoscale** is enabled in this template. Autoscale can be disabled after deployment.
MemoryThresholds	CommaDelimitedList	Specifying non-zero lower and upper threshold will create scale policies. If (0,0) is selected, no memory scaling alarm or policies will be created. Evaluation points and data points are at default or recommended values.

e) Click **Next**, then **Create stack**.

The Lambda functions manage the rest of the process, and the Firewall Threat Defense Virtuals will automatically register with the Firewall Management Center.

Figure 214: Deployed Resources

The status changes from **CREATE_IN_PROGRESS** to **CREATE COMPLETE** indicating successful deployment.

Step 5 Verify the cluster deployment by logging into any one of the nodes and using the **show cluster info** command.

Figure 215: Cluster Nodes

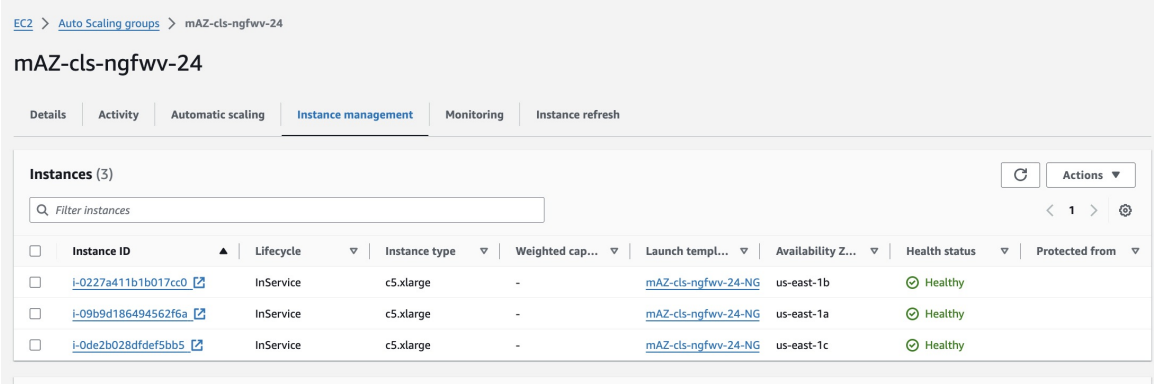


Figure 216: show cluster info

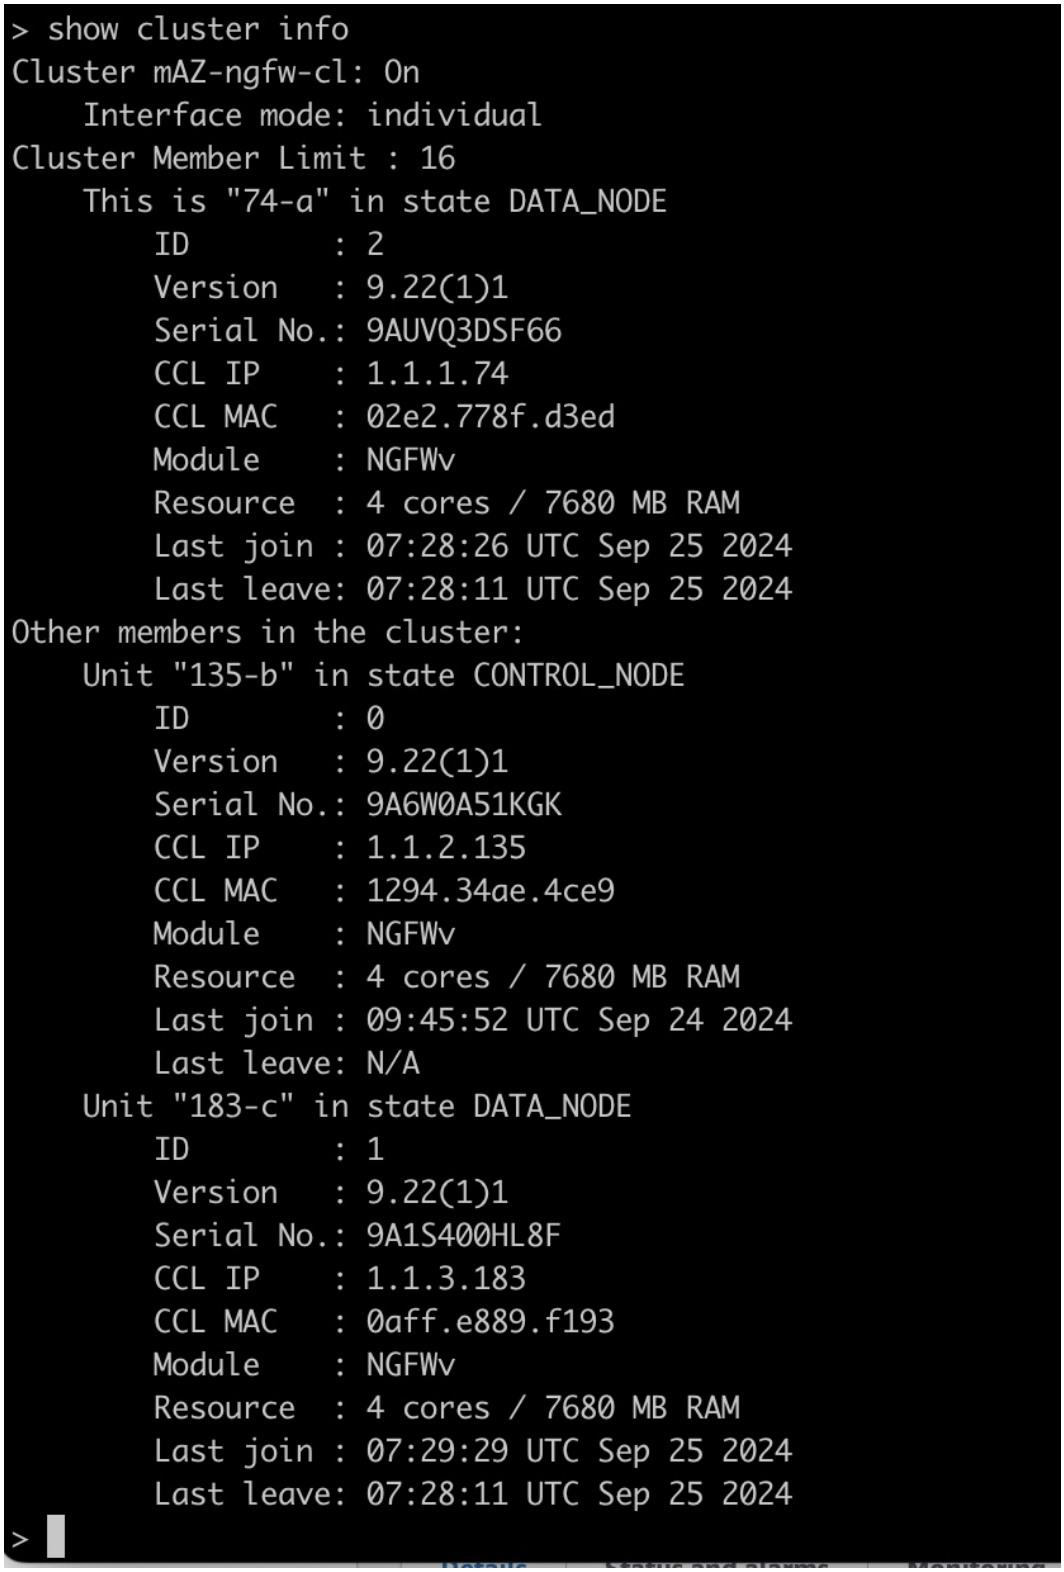

Deploy the Cluster in AWS Manually

To deploy the cluster manually, prepare the day 0 configuration, deploy each node, and then add the control node to the Firewall Management Center.

Create the Day0 Configuration for AWS

You can use either a fixed configuration or a customized configuration. We recommend using the fixed configuration.

Create the Day0 Configuration With a Fixed Configuration for AWS

The fixed configuration will auto-generate the cluster bootstrap configuration.

Single Availability Zone - Day0 Configuration with a fixed configuration for AWS

```
{
    "AdminPassword": "password",
    "Hostname": "hostname",
    "FirewallMode": "Routed",
    "ManageLocally": "No",
    "Cluster": {
        "CclSubnetRange": "ip_address_start ip_address_end",
        "ClusterGroupName": "cluster_name",
        [For Gateway Load Balancer] "Geneve": "{Yes | No}",
        [For Gateway Load Balancer] "HealthProbePort": "port"
    }
}
```

For example:

```
{
 "AdminPassword": "Sup3rnatural",
 "Hostname": "ciscoftdv",
 "FirewallMode": "Routed",
 "ManageLocally": "No",
 "Cluster": {
             "CclSubnetRange": "10.5.90.4 10.5.90.30",
  "ClusterGroupName": "ftdv-cluster",
  "Geneve": "Yes",
  "HealthProbePort": "7777"
 }
}
```

For the **CclSubnetRange** variable, specify a range of IP addresses starting from x.x.x.4. Ensure that you have at least 16 available IP addresses for clustering. Some examples of start (*ip_address_start*) and end (*ip_address_end*) IP addresses given below.

Table 57: Examples of Start and End IP addresses

CIDR	Start IP Address	End IP Address
10.1.1.0/27	10.1.1.4	10.1.1.30
10.1.1.32/27	10.1.1.36	10.1.1.62

CIDR	Start IP Address	End IP Address
10.1.1.64/27	10.1.1.68	10.1.1.94
10.1.1.96/27	10.1.1.100	10.1.1.126
10.1.1.128/27	10.1.1.132	10.1.1.158
10.1.1.160/27	10.1.1.164	10.1.1.190
10.1.1.192/27	10.1.1.196	10.1.1.222
10.1.1.224/27	10.1.1.228	10.1.1.254
10.1.1.0/24	10.1.1.4	10.1.1.254

Deploy Cluster Nodes

Deploy the cluster nodes so they form a cluster.

Procedure

Step 1 Deploy the Threat Defense Virtual instance by using the cluster day 0 configuration with the required number of interfaces - four interfaces if you are using Gateway Load Balancer (GWLB), or five interfaces if you are using non-native load balancer. To do this, in the **Configure Instance Details** > **Advanced Details** section, paste the cluster day 0 configuration.

Note
Ensure that you attach interfaces to the instances in the order given below.

- AWS Gateway Load Balancer - four interfaces - management, diagnostic, inside, and cluster control link.
- Non-native load balancers - five interfaces - management, diagnostic, inside, outside, and cluster control link.

For more information on deploying Threat Defense Virtual on AWS, see Deploy the Threat Defense Virtual on AWS.

Step 2 Repeat Step 1 to deploy the required number of additional nodes.

Step 3 Use the **show cluster info** command on the Threat Defense Virtual console to verify if all nodes have successfully joined the cluster.

Step 4 Configure the AWS Gateway Load Balancer.

a) Create a target group and GWLB.

b) Attach the target group to the GWLB.

Note
Ensure that you configure the GWLB to use the correct security group, listener configuration, and health check settings.

c) Register the data interface (inside interface) with the Target Group using IP addresses.

For more information, see Create a Gateway Load Balancer.

Step 5 Add the control node to the Management Center. See Add the Cluster to the Management Center (Manual Deployment), on page 760.

Deploy the Cluster in Azure

You can use the cluster with the Azure Gateway Load Balancer (GWLB), or with a non-native load-balancer. To deploy a cluster in Azure, use Azure Resource Manager (ARM) templates to deploy a Virtual Machine Scale Set.

Sample Topology for GWLB-based Cluster Deployment

Figure 217: Inbound Traffic Use Case and Topology with GWLB

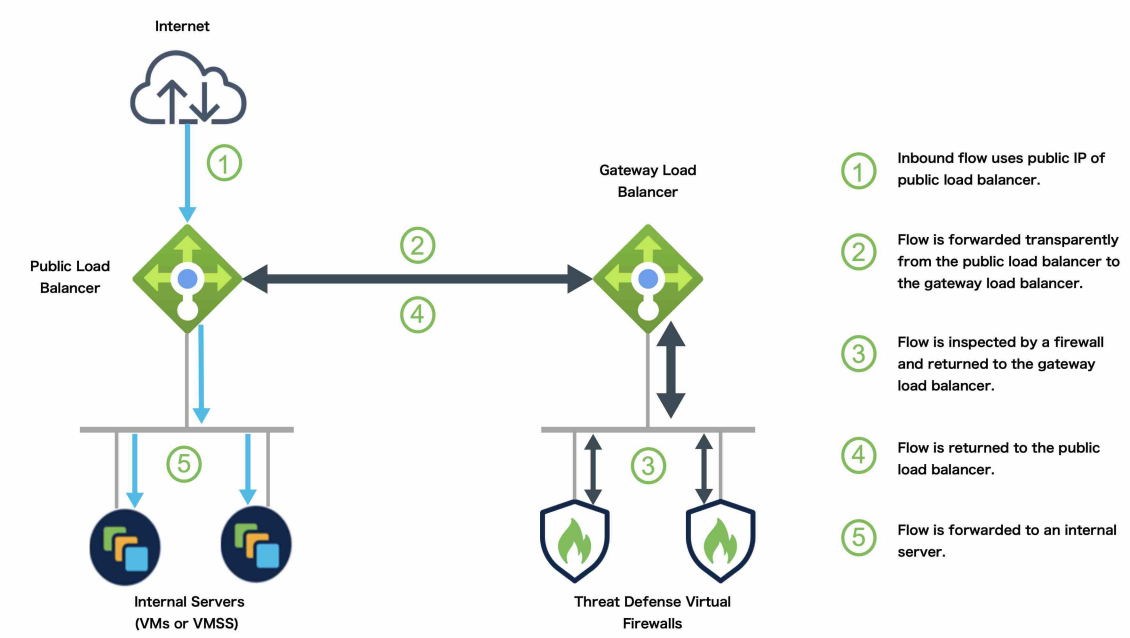

Figure 218: Outbound Traffic Use Case and Topology with GWLB

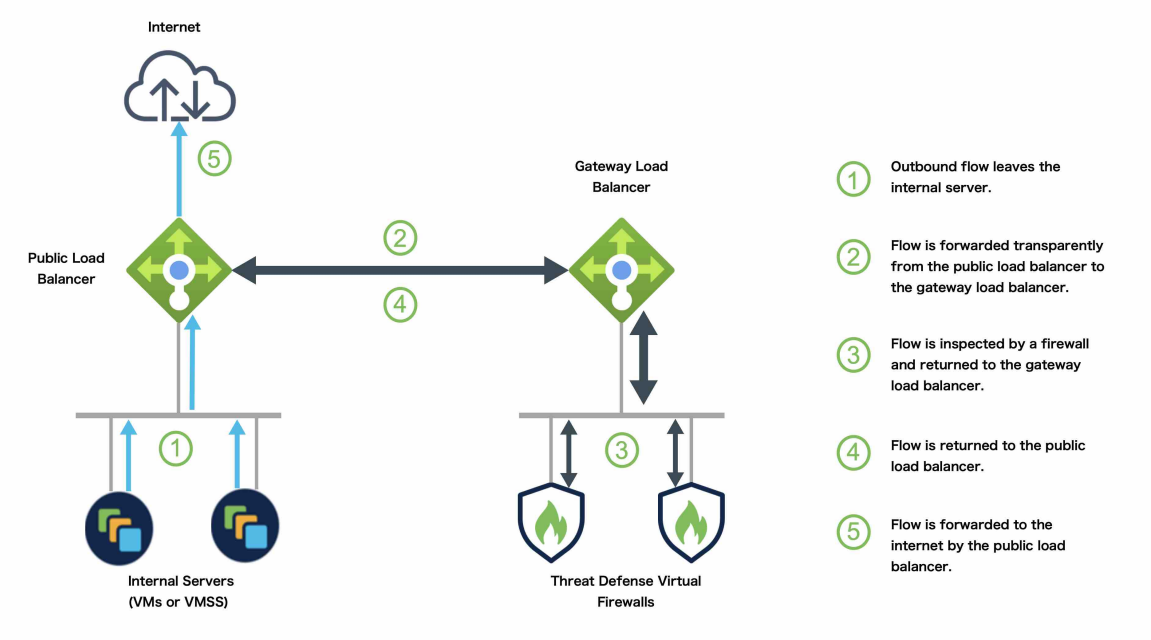
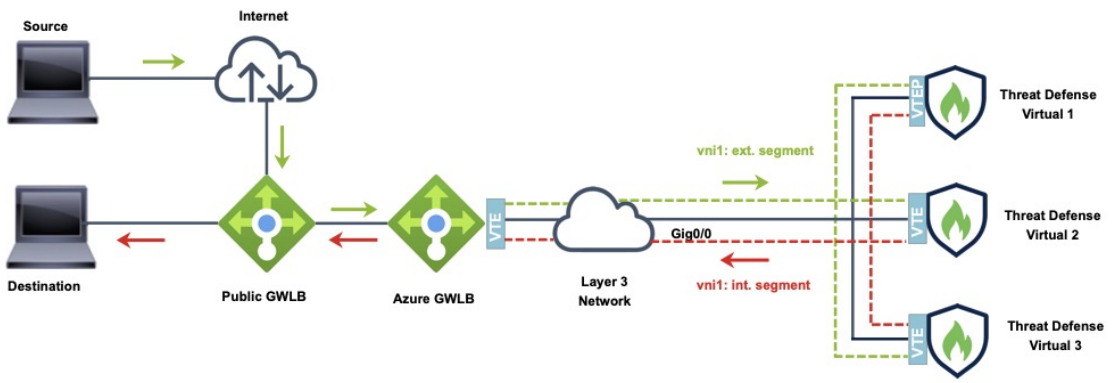


Azure Gateway Load Balancer and Paired Proxy

In an Azure service chain, Threat Defense Virtuals act as a transparent gateway that can intercept packets between the internet and the customer service. The Threat Defense Virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy.

The following figure shows traffic forwarded to the Azure Gateway Load Balancer from the Public Gateway Load Balancer on the external VXLAN segment. The Gateway Load Balancer balances traffic among multiple Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer on the internal VXLAN segment. The Azure Gateway Load Balancer then sends the traffic back to the Public Gateway Load Balancer and to the destination.

Figure 219: Azure Gateway Load Balancer with Paired Proxy



Traffic flow between GWLBe to GWLB (Geneve Single-Arm Proxy) in Azure

End-to-End Process for Deploying Threat Defense Virtual Cluster in Azure with GWLB

Template-based Deployment

The following flowchart illustrates the workflow for template-based deployment of the Threat Defense Virtual cluster in Azure with GWLB.

	Workspace	Steps
1	Local Host	Download templates and files from GitHub.
2	Local Host	Modify *azure_ftdv_gwlb_cluster.json* and *azure_ftdv_gwlb_cluster_parameters.json* with the required parameters.
3	Azure Cloud	Create the resource group, virtual network, and subnets.

	Workspace	Steps
4	Azure Cloud	Deploy custom template.
5	Azure Cloud	Configure instance details.
6	Cluster Node	Verify cluster deployment.
7	Azure Cloud	Use the Function app to register the cluster with the Management Center.
8	Azure Cloud	Create FTPS credentials.
9	Local Host	Upload *Cluster_Function.zip* file to the Function app.

Manual Deployment

The following flowchart illustrates the workflow of manual deployment of Threat Defense Virtual cluster in Azure with GWLB.

	Workspace	Steps
1	Local Host	Create a VMSS from the Marketplace image.
2	Local Host	Attach interfaces.
3	Local Host	Add day 0 configuration in the customData field.
4	Local Host	Update scaling instance count.
5	Local Host	Configure GWLB.
6	Management Center	Add control node.

Templates

The templates given below are available in GitHub. The parameter values are self-explanatory with the parameter names, and values, given in the template.

- azure_ftdv_gwlb_cluster_parameters.json – Template to enter parameters for the Firewall Threat Defense Virtual cluster with GWLB.
- azure_ftdv_gwlb_cluster.json – Template to deploy Firewall Threat Defense Virtual cluster with GWLB.

Prerequisites

- To allow the cluster to auto-register to the management center, create a user with Network Admin & Maintenance User privileges on the management center. Users with these privileges can use REST API. See the Cisco Secure Firewall Management Center Administration Guide.
- Add an access policy in the management center that matches the name of the policy that you will specify during template deployment.
- Ensure that the Management Center Virtual is licensed appropriately.
- Perform the steps given below after the cluster is added to the Management Center Virtual:

  1. Configure platform settings with the health check port number in the Management Center. For more information on configuring this, see Platform Settings.
  2. Create a static route for data traffic. For more information on creating a static route, see Add a Static Route.

     Sample static route configuration:

```
Network: any-ipv4
Interface: vxlan_tunnel
Leaked from Virtual Router: Global
Gateway: vxlan_tunnel_gw
Tunneled: false
Metric: 2
```

Note *vxlan_tunnel_gw* is the data subnet's gateway IP address.

Deploy Cluster on Azure with GWLB Using an Azure Resource Manager Template

Deploy the Virtual Machine Scale Set for Azure GWLB using the customized Azure Resource Manager (ARM) template.

Procedure

Step 1 Prepare the template.

a) Clone the github repository to your local folder. See https://github.com/CiscoDevNet/cisco-ftdv/tree/master/cluster/azure.

b) Modify *azure_ftdv_gwlb_cluster.json* and *azure_ftdv_gwlb_cluster_parameters.json* with the required parameters.

Step 2 Log into the Azure Portal: https://portal.azure.com.

Step 3 Create a Resource Group.

a) In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.

b) Choose the required **Region**.

Step 4 Create a virtual network with 4 subnets: Management, Diagnostic, Outside, and Cluster Control Link (CCL).

a) Create the virtual network.

1. In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.
2. Choose the required **Region**. Click **Next: IP addresses**.

In the **IP Addresses** tab, click **Add subnet** and add the following subnets – Management, Diagnostic, Data, and Cluster Control Link.

b) Add the subnets.

Step 5 Deploy the custom template.

a) Click **Create** > **Template deployment (deploy using custom templates)**.

b) Click **Build your own template in the editor**.

c) Click **Load File**, and upload **azure_ftdv_gwlb_cluster.json**.

d) Click **Save**.

Step 6 Configure the Instance details.

a) Enter the required values and then click **Review + create**.

b) Click **Create** after the validation is passed.

Step 7 After the instance is running, verify the cluster deployment by logging into any one of the nodes and entering the **show cluster info** command.

Figure 220: show cluster info

```
> show cluster info
Cluster gwlb-cluster-template-with-AN: On
    Interface mode: individual
Cluster Member Limit : 16
    This is "12" in state CONTROL_NODE
        ID          : 0
        Version     : 99.19(1)180
        Serial No.: 9AKGFV8VH4G
        CCL IP      : 10.1.1.12
        CCL MAC     : 000d.3a55.5470
        Module      : NGFWv
        Resource    : 8 cores / 28160 MB RAM
        Last join : 11:13:24 UTC Sep 5 2022
        Last leave: N/A
```

Step 8 In the Azure Portal, click the Function app to register the cluster with the Firewall Management Center.

Note
If you do not want to use the Function app, you can alternatively register the control node to the Firewall Management Center directly by using **Add** > **Device** (not **Add** > **Cluster**). The rest of the cluster nodes will register automatically.

Step 9 Create FTPS Credentials by clicking **Deployment Center** > **FTPS credentials** > **User scope** > **Configure Username and Password**, and then click **Save**.

Step 10 Upload the Cluster_Function.zip file to the Function app by executing the following **curl** command in the local terminal.

curl -X POST -u *username* **--data-binary @"Cluster_Function.zip" https://** *Function_App_Name***.scm.azurewebsites.net/api/zipdeploy**

Note
The **curl** command might take few minutes (~2 to 3 minutes) to complete command execution.

The function will be uploaded to the Function app. The function will start, and you can see the logs in the storage account's outqueue. The device registration with the Management Center will be initiated.

Figure 221: Functions

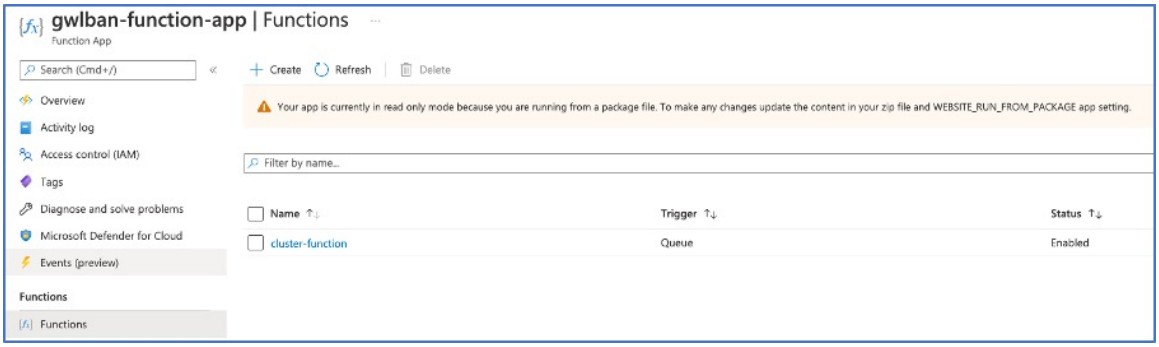


Figure 222: Queues

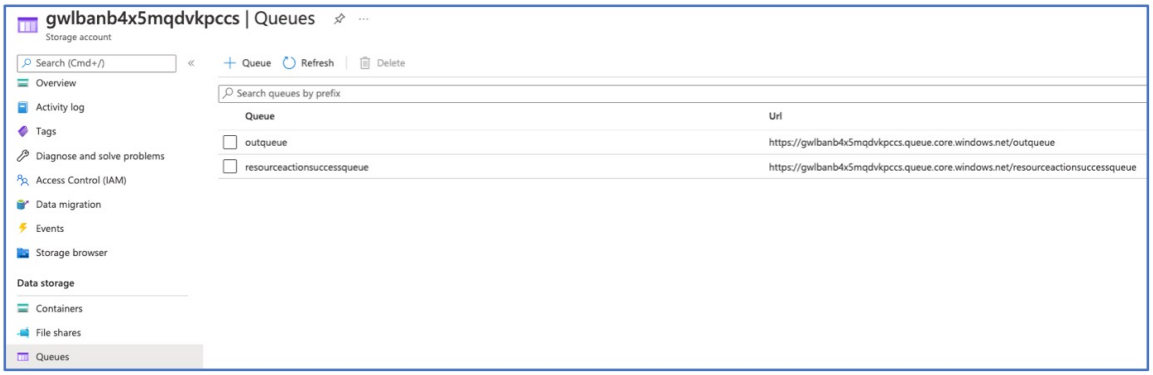

Figure 223: Outqueue

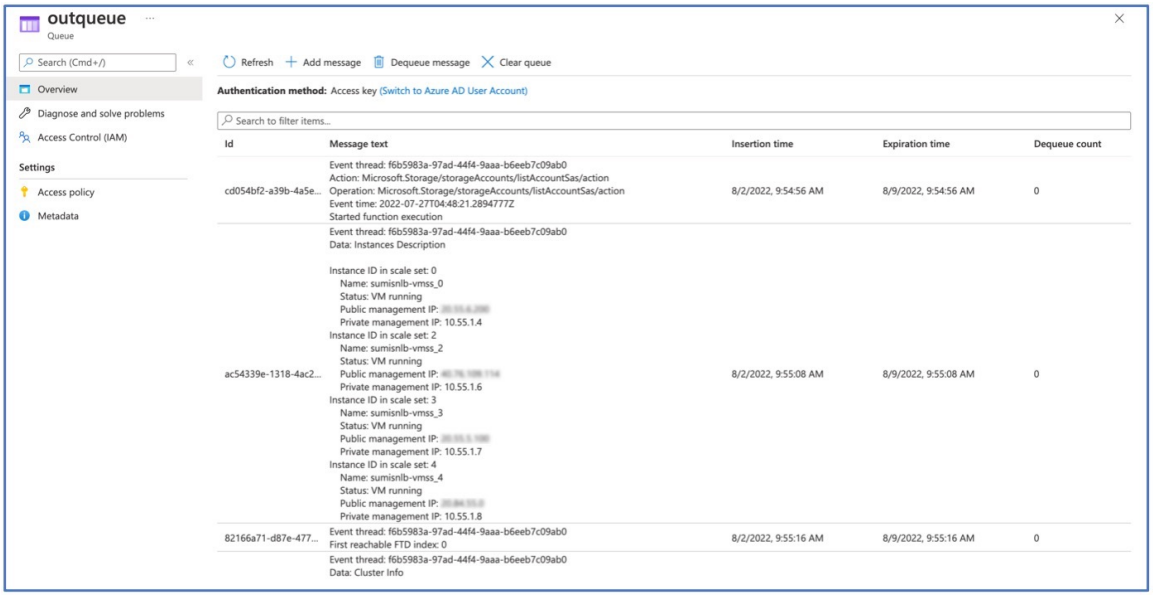
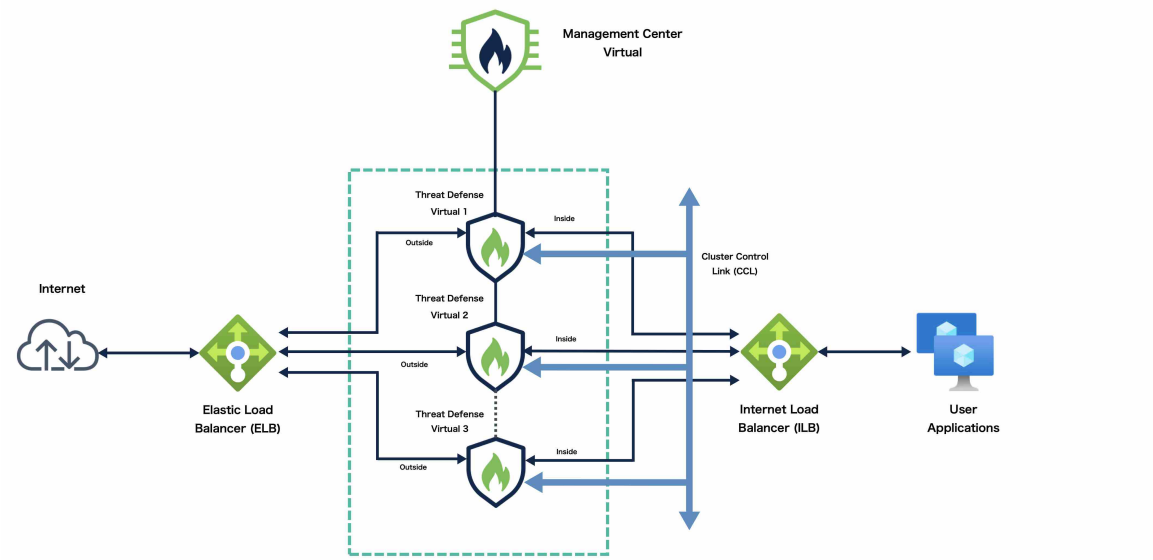


Sample Topology for NLB-based Cluster Deployment



This topology depicts both inbound and outbound traffic flow. The Threat Defense Virtual cluster is sandwiched between the internal and external load balancers. A Management Center Virtual instance is used to manage the cluster.

Inbound traffic from the internet goes to the external load balancer which then transmits the traffic to the Threat Defense Virtual cluster. After the traffic has been inspected by a Threat Defense Virtual instance in the cluster, it is forwarded to the application VM.

Outbound traffic from the application VM is transmitted to the internal load balancer. Traffic is then forwarded to the Threat Defense Virtual cluster and then sent out to the internet.

End-to-End Process for Deploying Threat Defense Virtual Cluster in Azure with NLB

Template-based Deployment

The following flowchart illustrates the workflow of template-based deployment of Threat Defense Virtual cluster in Azure with NLB.

	Workspace	Steps
1	Local Host	Download templates and files from GitHub.
2	Local Host	Modify *azure_ftdv_nlb_cluster.json* and *azure_ftdv_nlb_cluster_parameters.json* with the required parameters.
3	Azure Cloud	Create the resource group, virtual network, and subnets.
4	Azure Cloud	Deploy custom template.
5	Azure Cloud	Configure instance details.
6	Cluster Node	Verify cluster deployment.
7	Azure Cloud	Use the Function app to register the cluster with the Management Center.
8	Azure Cloud	Create FTPS credentials.

	Workspace	Steps
9	Local Host	Upload *Cluster_Function.zip* file to the Function app.

Manual Deployment

The following flowchart illustrates the workflow of manual deployment of Threat Defense Virtual cluster in Azure with NLB.

	Workspace	Steps
1	Local Host	Create a VMSS from the Marketplace image.
2	Local Host	Attach interfaces.
3	Local Host	Add day 0 configuration in the customData field.
4	Local Host	Update scaling instance count.
5	Local Host	Configure NLB.
6	Management Center	Add control node.

Templates

The templates given below are available in GitHub. The parameter values are self-explanatory with the parameter names, and values, given in the template.

- azure_ftdv_nlb_cluster_parameters.json – Template to enter parameters for the Threat Defense Virtual cluster with NLB.
- azure_ftdv_nlb_cluster.json – Template to deploy Threat Defense Virtual cluster with NLB.

Prerequisites

- To allow the cluster to auto-register with the Management Center, create a user with Network Admin & Maintenance User privileges on the Management Center. Users with these privileges can use REST API. See the Cisco Secure Firewall Management Center Administration Guide.
- Add an access policy in the Management Center that matches the name of the policy that you will specify during template deployment.
- Ensure that the Management Center Virtual is licensed appropriately.
- After the cluster is added to the Management Center Virtual:
  1. Configure platform settings with the health check port number in the Management Center. For more information on configuring this, see Platform Settings.
  2. Create static routes for traffic from outside and inside interfaces. For more information on creating a static route, see Add a Static Route.

     Sample static route configuration for the outside interface:

     ```
     Network: any-ipv4
     Interface: outside
     Leaked from Virtual Router: Global
     Gateway: ftdv-cluster-outside
     Tunneled: false
     Metric: 10
     ```

     Note *ftdv-cluster-outside* is the outside subnet's gateway IP address.

     Sample static route configuration for the inside interface:

     ```
     Network: any-ipv4
     Interface: inside
     Leaked from Virtual Router: Global
     Gateway: ftdv-cluster-inside-gw
     Tunneled: false
     Metric: 11
     ```

     Note *ftdv-cluster-inside-gw* is the inside subnet's gateway IP address.

  3. Configure NAT rule for data traffic. For more information on configuring NAT rules, see Network Address Translation.

Deploy Cluster on Azure with NLB Using an Azure Resource Manager Template

Deploy the cluster for Azure NLB using the customized Azure Resource Manager (ARM) template.

Procedure

Step 1 Prepare the template.

a) Clone the github repository to your local folder. See https://github.com/CiscoDevNet/cisco-ftdv/tree/master/cluster/azure.

b) Modify *azure_ftdv_nlb_cluster.json* and *azure_ftdv_nlb_cluster_parameters.json* with the required parameters.

Step 2 Log into the Azure Portal: https://portal.azure.com.

Step 3 Create a Resource Group.

a) In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.

b) Choose the required **Region**.

Step 4 Create a virtual network with 5 subnets: Management, Diagnostic, Inside, Outside, and Cluster Control Link.

a) Create the virtual network.

1. In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.
2. b) Choose the required **Region**. Click **Next: IP addresses**.

b) Add the subnets.

In the **IP Addresses** tab, click **Add subnet** and add the following subnets – Management, Diagnostic, Inside, Outside, and Cluster Control Link.

Step 5 Deploy the custom template.

a) Click **Create** > **Template deployment (deploy using custom templates)**.

b) Click **Build your own template in the editor**.

c) Click **Load File**, and upload **azure_ftdv_nlb_cluster.json**.

d) Click **Save**.

Step 6 Configure the instance details.

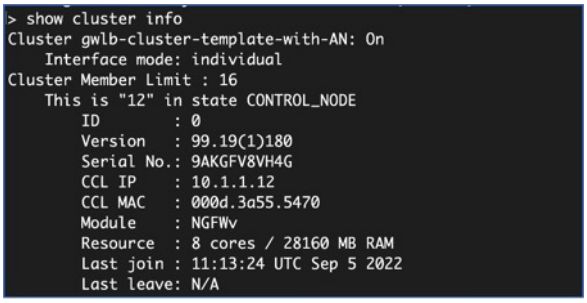
a) Enter the required values and then click **Review + create**.

Note
For the cluster control link starting and ending addresses, specify only as many addresses as you need (up to 16). A larger range can affect performance.

b) Click **Create** after the validation is passed.

Step 7 After the instance is running, verify the cluster deployment by logging into any one of the nodes and using the **show cluster info** command.

Figure 224: show cluster info



Step 8 In the Azure Portal, click the Function app to register the cluster to the Firewall Management Center.

Note
If you do not want to use the Function app, you can alternatively register the control node with the Management Center directly by using **Add** > **Device** (not **Add** > **Cluster**). The rest of the cluster nodes will register automatically.

Step 9 Create FTPS Credentials by clicking **Deployment Center** > **FTPS credentials** > **User scope** > **Configure Username and Password**, and then click **Save**.

Step 10 Upload the Cluster_Function.zip file to the Function app by executing the following **curl** command in the local terminal.

curl -X POST -u *username* **--data-binary @"Cluster_Function.zip" https://** *Function_App_Name***.scm.azurewebsites.net/api/zipdeploy**

Note
The **curl** command might take a few minutes (~2 to 3 minutes) to complete command execution.

The function will be uploaded to the Function app. The function will start, and you can see the logs in the storage account's outqueue. The device registration with the Management Center will be initiated.

Deploy the Cluster in Azure Manually

To deploy the cluster manually, prepare the day0 configuration, deploy each node, and then add the control node to the Firewall Management Center.

Create the Day0 Configuration for Azure

You can use either a fixed configuration or a customized configuration.

Create the Day0 Configuration With a Fixed Configuration for Azure

The fixed configuration will auto-generate the cluster bootstrap configuration.

```
"Cluster": {
"CclSubnetRange": "ip_address_start ip_address_end",
"ClusterGroupName": "cluster_name",
"HealthProbePort": "port_number",
"GatewayLoadBalancerIP": "ip_address",
```

```
"EncapsulationType": "vxlan",
"InternalPort": "internal_port_number",
"ExternalPort": "external_port_number",
"InternalSegId": "internal_segment_id",
"ExternalSegId": "external_segment_id"
}
```

Example

A sample day 0 configuration is given below.

```
"Cluster": {
"CclSubnetRange": "10.45.3.4 10.45.3.30",     //mandatory user input
"ClusterGroupName": "ngfwv-cluster",          //mandatory user input
"HealthProbePort": "7777",                    //mandatory user input
"GatewayLoadBalancerIP": "10.45.2.4",         //mandatory user input
"EncapsulationType": "vxlan",
"InternalPort": "2000",
"ExternalPort": "2001",
"InternalSegId": "800",
"ExternalSegId": "801"
}
```

Note If you are copying and pasting the configuration given above, ensure that you remove **//mandatory user input** from the configuration

For the Azure health check settings, be sure to specify the **HealthProbePort** you set here.

For the **CclSubnetRange** variable, specify a range of IP addresses starting from x.x.x.4. Ensure that you have at least 16 available IP addresses for clustering. Some examples of start and end IP addresses are given below.

Table 58: Examples of Start and End IP addresses

CIDR	Start IP Address	End IP Address
10.1.1.0/27	10.1.1.4	10.1.1.30
10.1.1.32/27	10.1.1.36	10.1.1.62
10.1.1.64/27	10.1.1.68	10.1.1.94
10.1.1.96/27	10.1.1.100	10.1.1.126
10.1.1.128/27	10.1.1.132	10.1.1.158
10.1.1.160/27	10.1.1.164	10.1.1.190
10.1.1.192/27	10.1.1.196	10.1.1.222
10.1.1.224/27	10.1.1.228	10.1.1.254

Create the Day0 Configuration With a Customized Configuration for Azure

You can enter the entire cluster bootstrap configuration using commands.

```
"Cluster": {
"CclSubnetRange": "ip_address_start ip_address_end",
"ClusterGroupName": "cluster_name",
```

```
"HealthProbePort": "port_number",
"GatewayLoadBalancerIP": "ip_address",
"EncapsulationType": "vxlan",
"InternalPort": "internal_port_number",
"ExternalPort": "external_port_number",
"InternalSegId": "internal_segment_id",
"ExternalSegId": "external_segment_id"
}
```

Deploy Cluster Nodes Manually - GWLB-based Deployment

Deploy the cluster nodes so they form a cluster.

Procedure

Step 1 Log into the Azure Portal: https://portal.azure.com

Step 2 Create a Resource Group.

a. In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.

b. Choose the required **Region**.

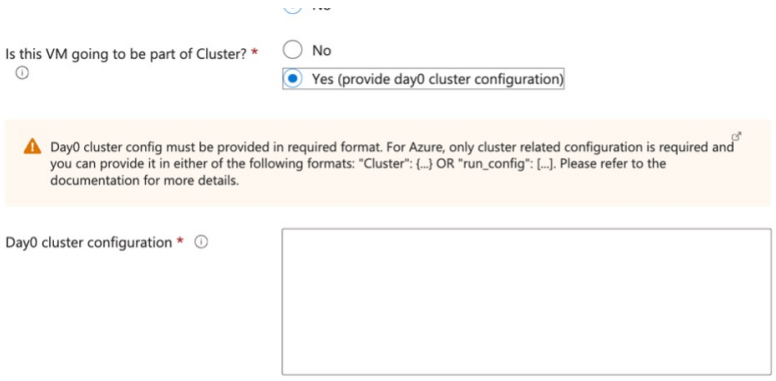
Step 3 Create a Virtual Network with the necessary subnets: Management, Data and Cluster Control Link (CCL).

Note
Configure the CCL with the smallest subnet mask as required. Wider subnets can impact performance.

See the Azure document for creating the Virtual Network and subnet: https://learn.microsoft.com/en-us/azure/virtual-network/quickstart-create-virtual-network?tabs=portal

Step 4 Go to the Marketplace and search for **Cisco Secure Firewall Threat Defense Virtual – BYOL and PAYG** and click **Create**.

Step 5 Fill the required details and choose **Yes** for **Is this VM going to be part of Cluster?**



Paste the following cluster-related configuration in the text box.

```
"Cluster": {
"CclSubnetRange": "ip_address_start ip_address_end", //mandatory user input
"ClusterGroupName": "cluster_name", //mandatory user input
"HealthProbePort": "port_number", //mandatory user input
"GatewayLoadBalancerIP": "ip_address",  //mandatory user input
```

```
"EncapsulationType": "vxlan",
"InternalPort": "internal_port_number",
"ExternalPort": "external_port_number",
"InternalSegId": "internal_segment_id",
"ExternalSegId": "external_segment_id"
}
```

Step 6 Click **Next** and select the **Virtual Network & Subnets**.

Ensure **GigabitEthernet 0/1 subnet** is configured with the CCL subnet.

Step 7 Click **Review + create**. Wait until the Threat Defense Virtual deployment is completed.

Step 8 Connect to the Threat Defense Virtual device and use the **show cluster info** command to confirm the cluster formation is successful.

```
> show cluster info
Cluster ngfwv-cluster: On
    Interface mode: individual
Cluster Member Limit : 16
    This is "4" in state CONTROL_NODE
        ID          : 0
        Version     : 9.23(1)
        Serial No.: 9AC1VMGJKAQ
        CCL IP      : 1.1.1.4
        CCL MAC     : 6045.bda8.e07b
        Module      : NGFWv
        Resource    : 4 cores / 14336 MB RAM
        Last join : 05:22:55 UTC Jul 14 2025
        Last leave: N/A
Other members in the cluster:
    There is no other unit in the cluster
>
```

Step 9 Configure the Azure Gateway Load Balancer. See Auto Scale with Azure Gateway Load Balancer Use Case for more information.

Step 10 Add the control node to the Firewall Management Center. See Add the Cluster to the Management Center (Manual Deployment), on page 760.

Deploy Cluster Nodes Manually - NLB-based Deployment

Deploy the cluster nodes so they form a cluster.

Procedure

Step 1 Log into the Azure Portal: https://portal.azure.com

Step 2 Create a Resource Group.

a. In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.

b. Choose the required **Region**.

Step 3 Create a Virtual Network with the necessary subnets: Management, Inside, Outside and Cluster Control Link (CCL).

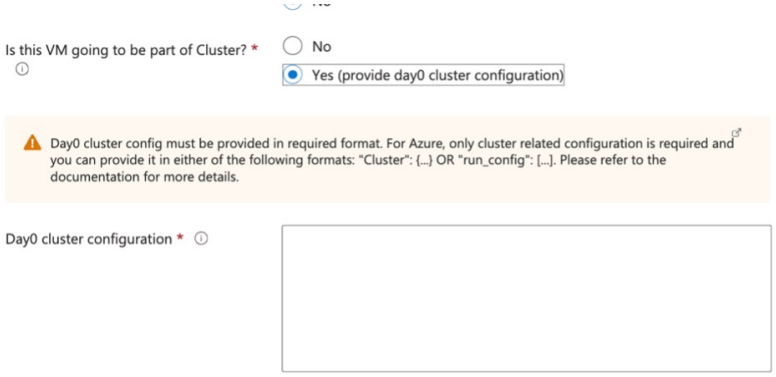
Note

Configure the CCL with the smallest subnet mask as required. Wider subnets can impact performance.

See the Azure document for creating the Virtual Network and subnet: https://learn.microsoft.com/en-us/azure/virtual-network/quickstart-create-virtual-network?tabs=portal

Step 4 Go to the Marketplace and search for **Cisco Secure Firewall Threat Defense Virtual – BYOL and PAYG** and click **Create**.

Step 5 Fill the required details and choose **Yes** for **Is this VM going to be part of Cluster?**



Paste the following cluster-related configuration in the text box.

```
"Cluster": {
"CclSubnetRange": "ip_address_start ip_address_end", //mandatory user input
"ClusterGroupName": "cluster_name" //mandatory user input
}
```

Step 6 Click **Next** and select the **Virtual Network & Subnets**.

If the diagnostic interface is enabled, user can attach maximum of four interfaces while deploying the Threat Defense Virtual VM. If the diagnostic is disabled, user can attach maximum of three interfaces while deploying the Threat Defense Virtual instance. So, the user must attach the extra interface for the cluster related communication after deploying the Threat Defense Virtual VM.

Step 7 Click **Review + create**. Wait until the Threat Defense Virtual deployment is completed.

Step 8 Power off the Threat Defense Virtual VM.

Step 9 Create a new interface using the CCL subnet and attach it to the Threat Defense Virtual VM. See the Azure document to create and attach new interface to the existing VM: https://learn.microsoft.com/en-us/azure/virtual-network/virtual-network-network-interface-vm

Step 10 Power On the Threat Defense Virtual VM.

Step 11 Connect to the Threat Defense Virtual device and use the **show cluster info** command to confirm the cluster formation is successful.

```
> show cluster info
Cluster ngfwv-cluster: On
    Interface mode: individual
Cluster Member Limit : 16
    This is "4" in state CONTROL_NODE
        ID        : 0
        Version   : 9.23(1)
        Serial No.: 9AC1VMGJKAQ
        CCL IP    : 1.1.1.4
        CCL MAC   : 6045.bda8.e07b
```

```
        Module    : NGFWv
        Resource  : 4 cores / 14336 MB RAM
        Last join : 05:22:55 UTC Jul 14 2025
        Last leave: N/A
Other members in the cluster:
    There is no other unit in the cluster
>
```

Step 12 Add the control node to the Management Center. See Add the Cluster to the Management Center (Manual Deployment), on page 760.

Troubleshooting Cluster Deployment in Azure

- Issue: No traffic flow

  Troubleshooting:

  - Check if the health probe status of the Threat Defense Virtual instances deployed with a GWLB is healthy.
  - If the Threat Defense Virtual instance's health probe status is unhealthy-
    - Check if the static route is configured in the Management Center Virtual.
    - Check if the default gateway is the data subnet's gateway IP.
    - Check if the Threat Defense Virtual instance is receiving health probe traffic.
    - Check if the access list configured in the Management Center Virtual allows health probe traffic.

- Issue: Cluster is not formed

  Troubleshooting:

  - Check the IP address of the nve-only cluster interface. Ensure that you can ping the nve-only cluster interface of other nodes.
  - Check the IP address of the nve-only cluster interfaces are part of the object group.
  - Ensure that the NVE interface is configured with the object group .
  - Ensure that the cluster interface in the cluster group has the right VNI interface. This VNI interface has the NVE with the corresponding object group.
  - Ensure that the nodes are pingable from each other. Since each node has its own cluster interface IP, these should be pingable from each other.
  - Check if the CCL Subnet's Start and End Address mentioned during template deployment is correct. The start address should begin with the first available IP address in the subnet. For example, if the subnet is 192.168.1.0/24. The start address should be 192.168.1.4 (the three IP addresses at the start are reserved by Azure).
  - Check if the Management Center Virtual has a valid license.

- Issue: Role-related error while deploying resources again in the same resource group.

Troubleshooting: Remove the roles given below by using the following commands on the terminal.

Error message:

```
"error": {
"code": "RoleAssignmentUpdateNotPermitted",
"message": "Tenant ID, application ID, principal ID, and scope are not allowed to be
updated.”}
```

- **az role assignment delete --resource-group** <*Resource Group Name*> **--role "Storage Queue Data Contributor"**
- **az role assignment delete --resource-group** <*Resource Group Name*> **--role "Contributor"**

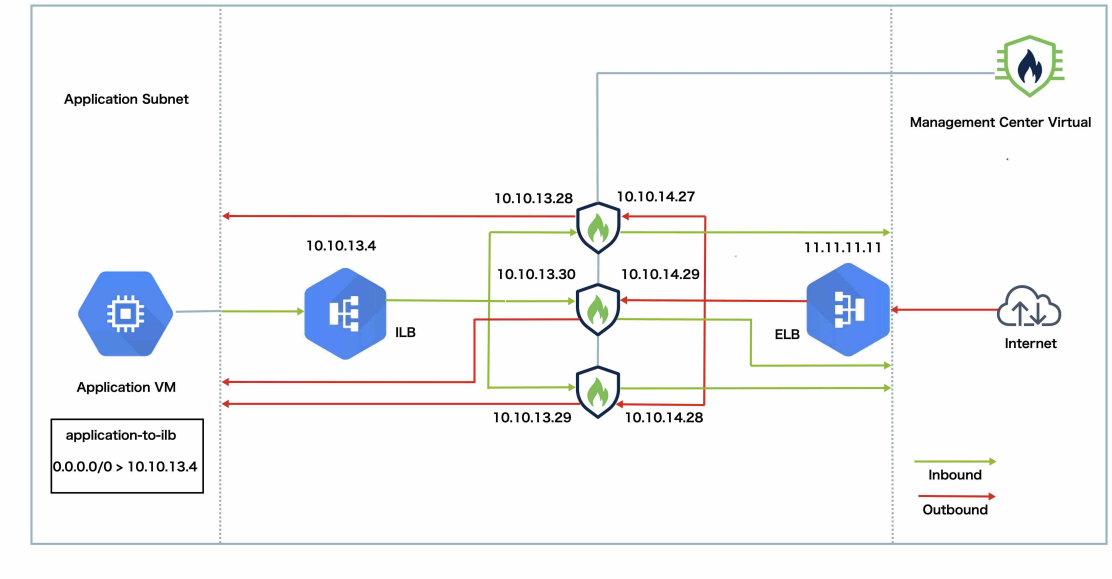
Deploy the Cluster in GCP

To deploy a cluster in GCP, you can either manually deploy or use an instance template to deploy an instance group. You can use the cluster with native GCP load-balancers, or non-native load balancers such as the Cisco Cloud Services Router.

Note Outbound traffic requires interface NAT and is limited to 64K connections.

Sample Topology of GCP Clustering Autoscale Solution

Figure 225: Sample Topology



The topology shows both inbound and outbound traffic flow.

1. The Threat Defense Virtual cluster is placed between the internal and external load balancers. A Management Center Virtual instance is used to manage the cluster.
2. Inbound traffic from the internet goes to the external load balancer, which then transmits the traffic to the Threat Defense Virtual cluster.
3. The Threat Defense Virtual instance in the cluster inspects the traffic, and after inspection, forwards the traffic to the application VM.
4. Outbound traffic from the application VM goes to the internal load balancer. The load balancer forwards this traffic to the Threat Defense Virtual cluster, which sends it to the internet.

End-to-End Process for Deploying Threat Defense Virtual Cluster in GCP

Template-based Deployment

The following flowchart illustrates the workflow for template-based deployment of the Threat Defense Virtual cluster on GCP.

	Workspace	Steps
1	Local Host	Download templates and files from GitHub.
2	Local Host	Edit template parameters.
3	Google Cloud Platform	Create GCP bucket.
4	Local Host	Create Google Cloud function source archive file *ftdv_cluster_function.zip*.
5	Google Cloud Platform	Upload the Google function source archive file.
6	Google Cloud Platform	Deploy infrastructure.yaml.
7	Google Cloud Platform	If private IP addresses are used, create VPC connector.
8	Google Cloud Platform	If external IP addresses are used, set *deployWithExternalIP* to *True* in *cluster_function_infra.yaml*.
9	Google Cloud Platform	Deploy cluster function infrastructure template.
10	Google Cloud Platform	Deploy cluster.

Manual Deployment

The following flowchart illustrates the workflow for manual deployment of the Threat Defense Virtual cluster on GCP.

	Workspace	Steps
1	Local Host	Create day 0 configuration script.
2	Google Cloud Platform	Create instance template using day 0 configuration.
3	Google Cloud Platform	Configure the interfaces.
4	Google Cloud Platform	Create instance group and attach instance template.
5	Google Cloud Platform	Create NLB and attach to instance group.
6	Google Cloud Platform	Create firewall rules for NLB.
7	Management Center	Create access rules for health check traffic.
8	Management Center	Add control node.

Templates

The templates given below are available in GitHub. The parameter values are self-explanatory with the parameter names, and values, given in the template.

- Cluster deployment template for East-West traffic - *deploy_ngfw_cluster_yaml*
- Cluster deployment template for North-South traffic - deploy_ngfw_cluster.yaml

Deploy the Instance Group in GCP Using an Instance Template

Deploy the instance group in GCP using an instance template.

Before you begin

- Use Google Cloud Shell for deployment. Alternatively, you can use Google SDK on any macOS/Linux/Windows machine.
- To allow the cluster to auto-register with the Management Center, you need to create a user with administrative privileges on the Management Center that can use the REST API. See the Cisco Secure Firewall Management Center Administration Guide.
- Add an access policy in the Management Center that matches the name of the policy that you specified in *cluster_function_infra.yaml*.

Procedure

Step 1 Download the templates from GitHub to your local folder.

Step 2 Edit **infrastructure.yaml** , **cluster_function_infra.yaml** and **deploy_ngfw_cluster.yaml** with the required *resourceNamePrefix* parameter (for example, ngfwvcls) and other required user inputs.

Note that there is a **deploy_ngfw_cluster.yaml** file in both the **east-west** and **north-south** folders in GitHub. Download the appropriate template as per your traffic flow requirement.

Step 3 Create a bucket using Google Cloud Shell to upload the Google cloud function source archive file *ftdv_cluster_function.zip*.

gsutil mb --pap enforced gs://*resourceNamePrefix***-ftdv-cluster-bucket/**

Ensure that the *resourceNamePrefix* variable here matches the *resourceNamePrefix* variable that you specified in **cluster_function_infra.yaml**.

Step 4 Create an archive file for the cluster infrastructure.

Example:

```
zip -j ftdv_cluster_function.zip ./cluster-function/*
```

Step 5 Upload the Google source archive that you created earlier.

gsutil cp ftdv_cluster_function.zip gs://*resourceNamePrefix***-ftdv-cluster-bucket/**

Step 6 Deploy infrastructure for the cluster.

gcloud deployment-manager deployments create *cluster_name* **--config infrastructure.yaml**

Step 7 If you are using private IP addresses, perform the steps given below:

a) Launch and set up the Management Center Virtual with a Threat Defense Virtual management VPC.

b) Create a VPC connector to connect the Google Cloud functions with the Threat Defense Virtual management VPC.

gcloud compute networks vpc-access connectors create *vpc-connector-name* **--region us-central1 --subnet** *resourceNamePrefix***-ftdv-mgmt-subnet28**

Step 8 If the Management Center is remote from the Threat Defense Virtual, and the Threat Defense Virtual needs an external IP address, ensure that you set **deployWithExternalIP** to **True** in **cluster_function_infra.yaml**.

Step 9 Deploy the cluster function infrastructure.

gcloud deployment-manager deployments create *cluster_name* **--config cluster_function_infra.yaml**

Step 10 Deploy the cluster.

a. For North-South topology deployment:

gcloud deployment-manager deployments create *cluster_name* **--config north-south/deploy_ngfw_cluster.yaml**

b. For East-West topology deployment:

gcloud deployment-manager deployments create *cluster_name* **--config east-west/deploy_ngfw_cluster.yaml**

Deploy the Cluster in GCP Manually

To deploy the cluster manually, prepare the day0 configuration, deploy each node, and then add the control node to the Firewall Management Center.

Create the Day0 Configuration for GCP

You can use either a fixed configuration or a customized configuration.

Create the Day0 Configuration With a Fixed Configuration for GCP

The fixed configuration will auto-generate the cluster bootstrap configuration.

```
{
    "AdminPassword": "password",
    "Hostname": "hostname",
    "FirewallMode": "Routed",
    "ManageLocally": "No",
                "Diagnostic": "OFF",
    "Cluster": {
        "CclSubnetRange": "ip_address_start ip_address_end",
        "ClusterGroupName": "cluster_name"
    }
}
```

For example:

```
{
    "AdminPassword": "DeanW1nche$ter",
    "Hostname": "ciscoftdv",
    "FirewallMode": "Routed",
    "ManageLocally": "No",
    "Cluster": {
        "CclSubnetRange": "10.10.55.2 10.10.55.253",     //mandatory user input
        "ClusterGroupName": "ftdv-cluster"               //mandatory user input
    }
}
```

Note If you are copying and pasting the configuration given above, ensure that you remove **//mandatory user input** from the configuration.

For the **CclSubnetRange** variable, note that you cannot use the first two IP addresses and the last two IP addresses in the subnet. See Reserved IP addresses in IPv4 subnets for more information. Ensure that you have at least 16 available IP addresses for clustering. Some examples of start and end IP addresses are given below.

Table 59: Examples of Start and End IP addresses

CIDR	Start IP Address	End IP Address
10.1.1.0/27	10.1.1.2	10.1.1.29
10.1.1.32/27	10.1.1.34	10.1.1.61
10.1.1.64/27	10.1.1.66	10.1.1.93
10.1.1.96/27	10.1.1.98	10.1.1.125
10.1.1.128/27	10.1.1.130	10.1.1.157
10.1.1.160/27	10.1.1.162	10.1.1.189
10.1.1.192/27	10.1.1.194	10.1.1.221
10.1.1.224/27	10.1.1.226	10.1.1.253
10.1.1.0/24	10.1.1.2	10.1.1.253

Create the Day0 Configuration With a Customized Configuration for GCP

You can enter the entire cluster bootstrap configuration using commands.

```
{
    "AdminPassword": "password",
    "Hostname": "hostname",
    "FirewallMode": "Routed",
    "ManageLocally": "No",
    "run_config": [comma_separated_threat_defense_configuration]
    }
```

The following example creates a configuration with Management, Inside, and Outside interfaces, and a VXLAN interface for the cluster control link. Note the values in bold that need to be unique per node.

```
{
 "AdminPassword": "W1nch3sterBr0s",
 "Hostname": "ftdv1",
 "FirewallMode": "Routed",
 "ManageLocally": "No",
 "run_config": [
  "cluster interface-mode individual force",
  "interface Management0/0",
  "management-only",
  "nameif management",
  "ip address dhcp",
  "interface GigabitEthernet0/0",
```

```
  "no shutdown",
  "nameif outside",
  "ip address dhcp",
  "interface GigabitEthernet0/1",
  "no shutdown",
  "nameif inside",
  "ip address dhcp",
  "interface GigabitEthernet0/2",
  "nve-only cluster",
  "nameif ccl_link",
  "ip address dhcp",
  "no shutdown",
  "interface vni1",
  "description Clustering Interface",
  "segment-id 1",
  "vtep-nve 1",
  "object network ccl#link",
  "range 10.1.90.2 10.1.90.17",
  "object-group network cluster#group",
  "network-object object ccl#link",
  "nve 1",
  "encapsulation vxlan",
  "source-interface ccl_link",
  "peer-group cluster#group",
  "cluster group ftdv-cluster",
  "local-unit 1",
  "cluster-interface vni1 ip 10.1.1.1 255.255.255.0",
  "priority 1",
  "enable",
  "mtu outside 1400",
  "mtu inside 1400"
 ]
}
```

Note For the cluster control link network object, specify only as many addresses as you need (up to 16). A larger range can affect performance.

Deploy Cluster Nodes Manually

Deploy the cluster nodes so they form a cluster. For clustering on GCP, you cannot use the 4 vCPU machine type. The 4 vCPU machine type only supports four interfaces, and five are needed. Use a machine type that supports five interfaces, such as c2-standard-8.

Procedure

Step 1 Create an instance template using the day 0 configuration (in the **Metadata** > **Startup Script** section) with 5 interfaces: outside, inside, management, diagnostic, and cluster control link.

See Cisco Secure Firewall Threat Defense Virtual Getting Started Guide.

Step 2 Create an instance group, and attach the instance template.

Step 3 Create GCP network load balancers (internal and external), and attach the instance group.

Step 4 For GCP network load balancers, allow health checks in your security policy on the Management Center. See Allow Health Checks for GCP Network Load Balancers, on page 759.

Step 5 Add the control node to the Management Center. See Add the Cluster to the Management Center (Manual Deployment), on page 760.

Allow Health Checks for GCP Network Load Balancers

Google Cloud provides health checks to determine if backends respond to traffic.

See https://cloud.google.com/load-balancing/docs/health-checks to create firewall rules for network load balancers. Then in the Firewall Management Center, create access rules to allow the health check traffic. See https://cloud.google.com/load-balancing/docs/health-check-concepts for the required network ranges. See Access Control Rules, on page 1817.

You also need to configure dynamic manual NAT rules to redirect the health check traffic to the Google metadata server at 169.254.169.254. See Configure Dynamic Manual NAT, on page 1121.

You can set up a route for GCP health checks across all interfaces that are used to configure their health probes. You can achieve this by creating a route with a higher metric on interfaces where a route for GCP health checks is not already available.

North-South NAT Rules Sample Configuration

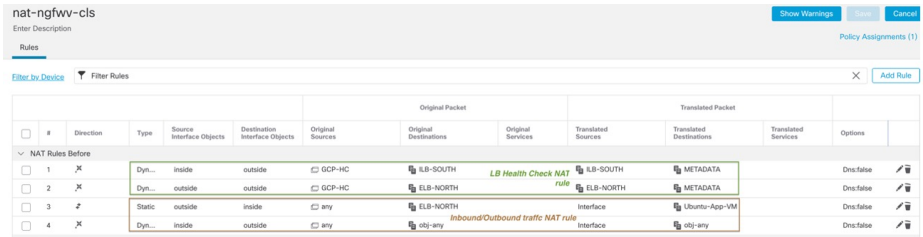
```
nat (inside,outside) source dynamic GCP-HC ILB-SOUTH destination static ILB-SOUTH METADATA
nat (outside,outside) source dynamic GCP-HC ELB-NORTH destination static ELB-NORTH METADATA

nat (outside,inside) source static any interface destination static ELB-NORTH Ubuntu-App-VM
nat (inside,outside) source dynamic any interface destination static obj-any obj-any

object network Metadata
 host 169.254.169.254

object network ILB-SOUTH
host <ILB_IP>
object network ELB-NORTH
host <ELB_IP>

object-group network GCP-HC
 network-object 35.191.0.0 255.255.0.0
 network-object 130.211.0.0 255.255.252.0
 network-object 209.85.204.0 255.255.252.0
 network-object 209.85.152.0 255.255.252.0
```



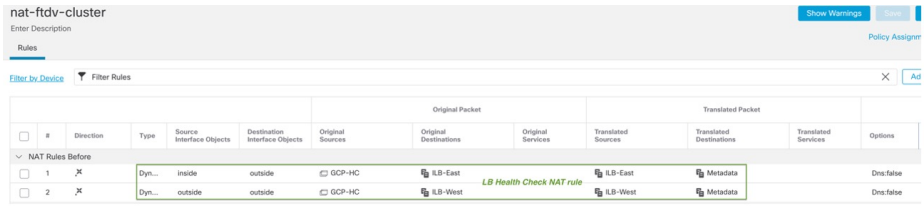
East-West NAT Rules Sample Configuration

```
nat (inside,outside) source dynamic GCP-HC ILB-East destination static ILB-East Metadata
nat (outside,outside) source dynamic GCP-HC ILB-West destination static ILB-West Metadata
```

```
object network Metadata
 host 169.254.169.254

object network ILB-East
host <ILB_East_IP>
object network ILB-West
host <ILB_West_IP>

object-group network GCP-HC
 network-object 35.191.0.0 255.255.0.0
 network-object 130.211.0.0 255.255.252.0
 network-object 209.85.204.0 255.255.252.0
 network-object 209.85.152.0 255.255.252.0
```



North-South and East-West Traffic Routing Configuration Sample

```
route outside 0.0.0.0 0.0.0.0 <Outside_Gateway> 1
route inside 35.191.0.0 255.255.0.0 <Inside_Gateway> 1
route inside 130.211.0.0 255.255.252.0 <Inside_Gateway> 1
route inside 209.85.152.0 255.255.252.0 <Inside_Gateway> 1
route inside 209.85.204.0 255.255.252.0 <Inside_Gateway> 1
```

If a default route is not available, then policy-based routing can be used to route the traffic for health checks.

Add the Cluster to the Management Center (Manual Deployment)

Use this procedure to add the cluster to the Firewall Management Center if you manually deployed the cluster. If you used a template, the cluster will auto-register on the Firewall Management Center.

Add one of the cluster units as a new device to the Firewall Management Center; the Firewall Management Center auto-detects all other cluster members.

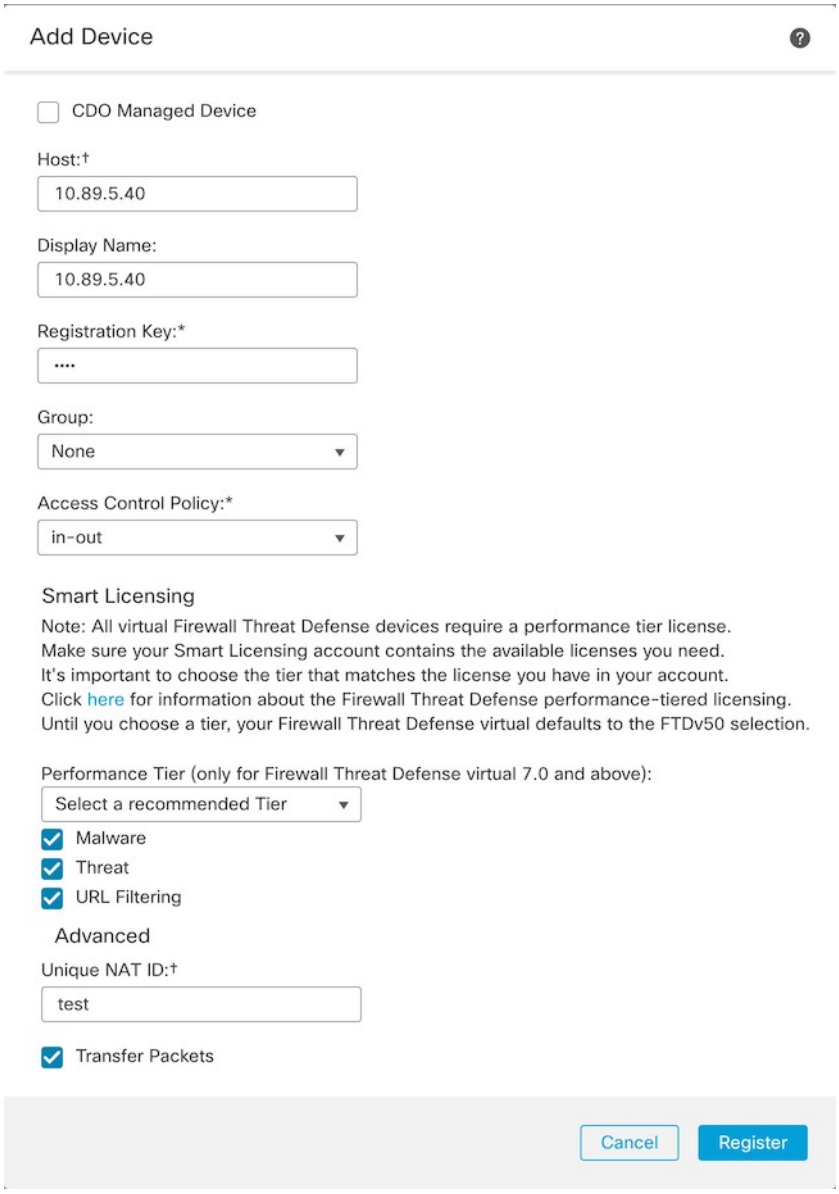
Before you begin

- All cluster units must be in a successfully-formed cluster prior to adding the cluster to the Firewall Management Center. You should also check which unit is the control unit. Use the Firewall Threat Defense **show cluster info** command.

Procedure

Step 1 In the Firewall Management Center, choose **Devices** > **Device Management**, and then choose **Add** > **Add Device** to add the control unit using the unit's management IP address.

Figure 226: Add Device



a) In the **Host** field, enter the IP address or hostname of the control unit.

   We recommend adding the control unit for the best performance, but you can add any unit of the cluster.

   If you used a NAT ID during device setup, you may not need to enter this field.

b) In the **Display Name** field, enter a name for the control unit as you want it to display in the Firewall Management Center.

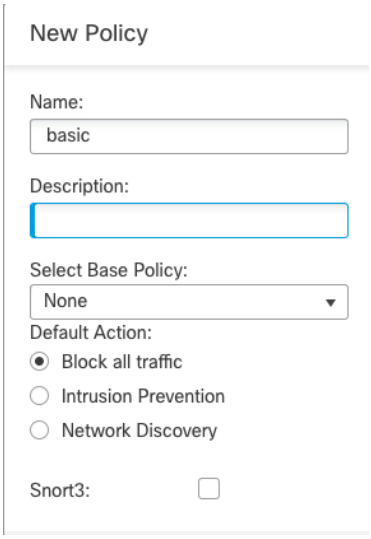
   This display name is not for the cluster; it is only for the control unit you are adding. You can later change the name of other cluster members and the cluster display name.

c) In the **Registration Key** field, enter the same registration key that you used during device setup. The registration key is a one-time-use shared secret.

d) (Optional) Add the device to a device **Group**.

e) Choose an initial **Access Control Policy** to deploy to the device upon registration, or create a new policy.

If you create a new policy, you create a basic policy only. You can later customize the policy as needed.



f) Choose licenses to apply to the device.

g) If you used a NAT ID during device setup, expand the **Advanced** section and enter the same NAT ID in the **Unique NAT ID** field.

h) Check the **Transfer Packets** check box to allow the device to transfer packets to the Firewall Management Center.

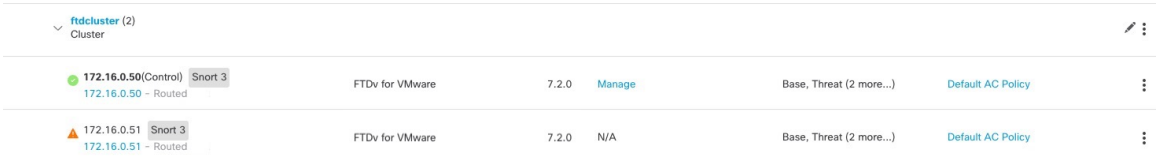
This option is enabled by default. When events like IPS or Snort are triggered with this option enabled, the device sends event metadata information and packet data to the Firewall Management Center for inspection. If you disable it, only event information will be sent to the Firewall Management Center but packet data is not sent.

i) Click **Register**.

The Firewall Management Center identifies and registers the control unit, and then registers all data units. If the control unit does not successfully register, then the cluster is not added. A registration failure can occur if the cluster was not up, or because of other connectivity issues. In this case, we recommend that you try re-adding the cluster unit.

The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster units.

Figure 227: Cluster Management

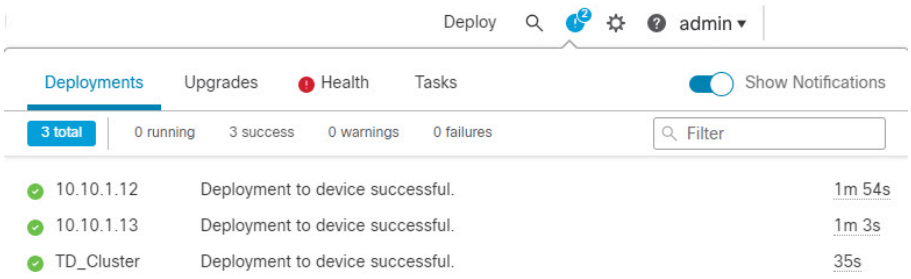


A unit that is currently registering shows the loading icon.

Figure 228: Node Registration

Note
GCP prioritizes nodes with public IP address during cluster node discovery. To ensure the Firewall Threat Defense Virtual cluster registers with the management center virtual using the private IP address, you must first disable the public IP address on the Firewall Threat Defense Virtual cluster node. This allows GCP node discovery to proceed using the private IP address for registration node with the management center virtual.

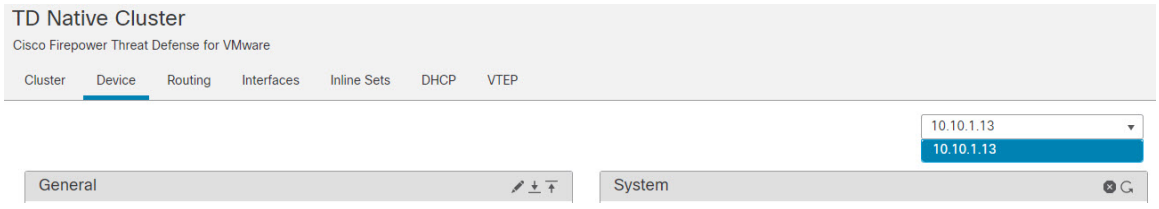
You can monitor cluster unit registration by clicking the **Notifications** icon and choosing **Tasks**. The Firewall Management Center updates the Cluster Registration task as each unit registers. If any units fail to register, see Reconcile Cluster Nodes, on page 772.



Step 2 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

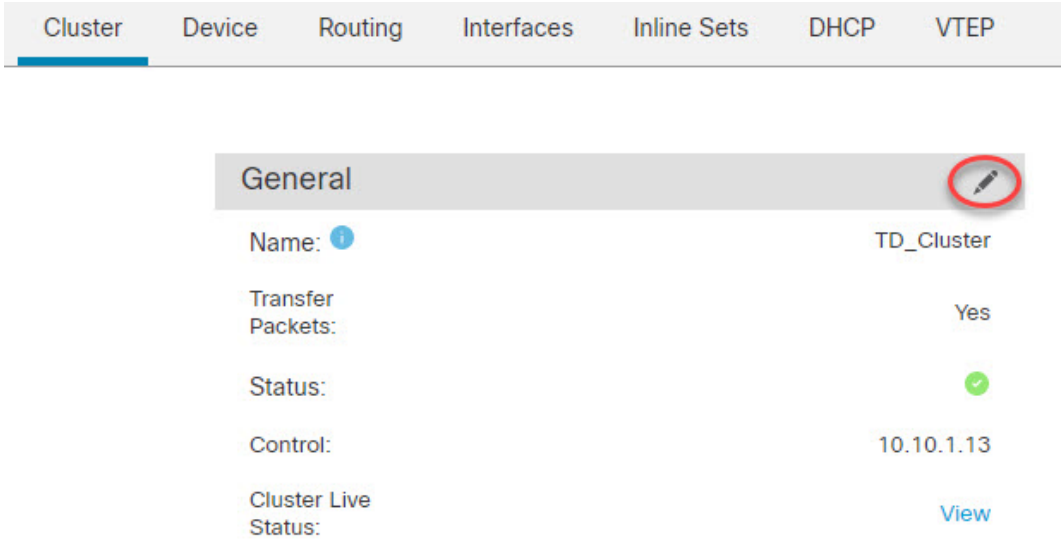
Most configuration can be applied to the cluster as a whole, and not nodes in the cluster. For example, you can change the display name per node, but you can only configure interfaces for the whole cluster.

Step 3 On the **Devices** > **Device Management** and then choose **Add**, **Cluster** screen, you see **General**, **License**, **System**, and **Health** settings.

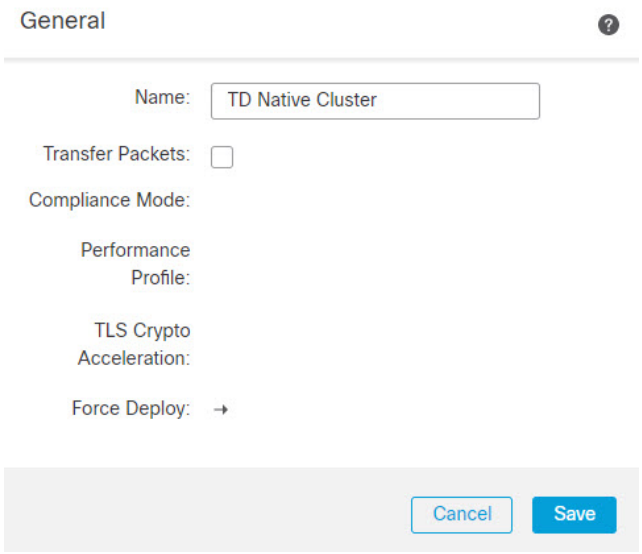


See the following cluster-specific items:

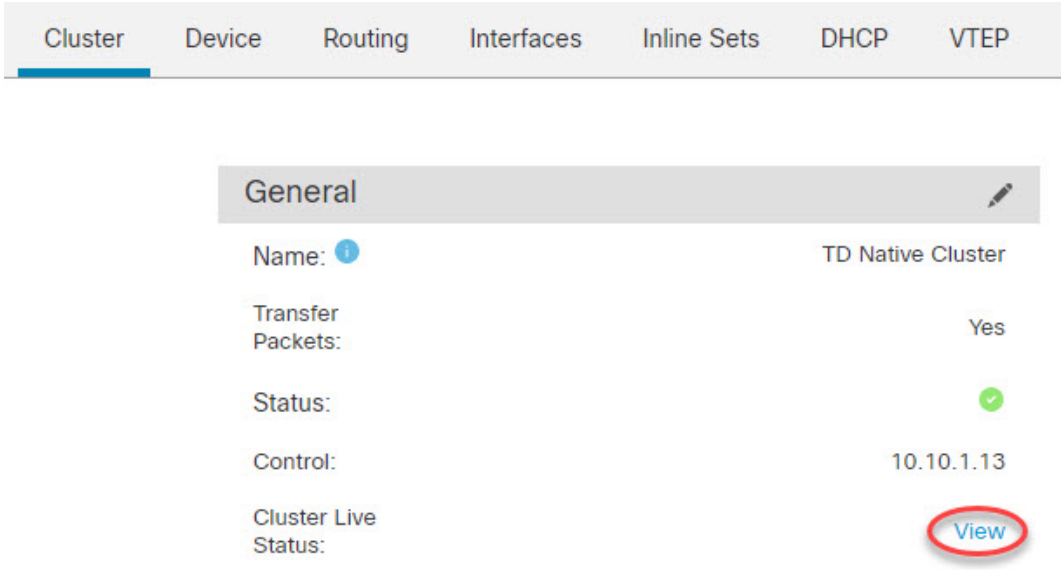
- **General** > **Name**—Change the cluster display name by clicking the **Edit** (✎).



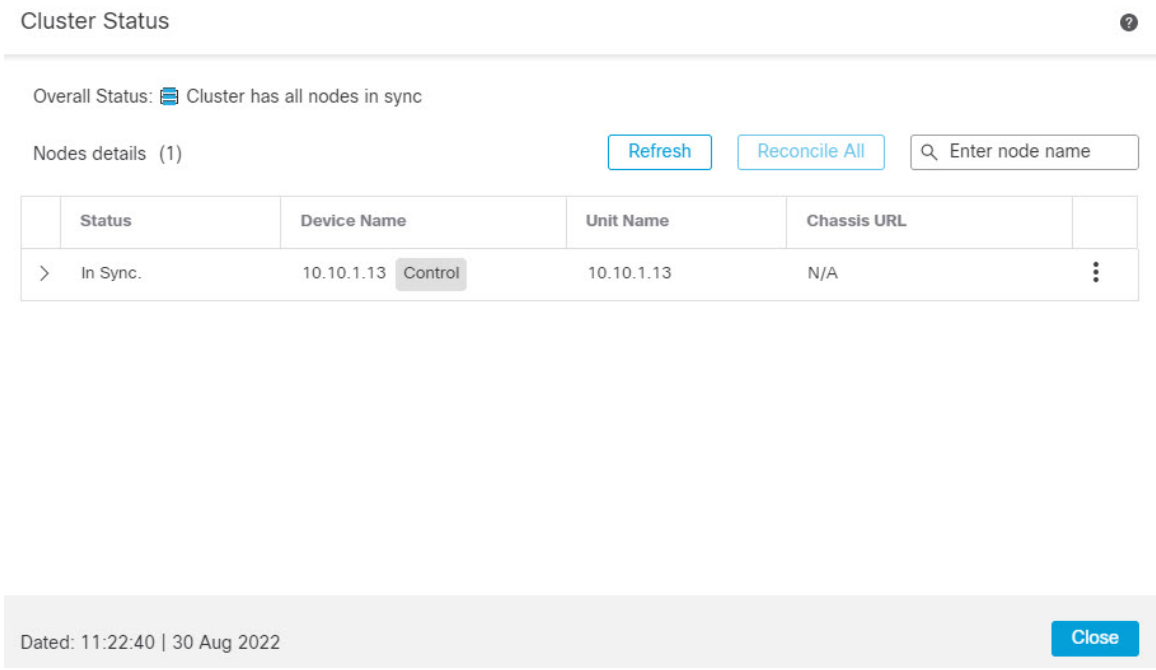
Then set the **Name** field.



- **General > Cluster Live Status**—Click the **View** link to open the **Cluster Status** dialog box.



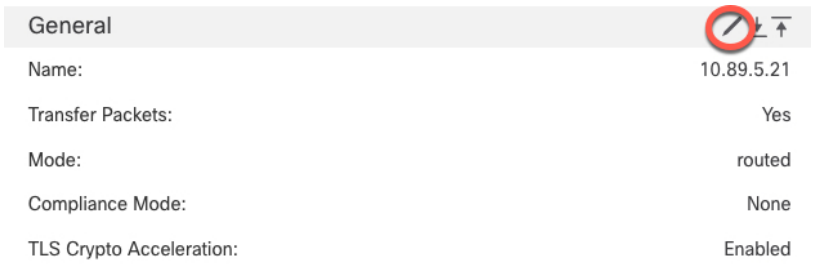
The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile**.



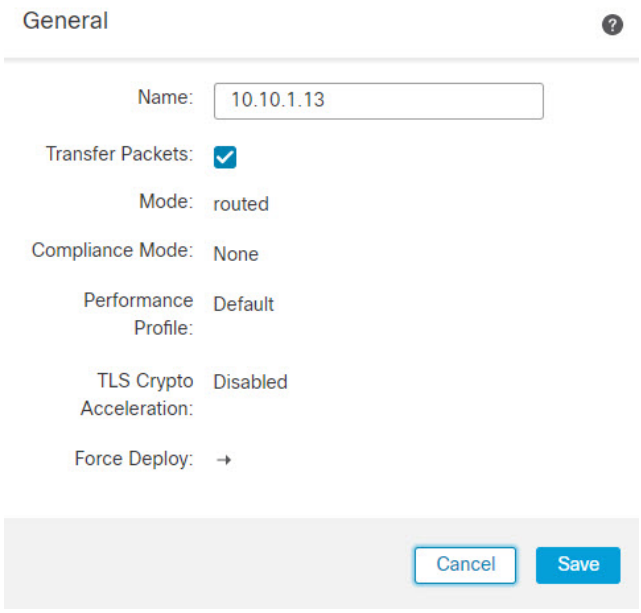
- **License**—Click **Edit** (✎) to set license entitlements.

Step 4 On the **Devices** > **Device Management** and then click **Add** > **Device** , you can choose each member in the cluster from the top right drop-down menu and configure the following settings.

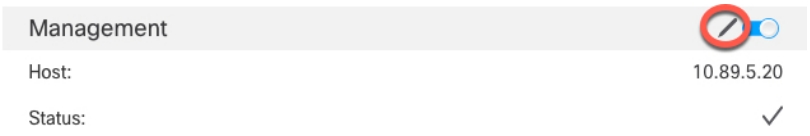
- **General > Name**—Change the cluster member display name by clicking the **Edit** (✎).



Then set the **Name** field.



- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the Firewall Management Center so that it can reach the device on the network; edit the **Host** address in the **Management** area.



Configure Cluster Health Monitor Settings

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings described in the table below.

Figure 229: Cluster Health Monitor Settings

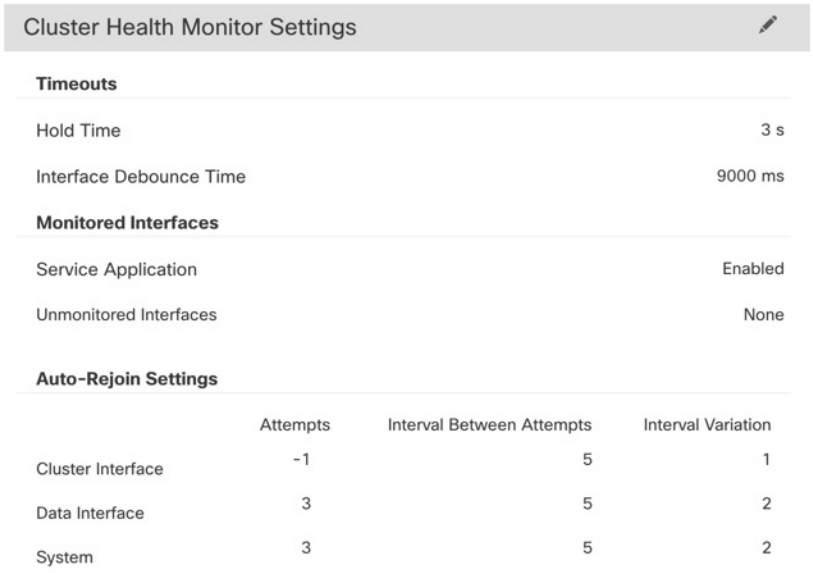


Table 60: Cluster Health Monitor Settings Section Table Fields

Field	Description
Timeouts	
Hold Time	Between .3 and 45 seconds; The default is 3 seconds. To determine node system health, the cluster nodes send heartbeat messages on the cluster control link to other nodes. If a node does not receive any heartbeat messages from a peer node within the hold time period, the peer node is considered unresponsive or dead.
Interface Debounce Time	Between 300 and 9000 ms. The default is 500 ms. The interface debounce time is the amount of time before the node considers an interface to be failed, and the node is removed from the cluster.
Monitored Interfaces	The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster.
Service Application	Shows whether the Snort and disk-full processes are monitored.
Unmonitored Interfaces	Shows unmonitored interfaces.
Auto-Rejoin Settings	
Cluster Interface	Shows the auto-rejoin settings after a cluster control link failure.

Field	Description
Attempts	Between -1 and 65535. The default is -1 (unlimited). Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 1x the interval duration. Defines if the interval duration increases at each attempt.
Data Interfaces	Shows the auto-rejoin settings after a data interface failure.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.
System	Shows the auto-rejoin settings after internal errors. Internal failures include: application sync timeout; inconsistent application statuses; and so on.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.

Note If you disable the system health check, fields that do not apply when the system health check is disabled will not show.

You can change these settings from this section.

You can monitor any port-channel ID, single physical interface ID, as well as the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link; it is always monitored.

Procedure

Step 1 Choose **Devices** > **Device Management**.

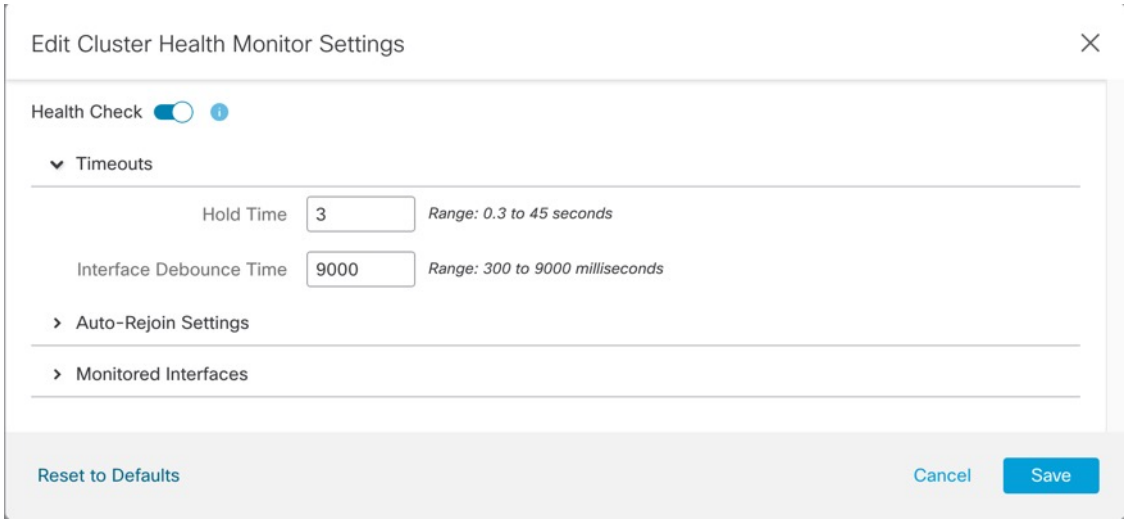
Step 2 Next to the cluster you want to modify, click **Edit** ( ).

Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider .

Figure 230: Disable the System Health Check



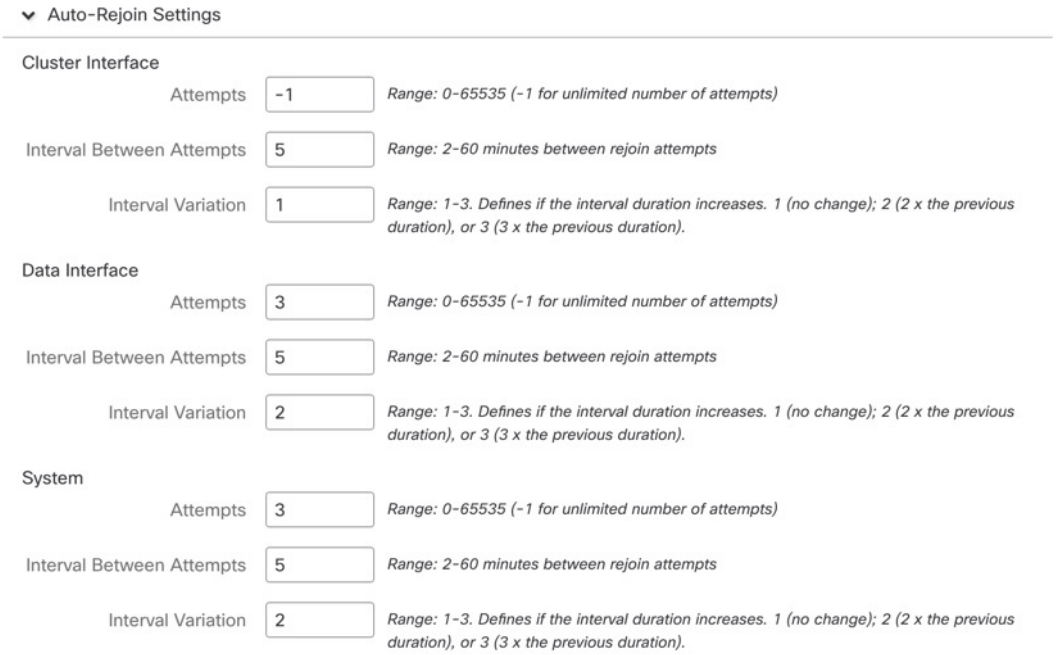
When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between .3 and 45 seconds; The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the number of milliseconds specified before marking the interface as failed, and the node is removed from the cluster. In the case of an EtherChannel that transitions from a down state to an up state (for example, the switch reloaded, or the switch enabled an EtherChannel), a longer debounce time can prevent the interface from appearing to be failed on a cluster node just because another cluster node was faster at bundling the ports.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 231: Configure Auto-Rejoin Settings

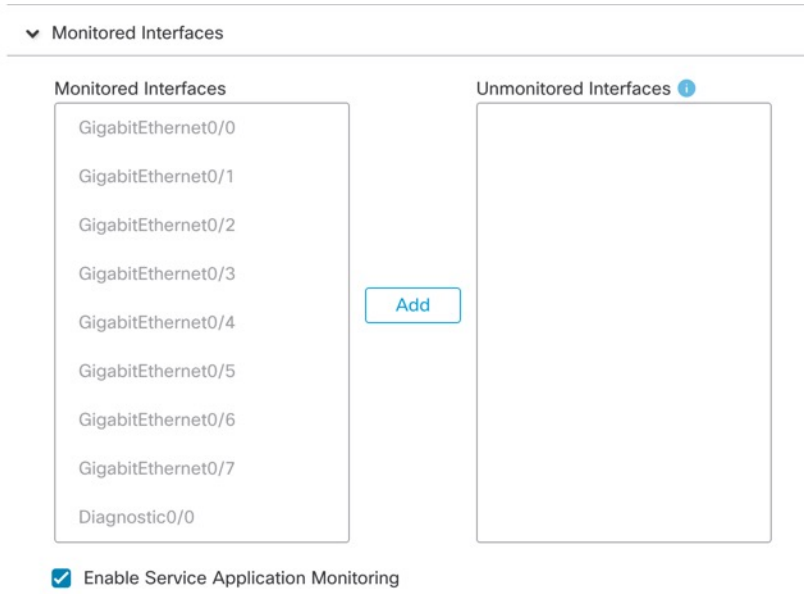


Set the following values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 232: Configure Monitored Interfaces



The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. Health check is enabled by default for all interfaces and for the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save**.

Step 10 Deploy configuration changes.

Manage Cluster Nodes

Disable Clustering

You may want to deactivate a node in preparation for deleting the node, or temporarily for maintenance. This procedure is meant to temporarily deactivate a node; the node will still appear in the Firewall Management Center device list. When a node becomes inactive, all data interfaces are shut down.

Note Do not power off the node without first disabling clustering.

Procedure

Step 1 For the unit you want to disable, choose **Devices** > **Device Management**, click the **More** (⋮), and choose **Disable Node Clustering**.

Step 2 Confirm that you want to disable clustering on the node.

The node will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.

Step 3 To reenable clustering, see Rejoin the Cluster, on page 772.

Rejoin the Cluster

If a node was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster.

Procedure

Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management**, click the **More** (⋮), and choose **Enable Node Clustering**.

Step 2 Confirm that you want to enable clustering on the node.

Reconcile Cluster Nodes

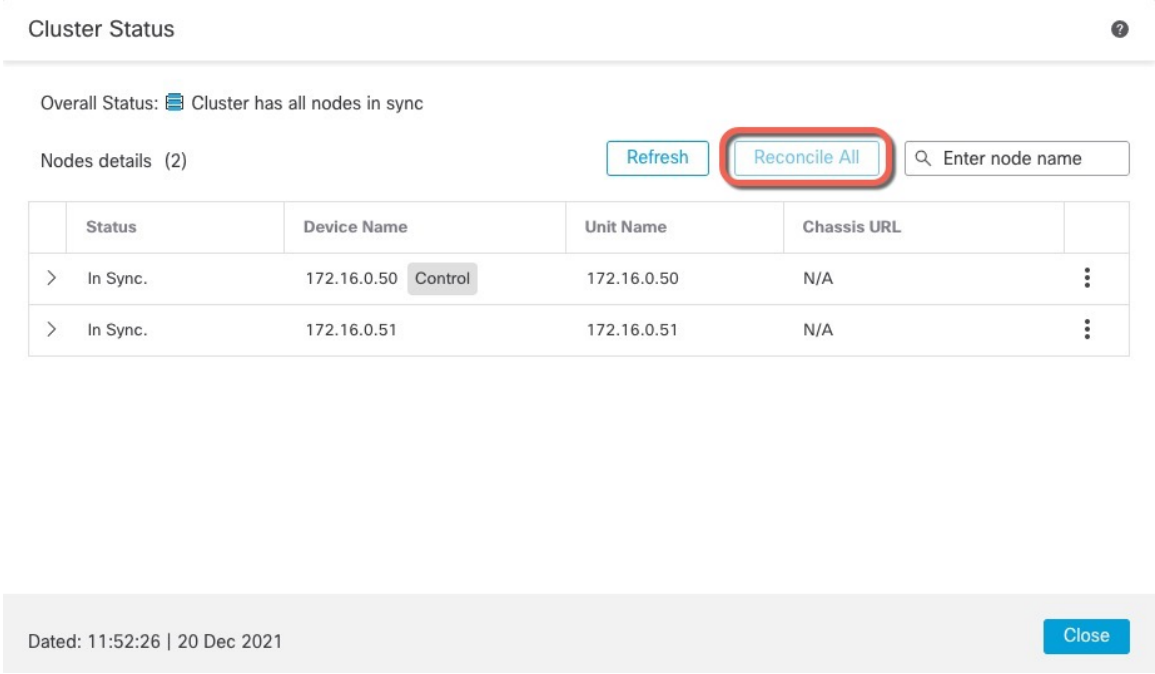
If a cluster node fails to register, you can reconcile the cluster membership from the device to the Firewall Management Center. For example, a data node might fail to register if the Firewall Management Center is occupied with certain processes, or if there is a network issue.

Procedure

Step 1 Choose **Devices** > **Device Management More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

Step 2 Click **Reconcile All**.

Figure 233: Reconcile All



For more information about the cluster status, see Monitoring the Cluster, on page 774.

Delete (Unregister) the Cluster or Nodes and Register to a New Firewall Management Center

You can unregister the cluster from the Firewall Management Center, which keeps the cluster intact. You might want to unregister the cluster if you want to add the cluster to a new Firewall Management Center.

You can also unregister a node from the Firewall Management Center without breaking the node from the cluster. Although the node is not visible in the Firewall Management Center, it is still part of the cluster, and it will continue to pass traffic and could even become the control node. You cannot unregister the current control node. You might want to unregister the node if it is no longer reachable from the Firewall Management Center, but you still want to keep it as part of the cluster while you troubleshoot management connectivity.

Unregistering a cluster:

- Severs all communication between the Firewall Management Center and the cluster.
- Removes the cluster from the **Device Management** page.
- Returns the cluster to local time management if the cluster's platform settings policy is configured to receive time from the Firewall Management Center using NTP.
- Leaves the configuration intact, so the cluster continues to process traffic.

  Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the cluster again to the same or a different Firewall Management Center causes the configuration to be removed, so the cluster will stop processing traffic at that point; the cluster configuration remains intact so you can add the cluster as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.

Before you begin

This procedure requires CLI access to one of the nodes.

Procedure

Step 1 Choose **Devices** > **Device Management**, click **More** (⋮) for the cluster or node, and choose **Delete**.

Step 2 You are prompted to delete the cluster or node; click **Yes**.

Step 3 You can register the cluster to a new (or the same) Firewall Management Center by adding one of the cluster members as a new device.

You only need to add one of the cluster nodes as a device, and the rest of the cluster nodes will be discovered.

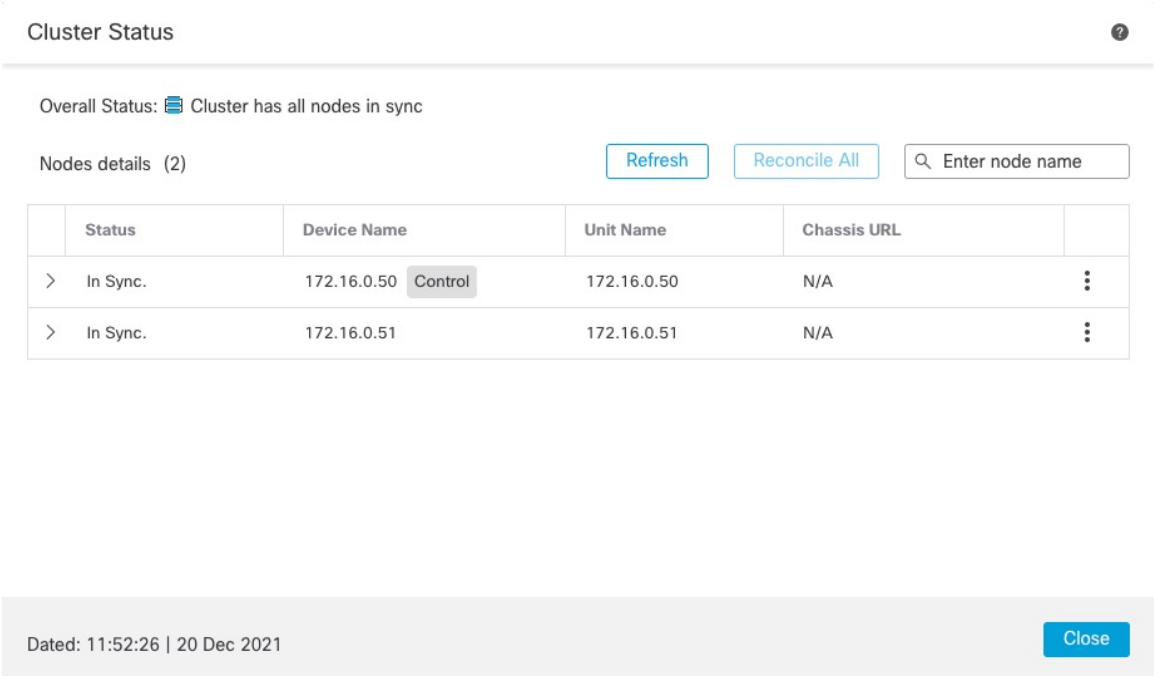
Step 4 To re-add a deleted node, see Reconcile Cluster Nodes, on page 772.

Monitoring the Cluster

You can monitor the cluster in the Firewall Management Center and at the Firewall Threat Defense CLI.

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management**, **More** (⋮) icon or from the **Devices** > **Device Management**, click **Add**, choose the **Cluster** page **General** area **Cluster Live Status** link.

Figure 234: Cluster Status



The Control node has a graphic indicator identifying its role.

Cluster member **Status** includes the following states:

- In Sync.—The node is registered with the Firewall Management Center.
- Pending Registration—The node is part of the cluster, but has not yet registered with the Firewall Management Center. If a node fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The node is registered with the Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the node from the cluster.
- Joining cluster...—The node is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Firewall Management Center.

For each node, you can view the **Summary** or the **History**.

Figure 235: Node Summary

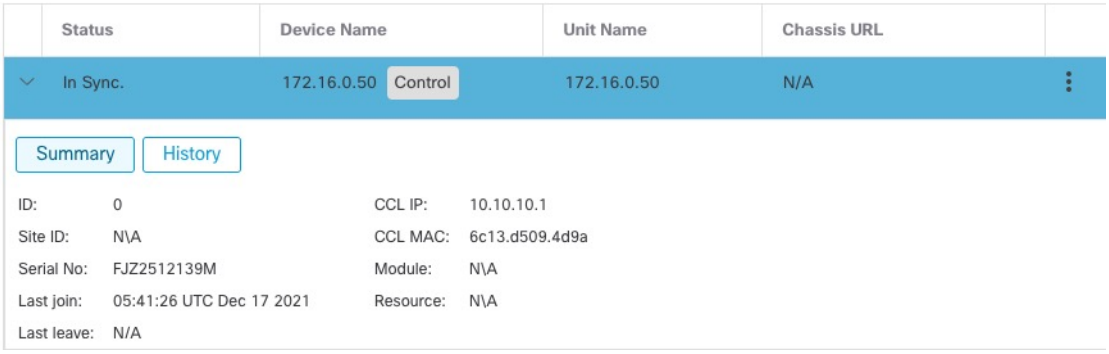


Figure 236: Node History

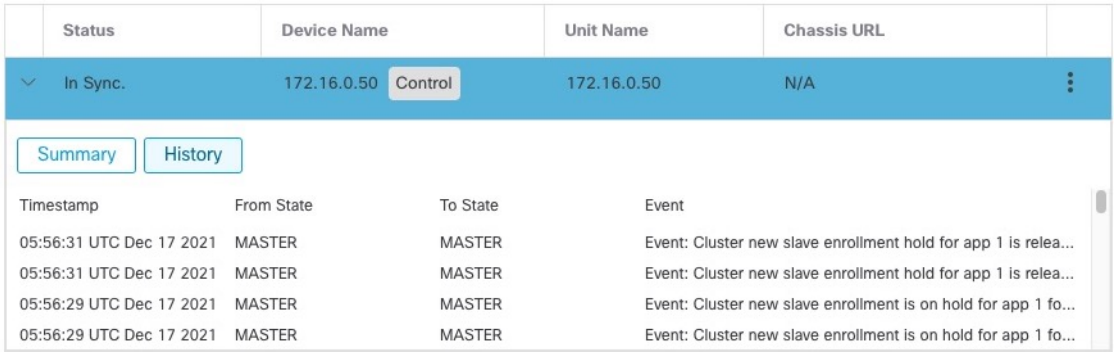


- **System** (⚙) > **Tasks** page.

  The **Tasks** page shows updates of the Cluster Registration task as each node registers.

- **Devices** > **Device Management** and then click **Add** > **Device** *cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member nodes, including the control node shown with its role next to the IP address. For nodes that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

Cluster Health Monitor Dashboard

Cluster Health Monitor

When a Firewall Threat Defense is the control node of a cluster, the Firewall Management Center collects various metrics periodically from the device metric data collector. The cluster health monitor is comprised of the following components:

- Overview dashboard—Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the Firewall Management Center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

  - The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.

- Load Distribution dashboard—Displays load distribution across the cluster nodes in two widgets:
  - The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
  - The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.
- Member Performance dashboard—Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard—Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links — Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range—An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard—Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

Viewing Cluster Health

You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

- Ensure you have created a cluster from one or more devices in the Firewall Management Center.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

Step 2 In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.

Step 3 To view the cluster health statistics, click on the cluster name. The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution — Traffic and packet distribution across the cluster nodes.
- Member Performance — Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL — Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, see Cisco Secure Firewall Threat Defense Health Metrics.

Step 4 You can configure the time range from the drop-down in the upper-right corner. The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

Step 6 (For node-specific health monitor) View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

Step 7 (For node-specific health monitor) The device monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU — CPU utilization, including the CPU usage by process and by physical cores.
- Memory — Device memory utilization, including data plane and Snort memory usage.
- Interfaces — Interface status and aggregate traffic statistics.
- Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort — Statistics that are related to the Snort process.
- ASP drops — Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. See Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 8 Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Cluster Metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

Table 61: Cluster Metrics

Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number
Distribution	Connection distribution count in the cluster for every second.	number

Metric	Description	Format
Packets	Packet distribution count in the cluster for every second.	number

Upgrading the Cluster

Perform the following steps to upgrade a Firewall Threat Defense Virtual cluster:

Before you begin

- Before you upgrade a cluster in the public cloud, copy the target version image to your cloud image repository and update the image ID in the cluster deployment template (we actually recommend replacing the existing template with a modified copy). This ensures that after the upgrade, new instances — for example, instances launched during cluster scaling — will use the correct version. If the marketplace does not have the image you need, such as when the cluster has been patched, create a custom image from a snapshot of a standalone Firewall Threat Defense Virtual instance running the correct version, with no instance-specific (day 0) configurations.
- For Firewall Threat Defense Virtual for AWS, suspend the HealthCheck and ReplaceUnhealthy processes before autoscaled cluster upgrade. This ensures that instances are not terminated by the Auto Scaling group during the post-upgrade reboot. You can resume the suspended processes afterwards. For instructions, see the Amazon EC2 Auto Scaling user guide: Suspend and resume Amazon EC2 Auto Scaling processes.

Procedure

Step 1 Upload the target image version to the cloud image storage.

Step 2 Update the cloud instance template of the cluster with the updated target image version.

a) Create a copy of the instance template with the target image version.

b) Attach the newly created template to cluster instance group.

Step 3 Upload the target image version upgrade package to the Firewall Management Center.

Step 4 Perform readiness check on the cluster that you want to upgrade.

Step 5 After successful readiness check, initiate installation of upgrade package.

Step 6 The Firewall Management Center upgrades the cluster nodes one at a time.

Step 7 The Firewall Management Center displays a notification after successful upgrade of the cluster.

There is no change in the serial number and UUID of the instance after the upgrade.

Reference for Clustering

This section includes more information about how clustering operates.

Threat Defense Features and Clustering

Some Firewall Threat Defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported Features and Clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

Note To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Firewall Management Center GUI. See FlexConfig Policies, on page 2645.

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- Firewall Management Center UCAPL/CC mode

Centralized Features for Clustering

The following features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Firewall Management Center GUI. See FlexConfig Policies, on page 2645.

- The following application inspections:
  - DCERPC
  - ESMTP

- NetBIOS
- PPTP
- RSH
- SQLNET
- SUNRPC
- TFTP
- XDMCP

- Static route monitoring

Cisco Trustsec and Clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

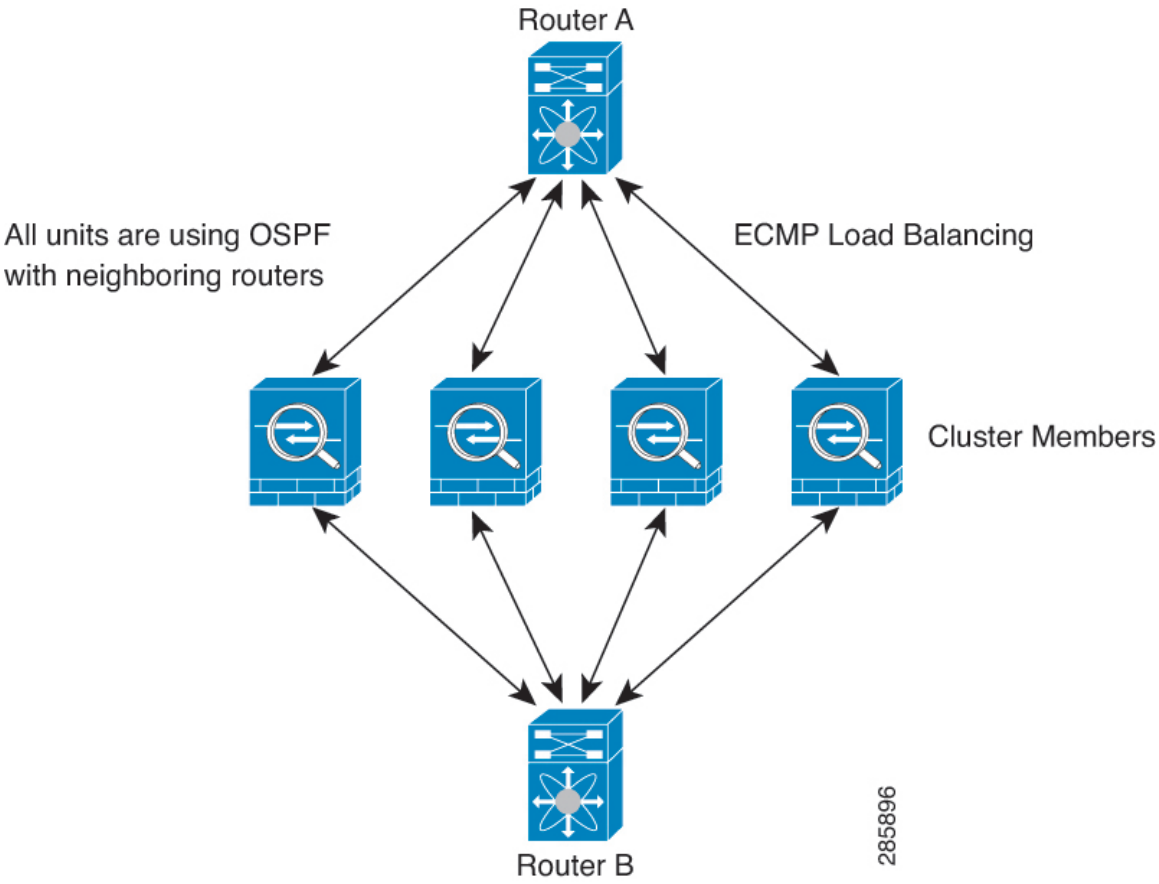
Connection Settings and Clustering

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

Dynamic Routing and Clustering

In Individual interface mode, each node runs the routing protocol as a standalone router, and routes are learned by each node independently.

Figure 237: Dynamic Routing in Individual Interface Mode



In the above diagram, Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when talking to external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

FTP and Clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

NAT and Clustering

For NAT usage, see the following limitations.

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different Firewall Threat Defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the Firewall Threat Defense that is not the NAT owner, it is forwarded over the cluster

control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- No Proxy ARP—For Individual interfaces, a proxy ARP reply is never sent for mapped addresses. This prevents the adjacent router from maintaining a peer relationship with an ASA that may no longer be in the cluster. The upstream router needs a static route or PBR with Object Tracking for the mapped addresses that points to the Main cluster IP address.
- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
  - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
  - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
  - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.

- No static PAT for the following inspections—
  - FTP
  - RSH
  - SQLNET
  - TFTP
  - XDMCP
  - SIP
- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

SIP Inspection and Clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and Clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and Clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

VPN and Clustering

Site-to-site VPN is a centralized feature; only the control node supports VPN connections.

Note Remote access VPN is not supported with clustering.

VPN functionality is limited to the control node and does not take advantage of the cluster high availability capabilities. If the control node fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control node is elected, you must reestablish the VPN connections.

For connections to an Individual interface when using PBR or ECMP, you must always connect to the Main cluster IP address, not a Local address.

VPN-related keys and certificates are replicated to all nodes.

Performance Scaling Factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

For example, if your model can handle approximately 10 Gbps of traffic when running alone, then for a cluster of 8 units, the maximum combined throughput will be approximately 80% of 80 Gbps (8 units x 10 Gbps): 64 Gbps.

Control Node Election

Nodes of the cluster communicate over the cluster control link to elect a control node as follows:

1. When you enable clustering for a node (or when it first starts up with clustering already enabled), it broadcasts an election request every 3 seconds.
2. Any other nodes with a higher priority respond to the election request; the priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a node does not receive a response from another node with a higher priority, then it becomes the control node.

Note If multiple nodes tie for the highest priority, the cluster node name and then the serial number is used to determine the control node.

4. If a node later joins the cluster with a higher priority, it does not automatically become the control node; the existing control node always remains as the control node unless it stops responding, at which point a new control node is elected.
5. In a "split brain" scenario when there are temporarily multiple control nodes, then the node with highest priority retains the role while the other nodes return to data node roles.

Note You can manually force a node to become the control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node.

High Availability within the Cluster

Clustering provides high availability by monitoring node and interface health and by replicating connection states between nodes.

Node Health Monitoring

Each node periodically sends a broadcast heartbeat packet over the cluster control link. If the control node does not receive any heartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining nodes.

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role.

Interface Monitoring

Each node monitors the link status of all named hardware interfaces in use, and reports status changes to the control node.

All physical interfaces are monitored; only named interfaces can be monitored. You can optionally disable monitoring per interface.

A node is removed from the cluster if its monitored interfaces fail. The node is removed after 500 ms.

Status After Failure

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The Firewall Threat Defense automatically tries to rejoin the cluster, depending on the failure event.

Note When the Firewall Threat Defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoining the Cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The Firewall Threat Defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The Firewall Threat Defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the Firewall Threat Defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means

the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The Firewall Threat Defense application attempts to rejoin the cluster every 5 seconds.

- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from Firewall Management Center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

Data Path Connection State Replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 62: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—
Dynamic routing	Yes	—
SNMP Engine ID	**No**	—

How the Cluster Manages Connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection Roles

See the following roles defined for each connection:

- Owner—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.

- Backup owner—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

  As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

  For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.

- Director—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

  As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

  ICMP/ICMPv6 hash details:

  - For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.

- Forwarder—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- Fragment Owner—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new

connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

Port Address Translation Connections

New Connection Ownership

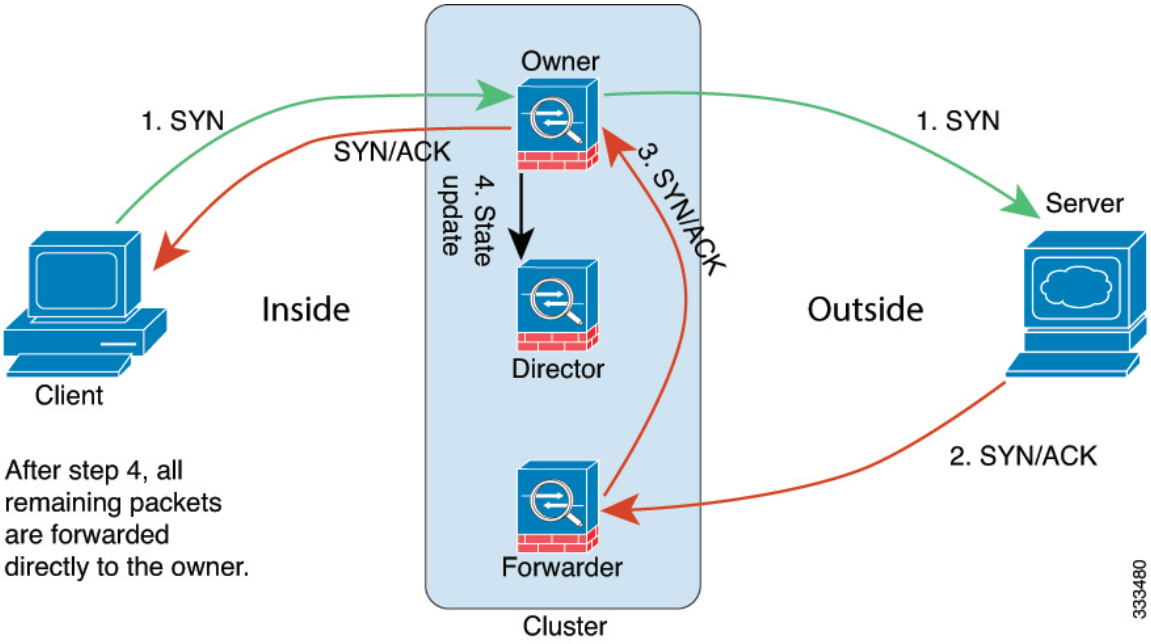
When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

Traffic redirection is not supported in this release. When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. All the subsequent packets for the same connection should arrive the same node. If any connection packets arrive at a different node, they will be dropped. If a reverse flow arrives at a different node, it will be dropped as well. For centralized features, if the connections do not arrive on the control node, they will be dropped.

By default, AWS GWLB uses 5-tuple to maintain flow stickiness. It is recommended to enable 2-tuple or 3-tuple stickiness on AWS GWLB to ensure the same flows are sent to the same node.

Sample Data Flow for TCP

The following example shows the establishment of a new connection.



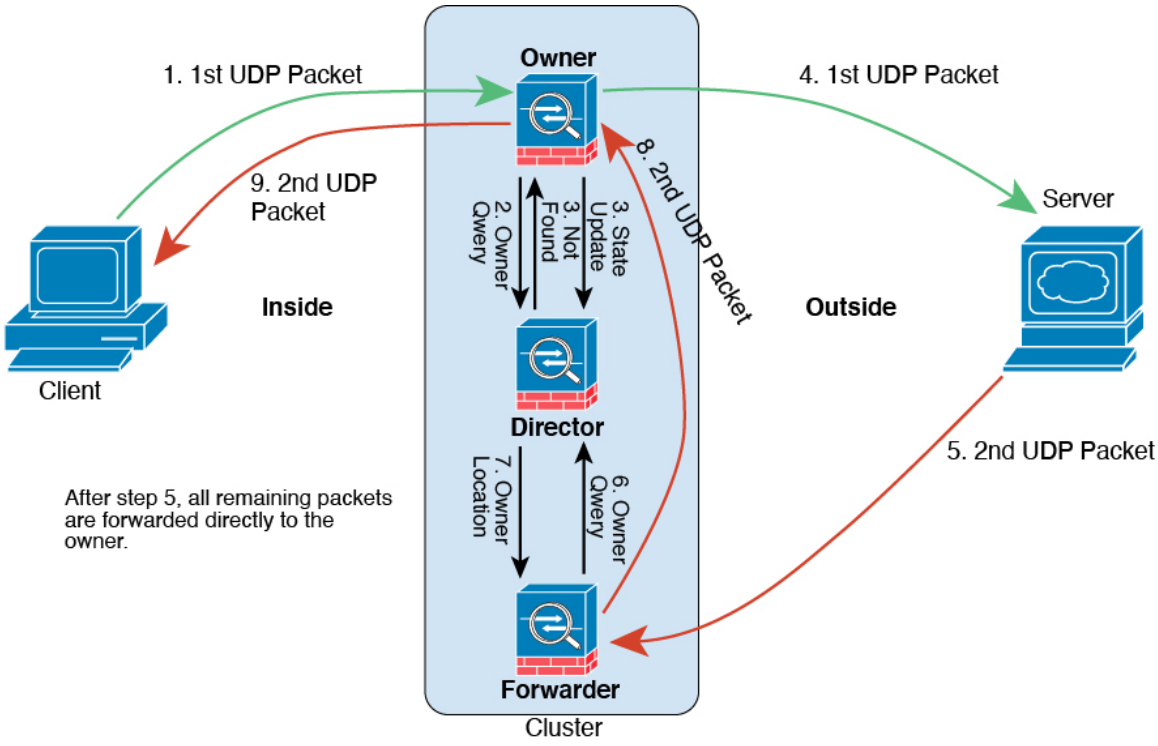
1. The SYN packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different Firewall Threat Defense (based on the load balancing method). This Firewall Threat Defense is the forwarder.

3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample Data Flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. ***Figure 238: ICMP and UDP Data Flow***



The first UDP packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.

5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

History for Threat Defense Virtual Clustering in the Public Cloud

CHAPTER 33

Clustering for the Firepower 4100/9300

Clustering lets you group multiple Firewall Threat Defense nodes together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices.

Note Some features are not supported when using clustering. See Unsupported Features with Clustering, on page 847.

About Clustering on the Firepower 4100/9300 Chassis

When you deploy a cluster on the Firepower 4100/9300 chassis, it does the following:

- For native instance clustering: Creates a *cluster-control link* (by default, port-channel 48) for node-to-node communication.

  For multi-instance clustering: You should pre-configure subinterfaces on one or more cluster-type EtherChannels; each instance needs its own cluster control link.

  For a cluster isolated to security modules within one Firepower 9300 chassis, this link utilizes the Firepower 9300 backplane for cluster communications.

  For clustering with multiple chassis, you need to manually assign physical interface(s) to this EtherChannel for communications between chassis.

- Creates the cluster bootstrap configuration within the application.

  When you deploy the cluster, the chassis supervisor pushes a minimal bootstrap configuration to each unit that includes the cluster name, cluster control link interface, and other cluster settings.

- Assigns data interfaces to the cluster as *Spanned* interfaces.

  For a cluster isolated to security modules within one Firepower 9300 chassis, spanned interfaces are not limited to EtherChannels, like it is for clustering with multiple chassis. The Firepower 9300 supervisor uses EtherChannel technology internally to load-balance traffic to multiple modules on a shared interface, so any data interface type works for Spanned mode. For clustering with multiple chassis, you must use Spanned EtherChannels for all data interfaces.

Note Individual interfaces are not supported, with the exception of a management interface.

- Assigns a management interface to all units in the cluster.

See the following sections for more information about clustering.

Bootstrap Configuration

When you deploy the cluster, the Firepower 4100/9300 chassis supervisor pushes a minimal bootstrap configuration to each unit that includes the cluster name, cluster control link interface, and other cluster settings.

Cluster Members

Cluster members work together to accomplish the sharing of the security policy and traffic flows.

One member of the cluster is the **control** unit. The control unit is determined automatically. All other members are **data** units.

You must perform all configuration on the control unit only; the configuration is then replicated to the data units.

Some features do not scale in a cluster, and the control unit handles all traffic for those features. .

Cluster Control Link

For native instance clustering: The cluster control link is automatically created using the Port-channel 48 interface.

For multi-instance clustering: You should pre-configure subinterfaces on one or more cluster-type EtherChannels; each instance needs its own cluster control link.

For a cluster isolated to security modules within one Firepower 9300 chassis, this interface has no member interfaces. This Cluster type EtherChannel utilizes the Firepower 9300 backplane for cluster communications. For clustering with multiple chassis, you must add one or more interfaces to the EtherChannel.

For a cluster with two chassis, do not directly connect the cluster control link from one chassis to the other chassis. If you directly connect the interfaces, then when one unit fails, the cluster control link fails, and thus

the remaining healthy unit fails. If you connect the cluster control link through a switch, then the cluster control link remains up for the healthy unit.

Cluster control link traffic includes both control and data traffic.

Size the Cluster Control Link

If possible, you should size the cluster control link to match the expected throughput of each chassis so the cluster control link can handle the worst-case scenarios.

Cluster control link traffic is comprised mainly of state update and forwarded packets. The amount of traffic at any given time on the cluster control link varies. The amount of forwarded traffic depends on the load-balancing efficacy or whether there is a lot of traffic for centralized features. For example:

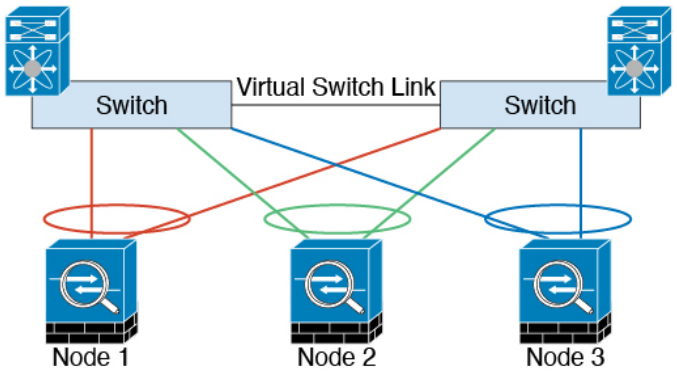
- NAT results in poor load balancing of connections, and the need to rebalance all returning traffic to the correct units.
- When membership changes, the cluster needs to rebalance a large number of connections, thus temporarily using a large amount of cluster control link bandwidth.

A higher-bandwidth cluster control link helps the cluster to converge faster when there are membership changes and prevents throughput bottlenecks.

Note If your cluster has large amounts of asymmetric (rebalanced) traffic, then you should increase the cluster control link size.

Cluster Control Link Redundancy

The following diagram shows how to use an EtherChannel as a cluster control link in a Virtual Switching System (VSS), Virtual Port Channel (vPC), StackWise, or StackWise Virtual environment. All links in the EtherChannel are active. When the switch is part of a redundant system, then you can connect firewall interfaces within the same EtherChannel to separate switches in the redundant system. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch. Note that this EtherChannel is device-local, not a Spanned EtherChannel.



Cluster Control Link Reliability for Inter-Chassis Clustering

To ensure cluster control link functionality, be sure the round-trip time (RTT) between units is less than 20 ms. This maximum latency enhances compatibility with cluster members installed at different geographical sites. To check your latency, perform a ping on the cluster control link between units.

The cluster control link must be reliable, with no out-of-order or dropped packets; for example, for inter-site deployment, you should use a dedicated link.

Cluster Control Link Network

The Firepower 4100/9300 chassis auto-generates the cluster control link interface IP address for each unit based on the chassis ID and slot ID: 127.2.*chassis_id*.*slot_id*. For multi-instance clusters, which typically use different VLAN subinterfaces of the same EtherChannel, the same IP address can be used for different clusters because of VLAN separation. The cluster control link network cannot include any routers between units; only Layer 2 switching is allowed.

Management Network

We recommend connecting all units to a single management network. This network is separate from the cluster control link.

Management Interface

You must assign a Management type interface to the cluster. This interface is a special individual interface as opposed to a Spanned interface. The management interface lets you connect directly to each unit. This Management logical interface is separate from the other interfaces on the device. It is used to set up and register the device to the Secure Firewall Management Center. It uses its own local authentication, IP address, and static routing. Each cluster member uses a separate IP address on the management network that you set as part of the bootstrap configuration.

Cluster Interfaces

For a cluster isolated to security modules within one Firepower 9300 chassis, you can assign both physical interfaces or EtherChannels (also known as port channels) to the cluster. Interfaces assigned to the cluster are Spanned interfaces that load-balance traffic across all members of the cluster.

For clustering with multiple chassis, you can only assign data EtherChannels to the cluster. These Spanned EtherChannels include the same member interfaces on each chassis; on the upstream switch, all of these interfaces are included in a single EtherChannel, so the switch does not know that it is connected to multiple devices.

You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces).

Individual interfaces are not supported, with the exception of a management interface.

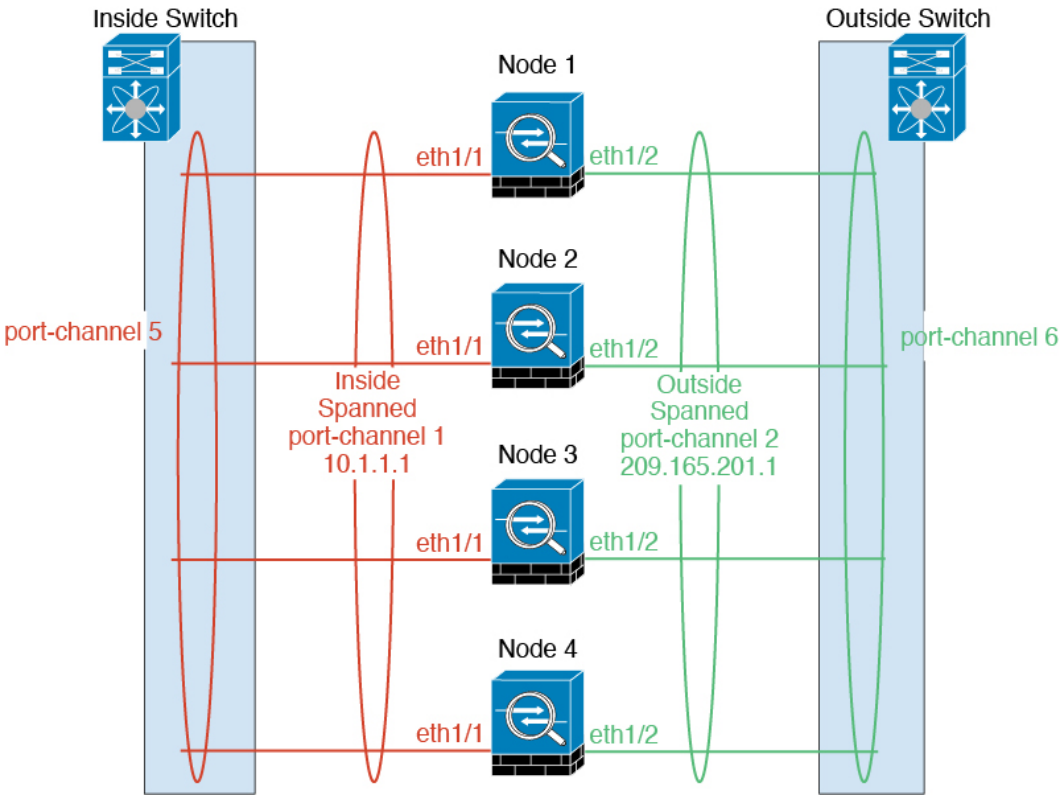
Spanned EtherChannels

You can group one or more interfaces per chassis into an EtherChannel that spans all chassis in the cluster. The EtherChannel aggregates the traffic across all the available active interfaces in the channel.

For regular firewall interfaces:A Spanned EtherChannel can be configured in both routed and transparent firewall modes. In routed mode, the EtherChannel is configured as a routed interface with a single IP address. In transparent mode, the IP address is assigned to the BVI, not to the bridge group member interface.

The EtherChannel inherently provides load balancing as part of basic operation.

For multi-instance clusters, each cluster requires dedicated data EtherChannels; you cannot use shared interfaces or VLAN subinterfaces.



Configuration Replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Licenses for Clustering

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add a cluster node to the Firewall Management Center, you can specify the feature licenses you want to use for the cluster. You can modify licenses for the cluster in the **Devices** > **Device Management** and the choose the **Add**, **Cluster**and then **License** area.

Note If you add the cluster before the Firewall Management Center is licensed (and running in Evaluation mode), then when you license the Firewall Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Requirements and Prerequisites for Clustering

Cluster Model Support

The Threat Defense supports clustering on the following models:

- Firepower 9300— You can include up to 16 nodes in the cluster. For example, you can use 1 module in 16 chassis, or 2 modules in 8 chassis, or any combination that provides a maximum of 16 modules. Supports clustering with multiple chassis and clustering isolated to security modules within one chassis.
- Firepower 4100—Supported for up to 16 nodes using clustering with multiple chassis.

User Roles

- Admin
- Access Admin
- Network Admin

Clustering Hardware and Software Requirements

All chassis in a cluster:

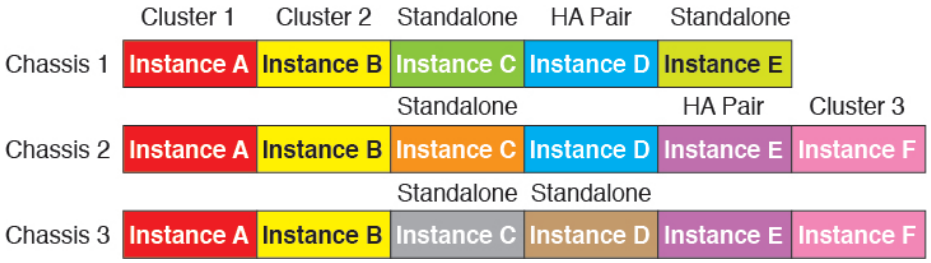
- Native instance clustering—For the Firepower 4100: All chassis must be the same model. For the Firepower 9300: All security modules must be the same type. For example, if you use clustering, all modules in the Firepower 9300 must be SM-40s. You can have different quantities of installed security modules in each chassis, although all modules present in the chassis must belong to the cluster including any empty slots.
- Container instance clustering—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.

- Must run the identical FXOS and application software except at the time of an image upgrade. Mismatched software versions can lead to poor performance, so be sure to upgrade all nodes in the same maintenance window.
- Must include the same interface configuration for interfaces you assign to the cluster, such as the same Management interface, EtherChannels, active interfaces, speed and duplex, and so on. You can use different network module types on the chassis as long as the capacity matches for the same interface IDs and interfaces can successfully bundle in the same spanned EtherChannel. Note that all data interfaces must be EtherChannels in clusters with multiple chassis. If you change the interfaces in FXOS after you enable clustering (by adding or removing interface modules, or configuring EtherChannels, for example), then perform the same changes on each chassis, starting with the data nodes, and ending with the control node.
- Must use the same NTP server. For Firewall Threat Defense, the Firewall Management Center must also use the same NTP server. Do not set the time manually.

Multi-Instance Clustering Requirements

- No intra-security-module/engine clustering—For a given cluster, you can only use a single container instance per security module/engine. You cannot add 2 container instances to the same cluster if they are running on the same module.

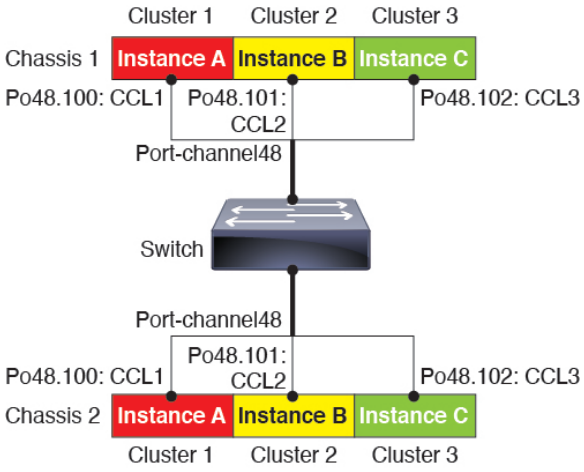
- Mix and match clusters and standalone instances—Not all container instances on a security module/engine need to belong to a cluster. You can use some instances as standalone or High Availability nodes. You can also create multiple clusters using separate instances on the same security module/engine.



- All 3 modules in a Firepower 9300 must belong to the cluster—For the Firepower 9300, a cluster requires a single container instance on all 3 modules. You cannot create a cluster using instances on module 1 and 2, and then use a native instance on module 3, or example.

- Match resource profiles—We recommend that each node in the cluster use the same resource profile attributes; however, mismatched resources are allowed when changing cluster nodes to a different resource profile, or when using different models.

- Dedicated cluster control link—For clusters with multiple chassis, each cluster needs a dedicated cluster control link. For example, each cluster can use a separate subinterface on the same cluster-type EtherChannel, or use separate EtherChannels.

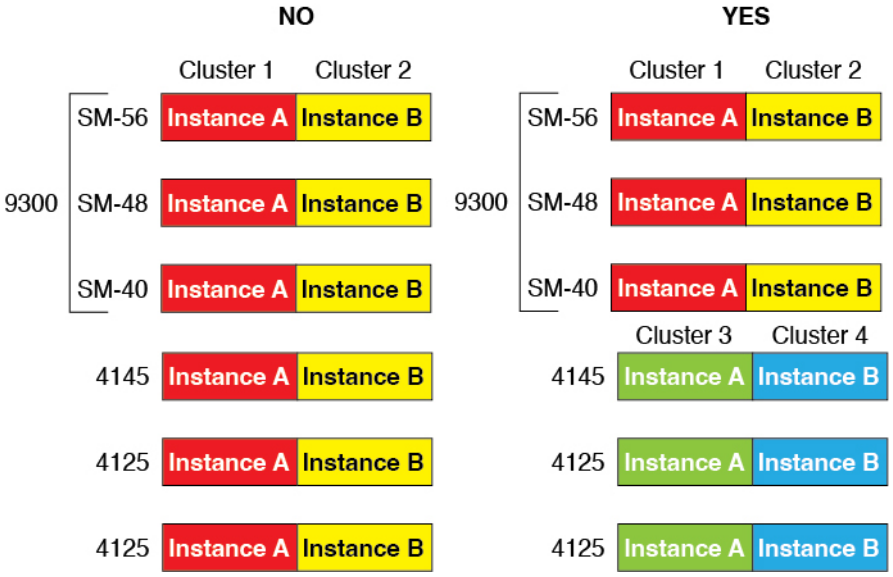


- No shared interfaces—Shared-type interfaces are not supported with clustering. However, the same Management and Eventing interfaces can used by multiple clusters.

- No subinterfaces—A multi-instance cluster cannot use FXOS-defined VLAN subinterfaces. An exception is made for the cluster control link, which can use a subinterface of the Cluster EtherChannel.

- Mix chassis models—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300

security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.



- Maximum 6 nodes—You can use up to six container instances in a cluster.

Switch Requirements

- Be sure to complete the switch configuration and successfully connect all the EtherChannels from the chassis to the switch(es) before you configure clustering on the Firepower 4100/9300 chassis.
- For supported switch characteristics, see Cisco FXOS Compatibility.

Clustering Guidelines and Limitations

Switches for Clustering

- Make sure connected switches match the MTU for both cluster data interfaces and the cluster control link interface. You should configure the cluster control link interface MTU to be at least 100 bytes higher than the data interface MTU, so make sure to configure the cluster control link connecting switch appropriately. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. In addition, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For Cisco IOS XR systems, if you want to set a non-default MTU, set the IOS XR interface MTU to be 14 bytes higher than the cluster device MTU. Otherwise, OSPF adjacency peering attempts may fail unless the **mtu-ignore** option is used. Note that the cluster device MTU should match the IOS XR *IPv4* MTU. This adjustment is not required for Cisco Catalyst and Cisco Nexus switches.

- On the switch(es) for the cluster control link interfaces, you can optionally enable Spanning Tree PortFast on the switch ports connected to the cluster unit to speed up the join process for new units.
- On the switch, we recommend that you use one of the following EtherChannel load-balancing algorithms: **source-dest-ip** or **src-dst-mixed-ip-port** (see the Cisco Nexus OS and Cisco IOS-XE **port-channel load-balance** command). Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the devices in a cluster.
- If you change the load-balancing algorithm of the EtherChannel on the switch, the EtherChannel interface on the switch temporarily stops forwarding traffic, and the Spanning Tree Protocol restarts. There will be a delay before traffic starts flowing again.
- Switches on the cluster control link path should not verify the L4 checksum. Redirected traffic over the cluster control link does not have a correct L4 checksum. Switches that verify the L4 checksum could cause traffic to be dropped.
- Port-channel bundling downtime should not exceed the configured keepalive interval.
- On Supervisor 2T EtherChannels, the default hash distribution algorithm is adaptive. To avoid asymmetric traffic in a VSS design, change the hash algorithm on the port-channel connected to the cluster device to fixed:

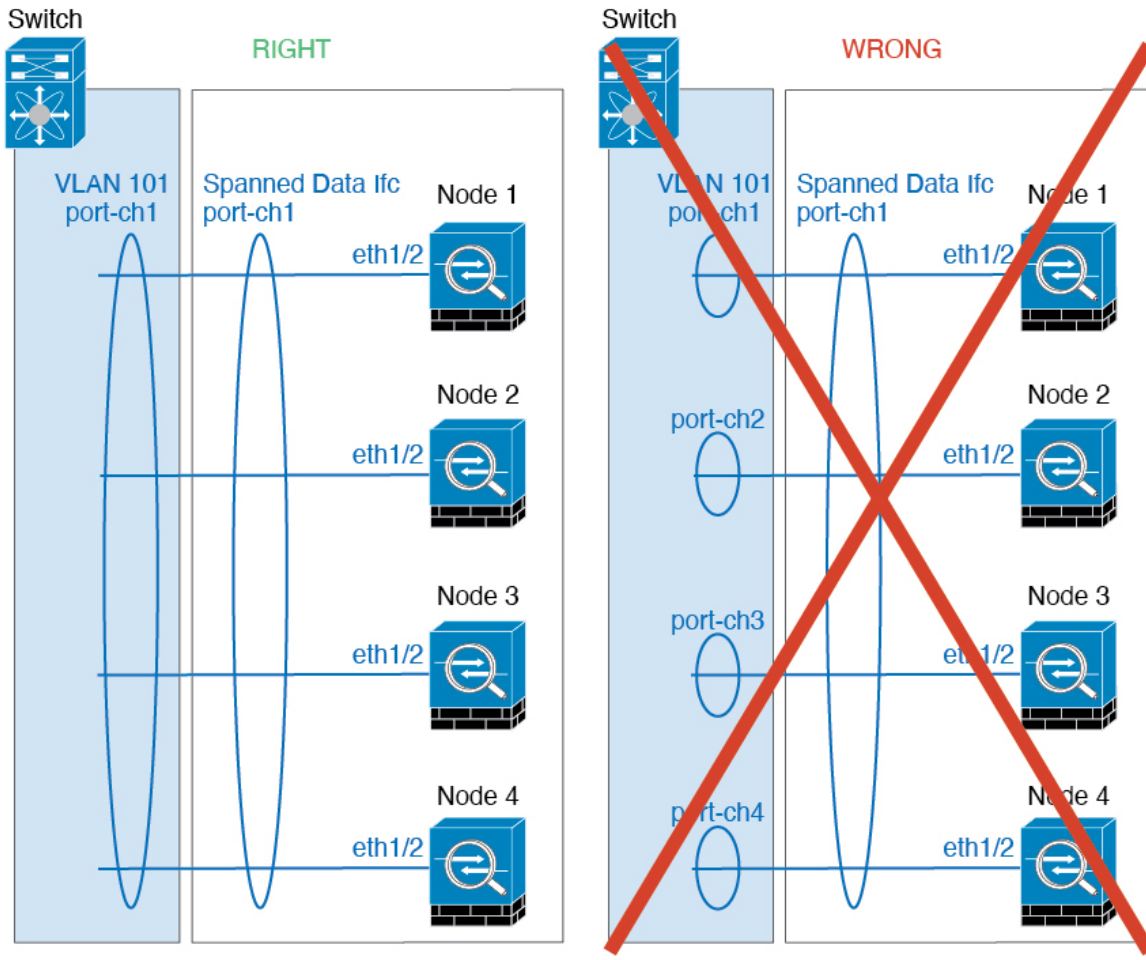
  router(config)# **port-channel** *id* **hash-distribution fixed**

  Do not change the algorithm globally; you may want to take advantage of the adaptive algorithm for the VSS peer link.

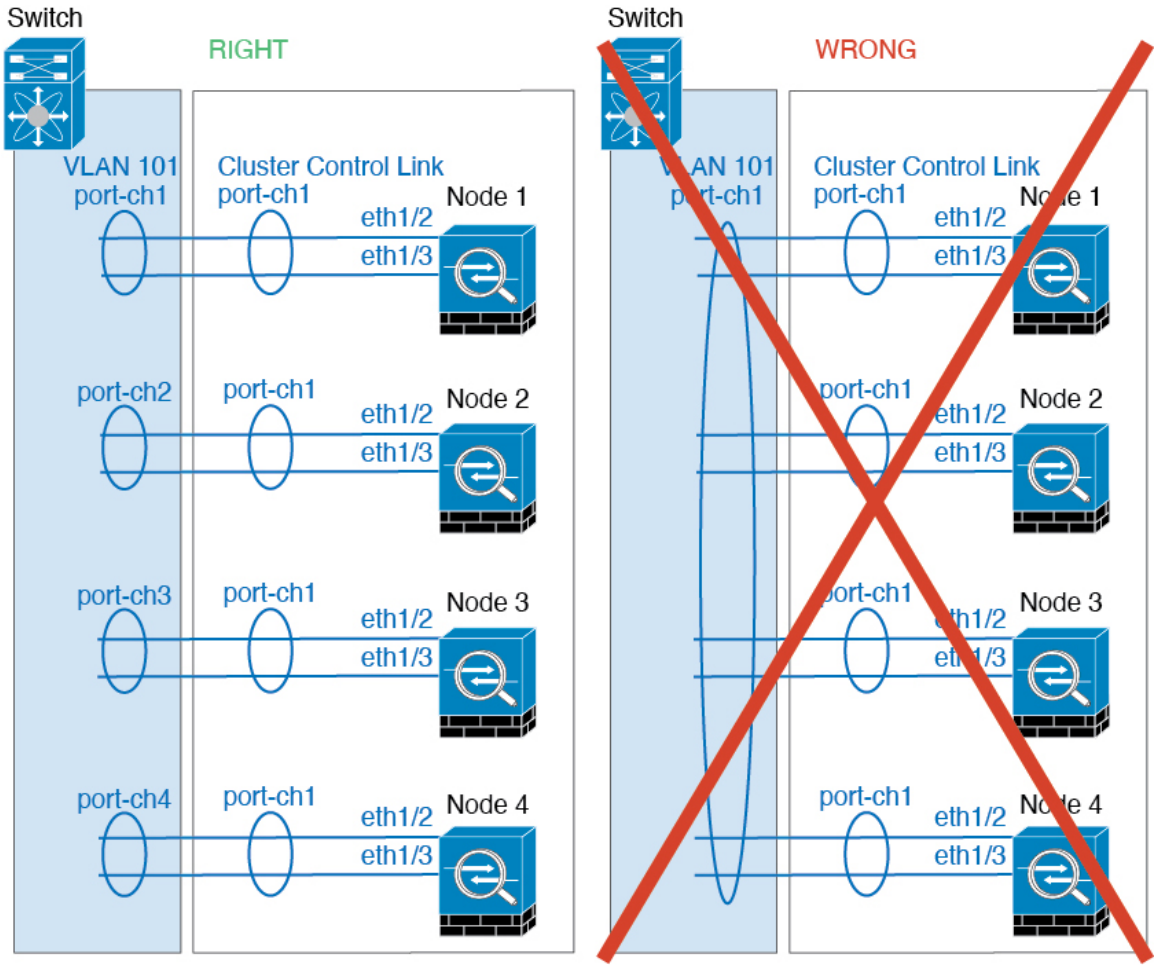
- Firepower 4100/9300 clusters support LACP graceful convergence. So you can leave LACP graceful convergence enabled on connected Cisco Nexus switches.
- When you see slow bundling of a Spanned EtherChannel on the switch, you can enable LACP rate fast for an individual interface on the switch. FXOS EtherChannels have the LACP rate set to fast by default. Note that some switches, such as the Nexus series, do not support LACP rate fast when performing in-service software upgrades (ISSUs), so we do not recommend using ISSUs with clustering.

EtherChannels for Clustering

- In Catalyst 3750-X Cisco IOS software versions earlier than 15.1(1)S2, the cluster unit did not support connecting an EtherChannel to a switch stack. With default switch settings, if the cluster unit EtherChannel is connected cross stack, and if the control unit switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.
- Spanned vs. Device-Local EtherChannel Configuration—Be sure to configure the switch appropriately for Spanned EtherChannels vs. Device-local EtherChannels.
  - Spanned EtherChannels—For cluster unit *Spanned* EtherChannels, which span across all members of the cluster, the interfaces are combined into a single EtherChannel on the switch. Make sure each interface is in the same channel group on the switch.



- Device-local EtherChannels—For cluster unit *Device-local* EtherChannels including any EtherChannels configured for the cluster control link, be sure to configure discrete EtherChannels on the switch; do not combine multiple cluster unit EtherChannels into one EtherChannel on the switch.



Additional Guidelines

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Firepower 4100/9300 chassis or the switch, adding an additional switch to form a VSS, vPC, StackWise, or StackWise Virtual) you should disable the health check feature, and also disable interface monitoring for the disabled interfaces . When the topology change is complete, and the configuration change is synced to all units, you can re-enable the health check feature.
- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang connections; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- If you use a Windows 2003 server connected to a Spanned EtherChannel interface, when the syslog server port is down, and the server does not throttle ICMP error messages, then large numbers of ICMP messages are sent back to the cluster. These messages can result in some units of the cluster experiencing high CPU, which can affect performance. We recommend that you throttle ICMP error messages.
- We recommend connecting EtherChannels to a VSS, vPC, StackWise, or StackWise Virtual for redundancy.

- Within a chassis, you cannot cluster some security modules and run other security modules in standalone mode; you must include all security modules in the cluster.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Defaults

- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is set to unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is set to 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Configure Clustering

You can easily deploy the cluster from the Firepower 4100/9300 supervisor. All initial configuration is automatically generated for each unit. You can then add the units to the Firewall Management Center and group them into a cluster.

FXOS: Add a Firewall Threat Defense Cluster

In native mode: You can add a cluster to a single Firepower 9300 chassis that is isolated to security modules within the chassis, or you can use multiple chassis.

In multi-instance mode: You can add one or more clusters to a single Firepower 9300 chassis that are isolated to security modules within the chassis (you must include an instance on each module), or add one or more clusters on multiple chassis.

For clusters on multiple chassis, you must configure each chassis separately. Add the cluster on one chassis; you can then copy the bootstrap configuration from the first chassis to the next chassis for ease of deployment

Create a Firewall Threat Defense Cluster

You can easily deploy the cluster from the Firepower 4100/9300 chassis supervisor. All initial configuration is automatically generated for each unit.

For clustering on multiple chassis, you must configure each chassis separately. Deploy the cluster on one chassis; you can then copy the bootstrap configuration from the first chassis to the next chassis for ease of deployment.

In a Firepower 9300 chassis, you must enable clustering for all 3 module slots, or for container instances, a container instance in each slot, even if you do not have a module installed. If you do not configure all 3 modules, the cluster will not come up.

Before you begin

- Download the application image you want to use for the logical device from Cisco.com, and then upload that image to the Firepower 4100/9300 chassis.
- For container instances, if you do not want to use the default profile, add a resource profile according to Add a Resource Profile for Container Instances, on page 483.
- For container instances, before you can install a container instance for the first time, you must reinitialize the security module/engine so that the disk has the correct formatting. Choose **Security Modules** or **Security Engine**, and click the Reinitialize icon (). An existing logical device will be deleted and then reinstalled as a new device, losing any local application configuration. If you are replacing a native instance with container instances, you will need to delete the native instance in any case. You cannot automatically migrate a native instance to a container instance.
- Gather the following information:
  - Management interface ID, IP addresses, and network mask
  - Gateway IP address
  - Firewall Management Center IP address and/or NAT ID of your choosing
  - DNS server IP address
  - Firewall Threat Defense hostname and domain name

Procedure

Step 1 Configure interfaces.

a) Add at least one Data type interface or EtherChannel (also known as a port-channel) before you deploy the cluster. See Add an EtherChannel (Port Channel), on page 479 or Configure a Physical Interface, on page 478.

For clustering on multiple chassis, all data interfaces must be Spanned EtherChannels with at least one member interface. Add the same EtherChannels on each chassis. Combine the member interfaces from all cluster units into a single EtherChannel on the switch. See Clustering Guidelines and Limitations, on page 803 for more information about EtherChannels.

For multi-instance clustering, you cannot use FXOS-defined VLAN subinterfaces or data-sharing interfaces in the cluster. Only application-defined subinterfaces are supported. See FXOS Interfaces vs. Application Interfaces, on page 446 for more information.

b) Add a Management type interface or EtherChannel. See Add an EtherChannel (Port Channel), on page 479 or Configure a Physical Interface, on page 478.

The management interface is required. Note that this management interface is not the same as the chassis management interface that is used only for chassis management (in FXOS, you might see the chassis management interface displayed as MGMT, management0, or other similar names).

For clustering on multiple chassis, add the same Management interface on each chassis.

For multi-instance clustering, you can share the same management interface across multiple clusters on the same chassis, or with standalone instances.

c) For clustering on multiple chassis, add a member interface to the cluster control link EtherChannel (by default, port-channel 48). See Add an EtherChannel (Port Channel), on page 479.

Do not add a member interface for a cluster isolated to security modules within one Firepower 9300 chassis. If you add a member, the chassis assumes this cluster will be using multiple chassis, and will only allow you to use Spanned EtherChannels, for example.

On the **Interfaces** tab, the port-channel 48 cluster type interface shows the **Operation State** as **failed** if it does not include any member interfaces. For a cluster isolated to security modules within one Firepower 9300 chassis, this EtherChannel does not require any member interfaces, and you can ignore this Operational State.

Add the same member interfaces on each chassis. The cluster control link is a device-local EtherChannel on each chassis. Use separate EtherChannels on the switch per device. See Clustering Guidelines and Limitations, on page 803 for more information about EtherChannels.

For multi-instance clustering, you can create additional Cluster type EtherChannels. Unlike the Management interface, the cluster control link is *not* sharable across multiple devices, so you will need a Cluster interface for each cluster. However, we recommend using VLAN subinterfaces instead of multiple EtherChannels; see the next step to add a VLAN subinterface to the Cluster interface.

d) For multi-instance clustering, add VLAN subinterfaces to the cluster EtherChannel so you have a subinterface for each cluster. See Add a VLAN Subinterface for Container Instances, on page 482.

If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster.

e) (Optional) Add an eventing interface. See Add an EtherChannel (Port Channel), on page 479 or Configure a Physical Interface, on page 478.

This interface is a secondary management interface for the Firewall Threat Defense devices. To use this interface, you must configure its IP address and other parameters at the Firewall Threat Defense CLI. For example, you can separate management traffic from events (such as web events). See the **configure network** commands in the Firewall Threat Defense command reference.

For clustering on multiple chassis, add the same eventing interface on each chassis.

Step 2 Choose **Logical Devices**.

Step 3 Click **Add** > **Cluster**, and set the following parameters:

Figure 239: Native Cluster

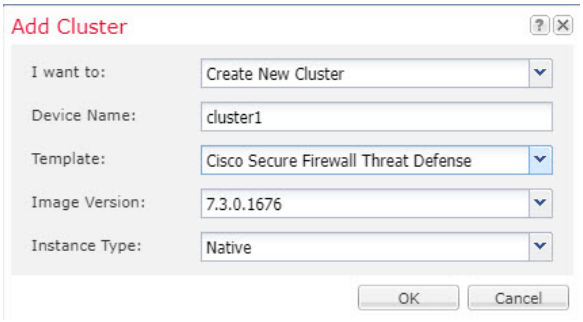


Figure 240: Multi-Instance Cluster

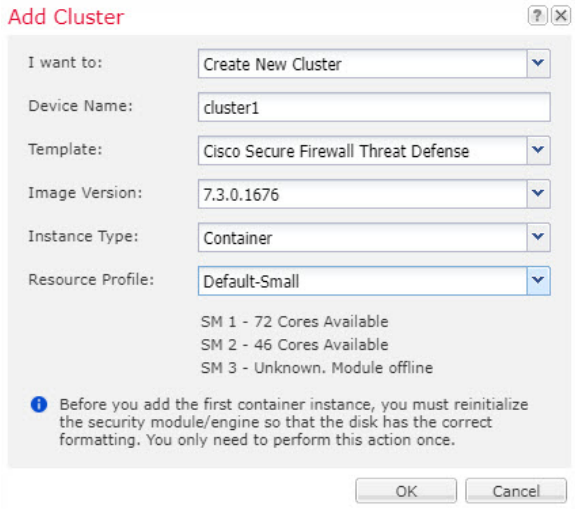


a) Choose **I want to:** > **Create New Cluster**
b) Provide a **Device Name**.

   This name is used internally by the chassis supervisor to configure management settings and to assign interfaces; it is not the device name used in the application configuration.

c) For the **Template**, choose **Cisco Firepower Threat Defense**.
d) Choose the **Image Version**.
e) For the **Instance Type**, choose either **Native** or **Container**.

   A native instance uses all of the resources (CPU, RAM, and disk space) of the security module/engine, so you can only install one native instance. A container instance uses a subset of resources of the security module/engine, so you can install multiple container instances.

f) (Container Instance only) For the **Resource Type**, choose one of the resource profiles from the drop-down list.

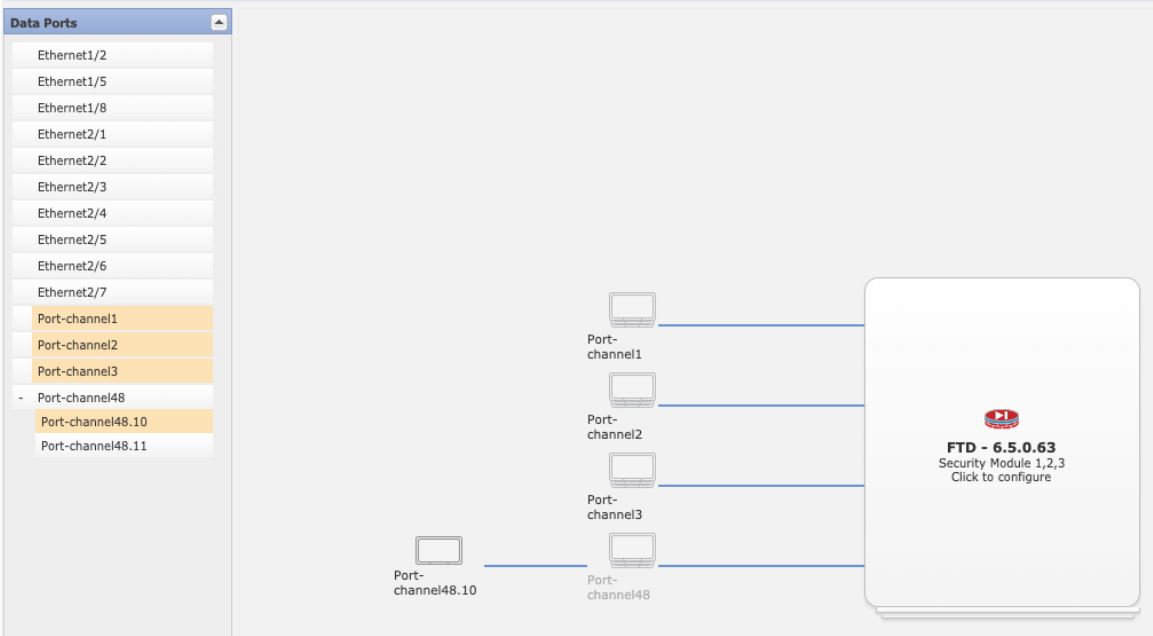
   For the Firepower 9300, this profile will be applied to each instance on each security module. You can set different profiles per security module later in this procedure; for example, if you are using different security module types, and you want to use more CPUs on a lower-end model. We recommend choosing the correct profile before you create the cluster. If you need to create a new profile, cancel out of the cluster creation, and add one using Add a Resource Profile for Container Instances, on page 483.

   Note
   If you assign a different profile to instances in an established cluster, which allows mismatched profiles, then apply the new profile on the data nodes first; after they reboot and come back up, you can apply the new profile to the control node.

g) Click **OK**.

   You see the Provisioning - *device name* window.

Step 4 Choose the interfaces you want to assign to this cluster.



For native mode clustering: All valid interfaces are assigned by default. If you defined multiple Cluster type interfaces, deselect all but one.

For multi-instance clustering: Choose each data interface you want to assign to the cluster, and also choose the Cluster type port-channel or port-channel subinterface.

Step 5 Click the device icon in the center of the screen.

A dialog box appears where you can configure initial bootstrap settings. These settings are meant for initial deployment only, or for disaster recovery. For normal operation, you can later change most values in the application CLI configuration.

Step 6 On the **Cluster Information** page, complete the following.

Figure 241: Native Cluster

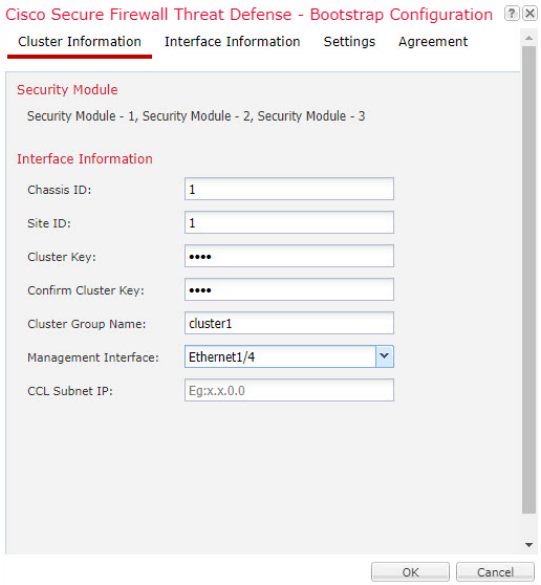


Figure 242: Multi-Instance Cluster

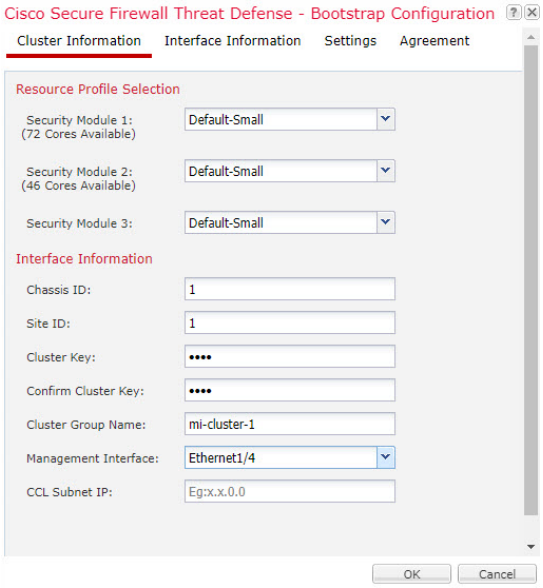


a) (Container Instance for the Firepower 9300 only) In the **Security Module (SM) and Resource Profile Selection** area, you can set a different resource profile per module; for example, if you are using different security module types, and you want to use more CPUs on a lower-end model.

b) For clustering on multiple chassis, in the **Chassis ID** field, enter a chassis ID. Each chassis in the cluster must use a unique ID.

   This field only appears if you added a member interface to cluster control link Port-Channel 48.

c) For inter-site clustering, in the **Site ID** field, enter the site ID for this chassis between 1 and 8. FlexConfig feature. Additional inter-site cluster customizations to enhance redundancy and stability, such as director

localization, site redundancy, and cluster flow mobility, are only configurable using the Firewall Management Center FlexConfig feature.

d) In the **Cluster Key** field, configure an authentication key for control traffic on the cluster control link.

The shared secret is an ASCII string from 1 to 63 characters. The shared secret is used to generate the key. This option does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in the clear.

e) Set the **Cluster Group Name**, which is the cluster group name in the logical device configuration.

The name must be an ASCII string from 1 to 38 characters.

Important
From 2.4.1, spaces in cluster group name will be considered as special characters and may result in error while deploying the logical devices. To avoid this issue, you must rename the cluster group name without a space.

f) Choose the **Management Interface**.

This interface is used to manage the logical device. This interface is separate from the chassis management port.

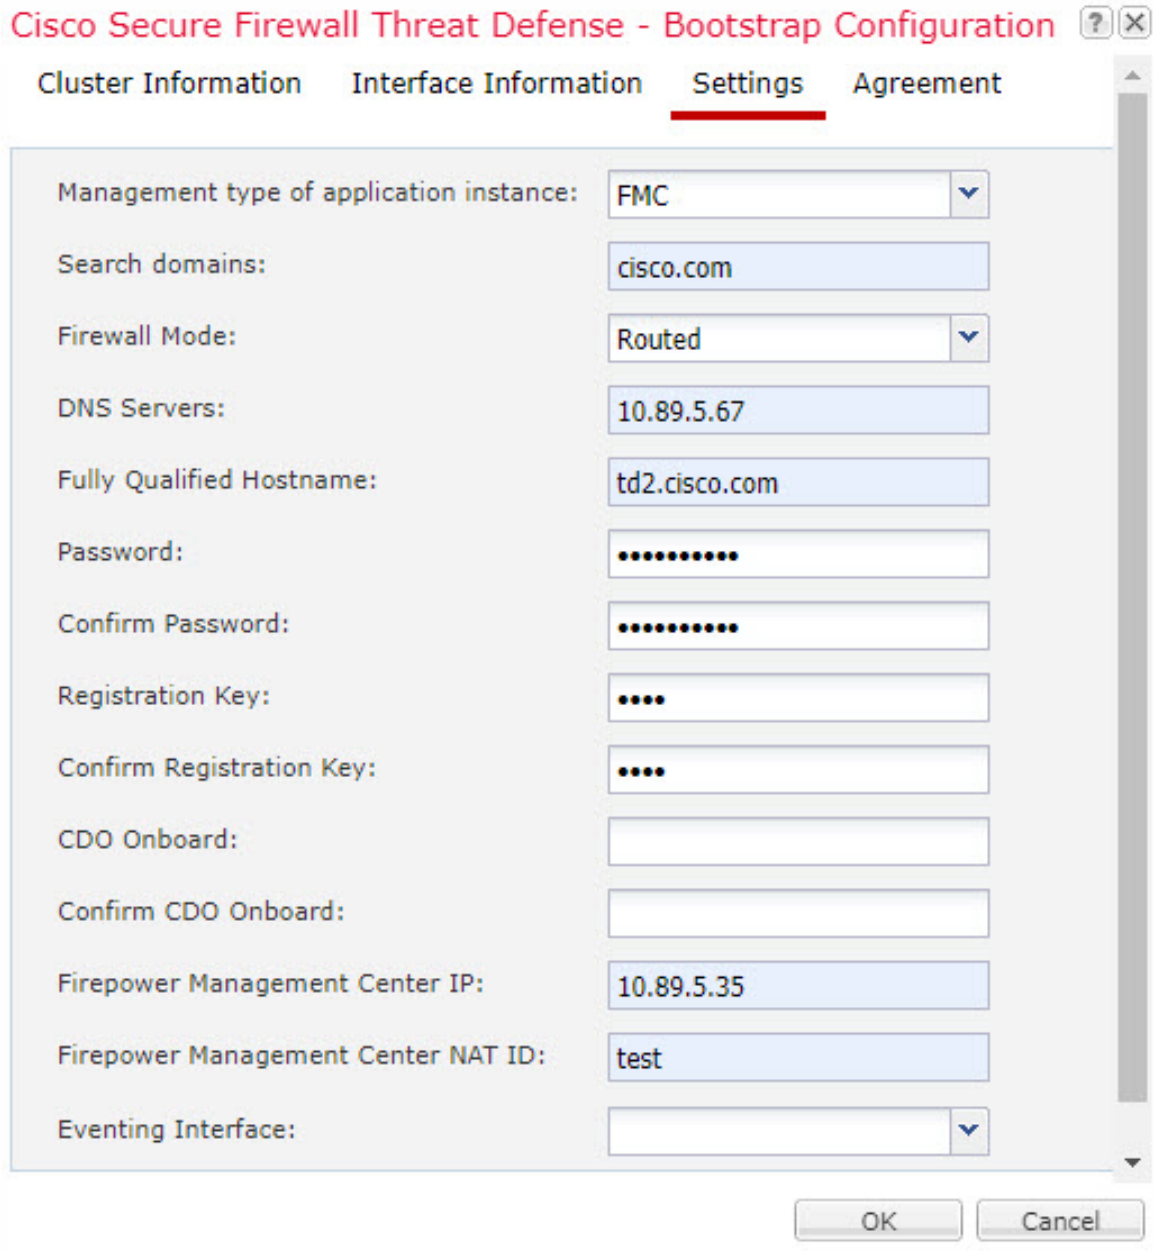
If you assign a Hardware Bypass-capable interface as the Management interface, you see a warning message to make sure your assignment is intentional.

g) (Optional) Set the **CCL Subnet IP** as ***a.b*.0.0**.

By default, the cluster control link uses the 127.2.0.0/16 network. However, some networking deployments do not allow 127.2.0.0/16 traffic to pass. In this case, specify any /16 network address on a unique network for the cluster, except for loopback (127.0.0.0/8), multicast (224.0.0.0/4), and internal (169.254.0.0/16) addresses. If you set the value to 0.0.0.0, then the default network is used.

The chassis auto-generates the cluster control link interface IP address for each unit based on the chassis ID and slot ID: *a.b.chassis_id.slot_id*.

Step 7 On the **Settings** page, complete the following.



a) In the **Registration Key** field, enter the key to be shared between the Firewall Management Center and the cluster members during registration.

   You can choose any text string for this key between 1 and 37 characters; you will enter the same key on the Firewall Management Center when you add the Firewall Threat Defense.

b) Enter a **Password** for the Firewall Threat Defense admin user for CLI access.

c) In the **Firepower Management Center IP** field, enter the IP address of the managing Firewall Management Center. If you do not know the Firewall Management Center IP address, leave this field blank and enter a passphrase in the **Firepower Management Center NAT ID** field.

d) (Optional) For a container instance, **Permit Expert mode from FTD SSH sessions**: **Yes** or **No**. Expert Mode provides Firewall Threat Defense shell access for advanced troubleshooting.

If you choose **Yes** for this option, then users who access the container instance directly from an SSH sesssion can enter Expert Mode. If you choose **No**, then only users who access the container instance from the FXOS CLI can enter Expert Mode. We recommend choosing **No** to increase isolation between instances.

Use Expert Mode only if a documented procedure tells you it is required, or if the Cisco Technical Assistance Center asks you to use it. To enter this mode, use the **expert** command in the Firewall Threat Defense CLI.

e) (Optional) In the **Search Domains** field, enter a comma-separated list of search domains for the management network.

f) (Optional) From the **Firewall Mode** drop-down list, choose **Transparent** or **Routed**.

In routed mode, the Firewall Threat Defense is considered to be a router hop in the network. Each interface that you want to route between is on a different subnet. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a "bump in the wire," or a "stealth firewall," and is not seen as a router hop to connected devices.

The firewall mode is only set at initial deployment. If you re-apply the bootstrap settings, this setting is not used.

g) (Optional) In the **DNS Servers** field, enter a comma-separated list of DNS servers.

The Firewall Threat Defense uses DNS if you specify a hostname for the Firewall Management Center, for example.

h) (Optional) In the **Firepower Management Center NAT ID** field, enter a passphrase that you will also enter on the Firewall Management Center when you add the cluster as a new device.

Normally, you need both IP addresses (along with a registration key) for both routing purposes and for authentication: the Firewall Management Center specifies the device IP address, and the device specifies the Firewall Management Center IP address. However, if you only know one of the IP addresses, which is the minimum requirement for routing purposes, then you must also specify a unique NAT ID on both sides of the connection to establish trust for the initial communication and to look up the correct registration key. You can specify any text string as the NAT ID, from 1 to 37 characters. The Firewall Management Center and device use the registration key and NAT ID (instead of IP addresses) to authenticate and authorize for initial registration.

i) (Optional) In the **Fully Qualified Hostname** field, enter a fully qualified name for the Firewall Threat Defense device.

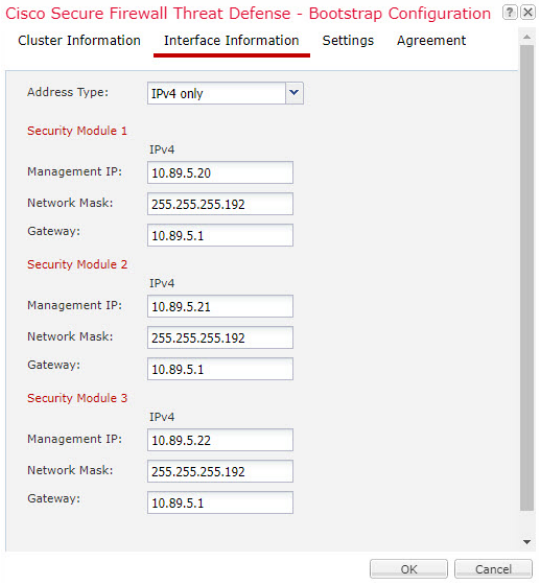
Valid characters are the letters from a to z, the digits from 0 to 9, the dot (.), and the hyphen (-); maximum number of characters is 253.

j) (Optional) From the **Eventing Interface** drop-down list, choose the interface on which events should be sent. If not specified, the management interface will be used.

To specify a separate interface to use for events, you must configure an interface as a *firepower-eventing* interface. If you assign a Hardware Bypass-capable interface as the Eventing interface, you see a warning message to make sure your assignment is intentional.

Step 8 On the **Interface Information** page, configure a management IP address for each security module in the cluster. Select the type of address from the **Address Type** drop-down list and then complete the following for each security module.

Note
You must set the IP address for all 3 module slots in a chassis, even if you do not have a module installed. If you do not configure all 3 modules, the cluster will not come up.



a) In the **Management IP** field, configure an IP address.

   Specify a unique IP address on the same network for each module.

b) Enter a **Network Mask** or **Prefix Length**.

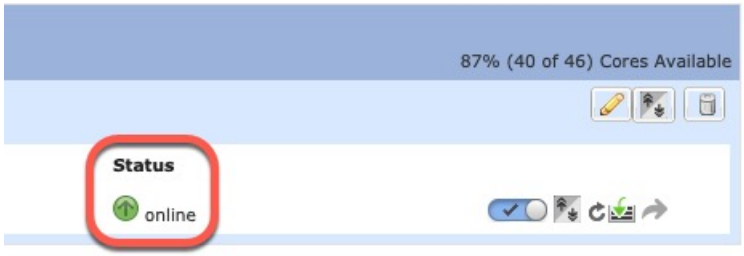
c) Enter a **Network Gateway** address.

Step 9 On the **Agreement** tab, read and accept the end user license agreement (EULA).

Step 10 Click **OK** to close the configuration dialog box.

Step 11 Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for the status of the new logical device. When the logical device shows its **Status** as **online**, you can add the remaining cluster chassis, or for a cluster isolated to security modules within one Firepower 9300 chassis, start configuring the cluster in the application. You may see the "Security module not responding" status as part of the process; this status is normal and is temporary.



Step 12 For clustering on multiple chassis, add the next chassis to the cluster:

a) On the first chassis of the Firewall Chassis Manager, click the **Show Configuration icon** at the top right; copy the displayed cluster configuration.

b) Connect to the Firewall Chassis Manager on the next chassis, and add a logical device according to this procedure.

c) Choose **I want to: > Join an Existing Cluster**.

d) Click **OK**.

e) In the **Copy Cluster Details** box, paste in the cluster configuration from the first chassis, and click **OK**.

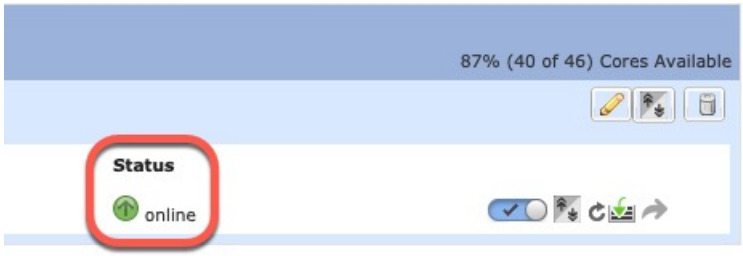
f) Click the device icon in the center of the screen. The cluster information is mostly pre-filled, but you must change the following settings:

- **Chassis ID**—Enter a unique chassis ID.
- **Site ID**—For inter-site clustering, enter the site ID for this chassis between 1 and 8. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the Firewall Management Center FlexConfig feature.
- **Cluster Key**—(Not prefilled) Enter the same cluster key.
- **Management IP**—Change the management address for each module to be a unique IP address on the same network as the other cluster members.

Click **OK**.

g) Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for each cluster member for the status of the new logical device. When the logical device for each cluster member shows its **Status** as **online**, you can start configuring the cluster in the application. You may see the "Security module not responding" status as part of the process; this status is normal and is temporary.



Step 13 Add the control unit to the Firewall Management Center using the management IP address.

All cluster units must be in a successfully-formed cluster on FXOS prior to adding them to Firewall Management Center.

The Firewall Management Center then automatically detects the data units.

Add More Cluster Nodes

Add or replace the Firewall Threat Defense cluster node in an existing cluster. When you add a new cluster node in FXOS, the Firewall Management Center adds the node automatically.

Note The FXOS steps in this procedure only apply to adding a new *chassis*; if you are adding a new module to a Firepower 9300 where clustering is already enabled, the module will be added automatically.

Before you begin

- In the case of a replacement, you must delete the old cluster node from the Firewall Management Center. When you replace it with a new node, it is considered to be a new device on the Firewall Management Center.
- The interface configuration must be the same on the new chassis. You can export and import FXOS chassis configuration to make this process easier.

Procedure

Step 1 If you previously upgraded the Firewall Threat Defense image using the Firewall Management Center, perform the following steps *on each chassis in the cluster*.

When you upgraded from the Firewall Management Center, the startup version in the FXOS configuration was not updated, and the standalone package was not installed on the chassis. Both of these items need to be set manually so the new node can join the cluster using the correct image version.

Note
If you only applied a patch release, you can skip this step. Cisco does not provide standalone packages for patches.

a) Install the running Firewall Threat Defense image on the chassis using the **System** > **Updates** page.
b) Click **Logical Devices** and click the Set Version icon ( ). For a Firepower 9300 with multiple modules, set the version for each module.

The **Startup Version** shows the original package you deployed with. The **Current Version** shows the version you upgraded to.

c) In the **New Version** drop-down menu, choose the version that you uploaded. This version should match the **Current Version** displayed, and will set the startup version to match the new version.
d) On the new chassis, make sure the new image package is installed.

Step 2 On an existing cluster chassis Firewall Chassis Manager, click **Logical Devices**.

Step 3 Click the **Show Configuration icon** at the top right; copy the displayed cluster configuration.

Step 4 Connect to the Firewall Chassis Manager on the new chassis, and click **Add** > **Cluster**.

Step 5 For the **Device Name**, provide a name for the logical device.

Step 6 Click **OK**.

Step 7 In the **Copy Cluster Details** box, paste in the cluster configuration from the first chassis, and click **OK**.

Step 8 Click the device icon in the center of the screen. The cluster information is partly pre-filled, but you must fill in the following settings:

Figure 243: Cluster Information

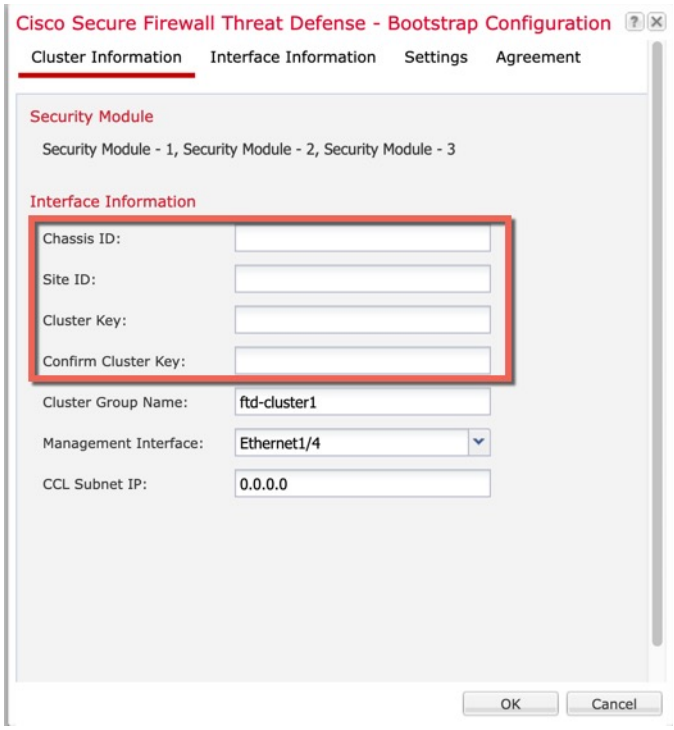


Figure 244: Interface Information

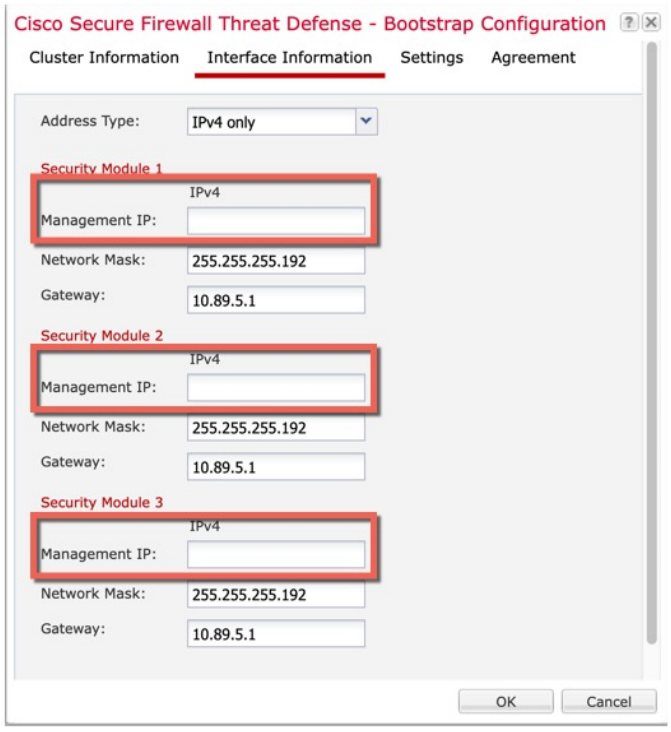

Figure 245: Settings

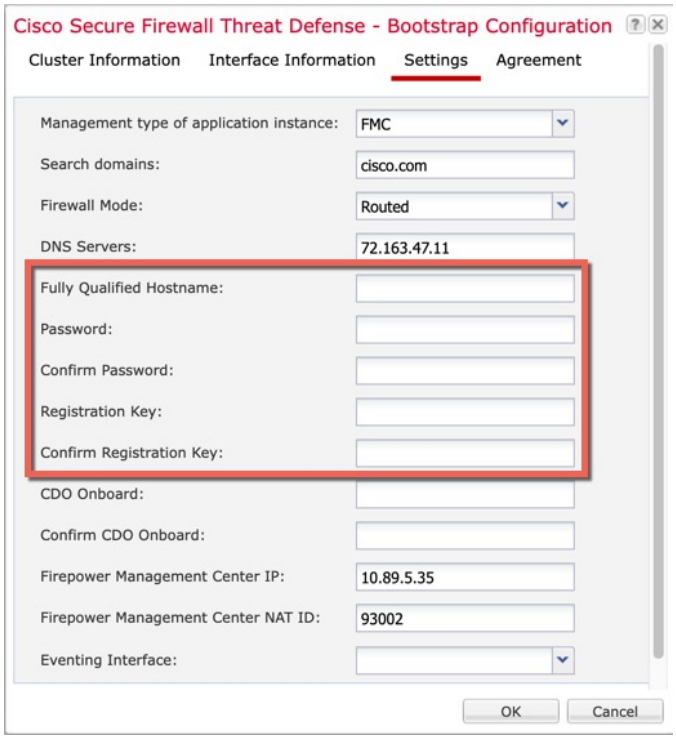


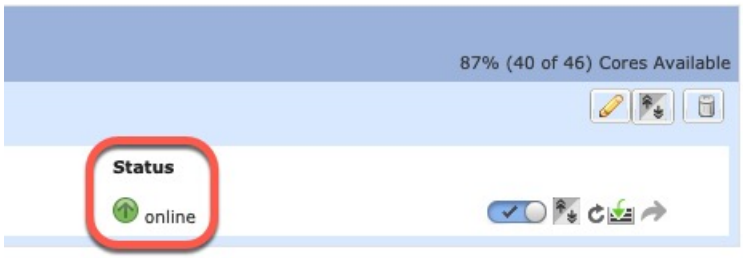
- **Chassis ID**—Enter a *unique* chassis ID.

- **Site ID**—For inter-site clustering, enter the site ID for this chassis between 1 and 8. This feature is only configurable using the Firewall Management Center FlexConfig feature.
- **Cluster Key**—Enter the *same* cluster key.
- **Management IP**—Change the management address for each module to be a *unique* IP address on the same network as the other cluster members.
- **Fully Qualified Hostname**—Enter the *same* hostname.
- **Password**—Enter the *same* password.
- **Registration Key**—Enter the *same* registration key.

Click **OK**.

Step 9 Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for each cluster member for the status of the new logical device. When the logical device for each cluster member shows its **Status** as **online**, you can start configuring the cluster in the application. You may see the "Security module not responding" status as part of the process; this status is normal and is temporary.



Firewall Management Center: Add a Cluster

Add one of the cluster units as a new device to the Secure Firewall Management Center; the Firewall Management Center auto-detects all other cluster members.

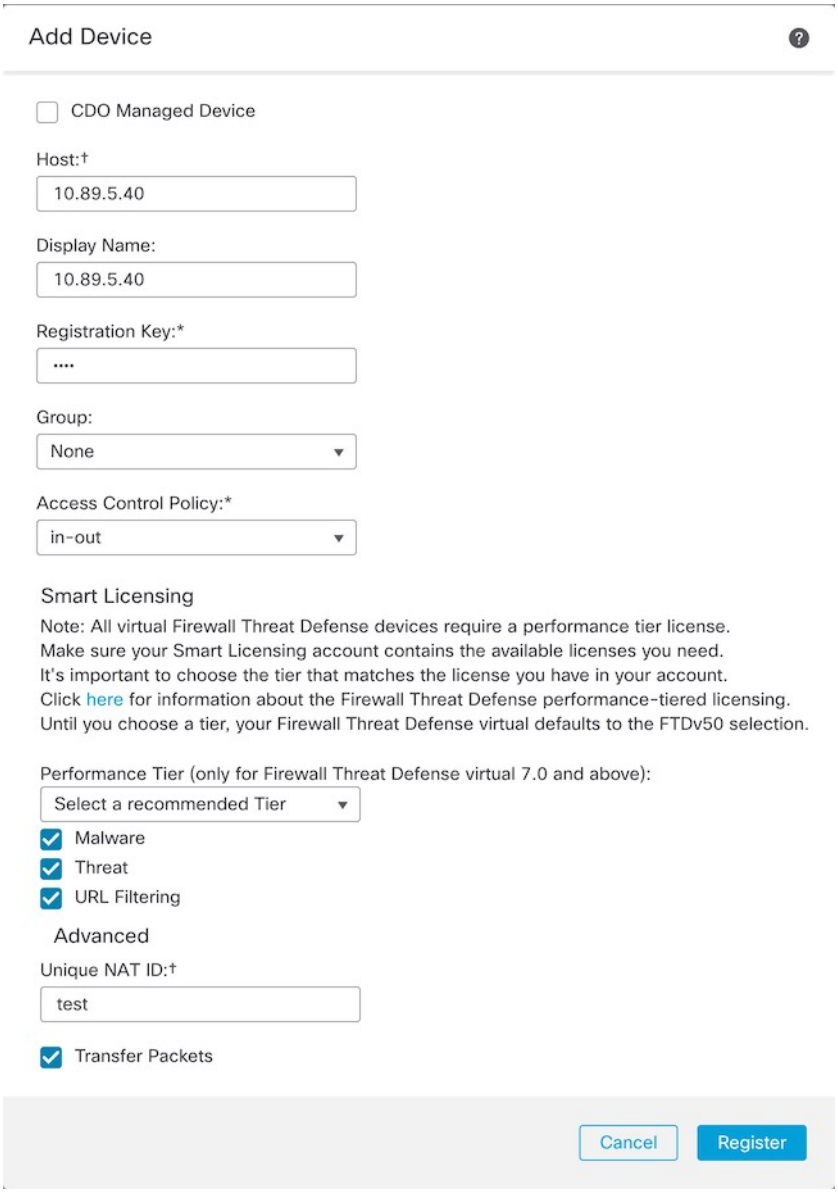
Before you begin

- All cluster units must be in a successfully-formed cluster on FXOS prior to adding the cluster to the Firewall Management Center. You should also check which unit is the control unit. Refer to the Firewall Chassis Manager **Logical Devices** screen or use the Firewall Threat Defense **show cluster info** command.

Procedure

Step 1 In the Firewall Management Center, choose **Devices** > **Device Management**, and then choose **Add** > **Add Device** to add the control unit using the unit's management IP address you assigned when you deployed the cluster.

Figure 246: Add Device



a) In the **Host** field, enter the IP address or hostname of the control unit.

We recommend adding the control unit for the best performance, but you can add any unit of the cluster.

If you used a NAT ID during device setup, you may not need to enter this field.

b) In the **Display Name** field, enter a name for the control unit as you want it to display in the Firewall Management Center.

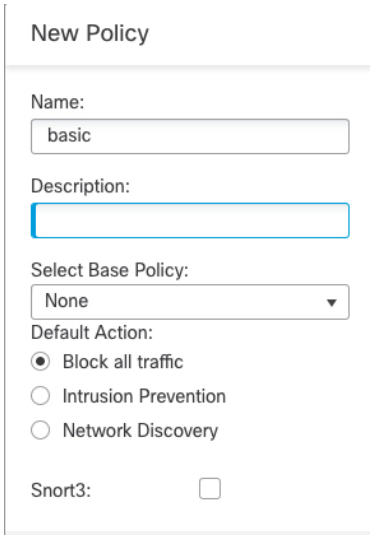
This display name is not for the cluster; it is only for the control unit you are adding. You can later change the name of other cluster members and the cluster display name.

c) In the **Registration Key** field, enter the same registration key that you used when you deployed the cluster in FXOS. The registration key is a one-time-use shared secret.

d) (Optional) Add the device to a device **Group**.

e) Choose an initial **Access Control Policy** to deploy to the device upon registration, or create a new policy.

If you create a new policy, you create a basic policy only. You can later customize the policy as needed.



f) Choose licenses to apply to the device.

g) If you used a NAT ID during device setup, expand the **Advanced** section and enter the same NAT ID in the **Unique NAT ID** field.

h) Check the **Transfer Packets** check box to allow the device to transfer packets to the Firewall Management Center.

This option is enabled by default. When events like IPS or Snort are triggered with this option enabled, the device sends event metadata information and packet data to the Firewall Management Center for inspection. If you disable it, only event information will be sent to the Firewall Management Center but packet data is not sent.

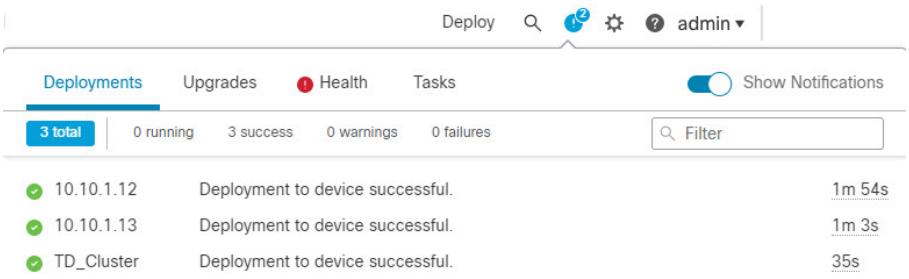
i) Click **Register**.

The Firewall Management Center identifies and registers the control unit, and then registers all data units. If the control unit does not successfully register, then the cluster is not added. A registration failure can occur if the cluster was not up on the chassis, or because of other connectivity issues. In this case, we recommend that you try re-adding the cluster unit.

The cluster name shows on the **Devices** > **Device Management** page; expand the cluster to see the cluster units.

A unit that is currently registering shows the loading icon.

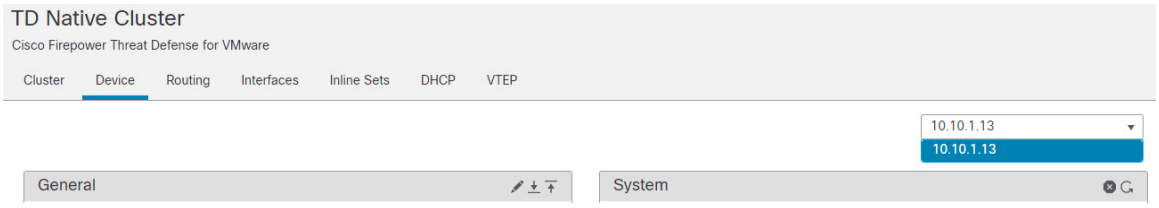
You can monitor cluster unit registration by clicking the **Notifications** icon and choosing **Tasks**. The Firewall Management Center updates the Cluster Registration task as each unit registers. If any units fail to register, see Reconcile Cluster Members, on page 840.



Step 2 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

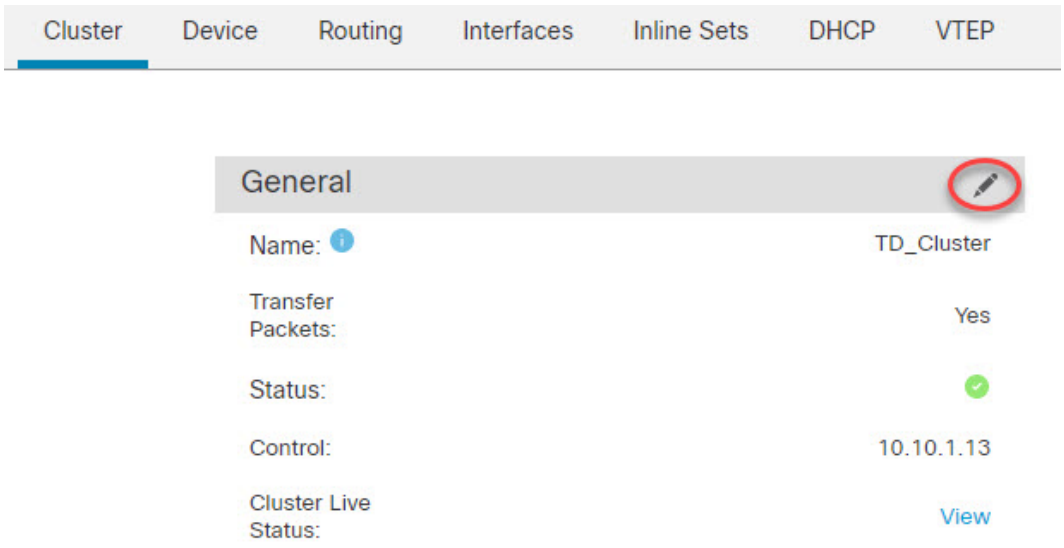
Most configuration can be applied to the cluster as a whole, and not member units in the cluster. For example, you can change the display name per unit, but you can only configure interfaces for the whole cluster.

Step 3 On the **Devices** > **Device Management**and choose the **Add**, **Cluster** screen, you see **General**, **License**, **System**, and **Health** settings.

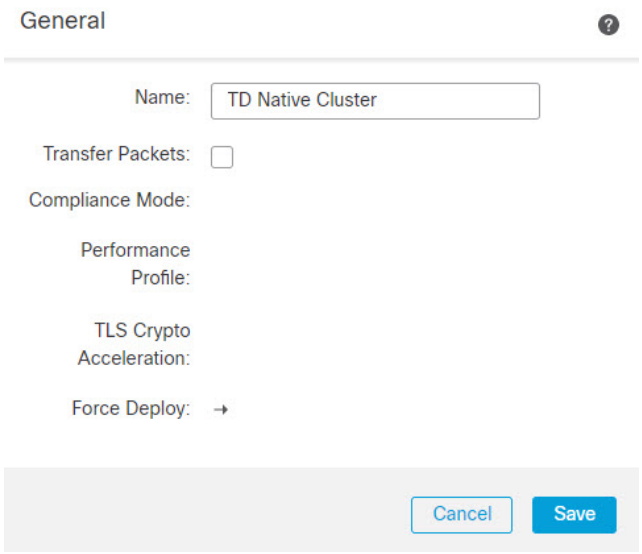


See the following cluster-specific items:

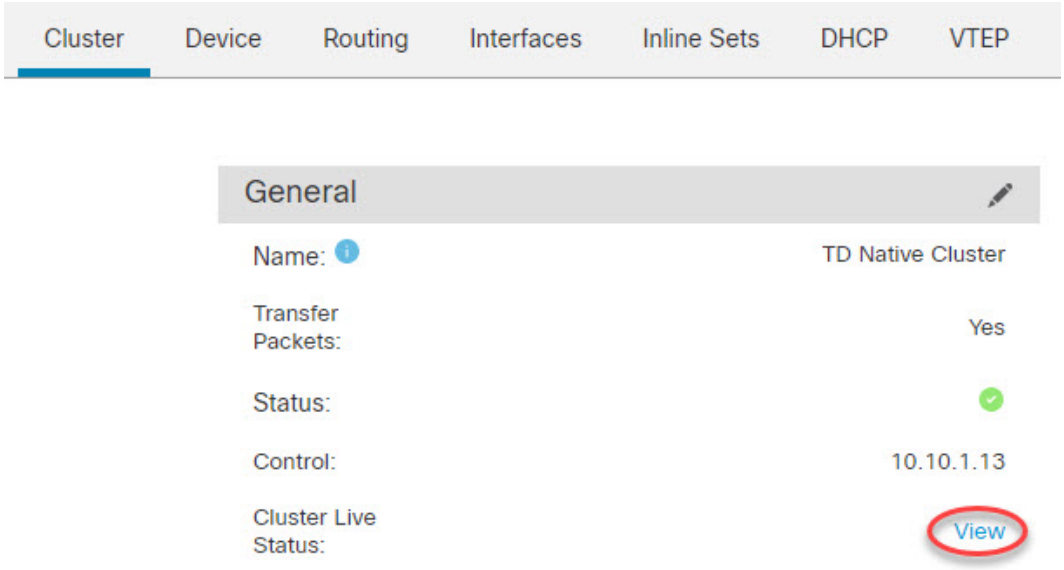
- **General > Name**—Change the cluster display name by clicking the **Edit** (✎).



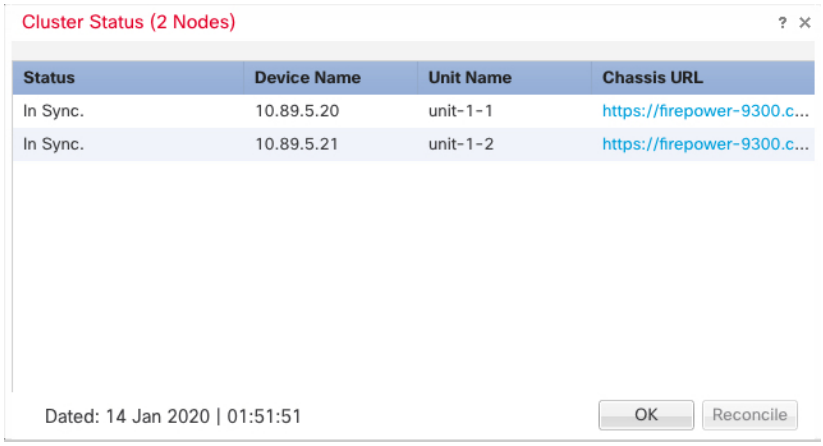
Then set the **Name** field.



- **General > View cluster status**—Click the **View cluster status** link to open the **Cluster Status** dialog box.



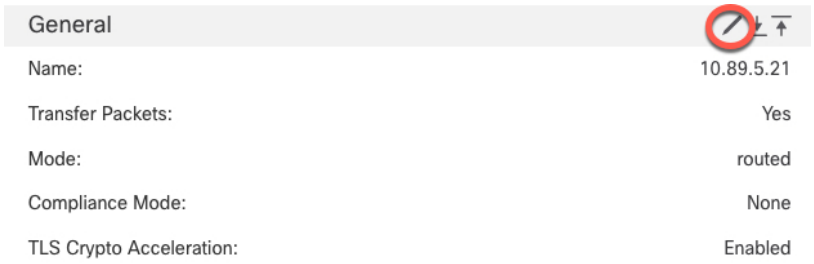
The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile**.



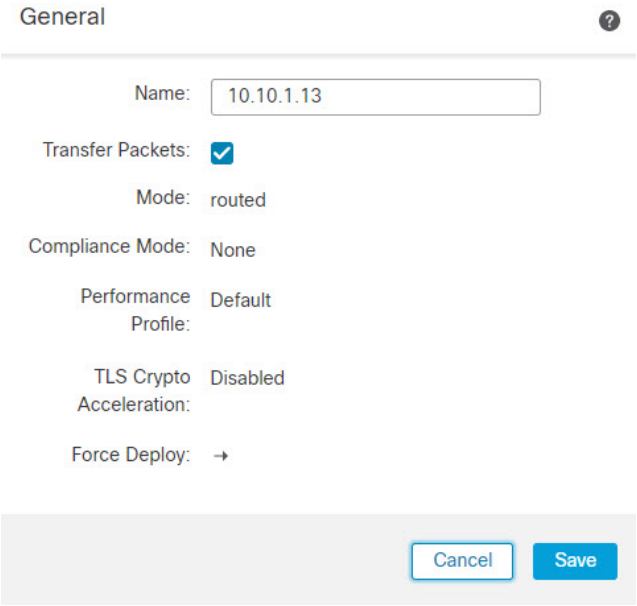
- **License**—Click **Edit** (✎) to set license entitlements.

Step 4 On the **Devices** > **Device Management** and then choose **Add Device**, you can choose each member in the cluster from the top right drop-down menu and configure the following settings.

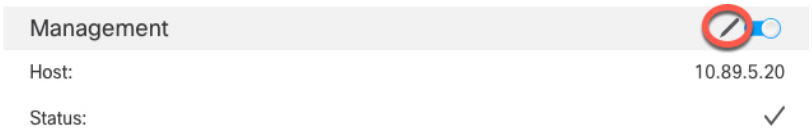
- **General** > **Name**—Change the cluster member display name by clicking the **Edit** (✎).



Then set the **Name** field.



- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the Firewall Management Center so that it can reach the device on the network; edit the **Host** address in the **Management** area.



Firewall Management Center: Configure Cluster, Data Interfaces

This procedure configures basic parameters for each data interface that you assigned to the cluster when you deployed it in FXOS. For clustering on multiple chassis, data interfaces are always Spanned EtherChannel interfaces. For the cluster control link interface for a cluster isolated to security modules within one Firepower 9300 chassis, you must increase the MTU from the default.

Note When using Spanned EtherChannels for clustering on multiple chassis, the port-channel interface will not come up until clustering is fully enabled. This requirement prevents traffic from being forwarded to a unit that is not an active unit in the cluster.

Procedure

Step 1 Choose **Devices** > **Device Management**, and click **Edit** (✎) next to the cluster.

Step 2 Click **Interfaces**.

Step 3 Configure the cluster control link.

For clustering on multiple chassis, set the cluster control link MTU to be at least 100 bytes higher than the highest MTU of the data interfaces. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. We suggest setting the MTU to the maximum of 9184; the minimum value is 1400 bytes. For example, because the maximum MTU is 9184, then the highest data interface MTU can be 9084, while the cluster control link can be set to 9184.

For native clusters: The cluster control link interface is Port-Channel48 by default. If you don't know which interface is the cluster control link, check the FXOS configuration for chassis for the Cluster-type interface assigned to the cluster.

a) Click **Edit** (✎) for the cluster control link interface.
b) On the **General** page, in the **MTU** field, enter a value between 1400 and 9184but not between 2561 and 8362. Due to block pool handling, this MTU size is not optimal for system operation. We suggest using the maximum, 9184.
c) Click **OK**.

Step 4 Configure data interfaces.

a) (Optional) For regular firewall interfaces, configure VLAN subinterfaces on the data interface. The rest of this procedure applies to the subinterfaces. See Add a Subinterface, on page 930.
b) Click **Edit** (✎) for the data interface.
c) Configure the name and other parameters. For regular firewall interfaces, see Configure Routed Mode Interfaces, on page 948 or, for transparent mode, Configure Bridge Group Interfaces, on page 953. For IPS-only interfaces, see Inline Sets and Passive Interfaces, on page 985..

Note
If the cluster control link interface MTU is not at least 100 bytes higher than the data interface MTU, you will see an error that you must reduce the MTU of the data interface. See, Step 3, on page 828 to increase the cluster control link MTU, after which you can continue configuring the data interfaces.

d) For clustering on multiple chassis, set a unique. manual global MAC address for the EtherChannel. Click **Advanced**, and in the **Active Mac Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

Do not set the **Standby Mac Address**; it is ignored.

You must configure a unique MAC address not currently in use on your network for a Spanned EtherChannel to avoid potential network connectivity problems. With a manually-configured MAC address, the MAC address stays with the current control unit. If you do not configure a MAC address, then if the control unit changes, the new control unit uses a new MAC address for the interface, which can cause a temporary network outage.

e) Click **OK**. Repeat the above steps for other data interfaces.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Firewall Management Center: Configure Cluster Health Monitor Settings

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings described in the table below.

Figure 247: Cluster Health Monitor Settings

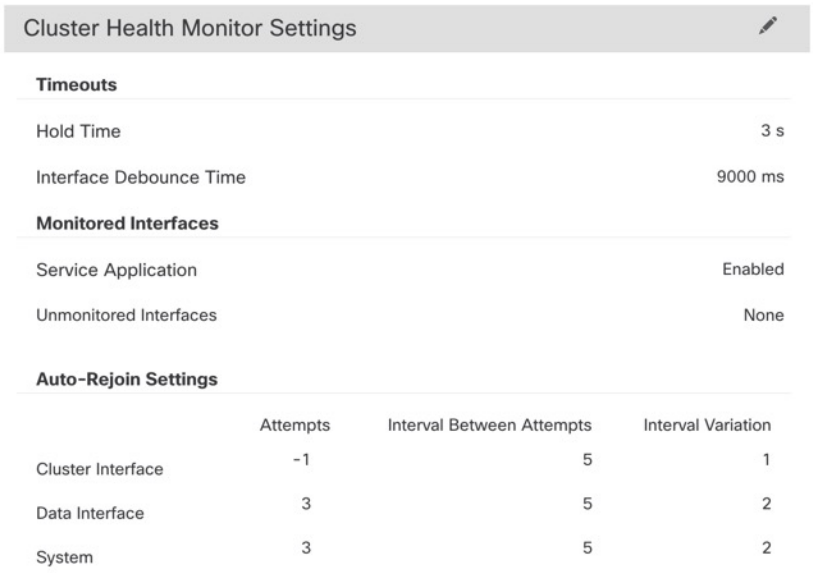


Table 64: Cluster Health Monitor Settings Section Table Fields

Field	Description
Timeouts	
Hold Time	Between .3 and 45 seconds; The default is 3 seconds. To determine node system health, the cluster nodes send heartbeat messages on the cluster control link to other nodes. If a node does not receive any heartbeat messages from a peer node within the hold time period, the peer node is considered unresponsive or dead.
Interface Debounce Time	Between 300 and 9000 ms. The default is 500 ms. The interface debounce time is the amount of time before the node considers an interface to be failed, and the node is removed from the cluster.

Field	Description
Monitored Interfaces	The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster.
Service Application	Shows whether the Snort and disk-full processes are monitored.
Unmonitored Interfaces	Shows unmonitored interfaces.
Auto-Rejoin Settings	
Cluster Interface	Shows the auto-rejoin settings after a cluster control link failure.
Attempts	Between -1 and 65535. The default is -1 (unlimited). Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 1x the interval duration. Defines if the interval duration increases at each attempt.
Data Interfaces	Shows the auto-rejoin settings after a data interface failure.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.
System	Shows the auto-rejoin settings after internal errors. Internal failures include: application sync timeout; inconsistent application statuses; and so on.
Attempts	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
Interval Between Attempts	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
Interval Variation	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.

Note If you disable the system health check, fields that do not apply when the system health check is disabled will not show.

You can change these settings from this section.

You can monitor any port-channel ID, single physical interface ID, as well as the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link; it is always monitored.

Procedure

Step 1 Choose **Devices** > **Device Management**.

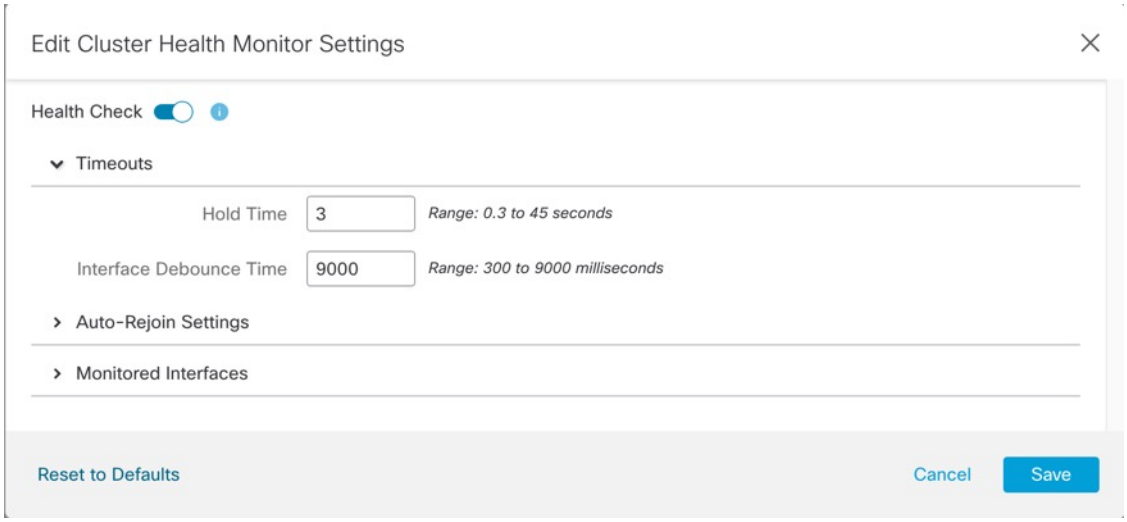
Step 2 Next to the cluster you want to modify, click **Edit** ( ).

Step 3 Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** ( ).

Step 5 Disable the system health check by clicking the **Health Check** slider .

Figure 248: Disable the System Health Check



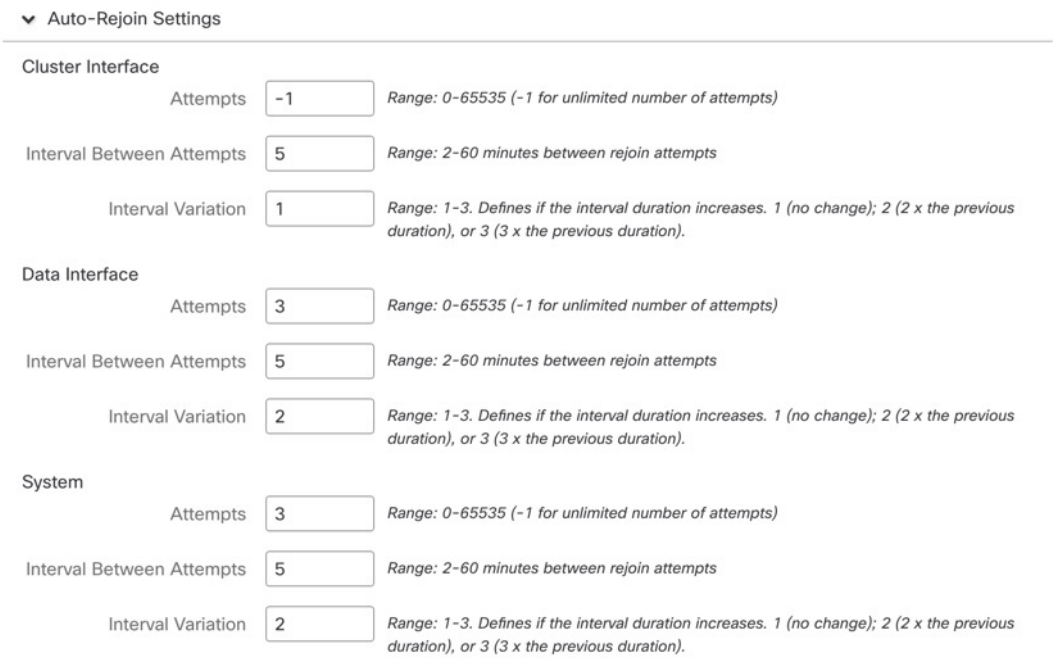
When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between .3 and 45 seconds; The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the number of milliseconds specified before marking the interface as failed, and the node is removed from the cluster. In the case of an EtherChannel that transitions from a down state to an up state (for example, the switch reloaded, or the switch enabled an EtherChannel), a longer debounce time can prevent the interface from appearing to be failed on a cluster node just because another cluster node was faster at bundling the ports.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 249: Configure Auto-Rejoin Settings

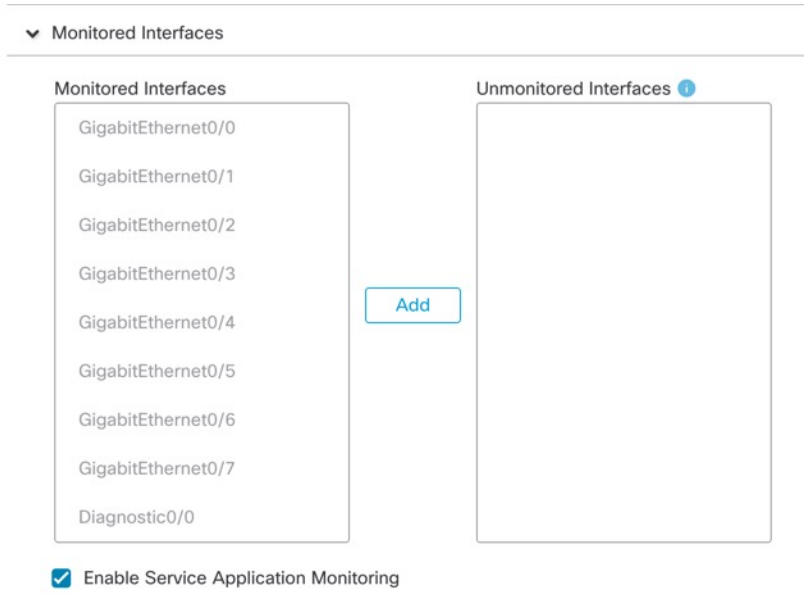


Set the following values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8 Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 250: Configure Monitored Interfaces



The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. Health check is enabled by default for all interfaces and for the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC or VNet) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save**.

Step 10 Deploy configuration changes.

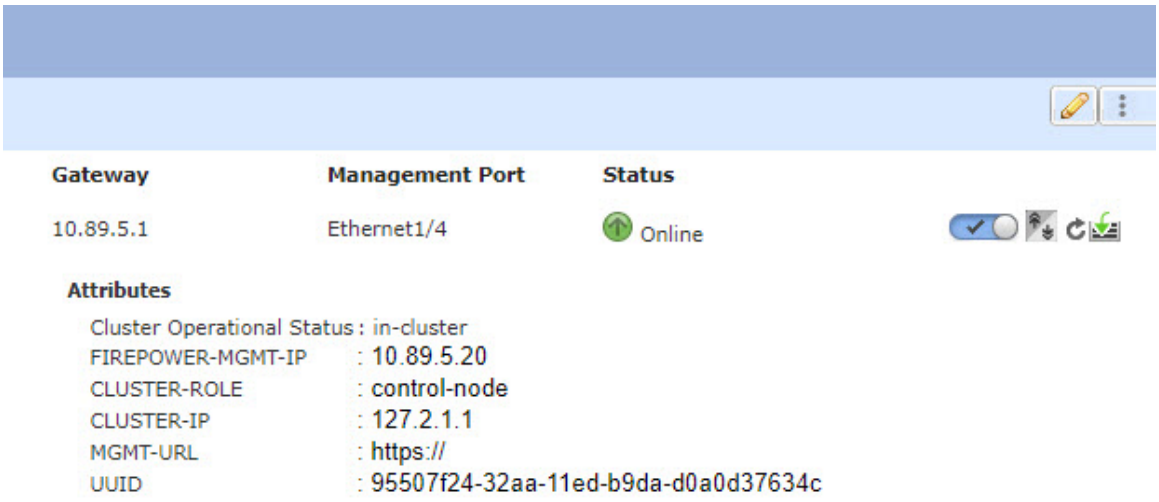
FXOS: Remove a Cluster Node

The following sections describe how to remove nodes temporarily or permanently from the cluster.

Temporary Removal

A cluster node will be automatically removed from the cluster due to a hardware or network failure, for example. This removal is temporary until the conditions are rectified, and it can rejoin the cluster. You can also manually disable clustering.

To check whether a device is currently in the cluster, check the cluster status on the Firewall Chassis Manager **Logical Devices** page:



For Firewall Threat Defense using the Firewall Management Center, you should leave the device in the Firewall Management Center device list so that it can resume full functionality after you reenable clustering.

- Disable clustering in the application—You can disable clustering using the application CLI. Enter the **cluster remove unit** *name* command to remove any node other than the one you are logged into. The bootstrap configuration remains intact, as well as the last configuration synced from the control node, so you can later re-add the node without losing your configuration. If you enter this command on a data node to remove the control node, a new control node is elected.

  When a device becomes inactive, all data interfaces are shut down; only the Management interface can send and receive traffic. To resume traffic flow, re-enable clustering. The Management interface remains up using the IP address the node received from the bootstrap configuration. However if you reload, and the node is still inactive in the cluster , the Management interface is disabled.

  To reenable clustering, on the Firewall Threat Defense enter **cluster enable**.

- Disable the application instance—In the Firewall Chassis Manager on the **Logical Devices** page, click the **Slider enabled** ( ). You can later reenable it using the **Slider disabled** ( ).

- Shut down the security module/engine—In the Firewall Chassis Manager on the **Security Module/Engine** page, click the **Power Off icon**.

- Shut down the chassis—In the Firewall Chassis Manager on the **Overview** page, click the **Shut Down icon**.

Permanent Removal

You can permanently remove a cluster node using the following methods.

For Firewall Threat Defense using the Firewall Management Center, be sure to remove the node from the Firewall Management Center device list after you disable clustering on the chassis.

- Delete the logical device—In the Firewall Chassis Manager on the **Logical Devices** page, click the **Delete** ( ). You can then deploy a standalone logical device, a new cluster, or even add a new logical device to the same cluster.

- Remove the chassis or security module from service—If you remove a device from service, you can add replacement hardware as a new node of the cluster.

Firewall Management Center: Manage Cluster Members

After you deploy the cluster, you can change the configuration and manage cluster members.

Add a New Cluster Member

When you add a new cluster member in FXOS, the Secure Firewall Management Center adds the member automatically.

Before you begin

- Make sure the interface configuration is the same on the replacement unit as for the other chassis.

Procedure

Step 1 Add the new unit to the cluster in FXOS. See the FXOS configuration guide.

Wait for the new unit to be added to the cluster. Refer to the Firewall Chassis Manager **Logical Devices** screen or use the Firewall Threat Defense **show cluster info** command to view cluster status.

Step 2 The new cluster member is added automatically. To monitor the registration of the replacement unit, view the following:

- **Cluster Status** dialog box (which is available from the **Devices** > **Device Management**, **More** (⋮) icon or from the **Devices** > **Device Management** and choose the **Add**, **Cluster** tab **General** area **Cluster Live Status** link)—A unit that is joining the cluster on the chassis shows "Joining cluster..." After it joins the cluster, the Firewall Management Center attempts to register it, and the status changes to "Available for Registration". After it completes registration, the status changes to "In Sync." If the registration fails, the unit will stay at "Available for Registration". In this case, force a re-registration by clicking **Reconcile**.
- System status **Tasks** —The Firewall Management Center shows all registration events and failures.
- **Devices** > **Device Management** and then choose **Add Device**—When you expand the cluster on the devices listing page, you can see when a unit is registering when it has the loading icon to the left.

Replace a Cluster Member

You can replace a cluster member in an existing cluster. The Firewall Management Center auto-detects the replacement unit. However, you must manually delete the old cluster member in the Firewall Management Center. This procedure also applies to a unit that was reinitialized; in this case, although the hardware remains the same, it appears to be a new member.

Before you begin

- Make sure the interface configuration is the same on the replacement unit as for other chassis.

Procedure

Step 1 For a new chassis, if possible, backup and restore the configuration from the old chassis in FXOS.

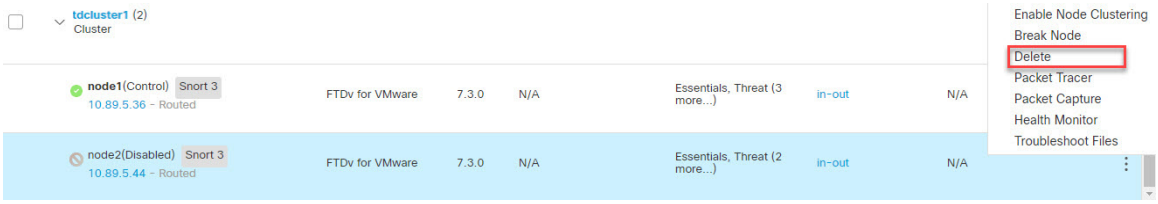
If you are replacing a module in a Firepower 9300, you do not need to perform these steps.

If you do not have a backup FXOS configuration from the old chassis, first perform the steps in Add a New Cluster Member, on page 835.

For information about all of the below steps, see the FXOS configuration guide.

a) Use the configuration export feature to export an XML file containing logical device and platform configuration settings for your Firepower 4100/9300 chassis.
b) Import the configuration file to the replacement chassis.
c) Accept the license agreement.
d) If necessary, upgrade the logical device application instance version to match the rest of the cluster.

Step 2 In the Firewall Management Center for the old unit, choose **Devices** > **Device Management**, **More** (⋮) > **Delete** .



Step 3 Confirm that you want to delete the unit.

The unit is removed from the cluster and from the Firewall Management Center devices list.

Step 4 The new or reinitialized cluster member is added automatically. To monitor the registration of the replacement unit, view the following:

- **Cluster Status** dialog box (**Devices** > **Device Management**, **More** (⋮) icon or **Devices** > **Device Management** and then choose **Add**, **Cluster** page, **General** area, **Cluster Live Status** link)—A unit that is joining the cluster on the chassis shows "Joining cluster..." After it joins the cluster, the Firewall Management Center attempts to register it, and the status changes to "Available for Registration". After it completes registration, the status changes to "In Sync." If the registration fails, the unit will stay at "Available for Registration". In this case, force a re-registration by clicking **Reconcile All**.
- Click **System** (⚙), and then click **Tasks**—The Firewall Management Center shows all registration events and failures.
- **Devices** > **Device Management**, and then click **Add** > **Device**—When you expand the cluster on the devices listing page, you can see when a unit is registering when it has the loading icon to the left.

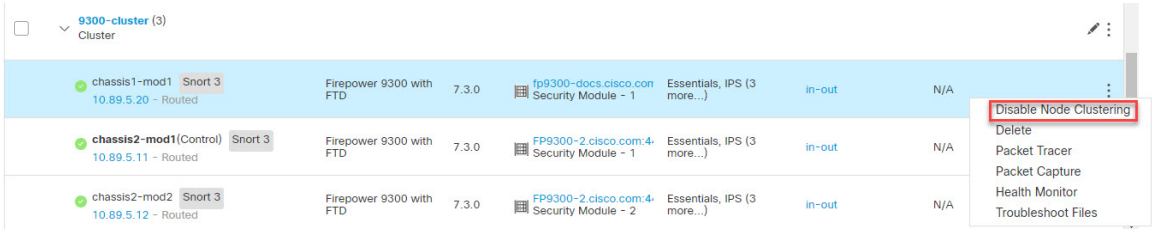
Deactivate a Member

You may want to deactivate a member in preparation for deleting the unit, or temporarily for maintenance. This procedure is meant to temporarily deactivate a member; the unit will still appear in the Firewall Management Center device list.

Note When a unit becomes inactive, all data interfaces are shut down; only the Management interface can send and receive traffic. To resume traffic flow, reenable clustering. The Management interface remains up using the IP address the unit received from the bootstrap configuration. However if you reload, and the unit is still inactive in the cluster, the management interface is disabled. You must use the console for any further configuration.

Procedure

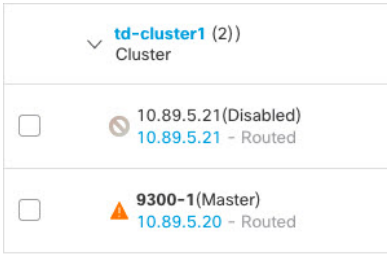
Step 1 For the unit you want to deactivate, choose **Devices** > **Device Management**, **More** (⋮), and then **Disable Clustering**.



You can also deactivate a unit from the **Cluster Status** dialog box (**Devices** > **Device Management**, **More** (⋮), and **Cluster Live Status**).

Step 2 Confirm that you want to disable clustering on the unit.

The unit will show **(Disabled)** next to its name in the **Devices** > **Device Management** list.



Step 3 To reenable clustering, see Rejoin the Cluster, on page 838.

Rejoin the Cluster

If a unit was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster.

Procedure

Step 1 For the unit you want to reactivate, choose **Devices** > **Device Management**, **More** (⋮) > **Enable Clustering**.

You can also reactivate a unit from the **Cluster Status** dialog box (**Devices** > **Device Management**, **More** (⋮) > **Cluster Live Status**).

Step 2 Confirm that you want to enable clustering on the unit.

Delete (Unregister) a Data Node

If you need to permanently remove a cluster node (for example, if you remove a module on the Firepower 9300, or remove a chassis), then you should unregister it from the Firewall Management Center.

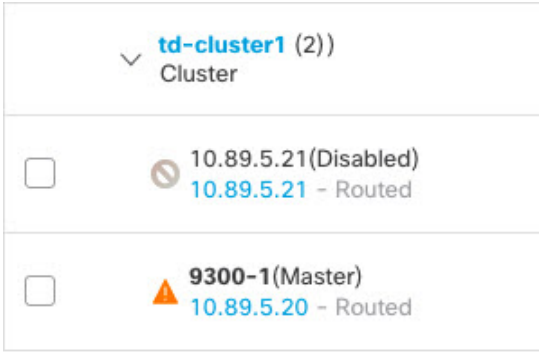
Do not unregister the node if it is still a healthy part of the cluster, or if you only want to disable the node temporarily. To remove it permanently from the cluster in FXOS, see FXOS: Remove a Cluster Node, on page 833. If you unregister it from the Firewall Management Center, and it is still part of the cluster, it will continue to pass traffic, and could even become the control node—a control node that the Firewall Management Center can no longer manage.

Before you begin

To manually deactivate the node, see Deactivate a Member, on page 837. Before you unregister a node, the node must be inactive, either manually or because of a health failure.

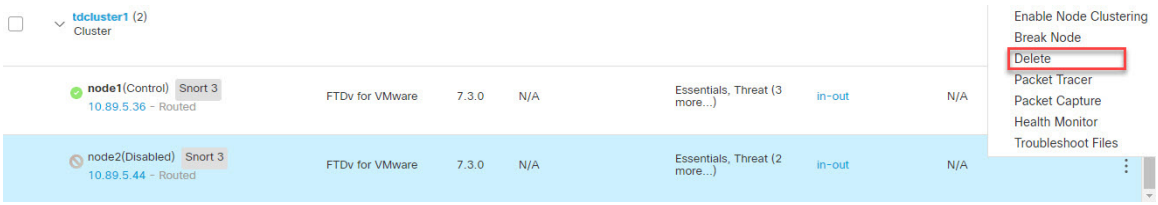
Procedure

Step 1 Make sure the node is ready to be unregistered from the Firewall Management Center. On **Devices** > **Device Management**, make sure the node shows **(Disabled)**.



You can also view each node's status on the **Cluster Status** dialog box available from **More** (⋮). If the status is stale, click **Reconcile All** on the **Cluster Status** dialog box to force an update.

Step 2 In the Firewall Management Center for the data node you want to delete, choose **Devices** > **Device Management** and then click **Add** > **DeviceMore** (⋮) > **Delete**.



Step 3 Confirm that you want to delete the node.

The node is removed from the cluster and from the Firewall Management Center devices list.

Change the Control Unit

⚠

Caution The best method to change the control unit is to disable clustering on the control unit, wait for a new control election, and then re-enable clustering. If you must specify the *exact* unit you want to become the control unit, use the procedure in this section. Note that for centralized features, if you force a control unit change, then all connections are dropped, and you have to re-establish the connections on the new control unit.

To change the control unit, perform the following steps.

Procedure

Step 1 Open the **Cluster Status** dialog box by choosing **Devices** > **Device Management**, **More** (⋮) > **Cluster Live Status**.

You can also access the **Cluster Status** dialog box from **Devices** > **Device Management** and choose the **Add**, **Cluster** page, **General** area, and **Cluster Live Status** link.

Step 2 For the unit you want to become the control unit, choose **More** (⋮) > **Change Role to Control**.

Step 3 You are prompted to confirm the role change. Check the check box, and click **OK**.

Reconcile Cluster Members

If a cluster member fails to register, you can reconcile the cluster membership from the chassis to the Secure Firewall Management Center. For example, a data unit might fail to register if the Firewall Management Center is occupied with certain processes, or if there is a network issue.

Procedure

Step 1 Choose **Devices** > **Device Management**, **More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

You can also open the **Cluster Status** dialog box from the **Devices** > **Device Management** page **General** area, **Cluster Live Status** link.

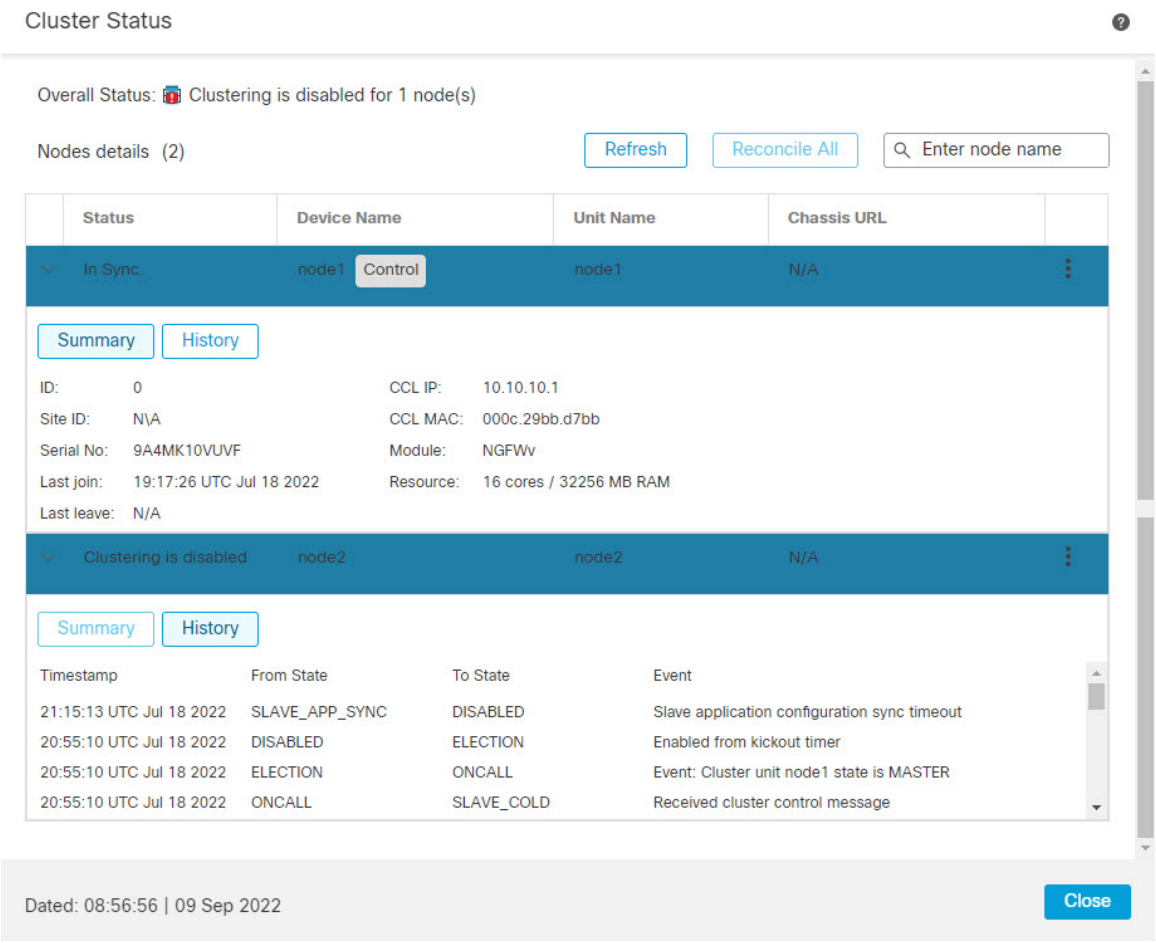
Step 2 Click **Reconcile All**.

For more information about the cluster status, see Firewall Management Center: Monitoring the Cluster, on page 840.

Firewall Management Center: Monitoring the Cluster

You can monitor the cluster in Secure Firewall Management Center and at the Firewall Threat Defense CLI.

- **Cluster Status** dialog box, which is available from the **Devices** > **Device Management**, **More** (⋮) icon or from the **Devices** > **Device Management** and then chose **Add**, **Cluster** page, **General** area, and **Cluster Live Status** link.



The Control unit has a graphic indicator identifying its role.

Cluster member **Status** includes the following states:

- In Sync.—The unit is registered with the Firewall Management Center.
- Pending Registration—The unit is part of the cluster, but has not yet registered with the Firewall Management Center. If a unit fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The unit is registered with the Firewall Management Center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the unit from the cluster.
- Joining cluster...—The unit is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the Firewall Management Center.

For each unit, you can view the **Summary** or the **History**.

For each unit from the **More** (⋮) menu , you can perform the following status changes:

- **Disable Clustering**
- **Enable Clustering**

- **Change Role to Control**

- Click **System** (⚙), and then click **Tasks**.

  The **Tasks** page shows updates of the Cluster Registration task as each unit registers.

- **Devices** > **Device Management** and then choose **Add Device** *cluster_name*.

  When you expand the cluster on the devices listing page, you can see all member units, including the control unit shown with its role next to the IP address. For units that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [**count**] | **cpu** [**usage**] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

  To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

  To view cluster information, use the **show cluster info** command.

Cluster Health Monitor Dashboard

Cluster Health Monitor

When a Firewall Threat Defense is the control node of a cluster, the Firewall Management Center collects various metrics periodically from the device metric data collector. The cluster health monitor is comprised of the following components:

- Overview dashboard—Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the Firewall Management Center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

  - The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.

- Load Distribution dashboard—Displays load distribution across the cluster nodes in two widgets:

- The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
- The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.

- Member Performance dashboard—Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard—Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links — Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range—An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard—Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

Viewing Cluster Health

You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

- Ensure you have created a cluster from one or more devices in the Firewall Management Center.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

Step 2 In the device list, click **Expand**(>) and **Collapse** (⌄) to expand and collapse the list of managed cluster devices.

Step 3 To view the cluster health statistics, click on the cluster name. The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution — Traffic and packet distribution across the cluster nodes.

- Member Performance — Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL — Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, see Cisco Secure Firewall Threat Defense Health Metrics.

Step 4 You can configure the time range from the drop-down in the upper-right corner. The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

Step 6 (For node-specific health monitor) View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

Step 7 (For node-specific health monitor) The device monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU — CPU utilization, including the CPU usage by process and by physical cores.
- Memory — Device memory utilization, including data plane and Snort memory usage.
- Interfaces — Interface status and aggregate traffic statistics.
- Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort — Statistics that are related to the Snort process.
- ASP drops — Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. See Cisco Secure Firewall Threat Defense Health Metrics for a comprehensive list of the supported device metrics.

Step 8 Click the plus sign **Add New Dashboard**(+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Cluster Metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

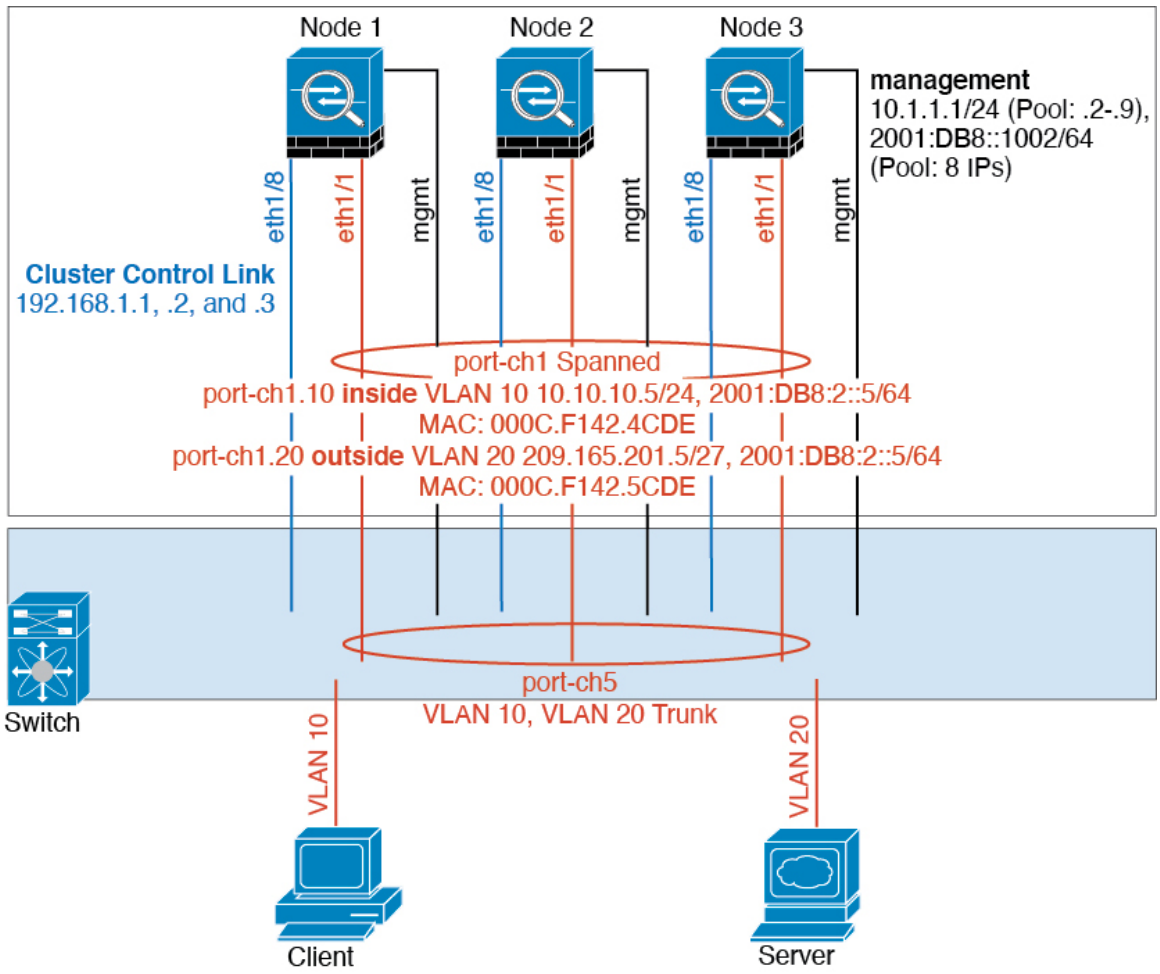
Table 65: Cluster Metrics

Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number
Distribution	Connection distribution count in the cluster for every second.	number
Packets	Packet distribution count in the cluster for every second.	number

Examples for Clustering

These examples include typical deployments.

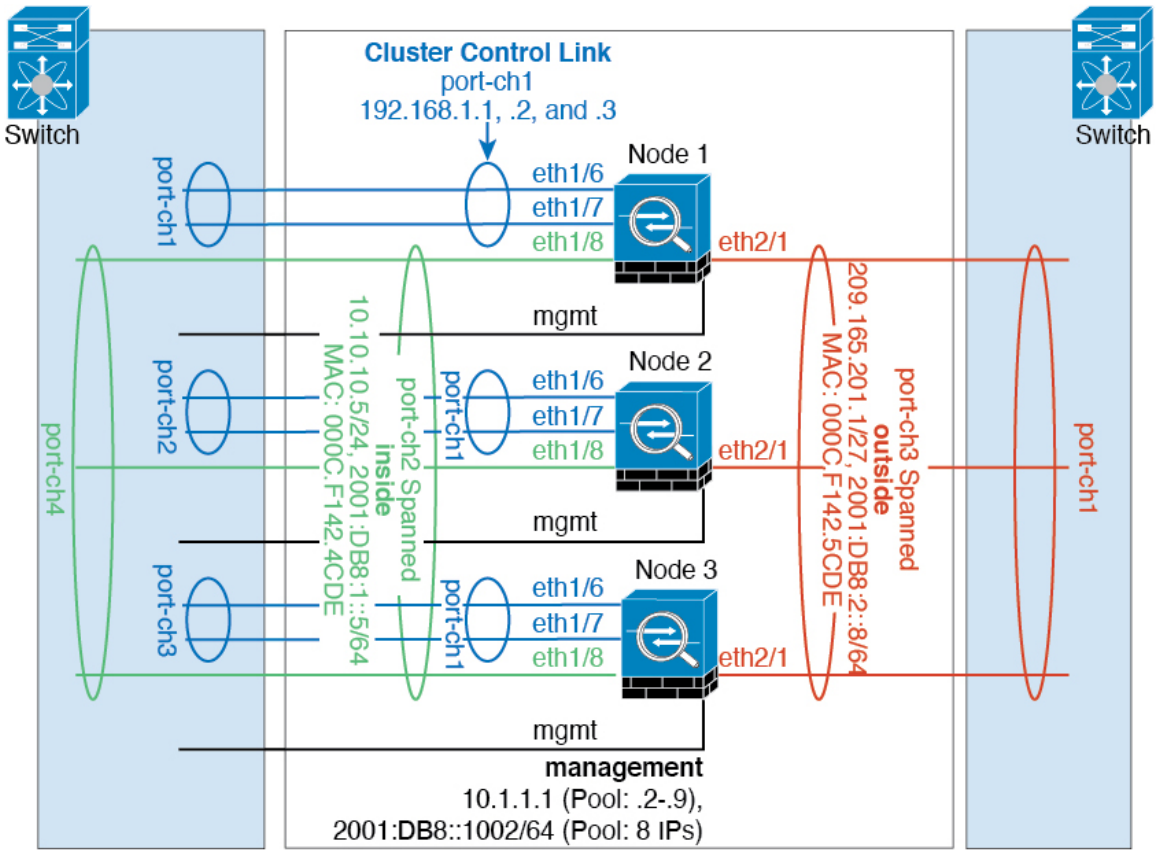
Firewall on a Stick



Data traffic from different security domains are associated with different VLANs, for example, VLAN 10 for the inside network and VLAN 20 for the outside network. Each has a single physical port connected to the external switch or router. Trunking is enabled so that all packets on the physical link are 802.1q encapsulated. The is the firewall between VLAN 10 and VLAN 20.

When using Spanned EtherChannels, all data links are grouped into one EtherChannel on the switch side. If the becomes unavailable, the switch will rebalance traffic between the remaining units.

Traffic Segregation



You may prefer physical separation of traffic between the inside and outside network.

As shown in the diagram above, there is one Spanned EtherChannel on the left side that connects to the inside switch, and the other on the right side to outside switch. You can also create VLAN subinterfaces on each EtherChannel if desired.

Reference for Clustering

This section includes more information about how clustering operates.

Firewall Threat Defense Features and Clustering

Some Firewall Threat Defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported Features with Clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

Note To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Firewall Management Center GUI. See FlexConfig Policies, on page 2645.

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- Firewall Management Center UCAPL/CC mode
- DHCP client, server, and proxy. DHCP relay is supported.

Centralized Features for Clustering

The following features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, see the ASA general operations configuration guide. FlexConfig lets you configure many ASA features that are not present in the Firewall Management Center GUI. See FlexConfig Policies, on page 2645.

- The following application inspections:
  - DCERPC
  - ESMTP
  - NetBIOS
  - PPTP
  - RSH
  - SQLNET

- SUNRPC
- TFTP
- XDMCP

- Static route monitoring
- Site-to-site VPN
- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Dynamic routing

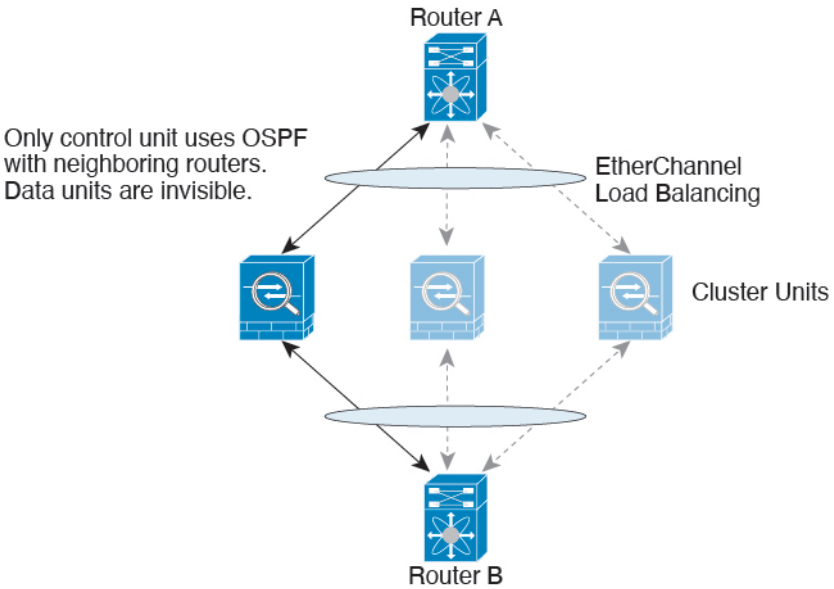
Connection Settings

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

Dynamic Routing and Clustering

The routing process only runs on the control unit, and routes are learned through the control unit and replicated to secondaries. If a routing packet arrives at a data unit, it is redirected to the control unit.

Figure 251: Dynamic Routing



After the data units learn the routes from the control unit, each unit makes forwarding decisions independently.

The OSPF LSA database is not synchronized from the control unit to data units. If there is a control unit switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

FTP and Clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

Multicast Routing and Clustering

The control unit handles all multicast routing packets and data packets until fast-path forwarding is established. After the connection is established, each data unit can forward multicast data packets.

NAT and Clustering

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different Firewall Threat Defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the Firewall Threat Defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
  - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
  - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
  - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the

nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.

- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP
  - RSH
  - SQLNET
  - TFTP
  - XDMCP
  - SIP
- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

SIP Inspection and Clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and Clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and Clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

TLS/SSL Connections and Clustering

The decryption states of TLS/SSL connections are not synchronized, and if the connection owner fails, then the decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Cisco TrustSec and Clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

VPN and Clustering

Site-to-site VPN is a centralized feature; only the control unit supports VPN connections.

Note Remote access VPN is not supported with clustering.

VPN functionality is limited to the control unit and does not take advantage of the cluster high availability capabilities. If the control unit fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control unit is elected, you must reestablish the VPN connections.

When you connect a VPN tunnel to a Spanned interface address, connections are automatically forwarded to the control unit.

VPN-related keys and certificates are replicated to all units.

Performance Scaling Factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

For example, for TCP throughput, the Firepower 9300 with 3 SM-40 modules can handle approximately 135 Gbps of real world firewall traffic when running alone. For 2 chassis, the maximum combined throughput will be approximately 80% of 270 Gbps (2 chassis x 135 Gbps): 216 Gbps.

Control Unit Election

Members of the cluster communicate over the cluster control link to elect a control unit as follows:

1. When you deploy the cluster, each unit broadcasts an election request every 3 seconds.

2. Any other units with a higher priority respond to the election request; the priority is set when you deploy the cluster and is not configurable.
3. If after 45 seconds, a unit does not receive a response from another unit with a higher priority, then it becomes the control unit.

Note If multiple units tie for the highest priority, the cluster unit name and then the serial number is used to determine the control unit.

4. If a unit later joins the cluster with a higher priority, it does not automatically become the control unit; the existing control unit always remains as the control unit unless it stops responding, at which point a new control unit is elected.
5. In a "split brain" scenario when there are temporarily multiple control units, then the unit with highest priority retains the role while the other units return to data unit roles.

Note You can manually force a unit to become the control unit. For centralized features, if you force a control unit change, then all connections are dropped, and you have to re-establish the connections on the new control unit.

High Availability Within the Cluster

Clustering provides high availability by monitoring chassis, unit, and interface health and by replicating connection states between units.

Chassis-Application Monitoring

Chassis-application health monitoring is always enabled. The Firepower 4100/9300 chassis supervisor checks the Firewall Threat Defense application periodically (every second). If the Firewall Threat Defense device is up and cannot communicate with the Firepower 4100/9300 chassis supervisor for 3 seconds, the Firewall Threat Defense device generates a syslog message and leaves the cluster.

If the Firepower 4100/9300 chassis supervisor cannot communicate with the application after 45 seconds, it reloads the Firewall Threat Defense device. If the Firewall Threat Defense device cannot communicate with the supervisor, it removes itself from the cluster.

Unit Health Monitoring

Each unit periodically sends a broadcast keepaliveheartbeat packet over the cluster control link. If the control node does not receive any keepaliveheartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining node.

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail

in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role. See Control Unit Election, on page 852 for more information.

Interface Monitoring

Each node monitors the link status of all hardware interfaces in use, and reports status changes to the control node. For clustering on multiple chassis, Spanned EtherChannels use the cluster Link Aggregation Control Protocol (cLACP). Each chassis monitors the link status and the cLACP protocol messages to determine if the port is still active in the EtherChannel, and informs the Firewall Threat Defense application if the interface is down. When you enable health monitoring, all physical interfaces are monitored by default (including the main EtherChannel for EtherChannel interfaces). Only named interfaces that are in an Up state can be monitored. For example, all member ports of an EtherChannel must fail before a *named* EtherChannel is removed from the cluster. You can optionally disable monitoring per interface.

If a monitored interface fails on a particular node, but it is active on other nodes, then the node is removed from the cluster. The amount of time before the Firewall Threat Defense device removes a node from the cluster depends on whether the node is an established member or is joining the cluster. The Firewall Threat Defense device does not monitor interfaces for the first 90 seconds that a node joins the cluster. Interface status changes during this time will not cause the Firewall Threat Defense device to be removed from the cluster. For an established member, the node is removed after 500 ms.

For clustering on multiple chassis, if you add or delete an EtherChannel from the cluster, interface health-monitoring is suspended for 95 seconds to ensure that you have time to make the changes on each chassis.

Decorator Application Monitoring

When you install a decorator application on an interface, such as the Radware DefensePro application, then both the Firewall Threat Defense device and the decorator application must be operational to remain in the cluster. The unit does not join the cluster until both applications are operational. Once in the cluster, the unit monitors the decorator application health every 3 seconds. If the decorator application is down, the unit is removed from the cluster.

Status After Failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The Firewall Threat Defense automatically tries to rejoin the cluster, depending on the failure event.

Note When the Firewall Threat Defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoining the Cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The Firewall Threat Defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The Firewall Threat Defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the Firewall Threat Defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The Firewall Threat Defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from Firewall Management Center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.
- Failed Chassis-Application Communication—When the Firewall Threat Defense application detects that the chassis-application health has recovered, it tries to rejoin the cluster automatically.

Data Path Connection State Replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 66: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—
Dynamic routing	Yes	—
SNMP Engine ID	**No**	—

How the Cluster Manages Connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection Roles

See the following roles defined for each connection:

- Owner—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- Backup owner—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

  As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

  For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.
- Director—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

  As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

  ICMP/ICMPv6 hash details:

  - For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.
- Forwarder—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- Fragment Owner—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

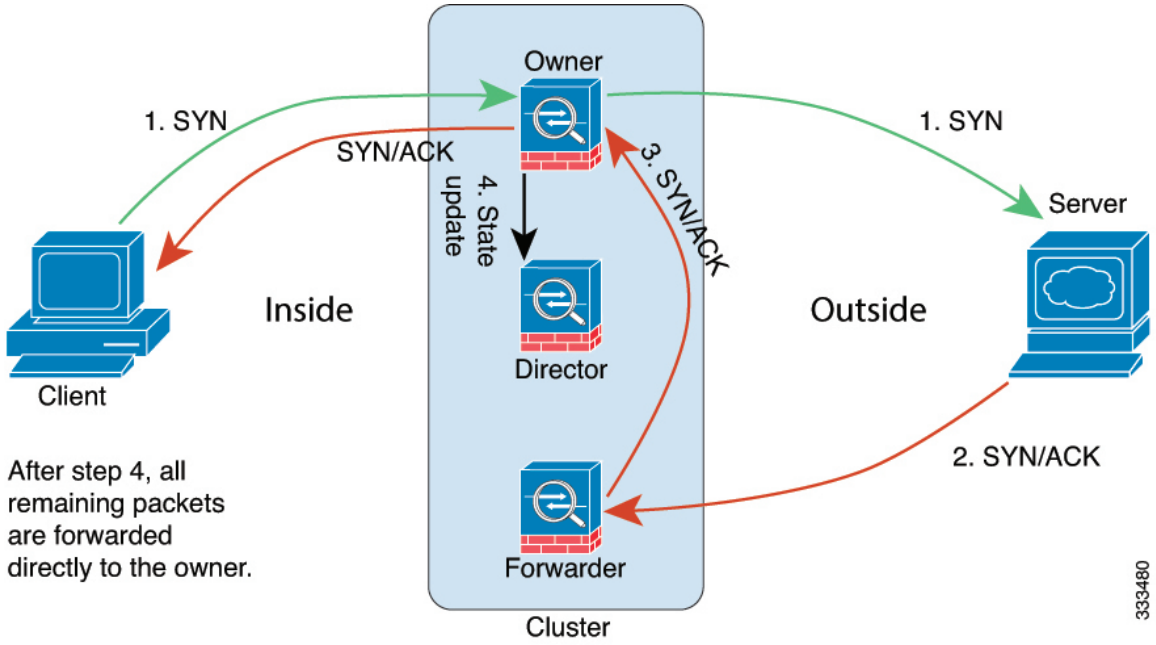
Port Address Translation Connections

New Connection Ownership

When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

Sample Data Flow for TCP

The following example shows the establishment of a new connection.

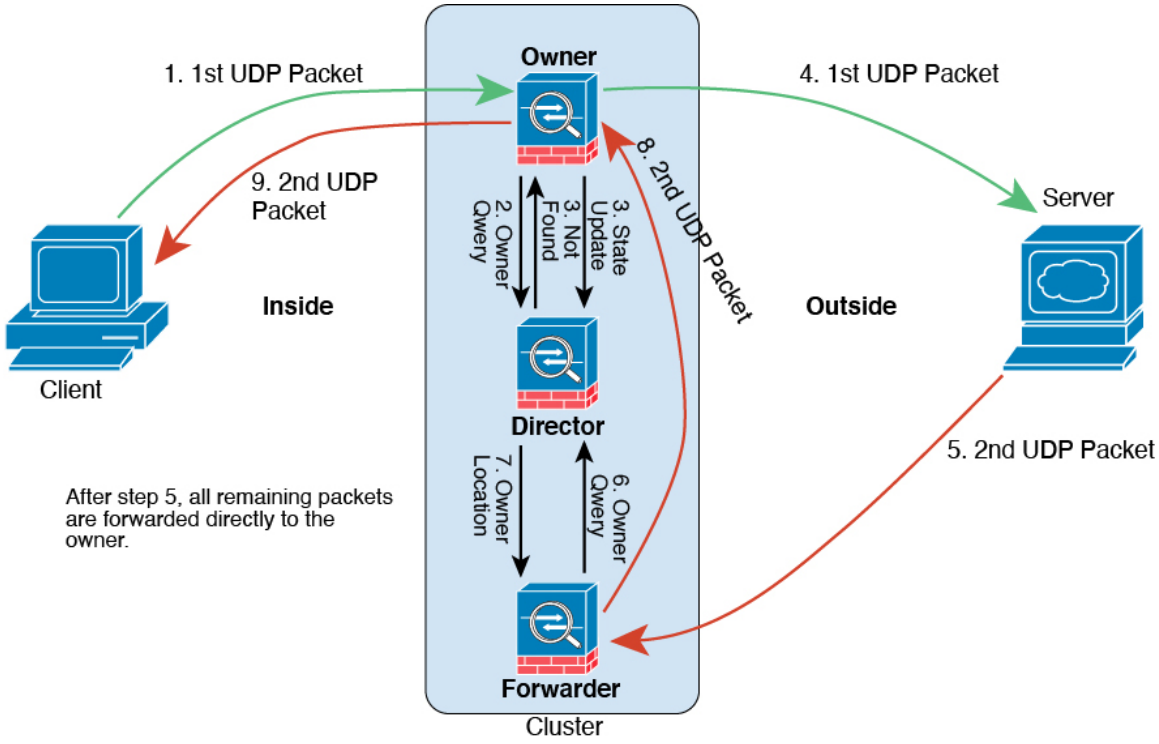


1. The SYN packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different Firewall Threat Defense (based on the load balancing method). This Firewall Threat Defense is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample Data Flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. ***Figure 252: ICMP and UDP Data Flow***



The first UDP packet originates from the client and is delivered to one Firewall Threat Defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

History for Clustering

Table 67:

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Cluster health monitor settings.	20221213	Any	You can now edit cluster health monitor settings. New/Modified screens: **Devices** > **Device Management** > **Cluster** > **Cluster Health Monitor Settings** **Note** If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.
Cluster health monitor dashboard.	20221213	Any	You can now view cluster health on the cluster health monitor dashboard. New/Modified screens: **System** > **Health** > **Monitor**
Support for 16-node clusters.	20220609	7.2.0	You can now configure 16 node clusters for the Firepower 4100/9300. Previously, the maximum was 6 units. New/Modified screens: none. Supported platforms: Firepower 4100/9300
Cluster deployment for firewall changes completes faster.	20220609	7.2.0	Cluster deployment for firewall changes now completes faster. New/Modified screens: none.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Improved PAT port block allocation for clustering.	20220609	7.0.3	The improved PAT port block allocation ensures that the control unit keeps ports in reserve for joining nodes, and proactively reclaims unused ports. To best optimize the allocation, you can set the maximum nodes you plan to have in the cluster using the **cluster-member-limit** command using FlexConfig. The control unit can then allocate port blocks to the planned number of nodes, and it will not have to reserve ports for extra nodes you don't plan to use. The default is 16 nodes. You can also monitor syslog 747046 to ensure that there are enough ports available for a new node. New/Modified commands: **cluster-member-limit** (FlexConfig), **show nat pool cluster** [**summary**], **show nat pool ip detail**
Cluster deployment for Snort changes completes faster, and fails faster when there is an event.	20220609	7.0.3	Cluster deployment for Snort changes now completes faster. Also, when a cluster has an event that causes a Firewall Management Center deployment to fail, the failure now occurs more quickly. New/Modified screens: none.
Improved cluster management.	20220609	7.0.3	Firewall Management Center has improved cluster management functionality that formerly you could only accomplish using the CLI, including: • Enable and disable cluster units • Show cluster status from the Device Management page, including History and Summary per unit • Change the role to the control unit New/Modified screens: • **Devices** > **Device Management** > **More** menu • **Devices** > **Device Management** > **Cluster** > **General** area **> Cluster Live Status** link **Cluster Status** Supported platforms: Firepower 4100/9300

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Multi-instance clustering.	20220609	7.0.3	You can now create a cluster using container instances. On the Firepower 9300, you must include one container instance on each module in the cluster. You cannot add more than one container instance to the cluster per security engine/module. We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. New/Modified FXOS commands: **set port-type cluster** New/modified Firepower Chassis Manager screens: • **Logical Devices** > **Add Cluster** • **Interfaces** > **All Interfaces** > **Add New** drop-down menu**Subinterface Type field** Supported platforms: Firewall Threat Defense on the Firepower 4100/9300
Configuration sync to data units in parallel.	20220609	7.0.3	The control unit now syncs configuration changes with data units in parallel by default. Formerly, synching occurred sequentially. New/Modified screens: none.
Messages for cluster join failure or eviction added to **show cluster history**.	20220609	7.0.3	New messages were added to the **show cluster history** command for when a cluster unit either fails to join the cluster or leaves the cluster. New/Modified commands: **show cluster history** New/Modified screens: none.
Initiator and responder information for Dead Connection Detection (DCD), and DCD support in a cluster.	20220609	7.0.3	If you enable Dead Connection Detection (DCD), you can use the **show conn detail** command to get information about the initiator and responder. Dead Connection Detection allows you to maintain an inactive connection, and the **show conn** output tells you how often the endpoints have been probed. In addition, DCD is now supported in a cluster. New/Modified commands: **show conn** (output only). Supported platforms: Firewall Threat Defense on the Firepower 4100/9300

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Adding clusters is easier.	20220609	7.0.3	You can now add any unit of a cluster to the Firewall Management Center, and the other cluster units are detected automatically. Formerly, you had to add each cluster unit as a separate device, and then group them into a cluster. Adding a cluster unit is also now automatic. Note that you must delete a unit manually. New/Modified screens: **Devices** > **Device Management** > **Add** drop-down menu **Device** > **Add Device** dialog box **Devices** > **Device Management** > **Cluster** tab**General** area**Cluster Registration Status** **Current Cluster Summary** link **Cluster Status** dialog box Supported platforms: Firewall Threat Defense on the Firepower 4100/9300
Support for site-to-site VPN with clustering as a centralized feature.	20220609	7.0.3	You can now configure site-to-site VPN with clustering. Site-to-site VPN is a centralized feature; only the control unit supports VPN connections. Supported platforms: Firewall Threat Defense on the Firepower 4100/9300
Automatically rejoin the cluster after an internal failure.	20220609	7.0.3	Formerly, many internal error conditions caused a cluster unit to be removed from the cluster, and you were required to manually rejoin the cluster after resolving the issue. Now, a unit will attempt to rejoin the cluster automatically at the following intervals: 5 minutes, 10 minutes, and then 20 minutes. Internal failures include: application sync timeout; inconsistent application statuses; and so on. New/Modified command: **show cluster info auto-join** No modified screens. Supported platforms: Firewall Threat Defense on the Firepower 4100/9300
Clustering on multiple chassis for 6 modules; Firepower 4100 support.	20220609	7.0.3	With FXOS 2.1.1, you can now enable clustering on multiple chassis of the Firepower 9300 and 4100. For the Firepower 9300, you can include up to 6 modules. For example, you can use 1 module in 6 chassis, or 2 modules in 3 chassis, or any combination that provides a maximum of 6 modules. For the Firepower 4100, you can include up to 6 chassis. **Note** Inter-site clustering is also supported. However, customizations to enhance redundancy and stability, such as site-specific MAC and IP addresses, director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature. No modified screens. Supported platforms: Firewall Threat Defense on the Firepower 4100/9300

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Clustering on multiple modules with one Firepower 9300 chassis.	20220609	7.0.3	You can cluster up to 3 security modules within the Firepower 9300 chassis. All modules in the chassis must belong to the cluster. New/Modified screens: **Devices** > **Device Management** > **Add** > **Add Cluster** **Devices** > **Device Management** > **Cluster** Supported platforms: Firewall Threat Defense on the Firepower 9300

- Enable the Physical Interface and Configure Ethernet Settings, on page 872
- Configure EtherChannel Interfaces, on page 875
- Sync Interface Changes with the Firewall Management Center, on page 883
- Manage the Network Module for the Secure Firewall 3100, on page 886
- Merge the Management and Diagnostic Interfaces, on page 900
- History for Interfaces, on page 907

Management Interface

In Version 7.3 and earlier, the physical management interface is shared between the Diagnostic logical interface and the Management logical interface. In Version 7.4 and later, the Diagnostic interface is merged with Management for a simplified user experience.

Management Interface

The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the Firewall Management Center. It uses its own IP address and static routing. You can configure its settings at the CLI using the **configure network** command. You can also view its status on the **Devices** > **Device Management** page. If you change the IP address at the CLI after you add it to the Firewall Management Center, you can match the IP address in the Secure Firewall Management Center in the **Devices** > **Device Management** area.

You can alternatively manage the Firewall Threat Defense using a data interface instead of the Management interface.

Diagnostic Interface

For new devices using 7.4 and later, you cannot use the legacy Diagnostic interface. Only the merged Management interface is available.

If you upgraded to 7.4 or later, and you did not have any configuration for the Diagnostic interface, then the interfaces will merge automatically.

If you upgraded to 7.4 or later, and you have configuration for the Diagnostic interface, then you have the choice to merge the interfaces manually, or you can continue to use the separate Diagnostic interface. Note that support for the Diagnostic interface will be removed in a later release, so you should plan to merge the interfaces as soon as possible. To manually merge the Management and Diagnostic interfaces, see Merge the Management and Diagnostic Interfaces, on page 900. Configurations that prevent an automatic merge include the following:

- A data interface named "management"—This name is reserved for use with the merged Management interface.
- IP Address on Diagnostic
- DNS enabled on Diagnostic
- Syslog, SNMP, RADIUS or AD (for remote access VPN) source interface is Diagnostic
- RADIUS or AD (for remote access VPN) with no source interface specified, and there is at least one interface configured as management-only (including Diagnostic)—The default route lookup for these services has changed from the management-only routing table to the data routing table, with no fallback to management. Therefore, you cannot use a management-only interface other than Management.
- Static routes on Diagnostic
- Dynamic routing on Diagnostic
- HTTP server on Diagnostic
- ICMP on Diagnostic
- DDNS for Diagnostic
- FlexConfig using Diagnostic

For more information about how the legacy Diagnostic interface operates, see the 7.3 version of this guide.

Interface Mode and Types

You can deploy Firewall Threat Defense interfaces in two modes: Regular firewall mode and IPS-only mode. You can include both firewall and IPS-only interfaces on the same device.

Regular Firewall Mode

Firewall mode interfaces subject traffic to firewall functions such as maintaining flows, tracking flow states at both IP and TCP layers, IP defragmentation, and TCP normalization. You can also optionally configure IPS functions for this traffic according to your security policy.

The types of firewall interfaces you can configure depends on the firewall mode set for the device: routed or transparent mode. See Transparent or Routed Firewall Mode, on page 431 for more information.

- Routed mode interfaces (routed firewall mode only)—Each interface that you want to route between is on a different subnet.
- Bridge group interfaces (routed and transparent firewall mode)—You can group together multiple interfaces on a network, and the Firewall Threat Defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. In routed mode, the Firewall Threat Defense device routes between BVIs and regular routed interfaces. In transparent mode, each bridge group is separate and cannot communicate with each other.

IPS-Only Mode

You can configure your device in either a passive or inline IPS deployment. In a passive deployment, you deploy the system out-of-band from the flow of network traffic. In an inline deployment, you configure the system transparently on a network segment by binding two interfaces together.

Security Zones and Interface Groups

Each interface can be assigned to a *security zone* and/or *interface group*. You then apply your security policy based on zones or groups. For example, you can assign the "inside" interface on one or more devices to the "inside" zone; and the "outside" interfaces to the "outside" zone. You can then configure your access control policy to enable traffic to go from the inside zone to the outside zone for every device using the same zones.

To view the interfaces that belong to each object, choose **Objects** > **Object Management** and click **Interface**. This page lists the security zones and interface groups configured on your managed devices. You can expand each interface object to view the type of interfaces in each interface object.

Note Policies that apply to **any** zone (a global policy) apply to interfaces in zones as well as any interfaces that are not assigned to a zone.

Note The Management interface does not belong to a zone or interface group.

Security Zones Vs. Interface Groups

There are two types of interface objects:

- Security zones—An interface can belong to only one security zone.
- Interface groups—An interface can belong to multiple interface groups (and to one security zone).

  You can use interface groups in NAT policies, prefilter policies, and QoS policies, as well as features that let you specify the interface name directly, such as Syslog servers or DNS servers.

Some policies only support security zones, while other policies support zones and groups. Unless you need the functionality an interface group provides, you should default to using security zones because security zones are supported for all features.

You cannot change an existing security zone to an interface group or vice-versa; instead you must create a new interface object.

Note Although tunnel zones are not interface objects, you can use them in place of security zones in certain configurations; see Tunnel Zones and Prefiltering, on page 1954.

Interface Object Types

See the following interface object types:

- Passive—For IPS-only passive or ERSPAN interfaces.
- Inline—For IPS-only inline set interfaces.
- Switched—For regular firewall bridge group interfaces.
- Routed—For regular firewall routed interfaces.
- ASA—(Security zones only) For legacy ASA FirePOWER device interfaces.
- Management—(Interface groups only) For management-only interfaces.
- Loopback—(Interface groups only) For loopback interfaces.

All interfaces in an interface object must be of the same type. After you create an interface object, you cannot change the type of interfaces it contains.

Interface Names

Note that the interface (or zone name) itself does not provide any default behavior in regards to the security policy. We recommend using names that are self-describing to avoid mistakes in future configuration. A good name signifies a logical segment or traffic specification, for example:

- Names of internal interfaces—InsideV110, InsideV160, InsideV195
- Names of DMZ interfaces—DMZV11, DMZV12, DMZV-TEST
- Names of external interfaces—Outside-ASN78, Outside-ASN91

Auto-MDI/MDIX Feature

For RJ-45 interfaces, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. Either the speed or duplex must be set to auto-negotiate to enable Auto-MDI/MDIX for the interface. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled. For Gigabit Ethernet, when the speed and duplex are set to 1000 and full, then the interface always auto-negotiates; therefore Auto-MDI/MDIX is always enabled and you cannot disable it.

Redundant Interfaces (Deprecated)

Redundant interfaces were supported for the ASA 5500-X platforms only. We don't recommend configuring them for other platforms.

Default Settings for Interfaces

This section lists default settings for interfaces.

Default State of Interfaces

The default state of an interface depends on the type.

- Physical interfaces—Disabled. The exception is the Management interface that is enabled for initial setup. Physical interfaces includes switch ports.
- VLAN subinterfaces—Enabled. However, for traffic to pass through the subinterface, the physical interface must also be enabled.
- EtherChannel port-channel interfaces (ISA 3000)—Enabled. However, for traffic to pass through the EtherChannel, the channel group physical interfaces must also be enabled.
- EtherChannel port-channel interfaces (Firepower and Secure Firewall models)—Disabled.

Note For the Firepower 4100/9300, you can administratively enable and disable interfaces in both the chassis and in the Firewall Management Center. For an interface to be operational, the interface must be enabled in both operating systems. Because the interface state is controlled independently, you may have a mismatch between the chassis and Firewall Management Center.

Default Speed and Duplex

By default, the speed and duplex for copper (RJ-45) interfaces are set to auto-negotiate.

By default, the speed and duplex for fiber (SFP) interfaces are set to the maximum speed, with auto-negotiation enabled. If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the Threat Defense interface as well. For example, N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, you must disable the default auto-negotiation on the platform and the switch for the port to be connected.

For the Secure Firewall 3100, the speed is set to detect the installed SFP speed.

Create Security Zone and Interface Group Objects

Add security zones and interface groups to which you can assign device interfaces.

Tip You can create empty interface objects and add interfaces to them later. To add an interface, the interface must have a name. You can also create security zones (but not interface groups) while configuring interfaces.

Before you begin

Understand the usage requirements and restrictions for each type of interface object. See Security Zones and Interface Groups, on page 869.

Procedure

Step 1 Choose **Objects** > **Object Management** > **Interface**.

You can alternatively choose **Objects** > **Other FTD Objects** to create objects.

Step 2 Click **Add** > **Security Zone** or **Add** > **Interface Group**.

Step 3 Enter a **Name**.

Do not use the same name as a network or port object. These object names are deployed to the device, and duplicate names result in a failed deployment.

Step 4 Choose an **Interface Type**.

Step 5 (Optional) From the **Device** > **Interfaces** drop-down list, choose a device that contains interfaces you want to add.

You do not need to assign interfaces on this screen; you can instead assign interfaces to the zone or group when you configure the interface.

Step 6 Click **Save**.

What to do next

- If an active policy references your object, deploy configuration changes.

Enable the Physical Interface and Configure Ethernet Settings

This section describes how to:

- Enable the physical interface. By default, physical interfaces are disabled (with the exception of the Management interface).
- Set a specific speed and duplex. By default, speed and duplex are set to Auto.

This procedure only covers a small subset of Interface settings. Refrain from setting other parameters at this point. For example, you cannot name an interface that you want to use as part of an EtherChannel interface.

Note For the Firepower 4100/9300, you configure basic interface settings in FXOS. See Configure a Physical Interface, on page 478 for more information.

Note For Firepower 1010 switch ports, see Configure Firepower 1010 Switch Ports, on page 911.

You can also click the **Virtual Tunnels** tab to view details of dynamic and static VTIs of route-based VPNs on the device. For more information, see View Virtual Tunnel Information, on page 1620.

Before you begin

If you changed the physical interfaces on the device after you added it to the Firewall Management Center, you need to refresh the interface listing by clicking **Sync Interfaces from device** on the top left of **Interfaces**. For the Secure Firewall 3100, which supports hot swapping, see Manage the Network Module for the Secure Firewall 3100, on page 886 before you change interfaces on a device.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Enable the interface by checking the **Enabled** check box.

Step 4 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 5 (Optional) Set the duplex and speed by clicking **Hardware Configuration** > **Speed**.

- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex.
- **Speed**—Choose a speed (varies depending on the model). (Secure Firewall 3100 only) Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.

  Note
  You cannot modify the speed of a HA or a Cluster Control Link interface.

- **Auto-negotiation**—Set the interface to negotiate the speed, link status, and flow control.

  Note
  If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the Threat Defense interface as well. For example, N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, you must disable the default auto-negotiation on the platform and the switch for the port to be connected.

- **Forward Error Correction Mode**—(Secure Firewall 3100 only) For 25Gbps and higher interfaces, enable Forward Error Correction (FEC). For an EtherChannel member interface, you must configure

FEC before you add it to the EtherChannel. The setting chosen when you use **Auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

Table 68: Default FEC for Auto Setting

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-SR	Clause 74 FC-FEC	Clause 108 RS-FEC
25G-LR	Clause 74 FC-FEC	Clause 108 RS-FEC
10/25G-CSR	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-AOC*x*M	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-CU2.5/3M	Auto-Negotiate	Auto-Negotiate
25G-CU4/5M	Auto-Negotiate	Auto-Negotiate

Step 6 (Optional) (Firepower 1100/2100, Secure Firewall 3100) Enable Link Layer Discovery Protocol (LLDP) by clicking **Hardware Configuration** > **Network Connectivity**.

- **Enable LLDP Receive**—Enables the firewall to receive LLDP packets from its peers.
- **Enable LLDP Transmit**—Enables the firewall to send LLDP packets to its peers.

Step 7 (Optional) (Secure Firewall 3100) Enable pause (XOFF) frames for flow control by clicking **Hardware Configuration** > **Network Connectivity**, and checking **Flow Control Send**.

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If the threat defense port experiences congestion (exhaustion of queuing resources on the internal switch) and cannot receive any more traffic, it notifies the other port by sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

Note
The Firewall Threat Defense supports transmitting pause frames so that the remote peer can rate-control the traffic.

However, receiving of pause frames is not supported.

The internal switch has a global pool of 8000 buffers of 250 bytes each, and the switch allocates buffers dynamically to each port. A pause frame is sent out every interface with flowcontrol enabled when the buffer usage exceeds the global high-water mark (2 MB (8000 buffers)); and a pause frame is sent out of a particular interface when its buffer exceeds the port high-water mark (.3125 MB (1250 buffers)). After a pause is sent, an XON frame can be sent when the buffer usage is reduced below the low-water mark (1.25 MB globally (5000 buffers); .25 MB per port (1000 buffers)). The link partner can resume traffic after receiving an XON frame.

Only flow control frames defined in 802.3x are supported. Priority-based flow control is not supported.

Step 8 In the **Mode** drop-down list, choose one of the following:.

- **None**—Choose this setting for regular firewall interfaces and inline sets. The mode will automatically be changed to Routed, Switched, or Inline based on further configuration.
- **Passive**—Choose this setting for passive IPS-only interfaces.
- **Erspan**—Choose this setting for ERSPAN passive IPS-only interfaces.

Step 9 In the **Priority** field, enter a number ranging from 0–65535.

This value is used in the policy based routing configuration. The priority is used to determine how you want to distribute the traffic across multiple egress interfaces.

Step 10 Click **OK**.

Step 11 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Step 12 Continue configuring interfaces.

- Regular Firewall Interfaces, on page 911
- Inline Sets and Passive Interfaces, on page 985

Configure EtherChannel Interfaces

This section tells how to configure EtherChannel interfaces.

Note For the Firepower 4100/9300, you configure EtherChannels in FXOS. See Add an EtherChannel (Port Channel), on page 479 for more information.

About EtherChannels

This section describes EtherChannels.

About EtherChannels

An 802.3ad EtherChannel is a logical interface (called a port-channel interface) consisting of a bundle of individual Ethernet links (a channel group) so that you increase the bandwidth for a single network. A port channel interface is used in the same way as a physical interface when you configure interface-related features.

You can configure up to 48 EtherChannels, depending on how many interfaces your model supports.

Channel Group Interfaces

Each channel group can have up to 8 active interfaces, except for the ISA 3000, which supports 16 active interfaces. For switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel

group: while only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.

All interfaces in the channel group must be the same type and speed. The first interface added to the channel group determines the correct type and speed.

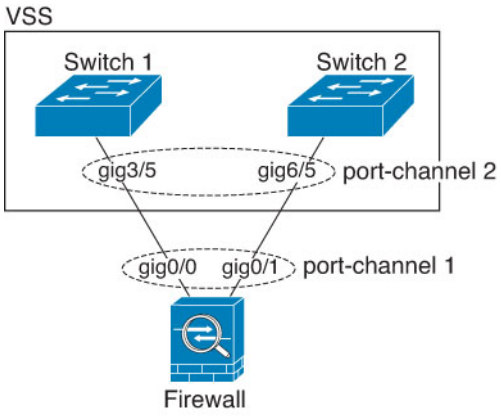
The EtherChannel aggregates the traffic across all the available active interfaces in the channel. The interface is selected using a proprietary hash algorithm, based on source or destination MAC addresses, IP addresses, TCP and UDP port numbers and VLAN numbers.

Connecting to an EtherChannel on Another Device

The device to which you connect the Firewall Threat Defense EtherChannel must also support 802.3ad EtherChannels; for example, you can connect to the Catalyst 6500 switch or the Cisco Nexus 7000.

When the switch is part of a Virtual Switching System (VSS) or Virtual Port Channel (vPC), then you can connect Firewall Threat Defense interfaces within the same EtherChannel to separate switches in the VSS/vPC. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch.

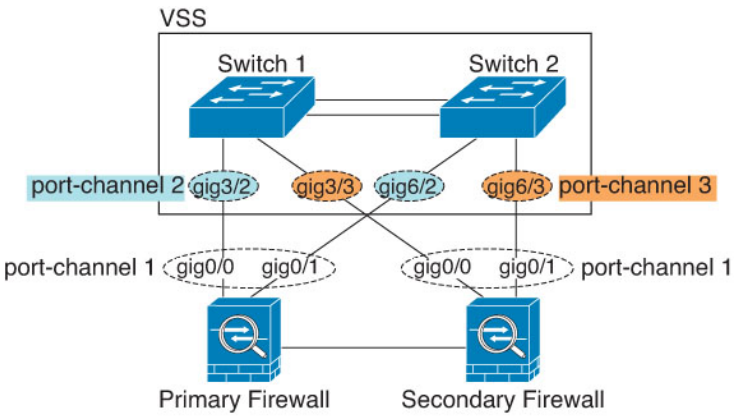
Figure 253: Connecting to a VSS/vPC



Note If the Firewall Threat Defense device is in transparent firewall mode, and you place the Firewall Threat Defense device between two sets of VSS/vPC switches, then be sure to disable Unidirectional Link Detection (UDLD) on any switch ports connected to the Firewall Threat Defense device with an EtherChannel. If you enable UDLD, then a switch port may receive UDLD packets sourced from both switches in the other VSS/vPC pair. The receiving switch will place the receiving interface in a down state with the reason "UDLD Neighbor mismatch".

If you use the Firewall Threat Defense device in an Active/Standby failover deployment, then you need to create separate EtherChannels on the switches in the VSS/vPC, one for each Firewall Threat Defense device. On each Firewall Threat Defense device, a single EtherChannel connects to both switches. Even if you could group all switch interfaces into a single EtherChannel connecting to both Firewall Threat Defense devices (in this case, the EtherChannel will not be established because of the separate Firewall Threat Defense system IDs), a single EtherChannel would not be desirable because you do not want traffic sent to the standby Firewall Threat Defense device.

Figure 254: Active/Standby Failover and VSS/vPC



Link Aggregation Control Protocol

The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices.

You can configure each physical interface in an EtherChannel to be:

- Active—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- Passive—Receives LACP updates. A passive EtherChannel can only establish connectivity with an active EtherChannel. Not supported on hardware models.
- On—The EtherChannel is always on, and LACP is not used. An "on" EtherChannel can only establish a connection with another "on" EtherChannel.

LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. "On" mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

Load Balancing

The Firewall Threat Defense device distributes packets to the interfaces in the EtherChannel by hashing the source and destination IP address of the packet (this criteria is configurable). The resulting hash is divided by the number of active links in a modulo operation where the resulting remainder determines which interface owns the flow. All packets with a *hash_value* **mod** *active_links* result of 0 go to the first interface in the EtherChannel, packets with a result of 1 go to the second interface, packets with a result of 2 go to the third interface, and so on. For example, if you have 15 active links, then the modulo operation provides values from 0 to 14. For 6 active links, the values are 0 to 5, and so on.

If an active interface goes down and is not replaced by a standby interface, then traffic is rebalanced between the remaining links. The failure is masked from both Spanning Tree at Layer 2 and the routing table at Layer 3, so the switchover is transparent to other network devices.

EtherChannel MAC Address

All interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links.

Firepower and Secure Firewall Hardware

The port-channel interface uses the MAC address of the internal interface Internal-Data 0/1. Alternatively you can manually configure a MAC address for the port-channel interface. All EtherChannel interfaces on a chassis use the same MAC address, so be aware that if you use SNMP polling, for example, multiple interfaces will have the same MAC address.

Note Member interfaces only use the Internal-Data 0/1 MAC address after a reboot. Prior to rebooting, the member interface uses its own MAC address. If you add a new member interface after a reboot, you will have to perform another reboot to update its MAC address.

Guidelines for EtherChannels

Bridge Group

In routed mode, Firewall Management Center-defined EtherChannels are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.

High Availability

- When you use an EtherChannel interface as a High Availability link, it must be pre-configured on both units in the High Availability pair; you cannot configure it on the primary unit and expect it to replicate to the secondary unit because *the High Availability link itself is required for replication*.
- If you use an EtherChannel interface for the state link, no special configuration is required; the configuration can replicate from the primary unit as normal. For the Firepower 4100/9300 chassis, all interfaces, including EtherChannels, need to be pre-configured on both units.
- You can monitor EtherChannel interfaces for High Availability. When an active member interface fails over to a standby interface, this activity does not cause the EtherChannel interface to appear to be failed when being monitored for device-level High Availability. Only when all physical interfaces fail does the EtherChannel interface appear to be failed (for an EtherChannel interface, the number of member interfaces allowed to fail is configurable).
- If you use an EtherChannel interface for a High Availability or state link, then to prevent out-of-order packets, only one interface in the EtherChannel is used. If that interface fails, then the next interface in the EtherChannel is used. You cannot alter the EtherChannel configuration while it is in use as a High Availability link. To alter the configuration, you need to temporarily disable High Availability, which prevents High Availability from occurring for the duration.

Model Support

- You cannot add EtherChannels in the Firewall Management Center for the Firepower 4100/9300 or the Firewall Threat Defense Virtual. The Firepower 4100/9300 supports EtherChannels, but you must perform all hardware configuration of EtherChannels in FXOS on the chassis.
- You cannot use Firepower 1010 switch ports or VLAN interfaces in EtherChannels.

General EtherChannel Guidelines

- You can configure up to 48 EtherChannels, depending on how many interfaces are available on your model.
- Each channel group can have up to 8 active interfaces, except for the ISA 3000, which supports 16 active interfaces. For switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group: while only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.
- All interfaces in the channel group must be the same media type and speed capacity. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, except for the Secure Firewall 3100, which supports different interface capacities as long as the speed is set to Detect SFP; in this case the lowest common speed is used.
- The device to which you connect the Firewall Threat Defense EtherChannel must also support 802.3ad EtherChannels.
- The Firewall Threat Defense device does not support LACPDUs that are VLAN-tagged. If you enable native VLAN tagging on the neighboring switch using the Cisco IOS **vlan dot1Q tag native** command, then the Firewall Threat Defense device will drop the tagged LACPDUs. Be sure to disable native VLAN tagging on the neighboring switch.
- The LACP rate depends on the model. When you set the rate (normal or fast), the device requests that rate from the connecting switch. In return, the device will send at the rate requested by the connecting switch. We recommend that you set the same rate on both sides.
    - Firepower 4100/9300—The LACP rate is set to fast by default in FXOS, but you can configure it as normal (also known as slow).
    - Secure Firewall 3100—The LACP rate is set to normal (slow) by default, but you can configure it as fast on the device.
    - All other models—The LACP rate set to normal (also known as slow), and it is not configurable, which means the device will always request a slow rate from the connecting switch. We recommend setting the rate on the switch to slow, so both sides send LACP messages at the same rate.
- In Cisco IOS software versions earlier than 15.1(1)S2, Firewall Threat Defense did not support connecting an EtherChannel to a switch stack. With default switch settings, if the Firewall Threat Defense EtherChannel is connected cross stack, and if the primary switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.
- All the Firewall Threat Defense configuration refers to the logical EtherChannel interface instead of the member physical interfaces.

Configure an EtherChannel

This section describes how to create an EtherChannel port-channel interface, assign interfaces to the EtherChannel, and customize the EtherChannel.

Guidelines

- You can configure up to 48 EtherChannels, depending on the number of interfaces for your model.
- Each channel group can have up to 8 active interfaces, except for the ISA 3000, which supports 16 active interfaces. For switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group: while only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.
- All interfaces in the channel group must be the same media type and speed capacity. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, except for the Secure Firewall 3100, which supports different interface capacities as long as the speed is set to Detect SFP; in this case the lowest common speed is used.

Note For the Firepower 4100/9300, you configure EtherChannels in FXOS. See Add an EtherChannel (Port Channel), on page 479 for more information.

Before you begin

- You cannot add a physical interface to the channel group if you configured a name for it. You must first remove the name.

Note If you are using a physical interface already in your configuration, removing the name will clear any configuration that refers to the interface.

Procedure

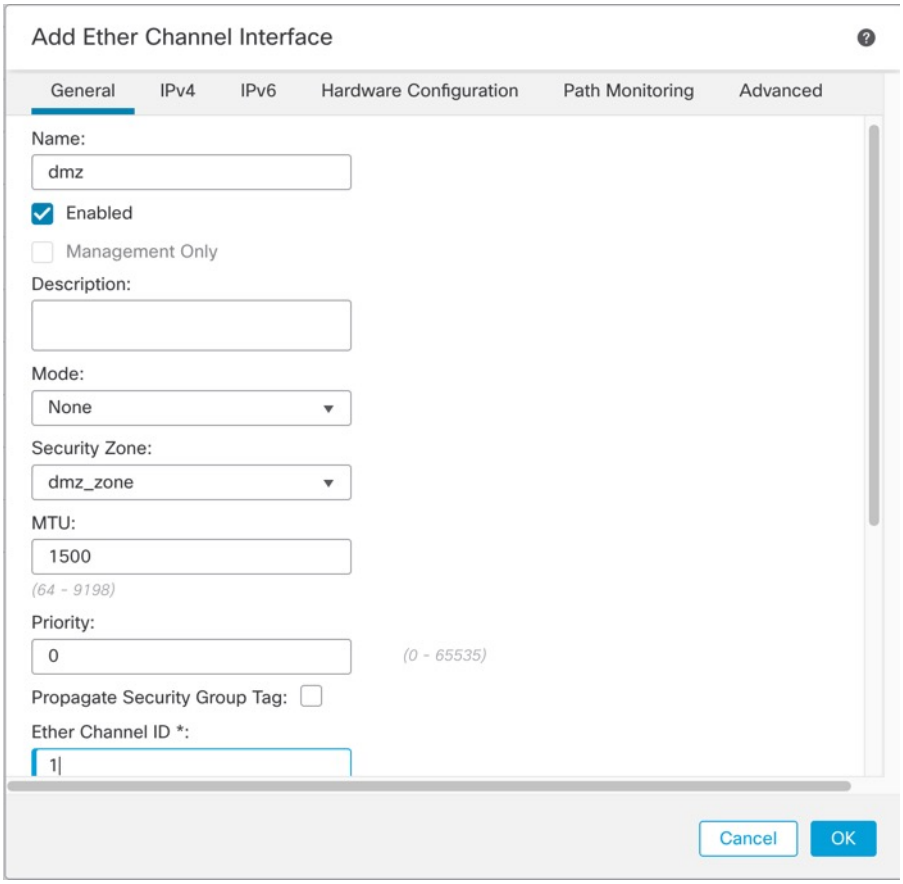
Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Enable the member interfaces according to Enable the Physical Interface and Configure Ethernet Settings, on page 872.

Step 3 Click **Add Interfaces** > **Ether Channel Interface**.

Step 4 On the **General** tab, set the **Ether Channel ID** to a number between 1 and 48 (1 and 8 for the Firepower 1010).

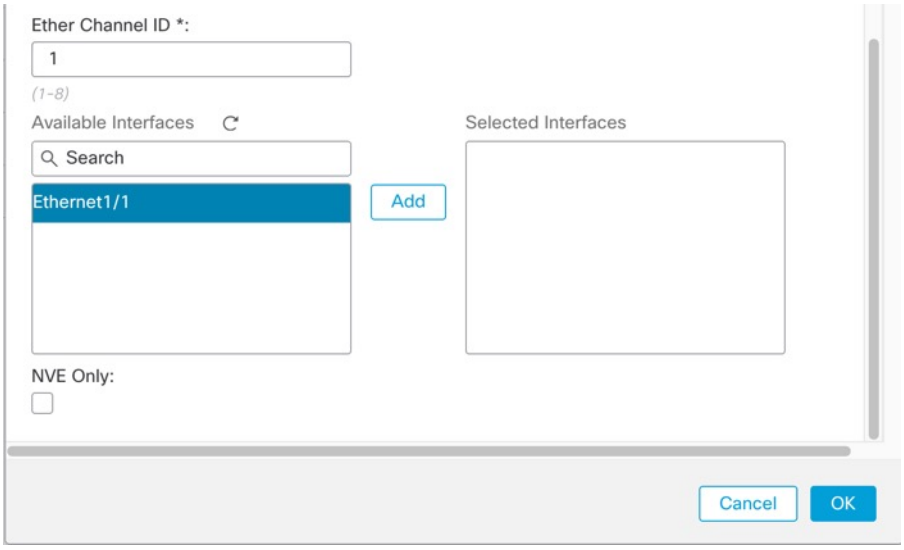
Figure 255: Add EtherChannel Interface



Step 5 In the **Available Interfaces** area, click an interface and then click **Add** to move it to the **Selected Interfaces** area. Repeat for all interfaces that you want to make members.

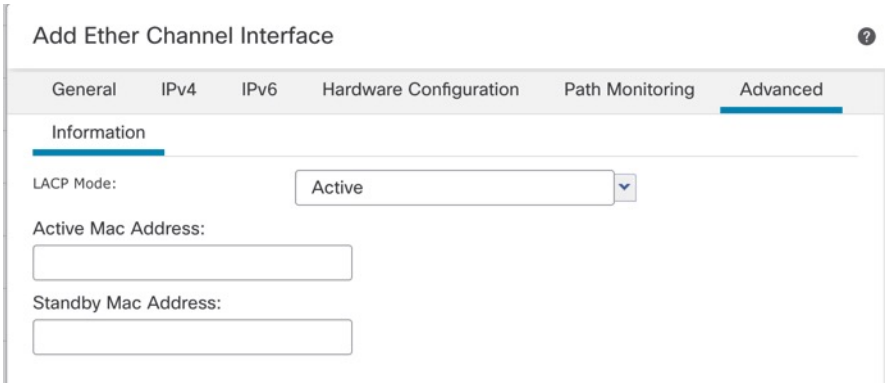
Make sure all interfaces are the same type and speed capability.

Figure 256: Available Interfaces



Step 6 (Optional) Click the **Advanced** tab to customize the EtherChannel. Set the following parameters on the **Information** sub-tab:

Figure 257: Advanced



- (ISA 3000 only) **Load Balancing**—Select the criteria used to load balance the packets across the group channel interfaces. By default, the Firewall Threat Defense device balances the packet load on interfaces according to the source and destination IP address of the packet. If you want to change the properties on which the packet is categorized, choose a different set of criteria. For example, if your traffic is biased heavily towards the same source and destination IP addresses, then the traffic assignment to interfaces in the EtherChannel will be unbalanced. Changing to a different algorithm can result in more evenly distributed traffic. For more information about load balancing, see Load Balancing, on page 877.
- **LACP Mode**—Choose Active, Passive, or On. We recommend using Active mode (the default). Passive mode is only available for the ISA 3000 only.
- (Secure Firewall 3100 only) **LACP Rate**—Choose Default, Normal, or Fast. The defualt is Normal (also known as slow). Sets the LACP data unit receive rate for a physical interface in the channel group. We recommend that you set the same rate on both sides.

- (ISA 3000 only) **Active Physical Interface: Range**—From the left drop-down list, choose the minimum number of active interfaces required for the EtherChannel to be active, between 1 and 16. The default is 1. From the right drop-down list, choose the maximum number of active interfaces allowed in the EtherChannel, between 1 and 16. The default is 16. If your switch does not support 16 active interfaces, be sure to set this command to 8 or fewer.
- **Active Mac Address**—Set a manual MAC address if desired. The mac_address is in H.H.H format, where H is a 16-bit hexadecimal digit. For example, the MAC address 00-0C-F1-42-4C-DE is entered as 000C.F142.4CDE.

Step 7 Click the **Hardware Configuration** tab and set the Duplex and Speed for all member interfaces.

Step 8 Click **OK**.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Step 10 (Optional) For regular firewall interfaces, add a VLAN subinterface. See Add a Subinterface, on page 930.

Step 11 For regular firewall interfaces, configure the routed or transparent mode interface parameters: Configure Routed Mode Interfaces, on page 948 or Configure Bridge Group Interfaces, on page 953. For IPS-only interfaces, see Inline Sets and Passive Interfaces, on page 985.

Sync Interface Changes with the Firewall Management Center

Interface changes on the device can cause the Firewall Management Center and the device to get out of sync. The Firewall Management Center can detect interface changes by one of the following methods:

- Event sent from the device
- Sync when you deploy from the Firewall Management Center

  If the Firewall Management Center detects interface changes when it attempts to deploy, the deployment will fail. You must first accept the interface changes.
- Manual sync

There are two types of interface changes performed outside of Firewall Management Center that need to be synched:

- Addition or deletion of physical interfaces—Adding a new interface, or deleting an unused interface has minimal impact on the Firewall Threat Defense configuration. However, deleting an interface that is used in your security policy will impact the configuration. Interfaces can be referenced directly in many places in the Firewall Threat Defense configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected. You can also edit the membership of an allocated EtherChannel without affecting the logical device or requiring a sync on the Firewall Management Center.

  When the Firewall Management Center detects changes, the **Interface** page shows status (removed, changed, or added) to the left of each interface.

- Firewall Management Center access interface changes—If you configure a data interface for managing using the **configure network management-data-interface** command, you must manually make matching configuration changes in and then acknowledge the changes. These interface changes cannot be made automatically.

This procedure describes how to manually sync interface changes if required and how to acknowledge the detected changes. If interface changes are temporary, you should not save the changes in the Firewall Management Center; you should wait until the device is stable, and then re-sync.

Before you begin

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 If required, click **Sync Device** on the top left of **Interfaces**.

Step 3 After the changes are detected, see the following steps.

Addition or Deletion of Physical Interfaces

a) You will see a red banner on **Interfaces** indicating that the interface configuration has changed. Click the **Click to know more** link to view the interface changes.

b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

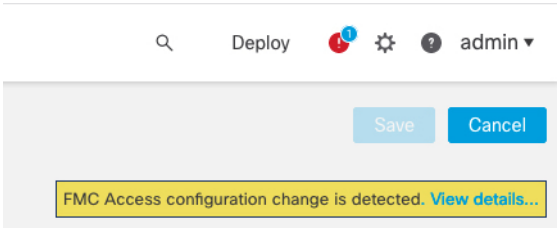
If there are any errors, you need to change your policy and rerun the validation.

c) Click **Save**.

You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices.

FMC Access Interface Changes

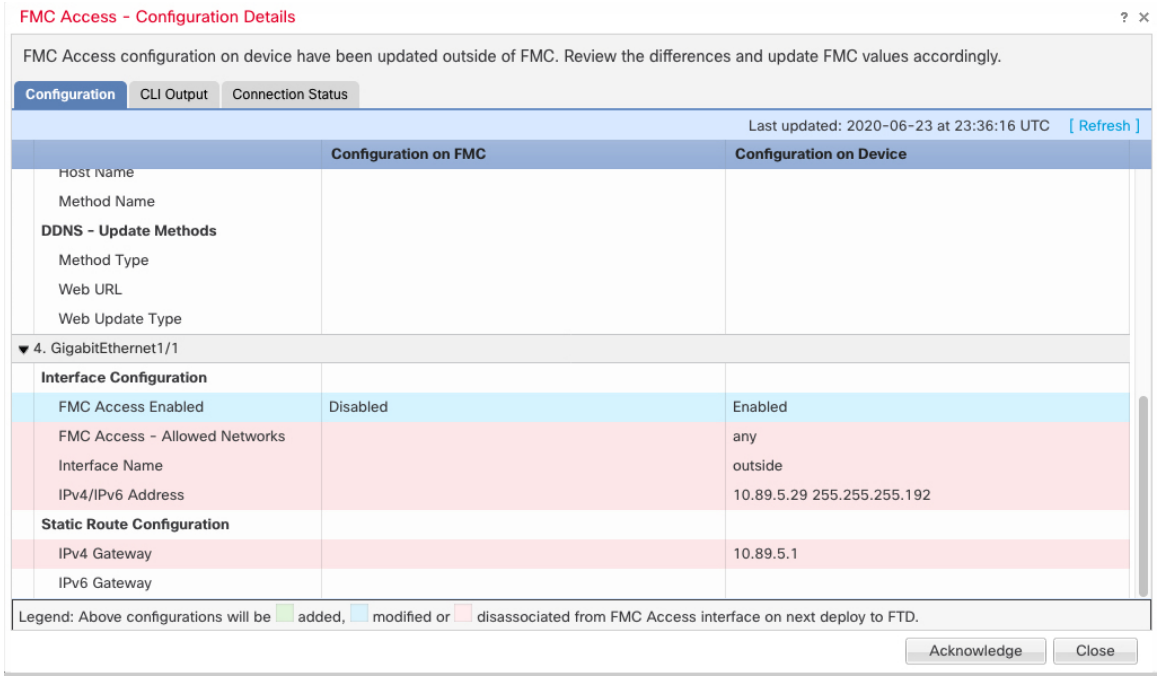
a) You will see a yellow banner in the top right of the **Device** page indicating that the Firewall Management Center access configuration has changed. Click the **View details** link to view the interface changes.



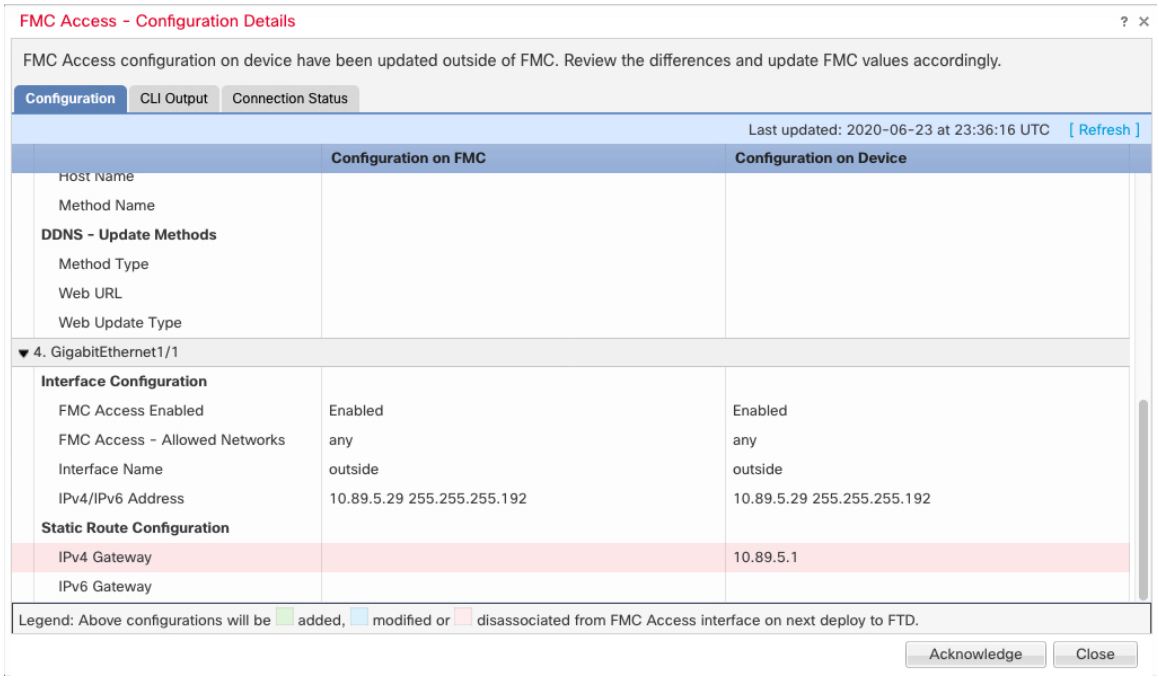
The **FMC Access - Configuration Details** dialog box opens.

b) Take note of all highlighted configurations, especially the pink highlighted ones. You need to match any values on the Firewall Threat Defense by manually configuring them on the Firewall Management Center.

For example, the pink highlights below show configuration that exists on the Firewall Threat Defense but not yet on the Firewall Management Center.



The following example shows this page after configuring the interface in Firewall Management Center; the interface settings match, and the pink highlight was removed.



c) Click **Acknowledge**.

We recommend that you do not click **Acknowledge** until you have finished the Firewall Management Center configuration, and are ready to deploy. Clicking **Acknowledge** removes the block on deployment. The next time you deploy, the Firewall Management Center configuration will overwrite any remaining

conflicting settings on the Firewall Threat Defense. It is your responsibility to manually fix the configuration in the Firewall Management Center before you re-deploy.

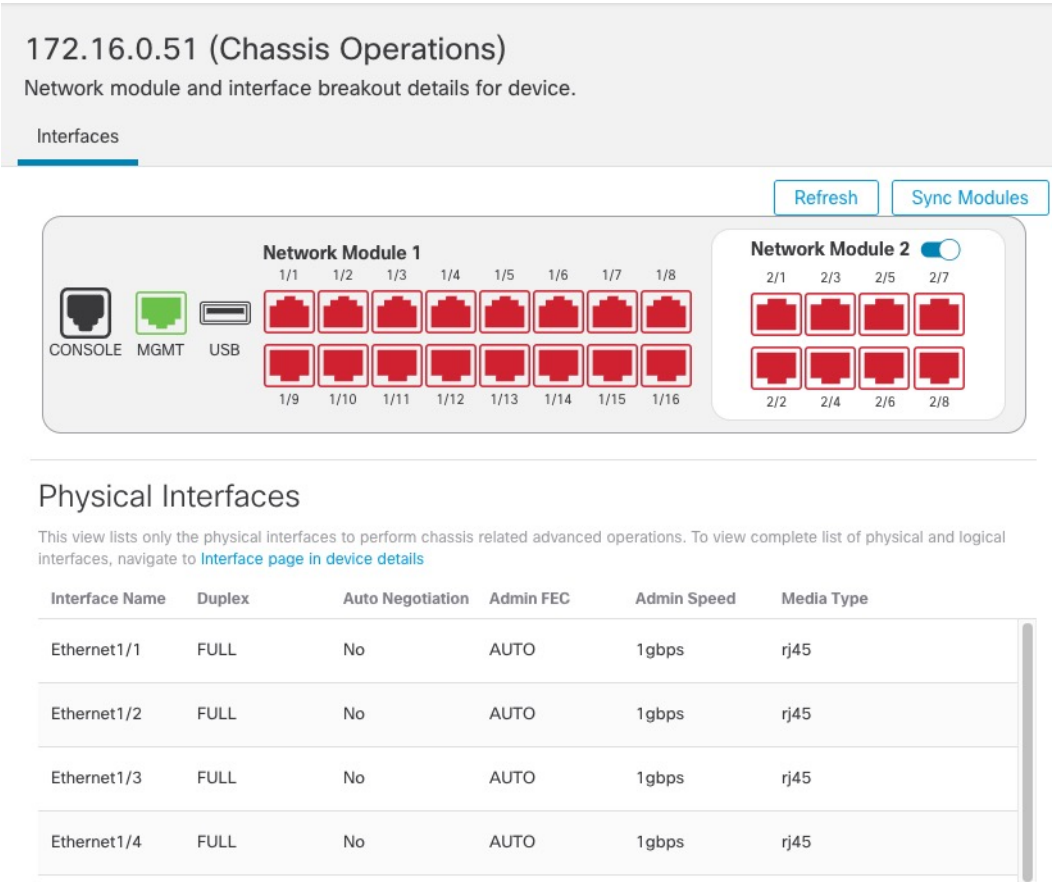
d) You can now go to **Deploy** > **Deployment** and deploy the policy to assigned devices.

Manage the Network Module for the Secure Firewall 3100

If you install a network module before you first power on the device, no action is required; the network module is enabled and ready for use.

To view physical interface details for the device, and to manage the network module, open the **Chassis Operations** page. From **Devices** > **Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit. The **Chassis Operations** page opens for the device.

Figure 258: Chassis Operations



Click **Refresh** to refresh interface status. Click **Sync Modules** if you made a hardware change on the device that you need to detect.

If you need to make changes to your network module installation after initial bootup, then see the following procedures.

Configure Breakout Ports

You can configure 10GB breakout ports for each 40GB or higher interface. This procedure tells you how to break out and rejoin the ports. Breakout ports can be used just like any other physical Ethernet port, including being added to EtherChannels.

Changes are immediate; you do not need to deploy to the device. After you break or rejoin, you cannot roll back to the previous interface state.

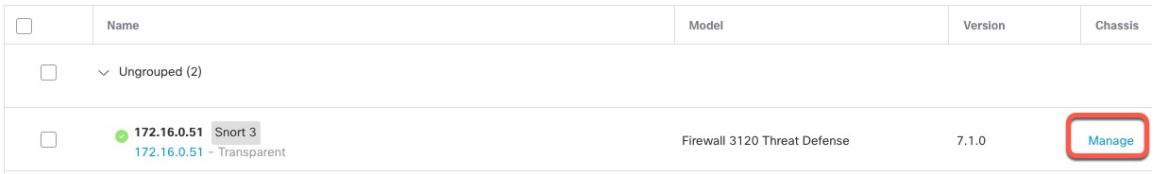
Before you begin

- You must use a supported breakout cable. See the hardware installation guide for more information.
- The interface cannot be in use for the following before breaking or rejoining:
  - Failover link
  - Cluster control link
  - Have a subinterface
  - EtherChannel member
  - BVI member
  - Manager access interface
- Breaking or rejoining and interface that is used directly in your security policy can impact the configuration; however, the action is not blocked.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

Figure 259: Manage Chassis



The **Chassis Operations** page opens for the device (in multi-instance mode, this page is called **Chassis Manager**). This page shows physical interface details for the device.

Step 2 Break out 10GB ports from a 40GB or higher interface.

a) click **Break** ( ) to the right of the interface.

Click **Yes** on the confirmation dialog box. If the interface is in use, you will see an error message. You must resolve any use cases before you can retry the breakout.

For example, to break out the Ethernet2/1 40GB interface, the resulting child interfaces will be identified as Ethernet2/1/1, Ethernet2/1/2, Ethernet2/1/3, and Ethernet2/1/4.

On the interfaces graphic, a port that is broken out has this appearance:

Figure 260: Breakout Ports

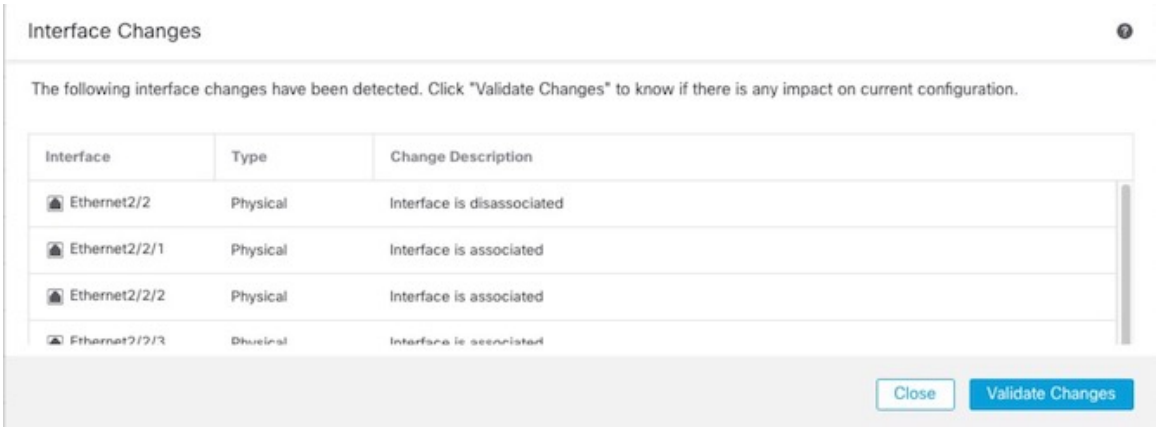
b) Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

Figure 261: Go to Interface Page

c) At the top of the **Interfaces** page, click **Click to know more**. The **Interface Changes** dialog box opens.

Figure 262: View Interface Changes

Figure 263: Interface Changes



d) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Replacing the parent interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

e) Click **Close** to return to the **Interfaces** page.
f) Click **Save** to save the interface changes to the firewall.
g) If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.

You do not need to deploy just to save the breakout port changes.

Step 3 Rejoin breakout ports.

You must rejoin all child ports for the interface.

a) Click **Join** ( ) to the right of the interface.

Click **Yes** on the confirmation dialog box. If any child ports are in use, you will see an error message. You must resolve any use cases before you can retry the rejoin.

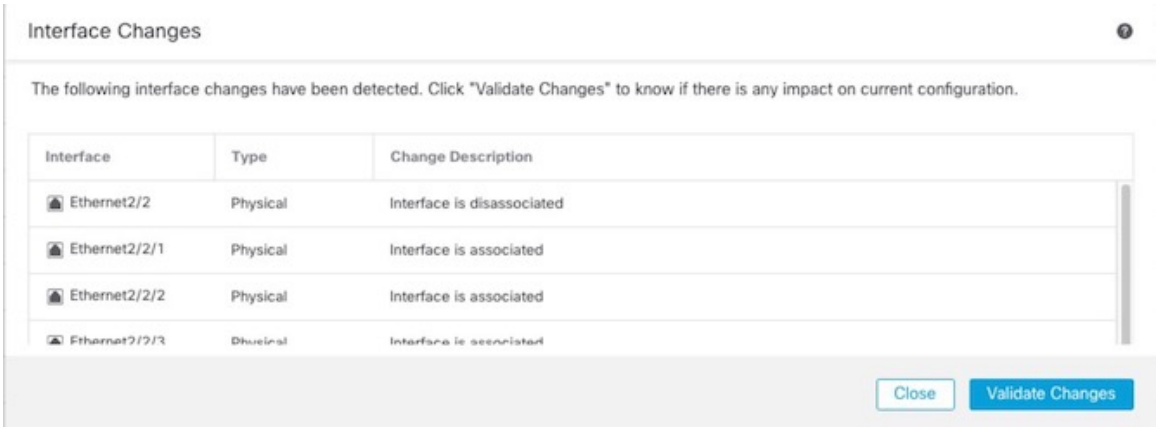
b) Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

Figure 264: Go to Interface Page

c) At the top of the **Interfaces** page, click **Click to know more**. The **Interface Changes** dialog box opens.

Figure 265: View Interface Changes

Figure 266: Interface Changes



d) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Replacing the child interfaces that are used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

e) Click **Close** to return to the **Interfaces** page.

f) Click **Save** to save the interface changes to the firewall.

g) If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.

You do not need to deploy just to save the breakout port changes.

Add a Network Module

To add a network module to a firewall after initial bootup, perform the following steps. Adding a new module requires a reboot.

Procedure

Step 1 Install the network module according to the hardware installation guide.

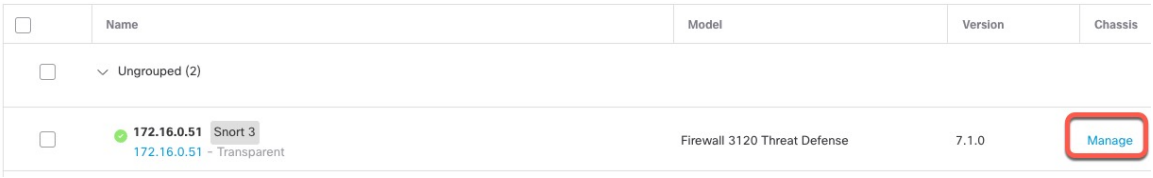
For clustering or High Availability, install the network module on all nodes.

Step 2 Reboot the firewall; see Shut Down or Restart the Device, on page 70.

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node or active unit (see Switch the Active Peer in the Firewall Threat Defense High Availability Pair, on page 589), and reboot the former control node/active unit.

Step 3 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

Figure 267: Manage Chassis

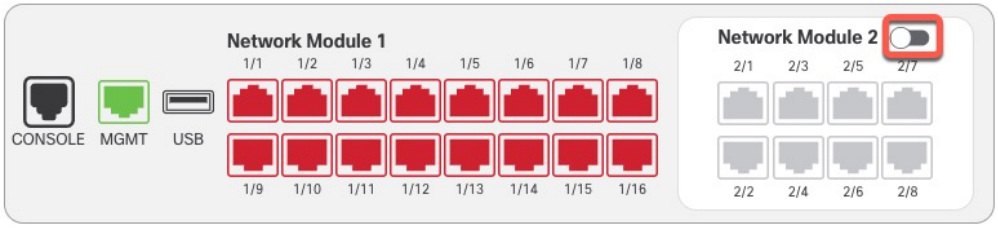


The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

Step 4 Click **Sync Modules** to update the page with the new network module details.

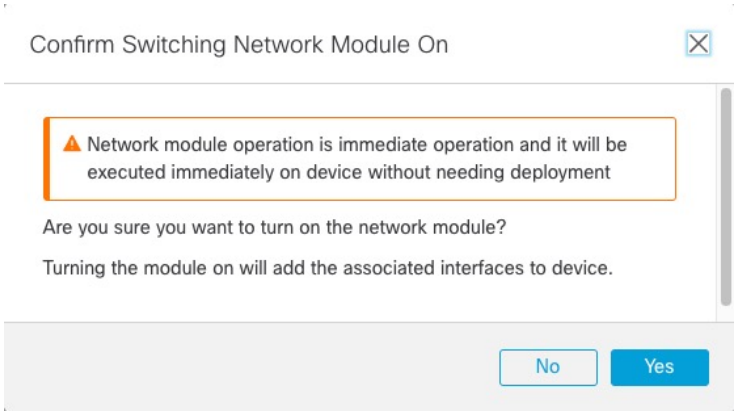
Step 5 On the interfaces graphic, click the slider ( ) to enable the network module.

Figure 268: Enable the Network Module



Step 6 You are prompted to confirm that you want to turn the network module on. Click **Yes**.

Figure 269: Confirm Enable



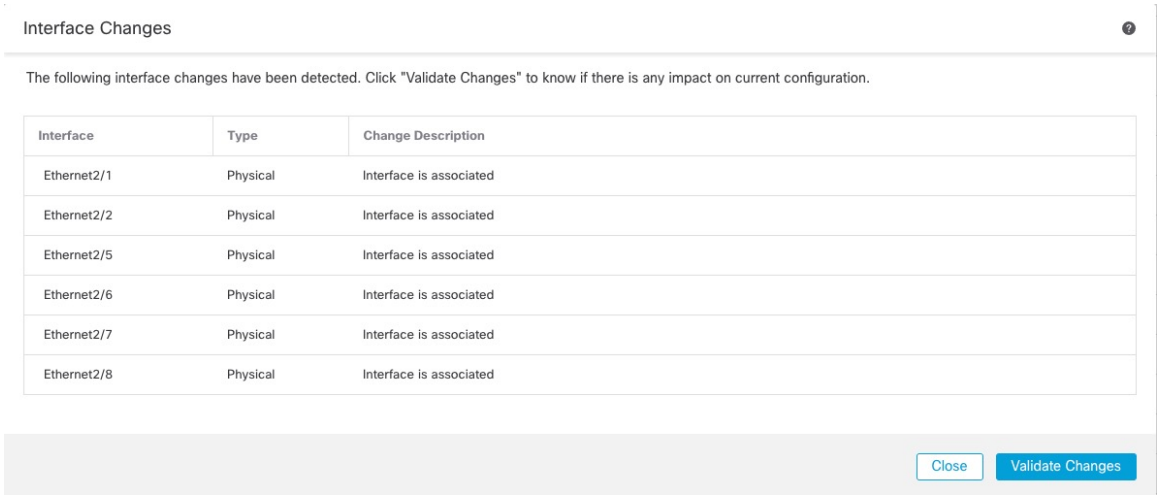
Step 7 You see a message at the top of the screen; click the link to go to the **Interfaces** page to save the interface changes.

Figure 270: Go to Interface Page

Step 8 (Optional) At the top of the **Interfaces** page, you see a message that the interface configuration has changed. You can click **Click to know more** to open the **Interface Changes** dialog box to view the changes.

Figure 271: View Interface Changes

Figure 272: Interface Changes



Click **Close** to return to the **Interfaces** page. (Because you are adding a new module, there shouldn't be any configuration impact, so you do not need to click **Validate Changes**.)

Step 9 Click **Save** to save the interface changes to the firewall.

Hot Swap the Network Module

You can hot swap a network module for a new module of the same type without having to reboot. However, you must shut down the current module to remove it safely. This procedure describes how to shut down the old module, install a new module, and enable it.

For clustering or High Availability, you can only perform chassis operations on the control node/active unit. You cannot disable a network module if the cluster control link/failover link is on the module.

Before you begin

Procedure

Step 1 For clustering or High Availability, perform the following steps.

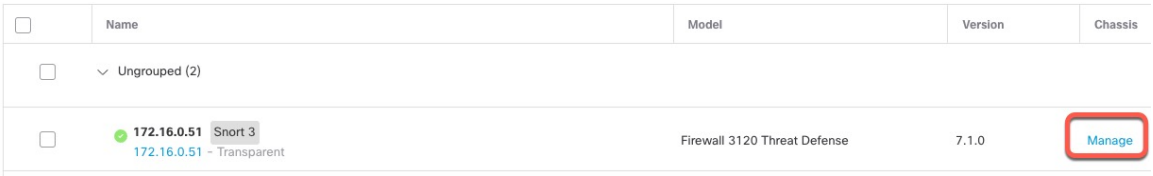
- **Clustering**—Ensure the unit you want to perform the hot swap on is a data node; then break the node so it is no longer in the cluster.

  You will add the node back to the cluster after you perform the hot swap. Alternatively, you can perform all operations on the control node, and the network module changes will sync to all data nodes. However, you will lose use of those interfaces on all nodes during the hot swap.

- **High Availability**—To avoid failing over when you disable the network module:
  - If the failover link is on the network module, you must break High Availability. See Break a High Availability Pair, on page 593. Disabling the network module with an active failover link is not allowed.
  - Disable interface monitoring for interfaces on the network module. See Configure Standby IP Addresses and Interface Monitoring, on page 587.

Step 2 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

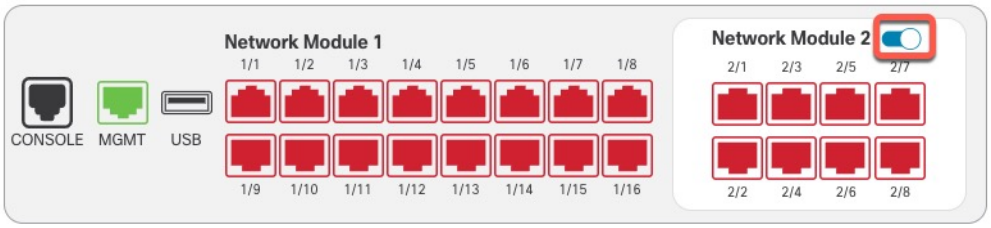
Figure 273: Manage Chassis



The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

Step 3 On the interfaces graphic, click the slider ( ) to disable the network module.

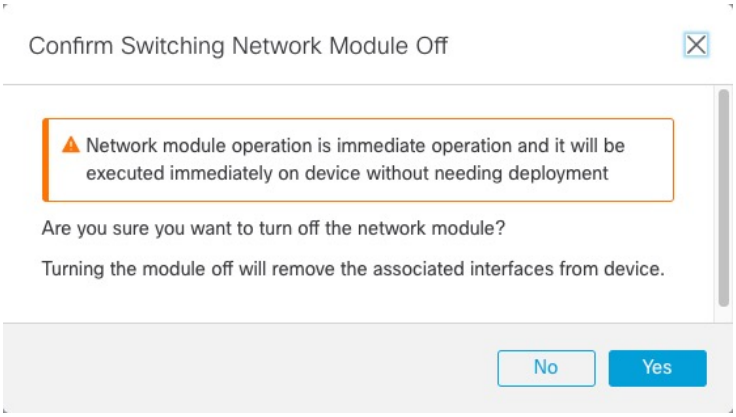
Figure 274: Disable the Network Module



Do not save any changes on the **Interfaces** page. Because you are replacing the network module, you do not want to disrupt any existing configuration.

Step 4 You are prompted to confirm that you want to turn the network module off. Click **Yes**.

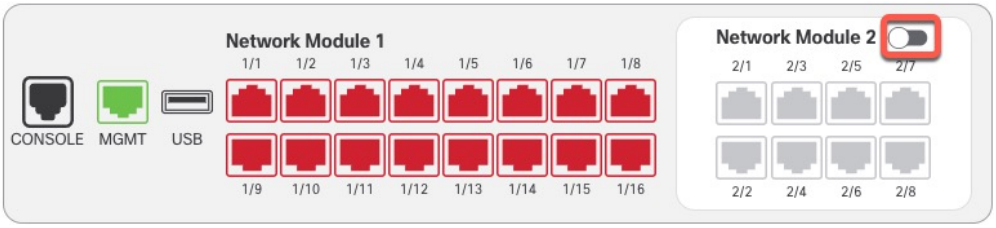
Figure 275: Confirm Disable



Step 5 On the device, remove the old network module and replace it with the new network module according to the hardware installation guide.

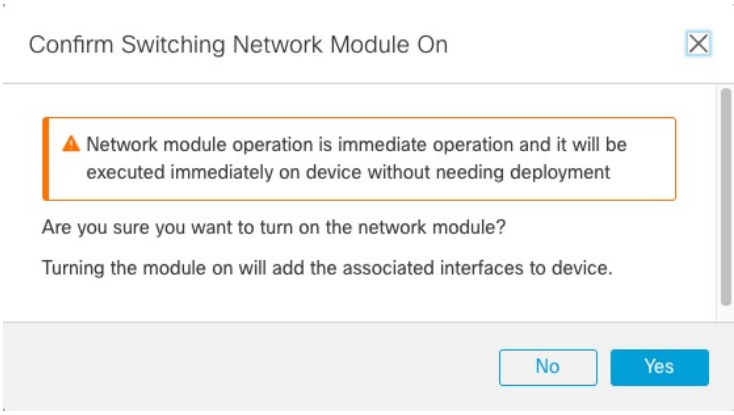
Step 6 In the Firewall Management Center, enable the new module by clicking the slider ( ).

Figure 276: Enable the Network Module



Step 7 You are prompted to confirm that you want to turn the network module on. Click **Yes**.

Figure 277: Confirm Enable



Step 8 For clustering or High Availability, perform the following steps.

- **Clustering**—Add the node back to the cluster.
- **High Availability**—
  - If you broke High Availability, then reform High Availability. See Add a High Availability Pair, on page 584.
  - Reenable interface monitoring for interfaces on the network module. See Configure Standby IP Addresses and Interface Monitoring, on page 587.

Replace the Network Module with a Different Type

If you replace a network module with a different type, then a reboot is required. If the new module has fewer interfaces than the old module, you will have to manually remove any configuration related to interfaces that will no longer be present.

For clustering or High Availability, you can only perform chassis operations on the control node/active unit.

Before you begin

For High Availability, you cannot disable a network module if the failover link is on the module. You will have to break High Availability (see Break a High Availability Pair, on page 593), which means you will have downtime when you reboot the active unit. After the units finish rebooting, you can reform High Availability.

Procedure

Step 1 For clustering or High Availability, perform the following steps.

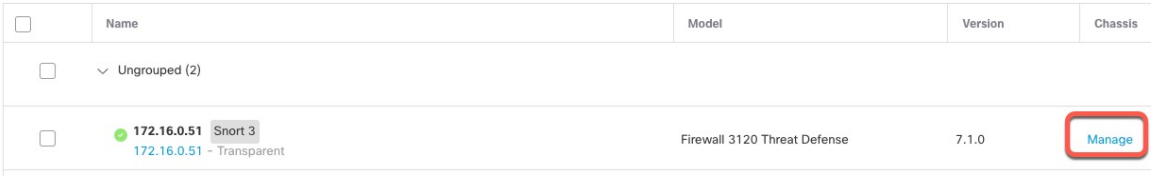
- **Clustering**—To avoid downtime, you can break each node one at a time so it is no longer in the cluster while you perform the network module replacement.

  You will add the node back to the cluster after you perform the replacement.

- **High Availability**—To avoid failing over when you replace the network module, disable interface monitoring for interfaces on the network module. See Configure Standby IP Addresses and Interface Monitoring, on page 587.

Step 2 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

Figure 278: Manage Chassis



The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

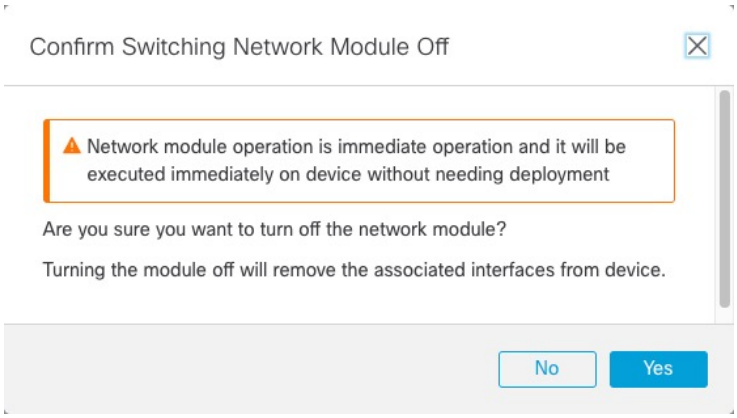
Step 3 On the interfaces graphic, click the slider ( ) to disable the network module.

Figure 279: Disable the Network Module

Do not save any changes on the **Interfaces** page. Because you are replacing the network module, you do not want to disrupt any existing configuration.

Step 4 You are prompted to confirm that you want to turn the network module off. Click **Yes**.

Figure 280: Confirm Disable



Step 5 On the device, remove the old network module and replace it with the new network module according to the hardware installation guide.

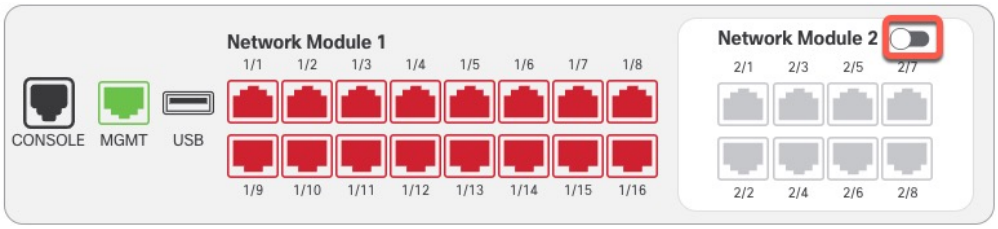
Step 6 Reboot the firewall; see Shut Down or Restart the Device, on page 70.

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node or active unit (see Switch the Active Peer in the Firewall Threat Defense High Availability Pair, on page 589), and reboot the former control node/active unit.

Step 7 In the Firewall Management Center, click **Sync Modules** to update the page with the new network module details.

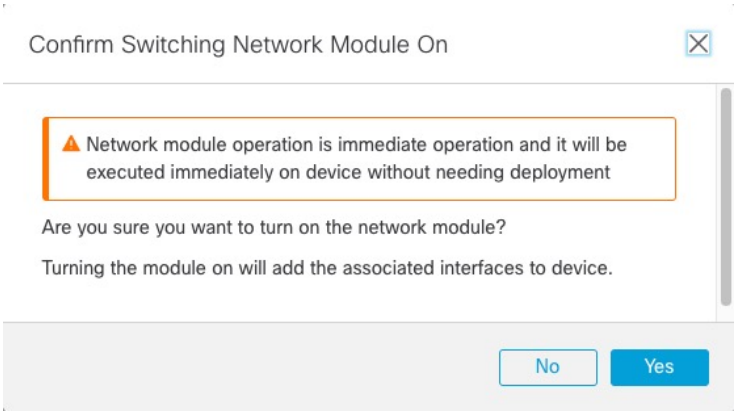
Step 8 Enable the new module by clicking the slider ( ).

Figure 281: Enable the Network Module



Step 9 You are prompted to confirm that you want to turn the network module on. Click **Yes**.

Figure 282: Confirm Enable



Step 10 Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

Figure 283: Go to Interface Page

Step 11 If the network module has *fewer* interfaces:

a) At the top of the **Interfaces** page, click **Click to know more**. The **Interface Changes** dialog box opens.

Figure 284: View Interface Changes

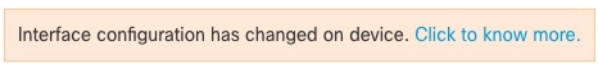


Figure 285: Interface Changes

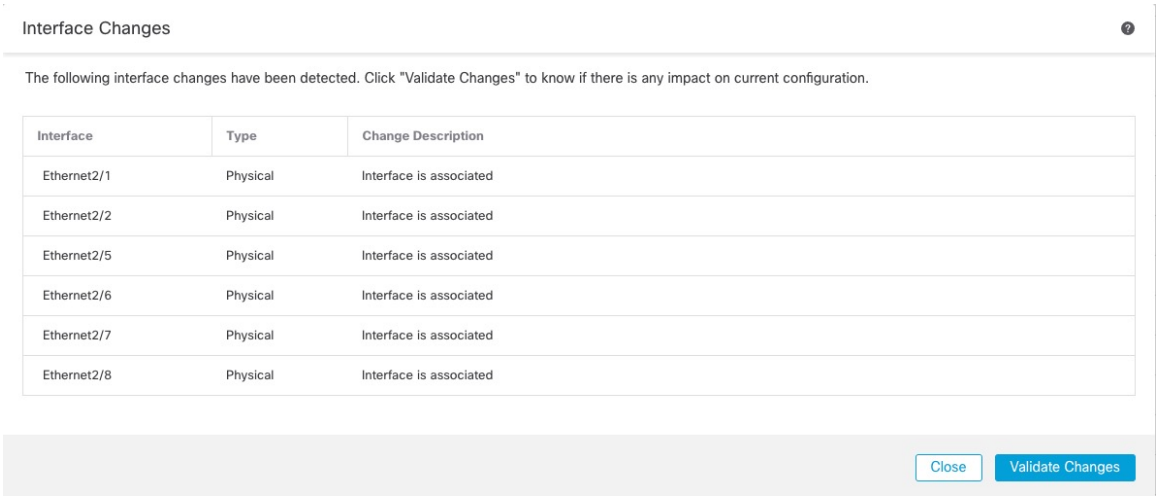


b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Deleting an interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

c) Click **Close** to return to the **Interfaces** page.

Step 12 To change the interface speed, see Enable the Physical Interface and Configure Ethernet Settings, on page 872.

The default speed is set to Detect SFP, which detects the correct speed from the SFP installed. You only need to fix the speed if you manually set the speed to a particular value and you now need a new speed.

Step 13 Click **Save** to save the interface changes to the firewall.

Step 14 If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.

You do not need to deploy just to save the network module changes.

Step 15 For clustering or High Availability, perform the following steps.

- **Clustering**—Add the node back to the cluster.
- **High Availability**—Reenable interface monitoring for interfaces on the network module. See Configure Standby IP Addresses and Interface Monitoring, on page 587.

Remove the Network Module

If you want to permanently remove the network module, follow these steps. Removing a network module requires a reboot.

For clustering or High Availability, you can only perform chassis operations on the control node/active unit.

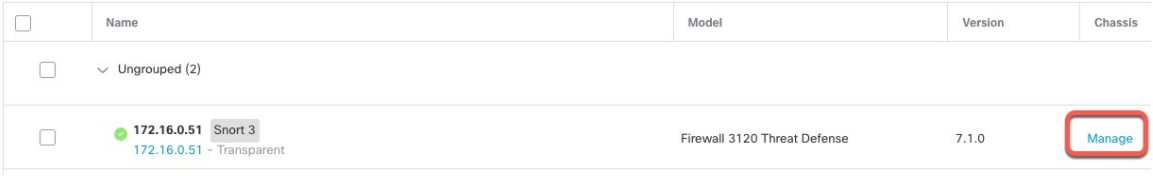
Before you begin

For clustering or High Availability, make sure the cluster/failover link is not on the network module.

Procedure

Step 1 From **Devices** > **Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

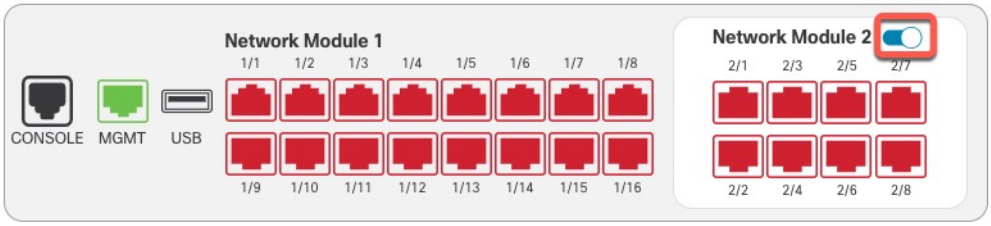
Figure 286: Manage Chassis



The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

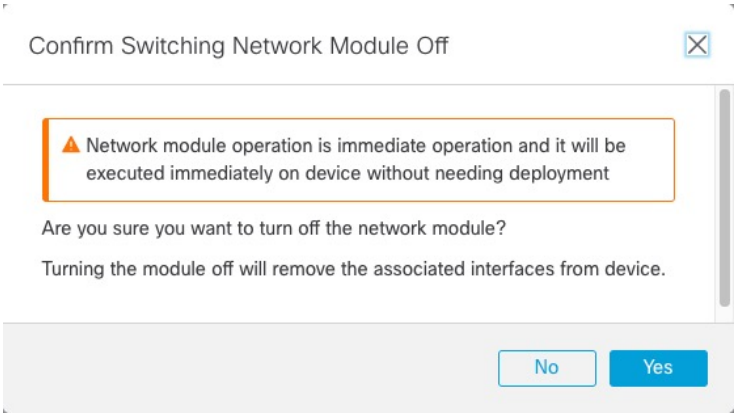
Step 2 On the interfaces graphic, click the slider ( ) to disable the network module.

Figure 287: Disable the Network Module



Step 3 You are prompted to confirm that you want to turn the network module off. Click **Yes**.

Figure 288: Confirm Disable



Step 4 You see a message at the top of the screen; click the link to go to the **Interfaces** page to save the interface changes.

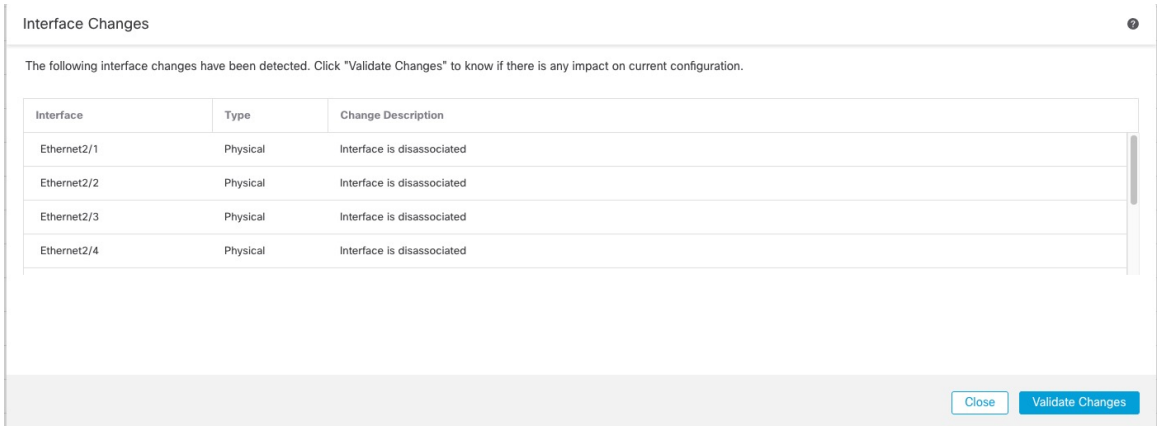
Figure 289: Go to Interface Page

Step 5 At the top of the **Interfaces** page, you see a message that the interface configuration has changed.

Figure 290: View Interface Changes

a) Click **Click to know more** to open the **Interface Changes** dialog box to view the changes.

Figure 291: Interface Changes



b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Deleting an interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

c) Click **Close** to return to the **Interfaces** page.

Step 6 Click **Save** to save the interface changes to the firewall.

Step 7 If you had to change any configuration, go to **Deploy** > **Deployment** and deploy the policy.

Step 8 Reboot the firewall; see Shut Down or Restart the Device, on page 70.

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node or active unit (see Switch the Active Peer in the Firewall Threat Defense High Availability Pair, on page 589), and reboot the former control node/active unit.

Merge the Management and Diagnostic Interfaces

Firewall Threat Defense 7.4 and later supports a merged Management and Diagnostic interface. If you have any configuration using the Diagnostic interface, then the interfaces will not be merged automatically, and you will need to perform the following procedure. This procedure requires you to acknowledge configuration changes, and in some cases, manually fix the configuration.

The Backup/Restore and Firewall Management Center configuration rollback functions save and restore the merged state, either non-merged or merged. For example, if you merge the interfaces, and then restore an old non-merged configuration, then the restored configuration will be in a non-merged state.

The following table shows the available configuration on the legacy Diagnostic interface, and how the merge is completed.

Table 69: Firewall Management Center Merged Management Interface Support

Legacy Diagnostic Interface Configuration	Merge Behavior	Supported on Management?
Interfaces		The "management" interface is now shown in read-only mode on the **Interfaces** page.
• IP address	Manual removal required.	The current Management IP address is used instead. For High Availability and clustering, the Management interface does not support a standby IP address or IP address pool; each unit has its own IP address that is maintained across failovers. Therefore, you cannot use a single management IP address to communicate with the current active/control unit. Set at the CLI using the **configure network ipv4** or **configure network ipv6** command.
• "diagnostic" name	Automatically changed to "management". **Note** No other interfaces can be named "management". You must change the name to proceed with the merge.	Changed to "management".

Legacy Diagnostic Interface Configuration	Merge Behavior	Supported on Management?
Static Routes	Manual removal required.	**No support.** The Management interface has a separate Linux routing table from the data interfaces. The Firewall Threat Defense actually has two "data" routing tables: for data interfaces and for management-only interfaces (which used to include Diagnostic, but also includes any interfaces you set to management-only). Depending on the traffic type, the Firewall Threat Defense checks one routing table, and then falls back to the other routing table. This route lookup no longer includes the Diagnostic interface, and does not include the Linux routing table for Management. See Routing Table for Management Traffic, on page 1247 for more information. You can add static routes for the Linux routing table at the CLI using the **configure network static-routes** command **Note** The *default* route is set with the **configure network ipv4** or **configure network ipv6** command.
Dynamic Routing	Manual removal required.	**No support.**
HTTP server	No change.	**No support.** This setting will no longer work on the merged device, but it is not removed from the Platform Settings. Platform Settings can be used for multiple devices, some of which may not yet be merged.
ICMP	No change.	**No support.** This setting will no longer work on the merged device, but it is not removed from the Platform Settings. Platform Settings can be used for multiple devices, some of which may not yet be merged.
Syslog Server	Automatically moved to Management interface.	Yes. The syslog server configuration already has the option to send syslogs out of the Management interface (starting in 6.3). If you had specifically chosen the Diagnostic interface for syslogs, it will be moved to use Management. **Note** If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices. **Note** The merged Management interface does not support Secure Syslogs.

Legacy Diagnostic Interface Configuration	Merge Behavior	Supported on Management?
SMTP	No change.	**No support.** The Firewall Threat Defense checks the data routing table only for the SMTP server, so you cannot use the Management interface or any other management-only interfaces. See Routing Table for Management Traffic, on page 1247 for more information.
SNMP	Automatically moved to Management interface.	Yes. The SNMP host configuration already has the option to allow SNMP hosts on the Management interface (starting in 6.3). If you had specifically chosen the Diagnostic interface for SNMP, it will be moved to use Management. **Note** If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices.
RADIUS server	Automatically moved to Management interface.	Yes. If you had specifically chosen the Diagnostic interface, it will be moved to use Management. **Note** If you specified a route lookup to find the source interface, then the Firewall Threat Defense will no longer be able to send traffic out of a management-only interface; you must explicitly select Management as the source interface. Other management-only interfaces cannot be used.
AD server	Automatically moved to Management interface.	Yes. If you had specifically chosen the Diagnostic interface, it will be moved to use Management. **Note** If you specified a route lookup to find the source interface, then the Firewall Threat Defense will no longer be able to send traffic out of a management-only interface; you must explicitly select Management as the source interface. Other management-only interfaces cannot be used.
DDNS	Manual removal required.	**No support.**
DHCP server	Manual removal required.	**No support.**

Legacy Diagnostic Interface Configuration	Merge Behavior	Supported on Management?
DNS server	Automatically moved to Management interface.	Yes. If you checked the **Enable DNS Lookup via diagnostic interface also** check box, then it will be moved to use Management. There is a routing lookup change when you do not choose any interfaces or check the **Enable DNS Lookup via diagnostic/management interface also** check box: the Firewall Threat Defense uses the data routing table only, and does not fall back to using the management-only routing table. Therefore, you cannot use a management-only interface for DNS other than the Management interface. **Note** The Management interface also has a separate DNS lookup setting for its management traffic only. Set at the CLI using the **configure network dns** command.
FlexConfig	Manual removal required.	**No support.**

Before you begin

- To view the current mode of the device, enter the **show management-interface convergence** command at the Firewall Threat Defense CLI. The following output shows that the Management interfaces are merged:

```
> show management-interface convergence
management-interface convergence
>
```

  The following output shows that the Management interfaces are not merged:

```
> show management-interface convergence
no management-interface convergence
>
```

- For High Availability pairs and clusters, perform this task on the active/control unit. The merged configuration will be replicated automatically to the standby/data units.

Procedure

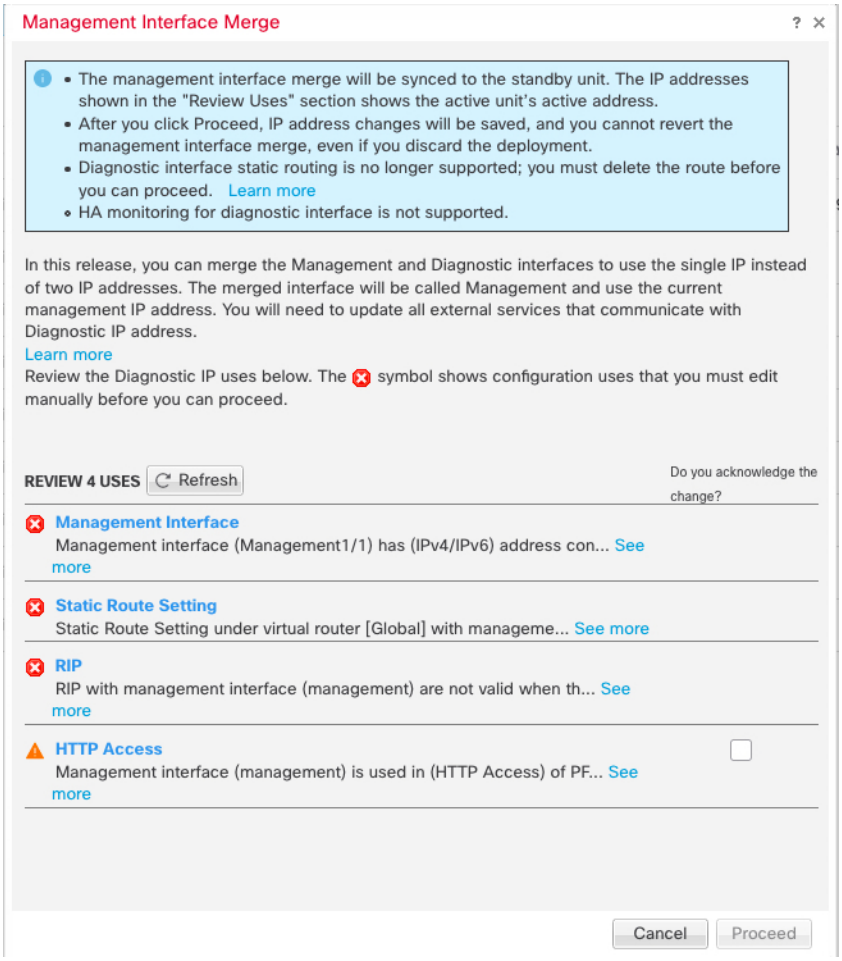
Step 1 Choose **Devices** > **Device Management**, and click **Edit** ( ) for your Firewall Threat Defense. The **Interfaces** page is selected by default. .

Step 2 Edit the Diagnostic interface, and remove the IP address.

You cannot complete the merge until after you have removed the Diagnostic IP address.

Step 3 Click **Management Interface Merge** in the **Management Interface action needed** area.

The **Management Interface Merge** dialog box shows all the occurrences of the Diagnostic interface in the configuration. For any occurrences that require you to manually remove or change the configuration, they will appear with a warning icon. Platform Settings that will no longer work on your device are marked with a caution icon and require your acknowledgement.



Step 4 If you need to manually remove or change any listed configurations, do the following.

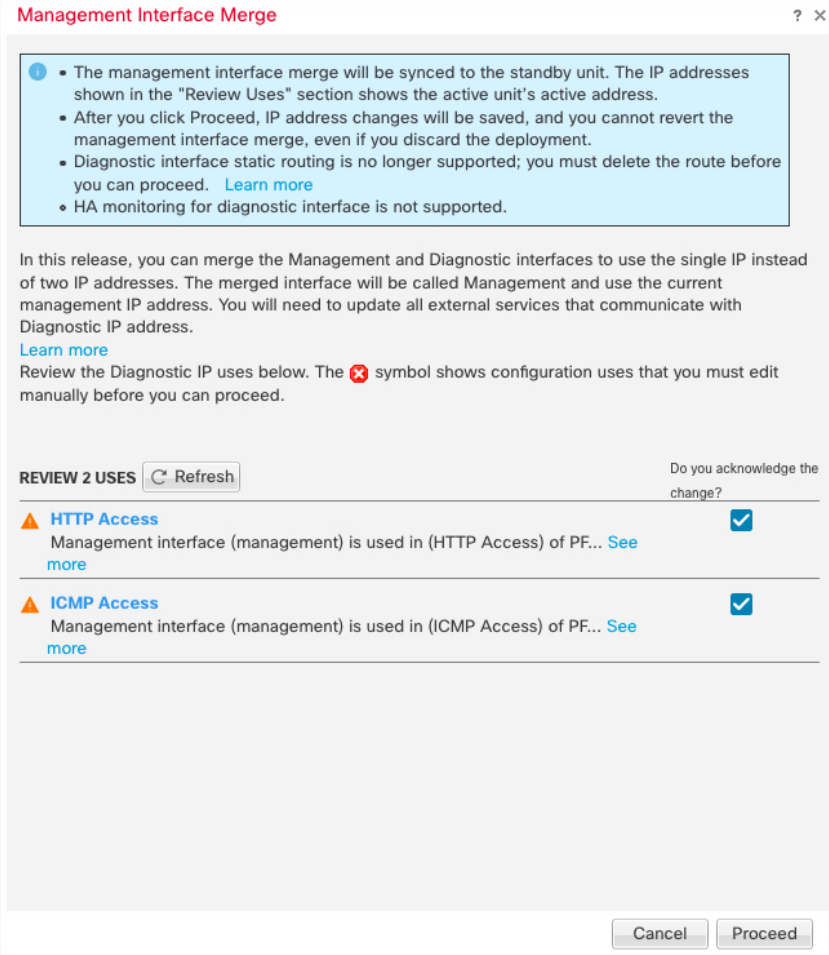
a) Click **Cancel** to close the **Management Interface Merge** dialog box.

b) Navigate to the feature area. You can then delete the item, or choose a data interface instead.

c) Reopen the **Management Interface Merge** dialog box.

There should no longer be any warnings.

Step 5 For each configuration caution, click the box in **Do you acknowledge the change?** column, and then click **Proceed**.



After the configuration is merged, you see a success banner:

Step 6 Deploy the new merged configuration.

Caution
After you deploy the merged configuration, you can unmerge the interfaces from Firewall Management Center; however the Diagnostic interface will have to be reconfigured manually. See Unmerge the Management Interface, on page 906. Also, if you restore a configuration that is unmerged, or roll back to an unmerged configuration, then the device will revert to that unmerged configuration.

After the merge, the Management interface is shown on the **Interfaces** page, although it is read-only.

Step 7 After the merge, if you had any external services that communicated with the Diagnostic interface, you need to change their configuration to use the Management interface IP address.

For example:

- SNMP client

- RADIUS server—RADIUS servers often verify the IP address for incoming traffic, so you need to change that IP address to the Management address. Moreover, for a High Availability pair, you need to allow both the primary and secondary Management IP addresses; the Diagnostic interface used to support a single "floating" IP address that stayed with the active unit, but Management does not support that functionality.

Unmerge the Management Interface

The Firewall Threat Defense 7.4 and later supports a merged Management and Diagnostic interface. If you need to unmerge your interfaces, perform this procedure. We recommend using unmerged mode temporarily while you migrate your network to a merged mode deployment. Separate Management and Diagnostic interfaces may not be supported in all future releases.

Unmerging the interfaces does not restore your original Diagnostic configuration (if you upgraded and then merged your interfaces). You will need to reconfigure the Diagnostic interface manually. Also, the Management interface will now be named "management"; you cannot rename it "diagnostic."

Alternatively, if you used the Backup function to save an old unmerged configuration, you can restore that configuration or you can use the or Firewall Management Center configuration rollback feature, and the device will be in an unmerged state with the Diagnostic configuration intact.

Before you begin

- To view the current mode of the device, enter the **show management-interface convergence** command at the Firewall Threat Defense CLI. The following output shows that the Management interfaces are merged:

```
> show management-interface convergence
management-interface convergence
>
```

  The following output shows that the Management interfaces are not merged:

```
> show management-interface convergence
no management-interface convergence
>
```

- For High Availability pairs and clusters, perform this task on the active/control unit. The merged configuration will be replicated automatically to the standby/data units.

Procedure

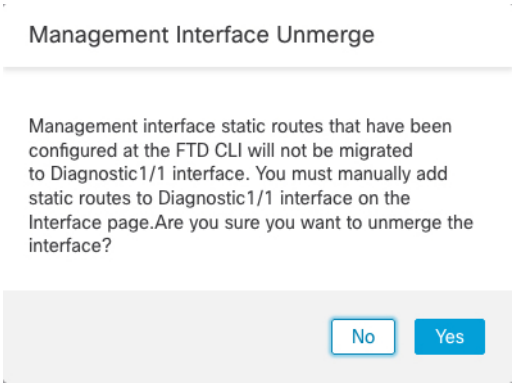
Step 1 Choose **Devices** > **Device Management**, and click **Edit** ( ) for your Firewall Threat Defense. The **Interfaces** page is selected by default. .

Step 2 For the Management interface, click **Unmerge Management Interface** ( ).

Figure 292: Management Interface Selection

Step 3 Click **Yes** to confirm that you want to unmerge the interface.

Figure 293: Unmerge Confirmation



Step 4 Deploy the new unmerged configuration.

Note
If you restore a configuration that is merged, or roll back to a merged configuration, then the device will revert to that merged configuration.

After the merge, the Management interface is no longer shown on the **Interfaces** page.

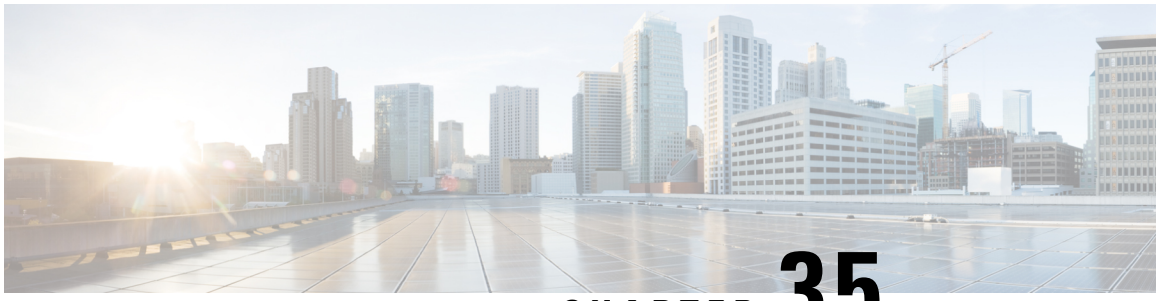
History for Interfaces

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Loopback and Management type interface group objects	7.4.0	7.4.0	You can now create interface group objects that include only management-only interfaces or only loopback interfaces. You can then use these groups for management features such as DNS servers, HTTP access, or SSH. Loopback groups are supported for any feature that supports loopback interfaces. Note that DNS does not support management interfaces. New/Modified screens: **Objects** > **Object Management** > **Interface** > **Add** > **Interface Group**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Merged Management and Diagnostic interfaces	7.4.0	7.4.0	For new devices using 7.4 and later, you cannot use the legacy Diagnostic interface. Only the merged Management interface is available. If you upgraded to 7.4 or later, and you did not have any configuration for the Diagnostic interface, then the interfaces will merge automatically. If you upgraded to 7.4 or later, and you have configuration for the Diagnostic interface, then you have the choice to merge the interfaces manually, or you can continue to use the separate Diagnostic interface. Note that support for the Diagnostic interface will be removed in a later release, so you should plan to merge the interfaces as soon as possible. Merged mode also changes the behavior of AAA traffic to use the data routing table by default. The management-only routing table can now only be used if you specify the management-only interface (including Management) in the configuration. New/Modified screens: **Devices** > **Device Management** > **Interfaces** New/Modified commands: **show management-interface convergence**
Default Forward Error Correction (FEC) on Secure Firewall 3100 fixed ports changed to Clause 108 RS-FEC from Clause 74 FC-FEC for 25 GB+ SR, CSR, and LR transceivers	7.2.4	7.2.4	When you set the FEC to Auto on the Secure Firewall 3100 fixed ports, the default type is now set to Clause 108 RS-FEC instead of Clause 74 FC-FEC for 25 GB+ SR, CSR, and LR transceivers.
LLDP support for the Firepower 2100, Secure Firewall 3100	7.2.0	7.2.0	You can enable Link Layer Discovery Protocol (LLDP) for Firepower 2100 and Secure Firewall 3100 interfaces. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Network Connectivity** New/Modified commands: **show lldp status, show lldp neighbors, show lldp statistics**
Pause Frames for Flow Control for the Secure Firewall 3100	7.2.0	7.2.0	If you have a traffic burst, dropped packets can occur if the burst exceeds the buffering capacity of the FIFO buffer on the NIC and the receive ring buffers. Enabling pause frames for flow control can alleviate this issue. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Network Connectivity**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Support for hot swapping the network module for the Secure Firewall 3100	7.1.0	7.1.0	You can add or remove the network module on the Secure Firewall 3100 while the firewall is powered up. To replace a module with another module of the same type, you do not need to reboot. After initial bootup, adding a module, permanently removing a module, or replacing a module with a new type requires a reboot. New/Modified screens: **Devices** > **Device Management** > **Chassis Operations**
Support for Forward Error Correction for the Secure Firewall 3100	7.1.0	7.1.0	Secure Firewall 3100 25 Gbps interfaces support Forward Error Correction (FEC). FEC is enabled by default and set to Auto. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **Hardware Configuration**
Support for setting the speed based on the SFP for the Secure Firewall 3100	7.1.0	7.1.0	The Secure Firewall 3100 supports speed detection for interfaces based on the SFP installed. Detect SFP is enabled by default. This option is useful if you later change the network module to a different model, and want the speed to update automatically. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **Hardware Configuration**
LLDP support for the Firepower 1100.	7.1.0	7.1.0	You can enable Link Layer Discovery Protocol (LLDP) for Firepower 1100 interfaces. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **LLDP** New/Modified commands: **show lldp status, show lldp neighbors, show lldp statistics**
Interface auto-negotiation is now set independently from speed and duplex, interface sync improved.	7.1.0	7.1.0	Interface auto-negotiation is now set independently from speed and duplex. Also, when you sync the interfaces in Firewall Management Center, hardware changes are detected more effectively. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Speed** Supported platforms: Firepower 1000, 2100, Secure Firewall 3100

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Firepower 1100/2100 series fiber interfaces now support disabling auto-negotiation.	6.7.0	6.7.0	You can now configure a Firepower 1100/2100 series fiber interface to disable flow control and link status negotiation. Previously, when you set the fiber interface speed (1000 or 10000 Mbps) on these devices, flow control and link status negotiation was automatically enabled. You could not disable it. Now, you can deselect **Auto-negotiation** and set the speed to 1000 to disable flow control and link status negotiation. You cannot disable negotiation at 10000 Mbps. New/modified screens: **Devices** > **Device Management** > **Interfaces** > **Hardware Configuration** > **Speed**



CHAPTER 35

Regular Firewall Interfaces

This chapter includes regular firewall Firewall Threat Defense interface configuration including EtherChannels, VLAN subinterfaces, IP addressing, and more.

Note For initial interface configuration on the Firepower 4100/9300, see Configure Interfaces, on page 478.

Configure Firepower 1010 Switch Ports

You can configure each Firepower 1010 interface to run as a regular firewall interface or as a Layer 2 hardware switch port. This section includes tasks for starting your switch port configuration, including enabling or

disabling the switch mode and creating VLAN interfaces and assigning them to switch ports. This section also describes how to customize Power over Ethernet (PoE) on supported interfaces.

About Switch Ports

This section describes the switch ports of Firepower 1010, and .

Understanding Switch Ports and Interfaces

Ports and Interfaces

For each physical 1010 interface, you can set its operation as a firewall interface or as a switch port. See the following information about physical interface and port types as well as logical VLAN interfaces to which you assign switch ports:

- Physical firewall interface—In routed mode, these interfaces forward traffic between networks at Layer 3, using the configured security policy to apply firewall and VPN services. In transparent mode, these interfaces are bridge group members that forward traffic between the interfaces on the same network at Layer 2, using the configured security policy to apply firewall services. In routed mode, you can also use Integrated Routing and Bridging with some interfaces as bridge group members and others as Layer 3 interfaces. By default, the Ethernet 1/1 interface is configured as a firewall interface. You can also configure these interfaces to be IPS-only (inline sets and passive interfaces).
- Physical switch port—Switch ports forward traffic at Layer 2, using the switching function in hardware. Switch ports on the same VLAN can communicate with each other using hardware switching, and traffic is not subject to the Firewall Threat Defense security policy. Access ports accept only untagged traffic, and you can assign them to a single VLAN. Trunk ports accept untagged and tagged traffic, and can belong to more than one VLAN. By default, Ethernet 1/2 through 1/8 are configured as access switch ports on VLAN 1. You cannot configure the Management interface as a switch port.
- Logical VLAN interface—These interfaces operate the same as physical firewall interfaces, with the exception being that you cannot create subinterfaces, IPS-only interfaces (inline sets and passive interfaces), or EtherChannel interfaces. When a switch port needs to communicate with another network, then the Firewall Threat Defense device applies the security policy to the VLAN interface and routes to another logical VLAN interface or firewall interface. You can even use Integrated Routing and Bridging with VLAN interfaces as bridge group members. Traffic between switch ports on the same VLAN are not subject to the Firewall Threat Defense security policy, but traffic between VLANs in a bridge group are subject to the security policy, so you may choose to layer bridge groups and switch ports to enforce the security policy between certain segments.

Power Over Ethernet

PoE is available on Ethernet 1/7 and Ethernet 1/8 using IEEE 802.3af (PoE) and 802.3at (PoE+) up to 30 watts per port.

PoE+ uses Link Layer Discovery Protocol (LLDP) to negotiate the power level. Power is only supplied when needed.

If you shut down the interface, then you disable power to the device.

Auto-MDI/MDIX Feature

For all switch ports, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. Either the speed or duplex must be set to auto-negotiate to enable Auto-MDI/MDIX for the interface. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled. When the speed and duplex are set to 1000 and full, then the interface always auto-negotiates; therefore Auto-MDI/MDIX is always enabled and you cannot disable it.

Guidelines and Limitations for Switch Ports

High Availability and Clustering

- No cluster support.
- You should not use the switch port functionality when using High Availability. Because the switch ports operate in hardware, they continue to pass traffic on both the active *and* the standby units. High Availability is designed to prevent traffic from passing through the standby unit, but this feature does not extend to switch ports. In a normal High Availability network setup, active switch ports on both units will lead to network loops. We suggest that you use external switches for any switching capability. Note that VLAN interfaces can be monitored by failover, while switch ports cannot. Theoretically, you can put a single switch port on a VLAN and successfully use High Availability, but a simpler setup is to use physical firewall interfaces instead.
- You can only use a firewall interface as the failover link.

Logical VLAN Interfaces (SVIs)

- You can create up to 60 VLAN interfaces.
- If you also use VLAN subinterfaces on a firewall interface, you cannot use the same VLAN ID as for a logical VLAN interface.
- MAC Addresses:
  - Routed firewall mode—All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique MAC addresses, you can manually assign MAC addresses. See Configure the MAC Address, on page 974.
  - Transparent firewall mode—Each VLAN interface has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See Configure the MAC Address, on page 974.

Bridge Groups

You cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.

VLAN Interface and Switch Port Unsupported Features

VLAN interfaces and switch ports do not support:

- Dynamic routing

- Multicast routing
- Equal-Cost Multi-Path routing (ECMP)
- Inline sets or Passive interfaces
- EtherChannels—Switch ports cannot be part of an EtherChannel. PoE is also not supported on a port in an EtherChannel.
- Failover and state link
- Security group tagging (SGT)

Other Guidelines and Limitations

- You can configure a maximum of 60 named interfaces on the Firepower 1010.
- You cannot configure the Management interface as a switch port.

Default Settings

- Ethernet 1/1 is a firewall interface.
- Ethernet 1/2 through Ethernet 1/8 are switch ports assigned to VLAN 1.
- Default Speed and Duplex—By default, the speed and duplex are set to auto-negotiate.

Configure Switch Ports and Power Over Ethernet

To configure switch ports and PoE, complete the following tasks.

Enable or Disable Switch Port Mode

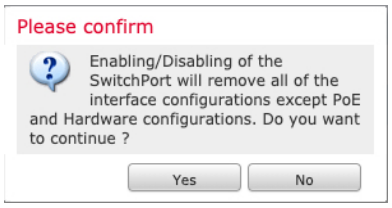
You can set each interface independently to be either a firewall interface or a switch port. By default, Ethernet 1/1 is a firewall interface, and the remaining Ethernet interfaces are configured as switch ports.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Set the switch port mode by clicking the slider in the **SwitchPort** column so it shows as **Slider enabled** ( ) or **Slider disabled** ( ).

By default, switch ports are set to access mode in VLAN 1. You must manually add a logical VLAN 1 interface (or whichever VLAN you set for these switch ports) for traffic to be routed and to participate in the Firewall Threat Defense security policy (see Configure a VLAN Interface, on page 915). You cannot set the Management interface to switch port mode. When you change the switch port mode, all unsupported configuration is removed:



In addition, the interface is disabled if it was already enabled. Be sure to reenable the interface.

Configure a VLAN Interface

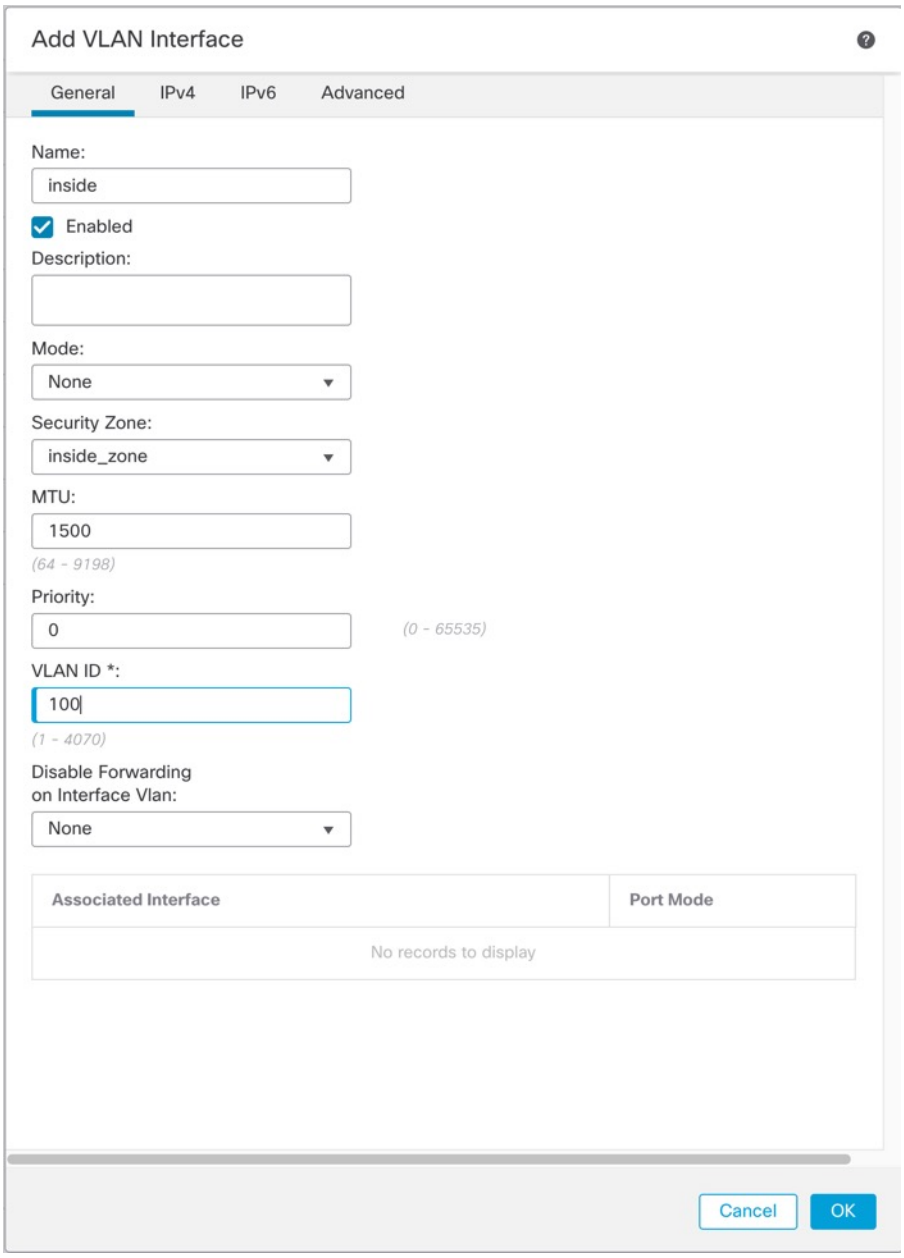
This section describes how to configure VLAN interfaces for use with associated switch ports. By default, switch ports are assigned to VLAN1; however, you must manually add the logical VLAN1 interface (or whichever VLAN you set for these switch ports) for traffic to be routed and to participate in the Firewall Threat Defense security policy.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Add Interfaces** > **VLAN Interface**.

Step 3 On **General**, set the following VLAN-specific parameters:



If you are editing an existing VLAN interface, the **Associated Interface** table shows switch ports on this VLAN.

a) Set the **VLAN ID**, between 1 and 4070, excluding IDs in the range 3968 to 4047, which are reserved for internal use.

   You cannot change the VLAN ID after you save the interface; the VLAN ID is both the VLAN tag used, and the interface ID in your configuration.

b) (Optional) Choose a VLAN ID for **Disable Forwarding on Interface VLAN** to disable forwarding to another VLAN.

For example, you have one VLAN assigned to the outside for internet access, one VLAN assigned to an inside business network, and a third VLAN assigned to your home network. The home network does not need to access the business network, so you can disable forwarding on the home VLAN; the business network can access the home network, but the home network cannot access the business network.

Step 4 To complete the interface configuration, see one of the following procedures:

- Configure Routed Mode Interfaces, on page 948
- Configure General Bridge Group Member Interface Parameters, on page 953

Step 5 Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Switch Ports as Access Ports

To assign a switch port to a single VLAN, configure it as an access port. Access ports accept only untagged traffic. By default, Ethernet 1/2 through Ethernet 1/8 switch ports are enabled and assigned to VLAN 1.

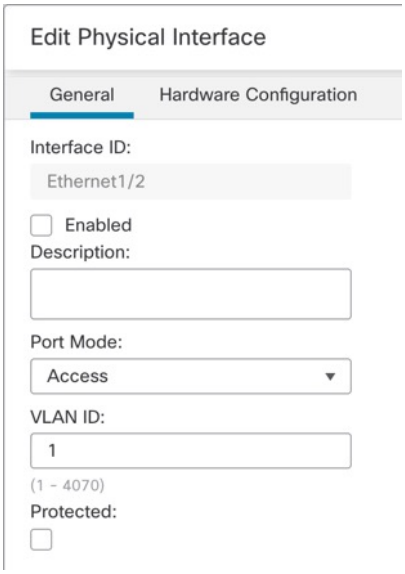
Note The device does not support Spanning Tree Protocol for loop detection in the network. Therefore you must ensure that any connection with the Firewall Threat Defense does not end up in a network loop.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Figure 294: Edit Physical Interface



Step 3 Enable the interface by checking the **Enabled** check box.

Step 4 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 5 Set the **Port Mode** to **Access**.

Step 6 In the **VLAN ID** field, set the VLAN for this switch port, between 1 and 4070.

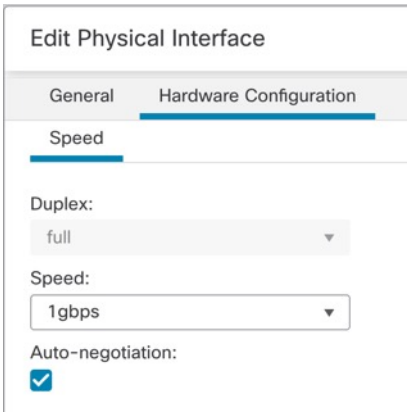
The default VLAN ID is 1.

Step 7 (Optional) Check the **Protected** check box to set this switch port as protected, so you can prevent the switch port from communicating with other protected switch ports on the same VLAN.

You might want to prevent switch ports from communicating with each other if: the devices on those switch ports are primarily accessed from other VLANs; you do not need to allow intra-VLAN access; and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you enable **Protected** on each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

Step 8 (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

Figure 295: Hardware Configuration



Check the **Auto-negotiation** check box (the default) to auto-detect the speed and duplex. If you uncheck it, you can set the speed and duplex manually:

- **Duplex**—Choose **Full** or **Half**.
- **Speed**—Choose **10mbps**, **100mbps**, or **1gbps**.

Note
If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the Threat Defense interface as well. For example, N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, you must disable the default auto-negotiation on the platform and the switch for the port to be connected.

Step 9 Click **OK**.

Step 10 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Switch Ports as Trunk Ports

This procedure describes how to create a trunk port that can carry multiple VLANs using 802.1Q tagging. Trunk ports accept untagged and tagged traffic. Traffic on allowed VLANs pass through the trunk port unchanged.

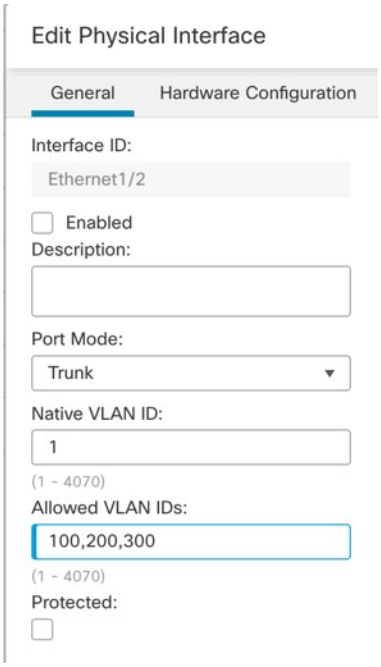
When the trunk receives untagged traffic, it tags it to the native VLAN ID so that the Firewall Threat Defense device can forward the traffic to the correct switch ports, or can route it to another firewall interface. When the Firewall Threat Defense device sends native VLAN ID traffic out of the trunk port, it removes the VLAN tag. Be sure to set the same native VLAN on the trunk port on the other switch so that the untagged traffic will be tagged to the same VLAN.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Figure 296: Set Trunk Port Mode



Step 3 Enable the interface by checking the **Enabled** check box.

Step 4 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 5 Set the **Port Mode** to **Trunk**.

Step 6 In the **Native VLAN ID** field, set the native VLAN for this switch port, between 1 and 4070.

The default native VLAN ID is 1.

Each port can only have one native VLAN, but every port can have either the same or a different native VLAN.

Step 7 In the **Allowed VLAN IDs** field, enter the VLANs for this trunk port between 1 and 4070.

You can identify up to 20 IDs in one of the following ways:

- A single number (n)
- A range (n-x)
- Numbers and ranges separated by commas, for example:

  5,7-10,13,45-100

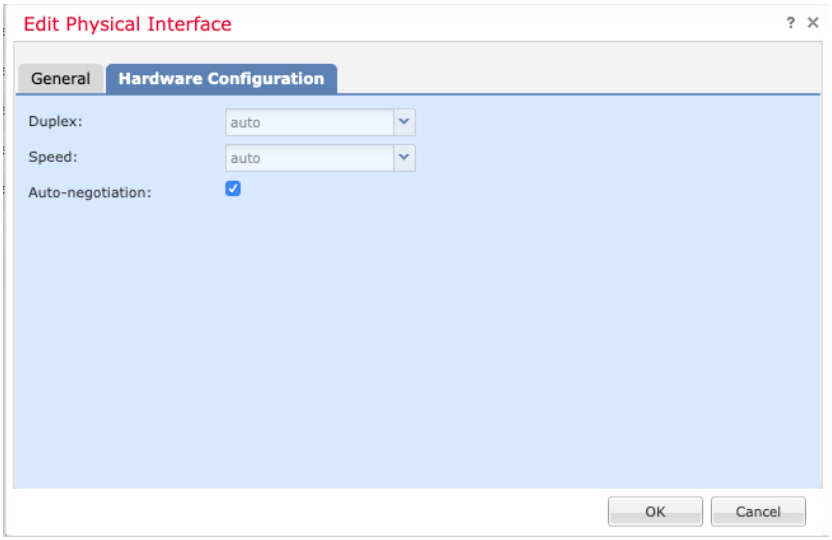
You can enter spaces instead of commas.

If you include the native VLAN in this field, it is ignored; the trunk port always removes the VLAN tagging when sending native VLAN traffic out of the port. Moreover, it will not receive traffic that still has native VLAN tagging.

Step 8 (Optional) Check the **Protected** check box to set this switch port as protected, so you can prevent the switch port from communicating with other protected switch ports on the same VLAN.

You might want to prevent switch ports from communicating with each other if: the devices on those switch ports are primarily accessed from other VLANs; you do not need to allow intra-VLAN access; and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you enable **Protected** on each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

Step 9 (Optional) Set the duplex and speed by clicking **Hardware Configuration**.



Check the **Auto-negotiation** check box (the default) to auto-detect the speed and duplex. If you uncheck it, you can set the speed and duplex manually:

- **Duplex**—Choose **Full** or **Half**.
- **Speed**—Choose **10mbps**, **100mbps**, or **1gbps**.

If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the Threat Defense interface as well. For example, N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, you must disable the default auto-negotiation on the platform and the switch for the port to be connected.

Step 10 Click **OK**.

Step 11 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Power Over Ethernet

Power over Ethernet (PoE) ports provide power for devices such as IP phones or wireless access points. PoE is enabled by default. This procedure describes how to disable and enable PoE and how to set optional parameters.

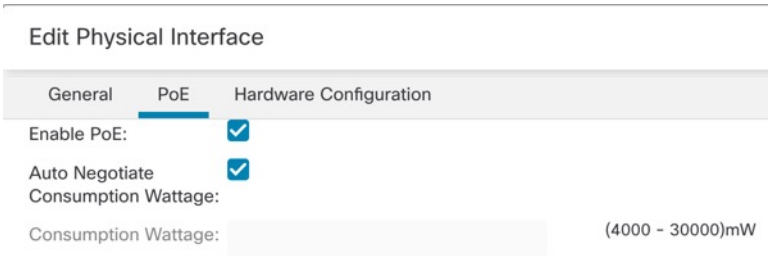
Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for Ethernet1/7 or 1/8.

Step 3 Click **PoE**.

Figure 297: PoE



Step 4 Check the **Enable PoE** check box.

PoE is enabled by default.

Step 5 Choose autonegotiation or manual power.

- **Auto Negotiate Consumption Wattage**—Delivers power automatically to the powered device using a wattage appropriate to the class of the powered device. The firewall uses LLDP to further negotiate the correct wattage. When you connect a device of a certain class, it will be provisioned up to the maximum for that class in case it ever needs to use more power. For example, if you add a class 4 device that requests 12.95W, it will be allocated 30W even if it doesn't currently use all that power. Some devices can renegotiate power needs. If you know your device needs less power than is allocated, you can instead set the **Consumption Wattage** manually to free up the power for other devices.
- **Consumption Wattage**—Uncheck the **Auto Negotiate Consumption Wattage** check box to set the manual wattage to manually specify the wattage in milliwatts, from 4000 to 30000. Use this option if you want to set the watts manually and disable LLDP negotiation. For manual allocation, the class will show in **show power inline** output as **n/a** because the class is not used to decide the power consumption.

  View the current PoE status using the **show power inline** command.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Loopback Interfaces

This section tells how to configure loopback interfaces.

About Loopback Interfaces

A loopback interface is a software-only interface that emulates a physical interface. This interface is reachable on IPv4 and IPv6 through multiple physical interfaces. The loopback interface helps to overcome path failures; it is accessible from any physical interface, so if one goes down, you can access the loopback interface from another.

Loopback interfaces can be used for:

- AAA
- BGP
- DNS
- HTTP
- ICMP
- IPsec flow offload—Secure Firewall /3100 only
- NetFlow
- SNMP
- SSH
- Static and dynamic VTI tunnels
- Syslog

The Firewall Threat Defense can distribute the loopback address using dynamic routing protocols, or you can configure a static route on the peer device to reach the loopback IP address through one of the Firewall Threat Defense's physical interfaces. You cannot configure a static route on the Firewall Threat Defense that specifies the loopback interface.

Related Topics

Guidelines and Limitations for Loopback Interfaces, on page 924
Configure a Loopback Interface, on page 924

Guidelines and Limitations for Loopback Interfaces

Firewall Mode

- Supported in routed mode only.

High Availability and Clustering

- No clustering support.

Additional Guidelines and Limitations

- TCP sequence randomization is always disabled for traffic from the physical interface to the loopback interface.

Configure a Loopback Interface

To add a loopback interface for a device:

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 From the **Add Interfaces** drop-down list, choose **Loopback Interface**.

Step 3 In the **General** tab, configure the following parameters:

a) **Name**—Enter a name for the loopback interface.
b) **Enabled**—Check the check box to enable the loopback interface.
c) **Loopback ID**—Enter the loopback ID between 1 to 1024.
d) **Description**—Enter a description for the loopback interface.

Step 4 Configure the routed mode interface parameters. See Configure Routed Mode Interfaces, on page 948.

Rate-Limit Traffic to the Loopback Interface

Before you begin

You should rate-limit traffic going to the loopback interface IP address to prevent excessive load on the system. You can add a connection limit rule to the global service policy.

Procedure

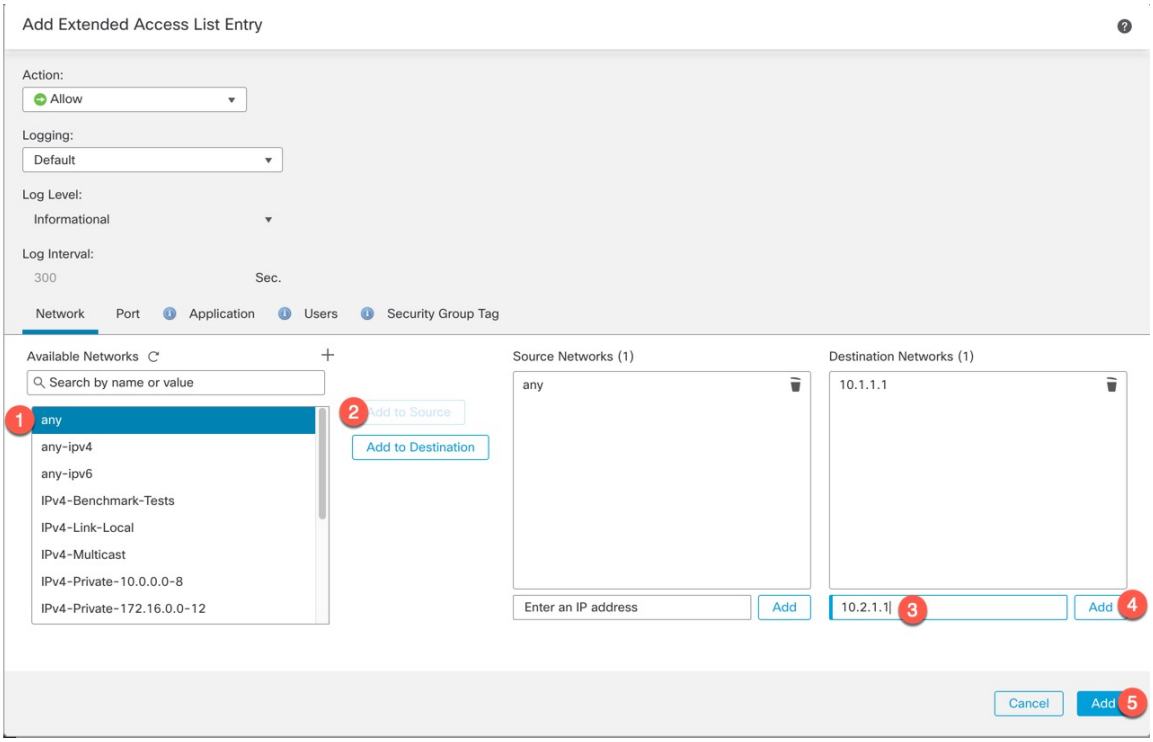
Step 1 Create an extended access list identifying traffic to the loopback interface IP address(es).

a) Choose **Objects** > **Object Management** > **Access List** > **Extended**.
b) Click **Add Extended Access List** to create a new ACL.
c) In the **New Extended Access List Object** dialog box, enter a name for the ACL (no spaces allowed), and click **Add** to create a new entry.

Figure 298: Name ACL and Add Entry

d) Configure the source (any) and destination addresses (loopback IP addresses) on the **Network** tab.

Figure 299: Source and Destination Networks

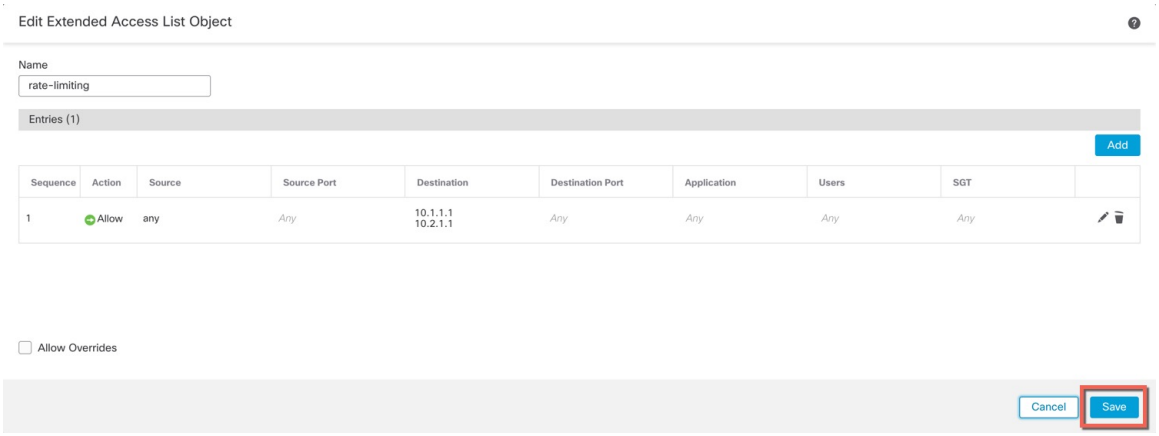


Note
Keep the default **Action** as **Allow** (match) and other settings as-is.

- Source—Select **any** from the **Available Networks** list, and click **Add to Source**. You can also narrow this access list by specifying the source IP addresses instead of **any**.
- Destination—Type an address in the edit box below the **Destination Networks** list and click **Add**. Repeat for each loopback interface.

e) Click **Add** to add the entry to the ACL.
f) Click **Save** to save the ACL.

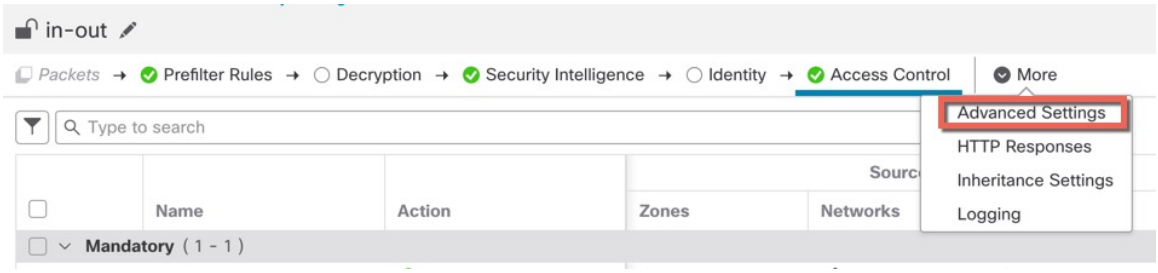
Figure 300: Save ACL



Step 2 Choose **Policies** > **Access Control heading** > **Access Control**, and click **Edit** (✎) for the access control policy assigned to your device.

Step 3 Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Figure 301: Advanced Settings

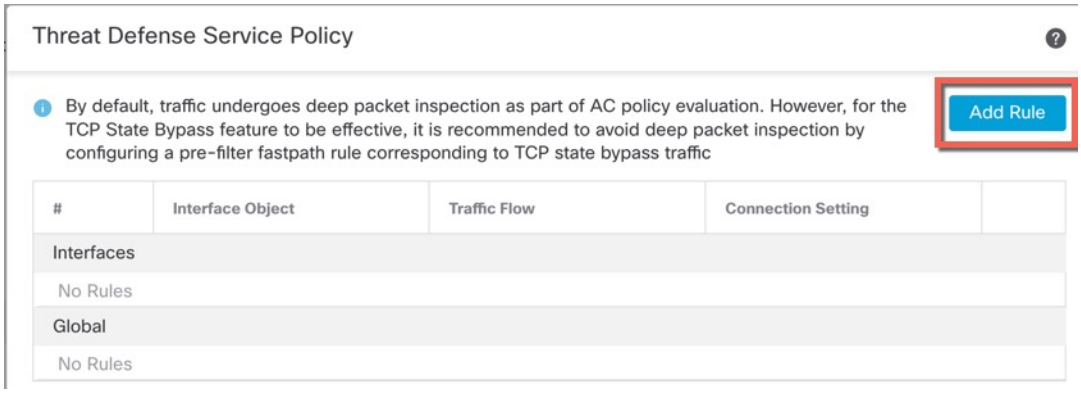


Step 4 Click **Edit** (✎) in the **Threat Defense Service Policy** group.

Figure 302: Threat Defense Service Policy

Step 5 Click **Add Rule** to create a new rule.

Figure 303: Add Rule



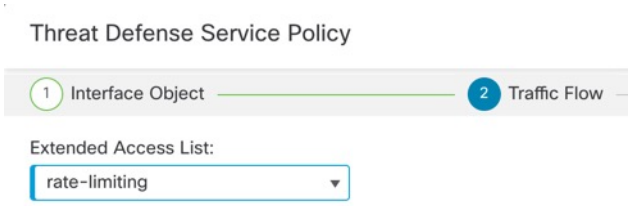
The service policy rule wizard opens to step you through the process of configuring the rule.

Step 6 In the **Interface Object** step, click **Global** to create a global rule, which applies to all interfaces, then click **Next**.

Figure 304: Global Policy

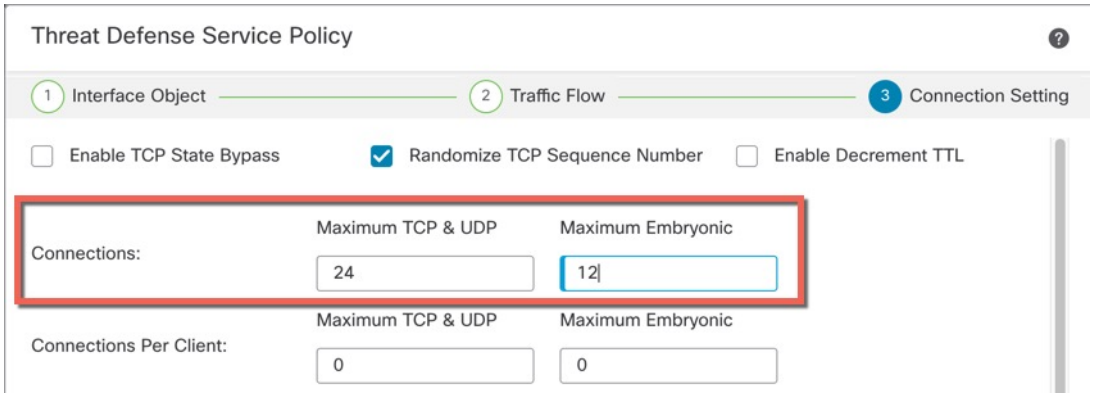
Step 7 In the **Traffic Flow** step, select the extended access list object you created in Step 1, on page 924, and then click **Next**.

Figure 305: Choose Extended Access List



Step 8 In the **Connection Setting** step, set the **Connections** limits.

Figure 306: Set Connection Limits



Set the **Maximum TCP & UDP** connections to the expected number of connections for the loopback interface, and the **Maximum Embryonic** connections to a lower number. For example, you can set it to 5/2, or 10/5, or 1024/512, depending on the expected loopback interface sessions you need.

Setting the embryonic connection limit enables TCP Intercept, which protects the system from a DoS attack perpetrated by flooding an interface with TCP SYN packets.

Step 9 Click **Finish** to save your changes.

Step 10 Click **OK**.

Step 11 Click **Save** on the **Advanced Settings** window.

Step 12 You can now deploy the changes to the affected devices.

Configure VLAN Subinterfaces and 802.1Q Trunking

VLAN subinterfaces let you divide a physical, redundant, or EtherChannel interface into multiple logical interfaces that are tagged with different VLAN IDs. An interface with one or more VLAN subinterfaces is automatically configured as an 802.1Q trunk. Because VLANs let you keep traffic separate on a given physical interface, you can increase the number of interfaces available to your network without adding additional physical interfaces or devices.

Guidelines and Limitations for VLAN Subinterfaces

Model Support

- Firepower 1010—VLAN subinterfaces are not supported on switch ports or VLAN interfaces.

High Availability and Clustering

You cannot use a subinterface for the failover or state link or for the cluster control link. The exception is for multi-instance mode: you can use a *chassis*-defined subinterface for these links.

Additional Guidelines

- Preventing untagged packets on the physical interface—If you use subinterfaces, you typically do not also want the physical interface to pass traffic, because the physical interface passes untagged packets. This property is also true for the active physical interface in a redundant interface pair and for EtherChannel links. Because the physical, redundant, or EtherChannel interface must be enabled for the subinterface to pass traffic, ensure that the physical, redundant, or EtherChannel interface does not pass traffic by not configuring a name for the interface. If you want to let the physical, redundant, or EtherChannel interface pass untagged packets, you can configure the name as usual.
- You cannot configure subinterfaces on the Management interface, either the dedicated Management interface configured at the CLI nor a data interface used for manager access.
- All subinterfaces on the same parent interface must be either bridge group members or routed interfaces; you cannot mix and match.
- The Firewall Threat Defense does not support the Dynamic Trunking Protocol (DTP), so you must configure the connected switch port to trunk unconditionally.
- You might want to assign unique MAC addresses to subinterfaces defined on the Firewall Threat Defense, because they use the same burned-in MAC address of the parent interface. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the Firewall Threat Defense.

Note If you manually assign a MAC address, be sure to assign MAC addresses to all subinterfaces on the same physical interface to avoid unexpected behavior and outages.

Maximum Number of VLAN Subinterfaces by Device Model

The device model limits the maximum number of VLAN subinterfaces that you can configure. Note that you can configure subinterfaces on data interfaces only, you cannot configure them on the management interface.

The following table explains the limits for each device model.

Model	Maximum VLAN Subinterfaces
Firepower 1010	60
Firepower 1120	512
Firepower 1140, 1150	1024
Firepower 2100	1024
Secure Firewall 3100, 4200	1024
Firepower 4100	1024
Firepower 9300	1024

Model	Maximum VLAN Subinterfaces
Firewall Threat Defense Virtual	50
ISA 3000	100

Add a Subinterface

Add one or more subinterfaces to a physical, redundant, or port-channel interface.

For the Firepower 4100/9300, you can configure subinterfaces in FXOS for use with container instances; see Add a VLAN Subinterface for Container Instances, on page 482. These subinterfaces appear in the Firewall Management Center interface list. You can also add subinterfaces in Firewall Management Center, but only on parent interfaces that do not already have subinterfaces defined in FXOS.

Note The parent physical interface passes untagged packets. You may not want to pass untagged packets, so be sure not to include the parent interface in your security policy.

Procedure

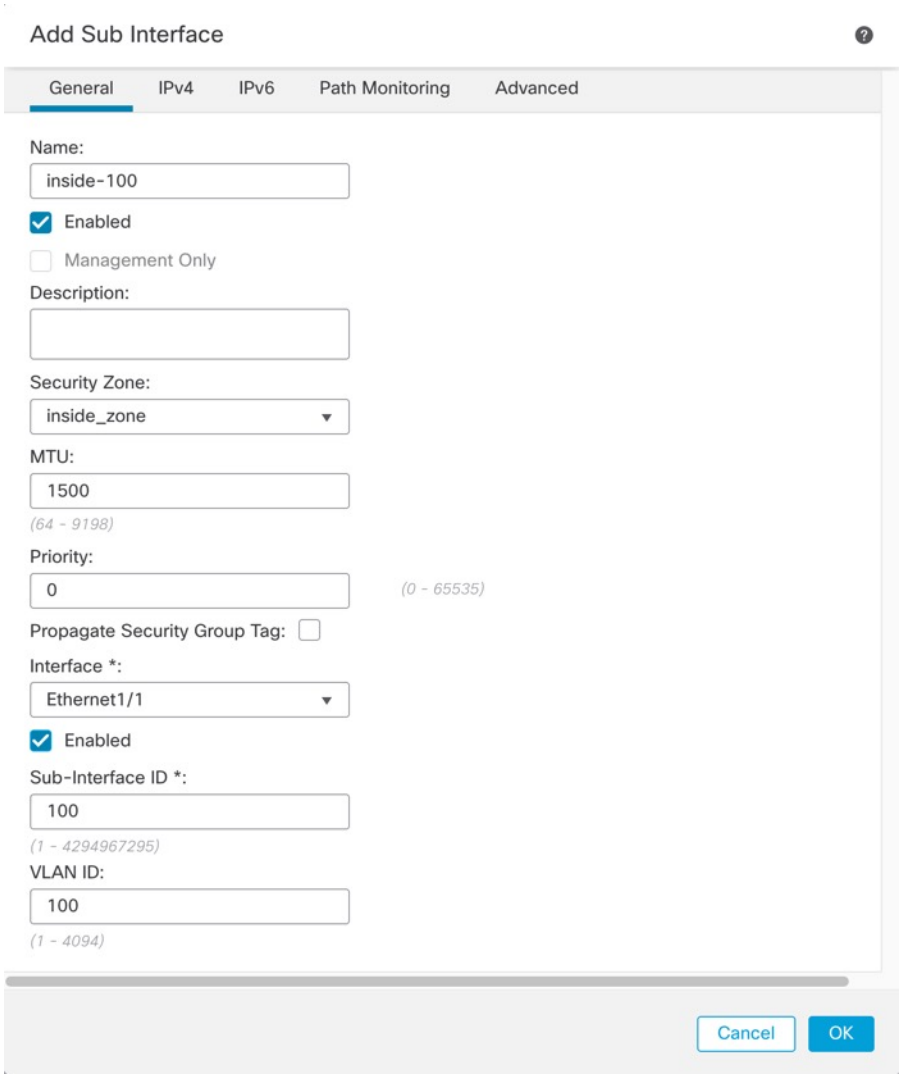
Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Enable the parent interface according to Enable the Physical Interface and Configure Ethernet Settings, on page 872.

Step 3 Click **Add Interfaces** > **Sub Interface**.

Step 4 On **General**, set the following parameters:

Figure 307: Add Subinterface



a) **Interface**—Choose the physical, redundant, or port-channel interface to which you want to add the subinterface.

b) **Sub-Interface ID**—Enter the subinterface ID as an integer between 1 and 4294967295. The number of subinterfaces allowed depends on your platform. You cannot change the ID after you set it.

c) **VLAN ID**—Enter the VLAN ID between 1 and 4094 that will be used to tag the packets on this subinterface.

   This VLAN ID must be unique.

Step 5 Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Step 7 Configure the routed or transparent mode interface parameters. See Configure Routed Mode Interfaces, on page 948 or Configure Bridge Group Interfaces, on page 953.

Configure VXLAN Interfaces

This chapter tells how to configure Virtual eXtensible LAN (VXLAN) interfaces. VXLAN interfaces act as Layer 2 virtual networks over Layer 3 physical networks to stretch Layer 2 networks.

About VXLAN Interfaces

VXLAN provides the same Ethernet Layer 2 network services as VLAN does, but with greater extensibility and flexibility. Compared to VLAN, VXLAN offers the following benefits:

- Flexible placement of multitenant segments throughout the data center.
- Higher scalability to address more Layer 2 segments: up to 16 million VXLAN segments.

This section describes how VXLAN works. For detailed information about VXLAN, see RFC 7348. For detailed information about Geneve, see RFC 8926.

Encapsulation

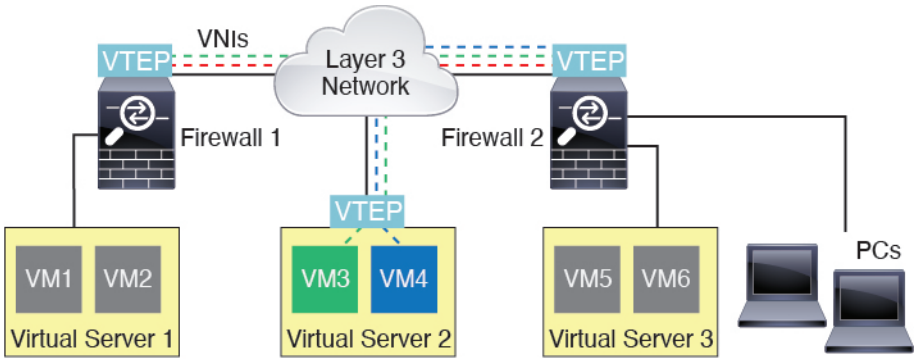
The Firewall Threat Defense supports two types of VXLAN encapsulation:

- VXLAN (all models)—VXLAN uses MAC Address-in-User Datagram Protocol (MAC-in-UDP) encapsulation. The original Layer 2 frame has a VXLAN header added and is then placed in a UDP-IP packet.
- Geneve (Firewall Threat Defense Virtual only)—Geneve has a flexible inner header that is not limited to the MAC address. Geneve encapsulation is required for transparent routing of packets between an Amazon Web Services (AWS) Gateway Load Balancer and appliances, and for sending extra information.

VXLAN Tunnel Endpoint

VXLAN tunnel endpoint (VTEP) devices perform VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces to which you apply your security policy, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

The following figure shows two Firewall Threat Defenses and Virtual Server 2 acting as VTEPs across a Layer 3 network, extending the VNI 1, 2, and 3 networks between sites. The Firewall Threat Defenses act as bridges or gateways between VXLAN and non-VXLAN networks.



The underlying IP network between VTEPs is independent of the VXLAN overlay. Encapsulated packets are routed based on the outer IP address header, which has the initiating VTEP as the source IP address and the terminating VTEP as the destination IP address. For VXLAN encapsulation: The destination IP address can be a multicast group when the remote VTEP is not known. With Geneve, the Firewall Threat Defense only supports static peers. The destination port for VXLAN is UDP port 4789 by default (user configurable). The destination port for Geneve is 6081.

VTEP Source Interface

The VTEP source interface is a regular interface (physical, EtherChannel, or even VLAN) with which you plan to associate all VNI interfaces. You can configure one VTEP source interface per Firewall Threat Defense Virtual. Because you can only configure one VTEP source interface, you cannot configure both VXLAN and Geneve interfaces on the same device. There is an exception for Firewall Threat Defense Virtual clustering on AWS or Azure, where you can have two VTEP source interfaces: a VXLAN interface is used for the cluster control link, and a Geneve (AWS) or VXLAN (Azure) interface can be used for the Gateway Load Balancer.

The VTEP source interface can be devoted wholly to VXLAN traffic, although it is not restricted to that use. If desired, you can use the interface for regular traffic and apply a security policy to the interface for that traffic. For VXLAN traffic, however, all security policy must be applied to the VNI interfaces. The VTEP interface serves as a physical port only.

In transparent firewall mode, the VTEP source interface is not part of a BVI, and you do configure an IP address for it, similar to the way the management interface is treated.

VNI Interfaces

VNI interfaces are similar to VLAN interfaces: they are virtual interfaces that keep network traffic separated on a given physical interface by using tagging. You apply your security policy directly to each VNI interface.

You can only add one VTEP interface, and all VNI interfaces are associated with the same VTEP interface. There is an exception for Firewall Threat Defense Virtual clustering on AWS or Azure. For AWS clustering, you can have two VTEP source interfaces: a VXLAN interface is used for the cluster control link, and a Geneve interface can be used for the AWS Gateway Load Balancer. For Azure clustering, you can have two VTEP source interfaces: a VXLAN interface is used for the cluster control link, and a second VXLAN interface can be used for the Azure Gateway Load Balancer.

VXLAN Packet Processing

VXLAN

Traffic entering and exiting the VTEP source interface is subject to VXLAN processing, specifically encapsulation or decapsulation.

Encapsulation processing includes the following tasks:

- The VTEP source interface encapsulates the inner MAC frame with the VXLAN header.
- The UDP checksum field is set to zero.
- The Outer frame source IP is set to the VTEP interface IP.
- The Outer frame destination IP is decided by a remote VTEP IP lookup.

Decapsulation; the Firewall Threat Defense only decapsulates a VXLAN packet if:

- It is a UDP packet with the destination port set to 4789 (this value is user configurable).
- The ingress interface is the VTEP source interface.
- The ingress interface IP address is the same as the destination IP address.
- The VXLAN packet format is compliant with the standard.

Geneve

Traffic entering and exiting the VTEP source interface is subject to Geneve processing, specifically encapsulation or decapsulation.

Encapsulation processing includes the following tasks:

- The VTEP source interface encapsulates the inner MAC frame with the Geneve header.
- The UDP checksum field is set to zero.
- The Outer frame source IP is set to the VTEP interface IP.
- The Outer frame destination IP is set the peer IP address that you configured.

Decapsulation; the Firewall Threat Defense only decapsulates a Geneve packet if:

- It is a UDP packet with the destination port set to 6081 (this value is user configurable).
- The ingress interface is the VTEP source interface.
- The ingress interface IP address is the same as the destination IP address.
- The Geneve packet format is compliant with the standard.

Peer VTEPs

When the Firewall Threat Defense sends a packet to a device behind a peer VTEP, the Firewall Threat Defense needs two important pieces of information:

- The destination MAC address of the remote device

- The destination IP address of the peer VTEP

The Firewall Threat Defense maintains a mapping of destination MAC addresses to remote VTEP IP addresses for the VNI interfaces.

VXLAN Peer

There are two ways in which the Firewall Threat Defense can find this information:

- A single peer VTEP IP address can be statically configured on the Firewall Threat Defense.

  For IPv4: The Firewall Threat Defense then sends a VXLAN-encapsulated ARP broadcast to the VTEP to learn the end node MAC address.

  For IPv6: The Firewall Threat Defense then sends an IPv6 Neighbor Solicitation message to the IPv6 solicited-node multicast address. The peer VTEP responds with an IPv6 Neighbor Advertisement message with its link-local address.

- A group of peer VTEP IP addresses can be statically configured on the Firewall Threat Defense.

  For IPv4: The Firewall Threat Defense then sends a VXLAN-encapsulated ARP broadcast to the VTEP to learn the end node MAC addresses.

  For IPv6: The Firewall Threat Defense then sends an IPv6 Neighbor Solicitation message to the IPv6 solicited-node multicast address. The peer VTEP responds with an IPv6 Neighbor Advertisement message with its link-local address.

- A multicast group can be configured on each VNI interface (or on the VTEP as a whole).

  For IPv4: The Firewall Threat Defense sends a VXLAN-encapsulated ARP broadcast packet within an IP multicast packet through the VTEP source interface. The response to this ARP request enables the Firewall Threat Defense to learn both the remote VTEP IP address along with the destination MAC address of the remote end node.

  For IPv6: The Firewall Threat Defense sends a Multicast Listener Discovery (MLD) Report message through the VTEP source interface to indicate that the Firewall Threat Defense is listening on the VTEP interface for the multicast address traffic.

  This option is not supported with Geneve.

Geneve Peer

The Firewall Threat Defense Virtual only supports statically defined peers. You can define the Firewall Threat Defense Virtual peer IP address on the AWS Gateway Load Balancer. Because the Firewall Threat Defense Virtual never initiates traffic to the Gateway Load Balancer, you do not also have to specify the Gateway Load Balancer IP address on the Firewall Threat Defense Virtual; it learns the peer IP address when it receives Geneve traffic. Multicast groups are not supported with Geneve.

VXLAN Use Cases

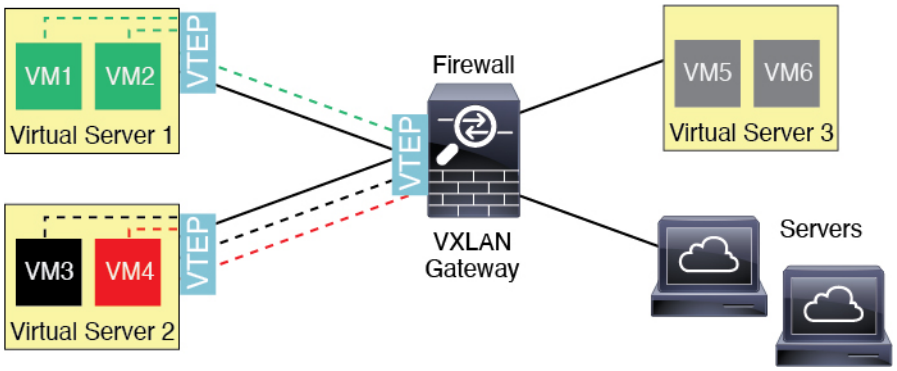
This section describes the use cases for implementing VXLAN on the Firewall Threat Defense.

VXLAN Bridge or Gateway Overview

Each Firewall Threat Defense VTEP acts as a bridge or gateway between end nodes such as VMs, servers, and PCs and the VXLAN overlay network. For incoming frames received with VXLAN encapsulation over the VTEP source interface, the Firewall Threat Defense strips out the VXLAN header and forwards it to a

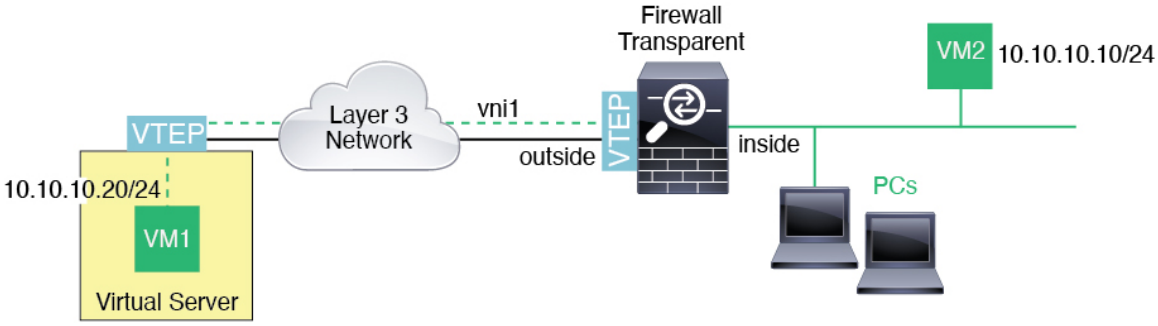
physical interface connected to a non-VXLAN network based on the destination MAC address of the inner Ethernet frame.

The Firewall Threat Defense always processes VXLAN packets; it does not just forward VXLAN packets untouched between two other VTEPs.



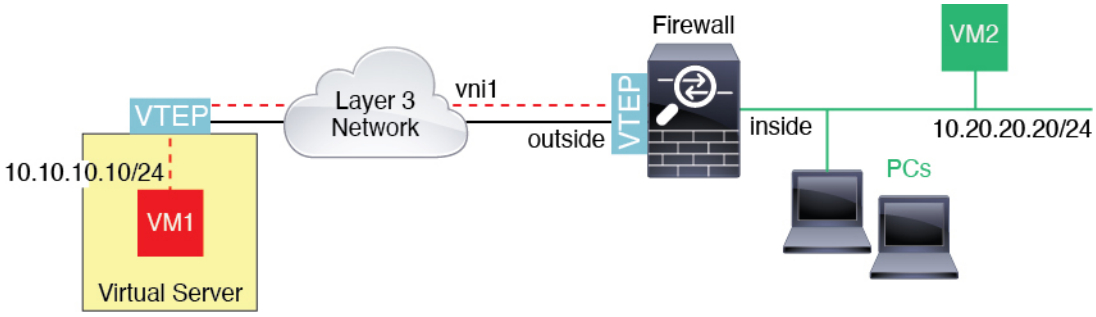
VXLAN Bridge

When you use a bridge group (transparent firewall mode, or optionally routed mode), the Firewall Threat Defense can serve as a VXLAN bridge between a (remote) VXLAN segment and a local segment where both are in the same network. In this case, one member of the bridge group is a regular interface while the other member is a VNI interface.



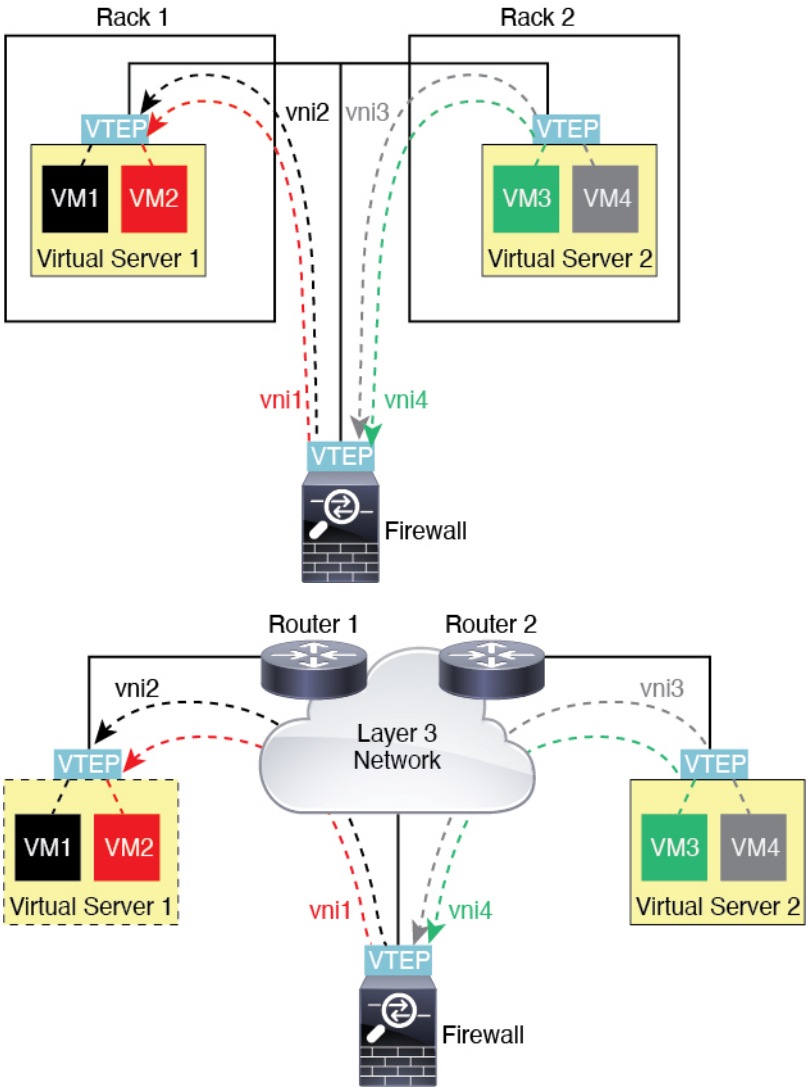
VXLAN Gateway (Routed Mode)

The Firewall Threat Defense can serve as a router between VXLAN and non-VXLAN domains, connecting devices on different networks.



Router Between VXLAN Domains

With a VXLAN-stretched Layer 2 domain, a VM can point to an Firewall Threat Defense as its gateway while the Firewall Threat Defense is not on the same rack, or even when the Firewall Threat Defense is far away over the Layer 3 network.



See the following notes about this scenario:

1. For packets from VM3 to VM1, the destination MAC address is the Firewall Threat Defense MAC address, because the Firewall Threat Defense is the default gateway.
2. The VTEP source interface on Virtual Server 2 receives packets from VM3, then encapsulates the packets with VNI 3's VXLAN tag and sends them to the Firewall Threat Defense.
3. When the Firewall Threat Defense receives the packets, it decapsulates the packets to get the inner frames.
4. The Firewall Threat Defense uses the inner frames for route lookup, then finds that the destination is on VNI 2. If it does not already have a mapping for VM1, the Firewall Threat Defense sends an encapsulated ARP broadcast on the multicast group IP on VNI 2.

Note The Firewall Threat Defense must use dynamic VTEP peer discovery because it has multiple VTEP peers in this scenario.

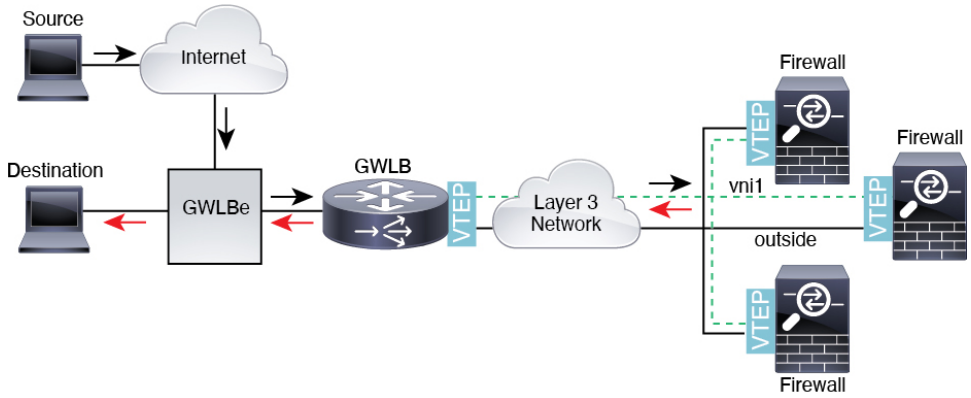
5. The Firewall Threat Defense encapsulates the packets again with the VXLAN tag for VNI 2 and sends the packets to Virtual Server 1. Before encapsulation, the Firewall Threat Defense changes the inner frame destination MAC address to be the MAC of VM1 (multicast-encapsulated ARP might be needed for the Firewall Threat Defense to learn the VM1 MAC address).
6. When Virtual Server 1 receives the VXLAN packets, it decapsulates the packets and delivers the inner frames to VM1.

Geneve Single-Arm Proxy

Note This use case is the only currently supported use case for Geneve interfaces.

The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The Firewall Threat Defense Virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint). The following figure shows traffic forwarded to the Gateway Load Balancer from the Gateway Load Balancer endpoint. The Gateway Load Balancer balances traffic among multiple Firewall Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer (U-turn traffic). The Gateway Load Balancer then sends the traffic back to the Gateway Load Balancer endpoint and to the destination.

Figure 308: Geneve Single-Arm Proxy



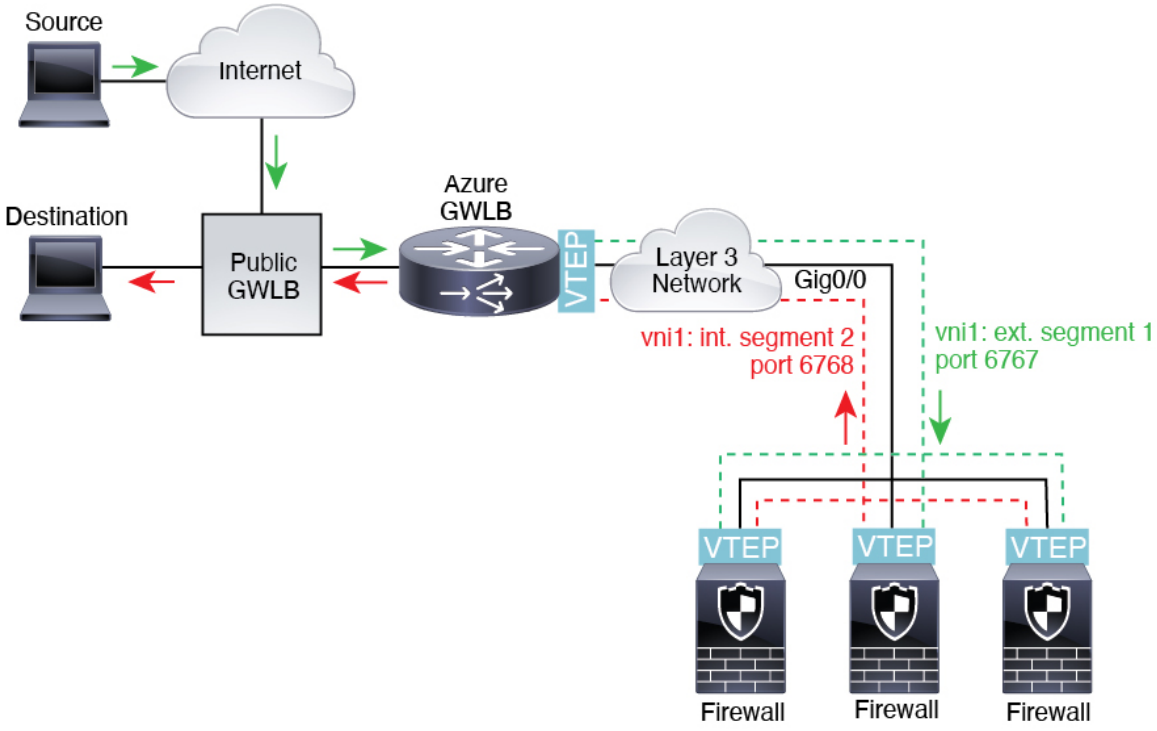
Azure Gateway Load Balancer and Paired Proxy

In an Azure service chain, Firewall Threat Defense Virtuals act as a transparent gateway that can intercept packets between the internet and the customer service. The Firewall Threat Defense Virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy.

The following figure shows traffic forwarded to the Azure Gateway Load Balancer from the Public Gateway Load Balancer on the external VXLAN segment. The Gateway Load Balancer balances traffic among multiple Firewall Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the

Gateway Load Balancer on the internal VXLAN segment. The Azure Gateway Load Balancer then sends the traffic back to the Public Gateway Load Balancer and to the destination.

Figure 309: Azure Gateway Load Balancer with Paired Proxy



Requirements and Prerequisites for VXLAN Interfaces

Model Requirements

- VXLAN encapsulation is supported on all models.
- Geneve encapsulation is supported for the following models:
  - Firewall Threat Defense Virtual in Amazon Web Services (AWS)
- VXLAN in *paired proxy mode* is supported for the following models:
  - Firewall Threat Defense Virtual in Azure
- Firepower 1010 switch ports and VLAN interfaces are not supported as VTEP interfaces.

Guidelines for VXLAN Interfaces

Firewall Mode

- Geneve interfaces are only supported in routed firewall mode.

- Paired proxy VXLAN interfaces are only supported in routed firewall mode.

IPv6

- The VNI interface supports both IPv4 and IPv6 traffic.
- For VXLAN encapsulation, the VTEP source interface supports both IPv4 and IPv6. The Firewall Threat Defense Virtual cluster control link VTEP source interface only supports IPv4.

  For Geneve, the VTEP source interface only supports IPv4.

Clustering

- Clustering does not support VXLAN in Individual Interface mode except for the cluster control link (Firewall Threat Defense Virtual only) Only Spanned EtherChannel mode supports VXLAN.

  An exception is made for AWS, which can use an additional Geneve interface for use with the GWLB and for Azure, which can use an additional paired proxy VXLAN interface for use with the GWLB.

Routing

- Only static routing or Policy Based Routing is supported on the VNI interface; dynamic routing protocols are not supported.

VPN

You cannot configure the VTEP source interface for VPN or use it as a VTI.

MTU

- VXLAN encapsulation—If the source interface MTU is less than 1554 bytes for IPv4 or 1574 bytes for IPv6, then the Firewall Threat Defense automatically raises the MTU to 1554 bytes or 1574 bytes. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. If the MTU used by other devices is larger, then you should set the source interface MTU to be the network MTU + 54 bytes for IPv4 or +64 bytes for IPv6. For the Firewall Threat Defense Virtual, this MTU requires a restart to enable jumbo frame reservation.
- Geneve encapsulation—If the source interface MTU is less than 1806 bytes, then the Firewall Threat Defense automatically raises the MTU to 1806 bytes. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. If the MTU used by other devices is larger, then you should set the source interface MTU to be the network MTU + 306 bytes. This MTU requires a restart to enable jumbo frame reservation.

Configure VXLAN or Geneve Interfaces

You can configure either VXLAN or Geneve interfaces.

Configure VXLAN Interfaces

To configure VXLAN, perform the following steps.

Note You can configure either VXLAN or Geneve (Firewall Threat Defense Virtual only). For Geneve interfaces, see Configure Geneve Interfaces, on page 943.

Note For Azure GWLB, the VXLAN interface is configured when you deploy the VM using the ARM template. You can use this section to change your configuration.

1. Configure the VTEP Source Interface, on page 941.
2. Configure the VNI Interface, on page 942.
3. (Azure GWLB) Allow Gateway Load Balancer Health Checks, on page 945.

Configure the VTEP Source Interface

You can configure one VTEP source interface per Firewall Threat Defense device. The VTEP is defined as a Network Virtualization Endpoint (NVE). VXLAN is the default encapsulation type. An exception is made for clustering on the Firewall Threat Defense Virtual in Azure, where you can use one VTEP source interface for the cluster control link and a second one for the data interface connected to the Azure GWLB.

Procedure

Step 1 If you want to specify a group of peer VTEPs, add a network object with the peer IP addresses. See Creating Network Objects, on page 1473.

Step 2 Choose **Devices** > **Device Management**.

Step 3 Click **Edit** (✎) next to the device on which you want to configure VXLAN.

Step 4 (Optional) Specify that the source interface is NVE-only.

This setting is optional for routed mode where this setting restricts traffic to VXLAN and common management traffic only on this interface. This setting is automatically enabled for transparent firewall mode.

a) Click **Interfaces**.

b) Click **Edit** (✎) for the VTEP source interface.

c) On the **General** page, check the check box of **NVE Only**.

Step 5 Click **VTEP** if it is not already displaying.

Step 6 Check **Enable NVE**.

Step 7 Click **Add VTEP**.

Step 8 For the **Encapsulation Type**, choose **VxLAN**.

For AWS, you can choose between **VxLAN** and **Geneve**. Other platforms have **VxLAN** chosen automatically.

Step 9 Enter the value for the **Encapsulation port** within the specified range.

The default value is 4789.

Step 10 Select the **VTEP Source Interface**.

Select from the list of available physical interfaces present on the device. If the source interface MTU is less than 1554 bytes for IPv4 or 1574 bytes for IPv6, then the Firewall Management Center automatically raises the MTU to 1554 bytes or 1574 bytes.

Step 11 Select the **Neighbor Address**. The available options are:

- **None**—No neighbor address is specified.
- **Peer VTEP**—Specify a peer VTP address.
- **Peer Group**—Specify a network object with the peer IP addresses.
- **Default Multicast**—Specify a default multicast group for all associated VNI interfaces. If you do not configure the multicast group per VNI interface, then this group is used. If you configure a group at the VNI interface level, then that group overrides this setting.

Step 12 Click **OK**.

Step 13 Click **Save**.

Step 14 Configure the routed interface parameters. See Configure Routed Mode Interfaces.

Configure the VNI Interface

Add a VNI interface, associate it with the VTEP source interface, and configure basic interface parameters.

For the Firewall Threat Defense Virtual in Azure, you can configure either a regular VXLAN interface, or you can configure a paired proxy mode VXLAN interface for use with the Azure GWLB. Paired proxy mode is the only supported mode with clustering.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device on which you want to configure VXLAN.

Step 3 Click **Interfaces**.

Step 4 Click **Add Interfaces**, and then choose **VNI Interface**.

Step 5 Enter the interface **Name** and **Description**.

Step 6 From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

Step 7 Enter a value for the **Priority** field within the specified range. By default, 0 is selected.

Step 8 Enter a value for the **VNI ID** between 1 and 10000.

This ID is only an internal interface identifier.

Step 9 (Paired Proxy VXLAN for Azure GWLB) Enable proxy paired mode and set the required parameters.

a) Check **Proxy Paired**.
b) Set the **Internal Port** between 1024 and 65535.
c) Set the **Internal Segment ID** between 1 and 16777215.
d) Set the **External Port** between 1024 and 65535.
e) Set the **External Segment ID** between 1 and 16777215.

Step 10 (Regular VXLAN) Enter a value for the **VNI Segment ID** between 1 and 16777215.

The segment ID is used for VXLAN tagging.

Step 11 Enter the **Multicast Group IP Address**.

If you do not set the multicast group for the VNI interface, the default group from the VTEP source interface configuration is used, if available. If you manually set a VTEP peer IP for the VTEP source interface, you cannot specify a multicast group for the VNI interface.

Step 12 Check **NVE Mapped to VTEP Interface**.

This option associates this interface with the VTEP source interface.

Step 13 Click **OK**.

Step 14 Click **Save** to save the interface configuration.

Step 15 Configure the routed or transparent interface parameters. See Configure Routed and Transparent Mode Interfaces, on page 945.

Configure Geneve Interfaces

To configure Geneve interfaces for Firewall Threat Defense Virtual, perform the following steps.

Note You can configure either VXLAN or Geneve. For information about VXLAN interfaces, see Configure VXLAN Interfaces, on page 940.

1. Configure the VTEP Source Interface, on page 943.
2. Configure the VNI, on page 944.
3. Allow Gateway Load Balancer Health Checks, on page 945.

Configure the VTEP Source Interface

You can configure one VTEP source interface per Firewall Threat Defense Virtual device. The VTEP is defined as a Network Virtualization Endpoint (NVE).

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device on which you want to configure Geneve.

Step 3 Click **VTEP**.

Step 4 Check **Enable NVE**.

Step 5 Click **Add VTEP**.

Step 6 For the **Encapsulation Type**, choose **Geneve**.

Step 7 Enter the value for the **Encapsulation port** within the specified range.

We do not recommend changing the Geneve port; AWS requires a port of 6081.

Step 8 Select the **VTEP Source Interface**.

You can select from the list of available physical interfaces present on the device. If the source interface MTU is less than 1806 bytes, then the Firewall Management Center automatically raises the MTU to 1806 bytes.

Step 9 Click **OK**.

Step 10 Click **Save**.

Step 11 Configure the routed interface parameters. See Configure Routed Mode Interfaces.

Configure the VNI

Add a VNI, associate it with (VTEP) source interface, and configure basic interface parameters.

Procedure

Step 1 Choose **Devices** > **Device Management**.

Step 2 Click **Edit** ( ) next to the device on which you want to configure Geneve.

Step 3 Click **Interfaces**.

Step 4 Click **Add Interfaces**, and then choose **VNI Interface**.

Step 5 In the **Name** and **Description** fields, provide relevant information.

Step 6 In the **VNI ID** field, enter a value between 1 and 10000.

Note
This ID is only an internal interface identifier.

Step 7 Check the **Enable Proxy** check box.

Note
When the AWS proxy is enabled on the VNI interface of your device, configuring NAT is not allowed.

This option enables single-arm proxy, and allows traffic to exit the same interface it entered (U-turn traffic). If you later edit the interface, you cannot disable single-arm proxy. To do that, you need to delete the existing interface and create a new VNI interface.

This option is only available for a Geneve VTEP.

Step 8 Select **NVE Mapped to VTEP Interface**.

This option associates this interface with the VTEP source interface.

Step 9 Click **OK**.

Step 10 Click **Save**.

What to do next

Configure the routed interface parameters. See Configure Routed Mode Interfaces.

Allow Gateway Load Balancer Health Checks

The AWS or Azure GWLB requires appliances to answer a health check properly. The GWLB will only send traffic to appliances that are considered healthy. You must configure the Firewall Threat Defense Virtual to respond to an SSH, HTTP, or HTTPS health check.

Configure one of the following methods.

Procedure

Step 1 Configure SSH. See Configure Secure Shell

Allow SSH from the GWLB IP address. The GWLB will attempt to establish a connection to the Firewall Threat Defense Virtual, and the Firewall Threat Defense Virtual's prompt to log in is taken as proof of health. An SSH login attempt will time out after 1 minute. You will need to configure a longer health check interval on the GWLB to accommodate this timeout.

Step 2 Configure HTTP(S) Redirection Using Static Interface NAT with Port Translation.

You can configure the Firewall Threat Defense Virtual to redirect health checks to a metadata HTTP(S) server. For HTTP(S) health checks, the HTTP(S) server must reply to the GWLB with a status code in the range 200 to 399. Because the Firewall Threat Defense Virtual has limits on the number of simultaneous management connections, you may choose to offload the health check to an external server.

Static interface NAT with port translation lets you redirect a connection to a port (such as port 80) to a different IP address. For example, translate an HTTP packet from the GWLB with a destination of the Firewall Threat Defense Virtual outside interface so that it appears to be from the Firewall Threat Defense Virtual outside interface with a destination of the HTTP server. The Firewall Threat Defense Virtual then forwards the packet to the mapped destination address. The HTTP server responds to the Firewall Threat Defense Virtual outside interface, and then the Firewall Threat Defense Virtual forwards the response back to the GWLB. You need an access rule that allows traffic from the GWLB to the HTTP server.

a) Permit HTTP(S) traffic on the outside interface from the GWLB network in an access rule. See Access Control Rules, on page 1817.
b) For HTTP(S), translate the source GWLB IP address to the Firewall Threat Defense Virtual outside interface IP address; then translate the destination of the outside interface IP address to the HTTP(S) server IP address. See Configure Static Manual NAT, on page 1139.

Configure Routed and Transparent Mode Interfaces

This section includes tasks to complete the regular interface configuration for all models in routed or transparent firewall mode.

About Routed and Transparent Mode Interfaces

Firewall mode interfaces subject traffic to firewall functions such as maintaining flows, tracking flow states at both IP and TCP layers, IP defragmentation, and TCP normalization. You can also optionally configure IPS functions for this traffic according to your security policy.

The types of firewall interfaces you can configure depends on the firewall mode set for the device: routed or transparent mode. See Transparent or Routed Firewall Mode, on page 431 for more information.

- Routed mode interfaces (routed firewall mode only)—Each interface that you want to route between is on a different subnet.
- Bridge group interfaces (routed and transparent firewall mode)—You can group together multiple interfaces on a network, and the Firewall Threat Defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. In routed mode, the Firewall Threat Defense device routes between BVIs and regular routed interfaces. In transparent mode, each bridge group is separate and cannot communicate with each other.

Dual IP Stack (IPv4 and IPv6)

The Firewall Threat Defense device supports both IPv6 and IPv4 addresses on an interface. Make sure you configure a default route for both IPv4 and IPv6.

31-Bit Subnet Mask

For routed interfaces, you can configure an IP address on a 31-bit subnet for point-to-point connections. The 31-bit subnet includes only 2 addresses; normally, the first and last address in the subnet is reserved for the network and broadcast, so a 2-address subnet is not usable. However, if you have a point-to-point connection and do not need network or broadcast addresses, a 31-bit subnet is a useful way to preserve addresses in IPv4. For example, the failover link between 2 Firewall Threat Defenses only requires 2 addresses; any packet that is transmitted by one end of the link is always received by the other, and broadcasting is unnecessary. You can also have a directly-connected management station running SNMP or Syslog.

31-Bit Subnet and Clustering

You can use a 31-bit subnet mask for cluster interfaces, excluding the management interface and the Cluster Control Link.

31-Bit Subnet and Failover

For failover, when you use a 31-bit subnet for the Firewall Threat Defense interface IP address, you cannot configure a standby IP address for the interface because there are not enough addresses. Normally, an interface for failover should have a standby IP address so the active unit can perform interface tests to ensure standby interface health. Without a standby IP address, the Firewall Threat Defense cannot perform any network tests; only the link state can be tracked.

For the failover and optional separate state link, which are point-to-point connections, you can also use a 31-bit subnet.

31-Bit Subnet and Management

If you have a directly-connected management station, you can use a point-to-point connection for SSH or HTTP on the Firewall Threat Defense, or for SNMP or Syslog on the management station.

31-Bit Subnet Unsupported Features

The following features do not support the 31-Bit subnet:

- BVI interfaces for bridge groups—The bridge group requires at least 3 host addresses: the BVI, and two hosts connected to two bridge group member interfaces. you must use a /29 subnet or smaller.

- Multicast Routing

Guidelines and Limitations for Routed and Transparent Mode Interfaces

High Availability, Clustering, and Multi-Instance

- Do not configure failover links with the procedures in this chapter. See the High Availability chapter for more information.
- For cluster interfaces, see the clustering chapter for requirements.
- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- When you use High Availability, you must set the IP address and standby address for data interfaces manually; DHCP and PPPoE are not supported. Set the standby IP addresses on the **Devices** > **Device Management** > **High Availability** tab in the **Monitored Interfaces** area. See the High Availability chapter for more information.

IPv6

- IPv6 is supported on all interfaces.
- You can only configure IPv6 addresses manually in transparent mode.
- The Firewall Threat Defense device does not support IPv6 anycast addresses.
- DHCPv6 and prefix delegation options are not supported with transparent mode, clustering, or High Availability.

Model Guidelines

- For the Firewall Threat Defense Virtual on VMware with bridged ixgbevf interfaces, bridge groups are not supported.
- For the Firepower 2100 series, bridge groups are not supported in routed mode.

Transparent Mode and Bridge Group Guidelines

- You can create up to 250 bridge groups, with 64 interfaces per bridge group.
- Each directly-connected network must be on the same subnet.
- The Firewall Threat Defense device does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.
- An IP address for the BVI is required for each bridge group for to-the-device and from-the-device management traffic, as well as for data traffic to pass through the Firewall Threat Defense device. For IPv4 traffic, specify an IPv4 address. For IPv6 traffic, specify an IPv6 address.
- You can only configure IPv6 addresses manually.
- The BVI IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255).

- Management interfaces are not supported as bridge group members.
- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- For the Firewall Threat Defense Virtual on VMware with bridged ixgbevf interfaces, transparent mode is not supported, and bridge groups are not supported in routed mode.
- For the Firepower 2100 series, bridge groups are not supported in routed mode.
- For the Firepower 1010, you cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.
- For the Firepower 4100/9300, data-sharing interfaces are not supported as bridge group members.
- In transparent mode, you must use at least 1 bridge group; data interfaces must belong to a bridge group.
- In transparent mode, do not specify the BVI IP address as the default gateway for connected devices; devices need to specify the router on the other side of the Firewall Threat Defense as the default gateway.
- In transparent mode, the *default* route, which is required to provide a return path for management traffic, is only applied to management traffic from one bridge group network. This is because the default route specifies an interface in the bridge group as well as the router IP address on the bridge group network, and you can only define one default route. If you have management traffic from more than one bridge group network, you need to specify a regular static route that identifies the network from which you expect management traffic.
- Transparent mode is not supported on threat defense virtual instances deployed on Amazon Web Services, Microsoft Azure, Google Cloud Platform, and Oracle Cloud Infrastructure.
- In routed mode, to route between bridge groups and other routed interfaces, you must name the BVI.
- In routed mode, Firewall Threat Defense-defined EtherChannel interfaces are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the Firewall Threat Defense when using bridge group members. If there are two neighbors on either side of the Firewall Threat Defense running BFD, then the Firewall Threat Defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.

Additional Guidelines and Requirements

- The Firewall Threat Defense supports only one 802.1Q header in a packet and does not support multiple headers (known as Q-in-Q support) for firewall interfaces.**Note:** For inline sets and passive interfaces, the FTD supports Q-in-Q up to two 802.1Q headers in a packet, with the exception of the Firepower 4100/9300, which only supports one 802.1Q header.
- Interface problems, such as frequent up/down status changes, can prevent the floating connection timer from applying correctly to the connections going through the interface. If you have problems with an interface's status, consider clearing all connections after the status becomes stable to clear invalid connections.

Configure Routed Mode Interfaces

This procedure describes how to set the name, security zone, and IPv4 address.

Note Not all fields are supported for all interface types.

Before you begin

- **Firepower 4100/9300**
  1. Configure a Physical Interface, on page 478
  2. (Optional) Configure any special interfaces.
     - Add an EtherChannel (Port Channel), on page 479
     - Add a VLAN Subinterface for Container Instances, on page 482 in FXOS
     - Configure a Loopback Interface, on page 924
     - Add a Subinterface, on page 930 in Firewall Management Center
     - Configure VXLAN Interfaces, on page 940
- (Optional) **All other models:**
  - Configure an EtherChannel, on page 880
  - Configure a Loopback Interface, on page 924
  - Add a Subinterface, on page 930
  - Configure VXLAN Interfaces, on page 940
  - Firewall Threat Defense Virtual on AWS: Configure Geneve Interfaces, on page 943
  - Firepower 1010: Configure a VLAN Interface, on page 915

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 In the **Name** field, enter a name up to 48 characters in length.

You cannot start the name with the phrase "cluster". It is reserved for internal use.

Step 4 Enable the interface by checking the **Enabled** check box.

Step 5 (Optional) Set this interface to **Management Only** to limit traffic to management traffic; through-the-box traffic is not allowed.

Step 6 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 7 In the **Mode** drop-down list, choose **None**.

Regular firewall interfaces have the mode set to None. The other modes are for IPS-only interface types.

Step 8 From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

The routed interface is a Routed-type interface, and can only belong to Routed-type zones.

Step 9 See Configure the MTU, on page 973 for information about the **MTU**.

Step 10 In the **Priority** field, enter a number ranging from 0–65535.

This value is used in the policy based routing configuration. The priority is used to determine how you want to route the traffic across multiple egress interfaces. For more information, see Configure Policy-Based Routing Policy, on page 1411.

Step 11 Click the **IPv4** tab. To set the IP address, use one of the following options from the **IP Type** drop-down list.

High Availability, clustering, and loopback interfaces only support static IP address configuration; DHCP and PPPoE are not supported.

- **Use Static IP**—Enter the IP address and subnet mask. For point-to-point connections, you can specify a 31-bit subnet mask (255.255.255.254 or /31). In this case, no IP addresses are reserved for the network or broadcast addresses. You cannot set the standby IP address in this case. For High Availability, you can only use a static IP address. Set the standby IP address on the **Devices** > **Device Management** page, click **High Availability** in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.
- **Use DHCP**—Configure the following optional parameters:
  - **Obtain default route using DHCP**—Obtains the default route from the DHCP server.
  - **DHCP route metric**—Assigns an administrative distance to the learned route, between 1 and 255. The default administrative distance for the learned routes is 1.
- **Use PPPoE**—If the interface is connected to a DSL, cable modem, or other connection to your ISP, and your ISP uses PPPoE to provide your IP address, configure the following parameters:
  - **VPDN Group Name**—Specify a group name of your choice to represent this connection.
  - **PPPoE User Name**—Specify the username provided by your ISP.
  - **PPPoE Password/Confirm Password**—Specify and confirm the password provided by your ISP.
  - **PPP Authentication**—Choose **PAP**, **CHAP**, or **MSCHAP**.

    PAP passes a cleartext username and password during authentication and is not secure. With CHAP, the client returns the encrypted [challenge plus password], with a cleartext username in response to the server challenge. CHAP is more secure than PAP, but it does not encrypt data. MSCHAP is similar to CHAP but is more secure because the server stores and compares only encrypted passwords rather than cleartext passwords as in CHAP. MSCHAP also generates a key for data encryption by MPPE.
  - **PPPoE route metric**—Assign an administrative distance to the learned route. Valid values are from 1 to 255. By default, the administrative distance for the learned routes is 1.
  - **Enable Route Settings**—To manually configure the PPPoE IP address, check this box and then enter the **IP Address**.

If you select the **Enable Route Settings** check box and leave the **IP Address** blank, the **ip address pppoe setroute** command is applied as shown in this example:

```
interface GigabitEthernet0/2
nameif inside2_pppoe
cts manual
  propagate sgt preserve-untag
  policy static sgt disabled trusted
security-level 0
pppoe client vpdn group test
pppoe client route distance 10
ip address pppoe setroute
```

- **Store Username and Password in Flash**—Stores the username and password in flash memory.

  The Firewall Threat Defense device stores the username and password in a special location of NVRAM.

Step 12 (Optional) See Configure IPv6 Addressing, on page 957 to configure IPv6 addressing on the **IPv6** tab.

Step 13 (Optional) See Configure the MAC Address, on page 974 to manually configure the MAC address on the **Advanced** tab.

Step 14 (Optional) Set the duplex and speed by clicking **Hardware Configuration** > **Speed**.

- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex.
- **Speed**—Choose a speed (varies depending on the model). (Secure Firewall 3100 only) Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.

  Note
  You cannot modify the speed of a HA or a Cluster Control Link interface.

- **Auto-negotiation**—Set the interface to negotiate the speed, link status, and flow control.

  Note
  If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the Threat Defense interface as well. For example, N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, you must disable the default auto-negotiation on the platform and the switch for the port to be connected.

- **Forward Error Correction Mode**—(Secure Firewall 3100 only) For 25Gbps and higher interfaces, enable Forward Error Correction (FEC). For an EtherChannel member interface, you must configure FEC before you add it to the EtherChannel. The setting chosen when you use **Auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

Table 70: Default FEC for Auto Setting

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-SR	Clause 74 FC-FEC	Clause 108 RS-FEC
25G-LR	Clause 74 FC-FEC	Clause 108 RS-FEC
10/25G-CSR	Clause 74 FC-FEC	Clause 74 FC-FEC

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-AOC*x*M	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-CU2.5/3M	Auto-Negotiate	Auto-Negotiate
25G-CU4/5M	Auto-Negotiate	Auto-Negotiate

Step 15 (Optional) Enable Firewall Management Center manager access on a data interface on the **Manager Access** page.

You can enable manager access from a data interface when you first setup the Firewall Threat Defense. If you want to enable or disable manager access after you added the Firewall Threat Defense to the Firewall Management Center, see:

- Enable manager access: Change the Manager Access Interface from Management to Data, on page 111

  Note
  You cannot enable manager access unless you first initiate the manager interface migration from Management to a data interface. After you initiate the migration, you can enable manager access on the **Manager Access** page and save the configuration successfully.

- Disable manager access: Change the Manager Access Interface from Data to Management, on page 115

If you want to change the manager access interface from one data interface to another data interface, you must disable manager access on the original data interface, but do not disable the interface itself yet; the original data interface must be used to perform the deployment. If you want to use the same IP address on the new manager access interface, you can delete or change the IP configuration on the original interface; this change should not affect the deployment. If you use a different IP address for the new interface, then also change the device IP address shown in the Firewall Management Center; see Update the Hostname or IP Address in the Firewall Management Center, on page 104. Be sure to also update related configuration to use the new interface such as static routes, DDNS, and DNS settings.

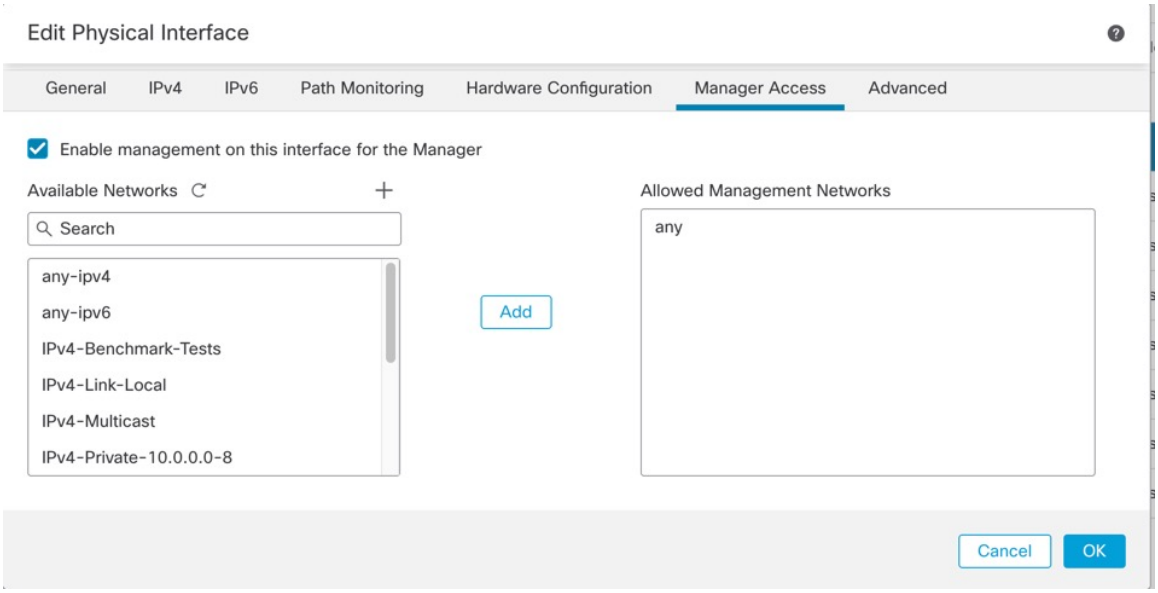
Manager access from a data interface has the following limitations:

- You can only enable manager access on a physical, data interface. You cannot use a subinterface or EtherChannel, nor can you create a subinterface on the manager access interface. You can also use the Firewall Management Center to enable manager access on a single secondary interface for redundancy.
- This interface cannot be management-only.
- Routed firewall mode only, using a routed interface.
- PPPoE is not supported. If your ISP requires PPPoE, you will have to put a router with PPPoE support between the Firewall Threat Defense and the WAN modem.
- The interface must be in the global VRF only.
- SSH is not enabled by default for data interfaces, so you will have to enable SSH later using the Firewall Management Center. Because the Management interface gateway will be changed to be the data interfaces, you also cannot SSH to the Management interface from a remote network unless you add a static route for the Management interface using the **configure network static-routes** command. For Firewall Threat Defense Virtual on Amazon Web Services, a console port is not available, so you should maintain your SSH access to the Management interface: add a static route for Management before you continue with

your configuration. Alternatively, be sure to finish all CLI configuration (including the **configure manager add** command) before you configure the data interface for manager access and you are disconnected.

- Clustering is not supported. You must use the Management interface in this case.

Figure 310: Manager Access



- Check **Enable management on this interface for the manager** to use this data interface for management instead of the dedicated Management interface.
- (Optional) In the **Allowed Management Networks** box, add the networks from which you want to allow manager access. By default, any networks are allowed.

Step 16 Click **OK**.

Step 17 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Bridge Group Interfaces

A bridge group is a group of interfaces that the Secure Firewall Threat Defense device bridges instead of routes. Bridge groups are supported in both transparent and routed firewall mode. For more information about bridge groups, see About Bridge Groups, on page 433.

To configure bridge groups and associated interfaces, perform these steps.

Configure General Bridge Group Member Interface Parameters

This procedure describes how to set the name and security zone for each bridge group member interface. The same bridge group can include different types of interfaces: physical interfaces, VLAN subinterfaces, Firepower

1010 VLAN interfaces, EtherChannels, and redundant interfaces. The Management interface is not supported. In routed mode, EtherChannels are not supported. For the Firepower 4100/9300, data-sharing type interfaces are not supported.

Before you begin

- **Firepower 4100/9300**
  1. Configure a Physical Interface, on page 478
  2. (Optional) Configure any special interfaces.
     - Add an EtherChannel (Port Channel), on page 479
     - Add a VLAN Subinterface for Container Instances, on page 482 in FXOS
     - Add a Subinterface, on page 930 in Firewall Management Center
- (Optional) **All other models:**
  - Configure an EtherChannel, on page 880
  - Add a Subinterface, on page 930
  - Firepower 1010: Configure a VLAN Interface, on page 915

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 In the **Name** field, enter a name up to 48 characters in length.

You cannot start the name with the phrase "cluster". It is reserved for internal use.

Step 4 Enable the interface by checking the **Enabled** check box.

Step 5 (Optional) Set this interface to **Management Only** to limit traffic to management traffic; through-the-box traffic is not allowed.

Step 6 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 7 In the **Mode** drop-down list, choose **None**.

Regular firewall interfaces have the mode set to None. The other modes are for IPS-only interface types. After you assign this interface to a bridge group, the mode will show as **Switched**.

Step 8 From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

The bridge group member interface is a Switched-type interface, and can only belong to Switched-type zones. Do not configure any IP address settings for this interface. You will set the IP address for the Bridge Virtual Interface (BVI) only. Note that the BVI does not belong to a zone, and you cannot apply access control policies to the BVI.

Step 9 See Configure the MTU, on page 973 for information about the **MTU**.

Step 10 (Optional) Set the duplex and speed by clicking **Hardware Configuration** > **Speed**.

- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex.
- **Speed**—Choose a speed (varies depending on the model). (Secure Firewall 3100 only) Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.

  Note
  You cannot modify the speed of a HA or a Cluster Control Link interface.

- **Auto-negotiation**—Set the interface to negotiate the speed, link status, and flow control.

  Note
  If a peer switch connecting to the port over a 50G cable does not support auto-negotiation, ensure to disable auto-negotiation on the switch and the Threat Defense interface as well. For example, N9K-C93400LD-H1 does not support auto-negotiation on a 50G cable. Hence, you must disable the default auto-negotiation on the platform and the switch for the port to be connected.

- **Forward Error Correction Mode**—(Secure Firewall 3100 only) For 25Gbps and higher interfaces, enable Forward Error Correction (FEC). For an EtherChannel member interface, you must configure FEC before you add it to the EtherChannel. The setting chosen when you use **Auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

Table 71: Default FEC for Auto Setting

Transceiver Type	Fixed Port Default FEC (Ethernet 1/9 through 1/16)	Network Module Default FEC
25G-SR	Clause 74 FC-FEC	Clause 108 RS-FEC
25G-LR	Clause 74 FC-FEC	Clause 108 RS-FEC
10/25G-CSR	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-AOC*x*M	Clause 74 FC-FEC	Clause 74 FC-FEC
25G-CU2.5/3M	Auto-Negotiate	Auto-Negotiate
25G-CU4/5M	Auto-Negotiate	Auto-Negotiate

Step 11 (Optional) See Configure IPv6 Addressing, on page 957 to configure IPv6 addressing on the **IPv6** tab.

Step 12 (Optional) See Configure the MAC Address, on page 974 to manually configure the MAC address on the **Advanced** tab.

Step 13 Click **OK**.

Step 14 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure the Bridge Virtual Interface (BVI)

Each bridge group requires a BVI for which you configure an IP address. The Firewall Threat Defense uses this IP address as the source address for packets originating from the bridge group. The BVI IP address must be on the same subnet as the connected network. For IPv4 traffic, the BVI IP address is required to pass any traffic. For IPv6 traffic, you must, at a minimum, configure the link-local addresses to pass traffic, but a global management address is recommended for full functionality, including remote management and other management operations.

For routed mode, if you provide a name for the BVI, then the BVI participates in routing. Without a name, the bridge group remains isolated as in transparent firewall mode.

Before you begin

You cannot add the BVI to a security zone; therefore, you cannot apply Access Control policies to the BVI. You must apply your policy to the bridge group member interfaces based on their zones.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Choose **Add Interfaces** > **Bridge Group Interface**.

Step 3 (Routed Mode) In the **Name** field, enter a name up to 48 characters in length.

You must name the BVI if you want to route traffic outside the bridge group members, for example, to the outside interface or to members of other bridge groups. The name is not case-sensitive.

Step 4 In the **Bridge Group ID** field, enter the bridge group ID between 1 and 250.

Step 5 In the **Description** field, enter a description for this bridge group.

Step 6 On the **Interfaces** tab, click an interface and then click **Add** to move it to the **Selected Interfaces** area. Repeat for all interfaces that you want to make members of the bridge group.

Step 7 (Transparent Mode) Click the **IPv4** tab. In the **IP Address** field, enter the IPv4 address and subnet mask.

Do not assign a host address (/32 or 255.255.255.255) to the BVI. Also, do not use other subnets that contain fewer than 3 host addresses (one each for the upstream router, downstream router, and transparent firewall) such as a /30 subnet (255.255.255.252). The Firewall Threat Defense device drops all ARP packets to or from the first and last addresses in a subnet. For example, if you use a /30 subnet and assign a reserved address from that subnet to the upstream router, then the Firewall Threat Defense device drops the ARP request from the downstream router to the upstream router.

For High Availability, set the standby IP address on the **Devices** > **Device Management** page, click the **High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.

Step 8 (Routed Mode) Click the **IPv4** tab. To set the IP address, use one of the following options from the **IP Type** drop-down list.

High Availability and clustering interfaces only support static IP address configuration; DHCP is not supported.

- **Use Static IP**—Enter the IP address and subnet mask. For High Availability, you can only use a static IP address. Set the standby IP address on the **Devices** > **Device Management**, click the **High Availability**

tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.

- **Use DHCP**—Configure the following optional parameters:
  - **Obtain default route using DHCP**—Obtains the default route from the DHCP server.
  - **DHCP route metric**—Assigns an administrative distance to the learned route, between 1 and 255. The default administrative distance for the learned routes is 1.

Step 9 (Optional) See Configure IPv6 Addressing, on page 957 to configure IPv6 addressing.

Step 10 (Optional) See Add a Static ARP Entry, on page 975 and Add a Static MAC Address and Disable MAC Learning for a Bridge Group, on page 976 (for transparent mode only) to configure the **ARP** and **MAC** settings.

Step 11 Click **OK**.

Step 12 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure IPv6 Addressing

This section describes how to configure IPv6 addressing in routed and transparent mode.

About IPv6

This section includes information about IPv6.

IPv6 Addressing

You can configure two types of unicast addresses for IPv6:

- Global—The global address is a public address that you can use on the public network. For a bridge group, this address needs to be configured for the BVI, and not per member interface. You can also configure a global IPv6 address for the management interface in transparent mode.
- Link-local—The link-local address is a private address that you can only use on the directly-connected network. Routers do not forward packets using link-local addresses; they are only for communication on a particular physical network segment. They can be used for address configuration or for the Neighbor Discovery functions such as address resolution. In a bridge group, only member interfaces have link-local addresses; the BVI does not have a link-local address.

At a minimum, you need to configure a link-local address for IPv6 to operate. If you configure a global address, a link-local address is automatically configured on the interface, so you do not also need to specifically configure a link-local address. For bridge group member interfaces, when you configure the global address on the BVI, the Firewall Threat Defense device automatically generates link-local addresses for member interfaces. If you do not configure a global address, then you need to configure the link-local address, either automatically or manually.

Modified EUI-64 Interface IDs

RFC 3513: Internet Protocol Version 6 (IPv6) Addressing Architecture requires that the interface identifier portion of all unicast IPv6 addresses, except those that start with binary value 000, be 64 bits long and be constructed in Modified EUI-64 format. The Firewall Threat Defense device can enforce this requirement for hosts attached to the local link.

When this feature is enabled on an interface, the source addresses of IPv6 packets received on that interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the IPv6 packets do not use the Modified EUI-64 format for the interface identifier, the packets are dropped and the following system log message is generated:

```
325003: EUI-64 source address check failed.
```

The address format verification is only performed when a flow is created. Packets from an existing flow are not checked. Additionally, the address verification can only be performed for hosts on the local link.

Configure the IPv6 Prefix Delegation Client

The Firewall Threat Defense can act as a DHPCv6 Prefix Delegation client so that the client interface, for example the outside interface connected to a cable modem, can receive one or more IPv6 prefixes that the Firewall Threat Defense can then subnet and assign to its inside interfaces.

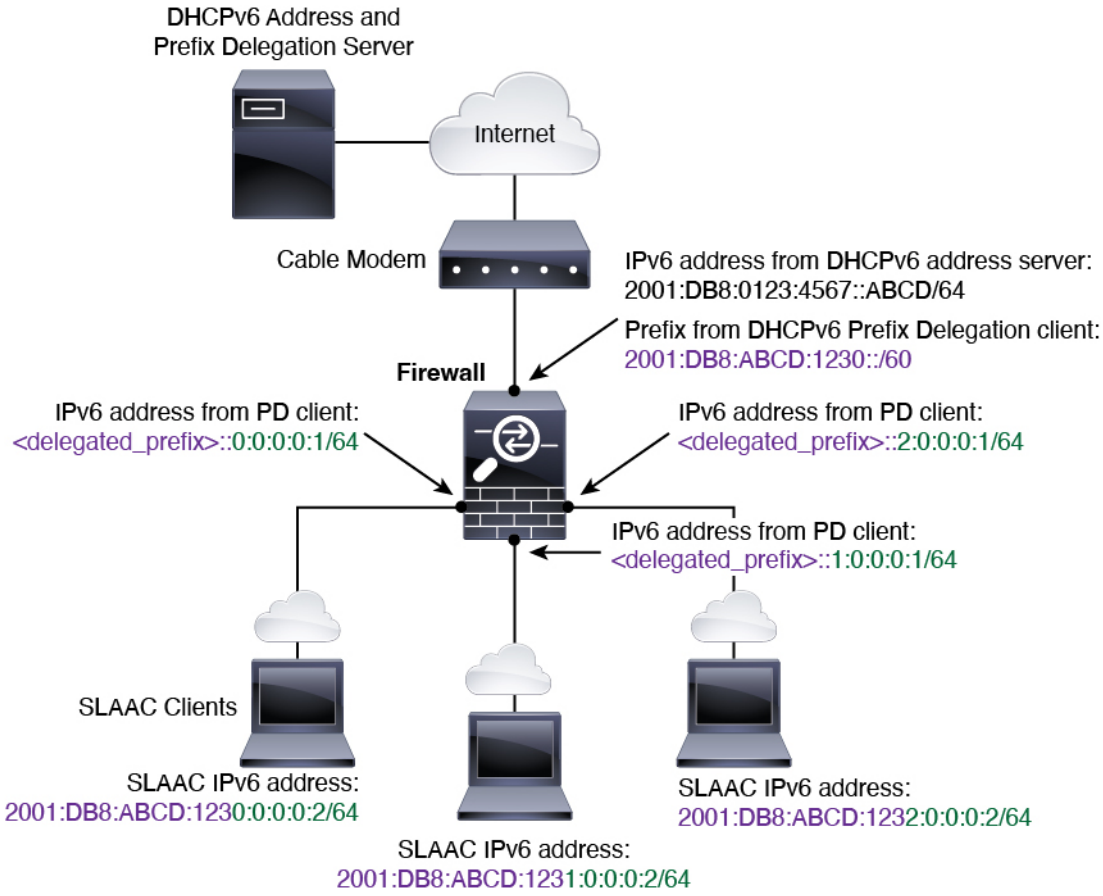
About IPv6 Prefix Delegation

The Firewall Threat Defense can act as a DHPCv6 Prefix Delegation client so that the client interface, for example the outside interface connected to a cable modem, can receive one or more IPv6 prefixes that the Firewall Threat Defense can then subnet and assign to its inside interfaces. Hosts connected to the inside interfaces can then use StateLess Address Auto Configuration (SLAAC) to obtain global IPv6 addresses. Note that the inside Firewall Threat Defense interfaces do not in turn act as Prefix Delegation servers; the Firewall Threat Defense can only provide global IP addresses to SLAAC clients. For example, if a router is connected to the Firewall Threat Defense, it can act as a SLAAC client to obtain its IP address. But if you want to use a subnet of the delegated prefix for the networks behind the router, you must manually configure those addresses on the router's inside interfaces.

The Firewall Threat Defense includes a light DHCPv6 server so the Firewall Threat Defense can provide information such as the DNS server and domain name to SLAAC clients when they send Information Request (IR) packets to the Firewall Threat Defense. The Firewall Threat Defense only accepts IR packets, and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the Firewall Threat Defense received using Prefix Delegation.

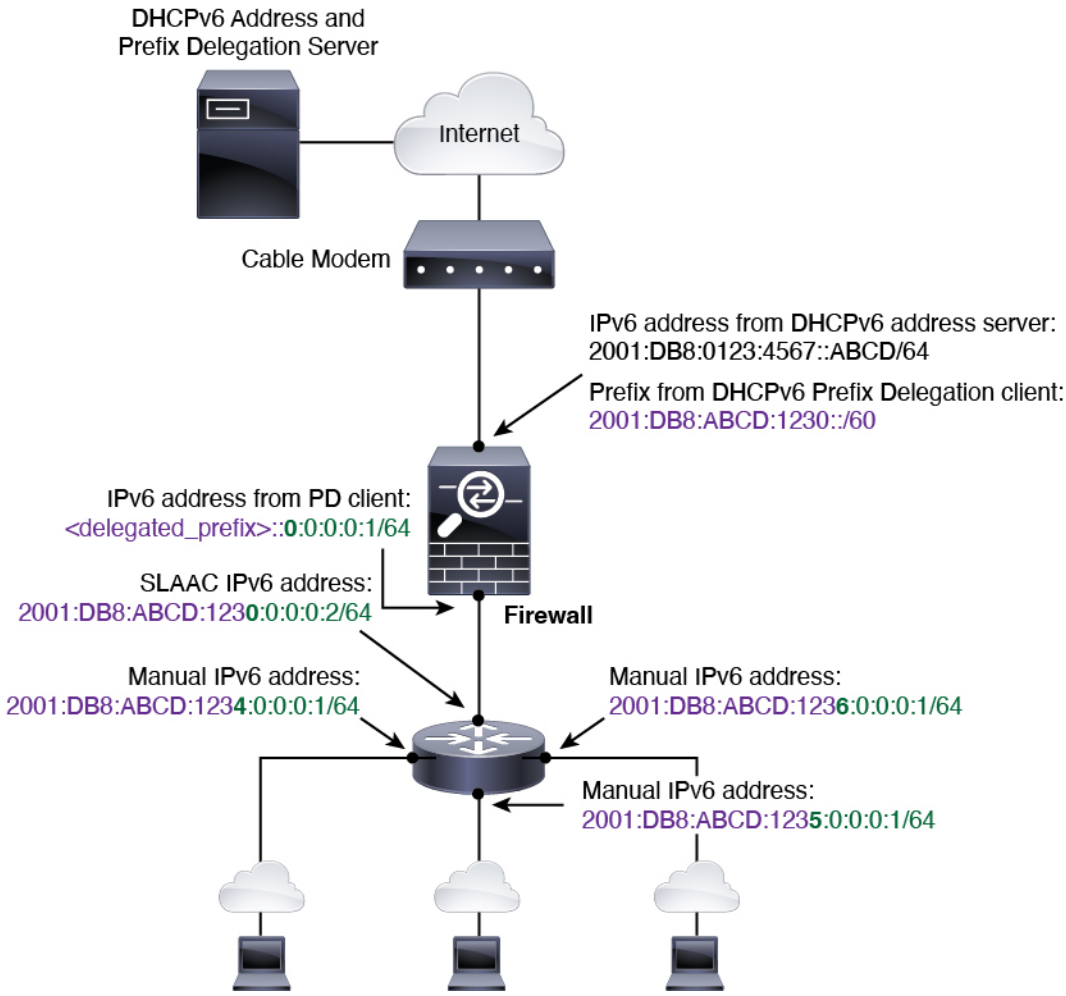
IPv6 Prefix Delegation /64 Subnet Example

The following example shows the Firewall Threat Defense receiving an IP address on the outside interface using the DHCPv6 address client. It also gets a delegated prefix using the DHCPv6 Prefix Delegation client. The Firewall Threat Defense subnets the delegated prefix into /64 networks and assigns global IPv6 addresses to its inside interfaces dynamically using the delegated prefix plus a manually configured subnet (::0, ::1, or ::2) and IPv6 address (0:0:0:1) per interface. SLAAC clients connected to those inside interfaces obtain IPv6 addresses on each /64 subnet.



IPv6 Prefix Delegation /62 Subnet Example

The following example shows the Firewall Threat Defense subnetting the prefix into 4 /62 subnets: 2001:DB8:ABCD:123**0**::/62, 2001:DB8:ABCD:123**4**::/62, 2001:DB8:ABCD:123**8**::/62, and 2001:DB8:ABCD:123**C**::/62. The Firewall Threat Defense uses one of 4 available /64 subnets on 2001:DB8:ABCD:1230::/62 for its inside network (::0). You can then manually use additional /62 subnets for downstream routers. The router shown uses 3 of 4 available /64 subnets on 2001:DB8:ABCD:1234::/62 for its inside interfaces (::4, ::5, and ::6). In this case, the inside router interfaces cannot dynamically obtain the delegated prefix, so you need to view the delegated prefix on the Firewall Threat Defense, and then use that prefix for your router configuration. Usually, ISPs delegate the same prefix to a given client when the lease expires, but if the Firewall Threat Defense receives a new prefix, you will have to modify the router configuration to use the new prefix. The DHCP unique identifier (DUID) is persistent across reboots.



Enable the IPv6 Prefix Delegation Client

Enable the DHCPv6 Prefix Delegation client on one or more interfaces. The Firewall Threat Defense obtains one or more IPv6 prefixes that it can subnet and assign to inside networks. Typically, the interface on which you enable the prefix delegation client obtains its IP address using the DHCPv6 address client; only other Firewall Threat Defense interfaces use addresses derived from the delegated prefix.

This feature is only supported in routed mode. This feature is not supported in clustering or High Availability.

Before you begin

When you use Prefix Delegation, you must set the Firewall Threat Defense IPv6 neighbor discovery router advertisement interval to be much lower than the preferred lifetime of the prefix assigned by the DHCPv6 Server to prevent IPv6 traffic interruption. For example, if the DHCPv6 server sets the preferred Prefix Delegation lifetime to 300 seconds, you should set the Firewall Threat Defense RA interval to be 150 seconds. To set the preferred lifetime, use the **show ipv6 general-prefix** command. To set the Firewall Threat Defense RA interval, see Configure IPv6 Neighbor Discovery, on page 966; the default is 200 seconds.

Procedure

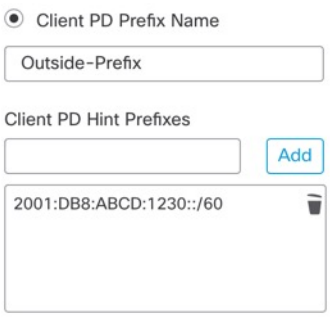
Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **IPv6** page, and then click **DHCP**.

Step 4 Click **Client PD Prefix Name** and enter a name for this prefix.

Figure 311: Enable the Prefix Delegation Client



The name can be up to 200 characters.

Step 5 (Optional) Enter the prefix and prefix length in the **Client PD Hint Prefixes** field to provide one or more hints to the DHCP server about the delegated prefix you want to receive, then click **Add**.

Typically you want to request a particular prefix length, such as ::/60, or if you have received a particular prefix before and want to ensure you get it again when the lease expires, you can enter the whole prefix as the hint. If you enter multiple hints (different prefixes or lengths), then it is up to the DHCP server which hint to honor, or whether to honor the hint at all.

Step 6 Click **OK**.

Step 7 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure a Global IPv6 Address

To configure a global IPv6 address for any routed mode interface and for the transparent or routed mode BVI, perform the following steps.

Note Configuring the global address automatically configures the link-local address, so you do not need to configure it separately. For bridge groups, configuring the global address on the BVI automatically configures link-local addresses on all member interfaces.

For subinterfaces defined on the Firewall Threat Defense, we recommend that you also set the MAC address manually, because they use the same burned-in MAC address of the parent interface. IPv6 link-local addresses are generated based on the MAC address, so assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the Firewall Threat Defense. See Configure the MAC Address, on page 974.

Before you begin

For IPv6 neighbor discovery for bridge groups, you must explicitly allow Neighbor Solicitation (ICMPv6 type 135) and Neighbor Advertisement (ICMPv6 type 136) packets through the Firewall Threat Defense bridge group member interfaces using a bidirectional access rule.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Click the **IPv6** page.

For routed mode, the **Basic** page is selected by default. For transparent mode, the **Address** page is selected by default.

Step 4 (Optional) On the **Basic** page, check **Enable IPv6**.

Use this option if you want to only configure the link-local addresses. Otherwise, configuring an IPv6 address enabled IPv6 processing automatically.

Step 5 Configure the global IPv6 address using one of the following methods.

For failover and clustering, and for loopback interfaces, you must set the IP address manually. For clustering, manually configuring the link-local address is also not supported.

- (Routed interface) Stateless autoconfiguration—Check the **Autoconfiguration** check box.

  Enabling stateless autoconfiguration on the interface configures IPv6 addresses based upon prefixes received in Router Advertisement messages. A link-local address, based on the Modified EUI-64 interface ID, is automatically generated for the interface when stateless autoconfiguration is enabled.

  Although RFC 4862 specifies that hosts configured for stateless autoconfiguration do not send Router Advertisement messages, the Firewall Threat Defense device does send Router Advertisement messages in this case. Click the **Settings** tab and click the **IPv6** tab and then uncheck the **Enable RA** check box to suppress messages.

- Manual configuration—To manually configure a global IPv6 address:

  a. Click the **Address** page, and click ( )**Add Address**.

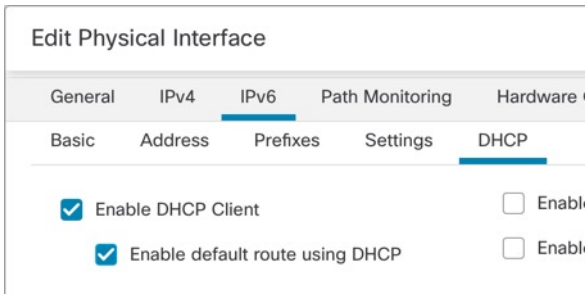
The **Add Address** dialog box appears.

b. In the **Address** field, enter either a full global IPv6 address, including the interface ID, or enter the IPv6 prefix, along with the IPv6 prefix length. (Routed Mode) If you only enter the prefix, then be sure to check the **Enforce EUI 64** check box to generate the interface ID using the Modified EUI-64 format. For example, 2001:0DB8::BA98:0:3210/48 (full address) or 2001:0DB8::/48 (prefix, with EUI 64 checked).

For High Availability (if you did not set **Enforce EUI 64**), set the standby IP address on the **Devices** > **Device Management** page, click **High Availability** in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.

- (Routed interface) Obtain an address using DHCPv6—To use DHCPv6:

Figure 312: Enable the DHCPv6 Client



a. Click the **DHCP** page.

b. Check the check box of **Enable DHCP Client**.

c. (Optional) Check the check box of **Enable default route using DHCP** to obtain a default route from Router Advertisements.

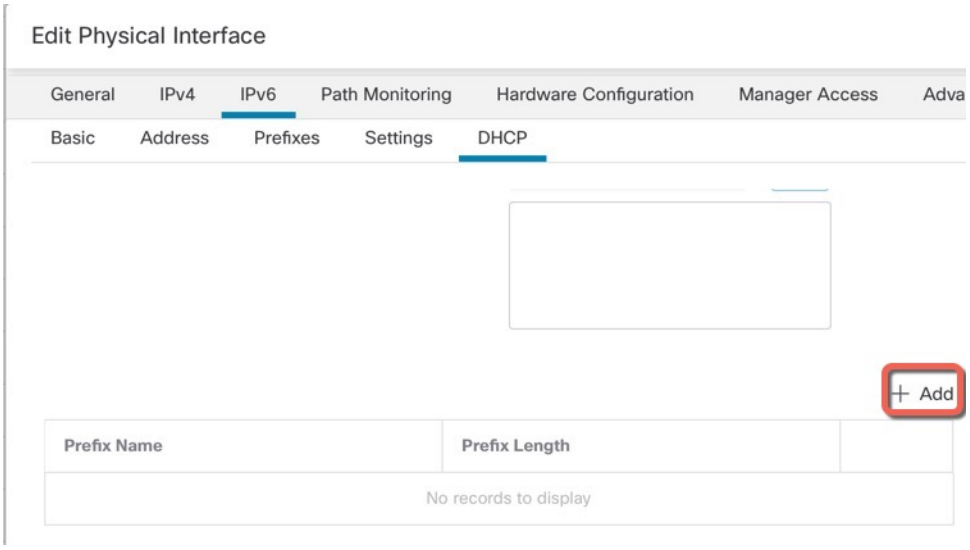
- (Routed interface) Use a delegated prefix—To assign an IPv6 address using the delegated prefix:

This feature requires the Firewall Threat Defense to have the DHCPv6 Prefix Delegation client enabled *on a different interface*. See Enable the IPv6 Prefix Delegation Client, on page 960.

a. Click the **DHCP** page.

b. Click (+).

Figure 313: Use a Delegated Prefix

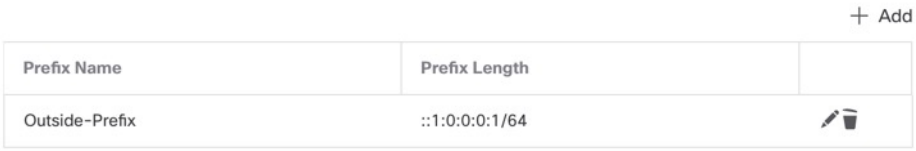


c. Enter the IPv6 address and **Prefix Length**.

Typically, the delegated prefix will be /60 or smaller so you can subnet to multiple /64 networks. /64 is the supported subnet length if you want to support SLAAC for connected clients. You should specify an address that completes the /60 subnet, for example ::1:0:0:0:1. Enter :: before the address in case the prefix is smaller than /60. For example, if the delegated prefix is 2001:DB8:1234:5670::/60, then the global IP address assigned to this interface is 2001:DB8:1234:5671::1/64. The prefix that is advertised in router advertisements is 2001:DB8:1234:5671::/64. In this example, if the prefix is smaller than /60, the remaining bits of the prefix will be 0's as indicated by the leading ::. For example, if the prefix is 2001:DB8:1234::/48, then the IPv6 address will be 2001:DB8:1234::1:0:0:0:1/64.

d. Click **OK**.

Figure 314: Prefix Delegation Table



e. Optionally enable the DHCPv6 stateless server on this interface (see Enable the DHCPv6 Stateless Server, on page 1005). If you do so, we recommend that you also check the **Enable DHCP for non-address config** option.

Step 6 For Routed interfaces, you can optionally set the following values on the **Basic** page:

- To enforce the use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link, check the **Enforce EUI-64** check box.
- To manually set the link-local address, enter an address in the **Link-Local address** field.

A link-local address should start with FE8, FE9, FEA, or FEB, for example fe80::20d:88ff:feee:6a82. If you do not want to configure a global address, and only need to configure a link-local address, you have the option of manually defining the link-local address. Note that we recommend automatically assigning the link-local address based on the Modified EUI-64 format. For example, if other devices enforce the use of the Modified EUI-64 format, then a manually-assigned link-local address may cause packets to be dropped.

Clustering does not support manual link-local addresses.

Step 7 For Routed interfaces, you can optionally set the following values on the **DHCP** page:

- Check the **Enable DHCP for address config** check box to set the Managed Address Config flag in the IPv6 router advertisement packet.

  This flag in IPv6 router advertisements informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain addresses, in addition to the derived stateless autoconfiguration address.

- Check the **Enable DHCP for non-address config** check box to set the Other Address Config flag in the IPv6 router advertisement packet.

  This flag in IPv6 router advertisements informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain additional information from DHCPv6, such as the DNS server address. Use this option when using the DHCPv6 stateless server with DHCPv6 prefix delegation.

Step 8 For Routed interfaces, see Configure IPv6 Neighbor Discovery, on page 966 to configure settings on the **Prefixes** and **Settings** pages. For BVI interfaces, see the following parameters on the **Settings** page:

- **DAD attempts**—The maximum number of DAD attempts, between 1 and 600. Set the value to 0 to disable duplicate address detection (DAD) processing. This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses. 1 attempt is the default.
- **NS Interval**—The interval between IPv6 neighbor solicitation retransmissions on an interface, between 1000 and 3600000 ms. The default value is 1000 ms.
- **Reachable Time**—The amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred, between 0 and 3600000 ms. The default value is 0 ms. When 0 is used for the value, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value. The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

Step 9 Click **OK**.

Step 10 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure IPv6 Neighbor Discovery

The IPv6 neighbor discovery process uses ICMPv6 messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), verify the readability of a neighbor, and keep track of neighboring routers.

Nodes (hosts) use neighbor discovery to determine the link-layer addresses for neighbors known to reside on attached links and to quickly purge cached values that become invalid. Hosts also use neighbor discovery to find neighboring routers that are willing to forward packets on their behalf. In addition, nodes use the protocol to actively keep track of which neighbors are reachable and which are not, and to detect changed link-layer addresses. When a router or the path to a router fails, a host actively searches for functioning alternates.

Before you begin

Supported in Routed mode only. For IPv6 neighbor settings supported in transparent mode, see Configure a Global IPv6 Address, on page 961.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Click **IPv6**, and then **Prefixes**.

Step 4 (Optional) To configure which IPv6 prefixes are included in IPv6 router advertisements, perform the following steps:

a) Click ( )**Add Prefix**.

b) In the **Address** field, enter the IPv6 address with the prefix length or check the **Default** check box to use the default prefix.

c) (Optional) Uncheck the **Advertisement** check box to indicate that the IPv6 prefix is not advertised. For the **Default** prefix, this setting only applies to on-link prefixes. Off-link prefixes will still be advertised unless you uncheck **Advertisement** for a specific off-link prefix.

d) Check the **Off Link** check box to indicate that the specified prefix is assigned to the link. Nodes sending traffic to addresses that contain the specified prefix consider the destination to be locally reachable on the link. This prefix should not be used for on-link determination.

e) To use the specified prefix for autoconfiguration, check the **Autoconfiguration** check box.

f) For the **Prefix Lifetime**, click **Duration** or **Expiration Date**.

- **Duration**—Enter a **Preferred Lifetime** for the prefix in seconds. This setting is the amount of time that the specified IPv6 prefix is advertised as being valid. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default is 2592000 (30 days). Enter a **Valid Lifetime** for the prefix in seconds. This setting is the amount of time that the specified IPv6 prefix is advertised as being preferred. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default setting is 604800 (seven days). Alternatively, check the **Infinite** check box to set an unlimited duration.
- **Expiration Date**—Choose a **Valid** and **Preferred** date and time.

g) Click **OK**.

Step 5 Click **Settings**.

Step 6 (Optional) Set the maximum number of **DAD attempts**, between 1 and 600. 1 attempt is the default. Set the value to 0 to disable duplicate address detection (DAD) processing.

This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses.

During the stateless autoconfiguration process, Duplicate Address Detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces.

When a duplicate address is identified, the state of the address is set to DUPLICATE, the address is not used, and the following error message is generated:

```
325002: Duplicate address ipv6_address/MAC_address on interface
```

If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface. If the duplicate address is a global address, the address is not used.

Step 7 (Optional) Configure the interval between IPv6 neighbor solicitation retransmissions in the **NS Interval** field, between 1000 and 3600000 ms.

The default value is 1000 ms.

Neighbor solicitation messages (ICMPv6 Type 135) are sent on the local link by nodes attempting to discover the link-layer addresses of other nodes on the local link. After receiving a neighbor solicitation message, the destination node replies by sending a neighbor advertisement message (ICPMv6 Type 136) on the local link.

After the source node receives the neighbor advertisement, the source node and destination node can communicate. Neighbor solicitation messages are also used to verify the reachability of a neighbor after the link-layer address of a neighbor is identified. When a node wants to verifying the reachability of a neighbor, the destination address in a neighbor solicitation message is the unicast address of the neighbor.

Neighbor advertisement messages are also sent when there is a change in the link-layer address of a node on a local link.

Step 8 (Optional) Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred in the **Reachable Time** field, between 0 and 3600000 ms.

The default value is 0 ms. When 0 is used for the value, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value.

The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

Step 9 (Optional) To suppress the router advertisement transmissions, uncheck the **Enable RA** check box. If you enable router advertisement transmissions, you can set the RA lifetime and interval.

Router advertisement messages (ICMPv6 Type 134) are automatically sent in response to router solicitation messages (ICMPv6 Type 133). Router solicitation messages are sent by hosts at system startup so that the host can immediately autoconfigure without needing to wait for the next scheduled router advertisement message.

You may want to disable these messages on any interface for which you do not want the Firewall Threat Defense to supply the IPv6 prefix (for example, the outside interface).

- **RA Lifetime**—Configure the router lifetime value in IPv6 router advertisements, between 0 and 9000 seconds.

  The default is 1800 seconds.

- **RA Interval**—Configure the interval between IPv6 router advertisement transmissions, between 3 and 1800 seconds.

  The default is 200 seconds.

  To prevent synchronization with other IPv6 nodes, the firewall randomly adjusts the value that you set (jitter).

Step 10 Click **OK**.

Step 11 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Advanced Interface Settings

This section describes how to configure MAC addresses for regular firewall mode interfaces, how to set the maximum transmission unit (MTU), and how to set other advanced parameters.

About Advanced Interface Configuration

This section describes advanced interface settings.

About MAC Addresses

You can manually assign MAC addresses to override the default. For container instances, the FXOS chassis automatically generates unique MAC addresses for all interfaces.

Note You might want to assign unique MAC addresses to subinterfaces defined on the Firewall Threat Defense, because they use the same burned-in MAC address of the parent interface. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the Firewall Threat Defense device.

Note For container instances, even if you are not sharing a subinterface, if you manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification.

Default MAC Addresses

For native instances:

Default MAC address assignments depend on the type of interface.

- Physical interfaces—The physical interface uses the burned-in MAC address.
- VLAN interfaces (Firepower 1010)—Routed firewall mode: All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique MAC addresses, you can manually assign MAC addresses. See Configure the MAC Address, on page 974.

  Transparent firewall mode: Each VLAN interface has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See Configure the MAC Address, on page 974.
- EtherChannels (Firepower Models)—For an EtherChannel, all interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. The port-channel interface uses a unique MAC address from a pool; interface membership does not affect the MAC address.
- EtherChannels (ASA Models)—The port-channel interface uses the lowest-numbered channel group interface MAC address as the port-channel MAC address. Alternatively you can configure a MAC address for the port-channel interface. We recommend configuring a unique MAC address in case the group channel interface membership changes. If you remove the interface that was providing the port-channel MAC address, then the port-channel MAC address changes to the next lowest numbered interface, thus causing traffic disruption.
- Subinterfaces (Firewall Threat Defense-defined)—All subinterfaces of a physical interface use the same burned-in MAC address. You might want to assign unique MAC addresses to subinterfaces. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the Firewall Threat Defense.

For container instances:

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. See Automatic MAC Addresses for Container Instance Interfaces, on page 465.

About the MTU

The MTU specifies the maximum frame *payload* size that the Firewall Threat Defense device can transmit on a given Ethernet interface. The MTU value is the frame size *without* Ethernet headers, VLAN tagging, or other overhead. For example, when you set the MTU to 1500, the expected frame size is 1518 bytes including the headers, or 1522 when using VLAN. Do not set the MTU value higher to accommodate these headers.

For Geneve, the entire Ethernet datagram is being encapsulated, so the new IP packet is larger and requires a larger MTU: you should set the Firewall Threat Defense device VTEP source interface MTU to be the network MTU + 306 bytes.

Path MTU Discovery

The Firewall Threat Defense device supports Path MTU Discovery (as defined in RFC 1191), which lets all devices in a network path between two hosts coordinate the MTU so they can standardize on the lowest MTU in the path.

Default MTU

The default MTU on the Firewall Threat Defense device is 1500 bytes. This value does not include the 18-22 bytes for the Ethernet header, VLAN tagging, or other overhead.

MTU and Fragmentation

For IPv4, if an outgoing IP packet is larger than the specified MTU, it is fragmented into 2 or more frames. Fragments are reassembled at the destination (and sometimes at intermediate hops), and fragmentation can cause performance degradation. For IPv6, packets are typically not allowed to be fragmented at all. Therefore, your IP packets should fit within the MTU size to avoid fragmentation.

For TCP packets, the endpoints typically use their MTU to determine the TCP maximum segment size (MTU - 40, for example). If additional TCP headers are added along the way, for example for site-to-site VPN tunnels, then the TCP MSS might need to be adjusted down by the tunneling entity. See About the TCP MSS, on page 970.

For UDP or ICMP, the application should take the MTU into account to avoid fragmentation.

Note The Firewall Threat Defense device can receive frames larger than the configured MTU as long as there is room in memory.

MTU and Jumbo Frames

A larger MTU lets you send larger packets. Larger packets might be more efficient for your network. See the following guidelines:

- Matching MTUs on the traffic path—We recommend that you set the MTU on all Firewall Threat Defense interfaces and other device interfaces along the traffic path to be the same. Matching MTUs prevents intermediate devices from fragmenting the packets.
- Accommodating jumbo frames—You can set the MTU 9000 bytes or higher when you enable jumbo frames. The maximum depends on the model.

About the TCP MSS

The TCP maximum segment size (MSS) is the size of the TCP payload *before* any TCP and IP headers are added. UDP packets are not affected. The client and the server exchange TCP MSS values during the three-way handshake when establishing the connection.

You can set the TCP MSS on the Firewall Threat Defense device for through traffic using the Sysopt_Basic object in FlexConfig; see FlexConfig Policies, on page 2645; by default, the maximum TCP MSS is set to 1380 bytes. This setting is useful when the Firewall Threat Defense device needs to add to the size of the packet for IPsec VPN encapsulation. However, for non-IPsec endpoints, you should disable the maximum TCP MSS on the Firewall Threat Defense device.

If you set a maximum TCP MSS, if either endpoint of a connection requests a TCP MSS that is larger than the value set on the Firewall Threat Defense device, then the Firewall Threat Defense device overwrites the TCP MSS in the request packet with the Firewall Threat Defense device maximum. If the host or server does not request a TCP MSS, then the Firewall Threat Defense device assumes the RFC 793-default value of 536 bytes (IPv4) or 1220 bytes (IPv6), but does not modify the packet. For example, you leave the default MTU as 1500 bytes. A host requests an MSS of 1500 minus the TCP and IP header length, which sets the MSS to 1460. If the Firewall Threat Defense device maximum TCP MSS is 1380 (the default), then the Firewall Threat Defense device changes the MSS value in the TCP request packet to 1380. The server then sends packets with 1380-byte payloads. The Firewall Threat Defense device can then add up to 120 bytes of headers to the packet and still fit in the MTU size of 1500.

You can also configure the minimum TCP MSS; if a host or server requests a very small TCP MSS, the Firewall Threat Defense device can adjust the value up. By default, the minimum TCP MSS is not enabled.

For to-the-box traffic, including for SSL VPN connections, this setting does not apply. The Firewall Threat Defense device uses the MTU to derive the TCP MSS: MTU - 40 (IPv4) or MTU - 60 (IPv6).

Default TCP MSS

By default, the maximum TCP MSS on the Firewall Threat Defense device is 1380 bytes. This default accommodates IPv4 IPsec VPN connections where the headers can equal up to 120 bytes; this value fits within the default MTU of 1500 bytes.

Suggested Maximum TCP MSS Setting

The default TCP MSS assumes the Firewall Threat Defense device acts as an IPv4 IPsec VPN endpoint and has an MTU of 1500. When the Firewall Threat Defense device acts as an IPv4 IPsec VPN endpoint, it needs to accommodate up to 120 bytes for TCP and IP headers.

If you change the MTU value, use IPv6, or do not use the Firewall Threat Defense device as an IPsec VPN endpoint, then you should change the TCP MSS setting using the Sysopt_Basic object in FlexConfig.

Note Even if you explicitly set an MSS, if a component such as TLS/SSL decryption or server discovery needs a particular MSS, it will set that MSS based on the interface MTU and ignore your MSS setting.

See the following guidelines:

- Normal traffic—Disable the TCP MSS limit and accept the value established between connection endpoints. Because connection endpoints typically derive the TCP MSS from the MTU, non-IPsec packets usually fit this TCP MSS.
- IPv4 IPsec endpoint traffic—Set the maximum TCP MSS to the MTU - 120. For example, if you use jumbo frames and set the MTU to 9000, then you need to set the TCP MSS to 8880 to take advantage of the new MTU.
- IPv6 IPsec endpoint traffic—Set the maximum TCP MSS to the MTU - 140.

ARP Inspection for Bridge Group Traffic

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

When you enable ARP inspection, the Firewall Threat Defense device compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the Firewall Threat Defense device drops the packet.
- If the ARP packet does not match any entries in the static ARP table, then you can set the Firewall Threat Defense device to either forward the packet out all interfaces (flood), or to drop the packet.

Note The dedicated Management interface never floods packets even if this parameter is set to flood.

MAC Address Table

When you use bridge groups, the Firewall Threat Defense learns and builds a MAC address table in a similar way as a normal bridge or switch: when a device sends a packet through the bridge group, the Firewall Threat Defense adds the MAC address to its table. The table associates the MAC address with the source interface so that the Firewall Threat Defense knows to send any packets addressed to the device out the correct interface. Because traffic between bridge group members is subject to the Firewall Threat Defense security policy, if the destination MAC address of a packet is not in the table, the Firewall Threat Defense does not flood the original packet on all interfaces as a normal bridge does. Instead, it generates the following packets for directly-connected devices or for remote devices:

- Packets for directly-connected devices—The Firewall Threat Defense generates an ARP request for the destination IP address, so that it can learn which interface receives the ARP response.
- Packets for remote devices—The Firewall Threat Defense generates a ping to the destination IP address so that it can learn which interface receives the ping reply.

The original packet is dropped.

Default Settings

- If you enable ARP inspection, the default setting is to flood non-matching packets.
- The default timeout value for dynamic MAC address table entries is 5 minutes.
- By default, each interface automatically learns the MAC addresses of entering traffic, and the Firewall Threat Defense device adds corresponding entries to the MAC address table.

Note Secure Firewall Threat Defense device generates a reset packet to reset a connection that is denied by a stateful inspection engine. Here, the destination MAC address of the packet is not determined based on the ARP table lookup but instead it is taken directly from the packets (connections) that are being denied.

Guidelines for ARP Inspection and the MAC Address Table

- ARP inspection is only supported for bridge groups.
- MAC address table configuration is only supported for bridge groups.

Configure the MTU

Customize the MTU on the interface, for example, to allow jumbo frames.

For the ISA 3000 and the Firewall Threat Defense Virtual: Changing the MTU above 1500 bytes automatically enables jumbo-frame reservation. You must restart the system before you can use jumbo frames. For the Firewall Threat Defense Virtual that supports clustering, you can enable jumbo-frame reservation in the Day0 configuration, so in that case, you do not need to restart. After you restart, you cannot disable jumbo-frame reservation. An exception is for the Firewall Threat Defense Virtual, where you can disable jumbo-frame reservation in the Day0 configuration, if supported. If you use an interface in an inline set, the MTU setting is not used. However, the jumbo-frame reservation setting *is* relevant to inline sets; jumbo frames enable the inline interfaces to receive packets up to 9000 bytes. To enable jumbo-frame reservation, you must set the MTU of *any* interface above 1500 bytes.

Jumbo frames are enabled by default on other platforms.

Caution Changing the highest MTU value on the device for a data interface restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Inspection is interrupted on all data interfaces, not just the interface you modified. Whether this interruption drops traffic or passes it without further inspection depends on the model of the managed device and the interface type. This caution does not apply to management-only interfaces. See Snort Restart Traffic Behavior, on page 172 for more information.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 On the **General** tab, set the **MTU**. The minimum and maximum depends on your platform.

The default is 1500 bytes.

Step 4 Click **OK**.

Step 5 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Step 6 For the ISA 3000 and the Firewall Threat Defense Virtual, if you set the MTU above 1500 bytes, restart the system to enable jumbo-frame reservation. See Shut Down or Restart the Device, on page 70.

Configure the MAC Address

You might need to manually assign a MAC address. You can also set the Active and Standby MAC addresses on the **Devices** > **Device Management** window by choosing **High Availability** from the **Add** drop-down list. If you set the MAC address for an interface on both screens, the addresses on the **Interfaces** > **Advanced** tab take precedence.

Note For container instances, even if you are not sharing a subinterface, if you manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **Advanced** tab.
The **Information** tab is selected.

Step 4 Set the active and standby MAC addresses.

a) In the **Active MAC Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

b) In the **Standby MAC Address** field, enter a MAC address for use with High Availability.

If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

Step 5 Click **OK**.

Step 6 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Add a Static ARP Entry

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection (see ARP Inspection, on page 1035). ARP inspection compares ARP packets with *static* ARP entries in the ARP table.

For routed interfaces, you can enter static ARP entries, but normally dynamic entries are sufficient. For routed interfaces, the ARP table is used to deliver packets to directly-connected hosts. Although senders identify a packet destination by an IP address, the actual delivery of the packet on Ethernet relies on the Ethernet MAC address. When a router or host wants to deliver a packet on a directly connected network, it sends an ARP request asking for the MAC address associated with the IP address, and then delivers the packet to the MAC address according to the ARP response. The host or router keeps an ARP table so it does not have to send ARP requests for every packet it needs to deliver. The ARP table is dynamically updated whenever ARP responses are sent on the network, and if an entry is not used for a period of time, it times out. If an entry is incorrect (for example, the MAC address changes for a given IP address), the entry needs to time out before it can be updated with the new information.

For transparent mode, the Firewall Threat Defense only uses dynamic ARP entries in the ARP table for traffic to and from the Firewall Threat Defense device, such as management traffic.

Before you begin

This screen is only available for named interfaces.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Click the **Advanced** tab, and then click the **ARP** tab (called **ARP and MAC** for transparent mode).

Step 4 Click ( )**Add ARP Config**.
The **Add ARP Config** dialog box appears.

Step 5 In the **IP Address** field, enter the IP address of the host.

Step 6 In the **MAC Address** field, enter the MAC address of the host; for example, 00e0.1e4e.3d8b.

Step 7 To perform proxy ARP for this address, check the **Enable Alias** check box.

If the Firewall Threat Defense device receives an ARP request for the specified IP address, then it responds with the specified MAC address.

Step 8 Click **OK**, and then click **OK** again to exit the Advanced settings.

Step 9 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Add a Static MAC Address and Disable MAC Learning for a Bridge Group

Normally, MAC addresses are added to the MAC address table dynamically as traffic from a particular MAC address enters an interface. You can disable MAC address learning; however, unless you statically add MAC addresses to the table, no traffic can pass through the Firewall Threat Defense device. You can also add static MAC addresses to the MAC address table. One benefit to adding static entries is to guard against MAC spoofing. If a client with the same MAC address as a static entry attempts to send traffic to an interface that does not match the static entry, then the Firewall Threat Defense device drops the traffic and generates a system message. When you add a static ARP entry (see Add a Static ARP Entry, on page 975), a static MAC address entry is automatically added to the MAC address table.

Before you begin

This screen is only available for named BVIs in transparent mode.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** ( ) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** ( ) for the interface you want to edit.

Step 3 Click the **Advanced** tab, and then click the **ARP and MAC** tab.

Step 4 (Optional) Disable MAC learning by unchecking the **Enable MAC Learning** check box.

Step 5 To add a static MAC address, click **Add MAC Config**.
The **Add MAC Config** dialog box appears.

Step 6 In the **MAC Address** field, enter the MAC address of the host; for example, 00e0.1e4e.3d8b. Click **OK**.

Step 7 Click **OK** to exit the Advanced settings.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Set Security Configuration Parameters

This section describes how to prevent IP spoofing, allow full fragment reassembly, and override the default fragment setting set for at the device level in **Platform Settings** .

Anti-Spoofing

This section lets you enable Unicast Reverse Path Forwarding on an interface. Unicast RPF guards against IP spoofing (a packet uses an incorrect source IP address to obscure its true source) by ensuring that all packets have a source IP address that matches the correct source interface according to the routing table.

Normally, the Firewall Threat Defense device only looks at the destination address when determining where to forward the packet. Unicast RPF instructs the device to also look at the source address; this is why it is called Reverse Path Forwarding. For any traffic that you want to allow through the Firewall Threat Defense device, the device routing table must include a route back to the source address. See RFC 2267 for more information.

For outside traffic, for example, the Firewall Threat Defense device can use the default route to satisfy the Unicast RPF protection. If traffic enters from an outside interface, and the source address is not known to the routing table, the device uses the default route to correctly identify the outside interface as the source interface.

If traffic enters the outside interface from an address that is known to the routing table, but is associated with the inside interface, then the Firewall Threat Defense device drops the packet. Similarly, if traffic enters the inside interface from an unknown source address, the device drops the packet because the matching route (the default route) indicates the outside interface.

Unicast RPF is implemented as follows:

- ICMP packets have no session, so each packet is checked.
- UDP and TCP have sessions, so the initial packet requires a reverse route lookup. Subsequent packets arriving during the session are checked using an existing state maintained as part of the session. Non-initial packets are checked to ensure they arrived on the same interface used by the initial packet.

Fragment per Packet

By default, the Firewall Threat Defense device allows up to 24 fragments per IP packet, and up to 200 fragments awaiting reassembly. You might need to let fragments on your network if you have an application that routinely fragments packets, such as NFS over UDP. However, if you do not have an application that fragments traffic, we recommend that you do not allow fragments through the Firewall Threat Defense device. Fragmented packets are often used as DoS attacks.

Fragment Reassembly

The Firewall Threat Defense device performs the following fragment reassembly processes:

- IP fragments are collected until a fragment set is formed or until a timeout interval has elapsed.
- If a fragment set is formed, integrity checks are performed on the set. These checks include no overlapping, no tail overflow, and no chain overflow.
- IP fragments that terminate at the Firewall Threat Defense device are always fully reassembled.
- If **Full Fragment Reassembly** is disabled (the default), the fragment set is forwarded to the transport layer for further processing.
- If **Full Fragment Reassembly** is enabled, the fragment set is first coalesced into a single IP packet. The single IP packet is then forwarded to the transport layer for further processing.

Before you begin

This screen is only available for named interfaces.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 Click the **Advanced** tab, and then click the **Security Configuration** tab.

Step 4 To enable Unicast Reverse Path Forwarding, check the **Enable Anti Spoofing** check box.

Step 5 To enable full fragment reassembly, check the **Allow Full Fragment Reassembly** check box.

Step 6 To change the number of fragments allowed per packet, check the **Override Default Fragment Setting** check box, and set the following values:

- **Size**—Set the maximum number of packets that can be in the IP reassembly database waiting for reassembly. The default is 200. Set this value to 1 to disable fragments.
- **Chain**—Set the maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets.
- **Timeout**—Set the maximum number of seconds to wait for an entire fragmented packet to arrive. The timer starts after the first fragment of a packet arrives. If all fragments of the packet do not arrive by the number of seconds specified, all fragments of the packet that were already received will be discarded. The default is 5 seconds.

Step 7 Click **OK**.

Step 8 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

History for Regular Firewall Interfaces

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
VXLAN VTEP IPv6 support	7.4	Any	You can now specify an IPv6 address for the VXLAN VTEP interface. IPv6 is not supported for the threat defense virtual cluster control link or for Geneve encapsulation. New/Modified screens: • **Devices** > **Device Management** > **Edit** > **VTEP** > **Add VTEP** **Devices** > **Device Management** > **Edit** > **Interfaces** > **Add Interfaces** > **VNI Interface** Requires Firewall Threat Defense version 7.4. You can specify an IPv6 address for the VXLAN VTEP interface for Secure Firewall 4200 Series devices only.

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Loopback interface support for BGP and management traffic	7.4	Any	You can use a loopback interface for: • AAA • BGP • DNS • HTTP • ICMP • IPsec Flow Offload • NetFlow • SNMP • SSH • Syslog Requires Firewall Threat Defense version 7.4.
Loopback interface support for VTI	7.3	Any	You can now add a loopback interface. The loopback interface helps to overcome path failures. If an interface goes down, you can access all interfaces through the IP address assigned to the loopback interface. For VTI, in addition to setting a loopback interface as the source interface, support has also been added to inherit the IP address from a loopback interface instead of a statically configured IP address. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Add Interfaces** > **Add Loopback Interface**

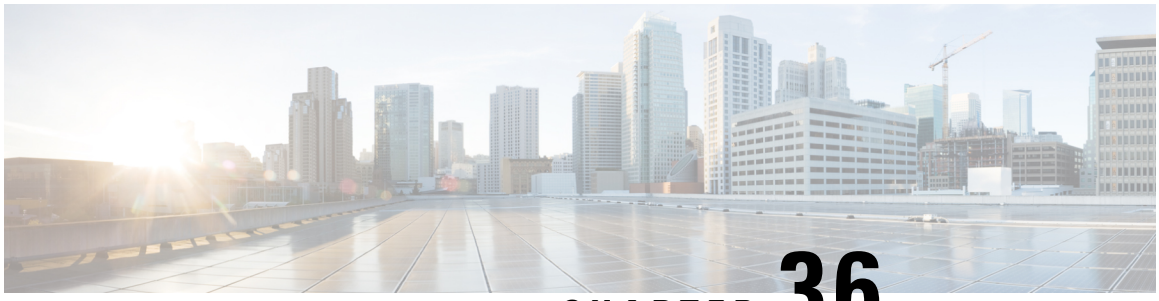
Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
IPv6 DHCP	7.3	Any	The Firewall Threat Defense now supports the following features for IPv6 addressing: • DHCPv6 Address client—The Firewall Threat Defense obtains an IPv6 global address and optional default route from the DHCPv6 server. • DHCPv6 Prefix Delegation client—The Firewall Threat Defense obtains delegated prefix(es) from a DHCPv6 server. The Firewall Threat Defense can then use these prefixes to configure other Firewall Threat Defense interface addresses so that StateLess Address Auto Configuration (SLAAC) clients can autoconfigure IPv6 addresses on the same network. • BGP router advertisement for delegated prefixes • DHCPv6 stateless server—The Firewall Threat Defense provides other information such as the domain name to SLAAC clients when they send Information Request (IR) packets to the Firewall Threat Defense. The Firewall Threat Defense only accepts IR packets, and does not assign addresses to the clients. New/Modified screens: • **Devices** > **Device Management** > **Interfaces** > **Add/Edit Interfaces** > **IPv6** > **DHCP** • **Objects** > **Object Management** > **DHCP IPv6 Pool** New/Modified commands: **show bgp ipv6 unicast, show ipv6 dhcp, show ipv6 general-prefix**
Paired proxy VXLAN for the Firewall Threat Defense Virtual for the Azure Gateway Load Balancer	7.3	Any	You can configure a paired proxy mode VXLAN interface for the Firewall Threat Defense Virtual in Azure for use with the Azure Gateway Load Balancer (GWLB). The Firewall Threat Defense Virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy. New/Modified screens: • **Devices** > **Device Management** > **Device** > **Interfaces** > **Add Interfaces** > **VNI Interface** Supported platforms: Firewall Threat Defense Virtual in Azure

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
VXLAN support	7.2	Any	VXLAN encapsulation support was added. New/Modified screens: • **Devices** > **Device Management** > **Device** > **VTEP** • **Devices** > **Device Management** > **Device** > **Interfaces** > **Add Interfaces** > **VNI Interface** • **Devices** > **Device Management** > **Device** > **Interfaces** edit physical interface **> General** Supported platforms: All.
Geneve support for the Firewall Threat Defense Virtual	7.1	Any	Geneve encapsulation support was added for the Firewall Threat Defense Virtual to support single-arm proxy for the Amazon Web Services (AWS) Gateway Load Balancer. The AWS Gateway Load Balancer combines a transparent network gateway (with a single entry and exit point for all traffic) and a load balancer that distributes traffic and scales Firewall Threat Defense Virtual to match the traffic demand. This feature requires Snort 3. New/Modified screens: • **Devices** > **Device Management** > **Device** > **VTEP** • **Devices** > **Device Management** > **Device** > **Interfaces** > **Add Interfaces** > **VNI Interface** • **Devices** > **Device Management** > **Device** > **Interfaces** edit physical interface **> General** Supported platforms: Firewall Threat Defense Virtual in AWS
31-bit Subnet Mask	7.0	Any	For routed interfaces, you can configure an IP address on a 31-bit subnet for point-to-point connections. The 31-bit subnet includes only 2 addresses; normally, the first and last address in the subnet is reserved for the network and broadcast, so a 2-address subnet is not usable. However, if you have a point-to-point connection and do not need network or broadcast addresses, a 31-bit subnet is a useful way to preserve addresses in IPv4. For example, the failover link between 2 FTDs only requires 2 addresses; any packet that is transmitted by one end of the link is always received by the other, and broadcasting is unnecessary. You can also have a directly-connected management station running SNMP or Syslog. This feature is not supported for BVIs for bridge groups or with multicast routing. New/Modified screens: **Devices** > **Device Management** > **Interfaces**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Synchronization between the Firewall Threat Defense operational link state and the physical link state for the Firepower 4100/9300	6.7	Any	The Firepower 4100/9300 chassis can now synchronize the Firewall Threat Defense operational link state with the physical link state for data interfaces. Currently, interfaces will be in an Up state as long as the FXOS admin state is up and the physical link state is up. The Firewall Threat Defense application interface admin state is not considered. Without synchronization from Firewall Threat Defense, data interfaces can be in an Up state physically before the Firewall Threat Defense application has completely come online, for example, or can stay Up for a period of time after you initiate an Firewall Threat Defense shutdown. For inline sets, this state mismatch can result in dropped packets because external routers may start sending traffic to the Firewall Threat Defense before the Firewall Threat Defense can handle it. This feature is disabled by default, and can be enabled per logical device in FXOS. **Note** This feature is not supported for clustering, container instances, or Firewall Threat Defense with a Radware vDP decorator. It is also not supported for ASA. New/Modified Firepower Chassis Manager screens: **Logical Devices** > **Enable Link State** New/Modified FXOS commands: **set link-state-sync enabled**, **show interface expand detail** Supported platforms: Firepower 4100/9300
Firepower 1010 hardware switch support	6.5	Any	The Firepower 1010 supports setting each Ethernet interface to be a switch port or a firewall interface. New/Modified screens: • **Devices** > **Device Management** > **Interfaces** • **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** • **Devices** > **Device Management** > **Interfaces** > **Add VLAN Interface**
Firepower 1010 PoE+ support on Ethernet 1/7 and Ethernet 1/8	6.5	Any	The Firepower 1010 supports Power over Ethernet+ (PoE+) on Ethernet 1/7 and Ethernet 1/8 when they are configured as switch ports. New/Modified screens: **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** > **PoE**

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
VLAN subinterfaces for use with container instances	6.3.0	Any	To provide flexible physical interface use, you can create VLAN subinterfaces in FXOS and also share interfaces between multiple instances. New/Modified Secure Firewall Management Center screens: **Devices** > **Device Management** > **Edit** icon **>** **Interfaces** tab New/Modified Secure Firewall Chassis Manager screens: **Interfaces** > **All Interfaces** > **Add New** drop-down menu **Subinterface** New/Modified FXOS commands: **create subinterface, set vlan, show interface,show subinterface** Supported platforms: Firepower 4100/9300
Data-sharing interfaces for container instances	6.3.0	Any	To provide flexible physical interface use, you can share interfaces between multiple instances. New/Modified Secure Firewall Chassis Manager screens: **Interfaces** > **All Interfaces** > **Type** New/Modified FXOS commands: **set port-type data-sharing, show interface** Supported platforms: Firepower 4100/9300

Feature	Minimum Firewall Management Center	Minimum Firewall Threat Defense	Details
Integrated Routing and Bridging	6.2.0	Any	Integrated Routing and Bridging provides the ability to route between a bridge group and a routed interface. A bridge group is a group of interfaces that the Firewall Threat Defense bridges instead of routes. The Firewall Threat Defense is not a true bridge in that the Firewall Threat Defense continues to act as a firewall: access control between interfaces is controlled, and all of the usual firewall checks are in place. Previously, you could only configure bridge groups in transparent firewall mode, where you cannot route between bridge groups. This feature lets you configure bridge groups in routed firewall mode, and to route between bridge groups and between a bridge group and a routed interface. The bridge group participates in routing by using a Bridge Virtual Interface (BVI) to act as a gateway for the bridge group. Integrated Routing and Bridging provides an alternative to using an external Layer 2 switch if you have extra interfaces on the Firewall Threat Defense to assign to the bridge group. In routed mode, the BVI can be a named interface and can participate separately from member interfaces in some features, such as access rules and DHCP server. The following features that are supported in transparent mode are not supported in routed mode: clustering. The following features are also not supported on BVIs: dynamic routing and multicast routing. New/Modified screens: • **Devices** > **Device Management** > **Interfaces** > **Edit Physical Interface** • **Devices** > **Device Management** > **Interfaces** > **Add Interfaces** > **Bridge Group Interface** Supported platforms: All except for the Firepower 2100 and the Firewall Threat Defense Virtual



CHAPTER 36

Inline Sets and Passive Interfaces

You can configure IPS-only passive interfaces, passive ERSPAN interfaces, and inline sets.

- About IPS Interfaces, on page 985
- Requirements and Prerequisites for Inline Sets, on page 988
- Guidelines for Inline Sets and Passive Interfaces, on page 990
- Configure a Passive Interface, on page 991
- Configure an Inline Set, on page 993

About IPS Interfaces

IPS interfaces include passive interfaces, passive ERSPAN interfaces, and inline sets. IPS-only mode interfaces bypass many firewall checks and only support IPS security policy (Snort). You might want to implement IPS-only interfaces if you have a separate firewall protecting these interfaces and do not want the overhead of firewall functions.

IPS-only mode interfaces bypass many firewall checks and only support IPS security policy (Snort). You might want to implement IPS-only interfaces if you have a separate firewall protecting these interfaces and do not want the overhead of firewall functions.

Note The firewall mode only affects regular firewall interfaces, and not IPS-only interfaces such as inline sets or passive interfaces. IPS-only interfaces can be used in both firewall modes.

Inline Sets

An inline set acts like a bump on the wire, and binds one or more interface pairs together to slot into an existing network. This function allows the Firewall Threat Defense to be installed in any network environment without the configuration of adjacent network devices. Inline interfaces receive all traffic unconditionally, but all traffic received on these interfaces is retransmitted out of the other interface in the inline pair unless explicitly dropped. When you have multiple inline pairs in an inline set, traffic can only pass between the interfaces in the pair; it can't pass between interfaces in different pairs.

With tap mode, the Firewall Threat Defense is deployed inline, but the network traffic flow is undisturbed. Instead, the Firewall Threat Defense makes a copy of each packet so that it can analyze the packets. Note that rules of these types do generate intrusion events when they are triggered, and the table view of intrusion events

indicates that the triggering packets would have dropped in an inline deployment. There are benefits to using tap mode with FTDs that are deployed inline. For example, you can set up the cabling between the Firewall Threat Defense and the network as if the Firewall Threat Defense were inline and analyze the kinds of intrusion events the Firewall Threat Defense generates. Based on the results, you can modify your intrusion policy and add the drop rules that best protect your network without impacting its efficiency. When you are ready to deploy the Firewall Threat Defense inline, you can disable tap mode and begin dropping suspicious traffic without having to reconfigure the cabling between the Firewall Threat Defense and the network.

Note Tap mode *significantly* impacts Firewall Threat Defense performance, depending on the traffic.

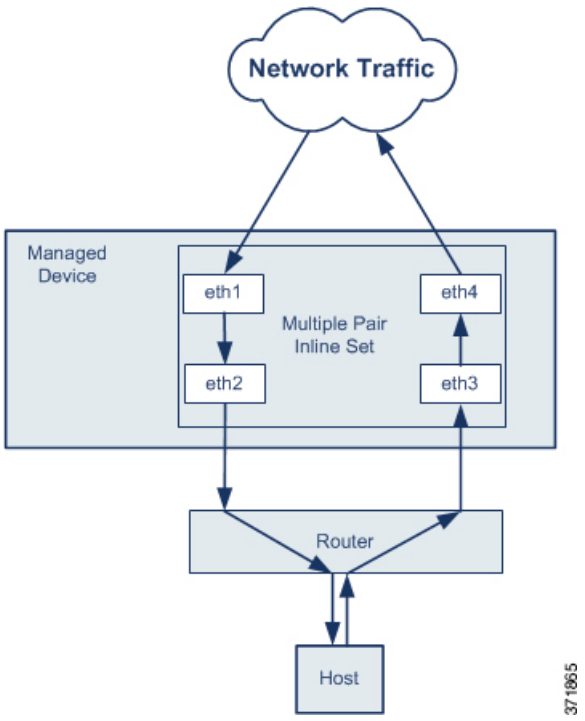
Note Inline sets might be familiar to you as "transparent inline sets," but the inline interface type is unrelated to the transparent firewall mode or the firewall-type interfaces.

Multiple Inline Pairs and Asynchronous Routing

You can configure the interfaces to route traffic between a host on your network and external hosts through different inline pairs, depending on whether the traffic is inbound or outbound. This is an *asynchronous routing* configuration. If you deploy asynchronous routing, but you include only one inline pair in an inline set, the device might not correctly analyze your network traffic because it might see only half of the traffic.

Adding multiple inline pairs to the same inline set lets the system identify the inbound and outbound traffic as part of the same traffic flow. For passive interfaces only, you can also achieve this by including the interface pairs in the same security zone.

Figure 315: Asynchronous Routing



Note If you assign multiple inline pairs to a single inline set, but you experience issues with duplicate traffic, you might need to reassign your inline pairs to separate inline sets or modify your security zones.

If fragments of a packet are received on different interface pairs, they are not reassembled and get dropped. Make sure all the fragments of the packet are received and sent on the same interface pair.

Passive Interfaces

Passive interfaces monitor traffic flowing across a network using a switch SPAN or mirror port. The SPAN or mirror port allows for traffic to be copied from other ports on the switch. This function provides the system visibility within the network without being in the flow of network traffic. When you configure the Firewall Threat Defense in a passive deployment, the Firewall Threat Defense cannot take certain actions such as blocking or shaping traffic. Passive interfaces receive all traffic unconditionally. and no traffic received on these interfaces is retransmitted. Encapsulated remote switched port analyzer (ERSPAN) interfaces allow you to monitor traffic from source ports distributed over multiple switches, and uses GRE to encapsulate the traffic. ERSPAN interfaces are only allowed when the Firewall Threat Defense is in routed firewall mode.

Note Using SR-IOV interfaces as passive interfaces on NGFWv is not supported on some Intel network adapters (such as Intel X710 or 82599) using SR-IOV drivers due to a promiscuous mode restriction. In such cases, use a network adapter that supports this functionality. See Intel Ethernet Products for more information on Intel network adapters.

About Hardware Bypass for Inline Sets

For certain interface modules on the supported models (see Requirements and Prerequisites for Inline Sets, on page 988), you can enable the Hardware Bypass feature. Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures.

Hardware Bypass Triggers

Hardware Bypass can be triggered in the following scenarios:

- Firewall Threat Defense crash
- Firewall Threat Defense reboot
- Security Module reboot
- Chassis crash
- Chassis reboot
- Manual trigger
- Chassis power loss
- Security Module power loss

Note Hardware bypass is intended for unplanned/unexpected failure scenarios, and is not automatically triggered during planned software upgrades. Hardware bypass only engages at the end of a planned upgrade process, when the Firewall Threat Defense application reboots.

Hardware Bypass Switchover

When switching from normal operation to hardware bypass or from hardware bypass back to normal operation, traffic may be interrupted for several seconds. A number of factors can affect the length of the interruption; for example, copper port auto-negotiation; behavior of the optical link partner such as how it handles link faults and de-bounce timing; spanning tree protocol convergence; dynamic routing protocol convergence; and so on. During this time, you may experience dropped connections.

You may also experience dropped connections due to application identification errors when analyzing connections midstream after the return to normal operations.

Snort Fail Open vs. Hardware Bypass

For inline sets other than those in tap mode, you can use the Snort Fail Open option to either drop traffic or allow traffic to pass without inspection when the Snort process is busy or down. Snort Fail Open is supported on all inline sets except those in tap mode, not just on interfaces that support Hardware Bypass.

The Hardware Bypass functionality allows traffic to flow during a hardware failure, including a complete power outage, and certain limited software failures. A software failure that triggers Snort Fail Open does not trigger a Hardware Bypass.

Hardware Bypass Status

If the system has power, then the Bypass LED indicates the Hardware Bypass status. See the Firepower chassis hardware installation guide for LED descriptions.

Requirements and Prerequisites for Inline Sets

User Roles

- Network Admin

Hardware Bypass Support

The Firewall Threat Defense supports Hardware Bypass for interface pairs on specific network modules on the following models:

- Firepower 2130 and 2140
- Secure Firewall 3100
- Firepower 4100

- Firepower 9300

Note The ISA 3000 has a separate implementation for Hardware Bypass, which you can enable using FlexConfig only (see FlexConfig Policies, on page 2645). Do not use this chapter to configure ISA 3000 Hardware Bypass.

Note You can use Hardware Bypass interfaces as regular interfaces without the Hardware Bypass feature enabled.

The supported Hardware Bypass network modules for these models include:

- Firepower 2130 and 2140:
  - Firepower 6-port 1G SX FTW Network Module single-wide (FPR2K-NM-6X1SX-F)
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR2K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR2K-NM-6X10LR-F)
- Secure Firewall 3100:
  - 6-port 1G SFP Fail-to-Wire Network Module, SX (multimode) (FPR3K-XNM-6X1SXF)
  - 6-port 10G SFP Fail-to-Wire Network Module, SR (multimode) (FPR3K-XNM-6X10SRF)
  - 6-port 10G SFP Fail-to-Wire Network Module, LR (single mode) (FPR3K-XNM-6X10LRF)
  - 6-port 25G SFP Fail-to-Wire Network Module, SR (multimode) (FPR3K-XNM-X25SRF)
  - 6-port 25G Fail-to-Wire Network Module, LR (single mode) (FPR3K-XNM-6X25LRF)
  - 8-port 1G Copper Fail-to-Wire Network Module, RJ45 (copper) (FPR3K-XNM-8X1GF)
- Firepower 4100:
  - Firepower 6-port 1G SX FTW Network Module single-wide (FPR4K-NM-6X1SX-F)
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR4K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR4K-NM-6X10LR-F)
  - Firepower 2-port 40G SR FTW Network Module single-wide (FPR4K-NM-2X40G-F)
  - Firepower 8-port 1G Copper FTW Network Module single-wide (FPR-NM-8X1G-F)
- Firepower 9300:
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR9K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR9K-NM-6X10LR-F)
  - Firepower 2-port 40G SR FTW Network Module single-wide (FPR9K-NM-2X40G-F)

Hardware Bypass can only use the following port pairs:

- 1 & 2

- 3 & 4
- 5 & 6
- 7 & 8

Guidelines for Inline Sets and Passive Interfaces

Firewall Mode

- ERSPAN interfaces are only allowed when the device is in routed firewall mode.

Clustering

- Link State Propagation for an inline set is not supported with clustering.

Multi-Instance Mode

- Multi-instance shared interfaces are not supported. You must use an unshared interface.
- Multi-instance chassis-defined subinterfaces are not supported. You must use a physical interface or EtherChannel.

General Guidelines

- Inline sets and passive interfaces support physical interfaces and EtherChannels only, and cannot use VLANs or other virtual interfaces, including multi-instance chassis-defined subinterfaces.
- Since IPS interfaces do not support regular firewall protections, the IPS security policy (Snort) requires that traffic flows pass through the same Firewall Threat Defense so that all traffic can be inspected.
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the Firewall Threat Defense when using inline sets. If there are two neighbors on either side of the Firewall Threat Defense running BFD, then the Firewall Threat Defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.
- For inline sets and passive interfaces, the Firewall Threat Defense supports up to two 802.1Q headers in a packet (also known as Q-in-Q support), with the exception of the Firepower 4100/9300, which only supports one 802.1Q header. **Note:** Firewall-type interfaces do not support Q-in-Q, and only support one 802.1Q header.

Hardware Bypass Guidelines

- Hardware Bypass ports are supported only for inline sets.
- Hardware Bypass ports cannot be part of an EtherChannel.
- Hardware Bypass is not supported in high availability mode.
- Hardware Bypass ports are supported with intra-chassis clustering on the Firepower 9300. Ports are placed in Hardware Bypass mode when the last unit in the chassis fails. Inter-chassis clustering is not

supported, because inter-chassis clustering only supports Spanned EtherChannels; Hardware Bypass ports cannot be part of an EtherChannel.

- If all modules in an intra-chassis cluster on the Firepower 9300 fail, then Hardware Bypass is triggered on the final unit, and traffic continues to pass. When units come back up, Hardware Bypass returns to standby mode. However, when you use rules that match application traffic, those connections may be dropped and need to be reestablished. Connections are dropped because state information is not retained on the cluster unit, and the unit cannot identify the traffic as belonging to an allowed application. To avoid a traffic drop, use a port-based rule instead of an application-based rule, if appropriate for your deployment.
- You can use Hardware Bypass interfaces as regular interfaces without the Hardware Bypass feature enabled.

Unsupported Firewall Features on IPS Interfaces

- DHCP server
- DHCP relay
- DHCP client
- TCP Intercept
- Routing
- NAT
- VPN
- Application inspection
- QoS
- NetFlow
- VXLAN

Configure a Passive Interface

This section describes how to:

- Enable the interface. By default, interfaces are disabled.
- Set the interface mode to Passive or ERSPAN. For ERSPAN interfaces, you will set the ERSPAN parameters and the IP address.
- Change the MTU. By default, the MTU is set to 1500 bytes. For more information about the MTU, see About the MTU, on page 969.
- Set a specific speed and duplex (if available). By default, speed and duplex are set to Auto.

Note For the Secure Firewall Threat Defense on the FXOS chassis, you configure basic interface settings on the Firepower 4100/9300. See Configure a Physical Interface, on page 478 for more information.

Before you begin

- If you are using EtherChannels, add them according to Configure an EtherChannel, on page 880.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 Click **Edit** (✎) for the interface you want to edit.

Step 3 In the **Mode** drop-down list, choose **Passive** or **Erspan**.

Step 4 Enable the interface by checking the **Enabled** check box.

Step 5 In the **Name** field, enter a name up to 48 characters in length.

Step 6 From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

Step 7 (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

Step 8 (Optional) On **General**, set the **MTU** between 64 and 9198 bytes; for the Secure Firewall Threat Defense Virtual and Secure Firewall Threat Defense on the FXOS chassis, the maximum is 9000 bytes.

The default is 1500 bytes.

Step 9 For ERSPAN interfaces, set the following parameters:

- **Flow Id**—Configure the ID used by the source and destination sessions to identify the ERSPAN traffic, between 1 and 1023. This ID must also be entered in the ERSPAN destination session configuration.
- **Source IP**—Configure the IP address used as the source of the ERSPAN traffic.

Step 10 For ERSPAN interfaces, set the IPv4 address and mask on **IPv4**.

Step 11 (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

The exact speed and duplex options depend on your hardware.

- **Duplex**—Choose **Full**, **Half**, or **Auto**. Auto is the default.
- **Speed**—Choose **10**, **100**, **1000**, or **Auto**. Auto is the default.

Step 12 Click **OK**.

Step 13 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure an Inline Set

This section enables and names two physical interfaces or EtherChannels per inline pair that you can add to an inline set. You can add multiple inline pairs per inline set. You can also optionally enable Hardware Bypass for supported inline pairs.

Note For the Firepower 4100/9300, you configure basic interface settings in FXOS on the chassis. See Configure a Physical Interface, on page 478 for more information.

Before you begin

- If you are using EtherChannels, add them according to Configure an EtherChannel, on page 880.
- We recommend that you set STP PortFast for STP-enabled switches that connect to the Firewall Threat Defense inline pair interfaces. This setting is especially useful for Hardware Bypass configurations and can reduce bypass times.

Procedure

Step 1 Select **Devices** > **Device Management** and click **Edit** (✎) for your Firewall Threat Defense device. The **Interfaces** page is selected by default.

Step 2 For each interface in the inline pair, name the interface and enable it. You can also configure other hardware settings. Be sure to match the hardware settings for each interface in the inline pair. You can configure multiple pairs of interfaces.

a) Click **Edit** (✎) for the interface you want to edit.
b) In the **Name** field, enter a name up to 48 characters in length.
c) Enable the interface by checking the **Enabled** check box.
d) (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

e) Leave the **Mode** as **None**.

After you add this interface to an inline set, this field will show Inline for the mode.

f) Do not set the security zone yet; you must set it after you create the inline set later in this procedure.
g) (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

The exact speed and duplex options depend on your hardware.

- **Duplex**—Choose **Full**, **Half**, or **Auto**. Auto is the default.

- **Speed**—Choose **10**, **100**, **1000**, or **Auto**. Auto is the default.

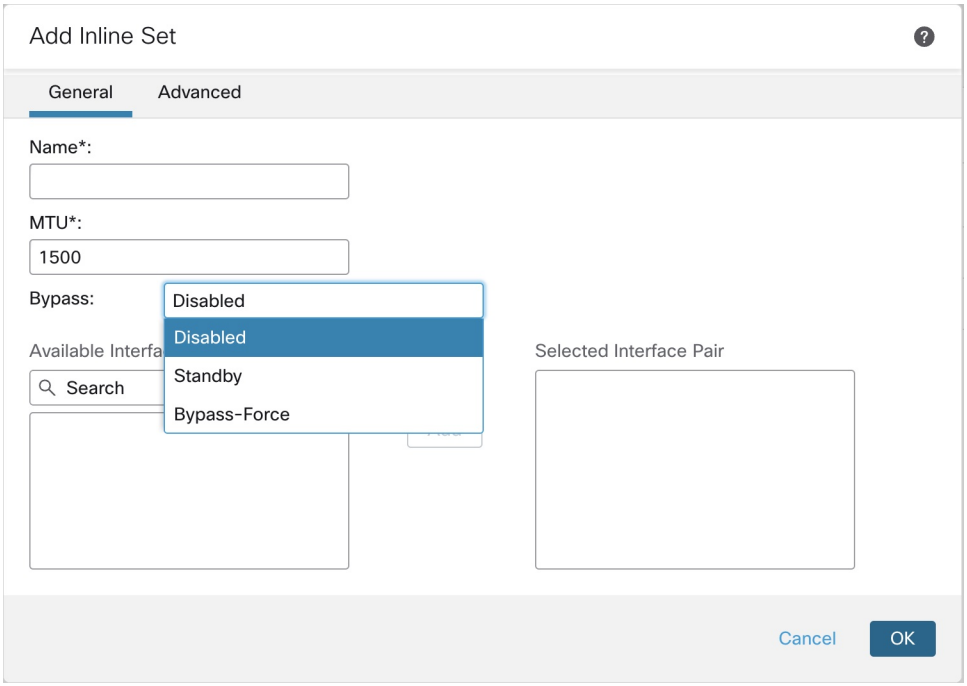
h) Click **OK**.

Do not set any other settings for this interface.

Step 3 Click **Inline Sets**.

Step 4 Click **Add Inline Set**.

Figure 316: Add Inline Set



The **Add Inline Set** dialog box appears with **General** selected.

Step 5 In the **Name** field, enter a name for the set.

Step 6 (Optional) Change the **MTU** to enable jumbo frames.

For inline sets, the MTU setting is not used. However, the jumbo frame setting *is* relevant to inline sets; jumbo frames enable the inline interfaces to receive packets up to 9000 bytes. To enable jumbo frames, you must set the MTU of *any* interface on the device above 1500 bytes.

Step 7 Configure Hardware Bypass.

a) For the **Bypass** mode, choose one of the following options:

- **Disabled**—Set Hardware Bypass to disabled for interfaces where Hardware Bypass is supported, or use interfaces where Hardware Bypass is not supported.
- **Standby**—Set Hardware Bypass to the standby state on supported interfaces. Only pairs of Hardware Bypass interfaces are shown. In the standby state, the interfaces remain in normal operation until there is a trigger event.
- **Bypass-Force**—Manually forces the interface pair to go into a bypass state. **Inline Sets** shows **Yes** for any interface pairs that are in Bypass-Force mode.

b) In the **Available Interfaces Pairs** area, click a pair and then click **Add** to move it to the **Selected Interface Pair** area.

All possible pairings between named and enabled interfaces with the mode set to None show in this area.

Step 8 (Optional) Click **Advanced** to set the following optional parameters:

- **Tap Mode**—Set to inline tap mode.

  Note that you cannot enable this option and strict TCP enforcement on the same inline set.

  Note
  If you need to enable or disable the Tap mode, you should do so during a maintenance window. Changing the mode while the device is passing traffic can cause traffic disruption.

  Note
  Tap mode *significantly* impacts the Firewall Threat Defense performance, depending on the traffic.

- **Propagate Link State**—Configure link state propagation.

  Link state propagation automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. When the downed interface comes back up, the second interface automatically comes back up, also. In other words, if the link state of one interface changes, the device senses the change and updates the link state of the other interface to match it. Note that devices require up to 4 seconds to propagate link state changes. Link state propagation is especially useful in resilient network environments where routers are configured to reroute traffic automatically around network devices that are in a failure state.

  Note
  Do not enable **Propagate Link State** when using clustering.

- **Snort Fail Open**—Enable or disable either or both of the **Busy** and **Down** options if you want new and existing traffic to pass without inspection (enabled) or drop (disabled) when the Snort process is busy or down.

  By default, traffic passes without inspection when the Snort process is down, and drops when it is busy.

  When the Snort process is:

  - Busy—It cannot process traffic fast enough because traffic buffers are full, indicating that there is more traffic than the device can handle, or because of other software resource issues.
  - Down—It is restarting because you deployed a configuration that requires it to restart. See Configurations that Restart the Snort Process When Deployed or Activated, on page 174.

  When the Snort process is down and comes back up, it inspects *new* connections. To prevent false positives and false negatives, it does not inspect existing connections on inline, routed, or transparent interfaces because initial session information might have been lost while it was down.

  Note
  When Snort fails open, features that rely on the Snort process do not function. These include application control and deep inspection. The system performs only basic access control using simple, easily determined transport and network layer characteristics.

  Note
  The **Strict TCP Enforcement** option is not supported.

Step 9 Set the security zone for each interface.

a) Click **Interfaces**.

b) Click **Edit** (✎) for the member interface.

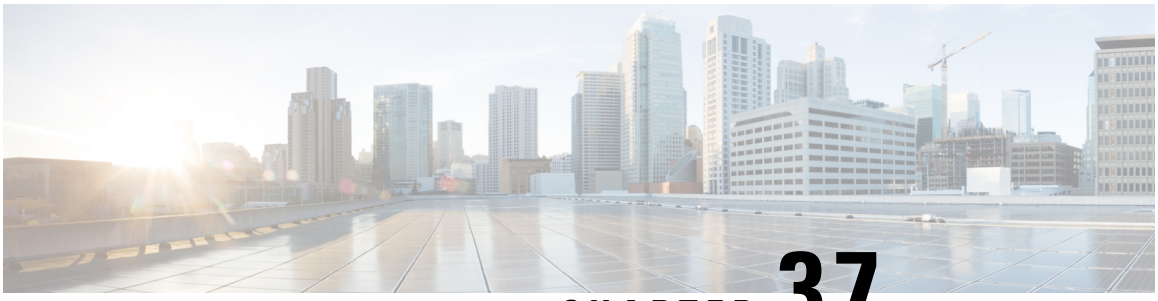
c) From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

You can only set the zone after you add the interface to the inline set; adding it to an inline set configures the mode to Inline and lets you choose inline-type security zones.

d) Click **OK**.

Step 10 Click **Save**.

You can now go to **Deploy** > **Deploy** and deploy the policy to assigned devices. The changes are not active until you deploy them.



CHAPTER 37

DHCP and DDNS

The following topics explain DHCP and DDNS services and how to configure them on Threat Defense devices.

- About DHCP and DDNS Services, on page 997
- Requirements and Prerequisites for DHCP and DDNS, on page 999
- Guidelines for DHCP and DDNS Services, on page 999
- Configure the DHCPv4 Server, on page 1001
- Configure the DHCPv6 Stateless Server, on page 1002
- Configure the DHCP Relay Agent, on page 1007
- Configure Dynamic DNS, on page 1008
- History for DHCP and DDNS, on page 1014

About DHCP and DDNS Services

The following topics describe the DHCP server, DHCP relay agent, and DDNS update.

About the DHCPv4 Server

DHCP provides network configuration parameters, such as IP addresses, to DHCP clients. The Firewall Threat Defense device can provide a DHCP server to DHCP clients attached to Firewall Threat Defense device interfaces. The DHCP server provides network configuration parameters directly to DHCP clients.

An IPv4 DHCP client uses a broadcast rather than a multicast address to reach the server. The DHCP client listens for messages on UDP port 68; the DHCP server listens for messages on UDP port 67.

DHCP Options

DHCP provides a framework for passing configuration information to hosts on a TCP/IP network. The configuration parameters are carried in tagged items that are stored in the Options field of the DHCP message and the data are also called options. Vendor information is also stored in Options, and all of the vendor information extensions can be used as DHCP options.

For example, Cisco IP Phones download their configuration from a TFTP server. When a Cisco IP Phone starts, if it does not have both the IP address and TFTP server IP address preconfigured, it sends a request with option 150 or 66 to the DHCP server to obtain this information.

- DHCP option 150 provides the IP addresses of a list of TFTP servers.

- DHCP option 66 gives the IP address or the hostname of a single TFTP server.
- DHCP option 3 sets the default route.

A single request might include both options 150 and 66. In this case, the DHCP server provides values for both options in the response if they are already configured on the Firewall Threat Defense.

You can use advanced DHCP options to provide DNS, WINS, and domain name parameters to DHCP clients; DHCP option 15 is used for the DNS domain suffix. You can also use the DHCP automatic configuration setting to obtain these values or define them manually. When you use more than one method to define this information, it is passed to DHCP clients in the following sequence:

1. Manually configured settings.
2. Advanced DHCP options settings.
3. DHCP automatic configuration settings.

For example, you can manually define the domain name that you want the DHCP clients to receive and then enable DHCP automatic configuration. Although DHCP automatic configuration discovers the domain together with the DNS and WINS servers, the manually defined domain name is passed to DHCP clients with the discovered DNS and WINS server names, because the domain name discovered by the DHCP automatic configuration process is superseded by the manually defined domain name.

About the DHCPv6 Stateless Server

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature (Enable the IPv6 Prefix Delegation Client, on page 960), you can configure the Firewall Threat Defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the Firewall Threat Defense by defining a DHCP IPv6 Pool and assigning it to the DHCPv6 server. The Firewall Threat Defense only accepts IR packets and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the Firewall Threat Defense received using Prefix Delegation.

About the DHCP Relay Agent

You can configure a DHCP relay agent to forward DHCP requests received on an interface to one or more DHCP servers. DHCP clients use UDP broadcasts to send their initial DHCPDISCOVER messages because they do not have information about the network to which they are attached. If the client is on a network segment that does not include a server, UDP broadcasts normally are not forwarded by the Firewall Threat Defense device because it does not forward broadcast traffic. The DHCP relay agent lets you configure the interface of the Firewall Threat Defense device that is receiving the broadcasts to forward DHCP requests to a DHCP server on another device.

Requirements and Prerequisites for DHCP and DDNS

Model Support

Threat Defense

User Roles

- Admin
- Access Admin
- Network Admin

Guidelines for DHCP and DDNS Services

This section includes guidelines and limitations that you should check before configuring DHCP and DDNS services.

Firewall Mode

- DHCP Relay is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.
- DHCP Server is supported in transparent firewall mode on a bridge group member interface. In routed mode, the DHCP server is supported on the BVI interface, not the bridge group member interface. The BVI must have a name for the DHCP server to operate.
- DDNS is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.
- DHCPv6 stateless server is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.

Clustering

- DHCPv6 stateless server is not supported with clustering.

IPv6

Supports IPv6 for DHCP stateless server and DHCP Relay.

DHCPv4 Server

- The maximum available DHCP pool is 256 addresses.
- You can configure a DHCP server on any interface with a name and IP address, such as a physical interface, a subinterface, or a BVI in routed mode.

- You can configure only one DHCP server on each interface. Each interface can have its own pool of addresses to use. However the other DHCP settings, such as DNS servers, domain name, options, ping timeout, and WINS servers, are configured globally and used by the DHCP server on all interfaces.
- You cannot configure an interface as a DHCP client if that interface also has DHCP server enabled; you must use a static IP address.
- You cannot configure both a DHCP server and DHCP relay on the same device, even if you want to enable them on different interfaces; you can only configure one type of service.
- The Firewall Threat Defense does not support DHCP clients behind DHCP relay servers; the client must be directly connected to the Firewall Threat Defense.
- The DHCP server does not support BOOTP requests.

DHCPv6 Server

The DHCPv6 Stateless server cannot be configured on an interface where the DHCPv6 address, Prefix Delegation client, or DHCPv6 relay is configured.

DHCP Relay

- You can configure a maximum of 10 DHCPv4 relay servers per virtual router, global (VRF) and interface-specific servers combined, with a maximum of 4 servers per interface.
- You can configure a maximum of 10 DHCPv6 relay servers per virtual router. Interface-specific servers for IPv6 are not supported.
- You cannot configure both a DHCP server and DHCP relay on the same device, even if you want to enable them on different interfaces; you can only configure one type of service.
- DHCP relay services are not available in transparent firewall mode or in routed mode on the BVI or bridge group member interface. You can, however, allow DHCP traffic through using an access rule. To allow DHCP requests and replies through the Firewall Threat Defense, you need to configure two access rules, one that allows DCHP requests from the inside interface to the outside (UDP destination port 67), and one that allows the replies from the server in the other direction (UDP destination port 68).
- For IPv4, clients must be directly-connected to the Firewall Threat Defense and cannot send requests through another relay agent or a router. For IPv6, the Firewall Threat Defense supports packets from another relay server.
- The DHCP clients must be on different interfaces from the DHCP servers to which the Firewall Threat Defense relays requests.
- You cannot enable DHCP Relay on an interface in a traffic zone.

DDNS Service

The firewall's DDNS supports only DynDNS service. Hence, ensure that the DDNS is configured with update URL in the following syntax:

https://*username***:***password***@***provider-domain***/***path***?hostname=<h>&myip=<a>**.

Configure the DHCPv4 Server

See the following steps to configure a DHCPv4 server.

Procedure

Step 1 Choose **Devices** > **Device Management**, and edit the Firewall Threat Defense device.

Step 2 Select **DHCP > DHCP Server**.

Step 3 Configure the following DHCP server options:

- **Ping Timeout**—The amount of time in milliseconds that Firewall Threat Defense device waits to time out a DHCP ping attempt. Valid values range from 10 to 10000 milliseconds. The default value is 50 milliseconds.

  To avoid address conflicts, the Firewall Threat Defense device sends two ICMP ping packets to an address before assigning that address to a DHCP client.
